Serum microRNA signatures identified by Solexa sequencing predict sepsis patients mortality: A prospective observational study
Huijuan Wang1,2,3, Pengjun Zhang4, Weijun Chen5, Dan Feng6, Yanhong Jia3, Lixin Xie1,3
1Department of Respiratory Medicine, Hainan Branch of Chinese PLA General Hospital, Sanya, Hainan Province, China; 2Medical College, Nankai University Medical College, Tianjin, China; 3Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 4Department of Clinical Biochemistry, Chinese PLA General Hospital, Beijing, China; 5Chinese Academy of Sciences, Beijing Institute of Genomics, Beijing, China; 6Department of Medical Statistics, Chinese PLA General Hospital, Beijing, China

Background: Sepsis is the leading cause of death in Intensive Care Unit. Novel biomarkers and targets of treatment were still needed to improve the mortality. Our goal of the prospective study was to investigate if serum miRNAs identified in genome-wide scans could predict sepsis mortality.

Methodology/Principal findings: 214 sepsis patients participated in the study. Solexa sequencing followed by qRT-PCR were used to test for differences in the levels of miRNAs between survivors and non-survivors of sepsis patients. miR-223, miR-15a, miR-16, miR-122, miR-193b* and miR-483-5p were significantly differentially expressed, and the area under curve of the six miRNAs predictive mortality value ranged from 0.610 (95%CI, 0.523-0.697) to 0.790 (95%CI, 0.719-0.861). Logistic regression analysis showed that sepsis stage, APACHE II score, miR-15a, miR-16, miR-193b* and miR-483-5p were correlated to the death of sepsis and area under curve of the six variables predictive value was 0.950 (95% Confident interval, 0.919-0.982), which was much higher than APACHE II score, SOFA score, and procalcitonin with area under curve of 0.782 (95% CI, 0.712-0.851), 0.752 (95% CI, 0.672-0.832) and 0.689 (95% CI, 0.611-0.784), respectively. When the cut off point set at 0.526, the predictive value of the six variables provided a 85.2% sensitivity and a 90.4% specificity. In addition, miR-193b* had highest odds ratio of 9.23(95% CI, 1.20-71.16).

Conclusion/Significance: Six miRNAs expression profiles could be used to predict septic mortality. The predictive value was better than the indicators that used in clinical.

P1985
The effect of peer-to-peer feedback on severe community acquired pneumonia
T.K. Lim1, H.F. Lim1, Jason Phua1, Malcolm Mahadevan2
1Medicine, National University Hospital, Singapore; 2Accidents & Emergencies, National University Hospital, Singapore

Delays in intensive care unit (ICU) admission are associated with higher mortality in community acquired pneumonia (CAP). (Phua J, Eur Resp J 2010;36:826). In 2008 we employed minor severity criteria from the 2007 IDSA/ATS guidelines plus point of care lactate to identify high risk patients in the emergency department.

Determining the best diagnostic biomarker for sepsis and prognosis assessment

Lonxue Xie1,2, Linxin Xie1,2, Lin Feng1,2, Qing Song1, Hongjian Kang1, Xiangdong Yang1, Yanhong Jia3, Qiang Jia4, Department of Respiratory Medicine, Hainan Branch of Chinese PLA General Hospital, Sanya, Hainan Province, China; 2Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 3Department of Critical Care Medicine, Chinese PLA General Hospital, Beijing, China; 4Department of Medical Statistics, Chinese PLA General Hospital, Beijing, China

Introduction: Current clinical practice lacks reliable diagnostic indicators for sepsis and its prognosis. Objectives: To describe the value of sTREM-1, CD163, PCT, CRP, WB carriage and SOFA score during the course of sepsis, as well as their value in prognosis. Methods: 130 subjects were picked out in 377 inpatients hospitalized at the RICU, ICU, and EICU. In light of Sepsis Guideline and 28-day survival, the 130 patients were divided into different subgroups. ELISA was applied, and test results were recorded on day 1,3,5,7,10, and 14.

Results: On ICU admission day, the sepsis group display higher levels of sTREM-1, CD163, PCT, and CRP than the SIRS group (180.92 (150.44) pg/ml vs. 29.4 (20.77) pg/ml, p=0.02; 2.36 (2.36) mg/dl vs. 0.88 (0.23) mg/dl, p=0.01). Although PCT, sTREM-1, and SOFA are good markers to identify the severity, sTREM-1 is more reliable. It proves to be a risk factor related to sepsis (OR=1.089, 95%CI,1.045–1.136); its area under the ROC curve, meant for diagnosis, turns out 0.978 (95%CI,0.958–0.997), and that for severity, 0.9 (95%CI,0.823–0.977). For 14-day observation, sCD163, sTREM-1, PCT and SOFA continue to climb among non-survivors, while WBC and CRP go down. Both have a known infectious source after clinical, physical, and imaging studies. Among these patients, 19 (16.2%) had a new diagnosis. In Group 1, 12 patients (14%) had a new infection, including pneumonia (4 patients), bed sore infection (2 patients), pulmon-

Elevated plasma EPCR levels early post ICU admission predict sepsis development

Alice Vassiliou1, Anastasia Kotanidou1,2, Nikolaos Maniatis1,3, Zafeiria Mastora2, Panagiota Albani2, Ioanna Dimopoulou2, Apostolos Armaganidis2,1,2, Xinjie Liang1, Zhixin Liang2, Yanhong Jia3, Dan Feng3, Department of Respiratory Medicine, Hainan Branch of Chinese PLA General Hospital, Sanya, Hainan Province, China; 2Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 3Department of Critical Care Medicine, Chinese PLA General Hospital, Beijing, China

Introduction: The endothelial protein C receptor (EPCR) mediates coagulation and inflammation. Early rise of circulating soluble (s)EPCR levels has been shown to correlate with poor outcome in critically-ill patients with severe sepsis (Guittin et al. Intensive Care Med 2011, 37: 950-6), yet potential associations of sEPCR measured early post ICU admission with subsequent sepsis development are still unknown. Aims: To investigate if sEPCR plasma levels of critically-ill subjects at ICU admission predict subsequent sepsis development.

Methods: 59 critically-ill patients suffering from medical, surgical and trauma-related pathologies were included in the study. Circulating sEPCR levels were measured ≤24h post ICU admission; all patients were free of sepsis. Demographic, APACHE II & SOFA scores were recorded and circulating PCT & CRP were measured.

Results: From the initial cohort, 30 patients subsequently developed sepsis and 29 did not. SOFA score (mean±SD: 6.4±2.7) and sEPCR levels (median & IQR: 173.4±104.5;223.5 ng/mL) were significantly higher in the subsequent sepsis group as compared to the non-sepsis group (5.6±2.3, p=0.037; and 98.3±147.7 p=0.004, respectively). ICU mortality and PCT tended to be higher in the sepsis group. Cox regression analysis identified sEPCR as the only parameter related to sepsis development with time (HR: 1.078 & 95% CI: 1.016-1.144, by 10 sEPCR units, p=0.013). When the whole cohort was dichotomized above (≥139.5) and below the sEPCR median (<139.5), the probability of developing sepsis with time was significantly elevated in the high-sEPCR group (Log-Rank test, p=0.028).

Conclusions: In our cohort, high sEPCR plasma levels at ICU admission (i.e. ≤24h) predict sepsis development.

P1988

Role of gallium-67 scintigraphy in the evaluation of occult sepsis in the medical ICU

Wei-Chun Chen1, Chia-Hung Chen1, Wei Chen1, Yao-Ling Lee1, Chun-Ming Shih1,2, Division of Pulmonary and Critical Care Medicine, China Medical University Hospital, Taichung, Taiwan; 2Division of Pulmonary and Critical Care Medicine, Cha-Yi Christian Hospital, Cha-Yi, Taiwan; 4School of Laboratory and Biotechnology, Chang Shan Medical University, Taichung, Taiwan

Patients in intensive care units (ICUs) frequently have multiple infections or persistent fever despite management. This study was to evaluate the diagnostics in critically-ill patients (≥18 years) who were admitted to our ICU between 01/01/2010 and 31/12/2010. Results: 130 subjects were picked out of 377 inpatients hospitalized at the RICU, ICU, and EICU. In light of Sepsis Guideline and 28-day survival, the 130 patients were divided into different subgroups. ELISA was applied, and test results were recorded on day 1,3,5,7,10, and 14.

Results: On ICU admission day, the sepsis group display higher levels of sTREM-1, CD163, PCT, and CRP than the SIRS group (180.92 (150.44) pg/ml vs. 29.4 (20.77) pg/ml, p=0.02; 2.36 (2.36) mg/dl vs. 0.88 (0.23) mg/dl, p=0.01). Although PCT, sTREM-1, and SOFA are good markers to identify the severity, sTREM-1 is more reliable. It proves to be a risk factor related to sepsis (OR=1.089, 95%CI,1.045–1.136); its area under the ROC curve, meant for diagnosis, turns out 0.978 (95%CI,0.958–0.997), and that for severity, 0.9 (95%CI,0.823–0.977). For 14-day observation, sCD163, sTREM-1, PCT and SOFA continue to climb among non-survivors, while WBC and CRP go down. Both have a known infectious source after clinical, physical, and imaging studies. Among these patients, 19 (16.2%) had a new diagnosis. In Group 1, 12 patients (14%) had a new infection, including pneumonia (4 patients), bed sore infection (2 patients), pulmon-
undertaken in cases of refractory hypoxemia that lasted for 30-45 min. Mechanical ventilation was carried out in 28 (71.8%) patients in the regime of PCV with "aggressive" parameters: PFiO2 - 0.8-1.0, PEEP - 15-20 cm H2O, PIP - 30-40 cm H2O, I - E - 1:1, FiO2 - 50-60% was achieved easily, indicating about preserved lung compliance. All patients required sedation at the beginning of mechanical ventilation in order to synchronize with the respirator. Muscle neuromuscular relaxants was not used. Duration of mechanical ventilation ranged from 7 to 81 days. NIV was excluded from the scheme of SDRS due to inefficiency.

Conclusion: A peculiar form of ARDS, without reducing elasticity of lung tissue, without sepsis, developed in patients with severe viral pneumonia. SDRS consisted of two phases: controlled oxygen therapy and invasive ventilation.

P1990
Overt disseminated intravascular coagulation in severe sepsis associated with specific organ dysfunction and poor survival
Hou-Tai Chang1, Kuo-Pin Chung2, Jih-Shun Cheng1, Chong-Jen Yu1.
1 Department of Pulmonary and Critical Care Medicine, Far Eastern Memorial Hospital, New Taipei, Taiwan; 2Department of Laboratory Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan; 3Department of Internal Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan.

Background: In sepsis, abnormal coagulation cascade cause disseminated intravascular coagulation (DIC). Little is known about the clinical characteristics in overt DIC in severe sepsis.

Objectives: To investigate the clinical features and dysfunction of different organ systems in overt DIC in severe sepsis.

Methods: This prospective observational study was conducted in the medical intensive care unit in a tertiary medical center in Taiwan. Adult patients admitted for severe sepsis would be enrolled. Patients with cirrhosis or advanced malignancies would be excluded. Baseline patient profiles were obtained, including APACHE II and SOFA scores. Overt DIC was defined according to the scoring system from the International Society on Thrombosis and Haemostasis.

Results: From Oct 2009 to Dec 2011, 248 consecutive patients admitted for severe sepsis were screened for the eligibility, and a total of 100 patients were enrolled. The APACHE II and SOFA scores were 25.9±0.8 and 9.9±0.4, respectively. Only 8 patients (8%) had overt DIC. The 28-day mortality was higher in patients with overt DIC than in those without (62.5% vs. 20.7%, P<0.001). Patients with overt DIC had higher SOFA scores than those without (14.1±4.0 vs. 9.5±0.4, P<0.001). Higher hepatic (P=0.003), cardiovascular (P=0.031) and coagulation (P<0.001) SOFA sub-scores were found in patients with overt DIC, while the respiratory, central nervous system, and renal sub-scores were not significantly different without overt DIC.

Conclusions: In our patients with severe sepsis, overt DIC is uncommon, and is associated with organ dysfunction mainly involving hepatic, cardiovascular, and coagulation systems.

P1991
Remifentanil attenuates LPS-induced neutrophil activation
Hyeyun Jeong1, Chihyeong Yun1. 1Department of Anesthesiology and Pain Medicine, Chonnam National University Medical School, Gwangju, Korea; 2Department of Cardiothoracic Surgery, Chonnam National University Medical School, Gwangju, Korea.

Surgical trauma and anesthesia are associated with a complex dysregulation of the immune system with neutrophil activation involving activation of both pro-inflammatory and anti-inflammatory cytokines. Several studies demonstrate that opioids modulate the immune response via opioid receptors expressed directly on the immune cells themselves. Neutrophils play a pivotal role in the coordination and regulation of immune responses. However, the ability of opioid directly participating in LPS-induced neutrophil activation has not been fully examined.

In the present experiment, the effects of various opioids including remifentanil, sufentanil, alfentanil and fentanyl were investigated. Remifentanil only could attenuate activation of neutrophils exposed to LPS. In particular, remifentanil decreased LPS-induced activation of intracellular signaling pathways, including p38 mitogen-activated protein kinase (MAPK) and ERK1/2, and expression of pro-inflammatory cytokines, including TNF-α, IL-6 and IL-8. There was no effect of remifentanil on LPS-induced activation of c-Jun N-terminal kinase (JNK) in neutrophils. These results demonstrate that remifentanil can attenuate LPS-induced neutrophil responses and also suggest that such effects are sufficiently important in vivo to play a major contributory role in neutrophil-mediated inflammatory responses by surgical and anesthetic trauma.

P1992
C-reactive protein (CRP) as a marker of disease severity in community acquired pneumonia patients with sepsis
Sanjukta Das1, Himayatullah Khan2, Dinesh Babu2, Vivek Gupta2, Ajith Rajagopal2, Anne Pramod2, Har1, Pulmonology, Ahania Hospital, Abu Dhabi, United Arab Emirates; 2Cardiology, Ahania Hospital, Abu Dhabi, United Arab Emirates; 3Anaesthesiology, Ahania Hospital, Abu Dhabi, United Arab Emirates.

Introduction: C - Reactive Protein (CRP), an early sensitive marker of inflamm-

ation is studied extensively in various common medical disorders. Until recently CRP measurement was not studied widely in Pneumonia. We intended to study its usefulness for assessment of disease severity in patients of Community acquired Pneumonia (CAP) with Sepsis.

Objective: To evaluate the utility of C - Reactive Protein as a marker of disease severity in patients of Community acquired pneumonia with Sepsis.

Methods: Study design: Prospective observational study.

Setting: 12 bedded ICU of a multi speciality hospital in Abudhabi, UAE.

Subjects: 40 patients admitted during June 2010 - January 2012, fulfilled the study criteria.

CAP and Sepsis were defined based on the ATS and ACCP/SCCM 1992 criteria respectively.

Results: Patients were divided into two groups, Group A with CRP < 300 mg/L and Group B with > 300 mg/L. Total mean age being 36.5 and 42.6 years respectively. Characteristics of disease severity were compared in both the groups.

Presentation of septic shock, severe sepsis and multiorgan dysfunction was significantly higher in group B (p< .05). Mean CRP value among nonsurvivors was 355.33 mg/L and 257.56 mg/L among survivors (p< .05).

Conclusion: CRP value of greater than 300 mg/L within first 48 hours of admission to ICU appears to be a good marker of disease severity in patients of Community acquired pneumonia with Sepsis and may be useful to identify high risk patients.

P1993
Impact of experience and education in treatment of adult respiratory distress syndrome (ARDS) using extracorporeal membrane oxygenation (ECMO)
To Woon Kim, Sang Bum Hong, Younsook Koh, Chue Min Lim, Jin Won Huh. Department of Pulmonology and Critical Care Medicine, Asan Medical Center, Seoul, Korea.

Background: Extracorporeal membrane oxygenation (ECMO) is a form of long-term cardiopulmonary bypass and recently have been used to treat adults with respiratory or cardiac failure despite maximal medical therapy. ECMO is a high risk procedure with 25% of mortality rate.

The previous a few studies showed that improving equipment and increased experience to manage ECMO are important to patient survival and improving results. ECMO training program is important in solving significant, life-threatening problems that can occur during ECMO application.

Aims: The aims in this study are to show our experience of ECMO management and reduction in mortality rate according to an accumulation of experience and knowledge.

Methods: A nonrandomized retrospective study was performed.

Results: In 2009-2011, ECMO was applied to 82 patients. Veno-venous and veno-arterial ECMO was 63.4% and 36.6%, respectively ECMO was applied to 47 patients in 2009–2010 and 35 patients in 2011. The most common cause of ECMO application was pulmonary problem.

The most common complication of ECMO was bleeding and the most common cause of death was pneumonia. 41.5% of patients were weaned off the ECMO.

Intensive care unit mortality was higher on 2009–2010 than on 2011 (84.9% vs 57.1%, OR 3.106, CI 1.235-7.812, p<.05). Hospital mortality was higher on 2009–2010 than on 2011 (89.4% vs 57.1%, OR 3.106, CI 1.235-7.812, p<.014).

Conclusion: According an accumulation of experience and knowledge, mortality was reduced in 2011 compared to 2009-2010.

P1994
Predictors of mortality in cancer patients requiring intensive care support: Two-centered cohort study
Durun Tatik1, Ozlem Yazicioglu Meqcin1, Pinar Cimen1, Zuhal Karakurt1, Cenk Kizilk1, Gokay Gungor2, Ozlem Ediboglu3, Nalan Adiguzel2, Emel Telligulu1, Caneyt Salurk1, Merih Balci1. 1Intensive Care Unit, Dr. Suat Seren Chest Diseases and Surgery Education and Training Hospital, İzmir, Turkey; 2Intensive Care Unit, Suryeyapapsa Chest Diseases and Surgery Education and Training Hospital, İstanbul, Turkey.

Aim: Acute respiratory failure (ARF) can be developed in cancer patients due to disease progression or as a complication of treatment. In our study we aimed to identify the factors associated with mortality in cancer patients admitted to the intensive care unit (ICU) due to ARF.

Method: A retrospective-cohort study was planned in two ICUs of training hospital of chest diseases between January 2008 and december 2011 period. Demographic data, type of cancer, cause of ARF, comorbid disease, APACHE II value, type of
P1995

Prognosis of patients with active tuberculosis requiring intensive care unit

Filiz Kosar1, Levent Dular1, Emel Eryukse1, Sibel Yurti1. 1Chest Diseases and Intensive Care Unit, Yedikule Chest Diseases and Chest Surgery Education and Research Hospital, Istanbul, Turkey, 2Chest Diseases and Intensive Care Unit, Marmara University/Medical Faculty, Istanbul, Turkey.

Tuberculosis remains an important health problem. The aim of this study to determine the mortality rate of patients with active tuberculosis requiring intensive care unit. We conducted an observational study. Patients with confirmed active tuberculosis admitted to our ICU from May 2010 and January 2012 were identified and enrolled. Clinical data and mortality rate were recorded. A total of 19 tuberculosis patients admitted to ICU were included. Mean Age ± SD 37 ± 18 years. Twelve patients (63%) required mechanical ventilation. The mortality was 12 of 19 (63%). The reasons associated with ICU admission were massive hemoptysis in two patients, empyema in one patient, active tuberculosis and sepsis in nine patients, tuberculous meningitis in one patient and tuberculosis in others. High APACHE II score and invasive mechanical ventilation use were significantly associated mortality (p = 0.005 vs p = 0.004, r = 0.74).

These data indicate a high mortality of patients with tuberculosis requiring intensive care unit and further studies needed to determine associated risk factors.

P1996

Extracorporeal membrane oxygenation as bridge in patients with non-iatrogenic massive hemoptysis

Jae-Hong Yoo1, Hee-Sung Kim2, Hong Mo Kang2, Cheon Woong Cho1, Myung Jae Park2, Jong Hoo Lee3. 1Pulmonary and Critical Care Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea; 2Pulmonary and Critical Care Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea; 3Pulmonary and Critical Care Medicine, Jeju National University Hospital, Jeju, Republic of Korea.

Despite advanced technologies in intensive care, massive hemoptysis can cause death in a small subset of patients. In special, extensive bleeding, hypoxia, decreased pulmonary function and/or other co-morbidities make it more difficult or impossible to perform bronchoscopy, arterial embolisation or resectional surgery. Extracorporeal membrane oxygenation (ECMO) is expected to provide adequate gas exchange, to reduce ventilator-induced lung injury and, eventually, to improve outcome in patients with respiratory and circulatory failure. However, it is not sure whether it is beneficial or not to perform ECMO in unstable patients with non-iatrogenic massive hemoptysis. The case applying ECMO to patients with iatrogenic massive hemoptysis is also very rare. A male with medical history of pulmonary tuberculosis received mechanically ventilator support because of severe community acquired pneumonia. As he abruptly showed severe hypoxemia and hypotension due to massive hemoptysis, ECMO was instituted. We herein describe detailed course of our case, helping physicians make a decision to initiate ECMO in patients with non-iatrogenic massive hemoptysis.

P1998

Clinical outcome and prognostic factors of acute respiratory failure due to pneumocystis pneumonia in non-HIV patients

Young-Jo Ko, Kyungsung Jeem, Division of Pulmonary and Critical Care Medicine, Samsung Medical Center, Seoul, Republic of Korea.

Pneumocystis pneumonia is a potentially life-threatening infection that occurs in immunocompromised individuals. While it is well-known that the clinical course of PCP in non-HIV patients differs in HIV-positive patients. But, the ICU mortality of patients with acute respiratory failure requiring mechanical ventilation dose not well be known. The objective of this study was to examine the outcome and prognostic factors of ICU mortality in patients with acute respiratory failure caused by Pneumocystis pneumonia.

We conducted a five-year retrospective review (from October 2005 to December 2010) of all patients who had histologic evidence in the non-HIV patients. Of the 44 adult patients investigated, 25 patients (56%) had solid or hematologic malignancies. 17 (33%) were known to have previous HIV infection. The mortality was 18 (41%) of 44 patients. Median APACHE II score was 139 (IQR: 116-187), SAPS 3 score on day 1 was 46 (IQR:36-58) and SOFA score on day 1 was 7 (IQR:5-9). The ICU mortality was 15 (34%) of 44 patients. Mortality was higher in female patients (p = 0.05).

Conclusion: PCP is a serious disease with a high mortality, and early treatment is essential. The survival rate of patients with acute respiratory failure due to PCP requires further study.

P1999

Inhaled colistin on Acinetobacter baumannii treatment

Gustavo Coimbra dos Reis1, Ana Martins2, Luís Bento3. 1Pulmonology Department, CHIRM, EPE, Barreiro, Portugal; 2Unidade de Urgência Médica, Hospital São José, CHLC, EPE, Lisboa, Portugal.

Introduction: Ventilator associated pneumonia and tracheobronchitis (VAP/VAT) due to multiresistant A. baumannii are preeminent causes of mortality and morbidity at ICU. Inhaled antibiotics, allowing high antibiotic concentrations at Airways and secretions, are described as an alternative or complement to systemic therapy.

Objectives: Primary – microbiology outcome on A. baumannii VAP/VAT treatment with inhaled colistin; loss of polymyxin sensitivity after inhaled colistin. Secondary – characterization of clinical outcome; of the A. baumannii isolated; of inhaled colistin use; of systemic antibiotic co-administration; of ICU and hospital mortality.

Material and methods: Observational, longitudinal, retrospective study, through file consult, of patients admitted at UUM from 01/2005 to 12/2011, with A. baumannii VAP/TAV, treated with inhaled colistin.

Results: 23pts included, 18 male, mean age 70±18 yrs, with mean ICU admission APACHE II and SAPS II score of 23 and 54. Microbiologic eradication was achieved on 19 (83%), with 4 relapses. At failure to eradicate or relapse no change was observed on resistance profile. Clinically, there was a positive evolution of SAPS II and SOFA score in 22 pts (95.7%) and in 1 patient (4%) respectively. There was no observed resistance profile.

Conclusions: Clinical outcome and microbiology outcome on A. baumannii VAP/TAV treatment with inhaled colistin was better than previously described in the literature. The treatment was efficacious and safe.
Intensive care unit acquired pneumonia with or without etiologic diagnosis: A comparison of outcomes

Valeria Giunta1,2, Marcelo Mercier 1,2, Mariano Esperatti 1,2, Otavio Tavares Ranzani1,2,3, Lina Maria Saucedo1,2, Guiang Liu Li Bassi1,2, Francesco Blasi1,3, Antoni Torres1,3,1. Servei de Pneumologia, Institut del Torai, Hospital Clinic, IDIBAPS. Universitat de Barcelona, Barcelona, Spain; 2 Centro de Investigación Biomédica en Red-Enfermedades Respiratorias, CibeRe, CR06/06/0028, Barcelona, Spain; 3. Respiratory Intensive Care Unit, Hospital das Clínicas, Faculdade de Medicina da Universidade de São Paulo, SP, Brazil; 4. Departamento Toraco-Pulmonar e Cardiocircolatorio, Università degli Studi di Milano, IRCCS Fondazione Ca Granda, Milan, Lombardia, Italy.

Background: The impact of intensive care unit acquired pneumonia (ICU-AP), without etiologic diagnosis, on patient outcomes is largely unknown.

Objective: To compare the clinical characteristics, inflammatory response and outcomes between patients with or without microbiologically confirmed ICU-AP.

Methods: We prospectively collected 270 patients with ICU-AP. Patients were clustered according to positive or negative microbiologic results. We compared the baseline characteristics and outcomes between groups.

Results: ICU-AP without etiologic diagnosis was found in 82 (38%) patients. In comparison with patients with microbiologically confirmed ICU-AP, patients without etiology presented more frequently chronic renal failure (15, 18% vs. 11, 6%, P=0.003), chronic heart diseases (35, 43% vs. 55, 29%, P=0.044), higher hypoxemia (PaO2/FiO2 165±73 vs 199±79 mmHg, p=0.001) and shorter intensive care unit (ICU) stay before the onset of pneumonia (5±5 vs 7±9 days, p=0.001).

The systemic inflammatory response was similar between groups. Despite similar severity at the ICU admission and onset of pneumonia, in patients with microbiologically confirmed ICU-AP there was higher in-hospital (84, 45% vs. 25, 31%, p=0.040), and 90-day mortality (87, 51% vs. 28, 36%, p=0.043).

Conclusion: Microbiologically not confirmed ICU-AP develops earlier and it is associated with better outcomes and specific underlying comorbidities that increase the risk of pulmonary edema, ultimately suggesting a potential misdiagnosis.

P2001

Post-resuscitation central venous pressure and serum lactate associated with survival in severe sepsis and septic shock

Koo-Pin Chang1, Hou-Tai Chang1, Jih-Shuin Cheng2, Chong-Jen Yu3.

1. Department of Laboratory Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan; 2. Department of Pulmonary and Critical Care Medicine, Far Eastern Memorial Hospital, New Taipei, Taiwan; 3. Department of Internal Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan.

Background: The survival in severe sepsis and septic shock is improved by quantitative resuscitation, with goals as mean arterial pressure (MAP), central venous pressure (CVP), oxygen saturation of central venous blood (ScvO2), and lactate clearance.

Objectives: To investigate whether post-resuscitation MAP, CVP, ScvO2, and lactate level predict the survival in severe sepsis and septic shock.

Methods: This prospective study was conducted in two tertiary medical centers in Taiwan. Adult patients admitted for severe sepsis or septic shock would be enrolled. Patients with cirrhosis or advanced malignancies were excluded. All patients received initial hemodynamic resuscitation before ICU admission. We evaluated the association between 28-day survival and post-resuscitation MAP, CVP, ScvO2, and lactate level.

Results: A total of 124 patients were enrolled from Aug 2009 to Dec 2011. The APACHE II and SOFA scores were 25±3±0.7 and 9.9±2.3, respectively. The 28-day mortality was 26.6%. Multi-variate logistic regression analyses showed that CVP (P<0.010) and serum lactate (P<0.011) were associated with 28-day mortality. Post-resuscitation hemodynamic scores were established with two subscores: CVP (1 if ≥13.5 mmHg) and serum lactate level (1 if ≥5.3 mmol/L). Higher post-resuscitation hemodynamic scores were associated with higher APACHE II and SOFA scores (P<0.001 and <0.001 by Kruskal-Wallis test, respectively), and higher risk of 28-day mortality (hazard ratio 3.14, P<0.001 by logistic regression).

Conclusions: In our patients with severe sepsis and septic shock, high post-resuscitation CVP and serum lactate were associated with organ dysfunction and high mortality.

Background: Infection complications are frequent after cardiac arrest and a few reports have demonstrated that infections may be even more frequent after therapeutic hypothermia. Pneumonia is the most frequent infectious complication in these patients.

Objectives: We investigated the effect of antibiotic prophylaxis on the development of pneumonia in cardiac arrest patients treated with therapeutic hypothermia.

Methods: We retrospectively reviewed medical records of patients who admitted for therapeutic hypothermia after resuscitation of out-of-hospital cardiac arrest between January 2010 and December 2011. Patients dying within the first 72 hours were excluded.

Results: Out of the 46 patients admitted after cardiac arrest, 31 patients were analyzed and 24 patients (77%) were treated with prophylactic antibiotics within the 24 hours. The frequency of pneumonia in the first three days (early pneumonia) and after the third day (late pneumonia) was not significantly different between the prophylactic antibiotics group and the control group (33.3% vs 11.1% for early pneumonia, P=0.639; 50% vs 18.6% for late pneumonia, P=0.412). And the antibiotic prophylaxis did not also influence the length of ICU stay (19.4 days in the prophylactic antibiotics group vs 16.4 days in the control group, P=0.659) and of mechanical ventilator (17.3 days in the prophylactic antibiotics group vs 12.7 days in the control group, P=0.372).

Conclusion: Antibiotic prophylaxis in cardiac arrest patients treated with therapeutic hypothermia did not reduce the frequency of pneumonia.
