Structural brain changes related to disease duration in patients with asthma
Andreas von Leupoldt¹,², Stefanie Brassen², Hans Jörg Baumann³, Hans Klöse³, Christian Büchel¹,². Department of Psychology, University of Hamburg, Hamburg, Germany; ²Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; ³Department of Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Dyspnea is the impairing, cardinal symptom patients with asthma repeatedly experience over the course of the disease. However, its accurate perception is also crucial for timely initiation of treatment. Reduced perception of dyspnea is associated with negative treatment outcome, but the underlying brain mechanisms of perceived dyspnea in patients with asthma remain poorly understood. We examined, whether increasing disease duration of asthma is related to structural brain changes and studied the associations between structural brain changes and perceived dyspnea.

By using magnetic resonance imaging in combination with voxel-based morphometry, gray matter volumes of the insular cortex and brainstem periaqueductal grey (PAG) were examined in fourteen patients with mild-to-moderate asthma and correlated with asthma duration and perceived affective unpleasantness of resistive load induced dyspnea.

Whereas no associations were observed for the insular cortex, longer duration of asthma was associated with increased gray matter volume in the PAG. Moreover, increased PAG gray matter volume was related to reduced ratings of dyspnea unpleasantness.

The present results demonstrate that increasing disease duration is associated with increased PAG gray matter volume in patients with mild-to-moderate asthma. This structural brain change might contribute to reduced perception of dyspnea in some patients with asthma and, thus, negatively impact treatment outcome.

**P2224**
The impact of obstructive sleep apnea on glucose regulation and liver injury in nondiabetic men
Qian Xiaosen, Liu Yi. Pulmonary Internal Medicine, Civil Aviation General Hospital, Beijing, China

**Objective:** We explored the effect of Obstructive sleep apnea syndrome (OSAS) on glucose regulation and liver injury in nondiabetic men.

**Research design and methods:** We enrolled 49 non-diabetic men of the OSAS patients without concomitant diseases/medications based on overnight polysomnography and blood tests. We measured fasting serum glucose (FPG), fasting insulin (FIS), C-reactive protein (CRP), liver enzymes such as alanine aminotransferase (ALT) and lactate dehydrogenase (LDH) and calculated new homeostasis model assessment estimates of insulin resistance (HOMA2-IR), insulin sensitivity (HOMA2-IS) and pancreatic beta-cell function (HOMA2-B).

**Results:** Median fasting insulin level, HOMA2-IR, and HOMA2-IR of the severe OSAS group were significantly higher than those of the other OSAS subgroups. OSAS patients. Subjects were stratified according to OSAS severity, and lipid profiles were compared between groups. The relationship between OSAS severity and metabolic health was examined using a hierarchical multivariate linear regression model. 239 subjects were studied. Those with severe OSAS were more obese, more likely to be male, and younger than those with mild-moderate disease. No significant difference was seen in total cholesterol, LDL-cholesterol, or serum triglycerides with OSAS severity. HDL-cholesterol was lower in subjects with severe OSAS (mild-moderate 1.8 mmol/l vs. severe 1.01 mmol/l; p<0.001). In univariate analysis, LDL level correlated inversely with apnoea/hypopnoea index (AHI) (r = 0.323; p = 0.001). This relationship persisted following adjustment for demographic, anthropometric, and other metabolic variables (r = 0.26; p = 0.043).

Interestingly, this relationship was stronger for AHI than for markers of nocturnal oxygenation.

OSAS severity is independently associated with dyslipidaemia. Mechanistic studies examining the interaction of OSAS with obesity and adipose tissue function are required.

**P2225**
Obstructive controlled blood pressure values in a population with obstructive sleep apnea syndrome (OSA) and arterial hypertension (HT)
Oana Claudia Deleanu¹, Andrea Elena Mălău², Ramona Elena Nedelcu², Ruxandra Ulmeanu², Ion Mierlus-Mazile², Florin Dumitru Mihaltan²,³
¹Pneumology III, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; ²Pneumology III, Institute of Pneumology “Marin Nasta”, Bucharest, Romania; ³Pneumology III, Faculty of Medicine and Pharmacy, Oradea University, Bucharest, Romania; ⁴Statistical Laboratory, Technical University of Civil Engineering, Bucharest, Bucharest, Romania

**Methods:** We analysed 162 OSA patients with treated HT, 46.9% with controlled BP (cBP), 53.1% with uncontrolled BP (uBP), and studied differences between groups regarding demographics, anthropometric data, symptoms, comorbidities, sleep study’s reports, therapy. We used SPSS (T, chi test).ListenRead phonetically.

**Results:** 76 cBP patients: 22 (28.9%) women, 54 (71.1%) men, mean age 56 ± 10.8 years, average apnea-hypopnea index (AHI) 49.5 ± 56.5; 86 uBP patients: 20 (%) women, 66 (%) men, mean age 55.3 ± 8.9 years, average AHI 58.1 ± 38.7. Statistically significant differences (p < 0.05): Ewpoor sleepiness score (970.5±61 in cBP group vs 11.65±6.51), snoring, morning headache, nocturnal dyspnea - more common in uBP group, nicturia - more common in cBP group, period elapsed since diagnosis (higher for uBP), AHI postCPAP (13.5±13.3 vs 21.5±19.9 cm H2O for uBP), explained by the higher proportion of CPAP usage among cBP (12.8% vs 5.2%). The hypothesis regarding existing differences related to the carcovascular comorbidities is not supported.

**Conclusions:** Controlled blood pressure deletes sleepiness and reduces some other symptoms. The results are that OSA is a more difficult to suspect in these patients, who, according to the results of this study, would benefit more from CPAP therapy. OSA may coexist in patients with HT controlled by medication in the absence of symptoms or signs and the patient, mostly young or middle-aged adult, cannot receive adequate treatment.

**P2226**
Severity of sleep-disordered breathing is an independent predictor of metabolic dysfunction in a population with obstructive sleep apnea
Brian Koen¹, Drzide Fitzgerald¹, Audrey Russell¹, Lynda Hayes¹, Geraldine Nolan¹, William McNicholas¹,². ¹Pulmonary and Sleep Disorders Unit, St. Vincent’s University Hospital, Dublin, Ireland; ²School of Medicine and Medical Science, University College Dublin, Dublin, Ireland

People with obstructive sleep apnoea syndrome (OSAS) are at increased risk of insulin resistance, dyslipidaemia, and adverse cardiovascular outcomes. However, obesity is a major confounding factor in studies examining the impact of OSAS on the development of these sequelae. It remains uncertain if sleep-disordered breathing is an independent driver of metabolic dysfunction.

We sought to assess the influence of OSAS severity on metabolic health by prospectively studying the fasting lipid & glycemic profiles of newly diagnosed OSAS patients. Subjects were stratified according to OSAS severity, and lipid profiles were compared between groups. The relationship between OSAS severity and metabolic health was examined using a hierarchical multivariate linear regression model. 239 subjects were studied. Those with severe OSAS were more obese, more likely to be male, and younger than those with mild-moderate disease. No significant difference was seen in total cholesterol, LDL-cholesterol, or serum triglycerides with OSAS severity. HDL-cholesterol was lower in subjects with severe OSAS (mild-moderate 1.8 mmol/l vs. severe 1.01 mmol/l; p<0.001). In univariate analysis, LDL level correlated inversely with apnoea/hypopnoea index (AHI) (r = -0.323; p<0.001). This relationship persisted following adjustment for demographic, anthropometric, and other metabolic variables (r = 0.152; p = 0.043). Interestingly, this relationship was stronger for AHI than for markers of nocturnal oxygenation.

OSAS severity is independently associated with dyslipidaemia. Mechanistic studies examining the interaction of OSAS with obesity and adipose tissue function are required.

**P2227**
Effect of CPAP treatment on endothelial function, inflammatory markers, blood pressure and glucose control in patients with OSAS with emphasis on gender differences
Athanasios Panoutopoulos¹, Anastasios Kallianos¹, Apostolis Pappas¹, Lemonia Velenzata¹, Christos Mermigkis¹, Konstantinos Kostopoulos¹, Vasileios Kouranou⁴, Angekili Rapti⁴, Elieni Koufogiorga⁴, Alexandros Mittakos², Charalampos Kostopoulos², Nikolaos Zakopoulos², Ioannis Nikolopoulos⁵. ¹Clinic of Thoracic & Cardiovascular Surgery, General Hospital of Athens “Sotiria”, Athens, Greece; ²3rd Pulmonary Clinic, 401 Army General Hospital, Athens, Greece; ³5th Pulmonary Clinic, General Hospital of Athens “Sotiria”, Athens, Greece; ⁴Clinic of Respiratory Failure, General Hospital of Athens “Sotiria”, Athens, Greece

**Introduction:** Research evidence suggests the presence of endothelial dysfunction...
and systemic inflammation in patients with obstructive sleep apnea syndrome (OSAS). The effects of CPAP on the aforementioned pathophysiologic pathways, as well as on the systemic disease that result or coexist with the OSAS remain elusive.

Aim: To assess the effect of CPAP therapy on endothelial-dependent dilation, plasma levels of inflammatory markers, blood pressure and glucose control in male and female patients with OSAS.

Methods: Our study group consisted of 40 patients with no prior history of cardiovascular disease, with an Apnea-Hypopnea Index (AHI) > 15 who were assigned to receive CPAP treatment. Measurements of Flow Mediated Dilation (FMD), 24-hour ambulatory blood pressure (BP) and blood analysis were performed at baseline and 3 months after CPAP therapy.

Results: Baseline FMD values were negatively correlated the AHI (r=0.55, p=0.001). After 3 months of CPAP there was a significant increase in the FMD values and a significant reduction in the patients’ 24hr systolic BP, diastolic BP and Pulse Pressure (PP), daytime systolic and diastolic BP, nighttime systolic BP and 24-hour mean systolic BP. When divided by gender, only male patients produced similar statistically significant results.

Conclusion: Our results suggest that CPAP therapy improves the endothelial function, the blood pressure and glucose control in male patients with OSAS. Further research is warranted in order to further elucidate the impact of CPAP on the cardiovascular risk of male and female patients with OSAS.

P2228
Endothelial function in obstructive sleep apnea syndrome
Evangelos Markozannes, Fotis Kapsimalis, Yannis Andrikidou, Konstantina Kyrkou, Konstantina Kosta, Manos Alachanis. 1st Respiratory Medicine Department, Sotiria Hospital, University of Athens, Athens, Greece

Introduction: Obstructive sleep apnea (OSA) is an independent risk factor for myocardial infarction and stroke. Endothelial dysfunction could be one of the pathogenetic mechanisms linked to OSA related risk for cardiovascular diseases.

Methods: We included 38 patients by polysomnography in the laboratory, 27-86 years with newly diagnosed AHAs (AHI≥15), free of known chronic diseases.

Endothelial functioning assessed by the reactive hyperemia peripheral arterial tone index (RH-PAT index) and the levels of urine albumin/creatinine ratio (ACR) testing for microalbuminuria.

Results: 24 out of 38 patients who had abnormally low RH-PAT defined as an index < 1.65 were compared with 13 OSA subjects with normal RH-PAT (1.4±0.1 vs. 2.1±0.5, p=0.01). They were slightly older (51±14 years vs. 43±3.1 years, p=0.09), with similar BMI (33.6±1.8 kg/m2 vs. 38.1±1.9 kg/m2, p=0.13), lower AHAs (28±23.4 vs. 49±24.9, p=0.02) and higher minimal SaO2 (80.7±6.9% vs. 71.7±7.7%, p=0.03). There was no correlation between RH-PAT with Epworth Sleepiness Scale. ACR was higher in patients with low RH-PAT index (7.92±2.7 mg/g vs. 4.7±2.5 mg/g, p=0.02) but without microalbuminuria per se (defined as ACR ≥ 30 mg/g).

Multiple regression analysis showed that the value of ACR was the most significant factor for RH-PAT variance (adjusted R2 =0.23, p=0.008, beta=0.450, p<0.01). The morning RH-PAT index was lower in patients over the age of 50 years (1.55±0.3 vs. 1.76±0.6, p<0.05).

Conclusion: Our findings suggest that the AHI is not related with markers of endothelial dysfunction. The harmful consequences of OSAS might be more prominent in the elderly and obese patients.

P2229
The lack of evidence based knowledge of metabolic syndrome in obesity hyperventilation syndrome
Alonda T, Alcvin M, Maller, Folkert Brijker. Pulmonary Diseases and Internal Medicine, Diakonessenhuis, Utrecht, Netherlands

Introduction: The obesity hyperventilation syndrome (OHS) is a severe sleep related breathing disorder, with obstructive sleep apnea syndrome (OSAS) as the predominant sleeping pattern. It is often accompanied by multiple organ tract involvement. In OSAS, the interaction with metabolic syndrome is well studied. We evaluated the presence of evidence based knowledge.

Methods: A Systematic PubMed and Cochrane search was performed, final check 24th February 2011, for metabolic syndrome in concurrence with OSAS and OHS, and related terms and synonyms in title and abstract (exclusion criterion: duplicates). The final data set was achieved by elimination of studies that contained predefined criteria: animal studies < 1990, age < 18 years, genetic diseases, case reports, and studies without original data. Outcome parameters were total number of studies and randomized controlled trials (RCT), before and after the elimination strategy, for OSAS versus OHS.

Results: 767 initial hits were found in OSAS, versus 273 for OHS. After the predefined elimination strategy, 171 remained, containing 5 RCT’s for OSAS, versus 6 studies, without any RCT, for OHS (Fischer exact p=0.0001 for final total number and p<0.05 for RCT’s).

Conclusion: A markedly lower number of hits was found for metabolic syndrome in OHS, as compared to OSAS. Within the complexity of clinical features in OHS, the metabolic syndrome seems to be an unexplored area in research.

P2230
C-reactive protein (CRP) levels in obstructive sleep apnea (OSA) patients and relation to severity of OSA
Juan-Jose Garrido1, Daniel Fernandez-Berges2, Francisco-Javier Felix3, Maria-Jose Zar01. 1Respiratory, Don Benito Hospital, Don Benito, Badajoz, Spain; 2Investigation Unit Don Benito-Villanueva, Fundasudal; Gerencia de Area Don Benito-Villanueva, Villanueva de la Serena, Badajoz, Spain; 3Primary Care, North Villanueva Primary Care Center, Villanueva de la Serena, Badajoz, Spain; 4Laboratory, Don Benito Hospital, Don Benito, Badajoz, Spain

Introduction: CRP has been proposed as a cardiovascular risk marker. OSA is associated to metabolic syndrome and major cardiovascular events.

Objectives: To study CRP levels in OSA patients in comparison to healthy people, and the relationship between severity of OSA and CRP levels.

Method: Case-control study including 100 consecutive diagnosed OSA patients and 113 healthy people randomly selected from general population. Age, sex, hypertension, diabetes, dementia, body mass index (BMI), smoking, Epworth scale, spirony, respiratory disturbance index (RDI) and high sensitivity CRP (hsCRP) were recorded.

Results: Cases and controls characteristics are shown in Table 1.

Conclusion: Although OSA patients shows slightly higher levels of hsCRP than healthy people in our sample, other factors rather than severity of OSA measured by the RDI influence that issue.

P2231
Efficacy of BiPAP AutoSV advanced in subjects with congestive heart failure and central apnea
Winfried J. Randarh1, Jr., Barnerje2, M, Treml1, W, Galete3, C, Priergib3, A. Ali4, S, Taheri1, S. Institut för Pneumologi, Krankenhaus Bethanien gGmbH, Solingen, Germany; 2Department of Respiratory Medicine, Birmingham Heartland Hospital, Birmingham, United Kingdom

Introduction: Auto-Servo Ventilation effectively suppresses Sleep Disordered Breathing (SDB) in patients with Congestive Heart Failure (CHF). This study compared the efficacy of a new mode of AVP that incorporates an automatic BiPAP (ASV-Advanced), with and without its Bi-Flex comfort feature, to manually titrated ASV (ASV) in patients with central SDB and CHF.

Methods: Following diagnostic PSG and titration, patients underwent 3 consecutive treatment nights in a random order: ASV, ASV-Advanced and ASV-Advanced with Bi-Flex. For the ASV night, EPAP was set to the level determined during the titration night and IPAP set at EAP+20cmH2O. For the ASV-Advanced nights, the

Metabolic and inflammatory profile in obese and non obese children with obstructive breathing disorders

Silke Weber1, Érico Moreira 1, Renata Mizusaki Iyomasa 1, Ana Almeida1, Przemyslaw Bielen 1, Luiza Jonczak 1, Dorota Gorecka 2, Pawel Sliwinski1.

1Department of Respiratory Failure, National TB and Lung Diseases Research Institute, Warsaw, Poland; 22nd Department of Respiratory Diseases, National TB and Lung Diseases Research Institute, Warsaw, Poland

Introduction: Obstructive sleep apnoea (OSA) is an unexplored in children. Obesity, an important cofactor, is increasing in the pediatric population. Aim: To study the metabolic profile and the levels of TNF-α in in obese and non obese children with obstructive breathing disorders.

Methods: Children of both genders, aged 6 to12 years, with obstructive breathing disorders were included. Children were divided in 2 groups, non obese and obese (Z score > +2) direspiratory sleep study. In the morning after the sleep study, blood samples were taken for analysis. The lipids, glucose, insulin, tyroxin and TNF-α levels were determined. Results were compared for the 2 groups.

Results: 17 children, median age of 6.5 years, 10 obese- and 7 non obese, were included. There glucose level was 85 mg/dL in both groups. Insulin level was higher in the obese group (10,7 ± 2.3 μM/L in the obese and 9,9 ± 2.7 μM/L in non obese, respectively). TGL levels were higher in the obese group (106.5 ± 37 mg/dL, X 6.4 ± 2.3 mg/dL). Thyroxin and TSH levels did not differ in both groups. The average TNF-α was 0,36 ± 0,09 pg/mL, but differed in obese 0,56 ± 0,33 pg/mL and 0,07 ± 0,07 pg/mL in the non obese patients.

Conclusion: Obesity may cause additional metabolic changes (increased insulin resistance and TGL levels) in children with obstructive breathing disorders. The metabolic inflammatory profile must be investigated for a better understanding of OBD in childhood.

P2233

Cognition, quality of life and adherence to CPAP after 18-months treatment in obstructive sleep apnea patients

Vincenza Castronovo1, Sara Marelli1, Renata Mizusaki Iyomasa 1, Ana Almeida1, Przemyslaw Bielen 1, Luiza Jonczak 1, Dorota Gorecka 2, Pawel Sliwinski1.

1Department of Respiratory Failure, National TB and Lung Diseases Research Institute, Warsaw, Poland; 22nd Department of Respiratory Diseases, National TB and Lung Diseases Research Institute, Warsaw, Poland

Objective: To evaluate neurocognitive functions, adherence to PAP and QoL in Obstructive Sleep Apnea (OSA) patients.

Methods: We anlysed 34 patients via polysomnography and simultaneous beat to beat measurement of systolic (Sys) and diastolic (Dia) blood pressure (BP) (Nexfin®HD). Group1: apnea/hypopnea index (AHI) 0-15/h, n=16; Group2: AHI >15/h, n=18. All results during 10 min. stable N2 sleep were calculated after data export using the SPSS software. A p<0.05 was considered significant.

Conclusions: Prevalence of impaired glucose tolerance in OSA subjects was high (more than 25%). IGT in OSA pts was related to higher incidence of arterial hypertension, elevated plasma fasting glucose and HbA1c concentration. There were no any significant correlations between AHI, BMI, overnight desaturation or other diseases and results of OGGT.

P2234

Association between arterial hypertension and impaired glucose tolerance (IGT) in obstructive sleep apnea (OSA) patients

Robert Fwyvaczelewski1, Puzemyslaw Bieni1, Łuiza Jonczak 1, Dorota Gorecka2, Pawel Świński1, 1Department of Respiratory Failure, National TB and Lung Diseases Research Institute, Warsaw, Poland; 22nd Department of Respiratory Medicine, National TB and Lung Diseases Research Institute, Warsaw, Poland

Obstructive sleep apnea is a risk factor of cardiovascular and metabolic disturbances. The aim of this study was to assess relationship between IGT and AHI, obesity and cardiovascular diseases in OSA subjects. We studied 255 OSA pts (195 males (76.5%) and 60 females (23.5%); mean age: 56 ± 10.7 years, AHI > 20.5, BMI = 33 ± 8.5 kg/m², SatO2 ≥ 97 ± 4.7%, T90 19-1 ± 5.2%). Impaired glucose tolerance (IGT) (plasma level ≥ 140 mg/dL after 2 hours of administration 75 g glucose in oral glucose tolerance test (OGTT)) was found in 69 subjects (27.1%). In 11 patients (4.3%) OGTT confirmed diabetes (glucose ≥ 200 mg/dL). Comparison of OSA patients with- and without IGT is shown in the table.

Discussion: We couldn’t show, that in OSA patients during a short period of sleep changes of the BP are not directly correlated with the expected sleep or respiratory parameters but with the variation of blood pressure values. The relevance of this result for the development of hypertension remains to be proven.

Perception of problems driving and driving simulator performance in obstructive sleep apnea syndrome (OSAS)

Dipankar Chosh, Subhajit Sen, Saurabh L. Jain, Paul D. Baxter1, Mark W. Elliott1
1Dept. of Respiratory Medicine, St.James’ University Hospital, Leeds, United Kingdom; 2Department for Transport Studies, University of Leeds, Leeds, United Kingdom; 3Centre for Epidemiology & Biostatistics, University of Leeds, Leeds, United Kingdom

Introduction: Advising patients with OSAS about driving is difficult. In the absence of an objective test reliance has to be given to a patient’s account of their driving ability. In simulated driving, OSAS patients perform worse than controls but an individual’s performance does not correlate with severity or symptoms of OSAS. Patients’ account is also likely to be influenced by worry of losing licence. The relationship between patients’ perception & driving simulator performance was explored as part of development of an advanced office based driving simulator (MiniSim) for patients with OSAS.

Methods: 72 patients (ESS 12±6.0, ODI 39±21) completed a questionnaire pertaining to their driving behaviour & completed 50 minutes of simulated motorway driving. Two events were programmed that required evasive action to avoid a crash, minor & major. A “fail” was defined as an unprovoked crash or crash at the minor event. A crash at the major event was deemed as “indeterminate”, the rest were deemed to have “passed”. Chi squared test was performed to see whether patients admitted to problem driving were more likely to fail “fail”. Logistic regression analysis was performed to predict a “fail” from the questionnaire.

Results: 54% subjects admitted to problem driving. Only the ESS was higher in these patients (p<0.0001). A “fail” could not be predicted from the questionnaire. Subjects who reported problem driving were not significantly more likely to fail than others. This highlights that patients’ perceptions are not a reliable indicator of driving ability. An objective test that is credible, reliable and practicable for everyday clinical use is needed to inform decision making.

P2237

Effects of non-surgical therapeutic program on the metabolic syndrome (MetS) in morbidly obese patients

Miodrag Vukcevic1, Milena Tanic2, Svetlana Vujovic2, 1Palomary Department, KBC B Kosa, University Medical School, Belgrade, Serbia; 2Clinic of Endocrinology, Clinical Center of Serbia, University Medical School, Belgrade, Serbia

Objective: The aim of this study was to assess the effects of non-surgical therapeutic program on the metabolic syndrome (MetS) in morbidly obese patients.

Design: Fifty-four patients were involved in the therapeutic program, which consisted of two alternating phases: the three-week therapeutic fasting or semi-fasting in hospital conditions and the low caloric diet (LCD) with dosed physical activity in outpatient conditions. At the baseline we measured: anthropometric parameters, blood pressure and lipid profile. Subjects underwent an oral glucose tolerance test (OGTT) and insulin resistance/sensitivity was evaluated by the homeostasis model assessment (HOMA) and the oral glucose insulin sensitivity (OGIS). After weight reduction by at least 10%, all mentioned assessments were repeated.

Results: None of the patients had significant adverse effects. Forty-one patients aged 43±10 years completed the study. The mean weight loss was 27 kg or 18% of the initial weight (p<0.01), which was followed by a significant decrease of the insulin resistance, the overall prevalence of MetS (32%) and all MetS parameters, without the significant change in high-density lipoprotein (HDL). In the subgroup of 15 patients weight reduction of 20% of the initial weight (p<0.01) resulted in HAI reduction of 31%.

Conclusions: The weight loss program substantially improves the MetS in extremely obese patients. The tailored alternating either fasting or semi fasting should be considered as an optional approach to manage extreme obesity and related metabolic adverse effects and reduce severity of sleep breathing disorders.

P2238

A study of insulin resistance in moderate to severe obstructive sleep apnea in non diabetics and its response to nasal CPAP treatment

Archana Babu Rao, George Albert D. Souza, Striram Sampath, Uma Subramanian Unni, Chest Diseases, Critical Care, St Johns Medical College Hospital, Bangalore, Karnataka, India

Background: The effects of normal continuous positive airway pressure (nCPAP) for obstructive sleep apnea (OSA) on insulin resistance (IR) are not clear and have found conflicting results.

Aims and objectives: To evaluate IR in non diabetic patients with moderate to severe OSA and the effect of treatment with nCPAP on IR in these patients.

Method: 30 consecutively newly diagnosed patients with moderate to severe OSA were enrolled in the study. Samples of peripheral venous blood for measurement of glucose and insulin were collected after overnight fasting and IR was calculated by HOMA (Homeostasis model assessment) method. Patients were treated with nCPAP for 1month and HOMA IR was again measured.

Results: 30 OSA subjects, with a mean apnoea-hypopnoea index (AHI) of 38.40 [57-224] were included in the study. The HOMA IR (5.78) was significantly higher, compared to normal south indian population. There was no positive correlation of HOMA IR with AHI. This may be due to the small sample size and IR attributable to OSA may be small and constant and not related to the severity. The HOMA IR was measured 1 month after use of CPAP. The HOMA IR significantly improved from 5.78 to 4.82 (p=0.024) after 1 month of treatment with nCPAP in OSA patients. There was also significant improvement in insulin levels from 21.75 to 19.39 (p=0.009).

Relationships between obstructive sleep apnea and antioxidant status

Ligia Punu, Andrea Didilescu, Ovidiu Fira-Mihailescu, Felicia Oliga, Maria Greaba, Alexandra Tocan, Nicoleta Muru, Anca Petrouan, Cristian Didilescu, Pneumology, Pneumopathiology Hospital, Bâcu-Mare, Bâcu-Mare, Maramures, Romania

Introduction: In Sleep Apnea Syndrome (SAS) the episodes of hypoxia/reoxygenation can generate reactive oxygen species and promote oxidative stress.

Aim of the study: Evaluation of changes of the levels of some antioxidants in SAS patients.

Methods: Two Romanian groups, consisting of 29 patients diagnosed with SAS and 17 healthy controls, were recruited. All patients underwent cardiorespiratory polygraphy. Plasma levels of homeostasis model assessment (HOMA) indices were measured. Also, the oral glucose tolerance test (OGTT) was performed.

Results: The levels of vitamin C and E were significantly lower in SAS patients than healthy controls. But the levels of glutathione peroxidase (GSH-Px), catalase (CAT) and superoxide dismutase (SOD) were similar in the two groups.

Conclusion: The reduced levels of vitamin C and E can be useful in the therapy of SAS patients.

Road traffic collisions caused by sleepiness in UAE

Mohammed Al-Houqani1, Ham Eid2, Fikri Abu Zadaan1, 1Internal Medicine, Faculty of Medicine, UAE University, Al-Ain, United Arab Emirates; 2Emergency Department, Towam Hospital, Al-Ain, United Arab Emirates

Introduction: Road traffic collision RTC is a major health problem in UAE. Sleep as a contributing factor to RTC is not well-studied in the Middle East.

Objective: We aimed to study to the proportion of RTC caused by sleep loss in UAE, by investigating the factors contributing to sleep related collisions.

Methods: All data of hospitalized drivers who were involved in RTC in Al-Ain city were prospectively collected during the period of April 2006-October 2007. Variables studied included; driver’s demographic data, time, date, location, mechanism of collision, speed at collision and whether sleepiness was a contributing factor reported by the drivers. A direct logistic regression model was performed to define factors related to sleep while driving.

Results: 444 drivers (92% males) were involved in RTC’s during the study period. Sleepiness of drivers was a contributing factor in 5%. Most of the drivers with SRC (79%) reported to speed 100 Km/hr or more during the collision. Rollover was the most frequent mechanism of SRC (58%). SRC was strongly over-represented during the month of Ramadan (42%), in driving in highway (38%) and in driving during the day time (67%). A logistic regression analysis model has shown that driving during the month of Ramadan (OR = 7.58) and on highways (OR = 2.01) are factors related to sleep while driving.

3.99) were the most significant independent contributors to increasing the odds of sleep-related collisions.

**Conclusion:** Sleep is an important contributing factor to RTC’s in UAE. Drivers should be advised to discontinue driving when feeling sleepy especially during the month of Ramadan.

**Relationship between obstructive sleep apnoea syndrome (OSAS) and the levels of endothelial progenitor cells (EPC) in patients with acute stroke**

Anna Mola¹, Ana Mª Foruña¹, Rosa Mª Miralda¹, Raquel Delgado²,

OSAS is a cardiovascular risk factor that has a high prevalence in patients with stroke. Endothelial progenitor cells (EPC) are an endogenous repair mechanism of endothelium, which could be altered in OSA and contribute to endothelial dysfunction. The aim of this prospective study is to assess the relationship of OSAS and circulating EPC levels in acute stroke patients. The patients underwent a respiratory polygraphic (RP) evaluation on the 7th day of stroke (acute phase). EPC were measured by flow cytometry at inclusion and were repeated at the 7th day. EPC were considered those that were positive for three markers: CD34, CD133 and KDR (VEGF receptor). 42 of 52 patients were included (age 69±12.5 years, 54.8% male, BMI 27±4 kg/m², Epworth 7±3.6). OSA prevalence in the acute phase of stroke was 54.76% (AHI>20) and 35.7% (AHI>30) with a predominant hypopnoea pattern. Significant differences between EPC levels on inclusion and on the 7th day (0.0004762%±0.00175636 vs 0.0034857%±0.0061183 (p=0.005) were found. There were no differences between non-OSAS patients and the group with AHI>10, except for age 59.73±15.58 vs 72.61±9.41 (p = 0.013). Patients with AHI>10 had lower EPC baseline levels but the analysis showed no significant differences compared to non-OSA patients. Neither AHI nor EPC values were significantly associated with neurological variables in acute stroke. The results suggest that EPC show a peak on the 7th day of acute stroke, which can express the endothelial repair capacity of the organism. OSA patients showed a lower baseline EPC values but failed to demonstrate significant differences regarding non-OSA population.
