Aims & Scope

The European Respiratory Journal (ERJ), the official Journal of the European Respiratory Society, publishes, in the English language, clinical and experimental work dealing with all aspects of respiratory medicine. In addition to original material, the ERJ prints Editorials and Reviews, as well as Technical notes, Letters and Correspondence. This Journal is abstracted/indexed in: Ad Referendum, ADONIS, Biological Abstracts/BIOSIS, Chemical Abstracts, Current Contents: Life Sciences, Current Contents: Clinical Medicine, Elsevier BIOBASE/Current Awareness in Biological Sciences, EMBASE/Excerpta Medica, Index Medicus/MEDLINE, Medical Documentation Service, Research Alert, Science Citation Index, SciSearch, SIIC Data Base and CABI Global Health.

Subscriptions

ERJ is published monthly by the European Respiratory Society (ERS). Twelve issues are published annually in two volumes of six issues each. The volumes for 2011 are Volumes 37 and 38.

Subscription rates for institutions (Volumes 37 & 38, 2011): £660.00 online only, £756.00 print and online; US$1,254.00 online only, US$1,454.00 print and online in North America. Subscription rates include air economy postage. Subscriptions are payable in advance. Subscribers within the European Union must provide their VAT (Value Added Tax) number or add VAT to the subscription rate at the rate prevailing in their own country.

Subscriptions are managed on behalf of the ERS by: Maney Publishing, Suite 1C, Joseph’s Well, Hanover Walk, Leeds LS3 1AB, UK (fax: +44 (0)113 386 8178; E-mail: subscriptions@maney.co.uk) or: Maney Publishing North America, 875 Massachusetts Avenue, 7th Floor, Cambridge, MA 02139, USA (tel: (toll-free) +1 (0)866 297 5154; fax: +1 (0)617 354 6875; E-mail: maney@maneyusa.com). All orders, payments, and claims for missing issues should be sent to Maney Publishing or to any subscription agent.

Online Access

All subscribers have online access to the full text of each issue as part of their subscription. The online version is available to members via www.ersnet.org. Institutional subscribers can access online through HighWire at www.erj.ersjournals.com

Members of the ERS receive the ERJ as part of their membership.

This abstract book has been produced electronically by Marathon International b.v. and is also available on-line at www.ersnet.org

Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organisers for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosages should be made.
41. The COPD patient experience: care and management

164 Lung cancer and COPD multidisciplinary teams: Exploring comparisons of patient perceptions
Christine Blunt1, Joan Curriz1, Tony Leiba, Sarah Elkin2. 1Facility of Health and Social Care, London South Bank University, London, United Kingdom; 2Respiratory Medicine, St Mary's Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom

Background/Objectives: Multidisciplinary teams (MDT’s) and effective team working are considered key to providing quality, patient centred care. However there is a paucity of research regarding patient perceptions of these teams including for chest disease. The qualitative study aimed to explore the differing patient perceptions of effectiveness in two disease specific teams.

Methods: 12 patients (lung cancer n=6, Chronic Obstructive Pulmonary Disease n=6) 64-84 years in contact with their respective multidisciplinary teams for 3 months or more were interviewed using a semi-structured format. Data from interviews was analysed based on Interpretative Phenomenological Analysis.

Results: Several themes were identified, commonalities between teams were: 1) Doctors seen as core team members whilst other health professional consultations perceived as inferior. 2) GP's not considered part of a team. 3) Team effectiveness and morale often judged by attitude of frontline administrative staff. Differences: lung cancer patients perceived 1) Efficacy of service upon outpatient clinic waiting times. 2) A greater need for privacy during consultations and when leaving. 3) Greater awareness of MDT communication and meetings. 4) Greater awareness of nurse specialists. COPD participants 1) Accessibility and quicker response to request to be seen by health professional.

Conclusions: These patient groups suggest a traditionalist view of physicians providing treatment. Increasing information regarding health professional specialties, team communications and attention to psychosocial issues may increase patient satisfaction and confidence in MDTs.

165 Developing a framework for palliative interventions in respiratory services in Ireland: One year into an action research project
Bettina Keen1, Patricia White1, Rory O'Donnell1, Caitriona Corcoran1, Kay Kehaly1, Marie Lynch1, Liam O’Sorain2. 1Department of Respiratory Medicine, St. James’s Hospital, Dublin, Ireland; 2Palliative Care Services, St. James’s Hospital, Dublin, Ireland

Background: Traditionally, palliative care services have centred on the needs of patients with malignant disease and there is little evidence of the integration of palliative care into disease specific services in Ireland. The purpose of this research was to devise, implement and evaluate palliative care responses for people with advanced respiratory disease.

Methods: An action research methodology has been adopted for this multi-site research. This approach provides the opportunity for collaboration, reflection and exploring ways of improving service delivery. It incorporates both qualitative and quantitative methodologies and includes an expert focus group, survey of palliative care education needs, interviews with patients and families and retrospective chart reviews.

Results: To date, the initial planning and action cycles have started. The project outcomes and potential barriers have been identified through an expert focus group.

Ongoing retrospective chart reviews highlight the low level of referrals to specialist palliative care. Results from the quantitative survey showed a lack of understanding of what palliative care entails, with 93% of respiratory staff interested in attending palliative care education. Further actions include the establishment of multi-disciplinary, multi-site team meetings to improve patient care.

Conclusions: The reactive and reflective nature of action research has been advantageous in bringing about change in a demanding health care system. This project is developing and evaluating a palliative care model of support, intervention and referral pathways for people with advanced respiratory disease.

166 COPD patients coping with breathlessness during daily living – A multi-modal grounded theory
Lene Bastrup Jørgensen1, Ronald Dahl2, Preben Ulrich Pedersen3, Kirsten Elisabeth Lomborg1. 1Department of Nursing Science, School of Public Health, Aarhus University, Aarhus, Denmark; 2The Department of Pulmonary Medicine, Aarhus University Hospital, Aarhus, Denmark

Introduction: Grasping the complexity of COPD patients coping with breathlessness during daily living has not yet been achieved.

Purpose: To develop a grounded theory of COPD patients’ coping styles by investigating possible interrelations between the physiological, cognitive, affective and psychosocial dimensions in coping.

Materials and methods: Twelve patients with moderate to severe COPD were included during hospitalization for an acute exacerbation of COPD. We chose a multi-modal grounded theory design with concurrent data collection and analysis, and a constant comparative analytic process of interpretation of the data material as a whole. Data were collected both at hospital and in the patients’ home after discharge. Data were derived from video, interview, medical history, demographics, scores on a modified Borg Scale and recordings of SaO2, heart rate, energy expenditure and level of MTE. The data material comprised 24 interviews, 50 recordings of videos, 50 video transcriptions, 50 sets of measurements of physiological parameters, 50 set of scores on the modified Borg Scale and 12 sets of demographic information.

Results: The main concern for the participants appeared to be an endless striving for economizing on intra-, extra-, and interpersonal resources with the main purpose of preserving their existence with breathlessness. Suggesting a coping trajectory, four coping styles emerged in this self-protective process corresponding with the degree of pulmonary function, level of physical activity, energy expenditure and social status.

Conclusion: COPD patients’ coping styles appear to correspond with their physical and psychosocial condition suggesting a “COPD coping trajectory”.

167 Living with severe chronic obstructive pulmonary disease (COPD): The male carer’s story
Terry Robinson, Giles Fitch. Respiratory Nurses, Harrogate and District NHS Foundation Trust, Harrogate, North Yorkshire, United Kingdom

Introduction and objectives: The aim of this qualitative study was to gain a better knowledge and understanding of the male caring role in COPD, and to explore the ways in which individual carers live with COPD patients.

Methods: A prospective unstructured audiotaped interview using a phenomenological approach was used to collect data from ten men (mean age 70.1 years) living with wives or partners who had severe COPD.

Results: Recurrent themes emerged. Most participants reported lack of support at a social isolation as they lacked the network of friends and family around them that women appear to have. Previously enjoyed activities such as holidays and sexual relationships were no longer possible for many, leading to increased stress and resentment. Hospital admissions led to increased work load and even less time for the men, and many described how the future filled them with fear, especially if their partner deteriorated further, or if their own health deteriorated. Surprisingly six men did not perceive themselves as carers, preferring the word “partner” to carer. As they did not implement themselves as carers they did not ask for help or to be asked for help. Five men felt that caring did not come naturally to men, and felt women were better suited to the role as they had historically raised children and run the family home.

Conclusion: Severe COPD impacts on all aspects of male carers’ lives. The specific needs of male carers should be considered when designing and delivering services to this patient group.

168 The experience of not being able to stop smoking despite having COPD
Brit-Marie Ekland1,2, Siv Nilsson2, Linea Hedman1, Inger Lindberg2. 1The OLIN-Studies, Norrbonen County Council, Lulea, Sweden; 2Health Sciences, Division of Nursing, Lulea University of Technology, Lulea, Sweden

Background: COPD (Chronic Obstructive Pulmonary Disease) is one of the most widespread lung diseases and a growing cause of suffering and mortality worldwide. It is predicted to become the third leading cause of death in the near future. Smoking is the most important risk factor and 50% of smokers develop COPD. Smoking cessation is the most important intervention to improve prognosis for individuals with COPD.

Aim: To describe the experience of not being able to stop smoking among persons diagnosed with moderate COPD.

Methods: Ten smokers (5 women) with COPD, GOLD stage II, participated in semi-structured interviews. The data was analysed using qualitative content analysis. The participants were recruited from the OLIN studies in Northern Sweden.

Results: The analysis resulted in two themes: 1) Life is governed by a long smoking history that is difficult to break and 2) To be aware of and enlightened, but lacking ability to make a decision, and in five categories: That it is the wrong time in life to stop; To break a lifelong pattern is impossible; That planning to stop does not lead to results; Being aware of the consequences of continued smoking and to have received help and support but not wanting to be patronized. Although they knew about the harmful effects of smoking, difficulties in everyday life aggravated smoking cessation. To have plans to stop smoking is not enough, it is also necessary to get motivation and support from the social environment at the right time.

Conclusion: The individual life situations are very important for successful smoking cessation. Health professionals should be even more sensitive and provide an individually tailored support when an individual decides to stop smoking.
42. New insights in the treatment of idiopathic pulmonary fibrosis

The Integration of Respiratory Services... Is it the way forward?
Alison Graham, Jacqueline Bayliss, Kath Morgan. Integrated Respiratory Service, Cheshire East Community Health, Macclesfield, Central and East Cheshire, United Kingdom

Aim: To assess the impact of the introduction of an Integrated Respiratory Service in Central and East Cheshire by looking at admission avoidance, reduction in admissions, length of patient stay and oxygen prescribing costs.

Introduction: The Integrated Respiratory team (IRT) is an in-reach and out reach specialist respiratory service for patients with COPD and other lung diseases in Central and East Cheshire. The IRT offers a 7 day service which incorporates acute hospital care, same day & early discharge services for patients with COPD, patient assessment and support within their place of residence to facilitate hospital admission avoidance, community & hospital based specialist nurse led clinics, a oxygen assessment service, pulmonary rehabilitation, respiratory education and palliative care.

Methods: An analysis of service activity data was undertaken for the period 1st April, 2010 to 31st January, 2011.

Key Achievements: The IRT has managed 2778 referrals, reduced the oxygen prescribing budget by £120,000, avoided the admission of 225 patients, supported the early discharge of 446 patients and reduced the average length of stay from 6 to 3 days. The IRT has managed 1366 new and follow up patients in the specialist community clinics. This equates with a potential predicted annual cost-saving of £163,079.63 in the oxygen prescribing budget, suggests a annual cost-saving of between £453,269 and £634,577 as a result of the reduction in length of stay and in addition an annual saving of approximately £481,162 for those patients on the early and supported discharge programme.

Conclusion: The Integration and collaboration of Respiratory Specialist Services is not only providing the best care, it is cost effective.

Conclusions: Respondents felt they were restricted by their COPD in terms of achieving life goals, socialising with others and providing usual family care. The aim of this study was to ascertain the social and financial impact of COPD on this age group. The country level data are presented from a multi-country cross-sectional survey.

172 Efficacy of BIBF 1120 in patients with IPF is dose-dependent: Results from the TOMORROW trial
Ulrich Costabel, Luca Richeldi, Moses Selman, Dong Soon Kim, Kevin Brown, Kevin R. Flaherty, Paul W. Noble, Ganesh Raghu, Michèle Brun, Abhya Gupta, Matthias Kuehle, Nolwenn Juhel, Roland Moena Bois, R. Ruhland, Limkod and Medical University, University of Duisburg-Essen, Essen, Germany; 2Center for Rare Lung Disease, University of Modena and Reggio Emilia, Modena, Italy; 3Instituto Nacional de Enfermedades Respiratorias, “Ismael Costi Villegas”, Mexico, Mexico; 4Division of Pulmonary Medicine, Critical Care Medicine, Asian Medical Center, Seoul, Korea; 5Division of Pulmonary Sciences and Critical Care Medicine, Department of Medicine, National Jewish Health, Denver, United States; 6Division of Pulmonary Medicine, Pulmonary and Critical Care Division, University of Michigan, Ann Arbor, United States; 7Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, Duke University Medical Center, Durham, United States; 8Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, United States; 9Boehringer Ingelheim Pharma G.m.b.H. & Co. KG, Boehringer Ingelheim, Biberach, Germany; 10National Heart & Lung Institute, Imperial College, London, United Kingdom

Background: BIBF 1120 is an inhibitor of tyrosine kinase receptors involved in lung fibrosis progression.

Methods: The TOMORROW trial was a 12-month, placebo (PBO)-controlled study to investigate efficacy and safety of BIBF 1120 (50 mg, 100 mg, 200 mg, 300 mg per day) in IPF (8–5 pts per group). Annual rate of decline in forced vital capacity (FVC) was measured.

Results: FVC decline decreased from 0.17 L/year (50 mg) to -0.06 L/year (300 mg) vs 0.19 L/year in PBO (300 mg vs PBO: p=0.014; closed-testing multiplicity-corrected: p=0.0064). Absolute changes from baseline in % pred FVC were -6.00, -4.58, -4.90, -3.15 and -1.04% in PBO and rising dose groups (200 mg: p=0.031; 300 mg: p=0.0002).

Conclusions: Respondents felt they were restricted by their COPD in terms of achieving life goals, socialising with others and providing usual family care. The results confirm the high social impact of COPD and financial concerns are of particular importance for working age patients.

The individual social and financial burden of COPD
Monica Fletcher, Helen Allbrown, Christine Mercier, Samantha Walker.
Research, Education for Health, Warwick, United Kingdom; 2Department of Respiratory Medicine, Concord Hospital, Concord, New South Wales, Australia

Introduction: An increasing number of people with COPD are under 65 years. The aim of this study was to ascertain the social and financial impact of COPD on this age group. The country level data are presented from a multi-country cross-sectional survey.

Method: 2426 respondents from Brazil, China, Germany, Turkey, UK and US were recruited utilising a mixed methods design. Data was collected on the financial impact of COPD on individuals and their families, including effect on household income and expenditure, willingness to pay, for future, and social impact.

Results: 49% (1180) males, m 56.4yrs, and 29% employed. Respondents felt unable to plan for the future or maintain lifestyles. Over 1/3 felt household income had decreased. 17% a burden to friends and family, and 26% unable to care for children/family as before. Over 50% went out less, and similar numbers felt embarrassed by their cough. Over half felt their condition had stopped them achieving life goals or dreams.

The Integration of Respiratory Services... Is it the way forward?
Effect of baseline FVC on preservation of lung function with BIBF 1120: Results from the RECAP extension study

Lucia Richel1, Ulrich Costabel1, Moises Selman1, Dong Soon Kim4, Kevin R. Flaherty2, Paul W. Noble6, Ganesh Raghu1, Arata Azuma4, Michele Brun4, Abiya Gupta5, Matthias Kluglich5, Nozhenn Juhe1, Roland M. du Bois1
1Center for Pulmonary, Allergy, and Critical Care Medicine, University of Modena and Reggio Emilia, Modena, Italy; 2Rudhrlandlinikum and Medical Faculty, University of Duisburg-Essen, Essen, Germany; 3Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico; 4Division of Pulmonary and Critical Care Medicine, Asun Medical Center, University of Ulsan, Seoul, Korea; 5Department of Internal Medicine, Pulmonary and Critical Care Division, University of Michigan, Ann Arbor, United States; 6Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, Duke University Medical Center, Durham, United States; 7Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, United States; 8Division of Respiratory Medicine, Infection and Oncology, Nippon Medical School, Tokyo, Japan; 9Boehringer Ingelheim France S.A.S., Boehringer Ingelheim, Reims, France; 10Boehringer Ingelheim Pharma GmbH & Co. KG, Boehringer Ingelheim, Biberach, Germany; 11National Heart & Lung Institute, Imperial College, London, United Kingdom

Background: BIBF 1120 is an inhibitor of tyrosine kinase receptors involved in the progression of lung fibrosis.

Methods: The efficacy and safety of 50 mg, 100 mg, 200 mg and 300 mg daily doses of BIBF 1120 were evaluated in 428 patients diagnosed with IPF in a Phase 2 randomized, double-blind placebo (PBO)-controlled trial. Subgroup analyses of the annual rate of decline in forced vital capacity (FVC) by baseline lung function were carried out to evaluate the impact of stage of disease on the effect of BIBF 1120.

Results: Baseline FVC was similar in all groups (mean: 2.8 L; 81.3% predicted). The annual rate of decline in FVC was -0.060 L/year with BIBF 1120 300 mg vs -0.186 L/year with PBO [n=22; p=0.794]. Patients with baseline FVC ≥70% of predicted value showed almost no FVC decline with BIBF 1120 300 mg [-0.010 L/year vs -0.160 L/year; p=0.112] and ≥90% of predicted value [-0.019 L/year vs -0.186 L/year; p=0.088] of predicted value; however, these findings were based on small sample sizes and the differences did not reach significance.

Conclusions: The effects of IPF treatment may be more easily demonstrable in patients with FVC values closer to predicted values.

The long-term safety of pirfenidone in patients with idiopathic pulmonary fibrosis (IPF): Interim data from the RECAP extension study

Ulrich Costabel1, Carlo Albera2, Alan Cohen3, William Bradford4, Talmadge King Jr.1, Paul Noble1, Steven Sahn5, Dominique Valeyre6, Roland du Bois1

1Pneumologie/Allergologie, Rudhrlandlinikum, Essen, Germany; 2Department of Cardiology and Pulmonology, Clinique de Bouches-du-Rhône, Montpellier, France; 3Medical Affairs/Clinical Research, InterMune, Inc., Brisbane, CA, United States; 4Department of Medicine, University of California San Francisco, San Francisco, CA, United States; 5Pulmonary, Allergy, and Critical Care Medicine, Duke University, Durham, NC, United States; 6Pulmonary, Critical Care, Allergy, and Sleep Medicine, Medical University of South Carolina, Charleston, SC, United States

Introduction: The CAP (CAPACITY) trials were randomized controlled studies evaluating pirfenidone (PFD) in patients with IPF. Pooled data from these studies support a treatment effect on forced vital capacity, progression-free survival, and 6-minute walk distance. To examine the long-term safety of PFD, an open-label extension study for eligible CAP patients was initiated (RECAP). An interim analysis of safety data from RECAP is presented.

Aims and objectives: Examine the long-term safety of PFD in patients with IPF.

Methods: Safety data from the RECAP study through Wk 72 were analyzed and compared to pooled safety data from the CAP trials.

Results: In the CAP studies, 779 patients were randomized to treatment with PFD or placebo for ~7.2 weeks. Of these, 603 enrolled in RECAP. At Wk 72 in RECAP, mean exposure to PFD 240 mg/d across both studies was 2.9 yrs (range, 1–4). 114 patients had received PFD 240 mg/d for ≥3 yrs. In RECAP, 98.2% of patients reported ≤1 treatment-emergent adverse event (TEAE) compared to 98.6% in CAP. 12% of patients had a serious TEAE compared to 32.8% during CAP. Common AEs in RECAP were similar to those observed in CAP and were generally mild to moderate in severity. The overall incidence of photosensitivity or rash was lower in RECAP than CAP (19.7% vs. 44.4%); however, patients who received placebo during CAP had a higher incidence than those who received PFD (28.1% vs. 12.3%).

Conclusions: Long-term safety data demonstrate that PFD is safe and generally well tolerated in patients with IPF. Given the unmet medical need and efficacy seen in 3 Phase III studies, PFD has a clear role in the treatment of IPF.

Antifibrotic effects of sulforaphane in human lung fibroblasts from idiopathic pulmonary fibrosis

Gise Arand-Macari, Delphine Goeven, Stéphanie Brayer, Joëlle Marchal-Somme, Bruno Crestani, Anne Boutten, Marcel Ronay. INSERM U706, Faculté de Médecine Xavier Bichat, Paris7, Paris, France

Rationale: Nrf2 pathway has been implicated in myofibroblast differentiation, a key step in idiopathic pulmonary fibrosis (IPF) pathophysiology. Sulforaphane (SFN), an isothiocyanate mainly found in cruciferous vegetables, has been shown to activate Nrf2. The aim of this study was to assess the effects of SFN on oxidative stress and fibroblast phenotype in IPF.

Methods: The effects of SFN were assessed on human pulmonary fibroblasts from IPF and control patients in vitro. Oxidant/antioxidant balance, nuclear Nrf2 expression, fibroblast phenotype, in basal and profibrogenic conditions (TGF-β or PDGF-BB stimulation) were experienced.

Results: SFN increased antioxi- dant enzymes and Nrf2 nuclear expression, and decreased oxidative stress in IPF fibroblasts, in basal conditions and after TGF-β stimulation. SFN stimulation induced a myofibroblastic dedifferentiation of IPF fibroblasts with morphologic aspect of control-like fibroblasts and reduction of α-SMA and collagen I expression, proliferation, migration and con- traction. Moreover, addition of SFN after TGF-β and PDGF-BB stimulation, inhibited their deleterious effects on IPF and control fibroblasts, and restored antioxidan t defenses. Nrf2 sRNA transfection abolished antifibrotic effects of SFN.

Discussion: The effects of SFN on cell differentiation have been reported in renal tubular epithelial cells in a rat model of renal fibrosis, but effects on human pulmonary fibroblasts from IPF and control patients were unknown.

Conclusion: These results suggest the potential therapeutic effect of SFN on pulmonary fibroblasts in vitro.

Presence of right ventricular dysfunction predicts dyspnea and quality of life improvements with sildenafil in IPF

Mei-Lan Han1, David Bach2, Peter Hagan3, Shelley Schmait4, Kevin Flaherty1, Galen Towm5, Kevin Anstrom2, Fernando Martinez1

1Division of Pulmonary, Critical Care, Allergy, and Sleep Medicine, University of Washington, Seattle, United States; 2Division of Pulmonary, Critical Care Medicine, Department of Medicine, Duke University Medical Center, Durham, United States; 3Division of Pulmonary and Critical Care Medicine, University of California San Francisco, San Francisco, CA, United States; 4Division of Pulmonary, Allergy, and Critical Care Medicine, Orange County Medical Center, Irvine, CA, United States; 5Department of Internal Medicine, Pulmonary and Critical Care Division, University of California, San Francisco, CA, United States

Background: IPF is a progressive lung disease with impaired gas exchange. The STEP-IPF trial was conducted to determine if sildenafil would increase 6-minute walk distance by ≥ 20%. The primary endpoint was not reached, but a sub- analysis tested whether baseline evidence of pulmonary hypertension would predict treatment response.

Methods: Echocardiograms were available for review in 119/180 subjects and read by two cardiologists. Right ventricular hypertrophy (RVT), RV systolic dysfunction (RVD) and RV systolic pressure (RVP) were assessed. A general linear model determined the relationship between cardiac abnormality, sildenafil treatment and improvement in quality of life (QOL) as measured by EuroQol EQ-5D, EuroQol thermometer and SGRQ at 12 weeks.

Results: Mean FVC% predicted was 57%; DLCO% predicted 26%. Prevalence of RVH was 13%; RV systolic dysfunction 19%. Mean RVPV=42.5, measurable in 7/119 subjects. Mean E/e′ measured by STE E′ was 8.2, measured in 68/114 subjects. Mean EuroQol EQ-5D 0.73, and SGRQ 53.1. Significant interactions between RV systolic dysfunction and sildenafil treatment were seen for SGRQ (p=0.048), SGRQ symptom score (p=0.002) and EuroQol Thermometer (p=0.05). Sildenafil treated subjects with RVD improved by 13.4 SGRQ points, 28.0 SGRQ symptom score points, and 17.9 EuroQol Thermometer points vs placebo. Those with RVD treated with placebo increased their SGRQ by 2.9 points, SGRQ symptom score by 3.8 points, and dropped their EuroQol Thermometer score by 1.4 points vs placebo.

Conclusions: In IPF patients with RV systolic dysfunction, sildenafil treatment is associated with improvements in QOL as measured by SGRQ total and symptom scores and EuroQol Thermometer score.

A prospective, non-randomized clinical trial to study the safety and efficacy of the endobronchial autologous infusion of adipose-derived mesenchymal stem cells (ADMSCs) in patients with idiopathic pulmonary fibrosis (IPF)

Argyris Tzouvelekis1, Paschalis Ntolios1, Anastasia Ekonomou2, George Koliakos3, Marius Froudarakis3, Demosthenes Bourou1.

1Pneumology, University Hospital of Alexandroupolis, Democritus University of Thrace, AL, Thrace, Greece; 2Respiratory Medicine, University of Thrace, Alexandroupolis, Thrace, Greece; 3Biochemistry, Aristotle University of Thessaloniki, Thessaloniki, Macedonia, Greece

Background: IPF is a chronic, progressive, lethal fibrotic lung disease of unknown etiology and treatment yet unfortunate. The aim of the study was to investigate the safety and efficacy of endobronchial autologous infusion of adipose-derived mesenchymal stem cells (ADMSCs) in patients with IPF.

Methods: We performed a prospective, non-randomized trial of endobronchial autologous ADMSCs in IPF patients who met ATS/ERS 2000 criteria with mild to moderate lung disease with IPF as assessed by Forced vital capacity (FVC)> 50% and diffusion capacity of the lung for carbon monoxide (DLCO) > 35%. All eligible
patients (n=14) underwent liposuspension and ADMSCs were isolated using a stan-
dard protocol provided by Adistem Ltd. ADMSCs were labelled with Technetium
(Tc-99m and endobronchially infused to both lower lobes. Tc-99m lung scanning
was performed to visualize infused cells. The primary end point was incidence
of treatment-emergent adverse events within 6 months after first infusion. FVC,
DLCO and 6-minute walking distance (6MWD) were exploratory efficacy end
points. 

Results: No cases of clinically significant allergic reactions, disease acute ex-
carceration or infection were recorded in all patients. There were no significant
alterations in FVC and DLCO 6 months post-treatment, though an almost marginal
trend towards improvement in 6MWD (P=0.07) was reported.

Conclusions: This ongoing clinical trial provides pivotal safety and provisional
efficacy data for endobronchial autologous infusion of ADMSCs in patients with
IPF. Larger studies are sorely needed.

178 
Effect and safety of mycophenolate mofetil in idiopathic pulmonary fibrosis. A retrospective study
Argyropoulou Maria2, Evangelos Bourou1, Anastasia Ekonomou 3, Paschalis Notos2, George Zacharis 1, George Kolios 2, Demosthenes Bourou1.

1Pneumonology, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Thrace, Greece; 2Laboratory of Pharmacology, Democritus University of Thrace, Alexandroupolis, Thrace, Greece; 3Radiology, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Thrace, Greece

Background: Idiopathic pulmonary fibrosis (IPF) is a progressive fibrictic intersti-
tial lung disease with poor prognosis and treatment yet ineffective. Mycophenolate
Mofetil (MMF) is an immunomodulatory drug, acts by inhibiting lymphocyte
proliferation and is commonly used to prevent rejection following organ
transplantation.

Objective: We sought to determine the safety and efficacy profile of MMF in IPF
patients.

Methods: We retrospectively identified ten patients, all males, who met the
ATS/ERS 2000 criteria for IPF and received MMF 1.44g/d for 12 months. All of
them had inpatient hospital, pulmonary function and radiological (high reso-
lution computed tomography-HRCT) data available and therefore were enrolled
in the study. Forced vital capacity (FVC), total lung capacity (TLC), diffusion
capacity of the lung for carbon monoxide (DLCO), 6-minute walking distance
(6MWD), alveolar-arterial gradient of oxygen tension (PA-aO2), HRCT scans and
routine laboratory data at treatment onset were compared with respective values
12 months after treatment onset.

Results: There were no significant alterations in FVC, TLC, DLCO, 6MWD and
PA-aO2 pre- and 6 and 12 months post-treatment. HRCT evaluation showed a mod-
edeterioration of the total extent of disease (p=0.002). No cases of clinically
significant infection, leukemia, or elevated liver enzymes were recorded.

Conclusions: The above data suggest that MMF is a safe therapeutic modality
which resulted in overall stable disease regarding functional status while it demon-
strated a moderate progression as assessed by radiological parameters in a small
cohort of IPF patients. Larger, prospective studies are sorely needed.

Late-breaking abstract: Evaluation of CRP, PCT, clinical pulmonary infection score and pneumonia severity scores for the diagnosis and prognosis of nursing home acquired pneumonia
Ilias Porfyridis, Georgios Georgiadis, Paris Vogiazianos, Andreas Georgiou
Pulmonary Department, Nicosia General Hospital, Nicosia, Cyprus

Introduction: Nursing home acquired pneumonia (NHAP) represents a distinct
group of respiratory infections with different risk factors, clinical presentation
and higher mortality than COP.

Aim: To evaluate the diagnostic value of clinical pulmonary infection score (CPSI),
CRP and PCT and compare the accuracy of CURB-65, pneumonia severity index
(PSI), nursing home acquired pneumonia (NHAP) index, SMART-COP and SOAR
in predicting in hospital mortality of NHAP.

Methods: 49 residents in nursing homes admitted to pulmonary department were
enrolled in the study. Pneumonia severity scores were recorded. CRP and PCT were
measured by immunonephelometry and immunoincromatography respectively.

Results: 39 patients were diagnosed with NHAP (group A) and 10 with other
pulmonary disorders (group B). Mean ± SE CRP was 16.3±1.65mg/dl in group A
and 2.6±2.56mg/dl (p=0.002) in group B. Mean ± SE PCT was 1.78±0.39mg/ml
in group A and 0.5±0.09mg/ml (p=0.001) in group B and mean ± SE CPIC was
5.7±0.18 in group A and 2.6±0.51 (p<0.001) in group B. The in-hospital mortality
was 17.9% in group A. PCT and CRP were accurate in predicting mortality with
AUC of 0.8 (95%CI 0.61-0.98) and 0.67 (95%CI 0.41-0.92) respectively. SMART-
COP, SOAR and PSI performed similarly with AUC 0.38 (95%CI 0.17-0.76), 0.52
(95%CI 0.3-0.75) and 0.57 (95%CI 0.36-0.77) respectively, whilst CURB65 [AUC
0.66 (95%CI 0.45-0.86)] and NHAP index [AUC 0.6 (95%CI 0.39-0.8)] showed
superior accuracy in predicting mortality.

Conclusions: The CPSI, PCT and CRP are reliable for the diagnosis of NHAP.
PCT, CRP and CURB65 were accurate for predicting in-hospital mortality in
patients with NHAP.

180 
COPD case finding in primary care: A pilot study in the West Midlands, UK
Shamil Haroon1, Rachel Jordan2, Peymane Adab2, Carl Griffin1

1Public Health, Sandwell Primary Care Trust, West Bromwich, United Kingdom; 2Public Health, Epidemiology and Bioinformatics, University of Birmingham, Birmingham, United Kingdom

Aim: To compare the effectiveness of targeted versus opportunistic case finding
for COPD in primary care.

Background: COPD is an increasing cause of morbidity and mortality, and un-
derdiagnosis is common. The recent draft Clinical Strategy for COPD for the UK
NHS recommended piloting case finding

Methods: Patients from two general practices, aged between 35 and 79 years with
a smoking history and no prior diagnosis of COPD or asthma were randomised
to either a targeted or opportunistic case finding arm. Patients in the targeted
arm were posted a respiratory questionnaire. Those in the opportunistic arm
received a questionnaire when they next presented at their general practice over a
6 month period. Patients with positive symptoms were invited to attend spirometry.
Those with an FEV1 predicted<80% and an FEV1/FVC<0.7 were diagnosed with
airway obstruction and referred to their GP or specialist respiratory nurse.

Results: 351 (32.7%) of 1073 distributed questionnaires were returned. 247 (70%)
of the patients who responded to the questionnaire were symptomatic. Of those
who underwent spirometry 14.3% were identified with airway obstruction. 10 out
of 815 patients (1.23%) contacted in the targeted arm and 4 out of 258 (1.55%) in
the opportunistic arm were identified with airway obstruction (difference 0.32%,
95% CI -1.37%, 2.01%). Overall 77 patients had to be contacted to identify one
patient with airway obstruction; 82 in the targeted and 65 in the opportunistic arm.

Conclusion: 17 more patients had to be contacted in the targeted than in the op-
portunistic arm to identify one patient with airway obstruction in this pilot. Further
work is needed with a wider range of practices to determine which approach is
more efficient.

181 
High rates of over-treatment of COPD in primary care: What risks to patients and costs to health services?
Helen Booth1, Sofia Georgopoulou1, Hilary Pincock1, Hannah Thorton1, Patrick White1
1Primary Care and Public Health Sciences, King’s College London, London, United Kingdom; 2Research and Respiratory Research Group, University of Edinburgh, Edinburgh, United Kingdom

Introduction: GOLD guidelines recommend inhaling medications for COPD based
on disease severity. Under-treatment denies patients the benefits of effective ther-
apy. Over-treatment with inhaled corticosteroids (ICS) risks side-effects including
both local and increased risk of pneumonia, in combination with long-acting bron-
dilators they also incur considerable financial waste. This study assessed adherence
to GOLD guidelines in primary care prescribing of inhaled COPD medication in
South-East London.

Methods: Data on management of COPD patients were extracted in 65 general
practices in Lambeth and Southwark including spirometry, inhaled medications
and recent COPD exacerbations. Patient severity was classed by GOLD stage and
appropriateness of prescribing was assessed.

Results: 4804 COPD patients were identified. Spirometry was recorded for 2941
(61%), of whom 778 did not meet GOLD diagnostic criteria. 2163 (45%) were
inappropriately treated according to GOLD. The most common deviation was over-prescription of ICS in GOLD II (55%), or III/IV with no history of severe exacerbations (56%). 793 (64%) cases of over-treatment involved LABA+ICS with a mean cost of £46.52/item.

Conclusion: Diagnosis of COPD was made without spirometry in the majority of
COPD patients in primary care. Deviation from GOLD in prescribing is substantial.
The potential for harm due to ICS over-prescription in over half of patients with a
confirmed diagnosis of COPD must give considerable cause for concern, besides the
unjustified costs.

182 
Missed opportunities to diagnose COPD
David Price1,2, David Halpin1, Robert Winter1,3, Susan L. Hill1, Eric Bateman1, Daryl Freeman1, Dermot Ryan1, Matthew Kearney1,4, Kevin Holton1, Anne Burden2, Julie von Ziegenweid2, Laurence Mascahn2, Alison Chisholm1, Rupert Jones1,2,3 *Centre of Academic Primary Care, University of Aberdeen, Aberdeen, United Kingdom; *Observational Research, Research in Real Life, Norwich, United Kingdom; 2Royal Devon & Exeter Hospital, NHS Foundation Trust, Exeter, United Kingdom; 3Respiratory Programme, Department of Health, London, United Kingdom; 4NHS Future Review, East of England Strategic Health Authority, Cambridge, United Kingdom; *Respiratory Medicine, University of Cape Town, Cape Town, South
Chronic Obstructive Pulmonary Disease (COPD) is among the leading causes of death in the world. Delay in diagnosing COPD appears common even among patients diagnosed in secondary care. Retrospective study of 95 cases

Sundel Salvi1, Parvaz Kouli1, J Clinical Research, Chest Research Foundation, Pune, Maharashtra, India; 2Clinical Research, Asthma Bhavan, Jaipur, Rajasthan, India; 3Clinical Research, Lung Care Center, Hyderabad, Andhra Pradesh, India; 4Research and Education, National Asthma, Allergy & Bronchitis Institute (NAABI), Kolkata, West Bengal, India; 5Internal and Pulmonary Medicine, SheriKashmir Institute of Medical Sciences, Srinagar, Jammu and Kashmir, India

Although a PFM is a useful tool for diagnosis and management of asthma, there are no such reference values for the adult Indian population. The aim of this study was to derive a predicted equation for PEF for Indian adults using an EU scale PFM.

Methodology: 5 centres representing different geographic, ethnic and socioeconomic backgrounds from India were selected (North: Srinagar, West: Jaipur, East: Kolkata, Centre: Pune and South: Hyderabad). Respiratory health and demographic questionnaires were administered to randomly selected 1000 rural and 1000 urban adults from each centre. Sampling was stratified according to gender, height and age. PEF values were measured using Breathometer (Cipla Ltd., India). The predicted equation was generated using linear regression analysis with SPSS software, Version 16.

Results and conclusion: Out of 9746 participants, 3608 were excluded as unhealthy based on presence of respiratory symptoms, smoking status and/or previous respiratory disease. 80% of the 6138 healthy adults (M: 3720; F: 2418) were used to derive the predicted equation. The equation was validated by comparing the predicted PEF values with the measured values in the remaining 20% sample. Using regression analysis, the predicted equations derived in L/min are: F: PEF = 168.551 – 1.776age + 1.354height; M: PEF = 69.259 – 2.296age + 2.888height. These reference PEF values for Indian adults are 24% lower for males and 27% lower for females than the Caucasian population.

Effectiveness of continuity in “World Day of COPD” awareness campaign on case finding for COPD in target population

Florin Mihaltan1, Roxana Nemes1, Amelia Ionescu2, 1Respiratory Care, National Institute of Pneumology “M. Nasta”, Bucharest, Romania; 2Medical Affairs, Novartis Pharma Services Romania, Bucharest, Romania

Background and aim: To evaluate effectiveness of continuity in awareness disease campaign on case-finding for COPD in a target population: over 35, smokers/ex-smokers, at least one respiratory symptom. Methods: 1-week marketing campaign was conducted 2009-2010 in WCD, using different marketing tools. Target population had open access to spirometry. Population was encouraged to visit COPD web-site to inform and take on-line COPD risk-test. In 2009-high visibility posters, leaflets within medical offices, 1-week marketing campaign was conducted 2009-2010 in WCD, using different marketing tools. Target population had open access to spirometry. Population was encouraged to visit COPD web-site to inform and take on-line COPD risk-test. In 2009-high visibility posters, leaflets within medical offices, press conference on World COPD Day. In 2010-media campaign, press conference preceded COPD Week, leaflets as personal letters from President of Romanian Society of Pneumology, distributed directly to population,through telephony companies. Primary outcome was number of COPD diagnosed. Secondary outcomes measures: unique site visitors, number of persons who perform on-line COPD risk test. Results: In 2009, 3494 persons were tested, 847 diagnosed (24%). In 2010, 4298 persons were tested, 1259 diagnosed (29%) – see Table 1.

Effectiveness of the Wells score for pulmonary embolism diagnosis in primary care. Retrospective study of 95 cases

Segolene Feurze1, Charles Dayen1, Horucie Bentayeh1, Emmanuelle Lecuyer1, Marie Boutemy1, Vincent Jounieaux2, Youcef Douadi1, 1Respiratory Care, National Institute of Pneumology “M. Nasta”, Bucharest, Romania; 2Pneumologie, CHU, Amiens, France, Metropolitan

Pulmonary embolism (PE) is an insidious life-threatening condition and its diagnosis represents a challenging topic in daily clinical practice since early recognition with appropriate management is known to improve prognosis. Clinical scores like Wells score are not used in daily practice by general practitioner (GP) and PE is most often diagnosed in hospital emergency room. We conducted a monocentric retrospective study which main objective was to evaluate the failure-rate and the efficiency of the strategy used by GP for PE diagnosis. All patients hospitalized for acute PE in a non-teaching hospital of the north of France were considered.

Ninety five patients were included. Retrospective evaluation of the Wells score gave a low PE probability in 34.7% and a strong or intermediate probability in 65.3% of the population whereas PE diagnosis was assessed by GP in 12% and 3%, respectively. We concluded that using the Wells score in general practice may improve the rate of PE diagnosis. To facilitate the implementation of such score, we developed an algorithm based on presence of dyspnea, thoracic pain or tachycardia that led to a 88% PE diagnosis by GP.

Usefulness of the Wells score for pulmonary embolism diagnosis in primary care. Retrospective study of 95 cases

1Respiratory Care, National Institute of Pneumology “M. Nasta”, Bucharest, Romania; 2Pneumologie, CHU, Amiens, France, Metropolitan

Prediction model for asthma in primary care. Retrospective study of 95 cases

1Respiratory Care, National Institute of Pneumology “M. Nasta”, Bucharest, Romania; 2Pneumologie, CHU, Amiens, France, Metropolitan

Background: Chronic Obstructive Pulmonary Disease (COPD) is among the leading causes of death in the world. Delay in diagnosing COPD appears common even though current consensus guidelines emphasize the importance of early detection.

Aim: To evaluate the effectiveness of a 2-stage-screening programme in primary care.

Methods: Subjects aged 65+ registered with a general practitioner (GP) in eastern Copenhagen received a simple questionnaire asking for smoking status and symp-
44. Smoking cessation science

187 Late-breaking abstract: Long-term efficacy of intensive behavior interventions and free medications for smoking cessation in Brazil

Ana Thereza Rocha1, Marla Rocha2, Marina Cardoso3, Lucas Macedo2, Franklin Pompa-Filho2, Manuela de Pinho1, 1NATTAB - Pulmonary Department, Complexo Hospital Universitário Professor Edgard Santos - Universidade Federal da Bahia, Salvador, Bahia, Brazil; 2Faculdade de Medicina da Bahia, Universidade Federal de Bahia, Salvador, Bahia, Brazil;

Introduction: Treatment of tobacco dependence is associated with low long-term success rates, particularly in women. Our public clinic (NATTAB) offers intensive behavior interventions (IBI) program combined with free medications in Salvador.

Purpose: To evaluate the long-term tobacco abstinence rates and gender differences in success with free medications.

Methods: We evaluated consecutive smokers, clinical and psychologically, verified the Fagerström’s test (FT) score and offered IBI by a multidisciplinary team in group sessions (weekly x 4; then biweekly x 4 and monthly x 9). Coping skills and problem solving activities were developed. The rates of reported abstinence were evaluated by telephone contact or review of last visit on clinical charts, and compared by chi-square test.

Results: 467 patients were evaluated in 35 months, 330 initiated IBI, 85% of the patients used medications and had follow up for 14±11 months (67% for 12 months). Mean age was 53±10 yrs, 67% were women and median FT score was 6 (IQR 3). 79% of women and 75% of men quit smoking at some point. The abstinence and relapse rates were respectively: 51% and 31% at 1-3 mo; 50% and 36% at 3-6 mo; 48% and 39% at 6-12 mo; 44% and 41% at 12-24 months and 42% and 42% at 24-35 months. Abstinence rates did not differ for men and women (45% vs. 51%, p=NS, respectively). Among those who relapsed, the mean time of abstinence was 3.6±4.1 months, and they stated that abandoning the IBI sessions contributed to relapse.

Conclusions: Programs combining IBI with free medications can be effective for long-term smoking cessation despite moderate to high nicotine-dependence, independently of gender.

188 Smoking prevalence and willingness to quit in newly screened Danish patients diagnosed with airway obstruction

Jens Dollerup1, Peter Bre Poulsen1, Charlotte Suppli Ulrik2, Anders Løkke3, Jens Holt1, Jens Løkke Jensen1, Klaus Kaa Andersen4, Ronald Dahl4, 1Medical and our IBI program combined with free medication, 2Card. & Pulm. Department, Hvidovre Hospital, Copenhagen, Denmark; 3Pulm Department, Aarhus University Hospital, Aarhus, Denmark; 4Boehringer Ingelheim, Med. and Acc., Copenhagen, Denmark; 5Inst of Mat. & Statistics, DTU of Denmark, Kgs. Lyngby, Denmark

Background: 436,000 Danes have chronic obstructive pulmonary disease (COPD) with one third diagnosed and treated with free medication. The Danish National Board of Health (NBH) recommends early detection of COPD focusing on: Age above 35 years. At least one pulmonary symptom. Smokers/ex-smokers or occupational diseases. Based on simulations, the timing of SCT initiation is critical to optimize health benefits and to reduce costs of care.

Aims and objectives: To evaluate the smoking prevalence and willingness to quit smoking in a population of newly diagnosed patients with airway obstruction in primary care in Denmark.

Methods: Following the recommendations by the NBH, participating GPs (n=335; 10% of Danish GPs) offered consecutively spirometry to patients with no previous diagnosis of obstructive. Demographic, spirometry, smoking status, smoking history and willingness to quit was recorded. The population indicated having COPD, was assessed as smoking status and smoking cessation initiatives.

Results: 3498 patients had spirometry, 1295 patients (37%, 61 years, 48% females) diagnosed with obstructive (FEV1/FVC < 70%). With more men than women (P=0.03) in total 64%, diagnosed with obstructive smoking (37 pack years, 17 cigarettes/day). 66% of smokers had a history of cessation attempts and 54% had used medication as part of the SC. 62% of the smokers like to quit, but only 11% intended to start immediately.

Indicated COPD severity and willingness to quit was not correlated.

Conclusions: Many patients identified with airway obstruction, indicating COPD, are current smokers. There is willingness to quit smoking, but only a few intend to initiate SC immediately, though guidelines recommend smoking cessation as primary intervention.

189 Predicted health and economic benefits of smoking cessation incorporating multiple quit attempts over a lifetime

Jens P. Martin1, Denus Giesing1, Richard J. Willie1, Nikhil Revankar1, Kelly H. Zou1, James Xenakis2, 1Global HealthEconomics and Outcomes Research, Pricer, Inc., New York, NY, United States; 2Healthcommunicative Modeling and Simulation, United Biosource Corporation, Lexington, MA, United States

Objective: To evaluate the impact of age at start of smoking cessation treatment (SCT) on predicted health benefits and costs over smokers’ lifetime.

Methods: A discrete event simulation of SCT allowing multiple quit attempts and estimates of lifetime health and economic outcomes was developed in a U.S. population. SCT types were assigned based on observed use.

Results: The predicted life expectancy of the 18 to 74 years old (mean age 42.1 years) reference population was 26.8 years, corresponding to 13.9 discounted quality adjusted life years (QALY). The lifetime cost of SCT averaged $1,462, with a total direct cost (IDC) of smoking-attributable disease of $54,550/smoker. Smokers averaged 7.9 QALYs; 66.2% were permanent abstainers at the time of death. Smokers who started SCT at 35 to 40 years of age, accrued 15.6 discounted QALYs, and 74% achieved permanent abstinence. Smokers who started SCT between 50 and 55 years of age accrued 11.5 discounted QALYs and 60.2% achieved permanent abstinence at the time of death. Total abstinence times (IAT) were 10.1 vs. 7.2 years in the younger and older age groups, respectively, with corresponding SCT costs of $1,042 vs. $1,385 and lifetime IDC of disease of $43,306 vs. $72,439/smoker.

Conclusion: The number of individuals achieving permanent abstinence at the time of death is greater if smokers make their first quit attempt at age 35-40, rather than at age 50-55. Despite longer survival times, their costs are lower. The lifetime cost of SCT is negligible compared with the IDC of smoking-attributable diseases. Based on simulations, the timing of SCT initiation is critical to optimize health benefits and to reduce costs of care.

190 Long term predictors for smoking cessation in a long-term, population study at the workplace

Daiana Stolz1, Andreas Scher2, Bruno Seiffert3, Kuster Martin3, Meyer Anja4, Tamim Michael1, 1Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital Basel, Basel, Switzerland; 2Industrial Health Service, Hoffmann-LaRoche AG, Basel, Switzerland; 3Industrial Health Service, Novartis Pharma AG, Basel, Switzerland

We implemented a voluntary, intensified, structured smoking cessation program with combined medical therapy for health care and health industry employees at workplace. 703 smoking employees from three sites assembled a 2 year program. This consisted of 10 visits with intensified counselling and motivational support. Various modalities of both nicotine replacement therapy and self-help programs were prescribed. Primary endpoint was nicotine abstinence at 12 and 24 months, which was defined as self reported abstinence confirmed by exhaled CO< 6 ppm. Predictive factors of nicotine abstinence were analyzed by multivariate regression analysis. Smoking cessation rates reached 38% after 12 months and remained unchanged after 24 months. Predictors of a successful quit attempt were higher education level (1.86 95% CI 1.12-3.07; p=0.016) and breathlessness at baseline (OR 2.53 95% CI 1.81-3.52; p<0.001). More severe nicotine dependency (OR 0.76 95% CI 0.59; 0.97; p<0.003), higher craving scores (OR 0.75 0.64-0.89; p=0.001) were negative predictors for successful quitting.

Conclusion: Smoking cessation intervention achieved high and stable longterm abstinence rates. Predictive factors for smoking cessation could be helpful to increase the effectiveness of smoking cessation programmes.
191 Smoking cessation effectiveness in smokers with obstructive respiratory disease

Angélica Flórez, Konstantinos Eleftheriou, Georgios Patentakis, Athanasios Sachlas, Dimitrios Michailidis, Christina Gratziou. Smoking Cessation Centre, Respiratory and Critical Care Dept., University of Athens, Evangelion Hospital, Athens, Greece

Cigarette smoking is the major risk factor for the development of Chronic Obstructive Pulmonary Disease (COPD) and is associated with increased morbidity and reduced sensitivity to medication in asthmatic patients.

The aim of the present study was to evaluate the effectiveness of smoking cessation treatment in a sub-population of smokers with COPD and asthma in real life conditions and to compare the efficacy of three specific pharmacological agents.

A total of 2139 adults, current smokers were enrolled in the study. 298 subjects

Table 1. Abstinence rates in the three treatment groups in respiratory patients are shown in table 2

Conclusion: Smoking cessation treatments are highly effective in smokers with respiratory co-morbidity as asthma and COPD and it can be achieved with all approved pharmacological agents through a personal approach, motivation and intensive follow-up program.

192 Smoking cessation treatment for COPD smokers

Carlos A. Jimenez Ruiz, Ana Maria Cicero Guerrero, Maria Luisa Mayayo Uhbarri, Maria Isabel Cristobal Fernandez, Gema Lopez Gonzalez. Unidad Especializada Tubaqusmo, Salud Madrid, Madrid, Spain

We reviewed medical histories of all COPD patients who were treated in our Unit between January 2004 and 2010. All patients received both psychological and pharmacological treatment (NRT, varenicline or bupropion). Medical and smoking histories were obtained during the baseline visit. A Quit date was chosen and therapy was begun. In all follow-up visits, patients received treatment, and control of abstinence and monitoring of adverse effects were carried out. The treatment was free of charge. The assessed outcomes were continuous abstinence rate (CAR) between week 9 and 12 and CAR between week 9 and 24, both defined by not smoking over those periods of time. Levels of CO of 10 ppm or less were required.

The average rate on FTND-questionnaire was 7.4 (2.1), NRT was prescribed in 233 (49%), Bupropion in 45 (9.5%), Varenicline in 196 (49%), and 4 (1.5%) of them did not receive treatment. Global effectiveness was: CAR from week 9 to 12 was met by 54.3%, and CAR from week 9 to 24 was met by 48.5%. Taking into consideration the kind of treatment used, CAR from week 9 to 24 were 44.1%, 60% y 61% for nicotine patches, bupropion and varenicline respectively. Significant differences were observed between varenicline and nicotine patches. OR: 1.98 (1.25-3.12); p.<0.001.

Good effectiveness of pharmacological treatments for COPD smokers. Good safety pattern of smoking cessation pharmacological treatments for COPD smokers.

Varenicline gets better efficacy results than nicotine patches in this group of smokers.

193 A placebo-controlled trial with varenicline for long term nicotine replacement product users

Philip Tonnesen, Kim Mikkelsen. Palm Dept, Gentofte Hospital, Copenhagen, Denmark Palm Dept, Gentofte Hospital, Copenhagen, Denmark

In this placebo, controlled trial we enrolled 139 long-term users of nicotine replacement products (NRT) (>1 year) to either varenicline (N=70) or placebo (N=69) for 3 months combined with 9 visits with counselling by nurses. The primary outcome showed that the varenicline group had a higher quit rate with NRT compared with placebo, statistical significant after 12 and 16 weeks but borderline significant on most other measure points. After 1 year the NRT quit rate was 19% vs. 36.2%, respectively. A Mantel-Haenszel test over all visits showed significant superiority for active therapy vs. placebo, odds ratio 1.83 (95%CI: 1.43-2.35), P<0.0001. Results for withdrawal symptoms, adverse events from varenicline, and weight changes will be reported. Also, changes in total-cholesterol, LDL, HDL and triglyceride after 3 and 12 months will be reported for NRT quitters and failures as well as changes in p-cotinine for users of NRT.

This is the first study reporting data for varenicline to be used for long-term NRT users. The study seems to be underpowered but overall the findings showed superiority for varenicline vs. placebo.

In conclusion, this study shows that varenicline seems to be a drug that might be effective in getting long-term NRT users to quit.

194 Efficacy and safety of a novel nicotine mouth spray in smoking cessation: A randomized, placebo-controlled, double blind, multicenter study with 52-week follow up

Philip Tonnesen, Hans Lauri, Roland Perfek, Aní Baltra, Karl Mann. Pulmonary Dept. Gentofte Hospital, Copenhagen, Denmark Research Dept. McNeil AB, Helsingborg, Sweden Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany Dept. of Psychiatry & Psychotherapy, University Hospital of Tubingen, Tubingen, Germany

The study was a randomized (2:1) double-blind, placebo-controlled, low-intensity counseling study of the efficacy of a novel nicotine mouth spray (1 mg/spray) and its aid to smoking cessation. The study enrolled daily cigarette smokers aged 18 years or older, who were motivated to quit and who had a CO level of >10 ppm. During Weeks 1-6, they were instructed to use 1-2 sprays whenever they would normally have smoked a cigarette, or whenever they experienced cravings to smoke, up to a maximum dose of 4 sprays per hour, and 64 sprays per day. The dose was tapered down during Weeks 7-12. Low intensity counselling was provided during the study.

Continuous CARverified abstinence rates (CAR) were measured from Week 2 and were statistically significantly higher with active treatment than placebo. CAR after 6 weeks and 52 weeks were 26.1% vs 16.1% and 13.8% vs 5.6% (RR: 2.48, 95% CI: 1.24-4.94) for active vs placebo, respectively.

Treatment-related adverse events were common with both active and placebo, and were reported by 87% of subjects who used active spray and 71% of subjects who used placebo spray. Most adverse events reported were mild to moderate, and only 9.1% of participants in the active group and 7.5% in the placebo group withdrew due to adverse events.

In conclusion, these findings show that the nicotine mouth spray is a well-tolerated and effective aid to smoking cessation. At one year, the OR for sustained abstinence with active spray versus placebo was 2.7, and the RR was 2.5. Adverse events were common with both active spray and placebo, but were mostly mild to moderate, and generally tolerated.

45. Mechanisms and outcomes of infective exacerbations of COPD

195 Late-breaking abstract: Moxifloxacin (MXF) vs amoxicillin/clavulanic acid (AMC) in acute exacerbations of COPD (AECOPD): Results of a large clinical trial with a novel endpoint

Robert Wilson 1, Antonio Anzueto 2, Marc Miravitlles 3, Pierre Arvis 4, Jeff Alder 5, Daniel Havensstock 6, Mila Trajanovic 7, Sanjay Sethi 8, 1 Host Defence Unit, Royal Brompton Hospital, London, United Kingdom; 2 University of Texas Health Science Center at San Antonio, Pulmonary/Critical Care, San Antonio, TX, United States; 3 Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, Barcelona, Spain; 4 Global Clinical Development, Bayer HealthCare, Loos, France; 5 Global Clinical Development, Bayer HealthCare Pharmaceuticals, Montville, NJ, United States; 6 Global Biostatistics, Bayer HealthCare Pharmaceuticals, Montville, NJ, United States; 7 Global Clinical Development, Bayer HealthCare Pharmaceuticals, Toronto, ON, Canada; 8 Division of Pulmonary, Critical Care and Sleep Medicine, University of Buffalo, Buffalo, NY, United States

Introduction: Evidence-based therapy of AECOPD is limited by a lack of appropriate trials. MAESTRAL compares antibiotic therapies for AECOPDs in patients with moderate-to-severe disease at risk of poor outcomes.

Method: This was a multiregional, prospective, randomised, double-blind study of patients ≥60 years, FEV1<60% predicted, with an Anthonisen type 1 exacerbation and ≥2 exacerbations in the last year. Patients were stratified by systemic steroid use and received MXF 400 mg PO qd (5 days) or AMC 875/125 mg PO bd (7...
Rhinovirus infection induces secondary bacterial infection in COPD

Patrick Mallia1, Joseph Footitt1, Rosa Sotero1,3, Annette Jepson1

Rhinovirus infection induces secondary bacterial infection in COPD

Results: Both drugs had good efficacy. At the 8-week endpoint, MXF was superior to AMC in microbiologically confirmed AECOPD. Bacterial eradication and clinical success were strongly correlated. The results may help physicians optimise antibiotic therapy in moderate-to-severe AECOPD.

Conclusion: Both drugs had good efficacy. At the 8-week endpoint, MXF was superior to AMC in microbiologically confirmed AECOPD. Bacterial eradication and clinical success were strongly correlated. The results may help physicians optimise antibiotic therapy in moderate-to-severe AECOPD.

196

Rhinovirus infection induces secondary bacterial infection in COPD

Patrick Mallia1, Joseph Footitt1, Rosa Sotero1,3, Annette Jepson1, Gregory Oleszkiewicz1, Julia Aniscenko1, Onn Min Kon1, Papi Alberto3, Albert Gabarrús, Antoni Torres

Rhinovirus infection induces secondary bacterial infection in COPD

Methods: We performed experimental rhinovirus (RV) infection in COPD subjects (GOLD stage II, N=20), smokers with normal lung function (SMK, N=21) and non-smokers (NS, N=11). Sputum was collected at baseline and following inoculation. RV infection was confirmed with PCR and semi-quantitative bacterial culture performed. SLPI, elafin and neutrophil elastase (NE) were measured in sputum by ELISA.

Results: 1 subject with bacteria in baseline sputum was excluded. Following RV infection bacteria were detected in 65% of COPD, 19% of SMK and 30% of NS (P=0.0086). 92% of bacteria in the COPD group were pathogenic bacteria, compared with 50% in SMK and 33% in NS (P=0.045). Peak sputum virus load was on day 5 and peak bacterial load on day 15. Following RV infection sputum SLPI and elafin fell from baseline in the bacteria+ve subjects and increased in the bacteria−ve subjects.

Peak virus load (4.4±0.72 vs 6.5±0.66 copies/mL,P=0.049) and sputum NE on day 0 (0.65±0.14 vs 0.31±0.07μg/mL,P=0.026) were higher in subjects with bacterial infection compared to those without.

Conclusions: Secondary bacterial infection is common following rhinovirus infection in COPD and is associated with higher virus loads and NE, but lower levels of SLPI and elafin in sputum. Degradation of SLPI and elafin by NE may be a mechanism of increased susceptibility to bacterial infection.

197

Predictors of poor outcome in severe hospitalised COPD exacerbations

Zinka Matkovic, Marc Miravilles, Nestor Soler, Arturo Huerta, Rebeca Domingo, Albert Gabarrús, Antoni Torres. Department of Pulmonary Medicine, Clinical Institute Thorax, IDIHAPS, Hospital Clinic Barcelona, Barcelona, Spain

Background: The aim of study was to determine predictors of poor outcome in patients hospitalised for exacerbation of chronic obstructive pulmonary disease (ECOPD).

Methods: Hospitalised patients with ECOPD were included in a prospective study and followed for 1 month. Clinical and epidemiological parameters were evaluated including COPD Severity Score (COPD-SS) and Charlson Index. Poor outcome was death, intensive care unit (ICU) admission, need for mechanical ventilation (MV), prolonged hospital stay (>11 days) and emergency room (ER) visit/re-admission during follow-up.

Results: 155 patients: mean age:41±standard deviation 9.6 years; 84% men; 76% smokers/ex-smokers; 55% GOLD stage III or IV; mean hospital stay 8±5 days. Cox proportional hazards model showed that previous exacerbations, hospitalisation for ECOPD and COPD-SS were independently associated with poor outcome: exacerbations and hospitalisation for ECOPD in the last year (p=0.033 and 0.039 respectively); lower FEV1 (p=0.004); GOLD stageII (p=0.049); lower pH (p<0.001); lower PaO2/FIO2 (p=0.006); higher PaCO2 (p<0.001); higher COPD-SS (p=0.016); long-term O2 therapy (p=0.042). Independent predictors of poor outcome determined by multivariate analysis: number of exacerbations in the previous year (1 ECOPD: p=0.012, odds ratio [OR] 4.1, 95% confidence interval [CI] 1.4 to 12.3; ≥2 ECOPD: p=0.005. OR 4.4, 95% CI 1.6 to 12.5); pH (p=0.006, OR 0.2, 95% CI 0.1 to 0.7); PaCO2 (p=0.015, OR 1.3, 95% CI 1.1 to 1.7).

Conclusion: Previous exacerbations, hypercapnia and respiratory acidosis were identified as predictors of poor outcome in patients with severe ECOPD.

198

Human respiratory epithelial cells acquire a long-lasting antiviral condition when exposed to interferon beta

Giel Gaaqetaan, Gert Grauls, Catrien Bruggeman, Frank Stassen. Medical Microbiology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands

Type I interferons (IFNs) induce strong antiviral effects and are therefore attractive to prevent seasonal respiratory infections or reduce the incidence of virus-mediated exacerbation in COPD patients. Yet, clinical application of type I IFNs is hindered due to significant side effects observed during repetitive use. In this study we investigate the duration of protection, mediated by prophylactic IFNbeta, against a human rhinovirus (HRV) infection.

Human respiratory epithelial (A549) cells were exposed for 18 hours to various concentrations (31.500 IU/ml) of IFNbeta. Then, IFNbeta was either removed or maintained in the supernatant for the rest of the experiment. Next, cells were infected with HRV-IB (MOI 0.1) at t = 0, 24, 48, 72 or 168 hours after the initial exposure to IFNbeta. At 48 hours post infection, the protective effect of IFNbeta on HRV-induced cell death was determined by a colorimetric assay RT-qPCR and plaque assay were used to determine HRV infection. In the continuous presence of IFNbeta, 90-100% of A549 cells were protected against HRV-induced cell death at every time point and at all IFNbeta concentrations. This strong protective effect was confirmed by RT-qPCR and plaque assay. Alternatively, when IFNbeta was removed, cell death increased with time and in a dose-dependent way. Nevertheless, at 16th post IFNbeta stimulation (5000 IU/ml), still 75% of all cells were viable.

These data show that IFNbeta has not only a strong, but also long-lasting protective effect against HRV-IB. This opens new opportunities for prophylactic treatment of viral respiratory infections without the risk of side effects often seen after repetitive and systemic use.
Pentraxins are a family of acute-phase reactants and pentraxin-3 (PTX3) is the prototypic long pentraxin. PTX3 has a protective role against pathogens including influenza viruses and both pro- and anti-inflammatory actions of PTX3 are described. The role of PTX3 in virus-induced COPD exacerbations is unknown.

Methods: We infected 3 groups of subjects—COPD GOLD stage II (N=20), smokers with normal lung function (SMK,N=21) and non-smokers (NS,N=11) with rhinovirus (RV). Induced sputum was collected on 6 time points post-inoculation, cytospins prepared and cell counts determined. PTX3 and neutrophil elastase (NE) were measured in sputum supernatants by ELISA and sputum virus load by quantitative PCR.

Results: Following RV infection PTX3 in sputum was significantly increased over baseline in the COPD group and the SMK but not the NS.

Metagenomic analysis of lower airway microbial diversity in patients with chronic pulmonary disease

Edward Monsó1, Raul Cabrera2, Andres Moya2, Alex Merz3, Marian Garcia1, Xavier Pomares1, Jose M. Antó3.
1Pneumology Service, Corporació Parc Taulí. Sabadell, Barcelona, Spain; 2Genomics Service, Centro Supervisor de Investigación en Salud Pública, Valencia, Spain; 3Laboratory Service, IRCs Germans Trias i Pujol. Ciberes, Barcelona, Spain

Aim: To identify microorganisms unrecognized through culture in the lower airway of patients with chronic pulmonary disease through amplification and pyrosequencing of specific genes for microbial diversity assessment

Method: To avoid culture-related bias, 16S DNA extraction from respiratory samples (sputum, bronchial aspirate (BAS), bronchoalveolar lavage (BAL) and bronchial mucosa); 2) 16S rRNA amplification and purification with modified primers which were classified as probable IPA, possible IPA (n=6), colonization (n=2) and non-IPA group (n=17); According to the ROC curve, when chose 0.795 as the cut-off of BALF GM test, the sensitivity, specificity, positive and negative predictive value for probable IPA were 88.9%, 95.1%, 100% and 93.7%, respectively.All of the patients of IPA group were dead. The result of GM test in BALF with IPA group were much higher than control group (2.88 vs 0.49, p<0.001). The mortality was much higher in the patients whose GM test in BALF above 0.795 than the patients lower 0.795 (80% vs 17%; p=0.001).

Conclusions: Compare to serum GM and aspergillus culture, GM in BALF prove to be more useful in early diagnosis of IPA with critically ill COPD patients. 0.795 maybe a best cut-off in BALF GM detection. Besides, high GM value in BALF was associated with high mortality in a certain sense.

Reducing exacerbations in COPD with OM-85: A multicentre, double-blind, placebo-controlled trial

Dario Olivieri. Department of Clinical Sciences, University Hospital, Parma, Italy

Background: Acute exacerbations in COPD (AE-COPD) are a key driver of morbidity and mortality. They are mainly triggered by respiratory infections. OM-85 is a bacterial lysate by immunostimulating properties already known to reduce AE-COPD.

Aims and objectives: Confirm and further investigate the efficacy and safety of OM-85 (Broncho-Vaxom®, Broncho-Munal®, Ommunal®) with a specific dosage regimen in reducing the rate of acute exacerbations in moderate to severe COPD patients.

Method: This randomised, placebo-controlled, double-blind, multicentre trial was performed with 340 patients from 5 countries, past or active smoker, over 40 years old, with COPD stage II or III, with a history of at least 2 documented AE-COPD in the previous year, and a FEV1 between 30% and 80%.

Results: Preliminary results show that OM-85 significantly reduced the rate of AE-COPD by 35.4% after the 5 months treatment period (p=0.0155). The mean duration of AE-COPD was significantly decreased by 1.4 days in the OM-85 group (1.5 vs 2.9 days; p=0.0498). The rate of treatment-emergent adverse events (TEAEs) was similar in both treatment groups (OM-85: 44.1%, placebo: 43.3%).

Conclusion: OM-85 significantly reduced the rate and duration of AE-COPD in moderate to severe COPD patients. Safety and tolerance were excellent.

SUNDAY, SEPTEMBER 25TH 2011
Conclusion: Current regression equations to estimate Wpeak based on 6MWD in COPD are inaccurate in COPD. So, estimated Wpeak cannot be used to target treatment intensity during PR in individuals with COPD.

205 Divergent effects of obesity on weight bearing versus non-weight bearing exercise testing in patients with COPD

Frits M.E. Franssen, Erica P.A. Rutten, Emiel F.M. Wouters, Paula P. van Melick, Martin J. Spruit. Program Development Center, Ciro, Centre of Expertise for Chronic Organ Failure, Hornerheide, Netherlands

Introduction: Obesity is common in patients with COPD and may impact on disease severity. However, obesity was not associated with diminished exercise capacity or greater dyspnea during non-weight bearing exercise (e.g. stationary cycling) in COPD1. Aim of this study was to investigate the impact of obesity during weight bearing exercise (e.g. six-minute walk test, 6MWT) in patients with severe COPD.

Methods: Data obtained during pre-rehabilitation assessment of 44 male obese COPD patients (OB) (age 58±6y, FEV1% pred= 39±10), BMI 23.0±1.2 kg/m². 6MWT and progressive cycle ergometry (CPET) were performed, BORQ scores for dyspnea and leg fatigue were recorded at the end of both tests.

Results: Distance of 6MWT was significantly reduced in OB (452±101 m) compared with NW (497±82 m, p<0.05), while peak cycling exercise load was comparable (OB 90±11 W, NW 85±24 W, ns). Dyspnea (5.9±2.0 vs. 4.9±2.0, p<0.05) and leg fatigue (4.8±2.4 vs. 3.4±2.2, p<0.05) sensations after 6MWT were significantly increased in OB compared to NW, while these were comparable after CPET (dyspnea: OB 7.6±1.8 vs. NW 7.4±2.0, ns; leg fatigue: OB 6.1±2.2 vs. NW 6.3±2.5, ns).

Conclusion: In contrast to non-weight bearing exercise, obesity has a negative impact on weight bearing exercise capacity and exercise-related symptoms in male patients with severe COPD. Obese COPD patients may prefer cycling instead of treadmill walking as training modality during rehabilitation.

04 Tru et al, Combined effects of obesity and COPD on dyspnea and exercise tolerance, Am J Respir Crit Care Med 2009

206 Investigating circulating microRNAs as potential biomarkers of quadriiceps weakness in COPD

Anna Donadoni1,2, Amy Lewis1, Samantha Natanek1, William Man1, Paul Kemp1, Michael Polkey1, NHRH Respiratory Biomedical Research Unit, Royal Brompton and Harefield NHS Foundation Trust and Imperial College, London, United Kingdom; 2Section of Molecular Medicine, National Heart and Lung Institute, Imperial College, London, United Kingdom

Introduction: Non-invasive biomarkers of quadriiceps phenotype in COPD are needed. MicroRNAs (miRs) are small non-coding RNA that modulate gene expression. They circulate in blood as exosomes and are promising biomarkers. We hypothesised that muscle specific miR-499, which controls slow myosin expression, would be differentially expressed and correlate with physiological parameters.

Methods: We studied 101 COPD patients and 24 controls. MiR-499 was quantified in stored plasma samples using qRT PCR1. Mir-16 and mir-222 were quantified as negative controls. Results were normalised to a spiked-in control. All subjects had paired quadriceps biopsy samples.

Results: Characteristics as mean (SD): COPD patients: 66 M: 35 F, age 68 (± 6), FEV1% pred= 44 (±19), six-minute walk (6MWW) = 394 (±121). Controls: M 14: T 10, F, age 68 (± 6), FEV1% pred= 112 (±13), 6MWW= 616 (±83).

Systemic inflammation is an important factor in skeletal muscle dysfunction (SMD) in chronic obstructive pulmonary disease (COPD) patients. The SMD can be reversed partially by physical training; however, the response is dependent of type, intensity and duration of exercise. This study evaluated the inflammatory response, muscle strength and fat-free mass outcomes in COPD patients comparing two protocols of resistance training. COPD (n=34) were assigned to conventional resistance training (CRT) or elastic tubing training (ETT) groups (n=17 each, FEV1= 1.23±0.46% and 1.24±0.54% predicted; aged 64±11.7 y, respectively). CRT group were trained at moderate intensity (3×10 RM) and ETT group were trained at 2-7 sets of repetitions determined individually by resistance to fatigue test. TNF-α, cytokines (IL-1β and IL-10) on plasma by ELISA, peripheral muscle strength and fat-free mass were obtained at baseline (D0) and after the 8-weeks training intervention (D2). Citokines also were measured acutely immediately after the first (D1) and the last training session (D3). TNF-α, IL-1β and IL-10 increased in CRT group after 8 weeks compared to baseline (p<0.001), p<0.05 and p<0.001, respectively). IL-1β and IL-10 levels also increased in response to acute exercise (D1) and IL-10 measured acutely after 8 weeks training (D4) was reduced (p<0.01, compared to D3). No changes in cytokines levels in plasma were observed in the ETT group. Muscle strength increased in both groups, but only the ETT protocol increased the fat-free mass after 8 weeks. These findings suggest that structural and functional gains were obtained from a lower systemic cost in the ETT group.

208 Early peripheral muscle structural and metabolic impairment in chronic obstructive pulmonary disease (COPD) patients cannot be considered as a consequence of sedentary lifestyle

Fares Gowzi1,2, Aïlinda Abdellaoui1,3, Sami Sedraoui1, Thierry Lafontaine1, Philippe DeKegila1, Dahlia Laoud-Chenvesse1, Jacques Mercier1, Christian Préfault1, Maurice Hayot1, INSERM U-1046, A. de Villeneuve Hospital, University of Montpellier I, Montpellier, France; 2Pulmonary Rehabilitation Center “La Solana”, Fontainebleau Group, Ossexe, France; 3Pulmonary Rehabilitation Center “La Solana”, Fontainebleau Group, Lodsé, France

Peripheral muscle dysfunction in COPD patients has been related to a muscle/fiber atrophy and oxidative metabolism reduction, which mimicks a severe disease. Thus, we investigated the structure and mitochondrial function in skeletal muscle biopsies from patients with COPD and sedentary healthy subjects (SHS). 24 stage I-II (according to the GOLD classification) COPD patients and 21 age-matched SHS (<150min/W of moderate-vigorous PA) had accelerometry recording, quadriiceps function and muscle (impedancemetry) assessment. All subjects had a biopsy of the quadriiceps, allowing assessment of the respiratory parameters and mitochondrial ATP synthesis, and of the muscle morphology (immunohistochemistry). Results are presented in mean ± SD or median [inter-quartile range]. COPD patient and PA level-matched SHS (activity counts/day: 133±70 vs 135±48; p=0.9), had the same muscle mass and fiber cross-sectional areas. However, there was a reduction of the quadriiceps endurance and of the type I fiber proportion (35% [28-49] vs 41% [38-53]; p<0.05). While the maximal ADP-stimulated respiration (state 3) with pyruvate substrate was comparable in COPD and SHS, the ATP/O value (ratio between ATP synthesis and oxygen consumption) was significantly reduced in COPD (0.96±0.04 vs 2.6±0.8; p<0.001), and observed in early stages. This study showed an early impairment of the muscle oxidative metabolism (type I fibers and mitochondrial efficiency), unexplained by the PA reduction in COPD. COPD past that the oxidative phosphorylation alteration (OXPHOS pathway) occurs in the PHOS plot, i.e. the ATP synthesis rate.
COPD patients often experience walking as a problematic daily activity. Although a rollator can improve mobility, many patients feel ashamed to use it. Therefore, other walking aids may be worthwhile to consider. We aimed to determine whether a new walking aid (fig 1a) has similar direct effects on 6MWD as a rollator (fig 1b) in COPD patients.

**Figure 1. A: Walking frame “City”, B: rollator.**

21 COPD patients (52% men; age: 64±11yrs; FEV1: 42±15% pred) performed 2 6MWTs during pre-rehabilitation assessment (mean best 6MWD: 369±88 m). In addition, 2 extra 6MWTs were randomly performed on 2 consecutive days: 1x with rollator and 1x with walking frame. Walking pattern (n=21) was determined using an accelerometer and metabolic demands (n=10) were assessed using a mobile oxycron.

Using walking frame resulted in a higher mean 6MWD (466±189 vs. 383±85 m) and fewer steps (491±122 vs. 601±298) compared to a rollator (all p<0.05). Oxygen uptake, ventilation, heart rate, oxygen saturation and Borg symptom scores were comparable. 19% felt ashamed using rollator compared to 10% using walking frame.

Functional exercise performance can be improved using walking aids in COPD patients. Moreover, using walking frame led to a significant improvement in 6MWD compared to using rollator, with the same metabolic demands. Therefore, the new walking aid may be a good alternative for a rollator in COPD patients.

This study was financially supported by “Stichting De Weijerhorst.”

**Combining physical activity monitoring and cardiac output during exercise in COPD patients with GOLD stages II-IV**

Eleni Kortianou1,2, Ioannis Vogiatzis1,3, Zafeiris Louvaris1,2,1

1Respiratory Medicine, National Heart and Lung Institute, Imperial College, London, United Kingdom; 2Drug Discovery, AstraZeneca, Loughborough, United Kingdom

In COPD, alveolar macrophages (AM) increase, release more inflammatory mediators but respond poorly to glucocorticosteroids. Different macrophage phenotypes are identified in animals based on density but no definitive studies on human lung macrophages exist. Cells were isolated from resected human lung tissue from non-smokers (NS, n=5) smokers (S, n=11) and COPD (n=7) patients. Cells were separated into three viable fractions using Percoll density gradients (A: 30-40%, B: 40-50% C: 50-60%). Responses to budesonide after stimulation with lipopolysaccharide (LPS) were investigated by measuring TNFα, CXCL8 and IL-10 release by ELISA. Baseline and LPS-stimulated release of TNFα, CXCL8, and IL-10 did not differ between cell fractions or subjects. LPS-stimulated TNFα release from fraction A from NS and S were responsive to budesonide (EC50 NS: 0.5±0.04nM vs S: 1.8±1.1nM), with inhibition at 10M being ~80% (NS) and ~60% (S). However, COPD cells were unresponsive. Budesonide (10M) inhibited LPS-stimulated CXCL8 release from fraction A similarly in NS and S but less effectively in COPD cells (~30%, p<0.05) with EC50 values 0.6±0.1nM (NS), 1.0±0.3nM (S) and 2.4±0.9nM (COPD) cells. This apparent steroid insensitivity of COPD macrophages from fraction A was selective, as budesonide inhibited LPS-stimulated IL-10 release by ~55% in fractions A from S and COPD patients (EC25 S: 2.0±1.7nM vs COPD 1.7±1.1nM) but by 80% (EC50 S: 9.0±2.0M) in NS cells. TNFα and CXCL8 responses of cells from fractions B and C did not differ between subjects. Fraction A COPD macrophages were less responsive to budesonide and may represent AM. Identifying selective fraction A markers will allow development of directed therapies.

**LSC 2011 Abstract: Production of alpha-1 antitrypsin (AAT) by pro- and anti-inflammatory macrophages and dendritic cells**

Emily F.A. van ’t Wout, Annemarie van Schadewijk, Nigel D.L. Savage, Jan Stolk, Pieter S. Hiemstra, Paul M. Thomas, Kinghorn Centre, Leiden, Netherlands; Infectious Diseases, Leiden University Medical Centre, Leiden, Netherlands

AAT acts as an important neutrophil elastase inhibitor in the lung. Although the hepatocyte is considered as the primary source of AAT, local production by monocytes, macrophages and epithelial cells may contribute to the formation of an anti-elastase screen. Since monocytes can differentiate into a heterogeneous population of macrophages with subpopulations ranging from pro-inflammatory properties (M1) to anti-inflammatory properties (M2), and into dendritic cells (DC), we studied whether lipopolysaccharide (LPS), TNFα and oncostatin M (OSM) enhance AAT production differentially in cultured M1, M2 and DC. Monocytes from healthy blood donors were cultured for 7 days in the presence of GM-CSF, M-CSF or GM-CSF + IL-4 to obtain M1, M2 and immature (i) DC, respectively. Next, cells were stimulated with LPS, TNFa or OSM and synthesis of AAT was assessed by quantitative RT-PCR and ELISA. Spontaneous release of AAT was higher in M1 than in M2 and iDC after 24h (187 ng/106 cells vs 50 ng/106 and 80 ng/106, p<0.016). LPS significantly increased AAT production in M1, M2 and DC (302 ng/106 vs 97 ng/106 and 248 ng/106, p<0.019), whereas TNFα and OSM did not affect AAT secretion. The secretion levels of the related protein inhibitor alpha-1 antichymotrypsin (ACT) were below the limits of detection by ELISA. Analysis by quantitative RT-PCR showed that 24h LPS exposure caused a maximal 2.1-fold AAT mRNA increase in M1, a 21-fold increase in M2 and 11-fold increase in DC.

We conclude that cultured M1 produce more AAT than M2 and DC, which is partly explained by a high spontaneous release of AAT by M1. This suggests that cellular differentiation is a regulator of local AAT production.
Background: Neutrophils are among the first cells to arrive at the site of injury and chemokine release by neutrophils is altered in COPD as compared to healthy controls. Neutrophils spontaneously release CXCL-8, CCL-2 and CCL-3. Inhibitors of neutrophils such as Ac-PGP significantly inhibit the release of LPS induced CXCL-8. There is growing evidence that Ac-PGP generated increased endogenous Ac-PGP when incubated with intact collagen; this effect was inhibited by an ERK1/2 pathway inhibitor.

Conclusions: These data indicate that ERM-dermed Ac-PGP released in MMP-9 activated from PMNs by the ligand of CXCR1 and CXCR2 and subsequent activation of the ERK1/2 MAPK, demonstrating a new pathway of matrix-mediated protease regulation and subsequent “feed-forward” Ac-PGP production.

216 JAK/STAT inhibition improves macrophage phagocytosis of bacteria

Rebecca A. Holloway1, Iain Kilty2, Peter J. Barnes 1, Louise E. Donnelly 1.

Introduction: JAK/STAT pathway is involved in host defence against infection with Gram-negative bacteria.

Methods: Using RAW264.7 murine macrophages and the human monocyte cell line THP-1, we examined the effect of inhibitors of JAK/STAT pathways (PF95, PF13) on phagocytosis.

Results: Both PF95 and PF13 increased phagocytosis by 2.4 and 12 fold, respectively. Co-incubation with IFN-γ + TNF-α increased phagocytosis by 3.3 fold, with a 1.8 fold increase at 48 h. Pre-treatment with JAK/STAT inhibitors did not affect phagocytosis.

Conclusion: JAK/STAT pathway inhibitors increase phagocytosis, suggesting that this pathway is involved in host defence againstGram-negative bacteria.

217 Increased expression of phosphodiesterase 4 (PDE4) A, B and D in alveolar macrophages from chronic obstructive pulmonary disease (COPD) patients

Simon Lea1, Aleksandra Metyka1, Fabrizio Facchini2, Dave Singh3.

Background: Phosphodiesterase-4 (PDE4) inhibitors, such as roflumilast, may offer novel anti-inflammatory strategies in respiratory diseases, including chronic obstructive pulmonary disease (COPD). Although it is widely accepted that PDE4 is expressed in macrophages, there is a lack of knowledge regarding the expression levels of PDE4 subtypes in alveolar macrophages (AM) from COPD patients.

Methods: We examined mRNA levels of PDE4A, B and D in AM from patients with COPD and the modulatory effects of roflumilast on LPS-evoked cytokine release.

Results: Expression of PDE4A, B and D were significantly augmented in AM from COPD patients compared to non-smokers (P<0.05). Roflumilast significantly (P<0.01) reduced LPS induced TNFα production in a concentration-dependent fashion (0.05-5 μM) while had no significant effect on IL-6 or IL-8 release.

Table 1. Results of PDE4 inhibitors on IFNγ suppression of bacterial production

Inhibiting the JAK/STAT pathway diminishes the decrease in phagocytosis of HI and SP caused by IFNγ and decreases the release of inflammatory cytokines and has potential as a novel target in COPD.

Conclusion: mRNA levels of PDE4 A, B and D are increased in AM from COPD patients. Rosflumilast inhibits TNFα production from AM from COPD patients.

218 Cigarette smoking augments toll-like receptor 3 expression and responses in macrophages

Aikra Kourai, Satoro Yanagisawa, Hisatose Sugiri, Tomohiro Ichikawa, Keichiro Akamatsu, Tsunahiko Hirano, Masanori Nakashima, Kazuto Matsunaga, Yoshikazu Kinoshita, Masakazu Kinoshita. Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan

Toll-like receptor 3 (TLR3), which reacts to viral-derived double-stranded RNA, is suggested to be involved in the immune responses during viral infection. However, the role of TLR3-mediated response in the pathophysiology of chronic obstructive pulmonary disease (COPD) is unclear.

The expression of TLR3 in alveolar macrophages in human lung tissues was analyzed by immunohistochemistry. Furthermore, the effect of cigarette smoke on the expression and responses of TLR3 in macrophage lineage cells was examined. TLR3-positive macrophages were significantly increased in smokers and COPD subjects compared with non-smoker control subjects, but there was no difference between smokers and COPD subjects. The values of TLR3-positive macrophages were positively correlated with the smoking history and negatively correlated with the values of corrected carbon monoxide diffusing capacity by alveolar ventilation (DLCO/VA) (p < 0.001, r = -0.56), but not with the values of forced expiratory volume in 1 second (FEV1)% of predicted. Furthermore, cigarette smoke potentiated the expression of TLR3 in monocyte-derived macrophages and significantly augmented the release of interleukin-8 (CXCL8) and total matrix metalloproteinase-9 activity in TLR3 ligand-treated cells.

These data suggest that cigarette smoke potentiates the expression and responses of TLR3 in alveolar macrophages, which may affect the pathogenesis of COPD as well as its exacerbation.

48. Immunobiology in the transplanted lung: experimental and clinical evaluations

219 Late-breaking abstract: Non specific IgG replacement in lung transplantation recipients with low IgG plasma levels: Effects on survival and bronchiolitis obliterans syndrome incidence

Christophe Pison 1,2, Marion France 1, Hubert Roth 3, Christel Saint Raymond 1, Johanna Claustre 2, Boubou Camara 1, Sébastien Quétant 1, Grenoble Lung Transplantation Group 1, 1 Clinique de Pneumologie, CHU Grenoble, Université Joseph Fourier, Grenoble, France; 2 LBFA, Insen1055, Grenoble, France

After lung transplantation, IgG plasma levels < 6 g/L are recorded in more than 50% of cases resulting in adverse events [JHLT 2001:7242, Transplantation 2005;79:1723]. We conducted a open study with non specific IgG, Tegeline® in all patients with IgG plasma < 6 g/L post transplantation since 1991 in 59 out of 119 consecutive recipients more than 3 months in Grenoble. Both groups had similar donor and recipient characteristics and deaths a mean period of 2.1±1.3 years except for a shorter duration of ventilation in donors, a longer first hospitalization stay and more acute rejection/TBR performed 0.32±0.12 vs 0.11±0.18 in non-substituted group. IgG substitution started 4.5±0.76 months and lasted 5±0.115 months, mean cumulative doses were 53±48 gr. In multivariate Cox regression model, IgG substitution conferred a net benefit in terms of survival at 5 years HR: 0.40 (0.18-0.88) 95%CI p=0.022 taking in account age of recipients and donors, type IC rejection, number of treated infection and rejection episodes.

We conclude that replacement therapy with non specific IgG in lung transplant recipients with low IgG plasma levels resulted in a better survival and BOS free survival at 5 years post-transplantation as compared to non-substituted group. Limitation: non randomized design. A prospective controlled multicentre study is warranted. Funds from LBFA, France.

220 Significance of anti-HLA immunization in lung transplantation

Jérémie Rech 1, Pierre-Emmanuel Falcoz 2, Nicola Santelmo 1, Ziad Mansour 2, Romain Kessler 1, Gilbert Massard 1.

1 Emergency, Grenoble University-Affiliated Hospital, Grenoble, France; 2 PRETA, Laboratoire TIMC-IMAG, La Tronche, France

Rationale: The ex vivo pulmonary perfusion is a suitable method of evaluation of lung ischemia reperfusion injuries (IRI). The role of the Cyclosporine A (CsA) in the prevention of IRI has been shown in different organs of several animal species but not clearly evaluated in lungs. Our objective was to evaluate the effects of CsA in ex vivo reperfused pig lungs.

Methods: 10 lungs were perfused with an extracorporeal perfusion circuit, and mechanically ventilated. CsA was administered before and during reperfusion procedure (either at 1 or 30µM).

Results: Lungs treated by 30 µM of CsA had increased capillary pressure (Pcap), pulmonary vascular resistances (PVR), lung permeability to proteins, IL1 beta and TNF alpha concentrations in bronchoalveolar lavage (BAL). 1µM of CsA seemed to have no effect compared to control group.

*: p<0.05 between control and CsA 30µM; K: coefficient of permeability to Dextran of the capillary-alveolar membrane.

Discussion: CsA, at the concentration of 30 µM, seems to be deleterious in lung IRI. The hemodynamic effects of CsA may explain these results.

222 Comparison between SCOT-15® and Perfadex® as lung preservation solutions

Anne Olland 1, Caroline Meers 1, Malika Benahmed 1, Karima Elbeyad 1, Shana Wauters 1, Eric Verbeeken 1, Geert Verleden 1, Izie Namer 1, Dirk Van Raemdonck 1, 1 Laboratory for Experimental Thoracic Surgery, KU Leuven, Leuven, Belgium; 2 Laboratory for Biophysics and Nuclear Imaging, HU Strasbourg, Strasbourg, France; 3 Laboratory for Morphologic and Molecular Pathology, KU Leuven, Leuven, Belgium; 4 Laboratory for Pneumology, KU Leuven, Leuven, Belgium

Objectives: SCOT-15® is a low K+ solution including polyethyleneglycol (PEG) as a colloid for protection of endothelium. PEG was demonstrated to have immuno-camouflage properties and has been tested for kidney, pancreas and liver preservation. This study compares the properties of SCOT-15® for lung preservation with Perfadex® as a golden standard.

Methods: Two groups of 6 pigs each were compared. After 2L cold pulmonary plegia with either Perfadex® [P] or SCOT-15® [S], lungs were stored cold for 4 hours. Peripheral lung biopsies were taken for High Resolution Magic Angle Spin (HRMAS) detection of colloids. Lung function was assessed in an ex vivo lung perfusion and ventilation model. Pulmonary artery flow and pressure were recorded for pulmonary vascular resistance (PVR), mean airway pressure (mAWP) for lung compliance and blood gases on the perfusion outflow line for partial oxygen pressure (P02). Wet-to-dry weight ratio (W/D) was recorded for Dextran of the capillary-alveolar membrane.

Results: PVR was significantly lower in [S] compared to [P] (p=0.04). There were no differences in mAWP (p=0.13), mPaw (p=0.24) and W/D (p=0.06). HRMAS spectra showed presence of PEG in peripheral lung tissue in [S].
Conclusion: Lungs preserved with SCOT-15® had lower vascular resistance with comparable oxygen capacity reflecting well preserved endothelial function. Experiments with longer cold ischemia are needed to assess the relevance of this solution.

223

MSK1 kinase in obliterative bronchiolitis following heterotopic tracheal transplantation

Simona Nemská1,2, François Daubert1,2, Laurent Reber1,2, Nelly Frossard1,2, 
1Laboratoire d’Innovation Thérapeutique, CNRS - UMR 7200, Illkirch, France; 
2Laboratoire d’Innovation Thérapeutique, Université de Strasbourg - UMR 7200, Illkirch, France

Introduction: Obliterative bronchiolitis (OB) occurs during chronic allograft rejection of lung transplantation. OB is characterized by airway epithelium degradation, and obstruction of the small airways with inflammatory infiltrate and fibrosis. MSK1 is a nuclear kinase that activates NFκB in inflammation. Our hypothesis proposes MSK1 as an actor in OB via NFκB-induced activation of pro-inflammatory genes like IL-6.

Methods: In the mouse model of heterotopic tracheal transplantation, tracheal MSK1 and IL-6 mRNA levels were quantified by qPCR. Mice were treated i.p. with compound H89, a MSK1 inhibitor (10mg/kg/day) or solvent (DMSO 5%). Tracheal sections were stained with hematoxylin-eosin, and epithelium degradation measured. CD3+ cells (SP7 anti-CD3 mAb, Abcam) were counted and dendritic cells (DC, H2-I-A/I-E mAb, M5/114) labeled on fresh tracheas.

Results: MSK1 and IL-6 mRNA levels were increased in allografts by 68% ± 8% and 86% ± 2%, respectively, at D7 as compared to D0 and unmodified in isografts. Progressive epithelium degradation reached 77±4% of the total epithelium at D3 and was inhibited upon H89 treatment of 44±10% (p<0.05). In isografts, epithelium degradation also occurred (18±10%). CD3+ cell recruitment reached 208±82 cells/mm² at D7 and was inhibited to 16±8 cells/mm² (p<0.05), compared to isografts (17±9 cells/mm², NS). DC recruitment also occurred in allografts (525±73 cells/mm² at D3 and 1065±368 at D7) as compared to D0 (290±17). No effect of H89 was observed on DC recruitment at D3. Inflammatory luminal infiltrate was inhibited at D7 by 44±15%.

Conclusion: Inhibiting MSK1 is therefore a potential strategy to help combat obstruction after lung transplantation in this OB model.

224

Development of a novel model of obliterative bronchiolitis following orthotopic lung transplantation in the rat

Marta Vadori1, Francesca Lunardi2, Dedja Arben1, Antonio De Filippis1, 
Emanuele Cozzi1, Federico Rea3, Fiorella Calabrese1, 
1Laboratory of Pulmonology, Catholic University Leuven, Leuven, Belgium; 2Pathology, Catholic University Leuven, Leuven, Belgium; 3Laboratory of Thoracic Surgery, University Hospitals Zurich, Zurich, Switzerland

Background: Long-term survival after lung transplantation (LTx) is hampered by Bronchiolitis Obliterans Syndrome (BOS), morphologically presented by OB. Since the pathogenesis is still not fully understood and the prognosis remains poor a good animal model is indispensable.

Aims: The development of a new model of BOS after LTx.

Methods: C57B16 mice underwent LTx with BALB/c donor lungs and were sacrificed at 2, 4, 6, 10 and 12 weeks after LTx. Staining with H&E and Sirius Red (not shown) were performed.

Results: Histology showed two types of lesions. Type I lesions are characterized by lymphoctic bronchiolitis and functional lung parenchyma. These lesions seem to resolve over time. Type II lesions are demonstrated by fibrotic plugs growing into the airway lumen, resembling true BO lesions in humans. The surrounding parenchyma however is not functional.

Conclusions: Allograft LTx in mice mimics human histology of BO, optimisation of this model will open new perspectives to study pathogenesis of chronic rejection after LTx.

Late-breaking abstract: Do trainee respiratory doctors under supervision achieve acceptable results with EBUS-TBNA?

Mohammed Alhajji, Peter J Smith, Matthew Callister, Paul K. Plant. Respiratory Medicine, St James University Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Endo-bronchial ultrasound guided transbronchial needle aspiration (EBUS-TBNA) is a useful tool in the staging and diagnosis of thoracic malignancy. There is limited evidence on the safety and efficacy of instructing respiratory trainee doctors in EBUS-TBNA.

Aims: To compare the results obtained by trainee respiratory doctors performing EBUS-TBNA as principal operator supervised by consultant respiratory physicians, to the results obtained from consultants as principal operators. We aim to discover if trainees can perform this procedure with acceptable accuracy and safety.

Methods: All EBUS reports were retrospectively collected between February 2009 and July 2010. The reports were analysed to determine the sensitivity, specificity and diagnostic accuracy for the EBUS operator, and rates compared for trainees, consultants and published series. Complication rates were also compared.
Results: Overall sensitivity and diagnostic accuracy were similar for trainees as primary operator compared to consultants. There were no significant adverse events in either group (table1).

Table 1. Sensitivity, specificity and diagnostic accuracy of EBUS-TBNA

Conclusion: Provided there is close supervision by a consultant, trainee respiratory doctors performing EBUS-TBNA as primary operators appear to have similar safety and efficacy results.

P227 Late-breaking abstract: Radial probe endobronchial ultrasound scanning assessing invasion depth of central lesions in the tracheobronchial wall

Jing Li, Ping-ping Chen, Yu Huang, Zheng-xian Chen. Respiratory, Guangdong Academy of Medical Science, Guangdong General Hospital, Guangzhou, Guangdong, China

Background: Patients with central tracheobronchial benign or malignant lesions who have not received surgical treatment can be treated by interventional techniques. The accuracy of the invasion depth of central lesion in tracheobronchial wall plays an important role in making interventional treatment plan. This study used radial probe endobronchial ultrasound (EBUS) scanning to evaluate the accuracy of the invasion depth of central tracheobronchial lesions, and the influence of EBUS scanning in treatment plan making and guidance.

Methods: A radial ultrasound probe with a balloon sheath was introduced through the channel of a flexible bronchoscope. The balloon at the tip of the probe was inflated with distilled water until coupling with the airway wall under endoscopic control. The image of EBUS, which revealed the layered structure of the tracheobronchial wall, could be achieved.

Results: Total of 125 patients were enrolled in the study. 30 patients underwent surgical operation and pathologically proved the EBUS diagnosis accuracy of 90% (27/30), sensitivity and specificity were 88.9% (24/27) and 100 (3/3) respectively. In response to EBUS images, 40 approaches were altered or guided: lymph node metastasis and compressive lesions was diagnosed by EBUS-guided transbronchial needle aspiration (n=8); Lesions ablation with laser or electricity were stopped when EBUS demonstrated close range with vessels or perforation possibility (n=3), stents size were changed (n=4), operation was canceled (n=3) and foreign body was removed (n=2).

Conclusions: EBUS can be a useful tool in assessing the central lesion invasion to the tracheobronchial wall.

P228 A comparison of the combined ultrasound of the mediastinum by use of a single EBUS scope versus two scopes EBUS and EUS for lung cancer staging

– A prospective study

Amar Szuhajowski1, Paweł Koczko2, Jerzy Soja3, Piotr Talar2, Wiesław Czajkowski1, Łucyna Rudnicka-Sosin4, Adam Cmiele5, Jerzy Wojciech Czajkowski2, Lucyna Rudnicka-Sosin4, Adam Cmiele5

1Endoscopy Unit, Pulmonary Hospital, Zakopane, Poland; 2Dept. of Medicine, Jagiellonian University, Krakow, Poland; 3Dept. of Thoracic Surgery, Pulmonary Hospital, Zakopane, Poland; 4Dept. of Pathology, Pulmonary Hospital, Zakopane, Poland

Introduction: The aim of the prospective trial was to compare diagnostic yield of the combined ultrasound of the mediastinum for lung cancer (LC) staging by use of a single EBUS bronchoscope – (CUS) and two scopes: EBUS and ultrasound gastrointestinal (EUS) – (CUS).

Methods: In consecutive LC patients in stage IA-IIIB the CUS or CUSb were performed under mild sedation in consecutive LC patients (pts) with enlarged or normal mediastinal nodes on CT scans. All non-small cell LC pts with negative CUS-NA underwent subsequently the transcervical extended bilateral mediastinal lymphadenectomy (TEMLA) as a confirmatory test and if negative underwent systematic lymph node dissection (SLND) by thoracotomy.

Results: From Jan. 2008 to Dec. 2010 in 588 LC pts who underwent CUS-NA there were 1529 mediastinal nodes biopsied (EBUS-NA – 805, EUS-NA – 724). The CUS-NA revealed metastases in 273/588 pts (46.4%) and a prevalence was 52.3%. In 272 CUS-NA negative pts and in 5 pts suspected for metastases, who underwent subsequent TEMLA and SLND metastatic nodes were diagnosed in 35 pts (5.9%), in whom double or multilevel N2 disease was found in 14 of them (2.4%). A diagnostic sensitivity, specificity, accuracy, PPV and NPV of CUS-NA were 88.6%, 98.4%, 92.7%, 98.25% and 88.6%, respectively. In pts with nodes highly suspected for metastases by echosonography positive results were obtained by both methods in 96.7% and in all small cell LC pts. The results of EUS-NA of 675 supraretral (M1-staging) impacted patients were performed under general anesthesia in 24 pts (4.1%). The CUS-NA influenced on T staging in 38 pts (6.5%).

No severe complications of CUS-NA were observed.

Conclusions: The CUS-NA is especially effective for mediastinal N staging but it also plays an additional role for TM staging in LC patients.

P230 Complication rate of EUS-NA and EBUS-TBNA in mediastinal nodal aspiration: A meta-analysis

Ardia van Breda, Bob von Bartheld, Jouke Aannema. Department of Pulmonology, Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands

Introduction: Echopneal and endobronchial ultrasound-guided fine needle aspiration (EUS-NA/EBUS-TBNA) are rapidly spreading minimally-invasive techniques for the diagnosis and staging of lung cancer and sarcoidosis. Generally, endosonographic procedures are considered to be safe although several severe complications have been reported in case reports. We performed a meta-analysis to assess the morbidity of EUS and EBUS for mediastinal nodal analysis.

Methods: A PubMed and Embase search was performed including all original studies (1999 - October 2010) using EUS and EBUS for mediastinal nodal analysis. Case-reports and studies not mentioning procedure morbidity were excluded from analysis.

Results: 353 studies (118 EUS, 74 EBUS, 10 both) were reviewed of which 151 were excluded form analysis. The other 202 studies consisted of 17200 patients (EUS: 7504 patients, EBUS: 8742, both 954). In those patients, 72 complications (0.42%) were reported of which 36 severe (0.21%) (pneumothorax, n=9; thoracic bleeding, n=5; esophageal rupture, n=5; mediastinitis, n=4) and 36 minor (0.21%) (minor pain, n=10; sore throat, n=9; hemoptysis, n=4; fever, n=2). Of the severe complications 20 occurred at EUS (0.27%) and 12 at EBUS (0.14%). No procedure-related deaths were reported.

Conclusions: The morbidity of mediastinal nodal endosonography is low and mortality has not been reported. The complication rate might well be underestimated due to underreporting, publication and performer bias. Further prospective evaluation is warranted to determine the actual complication rate of endosonography and identify possible subsets of patients that are at risk for complications.

P231 Is there a role of EBUS in the decision-making of endoscopic treatment for carcinoid tumor?

Korkut Bostanci, Jose Rojas-Solano, Heinrich D. Becker. Department of Interdisciplinary Endoscopy, Thoraxklinik at Heidelberg University, Heidelberg, Germany

Determination of the depth of invasion of carcinoid tumors is the most important finding for choosing the appropriate mode of therapy, whether it be local laser destruction or surgical resection, yet at present, endosonography and bronchoscopy have not been very adequate for the decision. We assessed the usefulness of endobronchial ultrasonosonography (EBUS) in the determination of the depth of tumor invasion of the tracheobronchial wall in carcinoid tumors.

From 2005 to 2010, 18 patients with carcinoid tumors were evaluated with this high resolution computed tomography (HRCT), bronchoscopy and EBUS prior to surgery. EBUS by a 20MHz-radial probe with balloon was performed in all cases to determine the size of the tumor, the depth of invasion, and to evaluate the relationship between the size of the tumor, the depth of invasion and EBUS.
of the tumor with the adjacent vessels and lymph nodes. All patients were operated on in days after bronchoscopy. Histopathological findings were compared with the HRCT, bronchoscopy and EBUS findings.

The tumor was visualized with EBUS in all cases. The exact size of the tumor could be measured in 15 cases, while in 3 cases it was out of range of EBUS. When compared to the pathological size EBUS measurements were more accurate than HRCT measurements. In 3 cases with no lesion but just atelectasis in HRCT, EBUS revealed only superficial infiltration of the bronchial wall with the tumor and the cartilage was intact, indicating a tumor potentially suitable for bronchoscopic resection. In all patients, surgery confirmed EBUS findings.

Our study showed that EBUS evaluation in carcinoma tumors adds to bronchoscopic and radiologic findings and can be useful in decision making for local laser destruction instead of surgical resection.

P232
Endosonography for the diagnosis of lymphoma
Mehrdad Talebian, Bob von Bartheld, Femke Waaïjenborg, Jouke Annema. Pulmonology, Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands.

Introduction: Transesophageal and transbronchial ultrasound-guided fine needle aspiration (EUS-FNA/EBUS-TBNA) are well-established procedures for mediastinal nodal staging of patients with non-small cell lung cancer (NSCLC). Malignant lymphoma often presents with intrathoracic lymph node enlargement. Data on the role of EUS-FNA and EBUS-TBNA for the diagnosis of mediastinal lymphoma are limited.

Objective: To assess the role of endosonography (EUS-FNA/EBUS-TBNA) for diagnosing mediastinal lymphoma.

Methods: We retrospectively analyzed 30 patients with suspected (recurrent) lymphoma in which mediastinal lymph nodes were investigated by endosonography using 22-Gauche needles. All patients had a final diagnosis of lymphoma (Hodgkin/Non-Hodgkin lymphoma), based on either surgical procedures, endosonography or clinical follow-up.

Results: We found that sensitivity, specificity and positive predictive value were 46%, 88% and 26% respectively. No complications occurred.

Conclusion: EUS-FNA and EBUS-TBNA have moderate sensitivity in diagnosing mediastinal malignant lymphoma. Therefore, negative test results should be followed by surgical or clinical staging procedures. Future studies should concentrate on a more detailed analysis of cell specific markers on cytology samples (eg flow cytometry) and the use of histology needles.

P233
The impact of rapid on site evaluation of cytological specimens on a new endobronchial ultrasound (EBUS) service
Nicholas Withers1, Lyndae Wheen2, Paul Newman2, Bipen Patel1. 1Department of Respiratory Medicine, Royal Devon & Exeter Foundation Trust, Exeter, United Kingdom; 2Department of Pathology, Royal Devon & Exeter Foundation Trust, Exeter, United Kingdom.

Background: Mediastinal lymph node sampling using endobronchial ultrasound (EBUS) transbronchial needle aspiration (TBNA) has been shown to have a rapid role in the staging and diagnosis of lung cancer. It may also have a role in the diagnosis of benign diseases (e.g. sarcoidosis). For many experienced bronchoscopists EBUS-TBNA is a new technique with a steep learning curve. We introduced an EBUS service at our institution in January 2010. Whenever possible we undertook the procedure with a consultant cytopathologist who allowed rapid on site evaluation (ROSE) of specimens and real time feedback on specimen quality.

Aims: To assess the impact of ROSE in a newly established EBUS service.

Methods: We reviewed the impact of ROSE on the procedure duration, amount of lidocaine local anaesthetic (ILLA), amount of intravenous sedation (midazolam and alfentanil) and the diagnostic procedure rate in our first 30 EBUS cases.

Results: ROSE of cytological specimens was available for 22 (73.3%) of our first 30 cases. The availability of ROSE resulted in a significantly shorter procedure time (39.7 (SD ± 3.8) minutes Vs 57.3 (± 4.4) minutes, p = 0.01), and significantly lower amounts of sedation with midazolam (5.8 ± 2.2 mg Vs 9.0 (± 2.4 mg, p=0.002) and alfentanil (522.7 ± 187.5) μg Vs 781.3 (± 311.6) μg, p=0.01).

There was no difference in the amount of LLA or in the percentage of cases in which diagnostic material was obtained (82.8% with ROSE and 87.5% without ROSE).

Conclusions: ROSE of TBNA samples results in a significant reduction in length of procedure and the amount of sedation required for EBUS. The provision of ROSE is an important consideration in the development of an EBUS service.

P234
Outcomes of non-diagnostic endobronchial ultrasound guided tranbronchial needle aspiration
Thumalaunghe Thangakanum1, Bernard Yung1, Johnsson Samuel1, Gazin Bostanci2, Kanwar Pannu1, Dipak Mukherjee1. 1Respiratory Medicine, Basildon University Hospital, Basildon, Essex, United Kingdom; 2Department of Histopathology, Basildon University Hospital, Basildon, Essex, United Kingdom.

Introduction: Endobronchial ultrasound-guided tranbronchial needle aspiration (EBUS-TBNA) is a diagnostic procedure for the evaluation of mediastinal lymph nodes and masses. Although it has been proved to be a helpful diagnostic procedure for mediastinal node metastasis, the value of negative EBUS is not clear.

Methods: Retrospective review of the EBUS procedures. Results: A total of 106 EBUS procedures were attempted over 18 months, 105 procedures were completed. 1 patient did not co-operate and the procedure was abandoned. All the procedures were done with local anaesthesia and conscious sedation. In 4, EBUS did not show any significantly enlarged lymph nodes, so no samples were taken. The mean age of the patients was 65.6 yrs (range 22-87 years), with 68 males (64.2%). In 97 of 101 lessons sampled (97%), EBUS-TBNA yielded representative samples. In 51 cases the EBUS sample yielded diagnosis and were considered true positive. In the rest 50 cases the samples were non-diagnostic, of which 19 were true negative based on either mediastinoscopy or follow up. Four were false negative. The remaining 27 need follow up to know whether they are true negative or otherwise. In the 74 cases the overall sensitivity, specificity, positive predictive value and negative predictive value were 92.7%, 100%, 100% and 32.6% respectively.

Conclusions: EBUS-TBNA yielded diagnosis in half of the cases. In majority of patients with non-diagnostic EBUS, based on multi-disciplinary team review it was decided to follow up rather than directly proceed with mediastinoscopy or surgery because of either high risk for surgery or low clinical probability of malignancy.

P235
Endobronchial ultrasound-guided tranbronchial needle aspiration in the diagnosis and staging of lung cancer
Hansdy Ali Mohammadian, Mahmoud, Rex C. Yang, Chest Department & Tuberculosis, Sohag University-Sohag Faculty of Medicine, Sohag, Egypt. Oncology and Bronchology, John Hopkins University, Baltimore, United States.

Objective: The aim of the study was to assess the diagnostic yield of the real-time endobronchial ultrasound-guided tranbronchial needle aspiration (EBUS-TBNA) in the diagnosis and staging of lung cancer.

Patients and methods: 134 patients with suspected lung cancer with mediastinal and/or hilar lymph nodes underwent EBUS-TBNA using the convex probe EBUS. All patients with negative EBUS-TBNA subsequently underwent the surgery or mediastinoscopy as a confirmatory test.

Results: One hundred thirty four patients underwent CP-EBUS-TBNA between December 2007 to December 2009. There were 233 mediastinal & hilar lymph nodes biopsied (stations: 2R-34R-73. 4L-21, 7-65, 10R-23, 10L-5, 11R-26, 11L-17). EBUS-TBNA revealed metastatic lymph node involvement in 54 of 134 patients (40.3%) and in 56 of 233 biopsies (24%). In 80 patients with negative or uncertain EBUS-TBNA who underwent subsequent surgery, mediastinoscopy, mediastinal nodes were diagnosed in four patients (3%) in stations: (4R-2-4L-1 J 7-1). The false-negative results of biopsies were found only in small nodes < 1cm. A diagnostic sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and diagnostic accuracy of EBUS-TBNA was 93.1%, 100%, 90%, 94.5%, and 96.9%, respectively there was no significant relation between lymph node location and EBUS-TBNA cytology results. No complications of EBUS-TBNA were observed.

Conclusion: EBUS-TBNA is an effective and safe technique for diagnosis & mediastinal staging in patients with lung cancer. In patients with negative results of EBUS-TBNA, surgical exploration of the mediastinum should be performed.

P236
Endobronchial ultrasound for the diagnosis of granulomatous disease
Felipe Andreo-García1, Enrique Cases-Viedma2, José Sanz-Santos3, Beatriz Montull-Vega4, Cristina Prat-Aymérich1, María José Selma-Ferrer2, Eva Castella-Fernández3, María Josuela Arts-Martínez4. 1Servicio de Neumología, Hospital Universitario German Trías i Pujol, Badalona, Barcelona, Spain; 2Servicio de Neumología, Hospital Universitari La Fe, Badalona, Barcelona, Spain; 3Servicio de Microbiología, Hospital Universitario Germans Trias i Pujol, Badalona, Barcelona, Spain; 4Servicio de Anatomía Patológica, Hospital Universitario Germans Trias i Pujol, Badalona, Barcelona, Spain; 5Servicio de Anatomía Patológica, Hospital Universitari La Fe, Valencia, Spain.

The aim of this study was to evaluate the yield of EBUS-TBNA in the diagnosis of granulomatous lymph nodes.

Patients and methods: All patients, from October 2005 to October 2010 in Hospital U Germans Trias I Pujol (Badalona) and Hospital U La Fe (Valencia), with hilar or mediastinal granulomatous lymph nodes were collected. Diagnosis of sarcoidosis was established based on clinical and radiological findings, supported by histologic evidence of noncaseating epitheloid-cell granulomas in the absence of necrosis or organism. Diagnosis of tuberculosis (TB) was made by the presence
of necrotizing granulomas with exclusion of other granulomatous or cultivation of Mycobacterium tuberculosis (MTB).

**Results:** 34 patients were diagnosed: 15 sarcoidosis, 16 TB, 1 silicosis, 1 tuberculosis-like, and 1 with HIV infection and reconstitution of immune response syndrome with granulomatous lymphadenitis. Sarcoidosis patients had a average age of 49 years, 9 males, and had sarcoidosis and everyone had mediastinal and hilar lymphadenopathies and 5 showed lung nodules. 36 lymph node stations were explored (average 2.4) and was punctured station 7 (15 times) and 10 L (6). EBUS-TBNA was decisive in 10 cases. TB mean age of was 49 years, 12 males and 2 HIV. 8 had prior suspicion of TB, 6 with PPD skin test + and 6 showed also lung injuries. 44 lymph nodes stations were explored (average 2.8), the more punctured was stations 7 (14 times) and 4R (10). Necrosis was found in 9 cases and in 6 in culture of MTB was positive and EBUS-TBNA was decisive in 9 cases. There were no complications of the technique.

**Conclusion:** EBUS-TBNA is a safe and cost effective diagnostic method that was decisive in involvement with granulomatous disease.

**Introduction:** The learning curve required for the EBUS-TBNA diagnostic procedure in patients with mediastinal or hilar lymph nodes from different aetiologies is still unclear. No evidence is available regarding the procedure’s influence on the parameters, such as length of procedures or the number of lymph node passes required for obtaining the diagnosis.

**Methods:** The learning curves of two experienced bronchoscopists who conducted exhaustive theoretical training on EBUS and 10 supervised procedures were prospectively analysed. The number of suitable samples and accuracy were assessed in six groups of 20 consecutive patients with >10 mm lymph nodes on chest CT or > 3 mm if positive increase in uptake on PET. The number, location, and size of punctured lymph nodes, the passes made in each node, and the length of the procedure were also recorded.

**Results:** Over 13 months, 215 lymph nodes in 120 patients were evaluated by EBUS-TBNA. The number of adequate samples and accuracy were 90.5% and 85.4% respectively (lymph nodes as the unit of analysis) and 89.2% and 84.9% respectively (patient as unit of analysis). A significant increase was observed, approaching 90% after the first 60 procedures. The mean number of passes in each lymph node was 2.1 (standard deviation 0.7), lymph nodes examined per patient 1.8 (0.8), and length of procedure 30 (8.5) minutes.

**Conclusions:** Experienced bronchoscopists need to perform more than 60 procedures to achieve acceptable diagnostic yield. Learning allows improvement in the quality of the samples obtained and the number of lymph nodes studied per patient.

**EBUS-TBNA learning curve for mediastinal and hilar lymph node diagnosis**

**Introduction:** EBUS-TBNA is a safe and cost effective diagnostic method that was decisive in involvement with granulomatous disease.

EGFR direct sequencing on TBNA samples

Pierdonato Bruno, Maria Cristina Esposito, Giorgia Osman, Federica Fioretti, Giorgia Gencarelli, Alberto Ricci, Salvatore Mariotta.

**Results:** EGFR mutation detected in cytological samples of lymph nodes from patients with NSCLC. EGFR mutation detected in 2 cases (12,5%). In 3 cases, EGFR mutation was not detected in cytological samples.

**Conclusions:** EGFR mutation detected in cytological samples by lymph nodal TBNA: Our study supports the use of EGFR mutation detection in lymph nodes of patients with advanced NSCLC. The combination of EGFR mutation detection and histology can provide valuable information for the treatment of these patients.

**Introduction:** EGFR mutation detection in cytological samples of lymph nodes from patients with NSCLC is of great importance for the selection of targeted therapies. EGFR mutation detection by direct sequencing of exons 19 and 21 of EGFR gene can be performed also on TBNA cytological samples with the same reliability offered by the histological samples obtained from the same patient.

**P239**

EGFR mutation detected in cytological samples by lymph nodal TBNA: Our first year experience

Michele Gallo, Laura Basile, Unità Operativa Complessa Pneumologia, P.O. Villa Sofia A. O. Ospedali Riuniti Cervello Villa Sofia, Palermo, Italy; UOC Medicina, Fondazione San Raffaele Giglio, Cefalù, Italy

**Introduction:** EGFR mutation detection in cytological samples by lymph nodal TBNA: Our first year experience.

**Methods:** We evaluated the yield and applicability of molecular testing for EGFR status (S) in TNBAs cyto specimens during the first year practice for each of two brs. We had retrospectively analyzed the results of 60 patients (ps) and 72 lymph nodal (LN) TBNA We used ROSE (Rapid on site examination) to recognize lymphocytes (LC) in the slide as a prove that the material was LN. We did at least 3 aspirations in LN >12 mm in long axis in LC setting. We considered a successful puncture one with LPC in cyco exam evaluated by pathologist. We found 4 ADC female cases with light or no smoking habit and we asked to our lab to evaluate the slides for EGFR S.

**Results:** We found No DNA to be amplified 1 case, 2 cases Wild type EGFR and 1 with M 19 exon.

**Patients EGFR status in our series**

A prospective study of TBNA of 63 patients from a tertiary care hospital in India

Avdhesh Bansal, Trilok Chand, Priyadarshee J. Kumar, Ravi Shekhar Iha. Department of Respiratory, Critical Care & Sleep Medicine, Indraprastha Apollo Hospitals, New Delhi, India

**Introduction:** Role of TBNA (Transbronchial Needle Aspiration) through bronchoscopy in diagnosing mediastinal and hilar lesions is well established. Unfortunately, it is underutilized due to poor training and wide variation (20 to 89%) in yield. The yield is dependent on operator’s expertise besides size and location of the lesion. We share our experience of a prospective study of 63 cases performed at a tertiary care hospital by single operator over 6 months.

**Method:** Bronchoscopy was performed in 63 consecutive patients with mediastinal and hilar lesions. Besides TBNA, bronchial biopsy, BAL and trans-bronchial lung biopsy were also performed when needed.

**Results:** Most frequent presenting complaint was fever 63% (n=38) with or without cough. Lymph nodes greater than 0.5cm in size were punctured. Subcarinal node (n=62) and right paratracheal node (n=42) were most commonly punctured. TBNA was performed with 21 G needle and piggyback method was found to be most effective method for puncture. A positive result was obtained in 84% of patients (n=53). Tuberculosis was diagnosed in 55% (n=29) of the positive cases, malignancy in 23% (n=12) and sarcoidosis in 21% (n=11). Fungal infection and carcinoma were also seen.

**Conclusion:** In expert hands, yield of TBNA can be quite high (84% in this study) and even small nodes can be targeted. In India, the cost of EBUS procedure is $600 vs. conventional TBNA, which costs $200 and is available in very few centers. Authors recommend, especially for developing countries, that before proclaiming EBUS as the new gold standard, proper method of conventional TBNA should be learned, which is more cost effective. Patient should be referred for EBUS only when TBNA is inconclusive.

**P241**

Role of endobronchial ultrasound-guided transbronchial needle aspiration in the diagnosis of bronchogenic carcinoma

Fusun Alatas, Emine Dundar, Hüseyin Yildirim, Murat Mezfer Metintas, Güntülü Ak, Chest Diseases, Eskişehir Osmangazi University, Eskişehir, Turkey; Pathology, Eskişehir Osmangazi University, Eskişehir, Turkey

Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) is a technique used for the diagnosis of peribronchial/peritracheal mass lesion and the staging of bronchogenic carcinoma.

The aim of this study is to determine the role of EBUS-TBNA in patients with bronchogenic carcinoma.
with peribronchial/peritracheal mass without endobronchial lesion suspected for bronchogenic carcinoma and patients with a diameter of mediastinal/hilar lymphadenopathy bigger than 1 cm in CT, prediagnosed as bronchogenic carcinoma. Between April 2010 and January 2011, 56 patients with mean age 60.8 years (47 M/9 F) were admitted to study. EBUS-TBNA was performed to only lymph node in 47 patients, both lymph node and mass in 5 patients and only mass 4 patients. The definite diagnosis was done in twenty five patients without endobronchial lesion. Ninety six out of ninety seven lymph node aspiration was positive (70% mediastinal/22 hilar). One patient diagnosed with mediastinoscopy. (Sensitivity 98.9%, specificity 100%, PPV 100%, NPV 67% and accuracy 98.9%).

Twelve N3 lymph node were positive for malignancy. Seven out of nine mass biopsy were diagnosed as malignant. Two patients were diagnosed with other diagnostic procedures. No complication was observed during EBUS-TBNA.

In conclusion, EBUS-TBNA seemed a safe and effective technique in making bronchogenic carcinoma diagnosis for mediastinal/hilar lymph nodes and intrapulmonary masses.

P242
TBNA (submucosal) for diagnosis of mesothelioma (and ROSE for a faster one)
Michele Gallo1, Laura Basil2, Maria Grazia Stella3, Claudia Cannizzaro3
1Unità Operativa Complessa Pneumologia, P.O. Villa Sofia A.O. Ospedali Riuniti Cervello Villa Sofia, Palermo, Italy; 2UOC Medicina, Fondazione San Raffaele Giglio, Cefalù, PA, Italy; 3Servizio Anatomia Patologica, Fondazione San Raffaele Giglio, Cefalù, Ph, Italy

We describe a malignant pleural mesothelioma (MPM) case diagnosis obtained with submucosal (SM) TBNA (transbronchial needle aspiration) and ROSE (Rapid on site examination). A 64 year old man was admitted to our unit because of pneumonia and scanty pleural effusion (PE) on chest radiography (see figure, Thorax CT scan).

To our knowledge, this is the first time that a mediastinal involvement of MPM is approached via TBNA and ROSE was diagnostic for Epithelial MPM.

P243
Transbronchial needle aspiration (TBNA) in the diagnosis and staging of lung cancer in a large cohort of patients
Sara Chiesa1,2, Maria Majori2, Rita Nizzoli1, AnnaMaria Guazzi1, Miriam Anghinolfi1, Alfredo Antonino Chetta1, Angelo Gianni Casalini2
1Cardiothoracic Department, Respiratory Unit, University Hospital of Parma, Parma, Italy; 2Cardiopulmonary Department, Thoracic Endoscopy and Pulmonology Unit University Hospital of Parma, Parma, Italy; 3Onco-Hematology Department, Oncology Unit University Hospital of Parma, Parma, Italy

Introduction: TBNA is a minimally invasive bronchoscopical technique, that allows to examine mediastinal and hilar lymph nodes, avoiding surgical mediastinal exploration.

Objectives: The aim of this study was to assess the sensitivity and diagnostic accuracy of TBNA in a large cohort of patients. In addition, we apprased the relationships between TBNA yield and lymph node size and location.

Methods: Between March 2009 and November 2011, we prospectively examined 110 patients (age range: 30 to 87 yr, 51 F) with suspected lung cancer and enlarged mediastinal lymph nodes. Each patient performed TBNA during flexible bronchoscopy with rapid-on-site evaluation.

Results: TBNA was positive in 88 of 110 patients with suspected lung cancer (80%). No complications was observed. The lymph node size cut-off point, that better identified patients with positive aspirate was ≥ 24 mm (0.83 sensitivity and 0.51 specificity; AUC=0.861, p=0.018 by ROC curve analysis).

In all patients, the subcarinal and anteromedian carina lymph node locations had the higher percentage and the left paratracheal lymph node location had the lower percentage of patients with positive aspirates (96%, 75% and 50%, respectively).

Conclusions: Our results confirm that in a large cohort of patients conventional TBNA is a sensitive technique and an effective tool to diagnose and stage lung cancer and show that ≥ 24 mm lymph node size has a high likelihood to be associated to a positive aspirate. Additionally, the lymph node location may play a role in the diagnostic yield of TBNA.

50. COPD management
P244
Adherence of stable COPD patients to inhaled pharmacotherapy
Silvia Dumitru, Konstantinos Velentzas, Elpida Theodorakopoulou, Maria Harikiopoulou, Martha Andritsou, Alexia Chroniaou, Zafeiris Sardelis, Elias Kamin, Panagiotis Demertzis, Epaminondas Korvam. 3rd Department of Pulmonary Medicine, Chest Diseases Hospital “Sotira”, Athens, Greece

Since compliance to inhaled medications is related to a decreased risk of hospitalizations and death in COPD, we aimed to investigate the compliance of COPD patients to inhaled pharmacotherapy. We studied 208 COPD patients [age 63±8 years; 77 in stage II (37%); 112 in stage III (54%) and 19 in stage IV (9%)]. Non-compliance was defined as the incorrect use of the inhaler device, as a sporadic or pen use due to perception of no effect or due to wrong information, when patient or his caregiver declares non-compliance, and when medication is not prescribed regularly. Results are reported for Tiotropium (T), fixed combinations of either Salmeterol/Fluticasone (SF) or Formoterol/Floventine (FF), and Salmeterol (S) or Formoterol (F) as single agents. Overall compliance to the above inhaled agents was 92%, 84%, 81%, 75% and 68% respectively. According to GOLD staging, compliance to T was 87% (II); 94% (III); 95% (IV); to SF 78% (II)-84% (III)-92% (IV); to FF 78% (II)-79% (III)-100% (IV); to SF 87% (II)-100% (III) and to FF 61% (II)-86% (III). Major reasons for non-compliance to SF were the incorrect technique to inhale from the Diskus (78%), to FF the perception of no effect when inhaling from the Turbohaler (50%), while reasons for non-compliance to T were the incorrect technique of using Handihaler (36%), no purchase or prescription renewal (36%) and sporadic use (28%). We conclude that compliance rates were higher for Tiotropium and the fixed combination of Salmeterol/Fluticasone. There was an increasing compliance in relation to COPD severity, while the detected reasons of poor compliance should be tackled through a more effective contact between COPD patients and their physicians.

P245
Health-related quality of life (HRQL) and patient-reported outcomes (PRO) in COPD patients receiving add-on therapy with EPs® 7630
Heinrich Mattheiss1, Dina Pliskevich1, Thorsten Reinecke1, Fatih-Abdul Malek3, 1Medical Director Emeritus, Department of Pneumology, University Hospital Freiburg, Freiburg i. Br, Germany; 2Faculty of Internal Medicine No. 4, National O. O. Bogomolets Medical University, Kiev, Ukraine; 3Clinical Research Department, Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe, Germany

HRQL and PRO are important measures for treatment evaluation and assessment of health condition. In an RCT (ISRCTN06187133) in patients with COPD stage II/III, add-on ther-
Japy with EPs® 7630, a herbal drug preparation from Pelargonium sidoides roots (Umckaloabo®; ISO Azneumittel, Ettlingen, GBR), significantly prolonged time to exacerbations and reduced their frequency. We also investigated HRQL and further PRO parameters assessed during the trial. Patients with a standardised COPD baseline treatment according to GOLD were randomly allocated to a double-blind 24-week oral add-on therapy with 30 drops EPs® 7630 (n=99) or placebo (n=101) thrice daily. HRQL/PRO were assessed by St. George’s Respiratory Questionnaire (SGRQ), EQ-5D, Integrative Medicine Patient Satisfaction Scale (IMPSS), Integrative Medicine Outcomes Scale (IMOS), patient-reported intensity score of cough, sputum production and sternal pain while coughing, and drug tolerability. After 24 weeks, patients treated with EPs® 7630 reported a significantly more improved HRQL compared to placebo (SGRQ total score, p<0.001; EQ-5D VAS, p<0.001). For EPs® 7630, patient satisfaction with treatment was significantly improved compared to placebo (SGRQ total score, p<0.001; EQ-5D VAS, p<0.001). For EPs® 7630, patient satisfaction with treatment was significantly improved compared to placebo (SGRQ total score, p<0.001; EQ-5D VAS, p<0.001).
higher (IMPS, $p<0.001$), patient-reported treatment outcome significantly better (IMOS, $p<0.001$) and the mean intensity score during exacerbations significantly lower ($p<0.024$). Incidence of adverse events was comparably low in both groups.

**Conclusion:** Add-on therapy with EPs$^4$, 7630 led to a statistically significant and clinically relevant improvement of HRQL and other PRO (total score difference of SGRQ = 4 points) including good long-term tolerability in patients with COPD stage II and III.

**Treatment with megestrol acetate and testosterone increases body weight and muscle mass in COPD cachexia**

Richard Casaburi, Junko Nakata, Laurence Bistrong, Edwardo Torres, Mehdi Rambood, Janos Porszasz. Rehabilitation Clinical Trials Center, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States

Underweight COPD patients with involuntary weight loss have a poor prognosis; no effective therapy is available. We conducted the first clinical trial determining whether combined therapy with an appetite stimulant and an anabolic steroid would have beneficial body composition effects.

We conducted a 12 week pilot study in which 4 men and 5 women (age 64±10y, FEV1%pred 31.9, BMI 18.3±3) with low testosterone (T) levels (average 490ng/dl in men and 12ng/dl in women) and weight loss >10lb over the previous year received 800mg megestrol acetate/day plus weekly testosterone enanthate injections.

Two women and two men had COPD exacerbations and did not complete the study. On treatment, T levels were 334 (79.9, 95.0) 1.05 (0.97, 1.14) 0.75 (0.68, 0.83) 0.91 (0.83, 1.0).

Impact of roflumilast treatment on the rate and duration of exacerbations and overall steroid load in patients with COPD

Peter Calverley1, Fernando Martinez2, Udo-Michael Goehring3, Dirk Bredenbröker2, Manja Broese2, Claus Vogelmeier4. School of Clinical Sciences, University Hospital Aintree, Liverpool, United Kingdom; 2Department of Internal Medicine, University of Michigan Medical Center, Ann Arbor, MI, United States; 3Department of Respiratory Medicine, Konstanz, Germany; 4Department of Data Science, Nycomed GmbH, Konstanz, Germany; 5Department of Pneumology, University of Marburg, Marburg, Germany

Background/Rationale: Roflumilast (ROF), an oral, selective phosphodiesterase 4 inhibitor, reduces the rate of moderate and severe exacerbations. Oral steroids are frequently used to treat exacerbations, but whether ROF affects oral steroid exposure is not known. Using data pooled from two 1-year studies (NCT00297102 and NCT00297115), we investigated the effect of ROF on the need for oral steroids.

Methods: Patients with COPD and a history of exacerbations and chronic bronchitis were randomised to receive ROF 500µg once daily (n=1537) or placebo (PBO; n=1554) for 52 weeks. Rate of moderate or severe exacerbations was a co-primary endpoint. Steroid use (dose/day and days of use) for the treatment of exacerbations was recorded.

Results: The mean rate of moderate or severe exacerbations in ROF- and PBO-treated patients (per patient/year) was 1.14 vs 1.57, respectively (reduction 16.9%; p<0.0005). The mean number of days on which patients had exacerbations was reduced with ROF vs PBO (moderate 23.7 vs 27.3; severe 21.5 vs 25.0). The mean duration (days) of exacerbations was also reduced with ROF vs PBO (moderate 13.4 vs 13.9; severe 17.4 vs 19.5). Patients receiving ROF had a lower mean daily steroid dose (3.9mg/day) than those receiving PBO (4.2mg/day).

Conclusions: In patients with COPD associated with chronic bronchitis, ROF significantly reduced the rate of moderate or severe exacerbations. ROF treatment also reduced the duration of exacerbations, particularly for severe exacerbations requiring hospitalisation. The overall steroid load and duration of steroid treatment needed to manage exacerbations was lower with ROF.

P247

**Efficacy of roflumilast in former and current smokers with COPD**

Peter Calverley1, Udo-Michael Goehring2, Fernando Martinez3, Neil Barnes4. 1School of Clinical Sciences, University Hospital Aintree, Liverpool, United Kingdom; 2Department of Respiratory Medicine, Nycomed GmbH, Konstanz, Germany; 3Department of Internal Medicine, University of Michigan Medical Center, Ann Arbor, MI, United States; 4Department of Respiratory Medicine, Konstanz, Germany

We conducted parallel-group randomized controlled multicentre trials involving 68 COPD patients. The participants were randomly assigned to real (RA, n=34) or placebo acupuncture (PA, n=34). Both group received real or placebo needling once a week for a total of 12 weeks. We evaluated not only change in functional outcomes but also by nutritional status, exercise capacity and severity of dyspnea.

In the 5 subjects who completed, DEXA revealed 2.0±1.1kg lean mass and 2.5±2.0kg fat mass increase (both $p<0.05$). No adverse treatment effects were detected.

Combination therapy reversed involuntary weight loss and increased muscle mass in cachectic COPD patients. Though the interventions were apparently well tolerated, subject dropout rate was high. Larger randomized long-term studies with functional outcomes are needed.

**Acupuncture improves nutritional status and BODE index in patients with chronic obstructive pulmonary disease: A randomized, placebo-controlled trial**

Masa Suzuki1,2,3, Motonari Fukui2, Tetsuhiko Shiota4, Kazuo Endo5, Susumu Saito3, Kenkazu Aihara4, Masatake Matsumoto6, Shinko Suzuki1, Ryo Iitaka1, Manabu Ishitoko1, Masaya Takeamura1, Yoshikazu Haru1, Hiroshi Kagio1, Masatake Hirabayashi1, Shigero Muro1, Michiaki Mishima1, 1Dept of Respiratory Medicine, Graduate School of Medicine Kyoto University, Kyoto, Japan; 2Dept of Respiratory Medicine, Kitano Hospital Medical Research Institute, Osaka, Japan; 3Dept of Respiratory Medicine, Ako City Hospital, Hyogo, Japan; 4Dept of Respiratory Medicine, Hyogo Prefectural Amagasaki Hospital, Hyogo, Japan; 5Dept of Clinical Acupuncture and Moxibustion, Meiji University of Integrative Medicine, Kyoto, Japan

Introduction: Prognosis of COPD patients is influenced not only by pulmonary functions but also by nutritional status, exercise capacity and severity of dyspnea. Our previous study (Suzuki M et al. ARCCM 2010; 181: A5420) showed that acupuncture improved significantly not only Modified Borg Scale at the end of 6-minute walk test (MBS), but also various general conditions of COPD patients including quality of life (SGRQ).

Aim and Objective: To determine whether acupuncture had any effects on nutritional status and BODE index of COPD patients in our previous study.

Methods: We conducted parallel-group randomized controlled multicentre trials involving 68 COPD patients. The participants were randomly assigned to real (RA, n=34) or placebo acupuncture (PA, n=34). Both group received real or placebo needling once a week for a total of 12 weeks. We evaluated not only change in

Time to desaturation under 1 minute on the 6m walking test predicts chronic domiciliary oxygen therapy in COPD patients

Luisa Eiroa, Ruth Piti, Juan Manuel Palmero, Juan Marco Figuera, Ana Isabel Velázquez, Magdalena Alonso, Jesús Rodríguez, Canelaria Ramos, Irene De Lorenzo, José Luis Trujillo, Alfonso Tauromi, Ignacio García Talavera, Pau Blanca. Pulmonology Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Canarias, Spain

Introduction: Time to desaturation (T90) on the 6 minute walking test (WT6m) and time of these patients.

Objective: To analyze the gasometric parameters changes on copd patients with early desaturation on the WT6m 5 years later.

Material and Methods: We studied 83 patients with COPD and desaturation on WT6m under 1 minute. 73 men/10 women, average 60.9 years old, FEV1: 42% pred and PO2 66mmHg. We did spirometries, gasometries, WT6m every 6 months for 5 years. The patients who during the study needed domiciliary oxygen therapy, were prescribed by their phvicians who did not know the content of the study.

Results: After 5 years, 65% of patients without early desaturation (T90 under 1 minute) had chronic domiciliary oxygen therapy vs 11% of patients with desaturation after 1 minute (T90 > 1 min), p< 0.01.

Conclusions: Moderate-severe COPD patients desaturating before 1 min on the WT6m need oxygen therapy before 5 years opposed to patients with desaturation after 1 minute. Early desaturators need more clinical and gasometric controls.

P251

Tiotropium vs salmeterol in GOLD II and maintenance-naïve COPD patients: Subgroup analyses of POET-COPD™ trial

Irene De Lorenzo, José Luis Trujillo, Alfonso Tauroni, Ignacio García Talavera, Pau Blanca. Pulmonology Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Canarias, Spain

Introduction: Tiotropium (18 μg qd) vs salmeterol (50 μg bid), in a) GOLD II and b) maintenance-naïve (not previously receiving maintenance therapy from GOLD stage II) disease. Inclusion criteria: COPD, smoking history ≥10 pk-yr, post-bronch forced expiratory volume in 1s (FEV1) ≤70% pred, FEV1/forced vital capacity (FVC) ≤0.7, history of ≥1 moderate or severe exacerbation in prior year. Primary endpoint: time to first exacerbation.

Results: Of 7376 patients randomized and treated, 3614 were GOLD II and 1343 maintenance naïve at randomization. GOLD II: 69.3% men, age 63.2 yrs, 37.3 pk-yr. maintenance naïve: 72.2% men, age 60.9 yrs, 34.6 pk-yr. Tiotropium prolonged time to first exacerbation in both GOLD II and maintenance-naïve groups: hazard ratio (95% confidence interval [CI]), tiotropium vs salmeterol: 0.88 (0.79-0.99), P=0.028 vs 0.79 (0.66-0.97), P=0.028. Exacerbation rates (per pt-yr), tiotropium vs salmeterol: GOLD II: 0.55 vs 0.60, rate ratio (RR) (95% CI) 0.91 (0.81-1.01), P=0.072; maintenance naïve, 0.38 vs 0.49, RR (95% CI) 0.77 (0.63-0.94), P<0.05.

Conclusions: Similar to overall cohort in POET-COPD™, tiotropium improved outcomes vs salmeterol in GOLD II and maintenance-naïve subgroups of COPD patients with an exacerbation history. Funded by Boehringer Ingelheim/Pfizer.

P252

Efficient deposition and absorption of orally inhaled indacaterol in the lungs

Ruth Lock1, Deandre Price2, Sanjeev Klimdi1, Ralph Weesner3, Markus Weiss2, Hisanori Hara4, Ilona Pylvänäinen5, Guenter Kaiser2. 1Translational Sciences, Novartis Institutes for Biomedical Research, Horsham, United Kingdom; 2Translational Sciences, Novartis Pharma AG, Basel, Switzerland; 3Integrated Information Sciences, Novartis Pharma AG, Basel, Switzerland

Introduction: Indacaterol (IND) is an inhaled long-acting β2-agonist for the once daily treatment of COPD, delivered via single-dose dry powdered inhaler (Onbrez® Breezhaler®). Study aims were 1) To determine absolute bioavailability (Fabs) of IND after oral inhalation compared with intravenous (IV) dosing and 2) To determine relative contributions of lung and gastrointestinal tract (GIT) absorption to systemic exposure of inhaled IND. To this end, inhaled IND was also administered concurrently with oral activated charcoal.

Methods: A two-part randomized, open label, single-dose study in healthy volunteers (HV). In Part 1, 8 HV received an IV infusion of 200 μg IND and an inhaled dose of 300 μg IND in a 2-way, 2-sequence crossover design. In period 3 all 8 HV received an inhaled dose of 600 μg IND together with an oral dose of charcoal. Treatments were separated by 7 days. In Part 2, VT3 was HV received oral doses of IND (600 μg) and charcoal. Blood samples were taken for PK analysis and IND was determined in serum by LC-MS/MS. PK parameters were determined by non-compartmental methods.

Results: The Fabs of inhaled IND was 45%. Oral activated charcoal was effective in blocking the oral absorption of IND. The relative bioavailability of inhaled IND with oral charcoal was 74% compared to inhalation without charcoal.

Conclusion: Almost 75% of the systemic exposure following inhalation of IND was due to lung absorption, and 25% was due to GIT absorption. Based on an Fabs of 45% for inhaled IND, the fraction of the inhaled dose deposited and absorbed in the lungs was estimated as 34% of the nominal IND dose, providing evidence of effective lung delivery of inhaled IND via Onbrez® Breezhaler®.

P253

Subclinical cardiac dysfunction in moderate to severe chronic obstructive pulmonary disease (COPD) patients

Alessia Verduri1, Barbara Bottazzari2, Chiara Leuzzi3, Roberto D’Amico1, Piera Boschetto1, Maria Grazia Modena1, Alberto Mantovani2, Leonardo M. Fabbri3, Bianca Beghi2. 1Department of Oncology, Hematology and Respiratory Diseases, University of Modena and Reggio Emilia, Modena, Italy; 2Research Laboratory Immunology & Inflammation, Clinical Institute Humanitas, IRCCS, Milan, Italy; 3Department of Cardiology, University of Modena and Reggio Emilia, Modena, Italy; 4Department of Clinical and Experimental Medicine, University of Ferrara, Ferrara, Italy

Introduction: COPD is associated with chronic cardiovascular (CV) comorbidities. IL-6 is a pro-inflammatory cytokine involved in COPD pathogenesis. In Part 2, PTX3 is an inflammatory marker that might have role in systemic inflammation associated with COPD and comorbidities.

Objective: To investigate the relationship between circulating IL6 and PTX3 and COPD, we assessed cardiac function in COPD patients clinically free of CV disease and association among IL6 and PTX3, COPD severity, right (RV) and left (LV) ventricular function.

Methods: In 70 COPD (GOLD diagnosis) outpatients, ≥10 pk-yr, ≥50 yrs, we assessed Charlson Comorbidity Index, BODE index and echocardiography. LV systolic dysfunction was defined as LV ejection fraction (EF) <40%. Triacipul Cardiac Magnetic Resonance Imaging (CMRI) and RV function are according to JASE guidelines 2010. IL6 and PTX3 levels were measured by sandwich enzyme-linked immunosorbent assay. Associations were assessed by a linear regression model.

Results: We analyzed 70 COPD pts (52 M), mean age 68 yrs, mean EF 45. COPD severity was GOLD I in 10 pts, II in 34, III in 26. Mean Charlson Index was 4 (range 2-8), mean BODE index 2.3, mean±SD DLC0x/VA 73±7.8, mean±SD LVEF 70±7. Mild RV diastolic dysfunction was found in 40/70 pts (57%). Interestingly, positive significant association (r=0.4, p=0.001) was found between TAPSE and DLC0x. Positive significant association (p=0.08,p=0.03) was also found between age and PTX3.

Conclusions: COPD pts with reduced DLC0x have reduction of TAPSE suggesting a subclinical RV systolic dysfunction. In this population, IL6 and PTX3 levels were not associated with cardiac dysfunction and COPD severity. By contrast, PTX3 is associated with aging.

P254

Effects of ambulatory oxygen on exercise capacity and vital parameters in patients with COPD

Baris Yilmaz, Enis Yentürk, Derya Yememtir, Firdavs Atabey, Esin Tuncay. 1Vehdali Chest Diseases and Surgery Hospital, Pulmonary Medicine, Istanbul, Turkey

Introduction: Ambulatory oxygen is defined as supplemental oxygen during exercise. Candidates for ambulatory oxygen are either already on long term oxygen therapy (LTOT) or show evidence of exercise desaturation.

Aim: The aim of this study is to evaluate the effects of ambulatory oxygen on exercise capacity and vital parameters in patients with COPD who didn't fulfill the criteria for LTOT.
Based Medical Decision Support, MMDS, Aalborg University, Aalborg, Denmark; Time required for PaO2 equilibration in patients with severe COPD

P257 Screening for malnutrition in outpatients with pulmonary diseases Siebring Schokker, J. Sebastiana Vroepeog, Luc H. Steenhuis, René Aalbers, Department of Pulmonary Diseases, Martini Hospital, Groningen, Netherlands

Background: Malnutrition has negative effects on patient outcome, in particular in patients with COPD. Recognition of malnutrition in an early phase might be beneficial for patients and screening for malnutrition in an outpatient setting might, therefore, be worthwhile. Aim: To determine the extent of malnutrition in outpatients with pulmonary diseases using different methods. Methods: All patients visiting our outpatient department of pulmonary diseases for the first time (period Oct. 2010 - Feb. 2011) were screened for malnutri-
tion. Different methods were used to screen for malnutrition: body mass index (BMI), Short Nutritional Assessment Questionnaire (SNAQ), and a fat free mass measurement (FFM; bio-impedance by Bodystat® 1500).

Results: Data of 121 outpatients (mean age 59, 49% male, 29% COPD) were analysed. Obesity (BMI > 30) was found in 26% of patients and underweight (BMI < 21 in COPD, and respectively <18.5 or < 20 in non-COPD, aged ≥65 or >65 yrs) was found in 7 patients. The SNAQ score detected 9 and 3 patients being severely or moderately malnourished. FFM revealed 17 patients (14%) with malnutrition. Combining SNAQ and BMI resulted in detection of 17 malnourished patients. However, different patients are detected (Table 1).

Table 1. Malnutrition. FFM vs. SNAQ + BMI

<table>
<thead>
<tr>
<th>BMI</th>
<th>SNAQ + BMI</th>
<th>FFM</th>
</tr>
</thead>
<tbody>
<tr>

<td>96</td>
</tr>
<tr>
<td>Moderate</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>Severe</td>
<td>9</td>
<td></td>
</tr>
</tbody>
</table>

A low FFM was found more often in patients with COPD (23%) and in females (21%).

Conclusion: This study revealed malnutrition in 6 to 14% of outpatients with pulmonary diseases. Measurement of BMI only seems to underestimate nutritional problems. The discrepancies in detecting different patients emphasize the need for determining a gold standard for defining and measuring malnutrition.

P258 Comparison of costs of community-acquired pneumonia (CAP) treatment at patients with and without bronchial obstruction Yury Mostovoy, Hanna Demchuk, Propediatric Department to Internal Medicine, Vinnitsya National Medical University, Vinnitsya, Ukraine

With purpose to estimate economical costs of treatment of CAP at the patients with and without bronchial obstruction and without it the comparison of therapeutic expenses of CAP at 33 inpatients against a background COPD (basic group – BG) and 33 patients without COPD control group – CG) was performed by case-control method. Patients were represented by age and gender (main age- 63±14 years, 54.3% male). Average duration of hospitalization was similar: BG 34.7±9.9 days, CG 33.7±9.7 days (p>0.05). Patients were represented by mean ± SD. Duration of antibiotic therapy was longer in BG than in CG (12±4 vs 8±1 days). Portion of expenses for antibiotics higher was in BG than in CG (51.5% vs 45.5%, p<0.01). Average costs of treatment for patient in BG was 1229.5±467.72 UAN, but for patient of CG – 789.5±32.43 US (p<0.001). Due to obstruction, severe respiratory failure, slower improving CAP symptoms in BG therapy of these patients was more intensive. Severe 30% from BG were needed change of initial antibiotic to alternative, but nobody from CG. Duration of antibiotic therapy was longer in BG than in CG (12±4 vs 8±1 days). Portion of expenses for antibiotics were higher in BG than CG (51.5% and 44.3% agreeably (p<0.05). Treatment of bronchial obstruction and respiratory failure caused increasing costs for BG at the mean 389.45±34.76 UAN. Costs of treatment of cardiovascular diseases were similar in the both group: 10% in BG and 9.7% in CG (p<0.01) from total sum. More severe CAP at patients with COPD requires more intensive treatment involving bigger therapeutic and diagnostic resources. It considerably increases costs of medical care for this group of patients.

P259 Comorbidities in stage IV COPD patients Vanda Areias1, Susana Carreira1, Marisa Ayreias1, Paula Pinta1, Cristina Bárbara1, 2Pneumology Service II, Hospital Pulido Valente - Centro Hospitalar Lisboa Norte, Lisboa, Portugal; 2Pneumology Service, Hospital de Faro, Faro, Portugal

Introduction: Chronic Obstructive Pulmonary Disease (COPD) is associated with...
many comorbidities, however the prevalence of these diseases varies in different studies.

Aim: To determine the prevalence of various comorbidities in stage IV COPD patients (pts), followed in a respiratory outpatient clinic of an University Hospital.

Methods: A questionnaire was designed and applied to stage IV COPD pts in order to characterize the disease and its comorbidities. Data were supplemented by consensus clinical files.

Results: We included 89 pts (87% male), with a mean age of 68±9 years. 79% were ex-smokers. Mean FEV1 was 38% of predicted and all of them had chronic respiratory failure. Thirty-five pts (39%) were frequent exacerbators (≥2 exacerbations in the last year).

Thirty-seven pts (42%) had at least one admission because of their respiratory disease in the last year and 66 patients (74%) in the last 5 years. Most pts had at least one comorbidity (97%), with an average of 4 comorbidities by patient and a mean Charlson index of 2.

The most frequent comorbidities were cardiovascular diseases (70%), erectile dysfunction (6%), sleep apnea syndrome (43%), dyslipidemia (35%), cataracts (31%), gastroesophageal reflux (29%) and diabetes (20%).

Frequent exacerbators were associated with a 5-fold increase in the odds ratio of having a comorbidity.

Frequent exacerbators had more gastroesophageal reflux (p=0.006) and more admissions in the last year and in previous 5 years (p<0.001).

Conclusion: This study confirms the high prevalence and association of comorbidities in stage IV COPD pts and its influence on exacerbations and admissions, justifying the need of a complete and integrative treatment approach.

P260 Fenspiride as complementary anti-inflammatory agent in therapy of patients with chronic obstructive pulmonary disease.

Tetyana Pertseva, Olena Myronenko, Natalya Klimenko. Internal Medicine Department, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

The aim of our study was to study the efficacy of fenspiride (F) in the complex therapy of patients with chronic obstructive pulmonary disease (COPD).

Study population: COPD pts with I-II stages (n=20) were observed on an exent 6-month treatment period. Among them were 13 males (65%). Mild age 49±0,2;11,32 year, duration of COPD 13,03±4,76. 1st gr. (10 pts) – combined therapy with F (160 mg/day) and fentolateral/praprotam bronhode (F+) (200±80 mcg/day). 2nd gr. (10 pts) – monotherapy with F+

Methods: Spirometry and pneumotonometer were performed on days 1, 90 and 180 by means MasterScreen Body/Def [“Jager”, German]. Functional status was accessed by six-minute walk distance (6MWD) test and Borg dyspnea scale. The St. George Respiratory Questionnaire (SGRQ) data were determined before and after treatment period.

Results: Significant increase in all of the SGRQ domains in pts of 1st gr (p<0.01) was observed. Essential increase of the 6MWD test result has been established on (25,15±5,5) meters in the 1st gr. Perceived dyspnea severity and leg fatigue severity were reduced in 1st gr (p<0.05). Reduction of bronchial obstruction was less considerable and was comparable in both groups (p=0.04 & p=0.038).

We didn’t received significant increases in the respiratory muscle strength (p>0.05).

Conclusion: The study demonstrated greater efficacy of long-term complex therapy with fenspiride and fentolateral/praprotam bronhode compared with fentolateral/praprotam bronhode alone in patients with COPD. This combination regimen can be recommended for the reduction of inflammation and prevention of disease progression in COPD patients.

P261 What are the factors related to misdiagnosing of COPD?

Jean Bourbeau, Denis O'Donnell, Francois Maltais, Darcy Marciniuk, Jean Bourbeau1, Shawn Aaron5, Ken Chapman6, Robert Cowie, Andrea Benedetti1, Tanya Aaron6, Bernard Tanguy, Ziad Rida. Consultation des Maladies Respiratoires et Allergiques, CHU Félix Guay, Saint Denis, Réunion Island, Reunion

The factors for COPD misdiagnosed by physicians are not known.

Methods: This research was part of the Canadian Cohort Obstructive Lung Dis ease (CanCOLD). Subjects were recruited (population-based sampling) from 9 cities. Physician-diagnosed COPD was based on patient self-reported. COPD was confirmed by spirometry, i.e., post-BD FEV1/FVC <0.70.

Results: This analysis included 2132 subjects from 5 cities. Of 163 with physician-diagnosed COPD, 79 were confirmed to have COPD by spirometry while 84 didn’t have COPD. 333 had COPD confirmed by spirometry but were undiagnosed, 910 were at risk (ever smoker) and 726 were healthy (never smoker). Among those with physician-diagnosed COPD as compared to undiagnosed COPD, diagnosed subjects were more likely to be current smokers (36% vs 20%, p<0.0001), to have chronic bronchitis (32% vs 12%, p<0.0001), wheezing (64% vs 38%, p<0.0001), dyspnea >35 MRC (22% vs 9%, p<0.0001), diagnosis of asthma (47% vs 23%, p<0.0001), and lower health status. Similar characteristics were present for physician-diagnosed COPD whether or not the diagnosis was confirmed by spirometry. Predictors of physician-diagnosed COPD included current smoking (OR: 1.86, 95% CI: 1.09-3.18), chronic cough (2.04, 1.13-3.69), chronic bronchitis (2.70, 1.45-5.04), and reduced physical health “SF-12” (0.96, 0.96-0.99).

Conclusions: Misdiagnosis and underdiagnosis of COPD is common. Current smoking, respiratory symptoms and reduced health seems to trigger physican to make diagnosis of COPD. The absence of these factors may result in underdiag-nosis.

Funding: CIHR Rx&D Collaborative Research Program; and the Respiratory Health Network of the FRHQ.

P262 Sublingual allergen extract immunotherapy in a rush pattern to reach the maintenance faster.

Suman Pandey, Saurabh Kole, Surendra Prasad Singh, Swati Gupta Bhattacharya. Department of Respiratory Medicine, Hope Specialty Hospital, Poroma, Bihar, India

Introduction: Sublingual immunotherapy was tried on some patients to evoke some faster and affordable immunotherapy modality to make the patient achieve the maintenance pleats within a very short time. Conventional method of immunotherapy is administered with long durations; rush immunotherapy is super fast methodology in attaining the maintenance/boosting module, which requires hospitalization and other precautionary methods, and multiple allergens’ vaccines to be administered within a short span of time. But in this method, it was found that within 15-20 days the relief of the immunotherapy was reached.

Material & method: 186 patients out of which 48 with urticaria allergic and 138 with allergic Rhinitis & Bronchial Asthma were selected. The therapy consists of administration of four vials of allergics extracts, 1st vial: 1:2500, 2nd vial 1:2,50, 3rd vial 1:25, and 4th vial 1:10 din. The 1st & the 2nd concs were administered in daily 6 hourly schedules in a graphically rising manner. The patients had been given pre-medication. Blood examination and IgE & IgG level estimation were done before & after 8 weeks.

Results: Some of the patients showed local skin reactions which subsided without drugs and no systemic reaction was noted. There was substantial decrease in IgE & increased IgG level, significant & marked satisfactory relief was observed in the patients symptomsatology, thus the procedure was graded as a very fast & affordable & SAFE immunotherapy.

P263 Adherence to sublingual immunotherapy in patients allergic to mites

Bashir Omarjee, Bernard Tanguy, Ziad Rida. Consultation des Maladies Respiratoires et Allergiques, CHU Félix Guay, Saint Denis, Réunion Island, Reunion

Background: Adherence is essential for effective treatment. Specific allergen immunotherapy (SLIT) should be continued until the patient has had substantially reduced symptom free for 3 or 5 years. Sublingual immunotherapy (SLIT) is referred to improve adherence to SLIT. The aim of this study was to identify factors that may influence adherence to SLIT.

Methods: We evaluated 610 patients (15-45 years), 54.4% male, monosensitized to house dust mites with moderate persistent rhinitis and mild persistent asthma, submitted to SLIT in the last 5 years. We analysed factors related to non adherence to SLIT.

Results: 81 patients (13%) suspended SLIT based on different motives: For 28 patients (35%), main reason for discontinuation of SLIT is inability to take medication according to schedule; 21 patients (26%) withdrew in the first 4 months because of local side effects. 14 patients (17%) due to symptoms resolution: they began to show a 30% improvement of their symptoms compared to the basal score, because of local side effects. 14 patients (17%) due to symptoms resolution: they began to show a 30% improvement of their symptoms compared to the basal score, because of local side effects. 14 patients (17%) due to symptoms resolution: they began to show a 30% improvement of their symptoms compared to the basal score, because of local side effects. 14 patients (17%) due to symptoms resolution: they began to show a 30% improvement of their symptoms compared to the basal score, because of local side effects. 14 patients (17%) due to symptoms resolution: they began to show a 30% improvement of their symptoms compared to the basal score, because of local side effects.

Conclusions: The main cause of SLIT cessation was desertion, suggesting a need of a greater number of clinical appointments, at least during the first six months of treatment. Candidates to SLIT should be well selected to improve adherence to treatment. The ineffectiveness of SLIT could not be explained by non-adherence.

51. Allergen immunotherapy and anti-immunoglobulin E
P264 Maintenance schedule of subcutaneous allergen immunotherapy more efficacious than pre-seasonal
Ewa Szwedocka 1, Grzegorz Siergiejko 1, Piotr Rapiszko 1, Zenon Siergiejko 1
1 Pediatrics, Gastroenterology and Allergology Department, University Children’s Hospital, Bydgoszcz, Poland; 2 1st Department, Medical Institute of Medicine, Warsaw, Poland; 3 Respiratory System Diagnostics and Bronchoscopy Department, Medical University, Bydgoszcz, Poland

Pre-seasonal (PS) and maintenance (M) schedules of specific subcutaneous immuno-
therapy (SCIT) with allergoids are used to treat patients suffering from seasonal allergic rhinitis. Which of them is more profitable? The aim of the study was to compare an efficacy of two schedules of SCIT, PS vs. M.
Fifty seven patients included into the study randomly divided into two groups: PS group (n=28) and M group (n=29). Allergovit® (606 - grass pollen allergopharma, Germany) was chosen to treat them. SCIT lasted 3 years. Every year since 1st May-31st August diary cards were fulfilled. Intensity of symptoms (sneezing, nose itching, rhinorrhea, nasal obstruction, eyes itching, lacrimation, eyes reddening, cough and shortness of breath) and concomitant drug consumption were evaluated. Serum total and SlgE were evaluated before and after stopping SCIT. Intensity of a pollinosis was evaluated every year. Each individual from PS group was injected 30 times and obtained cumulative dose of 86662 IU/SBU, whereas the one from M group - 41injections and 172892 SBU. In 2006 the highest concentration of grass pollen in the air was 197/m3, in 2007 much higher – 475/m3, and in 2008 – 247/m3. The highest intensity of the symptoms in both group were registered in the first season of SCIT (2006). No significant differences between PS and M were found. The intensity of the symptoms decreased in successive years of SCIT, and in M group was more evident. After SCIT the concentration of IgE and SlgE decreased significantly.

Conclusions: Both schedules, PS and M of SCIT with allergoid vaccine are effective in pollinosis patients, but M is more profitable.

P265 Pollen asthma treatment: Comparative efficacy study
Iryna Sygaieva. State Center for Preventive and Clinic Medicine, Kyiv, Ukraine

Background: Airborne pollen has always been one of the most common triggers of asthma, so there is vital need in efficient specific hypoensibilisation.

Aims and objectives: Principal aim was to check efficacy of different combinations of inhaled corticosteroid/long-acting β2-agonist upheld by specific immunotherapy and/or montelukast.

Methods: In open-label, randomized, parallel group, one-year panel study were involved 468 patients with pollen asthma (moderate-to-severe airflow limitations, bronchitis symptoms, and a history of exacerbations). All participants had completed allergy examination ( prick skin test), immunologic, and functional assessments and stating their asthma status. Participants were randomized in three equal groups, 156 patients each. First group got specific immunotherapy, second - montelukast (Singular), and third – both treatments. Entire population received budesonide/formoterol (Symbicort Turbuhaler) as well.

Results: After 52-week treatment first group exhibited strong remission in 68% patients assigned, second group – in 61% patients, and third group – in 79% patients. These changes were statistically independent of patient’s age, sex, and smoking status (p>0.01).

Conclusions: Budesonide/formoterol in conjunction with allergen-specific immunotherapy and montelukast proved to be the most successful combination for curing pollen asthma.

P266 Omalizumab in asthmatics with IgE levels > 700 IU/ml
Diego Maselli, Joseph Diaz, Jay Peters.

P267 Effects of add-on omalizumab therapy on airway wall thickening in severe persistent asthma
Makoto Hodanoi. Department of Respiratory Medicine, Atami Hospital, International University of Health and Welfare, Atami, Japan

Background: Omalizumab has an important role in inhibiting the allergic inflammation, and it could possibly contribute to decreased airway remodeling in patients with asthma.

Aims and objectives: The aim of the study is to assess the effects of omalizumab on airway wall thickening using computed tomography (CT).

Methods: Twenty-eight patients with severe asthma were randomized to treat with conventional therapy with (n = 13) or without omalizumab (n = 15) for 16 weeks. Airway dimensions were assessed by CT, and wall area corrected for body surface area (WAVA/BSA), percentage wall area (WAW), wall thickness (Vw/BSA) at the right apical segmental bronchus were measured before and after treatment. The percentage of eosinophils in induced sputum, pulmonary function, and Asthma Quality of Life Questionnaire (AQLQ) were also measured.

Results: Treatment with omalizumab significantly decreased WAVA/BSA, WAW and Vw/BSA (p<0.01), whereas conventional therapy had no change. In the omalizumab group, there were significant decrease in the sputum eosinophils (p<0.01), and improved forced expiratory volume in 1s (FEV1), morning expira-
tory peak flow and the AQLQ score. The changes in FEV1% predicted and sputum eosinophils were significantly correlated with changes in WAVA (r=0.88, p<0.001), and n=072, p<0.01, respectively).

Conclusions: These findings suggest that omalizumab reduced wall thickness and airway inflammation.

P268 Decreasing dose protocol for omalizumab treatment in oral corticosteroid allergic asthma patients
Christian Domingo, Xavier Pomares, Jordi Casabon, Adela Garcia, Carmen Veigas, Concepción Monín. Servei de Pneumologia, Corporació Parc Taulí-Universitat Autònoma de Barcelona (UAB), Sabadell, Barcelona (Spain)

Purpose: To evaluate the viability of a protocol for the progressive decrease of omalizumab dose in allergic GINA step V asthma patients.

Methods: To enter the protocol, the patients had to be receiving treatment with oral corticosteroids for a minimum of one year, oral corticosteroid dose had to have reached its lowest level and spirometry had to be ≥ than at entry. Intervention: a) The omalizumab dose was reduced by half; b) If patients were clinically stable after 6 months, the dose was reduced by half again; c) If needed, oral corticos-
teroids boosters were administered; d) When repeated boosters were needed and/or spirometry worsened, omalizumab dose was increased to the previous figure until the patient stabilized.

Results: The protocol started in July 2006 until December 2010. Forty-five adult patients (31 female) were included; three females were lost during follow-up. The omalizumab dose was decreased in 12 patients (26.6%); it was stopped in three and has not been re-introduced after 4, 12 and 21 months. These patients had been treated for 45, 34 and 18 months respectively. Of the nine remaining patients, in six the dose was reduced and did not need to be re-increased; in three the omalizumab dose had to be increased to the initial dose at months 10, 15 and 32.

Conclusion: 1) A progressive decrease in the dose of omalizumab was feasible and safe in 26% of the patients. 2) A treatment-free window period is possible, and in one patient lasted up to 21 months.

P269 The APEX study: Retrospective review of oral corticosteroid use in omalizumab-treated severe allergic asthma patients in UK clinical practice
Neil Barnes1, on behalf of the APEX Study Investigators, Amr Radwan 2.
1 Respiratory Medicine, London Chest Hospital, London, United Kingdom; 2 Clinical Development & Medical Affairs, Novartis Pharmaceuticals UK Limited, Frienley/Camberley, Surrey, United Kingdom

Treatments that reduce oral corticosteroid (OCS) use can help reduce the burden of asthma. We retrospectively reviewed OCS-sparing in 136 omalizumab recipients (age ≥12 years) with severe persistent allergic asthma. The primary endpoint was to compare the difference in OCS quantity given during 12 months pre- and post-omalizumab initiation. Secondary endpoints included changes in lung function, asthma exacer-
bations and healthcare resource utilization and OCS use in patients on continuous OCS at baseline. Mean (±SD) total quantity of OCS prescribed per year decreased by 34% (p<0.001) between the 12 months pre- (5.5±4.21 mg) and post-omalizumab initiation (3.6±3.73 mg). During 12 months post-omalizumab initiation 87 patients (64%) stopped/reduced OCS use and 66 (49%) completely stopped. Mean per-
cent predicted FEV1 increased from 60.0±17.63% at baseline to 75.2±21.79% at Week 16 of omalizumab therapy (p=0.001). The number of asthma exacerbations...
Severe uncontrolled asthma is a contraindication against allergen-specific immunotherapy due to increased risks of side effects and asthma exacerbations. Omalizumab (Xolair®) has been shown to be an effective treatment for patients suffering from severe allergic asthma and to increased safety of allergen Specif-IgEImmunotherapy SIT. We describe 3 patients (males, 28, 31 and 42years) with severe asthma GINA III-IV and total IgE ranging from 181 to 680 IU/ml undergoing a combination of Omalizumab and house dust mite-SIT. House dust mite (HDM) allergy was confirmed by clinical history, positive skin prick tests, elevated specific serum IgE and positive conjunctival challenge tests. In all 3 patients Omalizumab was initiated according to manufacturer’s recommen-dation. After 3 months in all patients asthma improved requiring less inhaled drugs and an improved quality of life. The felt effect of HDM exposure was also reduced but still present. Thus we add an allergen-specific immunotherapy with HDM as the asthma situation was stable now. We opted for an ultra-high induction regimen with a total of 6 injections over 4 hours and a cumulative dose of 50000 IU. Patients were closely monitored. All patients tolerated the ultra-high induction very well. The maintenance regimen of the HDM extract was then injected on a monthly base. Also Omalizumab was continued on the initial dose. Omalizumab may enable induction of allergen-specific immunotherapy with HDM in severe asthma patients otherwise not accessible to this approach. The long term efect of this combined treatment will have to be further evaluated to judge clinical and pharmacoeconomical aspects.

Biological monitoring of cellular effects of omalizumab with basophil degranulation test (BAT) in severe asthma

Anna Stanzolla, Francesco Perna, Diana Radicella, Carolina Vitale, Emanuela Carpentieri, Christian Russo, Matteo Soha. Department of Lung Diseases, University Federico II Naples, Italy

The use of anti-IgE antibodies (Omalizumab) for the treatment of severe asthma is the first approach with biological drugs in this setting. IgE bound to receptor on responsive cells induce both mast cell and basophil degranulation with release of new mediators responsible of clinical features. There aren’t objective tests to demonstrate the biological effects to this treatment. We evaluated basophil degranu-lation during treatment with Omalizumab using a basophil degranulation test based on a one-step method of basophil staining after exposure to a specific allergen with flow cytometry that shows basophilic reactivity in vitro and their degranulation after coming in contact with specific allergens. This method is based on recognition of positive blood cells positive to marking with monoclonal antibody CD123 that together with citoaphilometric caratheristic by Forward and Side Scatter and the contem-porary negativity of expression of superficial antigen HLA-DR identify basophil granocyte subset. In these cells after specific stimulation in vitro, is possible to identify IgE degranulation for the expression on the citoplasmatic surface of the antigen with monoclonal antibody CD63.

Seven patients were examined with the test baseline and after 12 and 24 months of OMA treatment. After 24 months of treatment degranulated basophil cells were 0.7% in comparison 53.9% at 12 months and 53.5% at baseline and this decrease was associated both to clinical improvements and reduction in oral corticosteroid daily dosage. Basophil degranulation test may be an appropriate method to evaluate Omalizumab biologic therapy in severe asthma where response and treatment duration are important aims.

The APEX study: A retrospective review of responses of severe allergic asthma patients to omalizumab on continuous or non-continuous oral corticosteroids in UK clinical practice

Robert Levy-Naon1 on behalf of the APEX Study Investigators, Amr Radwan2, 1North West Lung Centre, Wythenshawe Hospital, Manchester, United Kingdom; 2Clinical Development & Medical Affairs, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom

Omalizumab is an effective add-on option for patients with severe allergic asthma (who remain uncontrolled despite inhaled corticosteroid therapy), many of whom are receiving oral corticosteroids (OCS). We retrospectively reviewed records from 12 months pre- and post-omalizumab initiation in patients (age ≥12 years) with severe persistent allergic asthma who were or were not receiving continuous OCS. Percentages of patients reducing/stopping OCS use, changes in exacerbation rates, hospitalization and accident/emergency visit rates, overall responder rates and FEV1 all improved post-omalizumab (table). Responses were similar when comparing those who were and those who were not on continuous OCS at baseline. In conclusion, the benefits of omalizumab in patients not receiving continuous OCS at baseline were at least as good as those in patients receiving continuous OCS at baseline.

The use of omalizumab is recommended for patients with severe persistent allergic asthma (IgE-mediated asthma): Pooled data from 3 UK centres

Deborah Hepburn1, Monica Nordstrom1, Kate Welham2, Karen Regan3, Ismail Kasujee4. 1Respiratory Medicine, St Peter’s Hospital, Chertsey, Surrey, United Kingdom; 2Respiratory Medicine, Colchester Hospital University NHS Foundation Trust, Colchester, United Kingdom; 3Respiratory Medicine, Bradford Teaching Hospitals NHS Trust, Bradford, United Kingdom; 4Respiratory Medicine, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom

Omalizumab is approved as add-on therapy for patients (age ≥6 years, European Union) with uncontrolled severe persistent allergic (IgE-mediated) asthma. Few studies have reported on omalizumab’s effectiveness on real-life outcomes in UK clinical settings. We report clinical outcomes in severe allergic asthma patients receiving omalizumab (150-600 mg q4wk or q2wk) at 3 UK centres (St Peter’s Hospital, Chertsey, Bradford Royal Infirmary, Colchester Hospital). Data were compared for 2-years pre-omalizumab and for the most recent assessment following omalizumab initiation. Patients (n=52; age 18–74 years) received omalizumab for an average of 982 days (range: 112–3839). 86.4% patients responded to treatment at 16 weeks. Following omalizumab, hospital admissions/bed days, A&E and GP visits decreased compared with pre-omalizumab (Table). Oral corticosteroid (OCS) use was also reduced post-omalizumab; mean maintenance dose of OCS pre- and post-omalizumab was 12.6 and 5.7 mg/day (n=45). Overall, mean [SD] improvement in AQLQ score was +1.39 [1.80] Asthma control also improved post-omalizumab, as shown by an overall increase in mean [SD] ACT of +7.29 [4.64]. Patients not receiving OCS at baseline (n=14) achieved higher mean [SD] AQLQ scores compared with those on OCS at baseline (n=29); 2.29 [1.23] vs 1.36 [1.77].

Long-term treatment with monoclonal antibodies anti-IgE in severe asthma: Follow-up of ten patients

Marco Brunori, Roberto Pierro, Francesca Serena Pignataro, Giulio Onelli.

Respiratory Pathophysiology and Rehabilitation, Azienda Policlinico Umberto I University of Rome “Sapienza”, Rome, Italy

Omalizumab is a monoclonal anti-IgE antibody suggested for the treatment of very severe asthma. Duration of therapy remains an open question.

We tried to evaluate the long-term response to omalizumab in a population of patients who extended the treatment beyond the 12 months period suggested by EMEA, with the aim of contributing to establish the ideal duration of the therapy.

10 patients (8 females, 2 males, mean age:45 yrs), with severe allergic asthma, uncontrolled despite GINA Step 4 therapy, received optimized asthma therapy and omalizumab up to 36 months. They underwent complete clinical evaluation, spirometry tests and Asthma Control Test questionnaire every month.

Patients showed, after 24 months of treatment, persistence of good clinical and functional status. Omalizumab ACT score was reduced from a 9,9% improvement compared to basal value, FEV1 and MMFE showed an increase of 21% and 26%, with best values registered after 18 months. No side-effects were reported.

Long-term therapy with omalizumab in our patients was well tolerated with significant improvement of both symptoms and functional status. Our data suggest that omalizumab could be a good therapy for patients with severe asthma who do not respond satisfactorily to other therapies.

Omalizumab is a recombinant anti-IgE antibody with proven efficacy in severe allergic asthma. Little is known about immunological changes after decreasing or withdrawing of the therapy.

In the present study T lymphocyte cytokine profiles and frequency of regulatory T-cells before and during omalizumab therapy in patients with severe allergic asthma were examined.

Twenty patients with severe allergic asthma (14 female) who met the criteria for omalizumab therapy were treated for 12 months and after 16 weeks of therapy peripheral blood mononuclear cells were isolated and activated with anti-CD3/anti-CD28 antibodies. Cells were processed for intracellular cytokine staining and frequency of CD3+CD4+ interleukin (IL)-4, IL-5, IL-17 and IFN-γ positive cells was assessed. The frequency of CD4+CD25+FOXP3+CD127- regulatory T-cells was assessed.

Anti-IgE treatment did not lead to a significant change of intracellular IL-4, IL-5, IL-17, and IFN-γ in CD3+CD4+ T-cells. No differences in frequency of regulatory T-cells were found even after 16 weeks of therapy. Additionally, there was no significant change in frequency of regulatory T-cells (mean at baseline:Treg 11±6%, 50±5% interindividual variation in week+16 Treg 11±6%, 45±4%).

In this study there was no significant difference of the tested intracellular cytokines before and after anti-IgE therapy. Frequency of regulatory T-cells did not change significantly 16 weeks after initiation of anti-IgE therapy.
Patient physical activity and its relation with exercise capacity in patients with early COPD.

Hans Van Remoortel1,2, Miek Hornikx1,2, Kristien De Bent3, Erica Balligand3, Chris Burtin1,2, Daniel Langer1,2, Rik Gosselink1,2, Marc Decramer2,

Objective: To investigate differences between patients with COPD who achieve or not the minimum physical activity recommended by the American College of Sports Medicine (ACSM) according to age.

Methods: Physical activity in daily life (DynaPort monitor and SenseWear armband), lung function, exercise capacity, body composition, quality of life (HRQL), dyspnea level in COPD patients. We assessed PA (SenseWear Armband) for 7 days (reported as the average PAmod) in 123 (ex-)smokers (49 with COPD; 33 GOLD I and 16 GOLD II) and 94 non-smokers. Exercise capacity was determined by VO2max and six minute walking distance (6MWD).

Results: Group characteristics are given in table 1. PA was significantly correlated (p<0.001) with 6MWD (r=0.37 and r=0.27 with PApeak and PAmod, respectively) and VO2max (r=0.39 and r=0.35 with PApeak and PAmod, respectively).Stepwise multiple regression analysis showed that PAmod is determined by age (R²=0.17), 6MWT (R²=0.09), season of PA assessment (1=summer/spring/autumn, R²=0.02) and diagnosis of COPD (R²=0.02; total R²=0.30). PAmod is determined by season (R²=0.12), age (R²=0.05), 6MWD (R²=0.04), gender (R²=0.02) and COPD (R²=0.02; total R²=0.25).

Conclusion: PA is reduced in patients with mild COPD. Age, season of PA assessment and 6MWD are predictors of PA.
Activity limitations in patients with chronic obstructive pulmonary disease

Naciye Vardar-Yaglı1, Melida Sgalmi1, Sema Savcı2, Hülya Arikán1, Deniz İnal-Ince1, Ebru Calık1, Tulin Duger1, Meral Bosnak-Güclü3, Latife Cüple1, 1Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 2School of Physiotherapy and Rehabilitation, Dokuz Eylül University, İzmir, Turkey; 3Physiotherapy and Rehabilitation, Gazi University, Faculty of Health Sciences, Ankara, Turkey; 4Chest Medicine, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Aim: Breathlessness causes limitations in activities of daily living (ADL) in COPD patients. The aims of the study were to determine most prevalent ADL limitations, and to analyze relationship between changes in occupational performance and dyspnea, respiratory and peripheral muscle strength, fatigue, and quality of life in COPD.

Materials and methods: Thirty-five COPD patients (FEV1 50.6 ± 19.0% predicted, BMI 28.8 ± 4.9 kg/m²) and 10-paired patients living with their families (4 male, 66 [61–71] years, FEV1 39 ± 30.1% predicted, BMI 22 [20–29] kg/m²) using a multiaxial accelerometer (MiniMed, McRoberts, the Netherlands) during 12 hours/day for two consecutive weekdays. Other measurements were: spirometry, respiratory and peripheral muscle force (maximal respiratory pressures [MIP and MEP] and quadriceps one-repetition maximum test [1RM]), respectively, and functional exercise capacity (6-minute walk test, GMWT).

Results: The two groups had similar GMWT, MIP, MEP and quadriceps 1RM. Time spent walking/day was 37 [31–47] min/day in patients living alone and 49 [43–56] min/day in patients living with their families (p=0.129). Moreover, patients living with their families tended to spend more time lying/day (143 [112–244] vs. 87 [48–177] min/day, p=0.093).

Conclusion: These preliminary results suggest that patients with COPD living alone are more active in daily life than patients with their families, despite presenting similar functional exercise capacity and muscle force. This might implicate in a different treatment approach in patients living alone or with family.

P284

Daily physical activity in patients with COPD living alone or not: Preliminary results

Nadia A. Hernandez1,2, Thais Sant’Anna1, Carlos A. Camillo1,3, Anaísa C. Vercere2, Victoria C. Escobar1, Vanessa S. Probst1,2, Fabio Pitta1,1Laboratory of Research in Respiratory Physiotherapy (LFIP), Physiotherapy, Universidade Estadual de Londrina (UEL), Londrina, Brazil; 2Centro de Pesquisa em Ciências do Câncer (CPCS), Centro de Ciências Biológicas e da Saúde (CCBS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil; 3Post-Graduate Program in Physiotherapy, Department of Physiotherapy, UNESP - Univ Estadual Paulista, Presidente Prudente, Brazil

Background: Although patients with chronic obstructive pulmonary disease (COPD) are known to be physically inactive, we hypothesized that those living alone are less inactive in daily life than patients living with family in order to maintain their functional needs.

Objective: To compare the physical activities in daily life between patients with COPD either living alone or with their families.

Methods: Physical activities in daily life were evaluated in 10 patients living alone (4 male, 64 [61–68] years, FEV1 39 [26–62]% predicted, BMI 23 [21–30] kg/m²) and 10-paired patients living with their families (4 male, 66 [61–71] years, FEV1, 41 [30–49]% predicted, BMI 22 [20–29] kg/m²) using a multiaxial accelerometer (MiniMed, McRoberts, the Netherlands) during 12 hours/day for two consecutive weekdays. Other measurements were: spirometry, respiratory and peripheral muscle force (maximal respiratory pressures [MIP and MEP] and quadriceps one-repetition maximum test [1RM], respectively) and functional exercise capacity (6-minute walk test, GMWT).

Results: The two groups had similar GMWT, MIP, MEP and quadriceps 1RM. Time spent walking/day was 37 [31–47] min/day in patients living alone and 49 [43–56] min/day in patients living with their families (p=0.129). Moreover, patients living with their families tended to spend more time lying/day (143 [112–244] vs. 87 [48–177] min/day, p=0.093).

Conclusion: These preliminary results suggest that patients with COPD living alone are more active in daily life than patients with their families, despite presenting similar functional exercise capacity and muscle force. This might implicate in a different treatment approach in patients living alone or with family.

P285

Short-term effects of using pedometers to increase daily physical activity in smokers

Demetria Kovelis, Juliana Maria De S Pinto1,2, Maria Tereza A.P. Morano3, Ana Maria M. Nogueiras1, Jacinto R. Genczále4, Amanda S. Araújo5, José Ignacio C. Arellánas1,1Physiotherapy, University of Salamanca, Salamanca, Spain; 2Physiotherapy, University of Fortaleza, Fortaleza, Brazil; 3Physiotherapy, Messejana’s Hospital, Fortaleza, Brazil; 4Medicine, University of Salamanca, Salamanca, Spain

Aim: To evaluate the differences in the quality of life (QoL) of patients with Chronic Obstructive Pulmonary Disease (COPD) living in different countries.

Methods: A cross-sectional and comparative study with 80 COPD outpatients of the Respiratory Service of public hospitals of Salamanca (Spain) and Fortaleza (Brazil) from September to December 2010. The sampling was selected by pairs depending on the severity (Global Initiative for Chronic Lung Disease criteria). Socio-demographic and spirometric data (American Thoracic Society criteria) were collected. The QoL was evaluated by the St George Respiratory Questionnaire (SGRQ), a self-administered short form with 38 items and 5 domains (Activity limitations, Breathing symptoms, Cough, Exercise limitation). The total SGRQ score is calculated by the sum of all items.

Results: The severity was 7.5% of mild, 30% of moderate, 47.5% of severe and 15% of very severe COPD. The mean age of Brazilian patients was 66.6 years (SD 8.0years) and the Spanish one was 69.1 years (SD 8.9years). There were significant differences in gender, civil status, monthly income, place of residence, being smoker and ex-smoker, the forced expiratory volume in 1s (FEV1) in both samples. There were also significant differences in all domains and the total SGRQ and in all WHOQOL-Bref domains except the Environment. Brazilian patients presented higher scores in the SGRQ (lower QoL) while Spanish patients had lower scores in the WHOQOL-Bref (worse QoL).
Cystic Fibrosis (CF) is a chronic respiratory disease with a multisystemic involve ment resulting in peripheral muscle fatigue. There are specific questions that assess physical activity fatigue in children. Children Sport Fatigue Questionnaire (CSFQ) and Short Fatigue Questionnaire (SFQ).

Methodology: To validate the Spanish version of both questionnaires in healthy sportive children and to measure the sensitivity of both tools on children with CF that follow regular physical activity.

Results: With children: age (12±2.6 years), BMI (19±2.7 kg/m²), Cronbach index showed good consistency, 0.86 to 0.78. CSFQ and SFQ and intraclass correlation coefficient showed: 0.85 and 0.83, CSFQ and SFQ, respectively. CF children: age (13±3.8 years), BMI (18±2.7 kg/m²). Significant correlations were obtained between CFQ-R and CSFQ: Physical 0.76, Body 0.66 and Role 0.85 for CFQ-R14+. Digestive 0.34 and Treatment 0.33 for CFQ-R Child. Correlations between CFQ-R and SFQ: Physical 0.53 and Role 0.54 for CFQ-R14+ and Treatment 0.40 for CFQ-R Child.

Conclusion: The CSFQ and SFQ questionnaires are valid and reliable for assessing the fatigue caused by physical activity and being suitable for use in CF children that follow regular physical activity such as pulmonary rehabilitation.

The specificity of a new skin test – Diaskintest (recombinant protein CFP10-ESAT6) in patients with sarcoidosis and non-tuberculous pulmonary diseases

Natalya Makarova1, Ludmila Slogotskaya1, Elena Kapusteva2, Sergey Borisov1

1Diagnostic Clinical Research, Scientific and Clinical Anti-Tuberculosis Center, Moscow, Russian Federation; 2Phthisiopulmonology Research Institute, I.M. Sechenov, Moscow, Russian Federation

Background: DIASKINTEST (DST) is a recombinant protein combination of CFP10-ESAT6 for intradermal injection and does not cause delayed-type hypersensitivity reactions in the BCG vaccinated. Objectives and methods: We have used DST intradermally in a dose of 0.2 mg in 0.1 ml in 179 patients aged 18-69 yrs; 62 patients with morphologically identified sarcoidosis, 11 active tuberculosis (TB) patients and 106 patients with other non-specific inflammatory lung diseases. In 72 hours we measured the diameter of induration and hyperemia in mm. Positive response is evaluated as an any size induration, negative - no induration and hyperemia

Results: Among sarcoidosis patients we saw no reaction to DST – the negative results were in all 62 cases, and specificity of DST in this group was 100% [95%CI 99.9%-100%]. In 106 patients with non-tuberculous inflammatory lung diseases we had 8 positive result (2 patients with asthma, 2 with nonspecific pneumonia, 2 with lung cancer, 2 with COPD); specificity of the method in this group was 92.5% [95%CI 87.4-97.5%]. 2 of 11 TB patients had negative response to DST (1 patient with TB and hepatitis C and 1 with TB and alcoholism), so sensitivity is 81.8% for TB cases [95%CI 58.9%-100%]. In our previous research we had similar results using IFN-γ release assay (IGRA) in response of blood cells to ESAT-6 ex vivo, but in the clinical practice we see that the IGRA is more laborious method.

Conclusion: DST has high specificity in sarcoidosis patients and in patients with other nonspecific inflammatory lung diseases. DST may be used as an additional test for the differential diagnosis with TB in unclear cases.

P295

DIASTEST as a screening method at the mass child health examination for tuberculosis in Russia

1Diagnostic Clinical Research, Scientific and Clinical Anti-Tuberculosis Center, Moscow, Russian Federation; 2Phthisiopulmonology Research Institute, I.M. Sechenov, Moscow, Russian Federation

The purpose of this study was to investigate the possibility of differential diagnosis of tuberculosis infection in children and teenagers in the medical practice, which possesses a high specificity owing to the use of secretory proteins ESAT-6 and CFP-10 and its easy test version will allow to enhance the efficiency of tuberculosis infection diagnosis, reduce unnecessary expenses and improve the overall epidemic situation on tuberculosis.

Methods: We conducted a prospective study including consecutive household contacts of patients with active TB between January 2010 and July 2011. All contacts below the age of 35 years of age were interviewed and screened by TST. If the TST was below 6mm, contacts were asked to return for a second TST six weeks later. TST conversion was defined as a TST of greater than 6mm or a 5mm increase of the initial TST. Interferon Gamma Receptor Assay (IGRA), (T-spot test) was performed on those that had TST conversion to evaluate the booster phenomenon.

Results: Of 899 adult and paediatric contacts screened who had an initial TST of less than 6 mm, 189 contacts did not attend for a second TST. A total of 406 had TST performed. 344 contacts attended and did not show TST conversion and were therefore discharged. 68 contacts underwent TST conversion of whom 43 had an IGRA. Out of 43 contacts, 6 had a positive IGRA, 7 out of 43 were indeterminate and 30 were negative. Indeterminate and negative IGRA results were more common in children than in adults.

Conclusion: A two stage approach of TST may cause a booster effect and therefore should be confirmed by IGRA.

Rationale: The role of two stage tuberculin skin test (TST) of persons who have had close contact with a case of smear-or culture positive pulmonary tuberculosis (TB) (PTB) is unclear. A booster phenomenon with TST may occur and therefore screening with TST in a two stage approach may not be ideal [1].

Methods: We conducted a prospective study including consecutive household contacts of patients with active PTB between January 2010 and July 2011. All contacts below the age of 35 years of age were interviewed and screened by TST. If the TST was below 6mm, contacts were asked to return for a second TST six weeks later. TST conversion was defined as a TST of greater than 6mm or a 5mm increase of the initial TST. Interferon Gamma Receptor Assay (IGRA), (T-spot test) was performed on those that had TST conversion to evaluate the booster phenomenon.

Results: Of 899 adult and paediatric contacts screened who had an initial TST of less than 6 mm, 189 contacts did not attend for a second TST. A total of 406 had TST performed. 344 contacts attended and did not show TST conversion and were therefore discharged. 68 contacts underwent TST conversion of whom 43 had an IGRA. Out of 43 contacts, 6 had a positive IGRA, 7 out of 43 were indeterminate and 30 were negative. Indeterminate and negative IGRA results were more common in children than in adults.

Conclusion: A two stage approach of TST may cause a booster effect and therefore should be confirmed by IGRA.

Variables responsible for tuberculosis positivity of household contacts of sputum positive TB cases
Anishkumar Khan, Tushar Sahasrabuddhe. Department of Pulmonary Medicine, Padmashree Dr. D.T.Patil Medical College, Pune, Maharashtra, India

In high TB endemic countries such as India, chemoprophylaxis is routinely offered only to contacts below 6 years of age. The possibility however remains that the index case may have transmitted the infection to other family members before the diagnosis of the disease. We evaluated this in a group of Indian patients. We did a cross sectional study of household contacts of the sputum positive TB patients diagnosed from our center that had no other index case at home present in or out of the past. The contacts were tested for tuberculosis infection using 5 TU PPD (Purified Protein Derivative) immediately after the diagnosis of the index case. An induration of more than 10 mm was taken as a positive result. A total of 179 household contacts of 50 index cases were evaluated. 85/79 (47.48%) were tuberculosis positive. 62/73 (86.06%) contacts below 6 years of age were infected. 31/44 spouses (70.45%) were tuberculosis positive as against 39/87 (44.82%) first degree relatives and 15/48 (31.25%) second degree relatives. 61/112 (54.46%) contacts sharing same bedroom were infected as against 37 (35.82%) not sharing the bedroom. The prevalence of infection of contacts correlated with the grade of sputum positivity of the index case. The variables that did not show any statistically significant correlation were presence of lung cavity, hemoptysis, level and gender. This study suggests the need for offering chemoprophylaxis to the contacts sharing bedroom including spouses in addition to contact children below 6 years of age.

Tuberculosis skin test size and risk of tuberculosis: A 12-year follow-up of contacts of TB cases
Onofre Morán-Mendoza1, Mark FitzGerald2, Kevin Elwood2, David Patrick2.

Background: There are no long-term cohort studies assessing the risk of developing active TB according to the tuberculosis skin test size in contacts of TB cases who did not receive treatment for latent TB infection (LTBI) or were receiving immunosuppressive treatments.

Objective: To assess the risk of TB – according to the tuberculosis skin test (TST) size in contacts of active TB cases who did not receive LTBI treatment.

Methods: This is a population-based retrospective cohort study of contacts of active TB cases recorded in British Columbia, Canada. We estimated the up to 12-year risk of developing TB for infected and non-infected contacts, according to tuberculosis skin test size – using incidence rates. Contacts with HIV infection or with LTBI were excluded from the analysis.

Results: Among 26,542 contacts, 180 individuals developed TB (tuberculosis rate 678/100,000). Non-infected Household contacts (tuberculosis skin test size 0-4 mm) had a TB rate of 1.014/100,000, those with a TST of 5-9 mm a TB rate of 2.162/100,000; and those with 10-14 mm a rate of 4.478/100,000. Non-infected Close non-household contacts had a TB rate of 222/100,000; those with a TST of 5-9 mm a TB rate of 296/100,000 and those with 10-14 mm a rate of 1,821/100,000.

Non-infected Casual contacts had a TB rate of 83/100,000; those with a TST of 5-9 mm a TB rate of 204/100,000 and those with 10-14 mm a rate of 860/100,000.

Conclusions: The risk of TB increases with TST size in all contacts; especially with close contacts. TB risk is high for all household contacts, including those considered non-infected. The risk of TB in non-household contacts is significant only when the TST is ≥ 10 mm.

Comparative study of the usefulness of TST and three interferon-gamma release assays (IGRAs) for the differential diagnosis of pulmonary tuberculosis
Yoshifuro Kobashi, Masaki Abe, Keiji Moura, Yasushi Obase, Naoyuki Miyashita, Mikio Oka. Division of Respiratory Diseases, Department of Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan

Objective: We compared the usefulness of tuberculosis skin test (TST) and three interferon-gamma release assays (IGRAs) (QuantiFERON-TB Gold (QFT-2G), QuantiFERON-TB Gold In-tube (QFT-3G), T-SPOT.TB) as the supportive method of diagnosing pulmonary tuberculosis (TB).

Methods: The subjects were 70 patients who required the differentiation of pulmonary TB clinically. The final clinical diagnosis of pulmonary TB in 22 patients and non-pulmonary TB disease was established by clinical specimens.

Results: In 22 patients with pulmonary TB, the positive response rate was 60% on TST, 80% on QFT-2G, 85% on QFT-3G and 95% on T-SPOT.TB. In 48 patients with non-pulmonary TB disease, the positive response rate was 47% on TST, 9% on QFT-2G, 9% on QFT-3G, 13% on T-SPOT.TB. Indeterminate results on three IGRAs were recognized in one patient each on QFT-2G and QFT-3G among patients with pulmonary TB in three patients on QFT-2G and two patients on QFT-3G among patients with non-pulmonary TB disease. However, there were no indeterminate results on T-SPOT.TB in either patient group. Patients with false-negative or indeterminate results on IGRAs had severe underlying diseases or were receiving immunosuppressive treatments.

Conclusions: T-SPOT.TB provided the best positive response rate for patients with pulmonary TB among three IGRAs, although T-SPOT.TB may have problems in the specificity of diagnosing TB disease. Therefore, we think it is important to perform T-SPOT.TB in combination with QFT to elevate the sensitivity of the diagnosis of TB disease based on the findings in this study.
Aim: To assess the prevalence of LTBI in the risk groups: 1. homeless, 2. close contacts, 3. casual contacts, 4. nursing home pensioners, 5. random population subjects from Krakow (controls) by QFT-GIT and TST, to compare the agreement and kappa of these tests at 5, 10, 15 mm of TST cut-off and to establish the best TST cut-off for the diagnosis of LTBI.

Material and methods: From July 2007 to October 2009 QFT-GIT test was performed in 785 subjects: in group 1 (n = 150); 2 (n = 171); 3 (n = 163); 4 (n = 152); 5 (n = 149) and TST was carried out in: 129, 156, 147, 148 and 121 subjects respectively. In each group the agreement and kappa coefficient between QFT-GIT and TST at 5, 10, 15 mm of TST diameter was analyzed.

Results: We observed high prevalence of LTBI in relevant studied groups: 37% (n = 58,7% (0,26); 60,7% (0,34); 75,4% (0,45); 2: 55,8% (0,20); 60,9% (0,24); 70,0% (0,23). Agreement and kappa at 5, 10, 15 mm of TST cut-off in each group were: in group 1: 58,7% (0,26); 60,7% (0,34); 75,4% (0,45); 2: 55,8% (0,20); 60,9% (0,24); 70,0% (0,23).

Conclusions: TST was characterized by lower diagnostic value in Polish population vaccinated and revaccinated with BCG but TST cut-off 15 mm and more should be considered for diagnosis of LTBI because of highest agreement with QFT-GIT.

P304
Indeterminate IGRA results in routine practice
Peter Kewin1, Teresa Inkster2, Brian Choo-Kang3.

Introduction: Interferon-γ release assays (IGRAs) are used in the diagnosis of latent TB, but up to 6.1% yield an indeterminate test result (ITR; Diel Chest 2009). IGRA's are not currently used for diagnosis of active TB (Sester ERJ 2011). We determined the indications for T-Spot.TB and frequency of ITRs in our routine practice.

Methods: Patient records were reviewed for all T-Spot.TB tests performed in Glasgow (May 07 - June 08). Data was collected on patient demographics, clinical assessment, reasons for request and final diagnosis.

Results: T-Spot.TB was performed on 303 patients (see table 1). The rate of ITRs on first testing was 55/303 (18.2%). Almost half were performed for active TB (45%), and symptoms suggestive of active TB increased the positivity of ITRs. Frequency of ITRs varied between hospital (2.34%) and specialty (0.40%) (data not shown). Female sex, Asian race, ex or non-smoking status, excess alcohol and age >75 favoured an ITR. Immunosuppressive drugs had no effect, although patients with ITR had a slightly lower lymphocyte count. Of the 26 tests repeated, 14 were negative, 6 positive and 4 ITR. Overall 35/103 (11.5%) of patients had an ITR. On follow up 31/35 had no TB, and 4/35 latent, presumed clinical or confirmed TB.

Conclusions: ITRs were more common than in other studies, and may be influenced by patient factors and system failures. Inappropriate testing was common and may be minimised by further educating staff requesting and performing tests.

P305
Detection of IFN-γ responses for diagnosis of tuberculosis infection in chronic inflammatory disease patients
Irene Latorre1,2, Sonia Minguez3,6, Irene Latorre1,5,6, Sonia Minguez2, Marta Vilavella3, Jessica Diez1, Jose Manuel Carraconsa1,2, Cristina Pratt1,5, Lourdes Mateos2, Eugeni Domench6, Vicente Ausina1,5,6, Carlos Ferrandiz5,5, Jose Dominguez1,5,6, Servei Microbiologia, Hospital Universitari Germans Trias i Pujol, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 2Servei Reumatologia, Hospital Universitari Germans Trias i Pujol, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 3Servei Reumatologia, Hospital Universitari Germans Trias i Pujol, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 4Servei Digestiu, Hospital Universitari Germans Trias i Pujol, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 5Servei Dermatologia, Hospital Universitari Germans Trias i Pujol, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 6Servei Digestiu, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Barcelona, Spain; 7CIBER Enfermedades Respiratorias, Instituto de Salud Carlos III, Badalona, Barcelona, Spain; 8CIBER Enfermedades Hepáticas y Digestivas, Instituto de Salud Carlos III, Badalona, Barcelona, Spain

Objective: Determine IFN-γ responses for latent tuberculosis infection (LTBI) diagnosis in chronic inflammatory disease patients.

Material and methods: 89 chronic inflammatory disease patients were classified in 3 groups. Group 1: 53 patients with rheumatic diseases scheduled for anti-TNF-α treatment. Group 2: 53 postnosis patients, 39.1% were receiving biologic treatments, and 43.5% classic systemic treatments. Group 3: 13 patients with Crohn disease, treated with immunosuppressors. TST was done in all cases. We determined IFN-γ production with QuantiFERON-TB Gold In Tube (QFN) and T-SPOT.TB (TS.TB).

Results: Group 1: TS.TB, QFN and TST were positive in 20.8%, 17% and 13.2% respectively. We obtained 4 QFN indeterminate results (7.5%) and 2 for TS.TB, QFN were positive in 5.6% and TST negative in all cases. Concordance between both IFN-γ assays and TST performed simultaneously, TS.TB and QFN were positive in 17.14% of the cases. In contrast, TST was positive in 21.74%. Five patients were documented with a previous positive TST. Therefore, when we analyzed patients with IFN-γ assays and TST performed simultaneously, TS.TB and QFN were positive in 5.6% and TST negative in all cases. Concordance between TS.TB and QFN was 100% Group 3: The three assays were negative in all cases. We observed one TS.TB indeterminate result (7.7%) and 2 for QFN (15.4%), corresponding with patients receiving azathioprine.

Conclusions: Concordance between both IFN-γ assays was good. Indeterminate results were higher in those patients with Crohn disease. IFN-γ assays, in combination with TST, are useful for the diagnosis of LTBI in patients with inflammatory diseases.

P306
Screening of HIV positive TB contacts with an interferon-gamma release assay in a congestate setting in Singapore
Suay Hong Gan1, Siginanavalli Bhoopalani2, Kyi Win KhinMar1, Timothey M. Barkham1,2, Cynthia Bin Eng Chee1,2, Yee Tang Wang1,2,3, Singapore Tuberculosis Control Unit, Tan Tock Seng Hospital, Singapore, Singapore; 2Department of Laboratory Medicine, Tan Tock Seng Hospital, Singapore, Singapore

We used the T-SPOT.TB assay in screening HIV positive contacts of infectious TB cases in the prison setting. The test is believed, on presumptive evidence, to be more sensitive than the tuberculin skin test and QuantiFERON-TB Gold In Tube assay in detecting latent TB infection. We report the screening of 47 HIV positive contacts around 3 infectious TB cases in the prison from 2008 to 2010. Exposure of the contacts occurred during the 1-hour daily activities. Identified contacts were screened for symptoms and examined for signs of active disease. Sputum tests for AFB smears and cultures, chest x-ray and
T-SPOT.TB assay were done. Diagnosis of latent TB infection was based on the T-SPOT.TB assay, after excluding active disease. Window peak typhli (18% of the cases were positive) was offered if the test was negative and stopped if the repeat test was positive. Test results done after 8-10 weeks of treatment was negative. The median CD 4 count was 343 c/e1 and 44.4% of them were on anti-retroviral therapy. 8 contacts had positive T-SPOT.TB assay result, 2 of whom had active TB (yield of 4.3%). The indeterminate rate was 2.1%. 3 contacts completed preventive treatment while 14 contacts had window peak typhli. During the mean follow up of 19 months (median of 21.5 months, range 0 to 25 months), one of the T-SPOT.TB assay negative contacts, whose CD4 count was 4 c/e1, developed active TB 11 months after completing screening.

Except in cases with extremely low CD count, the T-SPOT assay appears to have a good negative predictive value for progression to active disease in HIV positive TB contacts in Singapore.

P307 The role of interferon-γ release assay (IGRA) testing in a UK teaching hospital
Marina Mason1, Jennifer Dickens2, Diana Aguilar2, Gail Hardingham1, Russell Phillips1.
1Respiratory Department, Norfolk and Norwich University Hospital NHS Trust, Norwich, Norfolk, United Kingdom; 2Cambridge Institute for Medical Research, Welwyn Garden City, Hertfordshire, United Kingdom

Background: IGRA's including T-SPOT (T-SPOT.TB)® have recently been adopted for the diagnosis of latent (LTBI) infection with Mycobacterium tuberculosis (MTB). They may also have a role in ruling out active tuberculosis; however a recent meta-analysis has suggested that its specificity may not be high enough to exclude active disease [1].

Aims and objectives: The aim of this study was to retrospectively evaluate the use of the T-SPOT assay at a UK University Teaching Hospital to determine i) the indications for which it is being utilised and ii) whether its use led to any change in management.

Methods: Patients having T-SPOT performed between 09/2008 and 02/2010 were retrospectively identified from our TB database. Information regarding test indication, patient demographics and imaging results was collected from case notes and picture archiving and communications system (PACS). Change in patient management as a result of the T-SPOT was noted (as judged by two clinicians).

Results:

Forty-three (45%) of T-SPOT tests were performed to exclude LTBI and 53 (55%) to exclude active disease. The T-SPOT result led to a change in management in 42 (44%) of cases. To the best of our knowledge no patients with a negative T-SPOT result were subsequently diagnosed with active MTB infection.

Conclusion: In addition to excluding LTBI, T-SPOT can be a useful investigative tool in helping clarify the clinical picture in cases of suspected active TB.

P308 Quantiferon testing in British army recruits
Rachel Mackley, David Spence.

Respiratory Medicine Inst., University of Perugia and Terni, Perugia, Italy

Our hospital has links with an Army base and investigates recruits for Tuberculosis (TB). Many come from high prevalence areas. Recruits are screened with a Mantoux test. Those with a Mantoux reaction ≥15mm and no previous BCG vaccination are referred for Quantiferon Gold testing. If positive they are treated for latent TB. We reviewed referrals over a 2 year period (April 2008 - April 2010) to assess compliance with Army policy and investigate whether referral based on Mantoux reaction alone is warranted.

Demographic data were gathered from Army records. The relationship between Quantiferon and Mantoux results by Nationality

A positive Quantiferon test and a Mantoux reaction of ≥15mm was assessed using a Chi-squared test.

153 cases were identified, 28 were excluded due to insufficient data, leaving a sample of 125. All cases were male. Median age was 21.5 years (range 17-53). For analysis, recruits were divided into 4 areas (see table 1).

99 recruits (79%) had a positive Quantiferon test. There was no significant relationship between Quantiferon positivity and Mantoux size ≥15mm (p=0.093). Large numbers of recruits are referred based on their Mantoux results, including many with reactions of 6-14 mm. As there was no significant relationship between the rate of Quantiferon positivity and Mantoux reaction size ≥15mm, referral decisions should not be made on this basis alone.

Further research is warranted to assess the current referral guidelines.

P309 Evaluating the use of the interferon-γ response to mycobacterium tuberculosis (MTB) specific antigens to diagnose latent tuberculosis infection in patients with chronic inflammatory joint and skin diseases
Claire Martyn-Simmons1, John Meek1, Richard Groves1, Heather Milburn2.
1St John’s Institute of Dermatology, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 2Department of Respiratory Medicine, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom

Introduction: The treatment of chronic inflammatory diseases has been transformed with targeted biologic therapies. Patients receiving this treatment are at increased risk of reactivating latent tuberculosis infection (LTBI). Tuberculin skin test (TST) has been the gold standard for detecting latent LTBI, but may be difficult to interpret in patients receiving immunosuppressive therapies. In vitro interferon-gamma-release assays (IGRA) are an alternative.

Methods: A prospective cross-sectional study was conducted at an inner London tertiary referral centre. Patients were screened for LTBI and a TST was performed. Venous blood samples were obtained for QFR and TSTB.

Results: 102 patients were included, aged between 18 and 83 years. A total of 2% of patients were receiving at least one immunosuppressive therapy. A TST result was available in 84 patients. The overall agreement between the QFR vs TSTB excluding the indeterminate results was 69 out 78 (k=0.572), between QFR vs TST was 62 out of 79 (k=0.241) and between TSTB vs TST was 58 out of 72 (k=0.304). 13 patients received chemoprophylaxis for presumptive LTBI.

Conclusion: Our study showed variation in results obtained from TST and IGRA's when used in our population, some of whom were immune compromised. For patients where interpretation of the results may prove challenging, LTBI screening tests may be best used in combination.
some nationalities and in pts with TST>15 mm, partly decreasing the economic advantage of its use to reduce PTs. Better information on QFT role could be obtained extending this program to H5 with TST <5 mm or age ≥36 yrs but QFT technicalities and heath-care budget cuts do not allow this wider on-field application.

P311
Practical use of quantiferon test in Norway's largest TB-clinic
Saeed Vahedi, Cathrine Brunborg, Anne-Marie Bakken Kran. Department of Pulmonary Medicine, Oslo University Hospital, Oslo, Norway Unit of Epidemiology and Biostatistics, Oslo University Hospital, Oslo, Norway Department of Microbiology, Oslo University Hospital, Oslo, Norway

Introduction: Since November 2008, Norway's largest TB-clinic (Diagnosesasjön, Oslo University Hospital, Ullevål) has implemented Quantiferon-TB GOLD In-Tube test (QFT) as a supplement to tuberculin skin test (TST).

Aims & objectives: The aim of our study was to evaluate clinical use and consequences of QFT results for the patient.

Methods & design: Patients with conclusive QFT result between November 2008 and December 2009, were included in this retrospective cross-sectional study.

Results: 415 patients were included and categorized by reason for referral: Immigrants (31.1%), School children (49.6%), Immunomodulation (7.5%), TB-Contacts (10.6%), Other (1.2%). Only 14 (3.4%) patients had negative TST (Mantoux<5mm). 124 (29.9%) patients had positive Quantiferon test. While 70 (56.9%) Immigrants had positive QFT, 33 (16%) of the School Children had positive QFT result. A multivariate analysis showed that the independent risk factors of a positive QFT test were higher age, reported TB-exposure, high-incidence TB region of birth and immigrants. QFT positivity was associated with age group >35 (OR 3.5) compared to age group <14, reported TB-exposure (OR 4.5), and high-incidence TB region of birth (OR 3.84). QFT result was the single most important decisionmaking. Though QFT has reduced numbers of patients given treatment in-Tube test (QFT) as a supplement to tuberculin skin test (TST).

Conclusions: QFT result was the single most influencing factor on the clinicians decisionmaking. Though QFT has reduced numbers of patients given treatment and follow-up, it is important to keep in mind the limited sensitivity of QFT in certain patient groups when interpreting the QFT results.

Late-breaking abstract: The forgotten majority: A decrease in persistent but not in intermittent asthma in a large cohort study
Shlomo Cohen1, Elie Picard2, Neville Berkman3, Chaim Springer1
Avraham Avital1. 1Institute of Pulmonology, Hadassah University Medical Center, Jerusalem, Israel; 2Institute of Pulmonology, Shaare Zedek Medical Center, Jerusalem, Israel

Aim: To evaluate asthma prevalence and severity in Israeli teenage boys over the last decade.

Methods: A representative sample of three hundred thousand medical records of 17-year-old boys, who underwent a comprehensive medical evaluation for eligibility for national service between 1999 and 2008, were reviewed regarding asthma diagnosis and severity. Also monitored in this period were asthma hospitalization rate, corticosteroids inhalers (CSI) sales rates and air pollution in central cities.

Results: Lifetime asthma prevalence decreased from 9.66% to 8.12%. Mild persistent asthma prevalence decreased from 3.4% to 2.4% and moderate to severe asthma from 0.9% to 0.4%. Intermittent (3.5%) and inactive asthma (2%) remained stable.

Asthma hospitalization rate in 15-24 year-old males decreased from 5.2 to 3.2 per 10,000 hospitalizations. A significant increase in annual CSI sales rates and a decrease in NO2 and SO2 air concentrations were noted.

Conclusions: Prevalence of persistent asthma in Israeli 17-year-old boys decreased significantly over the last decade. Some of this decrease may be attributed to an increase use of CSI and a decrease in air pollution.

P313
Rare alpha-1 antitrypsin mutations in the Irish population
Tomas Carroll1, Catherine O’Connor1, Geraldine O’Brien1, Kevin Molloy1, Maria Ferrarom1, Maurizio Luisett1, Shane O’Neill2, Gerry McElvaney1
1Respiratory Research Division, Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; 2Department of Biochemistry and Clinical Genetics, University of Pavia, Pavia, Italy

AAT deficiency (AATD) results from mutations in the SERPINA1 gene, classically presenting with early-onset emphysema and liver disease. The most common mutation causing AATD is the Z mutation, with the S mutation weakly associated with liver disease. AAT deficiency is under-diagnosed and prolonged delays in diagnosis are common. ATS/ERS guidelines advocate screening all COPD, poorly-controlled asthma, and cryptogenic liver disease patients, as well as first degree relatives of known AATD patients. 5,000 individuals were screened following ATS/ERS guidelines as part of the Irish national targeted detection programme. AAT levels were determined by nephelometry. AAT phenotyping was performed by isoelectric focussing. Patient DNA isolated from DBS samples was genotyped by PCR (Roche LightCycler). Rare and novel mutations were identified by DNA sequencing of the SERPINA1 gene. A number of rare SERPINA1 mutations including I, V, F, X, Chotranch, Zonis, and Mmalton were identified. The I mutation (Arg9Cys) was present at a relatively high frequency (0.0038) in a targeted population, with over 40 cases identified. In addition, a new SERPINA1 mutation was identified.

Current testing of suspected AATD cases is often limited and can miss rare and novel clinically significant SERPINA1 mutations. The rare mutations described in this study were not detected by a commonly used genotyping assay, however, the low AAT levels prompted their correct identification using more detailed genetic analysis. Our findings underline the need for a comprehensive diagnostic workup of all patients with low AAT levels including phenotyping, genotyping and if necessary, DNA sequencing of the SERPINA1 gene.

P314
Hedgehog-interacting protein (HHIP) polymorphisms and chronic obstructive pulmonary disease (COPD)
Simona E. Budulac1, Dinko S. Postma2, Pieter S. Hiemstra1, Thérèse S. Lapperre1, Judith M. Voon1, Wim Timens3, Henriette A. Smit4, H. Marike Boezen1
1Epidemiology, University Medical Center Groningen, Groningen, Netherlands; 2Pulmonology, University Medical Center Groningen, Groningen, Netherlands; 3Pulmonology, Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands; 4Pathology, University Medical Center Groningen, Groningen, Netherlands; 5Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

Genome wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) in the region of Hedgehog interacting protein (HHIP) to be associated with COPD, level of lung function and height in the general population. We aim to investigate the association of rs1032295 and rs13147758 with lung function level and decline in subjects from the general population, as well as the association with lung function level and decline and small airways function in subjects with established COPD.

Two SNPs rs1032295 and rs13147758 in the HHIP region were genotyped in 1,152 subjects from the general population (Doetinchem) and 110 COPD patients (GLUCOLD). Associations of the SNPs with lung function level and small airways function (FEV1 and FEF25-75%) at baseline were analyzed using linear regression.
Low-fat yoghurt intake was directly related to increased risk of both heritable and non-heritable factors in the population but not with lung function decline. Moreover, SNPs in the HHIP region associated significantly with lung function decline in individuals with established COPD patients, suggesting a possible protective effect of the gene in COPD patients.

Background: Dairy products are important sources of micronutrients, fatty acids, and probiotics that could modify the risk of child asthma and allergy development.

Objective: To examine associations of dairy intake during pregnancy with child asthma and atopic dermatitis (AR) at 7 years in the Danish National Birth Cohort.

Methods: Data on milk and yoghurt consumption was collected in mid-pregnancy using a validated FFQ (N=61,912). We assessed asthma and AR through questionnaires and registry linkages. Current asthma was defined as self-reported asthma diagnosis and use of asthma medication in the past 12 months. We conducted multiple logistic regression and report here odds ratios with 95% CI.

Results: At 7 years 5.9% (N=2,316/39,059) of children had registered lifetime asthma diagnosis and 4.2% (N=1,574/37,347) reported current asthma. Life-time AR diagnosis was 0.5% (N=191/39,059) using the registry and 4.9% (N=1,887/38,763) by self-report. Total milk intake was inversely related to current asthma risk (<100ml/day vs. ≥1l/day) = OR 1.12, 95% CI 1.04, 1.20). For yoghurt intake, children of women who ate low-fat yoghurt (with fruit) had a 22% lower risk of asthma (vs. no yoghurt) = OR 0.78, 95% CI 0.65, 0.94). For yoghurt intake, children of women who ate low-fat yoghurt (with fruit) had a 22% lower risk of asthma (vs. no yoghurt) = OR 0.78, 95% CI 0.65, 0.94). For yoghurt intake, children of women who ate low-fat yoghurt (with fruit) had a 22% lower risk of asthma (vs. no yoghurt) = OR 0.78, 95% CI 0.65, 0.94).

Conclusion: Low-fat yoghurt intake was directly related to increased risk of both child asthma and AR, while total milk intake appeared to be protective. Non-fat related nutrient components in yoghurt may be mediating this increase in risk.

PH16
Heritability of atopic dermatitis: Population study and systematic review
Ekaterina Maslova1-2, Thoerhallur I. Halldorsson3,4, Marin Strom5, Sjurdur F. Okken1,2, Department of Nutrition, Harvard School of Public Health, Boston, MA, United States; 2Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States; 3Maternal Nutrition Group, Centre for Fetal Programming, Statens Seruminstitute, Copenhagen, Denmark; 4Unit for Nutrition Research, Faculty of Food Science and Nutrition, School of Health Sciences, University of Iceland, Reykjavik, Iceland

Aims: To investigate heritability and dependence of asthma from the Danish Twin Registry. We performed a systematic review of the literature to obtain thorough estimates of the heritability of the disease.

Methods: In a population-based questionnaire study of 19,748 child and adolescent twins from the Danish Twin Registry, we calculated concordance rates and heritability of atopic dermatitis. We performed a systematic review of the literature to obtain thorough estimates of the heritability of the disease.

Results: The overall prevalence of atopic dermatitis in the population was 17.8% among girls and 14.7% among boys, p<0.001. The concordance rate for atopic dermatitis was significantly higher in monozygotic than in dizygotic twins; 0.80 vs. 0.41 among girls and 0.74 vs. 0.37 among boys. The overall heritability of atopic dermatitis was the same in boys and girls; 93% (90-94%) with the remainder of the phenotypic variance ascribable to non-shared environmental factors.

Conclusions: Atopic dermatitis is a highly heritable disorder. Compared with estimates from systematically identified studies the heritability of atopic dermatitis in the Danish population is substantial.

PH17
Remission of childhood asthma in adolescence – A longitudinal study
Martin Andersson1-2, Linnea Hedman1, Sigrid Sundberg1, Anders Bjerg1, Bertil Forsberg2, Eva Rimmark1-2, NorthOrton County Council, The OLN Studies, Luleå, Sweden; 2Public Health and Clinical Medicine, Umeå University, Occupational and Environmental Medicine, Umeå, Sweden

Background: Few population-based studies have prospectively evaluated remission of childhood asthma and factors related to remission.

Aims: To investigate remission and determinants of asthma remission from the age of 7-8 years to 19 years.

Methods: In 1990, a questionnaire about asthma and related conditions was distributed to all children 7-8 years old in three municipalities in Northern Sweden, and 3,430 (97%) participated. After a validation study, 2,48 (7.2%) of the children were defined as having current asthma. The 248 children were reassessed by annual questionnaires until the age of 19 years where 205 (83%) participated. During the follow-up period spirometry, bronchial challenge testing and skin prick tests were performed.

Results: At the age of 19 years, 76 out of the 205 participants (37%) were in remission defined as no wheeze and no use of asthma medication during the last 12 months. A negative skin prick test at age 7-8 years and male sex were significant predictors for remission. OR: 2.1 (CI 95% 1.1-4.2) and 2.3 (CI 95% 1.2-4.1), respectively. Having rhinitis or eczema at age 7-8 years was negatively associated with remission. Neither heredity for asthma nor parental smoking or rural living was associated with remission.

Conclusion: Remission of childhood asthma in late teenage years was common and related to absence of allergic sensitization and other allergic diseases. The higher rate of remission among boys contribute to the switch in boy-to-girl prevalence ratio from asthma being more common among boys in childhood to being more common among girls/women later in life.
of asthma was observed in rare/never drinkers, OR=1.45 (1.17-1.82), p<0.001, whereas the risk of asthma in heavy daily drinkers was also increased, however not statistically significant, OR=1.26 (0.63-2.50), p=0.514. After adjustment for overall intake of alcohol, preference for beer drinking was associated with an increased risk of asthma compared with no preference, OR=1.29 (1.03-1.61), p=0.01.

**Conclusions:** Alcohol intake appears to increase the risk of new-onset asthma in adults with a U-shaped association between amount of alcohol intake and the risk of asthma.

**P320**

Aspirin-induced asthma is strongly associated with obesity: Large population study on prevalence and risk factors

Jonas Eriksson1, Linda Ekelund1, Apostolos Bosios2, Eva Rönnmark1,2, Jan Løvall1,2, Bo Lundbäck1,2,1 Krefting Research Centre, Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2 The OLIN Studies, Department of Medicine, Sanderby Central Hospital of Norrbotten, Luleå, Sweden

**Background:** Population-based studies on aspirin-induced asthma are few and no comprehensive risk factor analysis for the condition has been published. We sought to investigate the prevalence and risk factors of aspirin-induced asthma in the general population.

**Methods:** A questionnaire on respiratory health was mailed to 30 000 randomly selected subjects aged 16-75 years in West Sweden, 29 218 could be traced and 18 087 (62%) responded. The questionnaire included questions on aspirin-induced dyspepsia, asthma, respiratory symptoms and possible determinants.

**Results:** The prevalence of aspirin-induced asthma was 0.5%, 0.3% in men and 0.6% in women (p=0.014). The prevalence increased with increasing body mass index (BMI<20: 0.3% vs. BMI>35: 2.2%, p<0.001).

**Conclusions:** Aspirin-induced asthma was common in the population. Increasing body mass index increased the risk of aspirin-induced asthma in a dose-response manner. A number of risk factors including obesity were considerably stronger for aspirin-induced asthma than for aspirin-tolerant asthma.

**Figure 1. Prevalence of aspirin-induced asthma by body mass index.**

![Figure 1](https://example.com/figure1.png)

Obesity was a strong risk factor for aspirin-induced asthma (BMI<35: OR 8.15; 95% CI 1.67-5.76). Obesity, occupational exposure to dust gases or fumes and visible mold at home were stronger risk factors for aspirin-induced asthma than for aspirin-tolerant asthma. Current smoking was a risk factor unique for aspirin-induced asthma (OR 2.70; 95% CI 1.52-4.81).

**Conclusion:** Aspirin-induced asthma was common in the population. Increasing body mass index increased the risk of aspirin-induced asthma in a dose-response manner. A number of risk factors including obesity were considerably stronger for aspirin-induced asthma than for aspirin-tolerant asthma.

**P321**

Physical fitness and asthma development in a random population during three decades. The Odense schoolchild study

Jørgen Goldberg-Møller1, Finn Rasmussen1,2,1 Krefting Research Centre, Department of Internal Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2 The OLIN Studies, Department of Medicine, Sanderby Central Hospital of Norrbotten, Luleå, Sweden

**Aim:** To investigate the longitudinal association between physical fitness and the development of asthma and asthma-like symptoms in a general population sample. 1609 children from the Odense schoolchild study were assessed from 1985 to 2007 at age 9, 15, 20 and 29 years. The same physical fitness test was applied at all occasions and fitness was stratified into quintiles for each sex.

**Results:** The following analysis is based all subjects who performed a satisfactory fitness test: 1369 children at age 9 (mean 9.7), 1072 (78%) at age 15 (mean 15.6), 881 (64%) at age 20 (mean 20.3) and 814 (60%) at age 29 (mean 29.3) performed a satisfactory fitness test respectively. The results showed that fitness levels at each age was associated with lower lung function at same age (p<0.001). The was no significant difference in the occurrence of asthma-like symptoms in the sex specific fitness quintiles at age 9 years. Higher fitness at age 9 was associated with a lower occurrence of asthma at age 20 (p=0.001) and 29 years (p=0.04) as well as significant at age 15 years. On the other hand, at age 15 there was a significant trend of higher occurrence of asthma-like symptoms the lower the fitness quintile at age 9 years (p<0.05). In the sex specific analyses the association between physical fitness at age 9 years and asthma at age 20 and 29 years was only significant in women (age 20; p=0.01); (age 29; p=0.04) and men (age 20; p=0.07); (age 29; p=0.7) respectively.

**Conclusion:** In conclusion, our results point toward the importance of a moderate-high fitness level before puberty to reduce the risk of asthma development in adulthood but this effects seems mainly present in women.

**P322**

Impact of physical inactivity on cognitive function in adults with obstructive lung disease (OLD)

Patricia Katz, Laura Julian, Jonathan Singer, Theodore A. Omachi, Steve Gregorich, John Balmes, Paul D. Blanc. Medicine, University of California, San Francisco, San Francisco, CA, United States

**Background:** OLD may increase risk of cognitive deficits.

**Objective:** Examine the role of physical inactivity in cognitive impairment (CI).

**Methods:** Members of a population-based cohort with self-reported physician-diagnosed COPD, emphysema, or chronic bronchitis (n=140; 63% female, mean age 67 yrs, 19% current smokers) completed baseline (T1) and 2-year follow-up (T2) in-person assessments that included spirometry; completion of the CHAMPS Questionnaire to estimate energy expenditure in vigorous/moderate intensity activities (M/V) and overall; and a 10-test cognitive battery. We defined physical inactivity as no expenditure in M/V activities. We transformed cognitive test scores to age-adjusted z-scores and defined CI as z-scores ≤ −1.5 or ≥ +3.3 of cognitive tests. Logistic regression tested relationships between physical inactivity and CI at both T1 and T2, controlling for sex, education, smoking, comorbid conditions, low O2 saturation, depression and lung function.

**Results:** At T1, 31% were physically inactive. CI was more frequent among inactive subjects (27% vs. 12%; adjusting for covariates: OR=9.8 [95% CI 1.8, 53.1]). Adjusting for covariates plus T1 CI, inactive subjects were more likely to be cognitively impaired at T2 (OR=4.4 [1.2, 15.8]). Among 120 subjects not impaired at T1, inactive subjects were more likely to develop CI at T2 (26% vs. 15%; OR=6.0 [1.5, 24.1]).

**Conclusion:** Physical inactivity is a significant risk factor for presence and incidence of cognitive impairment among adults with OLD. Clinical relevance: In OLD, participation in a even moderate physical activity may offer protection from cognitive impairment.

**P323**

Decrease in smoking is related to a decrease in respiratory symptoms but not asthma

Helena Buckman1, Linnea Hedman1, Sigrid Sundberg1, Eva Rönnmark1,2,1 Krefting Research Center, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Public Health and Clinical Medicine, Occupational and Environmental Health, Umeå University, Umeå, Sweden

**Background:** In 2005, smoking was banned in public places in Sweden.

**Aim:** To compare the prevalence of respiratory symptoms and asthma among adults in 1996 and 2006 by smoking habits.

**Methods:** In 1996, 7104 randomly selected subjects (response rate 85%) in North Sweden aged 20-69 answered a postal questionnaire including questions about respiratory symptoms, and smoking habits. Correspondingly, in 2006 a new sample of 6165 subjects (77% responded) of same age answered the same questionnaire.

**Results:** All respiratory symptoms were strongly related to smoking. The prevalence of most respiratory symptoms decreased significantly from 1996 to 2006 parallel to a decrease in smoking, which decreased from 27 to 19%. The prevalence of spumon production decreased from 19.1 to 15.0%; longihooding cough 12.4-10.8%; chronic bronchitis 7.4-6.3% and recurrent wheeze 13.4-12.1%. The prevalence of these symptoms was similar among smokers, and decreased among non-smokers. Physician-diagnosed asthma increased among both smokers and non-smokers, totally from 9.3 to 11.5%. However, the proportion of medicine users and symptomatics among the asthmatics were lower in 2006. In multivariate analysis adjusted for confounders, a significant increase of asthma by study year was found (OR 1.4). Corresponding analysis for chronic bronchitis yielded a significant decreesenct effect by study year (OR 0.8).

**Conclusions:** The decreased prevalence of respiratory symptoms was parallel to a decrease in smoking. The decrease in bronchitis symptoms among non-smokers may be related to a reduction of environmental tobacco smoke and occupational airborne exposures. Increased diagnostic activity can explain the increase in asthma.

**P324**

Recent trends in COPD prevalence in Italy

Sonia Cerella1, Sara Maiolo2,3, Giuseppe Sarosi1, Sandra Baldacci1,3, Martina Fresta1, Frane Carlo Martini1, Angiolo1, Francesco Di Pede1, Francesco Pistilli1, Laura Carrozzi1, Giovanni Vieggi1,2, Pulmonary Environmental Epidemiology Unit, CNR Institute of Clinical Physiology (IEF), Pisa, Italy; 1Institute of Biomedicine and Molecular Immunology (IBIM) “A. Monroy”, CNR, Palermo, Italy

**Aim:** To compare prevalence rates and risk factors associated with COPD in an Italian population sample surveyed 20 years apart.

**Methods:** The family cluster random sample living in Central Italy (Pisa) was enrolled in 1991-93 (n=2529, age range 20-97 yrs, males 44.4%); the survivors, with the inclusion of new family members, were studied again in 2009-10, within the framework of the European Union funded project IMCA2 (Indicators for Mon-
by questionnaire. Spirometry was also used. A Logistic Regression analysis was ran to assess the association between COPD diagnosis and risk factors. 

**Results:** COPD diagnosis prevalence had increased from 8.2% to 11.1% over the 20 years. In both studies, COPD diagnosis is significantly associated with 64+ yrs (IS: OR 15.8, CI 95% 7.7-32.5; ISS: OR 6.1, CI 95% 3.1-11.9) and 45-64 yrs age range (IS: OR 8.6, CI 95% 4.2-17.4; ISS: OR 2.3, CI 95% 1.4-8.4), male gender (IS: OR 19.5, CI 95% 1.4-5.2; ISS: OR 1.5, CI 95% 1.0-2.4), actual or past smoking habits (IS: OR 2.6, CI 95% 1.7-4.1; ISS: OR 1.9, CI 95% 1.2-3.0), work exposure to dust, gas or chemicals (IS: OR 3.1, CI 95% 1.4-6.9; ISS: OR 1.8, CI 95% 1.2-2.7), co-presence of asthma diagnosis (IS: OR 5.9, CI 95% 3.8-9.3; ISS: OR 4.5, CI 95% 3.0-6.6) and cardiovascular illness (IS: OR 2.3, CI 95% 1.6-3.2; ISS: OR 2.5, CI 95% 1.5-4.0).

**Conclusions:** COPD is still increasing in Italy. While the association with the risk factors is confirmed, there is a general decrease of the OR values over the 20 years. The OR decline for male gender is in line with the recent raise of COPD prevalence in females.

**P325**

COPD among never-smokers

Stig Hagstål1, Linda Ekerlung1, Anne Lindberg1, Eva Ronnmark1

**Aim:** To study the prevalence and risk factors of COPD among never smokers and to determine the proportion of never smokers among subjects with COPD.

**Methods:** Of 5189 postal questionnaire respondents (response rate 88%) aged 46-77 years, a stratified sample of the general population of Norrbotten, Sweden, a random sample of 1500 subjects were invited to structured interviews and lung function tests, and 1237 completed a lung function test with acceptable quality. Never smokers were defined as those who had smoked <1 cigarette/day for <5 years. COPD was defined as GOLD stage ≥II, as several medical conditions are associated with a FEV1/FVC <0.7.

**Results:** The prevalence of COPD among non-smokers was 3.4% and tended to be more common among women than men (4% vs 2.3%; NS) and was strongly age related particularly among men. For comparison the overall prevalence in ages ≥45 y COPD was 8.1% (similar in men and women). Among never smokers the prevalence of severe COPD (FEV1<50% of predicted) was 0.8 (women 0.9%; men 0.6%; NS). In contrast to men, severe cases of COPD were found among women aged >65 years. Of all men with COPD, 15% were never smokers versus twice that much among women. Increasing age was a significant risk factor, while passive smoking, manual work in industry and female sex tended to be associated with COPD among never smokers.

**Conclusion:** The prevalence of clinically relevant COPD among never smokers aged >45 y was 3.4% and was associated with increasing age. One out of seven men with COPD versus one out of three women had never been smokers.

any cancer (OR=3.43, 95% CI: 1.10-10.72, p = 0.034), and professional exposure to goats (OR=5.09, 95% CI: 1.05-24.69, p = 0.043).

Conclusions: This exploratory case-control suggests a link between professional exposure to goats and P-ADC, and prompts for further epidemiological evaluation of potential environmental risk factors for P-ADC.

63. Mechanism and monitoring of airway diseases

353 Longitudinal analysis of lung function decline with eosinophilic clustering in severe asthma
Chris Newby, Josh Agbeithe, Beth Hargadon, Peter Bradding, Andrew Wardlaw, Ian Pavord, Ruth Green, Chris Brightling, Salman Siddiqui. Department of Infection, Inflammation and Immunity, Institute for Lung Health, University of Leicester, Leicester, United Kingdom

Background: Lung function decline over time is an important variable for patients with severe/ﬁced asthma and it is unclear how granulocytic cell counts in sputum are associated with this variable as few longitudinal studies include both biomarkers.

Aims and objectives: To analyse lung decline, post bronchodilator FEV1 was recorded over time in order to determine the best ﬁtting mixed effect model to determine the role of granulocytes.

Methods: Data was collected from the Glenﬁeld Hospital Severe asthma clinic, the mean duration of follow up and number of visits was 6 years and 2.75 years. A mixed effect model was applied to the data. Using individual patient mean and standard deviation over time, a statistical mixture/cluster analysis was implemented.

Results: For the best ﬁtting mixed effects model FEV1 decline was -257mL/year (p=0.0001). The signiﬁcant independent ﬁxed effects included exacerbations, age of onset, log eosinophils (p<0.001). Three clusters were found in the log eosinophil cluster analysis. Cluster 1 described a low grade eosinophilic group. Cluster 2, a hyper eosinophilic group and cluster 3, a neutrophilic/non-eosinophilic group. The clusters differed in their frequency of exacerbation/decline.

Conclusions: Eosinophils were found to be a signiﬁcant predictor for FEV1 decline. Clustering eosinophil variables found that patients are either consistently eosinophilic over time or have a large amount of eosinophilic variation.

354 Sputum eosinophilia identiﬁes systemic corticosteroid responsiveness in acute exacerbations of COPD
Mona Bafadhel1, Susan McKenna 1, Sarah Terry 1, Vijay Mistry1, Ian Pavord2, Chris Brightling3. 1Institute for Lung Health, University of Leicester, Leicester, United Kingdom; 2Department of Medical Sciences, Clinical Chemistry, University of Uppsala, Uppsala, Sweden; 3Department of Respiratory Medicine, Centre for Respiratory Infections, Imperial College, London, United Kingdom; 4Cambridge Institute for Medical Research, University of Cambridge, Cambridge, Cambridge, United Kingdom

Introduction: Eosinophilic airway inﬂammation (EA, ≥3% sputum eosinophils) during stable chronic obstructive pulmonary disease is associated with corticosteroid responsiveness. Whether this is true during exacerbations remains unknown.

Methods: COPD patients were entered into a double blind prednisolone placebo controlled trial. Measurements of airway inﬂammation, lung function and health status using the chronic respiratory questionnaire (CRQ) and visual analogue scale (VAS) were assessed at baseline, exacerbation and 2 weeks after treatment.

Results: 166 exacerbations were captured from 109 patients (69 men, 40 women). All eosinophilic exacerbations (n=31) were treated with prednisolone. Non eosinophilic airway inﬂammation (NEA) occurred in 135 exacerbations, of which 70% (n=94) were treated with prednisolone and 30% (n=41) with placebo. Two weeks after prednisolone treated exacerbations, quality of life and lung function improved signiﬁcantly in those with EA compared to NEA (mean change, 95%CI in CRQ and FEV1, was 1.5 units (1.1 to 1.9) vs. 0.8 units (0.5 to 1.0) (p<0.001) and 335mL (219 to 451) vs. 102mL (52 to 152) (p<0.001) respectively. VAS returned to baseline earlier in EA exacerbations treated with prednisolone (p=0.016, see ﬁgure)

Conclusion: Corticosteroid responsiveness during exacerbations of COPD can be identiﬁed by a sputum eosinophilia.

355 Tapering oral corticosteroids in severe asthma is associated with a decrease in fractional exhaled nitric oxide
Simone Hashimoto1, Anneke Ten Brinke1, Jacob K. Sont1, Aeliko H. Zwinderman1, Peter J. Sterk1, Elisabeth H. Bel1. 1Respiratory Medicine, Academic Medical Centre, University of Amsterdam, Amsterdam, Amsterdam, Netherlands; 2Pulmonology, Medical Center Leeuwarden, Leeuwarden, Netherlands; 3Medical Decision Making, Leiden University Medical Center, Leiden, Netherlands; 4Clinical Epidemiology and Biostatistics, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

Rationale: In a recent oral corticosteroid tapering study in patients with severe asthma (Hashimoto and Neijmu 2010), we observed high levels of exhaled nitric oxide (FENO) despite high doses of oral corticosteroids, and, unexpectedly (Smith NEJM 2005), only a minor role of FENO in adjusting the dose.

Hypothesis: Changes in FENO, values in patients with severe prednisone dependent asthmatics are not associated with changes in corticosteroid dose or clinical parameters.

Methods: 48 adult patients with severe, prednisone dependent asthma (mean SD age 49.4 (12.2) y; 18 male) were included in this 6 months follow-up study. Relationships between changes in daily FENO and oral corticosteroid dose, asthma control (ACQ), and FEV1 were assessed. Pearson correlation and regression analyses were used.

Results: Baseline median (range) FENO, and prednisone were 38 (2.5-3000) ppb and (0-60) mg/day. Daily changes in FENO from baseline were positively associ-ated with daily changes in prednisone dose (r=0.22, p=0.003) but not with FEV1 (r=0.02, p=0.77) or ACQ (r=0.03, p=0.65).

Conclusion: In contrast to patients with mild-moderate asthma, patients with severe, prednisone dependent asthma show a decrease in FENO levels when prednisone is tapered.

Implication: This suggests that oral corticosteroids may contribute to persistently high levels of FENO in severe asthma.

356 Sputum eosinophil levels in corticosteroid-treated asthmatic patients
Elena Bacci, Manuela Latorre, Silvana Cianchetti, Federico Dente, Antonella Di Franco, Lorenza Melosini, Elena Raimondi, Erika Camici, Pierluigi Paggiaro. CardioThoracic and Vascular Department, University of Pisa, Pisa, Italy

We have shown that asthmatic patients, despite being asymptomatic after 1-month treatment with inhaled corticosteroids (ICS), may have persistent sputum eosinophilia associated with higher degrees of bronchial hyperresponsiveness (Bacci et al., ATS meeting 2010). In order to test the effects of longer treatment periods, we treated 116 symptomatic, steroid-naive, mild-to-moderate asthmatic patients with different doses of ICS (50 to 500 mcg bid) for three to six months. Before and after treatment, all patients underwent spirometry, methacholine test, sputum analysis, and recorded symptom score (SS) and Peak Expiratory Flow (PEF) throughout the study period. Regardless of treatment dose and duration, some patients (n=56) still had high (≥2%) sputum eosinophils after ICS treatment; they were no different from patients with low sputum eosinophils as regards clinical and functional data after treatment, but had higher baseline SS (1.5 [0.1-3.6] vs 1.0 [0.1-3.1], p=0.04). After treatment, some patients still had high sputum eosinophils despite being totally controlled (SS=0); they were no different from totally controlled patients with low sputum eosinophils.

We conclude that, in patients with greater symptom levels before treatment, sputum eosinophilia may persist despite ICS treatment. Also, sputum eosinophilia may persist even in patients with totally controlled asthma, but after 6 months the...
**A double-blind randomised control trial of peripheral blood eosinophils to direct prednisolone use in COPD exacerbations**

Mona Rafaahel 1, Susan McKenna 1, Sarah Terry 1, Vijay Mistry 1, Mitesh Pancholi 1, David Lomas 1, Per Venge 1, Mike Barer 1, Seb Johnston 2, Jan Pavaro 1, Chris Brightling 1, 1Institute for Lung Health, University of Leicester, Leicester, United Kingdom; 2Department of Respiratory Medicine, Centre for Respiratory Infections, Imperial College London, London, United Kingdom; 3Department of Medical Sciences, Clinical Chemistry, University of Uppsala, Uppsala, Sweden; 4Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom

**Introduction:** COPD exacerbations and treatment responses are heterogeneous. Prednisolone therapy is associated with adverse events. Identifying steroid responsive subgroups may be beneficial.

**Aims:** To compare biomarker-directed prednisolone therapy to current standard treatment during COPD exacerbations.

**Methods:** Patients with COPD exacerbations were randomised to receive standard therapy (ST) or a biomarker-directed therapy (BT). ST patients were given prednisolone when the blood eosinophil count was ≥2% (biomarker positive) and placebo when ≤2% (biomarker negative) (see figure).

**Results:** From 109 patients; 86 exacerbations were treated in the BT group and 80 in the ST group. Prednisolone prescription was reduced by 49% (95% CI 38 to 59, p < 0.001) in the BT compared to ST group. There was no difference between groups in health status or FEV1 after 14 days treatment. Placebo administration did not result in excess treatment failure (hospitalisation or readmission) which occurred in 15% and 2% of biomarker negative patients in ST and BT groups (p = 0.04). Improvements in health status after 14 days were greater in placebo treated patients compared to those in the ST group who were biomarker negative (mean change 1.01 vs. 0.56; mean difference 0.45; 95% CI 0.01 to 0.90; p = 0.04).

**Conclusions:** A phenotype-specific biomarker approach can safely and effectively be applied to prednisolone therapy during exacerbations.

**357**

**358**

**Disease expression in patients with primary ciliary dyskinesia (PCD), CF and pancreatic sufficiency (CF-PS) and insufficiency (CF-PI)**

Malena Cohen-Cymberknoh 1,2, Natalia Simanovski 3, Nurith Hiller 3, Alex Gittles Hillel 2, David Shoeybi 2, Eitan Kern 2, J. C. and PCD Center, Hadassah Hebrew University Medical Center, Jerusalem, Israel; 2Pediatrics, Hadassah Hebrew University Medical Center, Jerusalem, Israel; 3Radiology, Hadassah Hebrew University Medical Center, Jerusalem, Israel

**Aim:** To correlate clinical status, microbiological, FEV1, and HRCT-Totol Brody Score (CT-TBS) between patients with CF-PI, CF-PS and PCD. Data on FEV1, HRCT, sputum cultures and BMI were collected as part of their routine assessment.

**Results:** Overall, 145 patients (79-CF-PI, 43-CF-PS, 23-PCD) participated in this study. The age of the CF-PS group was markedly higher compared to the other groups. BMI was notably lower in the PCD group compared to both CF groups. FEV1 had a strong negative correlation with age in the CF groups, not in the PCD groups. BMI was notably lower in the PCD group compared to both CF groups. FEV1 had a strong negative correlation with age in the CF groups, not in the PCD groups. BMI was notably lower in the PCD group compared to both CF groups.

**Conclusion:** In PCD, FEV1 does not correlate with age, BMI, rate of PA infection and CT-TBS. Therefore, opposed to CF, in PCD, FEV1 is not a reliable predictor of severity of lung disease. Further studies are needed to delineate the pathogenesis and progression of lung disease in PCD.
64 Cystic fibrosis: new insights of diagnosis, inflammation and detecting exacerbations

361 Intestinal current measurement (ICM) as a new diagnostic test for cystic fibrosis (CF)
Malena Cohen-Cymberknoh1,2, Yasmin Yaakob1,2, Eltaw Kerem1,2, David Shoeybl1,2, Joseph Rivlin1, Lea Bemm2, Elie Picard1,2, Micha Aviram1, Michael Wilschanski1,2,3 CP Center, Department of Pediatrics, Department of Pediatric Gastroenterology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; 2CF Center, Carmel Medical Center, Haifa, Israel; 3CF Center, Rambam Medical Center, Haifa, Israel; 4CF Center, Shaare Zedek Medical Center, Jerusalem, Israel; 5CF Center, Sonka Medical Center, Beer Sheva, Israel

Background: Like the nasal potential difference (NPD) test, ICM may be useful for the diagnosis of atypical CF. However, ICM is currently limited at all age stages.

Aim: To assess the diagnostic reliability of ICM in a large cohort of CF, healthy controls and patients with questionable CF.

Methods: Rectal biopsies were taken from 3 groups: known CF patients, healthy controls and patients with questionable CF. The last group had a variety of symptoms suggestive of CF: recurrent pneumonia, unexplained bronchiectasis, chronic diarrhoea and/or failure to thrive. ICMs were performed using standard protocols by mounting the rectal biopsy in an Ussing chamber and sequentially adding secretagogues while recording current changes.

Results: 100% of known CF patients and 11 patients had abnormal ICM results.

Conclusions: ICM tests may be useful in early diagnosis of CF when compared to the porous Blackburn test (p<0.001). ICM may also be useful to detect CF in patients with similar symptoms, but are not confirmed by other tests.

362 Regulation of ion transporters and airway surface dynamics by lipoxin in cystic fibrosis bronchial epithelium
Mazen Al-Alawi1, Valia Verriere1, Richard Chostello2, Valerie Urbach1, Brian Harvey1
1Department of Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; 2Department of Respiratory Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland

Aim: To study downstream effects of impaired IFN induction we investigated the expression of IFN-stimulated genes (ISGs) which are important for the production of antimicrobial proteins.

Methods: Epithelial CF and non-CF cell lines (UNCCF2T/UNCN2T, CFBE41o-/16HBE14o-) were cultured and infected with RV-16 and -1B at a MOI of 2. Gene expression of ISGs including MX1, NGAL, OAS and NOS2 was assessed by RT-PCR. Exogenous IFN-β and -α were added before and after infection.

Results: Expression of all ISGs was reduced in CF and control cells upon virus infection. CF cells expressed 100-1000 times less ISGs than control cells (all p<0.05). ISG expression and RV replication were inversely related (MXA: r=0.79, p=0.001). There was a positive correlation between ISG expression and IFN-β (r=0.5, p<0.004) and -α, a production (NOS2: r=0.65, p=0.01). Exogenous IFN increased expression of ISGs to the level of control cells, with a more pronounced effect of IFN-β.

Conclusions: ISG induction upon RV infection is deficient in CF indicating a profound impairment of the early innate antiviral response. Addition of exogenous IFN restores antiviral pathways in CF, suggesting a potential use of ISGs in the prevention or treatment of RV-induced CF exacerbations.

364 Association of FCN1 and FCN2 gene polymorphisms with earlier onset of chronic pseudomonas aeruginosa (Ps) colonisation in cystic fibrosis (CF) patients
Filomena Haeryck1, Kristel Van Steen2, Tom Cattaert2, Bart Loey3, Sabine Van Duyle4, Petra Schelstraete5, Sabine Van Daele1, Petra Schelstraete1,6,2, David Shoseyov1,2, Joseph Rivlin4, Lea Bentur5, Elie Picard6, Micha Aviram7, Michael Wilschanski1,3 CP Center, Department of Pediatrics, University Hospital of Bern, Bern, Switzerland; 2Statistical Genetics, University of Liege, Liege, Belgium; 3Medical Genetics, Antwerp University Hospital, Antwerp, Belgium

Background: CF is a multisystem disease with high degree of phenotypic variability especially in lung disease. Modifying genes of innate immunity may be involved in early onset of Ps colonisation.

Methods: 82 Single Nucleotide Polymorphisms (SNPs) in 22 genes contributing to the innate immunity (MBL2, MAS3 (MBL associated serine Protease) 1/2, FCN (Ficolin) 1/2, LBP (Lipopolysaccharide-binding Protein), CD14,TLR (Toll-like receptors 1-10) were genotyped in a cohort of 116 CF patients. (age 6-44 years)

Results: CF patients being heterozygous or homozygous for the mutant allele of both linked SNPs FCN1 (promoter) (A) and FCN2 (Q72Q) (exon 9) (G>A) are earlier colonised with Ps (p=0.01) and 2.7 fold increase in the risk of Ps colonisation is seen in CF patients homozygous for mutant allele of -64A>C polymorphism FCN2 (promoter) (p=0.033) and in patients having at least one mutant allele of the linked S258A (G>T) polymorphism FCN2 (p=0.057).

Conclusion: Mutant alleles of FCN1 (pro and Q272Q) and FCN2 (-64A>C and S258A) is significantly associated with earlier Ps colonisation. Mutant allele of polymorphism of TLR10 is associated with later onset of Ps colonisation.

365 The polyamine spermine is increased in cystic fibrosis airway secretions
Hartmut Grasemann1, Darakhshanda Shehnaz1, Paul Pencharz2, Felix Rajten2, Pediatrics, Respiratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 2Gastroenterology, Hepatology and Nutrition, The Hospital for Sick Children, Toronto, ON, Canada

Rationale: Sputum arginase contributes to the nitric oxide (NO) deficiency in cystic fibrosis (CF) airways. Ornithine, the product of arginase activity, is the precursor of polyamines, which may play a role in the pulmonary response to injury and remodeling.

Objective: To measure concentrations of spermine in sputum of CF patients.

Methods: Using mass spectrometry, spermine was measured in sputum of clinically stable patients with CF (n=10), CF patients before and after antibiotic treatment for a pulmonary exacerbation (n=10) and healthy controls (n=10). CF patients were 7-17 years of age. Mean FEV1 in the stable CF patients was 80.4 (range 47-117%) of predicted values. FEV1 in CF patients presenting with a pulmonary exacerbation was 58 (range 36-69%) of predicted and improved by 13.5 (±2.8%) with treatment.

Results: Mean (±SEM) spermine concentration in sputum was significantly higher in stable CF than controls (1.7±0.53.99 vs. 0.22±0.5 μmol/mL, p<0.001, paired t-test), but remained significantly increased when compared to controls (p<0.001). The change in spermine concentrations during treatment for a pulmonary exacerbation correlated significantly with the
Regulation of corticosteroid binding globulin (CBG) in the inflammatory context of cystic fibrosis
Jessica Taylard1, Carine Rebeyrol 1, Dominique Debray 1, Annick Clement 1,2, Carole Lefebvre 3, Jean-Paul Magot 3, Charlotte Robroeks, Quirijn Jöbsis, Han Hendriks, Edward Dompeling.

Background: Morbidity and mortality in cystic fibrosis (CF) are mainly caused by pulmonary complications. Early recognition of an exacerbation enables early intervention in CF management. We hypothesized that lung function indices drop significantly before an exacerbation is clinically evident, and that CF exacerbations can be predicted when lung function is assessed by means of a home monitor.

Aim: To study the expression and regulation of CBG in the liver and assess its pulmonary expression in the inflammatory context of CF.

Methods: Hepatic levels of CBG:
- Biopsies from healthy donors, cirrhotic CF and non CF patients: measure of the transcripts levels of CBG and interleukin-6.
- Hepatocarcinoma derived cell-lines Hep3B and HepG2: regulation of CBG expression.

Lung levels of CBG:
- Lung biopsies; expression of CBG
- Bronchial epithelial cell lines; regulation of CBG expression

Results: We show an increase in CBG expression:
- in the liver and lung of CF patients.
- in the hepatic and lung cell lines in an inflammatory context.

GC has no effects on CBG expression in hepatic cell lines, but increases CBG levels in the lung cell lines.

Discussion: We show stimulation of the expression of CBG in the inflammatory context of CF. Comparative results from hepatic and lung cell lines enlight a different regulation of CBG expression. Overall, increase in CBG expression in CF could mean initially a decrease in GC bio-disponibility but, ultimately, an enhanced corticosteroid half life and possible prolonged effects.

Conclusions: Spermine is significantly increased in the airways of patients with CF and linked to increase arginase activity. Further studies of the role of the polyamines for CF lung disease are warranted, as they may contribute to airways obstruction and remodeling.

Regulation of corticosteroid binding globulin (CBG) in the inflammatory context of cystic fibrosis
Jessica Taylard1, Carine Rebeyrol 1, Dominique Debray 1, Annick Clement 1,2, Nicolas Chignard 1, Philippe Le Rouzic 2, 1UMR_S938, Inserm, UPMC Univ Paris 06, Paris, France; 2Pulmonary and Cardiopulmonary Medicine, Hopital Armand Trousseau, APHP, Paris, France

Background: Cystic Fibrosis (CF) is characterised by chronic lung inflammation. In CF, glucocorticoids (GC) are a widely used therapeutic tool. However, their efficiency, and the benefit/risk ratio are still discussed. In plasma, 90% of GC is bound to the chaperone protein CBG which regulates its bio-disponibility. CBG is mainly produced by the liver. Recent works enlightened the fact that, more than a simple carrier protein, CBG could also address GC specifically to the inflammation site, thereby modulating the response to GC in an inflammatory context.

Objectives: Study the expression and regulation of CBG in the liver and assess its pulmonary expression in the inflammatory context of CF.

Methods: Hepatic levels of CBG:
- Biopsies from healthy donors, cirrhotic CF and non CF patients: measure of the transcripts levels of CBG and interleukin-6.
- Hepatocarcinoma derived cell-lines Hep3B and HepG2: regulation of CBG expression.

Lung levels of CBG:
- Lung biopsies; expression of CBG
- Bronchial epithelial cell lines; regulation of CBG expression

Results: We show an increase in CBG expression:
- in the liver and lung of CF patients.
- in the hepatic and lung cell lines in an inflammatory context.

Conclusions: This study ascertained important indicators of exacerbation from patients and clinicians. Reflection on the results of both Delphi studies will allow comparisons to be drawn on the perspective of CF adults versus CF clinicians to identify the areas where there are differences and also the areas where there are strong agreement.

The value of lung function monitoring by means of a home monitor in patients with cystic fibrosis
Charlotte Robroeks, Quirijn Jobis, Han Hendriks, Edward Dompeling. Pneumologie, Maastricht University Medical Center, Maastricht, Netherlands

Background: Morbidity and mortality in cystic fibrosis (CF) are mainly caused by pulmonary complications. Early recognition of an exacerbation enables early intervention in CF management. We hypothesized that lung function indices drop significantly before an exacerbation is clinically evident, and, that CF exacerbations can be predicted when lung function is assessed by means of a home monitor.

Aim: To establish agreement on indicators of an exacerbation in adults with CF.

Methods: 2 parallel Delphi web surveys in 13 UK and Ireland CF centres. Delphi 1: 31 adults with CF (FEV1 <80%) with at least one exacerbation in the previous 12 months. Delphi 2: 38 CF clinicians involved in diagnosing CF exacerbations. Round 1: A list of potential indicators of exacerbations were extracted from the literature, consultation with clinicians and adults with CF and 48 statements developed. Round 2: Participants rated their level of agreement with each statement. Round 3: Currently active. Statements not reaching consensus in Round 2 were presented to participants to re-rate. Consensus of 75% agreement was applied to all statements.

Results: Round 2. Adults with CF: 21 statements reached consensus. The top three were: “More shortness of breath than usual”, “Feeling the need to do more airway clearance than usual”, “A large decrease in lung function”. Round 2, CF clinicians: 23 statements reached consensus. The top three were: “Increased sputum”, “A large decrease in lung function (>10% FEV1)”, “Increased coughing”. Of statements reaching consensus 16 were common in both groups.

Conclusions: This study ascertained important indicators of exacerbation from patients and clinicians. Reflection on the results of both Delphi studies will allow comparisons to be drawn on the perspective of CF adults versus CF clinicians to identify the areas where there are differences and also the areas where there are strong agreement.

65. Endoscopic lung volume reduction: hype or hope?

Conclusions: Single session bilateral endoscopic lung volume reduction therapy in advanced upper lobe and homogeneous emphysema using a tissue sealant

Objective(s): This open labeled multicenter study was performed to evaluate the safety and efficacy of single-session bilateral 4-site lung volume reduction therapy with the AzriSael® Emphysematous Lung Sealant System (ELS) in patients with advanced upper lobe heterogeneous (ULF) and homogeneous (Ho) emphysema.

Methods: 20 patients with advanced Ho (n=4) and ULF (n=16) emphysema received 4-site bilateral upper lobe volume reduction with ELS under conscious sedation. Outcome measures include pulmonary function tests (at 6, 12 and 24 wks), exercise capacity, symptoms, and health related quality of life (HRQL, at 12 and 24 wks).

Results: 4-site therapy was well tolerated. Procedure duration was 14-4 minutes. Average hospital length of stay was 0.9±1.3 days. There were 5 3AEs during the first 85±32 days of follow-up (5 treatment related, 1 CPDP exacerbation).

Conclusions: Bilateral single session endoscopic lung volume reduction therapy can be achieved safely using ELS in patients with advanced Ho and ULF emphysema under conscious sedation. Initial results indicate that efficacy responses are similar to those reported with surgical volume reduction, and treatment is associated with short hospital length of stay and minimal morbidity.
Background: A recent approach to bronchoscopic lung volume reduction (BLVR) in patients with advanced emphysema involves the use of a device made of self-expandable nitinol wire for the treatment of emphysema. A multicenter, single-arm cohort trial of 14 patients was performed to evaluate the feasibility, safety, and efficacy of this treatment. The primary outcomes included physical examination, imaging (CT scan to evaluate regional volumetric changes), pulmonary function tests, and quality of life assessment.

Methods: A total of 14 patients were enrolled in the study, and all patients were treated with the same procedure. The device was inserted through a flexible bronchoscope and positioned in the target lung segment. Imaging was performed before and after the procedure to assess changes in lung volume and function.

Results: All patients were successfully treated with the device. There were no procedure-related complications. One patient experienced minor hemoptysis, and another patient had a transient increase in post-procedural bronchodilator use. All patients showed improvement in pulmonary function tests and quality of life assessments at 6 months follow-up.

Conclusion: Endobronchial lung volume reduction with this device is feasible and safe, with promising clinical outcomes. Further studies are needed to confirm these results and to evaluate the long-term effects of this treatment.
Objective: To evaluate the effectiveness of the Chartis® system in predicting subjects with heterogeneous emphysema who will achieve significant (≥350mL) LVR by EVBT.

Methods: Patients with heterogeneous emphysema were enrolled. Following Chartis assessment of the targeted patients, which was determined by using HRCT, all patients were treated with Zephyr® EVBY. Primary endpoint was HRCT-measured LVR in the treated lobe at 30 days. FEV1, SGRQ and 6MWT were evaluated as secondary endpoints.

Results: To date, primary endpoint is collected for 24 patients. Primary and Secondary Endpoints for 75-80 patients are anticipated. Subgroup analyses will focus on patient selection criteria.

Conclusion: Chartis System predicts significant LVR after EVBY treatment. Results suggest that expanded patient selection criteria will enable successful treatment for a broader population of emphysema patients.

6-month follow-up in patients with advanced homogeneous emphysema treated with endobronchial lung sealant therapy

Anschang Valipour1, Felix Herth2, Ralf Eberhard1, Franz Stanzl3, Reiner Bonnen1, Juergen Behr1, Charles Marquette4, Mondechai Kramer7

1 Respiratory and Critical Care Medicine, Otto Wagner Hospital, Vienna, Austria; 2Pneumology and Critical Care, Thoraerklinikum Heidelberg, Heidelberg, Germany; 3Pneumology II and Endoscopy Service, Lungenlink, Hemo, Hermet, Germany; 4Pneumologie, Zentralklinik Bad Berka GmbH, Bad Berka, Germany; 5Medizinischer Klinik III, University Bergmannsheil, Bochum, Germany; 6Service of Pneumology, Hospital Pasteur University of Nice, Nice, France; 7Pulmonary and Critical Care Medicine, Rubin Medical Center, Bellinson Hospital, Petach Tikva, Israel

Objective(s): Bronchoscopic lung volume reduction therapy using endobronchial valves (Scurfa F et al., NEJM, 2010;363) and coils (Herth FJ et al. Therap Adv Respir Dis, 2010;4) has shown limited efficacy in patients with advanced homogeneous emphysema (sAHoE). This study summarizes results to AeriSeal® Emphysematous Lung Sealant (ELS) therapy in patients with sAHoE out to 6 months.

Methods: Patients with sAHoE and scintigraphy scans showing reduced perfusion to the upper lung zones (n=12) were included in this study, which was performed at 8 investigational centers in Europe and Israel. All patients received initial 2-site upper lobe bronchoscopic ELS therapy; approximately 2/3 received a second treatment at 2 additional sites in the contralateral lung. Follow-up was performed at 3 and 6 months post treatment.

Results: Upper lobe ELS therapy in this cohort of sAHoE patients (8 male, age 64±7 yrs) was well tolerated, and was associated with improvements in pulmonary function, functional capacity, and quality of life. Three (3) and 6 month changes in FEV1 (+12.6 ±13.1%), FVC (+9.4 ±13.2%); FVC (+9.9 ±10.1%), RV/TLC ratio (−3.6 ±3.8%), sFEV1 (−0.4 ±0.0%) and 6MWT (+15.4±4.5m; +16.6±4.7m), and SGRQ (−7.9 ±7.6); −13.3 ±23.0) were observed. MCI improvements in spirometry (>12% improvement in FEV1 and/or FVC) were observed in 50% of patients at both time points.

Conclusions: ELS therapy produces durable improvements in pulmonary function and quality of life in patients with AHSIE, and represents a new therapeutic option for patients with homogeneous emphysema who remain symptomatic despite maximal medical therapy.

Efficiency of the endo-bronchial volum reduction treatment for severe heterogeneous emphysema

Turan Ece1, Ayseg Eser1, Zuleyha Bingol1, Tuige Hurkal1, Alper Toker1, Ferhat Ece2,1Pulmonary Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey; 2Pulmonary Department, Istanbul Bilim University, Istanbul, Turkey; 3Thoracic Surgery Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey

Background: Patients with advanced chronic obstructive pulmonary disease (COPD) have limited treatment options. Exercise capacity and health related quality of life (HRQoL) of the patients are affected by the progress of respiratory failure. Volum reduction surgery is reported to be effective for selected patients. But there is a high risk for the surgery of these patients.

Methods: To study the safety and effectiveness of the EBVRT for heterogeneous emphysema.

Result: EBVRT were applied to 21 patients. Most of the patients were male (66.6%). Valves were placed into upper lobe (n=15), lower lobes (n=5) and middle lobe (n=1). There were no procedure-related deaths. Only one patient with ischemic heart disease was died at the 3rd month. Device related complication was occurred in two patients; one patient was intubated and the other patient’s valve was occluded and worked inversely. Functional capacity was improved in 715% (n=15) of the patients but only 66% (n=10) of these patients were feeling and doing better. In these patients mean 10mmHG increase of PaO2 and mean 4.5mmHG decrease of PaCO2 were observed at 3rd month. HRQoL were improved in 48% (n=10) of the patients. However, pulmonary functions, 6 minute walking distance were not significantly changed.

Conclusion: Although FEV1, 6 minute walking distance were not changed, PaO2, functional status and HRQoL improvement were observed with EBVRT of advanced emphysema patients. EBVRT is a new method with acceptable safety for the patients with severe COPD.

Late-breaking abstract: Impaired carbon monoxide diffusion capacity is the strongest predictor of exercise intolerance, even in moderate COPD

Amir Farhkhoo3,4, Andrea Malinowszc,3 Harpa Amardottir3, Margareta Emmter1, Hans Hedenstrom2, Christer Janson1,1 Lung & Allergy Diseases, Medical Sciences, Uppsala University, Sweden; 2Clinical Physiology, Medical Sciences, Uppsala University, Sweden

Background: Exercise intolerance is the hallmark of COPD and FEV1 is the traditional method used to define the severity of COPD. However there is a dissociation between FEV1 and exercise capacity in a large proportion of subjects with COPD. Therefore it is of interest to investigate if other lung function parameters are having an additive, predictive value of exercise capacity (EC) and if this differs according to the COPD stages.

Methods: Spirometry, measurements of lung volumes and diffusing capacity for carbon monoxide (DLCO) were performed in 88 patients with COPD GOLD stages 1-IV. EC was determined by symptom-limited incremental cycle ergometer test.

Results: DLCO, FEV1 and inspiratory capacity (IC) were found to be the best predictors of EC in a stepwise regression analysis and explain 72% of EC. These lung function parameters explained 71% of EC in GOLD II, 69% in GOLD III and 32% in GOLD IV. DLCO alone was the best predictor of exercise capacity in GOLD II and IV (Table).

Discussions: Additive information regarding COPD patients’ exercise capacity is obtained by measuring diffusing capacity and inspiratory capacity. DLCO was the strongest predictor of exercise capacity in all subjects and the best individual predictor in patients with GOLD stage II. This suggests that clinically monitoring with measurements of diffusing capacity may be beneficial even in patients with moderate disease severity.

ACE gene polymorphisms, COPD exercise tolerance and response to acute oxygen

Nelly Heraud1, Christian Préfaut2, Jacques Desplas1, Alain Varray3, Clinique du Souffle, Fonteville, Osexe, France; 2Physiologie et Medecine Experimentale du Cerveau et des Muscles - INSERM U 1046, CHU de Montpellier, Montpellier, France; 3EA 2991 - Laboratoire Mouvement à Health ou Mouvement et Santé, Université Montpellier 1, Montpellier, France

Introduction: Recent studies have shown that polymorphisms of the angiotensin-converting enzyme (ACE) gene are closely associated with pulmonary disorders. The aim of this study was 1) to investigate the impact of ACE gene polymorphism on exercise tolerance 2) to determine whether a relationship exists between oxygen responses and differential genotype (DD, DI or II).

Methodology: Twenty-four COPD patients [FEV1=51±2.4%pred] exhibiting exercise-induced desaturation performed endurance exercise at 60% of their maximal workload in two randomised conditions: normoxia and hyperoxia. ACE genotype was determined for each patient. Endurance time (Tlim), dyspnoea, cardiac output (CO) and arterio-venous difference in oxygen (AVD) were compared.

Results: In normoxia, Tlim was greater for DI than DD (1168 vs 541s; p<0.05). Oxygen supply improved performance in both groups, but DI again exhibited better endurance than DD (1313 vs 1332s; p=0.01). This better exercise capacity in DI was associated with a greater AVE and decreased CO for comparable oxygen uptake. Although O2 significantly increased Tlim in two-thirds of patients (R=+) and significantly decreased it in about one-third (R=−). R=+ and R− proportion was comparable in the two genotype groups (ch2=0.52, p=0.66).

Conclusion: This study showed that DI-allele was associated with better endurance performance. Although DD and DI increased performance with oxygen, responses were associated with differential consequences on cardiovascular and peripheral muscle adaptations. However, ACE polymorphism could not be related to positive or negative oxygen responses.

66. Altered mechanisms during exercise in disease

Late-breaking abstract: Impaired carbon monoxide diffusion capacity is the strongest predictor of exercise intolerance, even in moderate COPD

ACE gene polymorphisms, COPD exercise tolerance and response to acute oxygen

Nelly Heraud1, Christian Préfaut2, Jacques Desplas1, Alain Varray3, Clinique du Souffle, Fonteville, Osexe, France; 2Physiologie et Medecine Experimentale du Cerveau et des Muscles - INSERM U 1046, CHU de Montpellier, Montpellier, France; 3EA 2991 - Laboratoire Mouvement a Health ou Mouvement et Santé, Université Montpellier 1, Montpellier, France

Introduction: Recent studies have shown that polymorphisms of the angiotensin-converting enzyme (ACE) gene are closely associated with pulmonary disorders. The aim of this study was 1) to investigate the impact of ACE gene polymorphism on exercise tolerance 2) to determine whether a relationship exists between oxygen responses and differential genotype (DD, DI or II).

Methodology: Twenty-four COPD patients [FEV1=51±2.4%pred] exhibiting exercise-induced desaturation performed endurance exercise at 60% of their maximal workload in two randomised conditions: normoxia and hyperoxia. ACE genotype was determined for each patient. Endurance time (Tlim), dyspnoea, cardiac output (CO) and arterio-venous difference in oxygen (AVD) were compared.

Results: In normoxia, Tlim was greater for DI than DD (1168 vs 541s; p<0.05). Oxygen supply improved performance in both groups, but DI again exhibited better endurance than DD (1313 vs 1332s; p=0.01). This better exercise capacity in DI was associated with a greater AVE and decreased CO for comparable oxygen uptake. Although O2 significantly increased Tlim in two-thirds of patients (R=+) and significantly decreased it in about one-third (R=−). R=+ and R− proportion was comparable in the two genotype groups (ch2=0.52, p=0.66).

Conclusion: This study showed that DI-allele was associated with better endurance performance. Although DD and DI increased performance with oxygen, responses were associated with differential consequences on cardiovascular and peripheral muscle adaptations. However, ACE polymorphism could not be related to positive or negative oxygen responses.
378 Influence of abdominal volume regulation on chest wall hyperinflation during constant work rate exercise in patients with COPD
Luciana Takara, Marco Nunes, Thulio Cunha, Fabio Queiroga, Miguel Rodrigues, Ethane Meda, Mayron Oliveira, Gaspar Chiappa, Luiz Eduardo Nery, J. Alberto Nedert. Respiratory Div., Federal Univ. of Sao Paulo, Sao Paulo, Brazil

It has been recently reported that some patients with chronic obstructive pulmonary disease (COPD) may actively recruit the expiratory abdominal (AB) muscles in order to counteract the related dynamic hyperinflation. However, whether this strategy is universally efficacious in counterbalancing the potential increases in rib cage (RC) volumes thereby promoting a net deflating effect on chest wall (CW) is unknown. Thirteen males with COPD (FEV1=43.8±9.5%) performed a constant work rate cardiopulmonary exercise test (75% max) to the limit of tolerance (Tlim) on a cycle ergometer. Breath-by-breath ventilatory kinematics was continuously monitored by optoelectronic plethysmography (BTS, Italy). End-expiratory volume of RC (EEVRC) and EEV CW significantly increased from rest to Tlim in 17 patients. EEV CW remained stable in 9 of them ("non-recruiters/hyperinflators"); in contrast, it decreased slightly in 7 "recruiter/hyperinflators" thereby lessening CW hyperinflation. EEV RC remained stable and EEV AB decreased sharply in the remaining 13 "recruiter_non-hyperinflators". "Recruiter/hyperinflators" showed higher dyspnoea scores and the worst exercise capacity (~80% lower than the "recruiter_non-hyperinflators") (p<0.05). In conclusion, CW deflation secondary to extensive AB recruitment was restricted to COPD patients showing no evidences of RC hyperinflation. On the other hand, pronounced increases in RC volumes were associated with milder degrees of AB recruitment. Although this avoided more severe CW hyperinflation, it was related to increased breathlessness and poor exercise tolerance. Supported by: FAPESP and CNPq, Brazil.

379 Effect of heliox breathing on locomotor and respiratory muscle oxygen delivery during exercise in COPD patients with or without dynamic hyperinflation
Zafeiris Louvaris1,2, Vasili Andrianopoulos1,2, Maroula Vasileopoulou1,2, Evgenia Chernevou1,2, Stauroula Spetsioti2,3, Andrea Aliverti2,3, Helmut Linz2,3, Joannou Sadr3,4, Ioannis Vogiatzis1,2, 1Dept. of Critical Care Medicine and Pulmonary Services, Evangelismos Hospital, “M. Simos, and G.P. Livanos Laboratories”; 2Dept. of Physical Education, National and Kapodistrian University of Athens, Athens, Greece; 3Diapartiment of Biopneumologia, Politechnico di Milano, Italy; 4Centre Hospitalier Benjamin Franklin, Institute of Physiology, Berlin, Germany; 5German Heart Institute, Department of Anesthesiology, Berlin, Germany; 6Dept. of Medicine, University of California, San Diego, La Jolla, United States

Background: Dynamic hyperinflation and large intrathoracic pressure swings in ducd exercise in COPD. Heliox breathing reduces the degree of dynamic hyperinflation thereby improving peripheral muscle oxygen delivery. Whether this effect also applies to patients who do not hyperinflate during exercise, is unknown.

Methods: 17 COPD patients (n=8 hyperinflators [FEV1=37±4% pred] and n=9 non-hyperinflators [FEV1=48±4% pred]) performed two constant-load exercise tests to the limit of tolerance in air and whilst breathing heliox.

Results: The improvement in exercise tolerance by heliox was not different between hyperinflators and non-hyperinflators (by 3.8±1.9 and 4.2±2.0 min, respectively). This is probably due to the finding that systemic oxygen delivery significantly improved in both hyperinflators (from 1.48±0.10 to 1.70±0.11 L/min) and non-hyperinflators (from 1.68±0.12 to 1.93±0.15 L/min); however, the mechanism of improvement was different as heliox improved cardiac output in both hyperinflators (from 9.3±0.5 to 10.4±0.5 l/min) whilst arterial oxygen content increased only in hyperinflators (from 160±3 to 177±4 ml/dlO2). Nonetheless, quadriiceps and intercostal muscle oxygen delivery (measured by NIRS+ICG with arterial sampling) improved significantly and by the same magnitude in both hyperinflators (by 16.6±7.4 and 4.0±1.1 mlO2/min/100g, respectively) and non-hyperinflators (by 17.6±8.2 and 4.5±1.2 mlO2/min/100g, respectively).

Conclusion: Heliox improves peripheral and respiratory muscle oxygen delivery in all COPD patients regardless of the occurrence of exercise-induced dynamic hyperinflation.

380 Effects of oxygen supplementation on cerebral oxygenation during progressive exercise in patients with COPD and healthy controls
Mayronol Oliveira1,2, Peter Wagner3,4, Luciana S. Takara1, Erika Cristine Trepott1, Thulio C. Cunha1, J. Alberto Nedert. Respiratory Div., Department of Medicine, Federal Univ. of Sao Paulo, Sao Paulo, Brazil

The rate of change (Δ) in cerebral oxygenation (CO2) during exercise is modulated by cerebral blood flow and arterial O2 content (CaO2). It is currently unclear whether ΔCO2 would (i) be impaired during exercise in patients with chronic obstructive pulmonary disease (COPD) who are not overtly hypoxaemic and (ii) improve with hyperoxia (HiO2, FIO2=0.4) in these patients. Twenty non-hypcapnic males with COPD (FEV1=47±2%±11.5% predicted) and 9 age- and gender-matched controls performed a sub-maximal incremental exercise test under HiO2 and normoxia (NOX). ΔCO2 was determined by near infrared spectroscopy (fold-changes in HbO2 and cardiac output (QT) by impedance cardiography. A significant drop in SpO2 was found in 8/20 patients (peak SpO2=86±2% vs. 96±2% for “desaturators” (DESAT) and “non-desaturators” (NONDESAT), respectively. In NOX, ΔCO2 was lower in DESAT versus NONDESAT and controls; in contrast, arterial oxygen pressure (MAP) was higher in the former group (p<0.05). Increases in SpO2 with HiO2 were particularly pronounced in DESAT (86±2 vs. 99±1%); interestingly, no significant improvement in COPD was found only in this group (0.52±0.20 vs. 2.09±0.42; p<0.01). There was no significant effect of HiO2 on QT in control and COPD groups; MAP; however, decreased in DESAT (p<0.05). ΔCO2 is impaired in COPD patients with CTPH during progressive exercise even if they are not entitled to long-term O2 therapy. O2 supplementation (FIO2=0.4) is able to correct for these abnormalities, an effect that was related to enhanced CaO2 rather than improved cerebral haemodynamics. Supported by: CNPq and FAPESP, Brazil.

381 Locomotor muscle afferents contribute to ventilatory control during exercise in heart failure patients
Thomas Olson1, Michael Joyner1, John Eisenach2, Timothy Curry2, Bruce Johnson3. 1Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States; 2Anesthesiology, Mayo Clinic, Rochester, MN, United States

Background: Reduced ventilatory efficiency is a hallmark of heart failure (HF) and is linked to disease severity and worse prognosis. Mechanisms responsible for altered ventilatory efficiency remain poorly understood but may include neurologic feedback from locomotor muscles. This study was designed to determine the impact of blocking locomotor muscle afferent feedback on ventilation (VE) during exercise in HF patients.

Methods: 5 HF patients with reduced systolic function (age=60±11 yrs, hHF/EV1=31±6 l/min, w=94±7 kg, exercise at 75% peak work) underwent an incremental exercise test on a cycle ergometer. Breath-by-breath measures included VE, breathing frequency (fb), tidal volume (VT), end-tidal carbon dioxide (PaCO2), and carbon dioxide production (VCO2). Central chemoreceptor sensitivity was also measured via CO2 rebreathe.

Results: At end exercise, there was no difference in VO2 (1.4±0.2 vs 1.4±0.2 L/min, p=0.43), whereas VE was reduced with RBN (48.0±6.5 vs 41.8±6.0 l/min, p<0.05) through a reduction in fb (27.2±5.2 vs 23.9±4.2 breaths/min, p<0.01) with no change in VE (1.8±0.2 vs 1.8±0.2 L/min, p=0.81). Additionally, the V/PaCO2 ratio was reduced with RBN (33.2±3.5 vs 28.2±2.8, p<0.05). After exercise, there was no difference between the conditions for chemoreceptor sensitivity (V/PaCO2 slope: 2.4±0.9 vs 2.4±0.9, p=0.80).

Conclusion: In HF patients, blocking afferent neural feedback from the locomotor muscles during exercise reduces VE and improves ventilatory efficiency. Funded by NIH/NCC grant KL2-RR024151.

382 Comparing cardiopulmonary responses to incremental exercise in patients with chronic thromboembolic pulmonary hypertension and idiopathic pulmonary arterial hypertension
Robertta Pulcheri Ramos, Fabricio Martins Valois, Juliana Moura, Thais Melatto, Eliana Ferreira, Jaquegina Sonne Ota Arakaki, Luiz Eduardo Nery, J. Alberto Nedert. Respiratory Div., Federal Univ. of Sao Paulo, Sao Paulo, Brazil

Patients with chronic thromboembolic pulmonary hypertension (CTPH) are more likely to develop proximal locomotor lesions than those with idiopathic pulmonary arterial hypertension (PAH). Therefore, CTPH might present with poorer right ventricle pulmonary vascular coupling, worse ventilation-perfusion matching and, lower maximal exercise capacity compared to IPAH. We comparatively evaluated 26 patients with CTPH and 14 with IPAH who underwent a symptom-limited incremental exercise test on a cycle ergometer. Haemodynamic variables (systolic volume [SV] and cardiac index [CI]) were measured by impedance cardiography. Baseline characteristics were similar in CTPH and IPAH (age=48±4 vs 52±5 yrs; p=0.5). However, CTPH patients had higher AV El/AV CO2 (75±26 vs 52±17; p<0.05), lower end-tidal CO2 pressure at the anaerobic threshold (21±4 vs 28±6 mmHg; p=0.05) and greater oxyhaemoglobin desaturation (peak SpO2, 88±7 vs 93±6%; p<0.05). In conclusion, patients with CTPH had higher sub-maximal ventilatory response to progressive exercise compared to those with IPAH. Although this difference did not impact upon peak exercise capacity, it indicates that CTPH led to more extensive pulmonary gas exchange abnormalities despite similar resting and exercise haemodynamic impairment.

383 Do respiratory mechanics abnormalities contribute to exertional dyspnoea in patients with pulmonary hypertension?
Peranatov Lavenets1, Giles Garci2,3, Fabio Nicolas-Jalwan1, Christian Strat1,2, Xavier Jais 1,3, Laurent Savale2,3, David Montani2,3, Olivier Sitbon2,3, Gérald Simonneau2,3, Marc Humbert1,2, Thomas Similowski1.

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
GIP was associated with (p < 0.05) more neutropenia, thrombocytopenia, vomiting, while more cardiovascularity, diarreha and peripheral neuropathy was observed with DP and epicaplopathy with IG.

Conclusion: In this large phase III trial, a non-platinum CT regimen (ifosfamide-gemcitabine) had similar activity to cisplatin-based CT in terms of survival, PFS and response rates with a favourable toxicity profile.

386 Gemcitabine sensitizes lung cancer cells to Fas/Fas ligand system-mediated killing
Liborja Siena, Elisabetta Pace, Maria Ferraro, Caterina Di Sano, Mario Melis, Mirella Profita, Mark Gjomarkaj. Institute of Biomedicine and Molecular Immunology (IBIM), National Research Council (CNR), Palermo, Italy

Gemcitabine (GEM) is an agent commonly used in the treatment of non small cell lung cancer (NSCLC). GEM induces apoptosis in NSCLC cells indirectly by increasing functionally active Fas expression. To further explore the mechanisms involved in the activation by GEM of apoptosis extrinsic pathway in lung cancer cells, we evaluated the ability of GEM to up-regulate the expression of Fas, in NSCLC H292 (mucocoeplar cell carcinoma) line and to increase the sensitivity of these cells to Fas-mediated killing of cytotoxic lymphocytes. Cells were cultured with and without GEM (0.05 μM for 72, 48, 72 and 96 hrs) respectively and protein were evaluated by real-time PCR, and by western blot and flow cytometry, respectively. Apoptosis of cells expressing Fasl was evaluated by flow cytometry. Cytotoxicity of LAK and malignant pleural fluid (PF) lymphocytes against H292 cells was analyzed in presence of GEM, by flow cytometry-based assay. Expression of FasL, mRNA and protein in H292 cells after incubation with GEM was increased at all time-points and this increase was higher after 72 hrs. Accordingly, the percentage of apoptotic H292 cells expressing Fasl was higher after 72 hrs. Cytotoxicity of LAK and PF lymphocytes was significantly increased after incubation of H292 cells with GEM and was partially inhibited by neutralizing anti-Fas antibody.

These data demonstrate that: 1) GEM induces an up-regulation of FasL in NSCLC cells triggering cell apoptosis via an autocrine/paracrine loop; 2) GEM is able to increase the sensitivity of NSCLC cells to cytotoxic activity of LAK and PF lymphocytes by activation of Fas-Fasl signalling system.

387 Non-small cell lung cancer treatment by inhalation of Erbitux and gemcitabine in murine model
Cathda Schwarz1, Ofer Merinisky2, Alex Sturr1. 1Pathology Dept., Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Our study tested the efficacy of chemotherapy delivered by inhalation in murine model of lung cancer.

Methods: Mouse models of human (H226) and murine (3LL) non-small cell lung cancer (NSCLC) were used. Cultivated human NSCLC cells were inoculated orthotopically into the lung (H226) or intravenously (3LL) producing advanced disseminated lung cancer. Aerosols were delivered daily from day 5 to day 30 (after tumor cell inoculation) using an ultrasonic nebulizer in a cage specifically constructed to in total dosage 30mg/kg (Erbitux) and 0.5mg/kg (Gem). The effect of nebulization on Erbitux was assessed in terms of its affinity for membrane EGFr (using ELISA), inhibition of cell growth (XTT assay) and inhibition of EGFR phosphorylation (by immunoprecipitation).

Results: Significant inhibition of tumor growth by Erbitux alone or in combination with Gem was observed. Inhalation of Erbitux in 3LL resulted in 50% reduction of lung weights and number of tumor nodules. Nebulized Gem demonstrated 80% decrease in the lung weight and tumor foci whereas combination therapy resulted in complete disappearance of tumor masses. Inhalation in H226 with Erbitux demonstrated 10% reduction of lung weight, 40% reduction with Gem and 50% with combination therapy. Inhalations were well tolerated without toxicity to lungs, kidney, colon, skin, liver or spleen.

Conclusions: We demonstrated the efficacy of the aerosol treatment by Erbitux and Gem in animal model of NSCLC without any pulmonary toxicity. The study demonstrated therapeutic perspective of aerosol delivery of Erbitux/Gem in the treatment of patients with advanced disseminated lung cancer.

388 Late-breaking abstract: Relationship of aquaporin 1, 3 and 5 expression in lung cancer cells to cellular differentiation, invasive growth and metastatic potential
Miyako Shimasaki1, Yuichiro Machida3, Yutaka Takahara2, Hirohisa Toga2.
1Pathology, Kanazawa Medical University, Kahoku-gun, Ishikawa, Japan; 2Respiratory Medicine, Kanazawa Medical University, Kohoku-gun, Ishikawa, Japan; 3Respiratory Surgery, Kanazawa Medical University, Kohoku-gun, Ishikawa, Japan

An oncogenic capacity of aquaporins (AQPs), transmembrane channels for water, was recently proposed. This study seeks to elucidate the involvement of AQPI, 3 and 5 in the development and progression of lung cancer. Expression analyses of AQPI, 3 and 5 by immunohistochemistry, western blot and real time-PCR in 160 lung cancers showed that AQPI, 3 and 5 were expressed in 71, 40 and 56%, of lung cancers, respectively. AQPI expressing frequencies were frequent in adenosquamous carcinomas (ADCs), whereas in all healthy subjects IC decreased with 0.2L/min, dyspnoea intensity (by Borg scale) were assessed throughout CPET. In 70% of PH patients (n=14), IC decreased progressively throughout CPET by 0.3L/min on average (dynamic hyperinflation), whereas in all healthy subjects IC increased by 0.2L/min. Dyspnoea intensity and minute ventilation (VE) were greater in PH patients at any stage of CPET compared with healthy controls: at standardized work rate of 60watts, dyspnoea rating and V'E were 5 Borg units and 45L/min respectively in PH patients compared with 1 Borg unit and 33L/min respectively in healthy subjects. At standardized V'E of 60L/min, PH patients presented with greater dyspnoea (by 4 Borg units) and hypoxic apnea (by 2 Borg units and 33L/min respectively in healthy subjects. At standardized V'E of 60L/min, PH patients presented with greater dyspnoea (by 4 Borg units) and hypoxic apnea (by 2 Borg units and 33L/min respectively in healthy subjects. At standardized V'E of 60L/min, PH patients presented with greater dyspnoea (by 4 Borg units) and hypoxic apnea (by 2 Borg units and 33L/min respectively in healthy subjects. At standardized V'E of 60L/min, PH patients presented with greater dyspnoea (by 4 Borg units) and hypoxic apnea (by 2 Borg units and 33L/min respectively in healthy subjects. At standardized V'E of 60L/min, PH patients presented with great...
Carboplatin-paclitaxel alone or with bevacizumab in stage III-IV lung cells to gefitinib. Thus, FoxM1 could be used as a therapeutic target of gefitinib. These data suggest that FoxM1 confers the resistance of lung cancer SPC-A-1 cells with gefitinib treatment. Moreover, the increased protein level of and 0.1 \textsuperscript{46\%}, 54\% in H292 cells with 10 \textmu M and 1

The mRNA levels of FoxM1 in SPC-A-1 cells at 24, 48 and 72 hours cell survival and apoptosis in N-FoxM1 and vehicle groups. (N-FoxM1 group) was established. MTT assay and FCM were used to detect the cell survival and apoptosis in N-FoxM1 and vehicle groups. Results: The mRNA levels of FoxM1 in SPC-A-1 cells at 24, 48 and 72 hours after recombination of gefitinib increased by 38\%, 53\%, 72\%, while reduced by 23\%, 46\%, 54\% in H292 cells with 10 \textmu M and 1 \textmu M of gefitinib. The survival rates of N-FoxM1 and vehicle groups with incubation of 1, 6, 24, 48 and 72 hours. After preoperative treatment partial response of tumor was achieved in 16\% of cases and patients underwent surgery with radical intent. There was no post PDT complication. 14 operations were R0, 2 – R1. No major postoperative complications noted except cardiac arrhythmia in 3 patients (19\%). Average period of follow-up was 16 months (4 to 30 months), all patients are alive without any signs of recurrence. Conclusion: The first experience of the combined treatment including intraoperative PDT for locally advanced NSCLC demonstrates safety and effectiveness. Additional studies are needed to proof the value of intraoperative PDT.

68. Multidrug-resistant tuberculosis

The 2011 update of the World Health Organization guidelines for the programmatic management of drug-resistant tuberculosis

Methods: WHO commissioned systematic reviews of evidence, including meta-analysis and modeling studies, to summarize evidence on priority questions regarding case finding, treatment regimens for multidrug-resistant TB (MDR-TB), monitoring of response to MDR-TB treatment and models of care. The quality of evidence assembled varied from low to very low. A multidisciplinary expert panel used the GRADE approach to develop recommendations based on best available evidence.

Findings: The recommendations encourage the wider use of rapid drug-susceptibility testing with molecular techniques to detect rifampicin resistance and treat patients adequately. The use of culture remains important for the early detection of failure during MDR-TB treatment. The guidelines provide recommendations about the early use of anti-retroviral agents for TB patients with HIV who are on second-line TB drug regimens. Systems that primarily employ ambulatory stages of care to manage MDR-TB patients are recommended over others mainly on hospitalization.
Conclusion: Practitioners and decision makers involved in MDR-TB care should be guided in their work by these updated recommendations. Additional research is necessary to improve the quality of existing evidence, particularly on regimen composition and duration of treatment.

394 Treatment outcomes for multidrug-resistant tuberculosis (MDR-TB) patients in Africa

Valeria Crudu1, Victor Botnaru1, Ecaterina Stratan 1, Olga Golisceva1, Valeriu Crudu1, Victor Botnaru1, Ecaterina Stratan 1, Olga Golisceva1, Daniela Homorodean, Iuliana Husar, Cristian Popa, Felicia Cojocaru, Elmira Braim. Reference Laboratory, Clinical Hospital of Pneumology, Cluj-Napoca, Romania Service de Pneumologie, Centre Hospitalier de Dieppe, Dieppe, France Pneumology, Pneumology Institute Marius Nasta, Bucharest, Romania

Introduction: As countries in Africa scale up their treatment of multidrug-resistant tuberculosis (MDR-TB) patients, it is important to monitor the results of treatment efforts.

Methods: In 2010, as part of its global TB surveillance activities, the World Health Organization gathered information on treatment outcome cohorts of MDR-TB patients starting treatment in 2007. The delay allowed programmes time to recover data for patients whose treatment commonly lasts two years or more.

Results: Seventeen of the 46 countries in the African region reported treatment outcomes for an aggregate of 4532 MDR-TB cases, mostly from South Africa (3815). Thirteen of these countries had notified a total of 8234 MDR-TB cases in 2007 (4 countries had no data), and outcome cohorts varied in size between 20% and >100% of cases originally notified. Outcome reports were incomplete with five national cohorts having no information on >20% of the patients treated. Treatment success ranged between countries from 14% to 100% of patients (median: 60%) and deaths from 0% to 57% (median: 14%). Defaults were more frequently reported (12 countries; median 9%) than failures (5 countries; median 0%).

Conclusions: Coverage and success in the African cohorts are comparable with other regions in the world. Reports on enrolment of MDR-TB patients on treatment and their outcomes are incomplete in many countries even when compared to other regions by the countries capacity for scaling up care and ineffective reporting. Treatment success for MDR-TB patients remains low as a result of a high risk of dying, of failed treatment or of interruption of prescribed treatment.

395 Increasing TB drug resistance in Moldova during the 2006-2010

Valeriu Crudu1, Victor Botnaru1, Ecaterina Stratan 1, Olga Golisceva1, Valeriu Crudu1, Victor Botnaru1, Ecaterina Stratan 1, Olga Golisceva1, Valeriu Crudu1, Victor Botnaru1, Ecaterina Stratan 1, Olga Golisceva1, Daniela Homorodean, Iuliana Husar, Cristian Popa, Felicia Cojocaru, Elmira Braim. Reference Laboratory, Clinical Hospital of Pneumology, Cluj-Napoca, Romania Service de Pneumologie, Centre Hospitalier de Dieppe, Dieppe, France Pneumology, Pneumology Institute Marius Nasta, Bucharest, Romania

Background: The emergence of drug-resistance (DR) hampers tuberculosis (TB) control. The level of primary DR, particularly multidrug resistance (MDR) is one of the main causes of ineffective treatment of new TB cases. The aim of the study was to estimate the trends of TB DR in Moldova during the last 5 years.

Materials and methods: Retrospectively analysis of 11,193 cards of drug sensitivity tests performed in the National TB Reference Laboratory and three Regional TB Reference Laboratories during 2006-2010. DST was performed on L-J media using absolute concentration method and on liquid media (MGIT960) in laboratories with controlled quality (concordance with reference laboratory >95%). The last two years were implement the Hain method for rapid diagnosis of MDR TB.

Results: From all examined patients, 5241 (47,2%) were new TB cases tested for 1st-line drugs was conducted on all isolates; DST for selected 2nd-line drugs was performed at the Stockholm Supranational Reference Laboratory. External quality assessment of DST was performed at the Stockholm Supranational Reference Laboratory.

Conclusion: The level of primary DR has been increasing from 42.9% to 49.5% yearly. The first XDR-TB case has been reported in 2006. The level of secondary DR also has been increased from 70.5% to 80.2% respectively. In 28% of subjects no DST was performed before the survey. The most frequent MDR-TB cases were chronics (285-37.7%), followed by relapses (191-25.5%), new cases (103-13.4%), retreatments after failure (92-12.2%) and retreatments after default (80-10.6%). In 7 cases (0.9%) the category by treatment history was unknown. Out of 388 HIV tested MDR-TB patients 10 (2.6%) were positive.

Conclusions: The XDR-TB rate among MDR-TB cases in Romania is 11.2%. In order to early detect drug-resistant cases it’s necessary to test all strains from retreated TB cases and from new cases with high risk for MDR.

396 Drug-resistant tuberculosis in Belarus: Results of the first representative survey

Alena Skrakhina1, Aksana Zalutskaya1, Sahalychtch Evgvni, Andrei Astrazko2, Wayne Van Gemert3, Sven Hoffner2, Valeraniu Rusovich2, Matze Zignol2, Henadz Hurevich1, 1MDR Tuberculosis Clinic, Hospital General de Tijuana, Tijuana, Baja California, Mexico; 2TB and Refugee Health Branch, San Diego County Health and Human Services Agency, San Diego, CA, United States; 3Director, Facultad de Medicina, Universidad Autonoma de Baja California, Mexico; 4MDR Tuberculosis Clinic, Hospital General de Tijuana, Tijuana, Baja California, Mexico

Background: Multidrug resistant tuberculosis (MDR-TB) is expensive to diagnose and treat, and requires a high degree of expertise by the laboratory and medical team, resources that may be scarce in regions with the highest rates of MDR-TB. Baja California, a Mexican state that shares the international border with California, United States (USA) has the highest rate of tuberculosis in the country.

Methods: A binational consortium constituted by USA and Mexico partners started a program dedicated to the diagnosis and treatment of MDR-TB in the region. All regions were involved in the program and diagnosis was done through the national laboratory network. All the patients who were diagnosed with drug resistant tuberculosis were treated with the national program with guidelines provided by the World Health Organization (WHO). The program was supported with funding from the United States Agency for International Development (USAID) and the program was supported by the Drug Repatriation Program (DRP). A binational laboratory network was created to support the program. The network included the Regional Reference Laboratory, the National Reference Laboratory, and the State Reference Laboratory in Baja California.

Results: From June 2006 through December 2010 forty patients started treatment. The lapse between their initial diagnosis and the referral to the program was 43.6 months; they had received 2.15 treatment regimens in the past. Their strains were resistant to 4.15 drugs: 2 patients (5.1%) had an XDR-TB strain. All patients converted their culture on treatment, on average after 4.0 months.
Nineteen patients (47.5%) have been discharged as cured (mean follow-up after discharge 6.8 months), 3 patients died (7.5%) and one patient abandoned (2.5%).

Conclusion: Highly resistant cases can be cured under a well-organized, outpatient program. In this consortium the USA partner introduced program elements that have been gradually integrated into the state TB program. After 5 years, the consortium continues to fine-tune sustainable interventions and provides quality control.

Diseases, Menderes Universitesi Tip, Aydin, Turkey; 16Dept. of Pneumology, University of Bucharest, Bucharest, Romania, 17British Thoracic Society, British Thoracic Society, London, United Kingdom

Setting: The burden of tuberculosis disease amongst household contacts of multidrug-resistant tuberculosis patients is poorly understood and might represent a target for transmission-interrupting interventions.

Design: This retrospective cohort study conducted in Lima from June to September 2008, estimated the incidence of tuberculous disease among household contacts of multidrug-resistant tuberculosis patients in 358 households.

Results: 108 (5%) of 2121 household contacts in 80 households (22% of households) developed tuberculous disease during the study, equating to an incidence rate of 2360 per 100,000 contact follow-up years for each of the first 3 years after exposure. Drug susceptibility tests were available on 50 diseased contacts of whom 36 (72%) had multidrug-resistant tuberculosis. Forty-two pairs of index-contact drug susceptibility tests were available amongst which the contact had an identical or less resistant phenotype than the index case in 27 pairs. Multivariate clustered Cox regression demonstrated that contacts with a previous history of tuberculosis disease (Hazard Ratio 15.0, P<0.001) and with associated (non-HIV) comorbidities (Hazard Ratio 7.8, P<0.001) were significantly more likely to develop tuberculosis.

Conclusion: The high percentage of diseased household contacts highlights an opportunity for household level interventions to prevent transmission, whether or not these subsequent cases were all attributable to the index case.

Late-breaking abstract: Factors associated with medication adherence in patients with COPD
Ilkay Koca Kalinkad, A Fusun Kalkapikolu | Department of Pulmonary Medicine, Kirikkale University Faculty of Medicine, Kirikkale, Turkey

Background: Only about 50% of patients with COPD, 4th leading cause of death, adhere to prescribed regimen. Non-adherence is one of the most important obstacles in achieving optimized clinical-outcome. The purpose of this study is to identify the clinical predictors of medication adherence.

Method: 51 patients with prescribed regular medication due to COPD, were included in the study. Sociodemographic (age, sex, educational level, BMI, comorbidity, number of additional drugs), COPD-related (smoking habits, duration of disease, MRC-dyspnea-score, treatment, exacerbations) and spirometry variables were recorded. Personality traits (Eysenck Personality Questionnaire), self report of medication adherence (MARS) and health related quality of life (SF-36) were evaluated.

Results: The mean-age was 63±9.2 years, 48 (94%) were male, 68.6% had low educational level (<8 years), mean FEV1 was 40.4±20.9%, 58% had MRC-score of <3, exacerbations-per-year was 2.2±1.9. 22 of the patients had comorbidity diseases with mean number of 3.7±2.4 additional drugs and weren't correlated with MARS. Mean MARS was 20.6±4.1 and 33.3% were nonadherent. MARS was correlated neither with personality traits nor SF-36. MARS was significantly higher in patients who reported themselves as regular-medication-user and benefited from therapy (p=0.001, p=0.03 respectively). Patients taking nebulizer treatment found to have significantly lower MARS than patients taking LABA (p=0.001), which was found to be intentional.

Conclusions: We found that, neither the sociodemographic variables, personality traits nor the disease severity, but the routinization of recommended treatment and faith in the treatment are critical for optimal medication adherence in patients with COPD

Diagnosis and predictors of COPD exacerbation

949
Admission cTnI was “undetectable” (U, 0.02-0.05 μg/L) in 59%, “measurable” (M, 0.02-0.05 μg/L) in 35% and “elevated” (E, >0.05 μg/L) in 26% of patients. The table shows mortality at various timepoints. The classic triad of symptoms was reported in 40.2% of the pts. BGA on admission was measured in 74% and chest-x-ray was performed in 86.6% of the pts.

Conclusion: These results help us characterise unselected COPD exacerbations as seen in clinical practice. Whilst most are admitted with dyspnea, only a minority shows the classical triad of symptoms. The high number of current smokers and the low availability of spirometry suggest to improve implementation of evidence based interventions. The severe stage of COPD in the majority of hospital admissions would justify BGA and x-ray in all patients.

Any detectable admission cardiac troponin I level is associated with increased risk of early death following COPD exacerbations
Padman R. Vamadevan, Andrew W. Hitchings, Tejwant S. Grewal, Dana Ahnood, Emma H. Baker. Clinical Pharmacology Unit, Division of Biomedical Sciences, St George’s, University of London, London, United Kingdom

Background: Elevated cardiac troponin I (cTnI) levels during COPD exacerbations predict long-term mortality (COPD 2009:6:155-61). The times at which these deaths occur is unknown. We used a time-to-event approach to further characterise the prognostic significance of this biomarker.

Method: 237 COPD patients (127 male, 73±11yrs) admitted with exacerbations between July 2008-9, and with a measured cTnI within 24h of admission were retrospectively identified. Clinical information was retrieved from the electronic patient record.

Results: Admission cTnI was “undetectable” (U, <0.02 μg/L) in 15%, “measurable” (M, 0.02-0.05 μg/L) in 35% and “elevated” (E, >0.05 μg/L) in 26% of patients. The table shows mortality at various timepoints. Figure 1 illustrates survival post-admission by initial cTnI level.

Figure 1. Mean values from 13 European countries.

The classical triad of symptoms was reported in 40.2% of the pts. BGA on admission was measured in 74% and chest-x-ray was performed in 86.6% of the pts.

*Non-cumulative.

Figure 1

On Cox regression, cTnI level predicted survival (p<0.003) independently of inflammatory markers, haemoglobin, creatinine or cancer.

Conclusions: Any detectable cTnI is independently associated with increased post-exacerbation mortality, with increasing risk at higher concentrations. Excess deaths in patients with detectable cTnI occur in the first 30 days post-admission. Elucidating underlying mechanisms of cTnI rise may identify new opportunities to improve outcomes following COPD exacerbations.

402 Value of prothrombin fragments F1+2 in the diagnosis of pulmonary embolism in patients hospitalized due to COPD exacerbation

Marcela Beckerman, Palhel Weinler Internal Medicine A, Hillel Yaffe MC, Hadera, Israel Internal Medicine A, Hillel Yaffe MC, Hadera, Israel

Background: One of four COPD patients who require hospitalization for an acute exacerbation may have pulmonary embolism. Normal D-dimer is now considered to be safe enough for ruling out thromboembolism in patients with a low pre-test probability. However, 9% of patients with AECOPD with low clinical provability may still have PE, and D-dimer is normal only in minority of patients with AECOPD. The combination of D-Dimer testing with another markers of thrombosis may improve the diagnostic efficiency.

Aim: To assess the usefulness of F1+2 in the diagnosis of PE in hospitalized patients with exacerbation of COPD, and whether assay of F1+2 may have an additional value in the subgroup of patients with an abnormal D-dimer. To determine the sensitivity, specificity, NPV of F1+2 at various cut-off values.

Methods: Blood samples for F1+2 and D-dimer were obtained and CT pulmonary angiography was performed in 49 patients hospitalized due to AECOPD.

Results: Prevalence of PE was 18.37%. Patients with proved pulmonary embolism had higher values of F1+2 380 pmol/l (95% CI 235.5 - 523.7) than in patients with high D-dimer level in whom PE was not confirmed: 204 pmol/l (95% CI 140.2 - 278.6, p< 0.0042). At cutoff levels for F1+2 180 pmol/l, or lower the sensitivity was 100%, and negative predicted value -1.0. Taking a normal F1+2 level (cut-off 180) into account in the subgroup of patients with an abnormal D-dimer added significant clinical significance:11 of 29 patients (37.9%) could be withheld from further imaging testing.

Conclusions: Prothrombin fragment F1+2 assay may increase the proportion of patients in whom pulmonary embolism can be safely ruled out.

403 Association of the severe, frequent exacerbation phenotype with exercise capacity, sputum bacteriology and copeptin circulating levels in COPD

Background: The randomized, double-blind, double-dummy, 1-year POET-COPD™ trial compared with infrequent exacerbators in the POET-COPD™ trial.

Respiratory Research Institute, Wiesbaden, Germany

Results: Baseline characteristics of the 7376 patients who were randomized and treated are shown in the table.

Elucidating underlying mechanisms of cTnI rise may identify new opportunities to improve outcomes following COPD exacerbations.

404 Predictors of hospitalisation and death with acute exacerbations of COPD

Amir Soltani1,2, Steve Reid3, Steve Quinn1, Ian Almond1, Richard Wood-Baker1, E. Haydn Walters1,4, Respiratory Research Group, Menzies Research Institute, University of Tasmania, Hobart, Tasmania, Australia; 4Respiratory Medicine, Southmead Hospital, North Bristol NHS Trust, Bristol, United Kingdom

Background: Acute exacerbations of COPD (AECOPD) are common causes of attendance to hospital emergency department (ED), but there are limited data on decision making about hospitalisation.

Aims: To analyse decision making for hospitalisation and predictors of death in patients attended with AECOPD in a public hospital in Australia.

Methods: All patients with a diagnosis of AECOPD attending the ED of the Royal Hobart Hospital between November 2006 and July 2008 (21 months) were reviewed. Patients who were admitted to the hospital were compared with those who were discharged home. Survival analysis was performed using Kaplan-Meier survival analysis.

Results: 150 patients with 218 admissions (50% female, 42% current- and 58% ex-smokers, 24% with history of heart disease and 5% with previous history of myocardial infarction) were included in the study. Those discharged from ED had a lower heart rate/minute than those admitted [mean (SD) 96 (17) vs 105 (19), p<0.01] but there were no other differences. Age (HR=1.07, p<0.001), being female (HR=0.3, p=0.049) (female 80 and males1), having a past history of myocardial infarction (HR=5.36, p<0.001), hypercapnia (HR=1.04, p<0.003) and co-presence of heart disease (HR=5.7, p=0.03) were independently significant predictors of death during the period of the study.

Conclusions: Decision making for hospitalisation of patients in the ED seems largely arbitrary. Cardiac disease was the strongest predictor of death.

405 Baseline characteristics of patients with frequent exacerbations in the POET-COPD™ trial

Leonardo M. Fabbri1,2,3, Claus Vogelmeier1,2,3, Maureen P.M.H. Rutten-van Mölken4, Klaus F. Rabe5,6, Thomas Glaab5,7, Fee Rühmkorf5,8, Hendrik Schmidt5,9, Kai M. Beeh1,7,10, Department of Medical & Surgical Specialties, University of Modena & Reggio Emilia, Modena, Italy; 2Division of Pulmonary Diseases, Hospital of the Universities of Giessen and Marburg, Marburg, Germany; 3Department of Health Economics, Institute for Medical Technology Assessment (IMTA), Erasmus University, Rotterdam, Netherlands; 4Dept. of Pneumology, Grosshadern Hospital, Grosshadern, Germany; 5Medical Affairs, Boehringer Ingelheim GmbH, Ingleheim, Germany; 6Dept. of Internal and Pulmonary Medicine, Insuf Respiratory Research Institute, Wiesbaden, Germany

Background: The randomized, double-blind, double-dummy, 1-year POET-COPD™ trial showed that tiotropium (18 µg qd) was superior to salmeterol (50 µg bid) in preventing moderate or severe chronic obstructive pulmonary disease (COPD) exacerbations.

Aims and objectives: An exploratory post-hoc subgroup analysis to compare baseline characteristics of frequent and infrequent exacerbators (patients experiencing ≥2 and ≤1 exacerbations during the trial, respectively).

Methods: Important inclusion criteria were age ≥40 years, postbronchodilator forced expiratory volume in 1 s (FEV1) ≥70% predicted and ≥1 exacerbation in previous year.

Results: Baseline characteristics of the 7376 patients who were randomized and treated are shown in the table.

Conclusions: Compared with infrequent exacerbators, frequent exacerbators in POET-COPD™ were characterized at baseline by: more severe COPD; longer exacerbation in COPD, leading to the definition of a frequent exacerbation phenotype. We have assessed variables associated with a history of frequent, severe exacerbation according to the ERS definition in a well characterized cohort of COPD patients.

Methods: Data of 598 patients with stable COPD (GOLD II-IV) for 6 weeks, and seeking care in pulmonary tertiary hospitals in 10 European centers were analyzed. Assessment included history, systemic biomarkers (procalcitonin, proANP, copeptin, proadrenomedullin), lung function, SF-36, SGRQ, MMRC dyspnea score, and 6MWD test.

Results: Patients had a mean age of 66 years ± 12.448 were male. Mean FEV1% pred was 48.2% ± 18.5. A total of 387 patients (64.7%) reported no severe exacerbation, 170 (28.4%) reported one severe exacerbation, and 41 (6.9%) patients reported two or more severe exacerbations requiring hospitalization in previous year. ICU care was required in 45 (7.6%) of the cases. In the multivariate analysis, OR [95% CI] age 1.218 [1.043-1.422, p=0.013], positive sputum bacteriology at the stable state 8.88 [1.57-50.19, p=0.014], FEV1% pred 0.946 [0.902-0.992, p=0.021], MMRC 3.240 [1.021-10.281, p=0.040], 6MWD 1.014 [1.002-1.026, p=0.026], Borg 1.607 [1.010-5.588, p=0.045], and copeptin 0.305 [0.140-0.664, p=0.003] were independently associated with the severe, recurrent exacerbations phenotype.

Conclusions: Age, sputum bacteriology, lung function, dyspnea, exercise capacity and copeptin circulating levels are independently associated with the severe, frequent exacerbation phenotype.
## 406 BNP is a predictor of mortality following COPD exacerbations
Martin Knolle, David Meek, Linda Pearce, Sarah Tarrant, Clare Laroche, Thomas Pulimood. Martin Knolle, David Meek, Linda Pearce, Sarah Tarrant, Clare Laroche, Thomas Pulimood. Dept. of Respiratory Medicine, West Suffolk Hospital NHS Trust, University of Cambridge Teaching Hospital, Bury St. Edmunds, United Kingdom

**Introduction:** There is a scarcity of biomarkers to predict mortality following exacerbations of chronic obstructive pulmonary disease (COPD). Pro-BNP Natriuretic Peptide (pBNP) is a measure of cardiac function, elevated pBNP levels indicate cardiac failure. We measured pBNP levels in addition to standard assessments in patients referred to our COPD admission avoidance (AA) service.

**Methods:** 33 patients (current or ex-smokers) referred for AA over a one year period had their pBNP levels checked. 6 were excluded from analysis (3 troponin positive, 1 too well, 1 refused hospital admission, 1 admitted for cardiac failure). In addition to pBNP levels, most patients had several other assessments of their lung function performed. Of the 27 patients, 4 died over the following 12 months.

**Results:** Patient mortality was associated with higher levels of pBNP (8564 ± 4959 pg/mL non-survivors vs 1162 ± 553 pg/mL survivors, p = 0.004). There were no significant differences in spirometry, MRC scores or oxygen saturations. Only 2 patients in the mortality group had a previous diagnosis of heart failure, while 7 in the non-mortality group did. Only 2 patients in the mortality group were treated for congestive cardiac failure with diuretics. None were on ACE-inhibitors or other heart failure treatment.

**Discussion:** Despite the limitations of our study (small sample size, single center, relatively homogeneous population) pBNP may prove to be a powerful predictor for mortality following an exacerbation of COPD. In addition, our findings raise the question whether any element of underlying heart failure should be treated more aggressively in patients with COPD.

## 407 Pharmacological treatment with tetrahydrobiopterin in pulmonary hypertension
Bahaa Francis, Martin Wilkins, Lan Zhao. Centre of Pharmacology and Therapeutics, Imperial College London, London, United Kingdom

**Introduction:** Tetrahydrobiopterin (BH4), by “recouping” endothelial nitric oxide synthase (eNOS), increases NO bioavailability and decreases superoxide production. It is critical in maintaining pulmonary vascular homeostasis and may offer a treatment for pulmonary hypertension (PH).

**Methods:** BH4 administration was studied in both monocrotaline and hypoxia models of PH.

**Results:** In vivo BH4 administration (1mg bolus) caused minimal change in pulmonary artery pressure (PAP) in control rats (from 22.9 to 20 mmHg), but a significant acute reduction in the monocrotaline model (from 36 to 18 mmHg).

In a Langendorff heart preparation, BH4 increased right ventricular systolic pressure (RVSP) in the hypertrophied right ventricle (RVH) compared to control (ΔRVSP=5.7±1.3 mmHg vs 0.7±1.1 mmHg respectively, p<0.05) as well as contractility (Δdp/dtmax=640±247 vs 261±173 mmHg/sec, p<0.05).

**Discussion:** BH4 is a potential therapy which addresses the vasoconstrictive, hyperproliferative and hypertrophic nature of PH and warrants further investigation.

## 408 A role for ST2/IL-33 signalling in fibroblast proliferation utilising a novel transgenic mouse model of pulmonary hypertension
Colin Church1, Ammad Mahmood1, Charlie McSharry2, Damo Xu2, Andrew Peacock1, David Welsh2, Scottish Pulmonary Vascular Unit, Western Infirmary, Glasgow, United Kingdom; 2Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom

In this study, we determined if the ST2 receptor and its ligand, interleukin-33 (IL-33) was involved in mouse PAF proliferation and if ST2-/- mice displayed a pulmonary hypertensive phenotype (RHV).

Wild type (WT) and ST2 knockout mice (ST2-/-) were used. The effect of IL-33 on proliferation of WT cells was determined by incubation in hypoxia (35mmHg), p38 MAPK, which is involved in fibroblast proliferation, was detected by Western blotting. Right ventricular hypertrophy (RVH) was assessed by measuring the right ventricular wall (RV) and left ventricle with the septum (LV-S). ST2-/- cells proliferated to a greater level compared to WT cells (p<0.01). Proliferation of ST2-/- cells could be reduced by p38 MAPK inhibition (Fig. 1).

p38 MAPK was detected in ST2-/- cells but not in WT cells. Proliferation to hypoxia in WT cells could be blocked by IL-33. The ST2-/- mice displayed right ventricular hypertrophy (Fig. 2, p<0.005).

## 409 Safety and efficacy of bosentan in combination with sildenafil in pulmonary arterial hypertension: The COMPASS-3 study
Fernando Torres1, Hemanthu Gupta1, Francisco Soto1, Myung Park1, Noam Frey5, Srinivas Murali6, Raymond Benza6, Andrew Peacock1, David Welsh2, 1Internal Medicine - Pulmonary and Critical Care Medicine, University of Texas Southwestern Medical Center, Dallas, TX, 2Medicine - Cardiovascular Disease, University of Alabama at Birmingham, Birmingham, Al, 3Pulmonary, Critical Care and Sleep Medicine, Prevea Health/St. Nicholas Hospital, Sheboygan, WI, 4Medicine - Pulmonary and Critical Care Medicine, Prevea Health/St. Nicholas Hospital, Sheboygan, WI, 5Internal Medicine - Pulmonary and Critical Care Medicine, University of Texas Southwestern Medical Center, Dallas, TX, 6Pulmonary, Critical Care and Sleep Medicine, Prevea Health/St. Nicholas Hospital, Sheboygan, WI

In hypoxia, BH4 (100 mg/kg) reduced RVSP over 7 days (radioelectricity, from 63±1 to 44.5±1 mmHg). At two weeks, BH4 (100 mg/kg) partially reversed RVH compared to placebo and BH4 (10 mg/kg) (0.50±0.02, 0.58±0.03 and 0.57±0.1 respectively, p<0.05). Two weeks of hypoxia induced distal pulmonary vascular muscularization (from 15.6±2% to 79.2±7%, p<0.01). BH4 (100 mg/kg) induced partial reversal in vascular muscularization compared to placebo and BH4 (10 mg/kg) (65.2±6%, 81.4±9% and 74.3±10% respectively, p<0.01). BH4 (100 mg/kg) increased eNOS enzymatic activity in lung homogenates (but not protein levels). BH4 moderately increased cGMP (p>0.05) and significantly reduced superoxide.

Conclusions: BH4 is a potential therapy which addresses the vasoconstrictive, hyperproliferative and hypertrophic nature of PH and warrants further investigation.

## 410 70. Treatments for pulmonary hypertension in human and experimental models

### 407 Pharmacological treatment with tetrahydrobiopterin in pulmonary hypertension

Excessive proliferation of fibroblasts from ST2-/- mice involves p38 MAPK. Proliferation by hypoxia in WT cells can be blocked by IL-33. ST2-/- mice display a pulmonary hypertensive phenotype.
Effects of dasatinib and nilotinib on pulmonary vascular remodeling

Background: Tyrosine kinase inhibitors (TKIs) are used in the treatment of chronic myeloid leukemia (CML) and chronic lymphocytic leukemia (CLL). However, recent studies have shown that these compounds also modulate pathways involved in vascular remodeling.

Methods: To explore the effects of dasatinib and nilotinib on pulmonary vascular remodeling, we performed in vitro experiments using human pulmonary artery smooth muscle cells (HPASMCs). We examined the effects of these TKIs on PDGF-induced proliferation, cell cycle gene regulation, migration, and fibrosis.

Results: Dasatinib and nilotinib inhibited PDGF-induced proliferation and migration in HPASMCs. Treatment with dasatinib also reduced PDGF-induced fibrosis.

Conclusions: Dasatinib and nilotinib may have potential therapeutic effects in the treatment of pulmonary hypertension by inhibiting vascular remodeling.

Inhibition of microRNA-17 improves lung and heart function in experimental pulmonary hypertension

Introduction: Pulmonary arterial hypertension (PAH) is a progressive pulmonary vascular disorder with high morbidity and mortality. Current treatment options are limited, and patients with PAH have a poor prognosis.

Methods: To investigate the effects of microRNA-17 (miR-17) on PAH, we used an experimental PAH model in rats. Rats were treated with a combination of PDGF and hypoxia, and the effects of miR-17 were evaluated.

Results: Inhibition of miR-17 improved lung and heart function in experimental PAH. miR-17 inhibition caused a complete reversal of pulmonary vascular remodeling and achieved efficacy similar to Imatinib (100mg/kg/day) in monocrotaline-induced PAH rats.

Conclusions: The results suggest that targeting miR-17 may be a promising strategy for the treatment of PAH.
beneficial effects in some patients in a proof-of-concept study. The phase III, multinational, multicenter, double-blind, parallel-group IMPRES study evaluated the efficacy and safety and tolerability of imatinib to confirm these preliminary findings. Patients enrolled in IMPRES had severe stable PAH on at least two PAH-specific therapies and PVR >800 dynes sec cm⁻⁵ and were randomized to imatinib or placebo. Treatment was initiated at a dose of 200 mg once daily, which was increased to 400 mg once daily after 2 weeks if well tolerated. Doses could then be reduced to 200 mg once daily if treatment was not well tolerated. The primary objective was to evaluate the efficacy of imatinib versus placebo for the change in six-minute walk distance (6MWD), a primary endpoint in the baseline treatment arms to week 24. Secondary objectives included evaluation of time to clinical worsening (all cause mortality, hospitalization for worsening PAH, worsening of World Health Organization [WHO] functional class or a 15% drop in 6MWD), safety and tolerability (including adverse events, laboratory data and vital signs), changes in pulmonary hemodynamics, changes in Borg dyspnea scores and pharmacokinetics. The study has enrolled a total of 202 patients. Findings from the IMPRES study will be available during 2011 and will be presented.

71. Recent developments in COPD

P414 LSC 2011 Abstract: The role of lipoxin A4 in the chronic obstructive pulmonary disease
Liga Rasitsa, Gunta Strazda, Normunds Jurka, Ulidis Kopeika, Agnese Kislina, Marina Beinare, Maris Bukovskis, Immanuels Taivans. Faculty of Medicine, University of Latvia, Riga, LV Institute of Experimental and Clinical Medicine, University of Latvia, Riga, LV

The aim: Chronic obstructive pulmonary disease (COPD) is characterized by persistent inflammatory reaction with a dominance of neutrophil involvement. It is established, that during a healing of inflammatory reaction, a switching of arachidonic acid (AA) metabolism from leukotriene (Lt) to lipoxin (LX) production occurs. Therefore we hypothesized that in COPD patients the lipoxin production could be insufficient. Here we compared the content of LXA4 and LtB4 in induced sputum supernatant (IS) in COPD patients and healthy subjects.

Materials and methods: 17 COPD patients and 7 healthy persons were studied. The age and gender ratios were similar in both groups. Sputum induction was performed according to the ERS protocol. LXA4 and LtB4 content in sputum supernatant was assessed by ELISA.

Results: COPD patients had decreased concentration of LXA4 in induced sputum compared to healthy persons (0.514 ng/ml and 3.130 ng/ml, respectively, p=0.0078). LtB4 content in induced sputum did not significantly differ between COPD group and healthy persons (3.551 ng/ml and 3.754 ng/ml, respectively). The ratio LtB4/LXA4 in COPD patients was three times higher compared to healthy persons (i.e. 9.816 ng/ml and 3.425 ng/ml, p=0.00982).

Conclusions: We concluded that the chronic obstructive lung disease is characterized by suppressed production of lipoxins. This insufficiency may be responsible for a persistence of neutrophilic inflammation in airways.

P415 LSC 2011 Abstract: Inflammation and COPD: Protective effect of the recombinant anti-protease trappin-2 A62L, on lung epithelium
Annabelle Tanga, Alhame Saidi, Sandrine Dallet-Chossy, Marie-Jasmine Thierry Moreau. Inserm U618 Protéases et Vectorisation Pulmonaires, Université François Rabelais, Tours, FR

Introduction: Inflammation in chronic obstructive pulmonary diseases (COPD) results in a protease/anti-protease imbalance that leads to a massive release of neutrophil serine proteases (elastase, proteinase 3 and cathepsin G). These proteases stimulate secretion of mucus and pro-inflammatory cytokines. In order to target serine proteases, we designed a recombinant inhibitor derived from trappin-2 which is able to inhibit all three proteases at the same time. The aim of the study was to evaluate the inhibitory, anti-inflammatory and anti-secretory effects of trappin-2 A62L (T2A62L) on lung epithelium exposed to neutrophilic serine proteases.

Methods: A549 cells were exposed to proteases for 24h with or without addition of T2A62L. Protective effect of T2A62L towards the degradation of cell junctions by proteases was analyzed by immunofluorescence. Levels of mucous secretion were determined by measuring the rate of expression of mucin genes and the anti-inflammatory activity of T2A62L was investigated by measuring the rate of pro-inflammatory mediators release after LPS stimulation.

Results: Neutrophil serine proteases proteolytically degrade cellular junctions and increase mucin gene expression. T2A62L added to the culture medium inhibits the degradation of cell junctions proteins (E-cadherin, ZO-1), decreases MUC5AC and MUC5B mRNA expression induced by elastase and IL-6 and IL-8 productions.

Conclusion: Our results demonstrate that T2A62L inhibits anti-proteolytic, anti-inflammatory and anti-secretory effects. This new, anti-protease may therefore be of therapeutic value in treating inflammatory lung diseases such as COPD.

P416 Plant proteinase inhibitor from enterolobium contortisiliquum (EcTTI) attenuates elastase-induced inflammatory and remodeling alterations in mice
Omar A. Theodorou Jr.1, Rafael Almeida-Reis1, Leandro V. Oliva1, Bruno T. Martins-Oliveira1, Daniel S.S. Mello1, Fernanda D.T.Q.S. Lopes1, Carla M. Prado1, Milton M. Martins1, Maria L.V. Oliva2, Iolanda F.L.C. Tibério1. 1Clinical Medicine, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil; 2Biochemistry, Federal University of Sao Paulo, Sao Paulo, Brazil; 3Biological Sciences, Federal University of Sao Paulo, Diadema, Brazil

Aims: To evaluate if a plant Kunitz proteinase inhibitor EcTTI contributes to in-activation of elastase-induced mechanical, inflammatory and extracellular matrix remodelling alterations.

Methods: C57Bl/6 mice received elastase (50ml/rat/mouse - IN- group) Control group received saline (Ve group). Mice were treated with EcTTI (2mg/kg) at days 1, 7, 14, 21, 28 and 35 after elastase instillation (I-E group). At day 40, mice were anesthetized, mechanically ventilated and we analyzed respiratory system resistance and elasticity, tissue elastance, damping and airway resistance. Afterwards, BAL was performed and lungs were removed. By morphometry, we quantified the mean linear intercept (Lm), collagen and elastic fibers in distal lung.

Results: There were no differences in pulmonary mechanics comparing all groups. In E-group, there was an increase in BAL-total cells, BAL-lymphocytes, BAL-neutrophils, collagen, elastic fibers and LM compared to control (p<0.05). In I-E group, EcTTI attenuated the increase in BAL-total cells (65.2±3.3×10³ cells/mL) and BAL-neutrophils (3.2±1.7×10³ cells/mL) compared to E-group (respectively: 110.7±9.7×10³ cells/mL and 80.1±4.1×10³ cells/mL, p<0.05). There was a decrease in the collagen content in I-E group (43.2±4.3%) compared to E-group (54.2±5.5, p<0.05).

Conclusions: This proteinase inhibitor (EcTTI) reduced elastase-induced pulmonary inflammatory and extracellular matrix remodeling alterations induced by elastase. Although more studies need to be performed, this inhibitor may contribute as potential therapeutic tool for COPD management.

P417 Impaired respiratory function in mice exposed to cigarette smoke
Sofia Jonassen1, Bo Koch1, Linda Ellsfors1, Christine Akfir1, Anders Back1,2, 1Swedish Defense Research Agency, FOI, Division of CBRR Security and Defense, Umeå, Sweden; 2Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Introduction: We have aimed to develop a mouse model of cigarette smoke (CS)-induced small airway disease and emphysema. This model will be used for studies of pathogenic responses in the development of emphysema and for preclinical evaluation of new drug candidates.

Methods: BALB/c mice were exposed to CS (nose-only), 5 days a week during 10 weeks (Gr.1: 6 cigarettes during 10 min, twice a day; Gr. 2: 12 cigarettes once a day during 20 min; Gr. 3: 12 cigarettes during 20 min, twice a day; Gr 4: control, room air). The experiment ended on day 71-73 and day 85-87 (two additional recovery weeks without CS smoke) with thoroughly investigated lung mechanics (FlexiVent), inflammatory cell counts in bronchoalveolar lavage (BAL) and lung histology.

Results: CS induced an increased respiratory resistance (p<0.05), tissue resis- tance (p<0.05), tissue elastance (p<0.05), and decreased compliance (p<0.05), in all CS groups compared to control groups. However, there were no differences in lung mechanics and total cell counts in BAL within the CS-groups. After the recovery weeks, the CS-induced effects in the lung were sustained in all groups except for Gr 2. Lung histology showed no obvious alveolar damage in peripheral airways.

Conclusion: In our mouse model there is a marked effect on lung mechanics, suggesting that CS induce small airway inflammation which is not dose dependent. Our result indicates that it is the exposure time, rather than the number of cigarettes, that determines the detrimental effects in the mouse lung. Additionally, this model can be used for combined exposure of allergens and air-borne particulate pollution in order to investigate aggravating effects of inhaled particles on emphysema and COPD.

P418 Different effects of mesenchymal stem cells on elastase-induced pulmonary emphysema and macrophages activity in rats
Alexander Averyanov1, Anatoly Konoplennikova2, Andrey Chernyayev2, Vasili Petrov2, Oleg Kuzovlev2, Andrey Bruchovetsky2,1

1Institute of Experimental and Clinical Medicine, University of Latvia, Riga, LV 2Cell Therapy Department, Medical Radiological Scientific Center, Obninsk, Russian Federation; 3Morphology Departament, Pulmonology Research Institute, Obninsk, Russian Federation;

The aim of the study was to assess lung tissue changes and macrophages activity (MA) after mesenchymal stem cells (MSCs) transplantation in elastase model of pulmonary emphysema in rats.
Methods: Forty 3-months old Wistar rats were randomized into 4 groups. Control group (group 1) was injected intratracheally 0.4 ml of normal saline, other animals (groups 2-4) received one intratracheal injection of 20 μl (units) porcine pancreatic elastase in 0.4 ml of saline. Next day (group 2) and 7 day (group 4) rats were intravenously injected 200000 autologous MScs in 0.5 ml of saline. Group 4 was used as emphysema control. Before killing on 21-st day rats were undergone pleural lavage with analysis of hemi-luminescent macrophages activity in the obtained fluid.

Results: The lungs of groups 2-4 had various degrees of centriacinar emphysema. There were no significant differences between the sizes of dilated respiratory bronchioles in groups 2 & 4. Only in the 2nd group we observed the lymphoid infiltration around arterioles. The width of respiratory bronchioles in group 3 was on 41% less than in the 4-th. The Index of hemi-luminescent MAA has made 28.8±1.1 U (1 group), 35.8±1.6 U (2 group), 31.9±4.1 U (3 group), 57.3±3.1 U (4 group).

Conclusions: MScs have various effects on damaged lung tissue at different periods of transplantation. MScs can enhance the local vascular inflammatory response in the early period of lung injury. More later injection of MScs can repair the structure of acini in acute model of emphysema in rats.

P419

IL-10 resolves the neutrophilic inflammation in mice exposed to cigarette smoke

Manabu Higaki1, Hiroo Wada1, Tetsuo Yasutake1, Shinichiro Mikura 1

Introduction: IL-10 plays a suppressive role in the inflammation. In order to elucidate the role of IL-10 in the inflammation caused by cigarette smoke, mice exposed to cigarette smoke were investigated.

Materials & methods: Mice (C57BL/6) were exposed either to cigarette smoke or to environmental air for 5, 8 or 12 days. To characterize the inflammation, cellularity in bronchoalveolar lavage (BAL) fluid was investigated. The levels of inflammation-associated cytokines, such as IL-10, KC, MIP-2, TNF-α and GM-CSF were further determined by measuring both mRNA levels in the lungs and the protein levels in BAL fluid. Then, a group of mice was intranasally treated either with recombinant murine IL-10 or with vehicle and exposed to cigarette smoke, before the same analysis was performed.

Results: Cigarette smoke exposure provoked pulmonary inflammation in mice as neutrophil and macrophage counts in BAL fluid were increased (p<0.01). In parallel, the levels of various proinflammatory cytokines including KC and MIP-2 significantly increased (p<0.01), as did the IL-10 expression. The SVL in the neutrophil counts in BAL fluid caused by smoke exposure was significantly attenuated by the intranasal administration of IL-10 (p<0.05), while that in macrophage counts was not altered.

Conclusion: Our results suggested that IL-10 potentiates the suppression of the neutrophil-associated inflammatory reactions caused by cigarette smoke exposure.

P420

Activation of the inflammasome pathway during exacerbations of COPD

Patricia Sobrallodi1, Rosa Faneir2, Nestor Soler3, Eugeni Ballester4, Juan Ignacio Aróstegui5, Jordi Yagüe6, Juan Manel7, Alvar Aguist8, 4 CIBERES, Ciberes, Barcelona, Spain; 5Fundación Cátedra Ciber, Fundación Cátedra Ciber; Barcelona, Spain; 6Immunology, Hospital Clinic, Barcelona, Spain; 7Thorax Institute, Hospital Clinic, Barcelona, Spain

Introduction: Exacerbations of COPD (ECOPD) are characterized by a burst of inflammation. The inflammasome is an intracellular sensing mechanism that leads to activation of caspase-1 and processing of pro-IL-1β and pro-IL-18 into their mature forms.

Aim: To investigate if the inflammasome pathway is activated in ECOPD patients.

Methods: We studied 10 COPD patients hospitalized because of ECOPD, 7 of whom were revaluated 3 months after discharge (sECOPD), 13 patients with clinically stable COPD (SCOPD), 8 smokers with normal lung function (S) and 11 non smokers (NS). We determined: (1) in serum: caspase-1, IL-1β, IL-18, IL-1Ra, IL-6, IL-8 and TNF-α; (2) in circulating monocytes and lymphocytes: intracellular activity of caspase-1 (basally and after stimulation with inflammasome ligands: ATP, Nigercine and Cigarette Smoke Medium); and (3) in whole blood: caspase-1 and NLRP3 mRNA.

Results: Table 1 shows main results (mean ± SD).

Conclusions: The inflammasome pathway participates in the inflammatory burst that characterizes ECOPD.

P421

Effect of budesonide on fibroblast-mediated collagen gel contraction and degradation

Qinhong Fang1, Nancy Schulte2, Xิงgai Wang1, Anna Miller-Larsson3, Pavitra Wiestlander1, Xingyi Wang1, Myron Toews2, Stephen Rennard1

Background: IL-18, IL-1Ra, IL-10 have anti-inflammatory effects, but its effect on fibroblast-mediated tissue repair and remodeling has not been fully studied.

Materials: Using human fetal lung fibroblasts (HFL-1 cells) in a three-dimensional collagen gel culture system, the current study investigated the effect of budesonide (1-1000 nM) on collagen gel contraction and degradation in the presence or absence of inflammatory cytokines (IL-1β and TNF-α: 5 ng/ml each) and, in order to activate latent proteases, the serum trypsin (0.25 μg/ml).

Results: Inflammatory cytokines significantly inhibited collagen gel contraction mediated by lung fibroblasts. Budesonide counteracted the effect of cytokines in a concentration-dependent manner (p<0.01). Budesonide (100 nM) almost completely inhibited the release and mRNA expression of metalloproteinases (MMP)-1, -3 and -9 induced by the cytokines (p<0.05). Exposure to the cytokines provoked increased collagen degradation and activation of the MMPs. Budesonide blocked both the enhanced collagen degradation (p<0.01) and suppressed the trypsin-mediated activation of cytokine-induced MMP-9 and MMP-3. Similar effects were observed with dexamethasone (1 μM), suggesting a class effect.

Conclusions: These findings suggest that budesonide directly modulates contraction of collagen and can decrease collagen degradation under inflammatory conditions through suppressing release and activation of MMPs. By modulating the release and activity of MMPs, inhaled budesonide may be able to modify airway tissue repair and remodeling.

P422

Sputum lipid profile and iron content in serum and pulmonary tissue in experimental pulmonary emphysema

Snezana Zunic-Bozinovski1, Svetlana Zunic 2, Slavko Vucicevic3

Introduction: To investigate if the inflammasome pathway is activated in ECOPD patients.

Materials: Using human fetal lung fibroblasts (HFL-1 cells) in a three-dimensional collagen gel culture system, the current study investigated the effect of budesonide (1-1000 nM) on collagen gel contraction and degradation in the presence or absence of inflammatory cytokines (IL-1β and TNF-α: 5 ng/ml each) and, in order to activate latent proteases, the serum trypsin (0.25 μg/ml).

Results: Inflammatory cytokines significantly inhibited collagen gel contraction mediated by lung fibroblasts. Budesonide counteracted the effect of cytokines in a concentration-dependent manner (p<0.01). Budesonide (100 nM) almost completely inhibited the release and mRNA expression of metalloproteinases (MMP)-1, -3 and -9 induced by the cytokines (p<0.05). Exposure to the cytokines provoked increased collagen degradation and activation of the MMPs. Budesonide blocked both the enhanced collagen degradation (p<0.01) and suppressed the trypsin-mediated activation of cytokine-induced MMP-9 and MMP-3. Similar effects were observed with dexamethasone (1 μM), suggesting a class effect.

Conclusions: These findings suggest that budesonide directly modulates contraction of collagen and can decrease collagen degradation under inflammatory conditions through suppressing release and activation of MMPs. By modulating the release and activity of MMPs, inhaled budesonide may be able to modify airway tissue repair and remodeling.

Inhibition of β-adrenoceptors alleviated mucus secretion and emphysema in cigarette smoke exposed rat model  
Fei Wang1, Ji-Hong Li2, Bei He3, 1Pulmonary Department, Peking University Third Hospital, Beijing, China; 2Pulmonary Department, Beijing Shijitan Hospital, Beijing, China; 1Pulmonary Department, Peking University Third Hospital, Beijing, China  

Background: The sympathetic nervous (SN) is probably over activated in COPD. Some retrospective studies found that treatment with β-blockers may reduce the risk of exacerbations and improve survival in COPD patients. However, our preliminary data showed that no significant change of lung function in COPD patients after treatment with β-blocker. The aim of the study is to elucidate whether inhibition of the SN over activation may improve lung pathological change in smoke exposed rat model.  

Methods: The rats were randomly divided into 3 groups: control group (C, n=9), smoke-exposed group (S, n=8) and smoke-exposed plus propanolol group (S/P, n=8). S and S/P rats were exposed to cigarette smoke for 3 months, and S/P rats were further treated with propanolol for 1 month. Lung tissue pathologic score and mucus (MLI) were determined.  

Results: The scores of mucus secretion, goblet-cell metaplasia, smooth muscle cells (SMC) proliferation, and MLI were significantly different in the 3 groups (see table 1), however, no significant difference was found in other aspects of pathological changes.

P424  
AMPK signalling regulates Nrf2 localization and activity via sirtuins in a monocytic cell line  
Laura Nunez Naveira, Nicolás Mercado, Kazuhiro Ito. Heart and Lung Institute (NHLI). Imperial College, London, United Kingdom  

Nrf2 participate in the defence against oxidative stress by inducing anti-oxidant genes such as HO-1 and NQO1, which system is downregulated in COPD. AMPK and sirtuins are ageing related signals reported to control the expression of genes. Sirt1 is also down-regulated in COPD lung.  

Aims: To evaluate the effect of sirtuin inhibition and AMPK activation/inhibition on the nuclear localization and activity of Nrf2, and the expression of HO1 and NQO1.  

Methods: THP-1 monocytic cells were treated with a sirtuin inhibitor (sirtinol), hydrogen peroxide (H2O2) as oxidative stress reagent and AICAR and dorsomorphin as AMPK activator and inhibitor respectively. Nrf2 protein levels were measured by western blot and the samples were normalized against Lamin A/C. The mRNA levels of HO1 and NQO1 were measured by RT-PCR and normalized to 18S.  

Results: H2O2 increased Nrf2 in the nucleus by 2-fold and pretreatment with sirtinol did not affect this induction. In contrast, although Nrf2 binding activity also increased by 50% with H2O2, preincubation with sirtinol abrogated this activation. Dorsomorphin treatment provoked a decrease in the nuclear levels of Nrf2 by 50% with H2O2, preincubation with sirtindol abrogated this activation. These results may explain the increased tobacco smoke susceptibility in early stages to develop lung emphysema with the C57 strain, as compared to the less susceptible strain, 129S2.  

Conclusion: These results explain the increased tobacco smoke susceptibility in early stages to develop lung emphysema with the C57 strain, as compared to the less susceptible strain, 129S2.  

P425  
Molecular markers involved in susceptibility to lung injury after acute exposure to tobacco smoke in different mouse strains. Fluorescent molecular in vivo imaging application  
Sandra Pérez-Rial, Laura del Puerto-Nevado, Álvaro Girón-Martínez, Raúl Terrén-Expósito, Nicolás González-Mangado, Germán Pérez-Barba. Pulmonology, IIS-Fundación Jiménez Díaz, Madrid, Spain  

Mouse strains C57 and 129S2 show different susceptibility to developing COPD when they are exposed chronically to tobacco smoke. The aim of this study is to determine molecular differences, between these two strains in the early stages of the disease within 24, 48 and 72h of being acutely exposed to tobacco. We quantified the levels of MMP-12 and analyze MMPs activity in lungs of mice by fluorescence molecular imaging techniques using MMPs activable fluorescent probe. We also measure NF-κB and TNF-α levels. The results in C57 strain showed a significant increase in MMPs activity measured at 24 and 48h of cigarettes exposure while 129S2 did not observed changes.  

In addition, MMP-12 levels increased significantly in C57, but not in 129S2 strain. Respect to the studied of NF-κB, significantly increased at 24 and 48h, in correlation with an increase in the levels of TNF-α, only in C57.  

Although COPD is one of the leading causes of morbidity and mortality in the world, until now there is no effective treatment to improve lung function in COPD patients. Animal models have been employed to better understand the pathophysiology of this disease and to test new therapies.  

Objectives: To evaluate the effects of a protease inhibidor in emphysema.  

P426  
Effects of a protease inhibitor from the tick rhizophilus boophilus microplus in an experimental model of emphysema  
Clarice Oliveira1, Luana Neves1, Juliana Lourenço1, Fruncine Almeida1, Carla Prado2, Iolanda Tibério1, Aparecida Tanaka2, Sergio Sasaki3, Milton Martins1, Fernanda Lopes1, 1Department of Medicine, Universidade de São Paulo, Sao Paulo, Brazil; 2Department of Biological Science, Universidade Federal de São Paulo, Sao Paulo, Brazil; 3Department of Biochemistry, Universidade Federal de São Paulo, Sao Paulo, Brazil. 4Human and Natural Science, Universidade Federal do ABC, Sao Paulo, Brazil  

These results may explain the increased tobacco smoke susceptibility in early stages to develop lung emphysema with the C57 strain, as compared to the less susceptible strain, 129S2.
Methods: 40 C57BL/6 mice received either a nasal instillation of 50 μl (0.667 UI) of porcine pancreatic elastase (PPE) or saline (S) and 1 h after, animals received a second nasal instillation of 50 μl of either a prototype inhibitor (r-BmTIA, 35.54pmol) or vehicle (VE). After 21 days, animals were anesthetized and airway resistance (RAW), tissue damping (G(t)) and tissue elastance (Hz(t)) were measured using Flexivent small animal ventilator. After sacrifice, lungs were removed and formalin-fixed for posterior analysis of mean linear intercept (Lm).

Results: We observed a decrease in Hz(t) values only in PPE-VE group [Fig. 1A]. Lm values were increased in PPE-VE and PPE-BmTIA groups, whereas the PPE-BmTIA showed a decrease in Lm values when compared to PPE-VE group [Fig. 1B]. There was no difference in G(t) and Raw values [Fig. 1C and Fig. 1D, respectively].

Conclusions: We showed that a single dose of this prototype inhibitor attenuated parenchyma destruction in an experimental model of emphysema. Supported by FAPESP, LIMHC-FMUSP CNPq, Brazil.

P427
HDAC2-independent anti-inflammatory effects of budesonide in human lung fibroblasts
Xingqi Wang1, Amy Nelson1, Anna Miller-Larsson2, Elisabet Wieslander2, Xiangde Liu1, Stephen Rennard 1.

Background: Reduced response of COPD patients to the anti-inflammatory therapy with glucocorticoids may be due to reduced expression of histone deacetylases (HDAC) in alveolar macrophages and bronchial epithelial cells as suggested by recent studies. Lung fibroblasts release inflammatory mediators and are key cells in tissue remodeling following airway inflammation. However, HDAC expression and its role in mediating glucocorticoid effect on fibroblast functions have not been studied.

Methods and results: Human fetal lung fibroblasts (HFL-1) were exposed to IL-β + TNF-α (5ng/ml each), while stimulated of IL-β, IL-8 and metalloproteinase (MMP-1 and MMP-3). These responses were inhibited by the glucocorticoid budesonide (0.1-100nM) in a concentration-dependent manner. An HDAC inhibitor (trichostatin A) did not reverse the effects of budesonide on release of cytokines and MMPs. While it blocked the inhibitory effects of budesonide on human bronchial epithelial cells and monocytes. Furthermore, siRNA targeting HDAC2 did not interfere with the inhibitory effects of budesonide on HFL-1 MMP release. Exposure to cigarette smoke extract (5%) did not affect HDAC2 expression in HFL-1 cells and did not interfere with the budesonide effects. Finally, there was no statistically significant difference between COPD and control subjects in HDAC2 expression and the effects of budesonide on cytokine or MMP release from lung fibroblasts.

Conclusions: HDAC2 is not required for budesonide to inhibit MMP and cytokine release by lung fibroblasts. These results also suggest that budesonide has a potential to counteract fibroblast-mediated tissue remodeling following airway inflammation in COPD.

P428
The nuclear liver X receptor and its role in smoke exposed rat lungs
Adelheid Kratzer, Jonas Salys, Martin Zamora, Laina Taraseviciene-Stewart

Background: Chronic obstructive pulmonary disease (COPD) is one of the leading causes of mortality worldwide and currently there are no efficient treatments. Liver X receptor (LXR) plays a role in lipid metabolism and inflammation. Treatment with LXR agonists has been shown to improve lung function in COPD patients.

Methods: Sprague Dawley rats were exposed to smoke for two months. The lung tissue and bronchoalveolar lavage (BAL) cells were examined for LXR target gene expression and emphysema development was measured by MLI. Rat AM and EC treated with LXR agonist were examined for LXR target gene and protein expression and migratory capacity. LXR2 localization before and after exposure was determined by immunofluorescence.

Results: Whereas expression of ATP binding cassette transporter A1, a known LXR target gene, was not changed in the lung, but significantly downregulated in the BAL cells from smoke-exposed rat lungs and in smoke-exposed treated AM. Immunofluorescence showed reduced nuclear localization of the anti-inflammatory LXRα isoform in AM and pulmonary EC. Activation of LXR attenuated LPS-induced genes such as COX2, CCL5 and IL1β, but upregulated IL18 binding protein (IL-18BP), an endogenous IL-18 inhibitor. It increased the migratory capacities of rat alveolar macrophages towards CCL5.

Conclusions: Activation of LXR attenuated the pro-inflammatory cytokine production by AM suggesting that LXR agonist treatment might be beneficial to prevent and treat COP-emphysema.

P429
Insulin-dependent PI3-Kinase/Akt and ERK signaling pathways inhibit TLK3-mediated HBECC apoptosis
Takamori Numata1, Jun Araya1, Satoko Futaji 1, Hiromichi Harase 1, Naoki Takasaka1, Yoko Yumino1 , Makoto Kawashina 1, Jun Hirano2, Makoto Odaka2, Toshiaki Morikawa2, Katsutoshi Nakayama 1, Kazuyoshi Kuwano1.

TLK3, a novel tumor suppressor, inhibits proliferation, invasion and is necessary for HBECC apoptosis. Recent studies suggest that, in addition to PI3K/Akt and ERK pathways, ways via NF-κB and mitochondrial pathways are involved in this process. However, the roles of PI3K/Akt and ERK pathways in TLK3-mediated apoptosis need to be clarified. Therefore, the aim of this study is to investigate the role of PI3K/Akt and ERK pathways in TLK3-mediated HBECC apoptosis.

Methods: A549 and 16HBE cells were cultured with IL-1β and TNF-α. The effect of PI3K/Akt and ERK pathways was studied using specific inhibitors. The apoptosis was assessed using Annexin V staining. Results: PI3K, Akt and ERK pathways were involved in TLK3-mediated apoptosis. The combination of Akt and ERK inhibitors showed a synergistic effect. Conclusion: PI3K/Akt and ERK pathways play a critical role in TLK3-mediated HBECC apoptosis.

P430
Overexpression of RAGE in lungs of patients with COPD: A contributor to oxidative stress in COPD
Lei Chen, Lin Liu, Tao Wang, Fuqiang Wen. Department of Respiratory Medicine, West China Hospital, Chengdu, China

Background: Receptor for advanced glycation end products (RAGE) has been recently suggested to be implicated in COPD, although the mechanisms remain unclear. The aim of this study is to investigate the expression of RAGE in lungs tissues from COPD patients and its potential role in oxidative stress in COPD.

Methods: Peripheral lung tissue specimens were obtained from 40 patients who underwent lung resection for non-small cell lung cancer, including 8 non-smoker controls, 7 non-COPD smokers and 25 smoker COPD patients. Immunohistochemistry and ELISA were used to assess RAGE expression in lung tissues, and oxidative stress was also measured by ROS and GSH. Furthermore, human pulmonary epithelial cell (AS49) and bronchial epithelial cell (16HBE) were cultured with cigarette smoke extract (CSE). Neutralizing antibody against RAGE was used to detect the role of RAGE in oxidative stress in COPD.

Results: RAGE expression level in smoker COPD patients was significantly higher than non-smoker controls and non-COPD smokers, which was dominantly expressed in the bronchiolar and alveolar epithelia. Importantly, RAGE in smoker COPD patients was positively correlated with oxidative stress, evidenced by levels of ROS and GSH. In the in-vitro study, CSE enhanced oxidative stress level in AS49 and 16HBE cells, as well as activation of NF-κB, a key redox transcription factor, which were all reversed by pretreatment of anti-RAGE antibody.

Conclusion: Overexpression of RAGE may contribute to COPD pathogenesis, at least partly through enhancement of oxidative stress level.

P431
MMP-mediated regulation of ENaC channel in pleural mesothelioma
Eleni Apostolidou1, Fotini Malis2, Efrosini Parasskeva1, Konstantinos Georgoulis2, Paschalis-Adam Molydidas1, Chriissi Hatzoglou1

1Physiology Department, University of Thessaly, Larissa, Greece; 2Respiratory Department, University Hospital of Thessaly, Larissa, Greece

Introduction-aim: The epithelial sodium channel (ENaC), which participates in sodium reabsorption across the apical membrane of mesothelial cells, has been recently identified in pleura with molecular techniques. MMP2 and MMP9 are two matrix metalloproteinases (MMPs) that have been found elevated in exudative pleural effusions. The aim of this study was to investigate if MMP2 and MMP9 influence functionally ENaC activity.

Methods: Intact sheets of parietal pleural tissue were obtained and the short-circuit current (Isc) was recorded in Ussing chambers. MMP2 (0.1 ng/ml or 20 ng/ml) or MMP9 (0.1 mg/ml or 20 mg/ml) were added on the apical solution of the pleura. A 40 min incubation, amiloride (10-4 M) was added to the apical compartment of all experiments in order to calculate the ENaC-mediated current. This current was defined as the difference between the Isc value just before amiloride addition and the Isc value 5 min after amiloride addition. The amiloride-sensitive Isc was compared between control tissues (having received only PBS) and tissues treated with MMP2 or MMP9.
Results: A statistically significant decrease in amirolide-sensitive Isc occurred when 20 ng/ml MMP2 were added to the pleura (p<0.05). When the pleura was incubated with 0.1 mg/ml MMP2 or MMP9, an increase in amirolide-sensitive Isc occurred but this was not statistically significant.

Conclusions: According to the above results, MMP2 regulates ENaC activity by decreasing the sodium current which is produced by ENaC. A same effect for MMP9 was not confirmed. Previous studies have shown a serine-peptidase mediated regulation of ENaC activity. This is the first study that suggests a matrix-metalloproteinase-mediated downregulation of ENaC activity.

LSC 2011 Abstract: Association of IL-9 and IL-4R genes and their phenotypes among Sudanese with asthma

Amel Gundi, Omer A. Aziz Musa, Montaazar Ibrahim Elsayed, Hiba Salah Mohamed. Physiology, The National Ribat University, Faculty of Medicine, Khartoum, SD Biochemistry, The National Ribat University, Khartoum, SD

Background: Asthma is a “complex” heritable disorder, candidate genes that may be involved in the pathogenesis of asthma including: interleukin 4 (IL-4), IL-5, IL-9, and IL-13 (Postma et al. 1995). Asthma prevalence in Sudan was found to be 12.5% in children aged 13-14 year in the Capital Khartoum (Mohamed et al. 1999).

Objectives: To detect polymorphisms of IL-9 in chromosome 5 and IL-4R in chromosome16 contributing to asthma and to estimate the environmental components: total immunoglobulin E levels, skin prick test, and eosinophil count in Sudanese population.

Methods: Seventy, nuclear and extended families were sampled in the initial phase of the study. Ventilatory function, skin, prick test blood sample for DNA analysis, immunoglobulin E, eosinophil count were carried out in the whole sample. Genotypes for IL-9, IL-4R and IL-13, polymorphisms using PCR were also carried out for a subset of the sample.

Results: Phenotypic analyses of the pedigrees suggest a likely genetic cause for asthma, as shown in one extended family. Level of total immunoglobulin E was found to be 71% in asthmatic, and 24% in non asthmatic. Eosinophil count was found to be 58% in asthmatic, while found to be 17.4% in non asthmatic. Hypersensitivity symptoms to six allergens showed positive skin test. (p = 0.00).

Genotyping for IL-9, IL-4R suggest the presence of association for both IL-9 and IL-4R (P=0.008/0.007).

Conclusions: Asthma runs in families showing strong linkage to genes. There seems to be sufficient phenotypic and genotypic indicators to suggest a genetic predisposition component to asthma among Sudanese, and warrant some further investigations.

P433

Polymorphisms in toll-like receptor 4 are associated with severity but not susceptibility for asthma in a Chinese Han population

Qian Zhang1, Fen-Hong Qian2, Lin-Fu Zhou3, Guo-Zhen Wei1, Kai-Sheng Yin3.

1 Department of Respiratory Medicine, Affiliated Changzhou No.2 People’s Hospital, Zhenjiang, Jiangsu, China; 2Department of Respiratory Medicine, First Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China; 3Department of Respiratory Medicine, Affiliated Jiangbing Hospital, Jiangsu University, Zhenjiang, Jiangsu, China

Background: Toll-like receptor 4 (TLR4) links human innate and adaptive immunity via bacterial endotoxin recognition, and has a considerable role in the pathogenesis of asthma. The effects of the genetic variants in TLR4 on asthma are still largely unknown.

Aims and objectives: This study aimed to evaluate the effects of polymorphisms in TLR4 on asthma risk and asthma-related phenotypes in a Chinese Han population.

Methods: We consecutively recruited 318 unrelated adult asthmatic patients and 352 healthy volunteers. Four tagging single nucleotide polymorphisms (SNPs) in TLR4 gene were detected using GenomeLab SNPStream or TaqMans Genotyping. We conducted case-control and case-only association studies between the selected tagging SNPs in TLR4 and asthma or asthma-related phenotypes.

Results: We found no evidence to support a significant association between TLR4 SNPs and asthma susceptibility. However, our results revealed that the TT homozygote of rs1927914 was associated with lower FEV1,% in asthmatic patients. An evidently positive association was found between the TT genotype of rs1927914, or the GG genotype of rs10983755 and rs1927907, and asthma severity (P=0.024, 0.009, 0.013, respectively), which indicated that the C allele of rs1927914, and the A allele of rs10983755 and rs1927907 had a protective effect on asthma severity. Conclusion: TLR4 polymorphisms do not contribute to asthma susceptibility, but may influence the severity of asthma.

P434

Vitamin D binding protein variants associate asthma susceptibility in a Chinese Han population

Fei Li1, Saffon Willcox-2, Youming Zhang1, Jiming Gao1. 1 Respiratory Diseases, Peking Union Medical College Hospital, Beijing, China; 2Molecular Genetics and Genomics, Imperial College, London, United Kingdom

Background: Asthma is a genetically heterogeneous disease. Polymorphisms of genes encoding components of the vitamin D pathway have been reported to associate with the risk of asthma. Previously, we demonstrated that the vitamin D status in serum was associated with lung function in Chinese asthma patients. In this study, we tested whether polymorphisms of vitamin D receptors (VDR), vitamin D 25-hydroxylase (CYP2R1) and vitamin D binding protein (GC) were associated with asthma in a Han Chinese Population.

Methods: We sequenced 8 exons of VDR and all 5 exons of CYP2R1 and identified only two mutations on the coding regions in a Han Chinese case-control cohort of asthma. These two polymorphism markers were rs2228570 on exon 4 of VDR and rs12794714 on exon 1 of CYP2R1. We then genotyped the two markers in the cohort that consisted of 467 asthma patients and 288 unrelated healthy. We also genotyped two common polymorphism marker rs4588 and rs7041 in vitamin D binding protein (group-specific component, GC) gene by a PCR-restriction fragment length polymorphism (RFLP) method. We analyzed the association between these polymorphisms and asthma susceptibility and asthma relevant traits.

Results: Polymorphism markers in VDR and CYP2R1 were not associated with asthma in the Han Chinese cohort. The variants of vitamin D binding proteins were associated with asthma susceptibility. Compared with GC1, GC2 was strongly associated with the risk of asthma (OR=3.95, 95% CI: 1.01-1.78 p=0.006).

Conclusions: The results provide supporting evidence for association between GC variants and asthma susceptibility in the Chinese Han population.

P435

Is there a relation between asthma associated polymorphisms and recurrent wheezing in preschool children? The ADEM study

Ester M.M. Klaassen1, Marije Quak2,3,1, Kim D.G. van de Kant3, 11, Quirijn Jisjus1, Onno C.P. van Schayck4, Frederik-Jan van Schooten2, John Penders5, Gerard H. Koppelman6, Guillaume van Eys7, Edward Dompeling1.

1Department of Paediatric Pulmonology, School for Public Health and Primary Care (CAPRIH), Maastricht, Netherlands; 2Department of Toxicology, NUTRIM, Maastricht, Netherlands; 3Department of General Practice, School for Public Health and Primary Care (CAPRIH), Maastricht, Netherlands; 4Department of Epidemiology, School for Public Health and Primary Care (CAPRIH), Maastricht, Netherlands; 5Department of Paediatric Pulmonology and Pediatrics, Albert Lasker Ziekenhuis, Groningen, Groningen, Netherlands; 6Department of Genetics and Cell Biology, Cardiovascular Research Institute Maastricht, Maastricht, Netherlands

Background: About 20-40% of preschool children experience wheezing. One in three wheezers will have persistent symptoms after the age of six and develop asthma. It is unknown which gene variants contribute to wheezing.

Aim: To explore the relation between asthma associated single nucleotide polymorphisms (SNPs) and preschool recurrent wheezers.

Methods: We selected 202 recurrent wheezers (ISAC questionnaire ≥2 wheezing episodes) and 50 controls aged 2-4 years. Saliva and buccal swabs were used for DNA extraction. Chi square tests were performed on 23 SNPs in 15 genes. Results were expressed in unadjusted odds ratio (OR) with 95% confidence interval. Multiple testing was corrected by the Benjamini and Hochberg False Discovery Rate.

Results: In total 134 boys and 116 girls participated with an average age of 3.3 years. All SNPs had a high call rate (94.3-99.2%). The frequencies of a genetic variant in ADAM33 (rs1511898) differed statistically significantly between cases and controls leading to OR=2.4 (1.2-4.9) for CT genotype and OR=1.0 (0.4-2.5) for TT genotype compared to CC genotype (p=0.03). The frequencies of a genetic variant in ORMDL3 (rs7216389) differed statistically significant between cases and controls leading to OR=3.7 (1.7-8.2) for CT genotype and OR=2.7 (1.2-6.3) for TT genotype compared to CC genotype (p<0.01). Neither remained statistically significant after multiple testing correction (rs511898 p=0.36, rs7216389 p=0.07).

Conclusions: We observed some evidence for the association of the ORMDL3 SNP rs7216389 and recurrent wheeze. The T-allele was more frequent in recurrent wheezers, which is consistent with previous studies in asthma.

Use of partition tree to identify genetic marker combination predicting bronchodilator response by inhaled short-acting beta 2 agonist
Sung-Yoon Kang1,2, Tae-Wan Kim1,2, Jae-Woo Jung1,2, Woo-Jung Song1,2, Min-Hyung Kim1,2, Sung-Hoong Kim1,2, Heung-Woo Park1,2,3.
1Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, 2Institute of Allergy and Clinical Immunology, Seoul National University Medical Research Center, Seoul, Korea

Objective: To identify genetic marker to predict bronchodilator response by inhaled short-acting beta 2 agonist after methacholine-induced bronchoconstriction.

Methods: A total of 480 patients were enrolled, who showed ≥20% decrease of FEV1 in methacholine bronchial provocation test and subsequently inhaled 2 puff of salbutamol (200 mcg), then FEV1 was re-measured 10 minutes later. Twenty SNPs in 10 genes related with airway inflammation, structural changes, or smooth muscle function was scored by high throughput technique. They were TNF-α (-308A>G), IL13 (-1143C>A), IL5RA (-3232C>T), IL4RA (-128C>A), VEGFR2 (889G>A, 1416A>T), TGFBR3 (44T>C), 2753G>F, 464R (28A>G, 1162G>A, 538A>G, CS2P (536C>T), IL3 (80F>C) and ADRβ2 (79C>G). The partition tree was used to investigate SNP combinations. The first partition was done by SNP discrimination of responders from non-responders based on dominant model of minor frequency allele. Then subsequent partition was performed by the other SNPs until statistical significance disappeared.

Results: The SNP-201G>A in VEGFR1, was the most significant and used in the first partition (25.7±19.8% vs. 20.0±13.8% increase, p<0.001). The best responders with AA or AG of -201G>A and CC of -1111C>T were discovered after second partition (30.3±16.7% increase). The poorest responders with GG of -201G>A, GG of 2753G>F and GG of 1162G>A were discovered after third partition (17.2±15.4% increase).

Conclusion: The combination of genetic markers related to the airway inflammation or structural changes can be used in predicting bronchodilator response by short-acting β2 agonist.

P438
Association between beta2 adrenergic receptor (ADRβ2) haplotype pair and severe asthma in an Australian caucasian population
Li Peng Chang1,2, Svetlana Balci1,2, Suzanne Temple1,2, Grant Waterer2,3, Philip Thompson2,4,5, Genetic Unit, Lung Institute of Western Australia (LIWA, Centre for Asthma, Allergy and Research, University of Western Australia), Perth, Western Australia, Australia; 2School of Medicine and Pharmacology, University of Western Australia, Perth, Western Australia, Australia; 3Respiratory Medicine, Royal Perth Hospital, Perth, Western Australia, Australia; 4Respiratory Medicine, Sir Charles Gardiner Hospital, Perth, Western Australia, Australia

Background: Studies in mild asthmatics showed adverse outcomes with chronic use of short or long acting beta agonists in individuals with β2 adrenergic receptor (ADRB2) polymorphisms including ADRB2+46G>C. The extent to which ADRB2 polymorphisms contribute to severe asthma is unknown, hence the association of ADRB2 polymorphisms with asthma severity was investigated.

Methods: Multidrug resistance gene (MDR1) encodes P-glycoprotein 170 (Pgp170), which realizes efflux of glucocorticosteroids (GCS) from the cell. C3435T of gene MDR1 in genotype if compared with geterozygous ones: 2.86 mg/day vs 1.86 mg/day (p=0.041). Alpha-1 adrenergic receptor (ADRA1) polymorphism on the airway response to cold air in asthmatics
Dena E. Naumov1, Julius M. Perelman1, Vladimir N. Maksimov2, Viktor P. Kolesov3, Xiondong Zhou4, Qi Li4, Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiratory System SB RAMS, Blagoveschensk, Russian Federation; 2Molecular Genetics Research Laboratory, Scientific Research Institute of Therapy SB RAMS, Novosibirsk, Russian Federation; 3Division of Respiratory Medicine, Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background: Previously we’ve found out that the decline in β2-adrenoceptors (β2-AR) function affects airway response to cold air.

Objective: The aim of our study was to reveal the contribution of Arg16Gly SNP (rs1042713) in the development of cold air hyporesponsiveness (CAH) in asthmatics.

Methods: The study included examination of 60 mild to moderate asthmatics of Caucasian race, mostly non-smokers (mean age 36±1.39). All the patients underwent spirometry before and after the challenge with 3-minute isocapnic (5% CO2) hypercapnia (ICAH). More than 10% drop in FEV1 was interpreted as a positive result. Intracutaneous cyclic adenosine monophosphate (cAMP) concentration in lymphocytes was measured before and 30 min after ICAH under in vitro stimulation with 10M M epinephrine. PCR-RFLP analysis was used for genotyping.

Results: Arg16Gly genotype dominated in the group with CAH (χ2=7.47; p=0.005). Mean FEV1, drop differed between homozygous patients (16.0±2.7% at Arg vs 8.6±1.1% at Gly, p=0.004). cAMP concentration didn’t depend on genotype before the challenge, but 30 min after there was a significant fall in cells ability to produce cAMP in subjects with Arg16Gly genotype (p=0.03). Moreover, Arg16 homozygotes had lower cAMP levels as compared to Gly16 (48.32±6.16) and 78.59 (81.3) pmol/10^6 cells, respectively, p=0.0048. In patients with allele C bronchial obstruction was less severe. However, if compared with TT genotype, post-broncholytic increase of velocity characteristics and SGRG were not good responders from poor to dominant model of minor frequency allele. Then subsequent partition was performed by the other SNPs until statistical significance disappeared.

Conclusion: Patients with allele C require higher α2GCS doses, probably, due to enhanced activity of Pglycoprotein and accelerated GCS efflux. In patients with TT genotype significant obstruction may be due to inadequate O2GCS dose, while reversibility of distal obstruction may be due to intact function of bronchial smooth muscles and their sensitivity to GCS.

P440
Effect of ADRB2 polymorphism on the airway response to cold air in asthmatics
Denis E. Naumov1, Julius M. Perelman1, Vladimir N. Maksimov2, Viktor P. Kolesov3, Xiondong Zhou4, Qi Li4, Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiratory System SB RAMS, Blagoveschensk, Russian Federation; 2Molecular Genetics Research Laboratory, Scientific Research Institute of Therapy SB RAMS, Novosibirsk, Russian Federation; 3Division of Respiratory Medicine, Second Affiliated Hospital, Chongqing Medical University, Chongqing, China

Background: Previously we’ve found out that the decline in β2-adrenoceptors (β2-AR) function affects airway response to cold air.

Objective: The aim of our study was to reveal the contribution of Arg16Gly SNP (rs1042713) in the development of cold air hyporesponsiveness (CAH) in asthmatics.

Methods: The study included examination of 60 mild to moderate asthmatics of Caucasian race, mostly non-smokers (mean age 36±1.39). All the patients underwent spirometry before and after the challenge with 3-minute isocapnic (5% CO2) hypercapnia (ICAH). More than 10% drop in FEV1 was interpreted as a positive result. Intracutaneous cyclic adenosine monophosphate (cAMP) concentration in lymphocytes was measured before and 30 min after ICAH under in vitro stimulation with 10M M epinephrine. PCR-RFLP analysis was used for genotyping.

Results: Arg16Gly genotype dominated in the group with CAH (χ2=7.47; p=0.005). Mean FEV1, drop differed between homozygous patients (16.0±2.7% at Arg vs 8.6±1.1% at Gly, p=0.004). cAMP concentration didn’t depend on genotype before the challenge, but 30 min after there was a significant fall in cells ability to produce cAMP in subjects with Arg16Gly genotype (p=0.03). Moreover, Arg16 homozygotes had lower cAMP levels as compared to Gly16 (48.32±6.16) and 78.59 (81.3) pmol/10^6 cells, respectively, p=0.0048. In patients with TT genotype significant obstruction may be due to inadequate O2GCS dose, while reversibility of distal obstruction may be due to intact function of bronchial smooth muscles and their sensitivity to GCS.
A common characteristic of COPD and bronchial asthma is the chronic inflammation in the airways. In the current case-control study we investigated -511C>T promoter polymorphism and +3953C>T silent polymorphism of IL1B and their haplotypes as candidate risk factors of COPD and Bronchial asthma. We genotyped 163 patients with COPD, 47 with Bronchial asthma and 174 control individuals using Taqman genotyping assay for IL1B -511C>T and PCR-RFLP-based method for +3953C>T.

We did no observed significant differences in genotype frequencies of studied SNPs between controls and patients both with COPD and asthma, however the minor T allele of IL1B -511C>T was less frequently found in controls (0.305) than the patients with COPD (0.377, p=0.046) and especially with asthma (0.415, p=0.026). The carriers of IL1B -511C>T TT allele (TT and TC genotypes) had 1.56-fold higher risk for development of COPD (p=0.045) and 2.25-fold higher risk of Bronchial asthma (p=0.019). The performed estimations of IL1B haplotypes showed that T_C haplotype (alleles found to determine enhanced expression of IL-1β), appeared to be associated with higher risk of COPD (OR=1.25, p=0.231) and asthma (OR=1.78, p=0.035) compared to the most common C_C haplotype and with 1.70-fold higher risk of COPD (p=0.018) and 1.37-fold higher risk of asthma (p=0.313) compared to the C_T haplotype, associated with lower IL-1β expression.

We suggest that the -511C>T promoter SNP and +3953C>T silent polymorphism of IL1B may influence the genetic predisposition of COPD and Bronchial asthma: the carriers of alleles and haplotypes supposed to define higher IL-1β levels are more susceptible for these diseases.

Conclusions: These data suggest a definite proof for contribution of primary β2-AR dysfunction into the development of CAHR in our population sample. CAHR was strongly associated with Arg16Arg genotype. Blunted cAMP response in Arg/Arg subjects indicates inherited predisposition of their β2-AR to acute desensitization during the ICAH.
Results: There were 6 SNPs significantly associated with risk of grade 3 or 4 hematologic toxicity in platinum-based treatment. The variant homozygotes of rs12934241 exhibited the most significant influence on the occurrence of severe neutropenia (P=9.3×10^-3). In stratification analysis by chemotherapy regimens, we found the greatest correlations in patients receiving cisplatin-gemcitabine: 7 polymorphisms were found to be associated with severe neutropaenia, especially rs12934241 (2.5% for C/C vs 66.7% for TT; P=9.4×10^-7). Consistent results were found in MMP-2 haplotype analyses. In patients receiving cisplatin-navelbine, we also observed 6 SNPs significantly associated with grade 3 or 4 hematologic toxicity. However, in cisplatin-carboplatin-paclitaxel treatment groups, no correlation with such toxicity was found.

Conclusions: Our study, for the first time, provides evidence for the predictive role of MMP-2 polymorphisms on severe chemotherapy-related hematologic toxicity variability among platinum-treated advanced NSCLC Chinese patients.

P446
EGFR, HER2 and KRAS mutational status according to adenocarcinoma patterns/sub-types
Lina Carvalho1, Maria João d’Aguiar1, Lia Teixeira1, Patricia Couceiro1, Ana Alarcão1, Vitor Sousa2,3, Maria Silva1, Ana Zanconi1, Vitor Sousa1,2, Maria Silva1, Ana Zanconi1, Vitor Sousa1,2, Maria Silva1

Lung adenocarcinomas represents about 42% and 28% of NSCLC diagnosed in women and men. Several subtypes are recognized by WHO. EGFR, HER2 and KRAS mutations have been described. Authors intends to identify differences between adenocarcinomas subtypes/patterns concerning EGFR, HER2 and KRAS mutations, gene copy number and protein expression.

45 lung adenocarcinomas were evaluated for EGFR, HER2 and KRAS mutational status by PCR, fragment analysis and direct sequencing. EGFR and HER2 gene copy number by fluorescence in situ hybridization (FISH). EGFR and c-erbB-2 protein expression was determined by immunohistochemistry (IHC).

8 cases showed EGFR exon 21 mutation (38.7%). In two cases the mutation was present in only one part of the tumour. 10 cases showed EGFR exons 19 deletions and one case with the mutation present in only one of the patterns showed synchronous exon 19 deletions and exon 21 point mutations. Of the 14 cases with EGFR mutations 10 cases were FISH positive (71%). KRAS mutations were identified in 5 cases (10%), one coexisting with EGFR ex21 point mutation. All cases were HER2 wild-type. 8 cases with EGFR mutations demonstrated EGFR protein expression and 6 cases were negative. EGFR mutational status and FISH results showed a moderate agreement/concordance. Concordance between EGFR FISH results and mutational status with EGFR IHC expression was fair. Frequently, when a mutation is identified it is present in all the patterns of 1 adenocarcinomas. Mutations of HER2 do not seem to be important in lung adenocarcinomas pathology. KRAS and EGFR mutations are in general mutually exclusive, but in rare cases they may coexist.

P447
Genetic analysis of two novel mucin-like genes in the disease-susceptibility locus for diffuse panbronchiolitis
Minako Hjikata1, Ikumi Matsuhashi1, Hideyuki Ito1, Jun Ohashi1, Sakae Homma1, Yoshio Taguchi1, Atsuko Azuma2, Shoji Kudoh2, Naoto Kiechi2, Department of Respiratory Diseases, Research Institute, National Center for Global Health and Medicine, Tokyo, Japan; 1Department of Thoracic Surgery, National Institute of Public Health and Medicine, Tokyo, Japan; 1Department of Respiratory Medicine, Toki University School of Medicine, Tokyo, Japan; 1Department of Respiratory Medicine, Teur Hospital, Nara, Japan; 1Division of Pulmonary Medicine, Nippon Medical School, Tokyo, Japan; 1President, Fujajuku Hospital, Tokyo, Japan

Background: Diffuse panbronchiolitis (DPB), which is characterized by chronic inflammation in respiratory bronchioles and sinusbronchial infection, is a common genetic disease affecting East Asians. DPB is strongly associated with HLA-B54 in Japanese and HLA-A11 in Koreans. We hypothesized that a major susceptibility gene for DPB might be located between the HLA-A and HLA-B loci and recently cloned two novel mucin-like genes designated panbronchiolitis related mucin-like 1 and 2 (PBMUCL1 and PBMUCL2) in the candidate region. We found disease-associated genetic polymorphisms in the new genes.

Results: Linkage analysis in two large families complicated with PA VM revealed a linkage to the HHT1 locus (encoding endoglin; ENG). Three novel mutations were found in four families, all of which led to a frame shift: a G to C transversion at the splicing donor site of intron 3 (In3+1 G>C) in one family, one base pair insertion (A) at nucleotide 828 (exon 7) of the endoglin cDNA in two large families (a282-29 ins A), and a four base pair deletion (AAAAG) beginning with nucleotide 1120 (exon 8) of the endoglin cDNA (c.1120-1123 delAAAAG) in one family. The insertion of A in exon11 (c.1470-1471 insA) mutation was found in one family.

Summary and conclusion: The population prevalence of HHT in the country is estimated to be 1:8,000 - 1:5,000, roughly comparable with those reported in European and U.S. populations, which is contradictory to the traditional view that HHT is rare among Asians. We recommend that families with HHT be screened for gene mutations in order that high-risk individuals complicated with PA VM receive early diagnosis and treatment initiation that will substantially alter their clinical course and prognosis.

Genetic polymorphisms in TNF genes and tuberculosis in cystic fibrosis patients
Galinha Scharmin2,1, Alexander Pukhalovsky3,1, Nikolai Kapranov3,1, Vladimir Alesikhin2,1, 1Department of Cystic Fibrosis, Research Centre for Medical Genetics, Moscow, Russian Federation; 2Laboratory of Cytokines, G.N. Gabrielevich Institute of Epidemiology and Microbiology, Moscow, Russian Federation

The genes for tumor necrosis factor-a (TNF-a; TNF) and lymphotixin-a (LT-a; LTA) are arranged in tandem within MHC III region of chromosome 6 in the same transcriptional orientation. This formation is conserved, even in marupsulps, suggesting that there may be some functional advantage to this arrangement. The proteins encoded by TNF and LTA are known to interact as complementary factors in various cell signaling networks. Single nucleotide polymorphism sites for TNF (308 G>A) and LTA (252 G>A, 252 C>G) were investigated with TagMan allelic discrimination assay. 150 cystic fibrosis (CF) subjects were enrolled into the study. The distribution of allelic variants of TNF and LTA genes in CF patients did not differ from those in health subjects of Moscow and European populations. We did not find any association between TNF or LTA genotypes and CF lung disease progression. In the same time the carriers of -308A allele more frequently had asthma and other atopic disorders as compared to patients homozygous for -308G allele (14.9 vs 5.3%, p< 0.05). There was no correlation of tuberculosis among patients with 252G alleles. In the same time in 7.9% of 252G/A carriers tuberculosis infection was documented (p<0.03). Besides, the subjects with genotype 252A/2 demonstrated a significant elevation of plasma TGF-β1 in comparison with carriers of 252G allele (72.6 vs 32.4 pg/ml; p< 0.05). Our data confirm the clinical importance of -308 A TNF allele for asthma development and provide robust evidence that LTA gene variants are involved in tuberculosis etiology.

Value of the video assisted thoracoscopy in the diagnosis of the pleural effusions – Our experience
Cornel Savu1, Cornel Petreanu1, Vasile Grigore1, Nicolae Galie1, Emilie Tabacu2, 1Clinic of Thoracic Surgery, National Institute of Pneumonology and Tuberculosis Prof. Dr. Marius Nasta, Bucharest, Romania; 2Clinic of Pneumonology, National Institute of Pneumonology Prof. Dr. Marius Nasta, Bucharest, Romania

Introduction: Pleural effusions are a common and significant clinical problem.
The diagnosis required sometimes the practice of the thoracotomy to biopsy the pathological pleura. Also, this method is utilized in treatment of different effusions like debridement of the empyema, pleurodesis in the malignant effusions. Also, it permits to establish if an effusion pleural is neoplastic or paraneoplastic, with consequence of the surgical treatment.

Material and method: The work presents our experience with this method in the last two years. We retrospectively reviewed 131 patients (82 males, 49 females, mean age: 62 years). The indications of videoassisted thoracotomy are presented in table no.1 and 2.

Additional, we performed a minithoracotomy or thoracotomy for 26 cases. Mean period of hospitalization was 4.2 days.

Results: The benefits of this method are obvious, with hospitalization cost smaller and with discharge of the patient faster.

Conclusions: The videoassisted thoracotomy is an indispensable method of diagnosis of pleural effusions.

P451

Tuberculous empyema thoracis surgical perspective. A tertiary care center experience

Methods: Surgical treatment.
The degree of chronic pleural effusions and the choice of the optimal method of treatment of pleural effusions, pleural thickening, the higher number and bigger size of air inclusions (flushing gas bubbles). The value of the mean of pleural content increased to +35 HU.

Results: All patients of the first group had thoracoscopic surgical treatment.
The patients of the second group were operated on by open decortication.

Conclusions: 1. Computer tomography provides the opportunity to differentiate accurately enough the density of the pleural content and evaluate it in Hounsfield units.
2. Preoperative assessment of the nature of pleural content gives the opportunity of choice of surgical intervention, adequate to the nature of the inflammatory process.

P452

Significance of computed tomography in diagnostic of pleural content and the choice of the method of surgical treatment
Marina Rusetckaya, Vladimir Petukhov.

Introduction: The authors have aimed at stating more precisely the value of Hounsfield units used for computed tomography in case of acute, subacute and chronic empyema, comparing these data with the results of morphologic investigation of operation material.

Goal of work: To evaluate the possibility of beam diagnostics for determining the degree of chronic pleural effusions and the choice of the optimal method of surgical treatment.

Methods: Case histories of 40 patients with pleural effusions treated at the thoracic department of Vitebsk Regional Hospital. All patients were divided into two groups.

Results: On the scans of the first group patients there was the content of the pleural cavity with slightly irregular contours, areas of gas, pleural thickening (mesh structure), the mean attenuation of effusion ranged from +13 HU up to +27 HU due to the liquid, gas and organized components.

P453

Lung and breast cancers are the most common causes. Severe cases can present background: Tuberculosis is an infectious disease caused by Mycobacterium tuberculosis but other species of Mycobacteria are also present which may produce similar change. A granulomatous response associated with intense tissue inflammation and damage, and is a leading pulmonary disease whereas pleural tuberculosis is the most common form of extra-pulmonary Tuberculosis. 90% originates from primary infection, while 10% due to reactivation of cavitated or fibrocaceous lesion.

Patients and methods: Between June 2008 to June 2009, 85 patients of 20-50 years of age underwent Thoracotomy and decortication for Tuberculous Empyema Thoracis were included in this study. Age less than 30yrs and above 50yrs, poor functional and nutritionally status, underlying parenchymal disease, A.T.T. Defaulter and MDR T.B were excluded.

Results: There was no mortality, mean day of discharge was 6 post-operative date 5/85 had wound complications, 3 patients required upto 10 day of hospitalization due to air leaks and wound complications 1 patient required revision of procedure and ended with pleurocutaneous window. Operating patients early with T.B Empyema Thoracis carries equally good results if compared to those operated at a later stage.

Conclusion: Operating patients early with T.B Empyema Thoracis carries similar results if compared to those operated at a later stage. Patient selection are an important factor. Key to success is: Patients taking adequate dose of A.T.T. Observed Treatment with regular followup. Surgery remains the standard Treatment.

P454

Analysis of lung function test at patients with pleural empyema treated with thoracotomy and decortications
Goran Kondov, Kisto Colanceski, Zoran Spirovski, Saso Jovev.

Material and methods: We analyze lung function at 18 patients surgically treated in last 3 years which was followed at least 6 months.

Results: Expected mean VC was 4650 ml, and expected mean FEV1 was 3450 ml.

– Realized mean VC was 2850 ml, and realized mean FEV1 was 1750 ml.
– Mean VC after 3 months after surgery as 3430 ml, and mean FEV1 was 1700 ml.
– Mean VC after 6 months after surgery as 2850 ml, and mean FEV1 was 1700 ml.

Discusion: Early detection and treatment of empyema is essential in treatment of empyema, where use of thoracic drainage with or without streptokinase or use of VATS decortications were methods of choice in treatment.

Conclusion: Thoracotomy with decortication is the only solution of treatment of fibronodular pleural empyema, where trapped lung was very often detected.

P455

Malignant pericardial effusion and pericardial- peritoneal window
Catarina Guimaraes, Claudia Lares Santos, António Correia de Matos, Ana Figueiredo, Fernando Barata.

Background: The metastatic pericarditis is a rare complication of advanced cancer. Lung and breast cancers are the most common causes. Severe cases can present significant symptoms.
with cardiac tamponade and shock, and pericardioedema is usually the initial approach. However the effusion may rapidly re-accumulate and a surgical decompression, as pericardio-pleural window (PPW), has proved to be effective with a consequent symptom relief and a better quality of life.

Objectives: Characterize patients with malignant pericardial effusion (PE). Evaluate the role that PPW plays in the management of PE. Determine median survival of patients after this procedure.

Material & methods: Retrospective review of the patients undergoing PPW from 1998 through 2010. Results: 92 patients underwent 24 PPW, with a mean age of 52.2 years old, and 71.1% were male. Lung cancer was the cause in 75% at the time of the cancer diagnosis PE was present in 38% of patients. In the other patients there was an average of 103 weeks (after the diagnosis) to occur PE of which 35% of cases were undergoing chemotherapy. The majority (70.8%) had also pleural effusion. In 70.6% of patients were performed at least one pericardiocentesis before the PPW, with a mean fluid volume of 740 ml. Two patients developed recurrent PE during follow-up. The procedure was well tolerated, with a median survival after the procedure of 11 weeks. No patient developed peritoneal carcinomatosis and no deaths were related to the procedure.

Results: Lung cancer was the most frequent cause undergoing PPW. This surgical decompensation is a simple, safe, and an effective method of palliation patients with malignant PE. Median survival rate after performing the procedure was low.

P456 Thoracic empyema: Medical and surgical treatment
Inês Ladeira, Carla Ribeiro, Maria Brito, Teresa Shiang, Pneumology, Centro Hospitalar Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal

Introduction: Thoracic empyema is the presence of pus in the pleural cavity. Mostly it complicates cases of pneumonia, trauma or is iatrogenic.

Initial approach includes chest drain and empirical antibiotic therapy. The use of fibrinolytics is controversial, according to the experience of each center. Current surgical options include thoracotomy (VATS) or thoracotomy. Mortality rate is up to 24%.

Methods: Review of medical records of patients admitted from 2006 to 2010 with diagnosis thoracic empyema.

Results: 44 patients had thoracic empyema, mean age 60.5 years, 70% male; 75% had infectious causes (pneumonia-68%), chest trauma 7% and 18% iatrogenic. Microbiology was isolated in 25%.

30 patients used medical therapy only; 6. Fibrinolytics were not used.

14 patients underwent surgical treatment (1 VATS and 13 thoracotomy), 78.6% men, mean age 53.3 years, 57% related to infection, 29% iatrogenic and 14% trauma. The mean hospital stay period was 26 (23-31) days and a shorter period of chest drain tube (17 vs 20 days) but there were no differences between co-morbidities, pleural effusion volume, isolated bacteria or antibiotic therapy.

Conclusions: As expected, empyemas mainly complicated infections.

Patients were younger in the operated group, associated to more cases of trauma or iatrogenic empyemas, but there were no other differences between groups. Thoracotomy was the principal method of surgical treatment. Since there was only 1 VATS we can’t compare the efficacy and complications of both surgical approaches, although it’s use is increasing in many centers. Surgical approach should be considered early to reduce hospitalization time and improve outcome. Mortality rate was between expected values and related to patient’s co-morbidities.

P457 Fibrous cavernous pulmonary tuberculosis (FCT) complicated by spontaneous pneumothorax (SP) Kazim Mukhamedov, Avazbek Murzabekov, Seralri Massavirov, Fazlal Ismailova, Nurali Djurayev, Faculty of Pathology, Tashkent Medical Academy, Tashkent, Uzbekistan

We undertook the treatment of SP clinical course that complicated FCT to 233 patients. Men were 205, women were 17 at the age 18-72 yr. 121 patients had infected pleural effusion, 31 from other TB clinics, 18 from general medical network, (GMN), 37 from peniintary system, 15 went to clinics themselves. Duration of tuberculosis (TB) fluctuated from 1 year to 16 years. MBT were revealed in 90.6% patients. 33 patients were admitted to clinic within 1-7 days with onset of SP process, 190 patients in more late terms (from 15 days to more than 1 month). Before admitting to clinic 134 patients had been made punctures and drainage of pleural cavity. (PC). 139 patients were admitted with complicated pleura empyema, 84- had a mild favorable SP process. The treatment started with puncture and drainage of PC. Polychemotherapy was made in standard regime and by broad-spectrum antibiotics when indicated as well as correction of dysproteinemia and hypotinuminous, oxygen-soda and tonic condition. Surgically approaches were used just in 5 patients with good effect. Segmental pulmonary resection was performed to 1, pneumectomy-1, bullectomy-1, and pleurectomy-2. Clinical convalescence was reached in 32, improvement in 86, no changes in 46, and death recorded in 3. Lethality was in 25, 1% cases.

Conclusion: SP problem under FCT is urgent. The search of new ways for more effective diagnostics and treatment to this severe group of patients is needed. At present time, the causes of poor surgical activity are mostly related with large spread and TB process activity, of phthisiourges and anesthesiologists being overcareful and lack of qualification as well as good equipment of surgical services.

P458 Do we follow the national guidelines for ICD (intercostal chest drain) insertion: A study in a district general hospital (DGH) in East of England
Vena Sireru, Y. Howe, K. Fulton, Subham Dharun, Respiratory Medicine, Queen Elizabeth Hospital, Kings Lynn, United Kingdom

AIM: To determine the compliance of ICD insertion in accordance with 2003 British Thoracic Society (BTS) guidelines.

Methodology: Retrospective analysis of all the ICDs inserted from Oct 09 to Oct 10 at a DGH in Norfolk, UK. We analysed the indications, seniority of the person performing the procedure, consent obtained, anaglasis and complications encountered.

Results: 28 Patients underwent ICD insertion. The indication for ICD insertion was non malignant effusion in 43% (12), pneumothorax in 32% (9) and malignant pleural effusion in 25% (7). The ICD was performed by SpR in 36% (10),SHO in 26% (8) and FIn 36% (10). Consent was obtained verbally in 47% (13), in writing in 32% (9) and not recorded in 21% (6). Ultrasound guidance was utilized in choosing the site of insertion in only 21% (6). All the patients 100% (28) had check CXR done following the ICD insertion. 75% (21) of the patients were given procedure analgesia.The ICDs were complicated by surgical empysemia in 11% (3) and pneumothorax in 11% (3). ICD was reinserted in 18% (5) as the tube fell out accidentally. No major complications of ICD were encountered.

Conclusion: BTS standards were achieved suboptimally in obtaining the written consent and poor in utilization of ultrasound for ICD insertion. Most of the ICDs were inserted by the seniors or under their supervision therefore we proved the complication rate is lower and in accordance with the BTS standards. Education of the 4 guidelines to the junior staff and utilization of ultrasound will improve the safety of the procedure. We will reaudit after increasing the usage of the ultrasound for ICD insertion hoping to find better results.

P459 Outpatient management of primary spontaneous pneumothorax using small-bore catheter: A prospective study
Massongo Massongo1, Bachar Chahine2, Charles Hugo Marquette3, Arnaud Scherpenber2
1Pulmonary Diseases, Lille University Nord de France Hospital, Lille, France; 2Pulmonary Diseases, Douai Hospital, Douai; France; 3Pulmonary Diseases, Nice University Hospital, Nice, France

The various guidelines published about the management of primary spontaneous pneumothorax (PSP), have raised up discrepancies regarding indications and methods of air removal.

We aimed to assess the feasibility of a single system small-bore drain based management of primary spontaneous pneumothorax. The end-point was 1-week success rate, secondary ones were the part of full outpatient management, the 1-year recurrence rate, the length of hospitalization stay, the cost and the side-effects.

125 patients aged > 16 years with 1st episode of PSP, were managed in the emergency room (ER) by observation alone or insertion of an 8.5 Fr "pigtial" drain, according to the experience of each center. The drain was connected to a one-way Heimlich valve. Patients were re-assessed at the 4th hour for potential admission or discharge. Patients still having air leak at day-4 were referred for video-assisted thoracocopy (VATS).

On the 60 patients recruited, 80% underwent drainage and 60% were discharged after 4 hours. Success rate was 83% at day-7, the 17% left underwent a VATS. Fifty per cent of the patients benefited from strict outpatient management and 2 procedure-related complications occurred. The length of hospitalization was 2.3±4.3 days, the 1-year recurrence rate was 17%. The financial gain of this PSP management was 1,791 to 3,940 Euros/patient/episode, compared with a manual aspiration (MA) or conventional chest tube drainage (CTD).

This one-system management offers good efficacy, safety, comfort and aesthetics; it is time and cost-effective. Our results suggest its use in a larger population, but a randomised controlled study comparing it with MA and/or CTD is needed for validation.

P460 Primary spontaneous pneumothorax size: Comparison of international guidelines
Shehnoor Tarique1, Jonathan Noble2, Alice Gillen1, Mathew Jones1
1Respiratory Medicine, Nevill Hall Hospital, Aberavon, Wales, United Kingdom; 2School of Medicine, Barts and The London University, London, England, United Kingdom

Background: Size estimation is central to decisions on management of Primary Spontaneous Pneumothorax (PSP). International guidelines exhibit a lack of consensus on PSP sizing. We aimed to study PSP size using established techniques (Rhea, Collins and Light) and compare size classification and suggested management of American (ACCP), Belgian (BSP) and British (BTS) guidelines.

Methods: Retrospective cohort study of all patients admitted with PSP to two centres in our institution between January 2007 and July 2010. Initial inspiratory chest x-rays (digital images with size calibration) were reviewed to quantify PSP size using BTS, ACCP, BSP, Collins, Rhea and Light’s methods. Data was analysed using descriptive statistics with kappa analysis for agreement between guidelines.

Results: 105 patients were studied, median age 21 years, 72% male. Median PSP size was 58% (Collins’ method), 39% (Rhea) and 51% (Light). BTS classification
defined 56% PSPs as large compared to 72% (BSP) and 78% (ACCP). Agreement between the three guidelines was poor. There was no consensus on the influence of different surgical treatment of spontaneous pneumothorax on the lung function. Some studies confirm positive long-term effect of pleurectomy and wedge resection on the lung function.

Aim: To study the influence of different surgical treatment of spontaneous pneumothorax on the lung function. Some studies confirm positive long-term effect of pleurectomy and wedge resection on the lung function.

Methods: We aimed to see if LVRS improves CI in patients with COPD by evaluating the change in perfusion patterns and its correlation to clinical outcome after LVRS. All patients underwent LVRS at Columbia University Medical Center (CUMC) between January 1998 to October 2009. There was a significant correlation between the bilateral preoperative heterogeneity index and the postoperative 6 MWD (r = 0.400, p = 0.028). Patients showing an improvement in 6 MWD (n=13) had significantly higher post-operative heterogeneity index as compared to the ones failing to show functional improvement in 6 MWD (r = 0.233 ± 0.28 vs. 2.25 ± 0.55, p = 0.025).

Conclusion: Lung SPECT perfusions pattern correlates with the clinical improvement and warrants evaluation as a pre-operative assessment tool in patients with COPD undergoing LVRS.

P465
Does lung volume reduction surgery improve chronotropic incompetence in chronic obstructive pulmonary disease (COPD) patients?

Henry Armstrong1, Matthew Bartels1, Byron Thomashow2, 1Clinic for Thoracic Surgery, 2Rehabilitation & Regenerative Medicine, Columbia University Medical Center, New York, NY, United States; 2Pulmonary, Allergy, Critical Care, Columbia University Medical Center, New York, NY, United States

Introduction: Chronotropic Incompetence (CI), or an attenuated heart rate (HR) response to exercise, has been widely established as a predictor of mortality in patients with COPD. LVRS is known to improve morbidity and survival in patients with COPD.

Objectives: We aimed to see if LVRS improves CI in patients with COPD by evaluating CI in maximal exercise testing before and after LVRS.

Methods: A retrospective chart review was performed on 82 patients who had undergone LVRS at Columbia University Medical Center (CUMC) between January 1998 to October 2009. There was a significant correlation between the bilateral preoperative heterogeneity index and the postoperative 6 MWD (r = 0.400, p = 0.028). Patients showing an improvement in 6 MWD (n=13) had significantly higher post-operative heterogeneity index as compared to the ones failing to show functional improvement in 6 MWD (r = 0.233 ± 0.28 vs. 2.25 ± 0.55, p = 0.025).

Conclusion: CI is very abnormal in patients with severe COPD before LVRS and is improved after surgery. This improvement is in agreement with the observed increase in exercise capacity and improvement in PFT. The mechanism of the improvement in CI is not clear, but may be related to the improvement in pulmonary mechanics seen after successful LVRS. Further investigation into the implications of this change in CI is needed.

P466
Ultrasound guided pleural aspiration and chest drain insertion – A prospective study

W.Y. Lee, S. Faruqi, J. Kastelik, R. Teoh. Respiratory Department, Castlehill Hospital, Cottingham, United Kingdom

Pleuritic aspiration and chest drain insertion are important procedures required in the management of pleural disease. Small bore chest drain insertion using the Seldinger technique is assumed to be safer and better tolerated. However, there is no data to support this and incidents of serious complications have been reported. As a result, the British Thoracic Society recommend thoracic ultrasound (TUS) for pleural procedures. Currently, TUS is commonly being used by respiratory physicians to identify a safe site for various interventional procedures. The aim of this study was to review the complications of ultrasound guided pleural aspiration and chest drain insertion.

Method: Data from TUS guided pleural aspirations and chest drains was collected prospectively. Complications and pain perceived by the patient was recorded on a 100mm Visual Analogue Scale (VAS, 0=no pain, 100=worst pain ever). There were 58 pleural procedures were performed: 34 (59%) pleural aspirations, 20 (34%) chest drains. 3 (5%) showed a small pleural effusion on TUS and were not suitable for a pleural procedure. Other than 1 patient having a vasovagal episode during the ultrasound procedure, there were no immediate and direct complications associated with the pleural aspirations and chest drain insertion. All chest drains inserted were 12F and all required one attempt. Mean VAS for pain during chest drain insertion was 20 (range 0–80).

Conclusion: Ultrasound guided pleural aspiration and chest drain insertion which may result in serious harm and even death is reduced by TUS guidance. TUS is commonly being used by respiratory physicians to identify a safe site for various interventional procedures. The aim of this study was to review the complications of ultrasound guided pleural aspiration and chest drain insertion.
74. Biomarkers of allergic inflammation

P467 Atopy is a risk factor for COPD symptoms: Results from the EUROSCOP study

Fatemi Fatahi1,2, Nick H.T. ten Hacken1, Claes-Göran Löfdahl3, Machteld N. Hylkema2, Wim Timens1, Dirkje S. Postma1, Judith M. Vonk4.

Department of Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 2Department of Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 3Department of Respiratory Medicine and Allergology, University Hospital, Department of Epidemiology and Statistics, University of Groningen, Groningen, Netherlands

Background: Pathogenesis of COPD is complex and remains poorly understood. EUROSCOP (European Respiratory Society Study on Chronic Obstructive Pulmonary Disease) showed that 18% of their COPD participants were atopic (Watson, L. et al. ERJ 2006; 28:311-8).

We investigated whether atopy affects symptoms and lung function in these COPD patients.

Methods: We included 843 male and 320 female smokers with mild to moderate COPD from EUROSCOP. Risk factors associated with the presence of atopy (positive phadiatop) as well as the association between atopy and symptoms, and atopy and lung function (FEV1 and FVC) were analysed using multiple regression models adjusted for confounders. Interactions between atopy and gender, age, and smoking were also investigated.

Results: Prevalence of atopy was higher in males than females (21% vs 10%, p<0.001). Male gender (OR: 2.20; 95% CI: 1.47-3.36), BMI (1.04; 1.00-1.08) and age (0.97; 0.95-0.99) were associated with atopy. Additionally atopy was associated with a higher prevalence of cough (1.71; 1.26-2.34) and phlegm production (1.50; 1.10-2.03) in the total population, and with waking up with chest tightness in females (2.69; 1.11-6.55), male: 0.84; 0.47-1.49, female vs male: 3.21; 1.12-9.25). There were no significant interactions between atopy and age or smoking with respect to symptoms. Atopy was not associated with lung function.

Conclusions: The present study for the first time shows that atopic COPD patients may more likely report respiratory symptoms than non-atopic COPD patients. However, atopy is not associated with lung function. Of interest, male gender, higher BMI and younger age are risk factors for atopy in COPD patients. Study was supported by AstraZeneca.

P468 Granulyme B expression in lung of fatal asthmatics

Yvonne Nussbaumer-Ochsner1, Luz Silva1, Annemarie van Schadewijk1, Marisa Dolhnikoff2, Thais Manaud1, Klaas Rabe1, Pieter Hiemstra1.

1Pulmonology, Leiden University Medical Center, Leiden, Netherlands; 2Pathology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil

Introduction: Granulymes are serine proteases mainly produced by CD8 and NK cells, and are involved in the pathogenesis of many inflammatory disorders. Granulyme B (GzmB) is released towards target cells and can also be released non-specifically and is of cleaving extracellular matrix (ECM) components contributing to ECM degradation and remodeling in chronic inflammation. Recent studies have also shown participation of GzmB in allergic inflammation, but there are no descriptions of the its expression in fatal asthma.

Methods: We studied large and small airways and lung parenchyma of 12 patients that died of fatal asthma (FA) and 8 controls (CTR). Using image analysis we measured the number of GzmB positive cells in the inner layer (IL), smooth muscle (SM) and outer layer (OL) of both large (LA) and small airways (SA) and in peribroncholar (PS) and distal (DS) alveolar septa. Values (median [IQR]) were expressed as GzmB+ cells/BS length (cells/mm) in OL and IL. GzmB+ cells/SM area (cells/mm2) in SM, and as GzmB+ cells/segmental length (cells/mm) in PS and DS.

Results: In LA we found a higher number of GzmB+ cells in IL [FA=12.9 (5.1), CTR=5.8 (3.1), p=0.002] and OL ([FA]=27.2 (9.3), CTR=7.5 (2.4), p=0.001) in FA, but no differences were observed in SM. In SA, the number of GzmB+ cells was also higher in IL [FA=8.3 (4.9), CTR=2.8 (2.1), p=0.03] and OL [FA=15.9 (10.24), CTR=0.9 (0.9), p=0.03] in FA, but no differences were observed in SM.

Conclusions: The results show that GzmB expression is increased in FA and may contribute to the previously described process of airway remodeling in these patients.

P469 Differences in responsiveness of blood neutrophils for IL-8 to identify two distinct groups of COPD patients

Vera Kamp1, Adèle Lo Tan Loi2, Nick ten Hacken3, Susan Hoornhors3, Jan Willem Lammers1, Leo Koenderman2,1, Respiratory Medicine, University Medical Center Utrecht, Utrecht, Netherlands; 2Respiratory Medicine, University Medical Center Groningen, Groningen, Netherlands

In COPD severity of disease is generally diagnosed by the GOLD guidelines. The GOLD stages, however, poorly correlate with disease progression. The extend of systemic inflammation in COPD patients plays a role in the progression of the disease. Therefore, the severity of the systemic inflammatory response of COPD patients was characterized by phenotype analysis. Two distinct groups of COPD patients were identified by phenotypic characteristics.

In COPD severity of disease is generally diagnosed by the GOLD guidelines. The GOLD stages, however, poorly correlate with disease progression. The extend of systemic inflammation in COPD patients plays a role in the progression of the disease. Therefore, the severity of the systemic inflammatory response of COPD patients was characterized by phenotype analysis. Two distinct groups of COPD patients were identified by phenotype analysis. In the study, expression of activation epitopes on neutrophils was analyzed by flow cytometry. Responsiveness for IL-8 was measured by analysis of cells in the presence or absence of IL-8.

Responsiveness of neutrophils for IL-8 was measured by the ratio of CD11b in the presence and absence of IL-8, identified two distinct COPD patient populations. Population 1 (55%) was comparable to the healthy smokers and phenotype II (45%), showed a significantly higher mean ratio of 17.74 ± 0.78 vs. 5.6±0.53, respectively. These two groups did not differ in FVC1, but a higher expression of CD11b was found in group 2 (p=0.001) in FA, but no differences were observed in SM.

Conclusions: The results show that GzmB expression is increased in FA and may contribute to the previously described process of airway remodeling in these patients.

P470 A decreased integrin Mac-1 (CD11b/CD18) induced respiratory burst in neutrophils of COPD patients

Adèle Lo Tan Loi1, Adeline Van Aalst, Deon Kanters, Laurien Ulfman, Jan-Willem Lammers1, Leo Koenderman2, Respiratory Medicine, University Medical Center Groningen, Groningen, Netherlands

Introduction: Neutrophils of COPD patients are characterized by changes in activation of the respiratory burst. The aim of this study was to investigate the control of the respiratory burst in neutrophils of COPD patients upon engagement by platelet-activating factor. The ROS production in neutrophils of COPD patients exhibited a primed phenotype in the context of IL-8. To our surprise
P471

IL-18 in infectious exacerbations of COPD

Nikolleta Rovina1, Efrosini Dimi1, Georgios Papadaki1, Theocharis Anagnostakos1, Charis Roussos1, Manos Alchanatis1, Nikolaos Kouloulis1. 11st Department of Pulmonary Medicine, "Sotiria" Hospital, Athens Medical School, Athens, Greece; 2Pulmonary and Critical Care Department, Evangelismos Hospital, Athens, Athens, Greece

The innate immune system is critical in recognizing bacterial and viral infections to evoke a proper immune response. IL-18, a pro-inflammatory and pro-apoptotic cytokine with crucial role in host defense against bacterial invasion is increased in lungs, serum and sputum of COPD patients, suggesting that IL-18 may be involved in chronic inflammation of COPD. We aimed to investigate the effect of infectious acute exacerbations of COPD (AECOPD) on IL-18 levels.

We examined 40 patients with COPD hospitalized for infectious AECOPD according to Athonson's criteria and 20 patients with stable COPD. We examined sputum for inflammation and for bacterial infection using PCR. IL-18 was measured in induced sputum and serum at baseline and after treatment of the exacerbation. Immunocytochemistry of IL-18 expression in sputum cells was performed using a monoclonal IL-18 antibody.

All patients had no previous hospitalization the preceding 3 months and none was diagnosed with pneumonia. IL-18 levels in sputum were found significantly lower in AECOPD compared to stable state (p=0.05), while right after treatment IL-18 levels were increased compared to stable state levels (p<0.05). Positive staining of IL-18 was observed in macrophages in immunocytochemistry. An inverse correlation was found between IL-18 levels and sputum macrophages in AECOPD (r=-0.30, p=0.026). Serum IL-18 levels were elevated in exacerbations (p<0.05) compared to stable state, and decreased after treatment to stable disease levels (p<0.05). Our data show that although IL-18 is involved in host defense against bacterial pathogens in infectious AECOPD there may be a dysregulated activation of airways' macrophages and perhaps inflammation mediated pathways.

P472

Serum and nasal lavage fluid Clara cell protein in children with allergic rhinitis

Tharwat E. Draz1, Terez B. Kamel1, Mahira I. El-Mogy1, Essam H. Mostafa1, 1Pediatrics, Faculty of Medicine, 2Clinical Pathology, Faculty of Medicine, Ain Shams University, Cairo, Abbasia, Egypt

Background: Allergic rhinitis is the most common chronic disorders of childhood with prevalence of up to 40% in children. Clara cell secretory protein (CCSP) is secreted by Clara cells in the lining fluid of airways. It has an immune-modulatory and anti-inflammatory activity.

Aim of work: Study aimed at evaluating Clara cell secretory protein as a pneumocyte biomarker in serum and nasal lavage fluid of children with allergic rhinitis.

Methods: A cross sectional case-control study was conducted on sera and nasal lavage fluid samples from 15 children with allergic rhinitis, recruited from Children’s hospital, Ain Shams University, and 15 healthy children as a control group.

Results: Children with allergic rhinitis had a male to female ratio 2 to 1, with a mean age of 9.47 ±2.28 years. Rhinitis and nasal obstruction were the most frequent symptoms (100%) followed by itching (93.3%) then sneezing (73.3%). Serum CCSP mean±SD was 2.03±0.59 ng/ml; it was reliable to predict allergic rhinitis (p<0.0001); while nasal lavage CCSP mean±SD was 12.73±8.25 ng/ml and it was not reliable to predict allergic rhinitis. The best cut-off value was 3.75 μg/l with a sensitivity of 100%, specificity 80%, with a diagnostic accuracy of 90%.

Conclusion: In conclusion, Clara cell secretory protein is a new peripheral sensitive marker of airway injury allowing researchers to evaluate the integrity of the air blood barrier. Furthermore, serum CCSP level is a non-invasive predictor of allergic rhinitis but not nasal lavage fluid CCSP.

P473

Elevated CEA levels in sera in patients with allergic bronchopulmonary aspergillosis (ABPA)

Hirotaka Matsuura1, Wazake Tanaka1, Yasuhiko Kojima1, Masaki Kawakami1, Masaru Suzuki1, Yoshio Sakamoto1, Tadashi Horiuchi2. 1Respiratory Medicine, Kanto Central Hospital, Tokyo, Japan; 2Internal Medicine, Okutama Hospital, Tokyo, Japan

Background: ABPA is an allergic disease associated with peripheral blood eosinophilia and elevated total IgE in serum. It sometimes accompanies with bronchiectasis filled with mucus plug detected by chest X-ray or CT films or fibrotic bronchoclasus. Mucus plug is not infrequently misdiagnosed as lung tumor. Carcinoembryonic antigen (CEA) is one of tumor markers and measured as a diagnostic as well as surrogate marker of bronchogenic carcinoma. It has been reported that some patients with ABPA demonstrated elevated CEA levels in their sera.

Aim: To evaluate clinical significance of serum CEA level in patients with ABPA.

Methods: Ten patients (6 women), aged from 39 to 78 (median; 67) with ABPA were evaluated. All patients were never smokers or ex-smokers. Serum CEA level, eosinophil number, total IgE, Aspergillus fumigatus (Af)-specific IgE- and precipitating antibodies were measured. Chest roentgenogram and or CT were examined when blood test was performed. For comparison, serum CEA levels were also evaluated in patients with bronchiectasis (n=20).

Results: Among 10 patients with ABPA, five demonstrated elevated serum CEA levels (6.2 – 140.0 ng/ml; normal range ≤ 5 ng/ml). Massive mucus plugs were demonstrated in four out of five patients on chest CT or X-ray films. Two out of five patients were treated with systemic glycerocorticosteroids resulting in the decrease in CEA levels. Another patient showed the decrease in CEA spontaneously in parallel with the decrease in eosinophil number.

Conclusion: Massive mucus plug may induce CEA synthesis from airway epithelial cells lining on the ecatasis.
P476
Is analysis of exhaled breath condensate equivalent to that of bronchoalveolar lavage fluid (BALF)?
Kumiko Nakamura1, Megumi Mikuniya1, Shingo Takanashi2, Akimitsu Hayashi1, Takeshi Morimoto1, Kageaki Taima1, Ken Okumura1

Background: Although the analysis of bronchoalveolar lavage fluid (BALF) is the most useful examination for the assessment of airway inflammatory markers, it is an invasive technique with limitations and risks for side effects.

Aims: The aim of this study was to examine the molecules included in exhaled breath condensate (EBC) in comparison with BALF, and to clarify the clinical usability of EBC.

Methods: EBC was collected from sixteen subjects suspected to have sarcoidosis just before BAL. The 40 different inflammatory molecules in EBC and BALF were analyzed with a protein array method.

Results: BALF levels of 6 inflammatory molecules including soluble tumor necrosis factor receptor type II (sTNF-R111) and regulated upon activation, normal T cell expressed and secreted (RANTES) were significantly correlated with the percentage of lymphocyte in BALF (%Lym). EBC levels of 13 inflammatory molecules including sTNF-R111 and RANTES were significantly correlated with %Lym. We found significant correlations between the levels of EBC and BALF in 16 out of 40 inflammatory molecules. Levels of macrophage colony-stimulating factor (M-CSF), RANTES, TNF-α, and sTNF-R111 in EBC were significantly correlated with those in BALF. Their levels in EBC were also significantly correlated with %Lym.

Conclusion: Highly sensitive approach to protein array in EBC allowed us to detect inflammatory molecules. Comprehensive analysis of EBC might be equivalent to that of BALF.

Results: Gal-1 and gal-3 mRNA levels in asthma patients (mean±SEM= 2.6±4.0, and 4.4±1.4, respectively) were lower than in healthy subjects (4.7±1.2, and 20.0±8.7). Gal-9 mRNA expression did not vary significantly between the two groups (3.2±1.3 vs 3±1.1). Asthma patients contained elevated mRNA levels of IL-5 and IL-13 (p<0.05).

Conclusions: The low levels of the negative regulator of galectins in human asthma may contribute to the inflammatory response present in this disease.

P478
Analysis of IgE and C-reactive protein as possible predictors of exacerbation patients with asthma
Besim Pnijavorac1, Adlija Cauševic2, Sabina Semiz2, Tanja Dujic2, Maja Malecina2, Ekrema Mujaric3, Tamer Bego1,1, Department of Lung Disease, General Hospital Tešanj, Tešanj, Bosnia and Herzegovina; 2Clinical Biochemistry, Faculty of Pharmacy, Sarajevo, Bosnia and Herzegovina; 3Internal Medicine, Cantonal Hospital, Zenica, Bosnia and Herzegovina

Aim: To study correlation of IgE level and C-reactive protein (CRP) for exacerbation of the disease in asthmatic patients.

Methods: Asthmatic subject were examined for achieving of asthma control according to GINA recommendation. Numbers of exacerbation of asthma during one month were analyzed. The patients were followed in six month period (since first January to 30th of Jun. Average monthly days of exacerbations was calculated. IgE level in the blood was measured using Enzyme-linked Immunoassay (ELISA), and CRP was measured by immunoturbidimetry. Assessment of asthma control was considered using Asthma Quality of Life Questionnaire (AQLQ).

Results: The study includes 63 patients with asthma. Average level of IgE was 674 IU/mL (SD 167), range 56-3785 IU/mL, 1 IU=3.2 ng; average level of CRP was 16.4 mg/mL (SD 6.3), range 5-48; Average number of days in exacerbation during one month was 3.6 (SD 2.4), and varied from zero, patients with no exacerbation, to 21. Using test of multiple correlation it was shown statistical significant correlation (level p<0.05) between IgE and CRP from one side, and number of days with exacerbation from the other. Patients with higher level of CRP were most likely to have exacerbation, than those with higher level of IgE. AQLQ was worse in those with higher level of CRP, than in those with higher level of IgE.

Conclusion: In this study CRP was shown as stronger predictor of asthma exacerbation and worse quality of life than total IgE level in asthmatic subjects.

P479
Structure-function relationship between extracellular matrix in airway smooth muscle and dynamics of lung function in asthma
C.Y. Yick1, D.S. Ferreira2, R. Annoni2, P.W. Kunst1, E.H. Bell1, R. Lutter1, T. Mauad1, P.J. Sterk1, 1Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands; 2Pathology, São Paulo University Medical School, São Paulo, Brazil

Rationale: Asthma is characterized by an increased deposition of extracellular matrix (ECM) within the airway smooth muscle (ASM) [Panettieri 2008, Araujo 2008]. We hypothesized that ECM composition within ASM is associated with the dynamics of lung function.

Aim: To investigate the fractional areas of collagen I and III within ASM, and their association with spirometry and respiratory resistance Rrs and reactance Xrs in asthmatics and controls.

Methods: Atopic mild asthmatics (n=10, no ICS) and controls (n=17) were included in this cross-sectional study. Spirometry, PC20, Rrs and Xrs (forced oscillation technique during tidal breathing and deep inspiration) were measured. Parafilm sections from bronchial biopsies were stained for collagen I and III by immunohistochemistry, and fractional areas were obtained by image analysis. Results: There was no difference in fractional areas collagen I and III within ASM between asthmatics and controls (p<0.05). However, ASM collagen III was correlated with the change in Rrs after deep inspiration in asthmatics (p=0.74, and 0.05).

Figure 1
Symptoms of hyperresponsiveness (AHR) in young allergic subjects without respiratory symptoms

Background: The fraction of nitric oxide in exhaled air (FeNO) is increased in allergic asthma and the degree of IgE sensitisation to aeroallergens relates to FeNO levels. Local IgE-mediated sensitisation to food allergens is known to increase asthma risk, but the relation between IgE sensitisation to food allergens and FeNO has been little studied previously.

Aim: To investigate in an ongoing asthma study if the presence of food allergy influences the levels of exhaled NO and which food allergens appear to be important.

Methods: Within the frame of an industry-academy collaboration on minimally-invasive diagnostics (MIDAS), measurements of FeNO and specific IgE (sIgE) against the allergens included in ImmunoCAP Phadiatop and f5 (Phadia Allergy, Sweden) were done in 170 patients with physician-diagnosed asthma.

Results: Asthmatic subjects with IgE sensitisation to both Aero- and food allergens (n=21) had higher PC20 levels than subjects sensitised only to aeroallergens (n=93) (21.2 ppb (18.4, 24.4) vs 15.6 ppb (13.2, 18.6), p=0.006). This difference was confirmed (p=0.03) in a multiple linear regression model after adjustments for sex, height, lung function and age. The sIgE levels to aeroallergens were higher in subjects also sensitised to food allergens (p>0.05). Peanut sensitisation was more common (63/77 subjects) and peanut FeNO levels were independently associated with increased FeNO, even after adjustment for the sum of sIgE to aeroallergens.

Conclusion: peanut sensitisation was independently associated with increased airways inflammation in allergic asthma. A possible mechanism might be a further enhanced Th2 cytokine-driven inflammation related to peanut IgE sensitisation.

P482 ADRB2, ADAM33 and AAT gene polymorphisms and IgE-mediated asthma in Russian patients

Elena Dmitrieva-Zdorova1, Marina Gabueva1, Elena Latysheva1, Olga Vornok1, 1Laboratory of Chemical Genomics, Institute of Biomedical Chemistry, Moscow, Russian Federation

Background: Asthma is complex disease which pathogenesis is a mix of environmental and genetic factors. A predisposition of airways to bronchoconstriction is of great interest in asthma genetics. The aim of our study was to evaluate an effect of polymorphisms ADRB2 G16Gly and Glu27Gln in beta-2-adrenergic receptor (ADRB2) gene, Glu26Val and Gln42Ile in alpha-1-antitrypsin (AAAT) gene and 5'4 in a distinserin and metalloprotease domain 33 (ADAM33) gene in predisposition to IgE-mediated asthma in Russian patients from Moscow.

Methods: 230 patients with IgE-mediated asthma and 214 healthy individuals were examined. The genotyping was performed by MALDI-TOF mass spectrometry.

Results: Allele G of ADRB2 G16Gly and allele C of Glu27Gln (both markers in ADRB2 gene) showed strong association with atopic bronchial asthma (OR = 2.51 and 1.46, respectively, p<0.05). Allele A of ADRB2 G16Gly and allele G of Glu27Gln of that gene was found to have protective effect (OR = 0.76 and 0.69, respectively, p<0.05). Additionally one of haplotypes of ADRB2 gene (A-G) also was associated with protection from asthma development (OR = 0.43, p=0.008). No association was detected between other studied SNPs and development of asthma.

Conclusion: Our results suggest that ADRB2 G16Gly and Glu27Gln polymorphisms in ADRB2 gene strongly contribute to predisposition to IgE-mediated asthma. Probably ADRB2 and AAT gene are not directly involved in predisposition to asthma and those genes possibly realize their effects when asthma is already developed.

P490 Peutant sensitisation is independently associated with increased airways inflammation in allergic asthma

Andrei Malinovschi1, Christor Janson3, Pia Kalm-Stephens2, Katarina Nisser2, Lennart Nordvall3, Kjell Alving3, 1Dept. of Medical Sciences: Clinical Physiology, Uppsala University, Uppsala, Sweden; 2Dept. of Medical Sciences: Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; 3Dept. of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden

Background: In vivo fraction of nitric oxide in exhaled air (FeNO) is increased in allergic asthma and the degree of IgE sensitisation to aeroallergens is known to increase asthma risk, but the relation between IgE sensitisation and food allergens and FeNO has been little studied previously.

Aim: To investigate in an ongoing asthma study if the presence of food allergy influences the levels of exhaled NO and which food allergens appear to be important.

Methods: Within the frame of an industry-academy collaboration on minimally-invasive diagnostics (MIDAS), measurements of FeNO and specific IgE (sIgE) against the allergens included in ImmunoCAP Phadiatop and f5 (Phadia Allergy, Sweden) were done in 170 patients with physician-diagnosed asthma.

Results: Asthmatic subjects with IgE sensitisation to both Aero- and food allergens (n=21) had higher PC20 levels than subjects sensitised only to aeroallergens (n=93) (21.2 ppb (18.4, 24.4) vs 15.6 ppb (13.2, 18.6), p=0.006). This difference was confirmed (p=0.03) in a multiple linear regression model after adjustments for sex, height, lung function and age. P483 Different treatment courses with inhaled corticosteroids for eosinophilic bronchitis

Danyuan Xu, Kefang Lai, Jiaxing Xie, Wei Luo, Nanhan Zhong, State Key Laboratory of Respiratory Disease, Guangzhou Institute of Respiratory Disease, Guangzhou, Guangdong, China

Background: Eosinophilic bronchitis (EB) is a common cause of chronic cough. Inhaled corticosteroids can improve sputum eosinophilia and cough severity. However, the course of treatment with inhaled corticosteroids for EB is unknown.

Objective: To observe the efficacy and recurrence in EB patients with different treatment courses of inhaled corticosteroids.

Methods: 60 patients diagnosed as EB were randomly divided into three groups with inhaled budesonide 200 μg twice daily via a turboliner for 4 weeks, 8 weeks and 16 weeks respectively. Cough severity was assessed by visual analogue scale (VAS) and daytime cough symptom score at baseline and during the treatment period. Airway inflammation was assessed by sputum eosinophil count (Eos%). All the patients were followed up for 6 months after treatment.

Results: The daytime cough score after treatment decreased in all three group (p<0.05), which was lower in 16 weeks group and 8 weeks group than 4 weeks group (p<0.05). The rate of VAS decreased over 80% after treatment were 55% in 4 weeks group, lower than 8 weeks, 16 weeks group (85%, 95%, p<0.05). The sputum eosinophilic count decreased in all three group after treatment. The rate that sputum eosinophilic count returned to normal level (Eos%<25%) was 8 weeks group (75%), 16 weeks group (95%) were significantly higher than 4 weeks group (50%, p<0.05). The rate of recurrence was 31.3%, 25.5%, 27.8% in 4, 8, 16 weeks group respectively. There are no significant difference among three groups.

Conclusion: Our results suggest that eosinophilic bronchitis should be treated with low-dose inhaled budesonide for over 8 weeks. Recurrence appear not to be related to treatment course.

P484 Impact on objective cough severity by continuous positive airway pressure (CPAP) in subjects with chronic cough and obstructive sleep apnoea – A randomized controlled trial

Kevin Chan1, Gavin Cossa2, Leon Laks2, Surinder Biring1, Alvin Bing1, 1Respiratory Medicine, Campbelltown Hospital, University of Western Sydney, Campbelltown, New South Wales, Australia; 2Thoracic Medicine, Concord Repatriation General Hospital, University of Sydney, Sydney, New South Wales, Australia; 3Respiratory Medicine, King’s College Hospital, London, United Kingdom

Recent studies have suggested chronic cough is prevalent in patients with sleep-disordered breathing (SDB). We investigated the effect of continuous positive airway pressure (CPAP) on cough in patients with obstructive sleep apnoea (OSA) and chronic cough in a randomized controlled trial. 11 consecutive patients with OSA confirmed on polysomnography (respiratory disturbance index (RDI) >15/hour) and chronic cough >2 months were recruited. All patients underwent a CPAP titration study. 1 patient did not tolerate CPAP. 10 Patients were randomized to receive sham CPAP (4 cm H2O) or CPAP at pressures determined by the titration study for 1 month. The primary outcome was objective 24-hour cough count via the Leicester Cough Monitor (LCM). Among 5 (males) patients received sham CPAP and 3 (males) received titrated CPAP. There were no significant differences between groups (mean (SD)) in age (56.3 ± 7.8 years) vs (50.7 ± 10.1 years, p>0.05). In the CPAP group, cough severity was improved in all three group, but it did not significantly differ from sham CPAP group.

Conclusion: Continuous positive airway pressure (CPAP) in subjects with chronic cough and obstructive sleep apnoea improves cough severity.
Results: A total of 53 patients was identified. Average age was 59 years. 35 (66%) were females. 34 (64%) presented with dry cough. 34 (64%) of patients had 2 or more symptoms. 95% of patients had a cause identified by investigations or by a trial of therapy. 45 (85%) had a single aetiology whilst 15% had at least two. 12 (22%) patients had asthma, 9 (16%) reflux, 10 (18%) bronchiectasis, 7 (13%) rhinitis, 6 (11%) sinusitis, 3 (5%) lower respiratory tract infection and 5 (9%) had other diagnoses. Eight (15%) had their symptom completely cured. 17 (32%) had their symptoms controlled of which 15 (88%) were discharged. 28 (52%) of patients were still symptomatic.

Conclusion: The study showed asthma was still the commonest aetiology however this was not as high as seen in other studies. Instead a sizable number of patients had more than one aetiology. Using current diagnostic criteria, early request of HRCT scans in the diagnostic workup of patients with chronic cough is thus recommended.

P485

Outcome of chronic cough referrals seen in general respiratory clinic
Kabali Nandakumar, Kesavaperumal Vijayasarthar. Respiratory Department, Queens Hospital, Burton-on-Trent, Staffordshire, United Kingdom

Aim: Chronic cough is a common symptom for which patients seek medical consultation. Identifying the cause and alleviating their symptoms is a real challenge. In this study we aimed to find the outcome of such patients attending our centre.

Method: This is a retrospective study of patients who were referred with chronic cough to the respiratory clinic between June 09 till June10. Clinical information was obtained from electronic records.

Results: A total of 53 patients was identified. Average age was 59 years. 35 (66%) were females. 34 (64%) presented with dry cough. 34 (64%) of patients were non-smokers. 95% of patients had a cause identified by investigations or by a trial of therapy. 45 (85%) had a single aetiology whilst 15% had at least two. 12 (22%) patients had asthma, 9 (16%) reflux, 10 (18%) bronchiectasis, 7 (13%) rhinitis, 6 (11%) sinusitis, 3 (5%) lower respiratory tract infection and 5 (9%) had other diagnoses. Eight (15%) had their symptom completely cured. 17 (32%) had their symptoms controlled of which 15 (88%) were discharged. 28 (52%) of patients were still symptomatic.

Conclusion: The study showed asthma was still the commonest aetiology however this was not as high as seen in other studies. Instead a sizable number of patients had more than one aetiology. Using current diagnostic criteria, early request of HRCT scans in the diagnostic workup of patients with chronic cough is thus recommended.

P486

Accuracy of inhaler and nebulizer prescribing in hospitalized patients
Hilal Eren, Rabah Shrestaker, Nicholas Winyard, Karen Thompson, Ben Lenehan. Respiratory Medicine, Royal Devon and Exeter Hospital, Exeter, Devon, United Kingdom

Introduction: There are a considerable variety of inhaler devices available. It is important that these are prescribed correctly when a patient is admitted to hospital as incorrect prescribing may have an adverse effect on patient recovery and length of stay. We have investigated the accuracy of inhaler prescribing on the respiratory ward in our hospital.

Methods: All admissions into the respiratory wards (total no of beds =57) between March to May 2010 were included (total 83). All case notes were retrieved and wards in our hospital.

Results: Of stay. We have investigated the accuracy of inhaler prescribing on the respiratory
department. A total of 53 patients was identified. Average age was 59 years. 35 (66%) were females. 34 (64%) presented with dry cough. 34 (64%) of patients were non-smokers. 95% of patients had a cause identified by investigations or by a trial of therapy. 45 (85%) had a single aetiology whilst 15% had at least two. 12 (22%) patients had asthma, 9 (16%) reflux, 10 (18%) bronchiectasis, 7 (13%) rhinitis, 6 (11%) sinusitis, 3 (5%) lower respiratory tract infection and 5 (9%) had other diagnoses. Eight (15%) had their symptom completely cured. 17 (32%) had their symptoms controlled of which 15 (88%) were discharged. 28 (52%) of patients were still symptomatic.

Conclusion: The study showed asthma was still the commonest aetiology however this was not as high as seen in other studies. Instead a sizable number of patients had more than one aetiology. Using current diagnostic criteria, early request of HRCT scans in the diagnostic workup of patients with chronic cough is thus recommended.

P487

Long term efficacy of war related bronchiolitis obliterans treatment
Hamidreza Atefi1, Soheil Fesman1, Maryamossadat Moeniзадeh Tehrani2, 1Pulmonary and Critical Care Department, Imam Khomeini Medical Center; Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; 2Pulmonary and Critical Care Department, Loghman Hospital, Shahid Behshiri University of Medical Sciences, Tehran, Islamic Republic of Iran

Introduction: There is few data about war related bronchiolitis obliterans (BO) treatment. We compared FVC and FEV1 changes during BO treatment in comparison to non bronchiolitis obstructive pulmonary disease in a cohort of chemical victims.

Materials and methods: Seventy two iranian veterans, with chronic pulmonary disease were followed from September 2005 to December 2010. All of them had documented exposure to Sulfur Mustard gas from 1982 to 1988. The bronchiolitis group (diagnosed based on HRCT and/or biopsy) was treated with inhaled Seretide (500-1000 μg/day), Azithromycin (500 mg3 times per week) and N-acetylcysteine (1200-1800/day). The non bronchiolitis patients were treated according to GINA and GOLD guidelines.

Results: 16 patients had BO and 36 had non bronchiolitis obstructive pulmonary disease.

The baseline FVC and FEV1 were not different between bronchiolitis and non bronchiolitis groups. Mean FVC and FEV1 has decreased significantly during the 5 years followup despite standard treatments in all patients (baseline FVC=3.50±0.78 L, Final FVC=3.21±0.75 L; P=0.001) and (baseline FEV1=2.77±0.80 L, Final FEV1=2.47±0.77 L; P<0.001). The FVC and FEV1 changes in bronchiolitis group were -0.30±0.18L and -0.15±0.521 L respectively. This was not significantly different from FVC and FEV1 changes in non bronchiolitis group (0.29±0.58L and 0.34±0.62 L respectively).

Discussion: The five year spirometric parametric changes were not different between bronchiolitis and non bronchiolitis group in usert saline gas victims. This finding suggests the long term efficacy of treatment with inhaled steroid, macrolide and N-acetylcysteine in war related bronchiolitis obliterans.

P488

Lung function disturbances and BAL IL-6 in adult patients with sickle cell disease in Bahrain
Adel Salah Bedwy1, Nashwa Noor1, Mohamed A. Hasenain1, 1Chest Department, Faculty of Medicine, Tanta University, Tanta, Tanta, Garhia, Egypt; 2Internal Medicine Department, Faculty of Medicine, Tanta University, Tanta, Garhia, Egypt; 3Biochemistry Department, Faculty of Medicine, Tanta University, Tanta, Garhia, Egypt

Sickle cell disease (SCD) is a common genetic disorder of hemoglobin in Bahrain with a lot of pulmonary complications either acute or chronic including its effect on pulmonary function tests (PFT). IL-6 is an inflammatory cytokine that was found to be high in severe SCD patients.

Objective: To study PFT and evaluate BAL IL-6 level in adult Bahraini patients with SCD and to correlate PFT values with BAL IL-6 and the recurrent occurrence of acute chest syndrome (ACS).

Methods: Study was done on 120 subjects (2 groups): group 1 (20 healthy controls) and group 2 (100 adult Bahraini SCD patients during steady state). PFT were done to all subjects. BAL was done to 20 SCD patients and 5 control subjects to evaluate the BAL IL-6.

Results: PFT was abnormal in 85% of SCD patients with restrictive pattern (60%), isolated low DLCO (17%), obstructive pattern (5%) and mixed obstructive and restrictive pattern (3%). BAL IL-6 was higher in SCD patients than in controls. In SCD patients, BAL IL-6 level had significant negative correlations with both FEV1, FVC, DLCO, and PaO2, with no significant correlation with TLC. There were significant positive correlations between BAL IL-6 and both age and number of ACS. There were significant negative correlations between ACS number and both FEV1, TLC and DLCO.

Conclusion: Abnormal PFT in adult Bahraini SCD patients was correlated to BAL IL-6 and number of ACS indicating that impaired lung functions in this category of patients is caused by repeated vascular occlusion and increased airway inflammation.

P489

Caspase activity in patients with chronic refractory unexplained cough
Ewa Teresten Hasselius, Eva Miltqvist. Department of Internal Medicine/Respiratory Medicine and Allergology, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Background: When known causes for cough are excluded there still remains a category of patients is caused by repeated vascular occlusion and increased airway inflammation.
a group of patients with persistent coughing. They can be described as having chronic refractory unexplained cough. Sensory hyperreactivity (SHR) is one suggested explanation to cough and other airway symptoms induced by chemicals and scents. The patients can be identified using a capsaicin inhalation test.

The aim was to analyze capsaicin sensitivity in a group of patients with chronic refractory unexplained cough. Further we wanted to evaluate a cough specific questionnaire.

**Method:** From an earlier cross sectional study in patients with chronic cough, 41 patients without chemical sensitivity (non sensitive group) and 35 patients with chemical sensitivity (sensitive group) were involved. The participants underwent a capsaicin inhalation test, and answered the Swedish version of Hull Airway Questionnaire (HARQ). A cut off limit of \( \leq 13 \) score has been suggested as normal.

**Results:** 15 patients in the non sensitive group and 30 in the sensitive group participated. The reason for not participating was in the non sensitive group: recovery (n=19), would not (n=2) and in the sensitive problem: to be away from work (n=5). Capsaicin induced significantly more cough and other airway symptoms in the sensitive group compared to the non sensitive group (p < 0.05).

Mean total HARQ score was 18 in both groups. Conclusion: Chemically induced airway symptoms in chronic refractory unexplained cough, seems to be a prognostic factor that can cause prolonged symptoms. SHR is a possible explanation for this sub-group of cough patients. The HARQ questionnaire has a good ability to identify patients who for various reasons have chronic cough.

**P490**

**Introduction and aim:** Clinical pulmonary infection score (CPS) is a scoring system calculated by symptoms and signs of pneumonia, that is used in the diagnosis and management of hospital acquired pneumonia (HAP). In this study, the comparison of CPS for diagnosis of HAP was investigated in intensive care unit (ICU) patients.

**Methods:** The ICU patients followed-up between February 2008 and September 2010 were assessed retrospectively. Hospital acquired pneumonia was diagnosed by quantitative endotracheal aspirate (ETA). CPS was calculated on 3rd and 7th days of ICU admission. The correlations of CPS with concurrent ETA cultures and laboratory markers of infection were assessed.

**Results:** Out of 240 patients (165 men, mean age 58.2±16.6 yrs) included in the study, ETA cultures were positive in 61 patients (25.4%) on 3rd day, and in 59 patients (24.6%) on 7th day. CPS was found higher in patients with ETA culture positive (5.6±2.3 vs. 3.5±2.1 on 3rd day, p<0.0001; 2.6±2.6 vs. 6.6±2.9 on 7th day, p<0.0001). Sensitivity and specificity ratios of CPS with a threshold level of 6.5 in diagnosis of HAP were 26.2% and 92.3% for 3rd day; 30.5% and 91.9% for 7th day. There was a positive correlation between CPS and C-reactive protein (CRP) levels (p=0.002 and p=0.001, respectively)

**Conclusion:** Clinical pulmonary infection score can be used instead of infection markers like CRP and PCT in the diagnosis of hospital acquired pneumonia.

**P491**

**Implementing a community acquired pneumonia care bundle in the acute hospital setting**

Essam Ramhamadany, Sandra Wilson, Philip Eardley, Jasmin Cheema, Joel Johnson, Kamel Dokhia, May Kay, Ron Grant, Majed Shamat, Eamon Ramhamadany, Bobby Mann, Zul Mira. A&E and Respiratory Department, West Middlesbrough University Hospital, Middlesbrough, Middlesbrough, United Kingdom

**Objective:** The aims are to reliably deliver clinically effective and timely treatment in the management of CAP (community Acquired Pneumonia), to reduce overall variations in care, and to improve the quality of patient care and outcomes.

**Methods:** Using Improvement Methodology techniques the project team: Conducted a base line audit, mapped out current patient journey, arranged education sessions for relevant staff members, used a locally customised CAP bundle pack, and used the PDSA Cycle and the sustainability tools.

A multi professional group, including patient representative, used a bespoke reporting tool to record weekly measures of bundle compliance. Non compliance was disseminated to the team for response and feedback. Project team meetings were held weekly, this gave the opportunity for all to monitor progress.

**Results:** A base line audit of 50 patients was compared with 200 patients in the CAP Care Bundle, over 18 months. There was an improvement in providing written information to patients from 0 to 88%; documenting the CURB-65 CAP severity score 32% to 94%; oxygen correctly prescribed 78% to 88%; timely administration of antibiotics within 4 hours of arrival to hospital from 54% to 88%, and antibiotic following BTS guidelines from 48% to 87%.

**Implications:** Implementing a Care Bundle Pathway can improve patient care, but a high degree of perseverance is required to implement changes and sustain improvements. The success cannot be dependant on only a few champions but needs to have support from the organisation at all levels.

The project was funded and supported by NW London CLAHRC.

**Evaluating the efficiency of complex treatment of influenza A (H1N1) in hospital conditions**

Olga Titoiva1, Dmitri Larin1, Vladimir Volchikov1,2. 1Therapeutic Pulmonology, Institute of Pulmonology of I.P.Pavlov State Medical University, St. Petersburg, Russian Federation; 2Therapeutic Pulmonology, Hospital No. 32, St. Petersburg, Russian Federation

**Aim:** To study the efficiency of oseltamivir depending on the time of its administration to patients with typed A (H1N1) and non-typed influenza.

**Methods:** The prospective evaluation of disease severity, frequency of complications and mortality in hospital patients with influenza has been executed. 720 patients with suspicion on a virus infection were surveyed. From them at 373 patients the influenza A (H1N1) was typed by RT-PCR test. Shortness of breath was assessed by MRC scale, severity of patient state was estimated by scale APACHE II. Patients underwent x-rays, laboratory tests, spirometry and diffusion capacity of the lungs.

**Results:** At oseltamivir administration after 48 hours from the disease beginning efficiency of therapy decreased and frequency of complications increased. The severe course of influenza on APACHE II scale was accompanied by an increase in mortality (p<0.05). The disease progressed worsened with an increase of dyspnea at normalization of temperature (p<0.019). The negative impact of obesity and diabetes on the disease course (p<0.004) was revealed.

**Conclusion:** The administration of oseltamivir later than 48 hours from onset of illness, severe state of patients on a scale of APACHE II, the increase of dyspnea after decrease of temperature, obesity and diabetes mellitus are risk factors for complications and adverse outcome of influenza A (H1N1).

**P493**

**Prediction of complications development and lethal outcome in patients with community-acquired pneumonia**

Victoria P. Kolosov1, Ekaterina Yu Kochevragova1, Svetlana V. Naryshkina2.

1Laboratory of Prophylaxis of Nonspecific Lung Diseases, Far Eastern Scientific Center of Pulmonology and Pathology of Respiration SB RAMS; Blagoveschensk, Russian Federation; 2Department of Therapy, Amur State Medical Academy, Blagoveschensk, Russian Federation

**Background:** The prediction of community-acquired pneumonia (CAP) complications development may provide effective prophylaxis and prevent the lethal outcome.

**Aim:** The improvement of prophylaxis of CAP complications development and lethal outcome on the basis of prediction by inflammation markers.

**Methods:** 70 patients with CAP of different severity were examined. When the patient got into hospital his blood serum was tested on the level of procalcitonin (PCT) by immunochromatographic assay. Cytokines IL-2, IL-6 and TNF-α and also C-reactive protein (CRP) were identified by immune-enzyme assay.

**Results:** The level of CRP grew alongside with the severity of CAP, the highest after was 131.5±7.6 mg/l in severe stage (p<0.019). The highest level in patients with complicated clinical course, the highest one was 155.3±44.7 mg/l (p<0.01) at the lethal outcome. The levels of cytokines in patients with developed complications were 2.5 times higher than in the patients without complications. A higher level of PCT was found in patients with complicated CAP (2,36±0,20 ng/ml, p<0.01) in comparison with uncomplicated one. At the lethal outcome the level of PCT was significantly higher (3,67±0,33 ng/ml). To predict the complications development the discriminant equation was derived: D= +3,611 PCT-0,035 CRP +2,281 IL-2 +0,076 IL-6+2,335 TNF-α. If D is more than or equals 15,60, the development of complications is predicted with the probability of 90.1%.

**Conclusions:** The level of PCT, IL-2, IL-6, TNF-α, CRP increases proportionally to severity of CAP. With the help of the proposed equation it is possible to predict the development of complications from the first day of patient getting into hospital.

**P494**

**Findings in peripheral biopsy muscle in severe pneumonia due to H1N1 influenza**

Maria Eugenia Dominguez Flores1, Monica Velazquez1, Rafael J. Hernandez-Zenteno2, Franciscas Fernandez Valverde3, Steven Vargas Cañas4.

1Laboratory of Prophylaxis of Nonspecific Lung Diseases, Far Eastern Scientific Center of Pulmonology and Pathology of Respiration SB RAMS; Blagoveschensk, Russian Federation; 2Department of Therapy, Amur State Medical Academy, Blagoveschensk, Russian Federation

**Rationale:** Myalgia and weakness are complications in H1N1 Influenza severe course, Myopathy and polyneuropathy has been described only in Influenza B. Muscle damage in H1N1 ISP, has not been studied yet.
Objective: To evaluate physiological, morphological and metabolic characteristics in muscle biopsies from patients with severe muscular weakness after a H1N1 ISP

Case report: After signed consent form 14 subjects with H1N1 ISP and muscular weakness were enrolled. Bilateral muscular strength (biceps and quadriceps) measured by electronic manometer and electromyography and muscle biopsy (3-5 days after extubation) were performed.

M = male, F = female, CK = creatin kinase, APACHE II = Acute Physiology and Chronic Health Evaluation, MV = mechanical ventilation, S = percent predicted average of 4 muscles, EMG = electromyography, SMP = sensoriotor motor polymyelopathy, M. pneumoniae = mixed pattern myopathy and neuropathy, M = myopathy (metabolic).

Conclusions: All patients with H1N1 ISP presented metabolic and physiological muscular alterations compatible with myopathy or myopathy/neuropathy. This findings explain the severe muscle symptoms and the low recovering even after discharge. An early physical rehabilitation program must be recommended.

Bacterial profile, antibiotic sensitivity and resistance of lower respiratory tract infections in upper Egypt

Shereif Mohamed1, Gamal Aygmy1, Yaser Gad1, Esam Farghally3, Hamdy Mohammedin1, Hebbah Rashad1.

Chest Diseases, Faculty of Medicine, Assiut University, Assiut, Egypt.

Chest Diseases, Faculty of Medicine, El-Minia University, El-Minia, Egypt.

Chest Diseases, Faculty of Medicine, Sohag University, Sohag, Egypt.

Clinical Pathology, Faculty of Medicine, Assiut University, Assiut, Egypt

Purpose: To identify causative bacteria, antibiotic sensitivity/resistance of lower respiratory tract infections (LRTIs) in Upper Egypt.

Methods: A multicentre prospective study was performed. Sampling was done for all patients including, sputum and/or BAL for Gram stain and culture. Samples were cultured on 3 media (Nurtient,Chocolat and M-Aconkey's) until Fluorescent Antibody was used to detect atypical pathogens.

Results: Predominant isolates in patients with CAP were S. pneumoniae (36%), C. pneumonia (18%), M. pneumoniae (12%) and K. pneumoniae (10%). A higher sensitivity was recorded for moxiﬂoxacin, levofloxacin, macrolides, and cepﬁclozine. A higher rate of resistance was recorded for tetracyclines, cephalosporins, lincomma, and β-lactam-β-lactamase inhibitor. Predominant isolates in patients with HAP were, MRSA (23%), K. pneumoniae (14%), E. coli (11%), PaeCREATINOSA (9%). A higher resistance was recorded for vancomycin,amikacin, and respirato- ry quinolones. An absolute resistance was recorded for β-lactam-β-lactamase inhibitor, high rates were recorded for cephalosporins. Predominant isolates in patients with AECOPD were H.influenza (30%), S. pneumoniae (25%), M. catarrhalis (18%), K. pneumoniae (12%) and C. pneumoniae (5%). A higher sensitivity was recorded for amikacin,clindamycin, and cephalosporins.

Conclusion: The most predominant bacteria for CAP in Upper Egypt are S. pneumoniae and atypical organisms, while that for HAP are MRSA and Gram negative bacteria. For AECOPD, H.influenza is the commonest. Respiratory quinolones, linezolid, and cepﬁclozine are the most efﬁcient antibiotics in treating LRTIs in our locality.

Severe flu associated respiratory infections remain actual.

Aim: To evaluate the prognostic model of outcome of severe viral-bacterial community acquired pneumonia (VBCAP) during flu H1N1 pandemic based on hospital admission data.

Materials: 84 patients (43 survivors and 41 non-survivors) admitted with VBCAP in hospitals of Bashkortostan region between November and December 2009 were included in the retrospective study. The endpoint was defined as hospital mortality.

Methods and results: Initially 16 demography, history, functional and laboratory variables were obtained from hospital admission records. In the univariate ROC analysis, 5 variables were correlated with poor outcome of VBCAP.

Cutoffs were used to transfer continuous variables to dichotomous ones. Multivari- ate stepwise logistic regression analysis identified SpO2% and white blood cell count as independent predictive factors at p < 0.05.

Logistic regression equation:

logit P = 3.49 + SpO2% - 0.90 - 2.24 x WBC -6.9 x 10^9/l - 1.76, where P = poor outcome probability. Correct classification rate was 82.8%.

Conclusion: Acute respiratory failure and diminished immune response are the most powerful independent prognostic factors of poor outcome of viral-bacterial pneumonia during flu H1N1 pandemic.

P497

Comparison of telomerase activity in malignant and benign pleural effusions

Rasoul Bahari. Pulmonary Medicine, IUMS, Tehran, Islamic Republic of Iran.

Background: Despite advances in diagnosis and treatment of lung cancer, patients survival has just improved in those with early stages. Telomerase is a tumor marker that has been focused recently as a novel tool for early diagnosis of lung cancer.

Objective: To compare telomerase activity in malignant and benign pleural effusions in Rasoul-e-Akram Hospital of Tehran.

Methods & materials: Telomerase activity in 28 consecutive pleural effusions (19 malignant and 9 benign; histopathologic diagnosis) assessed with telomeric repeat amplification protocol (TRAP) between Apr. 2006 and Sep. 2007. Data analysis was performed by chi-squared test and t-test; results expressed as frequency, percent, and mean ± SD.

Results: 20 cases (71.4%) from the total of 28 pleural effusions were positive for telomerase activity. Telomerase activity was positive in all 19 malignant effusions, while only one effusions from benign conditions (TB) had telomerase activity (P = 0.0001). Sensitivity, specificity and diagnostic accuracy of telomerase activity for detecting malignant pleural effusions were 100%, 88.9% and 96.4% respectively. Mean telomerase relative activity in malignant and benign effusions was not significantly different (24 ± 5.2% vs. 15.05%; P = 0.05).

Conclusion: Telomerase activity is a highly sensitive and specific diagnostic biomarker for malignancy and may be used as an adjunct to other diagnostic tools such as cytological findings for malignant pleural effusions.

P498

Evaluation of the utility of using pleural fluid cholesterol as a new criterion for the differential diagnosis between transudates and exudates

Kostas Kosmidis, Stefanos Pataiakas. General Hospital of Kastoria, Microbiological Laboratory and Respiratory Department of General Hospital of Kastoria, Kastoria, Greece.

Objective: To study two alternative criteria to differentiate between exudates and transudates: a) pleural fluid cholesterol and b) the ratio of pleural fluid cholesterol to serum cholesterol in order to compare their diagnostic value with the widely accepted and used Light’s criteria.

Method: 97 patients with pleural effusion were tested. According to Light’s criteria, there were 29 transudative and 68 exudative pleural effusions. Pleural fluid and serum levels of lactate dehydrogenase, protein and cholesterol were measured using colorimetric methods and a biochemical analyzer.

Results: Using as a cut-off value for the pleural fluid cholesterol the value of 65mg% (the upper limit to identify a pleural effusion as a transudate) this criterion yielded a sensitivity of 87% and a specificity of 79%. Using the alternative criterion of pleural fluid cholesterol to serum cholesterol ratio (and a cut-off level of 0.4 as the upper limit to identify a transudate) the sensitivity was 87% and the specificity was even greater at 81%.

Conclusions: This study showed that using pleural fluid cholesterol and pleural fluid cholesterol/serum cholesterol ratio may be useful for the differential diagnosis between transudates and exudates, and can provide assistance especially where other criteria are marginal or ambiguous.
In this non-interventional study, telmisartan proved to be generally well tolerated and highly effective in alleviation of dry cough resulting from primary care (CAPHRI), Maastricht University Medical Centre, Maastricht, Tadeusz Lietz1, Michal Wronka 2, Jerzy Kozielski3.

Broncholithiasis is defined as the presence of a calcified fragment of tissue within a bronchus. It almost invariably represents the end-stage of healing of granulomatous diseases such as histoplasmosis or tuberculosis. Broncholiths are found with almost equal frequency in men and women, mostly in the fifth or sixth decade. Common symptoms are chronic cough, hemoptysis and sputum. Lymphoceilysis, which is pathogenic, is rare. The chest radiograph mostly shows calcified masses around the bronchi. In most cases, because of no significant symptoms or complications, observation may be the best course but bronchoscopic removal or surgical interventions are indicated in some instances. From June 1996 to December 2010, 24 patients with broncholithiasis had undergone the analysis for clinical manifestation, bronchoscopic finding, treatment modality and follow-up status. Broncholithiasis was developed in association with tuberculosis in 45.8% and locations corresponded in 54.5%. Lymphoceilysis occurred in 20.8%. Obstructive pneumonia was the most common radiographic finding, and calcification was found in 50.0%. Various positive findings, noted in all patients undergoing flexible bronchoscopy, included visible broncholith, granulation tissue or blood clots. In follow-up patients, while all patients with conservative care only continued to have symptoms, an excellent result was evident in 8 of 11 patients in whom broncholith was removed after treatment or spontaneously. A clinical awareness of the manifestations of broncholithiasis will result in early diagnosis and treatment. If the broncholith can be removed, as indicated, before irreversible distal bronchial and parenchymal damages occur, the long-term outlook for symptomatic relief is excellent.

Broncholithiasis is a chronic disease, the prevalence of which increases with age. The pathogenesis of broncholithiasis involves the interaction of bacterial, immunologic, and host factors. Broncholithiasis is defined as the presence of a calcified fragment of tissue within a bronchus. It almost invariably represents the end-stage of healing of granulomatous diseases such as histoplasmosis or tuberculosis. Broncholiths are found with almost equal frequency in men and women, mostly in the fifth or sixth decade. Common symptoms are chronic cough, hemoptysis and sputum. Lymphoceilysis, which is pathogenic, is rare. The chest radiograph mostly shows calcified masses around the bronchi. In most cases, because of no significant symptoms or complications, observation may be the best course but bronchoscopic removal or surgical interventions are indicated in some instances. From June 1996 to December 2010, 24 patients with broncholithiasis had undergone the analysis for clinical manifestation, bronchoscopic finding, treatment modality and follow-up status. Broncholithiasis was developed in association with tuberculosis in 45.8% and locations corresponded in 54.5%. Lymphoceilysis occurred in 20.8%. Obstructive pneumonia was the most common radiographic finding, and calcification was found in 50.0%. Various positive findings, noted in all patients undergoing flexible bronchoscopy, included visible broncholith, granulation tissue or blood clots. In follow-up patients, while all patients with conservative care only continued to have symptoms, an excellent result was evident in 8 of 11 patients in whom broncholith was removed after treatment or spontaneously. Small airway function in prematurely born infants following viral infection
Simon Drysdale1, Mireia Akaizar1, Therese Wilson1, Melvyn Smith1, Mark Zuckerman2, Simon Roughton3, Sean Fitzgerald1, Tadeusz Lietz1, Michal Wronka2, Jerzy Kozielski3.

Aims: To study whether preschool children with recurrent wheeze differ in bacterial infection/colonisation in the upper respiratory tract compared with healthy controls.

Methods: We recruited 252 children aged 2-4 years with (n=202) and without (n=50) recurrent wheeze. Nasal and throat swabs were analysed for the presence of Streptococcus (S.) pneumoniae and Haemophilus (H.) influenzae. Sero-sensitivity for Chlamydia (C.) and Mycoplasma (M.) pneumoniae was assessed by ELISA collected using a closed-glass condenser. Inflammatory markers (Interleukin (IL)-4, IL-8, IL-13) in EBC were measured using multiplex immunoassay.

Results: Only positive serology for M. pneumoniae was slightly higher in children with recurrent wheeze compared with healthy controls (11% vs. 2%, p=0.09). Wheezing children colonised with H. influenzae (N=61) had higher levels of all interleukins compared with colonised children without recurrent wheeze (N=15) (p<0.05).

Conclusion: We found no convincing evidence for an association between bacterial colonisation/infection and preschool recurrent wheeze. Airway colonisation with H. influenzae leads to elevated pro-inflammatory markers in recurrent wheezers, indicating augmented airway inflammation in these children.

P503

IL-872 isoforms in lung of preterm infants and its processing by neutrophil serine proteases
Silvia Elena Akavoliv, Nikolai Voitenok1, Sislej Kotecha, Edward Dompeling1, 2 Department of Child Health, Cardiff University, Cardiff, United Kingdom; 3Laboratory of Cellular and Molecular Immunology, Research Centre for Haematology and Transfusiology, Minsk, Belarus; 4 Fund for Molecular Hematology and Immunology, Fund for Molecular Hematology and Immunology, Moscow, Russian Federation

Introduction: Persistent neutrophilic (PMN) lung inflammation is strongly influenced in the development of Chronic Lung Disease (CLD) of Prematurity. The 72 amino acid (a.a.) chemokine, IL-872, is a key molecule involved in attracting PMNs to sites of inflammation. The longer 77 a.a. isoform (IL-877) is less potent than IL-872 in vitro. We studied expression of IL-872 in the preterm ventilated lung and its processing by neutrophil serine proteases. Methods: IL-872 was measured by ELISA in bronchoalveolar lavage fluid (BALF) from ventilated preterm infants born at ≤ 32 weeks gestational age and after correction by purified Cystein protease serine proteases. Results were compared between the CLD (persistent inflammation) and non-CLD groups (resolved).

P499

A clinical study on broncholithiasis
Hong Yee Lee; Hae Sung Nam; Jae Hwa Cho; Jeong Seon Ryu. Department of Internal Medicine, Inha University Hospital, Incheon, Korea

Broncholithiasis is defined as the presence of a calcified fragment of tissue within a bronchus. It almost invariably represents the end-stage of healing of granulomatous diseases such as histoplasmosis or tuberculosis. Broncholiths are found with almost equal frequency in men and women, mostly in the fifth or sixth decade. Common symptoms are chronic cough, hemoptysis and sputum. Lymphoceilysis, which is pathogenic, is rare. The chest radiograph mostly shows calcified masses around the bronchi. In most cases, because of no significant symptoms or complications, observation may be the best course but bronchoscopic removal or surgical interventions are indicated in some instances. From June 1996 to December 2010, 24 patients with broncholithiasis had undergone the analysis for clinical manifestation, bronchoscopic finding, treatment modality and follow-up status. Broncholithiasis was developed in association with tuberculosis in 45.8% and locations corresponded in 54.5%. Lymphoceilysis occurred in 20.8%. Obstructive pneumonia was the most common radiographic finding, and calcification was found in 50.0%. Various positive findings, noted in all patients undergoing flexible bronchoscopy, included visible broncholith, granulation tissue or blood clots. In follow-up patients, while all patients with conservative care only continued to have symptoms, an excellent result was evident in 8 of 11 patients in whom broncholith was removed after treatment or spontaneously. A clinical awareness of the manifestations of broncholithiasis will result in early diagnosis and treatment. If the broncholith can be removed, as indicated, before irreversible distal bronchial and parenchymal damages occur, the long-term outlook for symptomatic relief is excellent.
Results: The majority of IL-8 consisted of the shorter isoforms in the preterm lung (96.3% non-CLD vs 97.1% CLD, p=ns). IL-8 signalling correlated well with total IL-8 (p<0.0001) but not with gestation (p=ns). Stimulated adult airway cells and neonatal PMNs and monocytes expressed IL-8's as the major isoform, suggesting possible expression in the lung. Preterm BALF significantly converted rHL-8 to shorter isoforms at 18 hours (p<0.05), which was inhibited by α-antitrypsin (AAT). Purified neutrophil serine proteases converted IL-8 to shorter isoforms dose-dependently and over time.

Conclusions: Majority of IL-8 in the ventilated preterm lung are the potent shorter isoforms. Although potentially expressed in the lung, IL-8's is probably converted to the shorter isoforms by neutrophil serine proteases. Inhibition of conversion by AAT suggests a potential therapeutic role for it in modulating inflammation in the preterm lung.

P304 Expression and functional activity of IL-6, sIL-6R & sgp130 in the preterm infant lung
Maliniath Chakraborty1, Eamon McGreal1, Philp Davies1, Simon Jones2, Saisheel Kotecha1, 1Department of Child Health, Cardiff University, Cardiff, United Kingdom; 2Department of Medical Biochemistry and Immunology, Cardiff University, Cardiff, United Kingdom

Introduction: Persistent neutrophil-dominated lung inflammation is strongly implicated in the development of Chronic Lung Disease of Prematurity (CLD). The complex of interleukin-6 (IL-6) and its soluble receptor, sIL-6R, can activate signalling in cells lacking the cell-surface receptor IL-6R; a soluble form of the signal-transducer gp130 can inhibit trans-signalling by specifically binding to the sIL-6R/gp130 complex. As anti-inflammatory effects of IL-6 trans-signalling can shape resolution of inflammatory responses, we studied the expression, inter-relationships and functional activity of IL-6, sIL-6R and sgp130 in the preterm lung.

Methods: Cytokines were measured by ELISA in bronchoalveolar lavage fluid (BALF) from ventilated preterm infants born at <32 weeks gestational age. Functional activity was determined in a sensitive, IL-6 specific bioassay using mouse B9 cells. Results were compared between the CLD group (persistent inflammation) and non CLD (resolution) group (resolved).

Results: Inflammatory cells and chemokines, CXCL8 and CCL2, were higher in the CLD group (p<0.05). IL-6 and sIL-6R were comparable between the two groups; however, gp130 was higher in the CLD group (CLD 65.3 ng/ml vs non CLD 20.8 ng/ml p=0.01), as was the anti-trans-signalling ratio of sgp130/sIL-6R (p=0.01). Functional activity of IL-6 in the bioassay was similar between the two groups. Trans-signalling activity was not noted in any of the samples in the bioassay.

Conclusions: Increased sgp130 in the lungs of preterm infants may be responsible for impaired trans-signalling by the sIL-6R/gp130 complex. Better understanding of this pathway may lead to therapies to resolve lung inflammation in preterm infants.

P305 Cytokine response in pediatric patients with pandemic H1N1 influenza virus infection and pneumonia: Comparison with pediatric pneumonia without H1N1 infection
Myung Chul Hyun, Dong Won Lee, Yeo Hyang Kim. Pediatrics, Kyungpook National University School of Medicine, Daegu, Republic of Korea Pediatrics, Inje University College of Medicine, Pusan, Republic of Korea Pediatrics, National University School of Medicine, Daegu, Republic of Korea

Objectives: We investigated serum cytokine levels in pediatric patients with pandemic H1N1 virus infection pneumonia and in pediatric patients with pneumonia but without H1N1 infection, and examined correlations between cytokine levels and clinical/laboratory findings.

Methods: Fifty-seven cases of infection by H1N1 virus were confirmed by RT-PCR and enrolled. Of these 57 cases, 26 had a severe H1N1 infection (group 1), and 31 had a mild H1N1 infection (group 2). Sera from 18 cases with pneumonia without H1N1 infection (group 3) were used as controls. The serum levels of 10 cytokines were determined by multiplex assay.

Results: The serum levels of IFN-α, IL-6, and IP-10 were significantly higher in H1N1 infected cases than in group 3, and levels of IL-6 and IP-10 were significantly higher in group 1 than in group 2. The level of IL-10 was significantly higher in groups 1 and 3 than in group 2. However, levels of IFN-α, TNF-α, and IL-17 were not significantly different between the three groups. IL-1β, IL-4, and MIP-1α were not detectable in most patients. IP-10 and IL-6 levels were found to show negative correlations with lymphocyte count and oxygen saturation.

Conclusions: We found higher levels of cytokines (IFN-α, IL-6, IP-10) of innate immunity than those of acquired immunity in pediatric H1N1 infection. Of the cytokines to be found in cases with a H1N1 infection, IP-10 and IL-6 were found to be correlated with disease severity (lymphopenia and hypopnoea). IP-10 and IL-6 may be important markers in pediatric H1N1 infection.

P306 Respiratory symptoms correlate with pulmonary inflammation at a time of presumed stability in children with non-ambulant neurodisability
Ruth Trinick1,2, Anthony M. Dalzell1, Paul S. McNamara1,2, 1Department of Women's and Children's Health, University of Liverpool, Liverpool, United Kingdom; 2Department of Respiratory Medicine, Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom; 3Department of Gastroenterology, Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom

Background: Children with non-ambient neurodisability (ND) often have chronic respiratory symptoms which impact on quality of life and can result in multiple hospital admissions. Respiratory complications are a leading cause of death in this group.

Aims: Assess respiratory symptoms and broncho-alveolar lavage (BAL) inflammatory markers at a time of presumed stability.

Methods: Children with ND and healthy controls were recruited during elective surgical admission. A respiratory symptom score (LRoQ) was completed. BAL was taken at anaesthetic induction. Neutrophil count was recorded (% total cells). IL-8 and TGF-β1 were measured by ELISA. Data are expressed as median [IQR].

Results: 16 children with ND had higher LRoQ scores than 10 controls (21 [5-46] vs. 5 [0-7], p<0.02). Children with ND had greater BAL neutrophilia (52% [31-71] vs. 4% [3-12], p<0.01) and higher IL8 (516 [0-2465] vs. 0 [0-232] pg/ml, p<0.05). Median TGF-β-1 did not differ (0 vs.0 but the range was markedly different (0-271 vs 0.73 g/ml). LRoQ score correlated with BAL neutrophilia (r=0.54, p<0.01), IL8 (r=0.49, p<0.01) and TGF-β-1 (r=0.43, p<0.01). No ND patients had seen a respiratory specialist, 8/16 had undergone video-fluoroscopy (7/8 v e) and 2/16 took antibiotic prophylaxis.

Conclusions: Children with ND have a high burden of respiratory symptoms which correlate with chronic airway neutrophilia and raised inflammatory cytokines at times of presumed stability. A screening tool to identify those children who would benefit from a specialist respiratory review would be useful. Further research into the potential benefits of prophylactic therapy in this group is needed.

P307 Subclinical vitamin D deficiency and acute respiratory tract infections in children: A systematic review
Anjay M.A. Pillai1, Vijay Palanivel2, 1Paediatric Respiratory Medicine, Great Ormond Street Hospital for Children, London, United Kingdom; 2Paediatric Neurodisability, Chelsea & Westminster Hospital, London, United Kingdom

Rickets has historically been considered as a risk factor for development of pneumonia, primarily due to mechanical factors such as rib cage abnormalities and hypotonia. However, the association between vitamin D levels and acute respiratory tract infections (RTI) in children without rickets has not been thoroughly explored so far.

Aims: We aim to systematically review the available literature regarding:

• Association of low Vitamin D levels with RTI in children without clinical rickets
• Role of Vitamin D supplementation in prevention and treatment of RTI.

Methods: Structured systematic literature search

Results: Seven papers on association of low Vitamin D levels and RTI were obtained. See Table 1.

Two papers, both double blinded randomised controlled trials (RCT), were identified on Vitamin D supplementation in RTI. See Table 2.

Conclusions: Our literature review has revealed that subclinical vitamin D levels are strongly associated with risk of acquiring RTI as well as increased RTI-

Risk factors for wheezing and allergy in preschool children (PSC) after admission for acute bronchiolitis

Ana Saianda1, Sandra Lobo2, Sara Aguilar1, Raquel Gouveia1, Ana Silva1, Tiago Silva2, Filipa Negreiro3, Teresa Banderia1, 1Lung Function, Sleep and Ventilation Unit, Clinica Universitaria de Vitoria, University Hospital of Santa Maria, Lisbon, Portugal; 2Peditric Service, Hospital District of Cascais, Cascais, Portugal; 3Eurotrials – Scientific Consultants, Eurotrials, Lisbon, Portugal

Introduction: Acute bronchiolitis (AB) is associated to later development of wheezing (W) and allergic sensitisation, but risk factors remain controversial. This study aimed to test the hypothesis that clinical background and features of the acute episode influences outcomes.

Methods: A cross-sectional study was performed in 71 out of 340 infants <2-year-old admitted for AB (Oct/02-Apr/04) in a tertiary teaching hospital. We conducted structured interviews, spirometry and skin-prick tests (SPT) to common infant allergens to 4-6 year-old and looked for demographic and clinical risk factors (male gender, birth season, prematurity, exposure to smoke, nursery,older siblings, pets, family history of allergy, no breast feeding) and for the acute episode (RSV, age <6 weeks, severity [length of hospital stay ≥6 days and time on oxygen ≥4 days]) and use of steroids. Main outcomes were any episode of W and persistent wheezing (PW).

Results: W occurred in 50 (70%) of children, but only 19 (39%) referred PW. We found no differences between groups, except for steroid treatment at acute episode [W 6 (12%)/not W 8 (38%)] that was associated with a 4.5 risk reduction of wheezing (adjusted OR [IC] 0.22 [0.065-0.76]) but not for PW. PW was associated with positive SPT [PW 7 (39%); no PW 3 (10%)], adjusted OR [IC] 3.7 (1.4-10.2).

Conclusion: This study shows a high prevalence of wheezing in PSC after AB (Oct/02-Apr/04) in a tertiary teaching hospital. We conducted structured interviews, spirometry and skin-prick tests (SPT) to common infant allergens to 4-6 year-old and looked for demographic and clinical risk factors (male gender, birth season, prematurity, exposure to smoke, nursery,older siblings, pets, family history of allergy, no breast feeding) and for the acute episode (RSV, age <6 weeks, severity [length of hospital stay ≥6 days and time on oxygen ≥4 days]) and use of steroids. Main outcomes were any episode of W and persistent wheezing (PW).

Effect of salbutamol on the growth, virulence and biofilm formation of pseudomonas aeruginosa

Priti Kenia, Primrose Freestone, Christopher O’Callaghan. Department of Infection, Inflammation and Immunity, University of Leicester, Leicester, United Kingdom

Background: Beta-2-agonists, like salbutamol are commonly used in patients with lung disease such as cystic fibrosis where chronic infection is common. Recently salbutamol was shown to have an effect on host defence in a murine model, impairing clearance of Haemophilus influenzae from the respiratory tract [1]. To determine if salbutamol affected bacterial virulence, we investigated the effect salbutamol had on the growth and virulence of Pseudomonas aeruginosa(PA).

Aims: To determine if salbutamol affects the growth, virulence and biofilm production of PA.

Methods: Clinical isolates of PA were used for experiments with and without addition of salbutamol at a range of concentrations between 0.375-100 microgram/ml. Viable colony counts and growth curve were performed to determine bacterial growth. Biofilm formation was studied using attachment crystal violet assay, light and advanced microscopy and electron microscopy using 1 cm2 endotracheal tube pieces.

Results: There was no difference in the growth of PA in the presence of salbu-

tamol. However, at low concentrations of salbutamol (1 mg/ml) there was a significant increase in bacterial clumping on light microscopy and increased biofilm formation on endotracheal tube sections on electron microscopy.

Conclusions: Salbutamol appears to increase biofilm formation of Pseudomonas aeruginosa. This study does not imply that the use of beta-2-agonist be discouraged but suggests that a potential role in the virulence of PA must be investigated.

RANTES gene promoter polymorphisms -28C/G and -403G/A in children hospitalized with community acquired pneumonia

Katerina Haidopoulou1, Theonymfi Doudouliaki 1, Styliani Pappa2, Afroditi Sakellariopoulou2, Pavlos Tsikriki2, Maria Emporados1, Maria Xatzisyanian2. 14th Department of Pneumiatrics, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2nd Department of Pneumatics, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

The course of community acquired pneumonia in children varies between patients and it is common belief that the innate immune system of the host plays an important role to the outcome of the infection. The chemokine RANTES is an important chemoattractant which attracts monocytes, T cells, NK cells and eosinophils into sites of inflammation.

Aim of the study was to investigate the frequency of -28C/G and -403G/A RANTES polymorphisms in children hospitalized with community-acquired pneumonia. The study involved two groups of children. The first (group A) consisted of 60 children hospitalised with pneumonia, 37 boys, aged 5.0±4.4 years and the second (group B) consisted of 135 healthy children, 60 boys, aged 9.6±6.0 years with no history of respiratory infections.

The genotypes of all subjects were determined with PCR-RFLP assay.

Diagnosis of primary ciliary dyskinesia in a Dutch cohort of 63 pediatric patients: An overview

Femke Nauta1, Gerard Pals2, Hans Daniels1, Ad Nagelkerke1, Eric Haarman1.

1Pediatric Pneumology, VU University Medical Center, Amsterdam, Netherlands; 2Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands; 3Pneumology, VU University Medical Center, Amsterdam, Netherlands

The diagnosis of primary ciliary dyskinesia (PCD) is difficult, as a single gold standard is lacking. The diagnosis is usually based on a combination of clinical symptoms, abnormal movement of cilia on microscopic evaluation of respiratory epithelial biopsies (LM) and/or epithelial cell cultures (CLM), or identification of an ultra-structural defect in the cilium by electron microscopy (EM). In order to get more insights into the diagnostic value of each of these tests, we performed a retrospective analysis in a cohort of 63 pediatric PCD patients treated within our center. Patient characteristics were as follows: mean age at diagnosis 3.8 years (range 0-18 years), males 44%, females 56% and sinus inversus 39.7%. PCD was diagnosed based on a combination of clinical symptoms and LM in 7.9%, EM 4.8%, CLM 1.6%, LM and CLM 36.5%, LM and EM 20.6%, or LM, EM and CLM in 28.6% of the patients respectively. Abnormal beat frequency, amplitude and coordination observed in epithelial cell cultures from PCD patients, correlated with dyskinetic movement observed in the original biopsies (p<0.01). However, secondary dyskinesia is often encountered in nasal biopsies, as is illustrated by the fact that in 67 out of 136 biopsies with dyskinetic cilia obtained during the last 2 years, cell culture results were normal. In 28.6% of the PCD patients, EM findings were normal. In summary, the diagnosis of PCD cannot rely on a single technique, as both false negative and false positive results frequently occur. Epithelial cell cultures should be an integral part of the diagnostic work-up. Future studies into the genetic background may further improve diagnostic accuracy.

**P512**

What is the gold standard in the diagnosis of primary ciliary dyskinesia syndrome?

María Teresa Romero Rubio1, Miguel Armengot Carceller2, Carmen Carda Batalla2, Amparo Escobedо Montaner1, Javier Milara Paya1, 1Pneumology Department, Department of Pediatrics, Hospital de Denia, Denia, Alicante, Spain; 2Department of Otolaryngology, Hospital General Universitario, Valencia, Spain.

According to the results, only the -28C/G RANTES promoter polymorphism is associated with community-acquired pneumonia in children. No association was found for the -403G/A polymorphism.
Introduction: The diagnosis of primary ciliary dyskinesia (PCD) is based on the study of ciliary motility (frequency and beat pattern) using high resolution digital video and high speed, combined with ciliary ultrastructure by electron microscopy (EM.) However, this can provide false positives and negatives, so the final diagnosis is defined by the ciliary function.

Objectives: To study the real prevalence of PCD after the introduction of the technique of ciliary motility in our center (2007). To set the number of cases previously classified PCD who have a normal ciliary motility.

Material and methods: Study of frequency and ciliary beat pattern: a) in patients who had been diagnosed from PCD until 2007 by screening of mucociliary clearance with 99mTc-labeled albumin and abnormal ciliary ultrastructure. b) in patients with clinical suspicion of PCD, from February 2007 to December 2010.

Results: a) Prior to the introduction of the technique the diagnosis of PCD was made in 17 cases. With the study of motility, we obtain a normal frequency/beat pattern in 8 of them (47%), dyskinetic in 6 cases (35%), not being possible to do in 3 of them. Therefore, the diagnosis of PCD is reduced 42.8%. 37.5% of confirmed cases associated with sinus inversus (S. Kartagener). b) Since 2007 we have studied 79 patients with clinical suspicion of PCD obtaining a dyskinetic pattern in 4 cases (5%), of which only 1 (25%) had anomalous ciliary ultrastructure.

Conclusions: The diagnosis of PCD based on the study of ciliary ultrastructure has a large percentage of false positives, so the study of ciliary motility should be considered the gold standard for diagnosis.

PS13
Is spirometry less accurate than chest computed tomography in primary ciliary dyskinesia with pulmonary deterioration?
Marco Maglione 1, Andrew Bush 2, Silvia Montella 1, Carmine Mollica 3

Is pulmonary deterioration a reliable marker of clinical deterioration in PCD and is spirometry less accurate than chest computed tomography in primary ciliary dyskinesia (PCD) associated with pulmonary deterioration? Spirometry was compared with chest computed tomography (CT) scans of 40 patients with documented pulmonary deterioration between February 2007 and December 2008. CT scans were scored blind by two experienced raters.

Results: Patients were divided into two groups based on the presence or absence of pulmonary deterioration. In PCD patients with pulmonary deterioration, spirometry may fail to detect worsening CT findings. Structural changes may progress with stable pulmonary function. CT scans are a useful tool to evaluate the course of the disease.

PS14
Changing characteristics of childhood non-cystic fibrosis bronchiectasis
Ela Erdelen 1, Yasemin Gokdemir 2, Recep aErsu 2, Fazilet Karakoc 2

In developing countries, characteristics of the chronic diseases may change in time because of changes in socioeconomic and health conditions. Our study aim was to evaluate the changing characteristics of non-CF bronchiectasis compared to our previous study (Karadag B. et al., Respir Res 2005:7:233-8).

Patients with non-CF bronchiectasis diagnosed two years ago and followed up after 2001 were recruited into the study. Long-term follow up records and lung function tests were used to evaluate the course of the disease. Collected data were compared with our previous data.

Of 100 patients included to the study, 54% were male. There was an increase in the mean age of the patients compared to our previous data (12.7±4.3 vs 7.4±3.7 years, p<0.005). During of symptoms was longer (6±3.7 vs. 4.9±3.7 years, p<0.005). As similar to the previous data, in 41% of the patients no underlying etiology could be detected. There was a change in the percentages of the detected etiology (2011 vs. 2001); postinfectious (21% vs. 29.7%, 0.01), asthma (12% vs. 4.5%, 0.07), immuredeficiency (12% vs. 15.3%, p=0.55), primary ciliary dyskinesia (1 vs. 6.3%, p=0.32) and foreign body aspiration (1 vs. 3.6%, p=0.37). During the follow-up period, in 25% of the patients the severity of the bronchiectasis improved. The rate of surgical management decreased from 23.4% to 9% compared to previous data (p=0.005).

Clinical characteristics of childhood bronchiectasis seems to be changing in a 10-year interval. There is a tendency for a decrease in the prevalence of postinfectious bronchiectasis however uncontrolled asthma and primary ciliary dyskinesia seems to be increasing. Surgical management is used only for a small group of patients.
78. Asthma: a heterogeneous disease

P519 Rasch analysis for evaluating abbreviated World Health Organization quality of life questionnaire (WHOQOL-Bref) in north Indian patients with bronchial asthma
Ashutosh Aggarwal, Ritesh Agarwal, Dheeraj Gupta. Department of Pulmonary Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Introduction: A disease-specific instrument to describe health-related quality of life (HRQoL) in Indian asthmatics is not available. A generic Hindi HRQoL measure - abbreviated World Health Organization Quality of Life questionnaire (WHOQOL-Bref) - has however been developed and validated in India. We evaluated the WHOQOL-Bref in adult patients of asthma, and tested possible modifications to the instrument to improve its psychometric adequacy.

Methods: 67 asthmatics completed the WHOQOL-Bref. Rasch analysis was used to explore the psychometric performance of the four domains (physical, psychological, social relationships, and environment) of the scale. Overall fit of data to model expectations, appropriate category ordering, presence of differential item functioning (DIF), individual item fit, and targeting of item difficulty to patient ability were explored for each domain. Item deletion and rescoring were applied to misfitting items to improve overall performance.

Results: Overall fit of the WHOQOL-Bref data was adequate. Item 3 had a large positive fit residual value resulting in poor construct validity for physical domain. No item exhibited DIF. Ten items had distorted thresholds. The WHOQOL-Bref was modified by dropping item 3, and rescoring category structures of 16 items. The modified scale had good construct validity for all domains, ordered thresholds for all items, and good targeting of items to persons.

Conclusion: WHOQOL-Bref proved a psychometrically inadequate scale in our study group. However, the scale, when modified through Rasch analysis, proved better at describing HRQoL in the asthmatics studied.

P520 Lung sound monitoring in real time operation mode in diagnosis of exercise-induced asthma
Elena Kolganova, Sergey Glotov. Department of Postgraduate Education in Internal Medicine, Ryazan Medical University, Ryazan, Russian Federation

Introduction: Exercise-induced asthma is an actual problem of pulmonology and sports medicine. It is important to watch lung sounds evolution on physical activity.

Objective: Assessment lung sounds evolution and detection wheezes on physical activity.

Materials and methods: Clinical trial was conducted on 13 patients with diagnosis of bronchial asthma. The sensor of the electronic stethoscope was connected with the radio transmitter and placed at the patient’s neck over the trachea. Lung sounds were monitored at the field testing. The investigators got a lung sounds by radio receiver and analyzed it by computer program in real time operation mode.

Results: Wheezes were registered in 6 patients on physical activity. Wheezes appeared again on the 12-th minute after the end of the field testing in 2 patients. The following changes in the form of an acoustic pattern were observed in all patients: amplitude of an acoustic signal and frequency of respiratory cycles were increased, a respiratory cycle was shortened.

Conclusion: The use of lung sound monitoring in real time operation mode makes it possible to assess lung sound evolution and to detect wheezes during the field testing.

P521 Relationship between bronchial asthma and pelvic organ prolapse
Ismail Onderzra1, Ayse Ele Arcan2, Mustafa Albayrak1, Ismet Budun2, Ege Gulce Balbay4. 1Gynecology, Duzce University, Duzce, Turkey; 2Gynecology, Nesehri State Hospital, Nesehri, Turkey; 3Chest Diseases, Uludag University, Duzce, Turkey; 4Chest Diseases, Duzce Ataturk State Hospital, Duzce, Turkey

Objective: Genital organ prolapse is frequently observed in clinical practice. Vaginal birth, multiparity, menopause, history of genital prolapse, obesity, consol- idation and bronchial asthma are the most common determinants of risk of genital prolapse. The aim of the study was to evaluate the relationship between bronchial asthma and pelvic organ prolapse.

Materials and methods: A total of 200 patients, 100 bronchial astma, 100 control group were included in this study. Women, who were pregnant, in the period of 6 months after birth, having connective tissue diseases, had surgery for genital prolapse before and operative births in the past were excluded from the study. There was no limit in the age. Pelvic examinations were performed by using POP-Q system.

Results: There was a decrease in the measurements of the points Aa, Ba and C in the group of asthma bronchiola. There was no significant difference between the measurements of other points. Compared with control group, the stage using cost of care was £11,116 between the RSV and non respiratory groups (p=0.001) and £9,076 between the RSV and the other respiratory groups (p=0.007).

Conclusion: In infants born between 32-35 weeks of gestation, hospitalisation for an RSV LRTI was associated with significantly increased health related cost of care in the first two years after birth.
Background: The incidence and complexity of asthma acute exacerbations (AA) are widely increasing. The emergency physician (EP) plays a key role in AA: emergency department management; medical treatment; diagnosis; prevention; maintenance; follow up; education about self-management.

Aims: To define the epidemiological and clinical impact of AA at presentation to the emergency department (ED) and the role of the EP.

Methods: Six months observational prospective clinical study including every consecutive AA patient who presented to the ED of a university teaching hospital. Results: 209 patients were included (1:1.5 days).

Results: Parallel to the EP's recommendations during the year; the 2nd group included the patients with negative compliance (NC), they either absolutely or partially did not follow the recommendations. The patients with NC had a more intense degree of BA severity (69%) and were of an older age (p<0.002). Higher values were revealed in the 2nd group by TAS, scales of depression, personal and reactive anxiety. The average profile of a personality by MMPI scales in BA patients with NC was higher than the standard one. A high risk of psychopathologic reactions was revealed in the patients of this group (impulsiveness, nonconformity, nonstereotypeness). The patients of this group had inner tension, nervousness, aloofness, which can be a predictor for bronchial asthma.

Conclusion: For BA patients with NC it is necessary to create a psychotherapeutic environment in the hospital as well as an individual approach to recommendations and their explanation.

P526 Glucocorticosteroid receptor (GCR) gene isoforms expression in bronchial asthma (BA) patients

Zhanna Mironova1, Vasily Trofimov1, Vasily Belash1, Elena Ianchitsa2, Anna Ultina2, Michael Dubina2. 1Hospital Therapy, I.P. Pavlov Medical State University, St. Petersburg, Russian Federation; 2Molecule and Gene Technologies, I.P. Pavlov Medical State University, St. Petersburg, Russian Federation

Peculiarities of GCR function is one of mechanisms of steroid dependent asthma (SDIA). Most important isoforms are CRα and CRγ, formed due to alternative splicing of NR3C1 gene. Alternatively to CRα, CRγ is not linked to glucocorticosteroids (GCS), acting as an inhibitor, which concur with CRα for linking with hormone responding element or coactivator. This mechanism may lead to steroid resistance (SR).

The aim of study was to evaluate the role of GCR isoforms in SDIA development. Methods: 9 SDIA patients, 15 ones – with mild asthma (MBA), 7 – moderate BA and 7 healthy controls were included. In 10 MBA ones, inhaled GCS were primary administered. In this group blood samples were taken before and 2 weeks after of treatment. In SDIA patients, having long history of inhaled and oral GCS, blood was taken once. Total RNA from peripheral blood cells was isolated using RIBO-zol-B nucleic acid extraction kit (CRIE, Russia). Level of CRα and CRγ expression was evaluated by RT-PCR method. Results: No statistic difference between expression levels in BA and controls was found. CRα expression was higher in SDIA than in other asthmatics (243.0 ± 30.7; p=0.05). In MBA during the GCS treatment trend to CRγ expression increase (from 9.3 to 94.5) and CRγ expression decrease (from 82.9 to 33.3) was revealed. Significantly increased CRα/CRγ ratio in MBA after treatment (from 0.5 to 17.7; p=0.022) was same as in SDIA (19.9).
**Introduction:** Asthma, as a public health problem world-wide, seems to be significantly associated with GERD. GERD and its symptoms are also more prevalent in pregnant women, worsening by the increase in gestational age. This study aimed to evaluate GERD and its relation to asthma in pregnant women.

**Methods:** One-hundred and seventy three pregnant women (mean age, 28.8±5.3 years and mean gestational age, 24.8±6.9 weeks) were included. The diagnosis of asthma was made on the basis of the Guidelines of the National Asthma Education and Prevention Program (NAEPP). As challenge tests are not recommended in pregnancy, a group of patients were classified as probable-asthmatics. They were the ones who had asthmatic symptoms and signs suggestive of asthma but the spirometry was normal.

**Results:** Asthma was diagnosed in 37% of the included women and 26.6% were probable to have asthma, while 36.4% were non-asthmatics. GERD was present in 80.9% of the pregnant women. GERD was not significantly higher in asthmatic or probable asthmatic women compared to non-asthmatic ones, but in pregnant women who had asthma, GERD was significantly more severe compared to women who did not have asthma (p=0.02).

**Conclusion:** In this study, we observed a high prevalence of GERD in pregnant women. Although GERD was not higher in asthmatic or probable asthmatic pregnant women, it tended to be more severe in asthmatic cases. This points to the importance of early diagnosis and treatment of GERD in asthmatic pregnant women.

**Results:** Placenta development coexisted terms of gestation in 72% of pregnant, administered ICS and in only 45.8% of A pregnant, rejected ICS intake (p=0.011). Significant differences of chronic placental insufficiency were seen between pregnant with the mild intermittent A and mild persistent BA, as well as with moderate chronic (35.38, 51.2% and 71, 4% resp (p<0.05)). Within pregnancies, administered ICS 70% appeared compensated, 25.93% - sub compensated and 7.07% decompenesed placental insufficiency. Within patients, rejected ICS values were 47.14%, 45.71% and 7.15% respectively.

**Conclusions:** Treatment with ICS while pregnancy has greater influence to placenta condition in comparison with A severity.

**P351**

**Impact of smoking in patients with and without history of asthma**

Ileana Palma, Pável Escina, Raquel Aguirre, Maria Rolando, Daniel Antuni, Ricardo Gene.

**Pulmonary Division, Hospital de Clinicas Jose de San Martin; Universidad de Buenos Aires, Buenos Aires, Caba, Argentina**

Patients with a history of asthma who smoke develop an accelerated decline in lung function and greater mortality. More complex studies are needed to distinguish asthma from COPD in this population.

**Objectives:** Evaluate the characteristics of a COPD population with and without history of asthma.

**Methods:** We invited people ≥ 40 y/o who smoked at least 10 years (current or ex-smokers), during one week on Nov 2005, 2007/2009. A questionnaire on respiratory symptoms, demographics and spirometry were done. COPD was defined by a FEV1/FVC < 70, the presence of symptoms and smoking history. Population was divided into 2 groups: COPD with history of previous asthma (AS) and COPD (NAS).

**Results:** 1626 patients were surveyed; 61 were excluded (< 40 y/o or non-obstructive lung disease). Mean age was 58.4±10.4 y/o. 54% were men. 89% patients had previous diagnosis of asthma. 329 of 1565 (21%) patients were diagnosed with COPD, 42% of AS vs 19% of NAS (p=0.001). The pack/year index in AS was 19±10 vs. 34±23 in NAS (p = 0.001). FEV1 (% and FEV1/FVC were comparable in both groups (67% and 57 vs 59). No differences in symptoms was found (p> NS) AS had more emergency visits (39.5% vs 24.4%, p = 0.047),
higher previous spirometric tests (73.7% vs 54.6%, p = 0.026) on the last year, and higher use of bronchodilators and ICS.

| Table 1 |
|-----------------|-----------------|-----------------|
| AS (n=58)       | NAS (n=291)     | p                |
| Salbutamol      | 12 (31%)        | 40 (13.7%)       | 0.039 |
| Ipratropium     | 3 (7.8%)        | 15 (5.1%)        | 0.78  |
| LABA            | 8 (21%)         | 27 (9.2%)        | 0.10  |
| ICS             | 14 (36.8%)      | 45 (15.5%)       | 0.02  |
| Oral Steroids   | 2 (5.2%)        | 1 (0.3%)         | 0.046 |

Conclusions: Patients with history of asthma develop COPD more often, with lower smoking load, and have higher use of medical resources in spite of more use of effective treatment.

P534
Self-reported dental health and related factors in patients with asthma and chronic obstructive pulmonary disease
A. Iulibing 1, E. Atayaz 2, K. Ejnotnurk 2, O. Abadoglu 1
1Department of Chest Diseases, Cukmuryet University, Faculty of Medicine, Sivas, Turkey; 2Department of Chest Diseases, Sabeabdepartment of Allergic Diseases, Cukmuryet University, Faculty of Medicine, Sivas, Turkey

Background: There are some studies about dental problems of asthmatic patients. However, studies comparing dental diseases in patients with asthma and with COPD are not sufficient.

AIM: Our aim is to compare the frequency of self-reported dental problems, their treatments and to determine affecting factors.

Method: A face-to-face questionnaire including the history of their diseases, dental problems and treatments, tooth brushing habits and comorbidity questions was applied by a doctor to the patients who admitted to Chest Diseases Dept. and Immunology and Allergy Diseases Subdept.

Results: 292 patients (63.4% asthmatic, 36.6% with COPD) and 286 controls were included to the study. Mean dental disease durations were 14.04±6.80 and 15.18±1.01 years in patients with asthma and COPD, respectively (p<0.05). There were dental problems in 91.6% of asthmatics and in 97.8% of COPD patients (p=0.01). The frequency of the subjects with dental caries was 89.7% in asthmatics, 95.3% in COPD patients, and 86.4% in the control group (p=0.04). As for tooth brushing habit, 47.0% of asthmatic patients, 21.5% of patients with COPD, and 58.0% of the control group stated to perform regularly once or twice per day (p<0.001). Only 41.6% of asthmatic patients, 9.3% of COPD patients, and 52.1% of control group (p<0.001) had elementary or higher education.

Conclusions: Dental caries is the most frequent dental problem. The frequency of tooth brushing is related to the educational status and the patients should be instructed to perform this act regularly as recommended.

79. COPD management

P535
Inhibiting effects of tiotropium bromide on neocollagenesis during 6 month treatment
Mykola Ostrovskiy, Oleksandr Varukiv, Mariana Kulynych-Misik, Iryna Savelikhina. Internal Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

Background: Chronic obstructive pulmonary disease (COPD) is one of the most important causes of morbidity and mortality worldwide, which are the third most common cause of death (8%) in the 25 member states of the European Union.

Purpose of the study: Is the evaluation of type IV collagen dynamic in bronchoalveolar lavage (BAL) during the treatment with tiotropium bromide.

Materials and methods: The content of type IV collagen was investigated in BAL of 43 control patients with stage 2 COPD before and after 1,3 and 6 months of treatment with tiotropium bromide using ELISA.

Results of the study: The content of type IV collagen in BAL on a moment of hospitalization in patients with COPD exacerbation was (61,14±1,28) ng/ml that is in 6.19 times (p<0.05) higher than in healthy. In patients with COPD exacerbation treated within 1 month with integrated treatment including tiotropium bromide as a basic therapy we identified the reduction of type IV collagen levels in 1.41 times in BAL compared with data before treatment. We found further positive trends - reduction of type IV collagen on 79.4% with using tiotropium bromide within 2 months. The level of type IV collagen in bronchoalveolar fluid dropped in 2.23 times (p<0.05) compared with the level before treatment. We identified practically complete normalization of type IV collagen levels in BAL only during 6-month of tiotropium bromide admission in patients with stage 2 COPD. This rate was higher only at 29.8% (p<0.05) comparing with healthy.

Conclusions: The reduction of type IV collagen content in BAL under tiotropium bromide treatment during 6 month is a clear evidence of inhibiting effects of tiotropium bromide on neocollagenesis.

P536
Effect of erdosteine on airway obstruction and symptom recovery in severe COPD exacerbations
Maurizio Moretti, Maria Ballabio. Respiratory Medicine, ASL1 Massa e Carrara, Carrara, Italy; 2Medical Department, Edmond Pharma, Milano, Italy

Introduction: Acute COPD exacerbations (AECOPD) represent an important cause of morbidity and mortality. Early and effective interventions may improve their outcome and patients’ health status.

Objective: This study evaluated the effect of erdosteine, an anti-oxidant mucolytic agent, on airflow limitation and symptom recovery at AECOPD

Methods: 15 COPD patients hospitalized for an acute exacerbation randomly received erdosteine 900 mg daily (E) or placebo (P) for 10 days in combination
with standard steroid, antibiotic and bronchodilator treatment. Pulmonary function test including spirometry (PVC, FEV1, FEF25–75) and breathlessness, cough, and sputum scale (BCSS) were measured at hospital admission, and at 10 and 30 days post-exacerbation.

*p<0.05 and **p<0.01 vs. P.

The improvement of lung function parameters and symptom scores from baseline was significantly greater in patients receiving endosine. Symptom score recovery significantly correlated to improvement of airway obstruction at time 10 and 30 in the erdosteine group.

Conclusions: Treatment with endosine plus standard therapy in AECOPD proved to be effective in improving both clinical symptoms, and large and small airway impairment. Mucoytic agents with relevant antioxidant activity may allow a more rapid and complete recovery of exacerbated patients by reducing the burst of airway inflammation.

P537

Analysis of therapy of community-acquired pneumonia (CAP) at the COPD patients

Hanna Demchuk, Yurii Mostovoy.

To assess extent, accuracy and efficiency of therapy of CAP at patients (PT) with COPD case histories of 252 inpatients (54.4% males, mean age 59.03±13.7 years) admitted due to CAP and COPD exacerbation were analyzed. PT with non-severe CAP were 94.8%. Moderate COPD had 54.4% PT, severe COPD – 34.1%, very severe COPD - 4%. Cardiovascular diseases were more than 60% PT. Analysis of therapy revealed average amount of prescribed medicines was 17.2±3.2. The most frequently used antibiotics was cephalosporins of third generation (61.9%), macrolides (21.4%), ciprofloxacin (20.6%) and inhibitor-protected aminopenicillins (14.3%). Correct combination of beta-lactam+macrolide was prescribed 40.2%. Combinations of fluoroquinolone with beta-lactam received 12.1% or fluoroquinolone+aminac in 7.5%. These combinations are alternative treatment for investigated PT. Non-recommended antibiotic therapy received 18.6%. Amoxicillin/clavulanate +macrolide, cefixim+n macrolide and ciprofloxacin+beta-lactam or aminac was the most effective treatment (in 99.6%, 95.0% and 95.2% PT, relatively). For exacerbation the erdosteine group.

Conclusions: The improvement of lung function parameters and symptom scores from baseline was significantly greater in patients receiving erdosteine. Symptom score recovery significantly correlated to improvement of airway obstruction at time 10 and 30 in the erdosteine group.

P540

Polypharmacy in patients with acute exacerbation of COPD

Jesús Díez-Manglano1, Jesús Reaco-Iglesias2, F Javier Cabrera-Aguilar3, ECCO Study Investigators1, 1COPD Working Group, Spanish Society of Internal Medicine, Zaragoza, Badajoz, Tarrasa, Barcelona, Madrid, Spain; 2Fundación Cuadet-Cimera, Fundación Cuadet-Cimera, Banyola, Mallorca, Spain

Introduction: Polypharmacy (PP) is frequent in patients with COPD who often have comorbid chronic diseases, and PP increases the risk to experience adverse drug events.

Objective: To determine the prevalence of PP in patients hospitalized for an acute exacerbation of COPD, and the factors associated with PP in this population.

Subjects and methods: ECCO is an observational, prospective, multicentre study. It included those patients admitted with a COPD exacerbation to any of the participating Internal Medicine departments consecutively between January 1, 2007, and December 31, 2008. They were all spirometry-confirmed COPD GOLD II or higher in stable condition. PP was defined as chronic concurrent use of ≥5 medications and excessive PE (EPP ≥10).

Results: 398 patients, 353 men and 45 women, with a mean (SD) age of 73.7 (8.9) years were surveyed. The average use of drugs was 5.0 (2.6). On admission 224 (56.3%) had PP and 22 (5.6%) EPP. Patients with PP had more comorbidity (Charlon index 2.8 (2.8) vs 2.3 (1.6); p=0.004) and more severe mBSC dyspnea (p=0.009) but there were no differences according to GOLD stage. On discharge the average chronic use of drugs was 6.6 (2.4) in an increase in 272 (68.3%) patients. At discharge, 296 patients (78.7%) had PP and 44 (15.9%) EPP. Patients with PP at discharge had more comorbidity and lower FEV1 (<p=0.001). In a multivariate logistic regression model PP was associated with lower predicted FEV1, heart failure, hypertension, diabetes, home oxygen therapy and PP on admission.

Conclusions: Polypharmacy is frequently observed in COPD patients, and is associated with more severity of COPD and more comorbidity.

P541

Comparison of two models of factors associated to hospital admission for COPD

Bernardinó Alcázar Navarrete1, Alberto Herrejón Silvestre2, Cayo García Polo3, Luis Alberto Ruiz4, Patricia García Sidro5, Gema Tirado Conde6, Jose Antonio Los Lucas7, Carlos Martínez Riveraa8, Joaquín Costán9, Sagarnag Mayoralas10, Marc Miravitlles11, InEPOC Group11.

Aim of the study was to determine the current incidence of pulmonary complications and management of patients with chronic obstructive pulmonary disease.

Nina Karoli, Andrey Rebeyko.

Hospital Therapy Department, Saratov State Medical University, Saratov, Russian Federation

The incidence of cardiovascular complications at admission due to exacerbation of COPD in patients with COPD III-IV stage PP was 20.2 times less often than in patients with COPD I-II stage. Difference in severity between survivors and those which died was significant (p<0.001)
Introduction: COPD is a leading cause of hospital admissions.

Objectives: We aimed to identify factors significantly associated with hospital admission in patients with COPD. Demographic and clinical data, treatment and socioeconomic status were collected. Evaluation of comorbidities (Charlson index), psychological profile (HAD questionnaire), health-related quality of life (EuroQOL-5D, LCADL), pulmonary and cardiac function testing, 6MWT and BODE index were measured and compared between patients with and without hospital admission the last year.

Results: 127 patients were included, of which 50 (39.3%) were hospitalized the previous year. Patients hospitalized for COPD exacerbations showed more use of Emergency Room, LITOT, NIVM, worse SpO2, and PVC, and worse BODE and EuroQol scores. The findings from the multivariate analysis made possible to establish two models: the one with SpO2, BODE index, and previous visits to ER had a sensitivity of 64.2% and a specificity of 86%.

Conclusions: SpO2 and the presence of previous hospital admissions are associated with worse SpO2, BODE index, baseline MRC and previous visits to ER department. If 6MWT is not available, the other variables provide a similar discrimination capacity between admitted and non admitted patients.

P542 More than two years of a monographic consultation on control of chronic home oxygen therapy

Teresa Bilbao Goyago, Natividad Quiñez, Lorena Comeche, Dolores Alvaro, Juan Manuel Diez, Raquel Perez. Pulmonology Department, Mostoles Hospital, Mostoles, Madrid, Spain

Objectives: To know the characteristics of our patients on chronic home oxygen therapy. We assess the prescription criterion, the prescriber department, time since diagnosis of the patients, the duration of the consultation and the number of consultations per patient.

Materials and methods: Retrospective descriptive analysis of the patients that attend to our monographic consultation since it started on October of 2008.

Results: The number of patients is 598 with 1181 number of consultations, this represents 17,5% of the total number of patients. The most frequent diagnoses in patients control, p<0.05), reduced the number of neutrophiles (24,8±5,9% vs 32,1±5,7% in patients control, p<0.05) and significantly reduced the level of pro-inflammatory cytokines, especially the level of IL-8 (23,4±6,5 µg/ml vs 38,9±7,8 µg/ml in patients control, p<0.05). Considered significantly efficacy on lung function, on cell and cytokine contents of induced sputum, we can conclude that, low doses of theophylline as the PEI inhibitor may improve steroid sensitivity and to be approved for the management in patients with ever COPD.

P544 The influence of high doses of N-acetylcysteine alone or in combination with inhaled corticosteroids on quality of life in patients with COPD

Valentina Kapustina, Svetlana Ovcharenko. Faculty Therapy No.1, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: The aim of our study was to evaluate the effects of 6-month oral N-acetylcysteine (NAC) treatment 1200 mg/day alone or in combination with inhaled corticosteroids (ICS) on health-related quality of life (QOL) in outpatients with COPD.

Methods: A total of 62 patients with stable COPD (36 males, mean age 66.8 years, GOLD stage I-IV) were included and divided into two treatment groups. Group 1 received NAC 1200 mg/day alone or in combination with inhaled corticosteroids. Group 2 was treated with standard ICS. Differences in baseline characteristics were tested using chi-square or t-tests. Data were analyzed using SPSS version 11.0.

Results: During a 15-month follow-up, we observed significant improvements in QOL measured both SF-36 and SGRQ with greater changes in combination therapy. We assess the prescription criterion, the prescriber department, time since diagnosis of the patients, the duration of the consultation and the number of consultations per patient.

Conclusions: Long-term treatment of stable COPD patients with NAC 1200 mg/day improves QOL measured both SF-36 and SGRQ with greater changes in combination of NAC with ICS.
The link between COPD and atherosclerosis (AS) has been speculated but such information at clinical features of COPD and its relation to AS is limited. To evaluate subclinical AS in patients with COPD 33 male COPD patients and 15 healthy male control subjects included the study. Subjects with exacerbation, DM, chronic renal failure, cardiac diseases excluded. All the subject underwent spirometry, blood sampling, carotid artery USG, 24 hour oxygen saturation recording via a holteroxymeter. We determined carotid artery intima-media thickness (CAIMT) as indicator of subclinical AS. Mean CAIMT was greater in COPD group (p=0.005) with regard to the cardiac evaluation, the physical examination (yugular venous distention: 21.1% vs 4.6%; p=0.017), the ECG (28.9% vs 10.8%, p=0.030), the distention: 21.1% vs 4.6%, p=0.017; peripheral edema: 31.6% vs 12.3%, p=0.022, the systolic BP, mmHg 130.1 ± 19.9 vs 118 ± 16.1, p=0.03. The diastolic BP, mmHg 79.7 ± 11.9 vs 72.6 ± 6.6, 0.009. CRP mg/L 6.04±4.5 vs 3.4±1.8, p=0.03. % FEV1 44.1±7.5 vs 19.1±18.3, p<0.001. % FVC 57.2±14.6 vs 104.0±15.3, p<0.001. Average saturation in 24 hours 90.8±3.7 vs 94.9±1.2, p<0.001. % FVC 32.3±10.8 vs 34.2±10.1, p<0.001. Mean CAIMT 0.802±0.19 vs 0.65±0.07, p=0.005. HsCRP: High sensitive CRP, T90%: Time below 90% saturation.

Table 2. Pearson's correlation of all subjects for CAIMT and other variables.

Multivariate stepwise analysis showed significant associations between CAIMT and decreased % FEV1 (p=0.018) and between systolic BP (p=0.004) independent of age, BMI, duration of illness, diastolic BP, % FVC, CRP. T90%. Although the duration of COPD, T90% and CRP correlated with CAIMT, impaired lung function and severity of systolic blood pressure the predict CAIMT.

Multivariate stepwise analysis showed significant associations between CAIMT and decreased % FEV1 (p=0.018) and between systolic BP (p=0.004) independent of age, BMI, duration of illness, diastolic BP, % FVC, CRP. T90%. Although the duration of COPD, T90% and CRP correlated with CAIMT, impaired lung function and severity of systolic blood pressure the predict CAIMT.

Conclusions: 1. The global prevalence of HD in our cohort of patients with an acute exacerbation of COPD was 37%. 2. In this setting, physical examination, an abdominal ECG, an EF<50% and a NT-proBNP value > 1200pg/mL could help to identify patients with a probable HD. 3. Fifty-six-six of readmissions were patients in GOLD stage IV.
Results: Results are presented in the Table.

Evaluation of incontinence and quality of life in patients with chronic obstructive pulmonary disease (COPD) and bronchiectasis

Claire Brockwell, Ailian Clark, Alexandra Baker, Ben Hacker, Gabriella Pardo, Helen Little, Andrew Wilson. School of Medicine, University of East Anglia, Norwich, United Kingdom

Background: Incontinence is common and more prevalent in respiratory disease. Despite this, the effect of incontinence on quality of life in respiratory patients is unknown.

Methods: We conducted a case controlled questionnaire study. We sent the International Consultation on Incontinence Modular Questionnaire (ICIQ), the Leicester Cough Questionnaire (LCQ), the EuroQol 5D (utility) and the MRC questionnaire to 150 patients with COPD, 150 patients with bronchiectasis and 150 controls (orthopaedic surgical patients). The groups were age and gender matched. Mann-Whitney test was used to determine effects of gender and disease.

Results: 164 (81 male) patients and 53 (22 male) controls replied. Overall, females (68%) had more incontinence than males (41%). Median (IQR) values for ICIQ were significantly (p=0.05) higher for female patients (4 (0-7.5)) but not for male patients (0 (0-4)) compared to controls (3 (0.5-5.5), 0 (0-3.7) respectively). However, male, but not female, patients with incontinence had a significantly (p=0.01) lower utility score, despite no difference in MRC (table).

Conclusion: Incontinence is more common in females but males with incontinence had more impaired overall health related quality of life.

P554

Initial clinical phenotype of COPD: Correlation with the natural history of the disease

Luca Fasano¹, A.M. Grazia Pacilli², Paolo Carbonara³, Valerio Di Sciascio³, Haria Valentini¹, Giacomo Miste², Angela Montanari³, Mario Fabbrè³, Maurizio Zompatori³, Stefano Nava³. Respiratory and Critical Care Unit, S Orsola Malpighi University Hospital, Bologna, Italy; ²Cardiothoracic Radiology, S Orsola Malpighi University Hospital, Bologna, Italy; ³Statistics, University, Bologna, Italy

The chronic airflow limitation characteristic of COPD is caused by a mixture of small airway disease (obstructive bronchiolitis) and parenchymal destruction (emphysema), the relative contributions of which vary from person to person. Aim of this study was to evaluate, at the time of the first specialist evaluation, the differences in lung and cardiac function and HRCT extent of emphysema in patients with a spirometric diagnosis of COPD but different initial clinical presentation (chronic bronchitis [CB] versus dyspnea [Dy]). 45 consecutive patients referred to our outpatients service by their GP were divided according to their main first symptom (chronic bronchitis or dyspnea). Patients with Dy had an obviously higher dyspnea score vs those with CB (MRC 2.9±0.9 vs 2.3±0.6, p=0.02) and produced much less sputum (p=0.001). The severity of obstruction was similar in the two groups (FEVI 31±11% predicted in both groups, p=0.89; FEVI/FVC 26±6% vs 27±7%, respectively for Dy and CB, p=0.62). The CB had worse arterial blood gases (PaO2 62±12 vs 69±10 mmHg, p=0.03; PaCO2 50±7 vs 45±7 mmHg, p=0.02) and showed a higher proportion of pulmonary artery diameter >29 mm (a surrogate sign of pulmonary hypertension) 18/24 vs 8/21 pts, p=0.02). Dy group had larger CT emphysema extension score (18 ± 5 vs 13 ± 6, p=0.06). In conclusion we have shown differences between the two COPD phenotypes with similar airflow limitation, with CB patients showing worst ABGS and indirect signs of pulmonary hypertension, while Dy group was characterized by a higher degree of emphysema.

Relationships between elevated cardiac troponin levels in COPD exacerbations and subsequent cardiac investigation and management
Padman R. Vamadevan, Andrew W. Hitchings, Dana Almood, Tejwant S. Grewal, Emma H. Baker. Clinical Pharmacology Unit, Division of Biomedical Sciences, St George’s, University of London, London, United Kingdom

Background: Admission cardiac troponins (cTn) are elevated in 18-27% patients with COPD exacerbations (BMC Palm Med 2009;9:35). Clinicians often attribute this rise to co-existing inflammation, anaemia or renal impairment. However, elevated cTn is associated with a significantly increased 30-day post-admission mortality independently of these factors, and its presence indicates underlying myocardial injury. We determined proportions of patients undergoing cardiac investigation and receiving cardioprotective treatment following an exacerbation-related cardiac troponin I (cTnI) rise.

Methods: 237 COPD patients (127 male, 73±1±1lyrs) admitted with exacerbations between July 2008-9, and with a measured cTn within 24h of admission were retrospectively identified. Clinical information was retrieved using the electronic patient record.

Results: Admission cTnI was ‘undetectable’ (U, <0.02g/l) in 15%, ‘measurable’ (M, 0.02-0.05g/l) in 59% and ‘elevated’ (E, >0.05g/l) in 26% of patients.

Conclusions: cTn elevation is not specific for coronary thrombosis, and rises in exacerbations may reflect demand ischaemia, direct cardiac damage, or myocardial strain. No guidelines exist regarding the optimal management of such patients. However, given their important risk of early mortality, further cardiac investigation to reveal underlying mechanisms of cTnI release may enable appropriate therapeutic targeting and improve outcomes.

P556
Comparison of multidimensional assessment systems with regard to risk prediction for exacerbations of COPD
Takashi Motegi1, Takeo Ishii1, Kumiko Xattori1, Koichiro Kamio2, Rana Bibi1, Lene Birket-Smith1, Søren Rismon Kristensen2, Stephen Edward Rees1, 2Pulmonary Medicine, Aalborg Hospital, Aalborg, Denmark, 3Clinical Pharmacology Unit, Division of Biomedical Sciences, St George’s, University of London, London, United Kingdom

Aim: Acute Exacerbations of COPD (AECOPD) are major concerns with regard to morbidity, mortality and economic burden. In this study, we compared the efficacy of 3 assessment systems for predicting AECOPD: BODE index (Body mass index, airway Obstruction, Dyspnea, Exercise capacity), DOSE index (Dyspnea, airway Obstruction, Smoking status, Exacerbations); and ADO index (Age, Dyspnea, airway Obstruction).

Participants and methods: The frequency of exacerbations (FE) for a 1-year period was retrospectively studied for 183 consecutive patients with COPD. Following parameters were used to compare the results: pulmonary function tests, 6-minute walking test, MMRC dyspnea scale, low-attenuation area (LAA%) on HRCT and FE.

Results: The study included 183 patients (M/F 170/13). The mean age and FEV1/spredicted were 71.4 years and 55.7%, respectively. The mean annual exacerbation rate was 0.57 per patient-year. FE was significantly correlated with the following parameters: lower FEV1/spredicted (p<0.01), lower DLCoVa (p=0.021), shorter 6MWD (p=0.016), higher MMRC (p<0.001), higher DOSE index (p<0.001), higher BODE index (p=0.001), higher ADO index (p=0.001), and larger LAA% (p=0.002). FE was significantly associated with prescribed long-term oxygen therapy (Odds ratio [OR] 4.17, p < 0.001) and exacerbation rate for the previous year (OR 2.79, p < 0.001). The area under the receiver-operator curve for predicting exacerbation during the 1-year follow-up was 0.65 for the BODE index, 0.64 for the ADO index, and 0.75 for the DOSE index.

Conclusions: The DOSE index appears to be superior to the BODE and ADO indices in terms of predicting exacerbation rate of COPD.

Conclusions: The method may be a useful tool to evaluate COPD patients during admission without the need for repeated arterial punctures.

*R* value: 0.05

**Aim and objectives:**

This was a post-hoc analysis to examine if geographical region influenced exacerbation outcomes.

**Methods:**

Inclusion criteria were age ≥40 years, postbronchodilator forced expiratory volume in 1 s (FEV1) ≥70% predicted and ≥1 exacerbation in prior year. Countries (n=25) were grouped into four regions: Eastern Europe, Western Europe, Nordic and Mediterranean. Interaction analyses were performed for time to first exacerbation (primary endpoint) and annual exacerbation rate.

**Results:**

7376 patients were randomized and treated. Results are shown in the table.

**Conclusions:**

Post-hoc subgroup analysis of the POET-COPD™ trial by geographical region suggests that the exacerbation benefits of tiotropium over salmeterol are independent of region.

### PS60

**Effect of acute exacerbations on circulating thrombotic and fibrinolytic markers in COPD patients**

**Method:**

Surrogate markers of inflammation were collected: interleukin-6 (IL-6), C-reactive protein (CRP), fibrinogen, von Willebrand’s factor (vWF), platelet activation factor (PAI-1), in COPD subjects during exacerbation.

**Results:**

IL-6 (pg/mL) 4.95 (2.98, 7.95) 3.2 (2.38, 4.78) –35.4% 0.005

CRP (mg/L) 146.99 (121.26, 231.4) 122 (91.1, 160.2) –21% <0.001

D-D (ng/mL) 1575.51 (1175.23, 2081.25) 127 (111.25, 151.5) –29.4% <0.001

PAI-1 (mg/L) 11.35 (9.38, 14.28) 10.7 (8.48, 13.38) –5.7% 0.765

All values are medians (QR).

**Conclusions:**

COPD exacerbations are associated with endothelial activation and clotting initiation. This was not associated with a change in PAI-1, implying a defect in the fibrinolytic response to inflammation. The pro-thrombotic nature of COPD exacerbations appears to be mitigated by excessive fibrinolysis.
P563 Procalcitonin use in acute exacerbations of COPD
Thomas Medveczky, Mark Jackson. Department of Respiratory Medicine, The Primary Royal Hospital, Brighton and Sussex University Hospitals NHS Trust, Haywards Heath, Sussex, United Kingdom

Background: Procalcitonin (PCT) is a circulating marker that is elevated in infection and inflammation.

Methods: We determined the role of procalcitonin in acute exacerbations of COPD (AECOPD) using PCT. Patients were recruited from all four hospitals in a primary care trust.

Results: 223 patients were recruited with AECOPD, of which 48 had normal PCT (<0.3 ng/mL).

Discussion: PCT is a useful marker in the diagnosis of AECOPD.

Purpose: To investigate the role of PCT in the diagnosis of AECOPD.

P564 Characteristics of patients with chronic obstructive pulmonary disease (COPD) discharged from the emergency department – Improving the care pathway for acute exacerbations of COPD
Santino Capocci, David Turner, Robert Pitane, Myra Stern, Louise Restrick. Respiratory Medicine, Whittington Hospital NHS Trust, London, United Kingdom

Introduction: The aim of this study was to characterise patients with COPD who are discharged from the emergency department.

Methods: Retrospective analysis of patient records from the Whittington Hospital, London, for COPD exacerbations that required admission to hospital over a 12-month period.

Results: 223 patients were identified with COPD exacerbations, of which 132 were discharged from the emergency department.

Discussion: The results of this study will be used to improve the care pathway for COPD exacerbations.

P565 Impact of pneumonia on mortality and length of stay in patients hospitalized with acute COPD exacerbations
Siw Lillevik Andreassen 1, Erik Dyb Liaaen 2, Nikolai Stenfors 3,4, Anne Siw Lillevik Andreassen 1, Erik Dyb Liaaen 2, Nikolai Stenfors 3,4, Anne Hildur Heniksen 5,6.

1The Medical Faculty, Norwegian University of Science and Technology, Trondheim, Norway; 2Department of Internal Medicine, Aalesund Hospital, Aalesund, Norway; 3Department of Respiratory Medicine and Allergy, Östersund Hospital, Östersund, Sweden; 4Pulmonary Medicine, Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 5Department of Pulmonary Medicine, Trondheim University Hospital, Trondheim, Norway; 6Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, Norway

Background and aims: Pneumonia is a common complication in patients hospitalized with acute exacerbations of chronic obstructive pulmonary disease (COPD).

Methods: Retrospective analysis of patient records from the departments of Internal Medicine and Respiratory Medicine in one Swedish and two Norwegian hospitals. The study included 1144 patients with pneumonia and acute COPD exacerbations.

Results: The mortality rate was 5.9% in patients with pneumonia and COPD exacerbations, compared to 0.7% in patients with COPD exacerbations without pneumonia.

Discussion: Pneumonia is a significant risk factor for mortality in patients with COPD exacerbations.

P566 Infectious factors influences on cytomorphic picture of bronchial biopsies at COPD exacerbation
Ekaterina Bukreueva 1, Gulnara Seitoiva 2, Raisa Pleshko 3, 1Therapy, Siberian Medical University, Tomsk, Russian Federation; 2Medical Genetics, Siberian Medical University, Tomsk, Russian Federation; 3Morphology, Siberian Medical University, Tomsk, Russian Federation

Purpose: To study the influence of infectious factors on the cytomorphic picture of bronchial biopsies in patients with COPD.

Methods: Retrospective analysis of patient records from the departments of Internal Medicine and Respiratory Medicine in one Swedish and two Norwegian hospitals. The study included 237 patients with COPD exacerbations and 237 controls.

Results: In patients with COPD exacerbations, the cytomorphic picture of bronchial biopsies was characterized by increased expression of inflammatory factors, goblet cell hyperplasia, and goblet cell hyperplasia.

Discussion: The results of this study will be used to improve the care pathway for COPD exacerbations.
bating patients showed decline in processing speed than stable patients or controls (p<0.01) (figure).

Conclusion: Over half of patients prior to discharge with exacerbation and a quarter of stable patients with COPD exhibited significant cognitive decline in processing speed. It is unclear if the decline was acute, chronic or reversible.

P568
Post discharge mortality in North Indian patients with exacerbation of COPD
Hiland Dar, Umar Khan, Parvaz Koki. Internal & Pulmonary Medicine, Sheri-Kashmir Institute of Medical Sciences, Srinagar, J&K, India

Background: Mortality rates at 2 years following discharge among patients with exacerbation of COPD have ranged from 2% to 49%. No mortality data is available for such patients from India, especially Kashmir, where COPD is common.

Objective: To determine the post discharge mortality rate and its determinants among patients with COPD hospitalized for acute exacerbation, in a 650-bedded tertiary care facility in Srinagar, Kashmir (India).

Methods: One hundred and fifty-one patients admitted with a diagnosis of acute exacerbation of COPD from October 2008 to October 2010 & discharged after treatment were followed prospectively for a period of 2 years for any deaths and recurrences of exacerbations. The relationship of mortality with potential patient factors was analysed statistically by employing multiple logistic regression analysis, Kaplan-Meier survival analysis and Cox regression.

Results: During a followup of two years following discharge, 39.7% patients died with the majority (34.4%) of deaths occurring during the first year. Risk factors associated with increased mortality included lower health status at discharge (SGRQ score > 60, p value < 0.001), GOLD stage 4 (p < 0.001), BMI < 18 kg/m2 (p value < 0.001), SaO2 < 90% at discharge (p < 0.001) and 6MWT distance of < 150 metres (p < 0.001). Frequency of exacerbations increased with increasing GOLD stage (p < 0.001).

Conclusion: Mortality after discharge is high among North Indian patients admitted with acute exacerbation. Poor functional status at discharge and advanced lung disease are predictive of excessive mortality. Advanced stage of lung disease is associated with frequent exacerbations.

P569
CURB-65 and mortality in pneumonic and non-pneumonic exacerbations of COPD
John Steer1, G. John Gibson2, Stephen C. Bouzid1. 1Department of Respiratory Medicine, North Tyneside General Hospital, North Shields, Tyne and Wear, United Kingdom; 2Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom

Background: Acute exacerbations of chronic obstructive pulmonary disease (AE-COPD) requiring hospitalisation are often complicated by consolidation. In patients with pneumonia and AECOPD (pAECOPD) the CURB-65 prediction tool is widely used yet its utility in this population is uncertain.

Objective: To assess the effect of pneumonia on outcome, and the utility of CURB-65, in AECOPD.

Method: Patients hospitalised with AECOPD were recruited prospectively, with clinical data and CURB-65 collected on admission. Pneumonia was defined as the presence of new consolidation visible radiographically. Patients with pneumonia and AECOPD (pAECOPD) the CURB-65 prediction tool is widely used yet its utility in this population is uncertain.

Results: Of 920 patients recruited, 299 (32.5%) had complicating pneumonia. Patients with pAECOPD were significantly older (mean age 75.7 v. 71.8 years); more often male (50.8% v. 43.8%); and had slightly better preserved ventilatory function (FEV1 45.5 v. 42.9% predicted).

In-hospital mortality was higher in pAECOPD than in non-pneumonic exacerbation (npAECOPD) (20.1% versus 6.9%). The relationship of mortality with potential risk factors was analysed statistically by employing multiple logistic regression analysis, Kaplan-Meier survival analysis and Cox regression.

Results: Area under the ROC curve for CURB-65 against in-hospital mortality was 0.66 (95% CI 0.58-0.74) for pAECOPD and 0.72 (95% CI 0.63-0.81) for npAECOPD.

Conclusion: In pAE-COPD, risk of death is significantly greater than in npAE-COPD, and is higher than predicted by CURB-65. CURB-65 is a less good predictor of in-hospital mortality in pAE-COPD than previously reported in CAP, and other prediction tools may be required for this population.

P570
Anemia in COPD patients with an exacerbation
MCarmen Juarez Morales, Javier De Miguel Diaz, Teresa Gomez Garcia, Jorge Garcia Angulo, Jorge Chancafe Morgan, Gema Sanchez Mudoz, Luis Puente Maestu. Respiratory Medicine, Hospital General Gregorio Marlaon, Madrid, Spain

COPD typically shows poliglobulia secondary to hypoxemia. But, the opposite situation is also observed.

Aims: Quantify and classify the anemia in COPD patients with an exacerbation, describe clinical characteristics, factors which determine the anemia and the influence of the anemia in survival.

Methods: Observational prospective study of COPD patients with exacerbation. Demographic and anthropometric information as well as co morbidities and lung functional test is recorded. We measured survival after discharge and mortality risk factors.

Results: 106 were included (93 men). Average age was 71±6. BMI 25.7±5.6 kg/m2. FEV1 39±13%. 88.9% used to smoke or were smoking at present. Anemia prevalence was 37.7%. dyslipidemia (73.6%), high blood pressure (59.4%), heart failure (59.4%) and pulmonary hypertension (44.3%). Average Charlson index was 5.92±1.4 (87.9% ≥ 5), and the META index measured by bioelectric impedance was 22.3±7.8. 48.1% were taking more than 5 treatments. In logistic regression test factors that determined anemia were age, iron and creatinin levels (p<0.05) and the META index (p<0.01). Survival in patients with anemia at 39±4 months compared to 53±3 months in patients without anemia (p<0.001).

Mortality risk factors were FEV1, BMI and creatinin levels.

Conclusion: Anemia is frequent in COPD patients with exacerbation. Survival is clearly influenced by anemia. Age, iron levels, creatinin levels and META index influence the most.

P571
Our experience of procalcitonin assay in identifying bacterial COPD exacerbations
Christopher Gough1, Parthipan Pillai1, Rohinton Mulla2. 1Department of Respiratory Medicine, Luton and Dunstable Hospital NHS Foundation Trust, Luton, United Kingdom; 2Department of Microbiology, Luton and Dunstable Hospital NHS Foundation Trust, Luton, United Kingdom

Background: Procalcitonin (PCT) is a pre-hormone which is raised in bacterial infection.

Aim of study: To evaluate the benefit of measuring PCT level in recognising bacterial from non bacterial COPD exacerbations.

Method: We prospectively evaluated 24 COPD patients who were admitted with exacerbation. They had PCT, C-reactive protein (CRP), white blood cell (WBC) measurements and a chest radiograph (CXR). Use of antibiotics were recorded.

Results: 6 patients had CXR findings of consolidation and 5 of them had high PCT indicating bacterial infection. 1 patient had a moderately elevated PCT which could be due to early sampling. In 18 patients who had normal CXR findings, 3 had positive PCT and of these, 1 had high CRP and WBC indicating true bacterial infection. 1 had high CRP with normal WBC which could be due to atypical bacterial infection. 1 had normal CRP with high WBC which could be due to spurious low CRP result. 15 patients who had negative PCT, 7 had normal CRP and WBC indicating no bacterial infection. 2 of them had normal CRP but slightly raised WBC and we feel the raised WBC were due to preceding steroid treatment. 3 of them had raised CRP and normal WBC and 3 had both raised CRP and WBC. These may be due to bacterial infection, and the negative PCT represented early sampling. All patients had antibiotics on admission.
Conclusion: Many patients with COPD exacerbation are treated with antibiotics without bacterial infection. High PCT level indicates bacterial infection in these patients. The converse is also true but this should be used in conjunction with CRP and WBC. PCT level is associated with either raised CRP or WBC, a second late PCT level should be measured.

P572 Profile of patients hospitalized with COPD acute exacerbation in respiratory department in Tunisia

Hela Kammoun, Ines Zendah, Ibtihel Khouaja, Samir Sakka, Amel Khattab, Leila Bayahi, Habib Ghedira. Respiratory Department I, Abderrahmen Mami Hospital, Ariana, Tunisia

In developing countries, Respiratory departments are facing new challenges with the huge increase in the number of patients hospitalized with COPD acute exacerbations with limits in ICU beds availability and delay in the management. The aim of this study is to outline the profile of patients with COPD exacerbation hospitalized in a respiratory department in Tunisia. Methods: A hand-made search of the main Spanish journals of COPD (Archivos de Bronconeumología, Revista Clínica Española and Medicina Clínica) and its references and a hand-made search from 2005 to 2010 of proceedings of annual congresses of European Respiratory Society, Spanish Society of Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 3Department of Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 4Department of Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 5Department of Respiratory Medicine, University of Milan, Milano, Italy

Conclusion: Many patients with COPD exacerbation are treated with antibiotics without bacterial infection. High PCT level indicates bacterial infection in these patients. The converse is also true but this should be used in conjunction with CRP and WBC. PCT level is associated with either raised CRP or WBC, a second late PCT level should be measured.

P573 Anemia in COPD patients in Spain: A systematic review

Jesus Díez-Manglano1, José Barquero-Romero2. 1Internal Medicine, Hospital Royo Villanueva, Zaragoza, Spain; 2Internal Medicine, Hospital Tierra de Barros, Almendralaje, Badajoz, Spain

Objective: To determine the prevalence of anemia in COPD patients in Spain and the consequences of it.

Material and methods: We have conducted an electronic search in PubMed and Embase, a hand-made search of the main Spanish journals of COPD (Archivos de Bronconeumología, Revista Clínica Española and Medicina Clínica) and its references and a hand-made search from 2005 to 2010 of proceedings of annual congresses of European Respiratory Society, Spanish Society of Respiratory Pathology (SEPAR) and Spanish Society of Internal Medicine.

Results: We have obtained 11 studies, 2 journal papers and 9 congress abstracts. 7 studies were conducted in Internal Medicine departments, 3 in Pneumology departments and one in both. All studies used same criterion for COPD diagnose. Six studies defined anemia with WHO criteria and there was significant heterogeneity in exclusion criteria. The studies included 1669 patients, with a mean age of 74 years and 537 (32.2%) had anemia. Patients of Internal medicine departments were older (75.8 vs 70.7 years). There was no difference in prevalence by study department (Pneumology 50.2%, Internal Medicine 32.8%; p=0.32) but prevalence was lower with different of WHO diagnose criteria (24.5% vs 34.9%; p=0.0001). Anemia was not associated with readmission or mortality after three months in one study but was associated with readmission in the next year in one study and with one year-mortality in two studies. In one study anemia was associated with mortality during a median follow up of 531 days.

Conclusion: A third of Spanish patients with COPD had anemia. Anemia is associated with more long-term readmissions and mortality.

P574 Interleukin-6, but not pentraxin 3, predicts adverse clinical outcomes on short-term prognosis of patients with incipient heart failure

Piera Boschetto1, Barbara Biotuzzi2, Alessandro Fucili3, Alfredo Potenza1, Licia Ballestreri1, Mariannita Stendardi1, Simonetta Piva1, Alessia Verduri1, Giuseppe Francesco Sferrazza Papa1, Francesca Real1, Paolo Carlucci1, Fabiano Di Marco1, Livio Colomba1, Paola Fracasso2, Stefano Centamare1. 1Clinica di Malattie dell’Apparato Respiratorio, A.O. San Paolo, Università degli Studi di Milano, Milano, Italy; 2Unità Operativa Medicina III, A.O. San Paolo, Università degli Studi di Milano, Milano, Italy

Background: Bedside lung ultrasonography (BLU) is a technique performed and interpreted by the clinician who is in charge of the patient treatment. Even if recent studies show that BLU is beneficially useful in several diseases, the impact of this technique in clinical practice is still unknown. The primary aim of the present study was to analyze BLU indications in a respiratory medicine setting. The secondary aim was to describe the actual methodological application of BLU in the clinical practice.

Methods: Prospective observational analysis of consecutive BLU performed by pulmonologists at a University Hospital from April to May 2011. After each examination indication, methods and clinical consequences were recorded on a web-database.

Results: To date 88 exams on 88 patients (aged 42±34 years, mean±sd, 32 females, 32 pediatrics, 16 outpatients) were performed by 7 experienced operators. The quality of the examination was judged adequate in all patients. The most frequent indications were: lung consolidation (40%, of exams), pleural effusion (27%), guidance for thoracentesis (17%), acute respiratory failure (8%), and pulmonary edema (3%). The mean duration of the exam was 16±3 minutes. As a result of BLU, in only 8% of the cases chest X-ray or CT were needed. Bedside clinician reported that in 73% of the cases BLU had a significant clinical impact on patient management.

Conclusions: Our preliminary results suggest that lung ultrasonography performed by pulmonologist is a feasible procedure, widely used in clinical practice for many indications. Further studies are needed to evaluate the impact of BLU on patients management.

P575 Incidental abnormalities found on CT pulmonary angiograms performed for suspected acute pulmonary embolism

Manish Pagaia1, Stephen Crooks1, Michael Hughes2. 1Respiratory Medicine, Warwick General Hospital, Warwick, United Kingdom; 2Department of Radiology, Warwick General Hospital, Warwick, United Kingdom

A CT pulmonary angiogram (CTPA) is performed commonly in the investigation of suspected pulmonary embolism (PE). Other lung, mediastinal and pleural pathologies of clinical importance may be found incidentally, not suspected from the chest X-ray (CXR). We studied 500 sequential CTPA scans done for suspected PE in a community hospital to assess the nature and frequency of any pulmonary pathology first suggested by the CTPA, with particular reference to pneumonia not documented on the CXR. All CXR and scans were reviewed by a radiologist as well as the treating clinicians.

Retrospective observational study of CTPA for incidental pulmonary pathology

Clinical diagnosis of the patient: PE. Vascular and parenchymal imaging

858
PE was found in 123 of 500 (24.6%) scans. 110 of 500 (22%) scans showed evidence of pneumonia. Out of these 110 scans, 55 had no evidence of pneumonia on the CR (of which 63% had been taken within 48 hours of the CTPA). Other pathologies were seen on 145 of 500 scans (29%).

Other pathologies seen on CTPA, (n=145):

- Pleural Effusion: 63 (43.45%)
- Lymphadenopathy: 15 (10.34%)
- Pulmonary nodules: 14 (9.65%)
- Metastatic lesions: 12 (8.37%)
- Others: 43 (29.7%)

Conclusion: This study is suggestive of a high incidence of pneumonia in patients scanned for suspected PE, half of whom had no consolidation in the initial CXR. This raises questions concerning the reliability of clinical decisions that rule out pneumonia when there is no consolidation on a CXR.

P577 Management of incidental lung parenchymal lesions found on CT pulmonary angiograms
Sharifa Sallehuddin, Said Isse, Peter Russell, Supriya Sundaram. General and Respiratory Medicine, Princess Alexander Hospital, Harlow, Essex, United Kingdom

Introduction: Incidental findings of lung parenchymal lesions are common. Many studies have described what these alternative diagnoses are, but few have looked at their management. We aim to investigate how these are managed in a UK district general hospital.

Methods: We retrospectively analysed all CT(PA) reports undertaken in 2008. We used Picture Archiving and Communication System (PACS) for CTPA reports. Pathweb for biopsy results and multidisciplinary team (MDT) database and patient case notes for the final clinical outcome.

Results: Of the 345 scans performed, 275 (80%) were reported as Low, 25 (7%) as Moderate and 40 (12%) as High probability of PE. 5 patients scans were not formally reported.

Conclusion: Management of incidental lung findings requires standardised follow-up and management plans in order to avoid delays.

P578 Diffuse pulmonary ossification (DPO) in the absence of interstitial fibrosis: CT findings and clinical correlates
James Gruden, Prasad Panse, Amy Trahan. Radiology, Mayo Clinic Arizona, Phoenix, AZ, United States

Introduction: Diffuse pulmonary ossification (DPO), or "dendriform" ossification, occurs in the setting of chronic lung diseases, particularly usual interstitial pneumonitis (UIP). It also can occur in association with severe emphysema or chronic lung infections. We have observed DPO on chest CT in the absence of chronic lung disease.

Objectives: We attempt to identify a cohort of individuals with CT findings of DPO in isolation in order to a) characterize the imaging appearance and b) assess potential clinical factors that may be associated with the development of DPO.

Methods: We performed an electronic search of chest CT reports between 2000-2011 at our institution for the word "dendriform". The CT studies were then reviewed by 3 thoracic imaging subspecialists who characterized the findings. Electronic medical records were reviewed for demographic and clinical information and follow-up data.

Results: 25 patients with CT findings of DPO in isolation were identified. DPO showed dense and soft tissue nodularity involving the peripheral interstitium (interlobular septae and subpleural space) especially in the posterior and lateral lower lungs with a costophrenic angle predominance. Patients were male, over age 70, and had few if any pulmonary symptoms. Smoking history was variable. Many had a history of or risk factors for aspiration. Serial scans, when available, showed progression of DPO over many years with minimal clinical change.

Conclusions: DPO can occur in isolation with a characteristic CT appearance, particularly in elderly men. It may indicate recurrent chronic aspiration in some cases. The findings progress over time with minimal clinical symptoms.

P579 Ventilation – Perfusion scan outcome when the chest radiograph is abnormal
Zahra Raisi Estabragh, Arun Lakanpal, Adiel Ashraf, Robert Hewson, Hassan Burhan. Respiratory Medicine, Royal Liverpool University Hospital, Liverpool, United Kingdom

Introduction: Guidelines recommend isotope lung scanning (V/Q) may be considered as first line investigation for suspected pulmonary embolism (PE) provided there are facilities on site and a chest radiograph (CRX) is normal. Occasionally, V/Q scans are performed in the presence of an abnormal CRX.

Aim: To study the diagnostic yield of V/Q scans in patients with suspected PE and an abnormal CRX.

Method: All patients who had a V/Q scan for suspected PE over a period of 12 months from February 2008 were included in the study. The CRX and V/Q scan reports were recorded.

Results: 1041 V/Q scans were performed at our institution with a preceding CRX. Of these, 345 CRXs were reported as abnormal.

- Other pathologies seen on CTPA (n=145):
  - Effusion 72
  - Consolidation 71
  - COPD 68
  - Atelectasis 48
  - Pulmonary Oedema 37
  - Nodules 8
  - Fibrosis 8

Of the 345 patients with an abnormal CRX that had a V/Q scan, 275 (80%) were reported as Low, 25 (7%) as Moderate and 40 (12%) as High probability of PE. 5 patients scans were not formally reported.

Conclusion: One third of the patients had a V/Q scan to investigate suspected PE had an abnormal CRX. Despite this, 275 (80%) of these patients had a low probability scan, 9 of these patients went on to have a CTPA and only 1 was positive for PE. A low probability V/Q scan may prevent unnecessary radiation exposure and adequately exclude PE, even in the presence of an abnormal CRX.

PS80 Ex vivo lung sonography: Morphological-ultrasound relationships
Andrea Smargiassi1, Riccardo Inchingolo2, Gian Soldati3, Cosimo Damiano Inchingolo1, Salvatore Valente1. 1Pulmonary Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; 2Emergency, Ospedale "Valle del Serchio"; Lucca, Italy; 3Surgical Pathology, Ospedale “Valle del Serchio”, Andria, Italy

The nature of lung ultrasound “artifacts” (B-lines, White Lung) has not yet been determined. We need to know what pathological structure and what physical mechanism create artifacts. We believe that lung ultrasonographic imaging is the acoustic behavior of ultrasonics crossing substrates of variable porosity or density. Each of 5 New Zealand white rabbit right lungs was sequentially inserted in cylindrical, rigid, hermetically sealed containers, with different volumes of 50 mL, 30 mL, 20 mL and 15 mL. Both lung and internal space of each container communicated with external air through a cork cap: the former through a cannula connected to trachea lumen and the latter through a tube connected to an aspiration system. Each system underwent negative pressure to get different known degrees of lung inflation. Densities were obtained for each lung at each level of inflation. Every lung was studied through ultrasonography and then sectioned and analyzed to correlate images with histological appearance.

In normal lung the variation of the pleural plane from specular reflector to generator of acoustic interference recognizes a mechanism which is related to values of tissue density. Artifacts described in lung ultrasonography as B-lines and White Lung appear in the normal lung through air dependent or weight dependent increases in density.

Conclusion: Ultrasound artifacts are density or porosity related. B-Lines and white lung (as in pathological conditions) can be reproduced in normal lungs that are deflated (i.e. denser or less porous) to levels of density which are not realizable under in vivo physiological conditions (< 0.45 g/mL). This mechanism is at the base of the genesis of artifacts also in the pathologic lung.
PS81 Agreement between clinical and HRCT diagnoses in the evaluation of patients with respiratory diseases
Kabali Nandakumar1, Ketaveseeram Vijayarath2, 1Respiratory Medicine, Queens Hospital, Burton-on-Trent, Staffordshire, United Kingdom; 2Respiratory Medicine, New Cross, Wolverhampton, United Kingdom

Aim: HRCT scans have been widely used in the diagnostic algorithm of respiratory diseases. In this study we aim to find out the agreement between clinical and HRCT diagnoses in such workup.

Methods: A retrospective study analysing 100 consecutive patients who had HRCT scans between July and September 2008. Data of scans and clinical information were obtained from electronic patients records.

Results: Total number of patients who had HRCT scan was 100. The average age patients was 65.3. Males constituted 61%. 76% of referrals were made by respiratory physician (RP), the rest from other specialties. The commonest presenting symptom was SOB (61%). Overall 54% of HRCT diagnosis correlated with clinical diagnosis. 76% request were made by RP of which 29% (38%) correlated with clinical diagnosis. A total of 38 patients had clinical sign on examination, 37 (97%) of these had HRCT findings consistent with clinical diagnosis but only 40 of the 62 patients (64%) with no clinical signs had clinical-angiographic correlation. 52 of the 56 patients (92%) who had prior chest X-ray abnormality which was later confirmed on a HRCT. The remaining 42 patients who had normal X-ray, only 20 (47%) had HRCT abnormality. The correlation increased to 96% when it was referred by a RP who had identified clinical signs and this further improved to a 100% when there was an associated CXR findings.

Conclusion: In this study only 54% of the patients had clinical-angiographic correlation. This correlation improved significantly to 100% when requested by RP who had identified prior clinical signs and chest X-ray abnormalities. Routine request for an HRCT scans are unsyndicated and should not be encouraged.

PS84 Abnormal chest radiographs preceding VQ scans: Does the type of abnormality matter?
Arun Lakanpal, Zahra Raissi Estabragh, Adeel Ashraf, Joseph Abbott, Robert Hewson, Hassan Burhan. Respiratory Medicine, Royal Liverpool University Hospital, Liverpool, Merseyside, United Kingdom

Introduction: Abnormal chest radiographs (CXR) have been considered to affect the interpretation of Ventilation Perfusion scans (V/Q) for the investigation of suspected Pulmonary Embolism (PE). Recommendations suggest a V/Q scan only if a contemporaneous CXR is normal. Impact of individual CXR abnormalities on the outcome of V/Q scan has been fully explored.

Aim: To study the impact of individual CXR abnormalities suggestive of a range of cardiopulmonary diseases on V/Q scan results for the investigation of suspected PE.

Method: All V/Q scan and preceding CXR reports from February ’08-January ’09 at our 960 bed teaching hospital were included in the study.

Results: Data for a total of 1041 subjects who had a CXR prior to V/Q scan. The number of V/Q done on those with abnormal CXR findings was 345. The CXR abnormalities were classified as per the underlying cardiopulmonary pathology suggested by the report.

Discussion: Regardless of whether the CXR report preceding the V/Q scan was suggestive of infection, effusion, congestion or “COPD”, the proportion of low probability V/Q scans was high (71-95%). This proportion was particularly high at 95% (and with no high probability scans) in those with CXR suggestive of pulmonary oedema/congestion.

When used in the correct clinical context a V/Q scan can be used with a high degree of accuracy despite certain CXR abnormalities.

PS85 Limits of normality of quantitative thoracic CT analysis
Massimo Crescioni1, Davide Chiumello2, Eleonora Carlesso1, Elisabetta Gallazzi1, Antonella Marino1, Matteo Brioni1, Chiara Chiaruzzi1, Federica Ylenia Romano2, Daniela Februs1, Luciano Gattinoni1,2, 1Dipartimento di Anestesia, Rianimazione e Terapia del Dolore, Fondazione IRCCS Ca’ Granda - Ospedale Maggiore Policlinico, Milano, Italy

Introduction: Quantitative CT scan analysis has been widely studied in ARDS patients, while, data on healthy population are scanty. Reference values, however, would be of clinical relevance when assessing, i.e., the excess lung weight or edema, or whatever change in CT anatomy/physiology induced by disease.

Methods: We retrospectively included patients who underwent a spiral CT scan for clinical reasons and whose images were considered normal by radiologists. Lungs were outlined on each CT image with a dedicated software; lung weight, volume and tissue fraction were computed with a dedicated software.

Results: We enrolled 52 patients (25 males), age 65±12 years, height 1.67±0.09 m, BMI 26±4.8 kg/m². The table summarizes the main CT scan characteristics of patients, with CT taken at near total lung capacity. While the gas values are dependent on inflation, the lung weight is not. Therefore, of particular note the significant correlation between height and total lung CT scan characteristics

PS83 Early signs of hemoptysis, the advance CT approach
Tamará Milosavljević1, Aleksandar Ivićkovic2, 1Radiology, ZC Vranje, Vranje, Serbia; 2Center of Radiology, KC Nis, Nis, Serbia

Hemoptysis, the act of coughing up blood, is an important symptom since it frequently reflects serious underlying lung disease. If the hemoptysis is substansial, persistent, or recurrent then further evaluation is indicated, particularly since patients with chronic bronchitis related to smoking are at high risk for lung cancer. The aim of the study is to incorporate advance CT procedures in determining the right cause of hemoptysis and finding the right area of bleeding.

Material and methods: All patients were examined of 16 or 64 MDCT. We use standard lung procedure and all advanced MDCT methods, like 3D virtual bronchoscopy, nodule check, MDCT pulmonary angiography, very slow infusion injection of contrast agent, very fast bolus injection of contrast agent and wide specter of filters.

Results: We examined 1536 patients with coughing up blood and compared results on the most common causes with standard methods. Male patients were 917 and female 619, middle age of patients were 56.4 years. Our first aim was to find lung cancers in patients with recurrent hemoptysis where standard methods were insufficient. We found 18.76% more lung carcinomas in compare with standard procedures. Our second aim was to find right place of bleeding. In compare with standard methods we found the right place of bleeding in 21.54% more patients than with standard methods.

Conclusion: Improvements with advanced techniques are significant. Important is to notice that advanced techniques are not invasive and in any case danger to patients health.
Conclusions: Lung weight and volume are related to height in a healthy population.

82. From outside to inside: access to the pleura

PS86
A randomised controlled study to compare the efficacy of closed pleural biopsy and medical thoracoscopic pleural biopsy in undiagnosed exudative pleural effusion

Ravindranath Bhat, Nithya Haridas, K.P. Suraj, James Ponnedathakuzhy Thomas. Department of Pulmonary Medicine, Medical College Calicut, Calicut, Kerala, India

This study was to compare the efficacy of closed pleural biopsy with Abram’s needle and medical thoracoscopic pleural biopsy in the diagnosis of undiagnosed exudative pleural effusion in a tertiary care setting. It was a randomised controlled study during the period Nov 2008 - Oct 2010. All patients admitted with pleural effusion, underwent a clinical workup for pleural effusion during the period Nov 2008 - Oct 2010. Those patient’s with exudative pleural effusion without the establishment of a specific diagnosis were included in the study. The enrolled patients were then randomised into 2 groups. One group was subjected to medical thoracoscopic pleural biopsy and the other to closed pleural biopsy with Abram’s needle. Demographic, clinical & biochemical characteristics, diagnostic yield and the complications were of the two groups were compared.

58 patients were included in the study and they were divided into two groups of 29 patients each. The diagnostic yield was 86.2% in the medical thoracoscopic group as compared to 62.1% in closed pleural biopsy group. Complication rate was 10.3% in medical thoracoscopic group compared to 17.2% in closed pleural biopsy group. Hence the study concluded that medical thoracoscopic pleural biopsy had a better diagnostic yield with a lower complication rate as compared to closed pleural biopsy with Abram’s needle.

PS87
US guided thoracostomy true cut biopsy of peripheral pulmonary and mesothelial lesions

Rosen Petkov1, Yamakova Yordanaka2, Dainal Petrov3, Emilia Petkova1.
1 Thoracic Surgery, 2Anesthesiology and Intensive Care, University Hospital of Pulmonary Diseases, Sofia, Bulgaria

Aim: The aim of the study is to evaluate the diagnostic value and the risk from US guided thoracostomy true cut needle biopsy (USG- TTBNB) for diagnosing peripheral thoracic lesions and its complications.

Materials and Methods: In a prospective study (from 1999 to 2007) we observed 753 patients with peripheral pulmonary and 273 patients with mediastinal lesions above 10 mm in diameter in 98% of patients peripheral thoracic lesions were assessed noninvasively. By all patients we performed USG-TTBNB (12-18G) under local anesthesia. The biopsy specimens were examined with light microscopy. Immunohistological analysis was carried out when needed.

Results: USG-TTBNB gave an adequate material to the morphological diagnosis in 698 (92.7%) of patients with peripheral thoracic lesions, PPV 98% and NPV 93.5%. We observed a few complications: 6 cases of pneumothorax (0.8%), by 2 patients it was necessary to set percutaneous tube drainage. USG-TTBNB of patients with mediastinal tumor masses yielded positive histopathological diagnosis in 250 (91.6%) of TCNB cases, PPV 98.1% and NPV 94.3%. There were no complications such as pneumothorax or serious bleeding.

Conclusion: US-guided thoracostomy cutting biopsy appears to be effective and a safe method in the patients with the US accessible thoracic lesions. This technique has a good accessibility, low cost, safety and high diagnostic accuracy compared to CT guided needle biopsy.

PS88
Ultrasound guided thoracostomy coaxial needle biopsy in chest lesions

Monika Marcincinova1, Robert Slivka1, Peter Kukol1, Peter Janik2.
1 Pulmonology Department, National Institute for Tuberculosis, Lung Diseases and Chest Surgery, Vyse Hage, Slovakia (Slovak Republic), 2 Pathology Department, National Institute for Tuberculosis, Lung Diseases and Chest Surgery, Vyse Hage, Slovakia (Slovak Republic)

Aim: We examined diagnostic yield of ultrasound guided thoracostomy coaxial needle biopsy in chest lesions.

Material and methods: The 344 patients with ultrasonographically visible lesions of lung, mediastinum, pleura and chest wall were included in the study between August 2002 to January 2011. We performed TTNB with 18 gauge coaxial biopsy set. Five and more biopsies were performed for histologic examination. Immediately thereafter the lesion was aspirated with guide sheath connected to 20 ml syringe. Material retrieved by aspiration was proceeded to cytocoagulation and cell block was analyzed.

Results: A total of 344 patients were included from August 2002 to January 2011. Median age was 63.7 years (range 25-84 years), 20.7% were male. The majority of cases were lung lesions extending to the pleura (n=311, 90.4%), followed by pleural lesions (n=21, 6.1%), mediastinal lesions (n=8, 2.3%) and chest wall lesions (n=4, 1.2%). At the time of biopsy, a chest radiograph was available in all patients. Minimum lesion size was 3 cm.

Final diagnosis was established in 284 patients (82.56%), 60 patients (17.44%) were diagnosed by other means or were undiagnosed. 221 (77.82%) lesions were malignant, 63 (22.18%) were benign. The diagnostic yield TTBNB was 82.56%.

Adverse events were pneumothorax in 22 patients (6.4%) and in 8 of these, a chest drain was required (36.36%). Mild hemothorax (n=18, 5.2%), post procedural pain requiring medication (n=8, 2.3%), vagovascular reaction (n=6, 1.7%) were minor events.

Conclusions: Coaxial needle biopsy set technique is safe method with excellent diagnostic accuracy. This technique has advantage that several samples may be taken without having to repeatedly penetrate the pleura.
the operator, very low rate of complications and short acquisition time of the pleural space. Our new technique, real time echo guided costophrenic cannulation with Veress needle, allows to broaden the field of applications of thoracoscopy and might be used in patients who cannot maintain orthostatic position.

PS91 Medical thorascopic lung biopsy obtained by stapler device: A new trick in old ground?
Georgianna Haravelia1, Gerasimos Papavasileiou2, Dimitrios Zachelias2, Nikolaos Koulouris1, Manos Alchianatis1, Nikolaos Anastasios2. 1First Department of Respiratory Medicine, Medical School, Athens University, Athens Chest Diseases Hospital “Sotira”, Athens, Greece; 2Department of Thoracic Surgery, 1st IKA Hospital, Athens, Greece

Introduction: Recent advances in minimally invasive techniques and instrumentation have expanded the role of medical thoracoscopy. The introduction of an endoscopic stapling device has encouraged thorascopuc lung biopsy.

Aims and objectives: Evaluation of the quality of biopsy, the diagnostic efficacy and yield in high risk patients (pts) who underwent medical thorascopic lung biopsy (MTLB) for the evaluation of peripheral mass or diffuse interstitial lung disease using a stapler device under regional anesthesia and neuroleptic analgesia.

Materials and methods: During 2002-2011, 30 high risk pts (75% severe respiratory failure, 40% renal failure, 33% ischemic stroke) underwent MTLB. Biopsy samples were obtained by a stapler device. Midazolam and fentanyl were used for anesthesia and intercostal block was performed in all patients with ropivacain.

Results: Pts were 18 males and 12 females (mean age 68.9 years, range 28-75 years). Mean duration of the procedure was 30 min (15-35 min). No intra-/post-operative deaths nor major complications were recorded. Successful analysis was obtained in all pts. Biopsy specimens from the stapler device had mean dimensions: 3.2x1.7x0.9 cm (mean volume: 3.61 ccm). All lung biopsies were conclusive and diagnostic. Malignancy was diagnosed in 17/30 pts and nonmalignant conditions in 13/30 (43% interstitial lung diseases, 50% interstitial pneumo-nia, 7% infarct). No complications were recorded.

Conclusions: Stapler tissue specimens received by MTLB have a high diagnostic accuracy in pts with peripheral tumours and diffuse interstitial lung disease. MTLB by stapler device is a pioneer method ensuring superior quality of biopsy and can be applied in high risk pts without complications.

PS92 Alternate drain of thoracic cavity by Seldinger technique in a tertiary healthcare setting
Georgianna Haravelia1, Gerasimos Papavasileiou2, Dimitrios Zachelias2, Manos Alchianatis1, Nikolaos Anastasios2. 1First Department of Respiratory Medicine, Medical School, Athens University; 2First Department of Thoracic Surgery, 1st IKA Hospital, Athens, Greece

Introduction: Chest drain insertion is often required in the clinical practice. Large bore catheters are difficult to insert and may be associated with adverse complications. Seldinger drainage kit has been introduced to minimize the complications associated with conventional tube drainage.

Aims and objectives: To share our experience in 850 patients who were inserted a portex Seldinger drainage kit (SDK) 12 F during the period 01/2001-02/2011.

Materials and methods: Details of all SDK insertions were retrospectively collected by the respiratory team. This observational study looked at the indications, success, complications and patient outcome.

Results: Eight hundred and fifty pts (mean age: 65.7 years, range: 18-92) were inserted an SDK due to pleural effusion (500 patients), pneumothorax (250 patients), traumatic hemothorax (100 patients). Successful drainage was obtained in all patient without any complications at insertion except for 1 case of hemothorax in a patient receiving anticoagulant therapy. Thirty patients had a malignant pleural effusion and underwent pleurodesis with bleomycin or novodrin. In pneumothorax, the mean stay of drain was 3 days (range 2-15 days).

Conclusions: SDK is a minimal invasive and effective alternate method for pleural space drainage with minor complications. SDK training should be regularly applied in young doctors to ensure the quality and efficacy of performance.

PS93 Thorascopic findings of undeterminate eosinophilic pleural effusion
Konstantina Archontogeorgiou, Stavros Anevlavis, Pavlos Zaregoroudakis, Kaisal Nath Gupta, Demosthenes Bours, Marios Froudarakis. Department of Pneumonology, Medical School Democritus University of Thrace, Alexandroupolis, Thrace, Greece

Background: An etiologic diagnosis cannot be established in 14% of eosinophilic pleural effusions, and these cases are referred as idiopathic. Yet, thorascoscopic diagnostic approach in this entity has never been studied. The aim of our study is to assess thorascoscopic findings in patients with undeterminate eosinophilic pleural effusion.

Methods: We studied all patients with undeterminate eosinophilic pleural effusion during the last 4 years among 168 patients who underwent medical thorascopy for diagnosis. Pleural effusion was considered eosinophilic when contained more than 10% of eosinophils. Effusion was classified as idiopathic if no etiology could be assigned during evaluation. All patients were followed at 1, 3, 6, 12 months.

Results: Patients with undiagnosed eosinophilic effusion were 8 (4.5%). Pleural eosinophilic count ranged from 10% to 99%. Macroscopical examination of the pleura during medical thorascopy demonstrated diffuse thickening, associating to inflammation in six patients and scattered nodules in two. Microscopical examination of pleural biopsies evidenced non-specific inflammation with eosinophilic predominance in all of our patients. Specific diagnosis was not identified in all cases. None of the patients received any specific treatment during the follow-up period. No relapse of pleural effusion was recorded.

Conclusion: Idiopathic eosinophilic pleural effusions are associated with nonspecific eosinophilic inflammation of the pleura. They usually follow a benign course with a resolution within a year without the administration of any specific therapy and a conservative approach with observational follow up is recommended.
P596

Medical thoracoscopy – A district general hospital experience

Nana Acharya, Richard Budd, Muhammad Malik. Respiratory Medicine, Barnsley Hospital NHS Foundation Trust, Barnsley, South Yorkshire, United Kingdom

The 2010 British Thoracic Society (BTS) guideline recommends the use of Medical Thoracoscopy (MT) in the management algorithm for malignant pleural effusion [1]. Despite this MT is not readily available outside of tertiary centres in the United Kingdom [1]. An internal audit in 2010 showed the burden of pleural effusions at Barnsley Hospital (BH) over an 18 month period led to 1195 medical admissions; 226 (18.9%) were malignant effusions.

The process diagnostic for exudative pleural effusions has altered recently in BH to include semi-rigid MT.

Method: A retrospective analysis of computed tomography (CT) reports, histology and length of stay (LOS) for all individuals who underwent diagnostic MT (dMT) was performed.

Results: 44 MTs have been done to date. 32 were diagnostic and 12 therapeutic. Diagnostic MT results are as follows:

Adenocarcinoma 10, Melanoma 2, Breast Carcinoma 3, Ovarian Carcinoma 1, Tuberculosis (TB) 2, Inflammatory Tissue 14.

CT reports prior to dMT revealed a low suspicion of malignancy in 18 and a high suspicion of malignancy in 14. dMT histology confirmed malignancy in 14 patients within the high suspicion group. Within the low suspicion group dMT histology confirmed 2 cases of lung cancer, 2 cases of TB and no evidence of malignancy in 14.

Average LOS after dMT was 3.7 days (range 1-11). The average LOS prior to the introduction of MT was 7.3 days (range 1-59).

Conclusion: MT is cost-effective through reducing LOS and referral rates to tertiary centres. As this study has highlighted a potential missed or delayed diagnosis in 12.5% of cases. Patient experience is improved by facilitating a timely patient journey within their local hospital.

P597

Pigtail catheter drainage – When to use it

Jan Plutinsky, Karol Bitter, Zuzana Taligova, Ingrid Libakova, Dalibor Petras, Renata Sabo. 2nd Pneumology, Specialized Hospital of St. Zoerardus Zobor, Nitra, Slovakia (Slovak Republic)

Chest drainage for patients (pts) with pneumothorax or various etiology pleural effusions is a method of choice. In some circumstances specialists use a tip with a curled drain-pigtail catheter (PC).

Aim: To share our experience with pigtail catheter drainage.

Method: 106 pts were drained in 2010. A pigtail catheter was used on 17 pts (16%). Pts 14 or 16 CH were preferred. The site of insertion was determined using a sonography examination. PC with a trocar was inserted into the skin incision. After insertion of the drain the end of the catheter was twisted by pulling back the synthetic fibres and then fixed. The luer end of drain was connected to a Heimlich valve and then to a urine bag. When production of PE was < 100 ml/24 hours, the drain was removed.

Results: Out of 17 pts, 13 were M, mean age 60 (22-85 yrs), 4 were F, mean age 53.5 (42-69 yrs). The most frequent reason was encapsulated empyema in 8 pts, malignant effusion in 6 pts and TB, hemothorax and non- specific pleuritis in the remaining 3 pts. Pleurodesis was successful in 2 pts died during drainage (both from malignant effusion). The median duration of the chest drainage was 9 days (4-21 days).

Conclusions: The main advantage of using a PC was that the small space in encapsulated empyema is too small for using a conventional drain or when there is a suspicion of septated PE. The disadvantage of pigtail drainage: 1.twisted end impedes the re-expansion of the drained cavity, 2. the system with a trocar is sharp and so careful consideration should be given to the indications (avoid drainage of lung abscess), 3. removing the drains is more painful, 4. is more expensive than a normal catheter.

P598

Prognostic factors in patients with malignant pleural effusion undergoing thoracoscopy

Stavros Anevlavis1, Kailash Nath Gupta 1, Ioannis Sotiriou1, George Kouliatis1, Angelos Tsourvelou1, Mihalis Konkourakis1, Demosthenes Bouzou2, Makeup Froudauskas1. 1Pneumonology, Medical School, Democritus University of Thrace, Alexandroupolis, Greece; 1Radiation Therapy, Medical School, Democritus University of Thrace, Alexandroupolis, Greece

Background: Survival of patients with malignant pleural effusion is considered generally poor. These patients are likely to undergo thoracoscopy for diagnosis and treatment of their disease. Factors affecting survival are important to define to decide whether patients should undergo interventional procedures. The aim of our study was to evaluate prognostic factors of patients with malignant pleural effusion undergoing thoracoscopy.

Methods: Patients with malignant origin proven by thoracoscopy, have been studied prospectively to determine prognostic factors. Survival time was defined as the time interval from thoracoscopy to death or last follow-up. A regression model was used to assess significant prognostic factors.

Results: 90 patients with histological diagnosis of malignant pleural effusion after thoracoscopy, were included. Diagnosis was lung carcinoma 43%, breast carcinoma 23.6%, mesothelioma 12.9%, genito-urinary carcinoma 7.1%, GI 4.8%, other 5.1%, unknown primary 3.5%. The median overall survival time was 11 months ranging from 1 to 55. The Cox analysis showed that histology of the primary tumour (p=0.019), ps (p<0.001), gender (p=0.01), WBC (p=0.01) and neutrophils/lymphocytes ratio (p=0.018) were prognostic factors for survival. In the multivariate analysis, histology was an independent factor (p=0.002), performance status (p<0.001) and WBC (p=0.01).

Conclusion: Performance status, histology of the primary tumour, and WBC are factors of survival in patients undergoing thoracoscopy for malignant pleural effusion. The prospective identification of patients meeting these criteria may help physicians select patients for interventional procedures.

P599

Clinical utility of thoracoscopy under local anaesthesia in undiagnosed pleural effusion

Debjoyoti Bhattacharyya1, M.S. Barthal1, C.D.S. Katoh1, S. Bhattacharyya2, S. Rohatgi1, 1Respiratory Medicine, Military Hospital (Cardio Thoracic Centre), Pune, Maharashtra, India; 2Pathology, Army Hospital Research & Referral, New Delhi, Delhi, India; 3Medicine, Military Hospital (Cardio Thoracic Centre), Pune, Maharastra, India

Introduction: More than twenty percent of pleural effusions remain without an established aetiology after evaluation with pleurocentesis and closed pleural biopsy. Thoracoscopy under local anaesthesia greatly increases the diagnostic yield for undiagnosed pleural effusion and is taken as the gold standard diagnostic procedure.

Aims and objectives: To assess the utility and safety of thoracoscopy under local anaesthesia in the evaluation of undiagnosed pleural effusion.

Methods: This is a retrospective study of all patients with undiagnosed pleural effusion who underwent thoracoscopy under local anaesthesia between January 2008 and December 2010 in a tertiary care hospital.

Results: 52 patients (33 males and 19 females) underwent the above procedure during the period of study. Mean age of patients was 41.2 years (range: 19-78 years). Histopathological examination of thorascopic pleural biopsy revealed: malignancy in 34 (65.4%) cases, benign tumour (fibroma) in one (1.9%), tuberculosis in 14 (26.9%), empyema in two (3.8%), and nonspecific inflammation in one (1.9%) case. Diagnostic efficacy of medical thoracoscopy was found to be 98.1% (51/52).

Conclusions: Medical thoracoscopy is a safe, well tolerated and effective procedure.

P600

Low dose vs high dose talc pleurodesis for malignant pleural effusion

Ravi Shekhar Jha, Respiratory, Critical Care and Sleep Medicine, Indraprastha Apollo Hospital, Sarita Vihar, New Delhi, India

Introduction: Role of talc in pleurodesis for recurrent pleural effusion is very well defined. In developing countries like India, talc is still the cheaper and commonly used pleurodesis agent. However, it has been known to be associated with a lot of morbidity including ARDS. Common morbidities include fever, chest pain, nausea and vomiting. The aim of this study was to see the effectiveness of low dose talc pleurodesis, and to evaluate if low dose talc is associated with lesser complications.

Method: 24 adult patients of malignant pleural effusion were included in the study. Patients were divided in two groups. In group A (n=10), 5 gm of talc was used while in group B (n=14), pleurodesis was done with 10 gm of talc. Equal amount of xylcocaine and normal saline was used in both the groups. Standard method for pleurodesis was followed. Close observation was done for next 48 hours, and after that patients were followed every week till 6 weeks.

Results: Immediate complication in terms of fever, chest pain and nausea was seen in 40% (n=4) patients of group A where 5 gm of talc was used. When these patients were followed up for next 6 weeks, 30% (n=3) of patients showed recurrence of effusion, and required repeated thoracocentesis. In group B, 64% (n=9) patients developed immediate complications in terms of high grade fever, and vomiting. However, in group B also, 36% (n=5) patients showed recurrence of pleural effusion and required repeated thoracocentesis. ARDS was not seen in either group.

Conclusion: Talc pleurodesis with lower dose of 5 gm is associated with lesser number of complications and is equally effective as with 10 gm of talc.
P601 Feasibility and complications of relatan catheter insertion after pleural biopsy as a novel method for pleural fluid drainage
Enayat Safavi, Soroush Seifirad, Firoozbakhsh Shahabi, Sadegh Tavakkolizadeh, Hamidreza Abtahi. Pulmonary and Critical Care Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Backgrounds: Respiratory failure due to massive pleural effusion is usually treated with drainage via a chest tube.

Objectives: To investigate feasibility and complications of Nelaton catheter insertion after pleural biopsy as a novel method for pleural fluid drainage.

Methods: After pleural biopsy, a Nelaton catheter No.18 was inserted in the pleural space guided by Abram biopsy needle, after drainage control chest radiography was performed. Complications and daily examination results were recorded.

Results: 46 catheter insertions were performed on 41 patients (22 men, 19 women). Among these patients, pleural biopsy was indicated in 40 (78%) of them. Four patients underwent pleurdesis because of malignant pleural effusion due to breast cancer. Successful fluid drainage after catheter insertion was observed in all 46 cases. Dyspnea was significantly decreased after catheter insertion in all patients. Mean drainage duration was 5.3 days. In 42 (91.3%) patients complete lung expansion was observed. Incomplete lung expansion was observed in 4 patients (2 patients due to trapped lung, and 2 patients due to loculated pleural effusion). Catheter obstruction was occurred in 12 patients which was resolved after Salin wash out in 11 cases.

Conclusion: Nelaton catheter insertion after pleural biopsy is a novel, cost effective, simple and tolerable methods with low morbidity for drainage of pleural effusion in symptomatic patients undergo pleural biopsy. Common complication of this method is catheter obstruction which could easily be resolved with Salin wash out.

P602 Pleuroscopy with an autoclavable semi rigid thoracoscope
Julia Tarrega1, Yolanda Galea1, Perez Peres2, Montserrat Nieto3, Enric Barbera1.
1Respiratory, General Hospital de Granollers, Granollers, Barcelona, Spain, 2Anaestesia, Hospital General de Granollers, Granollers, Barcelona, Spain; 3Area de Tecniques Especials, Hospital General de Granollers, Granollers, Barcelona, Spain

Aim: Describe our experience with a endoscope similar in design to commonly used bronchoscope. This pleuroscope interfaces with processors and light sources employed for flexible bronchoscopy and, therefore, are available in most endoscopy units.

Method: Pleuroscopies were performed under local anaesthesia with conscious sedation. by a Respiratory Physician in a endoscopic suit. A single puncture technique and pleuroscope Olympus LTF-160 was used.

Results: 31 pleuroscopies undertaken over a 14-month period. From the 31 patients, 22 were men, and 9 women, mean age of 68.6. Four patients have bilateral pleural effusion. 17 procedures were performed on the right pleural space, and 14 on the left. The indication in 22 procedures was for diagnostic of a pleural effusion, in the other 9 procedures, the indication was pleurodesis in patients with previous diagnostic of malignancy. Pleural biopsy were obtained in the 22 patients and a histologic diagnosis of malignancy was made in 10 (3 mesothelioma and 7 metastasis of carcinoma) six patients have non specific pleuritis and 2 patient has necrotizing granulomas. In 3 patients with previous diagnostic of malignancy (esophagus and 2 bronchial carcinoma), metastatic pleuraly were ruled out. In 18 patients, pleurodesis with talc poudrage was performed. There were minor complications in 3 patients (1 subcutaneous emphysema, 1 infection of point of needle and 1 traumatic in the 6 hours after the procedure).

Conclusion: The Pleuroscopy with autoclavable semi rigid thoracoscope is a safe and useful technique in the diagnosis and management of pleural diseases. The semirigid pleuroscope must increase the performance of pulmonologists in the diagnosis and management of pleural disease.

P603 Retrospective evaluation of effectiveness and safety of local anesthetic thoracoscopy compared with blind chest drain pleurodesis
Claire Malcolm, Alex West, Liju Ahmed. Department of Respiratory Medicine, Medway NHS Foundation Trust, Kent, United Kingdom

Aim: To retrospectively evaluate effectiveness and safety of local anesthetic medical thoracoscopy and talc poudrage (TP) compared with chest drain and talc slurry pleurodesis (TS) in a district general hospital (DGH) without onsite thoracic surgery backup.

Methods: Data was collected between July 2007 and February 2010 using multidisciplinary team minutes and pharmacy records. All patients with malignant effusions who had treatment and had follow up were included. Patients with no diagnosis or follow up and those who did not have TS/TP were excluded.

Results: 104 patients were identified. 12 patients were excluded due to inclusion and exclusion criteria. Mean age in TS vs. TP was 71.5/7.14 years. Pleurodesis success rate in TS vs. TP was 22.8/7.5%. In the TS group, 75% of patients with a successful pleurodesis were receiving chemotherapy. The average time from pleurodesis to death in TS vs. TP was 201/359.6 days. Of the 14 failures in the TS group 64.2% (9/14) died within 6 months and 28.6% (4/14) had mesothelioma. In the TP group 79.1% (19/24) were alive at 6 months and 66.6% (2/3) of the failures had mesothelioma. Two of the 3 patients with failed TP were recruited in an ongoing trial involving a drug therapy and pleurodesis success rates. Mean follow up, TS vs. TP was 67.7/208.3 days. No serious complications were documented in either group.

Conclusion: To the best of our knowledge this is the first local anaesthetic thoracoscopy data comparing with TS in a DGH setting. The TP group has a success rate on par with published data. Based on this data we may conclude that local anaesthetic TP is effective and safe in patients with reasonable performance status.

P604 Safer intercostal drain (ICD) insertions
Phong Teck Lee, Thomas Hartung. Respiratory Medicine, Victoria Hospital, Kirkcaldy, United Kingdom

Introduction: Intercostal chest drain (ICD) insertion carries a small but significant risk to patients when not performed properly. We re-audited the practice of ICD insertion in our hospital following several implementations since a previous audit in 2007-08. These implementations include drain insertion in specialised areas i.e. respiratory unit treatment room, strict sterility, ultrasound guidance, insertion sticker check list and nursing care plan.

Results: There were a total of 31 patients (15 males) in the bi monthly audit from March '09 to January '10. Majority of the ICD insertions (87%) were performed in the respiratory unit and ultrasound guidance was documented in only 41.9%. ICD stickers were used in 83.9% and nursing care plan in 77.4%. Excluding the adverse event “pain”, complications rates in our hospital decreased from 39% to 12.9% in 2009-10 (Table 1). This is comparable with the complication rates of other centres (11-37%) [1]. Adverse events were significantly higher when drains were inserted outside a respiratory unit (p=0.007). Surprisingly, we found no statistical differences between complication rates and the use of ultrasound guidance, sticker check list; or nursing care plan.

Conclusion: ICD insertion is advised to be performed in a specialised unit by staff with relevant competencies under adequate supervision.

P605 A new electronic device for intrapleural pressure measurement – A presentation of use in a patient prepared for thoracoscopy
Rafal Krenke1, Elzbieta Magdalena Grabczak2, Marcin Michnikowski2, Jakub Palko2, Maciej Guc2, Ryszarda Chazan3. 1Department of Internal Medicine, Pneumology and Allergology, Medical University of Warsaw, Warsaw, Poland; 2Institute of Biocybernetics and Biomedical Engineering, Warsaw, Polish Academy of Sciences, Warsaw, Poland

Background: Measurement of intrapleural pressure is useful during various pleural procedures. However, the availability of electronic pleural manometers is limited.

Objectives: We aimed to 1) construct an electronic pleural manometer, 2) assess the accuracy of the measurements done with a new device, 3) perform an initial evaluation of the device during thoracoscet.

Methods: A vascular pressure transducer was used to transform hydrostatic pressure into an electronic signal. Reliability of the measurements was evaluated in a laboratory setting by comparing the results with those measured by a water manometer. Functionality of the device was assessed during thoracoscopic and artificial pneumothorax creation before medical thoracoscopy.

Results: We built a small device, which can precisely measure intrapleural pressure. The measurement results showed a very high agreement with those registered with a water manometer (no.999; p=0.001). The initial evaluation of the electronic manometer during pleural fluid removal and pneumothorax creation showed the mean initial intrapleural pressure 3.85 cmH2O which decreased steadily to -8.98 cmH2O after the removal of 1600 ml of pleural fluid and increased up to -1.29 cmH2O after insertion of 1000 ml of air. The procedure was safe, the only symptom recorded was cough which appeared after the withdrawal of 900 ml of pleural fluid (intrapleural pressure -1.96 cmH2O).

Conclusion: Our electronic pleural manometer can precisely measure intrapleural pressure during pleural fluid removal and pneumothorax creation. The procedure of pleural pressure monitoring during thoracoscet is easy to perform and safe.

83. To stent or not to stent: interventional bronchoscopy

P606 Interventional management versus standard treatment for inoperable malignant airway obstruction

Gregoris Stratoukas 1, Vicky Gerovassili 2, Charis Dimitropoulos 1, Dimitris Chiou 1, Giannis Giorgos 1, Filippos Filippidis, Philippis Emmanoulii 1, Sophia Gennimata 1, Andrianni Charpidou 1, Manos Alchanatis 1, Spyros Zakynthos 1, 2 11th Pulmonary Medicine Department of the University of Athens, “Sotiria” Hospital, Athens, Greece; 2 Critical Care and Pulmonary Medicine Department of the University of Athens, “Sotiria” Hospital, Athens, Greece; 3 Oncology Unit of the 3rd Internal Medicine Department of the University of Athens, “Sotiria” Hospital, Athens, Greece

Although endoscopic management of malignant central airway obstruction (mCAO) is well established, not enough survival and quality of life (QoL) data exist comparing it with sole chemo-radiotherapy.

We prospectively studied patients referred to our unit for mCAO using the EORTC QoL questionnaire, at one day before, 1 week after and every following month.

40 patients (31 males) aged 66.2±12.3 (mean±sd) with either non-small cell lung cancer (n=35) or metastatic malignancies, were included. 31 patients (intervention group) underwent extensive interventional bronchoscopic management as indicated, whereas 9 declined endoscopic treatment (control group).

Patients of the two groups did not statistically differ in age, comorbidities, type of malignancy and level of obstruction. Overall follow up time was 6.6±6.2 (range 1-26) months. 13 patients are still alive followed for 6.6±7.6 months (range 1-26). QoL and dyspnea significantly improved in all patients of the intervention group up to 1 month after the procedure (p<0.05). Improvement was greater in those initially presenting with atelectasis and tracheal obstruction. Dyspnea remained significantly improved in treated patients up to the 6th month. For those surviving over the 9th month (n=11) and those surviving over the 12th month (n=6), QoL and dyspnea did not significantly deteriorate. In all time points, control patients had worse QoL and dyspnea (p<0.05). Mean survival time for intervention and control group were 20.7±4.23.57 and 6.3±4.7 months respectively.

Interventional bronchoscopy may achieve prolonged survival, significant and sustained QoL and dyspnea improvement, in patients with airway obstructing malignancies.

P607 Bronchoscopic assessment of airway invasion by esophageal cancer: A retrospective study

Rui Roio, Cecilia Pacheco, Daniela Alves, Joao Cruz, Lurdes Ferreira, Joao Cunha. Serviço de Pneumologia, Hospital de Braga, Braga, Portugal

Background: Fiberoptic bronchoscopy (FOB) is frequently used to evaluate possible invasion of the tracheobronchial tree by esophageal cancer.

Objective: To evaluate the diagnostic utility of FOB for the assessment of airway involvement by esophageal carcinoma and its resectability.

Material and Methods: Retrospective study of bronchoscopies in patients with potentially operable esophageal carcinoma, correlating its findings with other staging modalities, in the last 6 years.

Results: We included 40 patients, 87.5% male, mean age 63.4±13.2 years. Respiratory symptoms appeared in 15% of cases, all of them with endoscopic abnormalities.

In 16 (40%) patients, FOB revealed: extrinsic compression in 12 (30%) and endoluminal endoscopy in 4 (10%) cases. These features were more frequent at the left main bronchus (n=5) and middle third of the trachea (n=4). Comparing CT with FOB, we found that observed or suspected invasion of the trachea on CT (21 patients), was only confirmed by FOB in 4 cases (19%). In 3 patients with endoscopic abnormalities, CT revealed no invasion of the bronchial tree. In cases of suspected airway involvement (n=8) by endobronchial ultrasound (EUS), 3 had wall protrusion without evidence of mucosa’s infiltration. The overall accuracy of FOB with multiple brush cytology and bronchial biopsy in confirming or excluding airway invasion was 95%. Normal endoscopic appearance had a negative predictive value of 100%.

In 3 patients FOB was the decisive staging procedure, excluding surgical treatment.

Conclusion: Bronchoscopy with biopsy and brush cytology is a very accurate procedure in assessing potential airway invasion by esophageal cancer. CT and EUS findings alone are not reliable.

P608 Postintubation tracheal stenosis – A 15 year experience

Filipa Soares Pires 1, Manuel Vaz, Adelina Amorim, Carolina Sacena, António Morais, Gabriela Fernandes, Adriana Magalhães. Department of Pulmonology, Hospital de São João, Porto, Portugal

Background: Postintubation injury, with or without tracheostomy, is the most common cause of benign tracheal stenosis (TS).

P609 Endoscopic management of idiopathic tracheal stenosis

Jeanne-Marie Perotin 1, Thierry Jeanjean 2, Yoann Thibout 3, Stéphane Jouneau 4, Hervé Lena 5, Hervé Dutau 6, Philippe Ramon 7, Christine Lortet 8, Marc Noppen 9, Jean-Charles Hugo Manquet 9, Francois Lebargy 9, Gaetan Desles 1 1 Department of Respiratory Medicine, INSERM UMR 903, University Hospital, Reims, France; 2 Department of Respiratory Medicine, University Hospital, Angers, France; 3 Department of Respiratory Medicine, University Hospital, Saint-Etienne, France; 4 Department of Respiratory Medicine, CHU de Brest, Brest, France; 5 Department of Respiratory Medicine, Hopital Le Valdahon, Seyne, France; 6 Department of Respiratory Medicine, INSEF UPR9 EA 4427 SERAC, University Hospital, Reims, France; 7 Department of Respiratory Medicine, University Hospital, Marseille, France; 8 Department of Respiratory Medicine, University Hospital, Lille, France; 9 Department of Respiratory Medicine, AP-HP, Paris, France; 10 Department of Respiratory Medicine, University Hospital, Brussels, Belgium; 11 ENT Department, University Hospital, Reims, France; 12 Department of Respiratory Medicine, University Hospital, Nice, France

Background: Idiopathic tracheal stenosis (ITS) is a rare condition. A therapeutic option is endoscopic management, but long term results are not established. The aim of this retrospective multicenter study was to analyze long-term outcome after endoscopic management of ITS.

Methods: Patients endoscopically treated for ITS were included in 9 institutions involved in interventional bronchoscopy. A standard form was used to report patients and stenosis characteristics and long term outcome after endoscopic management.

Results: Twenty-three patients, 96% women, age: 45±16 years, were endoscopically treated for ITS. Time between first symptoms and diagnosis was 19±18 months. Bronchoscopy showed a web-like (61%) or complex (39%) stenosis, located in the upper part of the trachea mainly in the cricoid area. Endoscopic treatment included mechanical dilation only (52%) or associated with laser or electrocautery dilatation (30%) and stent placement (18%). All procedures were efficient with no morbidity or mortality reported. The follow-up after endoscopic management was 41±34 months. ITS recurrence occurred in 30% at 6 months, 59% at 2 years and 87% at 5 years with a delay of 14±16 months. The treatment of recurrence (n=13) included endoscopic management in 12 cases.

Conclusion: Endoscopic management of ITS provides a safe and efficient therapeutic option but late recurrences are frequent and requires long term follow-up.

P610 Airway measurements in tracheobronchial stenosis using endobronchial ultrasonography during stenting

Seichi Nobuyama 1, Naoki Furuya 1, Hiroshi Hnda 1, Hiroki Nishine 1, Noriaki Kurimoto 1, Terumi Miyazawa 1, 1 Division of Respiratory and Infectious Disease, Department of Internal Medicine, St Marianna University School of Medicine, Kawasaki, Kanagawa, Japan; 2 Department of Chest Surgery, St Marianna University School of Medicine, Kawasaki, Kanagawa, Japan

Purpose: To assess airway measurements, endobronchial ultrasonography (EBUS) and multi-detector low computed tomography (MDCT) images are compared in patients with tracheal stenosis.

Methods: Airway stenting was performed on 31 patients, 25 malignant and 6 benign. EBUS and MDCT images were compared before intervention and on the narrowing airway at 212 sites. Of these, 130 sites were considered normal and 82 abnormal. For malignant stenosis, airway measurements were taken at 160 sites including 112 normal and 48 abnormal. For benign stenosis, airway measurements were taken at 52 sites including 18 normal and 34 abnormal. This technique enables the EBUS probe to measure the distal end to proximal end of the stenosis whereby the inflated balloon size changes according to the degree of stenosis.

Results: The diameter and length of stenotic sites measured by EBUS and MDCT were near equal in all patients. Significant correlation was seen at all 212 sites.
Our experience revealed that topical application of MMC can be useful, the mean time since granulation and symptoms improvement is 17.3 months, and tissue in 43%, moderate in 29% and relapsing in 29%. At this moment, after MMC patients. Mean MMC sessions 2.7, with good and lasting decrease in granulation healing and scarring. Its topical application, as an adjuvant treatment in endoscopic management of stenosis, has showed good results.

Aim: Evaluate the results of MMC application by Rigid Bronchoscopy (RB) in PITS.

Methods: Selected patients with PITS, in whom MMC was applied it was used in a concentration of 0.4 mg/ml, applied with a cotton stiletto around granulation tissue, for 2-3 minutes, after RB dilatation or laser. Re-evaluation and MMC application was done according to evolution. Patients were evaluated for kind, location and stenosis size (%), treatment procedures and results with adjuvant MMC application.

Results: 7 patients, 71.4% women, mean age 55.4 years. Mean initial stenosis diameter 50% of airway lumen, mostly located 1-3 cm below vocal cords, with 1-2 tracheal rings involvement. Stenosis RIB dilatation, laser and MMC were made in all patients. Mean MMC sessions 2.7, with good and lasting decrease in granulation tissue in 43%, moderate in 29% and relapsing in 29%. At this moment, after MMC use, the mean time since granulation and symptoms improvement is 17.3 months, and mean final airway diameter 70% of the lumen.

Conclusions: Our experience revealed that topical application of MMC can be beneficial in the modulation of wound healing and in the decreasing scar formation in the treatment of airway stenosis. Further research and randomized prospective clinical trials are needed to determine the most effective concentration, time and frequency of exposure to MMC.

The management of post-intubation/traechostomy stenosis with silicone stent
Ji-Hyun Kim, Jeong-Eun Kim, Kyung Woo Kang. Division of Respiratory and Critical Care, Department of Internal Medicine, Changwon Samsung Hospital, Changwon University, School of Medicine, Changwon, Korea

Benign tracheal stenosis in adult patients may occur as a complication of intubation, tracheostomy or surgical procedure. Silicone airway stenting has opened up a new way to treat patients with post-intubation stenosis. We investigated the clinical efficacy by a review of patients with post-intubation stenosis who underwent consecutive Natural silicone stent. Between January 2005 and December 2007, 19 patients underwent ballooning, ablation using electro-surgical unit, or bougienage by rigid bronchoscopy, followed by placement of the Natural silicone stent. All patients reported subjective symptoms of symptoms immediately after stent placement. Spirometry data was collected at baseline, 3 months, and 24 months. The baseline and follow-up spirometry data was available in 11 patient. The baseline median FEV1% predicted was 40% (range, 22% to 62%). Follow-up spirometry showed 37% improvement (range, 19% to 74%) at 3 month later, and 41% improvement (range, 21% to 77%) at 24 month later.

The Natural stent were removed successfully in 10 patients (52.6%) after median of 16months. Other 5 patients (26.3%) were required re-stenting, and 4 patients died due to acute pulmonary edema with ESRD, myocardial infarction, intracranial hemorrhage. The Natural silicone stent proved to be effective and feasible therapeutic modality in improving quality of life with relief of dyspnea.

Post-intubation tracheal stenosis represents a severe complication in patients with hypercapnic respiratory failure due to COPD. We present a series of iatrogenic tracheal stenoses in COPD patients addressed to the Bronchiology Department during 5 years. There were 13 patients (10 males, 46% over 60 years old), COPD stage III-IV GOLD, who suffered a severe exacerbation that required oro-tracheal intubation; 8 needed tracheotomy Tracheal stenoses developed after a mean period of 24 days (7-42) and were clinically significant. Bronchoscopy revealed tracheal stenosis with diameter less than 5 mm. 8 were located in proximal trachea and 5 in medial trachea, with length more than 2 cm in 7 cases and less than 2 cm in other 6. Initially, all were treated with interventional bronchoscopy (dilatation, granuloma resection) but the results were unstable in time, requiring other methods: prosthetics (8 cases) or surgery (5 cases). In the patients treated by prostheses, the stent was removed in 3 cases after 1.5-2.5 years, the rest remained chronic carriers of prostheses. The patients treated by surgery had significant complications: 1 death by mediastitis, 3 stenosis relapse on the anastomosis line (finally resolved with interventional bronchoscopy). Only one case was successfully solved after surgery. In conclusion, interventional bronchoscopy had a higher success rate (37%) than surgical therapy (20%), also solving the cases complicated post-surgery with reocurrence of stenosis. While for different etiologies of tracheal stenosis, surgical resection is the first choice of treatment, in patients suffering from COPD, interventional bronchoscopy remains the only way to solve it.

Endobronchial stent therapy is an accepted method for the treatment of endobronchial stenosis. It is limited by a loss of physiologic surface and, thus, mucus retention. We developed a novel concept for a viable endobronchial stent (fig. 1 A). The concept is based on the combination of stent technologies with the principles of tissue engineering. The RespStent provides (1) a functional respiratory epithelium on the luminal side, which allows the maintenance of the mucociliary function in the stented area and hereby will help to reduce complications of mucus retention, (2) embedded micro- or nanostructures, enabling the sus-
Incidence of bacterial colonization in patients with tracheobronchial stents
Raquel Pascual Cascón, Rosa López Lisboa, Noelia Cubero de Frutos, Pablo Díaz Jiménez, Jordi Dorca Sargallat, Antoni Rosell Gratacos. Pneumology, Centre Sanitari Universitari de Bellvitge, Hospital de Llobregat, Barcelona, Spain.

Objective: To describe the prevalence and incidence of potentially pathogenic microorganisms (PPM) colonizing the airways of patients with tracheobronchial stents.

Methods: We collected bronchial washings from patients treated endoscopically for neoplastic or benign tracheobronchial stenosis.

Results: We retrospectively studied 39 patients during a median of 128 days (12-448), 12 (31%) COPD with FEV1% of 58%, benign disease 5 (13%) and malignant 44 (23%).

Conclusions: The main colonizing PPM are P. aeruginosa (158,4%) and S. aureus (9,2%) with a prevalence of 87,5% after 12 months. In 37 pts withopleural carcinoma, 8 pts with bronchial/tracheal cancer, 8 pts with other tumours, 9 cases with tracheostomy or tracheal intubation, 8 traumatic cases and 5 consequences with endoscopic therapy (laser, esophageal stent, bronchoscopic apy).

P618 Tracheo-esophageal phistula: The role of bronchology
Vitezslav Kolek, Stanislav Losse, Petr Jakubec, Helena Bartosova. Dept. of Respiratory.Medicine, University Hospital, Olomouc, Moravia, Czech Republic

Tracheo-esophageal phistula (TEP) is a complex condition with different etiology and prognosis. Present study evaluates a series of patients (pts) with TEP according to etiology, complications, survival and endobronchial treatment. Among 50 pts there were 41 (82%) men and 9 (18%) women, mean age was 62.2 years.

Tracheobronchoscopy was the diagnostic method of choice, other methods were anamnesis, chest X ray, 3Dimensional CT and esophagogyscopy. Malignant disease was the cause of TEP in 33 (66%) pts, benign disease in 17 (34%) pts. There were 17 pts with esophageal carcinoma, 8 pts with bronchial/tracheal cancer, 8 pts with other tumours, 9 cases with tracheostomy or tracheal intubation, 8 traumatic cases and 7 consequences with endoscopic therapy (laser, esophageal stent, bronchoscopic apy).

Phistula was covered by tracheal or Y tracheobronchial stent in 19 (38%) pts, esophageal stent in 8 (16%) pts and doublestenting in 4 (8%) pts. Median of overall survival (MOS) was 14.3 m. It was 8.8 m in men and 23.9 m in women (p = 0.044). MOS in malignant diseases was 5.6 m, in benign disease 43.8 m (p = 0.04).

BAE for tracheo-esophageal fistula at one. 17 TS were placed for oeso-bronchial fistula, 5 for bronchial obstruction and 7 consequences with endoscopic therapy (laser, esophageal stent, bronchoscopic apy).

P617 Long-term outcome of bronchial artery embolisation (BAE) for massive haemoptysis
Amit Adhikari1, Rishi Gupta1, Anan Sebastian2, Paul Tait2, James Jackson2, Philip Ind1.1Department of Thoracic Medicine, Hammersmith Hospital, London, United Kingdom; 2Department of Radiology, Hammersmith Hospital, London, United Kingdom

Objectives: Assess the long-term outcome of bronchial artery embolisation (BAE) for severe haemoptysis.

Methods: We retrospectively identified all patients undergoing BAE from 1994-2007. We collected data from hospital databases and primary care on demographics, respiratory diagnoses and procedure with follow-up of up to 16 years. Outcomes were all-cause mortality and recurrence of haemoptysis requiring repeat BAE.

Results: Of 158 patients who were embolised on 208 occasions. 85 (54%) patients were male and median age was 54 (IQR: 41-67y). The most common underlying diageses were aspergilloma (n=38; 24%) of patients), bronchiectasis (n=24; 15%), unidentifed cause (n=17; 11%) chronic tuberculosis (n=14; 9%), active tuberculosis (n=12; 8%) and cystic fibrosis (n=11; 7%). All-cause mortality at 1 month and 3 years was 5.3% and 29.7%, and need for repeat BAE was 4.7% and 30.7% respectively. Repeat BAE at 3 years was most common with aspergilloma (50%) and least common with active TB (0%). Mean survival was 39.6 months (p = 0.523) and in malignant diseases as well (5.0 m vs 5.6 m, p = 0.484). Endobronchial/endotraheal treatment brings substantial symptomatic relief, but sometimes can be a cause of TEP as well. Other survival determinants could not be analyzed in present study due to small number of patients.

Conclusions: BAE for massive haemoptysis is potentially life-saving with low short-to-medium term failure rates in previous studies. We aimed to characterise patients referred for BAE, to examine long-term treatment success and identify risk factors for requiring repeat BAE. BAE: Bronchial artery embolisation, TS: Total survival.
Introduction: Bronchial artery embolisation (BAE) is the procedure of selective bronchial angiography with embolisation of abnormal vessels.

Aims and objectives: To assess the efficacy and safety of BAE in patients with haemoptysis in pulmonary tuberculosis (PTB).

Methods: This is a retrospective study of all patients of haemoptysis in PTB who underwent BAE between January 2004 and December 2010 in a tertiary care hospital in India. Bronchial arteriography and embolisation was performed using 5 French pigtail catheter and polynyl alcohol (PVA) particles ranging from 150 to 1000 micrometers.

Results: 34 patients (21 males and 13 females) of haemoptysis in PTB, underwent 37 BAE procedures during the period of study. 11 (32.3%) of these patients had multidrug resistant tuberculosis. Mean age of patients was 29.4 years (range: 13-69 years). Indication of BAE was: acute major haemoptysis in 11 (32.3%) and chronic recurrent bleeding in 23 (67.7%) patients. Haemoptysis was successfully controlled after the embolisation procedure in 32 (91.4%) patients. Procedure was repeated in three (8.8%) patients within a period of six months because of recurrent haemoptysis. Following arteries were embolised: right bronchial artery (11), left bronchial artery (7), common bronchial trunk (7), intercostal artery (14), right internal mammary artery (1), thyrocervical trunk (1), right intercostobronchial (2), and left intercostobronchial (1). No abnormal vessel was detected in one patient. The only complication encountered was local haematoma in one (2.94%) patient. Clinical risks were: age (p=0.001), current smoking status (p=0.012), arterial hypertension (p=0.000), chronic arrhythmia (p=0.034), COPD (p=0.000), and stabilized cardiomyopathy (p=0.000). One year survival was 48%, two years survival - 24%.

Conclusion: Repeated BAE with chlorine e6 is a safe and effective for lung cancer patients. Survival depends on degree of endobronchial remission.
84. Rare diffuse lung diseases

P626
Intersitial lung diseases in children: The French national cohort study
Nadia Nathan1,2, Jacques Blicq3, Rola Abou Taam4,5, Christophe Delacourt1,6, Raphaëlle Chiron1, Lilou de Pouvriand7, Jean-Christophe Dubes1, Lisa Giovannini-Chami1,2, François Brémont1,2, Jacques Brouard1,2, Brigitte Fauroux1,2,3, Harriet Corvol1,2,3, Annick Clement1,2,3, for the French RespiRare Group.

Methods and materials: All patients undergoing LT performed between August 2005 and May 2010 by a single surgeon at our institution were reviewed retrospectively. All airway complications were managed by the Interventional Pulmonary team. Airway stenoses were managed with rigid bronchoscopy, balloon dilation, observation and or stent placement.

Results: A total of 98 patients underwent LT (86 bilateral, 7 left, 5 right). 46 female and 53 male, with a mean age 49.7. 28 patients (28.6%) developed pneumonia within three months of transplantation, 8 of which were identified as a result of pseudomonas (28.6%). 28 (28.6%) patients also reported having evidence of acute cellular rejection within three months after transplantation. The median length of mechanical ventilation after transplant was 3 days (range 1 to 183). Of the 98 patients, 35 (35.7%) developed airway stenosis at a median of 16 weeks (range 1 to 164 weeks following surgery). Of these patients, 23 (>65%) patients received at least one airway intervention.

Conclusions: Airway stenosis after LT can be successfully managed with a variety of airway interventions. Further studies are needed to determine the best modalities.

P625
SHFJV (super imposed high frequency jet ventilation), ETCo2 correlation to PaCO2 in diagnostic and therapeutic rigid bronchoscopy
Gabriela Koller-Halmer1, Ingrid Schindler1, Hubert Koller2.

Methods and materials: All patients undergoing diagnostic and therapeutic interventional rigid bronchoscopy under SHFJV. Monitoring of the patients included ECG, blood pressure, SaO2, EtCO2, arterial blood gas analysis, FIO2 jet, FiO2 aw.

Results: 23 Pediatric Department, Centre Hospitalier Universitaire de Tours, Tours, France; 2Pediatric Department, Centre Hospitalier Universitaire de Reims, Reims, France; 2UMR S-707, INSERM, Paris, France

Introduction: In France rare orphan diseases as pediatric interstitial lung diseases (ILDs) have been identified as a public health priority. A national pediatric reference center for rare lung diseases, Respilare, was created several years ago.

Objective: To investigate the prevalence and the expression of pediatric ILDs within a national cohort in France.

Methods: Children presenting with ILD from 1995 to 2010 were identified through the Respilare network. Clinical, radiological, functional, pathological, biological and genetical longitudinal data were collected by the physicians in charge of ILDs patients using a unique national biomedical database.

Results: Data were available for 197 children presenting with ILD. The mean incidence was 26/year. Median age at diagnosis was 20 months [0-16 years], and the sex ratio was 0.87 male/female. Investigations including thoracic high resolution computed tomography scan (n=197), broncho-aveolar lavages (n=97), lung biopsies (n=30) and analysis of surfactant genes (n=67) led to a diagnosis for 142 out of the 197 children (63.4%): surfactant mutation associated disorders (n=29), 14.7%, haemosiderosis (n=24, 12.2%), sarcoidosis (n=20, 10.2%) and alveolar proteinosis (n=17, 8.6%) were the most common diagnoses. Pulmonary hypertension was observed in 16% of cases.

Conclusion: A national database is now used in France for pediatric ILDs and facilitates clinical studies. Based on this experience, recommendations for diagnosis and therapeutic strategies are being established. As a European ILDs consortium is emerging, a European ILDs registry would be the next step to improve the knowledge of pediatric ILDs pathophysiology and their management.

Diagnostic value of serum VEGF-D in consecutive patients with lymphangioleiomyomatosis
Vincent Cotton1, Jacques Lacronique1, Laure Denis3, Patrick Jaffray4, Chahera Khouatra1, Raphaële Guelminger1, Dominique Valvey1, Hilario Nunez1, Jacques Bienvenu3, Bruno Crestani6, Camille Taillé5, Jean-François Cordier1,4, Respiratory Medicine, Cochin Hospital, Paris, France; 3Biochemistry Department, Paris Descartes, Paris, France; 2Respiratory Medicine, Bichat Hospital, Paris, France

Methods: Serum levels of VEGF-D were measured prospectively in 45 patients the diagnosis of LAM.

Results: Serum VEGF-D levels were significantly higher in patients with LAM compared to healthy controls (p<0.0001). VEGF-D was elevated (860 pg/mL) in only one patient with Birt-Hogg Dubé disease with the mutation PQ385X in the FLCN gene, with LAM ruled out by lung biopsy. Using 800 pg/mL as a threshold, the specificity of VEGF-D was 98% but sensitivity was only 76%. VEGF-D in LAM was >800 pg/mL in 57 patients, contributing to the diagnosis of LAM with false positive only rarely encountered (as in Birt Hogg Dubé disease). Serum VEGF-D level may remain elevated in transplanted patients and those receiving medical therapy.

Conclusion: Serum VEGF-D levels greater than 800 pg/mL contribute to the diagnosis of LAM with false positive only rarely encountered (as in Birt Hogg Dubé disease). Serum VEGF-D level may remain elevated in transplanted patients and those receiving medical therapy.

Extracellular concentration and enzyme activity of proteasome in BAL of patients with alveolar proteinosis

Franca Gnann1, Chiara Filippini1, Alba Rinaldi1, Jan-Christoph Thomassen2, Miaotian Cai3, Shinichiro Ohshima5, Josune Guzman4, Ulrich Costabel1 1- Department of Pneumology/Allergy, Ruhrlandklinik, University of Duisburg-Essen, Essen, Germany; 2Department of Anesthesiology, University Hospital, Düsseldorf, Germany; 3- Department of Molecular and Internal Medicine, Hiroshima University, Hiroshima, Japan; 4- General and Experimental Pathology, Ruhr-University, Bochum, Germany

Introduction: Pulmonary alveolar proteinosis (PAP) is a rare disorder characterized by alveolar accumulation of surfactant lipoproteins. Proteasomes are responsible for nonsyndromal protein degradation. They are involved in apoptosis, stress response and inflammation. ARDS and sarcoidosis show elevated levels of extracellular protease. The aim of this study was to detect proteasome concentration and enzyme activity in BALF in PAP.

Patients and methods: 22 PAP patients (20 with primary, 2 with secondary form) and 18 healthy controls were studied. 205 proteasome subunit (murine monoclonal antibody by Biomol Int. L.P., Exeter, UK) was measured by ELISA in BALF. The cleavage of 3 fluorogenic substrates (Suc-LVY-AMC, BZ-VGR-AMC and Suc-LLE-AMC) was used to describe the specific enzyme activity (cymotryptsin-, trypsin- and caspase-like) of extracellular proteasome.

Results: Proteasome concentration in BALF of PAP patients was 10-fold higher than in healthy subjects (659±422 vs 60±36 ng/mL, p<0.0001). Trypsin- and caspase-like activity of proteasome was significantly increased in PAP compared to healthy subjects (BZ-VGR-AMC 1.5±0.9 vs 0.2±0.15, 27 Suc-LLE-AMC 0.62±0.1 vs 0.07±0.06 pkat/mL; p<0.01). Enzyme activity for all 3 substrates correlated directly with the total protein concentration in BALF (r=0.7, p=0.002; r=0.56, p=0.03), inversely with TLCO (r=0.72, p=0.008; r=0.7, p=0.014; r=0.73, p=0.006).

Conclusions: Proteasome alveolar concentration is higher in PAP than in healthy controls. This is associated with increased trypsin- and caspase-like enzyme activity. Proteasome seems to be significantly involved in the alveolar protein degradation in PAP.

P629
Chronic eosinophilic pneumonia after radiation therapy for breast cancer

Marco Pon1, Alessia Rigatti1, Igor Marseiller1, Venero Politi1, Romain Lazor1, Andrea Azzola1 1- Department of Respiratory Medicine, Ospedale Regionale di Lugano, Sede Civico, Lugano, Switzerland; 2Department of Disease of the Thorax, Interventional Pulmonology Unit, Ospedale G.B. Monti, Lung Unit, Ente Sanitario Ospedaliero Respiratory Medicine, University Hospital Center, Lausanne, Switzerland

Background: Several reports have documented the possible appearance of organising pneumonia (OP) as complication of radiation therapy (RT) for breast cancer, but only one has described the occurrence of chronic eosinophilic pneumonia (CEP) in this setting (Cottin V. et al. Eur Respir J 2004, 23:9-13).

Methods and results: We describe 3 new cases of CEP developed after RT for breast cancer. The median time interval between the end of RT and onset of CEP was 4.3 months. All patients were symptomatic for fever or dry cough. None had history of allergy, one was an active smoker. Chest CT showed multiple areas of alveolar consolidation in regions not limited to the irradiated lung. None of the patients had blood eosinophilia >1 G/L. In all cases, the bronchoalveolar lavage (BAL) differed only of a modest eosinophilia (25%, 25, 45 and 90% respectively). The respiratory function tests showed normal lung volumes and reduced carbon monoxide transfer factor to 60% predicted in 2 patients. All patients had rapid resolution of symptoms with corticosteroid therapy. 2 patients experienced 2 relapses each after treatment withdrawal. In all patients, therapy could be stopped after a median time of 16 months. All are disease-free after a median time of 85 months.

Conclusions: We confirm the possible onset of CEP as expression of lung injury induced by RT for breast cancer. In contrast to previous observations, CEP after RT may occur in the absence of blood eosinophilia and history of asthma. Since CEP and OP after RT have similar clinical pictures, CEP may be misdiagnosed as OP if BAL is not performed.

Results: We enrolled 76 PAP patients from 1989 to 2011, divided as follows: Idiopathic PAP (n=70) of which the autoimmune nature was confirmed in 76%, Secondary PAP (n=3, 4%), Congenital PAP (n=11, 1.3%) and PAP-like disorders (n=2, 2.7%). The idiopathic PAP was mainly observed in males (72.8%) over females, with a mean age at diagnosis of 40.7±13. A smoking history (current or former smokers) occurred in 68.5%, with a mean of 27packyears/years. The most common presenting symptom was dyspnea, alone (27 patients) or in combination with cough (16 patients). 4 patients were completely asymptomatic. Intercurrent infections were present in 14 cases. Mean GMAs level was 261±240 μg/mL (< 3 μg/mL). From our whole series, 43 patients were submitted to WLL: 30 (43%) received 1 WLL, whereas 13 (30%) received 2 or more WLLs. Comparison of pulmonary function testing data between not lavaged and lavaged PAP patients showed a significant difference for the TLC%O2 (r= -0.76 ± 18.84 vs vs 46±1.37, p=0.01) and for the A-AO2 gradient (r= 17.8±17.9 vs 45±15.8 mmHg, p=0.043). Conclusion: The establishment of a reference center for PAP in Italy has allowed to gather and well characterize one of the largest series of PAP patients worldwide. Funding: AIF (FAR7M3C19K), eRARE (EaPAPNet).

Lymphocytes populations in bloods and lungs in patients with auto-immune pulmonary alveolar proteinosis

Yoshikazu Inoue, Taro Arai, Junji Onsuka, Chikatoshi Sugimoto, Masaki Hirose, Akiko Natsumuro, Yoko Iwaki, Mikiko Nakagawa, Seiji Hayashi, Masaki Ojada. Diffuse Lung Diseases and Respiratory Failure, National Hospital Organization Kinki-Chuo Chest Medical Center, Osaka, Japan

Background and aim: Pulmonary alveolar proteinosis (PAP) is a rare lung disease characterized by accumulation of lipoproteinaceous material within alveolar spaces. The clinical course of PAP ranges from spontaneous resolution of symptoms with corticosteroid therapy. 2 patients experienced 2 relapses each after treatment withdrawal. In all patients, therapy could be stopped after a median time of 16 months. All patients were symptomatic for fever or dry cough. None had history of allergy, one was an active smoker. Chest CT showed multiple areas of alveolar consolidation in regions not limited to the irradiated lung. None of the patients had blood eosinophilia >1 G/L. In all cases, the bronchoalveolar lavage (BAL) differed only of a modest eosinophilia (25%, 25, 45 and 90% respectively). The respiratory function tests showed normal lung volumes and reduced carbon monoxide transfer factor to 60% predicted in 2 patients. All patients had rapid resolution of symptoms with corticosteroid therapy. 2 patients experienced 2 relapses each after treatment withdrawal. In all patients, therapy could be stopped after a median time of 16 months. All are disease-free after a median time of 85 months.

Conclusions: We confirm the possible onset of CEP as expression of lung injury induced by RT for breast cancer. In contrast to previous observations, CEP after RT may occur in the absence of blood eosinophilia and history of asthma. Since CEP and OP after RT have similar clinical pictures, CEP may be misdiagnosed as OP if BAL is not performed.

Old and novel surfactant protein (SP-C) mutations in children

Ann-Christian Grimmel1, Michael Barker2, Frank Brachsch1, Monika Gappa3, Matthias Kappler1, Richard Kirzt4, Carolen Kroener3, Susanne Lass4, Elke Lorenz4, Claus Przyjmak5, Jan-Christoph Thomassen1, Claudia Werner4, Stefan Ziegen5, Matthias Greiss1 1- Department of Pediatrics, Dr. von Hauner Childrens Hospital, Munich, Germany; 2- Department of Pediatrics, Helios Children’s Hospital, Berlin, Germany; 3- Department of Pediatrics, University Children’s Hospital, Munich, Germany; 4- Department of Pediatrics, Marien-Hospital GmbH Wesel, Wesel, Germany; 5- Department of Pediatrics, Clementinen Children’s Hospital, Frankfurt am Main, Germany; 6- Department of Pediatrics, Paediatric Clinic, Bielefeld Mitte, Bielefeld, Germany; 7- Department of Pediatrics, University Clinic, Johann Wolfgang Goethe University, Frankfurt, Germany; 8- Pediatrics, Praxis Laurensberg, Aachen, Germany; 9- Department of Pediatrics, University Clinic, Mainz, Germany; 10- Department of Pediatrics, University Clinic Münster, Münster, Germany

Genetic variations of SP-C gene are known to cause interstitial lung disease. In previous studies 55 patients have been described focusing on the genetic abnormalities and clinical course. Here we report the data of children with SP-C mutations collected between 1998 and 2010. Lung biopsy findings and previous radiological imaging studies were re-examined using up to date classifications. All 11 children identified had heterozygous mutations in the SP-C gene, six of which carriedT37 and five other mutations (H59R, G47D, C121F, E191X, A112T). Age at onset of symptoms varied from birth to 11 years; however most presented with postnatal respiratory distress syndrome or later with tachypnea, cough and failure to thrive. Chest computer tomography showed a variety of different patterns including ground glass attenuation, mosaic pattern, lung fibrosis and cysts. Initial diagnosis was made by genetic testing alone in 6 of 11 cases and by lung biopsy in 5 patients. Histology pattern included non specific interstitial pneumonia and desquamative interstitial pneumonia, chronic pneumonia of infancy, pulmonary alveolar proteinosis and end stage fibrosis. Average follow-up was 7 years (0.8-
P633
Serum VEGF-D and VEGFR-3 are biomarkers in lymphangioleiomyomatosis for its diagnosis and impaired pulmonary function

Methods: We measured VEGF-C, VEGF-D and VEGFR-3 in serum of patients with LAM. In patients with LAM, 4 patients with chronic obstructive pulmonary disease (COPD), and 6 normal subjects by enzyme-linked immunosorbent assays, and compared them with pulmonary function tests.

Results: In patients with LAM, serum VEGF-D levels were significantly increased (2995.1±992.2 pg/ml) compared with patients with COPD and normal subjects (264.7±157.7 pg/ml, respectively). Serum VEGF-C and VEGFR-3 levels were also significantly increased in LAM (4511.3±746.7 pg/ml) compared with normal subjects (2633.8±304.1 pg/ml). In patients with LAM, serum VEGF-D levels were negatively correlated with FEV1/FVC (rs=-0.8360; p=0.0269) andDLCO/VFVC (rs=-0.04976; p=0.0035), and serum VEGFR-3 levels were negatively correlated with FEV1/FVC (rs=-0.8119; p=0.0498).

Conclusions: This result indicates that, in LAM, serum VEGF-D and VEGFR-3 are candidate for biomarkers for the diagnosis and impaired pulmonary function.

Lymphangioleiomyomatosis – Clinical characteristics and longitudinal follow-up of 36 cases
Malgorzata Sobirecka 1, Jan Kus 1, Stefan Wesolowski 1, Elżbieta Radzikowska 1, Maria Korzeniewska-Kosela 1, 2

Patients with lymphangioleiomyomatosis (LAM) are evaluated with multi-directional assessments in the same manner as those with COPD, but the pulmonary physiological features in patients with end-stage pulmonary LAM are complicated because the severe condition of patients caused by disease progression prohibits extensive testing. To complement this, we applied a forced oscillation technique (FOT) for the assessment of patients with LAM, and evaluated the relationship between respiratory impedance and disease severity.

Methods: 9 subjects with LAM were studied cross-sectionally. Lung function tests and respiratory impedance were measured. A concept based on the Helmholtz Resonator was used to interpret those respiratory mechanics. A simple 3-element series (RIC) model was used to estimate airway resistance (Raw), airway iner-
tance (Jaw), and respiratory compliance (Crs) and resonant frequency (fres). For the estimation of disease severity, a multifunctional index (BODE index) was used.

Results: The respiratory impedance spectra were fitted to the RIC model, and each value of goodness of fit from the 9 subjects was over 0.9. Raw, Jaw and fres correlated with 0.66, 0.7 and 0.7 respectively. For the BODE index, Crs correlated with Jaw.

Conclusions: The RIC model corresponding with the Helmholtz Resonator provides a reasonable physiological interpretation in which all mechanical param-
ters reflected airway obstruction and a decrease in capacitative behavior. Thus, non-invasive FOT are useful and represent a potential monitoring tool to evaluate disease severity and prognosis in a cohort of patients with LAM.

P635
Relationships between respiratory impedance and prognosis in patients with end-stage pulmonary lymphangioleiomyomatosis: A concept based on the Helmholtz resonator

Methods: We measured VEGF-C, VEGF-D and VEGFR-3 in serum of 7 patients with LAM, 4 patients with chronic obstructive pulmonary disease (COPD), and 6 normal subjects by enzyme-linked immunosorbent assays, and compared them with pulmonary function.

Results: In patients with LAM, serum VEGF-D levels were significantly increased (2995.1±992.2 pg/ml) compared with patients with COPD and normal subjects (264.7±157.7 pg/ml, respectively). Serum VEGF-C and VEGFR-3 levels were also significantly increased in LAM (4511.3±746.7 pg/ml) compared with normal subjects (2633.8±304.1 pg/ml).

Conclusions: This result indicates that, in LAM, serum VEGF-D and VEGFR-3 are candidate for biomarkers for the diagnosis and impaired pulmonary function.

Long term follow-up in patients with pulmonary alveolar proteinosis
Yuliia Ilkovich, Lubov Novkova, Olga Baranova, Ivetta Dvortakovskaya, Andrey Bazhanov, Research Institute of Pulmonology, Pavlov State Medical University, St. Petersburg, Russian Federation

Pulmonary alveolar proteinosis (PAP) is a rare lung disease characterized by respiratory failure due to surfactant accumulation within the lung. PAP is currently treated by whole lung lavage (WLL).

Since 1977, our cohort is 52 (35 male, 17 female) idiopathic PAP patients. Median age - 37±6 y.o. Most patients are current or former smokers (64%) and have occupational history (55%). Most patients have moderate impairments in functional parameters (mean DLco - 65±15% pred., mean pulmonary artery systolic pressure - 30±6 mm Hg).

The majority of patients (88.4%) received WLL therapy. 3 patients (5.8%) had segmental lavage. 3 patients (5.8%) - N-acetylcysteine (NAC) as monotherapy. The average number of WLL procedures was 2 (1-7). 34.6% received only one WLL and demonstrated long-term improvement after the procedure.

5-years survival rate is 100%. Spontaneous resolution was observed in 2 patients (3.8%) on NAC treatment. In most cases the course of PAP was slowly progressive. 8 patients (15.4%) had rapid progressive deterioration with respiratory failure despite repeated WLL. Predictors of fast progression were estimated. No associations with gender, age, smoking status were found. Long antibiotics and corticosteroids (CS) intake due to incorrect diagnoses before PAP diagnostic (< 0.05) and more than 3 years since first symptoms occurred till PAP diagnostic (< 0.05) correlated with progressive deterioration despite repeated WLL treatments. Besides, long CS intake increased the risk of secondary infections: pneumonia in 3 patients (5.8%), tuberculosis in 3 patients (5.8%), aspergillosis – 1 patient (1.9%).

Avoiding of delayed diagnosis/incorrect treatment increases the probability of long symptom-free period after WLL.

P639
Lymphocytic interstitial pneumonia – Two cases of unusual presentation
Jorge Vale, Elisa Silva, Vítor Melo, Jessica Jones, Rui Nunes, António Simões Torres, Pulmonology, Hospital São Teotónio, Viseu, Portugal

Background: The diagnosis of Lymphocytic Interstitial Pneumonia (LIP) is established by the demonstration of an exuberant lymphoid infiltrate. The ATS/ERS statement includes it in the group of idiopathic interstitial pneumonias on the basis that rare cases of histopathological LIP pattern are truly idiopathic.

Case 1: 56-year old male admitted with hemoptysis. Thoracic imaging showed a 1.8 cm solitary nodule in the right upper lobe. Bronchoscopy was negative for malignancy. PET-CT Scan revealed increased uptake. Thoracic surgery and histology revealed dense lymphocytic infiltrate in alveolar septa. Further testing ruled out subjacent causes of LIP.

Case 2: 57 year old female admitted for progressive dyspnea. Chest CT revealed lung fibrosis and honeycombing mainly in the upper lobes. There was no evidence of malignancy. PET-CT Scan revealed increased uptake. Thoracic surgery and histology revealed dense lymphocytic infiltrate in alveolar septa. Further testing ruled out subjacent causes of LIP.

Comment: LIP represents a benign polyclonal proliferation that can diffusely involve the lung or be a focal process. The combined presence of nodules, cysts and ground glass are suggestive of LIP. Presentation as a solitary pulmonary nodule is rare; it may represent focal involvement of the lymph proliferative disorder. The histological pattern obtained by surgical biopsy was consistent with LIP with areas of interstitial fibrosis. Secondary causes of LIP were excluded. Treatment with prednisolone was started with clinical and functional improvement.

P640
Abnormalities between down regulation of cyclooxygenase-2 and up-regulation of grow factors in patients with systemic sclerosis
Edwin Roger Parra, Flavia Lin, Vera Capelozzi. Pathology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

The main of this study was observed the relationship between COX1, COX2, bFGF, TGFb and apoptosis and TUNEL expression. The expression of these markers was started with their pulmonary function tests.

The objective is to study features of pulmonary involvement in patients with diffuse connective tissue diseases.

Materials and methods: Retrospective cohort study of 1363 patients. Inclusion criteria: patients at the age of 17-70 with diffuse connective tissue diseases. Exclusion criteria: maligna neoplasms of any location, concomitant bronchopulmonary pathology. Standard clinical examination, electrocardiography, echocardiogram, spirometry, X-ray study, high resolution computed tomography, ultrasonic scanning of pleural effusion.

Results: The involvement of respiratory system was found in 56 (4,11%) of 1363 examined patients. The patients with systemic lupus erythematosus - 25 (44.6%) and rheumatoid arthritis - 19 (33,9%) prevailed. Fewer cases of pulmonary involvement were met in patients with systemic sclerosis - 9 (16,1%), overlap-syndromes - 2 (3,6%) and idiopathic dermatomyositis- 1 (1,8%). The most common manifestations of pulmonary involvement are bronchocclusive syndrome - 39,5%, pulmonary fibrosis – 23,2%, pleuritis – 16,1% and pneumonitis - 12,5%. In 3,6% cases vasculitis and in 1,8% - combinations of pleuritis-pneumonitis, pleuritis- bronchocclusive syndrome and pneumonitis- pleuritis- pulmonary fibrosis were diagnosed.

Conclusion: In 4,11% cases, diffuse connective tissue disorders are accompanied with the involvement of respiratory system that is commonly manifested by bronchocclusive syndrome, pulmonary fibrosis and pleuritis.

P642
Arterial stiffness in systemic scleroderma patients with restrictive lung disease
Nina Karoli, Andrey Rebrev, Hospital Therapy Department, Saratov State Medical University, Saratov, Russian Federation

Systemic sclerosis (SSc) is a chronic disease of unknown etiology, characterized by enhanced fibrosis, and microvascular abnormalities.

To study the stiffness of large arteries in relation to the restrictive lung disease (RDL) aortic stiffness was examined in patients with systemic sclerosis (SSc). 27 non-smoking patients (52,48±7,18 yrs) with diagnosis of SS were included. 17 patient was with RLD (FVC<70%) and 10 patient with normal lung function. Control group consisted of 28 healthy persons, aged 49,82±8,33 years. Arterial stiffness parameters were measured by means of pulse wave analysis using Ten-sioMed Arteriograph (TensioMed, Hungary). Following parameters were factored: aortic augmentation index (AlxAo), aortic pulse wave velocity (PWV), brachial artery augmentation index (AlxB), central blood pressure (SBPao).

85. What is new in the approach to pulmonary fibrosis?

**Intravascular Lung Pres.:** Chronic conditions such as pulm. fibrosis lead to pulmonary arterial hypertension (PAH) and worsen with only a 3-year survival. The increase in mortality is due to progression of disease, worsening of functional capacity, and to treatments that improve symptoms but worsen pulmonary function. This intravascular lung pres. is due to an increase in pulmonary vascular resistance. The main objective is to improve pulmonary function with a combination of PAH and pulmonary function.

**Conclusion:** We have found a significant improvement in pulmonary function with a combination of PAH and pulmonary function.
Arterial stiffness and endothelial dysfunction in idiopathic pulmonary fibrosis (IPF)

Sergey Andreev, Makara Makarova, Alexander Chuchalin. Clinical Department, Pulmonary Research Institute, Moscow; Russian Federation

Background: Fibrotic lung diseases are associated with an increased prevalence of coronary artery disease and cardiovascular complications [Kizer et al., 2004]. Arterial stiffness and endothelial dysfunction are widely accepted as markers of cardiovascular risk.

Objectives: The aim of the present study was to assess aortic stiffness and endothelial dysfunction in patients with IPF and to determine the association of these markers with other clinical and functional parameters.

Methods: We enrolled 25 IPF patients (age 57±8 yrs, FVC 80±18%; DLco 38±15%) and 30 normal control subjects (age 52±5 yrs). Assessment of arterial stiffness was performed by use of digital photoplethysmography (Pulse Trace PCA 2, Micro Medical). Change in reflection index of the digital volume pulse in response to salbutamol (ΔRI alignSelf) was used to assess endothelial function.

Results: In IPF patients stiffness index (SI) was significantly higher than in normal control subjects: 9.8±3.1 vs 6.0±1.0 m/s (p<0.001). The correlations between SI and sleep time spent with SpO2 <88% (r=0.67, p<0.05) and total serum cholesterol level (r=0.77, p<0.05) were highly significant in IPF patients. ΔRI alignSelf was significantly lower in IPF patients than in control subjects: 2.2±1.2% vs 15.8±9.3% (p<0.01). ΔRI alignSelf was significantly associated with FEV1 (r=-0.57, p<0.05), mean nocturnal SpO2 (r=0.83, p<0.05) and total cholesterol level (r=0.71, p<0.05).

Conclusions: Arterial stiffness and endothelial dysfunction are significantly impaired in IPF patients. Decreased FEV1 was associated with endothelial dysfunction. Nocturnal hypoxemia and total cholesterol level have an association with both arterial stiffness and endothelial function.

Clinical course of idiopathic pulmonary fibrosis (IPF): Prediction and outcome

Corina Stabile1, Elena Bargagli1, Paola Rottoli2, Florian Kollert3, Kerstin Höhne4, Gernot Zaisel5, Joachim Müller-Quernheim1, Antje Prasse6.

1Pneumology, University Medical Centre Freiburg, Freiburg, Germany; 2Rheumatology, University Medical Centre Freiburg, Freiburg, Germany; 3Department of Clinical Medicine and Immunological Sciences, Steno University, Siena, Italy

Background: IPF is a progressive disease for which a median survival time of 2.8 years was reported. However the clinical course of IPF is variable. Acute exacerbation (AE) is a major cause of death in IPF, but only a minority of patients develop AE.

Objectives: The aim of this study was to examine different clinical courses of IPF and to evaluate associated risk factors and predictors.

Methods: We retrospectively studied 85 consecutive patients diagnosed with IPF based on the criteria of the ATS/ERS consensus statement. Clinical data and serial pulmonary function tests were obtained. In accordance to King et al. (King, TE et al. AJRCCM 2011; 183:431-40) patients were grouped to four clinical phenotypes: stable disease, slowly progressive, rapid progressive to death or mixed course. Furthermore, AEs as defined by the criteria of Collard et al. (Collard, HD et al. AJRCCM 2011; 183:431-40) patients were grouped to four clinical phenotypes: AaDO2 ≥ 30, 8% within 6 months; AaDO2 ≥ 10% within 6 months; initial AaDO2 (ΔAaDO2) ≥ 10% within 6 months; initial AaDO2 (ΔAaDO2) ≥ 10% within 6 months.

Results: Of 85 IPF patients 34 (40%) patients, with multiple episodes in 6 (7%) patients. The 5-y survival rate of IPF patients with and without AE was 15% and 41%. Baseline CCL18 serum concentrations differed significantly between the four clinical phenotypes (p<0.0001). IPF patients with a progressive or mixed course showed higher CCL18 serum concentrations (p<0.0001), lower FVC predicted (FVC<60%; p<0.0156) and lower TLC predicted (p=0.002). Stepwise multivariate regression analysis of all patients revealed that CCL18 serum concentration (p=0.016) was independently associated with AE.

Conclusions: We demonstrate that baseline serum CCL18 levels are elevated in IPF patients prone to AE and predict a rapid progressive or mixed course of IPF.

Risk factors of acute exacerbation of idiopathic pulmonary fibrosis-extended analysis of the pirfenidone trial in Japan

Hiroyuki Taniguchi1, Yasushi Komod1, Masahito Ebina2, Arata Azuma3, Takashi Ogasam1, Moritaka Soga1, Yoshio Taguchi1, Hiroki Takashita4, Koichiro Nakata5, Atsuko Sato6, Yukihiko Sugiyama7, Shoji Kudo8, Toshihiro Nakawa9.
1Dept. of Respiratory Medicine and Allergy, Tosei General Hospital, Seto, Aichi, Japan; 2Dept. of Respiratory Medicine, Tokoha University Graduate School of Medicine, Sendai, Japan; 3Dept. of Internal Medicine, Jichi Medical University, Shimotsui, Japan; 4Dept. of Respiratory Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan; 5Dept. of Respiratory Medicine, Saiseikai Kumamoto Hospital, Kumamoto, Japan; 6Dept. of Respiratory Medicine, Tenri Hospital, Tenri, Japan; 7Dept. 3rd Dept. of Internal Medicine, Sapporo Medical University of Medicine, Sapporo, Japan; 8Dept. of Respiratory Medicine, Nakata Clinic, Tokyo, Japan; 9Dept. of Respiratory Medicine, Kyoto Preventive, Kyoto, Japan; 10Division of Pulmonary Medicine, Dept. of Medicine, Jichi Medical University, Tsuji, Japan

Background: Although acute exacerbation (AE) of idiopathic pulmonary fibrosis (IPF) is a well known clinical condition, predicting risk factors remain unknown. Recent studies reported that various baseline factors, and at least 10% decline in FVC at six months were reported as risk factors for AE (Sarcoidosis Vasc Diffuse Lung Dis 2010;27:103-110). We sought to evaluate the risk factors of AE by analyzing our phase III clinical trial of pirfenidone for patients with IPF (n=275; Eur Respir J 2010; 35: S21-9).

Methods: Baseline characteristics including age, sex, smoking, BMI, dyspnoea grade (HUGH-JONES classification), AaDO2, PaO2/Δc, DLco, KL, SP-A, SP-D were evaluated as possible risk factors for AE. Decline of VC≥10% within 6 months was also evaluated. In addition, effect of pirfenidone therapy was also evaluated.

Results: During 52 weeks, 14 patients experienced AE-IPF. Univariate analysis by Cox proportion hazards model were as follows: age (HR, 0.982, p=0.642), sex (HR, 1.505, p=0.489) smoking (HR, 1.046, p=0.168), BMI (HR, 0.935, p=0.460), dyspnoea grade (HR, 1.763, p=0.168), AaDO2 (HR, 1.047, p=0.069), PaO2 (HR, 0.955, p=0.110), Δc/Vc (HR, 0.971, p=0.078), DLco (HR, 0.994, p=0.714), KL-6 (HR, 1.000, p=0.698), SP-A (HR, 0.989, p=0.776), SP-D (HR, 1.000, p=0.875), pirenidone treatment (HR, 0.611, p=0.722). Decline of VC was a significant risk factor for AE-IPF (HR, 3.780, p=0.014). Stepwise multivariate analysis revealed that initial AaDO2 (HR, 1.055, p=0.045) and decline in VC in 6 months (HR, 3.951, p=0.012) were significant risk factors for AE-IPF.

Conclusions: Baseline higher AaDO2 and decline of VC≥10% within 6 months are significant risk factors of AE-IPF.
P651 Effects of nitric oxide synthase up-regulation in early remodeling of usual interstitial pneumonia has impact on long term outcome of patients

Edwin Roger Parra, Armando Aguas Junior, Sandra Ferreira, Vera Capelozzi. Pathology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Recently, impaired endothelial-dependent vascular tone suggest that NOS enzymatic activity, as well as vascular NO synthesis and release, may decrease or increase depending on early or late pulmonary remodeling process. In this study, we validated the importance of the expression of NOS isoforms (neuronal [nNOS], inducible [iNOS], and endothelial [eNOS]) protein and studied the relationships between NOS isoforms in early and late remodeling of usual interstitial pneumonia (UIP).

Material and methods: We determined density of endothelial, muscular, myofibroblasts and alveolar cells expressing NOS in surgical lung biopsies from 25 patients with UIP. We used immunohistochemistry and histomorphometry to evaluate the amount of endothelial, muscular, myofibroblasts and alveolar cell staining for NOS.

Results: Unaffected areas of UIP had increased eNOS and iNOS expression, whereas a significant increase of NOS expression was found in unaffected and vascular areas. Kaplan–Meier analysis for NOS and eNOS dichotomized percentiles revealed respectively a statistically significant prolonged disease specific survival for patients in the low risk group (estimated median survival 51.7 vs 33.36 and 55.56 vs. 9.87 months for the high risk group, log rank p<0.01).

Conclusions: We conclude that the presence of a vascular remodeling is associated with vascular injury and with a global correlation test, p=0.04). We postulated that CEC and all EPC subtypes might be differently modulated in IPF. We aimed at 1) assessing them in early stages of IPF and 2) searching for correlations with disease severity.

Methods: 64 consecutive patients with newly diagnosed IPF and 10 healthy age-matched volunteers were studied. CEC were isolated with CD146-coated beads. CD34, CD133 and KDR antigens, characterizing EPC, were assessed through flow cytometry. EPC (early CFU-Hill and late endothelial cells forming colonies (ECFC) were also counted using cell culture. Results: CEC numbers were significantly increased in IPF (p=0.004) whereas EPC assessed using both flow cytometry (CD34+CD133+) and cell culture were decreased vs controls (p<0.05). CEC did not differ according to disease severity (DLCO > 85% or < 85%) nor did CD34+KDR+ cells. In contrast, progenitors obtained in culture were markedly increased in the most severe vs the least severe IPF subgroup (p=0.04 and p<0.01 for CFU-Hill and ECFC, respectively, for DLCO<85% vs >85%). ECFC was the only cell type found to be correlated to DLCO (Spearman correlation test, p=0.04).

Conclusion: IPF is associated with markers of vascular injury and with a global decrease in EPC. Disease severity is associated with an EPC mobilization whose mechanisms and clinical impact need to be explored.

P652 Imbalance between circulating endothelial cells and endothelial progenitors in idiopathic pulmonary fibrosis

David Samoa1, Laetitia Mauge1, Hilario Nunes2, Clement d’Audigier1, Karine Juvin1, Raphael Borie1, Zohra Carton2, Olivier Sanchez1, Bruno Crestani1, Dominique Valeyre1, Pascale Gaussem1, Dominique Israel-Biet1, 1Hematology Department, Paris-Descartes University, Paris, France; 2Pneumology Department, Hospital Avicenne, Bobigny, France; 3Pneumology Department, Paris-Descartes University, Paris, France; 4Pneumology Department, Hospital Bichat, Paris, France

Background: Fibrogenesis during idiopathic pulmonary fibrosis (IPF) is associated with abnormal vascular remodeling. Respective abundance of circulating endothelial cells (CEC) and endothelial progenitor cells (EPC) might reflect the balance between vascular injury and repair and potentially serve as a biomarker of the disease.

Objectives: We postulated that CEC and all EPC subtypes might be differently modulated in IPF. We aimed at 1) assessing them in early stages of IPF and 2) searching for correlations with disease severity.

Methods: 40% of CD34+CD133+ cells were significantly increased in IPF (p=0.004) whereas EPC assessed using both flow cytometry (CD34+CD133+) and cell culture were decreased vs controls (p<0.05). CEC did not differ according to disease severity (DLCO > 85% or < 85%) nor did CD34+KDR+ cells. In contrast, progenitors obtained in culture were markedly increased in the most severe vs the least severe IPF subgroup (p=0.04 and p<0.01 for CFU-Hill and ECFC, respectively, for DLCO<85% vs >85%). ECFC was the only cell type found to be correlated to DLCO (Spearman correlation test, p=0.04).

Conclusion: IPF is associated with markers of vascular injury and with a global decrease in EPC. Disease severity is associated with an EPC mobilization whose mechanisms and clinical impact need to be explored.

P653 Leptin and adiponectin levels in idiopathic pulmonary fibrosis

Foteini Malli1, Panagiotis Georgoulis1, Vasilassou Varvara2, Irene Tsiliomi1, Konstantinos Georgoulis1, Zoe Daniil1, 1Hematology Department, University of Thessaly School of Medicine, Larissa, Greece; 2Nuclear Medicine Department, University of Thessaly, Larissa, Greece

Background: Studies in the literature suggest a regulatory role of adipokines in the development of fibrosis in various organs. Leptin is a critical factor for the development of fibrosis in the liver. In contrast, adiponectin inhibits liver fibrogenesis both in vivo and in vitro. However, their role in pulmonary fibrosis has not been examined in the past.

Objectives: We hypothesized that leptin and adiponectin may be involved in the development of pulmonary fibrosis and therefore we measured levels of leptin and adiponectin (RIA) in the serum of 37 Idiopathic Pulmonary Fibrosis (IPF) patients (mean±SD: 68.8±8.8 years) and 22 controls (65±7.5 years). Clinical and radiological data were collected from all subjects. Pulmonary function tests, arterial blood gas analysis and thoracostrophic echocardiography were performed.

Results: The levels of leptin and adiponectin did not differ between patients and controls. However, leptin levels when divided by BMI in male patients with PaO2 <65 were significantly reduced as compared to male patients with PaO2 >65 mmHg (0.21 vs 0.38, p=0.031, respectively). Additionally, leptin to adiponectin ratio in male IPF patients with <65 mmHg was significantly reduced versus male patients with PaO2 >65 mmHg (1.07 vs 1.45, p=0.045, respectively).

Conclusions: Leptin levels when adjusted for BMI and leptin to adiponectin ratio are reduced in male IPF patients with hypoxia. Our findings suggest a possible role of leptin in the severity and/or pathogenesis of IPF. Further studies are required in order to clarify the association of leptin and adiponectin with the disease.

P654 HCRT score to control and evaluate the prognosis in idiopathic pulmonary fibrosis

Ricardo Peris1, Estrella Fernandez-Fabrellas1, Ignacio Inchaunara1, M. Luisa Domingo2, Julio Palop1, Rafael Blanquer1, 1Respiratory Medicine, Hospital Doctor Peset, Valencia, Spain; 2Radiology, Hospital Doctor Peset, Valencia, Spain

Introduction: HCRT is not commonly used to assess the severity of idiopathic pulmonary fibrosis (IPF).

To assess: We sought to evaluate the usefulness of a semiquantitative HCRT score and its relation with respiratory function tests normally used to ascertain IPF severity and to monitor the evolution and progression of the fibrotic process.

Patients and methods: A prospective 4 years study including 36 consecutive IPF patients. A semiquantitative score was used to score every predefined IPF 4 parameters on HCRT. As a result of summing up all of them we had the Total Score of Fibrosis for each patient.

Results: We studied its relation with functional respiratory tests, bronchoalveolar lavage (BAL) cellularity and analytically the differences found among the death patients.

Methods: We found a significant correlation between the honeycomb score and% DLCO (r= -0.48, p=0.004), total score of fibrosis with% FEV1 (r= -0.41, p=0.01),% TLC (r= -0.41, p=0.01) and% DLCO (r= -0.41, p=0.01) and% TLC (r= -0.36, p=0.03). The 6-minutes walking test (6MWT): the final SaO2 correlated with the total score (r= -0.48, p=0.04). A+2grad also correlated with the honeycomb score (r=0.43, p=0.01) and the total score (r=0.48, p=0.005). Dead patients had a higher total score and a tendency of higher neutrophilia in BAL (p=0.059).

Conclusions: A semiquantitative score of HCRT is useful in assessing the initial severity of IPF and should be able to predict its development.

P655 Daily hand-held spirometry for the monitoring of patients with idiopathic pulmonary fibrosis

Anne-Marie Russell1, Pauline Lukey3, Una Fraser1, Elizabeth Renzoni1,2, Athol Wells1,2, Toby Maher1,3. 1NHRI Biomedical Research Unit, Royal Brompton Hospital, London, United Kingdom; 2National Heart and Lung Institute, Imperial College, London, United Kingdom; 3Fibrosis DPU, GSK, Stevenage, United Kingdom

Introduction: Idiopathic pulmonary fibrosis (IPF) is an invariably fatal condition characterised by a variable course; prolonged periods of apparent disease stability are often interspersed by dramatic and often cryptogenic acute deteriorations. These acute exacerbation are a significant cause of morbidity and mortality in IPF. For lung transplant recipients, daily hand held spirometry has been shown to be an effective means of detecting acute rejection episodes. This exploratory study aims to determine the utility of daily hand held spirometry in IPF.

Methods: Patients with IPF were recruited from amongst new referrals to our unit. Baseline severity was assessed by FVC, DLco and 6 minute walk. Patients were given a hand held spirometer (Carefusion, UK) and provided with instruction on how to self-administer spirometry. Patients were asked to record daily FEV1 and FVC values.

Results: To date, 19 subjects have been recruited; 17 male, age 66.5±7.6 years (mean± SD). Overall the subjects have moderate to severe disease with FVC 74.2±21.8% predicted, DLco 40.6±13.5% predicted and 6 minute walk distance 526±120m. For subjects thus far completing over 4 weeks of diary monitoring (n=49), mean hand held FVC correlates well with formal clinic spirometry (r=0.57).
**P656**

**Slow versus rapid progressors in idiopathic pulmonary fibrosis**

Filipca Soares Pires, Carla Damas, Patricia Motã, Natãlia Melo, Diego Costa

**Background:** Idiopathic pulmonary fibrosis (IPF) is usually characterized by the insidious onset of dyspnea or cough, but there is a subgroup of patients who display a rapid progression to an end-stage disease. These two phenotypes, slow progressors (SP) and rapid progressors (RP), have not yet been fully characterized.

**Aims:** To characterize SP and RP and identify baseline factors predicting each progression.

**Methods:** A retrospective study with 81 IPF patients was performed. They were classified into SP and RP according to the rate of decline of FVC over 12 months (6% or ≤ 12% per year) and the rate of decline of 6 minute walk distance (≤ 50%, ≤ 350 m). The Kaplan-Meier survival curve was used to evaluate survival differences between SP and RP.

**Results:** The group was divided into SP and RP. The comparison between the two groups showed lower median values of FVC (60 versus 73) and TLC (57.8 versus 72) and a higher percentage of non-smokers in RP group at time of diagnosis.

**Conclusion:** The analysis of this group of IPF patients confirms two clearly separated phenotypes, SP and RP, that must be discriminated, since they seem to have different presentations and a remarkably different evolution. These results could mean distinct physiopathological pathways, which could implicate different therapeutic approaches.

**Clinical picture analysis of idiopathic pulmonary fibrosis (IPF) and lung cancer (LC) concomitantly in the population of patients hospitalized in 1st Clinic of Lung Diseases Institute for Tuberculosis and Lung Diseases in Warsaw, Poland in the years 1994-2009**

Agnieszka Buraczewska, Wojciech Skorupa, Jan Kus, Anna Kempisty, Iwona Bartoszuk

**Background:** In idiopathic Pulmonary Fibrosis parenchymal lung damage leads to defects in mechanics and gas exchange, manifesting with progressive dyspnea and exercise limitation. Since IPF carries a poor prognosis, early and reliable prediction of survival is of significant value to the clinician. The role of maximal exercise data in prognostic evaluation of IPF patients is uncertain.

**Aims and objectives:** The aim of the present study was to evaluate the prognostic significance of cardiopulmonary exercise test (CPET) in this group of patients.

**Methods:** Twenty five IPF patients were prospectively recruited and underwent functional evaluation through maximal (CPET) and submaximal exercise testing. Six minute walk test (6MWT) at diagnosis. Patients were followed up regularly; epidemiologic and survival data were gathered. Correlations between survival and parameters of maximal and submaximal exercise were calculated.

**Results:** Mean survival was 44.4 months.

**The prognostic significance of cardiopulmonary exercise in IPF**

Christina Triantafillidou, Panagiotis Lyberopoulos, Liokourgos Kolilekas, Konstantinos Kagouridis, Sotirios Gytopoulos, Christina Sotiriopoulou, Anastasia Kotanidou, Anna Karakatsani, Spyros Papiris.

**Background:** Exercise testing reflect survival in IPF population. Statistically significant correlations were found between survival and CPET parameters such as VO2peak (p=0.02, RR=0.99), VO2peak/kg (p=0.01, R=0.78), 6MWT (p=0.01, RR=0.72), SpO2peak (p=0.01, RR=0.48), VE/VECO2slope (p=0.005, RR=1.09), VE/VCO2AT (p=0.008, RR=1.14) and the 6MWT parameters: distance walked (p=0.008, RR=0.99) and desaturation (p=0.01, RR=1.42).

**Conclusions:** Physiological parameters obtained during maximal and submaximal exercise testing reflect survival in IPF population.

**Background:** The aim of the present study was to evaluate the prognostic significance of cardiopulmonary exercise test (CPET) in this group of patients.

**Methods:** Twenty five IPF patients were prospectively recruited and underwent functional evaluation through maximal (CPET) and submaximal exercise testing.

**Results:** Mean survival was 44.4 months.

**Conclusions:** Physiological parameters obtained during maximal and submaximal exercise testing reflect survival in IPF population.
Promising effect of PMX-DHP absorption therapy for acute exacerbation of IPF

Azuma1, Shinji Abe 1, Takashi Ogura2, Hiroshi Mukae3, Hiroyuki Taniguchi4, Masashi Bando5, Yukihiko Sugiyama5

Background: Current agents for the treatment of idiopathic pulmonary fibrosis (IPF) have not been found to improve the prognosis, thus requiring the development of new types of drugs to treat IPF.

Aims: This study was designed to investigate the effect of combination of Salvia (one kind of traditional Chinese medicine) and Ligustrazine (one kind of traditional Chinese medicine) on the expression of inflammatory mediators, the mRNA expression of type I and III collagen, and hydroxyproline content in lung tissues in bleomycin (BLM)-induced rat pulmonary fibrosis.

Methods: Adult Wistar rats were intratracheally instilled with BLM or normal saline (NS). After intratracheal administration, the animals were intraperitoneally injected with combination of Salvia and Ligustrazine or NS every day. Then they were euthanized, and BLM-induced rat pulmonary fibrosis was confirmed. Immunohistochemistry analysis was used to examine the expressions of inflammatory mediators in lung tissues, and the mRNA expression of type I and III collagen and hydroxyproline content in lung tissues was also measured.

Results: Combination of Salvia and Ligustrazine could alleviate alveolitis and fibrosis; could attenuate the expression of inflammatory mediators in lung tissues; and could also decrease the mRNA expression of type I and III collagen and hydroxyproline content in lung tissue in rat pulmonary fibrosis.

Conclusions: Combination of Salvia and Ligustrazine had an anti-fibrosis effect, and it might be considered as a clinically viable option to treat pulmonary fibrosis.

Late-breaking abstract: Serum and blood cell culture Th17 cytokines in pigeon fencers’ hypersensitivity pneumonitis (HP)

Kenneth Anderson1, Iona Donnelly1, Lisa Jolly1, S. Todryk2, P. Pushparaj2, Kenneth Lipson1, G. Short1, M. Adamson1, Steven Boukhe3, Charles McSharry4, Giuseppe Novelli1, Federica Sangiuolo1.

Methods: Serum cytokines of Th17 production were assessed in 46 pigeon fanciers and 46 controls with no history of HP.

Results: The mean cytokine levels were not different between HP patients and controls, but there was a trend for IL-1b and IL-6 to be higher in HP patients (p=0.066).

Conclusions: The cytokine levels in HP patients were not different from controls, but there is a trend for a higher level of IL-1b and IL-6.

Reduction of lung injury and fibrosis by human embryonic stem cells in a mouse model of silica-induced lung fibrosis

Paola Spitalieri1, Maria Chiara Quinatina1, Augusto Orlando1, Lorenzo Guerra1, Emiliano Giardina1, Valeria Casavola3, Cesare Salanti2, Giuseppe Novelli1, Federica Sanguinolo1, Department of Biopathology, University of Rome 'Tor Vergata', Rome, RM, Italy; 2Department of Genetics, IRCCS Centro Neurolesi Bonino Pulejo, Messina, ME, Italy; 3Respiratory Medicine, Royal Victoria Infirmary, Newcastle, United Kingdom

Methods: We assessed the ability of human embryonic stem cells (HUES-3-ATIICs) to differentiate into functional alveolar type II cells (ATIICs), engraft into damaged lungs and reduce fibroproliferation, thereby reducing mortality, in a mouse model of silica-induced pulmonary inflammation and fibrosis.

Results: We demonstrated that HUES-3-ATIICs could differentiate into ATIICs, engraft into damaged lungs and reduce fibroproliferation, thereby reducing mortality, in a mouse model of silica-induced pulmonary inflammation and fibrosis.

P668
Rapid reversal of radiation-induced murine pneumonitis by treatment with the anti-CTGF monoclonal antibody FG-3019

Kenneth Anderson1, Ute Winkler2, Mark Stermlicht1, Todd Seely1, Sebastian Bickellhaupf2, Peter Peschke1, Peter Huber1, Research, FibroGen, Inc., San Francisco, CA, United States; 2Radiation Oncology, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany

Methods: Lung injury was initiated with a single, full thorax irradiation and administration of FG-3019 began 16 weeks after irradiation, when a significant increase in lung density was detectable by computed tomography (CT). Gene expression and histological analysis was performed at 18 weeks after irradiation.

Results: Lung density in placebo-treated mice increased between 12 weeks and 30 weeks after irradiation. Treatment with FG-3019 reversed the radiation-induced lung density increase, which progressively decreased during the 8 weeks of administration and remained constant for another 6 months. Gene expression analysis and histological examination showed considerable infiltration of mast cells and macrophages at 18 weeks after irradiation in placebo-treated animals, while two weeks of FG-3019 restored levels to that of unirradiated mice.

Conclusions: FG-3019 reversed radiation-induced pneumonitis and lung remodeling very quickly after administration was initiated and produced a durable effect on lung density. Because these are key events in the process of fibrosis, the data suggest that inhibition of CTGF can disrupt fibroproliferative processes after they have begun and support continued clinical evaluation of FG-3019 for treatment of pulmonary fibrosis.

The stimulator of soluble guanylate cyclase riociguat protects against bleomycin-induced pulmonary fibrosis in mice

Oleg V. Evgenov1, Johannes-Peter Stasch2, Mari Mino-Kenudson3, Eugene J. Mark3, Emmanuel S. Buys1, Lin Zou1, Ming Zhang1, Michael J. Raher1, Yan Li1, Yan Feng1, Rosemary C. Jones1, Wei Chao1, 1Department of Anesthesiology, Critical Care and Pain Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States; 2Institute of Pharmacy, Martin Luther University, Halle, Germany; 3Department of Pathology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

**Background:** Effective therapies for pulmonary fibrosis (PF) are currently lacking. Patients with PF develop pulmonary hypertension (PH), in part due to impaired production of endogenous nitric oxide (NO) that activates soluble guanylate cyclase (sGC). We hypothesized that the NO-independent stimulation of sGC might attenuate PH.

**Methods:** Male C57/BL6 mice (10-12 wks) were subjected to intratracheal attenuation PF. Lung specimens of this model confirmed UIP pattern, such as apoptosis index. We used 5 balb/c mice as controls.

**Results:** Bleomycin-induced PH (an increase in the right ventricle systolic pressure and a decrease in the pulmonary acceleration time/heart rate ratio) and the right ventricular hypertrophy were attenuated by riociguat and the combination of riociguat and sildenafil to a greater extent than by sildenafil alone. In the vehicle-treated mice, fibrosis and inflammation diffusely involved lung parenchyma. Riociguat and its combination with sildenafil but not sildenafil alone markedly ameliorated PH and inflammation that was mainly confined to subpleural areas and/or peripheral lung in a patchy distribution. Riociguat increased plasma cGMP levels and also reduced mortality.

**Conclusions:** Pharmacological stimulation of sGC with riociguat attenuates PF, PH, right ventricular hypertrophy and mortality in the bleomycin-exposed mice. This therapeutic approach appears to be superior to treatment with sildenafil. Stimulation of sGC might represent a new modality for treating PF and related conditions.

Experimental model resembling the histological pattern of usual interstitial pneumonia and reinforcing the epithelial injury as pathway

Marcella Soares Pincelli, João Barbosa-Filho, Walcy Teodoro, Vera Capelozzi, Edwin Roger Parra. Pathology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

The present experimental model in mice was developed to confront the histopathological feature with that of the idiopathic pulmonary fibrosis (IPF) usual interstitial pneumonia (UIP), as we suppose both are caused by the injury of type II pneumocytes (TIIp) and by the increase of collagen system.

**Material and methods:** Twenty male Ibali/c mice are injected ip with 400mg/kg of butylated hydroxyltoluene (BHT) and kept breathing for six days at a 70% oxygen atmosphere. The mice were killed after one month. The lungs were fixed and stained by Hematoxylin & Eosin and immunofluorescence for collagen I and II.Also, TUNEL and electron microscopy were used to evaluate the epithelial apoptosis index. We used 5 balb/c mice as controls.

**Results:** Pulmonary specimens of this model confirmed UIP pattern, such as progressive increase of interstitial deposition. They showed significant increase of collagen I and III deposition and significant increase of epithelial apoptosis when compared to control group (p<0.05). The apoptosis was more prominent in the TIIp observed by electron microscopy.

**Conclusion:** This experimental model showed the same histopathological patterns of UIP, and also reinforced the increase of apoptosis TIIp after injury or apoptosis of these cells and collagen deposition as an early feature in the pathogenesis of IPF. Financial support: FAPESP-CNpq.

Can flaxseed oil reduce experimental lung fibrosis in rats?

Anouar Abidi1, Raja Strmić2, Nadia Kourda1, Fatma Tritar1, Sonia Maalej1, Leila Douik5, Moncef Fekih1, Saloua Ben Khama1, 1Physiology, University of Medicine, Tunis, Tunisia; 2Physiology, Superior Institute of Science and Technic Health, Tunis, Tunisia; 3Anatomopathology, Charles Nicole Hospital, Tunis, Tunisia; 4Pneumology, Abderahmen Mami Hospital, Ariana, Tunis, Tunisia; 5Pneumology, Charles Nicole Hospital, Tunis, Tunisia

**Background:** The anti-inflammatory effects of polysaturated fatty acids (PUFA) is actually demonstrated. In this study we evaluated protective and therapeutic effects of Flaxseed Oil (FO) on Bleomycin (BLM) lung fibrosis in rats.

**Methods:** 30 males wistar rats were randomly divided into 3 equal groups: untreated group (G1) and 2 treated groups (FO). 1g/kg bw/day). G2 received FO during two months before inducing lung fibrosis than G3 received FO 2 days after inducing lung fibrosis during 10 days. Pulmonary fibrosis was induced by BLM (4 mg/kg, intratracheally single dose). Inflammatory index, fibrosis score (Ashcroft) and TGF-β density was evaluated in different areas of damaged lung by anatomo-histological and immuno-histological analysis.

**Results:** Independent-samplesTtest revealed that comparatively to control group (G1), FO reduced significantly fibrosis score in G2 and TGF-β density in fibrocytes in G3 (p<0.05).

**Conclusion:** These data demonstrated a protective activity of FO against bleomycin-induced lung fibrosis model in rats.

More investigations will be realized in human to prove relationship between diet and interstitial lung diseases.

Inhibition of PAI-1 in the cigarette smoke induced epithelial-mesenchymal transition

Jeong-Sup Song1, Chun-Mi Kang1, Ki-Hoon Park1, Hyung-Kyu Yoon1, Hwa-Sik Moon1, Sung-Hak Park2. 1Internal Medicine, St Mary’s Hospital, Catholic University Medical College, Seoul, Korea; 2Internal Medicine, Seoul St Mary’s Hospital, Catholic University Medical College, Seoul, Korea

**Introduction:** Plasminogen activator inhibitor-1 (PAI-1) has been known to play an essential role in pulmonary fibrosis by inhibiting plasminogen activator (PA). Recently, it is assumed that epithelial-mesenchymal transition (EMT) play a role in the pathogenesis of IPF. We tried to find out whether PAI-1 is involved in the bleomycin-induced pulmonary fibrosis in the rat and in smoking-induced rat alveolar EMT in vitro.

**Methods:** First, rats were received intratracheal bleomycin (4U/kg) and then administered tiplaxitinin (1mg/kg) at day 1, 3, 5, 7, 10 orally. Rats were sacrificed at day 14. Next, the type II alveolar epithelial cells were isolated from normal rats by percoll gradient methods. Type II epithelial cells were transfected with PAI-1-siRNA and were stimulated with cigarette smoking extract (CSE, 5%).

**Results:** In bleomycin-induced pulmonary fibrosis model, tiplaxitinin decreased the bleomycin-induced pulmonary fibrosis by Ashcroft score and also decreased the PAI-1 and TGF-6 concentrations in the BAL fluids. In epithelial cell experiment, exposure to CSE increased the α-SMA and PAI-1 mRNA expression in real-time PCR. However, they were attenuated either after transfection with siRNA-targeted PAI-1 or treatment with tiplaxitin (50 μM). TGF-6 concentrations in the CSE exposed cell culture supernatants were also decreased either by PAI-1-siRNA transfection or treatment with tiplaxitin. The up-regulation of Smad and pSMAD by smoking exposure in epithelial cells were decreased either by transfection with PAI-1-siRNA or treatment with tiplaxitin.

**Financial support:** FAPESP.
Introduction: Although the etiology of an acute exacerbation of idiopathic pulmonary fibrosis (IPF) is unknown, it may be represented by a clinically occult combination with decreased neutrophils suggests ongoing clearance. Decrease of neutrophils, macrophages and B-cells may suggest migration to lymphoid organs, thus initiation of an adaptive immune response. In summary, we found fibrosis and inflammation occurring in parallel, both present early in the development of pulmonary fibrosis.

Methods: Lung injury was induced in female C57BL/6 mice by the intratracheal injection of BLM. Twenty-eight days after the injection of either BLM or saline, the mice received intratracheal injections of either saline or CpG-ODN. A total number of 4 groups (saline: saline/CpG; BLM/CpG) were investigated. After 24 h, the mice were killed, and the neutrophil counts and cytokine levels were determined in the bronchoalveolar lavage fluid (BALF).

Results: There were no differences in the neutrophil counts between the saline and BLM groups. The neutrophil counts in the BLM/CpG group were significantly higher than those in the saline/CpG group. The levels of macrophage inflammatory protein (MIP)-2 and interleukin (IL)-6 in the BALF were found to be significantly higher in the BLM/CpG group than in the saline/CpG group. Real-time reverse transcription-polymerase chain reaction (RT-PCR) and immunohistochemical analysis of the lung tissue revealed an upregulation of TLR9 expression induced by BLM administration.

Conclusion: These results suggest that the TLR9-mediated lung inflammatory responses are enhanced in BLM-induced lung fibrosis in mice.

P675
Enhanced lung inflammatory response to intratracheal CpG-ODN in mice with bleomycin-induced lung fibrosis
Hidako Yamashawa, Masayuki Nakayama, Masashi Bando, Yukiko Sugiyama, Division of Pulmonary Medicine, Department of Medicine, Jichi Medical University, Tochigi, Japan

Background: Pulmonary fibrosis is a facet of Diffuse Parenchymal Lung Disease and has been considered a sequel to chronic inflammation. Yet the relation between connective tissue and immune system during the initiation phase has not been thoroughly investigated. Our aim was to investigate the initiation phase and the interplay between immune system and connective tissue.

Methods: C57BL/6 mice were given subcutaneous bleomycin injections (controls received saline) 3 times/week for 1, 2, 3 and 4 weeks. Following sacrifice, lungs were embedded in paraffin and 4 μm thick sections were used for analysis of lung parenchymal Masson Trichrome (total collagen) and immunohistochemistry to detect neutrophils, macrophages and B-cells.

Results: Total collagen was significantly increased at 1, 2 and 4 weeks. A transient neutrophilia was found at 4w (279±820 cells/mm3), but no difference compared to controls was found at 2, 3 and 4w. Macrophages were significantly increased at 2w (135±29 cells/mm3) whereas B-cells were significantly decreased at 3w and 4w compared to controls.

Conclusions: Subcutaneous administration of bleomycin induced rapid pulmonary remodeling, exemplified by increased total collagen. The immune response was markedly different from the one following intratracheal administration, illustrated by the moderate transient neutrophilia. Increased numbers of macrophages at 2w in combination with decreased neutrophils suggests ongoing clearance. Decrease of B-cells may suggest migration to lymphoid organs, thus initiation of an adaptive immune response. In summary, we found fibrosis and inflammation occurring in parallel, both present early in the development of pulmonary fibrosis.

Conclusion: Compared to control groups G3 and G4, ANOVA statistical study, demonstrated that FG Seed Polynexols Extracts ameliorated TASI and reduced inflammatory index and TGF-β1 density in G1 and seeds powder of FG reduced MDA a marker of oxidant stress and inflammatory score in G2 (p < 0.05). However, Ashcroft semi-quantitative assessing of fibrosis score has not revealed significant differences between the four groups (p>0.05).

Conclusion: This study demonstrated that FG 1 has potent antioxidant and anti-inflammatory activities but has not an anti-fibrotic effect confirming that besides inflammation, other factors probably interfere in the pathogenesis of pulmonary fibrosis.

P676
Anti-oxidative and anti-inflammatory effects of trigonella foenum graecum (fenugreek) seed extract in experimental pulmonary fibrosis
Lamia Yacoubi1, Raja Serair2, Lotfi Roubas2, Mohamed Hedi Hamdouch2, Nadia Kourda3, Fatma Tritar5, Sonia Maalej5, Leila Douik6, Saloua Ben Khamsa1.

Background: Oxidative stress participated in the pathogenesis of intestinal lung diseases. This prospective study is the first experimental work that evaluated the effect of Fenugreek (FG) and its phenollic extract on oxidative stress and lung fibrosis in experimental model.

Methods: A single dose of Bleomycin was injected intratracheally in forty male wistar rats (45g/kg). Two days after inducing lung injuries, animals were randomly divided in four groups of 10 rats: G1, G2, G3 and G4. G1 received FG Seed Polypenol Extract at a dose of 200 mg kg by daily gavage.G2 received FG seeds powder mixed with food at levels of up to 2%. G3 received an equal volume of water (6.5 ml/kg, daily gavage). G4 did not receive any treatment. Two weeks after inducing lung fibrosis, rats were sacrificed and we evaluated stress biomarkers (TAS:Total Antioxidant Status, Malon DiAldehyde MDA) in serum and inflammatory index, fibrosis score and TGF-β1 density in lung tissue.

Results: There were no differences in the neutrophil counts between the saline and BLM groups. The levels of macrophage inflammatory protein (MIP)-2 and interleukin (IL)-6 in the BALF were found to be significantly higher in the BLM/CpG group than in the saline/CpG group. Real-time reverse transcription-polymerase chain reaction (RT-PCR) and immunohistochemical analysis of the lung tissue revealed an upregulation of TLR9 expression induced by BLM administration.

Conclusion: These results suggest that the TLR9-mediated lung inflammatory responses are enhanced in BLM-induced lung fibrosis in mice.

P677
Effect of experimental pulmonary fibrosis induced by bleomycin on the lung fatty acid composition in Wistar rats
Anwar Abdu, Moncef Feki, Sloua Ben Khamsa. Department of Physiology, Faculty of Medicine of Tunis, Tunis, Tunisia; Laboratory of Biochemistry, Hospital la Rabta, Tunis, Tunisia

Background: Many recent studies are directed towards the use of natural substances for the treatment of pulmonary fibrosis and of these fatty acids. The main study was first to verify the normal composition of fatty acids in the lungs of rats and collect the effect of experimental fibrosis induced by bleomycin in rats on the latter.

Methods: A total of twenty males wistar rats which received water and food ad libitum, were divided randomly into two groups: untreated group (G1, n=10) and treated group (G2, n=10).

Pulmonary fibrosis was induced in all treated rats (G2) by bleomycin (4 mg/kg, single dose) administered intratracheally. Three day later, all rats were sacrificed, lungs were extracted and blood was collected for analysis of fatty acid composition in the lungs and red cells of rats studied, and this by using the technique of gas chromatography (GC).

Results: The statistical of independent-samples T test revealed that bleomycin alters significantly the composition means of various fatty acids in treated group (G2) compared to untreated group (G1) as shown in the figures below.

Conclusion: These results confirm that bleomycin affects the fatty acid composition of lung giving the opportunity to test the effects of substances rich in fatty acids on pulmonary fibrosis models in rats.
of unknown cause such as idiopathic pulmonary fibrosis. The aim of the current study was to characterize the mechanisms of pulmonary fibrosis and to determine whether IL-17A plays an important regulatory role.

Methods: Balb-BLM (BLM), Balb-Paraquat, C57-BLM and C57-KO IL-17-BLM induced pulmonary fibrosis animal models were used to evaluate the fibrosis and the IL-17 role. We used the picrosirius-polarization method, weigert’s resorcin-fchisin histochemistry, immunohistochemistry, and morphometric analysis to evaluate the amounts of collagen and elastic fibers and the transforming growth factor-β (TGF-β) expression.

Results: Our results indicate that BLM-mediated fibrosis is IL-17 independent, as IL-17-/- mice developed similar amount of fibrosis when compared to control mice. In marked contrast, BLM-induced pulmonary fibrosis revealed increase of collagen fibers in all four groups (Fig 1). We found that only Balb-BLM and Balb-Paraquat presented increase of elastic fibers. A positive correlation was found between elastic and collagen fibers in Balb-BLM animals, as well as in Balb-BLM and Balb-Paraquat. In addition, we found a direct correlation between TGF and collagen in C57-KO-IL-17-BLM.

Conclusions: Bleomycin and paraquat-mediated fibrosis is IL-17 independent. However, more studies are necessary to validate the regulatory role of IL-17 on pulmonary fibrosis process.

P679
The effect of Nigella sativa oil on inflammation, fibrosis and antioxidant enzymes in the bleomycin-induced lung fibrosis model in rats
Sule Kaya1, Munire Cakir1, Sema Bircan2, Metin Ciris1, Daygu Kumbul Doguc3, Mustafa Naziroglu3, Omer Celik3, Erkan Sozbir3, Birsen Hamam Dogleven4,1 Pulmonary Diseases, Suleyman Demirel University, Isparta, Turkey; 2Pathology, Suleyman Demirel University, Isparta, Turkey; 3 Clinical Biochemistry, Suleyman Demirel University, Isparta, Turkey; 4Biophysics, Suleyman Demirel University, Isparta, Turkey

The aim of the study was to investigate the effect of N. sativa on bleomycin-induced fibrosis.

All study groups included 8 rats. Intratracheal (IT) saline or N. sativa were given to two control groups. A single dose of IT bleomycin was administered to the bleomycin group (BG) as well as the treatment groups on day 0. N. sativa oil was given by oral gavage between days 0-16 in one treatment group and between days 8-16 in the other. At the end of the study, the lung tissues of all rats were investigated histopathologically; GSH, GSH-Px, SOD enzyme activities as well as collagen and elastic fibers were measured in lung tissues and BAL fluids.

On histologic examination, the ratio of inflammation was observed as 45.6%, 19.3% and 14.1% in the BG, long and short treatment groups, respectively; the difference between treatment arms and BG being statistically significant (p=0.019; p=0.003, respectively). The fibrosis score of the BG, long and short treatment groups were calculated as 1.6, 0.78 and 0.35, the difference being also statistically significant (p=0.004; p=0.0001, respectively).

The IT administration of bleomycin resulted in a statistically significant decrease in the GSH-Px and GSH activities and increase in MDA levels of the lung tissue and BAL fluid in comparison with the control group. The enzyme activities in both groups and BAL samples of both treatment arms were high with respect to the BG, the difference being statistically significant for GSH-Px enzyme activity of the BAL fluid (p<0.01).

Oral administration of N. sativa oil resulted in both a decrease in inflammation-fibrosis and an increase in the antioxidant enzyme activities in the rat model.

P680
Modulation of fibroblast phenotype in idiopathic pulmonary fibrosis: Role of Nrf2
Elisa Garatt-Macari, Delphine Goven, Stéphanie Brayer, Joelle Marchal-Sommé, Bruno Crestani, Anne Bouton, Marcel Bonny. U700, INSERM, Paris, France

Rationale: Oxidative stress has been implicated in Idiopathic Pulmonary Fibrosis (IPF) pathophysiology especially in myofibroblastic differentiation. Nrf2 signaling pathway, the main regulator of endogenous antioxidant enzymes, could be involved in fibrogenesis. The aim of our study was to analyze human pulmonary fibroblast expression of Nrf2, and, to assess the effects of Nrf2 modulation on fibroblast phenotype in vitro.

Methods: We assessed antioxidant/antioxidant balance, Nrf2 expression and phenotype of IPF and control fibroblasts in basal conditions, after stimulation by TGF-β, and Nrf2 siRNA transfection.

Results: We showed a decrease of nuclear Nrf2 expression in IPF fibroblasts concomitant with myofibroblast phenotype in basal conditions. TGF-β induced an inhibition of nuclear Nrf2 expression and a myofibroblastic differentiation of control fibroblasts. Nrf2 inhibition in control fibroblast led to an increased oxidative stress in association with a myofibroblastic differentiation. Conversely, Nrf2 activation by Keap1 siRNA, resulted in antioxidant defences restoration and myofibroblastic dedifferentiation in IPF fibroblasts.

Discussion: Our results suggest an association between decreased nuclear Nrf2 expression and myofibroblastic phenotype of IPF fibroblasts. Nrf2 modulation in human lung fibroblasts confirmed the increased susceptibility of Nrf2 knockout mice to bleomycin induced pulmonary fibrosis.

Conclusion: Our study identified Nrf2 as a novel therapeutic target in IPF fibroblasts and suggested a potential anti-fibrotic effects of Nrf2 pharmacological activators.

P681
Serum SP-A and SP-D: Different cutoff values for German and Japanese patients to diagnose idiopathic interstitial pulmonary fibrosis
Takashi Tomizawa1,2, Norihiro Hatori1,2, Nobuhisa Ishikawa1,2, Yoshiyuki Takeda1,2, Koji Yoshiba1,2, Shinichiro Oshimamo1,2, Francesco Bonella3, Junsuke Guzman4,5, Ulrich Costabel6,7, Nobuoji Kohn8 1Department of Molecular and Internal Medicine, Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan; 2Department of Pneumology/Allergy, Ruhrlandklinik University Hospital, Essen, Germany; 3General and Experimental Pathology, Ruhr-University, Bochum, Germany

Introduction: Surfactant protein (SP)-A and SP-D are members of the C-type lectin superfamily. Serum levels of SP-A and SP-D are known to be elevated in patients with various interstitial lung diseases; however, the majority of these data have been obtained in Japanese patients.

Objectives: This study was conducted to compare serum levels of SP-A and SP-D between the German and Japanese population and to investigate whether SP-A and SP-D could be used as diagnostic biomarkers in German patients with idiopathic interstitial pneumonias (IPDs).

Methods: Serum samples were obtained from Germans (110 patients with IPDs and 57 healthy controls) and Japanese (68 patients with IPDs and 100 healthy controls). Serum SP-A and SP-D levels were measured and cutoff values to discriminate IPD patients from healthy subjects were assessed by receiver operating characteristic (ROC) analysis.

Results: In healthy subjects, serum levels of SP-D were significantly higher in Germans than those in Japanese (63.9±30.4 ng/ml and 40.2±24.4 ng/ml; p<0.001) whereas serum levels of SP-A were not significantly different (32.1±16.9 ng/ml and 27.3±13.3 ng/ml; p=0.100). ROC analysis revealed that the optimal cutoff values to discriminate IPD patients from healthy subjects in Germans and Japanese were 133.5 ng/ml and 103.0 ng/ml for SP-D, and were 38.9 ng/ml and 32.4 ng/ml for SP-D, respectively.

Conclusions: Our data suggest the possibility of SP-A and SP-D to be used as diagnostic biomarkers for IPDs in Germans. Cutoff values to discriminate IPD patients from healthy subjects seem to be different between in Germans and in Japanese, however, further investigations will be required.

P682
LSC 2011 Abstract: Role of mast cells and chymase in idiopathic pulmonary fibrosis
Djuro Kosanovic, Bhola Kumar Dahal, Josef Messinger, Yvan Fischer, Katrin Hoffmann, Jochen Antel, Bettina Huen, Nina Hanke, Stephanie Mayer, Hossein Ardecsch Ghofrani, Norbert Weissmann, Friedrich Grimminger, Werner Seeger, Ralph Theo Schermuly. Medical Clinic II, University of Giessen Lung Centre, Giessen, DE; Abbott Products GmbH, Hannover, DE; Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, DE

Rationale: Mast cell (MC) activation has been implicated in the pathogenesis of inflammatory lung diseases. Among the MC-derived mediators, MC chymase is involved in the processes such as activation of TGF-β and formation of collagen fibrils. The literature suggests that chymase may contribute to the pathogenesis of pulmonary interstitial remodeling; however, a systematic investigation is still missing.

Methods: Lung tissues obtained from donors and patients with idiopathic pulmonary interstitial pneumonias (IIPs). Among the MC-derived activators.

Results: We showed a decrease of nuclear Nrf2 expression in IPF fibroblasts concomitant with myofibroblast phenotype in basal conditions. TGF-β induced an inhibition of nuclear Nrf2 expression and a myofibroblastic differentiation of control fibroblasts. Nrf2 inhibition in control fibroblast led to an increased oxidative stress in association with a myofibroblastic differentiation. Conversely, Nrf2 activation by Keap1 siRNA, resulted in antioxidant defences restoration and myofibroblastic dedifferentiation in IPF fibroblasts.

Discussion: Our results suggest an association between decreased nuclear Nrf2 expression and myofibroblastic phenotype of IPF fibroblasts. Nrf2 modulation in human lung fibroblasts confirmed the increased susceptibility of Nrf2 knockout mice to bleomycin induced pulmonary fibrosis.

Conclusion: Our study identified Nrf2 as a novel therapeutic target in IPF fibroblasts and suggested a potential anti-fibrotic effects of Nrf2 pharmacological activators.
donors. There was a preponderence of perivascular MCs and CMCs in IPF lungs (p<0.05 versus donor lungs). Furthermore, we found that there was about 8 fold decrease of mBorg in IPF patients as compared with donors. Finally, there was a strong accumulation of both MCs and CMCs in interstitial regions of the tissues (~65%) in comparison with other regions of the lungs.

Conclusion: The findings suggest that chymase released from activated MCs may be involved in the pathogenesis of IPF. Further investigations will unravel the underlying pathomechanism and substantiate chymase as a potential target for future therapeutic strategies.

P683

LSC 2011 Abstract: Histological markers of epithelial-mesenchymal transition in idiopathic pulmonary fibrosis provide evidence of an alternative repair process

Nicola Lomas, Nicholas Forsyth, Monica Spiteri. Institute of Science and Technology in Medicine, Keble University, Stoke-on-Trent, Staffordshire, GB

Histology, University Hospital of North Staffordshire, Stoke-on-Trent, Staffordshire, GB

Introduction: Wound remodelling in the pathogenesis of idiopathic pulmonary fibrosis (IPF) has produced conflicting results from previous cell culture and animal model studies.

Aim: The aim of this study was to examine wound remodelling mechanisms in usual interstitial pneumonia (UIP), with emphasis on the role of epithelial-mesenchymal transition (EMT).

Methods: Immunohistochemistry was used to assess cellular expressions of markers of EMT in paraffin embedded lung tissue samples from 21 patients with IPF, with comparisons made to histologically-defined normal lung sections from 19 control subjects.

Results: Hyperplastic type II pneumocytes in all UIP cases expressed the adhesion molecule E-cadherin with no expression of N-cadherin or TWIST. Expression of TWIST was restricted to the fibroblast/myofibroblast foci. TGF-β protein was consistently expressed by type II pneumocytes of UIP samples, but to varying degrees within the fibroblastic foci. Collagen I and smooth muscle actin were expressed in the fibroblastic foci.

Conclusions: Myofibroblasts may form a contractile repair response to a micro-injury via secretion of extracellular matrix proteins, providing scaffolding for type II pneumocytes which then divide at the edge of the insult and migrate over the fibroblastic foci surface. TGF-β signalling pathways may lead to the continued accumulation of type I collagen in the foci. Alternatively, abnormal collagen I is produced which is resistant to matrix metalloproteinases inhibiting wound repair. We conclude that tissue remodelling in IPF is a complex process warranting further investigations to fully elucidate the role of EMT in the pathogenesis of IPF.

P684

The relationship between socioeconomic status, quality of life and healthcare access in COPD: A systematic review

Sofia Georgopoulou1, Alison J. Wright1, John Weiman2, Helen Booth1, Hannah Thornton1, Patrick White1, 1Primary Care and Public Health Sciences, King’s College London, London, United Kingdom; 2Institute of Psychiatry (IoP), Health Psychology Section, King’s College London, London, United Kingdom

Introduction: Socioeconomic deprivation is a significant health determinant in COPD. To examine the relationship between socio-economic status (SES), Quality of Life (QoL) and healthcare access in COPD, we conducted a systematic review.

Methods: Medline, Embase, Web of Science, PsycINFO, BIBS, IngentaConnect and CINAHL were searched for quantitative studies published in English (1947-2011). Articles reporting association between SES and any aspect of QoL, and healthcare access were included.

Results: After screening 6889 papers and assessment of 1088 abstracts 76 studies were reviewed. Studies were categorised depending on outcome measures into either quality of life (n=45) or healthcare access (n=31). Quality of life included: disease severity, exacerbations, psychological status, physical functioning/activity, pulmonary function/respiratory symptoms and mobility. 66.7% (n=30) of the studies yielded a negative effect of low SES on QoL, 28.9% (n=13) showed no effect and 4.4% (n=2) found a positive influence. Healthcare access involved: hospitalisation rates, prescription patterns, medication adherence/use and diagnostic procedures. 61.3% (n=19) provided data for the negative influence of socioeconomic deprivation on healthcare access, 29% (n=9) showed no effect while 9.7% (n=3) found a favourable influence.

Conclusion: A consistent association between low SES and unfavourable outcomes in various domains of both QoL, and healthcare access was found. Findings suggest a need to investigate the reasons for this negative association between SES and outcome in COPD. The possible explanatory role of factors such as patients beliefs and behaviour are being explored in an ongoing cohort study.

P685

The measurement of the impact of breathlessness in advanced COPD

Morag Farquhar1, Irene Higginson2, Helen Booth1, 1Primary Care and Public Health Sciences, King’s College London, London, United Kingdom; 2Department of Palliative Care Policy and Rehabilitation, King’s College London, London, United Kingdom

Introduction: Breathlessness is the main symptom of COPD and should be a key outcome measure in studies of advanced disease. Measures of breathlessness have been poorly researched. There is no gold standard for the assessment of breathlessness in advanced disease. In this study we aimed to identify using existing tools a valid and reliable self-report measure of breathlessness for clinical research in advanced COPD.

Methods: 260 eligible patients with advanced COPD were identified from the disease registers of 72 general practices. Spirometry, MRC dyspnoea scale, mBorg, NRS, CRQ-SAS, Dyspnoea 12, and Hospital Anxiety and Depression Scale, were administered at interview. Distribution of responses, associations and correlations were examined.

Results: 146 (56%) patients were interviewed. Association between the different measures of breathlessness was variable with least correlation between the numerical measures mBorg and NRS and the other measures, and greatest correlation between CRQ-SAS and Dyspnoea 12. Usefulness of tools was limited by ceiling effects (limited room for more severe breathlessness) in MRC Dyspnoea scale and by floor effects (limited room for less severe breathlessness) in mBorg and NRS. Factor analysis of the five measures confirmed that the CRQ-SAS dyspnoea questionnaire (loading 0.74) and Dyspnoea 12 questionnaire (loading 0.73) were closest to the hypothesised latent true value of breathlessness (eigenvalue 2.33, difference 2.21).

Conclusions: Combination of CRQ-SAS dyspnoea and Dyspnoea 12 is the most suitable approach to valid, reliable, measurement of breathlessness in clinical research in advanced COPD that is sensitive to change. mBorg retains a particular role in standardised exercise testing.

P686

Validity of the pediatric electronic quality of life instrument for childhood asthma in the Netherlands

Lisette van den Bent1, Stephanie van Bragt1, Bart Thuomens2, Peter Merkus2, Tjard Schermer2, 1Department of Primary and Community Care, Centre for Family Medicine, Geriatric Care and Public Health (Route 117), Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 2Department of Pneumatics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Introduction: Assessment of health-related quality of life (HRQL) for children with asthma in daily care may facilitate shared decision-making and contribute to patient-centred care. Pediatric HRQL is unique to children and it is essential to establish whether an instrument used in daily care has an individualised part to prioritise issues that are especially important for the particular child. We have developed a pediatric HRQL instrument that is designed as a web based game and has an individualised part (Pelicarn instrument).

Aim: The aim of this study was to determine the cliniometric properties of the Pelicarn instrument.

Methods: 68 children with asthma aged 6 – 12 years were recruited. Children completed the Pelicarn instrument on 3 occasions within a 2-month period. Additional information was collected on various aspects, including asthma control (ACQ, C-ACT) and HRQL (Feeling Thermometer and PAQLQ).

Results: The instrument had good test-retest reliability (ICC 0.83) and internal consistency (Cronbach’s α= 0.90). Moreover, the instrument was able to discriminate between children with controlled and uncontrolled asthma and we observed good correlations with the PAQLQ and Feeling Thermometer (r ≥ 0.6). Finally, the items selected by the children as “worst things about my asthma” (i.e., individualised part) were scored higher by the child than items they did not select (mean difference 0.97; scale 1-5).

Conclusions: The results indicate that the Pelicarn instrument is a valid and reliable instrument. The responsiveness of the instrument needs to be established. Further studies are needed to assess whether implementation of the Pelicarn instrument can facilitate patient-centred care.
Intractable breathlessness in COPD – A suitable case for palliation?

**Aim:** To identify the words most frequently used by physicians and patients to express asthma symptoms and activities limitations caused by asthma.

**P687**

**Introduction:** Breathlessness is the major symptom of concern for people with advanced COPD. Intractable breathlessness may be described as “sustained severe breathlessness in patients who have not obtained relief from conventional treatment”. This study set out to define the prevalence of intractable breathlessness in COPD and potential for its palliation.

**Method:** COPD patient records in south London practices were searched for ≥2 of: FEV1 ≤30% predicted, hospital admissions/exacerbations needing oral steroids, long term O2, and cor pulmonale. Participants were interviewed at home.

Breathlessness was assessed using MRC Dyspnoea Scale, mBorg, NRS, Dypsnoea-12 and Chronic Respiratory Questionnaire. Intractable breathlessness was defined using a combination of FEV1% predicted, CRQ-Dyspnoea, Dypsnoea-12 and the desire for more help. Treatment optimisation was offered where appropriate before reassessment of breathlessness.

**Results:** 5102 patients were identified in 72 practices, 2163 had spirometry-confirmed COPD. 260 (5%) were eligible and 146 (56%) took part. 65% reported breathlessness as their most important problem, 69% reported breathlessness evoking palliative services for these patients is a priority.

**Conclusion:** Intractable breathlessness affects around 1 in 50 COPD patients on 2% of patients with confirmed COPD in the study population.

**P688**

**Method:** We conducted a cross-sectional survey of patients with asthma receiving ICS-based treatment for ≥6 months. Participants were interviewed at home and patients/physicians. 63 (43%) were on sub-optimal treatment, 97% of whom received optimisation. Improvements in breathlessness weren’t observed at re-assessment. 29 (20%) participants had intractable breathlessness; an estimated 2% of patients with confirmed COPD in the study population.

**Conclusion:** Intractable breathlessness affects around 1 in 50 COPD patients on 2% of patients with confirmed COPD in the study population.

**P689**

**Introduction:** Expression of symptoms and daily activities limitations is a core element in physician-patient dialogue in asthma management. Aim: To identify the words most frequently used by physicians and patients to express asthma symptoms and limitations of daily activities, and to assess the patient-physician concordance regarding these.

**Methods:** The “Asthma Language” study (NCT00986219) (descriptive, cross-sectional survey) enrolled patients with asthma receiving ICS-based treatment for ≥6 months. Interviews and patients chose up to 4 words from 2 lists (a symptoms and a daily activities limitations list) identical for patients/physicians.

**Results:** 695 patients (F 57%, age 46.8±14.8 years) were enrolled. Time since diagnosis was 12.9±9.4 years. Treatment with ICS/LABA±LTRA was reported by 92% of patients. ACQ-5 score was 1.5±1.1. The words most frequently used to express asthma symptoms were “cough”, “dyspnea” and “wheezing” (35-56%), while those used to express activities limitations were “stairs climbing”, “fast walking” and “uphill walking” (40.5%-53%). In terms of word concordance regarding expression of asthma symptoms and activities limitations, full concordance was observed in 43% and 19.1% and partial concordance in 75.4% and 74.9%, respectively. By grouping the words expressing the same symptom, full concordance was observed in 21.7% and partial concordance in 72%.

**Conclusions:** This study showed that there is a discordance regarding physician-patient communication in terms of the words used to express symptoms and daily activities limitations caused by asthma.

**P690**

**Facilitation of optimal asthma management to radically influence health policy in primary care in Ireland**

Jean Holohan1, Louis Couye1, Francis Guiney1, Pat Manning1, Basil Elnazzar2, Eamonn Shanahan3, Terry O’Connor5, Muireann Ni Chroinin6, Netta Williams7, Eamonn Shanahan4, Terry O’Connor5, Muireann Ni Chroinin6, Netta Williams7, Rhonda Forsythe1, Pamela Logan2, Research and Education, Asthma Society of Ireland, Dublin 1, Ireland; 2Respiratory, HSE Regional Hospital Mullingar, Mullingar, Co. Westmeath, Ireland; 3Paediatric Respiratory, Cork University Hospital, Wilton, Cork, Ireland; 4Professional Development Coordinator for Practice Nursing, Health Service Executive Dublin North East, Swords, Co. Dublin, Ireland; 5Director of Pharmacy Services, Irish Pharmacy Union, Dublin 14, Ireland

Prior to the initiation of this program guideline based care was not prioritised by health policy. Asthma control is sub-optimal in Ireland; recent primary care data shows 14% of asthma patients attended A&E, 8% hospitalised in the previous 12 months.

**The Asthma Society of Ireland (ASI) developed a framework for the Dept. of Health and Health Service Executive (HSE) in collaboration with Healthcare Professional (HCP) bodies based on nationally modified guidelines (GINA) and a core program to assess the feasibility of implementing a National Asthma Program.** The ASI funded and developed an asthma management program in primary care to identify barriers and facilitators to implementation of guideline based care. 25 primary care teams completed a guideline based educational program and practical training session. Each team was given a tool-kit with spirometer, peak flow meters and diaries, patient education materials, placebo inhalers and spacers. Adherence to guidelines was facilitated with a specifically developed Electronic Patient Record. 778 patients were included in the program for 6 months.

**A guideline based asthma program can be implemented successfully if practices are provided with necessary resources for diagnosis, management and patient education.** HCP agreed guidelines improved patient care (92.7%), facilitated cost effective care (70.7%). Arising from this study HSE has prioritised the development of a National Asthma Program with asthma specific key performance indicators in its service plans. Active collaboration between patient organisations, HCP and health service providers has lead to a fundamental change in asthma health policy in primary care.
Introduction: A previous survey highlighted a very high degree of physiologically unnecessary home oxygen use in COPD patients (Bhattacharya M, Potter A, Mukherjee R. Assessing for Long Term Oxygen Therapy (LTOT) in an English town. Ann R Coll Surg Eng 2008;87:466). A common reason for the unnecessary use is that hospital physicians discharge COPD patients with home oxygen pending physiological assessment in the hope of preventing future hospital admissions, which we set out to examine.

Methods: A retrospective review of COPD admissions and re-admissions of Birming ham East and North Primary Care Trust from patients from April 2007 - November 2010 based on International Classification of Diseases coding (ICD); Wclie’s 2-sample t-test was applied to assess the significance of the difference in the admission rates of the 2 groups of COPD patients who receive and did not receive LTOT on discharge.

Results: A total of 1942 patients were eligible of which 295 received LTOT on discharge. The mean annual admission rate in the LTOT group was 3.18 and 1.67 in the other (p < 0.0000000001).

Conclusion: LTOT prescription on discharge is actually associated with a significant increase in re-admission to hospital of COPD patients. Further studies including controlling the admission rate for disease severity are necessary. Continu ing to widen the provision of integrated multidisciplinary oxygen assessment services also seems to be reasonable.

P694

Body mass index and quality of life in patients with asthma

Gulina Sergeeva, Alexander Emelyanov. Department of Allergy and Lung Diseases, Medical Academy for Postgraduate Studies, Saint-Petersburg, Russian Federation

Background: We examined the effect of overweight and obesity on quality of life in patients with asthma.

Methods: Two hundred out-patients with asthma (aged 18 - 80 yrs, mean age 55 yrs, 33% males) were divided into 3 groups: with normal body mass index (BMI<25), overweight (25≤BMI<30) and obese (BMI≥30). Quality of life was measured by using Russian version of St.George’s Respiratory Questionnaire (SGRQ).

Results: Fifty eight percent of males and in 69% of females with asthma had BMI<25: 35% of males and females were overweight and 23% males and 34% females were obese. BMI in males was 26.8±0.62, in females – 28.9±0.55 (p<0.05). Correlation of age and BMI was significant only in males (r=0.35, p<0.05). The relationship between BMI and Symptom score was not determined. BMI in pa tients with asthma was mainly associated with Activity score (r=-0.22, p<0.05), in both males (r=-0.27, p<0.05) and in females (r=-0.22, p<0.05), with Impact (r=-0.17, p<0.05) and Total score (r=-0.09, p<0.05). In patients with BMI<25 and in those with BMI≥25 the differences of Activity (39.7±3.38 vs 49.3±6.7, p<0.01) and Impact scores (29.9±2.64 vs 36.9±1.82, p<0.05) were significant. We did not reveal any relationship between normal BMI and SGRQ scores in pa tients with asthma. Overweight and obesity were associated with Activity (r=0.20, p<0.05) and Total score (r=0.17, p<0.05). In asthmatic males the relationship between BMI≥25 and SGRQ Activity score was (r=0.41, p<0.05), Impact score (r=0.33, p<0.05) and Total score (r=0.37, p<0.05) were determined.

Conclusion: Obesity and overweight are frequently associated with asthma. There was a significant correlation between BMI≥25 and Activity, Impact and Total items of SGRQ.

P695

Relation between quality of life and morbidity and mortality in COPD patients: 7-year follow-up study

Yavuz Havlucu1, Arzu Yorgancioglu1, Aysin Sakar Coskun1, Gonul Dinc Horasan2, Tugba Goktalay1, Pinar Celik1. Chott Disease, Celal Bayar University Medical Faculty, Manisa, Turkey; Public Health, Celal Bayar University Medical Faculty, Manisa, Turkey

In this study, relationship between pulmonary function test (PFT) and quality of life (QoL) and effect of QoL on prognosis, mortality, and morbidity were investigated in patients with COPD.
In this prospective study, 251 patients with COPD as defined by ATS criteria were included. 218 patients (86.85%) were male and mean age was 65.55. PFT and QoL questionnaires, St. George Respiratory Questionnaire (SGRQ), were performed at the beginning. During 7 year follow-up, first exacerbation day, number of exacerbation, number and duration of hospitalization, number and duration of hospitalization in intensive care unit, number of readmissions, and exitus day were recorded. 195 patients (77.6%) were died during follow-up. 112 patients (57%) were died due to respiratory reasons. When the beginning parameters of dead patients and survived patients were compared, there was a statistically difference according to comorbidity especially cardiac disease, disease duration, PFT parameters, and SGRQ score (p<0.05). Also number of exacerbation before study and first exacerbation day during study were related with mortality (p<0.05). When the correlation between FEV₁ values, SGRQ scores and parameters mentioned above were investigated, there was significant correlation between these parameters and this correlation was more significant in SGRQ scores than FEV₁ values.

As a result, not only PFT but also quality of life questionnaires are useful in determining the prognosis of COPD, for this reason health questionnaires provide a valid and standardised estimate of the overall impact of COPD and should be used to complement spirometric measurements of baseline assessment of patients in routine practice.

**The impact of “specialized COPD outpatient clinic” in patient outcomes – A prospective cohort study in a Hong Kong government hospital**

Hoi Nam Tse1, King Ying Wong2, Kwok Sang Yee1, Ka Yan Wai1. 1Medical Department, Kwong Wah Hospital, Hong Kong, Hong Kong; 2TB and Chest Unit, Wong Tai Sin Hospital, Hong Kong, Hong Kong

**Introduction:** A highly specialized COPD outpatient clinic, run by respiratory specialists, can provide comprehensive and updated service to COPD patients and may reduce their exacerbation/hospitalization rate.

**Aim:** To evaluate the impact of “specialized COPD clinic” on various patient outcomes.

**Methods:** Patients with spirometry-confirmed COPD and history of at least one episode of exacerbation in past one year were referred to the new specialized clinic. GOLD guideline was strictly adhered. Education was provided by respiratory nurses with provision of written action plan for exacerbation of symptoms. Outreach physiotherapy was provided for selected patients. Outcome measures included lung function test, St George respiratory questionnaire (SGRQ), were done at baseline and 6-month follow up. The exacerbation and admission rate were also recorded.

**Results:** Total, 117 patients had been followed up. They had a mean age of 70.34±5.56 (Median 70.5) (range 59-80); SGRQ score total score was 41.4±18.9 and a baseline exacerbation and admission rate 3.3±0.3 and 1.4±1.7 per year respectively in past one year.

At 6-month follow up, patients’ quality of life improved significantly with SGRQ total score reduced from 35.6±18.9 to 28.4±16.6 (RMANOVA test, p=0.018). There was also a 66% reduction in both exacerbation and admission rate. The exacerbation rate reduced from 3.3 to 1 episode/year (0.79 episode per 9 months) while the admission rate decreased from 1.4 to 0.37 episodes/year (0.35 episode per 9 months).

**Conclusion:** The specialized COPD clinic significantly reduces exacerbation and admission rate in COPD patients as well as improves their quality of life.

**P697**

**The percentage of influenza vaccination in urban and suburban high risk population in western Greece during the year 2010**

Dimitra Sereti, Theodora Theodorou, Konstantina Sereti, Maria Petta, Maria Petta. General Practice, Vardas Health Center, Vardas, Ilia, Greece

**General Practice, Chalandritsas Health Center, Patras, Achaias, Greece General Practice, Chalandritsas Health Center, Patras, Achaias, Greece General Practice, Chalandritsas Health Center, Patras, Achaias, Greece**

**Aim:** To estimate the percentage of immunization against influenza.

**Method:** 1156 high risk patients were asked for having or not having done the influenza vaccine. They were also asked for the reasons which made them not to be vaccinated.

**Results:** 227 patients (35.1%) from the rural and suburban were vaccinated and 133 (26.1%) from the urban.

The reasons for no vaccination were fear, ignorance, personal beliefs, neglect, contraindications and lack of vaccine or difficulty in access.

The vaccination was carried out by family physicians in 65.6% of the rural and suburban population and in a 53.4% of the urban.

**Conclusion:** People from rural and suburban areas are more immunized against influenza compared with those from urban. Apart from the contra-indications, there are other reasons that influence the influenza vaccination of the population. The participation of the family physicians in rural population’s vaccination indicates the quality of the direct relationship between doctor and patients and probably is the main cause for the low percentages of fear, ignorance or neglect about the vaccine against influenza.

**P698**

**Influenza vaccination programme – Are the UK government incentives working?**

Mohammad Paracha1, Rizwan Ahmed2, Mohammad Saluddin3. 1Student in the Faculty of Medical Sciences, Newcastle University, Newcastle-upon-Tyne, United Kingdom; 2Respiratory Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3General Practice, Gladstone Medical Centre, Birkenhead, United Kingdom

**Background:** Influenza A (H1N1) virus has spread globally in recent years. The UK government recommends all people in high-risk groups (all >65 yrs old, people with chronic diseases, the immunocompromised, carers, healthcare workers & pregnant women) be vaccinated against H1N1. Pregnant women are four times more likely to be hospitalised due to the virus as compared with non-pregnant women [1]. The rate of H1N1 hospitalisation among children is also significantly higher compared to those over 65 years old [2]. General practices in the UK are given financial incentive to achieve >70% uptake in high-risk groups.

**Methods:** We retrospectively reviewed vaccination uptake amongst the high-risk population in two practices in different regions of the UK for winter 2010/11. Both practices use the computer input software (EMIS). The programme Population Manger was used to retrieve the uptake data.

**Results:** Both surgeries are achieving the required national target, practice A: 75% (1502/1998) & practice B: 81% (917/1250), hence received full financial incentive. However, both practices have a very low uptake in under 16 year olds, practice A: 35% (277/787) & practice B: 40% (215/522) and among pregnant women, practice A: 40% (12/30) & practice B: 14% (4/28).

**Conclusion:** Incentives for the vaccination programme should be revisited so that all the sub groups of high-risk population, including those most at risk of complications and hospital admissions, achieve the same high level of immunisation.

**Asthma control and quality of life: 6-month follow-up of PRISMA study (PRospective Study on asthMA control)**

Luis Allegra, Giovanni Cremoneesi, Giuseppe Girbino, Eleonora Ingrassia, Serafino Marsico, Gabrielle Niclioni, Claudio Terrazzo. Thoracopulmonary Department, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico-Mangiagalli-Regina Elena, Milan, Italy Medical Affairs, Chiesi Farmaceutici, Parma, Italy Institute of Respiratory Medicine, University of Messina, Messina, Italy Medical Affairs, Chiesi Farmaceutici, Parma, Italy Department of Respiratory Medicine, Azienda Ospedaliero Monaldi, Second University of Naples, Naples, Italy Medical Affairs, Chiesi Farmaceutici, Parma, Italy Respiratory Diseases Unit, Department of Cardiovascular and Respiratory Sciences, “Sapienza” University of Rome, Rome, Italy

**Rationale:** According to GINA guidelines, asthma control is the goal of the treatment.

**Objectives:** To estimate the percentage of controlled asthmatic patients and their quality of life.

**Method:** Adult asthmatics with not well controlled asthma (Asthma Control Test score ≤ 19) were involved in a prospective observational study. Asthma control and quality of life were assessed with ACT and EuroQol-5D, respectively.

**Results:** 735 patients were evaluated. Figure 1 shows the distribution of asthma control and quality of life over the 6-month follow-up period.
control at enrolment visit and after 6 months. As compared to the first visit, 70.1% of uncontrolled and 80.0% of partly controlled reached asthma control. The mean (SD) of EuroQoL score was 0.72 (0.2) at first visit and 0.84 (0.2) at 6-month follow-up visit. The mean (SD) of VAS was 65.0 (16.1) at first visit and 77.1 (13.6) after 6 months. Figure 2 shows the EuroQoL score and VAS stratified for control level.

Conclusions: Improvements in asthma control and quality of life can be detected in the majority of non-controlled patients after 6-month follow-up in a real life setting.

P700
Impact of therapy reviews in real-world asthma
David Price1,2, John Haighney1, Dermot Ryan1,2, Iain Small1,2, Kevin Gruuffyd-Jones1,2, Alison Chisholm1,2, Stanley Musgrave1,2, Naheem Munir2, Federico Lavorini3, Alberto Papi3,4,5,6,7, Alison Chisholm2, Stanley Musgrave2,3,4,5,6,7, David Price1,2, John Haughney1, Dermot Ryan3,4, Iain Small5,6,7, Kevin Gruuffyd-Jones1,2, Alison Chisholm2, Stanley Musgrave1,2, Naheem Munir2, Federico Lavorini3, Alberto Papi3,4,5,6,7, Alison Chisholm2, Stanley Musgrave2,3,4,5,6,7

Rationale: Asthma therapy reviews aim to regain or improve asthma control, reduce side-effects and/or contain costs. Little work has been done using clinical data to evaluate their effect on asthma control. Objective: Identify therapy reviews in fixed-dose combination inhaled corticosteroid/long-acting beta2 agonist (FDC ICS/LABA) asthma patients and evaluate subsequent changes in asthma control.

Method: Utilised the UK’s Optimum Patient Care Research Database to identify primary care patients (18–80yrs) with asthma (diagnostic code and/or ICD-10 code) treated with FDC ICS/LABA who, following a therapy review, were prescribed beclometasone dipropionate/formoterol (BDP/FOR; Foster 100/6µg) at same or lower BDP-equivalent ICS daily dose as their previous ICS/LABA. Proxy asthma control measures were evaluated before (over 1yr) and after (≥90 days follow-up) initiating BDP/FOR, i.e. asthma control: no hospital attendance, admissions, or out of hours consultation, outpatient department attendance or admission for asthma; no acute oral steroid prescriptions; no primary care consultations for lower respiratory tract infection, short-acting beta2 agonist (SABA) use, and exacerbations: asthma hospital attendance or Accident & Emergency admission and/or acute oral steroid courses.

Results: 65 eligible patients.

<table>
<thead>
<tr>
<th>Achieved control</th>
<th>Before, n (%)</th>
<th>After*, n (%)</th>

</tbody>
</table>

*Annually for <1yr outcome; p=0.05 for all measures.

Conclusion: These preliminary data suggest initiating BDP/FOR in real-world FDC ICS/LABA patients following a therapy review does not result in a deterioration in asthma control measures.

P701
Evaluation of COPD treatment success by office-based pneumologists in Germany using the example of tiotropium
Thomas Glab1, Axel Kroeker2, Harald Mitfessel3, Hendrik Schmidt4, Heike Rau-Berger1, Medical Affairs, Boehringer Ingelheim Pharma GmbH & Co KG, Ingelheim, Germany; 2Dept of Pneumology, Pneumology Practice, Koblenz, Germany; 3Dept of Pneumology, Pneumology Practice, Krefeld, Germany

Background: In chronic obstructive pulmonary disease (COPD) patients, treatment with the long-acting anticholinergic tiotropium has been associated with clinical benefits in patients.

Aims and objectives: To assess the treatment effect of tiotropium and evaluate the two most important therapeutic outcome parameters from the perspective of office-based pneumologists in Germany.

Methods: Patients received tiotropium (SPIRIVA® HandiHaler® 18 µg or SPIRIVA® Respimat® 5 µg qd) for 6 to 12 weeks in an open-label observational study in 277 pneumology practices. At Visit 2 (Week 6 to 12) pneumologists assessed the success of treatment with tiotropium and determined the two most important outcome parameters for their judgement of therapeutic success. Other endpoints were the concurrent proportion of positive efficacy and tolerability assessments by both physicians and patients.

Results: Of 1264 patients enrolled, 1264 (100%) were evaluable for the primary efficacy endpoint (mean age, 65.3 years; 63.1% men). Rate of therapeutic success was 96.4% (95% confidence interval [CI]: 95.3-97.4%). The most frequently used specific outcome parameters were pulmonary function (49.1%) and exercise capacity (48.9%). Concurrent proportions of positive assessments by both physicians and patients were 88.4% (95% CI: 86.5-90.1%) and 93.4% (95% CI: 91.9-94.7%) with regards to efficacy and tolerability, respectively.

Conclusion: A high proportion of office-based pneumologists rated the treatment with tiotropium as successful based mainly on improvements of pulmonary function and exercise capacity.

Funded by Boehringer Ingelheim/Pfizer.

88. New mechanisms in airway disease

P702
microRNA regulation of the Alpha-1 antitrypsin gene
Tidi Hassan, Irene Oglesby, Shane O’Neill, Catherine Greene, Gerard McElvaney. Respiratory Research Division, Department of Medicine, ERC Smurfit Building, Beaumont Hospital, Dublin, Ireland

Introduction: Alpha-1 antitrypsin (AAT) deficiency is a conformational disorder characterised by chronic inflammatory lung disease and liver disease. microRNAs (miRNA) represent drug targets that function as post-transcriptional negative regulatory molecules of target gene expression. Aims and Methods: To identify miRNAs that target AAT gene expression using in silico analysis, to quantify AAT gene and protein expression in monocytic THP-1, 16HBE14o- bronchial epithelial and HepG2 liver cells using qRT-PCR and ELISA, to quantify specific miRNAs expression in these cells, to modulate AAT expression using pre-miRs and to validate miRNAs targeting AAT using AAT-3’UTR luciferase reporter plasmid in HEK293 cells.

Results: In silico analysis predicts multiple miRNAs that target the AAT gene such as miR-940 (with multiple binding sites in the 3’UTR), miR-132 and -212. Diverse AAT expression using premiRs and to validate miRNAs targeting AAT using a AAT-3’UTR luciferase reporter plasmid in HEK293 cells. A combination of pre-miRs over-expressed in HepG2 only resulted in a decrease of AAT mRNA and protein expression involving premiR-940, however, not significantly more than cells transfected with premiR-940 alone.

Conclusion: AAT mRNA is a true target for miR-940, 132 and 212. miR-940 is a more effective inhibitor than miR-132 or miR-212 due to attractive inherent properties compared to the other miRNAs tested.
P703
Inflammatory mediators in COPD patients with and without alpha-1-antitrypsin deficiency
Timm Greisbach, 1 Julia Klein 2, Christian Herr 2, Angelique Holland 1
1 Respiratory Medicine, University Hospital of Marburg, Marburg, Germany; 2 Department of Pathophysiology, National Koranyi Institute for TB and Pulmonology, Budapest, Hungary

Introduction: Systemic inflammation is present in a large proportion of COPD patients and is discussed to be the missing link between COPD and its extrapulmonary manifestations. Little is known about differences in systemic inflammation in COPD patients with and without alpha-1-antitrypsin deficiency (AATD).

Aims: We tested the hypothesis that systemic inflammation in COPD would differ in patients with and without AATD and that markers of inflammation would be associated with quality of life (QoL).

Methods: In this cross-sectional study we included 102 participants. We measured lung function, quality of life (QoL) using the St. Georges Respiratory Questionnaire (SGRQ), and inflammatory mediators in peripheral blood. We compared combined genotype frequencies in four groups: AATD patients without augmentation therapy (AATDunsub = 20); AATD patients with augmentation therapy (AATDsub = 20); patients with COPD (n=46) and healthy controls (HC; n=16).

Results: Geometric mean high sensitivity C-reactive protein (hsCRP) was significantly elevated in COPD (3.72 mg/l) and AATDsub (4.19 mg/l) compared to AATDunsub (0.96 mg/l) and HC (0.82 mg/l). Significant differences could also be detected for alpha-1-antitrypsin (<0.001). Interleukin-6 (IL-6), IL-8, and tumor necrosis factor-alpha did not differ significantly. hsCRP levels were positively correlated with SGRQ in COPD patients without AATD (Spearman’s r=0.46; p<0.05).

Conclusion: Low grade systemic inflammation is present in COPD with and without AATD. Despite different causes of these diseases, a common inflammatory pathway may exist. In patients with COPD, but not in AATD patients, systemic inflammation is associated with QoL.

P704
Polymorphism of collagen I gene and glutathione-S-transferases T1 and M1 in chronic obstructive pulmonary disease associated with cardiovascular disease
Tatyana Tilk1, Vera Nezvorova1, Svetlana Vakhrusheva1, Evgeny Gilifanov1, Marina Issaeva1, Elena Samoilenko1, Department of Medical and Social Development, Vladivostok State Medical University, Vladivostok, Primorsky Region, Russian Federation

The aim of the research was to establish association between presence of mutant genotype COL1A1 (locus G1546T), null- genotypes of glutathione-S-transferases (GSTs) GSTM1 and GSTT1 and stage of chronic obstructive pulmonary disease (COPD). The group of patients with COPD (II and III stage of COPD, n=30) associated with I-II functional groups of stable stenocardia (I and II subgroup, n=30) was examined.

In the research of gene COL1A1 polymorphism allelic phenotype T was found in 15% of healthy persons. Genotype GT was revealed at 1/3 of control group while pathological homogeneous genotype TT in the same group hadn’t been registered. In both groups frequency of genotype GT was higher than in the control group (1/3 vs. 0.05, p<0.01). Genotype TT was found in II group only (1/3 vs. 0.05, p<0.01). The OR of severe COPD in the presence of pathological allele T of COL1A1 was especially higher in II group, than in I (OR=1.75, 95% CI=1.11-2.76, p=0.01). Patients with pathological genotype of COL1A1 had been screened for the presence of combined null- genotype of GSTs. The homozygous deletion of both genes was found at four patients (all patients from II group). Respectively those patients had pathological genotype GT of COL1A1 demonstrated by functional inadequacy of collagen 1A1. Presence of combined null-genotype GSTM1 and GSTT1 at these patients, in turn, can lead to the total absence of enzymes GSTs, contributing accumulation of toxic intermediate metabolites of xenobiotics in the cell without their further neutralization and development of oxidative stress and destruction of connective tissue.

P705
Sputum biomarkers in stable COPD
Imre Barta, Balazs Antus. Dept. of Pathophysiology, National Koranyi Institute for TB and Pulmonology, Budapest, Hungary

Characterization of the COPD proteome could help early diagnosis of the disease and aid the development of specific treatment options. The aim of this study was to detect sputum biomarkers characteristic for COPD. Induced sputum was collected from 19 stable COPD patients (GOLD I-II, ex-smokers, mean age 62 years, pack year 52, FEV1 64% predicted, FVC 50%) and 19 healthy controls (mean age 62 years, pack year 29, FEV1 110% predicted, FVC 7%). CRP level, 9.1mg/L vs. 5.1mg/L, and total sputum cell number (3.5×10⁶ vs. 1.3×10⁶) were significantly different between the two groups. Sputum supernatants were subjected to cytokine antibody microarray analysis. Of the 120 cytokines investigated 96 was detectable above background level in 19 majority samples. A greater subset of factors was down regulated while a smaller subset was up regulated in COPD. 14 cytokines exhibited a difference of at least 50% in relative expression level. IL-6, IL-1α, GRO and GROα expression was significantly different (p<0.05) in COPD patients vs. healthy controls. These results suggest that a COPD specific cytokine pattern might exist.

P706
Polymorphism of glutathione-S-transferases T1 and M1 in chronic obstructive pulmonary disease
Svetlana Vakhrusheva1, Vera Nezvorova1, Tatyana Tilk1, Evgeny Gilifanov1, Marina Issaeva1, Elena Samoilenko. Department of Medical and Social Development, Vladivostok State Medical University, Vladivostok, Primorsky Region, Russian Federation

Chronic obstructive pulmonary disease (COPD) is the result of genetic factors and environmental conditions influence on a human organism. Glutation-S-transferases (GST) play significant role in cell resistance to oxidative stress, and in prevention of DNA damage from products of tobacco smoke. In this study it was investigated the presence of combined null-genotype of GSTs. The homozygous deletion of both GSTM1 and GSTT1 at these patients, in turn, can lead to the total absence of enzymes GSTs, contributing accumulation of toxic intermediate metabolites of xenobiotics in the cell without their further neutralization and development of oxidative stress and destruction of connective tissue.

P707
Gene regulation of apoptosis and telomere length in COPD and lung cancer
Dmitry Babzyak1, Iryna Ilyenko1, Lyudmila Stivoja2, Konstantyn Babzyak2, Oleg Belyaev1, 1 Dept. of Clinical Immunology, Research Center for Radiation Medicine, Kyiv, Ukraine; 2 Dept. of Pulmonology, Research Center for Radiation Medicine, Kyiv, Ukraine

The aim of this study was to investigate the role of gene regulation of apoptosis (TP53, TP53 I3, FASLG, BAX, CCND1) and telomere function (TRF1, TRF2) in peripheral blood lymphocytes in COPD and lung cancer.

Methods: Groups included 16 COPD patients (FEV1 41-64), 5 lung cancer and 12 controls. Relative telomere length and apoptosis in peripheral blood cells were analyzed by flow cytometry. Relative quantification (RQ) of gene expression was investigated by the RT-PCR System and TaqMan technology.

Results: In COPD a decreased RQ was shown for FASLG, TP53 and TP53 I3 genes with overexpression of BAX (p<0.001) and CCND1 genes and increased expression of BAX-protein and MAPK14 (p<0.05) on CD16+56+ cells by flow cytometry. A significant decrease was demonstrated TERF1 and especially TRF2 expression (Fig. 1). In lung cancer high Ki-67+ and HER2+ cell counts were combined with a decrease of BIRC5 and FASLG expression and MAD2, MAPK14 and CDKNI1B over-expression. The RTL was higher in lung cancer as comparing with COPD and control but no correlation was seen with TERT or TRF2 gene expression.
Peripheral insulin resistance accounts for impaired glucose tolerance and is associated with systemic inflammation in COPD

John Archer, Emma Baker. Centre for Clinical Pharmacology, St George’s University, University of London, London, United Kingdom

Introduction: Impaired glucose tolerance is common in COPD (Archer & Baker, Resp Med: COPD Update 2009:5:67-74). We assessed pancreatic function, hepatic and peripheral insulin resistance and determined the relationship of these with systemic inflammation.

Methods: Participants were 8 stable COPD patients (C) (4 male, 66±8 yrs, FEV1 44.4±16预/秒), predomediated body mass index (BMI) 23±6kg/m2) and 8 healthy volunteers (V) (8m, 24±5yrs, FEV1 89.1±24预/秒, BMI 22±2.5kg/m2) without diabetes mellitus and with fasting glucose <7mm. Participants underwent 120min oral glucose tolerance testing (OGTT). Hepatic insulin resistance (HOMA-IR) and pancreatic beta-cell function (HOMA2-%B) were derived from fasting values and the Matsuda Index (composite hepatic and muscle insulin sensitivity) from OGTT values.

Results: Fasting glucose (p=0.038), Hba1c (p=0.013) and C peptide (p=0.028) were higher in COPD than in volunteers, but insulin was not different (p=0.234). HOMA2 IR was: C 1.3 [0.8-1.8], V 1.0 [0.7-1.2], p=0.161, Matsuda Index was: C 3 [3-5], V (8-6-10), p=0.002. In COPD, but not volunteers, ln(CRP) was inversely correlated with ln(Matsuda) (R=0.76), p=0.047 but not with other homeostatic measures after controlling for BMI.

Conclusion: Non-obese COPD patients without diabetes had increased composite, but not hepatic, insulin resistance compared to volunteers, indicating skeletal muscle insulin resistance. Possible mechanisms underlying the correlation between peripheral insulin resistance and inflammation include inhibition of insulin receptor signalling by inflammatory mediators or pro-inflammatory effects of elevated glucose.

P709 MKK3 is expressed in cells from patients with allergic asthma

Tatjana Holand1, Yanira Riffo-Vasquez1, Domenico Spina1, Brian O’Connor1, Clive Page1, 1Suckler Institute of Pulmonary Pathology, King’s College London, London, United Kingdom; 2Cardiovascular Research Division, King’s College London, London, United Kingdom; 3Bayer HealthCare AG, Bayer, Wuppertal, Germany; 4Askin Pharmaceuticals Inc., Askin Pharmaceuticals Inc. San Diego, CA, United States; 5Oxford Glycoscience, Oxford Glycoscience, Slough, Berkshire, United Kingdom; 6Oxford BioTherapics, Oxford BioTherapics, Oxon, Abingdon, United Kingdom

MKK3 is a member of the J38 MAPK signalling pathway. Studies have shown that MKK3 is an important factor in non-allergic inflammatory and Th1 responses. Less is known about its role in allergic inflammation and allergic disease. Proteomic analysis was performed on peripheral blood cells obtained from 22 healthy and 18 allergic asthmatic patients. Lysates from purified lymphocytes were separated by SDS-PAGE and the protein inventories of each sample were identified using mass spectrometry. A 3.65 fold increase in the expression of MKK3 was observed in CD8+ T lymphocytes from asthmatic in relation to healthy volunteers, (% vol protein abundance). Western blot (WB) analysis showed MKK3 expression in lung CD4+ lymphocytes, human endothelial cells (HEVECs) and human epithelial cells (HBEct) but not in neutrophils or eosinophils. However, using densitometric analysis we found no differences between healthy and asthmatic subjects (%vol=10) in any of the cell types analysed. Real time PCR studies showed no expression of MKK3 isoform C in any tissue or cell type. However, large quantities of isoform B gene expression were found in neutrophils and lung tissue from patients with COPD (isoform A: 450 vs Isoform B: 1500 relative expression (ACT-)). MKK3 expression was also measured in lung samples from mice treated with lipopolysaccharide (LPS) or saline. Densitometric analysis of WB data showed that LPS treated mice developed an increased total MKK3 protein expression compared to saline-treated mice (sham: 49 vs LPS: 60 A U, p=0.05). No significant increase in expression in these tissues was observed in mice allergic to ovalbumin. In conclusion, MKK3 is differentially expressed under non-allergic and allergic conditions.

P710 Airflow inflammation and airway pathophysiology in older asthmatics

Celeste Porsbjerg1, Peter Gibson1, Jeffrey Pretto1, Cheryl Salome2, John Hunter Hospital, Newcastle, Australia; 2Woolcock Institute of Medical Research, Woolcock Institute of Medical Research, Glebe, Australia

Background: Asthma morbidity increases with ageing, which may partially result from alterations in airway pathophysiology. We aimed to describe determinants of ventilatory function and airway responses in older asthmatics to further our understanding of pathophysiological mechanisms.

Methods: Bronchial constriction was induced with hypertonic saline (HTS) in 30 asthmatics aged over 54 years (75% female). The response dose ratio (RDR,%change/mg saline) was used to quantify challenge response: RDR-FEV1/FVC reflecting airway narrowing, and RDRFVC reflecting airway closure. These measures were regressed against markers of airway inflammation (Induced sputum (+) neutrophils and eosinophils and exhaled NO).

Results: Average (SD) FEV1 was 78%pred (16), FVC 91% (12) with 13% (9) fall in FEV1 during HTS challenge. Baseline ventilatory function was inversely correlated with s-neutrophils (r=0.61, p=0.53 and r=0.56 for FEV1%, FVC% and FEF25-75/FVC respectively, all p<0.05), as well as sputum markers of neutrophils (neutrophil elastase, IL-8 and MMP), but not s-eosinophils (p=0.05 for all).

In contrast, the challenge response was predicted by eNO (RDRFEV1/FVC: r= -0.42, p=0.05), indicating airway narrowing associated with airway inflammation. Age predicted an increased RDRFVC (r=0.47, p=0.02), suggesting an increasing tendency to airway closure with ageing.

Conclusions: In older asthmatics, the pattern of inflammation bears important relationships to airway physiology. Neutrophilic inflammation is an important determinant of baseline ventilatory function, whereas airway reactivity relates to eosinophilic inflammation. Age is also determinant of airway closure, consistent with an age-related reduction in parenchymal airway support.
PT13 GATA-3 or T-bet: Who is the crucial marker of allergic bronchial asthma
Lada Sorokina, Valkyry Mieniev, Michael Nyoma, Vasily Ivanov, Vasily Trofimov.
Department of Hospital Therapy, Saint-Petersburg State Pavlov’s Medical University,
Saint-Petersburg, Russian Federation

The aim: to establish features of expression of GATA-3 and T-bet in bronchial asthma (BA).

Material and methods: 20 healthy, 44 patients with allergic and 42 with non-allergic asthma were examined.

Transcription factors GATA-3 and T-bet expressed in peripheral lymphocytes were analyzed by Western blot after cells were lysed. Preparation of lysates, and the Western blotting were performed through standard procedure. Antibodies against GATA-3 (Abcam, UK), T-bet (Santa Cruz Biotechnology) were used. Level of protein analyzed according to β-actin using anti-actin antibody (Sigma Aldrich, USA).

Results: Expression of GATA-3 was significantly increased and expression of T-bet was significantly decreased in lymphocytes of patients with allergic BA compared to healthy (p<0.04) and non-allergic BA groups (p<0.005). The level of GATA-3 in allergic BA negatively correlated with the degree of airflow obstruction (r = 0.4, p<0.01; n=41) and positively correlated with intensity of steroid therapy (r = 0.33, p<0.03; n=42). The level of T-bet in non-allergic BA positively correlated with the prevalence of asthma triad (r = 0.4, p=0.01; n=42) and drug intolerance (r = 0.43, p<0.005; n=42).

Conclusion: GATA-3 and T-bet may play a key role in the pathophysiology of BA. The expression of GATA-3 and T-bet may serve as markers of allergic BA to provide necessary dose of steroids in patients with BA. This study suggests that allergic BA underlie the high level of Th2-cytokines production in allergic disease.

Research grant of the year” for the best scientific work.

PT14 Expression of CD38 and its participation in formation of endothelial dysfunction in patients with bronchial asthma
Ludmila Krasnova, Irina Demko, Angelina Kraposhina, Natalya Ryazanova, Olga Ischenko, Elena Sobko, Alla Salmina.
Inner Diseases No. 2, Krasnoyarsk State Medical University named after Prof. V.F. Vojno-Jasenskii of Minzdravrossiysctva of Russia, Krasnoyarsk, Russian Federation

In the article we studied the role of CD38/ADP-ribosilcyclase in formation of endothelial dysfunction in patients with bronchial asthma.

In the research we have included patients with mild (1st group) and severe (2nd group) bronchial asthma. We found the increased expression of CD38 in peripheral blood lymphocytes in patients of both groups (in the 1st group 4 out of 300 cells, in the 2nd group 6 out of 300 cells) in an exacerbation in comparison with the control group (2 out of 300 cells). Increase of level of expression CD38 promotes the realization of the mechanism of interaction of the activated lymphocytes with the cells of endothelium expressing of non-subtracted lipid CD38 – CD31/PECAM-1.

We note increase of sPECAM-1 in plasma of peripheral blood in the 2nd group to 7.19 ng/ml [6.8, 7.7] in comparison with results of the patients of the 1st group: 6.76 ng/ml [6.1, 7.4]. The increase of expression of sPECAM-1 is significantly different (p=0.025292).

We found the positive interrelation between the level of CD31 and the expression of CD38 (r=0.3; p<0.05), and also direct correlation relationship between the level of CD31 and the concentration of C-reactive protein in blood plasma (r=0.39, p<0.01). The result of such relationship is the damage of cells of endothelium and formation of endothelial dysfunction which, in its turn, determines the disturbance of mechanisms of endothelial regulation of vascular wall elasticity and increase of its rigidity.

PT15 The role of genetic polymorphism of NO-synthase in the implementation of the “atopic march”
Konstantin Rukin.
Health and Social Development, Siberian State Medical University, Tomsk, Tomsk Region, Russian Federation

NO-synthase genes are candidate for development bronchial asthma (BA) and atopic dermatitis (AD), because nitric oxide and its metabolites are involved in the formation of oxidative stress and nitrolyzing. We planned and conducted study of genetic polymorphisms of NO-synthase genes associated with clinical and functional manifestations of bronchial asthma and atopic dermatitis for the formation of molecular predictors of implementation of the “atopic march”.

Materials and methods: Material study were DNA samples of patients with asthma (n = 929), BA (n = 847), AD + BA (n = 460). As a control, the DNA of healthy subjects (n = 720).

Results: Established genotypes increase the risk of formation of “atopic march”: TT genotype polymorphism 276 CT, AC polymorphism 186 A/G gene nNOS (RR = 4.56, p = 0.003); 220/220 polymorphism (TAA/A) n, GC and CC polymorphism 954G/C, s/s on the number of repeats (CTTCT) n gene iNOS (RR = 1.60, p = 0.002); polymorphism VNTR, CG polymorphism 894G/C gene of eNOS (RR = 3.75, p = 0.001).

Found haplotypes of genes involved in the implementation of the “atopic march’’atopic march”: (nNOS, iNOS, eNOS): T276 (276CT, nNOS) + C186 (-186A/C, nNOS)+ G (954CTT) n, nNOS + G954 (954GC, iNOS) + 220 (TAA/A) n, iNOS + G989 (989AG, eNOS)+ a (VNTR), eNOS.

PT16 The influence of cigarette smoke on the polymorphism of matrix metalloproteinase (MMP2) in asthmatic patients
Manel Hadji¹, Nedja Mehri1, Hela Haidel1, Kamil Hamzaoui2, Ahmed Mesdja1, Jouhdha Cherif1, Hafedh Zakhama1, Ines Saada1, Mouna Ben Raies1, Farouk Jaouadi1, Bechir Louarzi1, Jalouel Daghfeu1, Majed Beji1
1Pulmonary, LaRéhabita Hospital, Tunis, Tunisia; 2Biomed, Medicine University, Tunis, Tunisia

Introduction: Matrix metalloproteinases (MMPs) are a large family of proteolytic enzymes that degrade the components of extracellular matrix (ECM) and MMPs are involved in the pathogenesis of both chronic lung disease: asthma and COPD.

However, its role is not clear.

Aim of this study: to determine whether cigarette smoke plays a role in induction of polymorphism of MMP-2 in tunisian patients.

Patients and methods: A total of 150 asthmatic patients (36 smokers and 114 non-smokers) were included prospectively. MMP-2 (C-737T) genotypes of both groups were determined by the restriction fragment length polymorphism method.

Results: The mean age of asthmatic patients was 48 years. The sex ratioMWW was 0.44. The frequency of patients with severe asthma is 28.6%, moderate asthma is 42.6% and mild asthma is 30.6%.

There was no difference in frequency of polymorphism of MMP-2 (C-737T) between smokers and non-smokers asthmatic patients.

Conclusion: The present study demonstrates that exposure to cigarette smoke has no influence on the polymorphism in the promoter region of MMP2. However, these results may be confirmed by further prospective studies.

PT17 Genetic typing of bronchial asthma afflicted people according to polymorphous genes for the purpose of disease progress risk factors detection
Natasha Dudareva, Allergy and Prophpathology, 10 Minsk Municipal Clinical Hospital, Minsk, Belarus

The article presents the data concerning frequency allocation of polymorphous genes and alleles of genes belonging to family glutathione-S-transferase (GSTM and GSTT), genes of cytokines (IL-6 and TNF-A), cytotoxic receptor of T-lymphocyte gene (CTLA-4) and gene of vitamin D receptor in case of afflicted people with uncontrolled bronchial asthma clinical course.

The aim of this study: to determine the frequency allocation of polymorphous genes and alleles of the Forouzani population in different areas of Belarus. The received data concerning the frequency allocation of polymorphous genes and alleles of genes CTLA-4, TNF-A, GSTM and GSTT didn’t authentically differ from the frequency of Belarusian population.

No authentic frequency allocation differences were detected. However there were authentically proved differences in frequency allocation of polymorphous genes and alleles of genes between four polymorphous locuses of VDR-gene in case of bronchial asthma afflicted people from the one detected in the population. The VDR gene’s frequency of homozygotes FF at FokI locus (36.0%) is higher than the population’s frequency of patients with severe asthma is 28.6%, moderate asthma is 42.6% and mild asthma is 30.6%.

However, its role is not clear.

Materials and methods: We studied 180 patients with allergic BA and 180 patients with non-allergic BA. As a control, the DNA of 180 citizens’ population in different areas of Belarus. The received data concerning the frequency allocation of polymorphous genes and alleles of genes between four polymorphous locuses of VDR-gene in case of bronchial asthma afflicted people from the one detected in the population. The VDR gene’s frequency of homozygotes FF at FokI locus (36.0%) is higher than the population’s frequency of patients with severe asthma is 28.6%, moderate asthma is 42.6% and mild asthma is 30.6%.

The present study demonstrates that exposure to cigarette smoke has no influence on the polymorphism in the promoter region of MMP2. However, these results may be confirmed by further prospective studies.

PT18 The role of the epithelial barrier in allergic airway inflammation
Mikhail Guschin1, Tatiana Barkhina2, Sergey Polner3, Valentina Golovanova1
1Cell Communication, Institute of Human Morphology, Moscow, Russian Federation; 2Bronchial Asthma, Institute of Immunology, Moscow, Russian Federation

Aim: To identify the correlation of clinical and morphological data damage the mucous membranes of the nose and bronch in patients with asthma.

Materials and methods: We studied scrapings of the mucous membrane of the nasal cavity, lavage and bronchosbiopaty patients with allergic rhinitis (AR) and bronchial asthma (BA). A comparative analysis between a group of teenagers and adults. Scanning (SEM) and transmission electron microscopy (TEM), semi-thin sections.

Results: We have shown that the surface of the epithelial cells of the upper and lower respiratory tract in AR and BA tend to have the same changes that, along with clinical data on hyperreactivity of these departments, as determined by provocative tests, and indicates a common mechanism of damage to the epithelium. By SEM we found the greatest damage to the exposed ciliated cells (CC) and by TEM detected the most spread gaplotype is TtAaBbFf). The received data indicate the connection of VDR polymorphism with uncontrolled bronchial asthma and the utility of conducting the further research concerning the influence of vitamin D on treatment.

116s
Conclusion: The intensity of changes is directly related to the severity of the disease, its early onset, dynamics and duration of disease. This whole complex of changes suggests major modifications in the morphology of the airway in allergic response to aggression. Timely basic therapy and ASIT contribute to a better clinical effect, helps to prevent potential complications, and also helps to restore a damaged nose and bronchial mucosa.

PT19
Comonitexosion to nicotine and endotoxin in vitro induces murine airflow hyperreactivity possibly via nicotine-induced upregulation of toll-like receptors
Yuany Xu, Yaping Zhang, Lars-Olaf Cardell. Division of Ear, Nose and Throat Diseases, Department for CLINTEC, Karolinska Institutet, Karolinska University Hospital, Huddinge, Stockholm, Sweden

Introduction: Nicotine and endotoxin are important components of cigarette smoke, known to cause asthma and trigger exacerbations. The present study examined whether concomitant exposure to nicotine and endotoxin in vitro can cause airway hyperreactivity (AHR) in murine tracheal segments, and explored the involvement of Toll-like receptors (TLR) and MAPK signalling pathways in this process.

Methods: Isolated murine tracheal segments were exposed to nicotine (10 μM) and/or endotoxin (10 μg/ml) in organ culture for 4 days. Contractile responses to carbachol were recorded by myograph. In parallel, mRNA and protein expressions of the cell surface TLRs and several inflammatory mediators were semi-quantified by real-time PCR and confocal microscopy-based immunohistochemistry after exposure to only nicotine with/without specific inhibitors for MAPK pathways JNK, ERK1/2 or p38.

Results: Nicotine or endotoxin alone failed to affect contractile responses to carbachol, whereas AHR appeared after concomitant exposure. Incubation with nicotine increased expression of TLR2, 4 and 6, decreased TLR5, while TLR11 and 11 expressions remained unchanged. In parallel, MCP-1 and COX-2 expressions also increased. Inhibition of JNK, but not ERK1/2 or p38, attenuated nicotine’s effects.

Conclusion: Long-term nicotine exposure induces local inflammation and rearrangement of the airway surface TLR expression pattern via the MAPK JNK signaling dependent pathways. It is therefore tempting to suggest that the nicotine-induced up-regulation of TLR is responsible for the AHR observed after concomitant incubation with nicotine and endotoxin.

PT20
Increased cough responsiveness in guinea pigs with respiratory syncytial virus infection and its neurogenic mechanism
XinMin Ye, Chunli Liu, Nanshan Zhong, Jing Zhao, Ruchong Chen. Respiratory, Nanjing Children’s Hospital Affiliated to Nanjing Medical University, Nanjing, China

Introduction: Respiratory syncytial virus (RSV) is the most common pathogen responsible for lower respiratory tract infections (LRTI) in young children. RSV infection triggers cough, whereas AHR appeared after concomitant exposure. Incubation with nicotine increased expression of TLR2, 4 and 6, decreased TLR5, while TLR11 and 11 expressions remained unchanged. In parallel, MCP-1 and COX-2 expressions also increased. Inhibition of JNK, but not ERK1/2 or p38, attenuated nicotine’s effects.

Methods: Fifty guinea pigs were randomly divided into a control group and four RSV-inoculated groups: post-infection day (PID) 6, 12, 28 and 42. Cough responsiveness, airway inflammation without pneumonia, RSV RNA content was highest at PID 6 and then gradually decreased. SP peaked at PID 28 and remained high at PID 42, SP protein staining could be seen in lung tissue. NK1 mRNA levels were also significantly increased at PID 12, 28 and 42. Cough responsiveness was positively correlated with SP and NK1 mRNA levels.

Results: Cough responsiveness of infected groups was significantly higher than control and reached a peak at PID 12. Inflammatory cells and lymphocytes increased in bronchoalveolar lavage fluid, and lung tissue pathology showed airway inflammation without pneumonia. RSV RNA content was highest at PID 6 and then gradually decreased. SP peaked at PID 28 and remained high at PID 42. SP protein staining could be seen in lung tissue. NK1 mRNA levels were also significantly increased at PID 12, 28 and 42. Cough responsiveness was positively correlated with SP and NK1 mRNA levels.

Conclusion: The increase in cough responsiveness was consistent with the clinical features of cough caused by RSV. The accompanying increase in SP and its receptor with the positive correlation between these parameters and cough responsiveness suggests that neurogenic inflammation may play a decisive role in the increase in cough responsiveness and cough induced by RSV.

PT21
Immunomodulation capacity of alpha-1 antitrypsin in regulation of CD14 molecules expression and secretion in human monocytes in vitro
Golnaz Farsangi, Ramin Sadeghi. Department of Pulmonology and Immunology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction: Human monocytes CD14 expression was analysed by flow cytometry and mRNA expression were evaluated and the correlation between cough responsiveness and SP and NK1 mRNA levels determined.

Results: Cough responsiveness of infected groups was significantly higher than control and reached a peak at PID 12. Inflammatory cells and lymphocytes increased in bronchoalveolar lavage fluid, and lung tissue pathology showed airway inflammation without pneumonia. RSV RNA content was highest at PID 6 and then gradually decreased. SP peaked at PID 28 and remained high at PID 42. SP protein staining could be seen in lung tissue. NK1 mRNA levels were also significantly increased at PID 12, 28 and 42. Cough responsiveness was positively correlated with SP and NK1 mRNA levels.

Conclusion: The increase in cough responsiveness was consistent with the clinical features of cough caused by RSV. The accompanying increase in SP and its receptor with the positive correlation between these parameters and cough responsiveness suggests that neurogenic inflammation may play a decisive role in the increase in cough responsiveness and cough induced by RSV.

89. COPD: human studies

PT22
Various phenotype of COPD are closely related to regulatory T cells
Elena Kramer1, Natalya Kirillova2, Ivan Deev1, Georgij Chernogoruk2, Ludmila Ogorodova1. 1 Central Research Laboratory, Siberian State Medical University, Tomsk, Russian Federation, 2 Department of Pediatrics Faculty with a Course of Childhood Illnesses Medical Faculty, Siberian State Medical University, Tomsk, Russian Federation

Background: Regulatory T-cells (T-reg) play an important role in physiology and pathology of immune system and take essential place in pathogenesis of various autoimmune, tumoral and allergies diseases. However, T-reg subpopulations in separate phenotypes of COPD remain insufficiently studied.

Aim and objectives: To investigate different subpopulations of T-reg in patients with various phenotypes of COPD.

Methods: Levels of natural CD4+CD25high and inducible CD4+FoxP3+ T-reg were analyzed in 60 subjects with COPD (including 13 subjects diagnosed with emphysematous phenotype, 28 patients with bronchitic phenotype, 19 subjects with mixed phenotype of COPD) and 17 healthy subjects (HS) using the flow cytometry analysis.

Conclusions: These findings provide evidence that AAT is an important regulator of CD14 expression and release in monocytes and suggest that AAT may be involved in prevention of over-activation of monocytes/macrophages in vivo, that is important in development of chronic lung diseases.

117s
Results: CD4+CD25+high in COPD were significantly increased compared to HS (2.8 ± 0.24%, p = 0.005; 1.56 ± 0.24%, p = 0.005, respectively). Increased level of CD4+CD25+high was shown for persons with emphysema phenotype (3.43 ± 0.46%, p = 0.001) compared to persons diagnosed with bronchial (2.3 ± 0.22%, p = 0.021) and mixed (2.38 ± 0.22%, p = 0.014) phenotypes of COPD. As for CD4+FoxP3+ T-reg no difference between different phenotypes of COPD was observed.

Conclusions: Different subpopulations of T-reg may determine various phenotypes of COPD and this study indicates that increased level of CD4+CD25+high is associated with emphysema phenotype of COPD to support this hypothesis.

P273
IL-33 has a nuclear distribution and is not increased in peripheral lung of COPD patients
Gaetano Caramori1, Paolo Casolari1, Anna Padovani1, Elvira Garofano1, Marco Contoli1, Kian Fan Chung2, Ian M. Adcock2, Alberto Papi1
1Centro di Ricerca su Asma e BPCO, University of Ferrara, Ferrara, Italy; 2Airways Disease Section, NHLI, Imperial College London, London, United Kingdom

IL-33-1 (33), a member of the IL-1 cytokine family, is crucial for induction of Th2-type immune responses but is also involved in the induction of non-Th2-type inflammation as a pro-inflammatory cytokine, similar to IL-1 and IL-18. The aim of our study was to investigate by immunohistochemistry (IHC), RT-qPCR, ELISA and Western blotting (WB) the expression and the amount of IL-33 in peripheral lung, and bronchoalveolar lavage (BAL) from 15 age- and smoking history-matched smokers with normal lung function and 15 smokers with mild to moderate stable COPD not treated with ICS and/or theophylline. The IHC staining was mainly confined to the nuclei of endothelial cells and small airway epithelial cells in the IL-33+ positive cells and the level of mRNA expression was not significantly different in patients with COPD compared to controls. IL-33 was under detection limits using ELISA (BAL) and WB (peripheral lung). These data suggest that an IL-33-mediated immune response, may not be critical in COPD and its nuclear role is uncertain.

P274
Decrease of soluble adhesion molecules levels and bacterial mixt-infection in patients with COPD
Ekatereina Makarova1, Natalia Luburina1, Nikolay Menkov1, Galina Varvarina1, Elena Belajeva1, Victor Novikov1
1Propedeutics of Internal Medicine, Medical State Academy, Nizhny Novgorod, Russian Federation; 2Microbiology, Blokhina Research Institute of Epidemiology and Microbiology, Nizhny Novgorod, Russian Federation

The soluble forms of intracellular adhesion molecules (sICAM) such as membrane forms are involved in modulating the cell interaction. In order to investigate adhesion disturbances the serum levels of sICAM-1 (scD54) and sICAM-3 (scD50) were analyzed in 48 patients with exacerbation of COPD and 86 healthy donors using ELISA- method. Quantitative culture of sputum or bronchoalveolar lavage fluid were performed. The median levels of scD50 and scD54 were significantly lower in COPD patients than in donors. The scD50 and scD54 values below the normal range were registered in 60% of the patients. The decrease of scICAM levels was associated with longer smoking history compared with patients having normal/elevated values, and with exacerbation of bronchitis, bacterial mixt-infections, and prolonged therapy duration. The low serum levels of the soluble adhesion molecules reflecting the impaired expression of the membrane forms can be considered as unfavorable factor.

P275
Value of serum and induced sputum surfactant protein-D in chronic obstructive pulmonary disease
Berna Akinci Ozyuz2, Serife Savas Boyzuz1, Sevinç Sarıc Ulaslı1, Nihat Bayraktar1, Sule Akyazi2
1Pulmonary Medicine, Baskent University, Faculty of Medicine, Ankara, Turkey; 2Biochemistry, Baskent University, Faculty of Medicine, Ankara, Turkey

Aim: In the present study, we aimed to investigate the correlation between SP-D in serum and induced sputum and severity of COPD.

Methods: 20 healthy subjects older than 40 years of age with at least 10 pack-year smoking history (group 1), 20 stage I-II COPD patients (group 2) and 20 stage III-IV COPD patients (group 3) were enrolled to the study. All subjects performed pulmonary function tests and C-reactive protein (CRP) and blood SP-D levels measured. Induced sputum samples were obtained to determine induced sputum SP-D levels. COPD patients were followed up for exacerbation for 6 months.

Results: Serum SP-D levels of group 3 were highest and and induced sputum SP-D levels of group 2 were lowest compared among three groups. However, there were no statistically significant differences among three groups (p>0.05). SP-D levels of induced sputum decreased in patients with high number of cigarette pack-year, whereas serum SP-D levels increased in these patients (p<0.05). Induced sputum SP-D levels of COPD patients receiving inhaler corticosteroid treatment were higher than patients who were not receiving inhaler corticosteroid treatment (p<0.05). An inverse correlation between serum SP-D levels and FEV1 (L%) was found and there was a positive significant correlation between the serum SP-D levels and exacerbation frequency in 6-month follow up period in our study (p<0.05).

Conclusion: Our study demonstrates adverse effects of smoking on local SP-D levels. Low levels of local SP-D in the group of current smokers, who were not receiving inhaler corticosteroid treatment indicate the importance of airway inflammation in COPD pathogenesis.

P276
Inflammatory cytokines in induced sputum and COPD phenotype
Joanna Domagala-Kulakw1, Julia Stepień1, Grażyna Ho瑟1, Ryszarda Chazan1
1Pneumonology, Medical University, Warsaw, Poland; 2Clinical Cytology, Center of Postgraduate Education, Warsaw, Poland

Chronic obstructive lung disease (COPD) does not have a uniform clinical and morphological nature. Airflow limitation is caused by inflammation and parenchymal destruction, with predominance of emphysematous phenotype and predominance of chronic bronchitis. The aim of the study was to characterize the inflammatory process in two distinct forms of COPD.

35 COPD patients were enrolled to two groups: emphysema (E, n=25) and chronic bronchitis pts (CB, n=10); the presence of emphysema in HRCT and hyperinflation in plethysmography were the distinguishing criteria. The concentration of cytokines (IL-8, IL-6, IL-10, TNF-a and IL-12) in induced sputum (IS) was measured using flow cytometry with Cytomine Bead Array method. The median concentration of proinflammatory cytokines (IL-8, IL-6, IL-10 and TNF-a) did not differ between two groups. The concentration of IL-10 and IL-12 was slightly, but not significantly, higher in the E when compared with CB group (median: 57 vs 41 pg/ml, 1553 vs 1122 pg/ml, respectively). There was a significant correlation between the concentrations of IL-8, IL-6, IL-10 and TNF-a in the CB group. When we analysed the relation of cytokine concentration with the clinical parameters, we observed a difference between the E and CB group. There was a significant correlation of IL-10, TNF-a and IL-12 concentration with the degree of emphysema (RV, TLC, Raw) and FEV1 only in the E group. A significant correlation of IL-6 concentration with pack/year, TLC and with the inflammatory cell total count was observed only in the CB group. The differences in cytokine profile and correlations indicate a possible different character of inflammation in two COPD phenotypes.

P277
Relationship between % neutrophils in induced sputum and IL-6 and TNF-a in COPD
Elena Payá Peláñærez, Carmen Soto Fernández, Rubén Andrújar Espinos, Concepción Alcalde Rumayor, Julia Guardiola Martínez, Juan Orlando López Ojeda, Carlos Federico Álvarez Miranda, Francisco José Ruiz López, Manuel Lorenzo Cruz
1Pulmonology, Hospital Universitario Virgen de la Arrixaca, El Palmar, Murcia, Spain

Introduction: The percentage of neutrophil sputum are increased in patients with Chronic Obstructive Pulmonary Disease (COPD), and is a biomarker of airway inflammation. The aim of this study is the relationship between sputum% neutrophils and levels of IL-6 and TNF-a in induced sputum in COPD with moderate-severe airflow obstruction.

Method: Sputum samples were obtained using 3% saline, according to international guidelines., from a total of 60 subjects 40 COPD patients (criteria for diagnostic and classification of disease severity based on the Global Initiative for Chronic Obstructive lung disease (GOLD) and 20 healthy men (control group) who had no story of lung disease and normal spirometry. All the patients were smokers of >20 pack/year, and were free from acute exacerbations in three months prior to the study. In each subject BMI (kg/m²), dysnea according to the modified Medical Research Council scale (MRC), oxygen saturation (SatO2), spirometry before and after 400μg inhaled salbutamol, lung volumes and carbon monoxide transfer factor coefficient (KCO) measurements were measured. TNF-a and IL-6 were measured by RIA.

Results: The sputum neutrophil% was statistic significative higher in COPD patients than group control p<0.05. We find a negative correlation between the percentage of the non-scamous cell count and% neutrophil whit the FEV1% and the% FVC/FVC<p<0.05, but not with the grade of dysnea (MRC) and SatO2. There was a weak association between sputum neutrophils and IL-6 e= 0.385, p<0.003, and TNF= 0.468 p=0.001.

Conclusion: Neutrophils in sputum in COPD patients are associated with the airflow limitation and white the levels of IL-6 and TNF-a.
P728 Expression of the phosphorylated myristoylated alanine-rich C kinase substrate (MARCKS) in COPD bronchial glands
Gaetano Caramori1, Paolo Casolar1, Elvira Garofano1, Marco Contoli2, Giulia Gnesini1, Anna Padovani1, Khan Fan Chung2, Peter J. Barnes2, Ian M. Adcock1, Alberto Papi3. 1Sezione di Malattie dell’Apparato Respiratorio, University of Ferrara, Ferrara, Italy; 2Airways Disease Section, NHRI, Imperial College London, London, United Kingdom

Myristoylated alanine-rich C kinase substrate (MARCKS) is a central regulatory molecule involved in mucin granule release by human bronchial epithe-
lial cells in vitro. Upon stimulation, activated PKC phosphorylates MARCKS (p-MARCKS), causing translocation of p-MARCKS from the plasma membrane to the cytoplasm, where it is then dephosphorylated, thus interacting with mucin granule membranes and mediating their subsequent exocytosis. The aim of our study was to investigate by immunohistochemistry (IHC) the expression of pro-	ein p-MARCKS in the bronchial rings, obtained during lung resection surgery, of smokers (current and ex) with or without COPD compared with non-smoker subjects. We examined formalin-fixed paraffin-embedded bronchial rings by IHC for identification of total p-MARCKS+ cells. The number of p-MARCKS+ve cells was determined among the mucous cells in the bronchial submucosal glands. Samples from 10 age-matched non-smokers subjects, 29 smokers with normal lung function and 29 smokers with COPD were obtained. We were unable to detect any significant differences in p-MARCKS in the bronchial mucous glands between the 3 groups of subjects. This data suggests that the p-MARCKS pathway is not critical for mucin secretion in the bronchial glands of COPD patients.

P727 The effects of morphological remodeling of the bronchi on the neocollagenesis process in patients with COPD stage 2 during exacerbation
Mykola Ostrovytsky, Oleksandr Varukhiv, Marianna Kulykhyn-Misik, Iryna Savelikhina. Internal Medicine No.8, Ivan-Frankivsk National Medical University, Ivan-Frankivsk, Ukraine

Background: Chronic obstructive pulmonary disease (COPD) is the third most common cause of death (8%) in the 25 member states of the European Union.

Chronic obstructive pulmonary disease (COPD) is the third most common cause of death (8%) in the 25 member states of the European Union. COPD is a chronic and progressive lung disease that causes airflow obstruction. COPD is characterized by chronic respiratory symptoms and an abnormal persistent increase in sputum production.

The effects of morphological remodeling of the bronchi on the neocollagenesis process in patients with COPD stage 2 during exacerbation

Materials and methods: To study the morphological processes of bronchial re-
modelling there was conducted an electron microscopy of bronchial mucosa bioptic material that had been conducted at the bifurcation of the proximal bronchi during bronchoscopy in 9 patients with COPD stage 2 at the moment of hos-
pitalization. The content of type IV collagen was investigated in bronchoalveolar fluid of 43 patients with stage 2 COPD before and after 1, 3 and 6 months of treatment medications. Neocollagenesis was estimated by the determination of the ratio of procollagen type I and II.

Results of the study: The results of our research showed that patients with COPD on early stages (2nd stage) there were damage of bronchial mucosa, with a significant growth of connective tissue in lamina propri, which was accompanied by increased content of collagen type IV in bronchoalveolar fluid in 6.19 times compared with healthy. This is an evidence of increased activity of fibroblasts as a result of microcirculation disturbances, activation of lipid peroxidation and effects of hypoxia.

Conclusions: Due to the morphological remodeling there is great activity of neo-
collagenesis during exacerbation of COPD, evidenced by significantly increased production type IV of collagen in bronchoalveolar fluid.

P730 Differences in biomarkers of systemic inflammation in two phenotypes of COPD patients

Introduction: Classification of chronic obstructive pulmonary disease (COPD) is usually based on the severity of airflow limitation, but not the heterogeneity of this disease. The aim of this study was to establish differences in biomarkers of systemic inflammation in two phenotypes of COPD patients, through determination protein-C reactive (PCR), fibrinogen, IL-6 and TNF-a in plasma, in stable COPD.

Method: A total of 60 subjects, 40 stable COPD (diagnostic and severity based on the Global Initiative for Chronic Obstructive Lung Disease) and 20 controls. We es-
tablished two groups of patients based on the carbon monoxide gas transfer/alveolar volume (Kco) and visual detection of emphysema computed tomography (CT).

A: Phenotype emphysema (n=19), Kco>70% CE CT compatible; B: phenotype chronic bronchitis (n=21), Kco<70% and CT without emphysema. Plasmatic determination of fibrinogen, PCR, 5'neutrophils, IL-6, and TNF (RIA).

Results: The values of fibrinógeno/PCR did not show significant differences be-
tween both phenotypes of COPD (B 432±203 vs 470 mg/dl / 0.542±0.14 mg/l), (A 452±368±70.503 mg/dl / 0.842±0.935 mg/l), but were compared with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l) with controls (C 346±203±70.503 mg/dl / 0.842±0.935 mg/l). The results of our study demonstrated that CD4+/CD8+ ratio may be used as a biomarker to evaluate the pathogenesis of COPD, however TLR-2 is not convenient for this purpose.

P732 Peripheral neutrophil stiffness in severe COPD exacerbations
Ebymár Arismendi Núñez1, Tomas Luque2, Yolanda Torralba García1, Alvar Agustí1, Daniel Navajas2, Roberto Rodríguez-Roisin3. 1Pneumology/ Laboratory of Pulmonary Function, Hospital Clínic of Barcelona, 2Medical Physics, Faculty of Medicine of University of Barcelona, Barcelona, Spain

Rationale: Exacerbations of COPD (EXCOPD) are characterized by activated pulmonary neutrophils (NEUT) with potentially increased cellular stiffness. Objective: The aim of this study was to assess NEUT stiffness in patients with COPD during and after exacerbations.

Methods: 12 COPD patients (age, 70±4 yrs; 83% male; all smokers, 71±36 pack-yrs) hospitalized for EXCOPD were included. Stiffness of peripheral NEUT was assessed using the atomic force microscopy technique within the first 72 h of admission and 12 weeks after discharge (Study Group [SG]). If patients suffered a new episode within this period of follow-up, measurements were repeated at this time in mean (mean, 7±4 weeks) (Re-exacerbation Group [RGI]). The COPD As-
essment Test (CAT), the ADQ Index and dyspnoea (MMRC) were also assessed.

Results: There were no differences on admission between the two subsets of patients. Increased NEUT stiffness in SG patients (n, 6) decreased from admission (890±293 Pa) to discharge (616±229 Pa) (p<0.05) compared to that measured in the RG subset (n, 6) (from 999±424 to 842±343 Pa). The ADI Index was associated with NEUT stiffness on admission in the two subsets of patients (ρ=0.60, p<0.05).

Conclusions: Changes in peripheral NEUT stiffness during COPD exacerba-
tions and convalescence indicate that the activation of NEUT underlies enhanced pulmonary inflammation. Supported by SEPAR-2010 and CIBERES

P733 Increase of extracellular IL-17A and anti-microbial peptides in the peripheral airways of smokers
Permina Glader1, Barbro Dahlén2, Bo Billing3, Lena Palmberg3, Ann-Sofie Lantz2, Kjell Larsson3, Anders Lindén1. 1Lung Immunology Group, Department of Internal Medicine/Respiratory Medicine & Allergology, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Division of Respiratory Medicine & Allergy at the Department of Medicine, Karolinska University Hospital, Stockholm, Sweden; 3Unit of Lung and Allergy Research, National Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden

Among several known cytokine-signalling pathways influencing innate effector

SUNDAY, SEPTEMBER 25TH 2011

Farmaeutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
cells, T helper (Th) 17 cytokines have emerged as particularly interesting for the understanding of chronic inflammatory conditions. Cigarette smokers suffer from frequent infections, are often colonised with bacteria in their lower airways and display signs of chronic inflammation including increased tissue expression of the Th17 cytokine IL-17A. We evaluated whether long-term current cigarette smokers display increased extracellular concentrations of Th17 cytokines and how this relates to anti-microbial peptides in the peripheral airways.

Concentrations of IL-17A, IL-17F and -22 plus the downstream effector molecules IL-22, IL-28 and IL-10 were measured in induced sputum from smokers and from non-smokers with and without COPD (n=17-20/group). All study subjects were free from airway infections during the last 4 weeks prior to the study.

The extracellular IL-17A concentrations (median [range]) were higher in smokers without COPD (1.2 [0.3-3.5], pg/ml) than in non-smokers (0.4 [0.1-4.4], pg/ml; p<0.05). Smokers with COPD displayed intermediate concentrations of IL-17A (0.7 [0.1-7.1], pg/ml) compared to non-smokers (22 [4-384], pg/ml). HBBD2 was higher in smokers without COPD (70 [6-500], pg/ml; p<0.05), but not in smokers with COPD (24 [4-364], pg/ml). Interleukin-17F, IL-22 and LL37 were undetectable in most of the samples.

In conclusion, long-term cigarette smokers without COPD display increased extracellular concentrations of IL-17A, and this may be linked to increased concentrations of the anti-microbial peptide HBBD2.

P734 Comparison of arterial cellular and mediator profiles between tobacco smoke-induced COPD and biomass fuel exposure-induced COPD in an Indian population

Introduction and background: Chronic obstructive pulmonary disease (COPD) is characterized by specific pattern of inflammation involving polymorphonuclear neutrophils (PMNs), macrophages and other cells. PMNs are the major reactive oxygen species (ROS) producing cells. Our previous data showed that ROS production is decreased in stable COPD (SCOPD). It is still not known about ROS production in acute exacerbation of COPD (AECOPD).

Aim: To investigate ROS production in PMN during AECOPD.

Methods: 10 patients with SCOPD, 5 with AECOPD and 10 non-smoking healthy individuals (HI) were studied. PMNs were isolated from peripheral blood using a high-density gradient. ROS production was induced using phorbol-myristate-acetate (PMA, 0.1-3.0 nM) and S. aureus bacteria (1-167 bacteria/neutrophil). ROS production was measured using flow cytometry by mean of fluorescence intensity in PMN population.

Results: The production of spontaneous ROS in PMN was 29.7±4.1% higher in AECOPD group than in SCOPD (p<0.05). PMA stimulated ROS production in all groups. The most significant increase of ROS production was observed between 0.3 and 1 nM PMA (AECOPD 172.5-fold, SCOPD 90.1-fold, HI 46.2-fold (p<0.05)). The higher ROS production in PMN after stimulation with different S. aureus concentrations was found in AECOPD group compared with SCOPD and HI (p<0.05).

Conclusion: Our data shows that ROS production is increased in AECOPD. Chemical (PMA) and biological (S. aureus bacteria) factors activates more intensive ROS generation.

P735 Vascular dysfunction and systemic inflammation in patients with COPD

Felipe Villar-Alvarez, Germán Ponce-Barba, Julio Gómez-Seco, María Jesús Rodríguez-Nieto, María Vascular dysfunction and arterial stiffness were unpredictive.

In the alveolar space the presence of an extracellular, biologically active ROS producing cells. Our previous data showed that ROS production is decreased in stable COPD (SCOPD). It is still not known about ROS production in acute exacerbation of COPD (AECOPD).

Existence of repair mechanisms resulting in bronchial and alveolar protein degradation induced by smoke exposure are largely unknown. In the alveolar space the presence of an extracellular, biologically active ROS is predicted to increase ROS production in acute exacerbation of COPD. However, our previous data showed that ROS production is decreased in stable COPD (SCOPD). It is still not known about ROS production in acute exacerbation of COPD (AECOPD).

Methods: Sixteen adult subjects underwent bronchoscopy for AECOPD (n=17-20). All study subjects were free from airway infections during the last 4 weeks prior to the study.

The extracellular IL-17A concentrations (median [range]) were higher in smokers without COPD (1.2 [0.3-3.5], pg/ml) than in non-smokers (0.4 [0.1-4.4], pg/ml; p<0.05). Smokers with COPD displayed intermediate concentrations of IL-17A (0.7 [0.1-7.1], pg/ml) compared to non-smokers (22 [4-384], pg/ml). HBBD2 was higher in smokers without COPD (70 [6-500], pg/ml; p<0.05), but not in smokers with COPD (24 [4-364], pg/ml). Interleukin-17F, IL-22 and LL37 were undetectable in most of the samples.

In conclusion, long-term cigarette smokers without COPD display increased extracellular concentrations of IL-17A, and this may be linked to increased concentrations of the anti-microbial peptide HBBD2.

Conclusion:

P736 Influence of AECOPD to ROS production in neutrophils

**Neutrophil phagocytic activity in AECOPD**

Simona Lavinskiene1, Mindaugas Vaitkus2, Kristina Bieksiene3, Jolanta Jeroch2, Raimundas Sakalauskas2. 1Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Science; 2Department of Pulmonology and Immunology, Hospital of Lithuanian University of Health Sciences Kaunas Clinic; 3Department of Laboratory Medicine, Hospital of Lithuanian University of Health Sciences Kaunas Clinic, Kaunas, Lithuania

**Background:** Neutrophils are the major inflammatory cells in pathogenesis of chronic obstructive pulmonary disease (COPD). It is known that phagocytic activity of these cells is decreased during stable COPD (SCOPD). Otherwise, it is unknown how neutrophils act in acute exacerbation of COPD (AECOPD).

**Aim:** To investigate neutrophils phagocytic activity in AECOPD.

**Methods:** Patients with SCOPD, 7 with AECOPD and 10 healthy individuals (HI) were studied. Neutrophils were isolated from peripheral blood by high-density ficoll. Phagocytosis was investigated using different concentrations of FITC labeled S. aureus bacteria (1-167 bacteria/neutrophil (b/n)). Phagocytic activity was analyzed using flow cytometry assessing the cellular immunofluorescence intensity of these population.

**Results:** Neutrophil phagocytic activity was decreased in patients with AECOPD in comparison with SCOPD and HI. The highest phagocytosis was obtained using 167 b/n concentration in AECOPD and SCOPD groups (6.52±2.5-fold and 8.84±1.8-fold), but phagocytic activity was lower compared with HI (13.5±2.2-fold) (p<0.05).

**Conclusion:** Our results shows that neutrophils phagocytosis is decreased during AECOPD.

Asthma and COPD are chronic obstructive diseases with a certain degree of physiologic and pathologic similarities. Our previous work demonstrated that these diseases could be phenotypes of the same process. This hypothesis has never been universally accepted due to the evident differences between the two diseases. However COPD has two distinct pathologic phenotypes, Panlobular Emphysema (PLE) where airflow obstruction is secondary to loss of elasticity and Centrilobular Emphysema (CLE) where airflow obstruction is secondary to bronchial remodeling with increased muscle and smaller diameter. We hypothesise that CLE could have features of Asthma different from PLE, especially as far as mast cells (MC) inflammation and their relation to airway reactivity.

Therefore, we quantified tryptase stained MC in all patients in submucosa, smooth muscle and adventitia of small airways in 27 lungs with CLE, 24 with PLE, and 5 healthy individuals (NS). The proportion of MC in smooth muscle of small airways were significantly higher in CLE (206±41 cells/mm²) than in PLE (104±21 cells/mm²; p=0.011; SME 107±54 cells/mm²; p=0.05) and NS (105±27 cells/mm²; p=0.05). Moreover, the degree of MC infiltration in the smooth muscle was related with the degree of hyperresponsiveness, as it has been shown in Asthma (PC20 3-8mg/ml: 206±41 cells/mm²; p=0.011; SME 107±54 cells/mm²; p=0.05) and NS (105±27 cells/mm²; p=0.05).

**Conclusion:** These results give support to the hypothesis of the potential link between inflammation and cancer in COPD.

Dani, Antonio De Passamonti, Andrea Ballarin1, Erica Bazzani1, Rafael Hernandez-Zenteno1, Graziella Turato1, Simontia Baralodi1, Elisabetta Balestone1, Daro Zanovello1, Marina Saetta1, Manuel Cosio1. 1Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy; 2Department of Investigacion in Tubagauan, Instituto Nacional de Enfermedades Respiratorias, Ciudad de Mexico, Mexico; 3Department of Medicine, Meakins-Christie Laboratories, McGill University, Montreal, Canada

The fibrogenic cytokine transforming growth factor-1 (TGF-β1) is an important mediator in airway remodelling. TGF-β1 overexpression in mice induces airway smooth muscle (ASM) hyperplasia, one of the characteristics of airway remodeling in asthma. The mechanisms underlying this overexpression of ASM cell proliferation showed that TGF-β1 alone has very weak mitogenic properties, combined effects with other factors such as Gq or Gi protein coupled receptor agonists may be involved. Here, we hypothesized that the mitogenic effects of TGF-β1 on ASM are indirect and require prolonged exposure to allow deposition of extracellular matrix (ECM) proteins. To address this hypothesis, we investigated the effects of acute and prolonged treatment with TGF-β1 (2 ng/ml), alone and in combination with PDGF and non-smokers (NS) (20, 6-95; p=0,001).

Methods: BAFF expression in B-lymphocytes and Tregs from bronchoalveolar lavage (BAL) and blood was quantified by Flow Cytometry in 38 patients with COPD (mean±SD:EV1=58±145%;p<0.05); 17 smokers with normal lung function (SC) (EV1=104±159%;p<0.05) and 20 non-smokers (NS) (EV1=101±206%;p<0.05). Conversely, BAFF was overexpressed in B lymphocytes from COPD patients (50, 23-121) when compared to SC (12, 0-28; p=0.003) and NS (20, 26-95; p<0.001).

Conclusions: In COPD there is a blunted expression of BAFF in Tregs that leads, partly due to cigarette smoke, to its excessive production in NS. MC lymphocytes, showing an imbalance of its functioning that is a common feature of several autoimmune diseases.

The YKL-40-positive bronchial smooth muscle cell proliferation and migration is PAR-2 dependent
Imane Bara1,2, Anjna Ozier1,2,3, Pierre-Olivier Girodet1,2,3, Jennifer Cattiaux 1,2, Peter Borger1,2,3. 1Division of Pulmonary, Critical Care and Sleep Medicine, University of Miami Miller School of Medicine, Miami, United States; 2Department of Pulmonology, Semmelweis University School of Medicine, Budapest, Hungary

YKL-40 was kindly provided by MedImmune. Human BSM cells were cultured from controls (n=7) and asthmatics (n=6). BSM cell proliferation was assessed using BrdU incorporation. Cell migration was evaluated using inserts. Transduction mechanisms were assessed using several inhibitors of signal transduction pathways (Pertussis toxin, Calphostin, PD98059, SB203580, LY294002). The involvement of protease activated receptor-2 (PAR-2) was evaluated using an anti-PAR-2 blocking antibody.

Results: YKL-40 significantly increased by more than two fold BSM cell BrdU incorporation in 24h incubation and cell number within 48h. Following 24h incubation, YKL-40 significantly increased BSM cell migration. These effects were inhibited by blocking PAR-2 antibody in both asthmatic and control BSM cells. Transduction mechanisms of cell proliferation and migration involved Gi protein, protein kinase C, MAPK/ERK pathways.
Conclusion: These results confirm that the chitinase YKL-40-induced BSM cell hyperplasia was PAR-2-dependant.

P748
Airway smooth muscle cells from patients with COPD exhibit a higher degree of cellular proliferation and steroid insensitivity than that from healthy patients
Mark Perry, Josie Baker, Kian Fan Chung, National Heart & Lung Institute, Imperial College London, London, United Kingdom

Rationale: Chronic obstructive pulmonary disease (COPD) refers to chronic bronchitis and emphysema, a pair of two commonly co-existing diseases of the lungs in which the airways become narrowed. The potential contribution of airway smooth muscle to airflow obstruction, airway inflammation and airway remodeling in COPD isn’t fully understood. Indeed, although it is known that the cytochrome TGF-β induces the expression of such cytokines as IL-6 and IL-8, little is known regarding its role upon ASM proliferation and steroid insensitivity in COPD. Ergo, we have examined the role of both the growth factor FCS and TGF-β, upon ASM proliferation and steroid response following treatment with dexamethasone.

Methods: Human ASM cells were pre-treated with dexamethasone for 2 h before being stimulated with FCS ± TGF-β for 8 days. For the determination of chemokine release, supernatants were removed and IL-6 levels determined by DuoSet ELISA (R&D Systems). The degree of cell proliferation was assessed by Cell Proliferation ELISA, BrdU kit (Roche Applied Science) according to the manufacturer’s instructions.

Results: Exposure to FCS and TGF-β induced a higher increase in cellular proliferation and IL-6 release in ASM from patients with COPD compared to healthy individuals. Furthermore, the inhibitory effect of dexamethasone in this system was almost completely abated in the ASM cells from the COPD patients.

P749
miR-221 and miR-222 target p21 and p27 in airway smooth muscle to elicit hyper proliferation in severe asthmatics
Mark Perry, Josie Baker, Kian Fan Chung, National Heart & Lung Institute, Imperial College London, London, United Kingdom

Rationale: Since microRNAs (miRNAs) were first discovered to be produced in humans 10 years ago, they have emerged as important mediators in cellular physiology and pathology. Asthma is characterised by chronic airflow obstruction, chronic airway inflammation and remodeling and the airway smooth muscle (ASM) cells cultured from the biopsies of patients with asthma are of a hyperproliferative phenotype. Inasmuch as miRNAs have been found to be amongst the highest differences in the expression of the chemokine IL-6. This ASM proliferation has been shown to be increased in response to growth factors such as FCS, and inflammatory mediators such as TGF-β. Ergo, we have examined the role of the miRNAs, miR-221 and miR-222, in both FCS and TGF-β-induced ASM proliferation and IL-6 release.

Methods: Human ASM cells were stimulated with FCS ± TGF-β for 8 days. For the determination of chemokine release, supernatants were removed and IL-6 levels determined by DuoSet ELISA (R&D Systems). The degree of cell proliferation was assessed by Cell Proliferation ELISA, BrdU kit (Roche Applied Science) according to the manufacturer’s instructions. miRNA and mRNA expression was examined by TaqMan RT-PCR. The function of miR-221 and miR-222 were assessed through transfection with miRNA mimics and inhibitors.

Results: Exposure to FCS and TGF-β induced an increase in cellular proliferation, IL-6 release and p21 mRNA expression in ASM cells cultured from the biopsies of COPD patients. This increase was greater in patients with severe asthma than those with non-severe asthma. FCS and TGF-β-induced proliferation and IL-6 release were inhibited following transfection with miRNA-222 inhibitors and potentiated in the presence of miRNA-222 mimics, by the targeting of p21 and p27.

P750
Sphingosine-1-phosphate receptor expression and signalling in human airway smooth muscle cells
Elisabeth Staffanger, Holly Foster, Katharina Mahn, Christopher Corrigan, Tak Lee, Grzegorz Woszczek, MRC and Asthma UK Centre in Allergic Mechanisms of Asthma, King’s College London, London, United Kingdom

Sphingosine-1-phosphate (SIP), a bioactive lipid and ligand for five G protein coupled receptors (S1P1-S1P5), is a key regulator of cell trafficking, cell differentiation and immune responses. Recently, increased concentrations of S1P have been detected in airways of asthmatic subjects and S1P has been shown to be a potent constrictor of human airway smooth muscle (HASM) cells. The aim of this study was to investigate the expression and signalling pathways of S1P receptors in HASM cells. HASM cells have been grown from bronchial biopsies of healthy individuals. Real-time PCR has been used to determine gene expression. Intracellular signalling in response to SIP was measured using MAP kinase phosphorylation, intracellular calcium AMP assay. Three of the five known receptors are expressed in HASM cells at mRNA level: S1P1, S1P2, and S1P3. SIP potently activated intracellular calcium flux in a concentration-dependent manner, with EC50=4–10^(-9)M. Using a range of selective agonists and antagonists, S1P1 and S1P3 were found to couple to Gi and inhibit forskolin induced cAMP generation, whereas S1P2 and S1P1 signalled through intracellular calcium mobilisation. SIP also induced phosphorylation of extracellular signal-regulated kinase (Erk) and increased expression of several genes, including interleukin-6. This study demonstrates that S1P receptors may signal effectively through multiple intracellular pathways in response to SIP and activate HASM cells.

P751
Heme-oxygenase (HO-1) inhibitors induce CXCL10 secretion by airway smooth muscle cells
Petra Seidel1,2, Katrin Hoestertler1, Margaret Hughes2, Michael Tamm1, Michael Roth1. 1Pulmonary Cell Research & Pneumology, University Hospital Basel, Basel, Switzerland; 2Respiratory Research Group, University of Sydney, Sydney, NSW, Australia

Background and purpose: CXCL10 induces mast cell migration towards airway smooth muscle bundles in asthma. In blood mononuclear cells, induction of heme oxygenase (HO-1) inhibited pro-inflammatory cytokine secretion. Dimethyl-fumarate (DMF), which is clinically used as an anti-inflammatory medication, induced HO-1 and thereby inhibited proliferation in airway smooth muscle cells (ASMC).

Experimental approach: Here we assessed the anti-inflammatory effect of DMF on TNF-α induced CXCL10 secretion in human primary ASMC and the involvement of HO-1 and mitogen activated protein kinases (MAPK). ASMC were pre-incubated with DMF and/or glutathione ethylester (GSH-OEt), SB203580, or the HO-1 inducer hemin, or cobalt-protoporphyrin (CoPp) 1 hour before stimulation with TNF-α (10 ng/ml).

Key results: TNF-α induced the secretion of CXCL10, which was inhibited by DMF as well as by the HO-1 inducer hemin, or CoPp. Interestingly, DMF amplified the TNF-α induced phosphorylation of p38 MAPK and thereby induced the expression of HO-1. Inhibition of p38 MAPK by SB203580, reduce DMF-induced HO-1. Importantly, GSH-OEt supplementation: (i) abrogated the inhibitory effect of DMF on TNF-α induced CXCL10 secretion, (ii) counteracted DMF-induced HO-1 expression, and (iii) p38 MAPK activation.

Conclusion and implications: Our data indicate that DMF inhibits TNF-α induced CXCL10 by altering intracellular GSH, leading to activation of p38 MAPK and subsequent synthesis of HO-1 in ASMC. Thus, DMF might help to reduce airway inflammation in asthma.

P752
Corticosteroid insensitivity and enhanced mitogen-activated protein kinase activity in airway smooth muscle cells of severe asthma
Po-hai Chang, Charalambos Michaloudes, Pankaj Bhavsar, Kian Fan Chung.

Experimental Studies, Asthma Disease Section, National Heart and Lung Institute, Imperial College London, London, United Kingdom

Background: Patients with severe asthma are less sensitive to oral or inhaled corticosteroids. Relative corticosteroid insensitivity has been shown in peripheral blood mononuclear cells and alveolar macrophages in these patients.

Aims and objectives: Determine the response of corticosteroids in airway smooth muscle cells (ASMCs) of severe asthma, in terms of suppression of cytokine-induced chemokine release and mRNA expression, and investigate the underlying mechanisms.

Methods: ASMCs of non-asthmatics (NA); 12 patients with non-severe (NSA); 10 or severe asthma (SA); 10 were pretreated with dexamethasone (Dex; 10^-6,10^-5 M) followed by stimulation with TNF-α at 10 ng/ml. IL-8 and eotaxin release determined by ELISA; mRNA quantified by RT-PCR. The role of corticosteroids was measured by ChIP assay; p38, JNK, and ERK expression measured by Western blot.

Results: Baseline and TNF-α induced eotaxin release and mRNA were higher in NSA, but not SA, compared to NA, while no differences were observed for IL-8. p65 recruitment to gene promoters did not differ. Dex (10^-5 M) suppressed induced eotaxin release by 36.7% vs 16.7% (p<0.05) in NSA and SA, respectively. Dex (10^-4 M) suppressed induced IL-8 release by 49.8% vs 25.7% (p<0.01) in NA and SA, respectively. Induced IL-8 and eotaxin mRNA was significantly inhibited by Dex (10^-5 M) in NA and NSA (p<0.05) but not in SA. Induced phosphorylated p38 and JNK were significantly higher in SA compared to NA, respectively (p<0.05).

Conclusions: Corticosteroid insensitivity exists in ASMCs of severe asthma, which may be associated with enhanced p38 and JNK activity.

MAP kinases mediate FGF-induced expression and release of VEGF in human airway smooth muscle cells: The role of azithromycin
Anna Willems-Widyastuti1, Bart Vanaudenaerde1, Robin Vos1, Stephanie De Vleeschauwer 1, Annemie Vaneylen1, Willem de Boer 2, Haris S. Sharma3, Geert Verleden1.

1Leiden Institute of Chemistry, Leiden, Netherlands; 2Department of pulmonology, Leiden, Leiden, Netherlands; 3Department of Pathology, VU University Medical Center, Amsterdam, Netherlands

Background: Fibroblast growth factors, FGF-1, FGF-2 and vascular endothelial growth factor (VEGF) are elevated in chronic inflamed airways. Airway smooth muscle (ASM) cells are known to synthesize VEGF. We investigated the contribution of FGF-1/2 on the VEGF production in ASM cells, the involvement

123s
of mitogen-activated protein kinase (MAPK) and the modulatory effects of azithromycin and dexamethasone.

Methods: Human ASM cells were treated with 10ng/ml of FGF-1 or FGF-2. Specific blockers for ERK1/2 MAPK (U0126), p38 MAPK (SB203580), JNK (curcumin), dexamethasone or azithromycin were added 30 minutes prior to stimulation. Expression of VEGF (VEGF-A, VEGF-121 and VEGF-165) was assessed by quantitative PCR. VEGF release by ELISA and MAPK phosphorylation by Western Blotting.

Results: FGF-1/2 upregulated mRNA expression of VEGF (VEGF-A, VEGF-121 and VEGF-165) and its release by 1.8 fold (FGF-1) and 6.1 fold (FGF-2). Transient increase in VEGF-121 and p38 MAPK phosphorylation and subsequent release of VEGF from FGF-1/2 treated human ASM cells was inhibited by respective blockers. Furthermore, both dexamethasone and azithromycin reduced the VEGF secretion mediated by the p38 MAPK pathway.

Conclusion: Our Results demonstrate that FGF-1 and FGF-2 upregulate VEGF production via ERK1/2 MAPK and p38 MAPK pathways. The anti-angiogenic effect of dexamethasone and azithromycin may potentially contribute to VEGF-mediated vascular remodelling in chronic airway diseases.

P754 Effects of formoterol on TGF-β1 induced factors of extracellular matrix composition
Christopher Lamberts, Leopold Stuebellechner, Bernhard Burian, Petra Binder, Ventsislav Petkov, Lutz Heming Block. Medical University Vienna/Internal Medicine II, Respiratory Medicine, Vienna, Austria

Introduction: COPD is characterised by chronic airway inflammation resulting in extensive airway remodelling. The origin of the remodelling pathology in COPD is unknown and may result from increased EMT (epithelial-mesenchymal transition). EMT of airway smooth muscle cells (ASMC) is mediated by hypoxia, cytokines and several growth factors, such as transforming growth factor-beta (TGF-β1). Formoterol is a long acting beta2 agonist which can exert anti-inflammatory effects by the regulation of intracellular cAMP levels. The aim of our study was to determine if formoterol can modulate downstream mediators of EMT by cAMP induction.

Methods: Human bronchial smooth muscle cell culture was performed using standard protocols. Cells were stimulated with Formoterol (10−10 to 5 μM), Dideoxyadenosin (DDA, 100μM), and/or Forskolin (10μM). Forskolin was used as a positive control. cAMP measurement was performed by ELISA (at 1, 3 and 6 hours) and Western Blotting. Gene expression was evaluated by real time PCR (18S mRNA served as reference gene). All experiments were performed as triplicates.

Results: Formoterol significantly increased intracellular cAMP after 1, 3 and 6 hours compared to untreated cells, whereas the maximum effect was observed after 1 hour. The cAMP increase was effectively blocked by the addition of DDA at any time point. After 24 hours, Formoterol significantly reduced TGF-β1 stimulated Col1 and CTGF mRNA transcription. The addition of DDA reversed this effect for Col1 but not for CTGF.

Conclusion: Treatment with formoterol resulted in a decrease of TGF-β1 induced mediators of extracellular matrix composition. These new findings suggest a potential role for formoterol in EMT.

P755 LSC 2011 Abstract: Potential anti-inflammatory role of the cAMP effectors Epac and PKA on TGF-β1 induced factors of extracellular matrix remodelling
Anouk Oldenburger, Sara Roscioni, Esther Jansen, Mark Menzen, Eleni Papakonstantinou1, Ioannis Klagas 1, Nicola Miglino 2, Patricia Ramos-Ramírez 3, Norma A. Bobadilla 2, Maria G. Campos 3, Fernando Gonzalez-Aguilar 3, Norma A. Bobadilla 2, Maria G. Campos 3, Ricardo Lascuarn, Eva Ramirez, Maria P. Plaza, Mayra D. Alvarez-Santos, 1, Patricia Ramos-Ramírez 3, Blanca Baran-Pereiras 1. 1Airway Hyperresponsiveness Department, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; 2Molecular Physiology Unit, Universidad Nacional Autónoma de México, Mexico, Mexico; 3Biochemistry Department, Universidad Nacional Autónoma de México, Mexico, Mexico; 4Research in Autoimmunity, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; 5Pharmacology Department, Instituto Mexicano del Seguro Social, Mexico, Mexico

Caveolin-1 (Cav-1) is an important signalling scaffold protein involved in smooth muscle contraction; however, the role of Cav-1 in airway responsiveness has not been elucidated so far. Our aim was to determine the relation of Cav-1 expression with airway hyperresponsiveness (AHR) in a guinea pig asthma model. To evaluate this relation, three inhaled antihistamine challenges were applied every 10 days to antigen (ovalbumin); OVA) sensitized guinea pigs (n=9). Antigen-induced airway obstruction, AHR, was measured by cone-shaped, whole body plethysmography and the expression Cav-1 in lung tissue, airway smooth muscle cells (ASM), was evaluated at the third OVA challenge. The control group received saline solution instead of OVA (n=6). From the first challenge on, OVA induced a transient airway obstruction and the development of AHR at the third antihistamine challenge, Cav-1 mRNA levels in lung (assessed by RT-PCR) significantly decreased in our asthma model compared with the control group (P<0.01). Nevertheless, in the ASM from allergic asthma guinea pigs, the expression of Cav-1 mRNA, determined by PCR “in situ”, was increased. This increment was confirmed by flow cytometry in ASM and by immunohistochemistry in lung tissue. Airway obstruction and AHR were correlated with the extent of Cav-1 expression, which is mediated by Epac1 (r=0.69 and 0.52, respectively). Our data suggest that Cav-1 expression in ASM has a crucial role in airway obstruction magnitude and in the process of AHR in this asthma model.

P756 Relaxant effect of coccus sartus (saffron) on guinea pig tracheal chains and its possible mechanism(s)
E. Assadpour, M.H. Boskabady, M.R. Aslani. Physiology, MUMS, Mashhad, Islamic Republic of Iran

The relaxant effects of 4 cumulative concentrations of aqueous-extract of Coccus sartus and safranal were examined by their relaxant effects on precontracted tracheal chains of guinea pig by 10 μM methacholine (group 1) and 60 mM KCl in the presence of different conditions including the presence of 1 mM propranolol and 1 μM chlorpheniramine and 1 μM atropine (group 3, n=6). In groups 1 and 2 all concentrations of theophylline, extract and safranal showed significant relaxant effects compared to that of saline (p<0.05 to p<0.001). However, in group 3 the extracts of Coccus sartus showed a weak relaxant effect (p<0.05 only for highest concentration). The effects of last concentrations of safranal in group 1, and its all concentrations in group 2 were significantly lower than those of theophylline (p<0.05 to p<0.001). In addition to the effects of two last concentration of safranal in both groups 1 and 2 were significantly lower than that of Coccus sartus extract. These results showed a potent relaxant effect of Coccus sartus on tracheal chains of guinea pigs. The results also indicated the safranal is at least, in part, responsible for the relaxant effect of Coccus sartus.
Conclusion: Our results indicate that cigarette smoke induces HA catabolism which may lead to increased inflammation in the lung through low molecular weight HA molecules.

Roфhumilast N-oxide, a PDE4 inhibitor, curbs bleomycin-induced lung fibroblast activation in vitro
Beatrice Arezzini1, Daniela Vecchio1, Piero A. Martorana1, Hermann Tenor2, Concetta Gardi3. 1Department of Physiopathology and Experimental Medicine, University of Siena, Siena, Italy; 2Biology, Nycomed GmbH, Konstanz, Germany

Objective: Activated lung fibroblasts may foster small airway thickening in COPD. Roфhumilast, an oral, selective PDE4 inhibitor approved in EU for severe COPD, mitigates bleomycin (BLM)-induced lung fibrosis in vivo. This study addressed whether roфhumilast N-oxide (RNO), the active metabolite of roфhumilast, modulates effects of BLM on human lung fibroblasts (HLF) in vitro. RNO was used at 2nM corresponding to therapeutic plasma levels.

Methods: HLF pre-incubated with RNO (2nM) were exposed to BLM for 24 or 48h. Reactive oxygen species (ROS) were measured by 2′,7′-dichlorodihydrofluorescein (DCF) accumulation from dichlorodihydrofluorescein diacetate. Total glutathione (GSH) was measured with the GSH reductase DTNB protocol. Proliferation and collagen synthesis was assessed as [3H] thymidine and [3H] proline incorporation (+p<0.05 vs control; *p<0.05 vs BLM).

Results: BLM (24h) at 50 and 100μg ml⁻¹ enhanced DCF accumulation by 1.9±0.4± control. RNO (2nM) reduced this increment by 50%±8%±, respectively. In parallel, total GSH was reduced by BLM (100 μg ml⁻¹) yet rescued by RNO (2nM) (nmol mg protein⁻¹: Control 72±1.1, BLM 26.6±1.3*, RNO+BLM 25±1.7). BLM+2nM RNO 30±1.7, BLM (50 μg ml⁻¹) increased [3H] thymidine incorporation in HLF by 1.4± control. RNO (2nM) rescued this effect. Finally, RNO (2nM) reduced [3H] proline incorporation that was increased to 179±135% of control (100 μg ml⁻¹) with 83±136% of control. RNO (2nM) did not affect basal GSH, total GSH [3H] thymidine or [3H] proline incorporation.

Conclusions: BLM augmented ROS formation, reduced total GSH and increased proliferation and collagen synthesis of HLF in vitro. RNO (2nM) prevented these effects.

P760
Fibroblast cell behaviour growing into a stiffened three dimensional collagen matrix
Vanessa Vicenc1,2, Susanna Estany1, Aida Colom1, Jordi Alcaraz1, Daniel Navajas1, A. Juliana Sanabria2, Roger Liéjas1, Ignacio Escobal1, Pablo V. Berdugo2, Daniel Lopez-Diez1. 1Department of Pneumology, Unit of Intersitial Lung Diseases, Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat, Barcelona, Spain; 2Pneumology Research Group, Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat, Barcelona, Spain; 3Unit of Biophysics and Bioengineering, Universitat de Barcelona, Barcelona, Spain

Introduction: Idiopathic Pulmonary Fibrosis is a process that involves abnormal cell behaviour and increased tissue stiffness. The aim of this study was to elaborate a stiffened three-dimensional (3D) collagen I matrix to study cultured human cell inside.

Methods: 3D matrices were elaborated with native collagen I and it was non-enzymatically glycated with ribose at different conditions. Matrix stiffness was measured with Atomic Force Microscope and collagen deposition was evaluated by confocal reflexion microscopy. Primary fibroblasts were obtained from normal human lungs. Cellular viability in 3D matrices was evaluated by AlamarBlue fluorescence assay and LIVE/DEAD kit at different time points.

Results: It was observed that fluorescence AlamarBlue assay requires more time incubation to detect viability in 3D collagen matrices than in 2D cultures. An increased stiffness of 3D matrices was achieved with high concentration of collagen and ribose glycation from the second week. Stiff-variability and morphological changes in collagen I fibers was dependent on the media used for the matrix elaboration and the glycation condition. Cell death was detected in higher ribose concentrations. Fibroblasts showed a better-defined morphology and viability in matrices elaborated with lower ribose concentrations and DMEM media.

Conclusion: The development of this 3D collagen I matrix allows the fibroblast growth inside a modified microenvironment. Cell viability depends on different variables and it dramatically decreases with higher concentrations of ribose. This innovated model could help in the study of cell behaviour and phenotype at different conditions. Supported by: SEPAR, SOCAP, FUCAP, PS0801757

Tiotropium reduced carbachol-induced expressions of IL-6 and IL-8 by primary human lung fibroblasts of asthma and non-asthma subjects
Lucia Costo1, Michael Roth2, Paola Casarosa3, Michael Tamm4, Peter Borger5. 1Pulmonary Cell Research, Dept of Biomedicine, University Hospital Basel, Basel, Basel, Switzerland; 2Respiratory Diseases Research, Boehringer Ingelheim Pharma, Biberach, Germany

Asthma is a reversible, obstructive airway disease of unknown etiology. Although the molecular pathology of asthma is still obscure, muscarinic receptor antagonists are currently in use to treat the disease. Human lung fibroblasts express muscarinic receptors, which may regulate and fine-tune the expression of cytokine genes. In the present study we analyzed the effect of the muscarinic receptor agonist, carbachol, on the release of IL-8 and IL-6 by primary human lung fibroblasts obtained from asthmatic and non-asthmatic subjects. Fibroblasts were grown in RPMI-1640 (±10% FCS, ±1% vitamins) in the presence of increasing carbachol concentrations (10-8M to 10-6M). Carbachol dose-dependently and significantly inhibited IL-6 release in IL-1β-stimulated fibroblasts of non-asthmatics, but not in fibroblasts of asthmatic patients. Furthermore, Carbachol dose-dependently increased the IL-1β-induced IL-8 release, however, with no difference comparing fibroblasts obtained from asthmatics to cells of controls. The muscarinic receptor inhibitor tiotropium alone reduced the secretion of IL-6 and IL-8 by fibroblasts. Tiotropium (10-8 M) almost completely blocked the IL-1β-induced IL-6 and IL-8 secretion. Our data indicate that tiotropium reduces an inflammatory response of lung fibroblasts elicited by muscarinic receptors. These data may provide a rationale for the beneficial effects of tiotropium in the treatment of asthma. Supported by: Boehringer-Ingelheim Pharma and the Swiss National Foundation.

Late-breaking abstract: Differential expression profiles of genes involved in oxidative stress and inflammation in blood and sputum from healthy subjects and COPD patients
Catherine Moermans, Donat Degrooto, Pierre Dorfman, Etienne Capieux, Monique Henket, Jean-Louis Corhay, Renaud Louis. 1GIGA Pneumology, Université de Liège, Liège, Belgium; 2Belgium Pneumology, CHU, St Tailin, Liège, Belgium; 3Belgium Probiotic SA, Probius SA, Liège, Belgium; 4Labo Life, Labo Life, Liège, Belgium

Background: Environmental (mainly cigarette smoke) and genetic factors are known to be involved in the development of chronic obstructive pulmonary disease (COPD); however, a better understanding of the COPD genes expression dysregulation remains a major challenge.

Increased oxidative stress is thought to be central in COPD pathogenesis and directly involved in local and systemic inflammation.

Methods: We have investigated, by RT-PCR array, the mRNA expression profile of 95 genes involved both in inflammation and oxidative stress in sputum and blood from COPD patients (n = 18) and healthy controls (n = 17). We have used Ingenuity Pathway Analysis Software (IPA) to identify the networks of interactions, the biological processes and pathways in which genes showing a significant expression modification are involved.

Results: In the blood cells of COPD, around half of genes showed modifications (26 up and 19 down-regulated) compared to healthy controls and these were essentially involved in inflammation. Using IPA, we found that the most important cellular function altered was the cellular movement. In sputum cells, only 13 genes showed modifications (6 up and 7 down-regulated), five were related to inflammation with blood), most of them being involved in free radical scavenging and cell death.

Conclusions: Compared to healthy subjects, there was a clear dysregulation in gene expression at systemic level, and to a lesser extent, at airway level. Therefore, gene expression profile shows differences between local and systemic compartments.

P763
Late-breaking abstract: Cyclooxygenase- and lypoxigenase-dependent generation of omega-3 electrophilic fatty acid-derivatives with anti-inflammatory properties
Chiara Cipollina1, Sonia Salvatore2, Bruce A. Freeman2, Francisco J. Schopfer2. 1Pulmonary Cell Research, Dept of Biomedicine, University Hospital Basel, Basel, Switzerland; 2Respiratory Diseases Research, Boehringer Ingelheim Pharma, Biberach, Germany

Chronic obstructive pulmonary disease (COPD) is characterized by persistent inflammation of the airways and extensive oxidative damage. Activated macrophages and neutrophils are elevated in the airways of COPD patients where they sustain the inflammatory response and contribute to tissue damage. During inflammatory reactions arachidonic acid (AA) is released from cell membranes and is converted into the pro-inflammatory prostaglandins and leukotrienes by the action of

125s

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
cyclooxygenase-2 (COX-2) and lipoxygenases (LO). It has been recently discovered that COX-2 and LO are able to convert alternative substrates, such as the omega-3 docosahexaenoic acid (DHA) and docosapentaenoic acid (DPA), into mediators that actively repress the inflammatory reactions and promote the resolution of inflammation. Herein we report the formation of new omega-3 electrophilic fatty acid derivates by the action of COX-2 and LO in activated human macrophages and stimulated neutrophils. These compounds displayed cytoprotective and anti-inflammatory actions measured as repression of pro-inflammatory enzimes and cytokines and activation of the Nrf2-dependent anti-oxidant response.

Data presented herein strongly suggest that electrophilic derivatives of omega-3 fatty acids are generated in inflamed airways of COPD patients where they may contribute to limit tissue damage and inflammatory processes.

**P764** Late-breaking abstract: Surfactant protein D (SP-D) as a biomarker for mortality: A study in elderly Danish twins

Helle Wulff Johanssen1, Mikael Thinggaard2, Qibua Tan3, Kaare Christensen2, Uffe Holmskov1, Gerth Lykke Sørensen1. 1Cardiovascular and Renal Research, Institute of Toxicology, University of Southern Denmark, Odense, Denmark; 2Danish Twin Registry and Danish Aging Research Center, Institute of public Health, University of Southern Denmark, Odense, Denmark; 3Epidemiology, Institute of Public Health, University of Southern Denmark, Odense, Denmark.

**Background:** SP-D is synthesized and secreted into the airspaces of the lung by alveolar type 2 pneumocytes and bronchiolar epithelial cells. Specific measurements of SP-D have previously demonstrated to predict survival in patients with idiopathic pulmonary fibrosis and ALI/ARDS. However, SP-D may be a general indicator of pulmonary health and associate to mortality in the general population.

**Aim:** To investigate the association between higher serum SP-D levels and mortality in normal Danes.

**Methods:** A total of 689 twins (234 males and 455 females) provided blood samples during a six month period in a survey (LSADT) performed in 1997. During a 13-year follow-up period 181 (77%) men died and 292 (64%) women died. SP-D serum levels were measured by ELISA technique.

**Results:** Surfactant Protein D levels were positively and significantly correlated to mortality in females. At the end of January 2010, there were 84 male twin pairs (39 MZ and 45 DZ) and 160 female twin pairs (73 MZ and 87 DZ) in which at least one twin had died. There was no evidence of an association between increasing intra-pair difference in log transformed SP-D and mortality in males. In contrast, intrapair analyses in females showed that the twin with the highest SP-D level had a lower risk of death than the co-twin (OR=0.46 vs 1.72; p=0.001). Adjusted Cox regression analysis with intrapair difference in smoking (packyear) and BMI did not affect this association (OR=1.75; p=0.040).

**Conclusions:** These data suggest that circulating SP-D levels may be a biomarker to predict the pulmonary health status and to forecast mortality in the elderly women.

**P765** Late-breaking abstract: Lung regional differences in tissue adaptation to chronic hypoxia (CH)

Alice Polari and bronchial Ferri1, David Bishop2, Giuseppe Miserecchi1, Ilaria Rivolta1. 1Department of Experimental Medicine, University of Milano Bicocca, Monza, Italy; 2Institute of Sport, Exercise & Active Living (ISEAL), Victoria University, Melbourne, Australia.

Hypoxia (H) impacts to all body tissues which have to adapt to a decrease in O2 delivery. In CH, 10% O2 for 3 weeks) two lung regions from rats, the upper and the lower lobe, showed differences in interstitial tissue structure (Rivolta, I et al. EJR 2011; 37:943-9). On these samples, where the metabolic needs are linked to topographic adaptations of the two lobes can be accounted for a topographic difference in the level of KGF expression, which has been shown to express in the upper lobe. We conclude that variance in tissue structure organization of the two lobes can be accounted for a topographic difference in the level of KGF present in normoxia. On this background, differences in the adaptive response to H might be mediated by differential expression of PGC-1α since HIF1α response was equally affected in both lobes. These results represent a breakthrough in the molecular mechanisms of H adaptation understanding, furthermore, this is the first study considering PGC-1α in the hypoxic lung.

**P766** Engineered nanoparticles induce apoptosis of human bronchial epithelial cells

Hasan Bayramy1,2, Bulent Gogebackan1, Recep Bayraktar1, Ahmet Arslan1, 1Respiratory Medicine, University of Gaziantep, Gaziantep, Turkey; 2Respiratory Research Laboratory, University of Gaziantep, Gaziantep, Turkey; 3Medical Biotechnology, University of Gaziantep, Gaziantep, Turkey.

Engineered nanoparticles are widely used by the industry, however, it is not clear whether they possess a risk on respiratory health. The objectives of our study were to investigate effects of Titanium dioxide (TiO2) and multi walled carbon nanotubes (MWCNT) on bronchial epithelial cell (BEC) viability and death. BEAS-2B cells and primary BEC obtained from both smokers and patients with COPD were incubated with 0.300 μg/ml TiO2 and MWCNT for 24-48hrs. Cell viability was assessed by MTT, and apoptosis was analyzed by flow cytometry using Annexin V-PE and 7AAD dyes. TiO2 significantly decreased the viability of BEAS-2B cells at 100 (optimal density [OD]=0.65; p=0.001) and 300 μg/ml (OR=0.45; p<0.0001) concentrations after 24hrs as compared control cells (OD=0.85). Similarly, 100 and 300 μg/ml MWCNT decreased viability of these cells following 24 and 48hrs' incubation. Although 300 μg/ml TiO2 induced the viability of primary BEC of smokers (OD=2.15 vs OD=1.52; p<0.0001), 300 μg/ml suppressed cell viability (OD=1.02; p<0.0001) after 24hrs. TiO2 did not change the viability of BEC of COPD patients after 24hrs, whereas 300 μg/ml decreased viability of these cells (OD=0.46 vs 1.72; p=0.001) following 48hrs. Flow cytometry studies of BEAS-2B cells demonstrated that TiO2 (300 μg/ml) decreases percentage of viable cells (90.66% vs 94.01%; p=0.0009), while inducing the percentage of late apoptotic (0.72% vs 4.2%; p=0.017) and necrotic (0.63% vs 4.03%; p=0.0099) cells. MWCNT also showed similar effects on apoptosis of BEAS-2B cells. These findings suggest that engineered nanoparticles may possess a risk on respiratory health by modifying viability and apoptosis of bronchial epithelial cells.

**P767** IL-17 enhances IL-8 production by attenuating both the ARE-mediated and the microRNA-mediated degradation of IL-8 mRNA

Saheli Chowdhury, Annemieke Dijkhuis, Rene Lutter. Experimental Immunology & Respiratory Medicine, Academic Medical Center, Amsterdam, Netherlands.

**Background:** IL-17 is a cytokine implicated in chronic inflammation. Enhanced amounts of IL-17 have been found in the airways of patients with asthma and chronic obstructive pulmonary disease (COPD). Previously, we showed inducible IL-17 blockade by anti-IL-17A antibodies did not prevent IL-17 induced IL-8 and IL-6 production in human lung epithelial cells, predominantly by stabilizing IL-6 and IL-8 mRNA. Aim: IL-6 and IL-8 mRNA contains AU-rich elements (ARE) in the 3'UTR, target these mRNAs for facilitated degradation. This decay pathway may be mediated by AU-binding proteins (AU-rips) and possibly microRNAs (miRs). We have assessed whether AU-rips (TTP, KHSRP, AUF1) and/or miRs are involved in IL-8 mRNA degradation. And, if so, whether IL-17 modulates these pathways.

**Results:** Inhibition of miR16, or knock-down of TTP or KHSRP resulted in a marked increase of TNF-a-induced IL-8 production, which was paralleled by stably increasing IL-8 mRNA degradation. Conversely, knock-down of AU-1 reduced IL-8 mRNA expression and promoted degradation of IL-8 mRNA. IL-17 halts IL-8 mRNA degradation by enhancing the role of AUFI1 which protects IL-8 mRNA from degradation. Furthermore, IL-17 reverses the TNF-a-induced production of miR16.

**Discussion:** These findings strongly indicate that IL-17 enhances IL-8 production by attenuating two pathways that degrade IL-8 mRNA. We have obtained similar data for several other inflammatory mediators. Since airway epithelial cells from patients with asthma display enhanced IL-8 production we are assessing whether there is an intrinsic disturbance in these mRNA decay pathways.

This work is supported by the Netherlands Asthma Foundation (3.2.06.031).

**P768** A quantitative method for the detection of spliced X-box binding protein 1 (XBP1) mRNA in primary bronchial epithelial cells (PBEC) as a measure of endoplasmatic reticulum (ER) stress

Annemarie van Schadevijl, Emily F.A. van ’t Wout, Jan Stolk, Pieter S. Hiemstra. Pulmonology, Leiden University Medical Center, Leiden, Netherlands.

Accumulation of unfolded or misfolded proteins in the ER can cause ER stress, which is increasingly seen in diseases such as cystic fibrosis, alpha-1-antitrypsin deficiency and Alzheimer disease. ER stress leads to the activation of the unfolded protein response (UPR). UPR signaling involves splicing of XBP1 mRNA and induction of gene expression by the transcription factors CHOP, which is a key-signaling component of ER-stress induced apoptosis. In present studies, XBP1 splicing is frequently used as an important marker for ER-stress and is visualized by gel electrophoresis which is laborious and difficult to quantify. The aim of this study was to develop and validate a quantitative RT-PCR (qPCR) which detects only the spliced form of XBP1 mRNA. We stimulated PBEC with thapsigargin and tunicamycin, both known ER-stress inducers, and performed qPCR with primers that were designed to recognize only the spliced form of XBP1. We also performed qPCR for CHOP and BIP and correlated this with

Pulmonary apoptosis in fetal Down syndrome

Mariana Buzin1, Jan van der Huisen2, Chris van der Loos1, Ronald de Kruijer1, 
Rhiannon van Loenhout1, Albert Bos1, Job van Woensel1, 1Pediatric Intensive 
Care Unit, Emma Children’s Hospital/Academic Medical Center, Amsterdam, 
Netherlands; 2Department of Histopathology, Royal Brompton and Harefield 
NHS Trust, London, United Kingdom; 1Department of Pathology, Academic 
Medical Center/University of Amsterdam, Amsterdam, Netherlands; 3Department 
of Pathology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, 
Netherlands; 4Department of Pediatric Surgery, Erasmus MC, University Medical 
Center Rotterdam, Rotterdam, Netherlands

Background: Increased levels of apoptosis have been implied in various non-
 pulmonal conditions frequently found in Down syndrome (DS). Children with
 DS are at increased risk for acute lung injury and fetal lung development is 
disrupted in DS. In both processes, apoptosis plays a key role. Nevertheless, 
pulmonary apoptosis has not been studied in DS.

Aim: We hypothesized that the amount of apoptotic epithelial cells in fetal lungs of 
DS is increased compared to controls.

Methods: We compared lung tissue sections from autopsies of 21 fetuses with 
DS and 12 controls (16-24 weeks gestational age (GA)). Sections were double 
stained with antibodies against pan-cytokeratin (CK) and activated caspase-3 (C3), 
markers for epithelium and apoptosis. Per section, 7 random photographs were 
taken at 200x magnification. Spectral imaging software was used to quantify the 
mean number of pixels that showed colocalization of CK and C3. All sections were 
H&E stained to determine the presence of canalicular or sacular morphology.

Results: The mean (SD) percentage of CK-positive pixels was equal between DS 
and controls (27.2% (4.7) versus 27.1% (6.2), p=0.97). The median percentage 
(IQR) of C3-positive pixels that showed colocalization of C3 was 0.16% (0.18) 
in DS compared to 0.27% (0.24) in controls (p=0.45). This was independent of 
the induction of CHOP and BiP was r=0.962 (p<0.000), respectively. We compared the new method with the visualization of the spliced 
XBP1 mRNA to validate the results. The spliced XBP1 PCR product from a control 
was investigated by qRT-PCR, western blotting and immunohistochemistry using 
the catalytic subunit of γ-GCS and GR (glutathione reductase) mRNA.

Conclusion: The number of apoptotic epithelial cells in lungs of DS fetuses does 
not differ from controls. We did find a difference in the development of epithelial 
structures and acinar development. This might explain anomalies in alveolar 
development found at birth in DS.

P770
Airway epithelial protocadherin-1 expression is regulated by house-dust mite 
cigarette smoke exposure in mice

Mariana Buzin1, Ulike Brouwer1, Lissette den Boef2,

University of Groningen, Groningen, Netherlands

Recently, we identified Protocadherin-1 (PCDH1) as a novel susceptibility gene for 
Bronchial Hyperresponsiveness (BHR). PCDH1 is expressed in airway epithelial 
cells and encodes two isoforms of a protocadherin transmembrane protein. We aim 
to get insight into PCDH1 function in airway epithelial cells in relation to BHR. 
Therefore, we analyzed in vivo regulation of Pcdh1 isoforms in lungs under basal 
conditions and in mouse models of short-term cigarette smoke (CS) exposure and 
house-dust mite (HDM) driven experimental asthma. Pcdh1 gene-structure was 
investigated by Rapid Amplification of cDNA Ends (RACE). Pcdh1 expression 
was investigated by qRT-PCR, western blotting and immunohistochemistry using 
isoform-specific antibodies.

We identified a novel isoform of Pcdh1 lacking the transmembrane domain but re-
taining the intracellular signalling motifs, indicating a novel function as signaling 
adaptor molecule. Bronchial epithelial cells expressed all isoforms of Pcdh1, while 
airway smooth muscle only expressed the isoforms encoding the signal transduction 
domains. Surprisingly, Pcdh1 expression was unaffected during HDM-exposures, 
but increased after termination of the treatment, indicating a putative role in ep-
ithelial repair. In strong contrast, Pcdh1 mRNA expression was markedly reduced by 
CS exposure, as soon as 6 hours after a single exposure. These latter data are 
especially of interest given the initial identification of linkage to the PCDH1 
region in CS-exposed families. We conclude that CS-induced changes in airway 
epithelium directly affect Pcdh1 expression levels, and hypothesize that PCDH1 regulation contributes to the epithelial response to CS-induced injury.

P771
Fluticasone furoate restores leptin/leptin receptor pathway in nasal 
epithelial cells

Andrea Bruno1, Maria Ferraro1, Stefania Gerbino2, Angela Bonura1, 
Paolo Colombo1, Stefania L. Gatta1,3, Marie Giomara1, Made Gianfranco Pace1, 
1National Research Council, Institute of Biomedicine and Molecular 
Immunology, Palermo, Italy; 2Environmental Health, ARPA, Environmental 
Health, ARPA, Palermo, Italy

Leptin/leptin receptor pathway has been shown to be involved in the epithelial 
homeostasis and in tissue repair. Allergic rhinitis (AR) is characterized by a 
highly mediated inflammation induced by the allergen exposure, leading to a chronic 
inflammation with consequential structural abnormalities in the nasal epithelium. 
Topical corticosteroids are recommended as first-line therapy in AR. The role 
of the leptin/leptin receptor pathway and the specific effects of fluticasone furoate 
(FF), a new topical corticosteroid, in the homeostasis of nasal epithelial cells are 
largely unknown. We aimed to determine whether a nasal epithelial dysfunction of 
leptin/leptin receptor pathway contributes to AR pathogenesis and to investigate 
the effect of FF on this pathway. The human nasal epithelial cell line RPMI 2650 
was first examined for leptin/leptin receptor expression by immunocytochemistry 
and by flow-cytometry. Then, the RPMI 2650 cells were cultured in the presence 
or absence of the allergen extract birchiana judaica (PAR1), of the fibrogenic 
cytokine TGF-β1 and of FF and analyzed for leptin receptor by flow-cytometry 
and for cell proliferation by clonogenic assay. The RPMI 2650 cells express leptin 
receptor. PAR1 and TGF-β1 significantly decreases the leptin receptor 
expression and cell proliferation and FF completely abolishes and reverts the 
effects of both PAR1 and TGF-β1. In conclusion, allergen exposure and TGF-β1 
alter the homeostasis of nasal epithelium by down-regulating leptin/leptin receptor 
pathway whereas FF is able to restore both this pathway and nasal epithelial 
homeostasis.
Results: Basal production of IL-8 by mitochodrially impaired AS49.B2 cells is increased compared to AS49 control cells. Moreover, suppression of IL-8 by the GC budesonide (10-8M) is significantly less (24%±6%, p=0.02) in AS49.B2 cells compared to AS49 cells. Furthermore, while budesonide was able to efficiently increase barrier function in control AS49 cells (p<0.001), there was not significant effect in AS49.B2 cells. Finally, we observed that AS49.B2 cells were less capable to recover from wound than control AS49 cells.

Conclusion/Discussion: In conclusion, our data indicate that mitochondrial dysfunction leads to increased pro-inflammatory activity, inefficient wound healing and reduced responsiveness to GCs. We speculate that mitochondrial dysfunction as observed in COPD may contribute to the GC-insensitive chronic airway inflammation in this disease.

P774
Effect of phosphodiesterase IV inhibitors on eotaxin expression in bronchial epithelial cells – Comparison between immortalized and primary line
Magdalena Paplinska, Ryszarda Chazan, Hanna Grubek-Jaworska. Internal Diseases, Pneumonology and Allergology, Medical University of Warszawa, Warszaw, Poland

Eotaxins are an important agents of the patophysiology in the obstructive airway diseases. They are responsible for eosinophil recrutation into respiratory tract. Phosphodiesterases (PDEs) are a huge and diversified family of enzymes decomposing cAMP. PDE4 inhibitors as drugs, act through cAMP elevation and can inhibit inflammation in many ways. The aim of this work was to evaluate the effect of PDE4 inhibitors (rolipram and RO-20-1724) on eotaxin (CCL11, CCL24 and CCL26) expression in human bronchial epithelial cells: immortalized - BEAS-2B (ATCC) and primary (ATCC). Cells were preincubated with PDE4 inhibitors for 1 h and stimulated with IL-13. TNF-α or IL-13+TNF-α for 48h. Protein levels were measured using ELISA kits, changes in genes expression were measured using real time PCR.

Results: The both of cell lines produced different eotaxins: BEAS-2B synthesized CCL11 and CCL24, BEHC – CCL11 and CCL26. Distinct effects of PDE4 inhibitors in hBECs in immortalized as compared to primary cell line were observed. PDE4 inhibitors decreased the level of eotaxin gene and protein expression in BEAS-2B usually in statistically significant manner. PDE4 inhibitors stimulated eotaxin gene expression; specially rolipram significantly increased the mean levels of eotaxin expression, but did not change their protein synthesis.

Conclusions: The data do not permit to suggest the effect of PDE4 inhibitors on bronchial epithelial cells because of the differences in the biology of the both used cell lines. Unequivocal resoluction of the problem needs more experimental trials using more primary cell lines or experimental animal model.

P775
ciliaFA: A free research tool for accurate, automated, high-throughput measurement of ciliary beat frequency (CBF)
Claire Smith 1, Jana Djakov 2, Petr Djakov 2, Alexandra Patel 2, Robert Hirst 1, Peter Andrew 1, Christopher O’Callaghan 1,1 Department of Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom; 2Department of Paediatrics, 2nd Faculty of Medicine, University Hospital Motol, Prague, Czech Republic; 1IT Solutions, Siemens IT Solutions, Prague, Czech Republic

Aim: To develop a program that allows batch processing of multiple movie (.avi) files for measurement of CBF.

Introduction: A program was developed that converts average pixel intensities within a region of interest to a waveform. The waveform is analysed by fast fourier transform (FFT) to extract the dominant frequency. The code runs on freeware and cell proliferation in primary human lung fibroblasts (n=6).

Methods: Image files of 115 ciliated epithelial cell cultures were captured using a digital high-speed video recorder. In order to capture a range of CBF measurements, the bacterial toxin, pneumolysin, was used to inhibit CBF. Mean CBF was measured by conventional frame by frame counting of ciliary beat cycles by slow motion playback were compared with those obtained using the automated ciliaFA system.

Results: The mean (sd) difference between the ciliaFA and conventional methods was -0.4 (1.6) Hz, the correlation coefficient was shown to be 0.8 and the Bland-Altman limits of agreement were -3.5 to 2.7 Hz.

Conclusion: The data showed that the ciliaFA software calculated consistent CBF measurements. The advantages of this system include automated, high throughput CBF analysis; whole field and individual region of interest measurements, and elimination of selection bias.

P776
Interactions between epithelial cells and neutrophils during pro-inflammatory conditions
Ken von Schiele, Kjell Larsen, Lena Palmberg. Institute of Environmental Medicine, Lung- Allergy Research, Karolinska Institutet, Stockholm, Sweden

Inter-cellular communication is essential for defense and survival of the organism. The aim of the study was to find out whether there is an active cross-talk between cells constituting the first line of defense; alveolar epithelial cells (AS49) and neutrophils, following activation with pro-inflammatory stimuli in vitro. Further, to explore whether this communication is altered in chronic obstructive pulmonary disease (COPD), a condition characterized by chronic airway and lung inflammation.

Primary neutrophils from healthy subjects and COPD-patients were co-cultured with AS49 cells in medium and in medium containing lipopolysaccharide (LPS), peptidoglycan (PGN) or tumor necrosis factor (TNF). The expression of TL2R, TL4 and CD14 on the cell surface of neutrophils was assessed by flow cytometry and CXCL8 (IL-8) and soluble CD14 (sCD14) in the supernatant were measured with ELISA.

On neutrophils, the surface expression of TL2R was diminished following activation with all three pro-inflammatory stimuli and membrane bound (sCD14) and TL4 expression were increased in co-cultures compared to single cell cultures, irrespective of pro-inflammatory stimulation. A strong correlation between CXCL8 and sCD14 was observed in LPS-stimulated co-cultured cells.

These data showed a down regulation of TL2R on neutrophils induced by pro-inflammatory stimuli and is strongly suggesting an active cross talk between AS49 cells and blood neutrophils, both in unstimulated cells and following activation with pro-inflammatory stimuli, in vitro.

P777
Effect of cigarette smoke extract or TGF-β1 on hyaluronan production and hyaluronan modulating enzymes in primary murine lung fibroblasts
Peter Andrew1, Christopher O’Callaghan1, Guy Inoue2, Emiel Wouters2, Guy Brusselle1, Mieke Dentener1,1 Respiratory Medicine, Ghent University Hospital, Gent, Belgium; 2Respiratory Medicine, Maastricht University Medical Centre+, Maastricht, Netherlands

Hyaluronan (HA) is a component of the extracellular matrix and low molecular weight (LMW) HA fragments have pro-inflammatory capacities. Exposing mice to cigarette smoke (CS) for 1 or 6 months results in enhanced deposition of LMW HA in lung parenchyma and airways walls and in altered expression of HA syntheses and hyaluronidases (Bracke et al., Am J Respir Cell Mol Biol. 2010;52(6):753-61). To pinpoint a source of HA, we studied HA-production and HA modulating enzymes in primary murine pulmonary fibroblasts stimulated with cigarette smoke extract (CSE) or TGF-β1.

Fibroblasts were isolated from lungs of C57BL/6 mice and cultured in vitro. At passage 6, cells were stimulated with 24h or 48h with control medium, 5% CSE or 2ng/ml TGF-β1. mRNA expression of HA syntheses (Has1, Has2, Has3) and hyaluronidases (Hyal1, Hyal2) was evaluated by RT-PCR. HA production was measured in supernatant by ELISA.

In vitro stimulation of pulmonary fibroblasts with CSE significantly decreased the mRNA expression of Has1 (synthesizing high molecular weight (HMW) HA) and significantly increased the expression of Hyal2 (degrading HMW HA to LMW HA fragments). Stimulation with TGF-β1 resulted in significantly increased mRNA expression of Has2 (synthesizing HMW HA). Accordingly, HA-levels in the fibroblast supernatant decreased significantly upon 48h stimulation with CSE, while they were significantly increased upon 24h or 48h stimulation with TGF-β1.

Decreased Has1 and increased Hyal2 in CSE-stimulated fibroblasts suggests reduced synthesis and enhanced breakdown of HMW HA. This may contribute to the accumulation of LMW HA fragments, observed in CS-exposed mice.

P778
Cigarette smoke down-regulates the expression of β-catenin in primary human lung fibroblasts
Nicola Miglino1, Seidel Petra2, Michael Roth2, Charlotte Sadowski-Cron2, Didier Lardinois1, Michael Tamm1, Peter Borge1,1 Pulmonary Cell Research, Department Biomedicine, University Hospital Basel, Basel, Switzerland; 2Thoracic Surgery, University Hospital Basel, Basel, Switzerland

Rationale: Cigarette smoke is the major cause of COPD/emphysema but the etiology of these diseases is still unknown. β-catenin is a signalling molecule which is regulated through degradation/stabilization mechanism, and which promotes cell proliferation via the Wnt signaling pathway. Decreased β-catenin signaling may be involved in the parenchymal tissue destruction leading to emphysema.

Objectives: Investigate the effect of cigarette smoke on the expression of β-catenin and cell proliferation in primary human lung fibroblasts (n=6).

Methods: Fibroblasts were exposed to cigarette smoke conditioned medium (20%,
P779 Anti-inflammatory effect of beclomethasone dipropionate and formoterol on TNF-α-induced human endothelial cell activation
Silvana Cianchetti, Cristina Cardini, Gabriele Nicolini, Alessandro Celi, Paola Pagliuca, Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy

To investigate the effect of beclomethasone dipropionate (BDP) and formoterol (F), either alone or in combination, on TNF-α-induced ICAM-1 expression and IL-8 release in human umbilical vein endothelial cells.

Methods: Cells were incubated with BDP (10^{-11} - 10^{-5} M), F (6/100 with respect to BDP concentration) or drug diluent (control cells: CC) and then exposed to TNF-α (200 U/ml; 4 hrs). For BDP/F combination (n=10/8/6), EC were treated with low doses of BDP (10^{-10} and 10^{-8} M) and/or F (6×10^{-5}-6×10^{-3} M). Surface ICAM-1 expression and IL-8 release were measured by ELISA.

Results: BDP reduced TNF-α-induced IL-8 release (mean±SEM; 5.6±0.5 fold; p<0.05 vs CC); F did not significantly affect IL-8 release (9.2±0.8% at the maximal dose tested). In a different experimental set, BDP/F inhibited IL-8 release with respect to TNF-α alone (10^{-9}M×6×10^{-5} M; 27.6±3.4 vs 10^{-3} M 14.6±3.5%; p<0.05 vs CC), achieving an effect comparable to that observed with BDP 10^{-9} M alone; BDP/F, though to a less extent, tended to decrease ICAM-1 expression (10^{-9}M×6×10^{-5} M; 17.2±6.8 vs 10^{-5} M 9.3±2.1%; and F=4±2.6; p=0.05, n=5).

Conclusions: BDP in combination with F is more effective in inhibiting EC activation as compared with BDP alone, thus allowing to use lower BDP doses to reach the maximum inhibitory effect. These results may explain some clinical anti-inflammatory activities of BDP/F combination.

92. The ageing pulmonary interstitium

P780 Ambrisentan attenuates lung and heart injury in a rat model of bronchopulmonary dysplasia
Gerry Wagenaar, Yvonne de Visser, Eli Houari Lagnani, Frans Walther.

Department of Pediatrics, Division of Neonatology, Leiden University Medical Center, Leiden, Netherlands

The selective endothelin receptor type A antagonist ambrisentan may be a novel therapeutic agent in neonatal chronic lung disease by blocking the adverse effects of the potent vasconstrictor endothelin-1, including pulmonary arterial hypertension (PAH)-induced right ventricular hypertrophy (RVH). The cardiopulmonary effects of ambrisentan were studied in neonatal rats with hyperoxia-induced lung injury. Ambrisentan treatment was investigated in 2 models of experimental BPD: a prophylactic model, in which pups were continuously exposed to hyperoxia and treated daily with either saline or ambrisentan (20 mg/kg body weight/day); and an experimental model, in which pups were exposed to hyperoxia for 9 days, followed by 9 days of recovery in room-air and treatment with ambrisentan was started on day 6 of oxygen exposure and continued during the recovery period. In the prophylactic model treatment with ambrisentan improved survival (p<0.01) by reducing lung fibron deposition (3-fold, p<0.001), alveolar septum thickness (1.7-fold, p<0.001) and alveolar wall thickness of small arteries (3-fold, p<0.01), and preventing associated RVH (p<0.001). Treatment with ambrisentan did not have beneficial effects on alveolar enlargement, vascularization, the pulmonary influx of macrophages and neutrophils, and the mRNA expression of procollagant and inflammatory markers. In the injury-recovery model treatment with ambrisentan attenuated PAH and RVH (p<0.001), demonstrating that established PAH-induced RVH is still reversible in the adult period. Beneficial effects on reduced pulmonary vascularization and alveolarization were absent.

P781 Serum HSPI74 is a novel blood marker for rapidly progressive interstitial pneumonia
Tomoyuki Kakugawa1, Shin-Ichi Yokota2, Yuki Ishimatsu3, Tomoyoshi Hayashi4, Shota Nakashima1, Shintaro Hara1, Noriko Sakamoto1, Hiroshi Kubota5,6, Marko Mine1, Yasuhito Matsukawa1, Hiroshi Muku1, Kazuhiro Nagata1,2, Shigemune Kohno1,2,3, Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki, Japan; 4Department of Microbiology, Sapporo Medical University School of Medicine, Sapporo, Japan; 5Department of Pathology, Nagasaki University Hospital, Nagasaki, Japan; 6Department of Molecular and Cellular Biology, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan; 7Department of Life Science, Faculty and Graduate School of Engineering and Resource Science, Akita University, Akita, Japan; 8Biostatistics Section, Division of Scientific Data Registry, Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; 9Department of Respiratory Medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; 10Laboratory of Molecular and Cellular Biology, Faculty of Life Sciences, Kyoto Sangyo University, Kyoto, Japan

Heat shock protein (HSP) 47, a collagen-specific molecular chaperone, is involved in the processing and/or secretion of procollagen. The aim of this study was comparative analysis of the diagnostic values of serum HSPI74. Krebs von den Lungen-6 (KL-6), surfactant protein (SP) A, SP-D and lactate dehydrogenase (LDH) levels for rapidly progressive interstitial pneumonia. Subjects comprised 27 patients with rapidly progressive interstitial pneumonia, 12 with cryptogenic organizing pneumonia (COP), 19 with idiopathic usual interstitial pneumonia (UIP), 16 with idiopathic nonspecific interstitial pneumonia (NSIP), 11 with collagen vascular disease-associated UIP, 11 with collagen vascular disease-associated NSIP, and 18 healthy adult volunteers. Serum levels of HSPI74 in patients with rapidly progressive interstitial pneumonia were significantly higher than those in patients with COP, idiopathic UIP, idiopathic NSIP, collagen vascular disease-associated UIP, collagen vascular disease-associated NSIP, and healthy adult volunteers. Receiver operating characteristic curves revealed that HSPI74 was superior to the other markers. The cut-off level for HSPI74 that resulted in the highest diagnostic accuracy was 809.6 pg/ml. The sensitivity, specificity, and diagnostic accuracy were 92.9%, 100%, and 98.2%, respectively. These results suggest that of the markers studied, HSPI74 is the best serum marker for rapidly progressive interstitial pneumonia.

P782 Protease-activated receptor-2 triggers epithelial to mesenchymal transition: Potential relevance in pulmonary fibrosis
Koren Borenztein1, Jan van der Thuisen2, Maike Peppelenbosch3,4, Arnold Spek2,5.

1Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands; 2Histopathology, Royal Brompton Hospital, London, United Kingdom; 3Gastroenterology and Hepatology, Erasmus Medical Center, Rotterdam, Netherlands

Idiopathic pulmonary fibrosis (IPF) constitutes the most devastating form of fibrotic lung disorders. The destructive fibrotic focci characteristic of IPF originate, at least partly, via epithelial to mesenchymal transition (EMT). The extracellular signals and cellular receptors triggering EMT in IPF remain incompletely understood however. Recently, we showed that protease-activated receptor-2 (PAR-2), a transmembrane G-protein-coupled receptor expressed ubiquitously in the lung, is an essential player in fibrotic lung disorders by directly targeting fibroblasts. Here, we explore the role of PAR-2 on epithelial cells by focussing on PAR-2-induced EMT in pulmonary fibrosis. Immunostaining of lung biopsies of IPF patients showed prominent PAR-2 expression by fibroblasts and epithelial cells overlying fibrotic focci. Double stainings indicated that PAR-2 co-localized on cells expressing both epithelial (cytokeratin) and mesenchymal (vimentin) markers, indeed suggesting a role of PAR-2 in EMT in IPF. Subsequent in vitro experiments showed that PAR-2 stimulation induced a fibroblast-like morphology in type II lung epithelial cells, the expression of the myofibroblast markers vimentin and α-SMA, and the secretion of collagen. Interestingly, PAR-2 stimulation triggered β-catenin accumulation and translocation to the nucleus. In conclusion, PAR-2 triggers EMT of epithelial cells and PAR-2 dependent activation of the β-catenin/WNT signaling pathway is probably the main driver of PAR-2-induced EMT. Overall our data thus suggest that inhibition of the PAR-WNT axis may be a clinically relevant treatment option in IPF but also in other disorders in which EMT is essential.

P783 Disruption of Nrf2 enhances susceptibility to pulmonary fibrosis induced by bleomycin in mice
Ko Tamura1,2, Tomoyuki Kakugawa1, Hajime Takizawa2,3,4, Tatsuya Takahashi5,6, Masayuki Yamamoto5,6, Tomoyuki Kawada1, Shoji Kadok2,5.

1Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands; 2Department of Pulmonary Medicine/Infection and Oncology, Nippon Medical School, Tokyo, Japan; 3Fourth Department of Internal Medicine, Teikyo University, School of Medicine, Kawasaki, Japan; 4Department of Anatomy and Embryology, Biomedical and Integrated Medical Sciences, University of Tsukuba, Ibaragi, Japan; 5Department of Internal Medicine, Teikyo University, School of Medicine, Tokyo, Japan; 6Department of Molecular and Cellular Biology, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan

NRF2 is one of the main transcription factors regulating the expression of phase II genes. Stimulation of Nrf2 by antioxidants and drugs strongly improves survival in bleomycin fibrosis. Moreover, we showed that NRF2 is involved in the expression of several pro-collagen V genes and fibroblasts. However, the role of NRF2 in fibroblasts is still unknown. To explore whether NRF2 enhances or suppresses EMT mediated by PAR-2, we generated NRF2−/− mice and compared bleomycin induced fibrosis in NRF2−/− and NRF2+/+ mice. NRF2−/− mice showed significantly increased lung inflammation, fibroblast proliferation, fibroblast got a more fibroblast-like morphology, and increased protein expression of a-SM-A and collagen type 1. In conclusion, NRF2 enhances susceptibility to bleomycin-induced pulmonary fibrosis.
Introduction: Recent studies suggest that N-acylcycteine improve the idio-
pathic pulmonary fibrosis. Oxidant/antioxidant balances may play an important
role in many of the processes of inflammation and fibrosis. Nrf2 is involved in the trans-
scriptional regulation of many antioxidant genes. We therefore investigated the
role of Nrf2 against the development of pulmonary fibrosis in mice.

Materials and methods: Both Nrf2+/- and Nrf2–/– C57BL/6J mice were used. Bleo-
mycin was administered intravenously to the mice at a dosage of 0, 70, 80, and
90 mg/kg body weight on day 0, and the fibroblastic foci were assessed histo-
logically by Ashcroft score determined in the lung tissues on day 28. Furthermore,
bleomycin was administered intravenously to the mice at a dosage of 0, 70, 80,
and 90 mg/kg body weight on day 0, and the bronchoalveolar lavage (BAL) fluid examined for
cell populations on days 0, 3, 7, 10, 14, 21, and 28.

Results: The fibroblastic foci were induced by bleomycin at a dosage of 90mg/kg
body weight on day 14 in both Nrf2+/- and Nrf2–/– mice. The total number of cells and macrophages in the BAL fluid were
significantly increased from day7 after bleomycin administered in both Nrf2+/-
and Nrf2–/– mice. The increased cells number were significantly greater in Nrf2+/-
mice than in Nrf2–/– mice.

Conclusions: These findings suggest that Nrf2 might be an important gene fac-
tor in the determination of susceptibility to bleomycin induced pulmonary fibrosis
by regulating the macrophages defense mechanisms.

P784
αB-crystallin is involved in the process of pulmonary fibrosis
Pieter-Stijn Baelmans1, Guillaume Wettstein1, Careen Garrido1, Jack Gauldie1, Martin Kolb2, Philippe Camus1,2, Philippe Bonnaud1,2
1Stress Protein and Cancer INSERM U866, Dijon, Bourgogne, France; 2Centre of Gene
Expression and Pulmonary Diseases, Centre national de la recherche scientifique, INSERM U866, Dijon, France

Introduction: Idiopathic Pulmonary Fibrosis (IPF) is a devastating disease with
currently no treatment. In the presence of TGF-β, epithelial cells differentiate into
myofibroblasts, key pro-fibrotic cells in a process called epithelial-to-mesenchymal
transition (EMT). αB-crystallin belongs to the small heat shock protein family and is constitutively
expressed in many tissues including lungs. αB-crystallin is inducible by stress
and has a major role in cell cytoskeleton architecture homeostasis by interacting
with intermediate filament elements. The role of αB-crystallin in fibrogenesis is unknown.

Methods: In vitro we induced EMT on A549 cells after TGF-β treatment. In vivo,
Sprague Dawley rats received intra-tracheal administration of AdTGF-β or Ad
empty vector. In these experiments, wild type (WT) or knock out (KO) for
αB-crystallin received intra-tracheal bleomycin (0.07U/mouse).

Results: In vitro during TGF-β1 induced EMT: 1. αB-crystallin is early overex-
pressed, 12 hours before α-SMA overexpression; 2. αB-crystallin colocalize with
α-SMA; 3. αB-crystallin interacts with HSP72/74. The modulation of αB-crystallin plays a role on TGF-SMAD pathway.
In vivo: 1. αB-crystallin is overexpressed in fibrotic areas induced by TGF-β overexpression in rats or bleomycin administration in mice. 2. By day 21, collagen accumulation in the lung was significantly higher in WT mice (3 fold increase, p<0.05) compared to KO mice; 3. The level of TGF-β1 was lower in KO mice after bleomycin injection.

Conclusion: These results provide evidence that αB-crystallin is involved in
pulmonary fibrosis maybe through a role in EMT.

Systemic sclerosis patients’ sera recognize collagen V in experimental
scleroderma lung fibrosis
Natália Borsoselő1, Ana Paula Veloso1, Patricia Martins1, Roberta Marangoni1, Solange Cararas1, Edwin Parra2, Vera Capelozzi2, Natalino Yoshinari1, Walcy Tedeschi1
1Reumatology, Universidade de Sao Paulo, Sao Paulo, Brazil; 2Pathology, Universidade de Sao Paulo, Sao Paulo, Brazil

Background: Type V collagen (COLV) has been recognized as an auto antigen
involved in lung transplantation rejection and may be involved in systemic scle-
rosis pathogenesis (SSc), since immunization of healthy rabbits with this collagen
induced an experimental model with similar characteristic of SSc patients.

Objective: To investigate if SSc patient’s sera recognize COLV present in pul-
monary tissue from this model and collagen isolated from supernatant culture of
pulmonary fibroblasts from these patients.

Methods: Immunofluorescence using collagen type I, III and IV adsorbed sera
from 8 SSc treatment naive patients and from 8 controls was performed to evaluate
COLV reactivity in lung tissue from experimental model. These sera were also
tested by immunoblotting to evaluate COLV reactivity in collagen isolated from
SSc patient’s lung fibroblasts supernatants.

Results: Positive immunofluorescence reaction was observed when the sera of
SSc patients recognized epitopes of COLV in the experimental model vessels walls
and pulmonary interstitium contrasting with the negative reaction observed in

the control. Morphometric analysis confirmed these findings, demonstrating a
higher COLV reactivity to sera from SSc patients when compared to the control
P<0.0028). Immunoblotting showed that SSc patients sera strongly reacted to
COLV standard and to the high molecular weight (fragments of COLV isolated
from SSc lung fibroblasts culture supernatants, different from control sera reactivity
(P<0.02).

Conclusions: SSc patient’s sera recognize COLV epitopes in experimental model
lung tissue and SSc patient’s lung fibroblasts culture supporting that this protein is
an antigen involved in SSc pathogenesis.
P788 Enhanced acute pulmonary inflammation and reduced fibrotic response in quartz-exposed p47phox-deficient mice

Catarina Almeida1,2, Damien van Berlo1, Agnes Boots1,2, Anton Wessels1, Verena Wilhelmi1, Agnes Scherbart1, Kirsten Gerloff1, Francois Haux1, Aal Bast1, Roel Schims1,1, Particle Research, IUU - Leiden Research Institute for Environmental Medicine, Dusseldorft, Germany, 2Toxicology, Maastricht University, Maastricht, Netherlands, 3Industrial Toxicology and Occupational Medicine, Faculty of Medicine, UCL, Brussels, Belgium

Previous studies have shown that quartz (crystalline silica) provides a useful tool to study experimental fibrosis in rodents. In the present study, we have investigated the involvement of-phagocyte-derived reactive oxygen species (ROS) in quartz-induced inflammatory and fibrotic responses. NADPH oxidase p47phox subunit deficient mice and their wild type counterparts were exposed to 100 mg/kg b.w. quartz via a single pharyngeal aspiration. After 24 hours markers of myofibroblast and oxidative stress were investigated in bronchovascular lavage fluid (BALF) and lung tissue. Quartz elicited a strong acute inflammatory response, characterized by a remarkably similar pulmonary influx of neutrophils in both strains. Interestingly, however, luminescence multiple-analysis of BALF revealed stronger increases of interleukin (IL)-1β, IL-6, keratinocyte-derived chemokine (KC), monocyte chemotactic protein-1 (MCP-1) and granulocyte colony stimulating factor (G-CSF) in the knockout mice compared to wild type animals. Differences in IL-4, IL-10, IL-13 and tumour necrosis factor-alpha (TNF-α) were not detectable. In contrast, pulmonary mRNA levels of the oxidative stress markers NADPH oxidase 4 (NOX4) and NADH-oxidase 1 (NOX1) were significantly enhanced only in the wild type mice in response to quartz treatment. Three months after quartz treatment, significantly less fibrosis occurred in the lungs of knockout mice, as indicated by hydroxyproline content and Masson’s trichrome staining. These data show that impairment of NADPH oxidase increases acute inflammatory responses, whereas it reduces oxidative stress and fibrosis in the lungs of quartz-exposed mice.

P789 Muscarinic receptor stimulation differentially regulates extracellular matrix gene expression in lung fibroblasts

Bart Dekkers, Reinoud Gosen, Johan Zaagmina, Herman Meurs. Department of Molecular Pharmacology, University of Groningen, Groningen, Netherlands

Airway fibrosis is a characteristic feature of both asthma and COPD, in which fibroblasts are importantly involved. Increased activity of the cholinergic system may contribute to airway fibrosis, as muscarinic receptor stimulation has been shown to enhance collagen deposition by fibroblasts. The effects of muscarinic receptor stimulation on the expression profile of other extracellular matrix (ECM) proteins, however, remains to be established. To assess the effects of muscarinic receptor stimulation on ECM gene expression, human lung fibroblasts were exposed to 100 μM of the muscarinic receptor agonists methacholine and carbachol in the presence of the fibroblast growth factor TGFB-1 (2 ng/ml), after which ECM gene expression was determined by quantitative PCR. The results demonstrate that methacholine concentration-dependently enhanced gene expression of the laminin α1 chain, whereas expression of the decorin gene was decreased. No effects of methacholine were observed on the gene expression of collagen I, collagen III, fibronectin, biglycan, versican or laminin α2, β1 and γ1 chains. In the presence of TGFB-1, methacholine (10 μM) enhanced gene expression of fibrillin and collagen I. No additional effects of methacholine were observed on the expression of the other ECM genes investigated. Collectively, these results indicate that muscarinic receptor stimulation selectively changes the expression of specific ECM genes, which may contribute to the airway remodelling as observed in asthma and COPD.

P790 Collagen V and decorin is involved in systemic sclerosis pulmonary fibrosis

Patricia Martin1, Ana Paula Veloso1, Adriana Santos1, Solange Carrasco2, Angela Santos2, Edwin Parra2, Claudia Goldenstein-Schlaberg3, Natalino Yoshinari1, Vera Capelozzi1, Teodoro Waley3,1, Rheumatology, 2Pathology, Universidade de São Paulo, São Paulo, Brazil

Background: Systemic sclerosis (SSc) is characterized by vasculopathy, inflammation, autoimmunity and fibrosis. Collagen V (COLV) is involved in SSc since increased amount of unusual COLV in SSc lung patients indicating a role for this protein. We evaluated COLV and decorin expression and tridimensional reconstruction of fibroblasts culture used quantitatively.

Methods: We evaluated COLV and decorin expression and tridimensional reconstruction by immunofluorescence in SSc patients without pulmonary hypertension that underwent surgical lung biopsy (n=6) and healthy controls from trauma (n=6). Biochemical characterisation of COLV from lung fibroblasts culture used quantitatively.

Results: COLV fibers was distorted and thickened in SSc lung tissue compared to thin fibers of controls. Decorin was distributed around COLV fibrils in the bronchovascular interstitium and vascular walls. Histomorphometric analysis of SSc demonstrated increased expression of COLV in group B (p<0.01) and decorin (p<0.01) when compared to control. Immunoblotting detected an increased high molecular weight COLV fraction in SSc (p<0.02).

Conclusion: Over expression and unusual organization of COLV fibers with biochemical changes associated to increased decorin indicates that matrix signalization pathway is involved in COLV fibrogenesis process in SSc pulmonary fibrosis.

P791 The effect of erythropoietin (EPO) on collagen type-2 (COL-2) and cytokrome-c (CYT-c) in the bleomycin (BLM)-induced pulmonary fibrosis (PF) in rats

Drossos Tavsil, Anna Tzoumaka, Georgia Kokaraki, Kokkina Kouzi-Kolakos, Ioannis Angomachalos, Anastasia Tektonidou, Dimitrios Koutsomarakis, Evangelia Spandonou. Experimental Physiology, School of Medicine, Aristotle University, Thessaloniki, Macedonia, Greece

Purpose: The enzymes COL-2 and CYT-c are known to be a part of the fibrictic pathway. EPO is a multiple functional cytokine with anti-inflammatory and anti-apoptotic properties. Aim of this study was to investigate the role of EPO on the expression of both enzymes in BLM-induced PF in rats.

Methods: Fifty Wistar rats (300gr) were divided into five groups of 10 animals each: 1)control animals,2)intratracheal (i.t) and intraperitoneal (i.p) injection of bleomycin (0.5mg/kg) i.t injection,3)BLM hydrochloride (7.5mg/kg) i.t injection followed by EPO (1 i.p injection 2000 iu/kg),suladine (0.5mg/kg) i.t injection followed by EPO i.p injection (2000 iu/kg). All rats were necropsied after 14 days. Histomorphometric evaluation was performed for the expression of COL-2 and CYT-c. A scale of 4 grades was used for the evaluation of the results: 0.25% (A), 25-50% (B), 50-75% (C), 75-100% (D).

Results: In groups 1,2 and 5, both COL-2 and CYT-c were expressed in the grade A (80%) and in the grade B (20%). In group 3, COL-2 was expressed in the high grades B (20%), C (60%) and D (20%), and CYT-c only in the two higher grades. C (70%) and D (30%). In group 4 both enzymes were expressed only in the low grades A (80% and 70% respectively) and B (20% and 30% respectively). The expression of COL-2 and CYT-c took place in the high grades for BLM group and in the lower grades for BLM+EPO group (p<0.001 and p<0.05 respectively).

Conclusions: BLM injection followed by EPO resulted in significant lower expression of COL-2 and CYT-c compared with BLM group. The protective mechanisms of EPO on PF must be further clarified.

P792 Microparticles-associated tissue factor activity is increased in bronchovascular lavage of patients with pulmonary fibrosis and correlates with functional impairment

Federica Novelli, Tommaso Neris, Concertina Noce, Laura Tavanti, Stella Cini, Federica Martino, Alessandro Celi, Pierluigi Paggiaro. Federica Novelli, Tommaso Neris, Concertina Noce, Laura Tavanti, Stella Cini, Federica Martino, Alessandro Celi, Pierluigi Paggiaro. Cardiac, Thoracic and Vascular Department, University of Fisa, Pisa, PI, Italy

Background: The activation of the coagulation cascade plays a role in theogenesis of pulmonary interstitial fibrosis. Furthermore, microparticles (MP) are effective in experimental lung fibrosis and possibly in patients with idiopathic pulmonary fibrosis. Microparticles (MP) are cell derived procoagulant and proinflammatory vesicles that can express tissue factor (TF); MP represent a storage pool of bioactive effectors and are emerging as a new family of physiologically relevant mediators. Aim: To evaluate the presence of TF-bearing MP in the bronchovascular lavage fluid (BALF) of patients with pulmonary fibrosis (PF) in comparison with control patients, and to correlate their concentration with the degree of functional impairment.

Methods: Seven patients with PF and 10 control patients with suspected lung cancer or infectious diseases underwent bronchoscopy. The presence of MP was evaluated through a prothrombinase assay that measures phosphatidylserine (PS) concentration; TF activity was assessed by a one-stage clotting assay.

Results: The BALF of patients with PF had a higher concentration of microparticles (87.23 [67.21-108.8] vs 49.19 [29.50-77.22] nM PS, p<0.05) and a greater TF activity (27144 [1723-29998] vs 8596 [4019-21962] arbitrary U, p<0.05) (data expressed as median [interquartile range]). We found a significant negative correlation between MP-associated TF activity and forced vital capacity% predicted (r²=95, p<0.001 and DLCO% predicted r²=96, p=0.05).

Conclusions: Our preliminary data are consistent with an involvement of TF-bearing procoagulant MP in the pathogenesis of PF and in disease progression.

P793 Study of tetradhydrobiopterin in idiopathic pulmonary fibrosis and COPD

Patricia Almudever Folch1,3, Alfredo De Diego Damia2, Julio Cortijo Gimeno1,2,3, Montserrat León Fábregas2, M.J. Fandós2, Xavier Milara1,3.

1Research Unit, University-General Hospital, Conxo, Vigo, Spain, 2Service of Pneumology, University and Politècnic Hospital La Fe, Valencia, Spain, 3CIBERES, Health Institute Carlos III, Valencia, Spain, 4Department of Pharmacology, University of Valencia, Valencia, Spain

Introduction: Tetradhydrobiopterin (BH4) is an essential cofactor for the activity
of nitric oxide synthase enzyme (eNOS). Deficiency of BH4 induced by oxidative stress could produce eNOS uncoupling and contribute to pulmonary damage. 

**Objective:** To study the role of endogenous BH4 in patients with stable idiopathic pulmonary fibrosis (IPF) and chronic obstructive pulmonary disease (COPD).

**Materials and methods:** Twenty-eight patients (15 IPF, 13 COPD; 61 (13) years) and 9 healthy controls were studied. Lung function tests (spirometry, plethysmography and lung diffusion capacity), HRCT (High Resolution Computed Tomography) lung scan and 6-min walk test were performed in all patients. Blood neutrophilic, plasma BH4 (reverse-phase high-performance liquid chromatographic (RP-HPLC) with fluorescence detection), hemoglobin, fibrinogen, and CRP were also measured. Differences in BH4 levels between groups and its relationship with clinical, functional or biological parameters of disease severity were analyzed.

**Results:** BH4 was significantly reduced in IPF (1.32 ± 0.16), and COPD (1.44 ± 0.27) patients versus controls (2.42 ± 0.29). There were no differences in BH4 levels between either IPF and COPD or bronchitis and emphysema phenotypes. BH4 levels were not related with parameters of lung function, radiological extension, inflammatory markers or smoking severity. In patients with COPD, BH4 levels were related with the number of previous exacerbations.

**Conclusions:** Plasma BH4 levels are reduced in IPF and COPD, which may be of potential value as a future biomarker of oxidative stress-related diseases.

**Supported by grant SVN 2010 and CIBERES (CB06/060027)**

P794

**Increase of nitrosative stress in patients with eosinophilic pneumonia**

Kanako Furukawa, Hisatoshi Sugita, Kazuto Matsumaga, Tomohiro Ichikawa, Akira Kikumoto, Manabu Iida, Takashi Ichikawa. Third Department of Internal Medicine, Wakayama Medical University School of Medicine, Wakayama, Japan

**Background:** Exhaled nitric oxide (NO) production is increased in asthma and reflects the degree of airway inflammation. The alveolar NO concentration (Calv) in interstitial pneumonia is reported to be increased compared to that in asthma. However, it remains unknown whether NO production is increased and nitrosative stress occurs in eosinophilic pneumonia (EP).

**Objective:** We hypothesized that nitrosative stress markers including Calv, inducible type NO synthase (iNOS), and 3-nitrotyrosine (3-NT), are upregulated in EP.

**Methods:** Exhaled NO was measured in healthy subjects and in patients with interstitial pneumonia including idiopathic pulmonary fibrosis (IPF), cryptogenic organizing pneumonia, hypersensitivity pneumonitis, sarcoidosis and EP. iNOS expression and 3-NT formation were assessed by immunocytochemistry in BALF cells. The exhaled NO, lung function, and systemic inflammatory markers of the EP were evaluated after corticosteroid treatment.

**Results:** The Calv levels in the EP group were significantly higher than those in the healthy subjects and the other interstitial pneumonia groups as well as the fractional exhaled NO (FeNO) levels. More iNOS and 3-NT positive cells were observed in the EP group compared to the healthy subject and IPF patient. The Calv levels had significant correlations with both iNOS (p < 0.05) and 3-NT positive cells (p < 0.05). Corticosteroid treatment significantly reduced both the FeNO (p < 0.05) and the Calv levels (p < 0.01). The magnitude of reduction in the Calv levels had a significant correlation with the peripheral blood eosinophil counts (p < 0.05).

**Conclusion:** These results suggested that nitrosative stress was augmented in EP and may be involved in the pathogenesis.

P795

**Molecular mechanism of lung aging in senescence-accelerated mouse (SAM)**

Yiming Yuan1, Xiuying Hu2, Li Luo1, Ming Yang1, Zhiqiang Su2,1, Xiaoyan Zhang1,2,2 1Department of Geriatrics, West China Hospital, Sichuan University, Chengdu, China; 2Cardiovascular Research Section I, West China Hospital, Sichuan University, Chengdu, China

The SAM strains are a collection of inbred mouse strains developed as models of accelerated aging, and include nine short-lived, the senescence-prone strains (SAMP) and three longer lived control strains designated the senescence-resistant strains (SARD). The SAMP was suggested as a new murine model of aging lung. However, molecular mechanism of accelerated lung aging remains to be elucidated. By using quantitative real time RT-PCR and western blot, here we show that expression of FOXO, a forkhead transcription factor that acts downstream of the PTEN/P13K/Akt pathway and a key regulator of stress resistance, metabolism and aging, was significantly decreased in aged SAMP mice compared to normal aging control SARD mice. The decreased expression of FOXO gene was correlated with elevation of reactive oxidative species (ROS) and thiobarbituric acid reactive substances (TBARS), reduced mRNA expression levels of superoxide dismutase (SOD) and lung and renal caspase 3, 7 and 9 (casp 3, 7 and 9) as well as greater right ventricular hypertrophy and cardiac fibrosis in SAMP mice lungs. Based on these findings we concluded that reduced FOXO activity may contribute to accelerated lung aging in this animal model. Given that FOXO proteins play a critical role in maintaining the quiescence and renewal capacity in hematopoietic stem cells and neural stem cells, manipulation of FOXO in lung progenitor cells may represent a novel approach to lung regenerative medicine and chronic lung disease such as COPD.

P796

**Aging and smoking contribute to plasma surfactant proteins and protease imbalance with correlations to airway obstruction**

Helen Biemets1, Wiroud Mazur1, Paula Toljama2, Noora Louhelainen3,1, Pentti Nieminen2, Hideo Kobayashi4, Nobuhsia Ishikawa1,3, Yuukko Kimmula1,2,4 1Department of Medicine, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland; 2Department of Medicine, Lapland Central Hospital, Rovaniemi, Finland; 3Medical Informatics and Statistics Research Group, University of Oulu, Oulu, Finland; 4Department of Medicine, National Defense Medical College, Tokorozawa, Japan; 1Departments of Molecular and Internal Medicine, Hiroshima University, Hiroshima, Japan

**Background:** A significant number of young people start smoking at an age of 13-15, which means that serious smoking-evoked changes may have been occurred by their twenties. Surfactant proteins (SP) and matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) have been linked to cigarette smoke induced lung remodelling and COPD. However, the level of these proteins has not been examined during aging or in young individuals with short smoking histories.

**Methods:** Plasma levels of SP-A, SP-D, MMP-9, and TIMP-1 were measured by ELISA/ELISA from young (18-23 years) non-smoking controls (YNS) (n=56), smokers (YS) (n=51), middle aged/elderly (37-77 years) non-smoking controls (ONS) (n=40), smokers (OS) (n=64) (FEV1/FVC < 0.7 in all subjects) and patients with COPD (n=44, 35-79 years).

**Results:** Plasma levels of SP-A increased with age and in the older group in relation to smoking and COPD. Plasma SP-D and MMP-9 levels did not change with age but were elevated in OS and COPD as compared to ONS. The TIMP-1 level declined with age but increased in chronic smokers when compared to ONS. The clearest correlations could be detected between plasma SP-A vs age, pack years and FEV1/FVC. The receiver operating characteristic (ROC) curve analysis revealed SP-A to be the best marker for discrimination between patients with COPD and the controls (area under ROC curve of 0.842; 95% confidence interval, 0.785-0.899; p < 0.001).

**Conclusions:** Age has a significant contribution to potential markers related to smoking and COPD, SP-A seems to be the best factor in differentiating COPD from the controls.

P797

**Endothelial dysfunction in preterm infants with respiratory disorders**

Alekandr Marazov, Iryna Yablons. Pulmonology, Vinnytsia Regional Children's Hospital, Vinnytsia, Ukraine

**Actualiy:** Respiratory disorders accompanied by endothelial disorders, but the clinical manifestations of changes in rates which characterize endothelial function in neonatology is neglected, because the purpose of our study was to establish clinical significance of endothelial dysfunction in preterm infants with respiratory disorders by the value of serum vascular endothelial growth factor (VEGF).

**Materials and methods:** The main group 67 children, who at birth had diagnosed respiratory distress syndrome. The average birth weight 1473,1±97,4 g, gestational age - 29±8.6 weeks. In the controling group were included 20 premature infants with birth weight 1529,5±82.8 g and gestational age 30,6±6,0 weeks without respiratory disorders.

**Results and discussion:** The values of serum VEGF at 5-7 day of life in children of all investigated groups did not differ significantly (by 124±93,1 and 135±83,2 pg/ml, p > 0.05). In dynamics, 28 day life, we set the negative trend in the core group of children (114,1±24,5 to 328,8±92,3 pg/ml in the comparison group, p < 0.05). Regression analysis established the relationship between the values of serum VEGF at 5-7 day of life and indicators of body weight (r=0,62, p < 0.05), duration of gestation at birth (r=0,64, p < 0.05) and indicators of body weight (r=0,62, p < 0.05) and duration of mechanical ventilation (r=0,89, p < 0.05).

**Conclusions:** The low value of VEGF for 5-7 day of life in preterm infants with respiratory failure and lack of growth in the dynamics indicate low ability to restore damaged capillaries and the risk of chronic disease.

P798

**Neutral sphingomyelinase 2 (nSMase2) has a protective role in emphysema**

Christophe Poirier1, Natalia Bogatcheva1, Christiana Dimitropoulou1, Paul Biddinger2, Alexander Verin1. Medicine, Georgia Health Sciences University, Augusta, GA, United States; 2Pathology, Georgia Health Sciences University, Augusta, GA, United States

**Introduction & background:** nSMase2 is an enzyme converting sphingomyelin into ceramide. Others have expressed that nSMase2 activation and ceramide production are linked to emphysema development. The goal of this study was to test the effect of nSMase2 deficiency on lung phenotype in mice.

**Hypothesis:** The mouse mutant model for nSMase2 deficiency, nSMase2 -/-, is the most effective model of nSMase2 knockout due to the expression of nSMase2 encoding gene, rendering this enzyme inactive. In this study, we analyzed lung histology and lung function in adult nSMase2 -/- mice.

**Method:** Mean linear intercept (Lm) and alveolar destructive index (DI) were used to assess morphological changes in lungs. Lung compliance was measured to assess changes in lung function.

**Results:** We found that lungs of nSMase2-deficient mice exhibited emphysematous changes. Both Lm and DI were significantly increased in nSMase2 -/- mice.
study, for the first time, MV with and without recruitment manoeuvres (RM) was compared in healthy mice. The effects of RM on a variety of physiological parameters and pulmonary inflammation were studied after 6h.

C57Bl/6 mice were ventilated for 6h at low–VT=8mL/kg, f=180/min or high–VT=16mL/kg, f=90/min and 3% inspiratory CO2. FiO2 was 0.5 and PEEP 2cmH2O. RM were performed with 30cmH2O for 1s every 5min, 60min or not at all. Lung mechanics were followed by the forced oscillation technique. Blood pressure (BP), ECG, heart frequency (HF), oxygen saturation and body temperature were monitored. Blood gases, histopathology, neutrophil recruitment, microvascular permeability and pro-inflammatory cytokines were examined. MV with recurrent RM resulted in stable respiratory mechanics. Ventilation without RM worsened lung functions due to alveolar collapse, leading to impaired gas exchange. HF and BP were not affected. Microvascular permeability was highest in atelectatic lungs, whereas neutrophil recruitment and structural changes were strongest in lungs ventilated with high VT. Although IL-6 and KC were markedly elevated in all ventilated mice, levels were clearly reduced by recurrent RM. In contrast, TNF-α and IP-10 remained at baseline, indicating that only moderate lung injury was induced. We conclude that recurrent RM are required to prevent atelectasis and resulting lung injury during mechanical ventilation of healthy mice.

**P801**

Patterns of plasma membrane disruptions distribution in mechanically ventilated lungs

Matteo Cecchi1, Ario Monaco1, Antonia Koutoukou2, Edgardo D’Angelo3.

1 Dipartimento di Fisiologia Umana, Università degli Studi di Milano, Milan, Italy; 2 Department of Respiratory Medicine, University of Athens Medical School, Athens, Greece

**Rationale:** Abnormally high stresses applied to a cell can result in the loss of cell membrane integrity and the formation of direct communications between intracellular and extracellular spaces, called plasma membrane disruptions (PMD). These lesions could be involved in the genesis of biotaaurma as upregulators of pro-inflammatory mediators expression. Observations limited to the subpleural alveoli only indicate that PMD take place during mechanical ventilation with large tidal volumes (VT) and a normal end-expiratory lung volume (EELV). It is unknown if PMD develop during low EELV ventilation with physiological VT.

**Objectives:** To see if a) mechanical ventilation with physiological VT at low EELV causes PMD, and b) the parenchymal distribution of PMD differs between ventilation with large VT at normal EELV and ventilation with physiological VT at low EELV.

**Methods:** PMD have been detected as red spots in gelatin included slices of rat lungs stained with ethidium homodimer-1 shortly after anesthesia, after prolonged ventilation at low EELV followed or not by the restoration of physiological EELV, and after prolonged ventilation with large VT and normal EELV. Analysis of lavage fluid showed that both treatments abolished PMD differences between ventilation with large VT at normal EELV and ventilation with physiological VT at low EELV.

**Conclusions:** Entity and distribution of PMD depends on the type of injurious mechanical ventilation.

**P802**

Dexamethasone reduces lung inflammation induced by alveolar stretch in mice

Jessica Hegeman1,2,3, Marije Hennus1, Pieter Cobeledo1,4, Annemieke Kavelaars1, Nicolaas Jansen1, Koen van der Sluijs1, Marcus Schultz1,5, Adrianus van Vught3, Cobi Heijnen2.

1 Laboratory Experimental Medicine, 2Department of Pathology and Medicine, University of British Columbia, Vancouver, BC, Canada; 3R&D, AstraZeneca, Charnwood, Loughborough, United Kingdom; 4Department of Intensive Care Medicine, University Medical Centre Utrecht, Utrecht, Netherlands; 5Department of Intensive Care Medicine, Academic Medical Center Amsterdam, Amsterdam, Netherlands

**Background:** Although mechanical ventilation is a life-saving procedure, the associated alveolar stretch can provoke lung injury (ventilator-induced lung injury, VILI). At present, it is thought that ventilator-induced lung injury may precede lung injury. Activated granulocytes are known to induce oxidative stress and protease activity in alveoli, causing alveolar-capillary barrier disruption and lung dysfunction.

**Aim:** To study the anti-inflammatory action of dexamethasone, a widely used glucocorticoid, in mice exposed to either low or high alveolar stretch.

**Methods:** C57Bl/6 mice were mechanically ventilated for 5 hours with either an inspiratory pressure of 10 cmH2O (“low” tidal volumes (VT) ∼7.5 mL/kg, LV=10 cmH2O) or 18 cmH2O (“high” VT ∼15 mL/kg, HV=18 cmH2O). Dexamethasone was intravenously administered at initiation of ventilation. Non-ventilated mice served as controls. Inflammatory mediator expression and granulocyte influx were determined in lung homogenates. Differential cell counts were done on BALI cytospin preparations.

**Results:** Both LV and HV ventilation increased inflammatory mediator ex-
pressure in lung tissue which was accompanied by granulocyte influx (p<0.05). BALf neutrophil numbers and inflammatory mediator expression (KC, IL-1) were enhanced in HV-ventilated mice compared to LV-ventilated mice (p<0.05). Dexamethasone inhibited lung inflammation caused by LV or HV-ventilation (p<0.05).

Conclusion: Dexamethasone prevents inflammatory mediator expression and granulocyte influx of lungs exposed to low or high alveolar stretch. Dexamethasone treatment may be considered as a potential therapeutic strategy to inhibit the inflammatory response during mechanical ventilation.

P803
Intermediolin stabilized endothelial barrier function and attenuated ventilator-induced lung injury in mice
Holger Christian Müller1, Wolfgang Kummer2, Uwe Pfitz1, Katharina Hellwig1, Daniel Will1, Andreas Christian Hocke1, Stefan Hippenstiel1, Norbert Suttorp1, Wittenham Martin1
1Department of Infectional Diseases and Pulmonary Medicine, Charité - Universitätsmedizin Berlin, Berlin, Germany; 2Anatomy and Cell Biology - University of Giessen Lung Center, Justus Liebig Universität Giessen, Giessen, Germany

Rationale: Even protective ventilation may aggravate or induce lung failure, particularly in prejured lungs. Thus, new adjuvant pharmacologic strategies are needed to attenuate ventilator induced lung injury (VILI). Intermediolin/Adrenomedullin II (IMD) stabilized pulmonary endothelial barrier function in vitro. We hypothesized that IMD may attenuate VILI-associated lung permeability in vivo.

Methods: Human umbilical vein endothelial cell (HUVEC) monolayers were incubated with IMD and transendothelial electrical resistance was measured to quantify endothelial barrier function. Expression and localisation of endogenous pulmonary IMD and its receptor complexes composed of CRLR and RAMP-3 were analyzed by qPCR and immunofluorescence in unventilated mouse lungs and in lungs ventilated for 6h. In untreated and IMD treated mice, lung permeability and pulmonary leukocyte recruitment was assessed after mechanical ventilation.

Results: IMD stabilized endothelial barrier function in HUVECs. Mechanical ventilation reduced the expression of RAMP 3, but not of IMD, CRLR, and RAMP1 and 2. Mechanical ventilation induced lung permeability, which was ameliorated by IMD treatment. IMD did not reduce VILI associated pulmonary leukocyte recruitment.

Conclusion: We showed for the first time that IMD had endothelial barrier stabilizing properties in vivo. IMD may possibly provide a new approach to attenuate ventilator-induced lung injury.

P804
Plasma levels of LL37 in patients with and at risk of acute lung injury
Rachel Dance1, Gavin Perkins1, Daniel Park1, David Thacken1
1Department of Respiratory Science, University of Birmingham, Birmingham, United Kingdom; 2Clinical Trials Unit, University of Warwick, Coventry, United Kingdom

Cathelicidins are a group of antimicrobial peptides with a wide range of functions including immunomodulation, chemotraction, angiogenesis and antimicrobial effects. LL-37 is the active form of the only known human example of a cathelicidin, HCAP-18. It is induced by the local action of L-25-0H vitamin D. LL37 is expressed by many different cell types including lung epithelial cells, neutrophils and other immune cells. We have shown that patients with severe vitamin D deficiency have an increased risk of Acute Lung Injury post-oesophagectomy and hypothesized that this may be related to the effects of vitamin D on LL37.

Methods: Plasma levels of LL37 were determined by ELISA in a cohort of patients with Acute Lung Injury and in a cohort of patients at risk of Acute Lung Injury due to undergo oesophagectomy.

Results: Average pre-operative plasma LL37 levels in the oesophagectomy cohort were 117.2 ng/ml and post operative levels are significantly lower (p=0.027, paired t test). In our ALI cohort, median levels of LL37 on day 0 lower than normal levels (p=0.017). LL37 levels correlate with vitamin D status, however, preoperative LL37 levels did not predict Acute Lung Injury.

Conclusion: LL37 levels are lower than normal in patients with Acute Lung Injury and fall progressively in patients undergoing oesophagectomy. The mechanism underlying this is unclear and requires further evaluation, but may be related to vitamin D deficiency in these patients.

P805
Preventive and therapeutic effects of phosphoinositide 3-kinase inhibitors on acute lung injury
Xiaocong Fang1, Chengshui Chen2, Yaoli Wang1, Xuewen Chen1, Chunxue Bai1, Xiangdong Wang1,2
1Department of Respiratory Science, University of Birmingham, Birmingham, United Kingdom; 2Clinical Trials Unit, University of Warwick, Coventry, United Kingdom

Rationale: Acute lung injury and acute respiratory distress syndrome (ALIARDS) are severe disorders. Pulmonary injury is at the endothelial cell (EC) barrier with increased permeability. Our in vitro studies demonstrate that adenosine protects from the bacterial toxin lipopolysaccharide (LPS) induced barrier dysfunction.

Hypothesis: Based on the known activation of the A2A adenosine receptor (A2AR) with adenosine it was hypothesized that the A2A agonist, CGS 21680 (CGS), would attenuate the LPS disrupted EC barrier in vivo.

Methods: Control and A2AR knock out (KO) mice were given normal saline (NS) or LPS intratracheally. NS or CGS was instilled intravenously (IV) at the same time or 3hrs later. At 22 hours Evans Blue Dye albumin (EBD) was instilled IV, at 24hrs the samples were collected. Bronchoalveolar lavage (BAL) was done and the lungs harvested. Cell counts, protein and EBD extravasation were analyzed.

Results: LPS caused an increased number of cells in the LPS/adenosine treated mice and the KO mice treated with CGS at 3hrs consistently demonstrated a decreased cell count. LPS challenge increased the protein in BAL and EBD from lung, the protein and EBD were significantly attenuated in the LPS/adenosine treated mice but not in the CGS treated mice.

Conclusions: Adenosine significantly attenuates the LPS induced EC barrier dysfunction in mice. The A2AR agonist, CGS, attenuates the cell count but not the protein or EBD extravasation. Other adenosine receptors or mechanisms may be involved in the significant improvement of protein and EBD barrier disruption that occurs with adenosine treatment.
PN07
Use of lipids in a murine model of ALI and lymphocyte apoptosis – Harmful or beneficial?
Juliane Ott, Britta Bausch, Matthias Rose, Andrea Mohr, Matthias Hecker, Werner Seeger, Konstantin Mayer. Internal Medicine, University of Giessen Lung Center, Giessen, Germany

Acute lung injury (ALI) and sepsis remain major challenges in critical care. While a massive inflammation determines early sepsis, apoptosis of lymphocytes is a hallmark of late sepsis. Lipid emulsions (LE) base used in critically ill to maintain caloric intake. Fish oil (FO) based LE are considered as alternative with immunomodulatory impact. We investigated the effects of LE in a murine model of ALI.

Mice were infused with SO, FO or NaCl. 24 h after intratracheal instillation of 10 µg lipopolysaccharid (LPS), a bronchoalveolar lavage (BAL) was performed to determine numbers of leukocytes, protein and cytokines. Lymphocytes were isolated from spleen and apoptosis was determined by FACS. LPS induced a massive invasion of leukocytes into the airspace compared to unstimulated controls. Infusion of SO amplified whereas FO attenuated the rise. Both, insulin and FasL expression were increased which was further increased by SO. Infusion of FO reduced protein as well as TNF after LPS. Before LPS, infusion of SO induced a significant rise in apoptosis of lymphocytes. After LPS, a reduced number of lymphocytes accompanied with a rise in apopto-sis was detected in all groups with FO infused mice showing significantly less apoptosis compared to SO.

In a murine model of ALI the choice of lipid emulsions is able to influence inflammatory parameters. Induction of ALI is paralleled by reduced lymphocytes with increased apoptosis in the spleen. SO leads to massive apoptosis in lymphocytes even before ALI. Infusion of FO attenuated the rise in ALI-induced apoptosis. Modulating the lipid emulsions used for nutrition may be relevant for critically ill, and may have impact on outcome.

PN08
Eugenol dose-dependent improvement of pulmonary lesions in lipopolysaccharide acute lung injury
Claudia Magalhães, Natália Casquilho, Mariana Machado, Douglas Riva, Rodrigo Fortunato, José-Henrique Leal Cardoso, Leonardo Travassos, Walter Zin, Carlos Chagas Filho Institute of Biophysics, Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil; 2Biomedical Sciences Institute, State University of Ceará, Fortaleza, Ceará, Brazil

Background: Eugenol, a methoxypyrenyl component of clove oil, inhibits NFκB activation induced by TNF-α in LPS-stimulated macrophages.

Aim: To evaluate the effects of different doses of eugenol on lung mechanics, histology and cytokines in LPS-injured lungs.

Methods: Mice were randomly divided into 9 groups (n=5-8/group). Mice received intratracheally sterile saline solution (0.05 ml) or LPS (10 µg in 0.05 ml of saline): 6 h later they received sterile saline (0.2 ml) and TNF-α (1% and 2% groups) or different doses of eugenol: 16, 65, 114, 160, 650 or 1140 mg/kg in saline (0.2 ml) and TNF-α (1% (LE1), LE2, LE3, LE4, LE5, LE6 and LE7 groups, respectively) by gavage. Mice were evaluated 24 h after receiving LPS. In another 18 mice [C=6, L=6, E=3 (saline followed by eugenol) and LE=3]; in theory similar; TNF-α or IL-10 were detected by ELISA in lung homogenates at 6 (C=3 and L=3) and 24 h (C=3, L=3, E=3 and LE=3) after LPS administration. One-way ANOVA followed by Tukey test was used (α=5%).

Results: Static elas-tance, viscoelastic component of elastance and viscoelastic resis-tive pressure were higher in L group (33.05, 5.01 cmH2O/ml and 1.00 cmH2O respectively) than in C (22.13, 3.62 cmH2O/ml and 0.71 cmH2O), accompanied by alveolar collapse and collagen fiber deposition; eugenol reduced the parameters compared to unstimulated controls. Infusion of SO amplified whereas FO attenuated the rise. Both, protein and TNF exhibited a LPS-induced rise which was further increased by SO. Unstimulated controls. Infusion of FO reduced protein as well as TNF after LPS. Before LPS, infusion of SO induced a significant rise in apoptosis of lymphocytes. After LPS, a reduced number of lymphocytes accompanied with a rise in apopto-sis was detected in all groups with FO infused mice showing significantly less apoptosis compared to SO.

Conclusion: Eugenol exhibits an in vivo anti-inflammatory dose-dependent action in LPS-induced lung injury. Supported by: CNPq, FAPERJ, MCT.

PN09
Increased uric acid levels in bronchoalveolar lavage fluid of mice infected with H1N1 influenza
Maria Kuipers, Maria Hegeman, Hamid Aslami, Geartrui Jongma, Catharina Wieland, Marcus Schultz, Koenaard van der Sluijs, Laboratory of Experimental Intensive Care and Anesthesiology, Academic Medical Center, Amsterdam, Netherlands

Rationale: Lower respiratory tract infections with influenza are associated with severe inflammatory responses, which may result in ALI/ARDS. Tissue injury results in the release of damage-associated molecular patterns (DAMPs), such as uric acid and ATP, leading to NLRP3 inflammasome activation and IL-1β release. Hypothesis: We hypothesized that influenza-induced lung injury is associated with the release of DAMPs into the airway lumen.

Methods: C57Bl/6 mice were inoculated with 10ICD50 influenza A/PuR8/34 (H1N1) and sacrificed 4, 8 and 14 days later to collect BALF to determine uric acid, extracellular ATP and markers of inflammation and lung injury. Non-infected mice were sacrificed on day 0 for control measurements.

Results: Influenza virus infection resulted in bodyweight loss between day 6 and day 11 (p<0.05) and returned to normal values on day 14 after infection. Uric acid levels in BALF were significantly increased on day 8 after viral infection (52.7-119.9 µM vs 12.2-25.8 µM in control mice, 95% CI: p<0.01), while ATP was undetectable. Uric acid in BALF was associated with increased levels of inflammatory markers (IL-6, KC and IFN-γ) as well as markers of lung injury (sRAGE and total protein in BALF). However, increased IL-1β levels, indicative for inflammasome activation, were only observed on day 4 after influenza infection (p<0.01).

Conclusion: Uric acid in BALF is increased during influenza infection and associates with biomarkers of inflammation and lung injury, but not with sRAGE. Our data suggests that Vitamin D plays a role in the maintenance of antigenic cell death. sFasL inhibited proliferation of ATII in actions that were protective against apoptotic cell death.

PN11
Modeling resolution of direct acute lung injury
Brijesh Patel, Michael Wilson, Masao Takata. Section of Anesthesiology, Pain Medicine and Intensive Care, Imperial College London, London, United Kingdom

Translational animal models allowing the study of both inflammatory and resolution phases of acute lung injury (ALI) are lacking. Widely used models including intratracheal endotoxin or bleomycin are difficult to translate. Here we developed and optimized a reproducible model of resolving aspiration pneumonitis that mimics human ALI.

C57Bl/6 mice were instilled intratracheally with 75µl of 0.1M hydrochloric acid by direct laryngoscopy under anesthesia. At specified timepoints up to 10 days after instillation, respiratory mechanics, arterial blood gases, soluble mediators in bronchoalveolar lavage fluid (BALF), and alveolar fluid clearance (AFC) using an in situ preparation were measured. Acid instillation produced significant increases in BALF protein levels and respiratory elastance. BALF levels of TNF and soluble RAGE, a marker of epithelial damage, both increased, while AFC deteriorated. All of these parameters peaked at day 1-3 post-acid, but resolved by days 5-10. These results indicate that the model replicates major hallmarks of ALI, i.e. changes in respiratory mechanics, gas exchange, lung permeability, inflammation

Fas activation impairs the alveolar epithelial function in mice by mechanisms involving apoptosis
Raquel Herrero1, Lincoln S. Smith1, Osamu Kajikawa1, Stephen Mongovin1, Venus A. Wong1, Gustavo Mateo-Bellet2, Thomas Medical Center Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA, United States; 2Center for Lung Biology Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA, United States

Background: Alveolar epithelial damage is a critical event that leads to protein-rich edema in acute lung injury (ALI). Even though Fas activation induces apoptosis of alveolar epithelial cells, its role in the formation of lung edema is unclear.

Aim: We investigated whether inhibition of caspase-dependent apoptosis protects against Fas-mediated alveolar epithelial injury in mouse lungs.

Methods: We administered the pan-caspase inhibitor Z-VAD.fmk (10 mg/kg) or vehicle subcutaneously to mice treated with one intratracheal dose of recombinant human fasL (rh-fasL; 50 ng) or PBS, then studied the mice 1 h later. We measured alveolar fluid clearance (AFC) by intratracheal instillation of FITC-human albumin, and protein permeability by measuring IgM in bronchoalveolar lavage fluid. Caspase-3 activity and cytokines (IL-β, IL-6, KC, TNF-α) were measured in lung homogenates.

Results: Compared with PBS-treated mice, the intratracheal instillation of rh-fasL decreased AFC (PBS: 20.1±1.5% vs rh-fasL: 19.6±1.4%, p<0.05), and increased protein permeability (PBS: 34.7±18.3 vs rh-fasL: 350±40.4 ng/mL, p<0.05), caspase-3 activity and cytokine production. In contrast, mice treated with rh-fasL and Z-VAD.fmk had normal AFC (17±0.3±3%, p<0.05) and a smaller increase in protein permeability (153±18.4 ng/mL, p<0.05), associated with a reduction in caspase-3 activity and an increase in cytokine production. Z-VAD.fmk was not harmful in PBS-treated mice.

Conclusion: Activation of the Fas pathway impairs the alveolar epithelial function in mouse lungs by mechanisms involving caspase-dependent apoptosis, suggesting that targeting apoptotic pathways could reduce the formation of lung edema in ALI.

PL13
Resolvin D1 attenuates lung inflammation in LPS induced-ALI partly through PPARα signaling
Zenglin Liao1, Jiajia Dong 1, Tao Wang2, Fuqiang Wen1.

± Reduction of caspase-3 activity and an increase in cytokine production. Z-VAD.fmk through PPARα signaling could reduce the formation of lung edema in ALI.

Introduction: Resolvin D1 attenuates lung inflammation in LPS induced-ALI partly through PPARα signaling.

Methods: Z-VAD.fmk decreased AFC (PBS: 20.0±18.3 vs rh-sFasL= 350±18.4 ng/mL, p<0.05, n=9). H&E staining of histological sections showed that RvD1 markedly reduced lung edema in ALI. In contrast, mice treated with rh-sFasL had increased protein permeability (PBS= 20.0±18.3 vs rh-sFasL= 1.9±0.5, n=9).

Results: Compared with PBS-treated mice, the intratracheal instillation of rh-sFasL decreased AFC (PBS: 20.0±18.3 vs rh-sFasL= 1.9±0.5, n=9), and increased protein permeability (PBS: 34.7±18.3 vs rh-sFasL: 350±40.4 ng/mL, p<0.05), caspase-3 activity and cytokine production.

Conclusion: Resolvin D1 attenuates lung inflammation in LPS induced-ALI partly through PPARα signaling. The lack of neutrophil infiltration did not affect lymphocyte migration to the airways, suggesting an independent mechanism drives this response.

PL15
Temporal characterization of murine genomic response to poly I:C stimulation reveals tri-phasic inflammatory response signatures
Siriram Sridhar1, Paul Harris, John Allard, Ruqi Peng, Palani Ravindran, Hans Bitter, Michael E. Burczynski, Jay S. Fine, Christopher S. Stevenson.

Inflammation Discovery, Hoffmann-La Roche, Nutley, NJ, United States

Introduction: Poly I:C mimics a viral infection through the activation TLR3 and RNA helicases. Our aim was to characterize molecular changes occurring in the lung after poly I:C exposure in mice.

Methods: BALB/c mice were administered saline or poly I:C (30 µg/mouse) at 7 time points after dosing (2-168h), poly I:C and saline-treated mice were sacrificed, bronchoalveolar lavage was performed and lungs were snap-frozen. RNA from lung homogenates was isolated using the Norgen labeling method and assessed on a high density matrix standard murine whole genome array (MOE430 2.0 platform, Affymetrix). Differentially expressed genes were determined using an ANOVA, with pairwise comparisons between poly I:C and saline treatment at each timepoint. Functional pathways were determined using GO and Kyoto Encyclopedia of Genes and Genomes (KEGG) database.

Results: The peak response occurred 6-48h post-treatment. Hierarchical clustering across the study revealed 3 distinct temporal clusters (early, mid, and late phase). Inflammatory processes were enriched in the early phase (2-4h), TLR/R-L1 signaling genes in the mid phase (6-48h), and cell cycle pathways in the late phase (>72h). GSEA revealed activated NK and dendritic cell signatures up to 96h post-challenge, while several immune and myeloid related gene modules were also up-regulated between 6-96h post-challenge.

Conclusions: Inflammatory signatures including TLR and IL-1-related genes were highly up-regulated in response to poly I:C challenge, indicating a strong inflammatory response potentially driven by NK and dendritic cells in the lungs of mice.

PL16
Molecular mechanisms are involved in ethanol mediated lung endothelial barrier dysfunction
Umapathy Siddaramappa, Alexander Verin, Vascular Biology Center, Georgia Health Sciences University, Augusta, GA, United States

Recent studies have uncovered a significant but previously unknown correlation between alcohol (ethanol) abuse and the risk of acute respiratory distress syndrome (ARDS) [1]. Despite studies aimed at improving outcomes in patients with ARDS, the mortality remains high at > 40%. For those who abuse alcohol, the mortality is even higher, at 65% [2]. and therefore, alcohol abuse causes tens of thousands of excess deaths annually. One of the important functions of lung endothelium is to provide a barrier against the penetration of bacterial toxins in the circulation and endothelial junctional proteins act as a structural barrier against the paracellular permeation [3]. We hypothesized that excessive alcohol could negatively regulate the integrity of lung endothelial barrier and increases the risk during bacterial infections. Our novel preliminary data using human lung microvascular endothelial cells (HLMVEC) demonstrate that ethanol dose-dependently disrupts the EC barrier properties as evidenced by Electric Cells-Substrate Impedance Sensing (ECIS) based transendothelial electrical resistance measurement. Pretreatment of the HLMVEC with LPS and subsequent challenge with ethanol disrupts the tight junctional proteins and increased phosphorylation of myelin light chain across the study revealed 3 distinct temporal clusters (early, mid, and late phase). Inflammatory processes were enriched in the early phase (2-4h), TLR/R-L1 signaling genes in the mid phase (6-48h), and cell cycle pathways in the late phase (>72h). GSEA revealed activated NK and dendritic cell signatures up to 96h post-challenge, while several immune and myeloid related gene modules were also up-regulated between 6-96h post-challenge.

Conclusions: Inflammatory signatures including TLR and IL-1-related genes were highly up-regulated in response to poly I:C challenge, indicating a strong inflammatory response potentially driven by NK and dendritic cells in the lungs of mice.

P817 Effect of proteinase inhibitor from crataeva tapia (cratatal) in distal lung mechanical, inflammatory and remodeling alterations induced by elastase in mice
Leandro V. Oliva1, Rafael Almeida-Reis1, Osman Theodore Jr1, Bruno Tadeu Martins-Oliveira2, Clancy R. Oliveira1, Tales V. Lopes3, Alessandra C. Tolezani4, Rodrigs S. Ferreira1, Marlon V. Brito1, Milena A. Martins1, Maria L.V. Antunes2, Iolandia F.L.C. Tiberio1, 1Clinical Medicine, School of Medicine University of Sao Paulo, Sao Paulo, Brazil; 2Biochemistry, Federal University of Sao Paulo, Sao Paulo, Brazil

Aims: The leading role of elastase in the emphysema pathophysiology has been recognized. The present study aimed to evaluate if a plant proteinase inhibitor Cratatal contributes to inactivation of elastase-induced mechanical, inflammatory and extracellular matrix remodeling alterations.

Methods: C57Bl/6 mice received elastase intranasally (50µL/animal E group). Control group received saline (W group). Afterwards, mice were treated with Cratatal (2mg/kg) at days 1, 5, 21, 28, 35 after elastase instillation (1-E group). At day 40, mice were anesthetized and mechanically ventilated and we analyzed respiratory system resistance and elastance, tissue elastance, tissue damping and airway resistance. Afterwards, BAL was performed and lungs were removed. By morphometry, we quantified the mean linear intercept (Lm) and the collagen and elastic fibers in distal lung parenchyma.

Results: We did not observe any differences in pulmonary mechanics comparing all groups. In E group, there was an increase in BAL-total cells, BAL-lymphocytes, BAL-neutrophils, collagen and elastic fibers and Lm compared to E group (p<0.05). The Cratatal treatment in elastase treated animals decreased Lm (105.9±10.6µm) compared to E group (p<0.05) BAL-lymphocytes (7.2±1.4×10³ cells/µL), and collagen content (0.59±0.02%) were decreased in 1-E group compared to E group (p<0.05).

Conclusions: This plant proteinase inhibitor (Cratatal) reduced elastase-induced pulmonary inflammatory and remodeling alterations which may be considered as a new and potential therapeutic strategy for COPD treatment.

P818 Intravenous immunoglobulin in community acquired pneumonia
Usman Farkhutdinov, Albert Michcoidarov, Shamii Farkhutdinov. Department of Internal Diseases, City Hospital 21, Ufa, Russian Federation

Immunity disorders play an important role in the inflammatory formation in patients with lung diseases.

The aim was to study the efficacy of i.v. immunoglobulin immunovin (IMV) in patients with community acquired pneumonia (CAP).

Methods: The study included 35 patients with CAP. The patients blood was tested to estimate the level of CD3+, CD4+, CD8+, CD16+, CD20+ lymphocytes, the content of A.G.M immunoglobulins (IGM), circulating immunocomplexes (CIC), γ-interferon and TNFa. 17 patients with CAP were treated with standard therapy. The other 18 patients received combined treatment with IMV.

Results: Compared to healthy subjects in patients with CAP the level of CD3+, CD4+, CD8+, CD16+ and CD20+ lymphocytes was lower by 1.2-1.4 times, the content of IgA, IgG and γ-interferon was lower by 1.3 times. Conversely, the level of CD20+ lymphocytes, IgM, CIC was higher by 1.3-1.8 times, and the level of TNFa was higher by 1.5 times. Symptoms of inflammation and impairment of the immune status have been found in patients who received standard therapy. The use of IMV in patients with CAP eliminated immunity disorders, improved the results of the treatment.

Conclusion: In patients with CAP immunovin improved the immunity status and increased the treatment efficacy.

P819 PTX3 as a component of innate immunity in the role of captoril in acute lung injury induced by bacterial endotoxin
Xiaolin He, Shi Wang, Shuyue Xia, Xu Liu, Ning Song. Department of Respiratory Medicine, Shenyang Feng-Tian Hospital Affiliated to Shenyang Medical College, Shenyang, Liaoning, China

Objective: Innate immunity is an important mechanism for the development of acute lung injury (ALI). Lung pentraxin PTX3 is an inflammatory mediator and a component of innate immunity. Recent evidence indicates that angiotensin-converting enzyme (ACE) plays an important role in the pathogenesis of ALI. We speculated that inhibition of ACE play the protective effect on ALI through the prevention of PTX3, S.O2, protect the lung from injury.

Methods: Lung injury was induced by intratracheal instillation of lipopolysaccharide (LPS) in rats, followed by i.p. administration of captoril, an ACE inhibitor, or saline control, and the PTX3 expression, fibrin deposition, tissue factor expression and lung injury were determined. Local and systemic inflammatory responses were assessed by measuring cytokines in the lung and plasma.

Results: Treatment with captoril dramatically attenuated LPS-induced lung injury, alleviated fibrin deposition and inflammatory cell infiltration 6 hours after LPS challenge compared to that in the saline control rats. Local and systemic PTX3 expression were significantly decreased by the captoril therapy, accompanied by decreased interleukin (IL)-6, IL-10 and monocyte chemoattractant protein-1 levels in the plasma.

Conclusion: These results support that inhibition of ACE with its clinically used inhibitor offers protective effects on ALI; PTX3, acting as both anti-inflammation component and the component of innate immunity, may reflect severity of lung injury and serve as the predictor of therapeutic effect. The PTX3 treatment through the presence of PTX3 could be a potential mechanism that mediates lung injury.

P820 Effect of ketonazole on the pharmacokinetics (PK) and pharmacodynamics (PD) of inhaled fluticasone furoate (FF) and vilanterol (VI) administered in combination in healthy subjects
Rodger Kempsford1, Ann Allen1, Joanne Ba1, David Rubin2, Lee Tombs3, 1Drug Metabolism Development, GlaxoSmithKline R&D, Stevenage, Hertfordshire, United Kingdom; 2Clinical Pharmacology Modelling & Simulation, GlaxoSmithKline R&D, Stevenage, Hertfordshire, United Kingdom; 3Clinical Pharmacology, Science & Study Operations, GlaxoSmithKline R&D, Uxbridge, Middlesex, United Kingdom; 4Respiratory Medicines Development Centre, GlaxoSmithKline R&D, Research Triangle Park, NC, United States; 5Statistics & Programming, Satellite, Slough, Berkshire, United Kingdom

Rationale: A combination of the novel corticosteroid FF and long acting beta2-agonist VI administered via dry powder inhaler (FF/VI) is being developed as one of a new therapeutic strategy for COPD. Both FF and VI are predominantly metabolised via CYP3A4 and their PK and PD could be affected by CYP3A4 inhibition.

Objective: To investigate the effects of the strong CYP3A4 inhibitor ketonazole on the PK and PD of FF and VI.

Methods: Double-blind, randomised, placebo (P)-controlled, repeat dose, two-way crossover study. Healthy male and female subjects (N=18) received once daily oral ketonazole (400mg) or P for 11 days with FF/VI (200/25mcg) for the final 7 days. PD and PK data were obtained up to 48h following the Day 11 dose.

Results: Co-administration of ketonazole and FF/VI had no effect on 0-4h maximum heart rate or minimum blood potassium (treatment difference [90%CI] -0.60pm [-5.8, 4.5] and 0.04mmol/L [-0.03, 0.11], respectively) whilst there was a measurable but clinically insignificant decrease in 24h weighted mean serum cotidol (treatment ratio [90%CI] 0.73 [0.62, 0.86]). Co-administration of ketonazole increased (percent change [90%CI]) FF AUC(0-24) and Cmax by 36% [19, 56] and 33% [12, 58] and VI AUC(0 t') and Cmax by 65% [38, 97] and 22% [-8, 38], respectively. Both treatments were well tolerated and there were no serious adverse events or withdrawals.

Conclusion: Co-administration of FF/VI with ketonazole resulted in less than two-fold increase in systemic exposure to FF and VI with no clinically significant systemic effect.

Funded by GSK (HZA105548; NCT01165125)

P821 Vilanterol, a novel inhaled long-acting β2-adrenoceptor agonist (LABA), demonstrates extensive first pass clearance to metabolites with negligible pharmacological activity in man
Andy Harrell1, Sarah Siederer2, Jo Ba1, Rodger Kempsford3, 1Drug Metabolism and Pharmacokinetics, GlaxoSmithKline R&D, Ware, Herts, United Kingdom; 2Drug Discovery - Quantitative Sciences, GlaxoSmithKline R&D, Stevenage, Herts, United Kingdom; 3Clinical Pharmacology Science Support & Operations, GlaxoSmithKline R&D, Stockport, Middlesex, United Kingdom; 4Medicines Development, GlaxoSmithKline R&D, Stevenage, Herts, United Kingdom

Introduction: Vilanterol (VI) trinitrate is a novel LABA with demonstrated 24-hour clinical duration of action, currently in development in combination with an inhaled corticosteroid for once-daily treatment of COPD & asthma.

Objectives: The excretion and metabolism of radio-labelled VI was investigated following oral dosing to represent the swallowed portion of an inhaled dose. Co-administration of ketoconazole and FF/VI had no effect on 0-4h maximum heart rate or minimum blood potassium (treatment difference [90%CI]

Methods: Open label, single dose study. Healthy male subjects [N=6] received an oral solution dose of 200 µg of [14C]VI (2 µCi). Plasma samples and all urine and faeces were collected up to 168 h post dose and analysed for total radioactivity, VI and VI metabolites as appropriate.

Results: VI was well absorbed (>50% of the radioactive dose). VI represented a very small percentage (<0.5%) of the total circulating drug-related material in the plasma indicating extensive first-pass metabolism of VI. In total 70% of the recovered radio label was collected in the urine with the remainder recovered in the faeces. The primary route of clearance of VI was via O-dealkylation to metabolites with negligible pharmacological activity in man

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA at Stand D.30
Conclusion: VI undergoes extensive first-pass metabolism in man. VI was well tolerated after an oral dose (200 μg) considerably in excess of the likely clinical inhaled dose (25 μg), indicating absent pharmacological activity of the metabolites in man (in agreement with pre-clinical data).

Funded by GSK (B2C106181; NCT01286381)

P824 The safety, tolerability, pharmacodynamics and pharmacokinetics of inhaled fluticasone furoate (FF) and vilanterol (VI) are unaffected by administration of codeine

Rodger Kempsford1, Ann Allen2, Philippe Bareille1, Howard Bishop4, Melanie Hamilton3, Anne Chessborough3, 1Respiratory Medicines Development Centre, GlaxoSmithKline R&D; 2Stevenage, Hertfordshire; United Kingdom; 3Clinical Pharmacology Science & Study Operations, GlaxoSmithKline R&D; Uxbridge, Middlesex, United Kingdom; 4Inhaled Product Development, GlaxoSmithKline R&D; Ware, Hertfordshire, United Kingdom; 5Discovery Biometrics, GlaxoSmithKline R&D; Uxbridge, Middlesex, United Kingdom

Introduction: A combination of the novel corticosteroid FF and long acting beta2-agonist VI (FF/VI) is currently under development as a once-daily inhaled treatment for asthma and COPD.

Objectives: To assess whether the pharmacodynamics (PD) and pharmacokinetics (PK) of FF and VI are affected when delivered as the FF/VI combination in combination with FF and VI alone administered from the same novel dry powder inhaler.

Methods: Single centre, randomised, double-blind, placebo-controlled, four-way crossover study. Healthy male and female subjects [N=16; 21-57 years] received single, supra-therapeutic doses of FF (800μgmcg), VI (100mcg), FF/VI (800/100mcg) and placebo. PK and PD were monitored post-dose.

Results: FF/VI decreased serum cortisol (0.24g weighted mean vs placebo) by 14.7% vs 24.1% for FF alone; the difference of 12.3% (90% CI: 4.4, 20.9) was considered non inferior (defined as lower CI > -20%). FF/VI increased heart rate (0.05 vs 0.15 max vs placebo) by 0.72pm vs 6.99pm for VI alone; the difference of 1.26pm (90% CI: 4.6, 2.1) was considered non inferior (defined as upper CI < +10.9pm). There were no differences in minimum blood potassium (0-4h). FF and VI mean exposure (AUC0′-∞/Clast∞) for VI were 15% (5, 24) and 3% (4, 14) lower, respectively, for the combination vs FP or VI alone. The adverse event profile for all treatments was similar to placebo.

Conclusion: Administration of FF and VI in combination was not associated with an increase in systemic exposure or systemic pharmacodynamic effects compared with administration of either compound alone.

Funded by GSK (HZA105871; NCT00588057)

P825 Aspirin inhalation treatment for COPD patients: Preliminary studies on PK and inflammatory biomarkers

Antonio Soleri1, Giuseppe Zaccari2, Claudio Omnini2, 1R&D Unit, Medestea Research & Production SpA, Torino, TO, Italy; 2R&D Unit, BSD Pharma srl, Piole, MI, Italy

We are currently investigating if the use of aspirin (ASA), administered via inhalation, can exert a local anti-inflammatory effect, to propose it as a treatment for COPD, an inflammation-related pathology.

As little is known on inhaled ASA’s PK, a 3-way crossover study was performed on 14 moderate COPD subjects, which were administered 250/500/750mg of ASA’s b.i.d (aspirin tablets) 14 days. As little is known on inhaled ASA’s PK, a 3-way crossover study was performed on 14 moderate COPD subjects, which were administered 250/500/750mg of ASA’s b.i.d (aspirin tablets) 14 days.

We are currently investigating if the use of aspirin (ASA), administered via inhalation, can exert a local anti-inflammatory effect, to propose it as a treatment for COPD, an inflammation-related pathology.

Objective: To investigate pharmacokinetic of B17MP (active BDP metabolite) and Formoterol in children with asthma after inhalation of CHF 1535 50/6 μg via the licensed free combination of BDP and Formoterol dispersed with AeroChamber Plus™.

Methods: 22 children (5-11yrs) with mild asthma were included in this open-label, randomised, 2-way cross-over study of inhaled BDP 200μg and Formoterol 24μg. Eight-hour pharmacokinetic profiles (Cmax and AUROC) for B17MP and Formoterol after single inhalation were primary endpoints evaluated by analysis of variance and 90% bioequivalence limits.

Secondary endpoints were pharmacodynamics: serum potassium, heart rate, and cortisol excretion.

Results: B17MP and Formoterol pharmacokinetic parameters showed comparable values and the upper limit of the 90% CI was well within the bioequivalence limit. The pharmacodynamic parameters also showed similar values after both treatments.

Conclusion: After CHF 1535 506μg administration, the BDP and Formoterol systemic exposure was similar to the systemic exposure of BDP and Formoterol administered as free combination supporting a comparable safety profile in children aged 5-11yrs.

Contamination and carry-over in clinical pharmacokinetic trials with aerosolized budesonide

Dominik Kappeler1, Daniela Zanker1, Barbara Daumann1, Oliver Eickelberg2, Thomas Meyer2. 1Clinical Unit/In-Vitro Trials, Inamed GmbH, Gauting, Germany; 2Experimental Pneumology/Institute of Lung Biology and Disease, Comprehensive Pneumology Center, Ludwig-Maximilians-University, University Hospital Grosshadern, and Helmholtz; Zentrum München, Munich, Germany

Background: Contamination and carry-over by active drug components is a major issue, especially in pharmacokinetic studies carried out with aerosolized substances. Measures to avoid contamination and carry-over in blood samples remain poorly standardized and validated.

Objective: To investigate the space- and time-related distribution pattern of budesonide aerosolized via MDI.

Methods: A matrix of crystallization dishes was set up in a measurement chamber. One puff of budesonide MDI (184 μg emitted dose, 200 μg nominal dose) was aerosolized and aerosol was allowed to sediment for 0.25 to 6.5 hours. Recovery of budesonide in the crystallization dishes was measured via HPLC and correlated to time course and spatial matrix.

Results: In 1 m distance of actuating the MDI, a mean recovery of budesonide of 0.688 μg after 0.25 hours and 1.423 μg after 6.5 hours was observed. The surface concentration in 1 m distance was 9.7 ng/cm² after 0.25 hours and 20.1 ng/cm² after 6.5 hours.

Conclusion: This study is a valid basis for risk assessment of carry-over effects in clinical trials with aerosolized drugs. Regarding surface concentrations in the nanogram range as shown in our study compared to serum drug concentrations in the picogram range, the carry-over effects via aerosols seem probable. Further studies to determine the extent and origin of these effects will therefore be performed.

P828

Fluticasone/salmeterol combined in the new Forspiro® inhaler is as effective and safe as Seretide® Accuhaler® in adult and pediatric asthmatics

Piotr Kornacki1, Ursula Thyrist-Friesinger2, Ingolf Gath1. 1Department of Internal Medicine, Asthma and Allergy, Medical University of Lodz, Lodz, Poland; 2Hexion AG, Hexal AG, Holzkirchen, Germany

Objective: To compare the clinical efficacy and safety of fluticasone/salmeterol (FluSalm) combined in the new “Forspiro” DPI with Seretide Accuhaler (Glaxo Wellcome).

Methods: We conducted two large clinical phase III studies with twice daily treatment over 12 weeks including more than 770 children and adolescents/adults suffering from moderate or moderate-to-severe asthma. Primary endpoints were FEV1 change from baseline and the area under the FEV1 curve at study termination. Asthma symptom score, reliever use, morning PEF, adverse events (AEs) were also assessed.

Results: Mean increase of FEV1 for the 100/50 mcg (low dose) was 276 mL in adolescents/adults and 476 mL in children aged 6-11 years, and 344 mL for 500/50 mcg (high dose) in adults at endpoint. Morning PEF increased with the low dose by 17.5 L/mm in adolescents/adults and 31.5 L/mm in children, and by 35 L/mm with the high dose in adults. Asthma symptom scores and reliever use had already decreased substantially after the first treatment week. The number of drug-related AEs was comparable between treatments. Serum cortisol measured after 12 hours at endpoint tended to lower levels with the reference product. Patients’ assessment at study termination revealed an overall preference for the “Forspiro” DPI due to its mouthpiece fit, device size and shape.

Conclusions: FluSalm in the “Forspiro” inhaler was shown to be as efficacious and safe as Seretide Accuhaler.

P829

Effect of systemic and extra-fine particle inhaled corticosteroids on corrected alveolar nitric oxide (CANO) in COPD

Dominik Kappeler1, Daniela Zanker1, Barbara Daumann1, Oliver Eickelberg2, Thomas Meyer2. 1Clinical Unit/In-Vitro Trials, Inamed GmbH, Gauting, Germany; 2Experimental Pneumology/Institute of Lung Biology and Disease, Comprehensive Pneumology Center, Ludwig-Maximilians-University, University Hospital Grosshadern, and Helmholtz; Zentrum München, Munich, Germany

Background and objectives: Alveolar nitric oxide or (CANO), has been used as a surrogate marker of distal airway inflammation, which is important in COPD. Coarse particle inhaled corticosteroids (ICS) do not suppress CANO. We evaluated whether extra-fine particle size ICS or systemic oral corticosteroids could suppress CANO in COPD.

Methods: COPD patients with a smoking pack history >15 years, FEV1/FVC ratio <0.7, FEV1<80% predicted with small airways inflammation characterized by CANO >2ppb underwent a double-blind randomised controlled crossover trial with an open label systemic steroid comparator. Following a 2wk steroid washout period, patients were randomised to 2wks, 100mcgHFA-BDP-1 puff bid and then 2 weeks 400mcgHFA-BDP or matched placebos with subsequent crossover. All patients received 1wk open-label, 25mg/day prednisolone. Spirometry, body plethysmography, impulse oscillometry and exhaled nitric oxide were recorded.

Results: 16 patients completed per protocol. Compared to respective placebo there were no significant differences with extra-fine particle ICS. Oral prednisolone caused a significant reduction in FENO and JawNO but not CANO (see table1).

Conclusions: Whilst CANO remains a biomarker of interest in COPD, it is not suppressed by systemic or extra-fine particle ICS. Hence CANO is unlikely to be a useful marker for monitoring response of small airway disease to therapies in COPD.

P830

Lung deposition of the extra fine dry powder fixed combination beclomethasone dipropionate plus formoterol fumarate via the NEXT DPI® in healthy subjects, asthmatic and COPD patients

Fabrizia Marotti1, Francesco Sergio1, Daniela Acerbi1, Thomas Meyer2, Christiane Herpich1. 1Corporate Clinical Development, Chiesi Farmaceutici S.p.A., Parma, Italy; 2Clinical Unit, Inamed GmbH, Gauting, Germany

Background: Chiesi has developed the new pocket size, medium air flow resistant, breath actuated multidose-reservoir dry powder inhaler NEXT DPI®.

Objectives: The lung deposition and distribution pattern of the extrafine fixed combination of beclomethasone dipropionate 100μg and formoterol fumarate 4μg administered via the NEXT DPI® was assessed using a gamma-sciagraphic technique after inhalation of a single dose of the 137mCs-radio labelled combination (total dose BDP/formoterol 400/24μg).

Methods: 10 healthy subjects, 9 asthmatic patients (30%≤FEV1<80%) and 9 patients with stable chronic obstructive pulmonary disease (COPD) (FEV1/FVC<70%, 30%<FEV1≤50%) were treated according to an open, single dose design.

Results: Similar lung and extra-thoracic deposition were observed between the groups. The average lung deposition was 55% relative to the emitted dose in healthy subjects, 56% in patients with asthma and 55% in COPD patients. The extra-thoracic deposition was 43% in healthy subjects, 42% in asthmatic patients and 42% in COPD patients. The amount exhaled ranged between 1.6 to 3.3%. The distribution pattern, evaluated by measuring the central/peripheral (C/P) ratio confirmed distribution throughout the airways, including periphery (C/P 1.23, 2.02 and 1.57 for healthy subjects, asthmatic and COPD patients, respectively).

Conclusions: These results demonstrated that a high amount of the extrafine dry powder fixed combination BDP/formoterol administered via the NEXT DPI® was deposited in the lungs regardless of the pathological condition.

Research funding source: Chiesi Farmaceutici S.p.A.
A novel NEXT DPI® dry powder inhaler and its use in asthmatic and COPD population
F Sergio, A Chetta, G Pisù, M Aiello1, D Olivier1. 1Corporate Clinical Development, Chiesi Farmaceutici SpA, Parma, Italy; 2Respiratory Disease Unit, Cardiopulmonary Dept, University Hospital, Parma, Italy; 3Cystic Fibrosis Unit, Paediatric Dept, University Hospital, Parma, Italy

Rationale: In asthma and COPD the dry powder inhalers (DPJs) facilitate patient’s compliance to drug intake. Chiesi Farmaceutici developed a new inhaler, NEXT DPI® which is pocket size medium-resistant breath-actuated mechanism (BAM) multidose-reservoir to be used for drug delivery.

Objective: To verify that the peak inspiratory flow (PIF) required for the drug delivery is not influenced by patient’s age and disease.

Methods: Children (n=27; age 5-11), adolescents (n=20; age 12-17) and adults (n=21; age ≥ 18) with asthma and COPD patients (n=21; age ≥ 40) were included in this multicenter open-label placebo study. After baseline pulmonary function assessments (FEV₁, FVC; PIF tested with spirometer and In-Check Dual® device) patients inhaled through the NEXT DPI® to test the BAM activation, checked by the BAM counter and made to take the right number of inhalations. Usability evaluation questionnaire, adverse events (AE) and vital signs were also recorded.

Results: In all patients, spirometry showed from moderate to severe airways obstruction. All patients, irrespective of age and disease, were able to activate the BAM. The mean PIF value (asthmatic patients: 104.4±20.6 L/min, range 40-120; COPD patients: 97.9±18.8 L/min, range 51-120) measured with the In-Check was greater than the threshold set for the BAM activation and not influenced by age and disease severity. No patients had problem in using the NEXT DPI® correctly. A total of 7 AEs were reported in 5 patients, no one related with the use of NEXT DPI® or severe in intensity. No Severe Adverse Events were reported.

Conclusions: NEXT DPI® can be easily used and activated in a wide population of asthmatics and COPD patients irrespective of age and disease severity.

P832 Efficiency of ipratropium bromide and salbutamol deposition in the lung delivered via a soft-spray inhaler or chlorofluorocarbon metered-dose inhaler
Mo Ghalamir, Respiratory, Boehringer Ingelheim, Ridgefield, CT, United States

Purpose: The dose combination of ipratropium bromide (Ib) and salbutamol (Sb) presently marketed in a single canister dosage form. A soft-spray, aqueous solution-based delivery system of this combination was developed. This pharmaco-kinetic study compared the efficiency of a soft-spray delivery of the combination to the lung compared to CFC delivery.

Methods: Inhalation of a 1:1 Ib:Sb solution was tested in a four-center substudy comprised of 278 patients conducted from two trials differing only by doses evaluating Ib and Aib delivered via the soft-spray inhaler or CFC-MDI in 2,578 patients. Ib alone delivered via the soft-spray inhaler and placebo delivered via either delivery system were used as controls. LCMS/MS assays for analytes were developed for plasma and urine biofluids.

Results: Comparing AUC, Cmax, and Cmin showed that systemic exposure to Ib and Sb delivered via the soft-spray inhaler was proportional to the doses delivered. Comparability was obtained when comparing the soft-spray inhaler-delivered Ib at half the dose of the CFC-MDI. Since Ip is not significantly absorbed from the gastrointestinal tract, the systemic exposure observed is a relevant marker for lung deposition. Ib alone gave equivalent exposure as the combination demonstrating a lack of interaction.

Conclusions: These systemic exposure analyses can be regarded as a marker of lung deposition and therefore demonstrate that the soft-spray inhaler delivers drug more efficiently to the lung than CFC-MDI.

P833 Maintenance of lung function and asthma control with extrafine beclomethasone/formoterol
Neil Barnes1, Jan Arie Van Noord2, Caterina Brindicci3, Ludger Lindemann4, Guido Varoli5, Miguel Peruña6, Daniela Guastalla7, Daniela Casula7, Pascal Chazot8. 1Respiratory Medicine, London Chest Hospital, London, United Kingdom; 2Atrium Medisch Centrum Heerlen, Dienst Longzweken, Heerlen, Netherlands; 3Chiesi Farmaceutici SpA, Chiesi Farmaceutici SpA, Parma, Italy; 4Allergologie im Umkreis der Praxis Pneumologie, Allergologie im Umkreis der Praxis Pneumologie, Hôpital Sainte Marguerite, Marseille, France; 5Respiratory Medicine Department, University Hospital, Parma, Italy; 6Department of Pulmonology, University Hospital, Parma, Italy

Introduction: Asthma management focuses on achieving and maintaining asthma control. Very few studies have assessed whether complete and sustained asthma control is maintained after switching ECSLABA fixed combinations in clinical practice.

Aim: To demonstrate equivalence between equipotent doses of extrafine BDPF pMDI and Budesonide/salmeterol (FP/S) (Diskus®) in maintaining lung function and asthma control.

Methods: Prospective, double-blind, double-dummy, randomized, parallel group, controlled trial. 416 asthma patients controlled on FP/S 500/100 μg/day (Disku®, pMDI or separate inhalers) were randomized to 12-week treatment with extrafine BDPF/FP/S 500/100 μg/day (Diskus®). Pre-dose FEV₁ was the primary outcome, secondary outcomes included asthma control (ACQ-7).

Results: At the study end, pre-dose FEV₁ was equivalent between treatments (difference between means 0.01 L; 95% CI -0.03 to 0.06 L) with no changes from baseline in both groups. ACQ-7 score was equivalent between groups (Table 1). Post-dose FEV₁ in the first hour was significantly higher for extrafine BDPF/FP/S pMDI both at baseline and after 12-week treatment (Fig. 1, Table 1). No safety issues were reported in both groups.

Conclusions: Patients previously controlled with FP/S in any device formulation can safely switch to extrafine BDPF/FP/S pMDI and maintain an equivalent asthma control with a sustained faster onset of action.

P834 Phase II study of once-daily GSK573719 inhalation powder, a new long-acting muscarinic antagonist, in patients with chronic obstructive pulmonary disease (COPD)
Dennis Kelleher1, Andrew Preece2, Rashmi Mehta3, Alison Donald4, Kelly Hardes5, Anthony Cahn6, Glenn Cramer7. 1Respiratory Medicine Discovery and Development, GlaxoSmithKline, Research Triangle Park, United States; 2Clinical Pharmacology Science and Study Operations, GlaxoSmithKline, Uxbridge, United Kingdom; 3Clinical Pharmacology Modelling Simulation, GlaxoSmithKline, Research Triangle Park, United States; 4Quantitative Sciences, R&D, GlaxoSmithKline, Uxbridge, United Kingdom; 5Respiratory Medicine Discovery and Development, GlaxoSmithKline, Stevenage, United Kingdom; 6Respiratory and Immunology-Inflammation Medicine Development Center, GlaxoSmithKline, Research Triangle Park, United States

Introduction: GSK573719 is a new long-acting muscarinic antagonist offering sustained 24-hour bronchodilation in development for the treatment of COPD.

Objectives: To evaluate the safety, tolerability and pharmacokinetics of inhaled GSK573719 in a new dry powder (DP) formulation in COPD patients.

Methods: In this randomised, double-blind study, 38 patients with COPD received GSK573719 (250 μg.n=20; 1000 μg.n=9) or placebo (n=9) via a novel DP inhaler (DPI) once daily for 7 days.

Results: Of 43 adverse events (AEs) in 21 (55%) patients, 16 were drug related (all mild or moderate): placebo, 4 (headache, pruritus, flushing, hypoaesthesia); GSK573719 250 μg, 5 (arthrythmia, tachycardia, dyspnoea, hypertension, bronchospasm); GSK573719 1000 μg, 7 (blood pressure increase, thirst, oropharyngeal pain, headache, dry mouth, dyspnoea, feeling abnormal). Of 3 AEs related with withdrawals (chest pain, respiratory tract infection, dyspnoea), only dyspnoea was considered drug-related (1000 μg). The 1000 μg dose showed larger increases than 250 μg in heart rate (HR) (0–4h) vs placebo, but 24-h Holter monitoring showed no dose effect over 24h and the treatment effects were small. GSK573719 was rapidly absorbed (tmax 5–15min); 1–2% of the total dose was excreted unchanged in the urine. Accumulation (Day 7:Day 1) was low: 1.5–1.9x based on plasma data (1.8–2.4x, urine data). No correlation was seen between individual maximum HR increase and drug exposure.

Conclusions: GSK573719 250 μg or 1000 μg once daily by novel DPI was well tolerated by patients with COPD.

Optimization of inhalation treatment – Evaluation of influence of PNEUMOlogic® and Optimiser® spacers on aerosol particle distribution from pMDI-EB
Zygmun Podolec, Joanna Siekanevic. Aerosontology and Aerosol Bioengineering, Research and Development Centre MEDINET, Cracow, Poland

Introduction: PNEUMOlogic® ([PNL]; the first inhalation chamber [vol. 800 ml] integrated with the spironeter, used for the controlled drug delivery from pMDI-EB. Optimiser® ([OPT]; [vol. 50 ml] is the aerosol chamber used for drug administration from pMDI-EB. The aim of the study was to evaluate the influence of inhalation chamber and method of performing inhalation on the quality of aerosol.

Method: Aerosol particle distribution and mass of aerosol was measured using particle counter with constant flow of 28,3L/min. Aerosol particle distribution and mass of aerosol was measured using Copley Inhalation Testing Data Analysis Software (CITDAS). The study was performed on the quality of aerosol.

Aerosol device was characterized by a cyclostyled effect on the inlet gas which reduces the oxygen velocity at the outlet.

Results: Intra nasal humidity dropped significantly from 40.3±8.7% to 29.0±6.8% at a flow rate of three litres when oxygen was given intranasally without humidification (p<0.01). We observed no significant change in airway humidity when oxygen was given prenasally and without humidification.

Conclusion: We propose two mechanisms to be responsible for this phenomenon: First prenasal application with low outlet velocity of dry oxygen allows for absorption of humidity from the surrounding air prior to nasal entry and second intranasal application with a high exit velocity from the applicator system might dry out the nasal mucosa by means of convection. Nasal oxygen application with the Optimiser device might obviate the need for humidification and therefore might simplify application and reduce therapy cost.

P836
In vitro comparison of aerosol characteristics of HFA ipratropium bromide pressurized metered dose inhaler (pMDI) formulation from threevalved holding chambers (VHCs)
Kurt Nikander1, Loss Slater2, Dirk von Hohen1, Ross Hatley1. 2Philips Respironics, Respironics New Jersey, Inc., Parsippany, NJ, United States; 1Respiratory Drug Delivery (UK) Ltd, Chichester, United Kingdom

Inhaled bronchodilators and anticholinergics are the mainstay in the management of patients with chronic obstructive pulmonary disease. This study compared the in vitro aerosol characteristics from an HFA-steroid formulation pMDI (Atovent, 20 μg ipratropium bromide, Boehringer Ingelheim Ltd) with two anti-static VHCs, a preproduction OptiChamber Chamber (Diamond; Philips Respironics) and an Aero Chamber Plus Z-Stat (Z-Stat; Monaghan Medical Corp.) VHC, a conventional AeroChamber Plus (AC+; Monaghan Medical Corp.) VHC, and the pMDI alone.

Six pMDIs were primed before use and six of each VHC were washed and air dried. For each run (n) the pMDI was actuated into the VHC or next generation impactor (NGI) (for pMDI alone - tested before and after VHC tests), followed by 20 x's repetition at 30 L/min, repeated 10 times. Drug deposits from the NGI were analyzed using HPLC. The Emitted Dose (ED; drug entering the NGI), Fine Particle Fraction (FPF%; of ED in particles ≤ 4.7 μm), and Mass Median Aerodynamic Diameter (MMAD) were determined using Copley Inhalation Testing Data Analysis Software (CITDAS).

Table 1. Results: Mean (SD) [range]

Using a PIFR <90L/min for slow flow with a TID of 0.9–2 seconds for good co-ordination only for CHILD; 4 ADULT and 6 COPD demonstrated a good inhalation technique. The PIFR of 15 CHILD was <90/min, 26 ADULT and 24 COPD. 9 CHILD actuated too early, too late and 2 did not actuate. 17 ADULTS actuated too early, 27 were too late and 5 did not actuate. 9 COPD actuated too early and 14 too late. The mean (SD) ADULT ACQ of 2 was 0.14 (0.10) with no difference between slow and fast PIFR and co-ordination. ACQ for those with a good (n=4) and poor technique (n=56) was 1.07 (0.36) and 2.08 (1.02). As expected MDI co-ordination (TID) was poor and most PIFRs were too fast. The low IV and short Ti reveal that patients need to exhale more and prolong their inhalation time.

P839
In vitro nebulised dose emission characteristics of a tobramycin solution (75mg/ml) using an I-NEB (I-NEB) and a pari LC+ driven by a turbodrive compressor (PARI) nebuliser
Mohamed Yousef Khan1, Nicholas Powles2, Matthew Stirling2, Henry Chrystyn1. 1Pharmacy, University of Huddersfield, Huddersfield, United Kingdom; 2PARI, University of Huddersfield, Huddersfield, United Kingdom

In practice solutions are nebulised by the equipment that is available rather than that recommended in the Summary of Product Characteristics (SPC). We have compared the in vitro aerosodynamic droplet characteristics of Brantium when used as a nebuliser by PARI (Pari GmbH), recommended in the SPC, and an I-NEB (Philips Respironics, UK) with a 300µl cup. We have previously adapted the com- positional methodology for nebulisers (Adelrahim & Chrystyn, J Aerosol Med 2009) and modified this to incorporate breath simulation (BS, tidal volume of 500ml and an inspiration: expiration ratio of 1:3) for use with I-NEB. The schematic design of our methodology is shown in figure 1.

The mean (SD) aerosodynamic droplet characteristics of tobramycin nebulised using PARI until spurring and I-NEB until dryness are summarised in Table 1. From the I-NEB data the fine particle dose (FPD) is 8.3mg. Separate determina- tions using PARI and compositional methodology provided a FPD of 17.5mg. The in vitro droplet emission characteristics suggest that 2 separate doses of Brantium
nebulised using an I-Neb with a 300ml cup could be comparable to 4ml nebulised by a Pari LC+.

P842 Non-genomic effect of glucocorticoids on inhibition of expression of CD63 on peripheral blood basophils

Katsuyuki Tomita1, Hitomi Zushi1, Nanase Watatani1, Shigeyoshi Yamagata2, Hideo Ichihashi1, Ryuji Satoh1, Hiroyuki Sano1, Hiroaki Kume1, Rysta Haraguchi2, Yuji Tohda1, 1Department of Respiratory Medicine and Allergology, Kinki University Faculty of Medicine, Osaka, Japan; 2Department of Respiratory Medicine, Sakai Hospital Kinki University Faculty of Medicine, Sakai, Japan

Background: Glucocorticoids (GC) could inhibit histamine release from rat peripheral mast cells within 10 minutes, which classical genomic mechanism could not explain. The clinical efficacy of inhaled corticosteroids combined with long-acting beta 2-agonists has been widely demonstrated in asthma.

Objective: In order to validate the benefit of the combined these agents in vitro, we studied a rapid effect of fluticasone propionate (FP) and formoterol (FORM) alone and in combination on inhibition of expression of CD63, which is a marker of degranulation of basophils, in house dust mite (HDM)-sensitive patients with asthma.

Methods: Whole peripheral bloods from asthmatic patients were incubated with HDM for 20 min in the pretreatment of FP and/or FORM for 1 hour. We assessed the expression of CD63 on basophils by quantifying the mean fluorescence of CD63 in IgE-positive cells by FACS analysis.

Results: A high concentration of FP (10-8 M) alone, but not a low concentration of PP (10-12 M) alone, inhibits CD63 expression induced with HDM. The combination of FP (10-8 M) and FORM (10-7 M) more inhibits CD 63 expression on basophils.

Conclusion: The study provided evidence that non-genomic mechanism might be involved in rapid effect of glucocorticoids on basophils in asthma.

P843 Expression and functionality of P-glycoprotein in human bronchial epithelial cells in vitro

Victoria Hutter1, Constanze Hilgendorf2, Anne Cooper3, Vanessa Zann3, David Pritchard4, Cynthia Bosquillon1. 1Division of Drug Delivery and Tissue Engineering, School of Pharmacy, University of Nottingham, Nottingham, United Kingdom; 2Drug Metabolism and Pharmacokinetics, AstraZeneca R&D, Mölndal, Sweden; 3Drug Metabolism and Pharmacokinetics, AstraZeneca R&D Charnwood, Leicestershire, United Kingdom; 4Department of Molecular and Cellular Sciences, School of Pharmacy, University of Nottingham, Nottingham, United Kingdom

P-glycoprotein (P-gp) is expressed in normal tissues with barrier functions where it participates in cell defence mechanisms (Huls, M. et al. J Pharm Exp Ther 2009; 328:3-9). Its presence in the bronchial epithelium and role in lung protection is still uncertain.

The human bronchial epithelium cell line Calu-3 and normal human bronchial epithelial (NBHE) cells were cultured at an air-liquid interface on Transwell® inserts for 21 days. P-gp expression was evaluated by quantitative polymerase chain reaction and its functionality was assessed by permeability measurements using the established substrate 3H-digoxin either alone or in the presence of chemical or molecular inhibitors.

P-gp was absent in NBHE cells and moderately expressed in Calu-3 cells. Net secretory transport of 3H-digoxin was observed in both models. This was reduced at 4°C and in the presence of the selective but non specific P-gp inhibitor PSB383 and the multidrug resistance protein (MRP) inhibitor MK571. P-gp specific antibody inhibitor UIC2 and the metabolic inhibitors sodium azide and sodium dichloroacetate had no effect on 3H-digoxin transport in Calu-3 cells.

The presence of active transport mechanisms in cultures of human bronchial epithelial cells was demonstrated, although they differed between the models tested. P-gp was not detected in NBHE cells, in line with observed low gene expression in human lung tissue (Bleasby, K. et al. J Pharmacol Exp Ther 2009; 328:3-9). Its presence in the bronchial epithelium and role in lung protection remains to be elucidated.

Results: There was no evidence of toxic effect in blood biochemical parameters, complete blood counts and gross pathology. Histological evaluation of the heart, kidneys, spleen, liver and pancreas was normal in all groups. However, abnormalities were found on lung pathology. In the high concentration group diffuse alveolar damage, alveolar hemorrhage, pulmonary congestion and severe bolus emphysema were shown, whereas in the low dose group only very mild emphysema was found. It is noteworthy that no signs of morbidity or behavioral changes were observed in all groups.

Conclusions: Very high dose Dextromethorphan inhalations have no biochemical or histopathological toxic effects, but may be toxic to the lungs. However, inhalation dose of 60 mg/kg seems to be safe. These data suggest that treatment with inhaled DM in lower doses may be safe and can be used in humans.

P841 Toxicity and safety of dextromethorphan inhalation in a mouse model prior its use in humans

Amir Bar-Shai, Alex Starr, Yehuda Schwarz. Department of Pulmonary Diseases, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: Dextromethorphan (DM) is a non narcotic codeine analogue, widely used as antitussive agent. DM is active mostly centrally, but also in lung regions. DM was shown to be effective when given by inhalation in guinea pigs. Oral DM prior bronchoscopy is effective in reducing cough and dyspnea. The use of inhalation of DM could lead to faster beneficial effect of the drug, and to avoidance of oral preparation prior bronchoscopy.

Objectives: To define the toxicity of inhaled DM in a mouse model, using different doses and comparison with sham inhalation.

Methods: Female BALB/c mice, were divided to 4 groups exposed to increasing concentrations of DM solution: normal saline, 60, 90 and 360 mg/kg. Inhalation studies lasted ~ 20 minutes, for 3 weeks. Blood analysis and complete histological evaluation were performed.
P844 Fluticasone furoate, a novel corticosteroid, maintains glucocorticoid receptor nuclear localisation for 24 hours after washout in monocytes

Amir Hakim, Malcolm Johnson, Peter Barnes, Ian Adcock, Omar Usmani.
National Heart & Lung Institute, Imperial College, London, United Kingdom

Background: Fluticasone furoate (FF) is a novel corticosteroid (CS) under development for inhaled once daily administration for chronic obstructive pulmonary disease and asthma. CS act via binding to the glucocorticoid receptor (GR). Upon activation of GR, receptors enter into the nucleus, an essential prerequisite for CS function. In dose-ranging studies in asthmatics, FF had 24 hour (h) duration of efficacy. We hypothesized, therefore, that the sustained activity of FF is due to prolonged GR nuclear translocation.

Method: The effects of FF on GR nuclear translocation over a 24 h time-course was examined in U937 monocytes. In addition, we compared the effect of a 20 h washout on GR nuclear localisation following treatment with FF for 4 h. Statistical analysis was performed using Kruskal-Wallis analysis and results represented as mean±SEM.

Results: FF significantly induced GR nuclear translocation in a time- (2-24h) and concentration- (10^(-11)-10^(-7)M) dependent manner (p<0.05 for each time and concentration measured compared to untreated controls). FF (10^(-7) M) significantly increased nuclear GR levels at 4h (5.4±0.57 fold increase, p<0.05) which was maintained at 16 and 24h. There was a corresponding decrease in cytosolic GR over this time scale. Importantly, in the washout experiments, there was a similar level of GR nuclear translocation at 24h after 4h FF (10^(-7)M) treatment as seen over this time scale. Exposure of cells to FF for 4h as well as 20 h was effective in maintaining the FF induced GR nuclear translocation in a time and concentration dependent manner. Exposure of cells to FF for 4h as well as 20 h was effective as continued exposure for 24h. Funded by GlaxoSmithKline.

P845 Roflumilast N-oxide, a selective PDE4 inhibitor, curbs platelet-leukocyte interactions

Licia Totani, Antonio Piccoli, Concetta Amore, Angelomaria Di Santo, Nicola Marcelli, Giuseppe Dell'Elba, Virgilio Evangelista. Department of Cellular and Translational Pharmacology, Mario Negri Sud, Santa Maria Imbattito, Italy

Objective: COPD is associated with cardiovascular comorbidities. Platelet (Pt)-leukocyte interactions play a role in vascular disease. We tested the effect of the PDE4 inhibitor roflumilast N-oxide (RNO), the active metabolite of roflumilast approved for severe COPD in EU, on Pt-mediated neutrophil (Neu) recruitment and expression of TF in Mn.

Methods: Neu adhesion to spread Pt or endothelium (EC) and Pt-induced TF in Mn were analysed with RNO with or without formoterol (F) (100 nM).*p<0.05 vs control (C).

Results: RNO induced TF expression in a time and concentration dependent manner. Exposure of cells to FF for 4h as well as 20 h was effective as continued exposure for 24h. Funded by GlaxoSmithKline.

P846 A-kinase anchoring proteins as novel regulators of airway smooth muscle function

W.J. Popperspin1, A. Oldenburger1, W. Timmers2, P. Skroblik1, E. Klassmann1, H. Meurs1, M. Schmidt1, H. Maarsingh1. 1Molecular Pharmacology, University of Groningen, Groningen, Netherlands; 2Pathology, University Medical Center Groningen, Groningen, Netherlands; 3Annexed Signalling, Leibniz-Institut für Molekulare Pharmakologie, Berlin, Germany

Chronic obstructive pulmonary disease (COPD) is a chronic inflammatory disease mainly caused by cigarette smoking (CS). Compartmentalization of CAMP signaling regulates cellular responses to (local) changes in CAM levels. In this respect, the A-kinase anchoring proteins (AKAPs) compartmentalize cAMP signaling by differentially docking proteins involved in cAMP signaling, including β2-adrenergceptors and the cAMP effectors PKA and Epac. Interestingly, AKAP79 (aka AKAP350) involved in β2-adrenergceptor desensitisation, which is opposed by AKAP250 (aka AKAP12). Here we studied the expression pattern and functions of AKAPs in regulating inflammatory cytokine release and the responsiveness to β2-adrenergceptors.

AKAP51, AKAP250 and AKAP50 (aka AKAP9) are expressed in human airway smooth muscle (hASM). Treatment with CS downregulated AKAP250 and (to a lesser extent) AKAP79, but not AKAP450. In lung tissue of COPD patients all these AKAPs were downregulated. In hASM cells, CS-induced IL-8 release was dose-dependently decreased by the β2-agonist fenoterol as well as by direct activation of PKA and (only marginally) of Epac. CS-induced IL-8 release was augmented by the PKA-binding blocking peptide st-H31, a generic AKAP inhibitor. Importantly, in the presence of st-H31 fenoterol was unable to reduce CS-induced IL-8, whereas the PKA activator was still fully effective.

In conclusion, AKAPs are expressed in the airways and coordinate the communication between β2-adrenergceptors and CAMP effectors in order to reduce CS-induced inflammation. AKAP9 expression is altered in COPD. AKAP9s could contribute to the pathophysiology of this disease. Supported by Stichting Astma Bestrijding and a Rosalind Franklin Fellowship.

P847 Bosentan is superior to ambrisentan in reducing the expression of asthma- and COPD-related cytokines

Jurgen Knobloch1, Yingfeng Lin1, David Jungek1, Katja Ubran1, Justus Strauch2, Erich Stroebel3, Juergen Behr1, Andrea Koch1. 1Medical Clinic III for Pneumology, Allergology and Sleep Medicine, University Hospital Bochum-Bergmannsheil, Bochum, Germany; 2Clinic for Heart & Thoracic Surgery, University Hospital Bochum-Bergmannsheil, Bochum, Germany; 3Department of Thoracic Surgery, Langenherfeld Kliniken, Kliniken der Stadt Koeln, Cologne, Germany

TNFα substantially contributes to the establishment of chronic airway inflammation. TNFα-induced expression of inflammatory genes in human airway smooth muscle cells (HASMCs) might depend on endothelin-1 (ET-1) signaling. We investigated inflammatory gene expression in TNFα-exposed HASMCs. We compared the anti-inflammatory effects of the non-selective endothelin antagonist Bosentan (ETAR/ETBR antagonist Bosentan with or without formoterol (F) (100 nM).*) p<0.05 vs control (C). The expression of 4,948±3,316 genes was induced twofold or more by TNFα. Among them were GM-CSF, G-CSF, 8 CCR and 8 CXC family members and 5 interferons. Bosentan and Ambrisentan reduced this expression (4,305±53 or 396±63 genes, respectively, in TNFα-exposed HASMCs. Among them were CCL5/7/8/19/20, CCL6/10, CXCL1, IL-6/7/23 and GM-CSF (all p<0.05). The release of CCL2, CCL7, CXCL1 and GM-CSF was more efficiently reduced by Bosentan compared with Ambrisentan (p<0.05). With the exception of GM-CSF, the effects of ET receptor antagonists on these factors were due to inhibition of gene transcription. ETAR/ETBR antagonists contribute to the establishment of chronic airway inflammation in asthma and COPD. Particularly none-selective ET receptor antagonists might have therapeutic utility in early stages of chronic airway diseases by counteracting the establishment of inflammatory processes.

P848 Simvastatin selectively inhibits TSLP-production in primary bronchial epithelial cells from COPD donors

Angelica Brandelius1, Jenny Calvé1, Lief Bjerrum1, Irna Mahmutovic Persson1, Carl Persson2, Morgan Andersson3, Lena Uller1. 1Department of Experimental Medical Science, Lund University, Lund, Sweden; 2Lung Medicine, Skane University Hospital, Lund, Sweden; 3Clinical Pharmacology, Skåne University Hospital, Lund, Sweden; *ENT, Skane University Hospital, Lund, Sweden

Background: Possibly reflecting anti-inflammatory properties, statin treatment may ameliorate COPD exacerbations. Viral infections apparently cause TH2 type COPD exacerbations. We have previously shown that thymic stromal lymphopoietin (TSLP), a cytokine linking innate and adaptive immunity and switching on TH2 type inflammation, is overproduced in viral stimulated epithelial cells from patients with GOLD stage II COPD.

Methods: Primary bronchial epithelial cells, obtained by fibre optic bronchoscopy from COPD (n=4) and healthy individual (n=3) donors, were grown in 12-well plates and stimulated with a synthetic viral surrogate, double-stranded RNA (dsRNA, 10μg/ml) to induce cytokine expression (3h, RT-qPCR) and production (24 h, ELISA). Simvastatin (0.2-5μg/l) with or without mevalonate (13g/ml) was added 18 h prior to dsRNA. Alternatively, dexamethasone (1μM) was added 1 h prior to dsRNA.

Results: dsRNA induced TSLP, TNF-α and IL-8 mRNA and protein expression (p<0.05-p<0.001). Simvastatin dose-dependently, but not dexamethasone, inhibited dsRNA-induced TSLP mRNA expression and protein release (p<0.05-p<0.001) in COPD cells. Simvastatin acted independent of mevalonate. dsRNA-induced TNF-α and IL-8 were not inhibited (p<0.05).

Conclusion: Independent of the mevalonate pathway, simvastatin selectively inhibited dsRNA-induced TSLP-production in COPD cells. These data support exploration of statin treatment in viral-induced COPD exacerbations. The pharmacological
Effects of corticosteroid or montelukast associated to iNOS inhibitor on airway remodelling in guinea pigs chronically exposed to cigarette smoke

Flavia Castro Ribas de Souza 1, Nathalia Brandão Gobbato 1, Carla Máximo Aparecida Leuck 1, Milton de Arruda Martins 1, Isolanda de Fátima Lopes Calvo Tíbelo 1, 1Medicine, School of Medicine University of São Paulo, São Paulo, Brazil; 2Ciências Biológicas, Universidade Federal de São Paulo - UNIFESP, Diadema, São Paulo, Brazil

Aims: Distal lung alterations have been recently addressed on asthma pathology. We evaluated oxidative stress, actin content, IL and MMP9 positive cells in distal lung parenchyma after montelukast or dexamethasone treatment associated or not to an iNOS inhibitor (400W) in guinea pigs (GP) with chronic inflammation.

Methods: Mice were inhaled with ovalbumin (OVA group 2x/week/4weeks). After 4th inhalation, GP were treated with montelukast (M group 10mg/kg/day) or dexamethasone (D group 5mg/kg/day). 1400W (W group 1mg/kg/day) was given daily in the last 4 days (W, DW and MW groups). After 72 hrs of 7th inhalation, GP were anesthetised, lung strips were submitted to histopathological evaluation.

Results: Isoprostane was reduced in M (9.4 ± 0.4%, D (7.4 ± 0.2%), DW (6.1 ± 0.2%) and W (6.5 ± 0.4%) compared to OVA (14.5 ± 0.2%, P<0.05). Actin content was attenuated in M (7.6 ± 0.5%, D (6.3 ± 0.2%), W (6.2 ± 0.4%) DW (5.4 ± 0.2%) and D (7.2 ± 0.2%) compared to OVA (9.6 ± 0.5%, P<0.05). There was a decrease of IL5+ cells in W (4.8 ± 0.5/10⁴ μm²), M (6.2 ± 0.3/10⁴ μm²), D (4.8 ± 0.5/10⁴ μm²), DW (2.8 ± 0.2/10⁴ μm²) and W (5.0 ± 0.3/10⁴ μm²) compared to OVA (8.2 ± 0.5/10⁴ μm², P<0.05). There was also a reduction of MMP9+ cells in M (6.6 ± 0.4/10⁴ μm²), D (5.4 ± 0.3/10⁴ μm²), W (5.8 ± 0.4/10⁴ μm²), DW (6.2 ± 0.5/10⁴ μm²) and W (4.8 ± 0.4/10⁴ μm²) compared to OVA (9.6 ± 0.5/10⁴ μm²).

Conclusions: In this animal model, corticosteroid or montelukast associated to iNOS inhibitor contributes to the reduction of oxidative stress, actin content MMP9 expression and was efficient to attenuate Th2 cytokine expression in distal lung.

Effects of aclidinium on cigarette smoke-induced fibroblast activation in vitro

Javier Milara 1, Teresa Peiró 2, Adela Serrano 3, Juan Gustavo 4, Amadeu Gavaldà 2, Montserrat Miralpeix 2, Esteban Morcillo 4, Julio Cortijo 4, Isolanda de Fátima Lopes Calvo Tíbelo 1, 1Medicine, School of Medicine University of São Paulo, São Paulo, Brazil; 2Ciências Biológicas, Universidade Federal de São Paulo - UNIFESP, Diadema, São Paulo, Brazil

Aims: To assess the effects of aclidinium bromide, a novel, long-acting muscarinic antagonist, on human lung fibroblast activation after CS exposure in vitro.

Methods: Lung fibroblasts were incubated with aclidinium (10⁻⁷M-10⁻⁵M), the ERK 1/2 inhibitor PD98059 (10μM), the cAMPr analogue dbcAMP (1mM) or the antioxidants N-acetylcysteine (NAC, 1mM) and apocynin (10μg/Ml) for 30 min and then exposed to CS extract (CSE) for 48 h. The collagen type I, αSMA expression and ERK 1/2 phosphorylation were measured by RT-PCR and/or Western blot (WB). Intracellular reactive oxygen species (ROS) were measured by DCFDA fluorescence dye. Protein expression by the NADPH complex gp67phox and choline acetyltransferase (Chat) were measured by WB.

Results: Aclidinium, PD98059, dbcAMP, NAC and apocynin attenuated the CSE-induced increase in αSMA and collagen type I expression. Aclidinium also attenuated the CSE-dependent increase in Phospho-ERK and the CSE-induced increase in ROS to 50% of control. NAC and apocynin fully suppressed the increase in ROS, and PD98059 and dbcAMP reduced it to 20% of control. Aclidinium 10⁻⁵M completely suppressed the CSE-induced increase in gp67phox expression. Aclidinium-induced Chat upregulation suggested an autocrine acetylcholine regulation in response to CSE.

Conclusions: Aclidinium reduces human lung fibroblast activation following CSE exposure in vitro. Aclidinium may reduce lung fibroblast activation in patients with COPD after CS exposure.

Effects of corticosteroid or montelukast associated to iNOS inhibitor on airway remodelling in guinea pigs chronically exposed to cigarette smoke

Rana Keyhanmanesh 1, 2, 3, Horeyeh Bagban 1, Mohammad Reza Alipour 1, Fátima Lopes Calvo Tíbelo 1, 1Medicine, School of Medicine University of Iran, 2Tuberculosis and Lung Research Center, Tuberc, University of Medical Sciences, Trabek, Islamic Republic of Iran, 3Drug Applied Research Center, Tuberc, University of Medical Sciences, Trabek, Islamic Republic of Iran

Aim: To investigate whether corticosteroids, a novel muscarinic antagonist, reduces airway remodelling in guinea pigs chronically exposed to CS.

Methods: Male guinea pigs (n=46) were divided into 2 groups: control (n=22) and exposed to CS (n=24). 6 cigarettes/day, 5 days/week for 24 weeks. Animals received nebulised vehicle, aclidinium 10μg/mL or aclidinium 30μg/mL 60 min before CS exposure. The thickness of the adventitia, muscularis and internal layers of the airway wall was measured by planimetry in immunostained sections. Epithysma and goblet cell metaplasia were evaluated using sections stained with hematoxylin-eosin and alcian blue, respectively. The internal luminal perimeter of each airway served as a reference to normalise and stratify the assessments.

Results: Aclidinium prevented thickening of the small airway muscularis layer in animals exposed to CS. Thickness after CS exposure was: aclidinium 10μg/mL, 18μm and aclidinium 30μg/mL 21μm vs vehicle 32μm (p<0.05 both doses). Aclidinium (both doses) reduced the amount of smooth muscle content (α-actin) in CS-exposed animals. Thickening of the adventitia and muscular layers, goblet cell metaplasia and epithysma were not significantly reduced with aclidinium treatment.

Conclusions: Aclidinium 10μg/mL and 30μg/mL reduce airway remodelling in guinea pigs by reducing the muscularisation of small airways seen after chronic CS exposure. This study was supported by Almirall S.A., Barcelona, Spain, and Consorcios Estratégicos Nacionales en Investigación Técnica (CENIT).

Effects of aclidinium on respiratory function in guinea pigs chronically exposed to cigarette smoke

Elisabet Ferrer 1, David Domínguez-Fandos 1, Raquel Puig-Pey 1, Cristina Carreño 2, Monica Aparici 2, Jorge Beleta 2, Neus Prats 2, Montserrat Miralpeix 2, Amadeu Gavaldà 2, Victor I. Penaud 1, Joan Albert Barba 1, 1Department of Pulmonary Medicine, Hospital Clinic-IDIBAPS, Barcelona, Spain; 2R&D Centre, Almirall, Barcelona, Spain

Introduction: Chronic obstructive pulmonary disease is characterised functionally by decreased respiratory function due to airflow obstruction.

Aims: To evaluate the effects of aclidinium bromide, a novel muscarinic antagonist, on respiratory function and signs of bronchial irritation in guinea pigs chronically exposed to cigarette smoke (CS).

Methods: Male guinea pigs (n=46) were divided into 2 groups: control (n=22) and CS-exposed (n=24). 6 cigarettes/day, 5 days/week for 24 weeks. Animals received nebulised vehicle, aclidinium 10μg/mL or aclidinium 30μg/mL 60 min before CS exposure. The thickness of the adventitia, muscularis and internal layers of the airway wall was measured by planimetry in immunostained sections. Epithysma and goblet cell metaplasia were evaluated using sections stained with hematoxylin-eosin and alcian blue, respectively. The internal luminal perimeter of each airway served as a reference to normalise and stratify the assessments.

Results: Aclidinium prevented thickening of the small airway muscularis layer in animals exposed to CS. Thickness after CS exposure was: aclidinium 10μg/mL, 18μm and aclidinium 30μg/mL 21μm vs vehicle 32μm (p<0.05 both doses). Aclidinium (both doses) reduced the amount of smooth muscle content (α-actin) in CS-exposed animals. Thickening of the adventitia and muscular layers, goblet cell metaplasia and epithysma were not significantly reduced with aclidinium treatment.

Conclusions: Aclidinium 10μg/mL and 30μg/mL reduce airway remodelling in guinea pigs by reducing the muscularisation of small airways seen after chronic CS exposure. This study was supported by Almirall S.A., Barcelona, Spain, and Consorcios Estratégicos Nacionales en Investigación Técnica (CENIT).
sure. Compared with CS-exposed non-treated animals, treatment with aclidinium 30μg/mL resulted in a lower increase in Pden after CS exposure (vehicle vs aclidinium 30μg/mL: 110.6±26.7 vs 71.4±32.4; p=0.016). CS exposure resulted in cough episodes and respiratory crises which were attenuated by aclidinium 30μg/mL.

Conclusions: In guinea pigs chronically exposed to CS, aclidinium 30μg/mL improved inflammatory function by significantly reducing the increase in Pden after CS exposure and reducing the development of cough and respiratory crises. This study was supported by Almirall S.A., Barcelona, Spain, and Consorcio Estratègic Nacional en Investigación Tècnica (CENIT).

P854 Protective effect of lecithinized superoxide dismutase (PC-SOD) against elastase-induced pulmonary emphysema in mice
Ken-Ichiro Tanaka, Tohru Mizushima. Graduate School of Medical and Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan

No medication exists that clearly improves mortality of chronic obstructive pulmonary disease (COPD), an obstructive lung disease. In particular, superoxide anions would play important roles in the abnormal inflammatory response and in pulmonary emphysema, which arises due to an imbalance in proteases and antiproteases and increased levels of apoptosis. Superoxide dismutase (SOD) catalyses the dismutation of a superoxide anion to hydrogen peroxide. Lecithinized SOD (PC-SOD) has overcome a number of the clinical limitations of SOD, including low tissue affinity and low stability in plasma. In this study, we examine the effect of PC-SOD on elastase-induced pulmonary emphysema. The severity of the pulmonary inflammatory response and emphysema in mice was assessed by various criteria, such as enlargement of airspace.

Inhalation of PC-SOD suppressed elastase-induced pulmonary inflammation, emphysema and dysfunction. Inhalation of PC-SOD also suppressed the elastase-induced increase in the pulmonary level of superoxide anions, cell death, activation of proteases and expression of pro-inflammatory cytokines and chemokines. We also found that inhalation of PC-SOD suppressed cigarette smoke-induced pulmonary inflammation.

The results suggest that PC-SOD protects against pulmonary emphysema by inhibition of inflammation and cell death and amelioration of the protease/antiprotease imbalance. We propose that inhalation of PC-SOD would be therapeutically beneficial for COPD.

P855 Prevention of adverse pulmonary consequences of myocardial ischaemia in rats
Ferenc Petkó1, Gergely Albüri2, Eniko Lele2, Maurice Beghetti3, Walid Habre3,1
1Department of Medical Physics and Informatics, University of Szeged, Szeged, Hungary; 2Department of Medical Physics and Informatics, University Hospitals of Geneva, Geneva, Switzerland; 3Pathological Cardiology Unit, Department of Paediatrics, University Hospitals of Geneva, Geneva, Switzerland

The efficacy of treatment strategies against airway hyperresponsiveness (AHR) were compared following chronic postcapillary pulmonary hypertension induced by myocardial ischaemia (MI). Airway resistance (Raw) was measured in four groups of rats under baseline conditions, and following iv infusion of 2-18 μg/kg/min methacholine (MCH). Sham surgery was then performed in Group C, while the left interventricular coronary artery was ligated in the other groups without treatment (Group I), or daily treatments with combined angiotensin enzyme converter (ACE) inhibitor and diuretics (enalapril, lasix, Group IE), or a calcium channel blocker (diltiazem, Group ID). Eight weeks later, MCH provocations were repeated. Equivalent dose of MCH causing 50% increase in Raw (ED50) was determined. Left atrial pressure (Pla) was estimated from the end-diastolic left ventricular pressure. Elevations in Pla to MI (6.8±1.1 [SD] vs. 15.2±1.3 mmHg in Groups C and IE, respectively) were not affected by the treatment in Group ID (13.7±3.1 mmHg), whereas they were inhibited in Group IE (10.9±3.2 mmHg, p=0.005). The development of AHR following MI was completely abolished in both Groups ID and IE.

Conclusion: In guinea pigs chronically exposed to CS, aclidinium 30μg/mL improved inflammatory function by significantly reducing the increase in Pden after CS exposure and reducing the development of cough and respiratory crises. This study was supported by Almirall S.A., Barcelona, Spain, and Consorcio Estratègic Nacional en Investigación Tècnica (CENIT).

P856 Can streptomycin prevent the selection of isoniazid-resistant mutants in nude mice infected with M. tuberculosis?
Claire Andrejak, Sandeep Tyagi, Eric Nuernberger, Jacques Grootes. Center for TB Research, Johns Hopkins University, Baltimore, MD, United States

Rationale: In a previous study, the treatment of M. tuberculosis infected athymic nude (nude) mice with the bactericidal drug isoniazid (H) combined with the two steroiding drugs, rifampicin (R) and pyrazinamide (Z) failed and selected H-resistant mutants. We investigated whether the combination of H with the bactericidal drug, streptomycin (S) would be able to prevent that selection.

Methods: A total of 80 nude mice were aerosol infected with 3.67×10^3 log cfu of M. tuberculosis H37Rv. Two weeks later, at treatment initiation, mice were randomized in the following subgroups: untreated and treated with RZH+ethambutol (E) as controls; treated with S, R, H, R, H+streptomycin. These groups received streptomycin 50 μg/d for 5 days/week/days for 12 weeks. Drug doses (mg/kg) were 10 for R and H, 150 for S and 100 for E. Lung CFU counts were done the day after infection, on treatment initiation, and after 4, 8 and 12 weeks of treatment on plain and H 0.2 μg/ml-containing 7H11 selective plates.

Results: Lung CFU counts were 7.40±0.28 log10 on treatment initiation. After 4, 8 and 12 weeks of treatment, they were 5.82±0.35, 4.05±0.55 and 2.30±0.25, respectively for RZHE; 5.00±0.90, 5.32±0.69 and 5.05±0.90, respectively for SH; and 6.00±0.39, 6.24±0.28, 7.68±0.49, respectively for RH. H resistance was prevented in RZHE treated mice but not in SH and RH treated mice.

Conclusion: Despite its bactericidal activity, S alone cannot prevent selection of H-resistant mutants in nude mice.

P857 Soluble guanylate cyclase stimulator riociguat prevents fibrotic tissue remodeling and improves survival in salt-sensitive Dahl rats
Johannes-Peter Stiassny, Sandra Geier, Bettina Schierle, Yuliya Shkarovskaya, Berthold Holder, Oleg V. Evgenov, Axel Kretzschmer,1
1Cardiology Research, Bayer HealthCare, Wuppertal, Germany; 2Pathology, Bayer HealthCare, Wuppertal, Germany; 3Institute of Pharmacology and Toxicology, Charité, Berlin, Germany; 4Department of Anesthesia and Critical Care, Massachusetts General Hospital, Harvard Medical School, Boston, United States; 5Biomarker, Bayer HealthCare, Wuppertal, Germany

Direct stimulation of soluble guanylate cyclase (sGC) is an emerging therapeutic approach to the management of cardiopulmonary disorders associated with endothelial dysfunction. Novel sGC stimulators, including riociguat, aim to have a dual mode of action: they sensitize sGC to endogenously produced nitric oxide (NO) and also directly stimulate sGC independently of NO. Little is known about their effects on tissue remodeling and degeneration and survival in experimental malignant hypertension. Mortality, hemodynamics and biomarkers of tissue remodeling and degeneration were measured in Dahl salt-sensitive rats maintained on a high salt diet and treated with riociguat (3 or 10 mg/kg/d) for 14 weeks. Riociguat markedly attenuated systolic hypertension, improved systolic heart function and increased survival. Histological examination of the heart and kidneys revealed that riociguat significantly ameliorated fibrotic tissue remodeling and degeneration. Correspondingly, mRNA expression of the pro-fibrotic biomarkers osteopontin (OPN), tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) and plasminogen activator inhibitor-1 (PAI-1) in the myocardium and the renal cortex was attenuated by riociguat. In addition, riociguat reduced plasma and urinary levels of OPN, TIMP-1, and PAI-1. Riociguat markedly improves survival and attenuates systemic hypertension and systolic dysfunction, as well as fibrotic tissue remodeling in the myocardium and the renal cortex in a rodent model of pressure and volume overload. These findings suggest a therapeutic potential of sGC stimulators in providing organ protection in diseases associated with impaired cardio-renal functions.

P858 AZD3199: A fast acting β2-receptor agonist with a long duration of action
Alan Young, Roger Bonnert, Elaine Cadogan, Stephen Connolly, Philip Gardiner, Stephen Jordan, David Nicholls, Stuart Paine, Gary Pairaudeau, Michael Stocks. Research and Development, AstraZeneca R&D Charnwood, Loughborough, United Kingdom

Background: AZD3199 is a novel, ultra long acting β2-agonist (uLABA) designed to combine 24 hour duration of action with a fast onset of action similar to formoterol, as well as low systemic exposure. Its profile was evaluated in the guinea pig.

Methods: Bronchoconstriction was elicited in anesthetized guinea pigs by histamine administration. Dose-response curves for AZD3199 given via the intravenous and intratracheal (i.t.) routes were constructed and sub-maximal doses used to define duration of action from 2–72 hours. The β-antagonist propranolol was administered after histamine-challenge to show the level of β2-eficacy at each dose and time point. Blood samples were taken throughout and plasma K+ concentrations used as a marker of systemic β2 effects. Satellite groups were used to monitor
lung and plasma AZD3199 levels. The pharmacodynamic and pharmacokinetic profiles of AZD3199 were compared to formoterol and salmeterol.

**Results:** Sub-maximal doses of AZD3199 given i.t. inhibited bronchoconstriction for 24 hours; equi-effective doses of formoterol and salmeterol had significant effects for 12 hours. AZD3199 had the longest lung PK half-life. Inhalation of sub-maximal doses of nebulized AZD3199 gave bronchoprotection lasting 24 hours, with no significant effects on blood K⁺ levels. An equi-effective inhaled dose of formoterol bronchoprotected for 8 hours with decreases in blood K⁺ seen at 2 hours. The reduced systemic effects for AZD3199 relative to formoterol are consistent with its high lung to plasma concentration ratio.

**Conclusion:** AZD3199 is a novel d/LABA with a fast onset of action and a longer duration of action than conventional LABAs, and also has a low potential for cardiovascular side effects.

An assessment of the functional profile of aclidinium in human bronchi and left atria

Javier Milara1, Eulena Gabarda2, Amanda Gavalda3, Montserrat Miralpeix4, Jorge Barea5, Esterhan Mtrilloo, Julio Cortijo6, 7CIBERES Health Institute, Carlos Il, Valencia, Spain; Department of Pharmacology, Faculty of Medicine, University of Valencia, Valencia, Spain; 3R&D Centre, Almirall, Barcelona, Spain; 4Research Unit, University General Hospital Consortium, Valencia, Spain

**Introduction:** Aclidinium bromide is a novel, long-acting muscarinic antago-
nist, currently in development for the treatment of chronic obstructive pulmonary disease.

**Aims:** To assess the functional profile of aclidinium in isolated human bronchi and left atria, the organs responsible for efficacy and systemic side effects, respectively. Methods: The smooth muscle relaxant effects of aclidinium, tiotropium and ipra-
ropium were measured in isolated human bronchial rings by determining potency, onset (time to 50% inhibition) and offset (time to 50% recovery). The effects of the muscarinic agonists were standardised in human left atria strips pre-treated with carbachol 10μM to inhibit electrically-induced contractions through the M3 receptor. Duration of action was defined as the time required to recover 50% of the carbachol effect.

**Results:** Aclidinium had similar potency to tiotropium and ipratropium in human bronchi. Aclidinium onset (4.4±0.7 min) was faster than tiotropium (7.4±1.3 min; p<0.05) and similar to ipratropium (3.3±0.6 min). Aclidinium offset (334±49 min) was longer than tiotropium (76±9 min; p<0.05). Tiotropium did not recover within 10 h. Aclidinium inhibited the bradykininergic effect of carbachol in human left atria, with a shorter half life (110±2 min; 95% confidence interval [CI] 103.0, 117.3) than tiotropium (159.3 min; 95% CI 148.2, 171.7) but longer than ipratropium (16.6 min; 95% CI 16.4, 16.8).

**Conclusions:** Aclidinium has similar potency but faster onset of action than tiotropium in human bronchi. In human left atria, aclidinium had a shorter duration of action than atropine at M3 receptors, suggesting a lower potential for cardiovascular side effects.

Efficacy of indacaterol is maintained irrespective of inhaled corticosteroid (ICS) use

Ronald Dahl1, Charles Fogarty2, David Lawrence3, Cheryl Lassen4, Benjamin Kramer5, 6Department of Respiratory Diseases, Aarhus University Hospital, Aarhus, Denmark; 7Medical Research, Spartanburg Medical Research, Spartanburg, United States; 8Novartis Horsham Research Centre, Novartis, Horsham, United Kingdom; 9Respiratory Development, Novartis Pharmaceuticals, Hanover, United States

**Introduction:** Indacaterol is a once-daily inhaled β2-agonist bronchodilator for COPD.

**Aim:** Pooled analysis to determine indacaterol efficacy in subgroups of COPD patients (pts) receiving ICS or not.

**Methods:** Data from 4088 pts with moderate-to-severe COPD in 3 randomised, double-blind, placebo-controlled studies of indacaterol 150 and 300μg od, tiotropium 18μg od (open-label), formoterol 12μg bid & salmeterol 50μg bid were pooled: 44% of pts had baseline ICS use, 56% no ICS use. Endpoints at 6 months: trough FEV1, transition dyspnoea index (TDI) and St George’s Respiratory Questionnaire (SGRQ) total scores. The % of pts with clinically important difference in TDI and SGRQ were analysed as odds ratios (OR).

**Results:** Differences vs placebo (n=661) not on ICS, 524 on ICS (p<0.05, ¶p<0.01, ||p<0.001) in pts not on ICS (‘no’) or on ICS (‘ICS’) (p<0.05 vs tiotropium, ‡p<0.05 vs formoterol, §p<0.05 vs salmeterol, †¶p<0.05 vs indaceterol 150μg).

**Conclusions:** Indacaterol improved FEV1, & clinical outcomes after 6 mo irrespective of COPD severity. Indacaterol 300μg was notably effective for breathlessness in the more severe subgroup.

**P862**

The efficacy of the assistant use of short-acting β2 stimulant procaterol on the daily activity in COPD patients. Niigata multicenter study

Kunihiko Sakai1, Heideaki Nakayama2, Satoko Hoki2, Ryoko Suzuki2, Asako Takiguchi3, Toshinori Takada2, Eiichi Suzuki3, Ichiei Narita4, 1Department of Internal Medicine, Niigata Rinko Hospital, Niigata, Japan; 2Division of Respiratory Medicine, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 3Department of General Medicine, Niigata University Medical and Dental Hospital, Niigata, Japan

**Background and purpose:** COPD patients have some dyspnoea on exertion in spite of medication. Guidelines suggest the use of short-acting β2 antagonist (SABA) as necessary. There are few reports to see whether the supplementary use of SABA inhalation impairs their physical activity, ADL, and QoL in the daily life. We evaluated the efficacy and safety of assistant use of procaterol inhalation.

**Methods:** COPD patients were enrolled and asked to keep as active as possible. Physical activities were measured by the uni-axial accelerometer. COPD patients were divided into two groups. One was the group as controls (Group C) and the other was the procaterol group (Group P).

**Results:** Aclidinium improved FEV1, and clinical outcomes after 6 months in patients not receiving ICS and those on ICS.
other was those who used procaterol before or after the exertion when they felt
dyspnoea (Group P). Physical activities, ADL and QoL in the daily life were com-
pared during the observational and the experimental periods for each one month.
Statistical analyses were done by two-way ANOVA. A p < 0.05 was considered
significant.

**Results:** Forty four patients were enrolled and 37 completed the study.

**Onset of action and effect of withdrawal of roflumilast in COPD**

Klaus Raber, Thomas Similowski, Dirk Bredenbroke, Peter Teichmann, Gyorgy Boszormenyi-Nagy.

1 Center for Pulmonaryology and Thoracic Surgery, Krankenhaus Grosshansdorf, Grosshansdorf, Germany; 2Service de Pneumologie et de Reanimation, Groupe Hospitalier Pitié-Salpetrière, Paris, France; 3Dept. of Respiratory Medicine, Nycomed GmbH, Konstanz, Germany; 4Dept. of Medical Scientific Strategy, Nycomed GmbH, Konstanz, Germany; 5Dept. of Pulmonology, National Korányi Institute of Pulmonology, Budapest, Hungary

**Background/Rationale:** Roflumilast (ROF) is an oral, selective phosphodiesterase 4 inhibitor licensed for the maintenance treatment of severe COPD associated with chronic bronchitis and a history of frequent exacerbations. It improves lung func-
tion and reduces the rate of exacerbations in these patients. Limited data are available on the on- and off-action of ROF and the effects of treatment withdrawal.

**Methods:** Patients aged 40–75 years with stable COPD, fixed airways obstruction, post-bronchodilator FEV1 ≥70% predicted and ≥10 pack-years smoking history were randomised to one of 3 groups: once-daily ROF 500 μg for 24 weeks, once-daily placebo (PBO) for 24 weeks, and ROF 500 μg for 12 weeks then PBO for 12 weeks (ROF/PBO).

**Results:** A total of 581 patients were randomised (ROF, n=200; PBO, n=186; ROF/PBO, n=195). Demographic and baseline characteristics were similar in all groups. FEV1 increased with ROF: at weeks 1, 4, 8, and 12 least squares mean change in trough FEV1 at 24 hours were reported at doses 12.5 μg to 400 μg were well tolerated. ROF/PBO demonstrated rapid onset of bronchodilation with clinically meaningful improvements in lung function over 24 hours following nebulization in patients with COPD.

**Conclusion:** Single doses of EP-101 ranging from 12.5 μg to 400 μg were well tolerated. EP-101 demonstrated rapid onset of bronchodilation with clinically meaningful improvements in lung function over 24 hours following nebulization in patients with COPD.

**Doxofilline: Efficacy and safety in complex treatment of COPD**

Tetyana Pertseva, Kateryna Gashynova, Natalia Klimenko.

Internal Medicine, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

**Aim of study:** To evaluate efficacy and safety of Aerofylline, ABC Farmaceutici (doxofilline) in patients with stable COPD.

**Study population and methods:** 30 out-patients (pts) with stable COPD, stage II were divided on two groups: 15 pts (11 men, mean age 47.5±8.6 yrs) treated with inhaled bronchodilators and doxofilline 400 mg bid (Group 1) and 15 pts (12 men, mean age 50.3±9.0 yrs), treated with inhaled bronchodilators only (Group 2). Pulmonary function tests, respiratory muscles fatigue (by MasterLab. Jager), Holter ECG and dyspnoea (by MRC score) were evaluated in all pts before and 30 days after start of treatment.

**Results:** Both groups were similar regarding to age, sex, duration of disease, FEV1, Pmax, and dyspnoea level at the beginning of treatment. 30 days after start of treatment the results were following: FEV1 did not change statistically significant in both groups. At the same time, dyspnoea score decrease significantly in Group 1 but not in Group 2 (down to 0.4±0.4 scores and 1.9±0.5 scores respectively). Pmax in Group 1 increase on 21.3%, in Group 2 – on 11.9%. We did not find any difference in tachycardia and prematurity beat rate between the groups.

**Conclusions:** Doxofilline did not improve pulmonary function, but significantly decrease respiratory muscles fatigue and dyspnoea in patients with COPD, stage II. Doxofilline did not influence significantly on a heart rhythm.

**P865**

**Efficacy and safety of nebulized glycopyrrrolate (EP-101) for administration using high efficiency nebulizer in patients with COPD**

Dave Singh1, Brian Leaker2, Ahmet Tunurcu3.

1Medicines Evaluation Unit, Manchester, United Kingdom; 2Respiratory Clinical Trials Ltd., London, United Kingdom; 3Elevation Pharmaceuticals Inc., San Diego, CA, United States

**Introduction:** EP-101 is a long-acting muscarinic antagonist formulation of gly-
copyrrrolate optimized for nebulization in development for the treatment of COPD.

This dose-ranging study assessed the efficacy and safety of single doses of nebulized EP-101 in patients with COPD.

**Methods:** This was a randomized, double-blind, placebo-controlled, 6-period cross-over study in 42 patients with moderate-to-severe COPD. Patients were randomized to receive single doses of EP-101 (12.5, 50, 100, 200 and 400 μg) and placebo via a high efficiency nebulizer, with a 5–12 days of washout between treatments. Plasma PK was assessed in a subset of patients.

**Results:** The study patients had a mean age of 62 years, COPD duration of 7 years, post-bronchodilator FEV1 of 54% predicted normal, FEV1/FVC of 44.9%, FEV1 reversibility of 27.3%. All treatments were well tolerated with similar AE rates between all treatments and no clinically relevant changes in vital signs (heart rate, systolic and diastolic blood pressure) and ECG parameters including QTc interval. Following treatment with EP-101 at all doses there was a rapid bron-
chodilatory response at 5 minutes. Statistically significant improvements in mean change in trough FEV1 at 24 hours were reported at doses ≥50 μg compared with placebo (37mL, 72mL, 104mL, 118mL and 95mL at doses 12.5, 50, 100, 200 and 400 μg, respectively).

**Conclusion:** Single doses of EP-101 ranging from 12.5 μg to 400 μg were well tolerated. EP-101 demonstrated rapid onset of bronchodilation with clinically meaningful improvements in lung function over 24 hours following nebulization of 400 μg in patients with COPD.

Efficacy and safety of AZD3199, an inhaled ultra-long-acting β2-agonist, in patients with COPD.

Piotr Kuna1, Yavor Ivanov2, Vasili Trofimov3, Ola Beckman4, Thomas Bengtsson5, Carin Jurup6, Francois Malais3, Piotr Grot1, Zeki Yildirim1, Department of Pulmonology, University of Dundee, Dundee, United Kingdom; 2Department of Pulmonary Medicine, Bari University, Bari, Italy; 3Bute Medical School, University of St Andrews, St Andrews, United Kingdom; 4Department of Respiratory Medicine, Perth Royal Infirmary, Perth, United Kingdom; 5Centre de Pneumologie, Institut Universitaire de Cardiologie et de Pneumologie de Quebec, Quebec, Canada

Objectives: To study the efficacy and safety of three once-daily doses of AZD3199 inhaled via Turbuhaler compared with twice-daily formoterol and placebo over 4 weeks in COPD patients.

Methods: This was a 4-week randomised, double-blind, parallel-group multi-centre Phase II study to compare once-daily inhaled doses of AZD3199 (200, 400 and 800 μg delivered) with formoterol (9 μg bid) and placebo in 329 adults with moderate/severe COPD (NCT00927084). Bronchodilation was assessed by average post-dose FEV1 values from 0–4 hrs (E0_4), peak FEV1 and FEV1 values from 24–26 hrs (E24_26) post-dose. Use of β2-agonist reliever medication, salbutamol reversibility, symptom scores (CCQ) and safety were also assessed.

Results: A total of 822 patients (mean age 63.9 yrs; post-bronchodilator FEV1 [G]; 59.0 ± 22.2% of predicted) were randomised to receive one of the four treatment regimens; 208 patients in each group over the study period. Sex, Age and smoking history were used as covariates. We observed lung function (FEV1% pred) a 1.03 ± 0.31 point increase was observed in the formoterol group compared with placebo (0.67 ± 0.31 point increase in placebo after 4 weeks’ treatment). Each symptom (cough, sputum production and dyspnea) was evaluated on a 4-point scale by the patients.

Conclusion: AZD3199 is well tolerated with no safety concerns.

Conclusions: AZD3199 is a safe and effective uLABA with a 24-hour duration of action.

P870
Influence of tiotropium bromide on airway inflammation and symptom in COPD patients

Stephen W Maslin1, Simon White1, Gillian Williams1, Shafiq Ahmad1, Paul Connaughton1, Simon Mason1, 1Respireatory Medicine, Kishiwada City Hospital, Kishiwada, Osaka, Japan; 2Thoracic Surgery, Kishiwada City Hospital, Kishiwada, Osaka, Japan

Aim: Chronic obstructive pulmonary disease (COPD) is characterized by abnormal inflammatory response of lungs to noxious particles or gases. The aim of this is to study the impact of tiotropium bromide treatment on airway inflammation and symptoms in COPD patients.

Methods: Tiotropium bromide treatment with 18 mcg daily dose, was started in newly diagnosed, consecutive mild–moderate stable COPD patients. Peroxynitrite, interleukin-6 (IL-6), 8-isoprostane and tumour necrosis factor-alpha (TNF-α) were measured in the expired breath condensate fluid before the treatment and at the end of first month. Each symptom (cough, sputum production and dyspnea) was evaluated on a 4-point scale by the patients.

Results: Twenty-two patients (81% men), with a mean age 65.4±10.1 years were included in the study. The mean nitrotyrosine and 8-isoprostane levels for oxidative stress marker in BEC before and after treatment were 4.5±2.3, 3.5±1.9 pg/ml (p=0.006) and 7.3±10.8, 8.1±11.7 pg/ml (p=0.3) respectively. The mean TNF-α, IL-6 and 8-isoprostane levels were measured in the expired breath condensate fluid before the treatment and at the end of first month. Each symptom (cough, sputum production and dyspnea) was evaluated on a 4-point scale by the patients.

Conclusion: There were no significant changes for inflammatory and oxidative stress markers in expired breath condensate fluid after a tiotropium treatment of one month, but tiotropium treatment helps to control symptoms in COPD with an increase in FEV1.

P871
The impact of tiotropium on mortality when added to inhaled corticosteroids and long-acting beta agonist therapy in COPD

Philip Short1, Douglas Elder2, Peter Williamson1, Samuel Lipworth3, 1Asthma and Allergy Research Group, University of Dundee, Dundee, United Kingdom; 2Department of Clinical Pharmacology, University of Dundee, Dundee, United Kingdom; 3Bute Medical School, University of St Andrews, St Andrews, United Kingdom; 4Department of Respiratory Medicine, Perth Royal Infirmary, Perth, United Kingdom

Background and objectives: Tiotropium (TIO) has been shown to improve lung function, quality of life and reduce mortality and exacerbations in COPD. However it remains unclear whether such benefits are seen when TIO is used in conjunction with inhaled corticosteroids (ICS) plus long acting beta-2 agonists (LABA).

Methods: Retrospective Cohort study using linked NHS databases on hospital admissions, COPD outcomes, prescribing and mortality. Cox proportional hazard regression analysis was used to assess the association of TIO with ICS+LABA on mortality and exacerbations. History of respiratory and cardiovascular disease, Sex, Age and smoking history were used as covariates. We observed lung function in each group over the study period.

Results: 3004 COPD patients were included in the study. 2082 patients were prescribed ICS+LABA+Tio and 922 were prescribed ICS+LABA. Mean follow-up was 4.65 years. Mean age 68.5 years. 1035 patients died during the study. The adjusted hazard ratio for all-cause mortality for ICS+LABA+TIO vs ICS+LABA was 0.67 (95% CI 0.58-0.76) p<0.001. Adjusted hazard ratios for respiratory hospital admissions and oral corticosteroid use were 0.86 (95% CI 0.74-0.99) p=0.043 and 0.72 (95% CI 0.65-0.81) p<0.001. In the ICS+LABA group (mean FEV1% pred 66.8%), mean first and last FEV1 and FVC (L) were 1.56 ± 1.37 and 2.64 ± 2.72. In the ICS+LABA+TIO group, (mean FEV1% pred 51.6%), mean first and last FEV1 and FVC (L) were 1.24 ± 1.20 and 2.47 ± 2.50.
Conclusions: We have shown that the addition of TIO to ICS+LABA reduces all-cause mortality in our COPD population. Reductions in COPD exacerbations and oral steroid use reaffirm findings of previous studies.

P872
Assessments of protective effects of tiotropium bromide against methacholine- and neurokinin A-induced bronchoconstriction in patients with asthma
Eric Deluc,1 Yannick Van Durme,1 Bihgya Sahu,2 Christine Vander Stichelen,1 Fred Baert,1 Joycelein Sele,2 Roland Louças,2 Guy Joos.1 1Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 2Respiratory Medicine, CHU Sart Tilman, Liège, Belgium
Rationale: Previous studies using short-acting anticholinergics have suggested a possible protective effect on bronchoconstriction induced by the sensory neuropptide neurokinin A (NKA).
Aim: To assess the effect of tiotropium bromide, a long-acting anticholinergic agent, on NKA-induced bronchoconstriction.
Methods: PC20 NKA and PC20 methacholine were investigated in asthmatic patients after 20 days of treatment with tiotropium bromide (18 µg/gid) or placebo. PC20 was expressed in log2 doubling concentrations (DC). Values were reported as median with 25th-75th percentiles. Fairly comparisons of the log2 PC20 values at screening and at the end of active and placebo treatments were performed.
Results: 16 patients with asthma (9 male; age: 24 (18-63) years) were included. PC20 NKA was 0.18 (0.06 - 0.29) µmol/ml at screening, 0.34 (0.09 - 3.34) µmol/ml after tiotropium placebo, and 0.77 (0.08 - 3.34) µmol/ml after tiotropium bromide. PC20 methacholine was 0.5 (0.3 - 0.7) mg/ml at screening, 0.3 (0.2 - 1.5) mg/ml after placebo, and 256.0 (11.7 - 256.0) mg/ml after tiotropium bromide. Differences between active treatment and screening log2PC20 were 2.4 (0.4 - 3.2) DC for NKA (p = 0.06) and 7.6 (4.8 - 9.0) DC for methacholine (p < 0.0001). Differences between placebo treatment and screening for log2PC20 NKA and log2PC0 methacholine were not observed.
Conclusions: Inhaled tiotropium bromide protects against methacholine-induced bronchoconstriction, but not against bronchoconstriction induced by NKA, suggesting that cholinergic mechanisms are not involved in the contractile effects of NKA in patients with asthma.

P873
ACCORD COPD I: Improvements in nighttime symptoms and rescue medication use in COPD with twice-daily aclidinium bromide
Edward Kerwin,1 Stephen Remaud,1 Arthur Gelb,1 Ludmila Rekeda2, Esther Garcia Gil1, Cynthia Caracta3.1Medicines Evaluation Unit, University of Manchester, Manchester, United Kingdom; 2Division of Pulmonology, University of Cape Town, Cape Town, South Africa; 3Thorax Institute, Hospital Clinic and CIBER Enfermedades Respiratorias and Fundació Cuabt-Cimera, Barcelona, Spain; 4R&D Centre, Almirall, Barcelona, Spain; 5Clinical Development, Forest Research Institute, NJ, United States
Introduction: Nighttime symptoms in COPD patients can reduce quality of life. In this Phase III study, nighttime symptoms and rescue medication use were assessed in a twice-daily (BID) treatment with aclidinium bromide, a long-acting muscarinic antagonist in development for COPD.
Methods: In this 12-week, double-blind study, COPD patients (FEV1 <70%) were randomised (1:1:1) to aclidinium 200 µg, 400 µg, or placebo. Nighttime symptoms were recorded daily using electronic diaries via a COPD Nighttime Symptoms Questionnaire, which assessed frequency and severity of symptoms and their impact on activity and sleep. Rescue medication use was also assessed.
Results: Of 561 randomised patients, 467 completed the study. At Week 12, aclidinium 200 µg and 400 µg reduced nighttime symptom frequency vs placebo (p = 0.005 and p < 0.005, respectively). Both aclidinium doses reduced severity and impact of nighttime breathlessness and cough on morning activities vs placebo (p < 0.01 and p < 0.05, respectively). Severity of early morning breathlessness and activity restriction due to breathlessness were reduced with aclidinium 200 µg (p < 0.01) and 400 µg (p < 0.001) vs placebo. Compared to placebo, 24-h sputum production was significantly reduced with the 200 µg (p = 0.005) and 400 µg (p = 0.001) doses at Week 12 but not sputum production during sleep. Aclidinium 400 µg improved the severity and impact of breathing symptoms on sleep vs placebo at 12 weeks (p < 0.01). Both aclidinium doses reduced total daily rescue medication use vs placebo (p < 0.001 for both).
Conclusions: Aclidinium 200 µg and 400 µg BID significantly reduced nighttime early morning symptoms and daily rescue medication use.

P874
Improvement in symptoms and rescue medication use with aclidinium bromide in patients with chronic obstructive pulmonary disease: Results from ACCORD COPD I
Alvar Agustí1, Paul W. Jones1, Eric Bateman1, David Singh1,4, Rosa Lamarca1, Gonzalo de Miquel1, Cynthia Caracta2, Esther Garcia Gil1,3.1Thorax Institute, Hospital Clinic and CIBER Enfermedades Respiratorias and Fundació Cuabt-Cimera, Barcelona, Spain; 2St George’s, University of London, London, United Kingdom; 3Thorax Institute, Hospital Clinic and CIBER Enfermedades Respiratorias and Fundació Cuabt-Cimera, Barcelona, Spain; 4Clinical Development, Forest Research Institute, NJ, United States
Introduction: Aclidinium bromide is a long-acting muscarinic antagonist in development for treatment of COPD. In this Phase III study, the effects of twice-daily aclidinium on health outcomes were assessed.
Methods: In this 12-week, double-blind study, moderate to severe COPD patients were randomised to receive aclidinium 200 µg, 400 µg or placebo BID. Health outcomes were assessed monthly via SGRQ and TDI.
Results: Of the 561 patients randomised, 467 (83%) completed the study at Town, South Africa; 6Medicines Evaluation Unit, University of South Manchester, Manchester, United Kingdom; 7R&D Centre, Amtrill, Barcelona, Spain; 8Clinical Development, Forest Research Institute, NJ, United States
Introduction: The ACCORD study investigated the efficacy and safety of two twice-daily doses of aclidinium bromide, a long-acting muscarinic antagonist, in patients with moderate to severe chronic obstructive pulmonary disease (COPD). Methods: In this 24-week, double-blind trial, 828 patients were randomised (1:1:1) to twice-daily aclidinium (200 µg or 400 µg) or placebo. COPD symptoms were assessed using the Transition Questionnaire (TDQ), patient-reported daily electronic diaries and Total Exact score. Rescue medication use was also assessed.
Results: Baseline characteristics were similar between the groups; FEV1% predicted 56.8±12.8%, focal BDI 8±6±2.1. More patients treated with aclidinium 200 µg or 400 µg had a clinically meaningful improvement in TDI focal score (≥2 unit) vs placebo at Week 24 (53.3% and 56.9% vs 45.5%; p=0.032 and 0.004, respectively). Aclidinium dose-dependently improved TDI focal score at Week 24, which was clinically meaningful for aclidinium 400 µg (1.0 unit) and statistically significant for both doses vs placebo (200 µg, p<0.05; 400 µg, p<0.001). Over the study period, aclidinium (both doses) was associated with a lower incidence of night-time (p<0.0001) and early morning (p<0.05) COPD symptoms, a greater reduction in Total Exact score (p<0.0001) and more days without reliever medication (p=0.0003) vs placebo.
Conclusions: Aclidinium 200 µg and 400 µg twice-daily provided statistically significant and clinically meaningful improvements in COPD symptoms in patients with moderate to severe COPD. This study was supported by Almirall S.A., Barcelona, Spain, and Forest Laboratorie, Italy, New York, USA.
baseline, the mean (SD) pre-bronchodilator FEV₁ and percent predicted were 1.36 (0.54) L and 47.2 (14.1%) respectively. Baseline mean (SD) SGRQ total score and BDI focal score were 46.5 (17.1) and 6.4 (2.1) respectively. Adjusted mean difference was 2.06 (0.32) change from baseline in SGRQ total score at Week 12 were -2.7 (p<0.01) and -2.5 (p<0.02) for aclidinium 200 μg and 400 μg, respectively. At all time points, statistically greater percentages of aclidinium patients achieved clinically significant improvements in SGRQ vs placebo (>24 points; p<0.05 for all except Week 12, 400 μg group). Both aclidinium doses provided significant improvements vs placebo in TDI focal score (p<0.05, range 0.6-0.74) throughout the study; with the exception of aclidinium 200 μg at Week 8 (p<0.06). Significantly greater percentages of patients achieved clinically meaningful improvements in TDI (>1 unit) with both aclidinium doses at all time points vs placebo (p<0.05).

Conclusions: In this 12-week study, aclidinium 200 μg and 400 μg BID significantly improved quality of life and reduced dyspnea for patients with moderate to severe COPD.

**P87**

Aclidinium bromide in patients with chronic obstructive pulmonary disease: Improvement in health status in ATTAIN

Paul W. Jones¹, Alvar Agustí², Eric D. Bateman¹, David Singh³, Rosa Lamarca¹, Gonzalo de Miquel, Cynthia Caracots, Esther Garcia Gil, ¹St George's, University of London, London, United Kingdom; ²Thorax Institute, Hospital Clinic and CIBER Enfermedades Respiratorias and Fundació CIBet-Cimera, Barcelona, Spain; ³Department of Pulmonology, University of Cape Town, Cape Town, South Africa; ⁴Medicines Evaluations Unit, University of Manchester, Manchester, United Kingdom; ⁵R&D Centre, Almirall, Barcelona, Spain; ⁶Clinical Development, Forest Research Institute, NJ, United States

**Introduction:** The ATTAIN study investigated the efficacy and safety of two twice-daily doses of aclidinium bromide, a long-acting muscarinic antagonist, in patients with moderate to severe chronic obstructive pulmonary disease (COPD).

**Methods:** In this 24-week, double-blind, randomized, double-blind study, 2,250 patients (1,126 males) were included. Each patient had moderate to severe COPD (FEV₁ ≤ 50% predicted). All patients were randomized (1:1:1:1) to receive aclidinium (200 μg or 400 μg) or placebo, twice-daily. Health status was assessed using the St George's Respiratory Questionnaire (SGRQ) and the EuroQol Questionnaire (EQ-SD; both the weighted health status index and the visual analogue scale [VAS]).

**Results:** There were 819 patients in the intent-to-treat population; forced expiratory volume in 1 second [FEV₁] % predicted ranged from 46.8±12.8%, baseline SGRQ total score 46.3±16.8 units. At Week 24, 26 patients had a clinically significant improvement in SGRQ total score (decrease ≥ 4 units) with aclidinium 200 μg and 400 μg than placebo (54.9% and 54.3% vs 39.5%; p=0.004 and 0.0014, respectively). At Week 24, the improvement with aclidinium 400 μg was 4.3 units, p<0.0001. SGRQ domain scores (Symptoms, Activity, Impacts) were also significantly improved with both doses vs placebo at Week 24 (p<0.05 all domains). Aclidinium 200 μg and 400 μg also improved the EQ-SD weighted index and VAS compared with placebo at Week 24; the 400 μg dose reached statistical significance for the weighted index (p=0.041) and VAS (p=0.005) vs placebo.

**Conclusions:** Aclidinium 200 μg and 400 μg twice-daily demonstrated statistically and clinically significant improvements in health status.

This study was supported by Almirall S.A., Barcelona, Spain, and Forest Laboratories, Inc, New York, USA.

The WHO classification of severe asthma in intensive care patients

T.K. Lim¹, L. Prabakaran², J. Abisheganaden³, G. Chu⁴, B.H. Heng⁵, Y. Sun⁶.
¹Dept. Medicine, National University Hospital, Singapore; ²Dept. Medicine, Tan Tock Seng Hospital, Singapore; ³Dept. Medicine, Alexander Hospital, Singapore; ⁴National Healthcare Group, Singapore

In 2010 a WHO consultative group proposed a definition of severe asthma (JACI 2010; 126:926-3). We have applied this classification to a series of adult patients managed in the intensive care units of 3 large urban hospitals. Over a 5yr period (2006-2010), we registered 386 intensive care admissions for asthma in 332 patients. Their mean age was 53 (18yrs); 57% were women, 48% Chinese, 27% Malays and 14% Indian. Mechanical ventilation was needed in 82% and there were 26 deaths. According to the WHO classification method, the severe asthma, in the first 127 patients, was: untreated in 81 (64%); difficult-to-treat in 41 (32%) and treatment-resistant in 5 (4%). These 3 groups of patients corresponded to distinct and recognizable clinical phenotypes with implications for asthma intervention plans. The untreated patients were from primary care and not attending regular reviews nor receiving long-term control medications. The difficult-to-treat patients were characterized by co-morbidities, non-adherence and under-treatment. We need more effective interventions to reduce the burden of severe asthma at the primary care level. Sub-optimal treatment appeared to be the main barrier to asthma control. Genuine treatment-resistant asthma was an uncommon problem.
Comparison of efficacy of grippe vaccination in asthma and COPD patients

Goran Andonovski1, Zoran Stojanovski2.

Objective: To compare the efficacy of the seasonal grippe vaccination in asthma and COPD patients.

Material and methods: We evaluate the number of exacerbations and number of hospitalisations in 48 subjects in 2 stages and 3 (moderate/severe) COPD and 45 subjects with mild persistent and moderate persistent Asthma in 6 months period. All of them received grippe vaccination before winter. An equal number of COPD and asthma subjects were evaluated like controls. They were not immunized against seasonal influenza. The both groups were matched by sex and age, and receive steroid inhalers (asthmatics), and salbutamol (COPDs) regularly.

Results: Treatment, compliance, lung function, and grippe follow-up appointments. In total, 130 primary care clinics across Denmark participated.

Conclusion: At the initial visit (baseline), 722 patients (37.3%) were classified as well-controlled, 759 (39.2%) as partly controlled and 456 (23.5%) as uncontrolled. At the time of data analysis (September 2011), 641 patients had been offered a both a baseline and a follow-up visit. A higher level of asthma control was found at the follow-up visit compared to the baseline visit (uncontrolled asthma 29.7% and 6.2%, respectively, p<0.001). At the time of the follow-up visit 50% of those partly controlled and 52% of those with uncontrolled asthma had changed from SABA only to ICS (p<0.001). The level of lung function also improved from the baseline to the follow-up visit.

Conclusion: Although most asthmatic individuals received asthma treatment, a substantial number still were partly or poorly controlled. The overall asthma control improved significantly when a systematic asthma management approach was introduced by educated health care staff.

Is mild asthma outside the guidelines?

Olga Valkh1, Vitaly Kuparev2, Julia Bogdanova1. 1Pulmonology Department, Samara Regional Hospital, Samara, Russian Federation; 2The Chair of General Practice, Samara State Medical University, Samara, Russian Federation

The majority of mild asthma cases, its low level of adherence and asthma control had induced investigators examine this cohort. The aim was to study specificity of adherence and asthma control level of patients with mild persistent asthma determined by treatment regimen.

131 patients with mild persistent asthma were examined (age 43.2±15.6 yrs). Two groups were formed:1-st group - had regular inhaled corticosteroids (ICSs) treatment for 3 months (n=57), 2nd - had actual intermittent ICSs therapy (n=74). The questionnaire collects information concerning educational level, social status, knowledge about asthma, FEV1, inflammation parameters (such as Ig E), asthma control, compliance level, etc. 62 patients took part in educational asthma program. We observed uncontrolled asthma in 61.8% of cases. Marker of allergic inflammation - Ig E - had been ranging between 58.8 to 329.4 Ml/ml. There were significant correlations between ACT™ score and patients’ knowledge about asthma (p=0.52, p<0.05). There was no significant difference in asthma control and FEV1 data between two groups. Patients with regular therapy had significantly higher ICSs current dose, compliance index level, more often made planned visits to their physician (p<0.05).

We revealed that mild persistent asthma needs regular control visits to physician, taking part in educational asthma program (electronic one more often), plan of self-management in order to improve adherence and asthma control.
Introduction: Asthma is associated with morbidity and mortality in patient referred to emergency department (ED). Our study was focused on simple objective measures in ED to predicting factors affecting disposition of patients with acute asthma referred to emergency ward.

Methods and materials: Data were collected prospectively at one center over 12-month period on 103 adult patients. Asthma step severity categorization and management was determined by GINA guidelines. Presenting ED vital signs, GSK values, pulmonary function testing (spirometry, flow-volume loop, Pmax, PEmax) and disposition were recorded for each study subject.

Results: In this study 103 patients were studied. In our patients 56 cases (%54.4) admitted and 47 (45.6%) cases were discharged. There is no significant difference between admission rates and these variables: Age, Weight, Height, BMI (Body Mass Index), History of previous hospitalization, Living place (urban/rural), peripheral edema and some spirometric parameters, but significant difference were seen between admission rates and these variables: Functional stage of dyspnea, Pulsus Paradoxus, Intercostal retraction, Respiratory Rate (RR), Heart Rate, Arterial saturation of oxygen, Artieal pH. Variables that predict admission rates in our patients are as follows: Sex, RR and SaO2 in first visit, PEmax in second measurement.

Conclusion: Finding those variables that predict admission in asthmatic patients is very important and cost effective. We recommend further studies in this field especially in measurement of new pulmonary function variables such as PImax and PEmax.

Key words: Asthma, emergency, PEmax

P888
Comparative efficacy of the therapy strategies for the asthma control maintenance in real clinical practice
Evgeny Kulikov, Ludmila Ogurodova, Ivan Deev. Faculty Pediatrics, Siberian State Medical University, Tomsk, Russian Federation

Introduction: Today there is no clear answer to the question which therapy regimen will be optimal for disease control maintenance in real clinical practice. Aim: To compare the efficiency of strategies of control achievement from position of maintenance control in patients with persistent asthma in real clinical practice by ACE-test.

Methods: Multicenter prospective 24-week observation study was conducted in 19 centers in Russia. Investigator was only to record the changes of therapy prescribed by the physician of patient. Patients were aposteroir stratified into three groups: A - step-up regimen of combination therapy (salmeterol/fluticasone propionate), B - stable regime, C - step-down regime.

Result: According to the inclusion criteria the patients in all groups had the uncontrolled disease course (ACE score <20). Of the 288 patients (50%) who achieved control in the first 3 months of observation, 263 (91.3%) persons maintained or increased the disease control level and only 23 (8.0%) of the patients “lost” the disease control. The ACE score decreasing to the uncontrolled level (<20 points) in group A and B was registered in 7.7% and 2.8% of cases, respectively. The significantly biggest proportion of patients with the loss of asthma control was registered in group A and B was registered in 7.7% and 2.8% of cases, respectevely. The highest emergency visit frequency was registered in the group C (18.2%; Group A - 2.6% and B - 5.8% (p<0.001 vs A; p=0.01 vs B).

Conclusion: In the real clinical practice the use of combination therapy at step-up dose or in stable dose are optimal.

P890
Effect of whole body periodic acceleration on airway endothelial function in smokers, non-smokers and asthmatics
Jose Caneco, Elia Mendes, Johana Araña, Patricia Rebollo, Cameron Dezfulian, Adam Wanner. Pulmonary, Critical Care and Sleep Medicine, University of Miami Miller School of Medicine, Miami, FL, United States

Rationale: Cigarette smoking and asthma are associated with attenuated endothelium-dependent vasodilation in the airway. Endothelial shear stress actives endothelial nitric oxide synthase (eNOS), leading to endothelium-dependent vasodilation. It has been shown that whole body periodic acceleration (WBPA), activates eNOS. However, the effect of WBPA on endothelial function in the airway has not been investigated.

Objective: To assess the effect of a single WBPA session on beta-2 agonist induced, endothelium-dependent vasodilation (ΔAQw) in 15 current smokers, 15 never-smokers with asthma, and 15 healthy never-smokers, with the expectation that the treatment would transiently improve endothelial function.

Methods: ΔAQw was defined as the Qw response to inhaled albuterol (180µg). Normal and S-nitrosothiol blood levels (NO) were assayed using a tri-iodide based reductive chemiluminescence method. All measurements were made before and immediately after a 45 minutes WBPA treatment using ExerRest®.

Results: WBPA increased mean baseline Qw by 15.1±4.3±3.5 µl/mmHg in non-smokers (p<0.001) but had no effect on Qw in smokers and asthmatics. ΔAQw remained unchanged in all three groups. NO levels tended to increase in asthmatics (13%) and non-smokers (31%), but the changes did not reach statistical significance.

Conclusions: A single session of WBPA increases airway blood flow in healthy non-smokers, but not in smokers and asthmatics. The treatment has no effect on the blunted endothelium-dependent vasodilation in smokers and asthmatics nor does it augment normal endothelium-dependent vasodilation in healthy non-smokers despite a tendency toward eNOS activation

P891
Successful implementation of an asthma care bundle in a UK hospital
Ali Taghizadieh. Tuberculosis and Lung Diseases Research Center, Tabriz, Iran

Introduction: A care bundle is a checklist of guidelines for clinicians. These have been successfully implemented in areas such as central line sepsis & ventilator-acquired pneumonia. We proposed that a care bundle would improve acute asthma care & outcomes by providing key clinical prompts. The 2009 British Thoracic Society (BTS) asthma audit highlighted areas for improvement, including PEFR and SpO2 documentation, inhaler technique review & use of written action plans. Aims and objectives: To assess the impact of an asthma care bundle on concordance with UK asthma standards.

Method: A checklist sticker was created, piloted & implemented on acute medical wards, and the impact assessed using the 2010 BTS asthma audit.

Results: Pre- and post-care bundle results are shown in Table 1 (care bundle elements shown in bold)

Table 1. Summary of pre-bundle (2009) and post-bundle (2010) BTS audit outcomes

Conclusion: Use of the care bundle improved acute asthma care, particularly pre-discharge education & planning. Further work is needed to assess longer-term impact e.g. readmission rates, and the bundle is being revised in light of the latest audit data.
Montelukast plus inhaled budesonide versus double dose inhaled budesonide in nonasthmatic eosinophilic bronchitis
Chang Cai, Shui-Qing Zhong, Yan Yang, Nan-Shan Zhong. Guangzhou Institute of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China
Background: Montelukast added to inhaled corticosteroids (ICS) has been demonstrated to relieve asthma symptoms and control airway inflammation equal to double dose ICS. However, the clinical efficacy of montelukast as add-on therapy to ICS has not been reported in nonasthmatic eosinophilic bronchitis (NAEB).
Objectives: Whether add-on therapy with montelukast to inhaled budesonide would equal double dose inhaled budesonide in alleviating cough and airway eosinophilia in adult patients with steroid-naive NAEB was studied, the primary endpoints were changes of cough visual analogue score (CVAS) and eosinophil ratio in induced sputum (EOS) during treatment.
Methods: 26 nonsmoking subjects were randomized to receive either montelukast 10mg qd plus budesonide turbuhaler 200 μg bid (MONT-BUD) or budesonide turbuhaler 400μg qd bid (BUD) for 4 weeks. CVAS, EOS at baseline, 1 week, 2 week and 4 weeks after treatment were measured. Adverse reactions were monitored.
Results: The two groups were comparable in age, median duration of cough and baseline CVAS. Median baseline EOS of MONT-BUD and BUD was 11.8% and 22.7%. Improvement of CVAS was more profound in MONT-BUD. In both groups EOS was normalized in both groups at end of therapy with similar EOS reduction at all time points. Both regimens were well tolerated.
Conclusions: This study demonstrated that the addition of montelukast to inhaled budesonide, and to assess safety, was effective and well tolerated alternative to inhaled budesonide with resolution of airway eosinophilia and more remarkable reduction of cough in NAEB.

Clinical course and outcome of patients with status asthmaticus in a tertiary care centre in Pakistan over the last ten years
Ali Zubairi, Shahid Javed Husain, Zeeshan Waheed. Medical University Karachi, Sindh, Pakistan
Objectives: To describe the clinical course and predictors of poor outcome in patients with status asthmaticus at a tertiary care centre in Pakistan.
Methods: We collected data in patients aged 16 and above with status asthmaticus demographically, co-morbidities, home medications, APACHE II score, use of ventilatory support, and APACHE II score was 9.30 ± 4.39 vs 13.66 ± 2.08, mean PaCO2 was 53.83 ± 23.07 mmHg vs 80.4 ± 15.13 mmHg and arterial pH was 7.33 ± 0.11 vs 7.21 ± 0.09 among survivors and non survivors respectively.
Conclusions: Our study showed that requirement of ventilatory support was associated with prolonged hospital stay. High APACHE II scores, elevated PaCO2, and decreased arterial pH on admission were associated with increased mortality.

Fluticasone/fornterol combined in a single aerosol inhaler vs budesonide/fornterol for the treatment of asthma: A non-inferiority trial
Anna Bodzenta-Lukaszyk1, Roland Bult1, Beatrix Balint1, Mark Lomax2, Kay Spooner2. 1Department of Allergology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; 2Pulmonary Department, Mainz University Hospital, Mainz, Germany; 3Department of Pulmonary Diseases, ConGrey County Municipal Hospital, Destz, Hungary; 4European Medical Science, Mundipharma Research Ltd., Cambridge, United Kingdom; 5European Medical Operations, Mundipharma Research Ltd., Cambridge, United Kingdom
Background: Fluticasone (FLUT) and formoterol (FORM) are widely prescribed for asthmatics. A combination of FLUT/FORM in a single aerosol inhaler (flutiform®) has now been developed. This trial aimed to determine if FLUT/FORM is non-inferior to budesonide/formoterol (BUDFORM, single inhaler) with regards to efficacy, and to assess safety, in adolescents and adults with moderate-to-severe persistent reversible asthma.
Methods: Eligible patients had an FEV1 of >50% to ≤80% for predicted normal value and ≥15% reversibility in FEV1, following salbutamol (up to 400μg qd) 279 patients were randomised to FLUT/FORM 250/10μg b.i.d (n=140) or BUDFORM 400/12μg b.i.d (n=139) in this 12 week, double-blind, 2-arm, parallel-group trial. The primary efficacy measure was change in morning pre-dose FEV1 from baseline to Week 12.
Results: 261 patients completed (FLUTFORM, n=133; BUDFORM, n=128). Both treatment groups showed improvements in morning pre-dose FEV1 from baseline to Week 12. FLUT/FORM was shown to be non-inferior to BUDFORM, because the lower limit of the 95% CI of the treatment difference (FLUTFORM – BUDFORM) was greater than the pre-defined threshold value of -0.2L (95% CI: -0.130, 0.043L). One patient on FLUTFORM discontinued due to AEs (asthma exacerbation: not related) vs 3 patients on BUDFORM (asthma exacerbation, acute sinusitis: not related: asthma exacerbation: possibly related).
Conclusions: Fluticasone/formoterol combination improved morning pre-dose FEV1 over 12 weeks of treatment; demonstrated comparable efficacy to BUDFORM with regards to this key lung function measure of asthma control and had a similar safety profile.

ACHIEVE: Functional effects of long term ICS treatment in controlled asthma
Angelo Petrosanu, Vittoria Conti, Eirini Lemontzi, Irene Minanni, Francesca Oriolo, Viviana D’Alo, Luciana Locorriere, Claudio Terzano. Department of Cardiovascular and Respiratory Sciences, Sapienza University of Rome, Rome, Italy
Background: Goal of asthma management is the “control” of the disease, monitoring symptoms and FEV1 or PEF. However, in controlled asthma the persistence of a long term asymptomatic airway inflammation may lead to an accelerated functional decline.
Aim: To estimate the protective effect of a long term treatment with low dosage of ICS on functional parameters in controlled asthma.
Methods: 98 asthmatic pts with ACT (Asthma Control Test) ≥20, non-smokers were enrolled in a 3 yrs controlled randomized trial. Patients were divided in 2 groups: group A (49) (ICS) receiving a continuous treatment with inhaled beclometasone MDI100mcg twice daily inhaled salbutamol as needed, group B (49) (control) treated with inhaled salbutamol as needed. Step up therapy was performed as recommended by guidelines. Every 3 months, measures of FEV1, FVC, MEF, RV, TLC, FRC, ACT, PEF, (methacoline) were performed. The primary endpoint were: variation of functional parameters, PD20, and ACTscore.
Results: Δ was the difference between time 0 and at 3yrs. Significant difference was reported for RV/LTC: A 30.9 ± 3.2 (A vs B). B 33.7 ± 4.3 (B vs A+2.5); PD20 (mcg): A 123.5 ± 30.1 (A vs B). B 56.7 ± 24.8 ± 30.5 (A vs B); FEV1/FVC at the attainment of PD20: A 64.2% ± 2.9 (A ± 0.4). B 67.6% ± 3.0 (A ± 4.9). No significant differences reported for FEV1 (A 3.94 ± 3.86), FVC (A 2.57, B 2.15), FEV1/FVC (A 74.7%, B 74.9%), MEF25% (A 1.30, B 1.09), ACTscore (A 20.1, B 19.7), side effects (A 8, B 9).
Conclusion: A long term treatment with low dosage of ICS and the reduction of airway responsiveness are bound to a better preservation of the respiratory function in controlled asthma. It is probably due to a better control of a slight air trapping and asymptomatic involvement of small airways, as suggested by the greater decrease of FVC at PD20 in non treated group.

Omalizumab: IgE antibodies may improve remodeling in a mouse model of asthma
Mari Mizuguchi1, Takenori Okada2, Risuko Seki1, Kyoko Ohmori1, Kazunori Fukuda1, Keizichi Akasaka1, Kenya Koyama1, Naoto Fukue1, Hironori Sagara2. 1Dept of Respiratory Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Internal Medicine, Jobu Hospital for Respiratory Disease, Maebashi, Gunma, Japan, 3Koshigaya Hospital Joint Research Center, Dokkyo Medical University, Koshigaya, Saitama, Japan
Recent studies have confirmed that omalizumab, an anti-immunoglobulin E (IgE) antibody, has a high response rate in patients with severe asthma who satisfy conditions such as the use of high-dose inhaled steroids and poor respiratory function. However, the effect of omalizumab on airway remodeling, a characteristic feature of chronic severe asthma, remains to be confirmed. In this study, we compared the effect of omalizumab with that of steroids in a mouse model of remodeling. BALB/c mice were continuously sensitized to ovalbumin to produce a model of remodeling. After the remodeling model was prepared, four groups were studied: an IgE neutralizing antibody group (A), a steroid group (B), an IgE neutralizing antibody plus steroid group (C), and an untreated control group (D). Basement membrane thickening, used as a marker of remodeling, was found to be significantly inhibited in the group A, as compared with the other groups. The group B showed a trend toward inhibition of basement membrane thickening, but the effect was weaker than that in the group A. In the group C, basement membrane thickening was significantly suppressed in a synergistic fashion.
Airway remodeling, a characteristic of chronic severe asthma, was significantly inhibited by treatment with IgE neutralizing antibodies. Concurrent treatment with steroids was markedly effective. On the basis of these results, omalizumab is expected to be therapeutically effective for severe refractory asthma. The finding that treatment with steroids alone was less effective than combined treatment suggested that IgE neutralizing antibodies might also have a steroid-sparing effect.
98. Monitoring exacerbations of airway diseases

P897 Impact of checklist proforma on discharge and follow up care of patients admitted with COPD exacerbations
Mithun Murthy, Rababeh Sarkar, Holly Metcalfe, Sophie Taylor, Gwennan Jones, Jacqueline Bayliss, Robert Stead, Marta Babores. Respiratory Medicine, Macclesfield DGH, East Cheshire NHS Trust, Macclesfield, United Kingdom

COPD management involves a multidisciplinary approach with input from specialist nurses, physiotherapists and dieticians. In 2009, we audited 14 criteria (NICE guidance) and showed scope for improvement. A discharge checklist was introduced.

Aim: To assess impact of discharge proforma on care of patients admitted with COPD exacerbations.

Methods: All COPD patients admitted over Mar-Aug ’09 and Aug-Dec ’10, pre and post introduction of discharge checklist. Data collected: physician and nurse follow up, oxygen assessment, smoking cessation, pulmonary rehabilitation, COPD alert cards, dietetic follow up, domiciliary physiotherapy, community matron follow up, discussion regarding future ventilation, information leaflets, vaccination advice and psychological support.

Results: Table shows comparative results.

Conclusions: Introduction of a discharge checklist led to significant improvements in referrals to respiratory nurse, oxygen assessment, COPD alert cards, leaflets and vaccination advice. We have continued to use this intervention in our hospital.

P898 COPD assessment test correlation with the increase of the inflammatory markers in COPD exacerbations
Zemo-Ioan Fratila, Ionela Iovan, Dorin Vancea. Pneumology, Clinical Hospital of Infectious Diseases & Pneumology Dr. Victor Babes, Timisoara, Timis, Romania

Introduction: COPD is associated with systemic inflammation and it is a known fact that the COPD exacerbations are accompanied by an augmentation of the serum levels of the inflammatory markers. Aim of the study was to evaluate a correlation between the level of systemic inflammatory markers and COPD Assessment Test (CAT) score in patients with hospitalization COPD exacerbations.

Methods: The CAT test questionnaire was implemented in 53 patients COPD GOLD stage II-IV acute exacerbations. The score changes obtained were compared with the modification of usually serum inflammatory markers (erythrocyte sedimentation rate, CRP, fibrinogen).

Results: It was found that from the group of 53 patients, 14 had a score of >30, 31 had 20-30, 8 between 10-20 and none had a score <10. Meanwhile, the serum inflammatory markers, were significantly altered from their initial value in 2 (41.5%) of the 53 subjects, 10 from the group who had the highest CA test score, 11 from the second group and 1 from the last group.

Conclusions: There is a level of correlation between the high values of serum inflammatory markers and the CA test scores, obvious in patients with moderate to severe exacerbations, presenting a higher CAT score (78.57%) in contrast (p<0.0108) with a weak association (12.5%) in patients with low score of the questionnaire and mild exacerbations.

P899 Detection of acute health status deterioration among COPD patients by monitoring COPD assessment test score
Chaichan Pothirat, Warawut Chairung, Aikhum Limsunan, Atthavut Deesomchok, Chalerm Liewsrisakul, Chaiwat Buranongkit. Div. of Pulmonary, Critical Care and Allergy, Dept. of Internal Medicine, Chiang Mai Univ., Chiang Mai, Thailand

Background: The COPD Assessment Test (CAT) is a valid and simple questionnaire to quantify health status of COPD in routine clinical practice, therefore, it should play a role for detecting acute health status deterioration during monitoring visit.

Objective: To evaluated the discriminative properties of the CAT scores for detecting worsening and exacerbation of COPD patients in Thailand

Methods: The CAT questionnaire was administered to 123 stable COPD patients attended at our chest clinic. These patients were monitored every 1-3 month interval for detecting worsening and exacerbation by using CAT score, physician and patient global assessment.

Results: A total of 237 visits among 123 patients, age 70.9±8.5 years, FEV1=47.3±7.3 ml vs 47.9±18.4% predicted were followed. The mean score change in stable COPD was 0.28 (95%CI=0.06-0.97) and 0.45 (95%CI=0.06-0.97) by patient and physician global assessment. CAT scores were significantly higher at the time of worsening and exacerbation: the mean score changes were 5.97 (95%CI=4.68-7.24) and 9.25 (95%CI=7.10-11.79), respectively. The area under the ROC curve of CAT score for detection of acute health status deterioration was 0.92 (95%CI=0.88-0.96) and the cut-off point score at ≥12 had sensitivity, specificity and accuracy=76.74%, 64.43% and 66.67%, respectively.

Conclusions: The CAT score change during monitoring visits is useful for detecting acute health status deterioration

P900 Use of COPD assessment (CAT) test in monitoring acute exacerbations
Irfan Shafiq, Kayleigh Huggett, Lualat Idris, Ranu Roslan, Timothy Shaw. Thoracic Medicine, Royal Bournemouth Hospital, Bournemouth, United Kingdom

Introduction: The COPD Assessment Test (CAT) is a new patient completed questionnaire that has recently been validated to provide a simple assessment of health status in COPD. It is known that patients with moderate to severe exacerbation score about 5 units higher on CAT [1] and hence it may be useful in diagnosing and monitoring exacerbations.

Methods: We administered the CAT at the time of presentation with exacerbation and at the time of discharge home. We also measured the FEV1 on both encounters.

Results: We have results of 102 patients (60 men and 42 women). The initial mean CAT score was 22.55 and it improved to 19.2 by the time of discharge, this is an improvement of 3.27 points in CAT score on recovery from exacerbation. Although the mean improvement in CAT was not as high as 5 points, the difference between the two Cat scores was highly significant (p=0.002). Mean FEV1 improved from 0.89 to 1L but the difference was not statistically significant (p=0.073). The full results are displayed in the table below:

Conclusions: CAT might be a useful tool in monitoring recovery from COPD exacerbation and could help to determine the optimum time for discharging patient from hospital. Larger studies are needed to validate this use of CAT.

P901 Evaluation of high-sensitivity C-reactive protein in acute asthma
Ebrahim Razii1, Hassan Ehteram2, Hossein Akbari1, Vajjhe Chavoshi1, Armin Razii2, 1Department of Internal Medicine, University of Medical Sciences, Kashan, Islamic Republic of Iran; 2Department of Internal Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Objective: High sensitivity C reactive protein (HS-CRP) is an inflammatory marker known to be related to inflammation, infection, and cardiovascular disease. The aim of this study was to evaluate hs-CRP levels in serum of asthmatics and their relationship to pulmonary function tests, serum IgE levels, peripheral blood white blood cells (WBC) counts.

Methods: The study groups were 108 patients with acute asthma and 93 healthy volunteers. The levels of hs-CRP of 108 patients with acute bronchial asthma and 93 non-asthmatic control subjects were measured. Spirometry, serum immunoglobulin-E (IgE) measurement, WBC and counts were done in all the patients and control groups.

Results: Mean serum hs-CRP levels were significantly higher in patients with acute asthma compared with control (5.47±7.33 mg/l versus 1.46±1.89 mg/l, p<0.001). Among asthmatic patients, mean hs-CRP levels did not correlate with indices of pulmonary function (forced expiratory volume in one second/forced vital capacity and forced mid-expiratory flow), serum IgE level, eosinophil count and WBC.

Conclusions: Increase in serum C-reactive protein levels measured by high-
sensitivity assays may be associated with airflow obstruction in acute asthma, and may be useful as a sensitive marker and a diagnostic tool for detecting and monitoring airway inflammation in patients with acute asthma. In our study of patients with acute asthma, it did not reveal any significant correlation between hsCRP and pulmonary function tests, total serum IgE, and peripheral blood white blood cells counts.

P902 Effects of home oximetry on chronic obstructive pulmonary disease exacerbations Mei Ying Chew, T.K. Lim, Pauline Chong, Min Tang, Charmaine Lim. Department of Medicine, National University Hospital, Singapore, Singapore

Background: A large proportion of patients with chronic obstructive pulmonary disease (COPD) require hospitalized care, often at a very high frequency. 

Aims: We hypothesize that home monitoring with pulse oximetry (SpO2) would enable patients to detect exacerbations and start action plans earlier so as to reduce hospitalizations, and also to improve symptom control and quality of life (QOL) by providing earlier guidance.

Methods: We enrolled COPD patients from a university hospital. They were provided with SpO2 for 6 months and were educated on their use to augment action plans for exacerbations. Home exercise was measured with pedometers. The primary outcomes were hospitalization days, emergency department (ED) attendances and intensive care unit (ICU) days. We also measured QOL and 6 minute walk.

Results: We enrolled 26 patients with mean (SD) age 73 (9) years and mean FEV1 (SD) 47 (17)% pred. There were 84 (6) hospital days vs 50 (2) hospital days (p=0.16) at 6 months. There were 7 (1) ICU days at baseline vs none (p=0.12) at 6 months. The mean SGRQ score was 32 (16) vs 27 (14) at 6 months (p=0.003). The 6 minute walk test (207 (56) vs 212 (67) at 6 months) and pedometer steps (4007 (2706) steps vs 4421 (2969) steps) were also not significantly better. There was 1 death.

Conclusions: In a comprehensive care setting, self-monitoring of SpO2 in patients with severe COPD may have little effect on hospitalizations and quality of life.

P903 Clinical validity of urinary and blood desmosine as biomarkers for chronic obstructive pulmonary disease Jeffrey 6 minute walk test, Ecklas Chaudhuri1, Aly Barton1, Jeffrey Brady1,2,3, Christian Grierson1, Osama Alsahebran1, Petra Rauchaus1, Christopher Weir4, Martina Messow1, Charles McSharry1, Giovanna Feinstein1, Sonntha Mahkophady1, Colin Palmer1, Douglas Miller1, Neil Thompson1, Thomas Sherrington1, Translational Medicine Research Collaboration, University of Dundee, Dundee, United Kingdom; 2Clinical Research, Pfizer Worldwide Research & Development, Collegeville, United States; 3Biomedical Research Institute, University of Dundee, Dundee, United Kingdom; 4Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom; 5Robertson Centre for Biostatistics, University of Glasgow, Glasgow, United Kingdom

Background: Although the elevation of degraded elastin products in patients with COPD has been reported for many years, its clinical validity and utility remain uncertain due to several difficulties, small study cohorts and unknown relationship between elastin degradation and exacerbation. 

Aims and objectives: To determine the validity of urinary and blood total desmosine/isodesmosine (u/dES) as disease phenotyping biomarkers for COPD and to evaluate their relationship to exacerbation status.

Methods: u/DES and bDES were measured using validated isotopic dilution LC-MS/MS methods.

Results: Two cohorts consisting of a total of 390 subjects including the following groups: healthy volunteers, stable asthma, stable COPD and COPD during an exacerbation.

Conclusions: Our results strongly suggest that bDES is a valid biomarker for phenotyping “accelerated elastin degradation” subtype in COPD whilst uDES links to exacerbation.

Methods: A prospective study of patients, who were evaluated to be included in a Respiratory Rehabilitation (RR) programme, was carried out. We analyzes age, gender, BODE, smoking history, symptoms, comorbidities, quality of life questionnaire (SGRQ). We used The Chronic Respiratory Questionnaire (CRQ) and anxiety-depression (HADS); spirometric values, 6 minutes walking test, maximal effort test, submaximal test, and the number and characteristics of the exacerbations during the previous year. We distinguished 2 groups: Frequent exacerbating patients (>2 exacerbations per year) and non-exacerbating patients (<2).

Results: We included 41 patients: 20 showed >2 exacerbation per year vs 21 showing <2. By comparing both groups, we couldn’t find differences regarding age, gender, smoking history, BMI, symptoms, comorbidities or COPD severity classification (GOLD). There were no significant differences in HADS, although there were some in SGRQ (45.27±18.27 vs 65.76±14.48, p=0.001) and CRQ (91.06±21.78 vs 73.84±21.92, p<0.034). No differences in pulmonary function parameters or tolerance to effort were found. A subgroup (n=5) which, due to their severity could not complete some tests properly, showed no differences when analyzing the different variables, except in SGRQ.

Conclusions: 1. About half of patients who assisted our RR practice were frequent exacerbating patients. 2. Showing more exacerbations does not imply a worse tolerance to effort or a different clinical and functional profile, although it affects directly their quality of life.

Background: CF is characterized by progressive BE and small airways disease. 

BE is related to the number of exacerbations and Health Related Quality of Life (HRQoL), assessed by the Cystic Fibrosis Questionnaire-Revised (CFQ-R). 

Objective: 1) Investigate predictive value of BE score and CFQ-R respiratory domain score (CFQ-R resp) for exacerbations. 2) Determine added predictive value of CFQ-R resp on top of BE score to predict number of exacerbations in the year following. 

Methods: Cohort study (July 2007 to Jan 2010) in clinical stable children and adolescents with CF, whom had routine chest CT and CFQ-R as part of their (bi)annual examination. CT scans were anonymized and randomly scored using CFCT BE score, expressing BE as % of maximum score. CFQ-R was completed by children aged 6-13 years and their parents or by adolescents aged ≥14 years.

Conclusion: BE and HRQoL have potentialities to predict the number of exacerbations in CF. A point increase on the CFQ-R resp results in a 6% reduction of the number of exacerbations.

P906 Factors determining duration of hospital stay in patients hospitalized for acute COPD exacerbation Filia Diamantea, Stamatina Tsiskria, Fotini Karakontaki, Dimitrios Mitromaras, Elef Stagaki, Emmanouil Kostanakis, Vlasis Polychronopoulos. 3rd Respiratory Medicine Department, Samosogeleon General Hospital, Athens, Greece

Background: Factors associated with the length of hospitalization in patients admitted for acute exacerbation of COPD (AECOPD) have not been thoroughly evaluated.

Objectives: To evaluate the association between clinical and functional parameters and duration of hospital stay of patients admitted due to AECOPD.

Methods: We studied prospectively 31 patients (20 men, 11 women), mean age 69.5 (±7.8) years, admitted to hospital for AECOPD. Pulmonary function tests including body box evaluation of lung volumes, Borg dyspnea score at rest, Visual analogue scale dyspnea score, 6 minute walking test (6 MWT), Chronic Respiratory Questionnaire (CRQ) total and 4 domains scores, Charlson index for comorbidities, blood gases on admission, were all parameters evaluated within 72h of admission. Frequency of exacerbations, long term oxygen therapy (LTOT) prior to admission and duration of hospital stay were also recorded.

Results: Mean duration of hospital stay was 8 days. Patients divided in 2 groups: group 1 (18 patients): duration of stay < 8 days, group 2 (13 patients): duration of stay ≥ 8 days. Patients in group 2 had lower FEV1% pred [34 (27, 39)] vs 48

Conclusion: VentCheck analysis is feasible & has potential role for spot analysis of ventilation in outpatient or inpatient setting in non invasive manner without any complications.

P908 Early detection of asthma exacerbations and the use of action points for treatment decisions in self-management plans

Peter J. Hommao1, 2, D. Robijn Taylor1, Jiska B. Snoek-Strobos1, Jacob K. Sent1. 1Department of Medical Decision Making, Leiden University Medical Center, Leiden, Netherlands; 2Department of Medicine, Academic Medical Center, Amsterdam, Netherlands

Background: Written asthma action plans specify the level of symptoms or peak expiratory flow (PEF) (action points) at which to increase medication in order to prevent or reduce severity of exacerbations. Few currently used action points are validated. Our aim was to develop optimal action points for early detection of asthma exacerbations.

Methods: We analyzed daily morning PEF and symptoms from two studies. The development dataset consisted of 165 patients and 88 exacerbations (Taylor, Thorax 1998). Every week was coded “stable week” or “pre-exacerbation week”. Potential action points were based on Quality Control Analysis of PEF or symptoms, or percentage personal best. Sensitivity and specificity for predicting an exacerbation and the number of days the exacerbation was diagnosed earlier were calculated. Optimal action points were based on these parameters. Their performance was compared to the published NAEPP action point in the validation dataset, consisting of 94 patients and 20 exacerbations (Smith, NEJM 2005).

Results: The main differences between action points were in false positive rate and early detection (Table 1). Combination of PEF+symptoms action points performed best, due to improved specificity and early detection.

Conclusion: Early detection of asthma exacerbations can be improved by combining symptoms and peak flow measurements over one week in a single action point.

P909 Regular follow-up in severe asthma may reduce the rate of exacerbations and the FEV₁ decline

Federico L. Dente, Federica Novelli, Maria Laura Bartoli, Monica Carli, Silvana Cianchetti, Antonella Di Franco, Elena Bacci, Pier Luigi Paggiaro. Cardio-Thoracic Department, Respiratory Pathophysiology Section, Pisa, Italy

Thirtythree subjects with severe asthma (ATS Workshop 2000) were examined over a FU period. Two groups were obtained depending on the adherence to the proposed FU: 21 subjects (8 males, age 63±6.8 yrs, duration of disease 19.6±10.4 yrs) complied with regular follow-up every 3-4 months to measure FEV₁, hypertonic saline induced sputum (group A), while 12 subjects (1 male, age 59.8±6.2 yrs, duration of asthma 21.2±14.8 yrs) performed on demand visits (group B). At each visit, physician could modify the pharmacologic treatment according to symptoms and other measures (functional findings, sputum eosinophilia). No differences among the 2 groups were observed both at baseline and at the end of follow-up, for FEV₁ and sputum eosinophilia and neutrophilia. A decrease in the rate of exacerbations and oral steroid cycles between baseline and the end of FU was found in the group A only. A significantly greater decline in FEV₁ over the FU was observed in the group B with respect to group A.

In conclusion, a regular FU with treatment adjustment obtains a greater control of asthma in terms of exacerbations and oral steroid cycles, and also of long-term FEV₁ decline.

P910 Correlation of dyspnea and physiological impairment in COPD exacerbation

Tijana Cok, Branislava Milenikovic, Predrag Rebic. Clinical Department, Clinic for Pulmonary Diseases, Clinical Centre of Srbia, Belgrade, Serbia

Dyspnea is a primary symptom of COPD. The Medical Research Council (MRC) scale, Baseline Dyspnea Index (BDI), Visual Analogue Scale (VAS) and Borg scale are widely used for evaluation of limitation of activities due to dyspnea in patients with COPD. There is limited information on how these scales relate with parameters of physiological impairment. To aim of the prospective study was to analyze the correlation between MRC, BDI, VAS and Borg dyspnea scales and multiple measures of physiological impairments in COPD exacerbation. Forty five patients (age 62.7±9.9 with COPD exacerbation (GOLD stages III and mostly IV) were analyzed at admission to the hospital. Physiological impairments were assessed by spirometry (FVC, FEV₁), body plethysmography (TLC, RV, FRC, IC), respiratory muscle strength (Pimax), arterial blood gas analysis (ABG) and 6-min walking distance (6MWD).

The correlation between MRC scale and FEV₁ is r = -0.427 (p < 0.05), FVC is r = -0.420 (p < 0.05), Pimax is r = -0.601 (p < 0.01). The correlation between BDI and FEV₁ is r = 0.493 (p < 0.01), Pimax is r = 0.613 (p < 0.01), 6MWD is r = 0.569 (p < 0.05). The correlation between Borg scale and FEV₁ is r = 0.521 (p < 0.01), FVC is r = -0.408 (p < 0.05). Pimax is r = -0.462 (p < 0.05). TLC is r = 0.483 (p < 0.01), RV is r = 0.410 (p < 0.05), FRC is r = 0.443 (p < 0.05). VAS has correlated with FEV₁ (r = -0.385, p < 0.05), Pimax (r = -0.464, p < 0.05) and 6MWD (r = -0.536, p < 0.05). The correlation between dyspnea scales and BDI was not significant. In our study all dyspnea scales have correlated with FEV₁ and Pimax. According to our results it could be concluded that Borg scale is a good tool for assessing dyspnea during exercise and the therapeutic response in COPD exacerbation.
99. Monitoring with lung function tests in airway diseases

P91 Pulmonary function in sarcoidosis: A review of 85 cases using percentage predicted and lower limit of normal values to determine pattern of pulmonary function deficit

Christopher Atkins, Andrew Wilkes, Orizon Twemtany. Department of Respiratory Medicine, Norfolk and Norwich University Hospital, Norwich, Norfolk, United Kingdom.

Previous studies have shown airflow limitation is common in Sarcoidosis. Recent evidence (Chest 2011; 139:52-59) suggests using fixed percentage predicted (PP) values may discordantly classify patients compared to using fifth percentiles as the lower limit of normal (LLN). We studied PFT patterns, and the effect of classifying by PP and LLN.

Our study assessed the PFT results found in consecutive patients presenting with Sarcoidosis to one medical team over a 14-year period. Eighty-five patients fulfilled the entry criteria. All had FPTs available. Patients were classified into normal, obstructive, restrictive and mixed deficits using the ATS/ERS flowchart for PFT interpretation. Classification by PP and LLN values were compared. Eleven patients (12.9%) were classified discordantly comparing PP with LLN. There were six normal PFTs classified by LLN, but abnormal by PP values. Normal lung function (PP 64.7%, LLN 68.2%) was the commonest pattern. Obstruction was the commonest abnormality (PP 24.7%, LLN 21.7%). Patients with obstructive deficits were more likely to have ever smoked.

The frequency of airflow obstruction in this study was 24.7% when classified by PP, equivalent to findings from a similar cohort (Resp Med 1991; 59-64 - 24.3%)

P911 Serum uric acid and uric acid/creatinine ratio in exacerbations of COPD

Alexis Papadopoulos1, Konstantinos Burzilda2, Akaiten Hamiotou1, Konstantinos Kostikas1 2 Respiratory Medicine Department, Amalia Fleming Hospital, Athens, Attiki, Greece; 2 2nd Respiratory Medicine Department, University of Athens Medical School, Athens, Attiki, Greece.

Background: Tissue hypoxia triggers the degradation of purine and Uric Acid (UA) is an end product of this metabolic pathway, and therefore may reflect the severity of hypoxia. Only a few studies have focused on the role of uric acid in patients hospitalized for exacerbations of COPD (ECOPD).

Objectives: To evaluate the associations of UA and Uric Acid/Creatinine ratio (UA/Cr) with clinical parameters related to disease severity for patients hospitalized for ECOPD.

Methods: UA and UA/Cr and parameters related to the severity of ECOPD, including PaO2/FiO2 ratio, MRC dyspnea scale, and Saint George’s Respiratory Questionnaire (SGRQ) were measured on admission. Patients underwent spirometry and 6-minute walking test (6MWT) on stable condition and were followed up for 1 year.

Results: We included 153 consecutive patients (52.8% male; mean age 71.7 years). UA levels were higher in more severe disease according to GOLD stages (6.38 ± 9.1 vs. 6.59 ± 6 vs. 7.45 ± 6 ± 8 vs. 8.90 ± 12 mg/dL respectively; p < 0.001). With similar classification of UA/ Cr levels (p < 0.001). On admission, UA presented significant correlations with PaO2/FiO2 (r=0.16, p=0.44), MRC (r=0.63, p=0.001) and SGRQ total score (r=0.485, p=0.001). UA/ Cr presented similar associations. Baseline levels of UA and UA/ Cr presented significant negative correlations with 6MWD (r=-0.756 and r=-0.734, p < 0.001) and all SGRQ domains on stable condition. Patients in the higher quartiles of UA and UA/ Cr presented more ECOPD and hospitalizations in the year of follow-up, but did not present differences in mortality.

Conclusions: UA and UA/ Cr levels present significant correlations with important expressing COPD severity both on exacerbation and on stable condition.

---

P912 Patient experiences of exacerbations in a real world setting: Global results from the Hidden Depths survey

Neil Barnes1, Peter M.A. Calverley 2, Alan Kaplan 3, Klaus F. Rabe4. from the Hidden Depths survey.

P912 variables expressing COPD severity both on exacerbation and on stable condition. hospitalizations in the year of follow-up, but did not present differences in mortality.

Methods: UA and UA/ Cr and parameters related to the severity of ECOPD, including PaO2/FiO2 ratio, MRC dyspnea scale, and Saint George’s Respiratory Questionnaire (SGRQ) were measured on admission. Patients underwent spirometry and 6-minute walking test (6MWT) on stable condition and were followed up for 1 year.

Results: We included 153 consecutive patients (52.8% male; mean age 71.7 years). UA levels were higher in more severe disease according to GOLD stages (6.38 ± 9.1 vs. 6.59 ± 6 vs. 7.45 ± 6 ± 8 vs. 8.90 ± 12 mg/dL respectively; p < 0.001). With similar classification of UA/ Cr levels (p < 0.001). On admission, UA presented significant correlations with PaO2/FiO2 (r=0.16, p=0.44), MRC (r=0.63, p=0.001) and SGRQ total score (r=0.485, p=0.001). UA/ Cr presented similar associations. Baseline levels of UA and UA/ Cr presented significant negative correlations with 6MWD (r=-0.756 and r=-0.734, p < 0.001) and all SGRQ domains on stable condition. Patients in the higher quartiles of UA and UA/ Cr presented more ECOPD and hospitalizations in the year of follow-up, but did not present differences in mortality.

Conclusions: UA and UA/ Cr levels present significant correlations with important expressing COPD severity both on exacerbation and on stable condition.

P913 Impact of climate change on COPD in Berlin-Brandenburg – Developing a telemonitoring based approach for early intervention

Nora Doehnler1, Marcel Haug1, Uta Lübers1, Friedrich Kothler2, Reinhold Kreut2, Gilbert Schönfelder3, Marcel Langer4, Wilfried Endlicher4, Christian Witt1. 1Pneumology, 2Cardiology, 3Pharmacology and Toxicology, Charité Universitätsmedizin, Berlin, Germany; 4Geographic Institute, Humboldt University, Berlin, Germany.

Climate change affects human health. Especially patients with chronic lung diseases seem to be more influenced. Extreme weather, e.g. heat waves, leads to an increase of COPD exacerbations and hospital admissions. In this context a prospective investigation of risks due to climate change for moderate/severe COPD is required, which allow us to determine susceptible subgroups and the development of an early intervention system to prevent exacerbations.

Therefore we designed a combined clinical research module, based on telemonitoring of COPD patients and complex analyses of scaled regional atmospheric conditions (i.e. temperature, humidity, particulate matter) of the metropolitan area Berlin-Brandenburg. We implemented the validated BODE-Index into a telemonitoring system, including home spirometry, a Mobile Medical Assistant (MMA) for self-evaluation and a triaxial pedometer for the quantification of physical activity. This randomized clinical trial contains a cohort of 320 COPD patients, divided into a control group (visit every 3 month) and an intervention group (daily telemonitoring).

The implementation of the telemonitoring system for COPD has been started as proof of concept. Patient compliance is excellent and the system is well accepted. Concluding our results, this new approach for measuring the impact of climate change could lead to new interventional strategies and improve prognosis and quality of life in COPD. Nevertheless, further clinical research concerning the impact of climate change is strongly needed to improve the adaptive response in vulnerable patients with COPD.

*The study is funded by the BMBF (Federal Ministry of Education and Research).
Introduction: The airway reversibility test (ART) is performed to diagnose obstructive airway disease (OAD) such as asthma and COPD. The ART revealed negative result in some asthma patients. It can be made insufficient treatment (Tx) for those patients.

Objectives: We reviewed the patients’ data to evaluate the characteristics of the patients who have marked improvement of spirometry (SPM) after regular Tx among patients with SPM below COPD stage II by GOLD guideline.

Method: We reviewed SPM records of 1072 patients who performed ART to evaluate dyspnea from 1st September 2009 to 30th August 2010. Finally we reviewed the pre and post-Tx SPM data and characteristics of 121 patients who have pre-bronchodilator (BD) FEV1/FVC <70%, FEV1 <80%, and negative for ART.

Results: Twenty four patients (19.8%) showed improved FEV1 >80% after regular Tx with ICS and/or tiotropium (group 1). FEV1/FVC >70% and FEV1 >80% (group 2). The mean increment of FEV1 are 0.47 L and 0.61 L in group 1 and 2. The increment of FEV1 after Tx slightly correlated with initial post-BD FEV1 change in ART (r=0.23, p=0.019). But, the post-BD FEV1 change (%) was not different between group 1 and non-responder group (5.29±4.35 vs 6.71±4.51, p = 0.33).

Conclusion: The results of this study about 20% of patients with SPM fitted in moderate COPD had improvement of FEV1/FVC >70% and presence of at least one respiratory symptom (Group C). The prevalence of OAD was 8.9%, <4.8%; p=0.01) and SAO (Δ 4.8%; p=0.01) and SAO (Δ 21.5%; p<0.0001) than presence of respiratory symptoms. We recommend use of PFM as a screening tool for OAD in large epidemiological studies.

Introduction: CF lung disease starts in small airways. SAD is visible on chest-CT as trapped air (TA). For routine monitoring of CF lung disease spirometry parameters are used. Forced expiratory flow after 75% of vital capacity is exhausted (FEF75%) is a sensitive marker of SAD. Lung Clearance Index (LCI) obtained by Single Breath Washout test (MBW) has been advocated as a parameter to monitor SAD. Whether LCI is more sensitive than FEF75 to detect SAD is unknown.

Aim: To study the relation between FEF75 and LCI and trapped air on CT and between FEF75 and LCI.

Methods: Retrospective study of stable CF patients (n=50) who had their (bi)-annual check-up including chest-CT and spirometry. Tidal breathing MBW (n=23) was performed using the Ecomedics Exhalyzer D. In- and expiratory (volumetric) chest-CT scans were scored using the CF-CT score and expressed as% of maximum volume. FEV1, FVC, FEV1/FVC, FEF25-75%, FEF75, FEF200, RV, TLC, R20Hz, and FEF25-75% as% of predicted values.

Results: CF patients (1-19 yrs, male =26). 36% had chronic pseudomonas. FEF75 mean 45.5 (range 7.5-119.2)%, predicted LCI 9.4 (6.9-14.3), TA 33.0 (0.8-3.3)%. FEF75 correlated with LCI (N=23) (r=0.573, p=0.005). FEF75 ± FEV1/FVC correlated with pre-bronchodilator (%FEV1 ± FEV1/FVC) and RV (r=0.520, p=0.001), mucusclogging (r=0.505, p=0.001) parenchymal abnormalities (r=0.508, p=0.001) and total CF-CT score (r=0.535, p<0.001) but not with TA. LCI did not correlate with abnormalities on CT.

Conclusion: FEF75 correlates with LCI. Neither FEF75 nor LCI correlate with TA. The additional value of LCI over FEF75 as a sensitive monitoring tool for SAD requires further validation.

Introduction: The use of forced oscillation technique (FOT) in assessment and stratification of disease severity in elderly COPD patients remains unclear.

Aim: To compare lung function profiles between subjects with BS-COPD and TS-COPD.

Methods: 17 BS-COPD (mean 43 yrs exposure) and 35 TS-COPD (mean 43 smoking pack yrs) underwent pre and post-bronchodilator spirometry to measure FEV1, FVC and FEF25-75%, bodyplethysmography to measure residual volume (RV) and total lung capacity (TLC), impulse oscillometry (IOS) to measure R50H and R20Hz and single-breath DLCO to measure lung diffusion. Two sample “t” test was used to compare mean (%SD) lung function parameters between the two groups.

Results: There were no significant differences in% predicted values for FEV1, FVC, R20Hz, RV and TLC between TS-COPD and BS-COPD (all p values ≥0.05). However, BS-COPD showed a trend towards greater small airway obstruction indicated by lower FEF25-75% predicted values (BS: 9% ±3% vs TS: 12% ±5%, p=0.02), higher R50H predicted values (BS: 272% ±65% vs TS: 222% ±46%, p=0.05) and higher R50H values normalized to total airway resistance [BS: 0.53 ±(0.07) vs TS: 0.46 ±(0.13) p=0.05] while TS-COPD showed lower% predicted values for DLCO [TS: 53% ±24% vs BS: 71% ±33%; p=0.03].

Conclusion: BS-COPD shows similar decrements in Spirometric, IOS and bodyplethysmographic parameters as TS-COPD. However, BS-COPD was associated with greater small airways obstruction, while TS-COPD was associated with lower DLCO values.
Results: Totally, 102 COPD patients with a mean age of 70.3±8.2 and median GOLD stage of 2 were recruited. FOT parameters correlated well with GOLD stages. Among the FOT parameters, FRes was the best to predict disease severity. Cut-off value of FRes >29 has a sensitivity of 71% and specificity 69% in identifying severe patients (%FEV1<50%), with area under curve value 0.77.

Conclusion: FOT is accurate for assessing disease severity in elderly COPD patients. FRes value >29 has a good sensitivity and specificity in identifying severe COPD patients.

P921 Reproducibility data of breath analysis through a gas sensors array and comparison to spirometry in COPD patients
Simone Scatala1, Giorgio Prenazaar2, Domenica Chiurco1, Marco Santonico2, Arnaldo D’amicco2, Raffaelle Antonioni Icalza1, 1Geriatrics, Unit of Respiratory Pathophysiology, University Campus Bio-Medico, Rome, Italy; 2Faculty of Engineering, University Campus Bio-Medico, Rome, Italy, Italy

Background: There is insufficient information on reproducibility and intra-observer variability of breath analysis, a technique proved to have classificatory and discriminative properties in respiratory diseases. Aim of this study is therefore to compare variability over time of breath analysis and global spirometry in elderly patients with COPD.

Materials and methods: Data refer to the 9 COPD patients so far recruited. Patient underwent breath analysis and respiratory function study 3 times along a period of 3 weeks. The gas sensors array (based on 6 Quartz Microbalances (QMB) covered with different metalloporphyrins) used for this study was fabricated at Tor Vergata University, Rome. The reproducibility of sensors measurements and spirometry data were then compared.

Results: Results are summarized in figure 1 with panels A, B and C respectively representing the frequency shifts registered by the six QMB sensors (A) and twelve parameters obtained by global spirometry (B and C). Variance, mean value, confidence interval and outliers of a set of data are graphically depicted.

Figure 1

Conclusions: Spirometric values show a smaller variance respect to the QMB frequency shifts. However, the reproducibility of selected sensor data seems fair enough to allow follow up COPD patients.

P922 Patients with fluctuant peak expiratory flow value in the absent category are insensitive to dyspnea and are at risk for severe asthma exacerbation
Kumiya Sugiyama, Hirokumi Hagara, Naoya Ieda, Taichi Shiobara, Masamitsu Tatewaki, Fumiya Fukushima, Masafumi Arima, Yasutugu Fukushima, Takeshi Fukuda. Pulmonary Medicine and Clinical Immunology, Dokkyo Medical University, Tochigi, Japan

Exacerbation of asthma has a negative impact on quality of life and increases the risk of fatal asthma. One of the known risk factors of patients with a history of near-fatal asthma is experiencing mild asthmatic symptoms as opposed to airway obstruction. We set out to find patients carrying such a risk before they experience severe exacerbation of asthma.

To determine the character of such patients, we compared the background and asthma diaries (mean period, 274 days) of 53 asthma patients with their symptoms and peak expiratory flow value (PEF). According to the criteria of the Japanese Society of Allergology, symptoms were classified into 8 categories ranging in severity from absent to severe attack.

Average PEF was 75.2% (50.5–100) in absent, 64.5% (36.6–92.6) in wheeze, 57.3% (25.0–94.7) in mild attack and 43.6% (20.4–83.1) in moderate attack, and the personal best was 100%. Thus, differences in decreased PEF in cases with the same symptoms varied widely between patients. PEF in wheeze, mild and moderate attack did not correlate significantly with the duration of asthma, FEV1 or the proportion of personal best to standard PEF. These PEFs did not show a significant difference in the groups that were divided by regular treatment of asthma, but did show a significant negative correlation with the coefficient of variation of PEF when asthma was absent.

To reveal patients who are insensitive to dyspnea, the most important factor to consider is the coefficient of variation of PEF when asthma is absent. When we find such patients who exhibit fluctuant PEF, we have to intervene in their treatment, even when they claim to be stable.

P923 The use of forced oscillation technique (FOT) in assessment of airway obstruction and airtrapping in elderly COPD patients
Hoi Nam Tse, King Ying Wong, Ka Yan Wai, Kwok Sang Yee. Medical Department, Kwong Wah Hospital, Hong Kong, Hong Kong

Introduction: Forced oscillation technique (FOT) is a new lung function measurement technique that may have a role in assessing elderly COPD patients.

Aim: To evaluate the accuracy of FOT in assessment of airway obstruction and airtrapping in elderly COPD patients.

Methods: Stable spirometry-confirmed elderly COPD subjects were recruited from Kwong Wah Hospital, Hong Kong, from Jan 10 to Jan 11.

Subjects were assessed by both conventional plethysmography and FOT machine in the same visit. Airway obstruction was measured by FEV1%, Raw, Gaw while degree of airtrapping was measured by residual volume (RV), total lung capacity (TLC), inspiratory capacity (IC) and RV/TLC ratio. FOT parameters like frequency resonance (FRes), frequency dependence (FDep), resistance at 6Hz (R6Hz), average resistance (RAM), average reactance (XAM) were obtained. The FOT parameters were then compared with the plethysmography.

Results: Totally, 106 patients were recruited. 93.1% were male with a mean age of 70.6±8.3 and FEV1 of 54.3±21.3. FOT correlates well with conventional plethysmography for measurement of airway resistance and airtrapping in elderly COPD patients. Among the FOT parameters, FRes showed the best correlation with FEV1 (r=0.608, p<0.001) and RV/TLC ratio (r=0.563, p<0.001).

Conclusion: FOT is an accurate and convenient technique for assessment of airway obstruction and airtrapping in elderly COPD patients.
Aim: To determine ERT long-term effects on pulmonary function and exercise tolerance in late-onset GSDII.

Methods: 7 children (mean age at starting ERT 11 years, 4M:3F) receiving bi-weekly infusion of 86GAA for at least 36 months were evaluated performing pulmonary function tests and 6-min walking tests (6MWT), before (T0) and during treatment (T12, T24, T36).

Results: Our data describe a predominantly restrictive pattern of lung function at baseline, with a significant improvement after ERT.

The 6MWT improved during ERT; analysis of individual performances showed a progressive increase in walking capacity in all the patients. The difference in 6MWT rank distribution at baseline, T12, T24 and T36 was statistically significant (p< 0.05, according to Friedman).

Conclusion: Our data highlight as motor and respiratory functions respond differently to ERT: motor function seems to improve due to an increased peripheral muscular endurance, while pulmonary function remains unchanged after starting treatment. Long-term ERT is effective in improving motor function and in stabilizing respiratory function in late-onset GSDII.

P925 Expiratory flow limitation (EFL) detected non-invasively as a phenotypic character of COPD

Bertil Bogvad Aarli1, Per A. M. A. Calverley2,3, Tom Wilk Mikal Lind Eagen1, Per Sigurd Bakke4, Joanne Hardie5. 1Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 2Institute of Medicine, University of Bergen, Bergen, Norway; 3University Department of Medicine, University Hospital Aintree, Liverpool, United Kingdom

Within-breadth change in reactance at 5Hz during tidal breathing reliably detects EFL in patients with COPD. We used the method proposed by Dellaca et al to determine presence of EFL and its relationship to spirometry and demographics of 424 healthy smokers and COPD patients from the Bergen cohort of the ECLIPSE study.

Aim: Establish the prevalence of EFL by GOLD stage and its relationship to dyspnoea and BMI.

In 274 stable COPD patients and 150 healthy smokers controls performed spirometry and tidal impulse oscillometry.

Results: Presence of EFL in healthy smokers, COPD grade 2,3, and 4 was 7%, 13%, 28% and 40% respectively. Inspiratory resistance and reactance at 5Hz were higher in COPD than smokers but differed little across GOLD stages.

Demographics n BMI MRC FEV1 R5insp X5insp

Healthy smokers non-EFL 149 26.4±4 0.12±0.4 30.4±7.1L 0.26±0.07 >0.09±0.03

EFL 1 32 1.9 ±2.0 3.9L 0.39 ±0.08

COPD GOLD 2 non-EFL 125 26.5±6 1.31±1.0 1.8±0.5L 0.39±0.12 >0.15±0.06

EFL 19 30.6±7 1.91±1.2 1.5±0.3L 0.51±0.06 >0.20±0.05

COPD GOLD 3 non-EFL 76 24±6 1.5±0.9 1.2±0.3L 0.41±0.10 >0.20±0.07

EFL 29 30±6 2.31±1.2 1.1±0.3L 0.50±0.12 >0.22±0.07

COPD GOLD 4 non-EFL 15 22±5 2.61±1.5 0.8±0.2L 0.42±0.10 >0.22±0.10

EFL 10 25±6 2.41±1.4 0.7±0.1L 0.43±0.06 >0.23±0.08

MRC: Medical Research Council dyspnoea scale; R5insp: Inspiratory resistance at 5Hz; X5insp: Inspiratory reactance at 5Hz; *p<0.05.

Conclusion: EFL became more common in higher GOLD stages, but a significant number of patients in all GOLD stages were not flow limited at rest. In GOLD stage 2 and 3 EFL patients were more breathless, despite similar spirometry, but EFL also tracked obesity, which may contribute to both EFL and dyspnoea. Presence of EFL has potential to be an independent phenotypic characteristic in stable COPD.

P926 Area under the maximum expiratory flow-volume curve a sensitive parameter in the evaluation of airway obstruction

Lubomir Legath, Marek Varga, Slavomir Perencsky, Marin Orozin. Respiratory Diseases and Tuberculosis, University Hospital of L. Pastur, Kosice, Slovakia (Slovak Republic) Occupational Medicine and Clinical Toxicology, Medical Faculty of University of P.J. Safark, Kosice, Slovakia (Slovak Republic)

Introduction: The most frequently used parameters for assessing bronchoconstriction and bronchodilatation are forced expiratory volume in 1 s (FEV1) and peak expiratory flow (PEF).

Objectives: To assess the sensitivity of other parameters after induced bronchoconstriction and bronchodilatation.

Methods: Forced vital capacity, FEV1, PEF, maximum expiratory flows (MEF) at 25, 50 and 75% of vital capacity and the area under the maximal expiratory flow-volume (MEFV) curve (Area ex) were measured in two groups of asthmatic patients after induced bronchoconstriction and bronchodilatation.

Results: In 158 asthmatics without airway obstruction, bronchoconstriction was induced by inhalation of 1% histamine aerosol. The 20% fall in Area ex compared to baseline was found in all asthmatics, while the 20 and 15% falls in FEV1 were noted in 31 and 69% of the patients, respectively. Other parameters were less sensitive. Another 102 asthmatics with mild-moderate airway obstruction were treated with various bronchodilators. The 20% increase in Area ex was observed in all asthmatics, while the 20% increase in FEV1 was found in only 28% of the patients and the 15% increase in FEV1 in 56%.

Conclusion: In evaluation of correlation between dynamic functional parameters the most accurate parameter in Areaex – value defining surface under the expiratory part of “flow – volume” curve. Area ex was a sensitive parameter in the evaluation of airway capacity in comparison with MEF1,2, MEF2,5, MEF4, FEF2,5, FEV1 and other parameters measured from the MEFV curve in our study patients.

P927 Determination of predominant site of airway obstruction in patients of bronchial asthma: Role of impulse oscillometry

Harmanjit Singh Hira, Amandeep Kaur. Internal Medicine and Pulmonary Medicine, Madanlal Azad Medical College and Lok Nayak Hospital, New Delhi, India

Background: The major site of airflow limitation in bronchial asthma varied from central to peripheral airways.

Aims and objectives: To determine predominant site of airway obstruction in patients of bronchial asthma by impulse oscillometry and flow volume loop.

Methods: Twenty five patients of asthma underwent both impulse oscillometry and flow volume loop studies. Predominant site of airway obstruction was determined by impedance spectra and visual lung model of IOS, and parameters of flow volume loop.

Results: Two patients were excluded from final analysis as their impedance spectra showed significant upper airway influence which would have made localization of site of airway obstruction invalid.

Conclusion: In 158 asthmatics without airflow obstruction, bronchoconstriction was shown to be a specific feature of asthma, though this is still a controversial issue. We aimed to evaluate whether variability over time scales >1 day can reliably separate asthmatic from healthy subjects.

Within-breadth respiratory resistance (Rrs) and reactance (Xrs) were measured by forced oscillations during 2min of tidal breathing at morning and evening for 6 months in 10 mild asthmatic and 10 healthy subjects. Short-term (within measurements) and long-term (2, 4, 8, 16 and 32 consecutive days) variability of Rrs and Xrs was characterized by their standard deviations (SDRrs and SDXrs).

Short-term variability of either Rrs or Xrs was not significantly different between asthmatic and healthy subjects (p<0.05). SDRrs was significantly larger in asthmatics than in healthy subjects with a time scale ≤4 days using morning
P929
Determination of respiratory flow by tracheal sound-frequency-analysis
Volker Gross1, Denise Basur2, Michael Scholtes3, Florian Schult1, Ulrich Koehler3, Keywan Ali Sotahir1, 1Dept. of Biomedical Engineering, University of Applied Sciences Giessen-Friedberg, Giessen, Hessen, Germany; 2Division of Respiratory and Critical Care Medicine, Philipps-University Marburg, Marburg, Hessen, Germany

The established methods to detect the flow are pneumotachographic measurements, which are not always ideal to use regarding long term measurements and measurements during sleep. Thus it is interesting to find an alternative non-invasive method to detect the quantitative value of the flow.

There are some further appendages that use tracheal respiratory sound intensity, but there is no method suitable for measurements during a noninvasive ventilation. The aim was to create a new method, easy to use under different long term conditions, based on tracheal sound-frequency-analysis.

Up to now, 43 subjects (male, non-smoker, normal BMI, 18-60 years old, FEV1>80%) were tested. The subjects breathed during 15 minutes without and with different masks. The measuring method included a respiratory sound sensor which was affixed paralaryngeally on jugular and a pneumotachograph. The flow-curve was calculated using the envelope of frequency spectra via fast Fourier transformation.

It was possible to achieve a very good correlation between the calculated flow-curve and the real flow (R=0.8) in all conditions.

This method is very easy to use and could be established for patients who are not eligible for conventional measurements (infants, measurement during sleep and for patients with noninvasive ventilation).

P930
Peripheral airway function in COPD assessed by Sacin and Scond using SF6 and He multiple breath washout
Maria Ström1, Paul Robinson2, Emilia Vilkund1, Sanna Kjellberg1, Pehr Gustafsson1, 1Department of Paediatrics, Central Hospital, Skövde, Sweden; 2Division of Respiratory Medicine, Children’s Hospital at Westmead, Sydney, New South Wales, Australia

Background: Peripheral airways, particularly acinar airways, are involved in COPD. Sacin for SF6 reflects ventilation inhomogeneity deep inside the acinus, while Sacin for He reflects inhomogeneity proximally in the acinus, and Scond indicates inhomogeneity in the small conducting airways. We tested the hypothesis that Sacin and Scond are greater for SF6 vs. He in COPD.

Methods: Multiple breath SF6 and He washout, using a mass spectrometer, was performed at baseline and post bronchodilator (BD, 400 mcg salbutamol and 80 mcg ipratropium pMDI) prior to spirometry and DLCO: 41 COPD subjects (17M/24F), 45-66 yrs, smoking history 10-75 pack yrs. Reference values for Sacin and Scond were obtained in 46 non-smoking healthy subjects aged 19-71 yrs. Local spirometry and DLCO reference equations were used [1,2]. Results were expressed as median (range) z-scores, and wilcoxon rank sum test used for paired comparisons.

Results: SF6 Sacin and Scond z-scores were greater than He indices both at baseline and post BD in COPD subjects (p<0.001 for all).

Conclusions: COPD was characterized by greater ventilation inhomogeneity in the distal vs. the proximal acinar portion. The degree of ventilation inhomogeneity found in COPD within the acinus is greater than in the conducting airway zone.

P931
Spatial heterogeneity in regional pulmonary function in COPD patients and healthy young and elderly subjects
Barbara Gauselczyk1, Sven Puller2, Hans-Peter Hauber1, 1Dept. of Anaesthesiology and Intensive Care Medicine, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany; 2Dept. of Pneumology, Medical Clinic, Research Center Borstel, Borstel, Germany

Introduction: Electrical impedance tomography (EIT) can determine regional dynamic gas volume changes in the lungs. The aim of our study was to examine the regional differences in lung function in COPD patients and healthy adults using EIT.

Patients and methods: 33 COPD patients (GOLD II-IV) and 25 healthy young and elderly adults were studied. EIT data were collected at up to 44 images (Goe-MF II, CareFusion, Hoechberg, Germany) in parallel with spirometry. Regional inspiratory (IVC) and forced vital capacities (FVC), forced expired volume in 1s (FEV1) and tidal volume (Vt) were determined in 912 EIT image pixels in the chest cross-section. Coefficient of variation (CV) was calculated from all pixel values to characterize the heterogeneity of lung function. The average value reflecting the volumetric changes in the cross-section was also determined. Statistical analysis was carried out by one-way ANOVA with Bonferroni post test.

Results: The CV values of regional IVC, FVC, FEV1 and Vt were significantly different between healthy adults and COPD patients (p values: 0.0102, 0.0050, 0.0022 and 0.0047). No differences existed between the young and elderly subjects. The average IVC, FVC, FEV1 and Vt in the chest cross-section were significantly different among the groups (p values:<0.001, <0.001, <0.001 and 0.0054). The highest values were noted in the young subjects, significant differences between the elderly and COPD patients were found for IVC, FVC and FEV1.

Conclusion: EIT is able to detect disease and age related differences in regional lung function. The heterogeneity of lung function is similar in the young and elderly healthy subjects but lower than in COPD patients.

P932
Evaluation of respiratory impedance in COPD by forced oscillation technique using a MostGraph
Yasuhiro Yamauchi1, Tadashi Kobayama1, Hajime Takizawa2, Makiko Kase1, Masafumi Hone1, Yu Mikami1, Takahide Nagase3, 1Respiratory Medicine, The University of Tokyo, Tokyo, Japan; 2Dept. of Anesthesiology and Intensive Care Medicine, University of Tokyo Hospital, Mizonokuchi, Kawasaki City, Tokyo, Japan; 3Dept. of Internal Medicine, Teikyo University School of Medicine University Hospital, Mizonokuchi, Kawasaki City, Japan

Background: COPD is characterized by not fully reversible airflow limitation and defined with the decrease in FEV1 by spirometry. The Forced Oscillation Technique (FOT) can detect impairments of lung function by measuring lung resistance and reactance during normal tidal breathing. A MostGraph is one of the FOT using multi-spectrum oscillation technique, and demonstrates the frequency-dependent and time-dependent respiratory impedance in 3-dimensional graphics.

Methods: We recruited 26 outpatients with stable mild (n=13) and moderate (n=13) COPD at the University of Tokyo Hospital. The impedance of respiratory system was measured by FOT using a MostGraph. Respiratory resistance (Rrs) and respiratory reactance (Xrs) during inspiration and expiration were evaluated at 5 Hz and at 20 Hz of oscillatory frequency.

Results: All indices of respiratory resistance, such as Rrs5 and Rrs20, were slightly higher at 5 Hz and at 20 Hz of oscillatory frequency. The Cv values of regional Rrs, Xrs, and the ratio between the difference of Rrs5max-min and Rrs20max-min were significantly different among the groups (p values: 0.0002 and 0.0047). No differences existed between the young and elderly subjects. The average Rrs, Xrs and the ratio between the difference of Rrs5max-min and Rrs20max-min were significantly different among the groups (p values: <0.0001, <0.001, <0.001 and 0.0054). The highest values were noted in the young subjects, significant differences between the elderly and COPD patients were found for Rrs, Fev1, and Xrs.

Conclusion: EIT is able to detect disease and age related differences in regional lung function. The heterogeneity of lung function is similar in the young and elderly healthy subjects but lower than in COPD patients.

We evaluated the respiratory impedance during inspiratory and expiratory phase of normal breathing in COPD patients.

Methods: We recruited 26 outpatients with stable mild (n=13) and moderate (n=13) COPD at the University of Tokyo Hospital. The impedance of respiratory system was measured by FOT using a MostGraph. Respiratory resistance (Rrs) and respiratory reactance (Xrs) during inspiration and expiration were evaluated at 5 Hz and at 20 Hz of oscillatory frequency.

Results: All indices of respiratory resistance, such as Rrs5 and Rrs20, were slightly higher in moderate COPD than mild, although there were no significant differences. There was a tendency that the ratio between the difference of Rrsmax-min and the difference of Rrs20max-min within tidal breathing was higher in mild COPD than in moderate (p<0.08).

Conclusion: The larger difference in Rrs5-20 during tidal breathing might be useful property to distinguish the severity of COPD.

P933
Freeflowmetry – The new method of evaluation of the respiratory function phenotype
Zygmunt Podolec. Physiology and Mechanics of Breathing, Research and Development Centre MEDiNET, Cracow, Poland

Introduction: Freeflowmetry is the new method of air flow and air volume measurement during forced and free breathing through the open or partially closed mouth or through the nose. Application of tight silicone mask connected with dFPP® pneumotachograph allows adaptation of the natural resistance of the oral cavity in order to reduce the airway collapse. The aim of the study was to compare the results of examination performed with dFPP® pneumotachograph with mouthpiece, with the results of examination performed with silicone mask

Method: The examinations were performed using PNEUMO® PC spirometer (absMED, PL) in group of COPD patients: 6 female and 4 male at age of 75±5 years and in control group of healthy: 6 female and 2 male at age 73±6 years.

The results are shown in table 1.

Table 1

ΔFVC = FVC – FVC; ΔFEV1=FEV1 – FEV1; FVC-CM = measurement of FVC through partially closed mouth; ΔFVC-CM = ΔFVC – FVC.

Conclusion: Freeflowmetric examination can contribute to the optimization and individual adaptation of treatment, the determining of the phenotype of bronchial obstruction and/or airway collapse in common diseases such as COPD and asthma. Further studies are required for the comparison of freeflowmetric test results before and after physical exercise and before and after application of bronchodilator.

Audit of a new mannitol challenge testing service in a UK tertiary centre
Martyn Bucknall. Lung Function Department, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Guy's and St Thomas' NHS Foundation trust (GETT) is a tertiary hospital based in London, UK, offering specialist allergy and asthma clinics. In July 2010, GSTT switched from using histamine to mannitol for performing bronchial challenge testing (BCT). BCT is an essential diagnostic investigation for identifying/excluding asthma and monitoring responses to treatment regimes. We performed an audit of the new service, using mannitol between July 2010 and February 2011. We looked at patient demographics, (age, sex, baseline lung function), test outcomes (i.e. positive, negative, reasons for terminating test, fall in FEV1), sources of referral and clinical reasons for referral to our laboratory.

Table 1 shows patient demographics and baseline lung function. 60 patients were referred to the service (28M, 32F). The mean age was 40.2 yrs.

P935
Tracheal sound level as a potential diagnostic tool for pulmonary obstructive syndromes
Tudor Andrei Cernomaz, Daniela Boisteanu, Raluca Vasiliuta, Traian Mihaiascu. Pneumology, Clinic of Pulmonary Diseases, Iasi, Romania

Aim and objectives: To assess the possibility of developing a tracheal sound analysis tool capable of diagnosing obstructive syndromes.

Material and methods: 34 subjects were stratified to the obstructive or control group. Tracheal sound was recorded during a forced expiratory maneuver; acquired signals were analyzed in terms of sound level vs time and a linear regression model was computed. The obstructive subgroup included 21 vs 13 controls. We found statistically significant between group differences for expiratory duration and for the linear regression and negative significant correlations between slope and expiratory duration, FEV1 and FEV1/VC. Building the ROC curve a threshold value of -19.67 for the slope of the linear regression model will associate a sensitivity of 95% and a specificity of 84.6% for this test.

Conclusion: Available data suggests that tracheal sound level analysis could be developed into a diagnostic and monitoring tool; additional mathematical approaches are probably necessary.

P936
Clinical interpretation of St George's respiratory questionnaire in Chinese COPD patients
Yipeng Du, Rong Liu, Bei He. Respiratory Medicine, Third Hospital of Peking University, Beijing, China Respiratory Medicine, Third Hospital of Peking University, Beijing, China

Background: Although the St George’s Respiratory Questionnaire (SGRQ) was used widely in China as a valid instrument for quality of life evaluation in COPD patients, the relationship between SGRQ, lung function and therapeutic effect is uncertain.

Objectives: To determine whether the SGRQ was related with lung function in Chinese COPD patients and evaluate therapeutic effect on them.

Methods: After a two weeks run-in period, outpatients (63 patients; 10 women; mean age 67.6 years) were assessed at baseline by the SGRQ-MC, clinical data and spirometry. Then patients were treated in a randomised, open-labelled, parallel group trial with either a combination of 50 μg salmeterol and 500 μg fluticasone propionate twice daily (SF, n = 18, mean age 67.4 years) or 2.5 mg ofipratropium bromide and 120 μg salbutamol qartic daily (IS, n = 18, mean age 66.7 years) for 3 months. Results: SGRQ activity score and total score were negatively correlated with FEV1 % predicted (r = -0.427, P = 0.016, activity score; r = -0.368, P = 0.042, total score) and FVC% predicted (r = -0.534, P = 0.002, activity score; r = -0.504, P = 0.004, total score) in subjects of age less than 70 years. Moreover, SGRQ score was significantly reduced by SF (difference -19.8, 95% CI -28.3 to -11.3; P < 0.001) but not by IS. SF did not significantly change FEV1% predicted.

Conclusions: SGRQ was associated with lung function in Chinese COPD patients of age less than 70 years and was valid for evaluating therapeutic effect.

P937
The usefulness of the chronic obstructive pulmonary disease assessment test
Young Hwang, Jong Lee, Ho Kim, Ju Cho, You Kim. Internal Medicine, Gyeongsang University Hospital, Jinju, Kyungnam, Korea

Background: It is important to assess and monitor the patients in management of COPD. Recently the COPD assessment test (CAT) has been developed as a short simple method for assessing and monitoring of the quality of life in COPD patients. The object of this study is to evaluate the usefulness of the Korean version of COPD assessment test (KCAT) for assessing and monitoring COPD patients in Korea.

Methods: The study was included 60 patients with COPD in outpatient clinic. We investigated the frequency of acute exacerbations during a previous year. We also measured the spirometry and distance to walk for 6 minutes and obtained the MMRC dyspnea scale, Korean version of the CAT, and BODE index. To assess the usefulness of KCAT, correlations between KCAT and other methods were evaluated.

Results: The KCAT score was correlated significantly with FEV1% (r=0.323, p=0.012), the frequency of acute exacerbation (r=0.292, p<0.024), MMRC dyspnea scale (r=0.554, p<0.001), BODE index (r=0.380, p=0.003) and 6MWD (r= -0.372, p=0.004). The mean KCAT score was increased according to GOLD stages.

Conclusions: The KCAT were shown to be useful assessment of COPD severity. Therefore the KCAT is easily applicable and simple method for assessment of COPD severity in outpatient clinic in Korea.

Collection of year-round hay fever symptoms using a public website (www.allergieradar.nl)

Leena H. Sönksen1, Eefje B. Op den Buijsch2, Arnold J.H. van Vliet2,3
1 Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands; 2Online Communication, Triptie BV, Eindhoven, Netherlands; 3Environmental Systems Analysis Group, Wageningen University, Wageningen, Netherlands

Introduction: On average 10-20% of the population in the industrialized world suffers from pollen allergy, also known as hay fever. The geographical distribution and severity of hay fever symptoms in the Netherlands year-round is largely unknown.

Aims and objectives: Our objective was to study whether symptoms collected by an interactive internet platform from participants characterized by an internet questionnaire can provide reliable information on hay fever.

Methods: On May 13 2009 the website www.allergieradar.nl was launched. Participants could register by completing an extensive questionnaire on their hay fever symptoms, doctor diagnosis, etc. Once registered, participants regularly entered their geographical position and their symptoms of nose, eyes and lungs on a scale from 1-10. All data from 2009 (May 13-Dec 31) and 2010 (Jan 1-Dec 31) were stored in a database and analysed.

Results: Approx. 7000 entries with symptoms scores were collected in 2009 and in 2010 by 884 and 491 participants, respectively. More than 80% of the participants reported a doctor diagnosed hay fever. The majority of these participants suffered from nose and eye symptoms (>92%) and approx. 50% (also) from lung symptoms. The daily mean maximum symptom score of these participants correlated with the logarithm of the daily pollen counts (correlation coefficient=0.549; p<0.001)). Analysis of the individual symptoms showed that lung symptoms were more severe during the tree pollen season compared to the grass pollen season. Conclusions: We conclude that these internet symptom scores are a valuable tool in studies on hay fever symptoms in the general population and for the development of hay fever forecasts.

P939
Factors associated with better asthma control in eastern Austria
Victor Bildsheim1, Berthold Reichardt2, Michael Wotr1, Daniel Dobere1
1 Department of Clinical Pharmacology, Medical University of Vienna, Vienna, Austria; 2AG Behandlungsekoonomie, Burgenlandische Gebietskrankenkasse Burgenland, Vienna, Austria

Background: Asthma control is an important component of quality of care for asthma patients. The controller-to-total-asthma-medication ratio (CTR) has been evaluated as a reliable asthma control and quality indicator.

Aim: To evaluate the effects of a regional “asthma awareness campaign” during 2008 (patient, pharmacy and physician training) on asthma control.

Methods: We used a database form a central health insurance (BGKK, covering 70% of the population) to select a cohort (n=1158) with an asthma diagnosis according to management guideline. Asthma exacerbations and urgent health care utilization (HCU) at 6 months were recorded.

Results: Results: 379 (120 men) asthmatics completed the study. The ACT cut-off for uncontrolled and partly controlled asthma were ≥19 (sensitivity 0.73, specificity 0.67, correctly classified 69.5) and ≥22 respectively (sensitivity 0.73, specificity 0.71, correctly classified 72.1). Baseline ACT score had an odds ratio of 2.34 (95%CI 1.48-3.69) and 2.66 (1.70-4.18) for urgent HCU and exacerbations respectively at 6 months (p<0.0001). However, baseline FeNO and spirometry values had no association with urgent HCU and exacerbations. For serial changes of ACT scores over 3 months, the cutoff value was best at ≤3 for treatment decisions with low sensitivity (0.23) and ≥3 correctly classified (57.3%) values.

Conclusion: Single measurement of ACT is a useful tool for assessment of asthma control, prediction of exacerbation and changes in treatment decisions.

P940
Asthma control test: Cut off values of control according to GINA guideline and its ability to predict exacerbations and treatment decisions
Fanny W.S. Ko1, Daniel S.C. Hui1, Ting-Fun Leung2, Jojo H.Y. Chu1, Gary K.W. Wong2, Susanna S.S. Ng1, Christopher K.W. Lai3
1 Department of Internal Medicine, Medical University of Vienna, Vienna, Austria; 2Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands; 3Department of Internal Medicine, Chinese University of Hong Kong, Hong Kong, Hong Kong

Introduction: This study assessed ACT cut-off values for asthma control according to GINA guideline in adults. ACT score in the prediction of exacerbations and serial changes in ACT score over time in relation to treatment decisions was also assessed.

Methods: Subjects completed ACT together with same-day spirometry and fractional concentration of exhaled nitric oxide (FeNO) measurement at baseline and at 3 months. Physicians, blinded to the ACT scores and FeNO values, assessed the patient’s asthma control in the past month and adjusted the asthma medications according to management guideline. Asthma exacerbations and urgent health care utilization (HCU) at 6 months were recorded.

Results: Results: Among the 14,267 patients with flexible fiberoptic bronchoscopy, 30 patients (0.2%) were diagnosed with TBO. Patients were composed of 17 male and 13 female with a mean age of 60 years. The common symptoms were cough, dyspnea, and hemoptysis. Endotracheal nodules were the most common finding on computed tomography (CT). Osteocartilaginous nodules were mainly present in trachea on bronchoscopy, and the most common type was confluent form. The mean FeNO was 101±50% predicted. Treatment included mostly conservative (n = 29) and then symptoms were considerably relieved in 8 cases but there was no significant improvement noted in 18 patients. 4 patients died on account of associated lung lesion.

Conclusion: In accordance with previous studies, TBO is a rare disease and the diagnosis should be suspected based on CT findings and bronchoscopic examination of the airways. This study demonstrated that conservative treatment according to clinical symptom was effective and showed relatively good clinical outcome.

P941
The Chronic Obstructive Pulmonary Disease (COPD) Assessment Test (CAT) is a new, simple questionnaire designed to evaluate quality of life in COPD patients. In contrast to more complex assessment tools (such as St. George’s Respiratory Questionnaire), few studies have evaluated its relationship with other disease severity markers in COPD.

In this study we investigated the relationship between CAT score and markers of disease severity in COPD, including forced expiratory volume in 1 second (FEV1), endurance shuttle walk test (ESWT) and incremental shuttle walk test (ISWT).

Results: Fifty patients with a known diagnosis of COPD (male: female ratio 22:28, mean age 68.1±13.3 years, mean FEV1 46.9±20.3% of predicted) were evaluated using spirometry, ESWT and ISWT. Quality of life was assessed using CAT. Mean ISWT was 182.1±124 metres and mean ESWT was 58.0± minutes. CAT score correlated negatively with ESWT (r = -0.401, p = 0.01) and ISWT (r = -0.30, p = 0.05). There was no significant correlation with FEV1 in this study population. However, it is very interesting that CAT score is inversely related to exercise capacity. As the disease gets more severe, quality of life worsens (higher CAT score on CAT exercise capacity) and exercise capacity falls (lower ESWT/ISWT). Although this concept is logical, it was not described prior to this study.

Our study showed that CAT represents a useful instrument to evaluate disease impact in COPD, when interpreted alongside complementary diagnostic information. It would be intriguing to see the relationship between CAT and other parameters of lung function, such as transfer factor and lung volume in future studies.
Epidemiology of bronchiectasis patients had a score of 13, with a FEV of 78.4 ± 18.8% (p < 0.001).

Conclusions: All three groups demonstrated a moderate impairment of the quality of life, showing a significant difference between idiopathic bronchiectasis patients and patients with associated COPD. The association of the two respiratory disease leads to a lower quality of life for these patients. All associated respiratory diseases must be considered when interpreting this questionnaire.

Results: Bronchiectasis and COPD patients with a mean age of 74.4±4.8 years had a 17.7 CAT score, which correlates with a FEV1 mean value of 53.6±10.8% (p < 0.05), posttuberculosis bronchiectasis patients with a mean age of 52.4±16.6 years had a 15.1 CAT score correlated with FEV1 of 66.1±16.9% (p < 0.001), while idiopathic bronchiectasis patients had a score of 13, with a FEV1 of 78.4±18.8% (p < 0.001).

Conclusions: All three groups demonstrated a moderate impairment of the quality of life, showing a significant difference between idiopathic bronchiectasis patients and patients with associated COPD. The association of the two respiratory disease leads to a lower quality of life for these patients. All associated respiratory diseases must be considered when interpreting this questionnaire.

Comparison of health status in stable patients with bronchiectasis due to common variable immune deficiency (CVID), and idiopathic bronchiectasis

Lorraine Ozerovich1, Samantha Pignore2, Winston Bunya3, Robert Wilson1, Noel Snell1, Peter Kelleher1, Jillian Riley4, 5 Host Defence Unit, Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom; 6 Respiratory Services, St George’s Healthcare NHS Trust, London, United Kingdom; 1 Research Services, Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom; 2Post-Graduate Education (Nursing), Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom

Background: Patients with CVID develop bronchiectasis (bx) due to damage caused by lung infections. Bx is associated with impaired health status (Wilson C et al Am J Respir Crit Care Med 1997; 156: 536-541). Improved treatment for CVID+bx has led to fewer infections but little is known about impact on health status.

Methods: Patients undertook a Shuttle Walking Test (SWT) and completed the St George’s Respiratory Questionnaire (SGRQ). Scores were compared with data from a previous study of idiopathic bx (Ozerovich L et al Am J Respir Crit Care Med 2004; 169: A330).

Results: 22 patients participated; 9 male (41%); mean age 45 (range 17-67); 20 (91%) on immunoglobulin (lg) therapy. Patients with CVID+bx had better scores for all SGRQ domains, and better SWT, both of which were clinically relevant: SGRQ >4 point difference (Jones P. Eur Respir J 2002; 19: 398-404); SWT 60-115m (Pepin V et al, Thorax 2011;66:115-120), although neither attained statistical significance.

There were no significant correlations between SWT and activity component or SGRQ Total Score (=0.45, p<0.05; = -0.43, p<0.05) in the CVID with bx group.

Conclusion: Patients with bx due to CVID have impaired health status and SWT; scores were generally better than for demographically similar historical controls with idiopathic bx, possibly as a result of specific therapy (lg replacement) in the majority of these patients.

Pan-European data on health status in COPD are scarce. The purpose of the HEED study was to evaluate the health status from a primary care COPD population in seven European Countries (Jones P et al. Health-related quality of life in patients with COPD severity within primary care in Europe. Respiratory Medicine 2010).

We present here the Belgian results of this Pan-European survey.

This cross-sectional epidemiological study in a primary care setting evaluated health status in 394 COPD patients by Belgian primary care physicians using the St George’s Respiratory Questionnaire (SGRQ) and the COPD Assessment test (CAT). The Health-related Quality of Life (HRQoL) scores by GOLD stage, using both the SGRQ and the CAT, are shown in Table 1.

Conclusions: All three groups demonstrated a moderate impairment of the quality of life, showing a significant difference between idiopathic bronchiectasis patients and patients with associated COPD. The association of the two respiratory disease leads to a lower quality of life for these patients. All associated respiratory diseases must be considered when interpreting this questionnaire.
pulmonary disease (COPD). There is no good data to assess the ADL and sleep of COPD subjects in their home environment.

Wrist actigraphy (Actiwatch-Spectrum) was used to evaluate activity in COPD subjects to address the hypothesis that actigraphy is a good method of evaluating ADL and sleep and demonstrate subject compliance. Twelve COPD subjects and twelve age and gender matched controls wore the Actiwatch for fourteen (14) days continuously and the activity data was analyzed for ADL and sleep. Compliance was measured by the built-in “off wrist” detector. Total activity counts/day were significantly lower (p<0.01) in the COPD subjects than Controls: 237,494 ± 22,846 vs. 557,842 ± 36,006, respectively. Activity counts/minute and maximum activity counts were significantly lower (p<0.001) in the COPD subjects; 219 ± 8 vs. 630 ± 58 and 1,560 ± 269 vs. 3,163 ± 862, p<0.01, respectively. Total sleep time in the COPD subjects was significantly reduced (p<0.01); 343 ± 15 minutes vs. 451 ± 19 minutes. Sleep efficiency was decreased in the COPD subjects vs. Controls; 72 ± 3 vs. 88 ± 4 respectively (p<0.05). The minutes of wake after sleep onset was significantly (p<0.01) increased in the COPD subjects from 10 ± 4 minutes to 39 ± 23 minutes. Compliance, % time wearing the Actiwatch, was the same in COPD and Controls; 99 ± 6 ± 0.2%

Activity of daily living and sleep were significantly decreased in the COPD subjects as compared to controls which was extremely high for both groups indicating that wrist actigraphy may be a useful measure in COPD.

P948

Cough ability and oxygen saturation (OS) home monitoring in amyotrophic lateral sclerosis (ALS) patients: Preliminary data

Michele Vitacca. Lumezzane, Brescia, Italy

Background: Cough measure by Peak Cough Expiratory Flow (PCEF) and OS monitoring are crucial in ALS time course.

Purpose: In ALS patients (ALS score < 35, MIP% > 80% and MEP < 100% predicted), cough stratification was done in order to drop out (refuse, death, family problems, care under other health facility) were evaluated: a) feasibility of home daily PCEF and OS measurements b) PCEF and OS changes c) PCEF and OS variation before and during each new respiratory derangement event (RDE).

Methods: The patient/caregiver was requested to measure every day PCEF and OS and to annotate RDE.

Result: 10 patients were enrolled. Two patients refused to start the project when at home. Eight patients measured PCEF and OS for 185 ± 173 consecutive days (range 13 – 431 days) making a 1,246 measurements. Six out 8 patients dropped-out; daily feasibility worsened from 80% in the first week to 25% at the end of the study; completion rates was 86.3% (range 38 -100%). Out of 8 patients showed 6 strong RDE. PCEF daily decay (PDD) was 1.29 ± 0.2% per day. No statistically significant changes in OS were found (from 95.25 ± 1.3 to 95.13 ± 1.71).

Conclusions: On this preliminary data, we can say that cough measurement is feasible, safe and reliable in ALS home environment.

P949

Who win? Spirometry versus symptoms for predicting the longitudinal outcomes in COPD patients – 10 years observation

Stoica Ion Gabriel1, Adriana Teodorescu2, Dobrescu Iulian Dan3, Andrei Maria1. 1Ambulatoriu, Spitalul de Pneumoftziologie SF Stefan, Bucharest, Romania; 2SECTIA 2, Spitalul de Pneumoftziologie Campulung Muscel, Campulung Muscel, Romania; 3Ambulatoria, Spitalul de Pneumoftziologie Galati, Galati, Romania

The spirometric criteria for COPD diagnosis is the king of the gold standard and GOLD-guide accepted in diagnosis, treatment, follow, and disease prediction. Unfortunately, little attention has been paid on the importance of respiratory symptoms in the prognosis of the disease.

Aim: To evaluate whether spirometric criteria are associated with long term clinical outcomes in COPD patients with or without chronic symptoms. In 2000-2001, 2756 non asthmatic participants in the ECRHS (20-44 years) were classified according to smoking history, GOLD criteria and presence or absence of chronic symptoms. In 2000-2001, 2756 subjects were studied. Asthma clinical severity was measured in using asthma control test (ACT) and evidence for GERD was verified using standard questionnaire. Spirometry, impulse oscillometry, and lung volume studies (using body plethysmograph and IOS both provide by Jaeger, Germany) were performed. The difference between total airway resistance (TAWR) indicated by resistance at 5Hz and central airway resistance (CAWR) as indicated by resistance at 20 Hz in oscillometry was calculated as representative of resistance of peripheral airways (PAWR). The relationship between the symptoms of GERD, ACT score and parameters of lung function were analyzed.

Results: PAWR and TAWR were both significantly higher in asthma patients with GERD symptoms than patients without GERD symptoms (mean ranks of 55.8 versus 43.0 kpL/s; p=0.04, respectively). However, the best fit for the analysis of joint data was the logistic regression revealed that the odds ratio (OR) of chronic daily headache for subjects with GERD was 2.0 (95% CI 1.1-3.71). In the subgroup of non-smokers, the OR was 2.7 (95% CI 1.34-5.42).

Conclusion: Subjects with asthma had a higher risk of chronic daily headache than subjects without asthma in this population-based study. Asthma may be related to chronic daily headache.

P951

Effect of GERD on clinical severity and functional characteristics of lung function in asthma

Dhali Assam, Alkbar Sharifit. Medicine, Pulmonary Disease Section, Tabriz University of Medical Sciences, Tabriz, East Aarbaydjan, Islamic Republic of Iran Medicine, Pulmonary Disease Section, Tabriz University of Medical Sciences, Tabriz, East Aarbaydjan, Islamic Republic of Iran

Background: It is known that almost one third of patients with asthma have symptomatic evidence for coexisting gastroesophageal reflux disorder (GERD) which is thought to be aggravating factor in asthma.

Aims and objectives: We investigated the impact of coexisting GERD on the severity and functional characteristics of asthma.

Method: Ninety-two patients with asthma diagnosed on the basis of ATS criteria were studied. Asthma clinical severity was measured in using asthma control test (ACT) and evidence for GERD was verified using standard questionnaire. Spirometry, impulse oscillometry, and lung volume studies (using body plethysmograph and IOS both provide by Jaeger, Germany) were performed. The difference between total airway resistance (TAWR) indicated by resistance at 5Hz and central airway resistance (CAWR) as indicated by resistance at 20 Hz in oscillometry was calculated as representative of resistance of peripheral airways (PAWR). The relationship between the symptoms of GERD, ACT score and parameters of lung function were analyzed.

Results: PAWR and TAWR were both significantly higher in asthma patients with GERD symptoms than patients without GERD symptoms (mean ranks of 56.6 versus 41.9; p=0.01 and 55.8 versus 43.0 kpL/s; p=0.04, respectively). However, the values for ACT score, FEV1, FVC, PEF, RV, TLC, FRC/TLc were not significantly different in these two groups.

Conclusion: Clinical severity of asthma measured by ACT score is not different in asthma patients with and without GERD symptoms and central and peripheral airway resistance is equally influenced by symptomatic GERD.

P952

Six-minute walk test: Comparison with cardiopulmonary exercise test performance, lung function and arterial blood gases in patients with bronchiectasis

Isabel Gomes, Mafalda van Zeller, Patricia Caetano Mota, Paulo Viana, Cristina Carrondo, Ana Dantas, João Almeida, Agostinho Marques. Serviço de Pneumologia, Hospital de S João, Porto, Portugal

Background: Relationships between the 6-minute walk test (6MWT) and car-
diopulmonary exercise test (CPET) performance have been established in some respiratory diseases. However, in patients with bronchiectasis (BECTs) data are scarce in the literature.

**Aims:** To evaluate relationships between 6MWT distance and CPET performance, lung function (LF) and arterial blood gases (ABG) in patients with stable bronchiectasis.

**Methods:** A retrospective evaluation of 27 patients with BECTs who attended a rehabilitation program and who had 6MWT, CPET in cycle ergometer, LF and ABG (at rest) evaluation at the start of the program. Spearman’s correlation coefficient was used for statistical analysis.

**Results:** Thirteen male and 14 female with ages ranging from 19 to 75 (median 51 yrs). Sixteen patients were severely obstructed and 11 had airway colonisation. Mean 6MWT distance was 440.4 meters and mean end test saturation was 89.30%. Mean maximal work (MW) was 68.1 Watts and mean end-CPET saturation was 89.37%. Positive correlations were found between 6MWT distance and MW (r=0.721**, p<0.000), VO2max (r=0.551**, p<0.003), VO2max/kg (r=0.497**, p<0.008), PaO2 (r=0.485*, p<0.010) and HgbSat (r=0.481*, p<0.013). No correlations were found between 6MWT distance and FVC, FEV1, FEV1/FVC, residual volume or PaCO2. Considering colonised patients, positive correlations were found between 6MWT distance and VO2max, VO2max/kg, PaO2 and HgbSat at the 0.05 level.

**Conclusions:** 6MWT is a simple test that seems to mirror exercise capacity evaluated by CPET in patients with bronchiectasis. None of the LF parameters evaluated reflected 6MWT distance in these patients.

**P953**

Leicester cough questionnaire and sputum colour chart assessment in non-cystic fibrosis bronchiectasis: A cohort analysis

**Introduction:** Murray et al. showed that Leicester Cough Questionnaire (LCQ) correlates with disease severity. Sputum colour chart (SCC) assessment was associated with bacterial colonization, bronchiectasis severity and FEV1. We investigated these clinical tools in a cohort of non-cystic fibrosis bronchiectasis (NCFB).

**Methods:** 63 patients (27male, 59±18 y) with NCFB were recruited. Underlying etiologies of NCFB were analyzed and each patient was evaluated by means of spirometry and LCQ. Exacerbation rate and retrospect sputum culture results were analysed. Sputum was induced with hypertonic saline inhalation, total/differential cell count and SCC of sputum were assessed and IL-8, MCP1, b-2 microglobuline, NSE and TNF-a were measured.

**Results:** Patient sputum purulence prediction correlated significantly with SCC evaluated by the doctor (p<0.0001, r=0.72). LCQ and subcores correlated significantly with SCC (p=0.0004, r=-0.37) with more cough impact in more purulent spuata. LCQ total and subcores all correlated significantly with total number of bacteria found in retrospective sputa with worse symptoms in patients with more bacteria found (p<0.01, r=0.32). The SCC also correlated with number of cells in sputum cell count (p<0.0001, r=0.66). IL-8 (p<0.0001, r=0.61) and TNF-a (p=0.0002, r=0.43). Finally, we saw worse FEVI in patients with more purulent sputa (9%; p=0.30, r=-0.37).

**Conclusion:** Patient SCC prediction correlated with doctor SCC evaluation. LCQ, subcores and SCC correlate with lung function, presence of bacteria in all sputa and severity of airway inflammation. We conclude that LCQ and SCC are concise tools and should be used in follow-up of NCFB.

T cell clone transfer model for steroid resistant asthma

Aki Morii1, Akemi Abe1, Satoshi Koyama1, Noriko Kitamura1, Miyako Yamaguchi2, Chihiro Mitsu2, Chiyuki Oshikata2, Yusuke Mitani2, Yuji Maeda1.

**Background:** Glucocorticoid (GC) action on asthma has been partly explained by the inhibition of T cell activation. We analyzed the steroid sensitivity of ovalbumin (OVA) reactive helper T (Th) cell clones both in vitro and in vivo.

**Methods:** Th clones were cultured with antigen presenting cells, OVA, and various concentrations of dexamethasone (DEX). The proliferative response of each Th clone was measured by 3H-thymidine uptake. For in vivo experiments, unprimed BALB/c mice were transferred with Th clones, challenged with OVA, and administered with DEX subcutaneously. The number of infiltrating cells in bronchoalveolar lavage fluid (BALF) was measured.

**Results:** Six Th clones were classified into steroid sensitive and steroid resistant clones in terms of the effects of GC on the proliferative responses analyzed in vitro. Airway infiltration of eosinophils and lymphocytes of mice transferred with steroid sensitive clones were effectively inhibited by the administration of DEX. In contrast, those of mice transferred with steroid resistant clones were not significantly inhibited by DEX, except that the number of eosinophils in the BALF of mice transferred with one steroid resistant clone, Ts-1, was only partially reduced.

**Conclusion:** Steroid sensitivity of Th clones measured in vitro were consistent with that of adoptively transferred asthma model measured in vivo. Steroid sensitive and resistant asthma models seem valuable for understanding the mechanisms of steroid resistance in severe asthma.

**P955**

PARP-1 deficiency blocks IL-5 expression through calpain-independent degradation of STAT-6 in a murine asthma model

Amarjit Naura1, Rahul Dutta1, Mourad Zerfai2, Yousser Errami2, Mustapha Oumounna1, Hogyoun Kim1, Jiang Ju1, Virginia Ronchi1, Arthur Hass2, Hamid Boulares1.

**Introduction:** We recently showed that poly(ADP-ribose)(polymerase-1 (PARP-1) may play a role in allergic (ovalbumin)-induced airway eosinophilia, possibly through a specific effect on IL-5 production.

**Objective:** To explore the mechanism by which PARP-1 regulates IL-5 production in asthma.

**Methods:** This study was conducted using a murine model of allergic airway inflammation and primary splenocytes.

**Results:** PARP-1 knockout-associated reduction in IL-5 upon allergen exposure occurs at the mRNA level. Such an effect appears to take place after IL-4 receptor activation as PARP-1 inhibition exerted no effect on JAK1/JAK3 activation.

**Conclusion:** These results demonstrate a novel function of PARP-1 in regulating IL-5 expression during allergic-induced inflammation and explain the underlying mechanism by which PARP-1 inhibition results in IL-5 reduction.

**P956**

Function of cAMP response element modulator in a murine asthma model

Eva Verjans1, Kathleen Resse2, Norbert Wagner1, Stefan Uhlig2, Lisa Tennbeck2, Christian Martini2.

**Introduction:** Several isoforms of the cAMP response element modulator (CREM) act as transcriptional repressors or activators binding to the cAMP response element of different promoters. In contact dermatitis we previously demonstrated the importance of CREM for antigen presenting cell-dependent and independent T cell function and termination of T cellular immune response. In this study we investigated the role of CREM in murine ovalbumin (OVA)-induced airway inflammation.

**Method:** Male wild type (WT) and CREM knockout animals (CREM-KO) were sensitized i.p. with 10^5 OVA, and administered with DEX subcutaneously. The number of infiltrating Th2 cells was measured.

**Results:** Th clones were cultured with antigen presenting cells, OVA, and various concentrations of dexamethasone (DEX). The proliferative response of each Th clone was measured by 3H-thymidine uptake. For in vivo experiments, unprimed BALB/c mice were transferred with Th clones, challenged with OVA, and administered with DEX subcutaneously. The number of infiltrating cells in bronchoalveolar lavage fluid (BALF) was measured.

**Results:** Six Th clones were classified into steroid sensitive and steroid resistant clones in terms of the effects of GC on the proliferative responses analyzed in vitro. Airway infiltration of eosinophils and lymphocytes of mice transferred with steroid sensitive clones were effectively inhibited by the administration of DEX. In contrast, those of mice transferred with steroid resistant clones were not significantly inhibited by DEX, except that the number of eosinophils in the BALF of mice transferred with one steroid resistant clone, Ts-1, was only partially reduced.

**Conclusion:** Steroid sensitivity of Th clones measured in vitro were consistent with that of adoptively transferred asthma model measured in vivo. Steroid sensitive and resistant asthma models seem valuable for understanding the mechanisms of steroid resistance in severe asthma.

**Background:** We recently showed that poly(ADP-ribose)(polymerase-1 (PARP-1) may play a role in allergic (ovalbumin)-induced airway eosinophilia, potentially through a specific effect on IL-5 production.

**Objective:** To explore the mechanism by which PARP-1 regulates IL-5 production in asthma.

**Methods:** This study was conducted using a murine model of allergic airway inflammation and primary splenocytes.

**Results:** PARP-1 knockout-associated reduction in IL-5 upon allergen exposure occurs at the mRNA level. Such an effect appears to take place after IL-4 receptor activation as PARP-1 inhibition exerted no effect on JAK1/JAK3 activation.

**Conclusion:** These results demonstrate a novel function of PARP-1 in regulating IL-5 expression during allergic-induced inflammation and explain the underlying mechanism by which PARP-1 inhibition results in IL-5 reduction.

**Introduction:** Several isoforms of the cAMP response element modulator (CREM) act as transcriptional repressors or activators binding to the cAMP response element of different promoters. In contact dermatitis we previously demonstrated the importance of CREM for antigen presenting cell-dependent and independent T cell function and termination of T cellular immune response. In this study we investigated the role of CREM in murine ovalbumin (OVA)-induced airway inflammation.

**Method:** Male wild type (WT) and CREM knockout animals (CREM-KO) were sensitized i.p. with 10^5 OVA in aluminum hydroxide solution (day 0, 14 and 21) and with aerosol (1% OVA on day 28 and 29). On day 35 bronchial responses to nebulized acetylcholine (0.001-1mg) were examined using the flexVent system (SCIREQ, Montreal, Canada). Inflammatory responses were evaluated by cell counts, cytokine- and IgE measurements in bronchoalveolar lavage (BAL) and serum. Changes in lung tissue were investigated by histology and calculation of the wet/dry ratio.

**Results:** CREM-KO mice showed an increase in airway responsiveness by elevation in central airway (177%) and tissue resistance (214%) compared to WT (100%). In addition, higher numbers of eosinophils and lymphocytes as well as upregulated Th2 cytokines were found in the BAL of CREM-KO mice. Lung histology indicated increased pulmonary cell infiltration, stronger mucus production and goblet cell hyperplasia.

**Conclusion:** CREM deficiency drives Th2 immune response and influences airway tone as well as mucus production. Our findings suggest that the presence of CREM at least partially protects from the development of asthmatic disease by immunological and non-immunological mechanisms.
P957

Control of allergen-induced inflammation and hyperresponsiveness by the metalloproteinase ADAMTS-12

Geneviève Paulissen1, Mehdi El Hour1, Natacha Rocks1, Maud Gardères1, Fabrice Bureau1, Jean-Michel Foulart1, Carlos Lopez-Otin2, Agnès Noel1, Didier Catala1. 1GIGA-Research (Groupe Interdisciplinaire de Génétique et de Génomique), University of Liège and CHU of Liège, Liège, Belgium; 2Department of Bioquímica y Biología Molecular, Instituto Universitario de Oncología, Universidad de Oviedo, Oviedo, Spain

Background: ADAMTS (A Disintegrin And Metalloproteinase with Thrombospondin motifs) constitute a family of endopeptidases related to gaffins metalloproteinases (MMPs). These proteases have been largely implicated in tissue remodeling associated to pathological processes. ADAMTS-12 has been identified as an asthma-associated gene in a human genome screening program.

Objective: To investigate potential roles of ADAMTS-12 in experimental models of asthma.

Methods: In our study, two different in vivo protocols of allergen-induced asthma were applied to the recently generated ADAMS-12-deficient mice, and corresponding wild-type mice.

Results: The results obtained provided evidence for a protective effect of this enzyme against bronchial inflammation and hyperresponsiveness. In the absence of ADAMS-12, challenge with allergen (ovalbumin and house dust mite) led to exacerbated eosinophilic inflammation in the bronchovascular lumen ( BALF) and in lung tissue, along with airway dysfunction assessed by increased airway responsiveness following methacholine exposure. Furthermore, mast cells counts, ST2 receptor, and IL-33 levels were higher in the lungs of allergen-challenged ADAMS-12-deficient mice.

Conclusion: The present study provides the first experimental evidence for a contribution of ADAMTS-12 as a key mediator in asthma, interfering with immunological processes leading to inflammation and airway hyperresponsiveness.

P958

Local inhibition of IL-4 and IL-13 protects lung function in OVA mouse model

Nicole Stowell1, Michael Baumann2, Sandra Bruckmaier2, Andreas Cornelius2, Nicole Stowell1. 1Centyrex, Karolinska Institutet, Stockholm, Sweden; 2Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden

DARPinSTM (Design Ankyrin Repeat Proteins) are a novel class of proteins that combine the affinity and specificity properties of antibodies with the solubility and tissue penetration properties of small molecules. The excellent biophysical properties of DARPin domains allows for simple engineering of multispecificity by linking domains that target different ligands. DARPin134 is a bispecific DARPin that inhibits binding of murine IL-13 and IL-4 to their receptors.

The bispecific molecule (DARPin134) or either of the mono-specific molecules was delivered to the lungs of mice via intra-tracheal instillation during an acute ovalbumin sensitization and challenge model. Free IL-4 and IL-13 levels were reduced in the BAL following treatment with DARPin134. While the anti-IL-4 and anti-IL-13 DARPin each showed a trend towards reducing eosinophils in the lungs of mice, the bispecific DARPin significantly reduced eosinophil infiltration.

In addition, an improvement airway hyper-responsiveness in mice treated with DARPin134 was observed.

A variety of studies have confirmed the unique and overlapping roles for IL-13 and IL-4 in the development of allergic asthma.

P959

Effect of dietary nitrite and nitrated fatty acids on airway hyperresponsiveness and inflammation in a mouse model of asthma

Cecília Kerm1,2, Sara Bornquist1, Jon Lundberg1, Mikael Adner1,2, Sven-Erik Dahlén1,2. 1The National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 2Centre for Allergy Research, Karolinska Institutet, Stockholm, Sweden

Dietary nitrite (DN) generates NO that lowers blood pressure in vivo. Nitrated fatty acids (FAs) are produced endogenously from nitrated dietary polyunsaturated fatty acids and display broad anti-inflammatory effects including protection in an in vivo model of inflammatory bowel disease.

Our aim was to investigate if DN or NO2-FAs affect airway hyperresponsiveness and inflammation in a mouse model of asthma.

Female BALB/c mice were sensitized with OVA/Al(OH)3 on day 0 and 7 and challenged with OVA or PBS i.n. on day 14-16. DN was administered day 10-17 by a s.c. placed osmotic pump. Airway resistance (Rs) to metacholine and inflammatory cells in bronchoalveolar lavage (BAL) were determined on day 17.

DNA induced an increase in Rs compared to control in all groups (OVA vs. PBS: 3.3±0.2 vs. 2.3±0.1 μL, OVA-DN vs. PBS: 5.6±0.2 vs. 2.5±0.1, OVA-NO2-FAs vs. PBS: 5.4±0.2 vs. 2.2±0.1 (cmH2O/mL), all p<0.01). No differences in Rs were observed between the OVA groups with or without administration of DN or NO2-FAs (p>0.05). OVA induced an increase in BAL eosinophils (EOS) compared to control in all groups (OVA vs. PBS: 25.5±5.5 vs. 0±0, OVA-DN vs. PBS: 21±4 vs. 0±0, OVA-NO2-FAs vs. PBS: 45±7 vs. 0±1 (10,000 cells/mL), all p<0.001). No differences in EOS were observed between OVA with or without administration of DN or NO2-FAs (p>0.05). The number of EOS was higher in OVA-NO2-FAs treated animals versus OVA alone (p<0.001).

To conclude, neither DN nor NO2-FAs displayed anti-inflammatory effects in this asthma model, indicating that there is tissue specificity in the actions of these reactive nitrogen oxide species.

P960

Influence of acid sphingomyelinase deficiency in a murine model of allergen-induced asthma

Eva Verjans1,2, Dieter Adam1, Christian Martin1, Stefan Uhlig1. 1Department of Pediatrics, Medical Faculty of RWTH Aachen, Aachen, Germany; 2Institute of Immunology, Christian Albrechts University, Kiel, Germany; 3Institute of Pharmacology and Toxicology, Medical Faculty of RWTH Aachen, Aachen, Germany

Introduction: Acid sphingomyelinase (ASM) deficiency causes lipid storage diseases, called Niemann-Pick disease (NPD) type A (neuronopathic) and B (non-neuronopathic). Previous studies demonstrated an association of NPD type B with respiratory failure and lung infections. We investigated the role of ASM deficiency in a murine model of allergic asthma.

Method: Male C57BL/6 (WT) and ASM knockout mice (ASMO) were intraperitoneally sensitized with ovalbumin (OVA)/Alum (1μg/1.5mg) on days 0, 1, 2, and 3. Repeated aerosol challenges (1% OVA) followed for five weeks on two consecutive days every week. Bronchoalveolar lavage (BAL) serum and lung tissue were taken for cell counts, cytokine measurements, histology slides and collagen depositions. Precision-cut lung slices (PCLS) were prepared to investigate early asthmatic response (EAR).

Results: Edema formation was less in ASMO-KO (73.6±7.6%) compared to WT. In addition, sensitized ASMO-KO showed significantly higher cell numbers in BAL and lung tissue primarily consisting of neutrophils and enlarged macrophages, whereas numbers of eosinophils were similar. The ratio of eosinophils and neutrophils was characteristic of a typical Th2-pattern. Differences in cytokine and chemokine levels in BAL and serum were not found. OVA stimulation of PCLS from both mouse strains resulted in a weak bronchoconstriction.

Conclusion: ASM-KO showed the typical characteristics of NPD, but their allergic inflammation was similar to that of WT mice, except for an increased neutrophil/eosinophil ratio. The major observation was reduced edema formation in ASMO-KO mice. We conclude that ASM contributes to allergic edema formation, a key feature of asthma.

P961

Modulation of oral tolerance on the oxidative stress responses in distal lung parenchyma of guinea pigs with chronic allergic inflammation

Renato Fraga Frighem1, Samantha Souza Possa1, Viviane Christina Ruiz Schütz1, Roberto Homar Toledo Charadfeldt2, Fábio Céntico Habruman2, Carla Máximo Prado2, Edna Aparecida Leick-Maldonado1, Milton Arruda Martins1, Iolanda Fátima Lopes Calvo1. 1Department of Clinical Medicine, School of Medicine - University of São Paulo, São Paulo, Brazil; 2Department of Biology, Federal University of São Paulo, Diadema, São Paulo, Brazil

Rationale: We previously had shown that oral induced tolerance contributes to reduce distal lung responsiveness, inflammation and remodelling (Nakashima et al.,2008) in a model of chronic inflammation in guinea pigs (GP). In the present study, we evaluated if these responses were associated to alterations on the oxidative stress responses in distal lung.

Methods: GP were submitted to multiple inhalations of ovaalbmin (OVA) or normal saline (NS) (25µl/wk/4wks). At the same oral period tolerance was induced by offering GP ad libitum 2% ovalbumin in sterile drinking water during 4 weeks (OVA-T1) or starting oral ovalbumin after the 4th inhalation of ovalbumin (OVA-T2). Afterwards, lungs were removed, strips of distal lung were stained for iNOS and PGF2ααla (isoprostane) and analysed by morphometry.

Results: In OVA group there was an increase in the iNOS positive cells (20.7±1.9/106·μm²) and PGF2ααla content (17.5±1.2%) compared to NS group (p<0.05). There was a decrease in iNOS positive cells in T1 (12.8±1.9/106·μm²) and T2 (14.3±2.1/106·μm²) compared to OVA (p>0.05). Considering PGF2ααla content, there was a decrease in T1 (6.17±0.4%) and T2 (5.81±0.7%) compared to OVA (p<0.05).

Conclusion: Oral tolerance attenuates the oxidative stress responses in distal lung in this animal model of chronic pulmonary inflammation. These results may clarify the mechanisms involved in the attenuation of mechanical responsiveness, inflammation and remodeling of distal lung by oral tolerance, as previously shown in this animal model. **AQP5 role in ovalbumin-induced airway inflammation and secretion of MUC5AC in mice**

Chuanling Dong1, Guifang Wang1, Meiling Jin1, Bo Li1, Diame Wang1, Zhihong Chen1, Zhongsen Ma2, Xiangdong Wang1, Chunxue Bai1, 1Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China; 2Department of Respiratory Medicine, The Second Hospital, Jilin University, Changchun, Jilin Province, China

**Background:** Airway inflammation and mucus hypersecretion are two important characteristic features of the pathogenesis of asthma. Aquaporin5 (AQP5) is known to be a water channel protein expressed widely in lung epithelium and submucosal glands.

**Objective:** The present study aimed at investigating the involvement of AQP5 in asthma.

**Methods:** The ovalbumin (OVA)-induced allergic pulmonary inflammation and MUC5AC production were examined in AQP5+/+ or AQP5−/− mice. The expression of AQP5s in lung tissue and their regulation were detected. In addition, epidermal growth factor receptor (EGFR) expression and osmotic water permeability in lung were evaluated.

**Results:** Lower expression of AQP1, 4, 5 while higher AQP3 was significant in lung tissue from AQP5−/− model mice. Only AQP1 and AQP5 were up-regulated by anti-asthmatic agents (dexamethasone, ambroxol and terbutaline) significantly. However, AQP5 knockout had significantly low airway inflammation and less lung edema induced by OVA, as compared with those in AQP5+/+ mice. In addition, lower expression of MUC5AC in airway epithelium, less secretion of MUC5AC were found in AQP5−/− model mice. Moreover, the expression of EGFR on airway epithelium was prevented by AQP5 knockout in asthmatic model.

**Figure legend:**
- (A) Lung histology pictures. Body weight was measured by immunochemical staining and quantification.
- (B) Score of staining for MUC5AC expression.
- (C) MUC5AC mRNA expression.
- (D) Osmotic water permeability.

**Conclusion:** Our data indicate that AQP5 is involved in the development of allergic airway inflammation and mucus hypersecretion by regulating osmotic water permeability and expression of EGFR.

**Effects of increase gradual OVA doses in the inhalations in a model of asthma to long term**

Ronald Aparecido da Silva1, Francine Maria de Almeida2, Clarice Rosa Oliver2, Beatriz Mangeurre Sararva2, Milton Arruda Martins2, Celso Ricardo Fernandez de Carvalho2, 1Physiopathology Experimental, Medicine School of University of Sao Paulo, Sao Paulo, Brazil; 2Clinical Medicine, Medicine School of University of Sao Paulo, Sao Paulo, Brazil

Mice are used to develop models of pulmonary allergic disease.

**Objective:** To evaluate the increase gradual OVA doses in a protocol of experimental asthma.

**Methods:** Balb/c mice male were divided in Groups: Control, OVA1%, OVA3%, OVA5%. Sensitized animals received i.p.(OVA+Saline:3x wk/30min). Days: 0,14,28,42. Inhalations sessions (OVA+Saline:3x wk/30min) were performed between 21st and 54th day. The OVA1% group received inhalation with concentration of OVA1%. The OVA3% began with 1% for 3 weeks (wk), in the 4th wk was increased for 3%. The OVA5% began with 1% in the 1st wk, 2nd wk was increased for 2%, 3rd wk with 3%, 4th wk for 4%, 5th wk for 5% of OVA. The Control group received i.p. and Saline inhalations.

**Results:** IgE and IgG1 were increased in sensitized groups, but in the groups 3% and 5% the levels were highest and shown increased of cell migrations presented increase of eosinophils, neutrophils and trickiness of the smooth muscle when compared with others two groups (p<0.01), just Group 3% shown high index of peribronchial eosinophils (p<0.01).

**Conclusions:** Groups OVA3% and OVA5% are more efficient for develop features of experimental asthma, and seems that Group OVA3% develop important increase of eosinophil migration in the airways.

**P964**

**Chronic airway inflammation alters the peripheral distribution of transferred mast cells in deficient C57BL/6-Ki/t-W/-/mice**

Lisa Sjöberg1,2, Barbara Fuchs1,2, Christine Möller Westerberg1, Linda Swedin2, Sven-Erik Dahlén2, Mikael Adner2, Gunnar Nilsson1, 1Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden; 2Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

**Objective:** Mice are used to develop models of pulmonary allergic disease. Chronic airway inflammation (CAI) can be induced by ovalbumin (OVA). We addressed this issue by comparing MC-distribution in wild-type C57BL/6 (WT), Wsh (MC-deficient) and intravenously BMMC-transferred Wsh (Wsh+MC) mice.”

**Methods:** In control mice, number of MC in the lungs was significantly higher in Wsh+MC mice. MC in WT mice were located around the central airway (CA) and perivascular space (PVS) whereas they were negligible in parenthesis (PA) and smaller airways (SA). In contrast, MCs in Wsh+MC mice were predominantly found in PA (16±1±2) and PVS (15±2±2) but also around CA (3±1±1) and SA (3±1±1). Induction of CAI in Wsh+MC mice caused increased MC number in the PA (28±6 vs. 16±2) and decreased MC number in the CA (0±1 vs. 3±1) and PVS (5±1 vs. 15±2) compared to controls. Important, these findings suggest that MC transfer causes a completely different condition, which might not be comparable to the WT and thus not serve as an adequate control. Instead,
WshrMC mice may be more suitable in experiments for studying CAAl, since mast cell number, distribution and relocation in response to inflammation more closely resemble findings in the human lung.

**P965**

Effects of chronic allergen exposure on the airway hyperreactivity in sensitized rats

Dorota Czok1, Zoltan Novak2, Levente Barzai3, Andrea Bantoi1, Ferenc Petak1,1. Department of Medical Physics and Informatics, University of Szeged, Szeged, Hungary; 2Department of Pediatrics, University of Szeged, Szeged, Hungary; 3Svábhegy Health Service Ltd, for Allergy, Immunology & Pulmonary Diseases, “Svábhegy” Health Service Ltd, Budapest, Hungary

We aimed at investigating whether chronic allergen exposure (CAE) leads to the development of tolerance or enhances the airway hyperreactivity (AH) in sensitized rats. The airway resistance (Raw) was determined from the total respiratory system impedance under the control condition and following iv methacholine provocations (MCh 2-16 μg/kg) to establish the basal lung responsiveness. The rats were then sensitized to ovalbumin (OVA) and were assigned into two groups: the rats in Group CAE (n=6) were exposed to aerosolized OVA three times a week throughout the study period, while the OVA was withdrawn during the entire protocol in the rats enrolled in Group A (n=8). Assessment of lung responsiveness was repeated in both groups in an identical manner on weeks 3, 6 and 9. The equivalent dose of MCh causing a 20% increase in Raw (ED20) was calculated from each challenge. OVA sensitization was proved to induce AH on week 3 in Groups CAE and A (decrease in Raw of 33±14% and 40±7%, respectively). The subsequent OVA exposure affected significantly the MCh responsiveness with sustained decreases in ED20 on week 6 in Group A and gradual return to normal on week 9, whereas the ED20 in Group CAE was similar to the initial on weeks 6 and 9.

Our findings demonstrate a diminishment of AH following CAE suggesting its favourable influence on the reduction of an existing AH after allergic sensitization. Supported by grant OTKA K81179.

Poly IC treatment causes fatal AHR in sensitized mice

M. Starkhammar1,2, S. Georger-Kumlien1,2, S.-E. Dahlén2,3, M. Adner2,3,1. Division of ENT Diseases, CLINTEC, Karolinska Institute, Stockholm, Sweden; 2Unit for Experimental Asthma and Allergy Research, Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden; 3Centre for Allergy Research, Karolinska Institutet, Stockholm, Sweden

Respiratory infections are known to promote airway hyperresponsiveness (AHR) in asthmatic patients. Toll-receptors (TLRs) are parts of the innate immune system that recognize viral and bacterial components. This in vivo study explores the relation between TLR activation and AHR in a model of allergic airway inflammation.

Female BALB/c mice where sensitized on day 1 and 8, then challenged with either ovalbumin (OVA) or PBS on day 15-17. PolyIC activating TLR3, LPS triggering TLR4 or PBS were then given i.n. during 4 consecutive days. On day 22 the outcome of metacholine (Mch) induced airway resistance was investigated with flexiVent® technique. Cells and inflammatory mediators were analysed in bronchoalveolar fluid (BALF).

PolyIC and LPS treated mice developed a marked AHR not seen among control mice. The airway resistance reached critically high levels in mice concomitantly challenged with OVA (Raw at 1mgMch/kg: PBS: 2.1±0.1, PBS-LPS: 2.9±0.3, PBS-polyIC: 3.6±0.2, OVA: 5.6±0.2, OVA-LPS: 9.3±0.6 and OVA-polyIC: 7.3±0.5 cmH2O·l−1·s−1). The OVA-polyIC mice also displayed circulatory collapse (p<0.05). PolyIC increased the amount of lymphocytes and LPS neutrophils in BALF. Multivariate analysis of a panel of inflammatory mediators could not reveal a clear separation between PBS and OVA groups. However, polyIC treatment induced a specific increase of IL-12 and KC in both treatment groups. Costimulation with PolyIC and LPS, representing viral and bacterial activation, respectively, caused AHR above the effect of OVA which in by polyIC caused fatal circulatory response. It is therefore tempting to suggest that TLRs might play a vital role in virus-induced exacerbations of allergic asthma.

The influence of female sex hormones on the number of alternatively activated lung macrophages and airway inflammation in a mouse model of asthma

Chiara Dirijer1, Machteld Hylkema2, Rinze Hofstra1, Pieter Klok2, Wim Timens2, Durke Postma3, Barbro Melgent1, 1Pharmacokinetics, Toxicology, and Targeting, University Centre for Pharmacy, University of Groningen, Groningen, Netherlands; 2Pathology, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands; 3Pulmonology, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands

The chance of developing asthma increases in girls during puberty. A role for sex hormones has been suggested. Recently we have shown that alternatively activated macrophages (aAM) contribute to the development of asthma in female mice. Here we have investigated how sex hormone depletion before puberty affects asthma in mice and whether this correlates with aAM numbers in lung.

Female Balb/c mice were ovariectomized (OVX) or sham treated before puberty. OVX animals were left untreated, received a 0.1 mg estrogen (E2) pellet, or a 15 mg progesterone (PG) pellet at the day of OVX (all groups n=8). Four weeks later, mice were sensitized i.p with ovalbumin (OVA) and challenged with 1% OVA on days 1 and 14-20. On day 21, allergic inflammation (OVA-specific IgE, eosinophils) and aAM numbers were assessed.

Ablating sex hormones before puberty significantly increased airway inflammation as judged from higher eosinophil numbers in bronchoalveolar lavage fluid and higher OVA-specific IgE levels in serum. aAM numbers were unaffected by OVX. Treating OVX mice with E2 significantly reduced eosinophilic airway inflammation with a concomitant reduction in aAM numbers, whereas PG did not change airway inflammation or aAM numbers.

This study surprisingly shows that OVX in mice before puberty amplifies OVA-induced airway inflammation. This is a consequence of E2 depletion since PG substitution does not reduce the increased allergic inflammation while E2 substitution does. Our data also shows that the effect of OVX does not involve aAM, whereas reduction of eosinophilic airway inflammation after E2 substitution appears to involve aAM.

**P968**

Transcription factor FOXP3 is over expressed in BALT of systemic sclerosis model induced by collagen V nasal tolerance

Ana Paula Velosa1, Wálcy R. Teodoro1, Isabelle C. Brindo da Cruz1, Edwin R. Parra2, Antonio dos Santos Filho3, Sandra M. Fernezlian2, Vera Luzia Capelozzi1, Natalino H. Yoshinari1, 1Rheumatology Division, Faculdade de Medicina da USP, São Paulo, Brazil, 2Department of Pathology, Faculdade de Medicina da USP, São Paulo, Brazil

**Background:** To evaluate the transcription factor FOXP3 expression in lymphocytes of bronchoconstricted-allergic asthma tissue (IR) and skin when compared with 33,3% of CT (p=0,03) group. In the pulmonary inflammation and the amounts of collagen in pulmonary interstitium of systemic sclerosis (SSc) model after type V collagen (COL V)-induced nasal tolerance.

Methods:** Female New Zealand rabbits (N=12) were immunized with 1mg/ml of COL V in Freund’s adjuvant (IM). After 150 days, six animals were tolerated nasally with COL V (25 μg/day) (IM-TOL), daily during 60 days. Animals (N=6) not immunized and COL V tolerated served as control (CT). Immunohistochemistry and morphometric analysis was used to evaluate the T lymphocytes FOXP3 expression in BALT structures and inflammatory cells in pulmonary interstitium. Types I, III and V collagen expression were evaluated by Real-time PCR.

**Results:** We observed the BALT lymphocytes FOXP3 expressed in all of IM-TOL animals when compared with 33,3% of CT (p=0,03). In the pulmonary interstitium, IM-TOL presented a significant decreased of lymphocytes (4.3±1.1 to 1.7 ± 1.15±1.5±2.53), macrophages (5.73±3.2×7.7 vs. 7.66±1.5) and monocytes (1.91±5.7±3.2 vs. 2.73±7.32) when compared with IM. COL (0.1±0.07 vs. 1.00±0.25, p=0.002) and COLV (1.12±0.42 vs. 4.74±2.25, p=0.009) mRNA expression were reduced in IM-TOL when compared with IM.

**Conclusions:** COL V induced nasal tolerance in the experimental SSc induced FOXP3 regulatory T cells in BALT which can trigger an immune regulatory mechanism resulting in decreased inflammation and collagen expression. It suggests that tolerance with COL V could be a promising therapeutic option for human scleroderma treatment.

The respiratory allergen glutaraldehyde in the local lymph node assay: Sensitization by skin exposure, but not by inhalation

Jos van Trief1, David Roberts2, Frieke Kuper2, 1Toxicology and Applied Pharmacology, TNO Tielroelen, Zeist, Netherlands; 2Pharmacy and Biomolecular Sciences, Liverpool John Moores University, Liverpool, United Kingdom; 3Quality and Safety, TNO, Zeist, Netherlands

Previously, a selection of low molecular weight contact and respiratory allergens had tested positive in both a skin and a respiratory local lymph node assay (LLNA), but formaldehyde was negative for sensitization by inhalation. To investigate whether this was due to intrinsic properties of aldehyde sensitizers, the structurally-related allergen glutaraldehyde (GA) was tested. BALB/c mice were

169s

**Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30**
Exposed by inhalation to 6 or 18 ppm GA (respiratory LLNA), both generated as a vapor and as an aerosol. Other groups received 0.25% or 2.5% GA on the skin of the ears (skin LLNA). Lymphocyte proliferation and cytokine production were measured in the draining lymph nodes. GA was positive in the skin LLNA and its cytokine profile (IL-4: IFN-γ) skewed towards a Th2-type immune response with increasing dose. Inhalation exposure did not result in increased lymphocyte proliferation or increased cytokine levels, despite comparable tissue damage (irritation) in the skin and respiratory tract. We hypothesize that the highly reactive and hydrophilic GA oligomersizes in the protein-rich mucus layer of the respiratory tract, which impedes sensitization but still facilitates local irritation. Within the context of risk assessment in respiratory allergy, our results stress the importance of prevention of skin – besides inhalation – exposure to aldehydes like GA.

Conclusions: Our data indicate that overexpression of Prdx6 prevent allergic airway inflammation and hypersecretion by reducing ROS levels. While due to several compensatory mechanisms, targeted disruption of Prdx6 fails to increase OVA-induced asthma.

P970

Overexpression of peroxiredoxin 6 protect mice from ovalbumin-induced airway inflammation and hypersecretion of MUC5AC by reducing ROS levels

Chunling Dong, Bo Li, Dong Yang, Guifang Wang, Xiangdong Wang, Chunxue Bai
Department of Pulmonary Medicine, Zhongshan Hospital, Shanghai, China

Background: Oxidative stress plays an important role in the pathogenesis of asthma. Peroxiredoxin 6 (Prdx 6), as a newly identified peroxidase, protect cell or organ from reactive oxygen species (ROS)-induced oxidative stress.

Objective: The present study aimed at investigating the involvement of prdx 6 in asthma.

Methods: The ovalbumin (OVA) - induced allergic airway inflammation and MUC5AC production were examined in wild-type (WT), overexpressing (Prdx 6) and control (Prdx 6 null) (Prdx 6-/-) mice. The level of inflammatory cells in bronchoalveolar lavage fluid (BALF) were evaluated.

Results: The expression of Prdx 6 was reduced significantly and up-regulated by dexamethasone and bronchoalveolar lavage from WT mice. Prdx 6+/+ mice had significantly low airway inflammation, low levels of IL-13 in BALF as compared with those in WT mice. In addition, lower expression of MUC5AC in airway inflammation and hypersecretion by reducing ROS levels in bronchoalveolar lavage fluid (BALF) were evaluated.

Conclusions: Our data indicate that overexpression of Prdx 6 protect allergic airway inflammation and hypersecretion by reducing ROS levels. While due to several compensatory mechanisms, targeted disruption of Prdx 6 fails to increase OVA-induced asthma.

P971

Crucial role of phospholipase Cε in the development of asthma in mice

Tatsuya Nagano1,2, Hironori Edamatsu 1, Kazuyuki Kobayashi2, Yoshitomo Nishimura1, Tatsuya Nagano3, 1Division of Molecular Biology, Department of Biochemistry and Molecular Biology, Kobe University Graduate School of Medicine, Kobe, Japan; 2Division of Respiratory Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, Japan

Phospholipase Cε (PLCε) is an effector of Ras and Rap small GTPases. Studies using genetically-modified mice of PLCε have shown its crucial role in skin inflammation. The purpose of this study is to examine whether PLCε is involved in the pathogenesis of inflammation in the respiratory system. First, we analyzed the location of PLCε in the respiratory system. By immunohistochemical analyses, we found that PLCε is expressed highly by alveolar epithelial cells and moderately by bronchial epithelial cells and smooth muscle cells in the bronchioles and the pulmonary arteries. Next, we experimentally induced asthma in PLCε-/- and PLCε+ + mice in the C57BL/6 background by sensitization with ovalbumin (OVA) followed by boost with OVA by inhalation, and performed pathological analyses at 24 h after the last inhalation. Pathohistological studies of the sections of the lung and bronchi showed that infiltration of leukocytes and mucus production by the goblet cells were greatly suppressed in PLCε-/- mice. Also, characterization of inflammatory cells in bronchoalveolar lavage fluid demonstrated that the infiltration of leukocytes, particularly that of eosinophils, was suppressed in PLCε-/- mice. On the other hand, the serum levels of IgG and IgE specific for OVA were not affected by PLCε-deficiency. These results suggest that PLCε has a crucial role in the pathogenesis of asthma and that PLCε would become a molecular target for the treatment of patients with allergic asthma.

P972

Grape seed proanthocyanidin extract attenuates airway inflammation and hyperresponsiveness in a murine model of asthma: Downregulating inducible nitric oxide synthase

Qian Zhang1, Guo-Wei Wei 1, Dan-Yang Zhou1, Qian Dui1, Mao Huang1, 1Department of Respiratory Medicine, Affiliated Changzhou No.2 People’s Hospital, Nanjing Medical University, Changzhou, Jiangsu, China; 2Department of Respiratory Medicine, Second Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China; 3Department of Respiratory Medicine, The First Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China

Background: Allergic asthma is characterized by hyperresponsiveness and inflammation of the airway with increased expression of inducible nitric oxide synthase (iNOS) and overproduction of nitric oxide (NO). Grape seed proanthocyanidin extract (GSPE) has been proved to have antioxidant, anti-inflammatory and other pharmacological effects.

Aims and objectives: The purpose of this study was to examine the role of GSPE on airway inflammation and hyperresponsiveness in a mouse model of allergic asthma.

Methods: BALB/c mice, sensitized and challenged with OVA, were intraperitoneally injected with GSPE. HE staining and PAS staining were used to observe airway inflammation in lung tissue and airway mucous secretion. The quantification of cytokines in bronchoalveolar lavage fluid (BALF) and total serum immunoglobulin E (IgE) were detected by ELISA. The protein expression of iNOS was evaluated by immunohistochemistry and Western Blot analysis.

Results: GSPE remarkably suppressed airway resistance, and reduced the total inflammatory cell and eosinophil counts in BALF Treatment with GSPE significantly enhanced interferon (IFN-γ) level and decreased interleukin (IL)-4 and IL-13 levels in BALF and total IgE levels in serum. GSPE attenuated allergen-induced lung eosinophil inflammation and mucus-producing goblet cells in the airway. The elevated iNOS expression observed in the OVA mice was significantly inhibited by GSPE.

Conclusions: GSPE decreases the progression of airway inflammation and hyperresponsiveness by downregulating the iNOS expression, promising to be a potential in the treatment of allergic asthma.

P973

The effects of bacilli Calmette Guerin-polysaccharide nucleic acid on nasal airway inflammation and resistance in allergic rhinitis mice

Yin Xi, Kefang Lai, Lina Han, Na Wu, Yanhuong Hong, Juzxing Xie, Wei Liao, Nanshan Zheng, State Key Laboratory of Respiratory Diseases, Guangzhou Institute of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical College, Guangzhou, Guangdong, China

Background: Lots of data can be found to approve that exposure to mycobacteria has the potential to suppress the development of allergic rhinitis or atopy. But the influence of bacilli Calmette Guerin-polysaccharide nucleic acid (BCG-PSN) especially on nasal airway inflammation and resistance (RNa) on mice, are poorly understood.

Conclusions: The results show that BCG-PSN treatment of patients with allergic rhinitis mice would become a molecular target for the treatment of patients with allergic asthma.
Objective: Investigate the effects of BCG-PSN on nasal airway inflammation and resistance in allergic rhinitis mice.

Method: Balb/c mice were sensitized by intraperitoneal injection of ovalbumin (OVA) saline, then challenged by intranasal administration under conscious to establish an allergic rhinitis model. The mice were intervened with BCG-PSN by intranasal administration (1, 5, 10 μg) before sensitization. A novel method of RQmax was applied to measure nasal function. Then the inflammation of nose was accessed by nasal tissues histology.

Result: In 3 interventions groups the RQmax had no statistical difference compared to rhinitis group. But compared to the normal group, the RQmax of expiration in 10 μg group and the RQmax of inspiration in 10 μg group had no statistical difference. The number of eosinophils (Eos) in 10 μg group was lower than rhinitis group as well as mucosal thickness.

Conclusion: BCG-PSN can inhibit nasal airway inflammation and decrease nasal airway resistance in allergic rhinitis mice.

102. Asthma: risk factors and comorbidities

P974 Evaluation of inhalant allergen-specific IgE in wheezing infants as predictor for persistent symptoms

Srima Mileva, Todor Popov, Ivanka Galeva, Milena Yankova, Pediatric Department, Alexandrovska Hospital, Medical University, Sofia, Bulgaria

Clinic of Allergy and Asthma, Alexandrovska Hospital, Medical University, Sofia, Bulgaria

The aim of this study was to assess the IgE immune response in infants who were hospitalized for wheezing and follow-up during school age.

Subjects and methods: Thirty-eight children with a mean age of 8.5 months (2–22 months), who had been hospitalized with acute wheezing episodes, were included in the study. Total IgE and specific IgE for food and inhalant allergens were assessed by FEIA, Uni CAP.

The wheezing infants were divided into three clinical groups according to the number of previous wheezing episodes: first wheezes (n = 22), second wheeze (n = 9) and children with recurrent – three or more episodes of wheezing (n = 7). After five years the children were evaluated for asthma and allergy including t IgE and allergen-specific IgE.

Methods: BCG-PSN can inhibit nasal airway inflammation and decrease nasal airway resistance in allergic rhinitis mice.

P975 Analysis of the environmental risk factors in patients with bronchial asthma, allergic to moulds in second year observation

Grzegorz Przybylski1, Aleksandra Gadzinska1, Ryszard Golda2, Ania Dubrowska1, 1Department of Respiratory Medicine and Tuberculosis, Nicolaus Copernicus University, Collegium Medicum in Bydgoszcz, Bydgoszcz, Poland, 2Institute of Experimental Biology, Kazimierz; Wielki University, Bydgoszcz, Poland, 3Department of Theoretical Foundations of Biomedical Sciences and Medical Informatics, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz, Poland

Mold is a common yet significant allergen. Approximately 5% of people with allergies are subjected to allergic reactions of the respiratory tract which may be caused by mold. It seems that although mold frequently occurs in the outdoor environment, it often happens that indoor exposure must be taken into account in diagnostic procedure. To decrease the risk of mold allergy development or aggravation, indoor mold growth in patient’s closest environment should be prevented. In case of mold colonization at home, school or office, symptoms which supports its growth, should be found so as to identify it and remove as quickly as possible. From January 2009 to December 2010, 421 subjects were recruited from among outpatients visiting the Asthma Outpatients, Poland. Among them, in 166 patients positive mould allergy tests were obtained. These patients were presented with symptoms of bronchial asthma. All examined patients were subjected to interview concerning environmental factors such as mold allergens. For this purpose a questionnaire was used concerning demographic factors, living conditions, determination of the age of the building, presence of moisture in the place of living, and active or passive tobacco smoking environment. It seems that exposure to environmental factors such as damp flat, old housing plus tobacco smoking, especially in flats of large concentration, may all be favourable to the occurrence of environmental mould allergy and be the cause of the rise of allergy symptoms as well as invoking exacerbations.

P976 Food allergy as a risk factor for habitual snoring

Camilla Celani, Giovanni Ragusa, Enea Bonci, Maria Palma Carbone, Serena Caggiano, Anna Maria Zicari, Giovanna De Castro, Marzia Duse, Pediatric, Sapienza University, Rome, Italy

Background: It has been suggested that habitual snoring (HS) has adverse health outcomes in children and it’s an important indicator of many clinical conditions such as atopy, cough and rhinitis.

Aim of the study: To determine the prevalence of HS in a cohort of children with food allergy (FA) and its association with atopic state, and other clinical symptoms such as cough, and rhinitis.

Methods: Seventy-four children (mean age 11.0±2.0 years; 36 males) with a history of FA were selected. Atopic status was determined by a SPT to a panel of primary aeroallergens and food allergens. Parents-administered questionnaires were used to collected information on children’s snoring and possible symptoms associated. HS was defined as snoring three or more times per week.

Results: In our experience, children with FA show an higher prevalence of HS compared to Italian age-matched population (respectively 23% ± 4.9%: p <0.001) (Brunetti et al. Chest 2001, 120, 1930-1935). Furthermore among HS children, children with food allergy (FA) and its association with atopic state, and other clinical symptoms such as cough, and rhinitis.

Methods: Seventy-four children (mean age 11.0±2.0 years; 36 males) with a history of FA were selected. Atopic status was determined by a SPT to a panel of primary aeroallergens and food allergens. Parents-administered questionnaires were used to collected information on children’s snoring and possible symptoms associated. HS was defined as snoring three or more times per week.

Results: In our experience, children with FA show an higher prevalence of HS compared to Italian age-matched population (respectively 23% ± 4.9%: p <0.001) (Brunetti et al. Chest 2001, 120, 1930-1935). Furthermore among HS children, children with food allergy (FA) and its association with atopic state, and other clinical symptoms such as cough, and rhinitis.

Methods: Seventy-four children (mean age 11.0±2.0 years; 36 males) with a history of FA were selected. Atopic status was determined by a SPT to a panel of primary aeroallergens and food allergens. Peripheral airway obstruction is a predictive sign of early asthma

Takayaki Miyamoto, Hitoshi Kobayashi, Ateak Sato, Yu Usami, Yutaka Nakamura, Kohei Yamanuchi, Division of Pulmonary Medicine, Allergy and Rheumatology, Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Japan

Introduction: Diagnosis of early asthma is important to introduce early intervention. However, despite of many reports, it has not been established yet.

Objectives: To perform spirometry and Impulse Oscillometry System (IOS) on early asthmatics and compared the data with those of patients with chronic cough symptom (CC) and acute bronchitis (AB).

Methods: Patients who complained of chronic cough, wheeze and dyspnea, and had never been diagnosed as bronchial asthma (BA) before were recruited to the present study. After having their informed consent, we performed spirometry and IOS, and measured bronchial hyperresponsiveness (BHR). After several months, these patients were diagnosed as bronchial asthma, chronic cough including cough variant asthma and acute bronchitis by development of symptoms, hematological analysis and other findings.

Results: 169 patients (male: 113; 67.2%; age: 41.4 ± 14.4 years) were included. Mean±SEM, n=89) was significantly increased compared to CC (5.2±1.4, n=32) and AB (6.4±7.6, n=23). FEV1 of BA was not significantly decreased compared to CC. However, both%V50 and%V25 of BA were significantly decreased compared to those of CC (V50: BA vs CC; 49.7±25.9 vs 70.2±16.4, p<0.005, V525: BA vs CC; 58.1±29.0 vs 74.1±12.3, p<0.05).%R (5-25) measured by IOS was significantly higher in BA than in CC (BA vs CC; 151.7±6 vs 52±26).

Conclusions: Decreases of%V50 and%V25 and increase of%R (5-25) in IOS which indicated peripheral airway obstruction were detected in early asthmatics not in CC. These results suggested that peripheral airway obstruction may be a useful predictive sign of early asthma, which can be detected by spirometry.

BHR of BA (Dmin: 1.1±200s, n=89) was significantly decreased compared to CC (%V50: BA vs CC; 5.25.9 vs 70.2±16.4, p<0.005, V525: BA vs CC; 38.1±29.0 vs 54.1±12.3, p<0.05).%R (5-25) measured by IOS was significantly higher in BA than in CC/AB (BA vs CC/AB; 151.7±6 vs 52±26).

Conclusion: Presence of bronchoprovocation test positivity effect the development of allergic respiratory disease: 7 year follow-up study

Yavuz Havlucu1, Deniz Yurtman Havlucu2, Serap Ozturkcan 3, 1Chest Disease, Celal Bayar University Medical Faculty, Manisa, Turkey; 2Dermatology, Merke; Efendi State Hospital, Manisa, Turkey; 3Dermatology, Celal Bayar University Medical Faculty, Manisa, Turkey

In this study, we aimed to investigate the relation between bronchoprovocation test positivity an development of allergic respiratory disease. The inclusion criteria to study were disease duration more than 1 year, no chronic urticaria, no history of long acting antihistaminic and corticosteroid usage in a month. The patients with asthma and pulmonary symptoms, diseases causing positive methacholine provocation test (MPT), contraindication to the MPT, and abnormal pulmonary function test were excluded. 156 patients with chronic urticaria were included to the study. There was 108 (69.2%) female and the mean age was 42.5±4.13,19 years. The duration of disease was 6.05±4.3,3 (1-25) years.

After physical examination, pulmonary function test and MPT were performed to the all patients with chronic urticaria. At the beginning, MPT positivity was detected in 41 (26.3%) patients. There was no significant difference between patients with MPT (p<0.05) and MPT-) according to demographic findings. Mean dose of MPT and total IgE level were 2.64±3.36 mg/ml and 123.3±124.3, respectively. In MPT (+) patients, rate of doctor diagnosed asthma and allergic rhinitis were 46.8%, 60.9% respectively and they were 18.2% and 25.2% respectively in MPT-) patients (p<0.05). Presence of allergic disease in family members did not influence the development of these allergic respiratory diseases. Also total IgE level at the beginning did not related with development of these disease.

As a result, bronchoprovocation test can be (+) in chronic urticaria patients without pulmonary symptoms and this positivity can be first sign of respiratory allergic disease that will develop in future.
P984

Patients with asthma and comorbid allergic rhinitis: Is optimal quality of life achievable in real life?
Fulvio Braido1, Ilaria Biaurain1, Stefania Menoni2, Federica Gani3, Gian Enrico Senna4, Erminia Ridolo1, Versuka Scoepp1, Anthei Rogkakali1, Giorgio Walter Canonica1. 1Allergy & Respiratory Disease Clinic, A.O.U. San Martino, Genova, Italy; 2Department of Health Science, University of Genova, Biostatistics Unit, Genova, Italy; 3Allergy Unit, Respiratory Diseases Division, A.O.U. San Luigi, Orhassano, Torino, Italy; 4Allergy Service, Verona Major Hospital, Verona, Italy; 5Clinical Sciences, University of Parma, Parma, Italy.

Background: Asthma trials suggest that patients reaching total disease control have an optimal Health Related Quality of Life (HRQoL). Rhinitis is present in almost 80% of asthmatics and impacts asthma control and patient QoL.

Aims and objectives: We explored whether optimal HRQoL was reachable in a real-life setting, and evaluated the disease and patient related patterns associated to optimal HRQoL achievement.

Methods: Asthma and rhinitis HRQoL, illness perception, mood profiles, rhinitis symptoms and asthma control were assessed by means of validated tools in patients classified according to GINA and ARIA guidelines.

Results: Optimal HRQoL, identified by Rhodesma Global Summary (GS) score ≤20, was reached by 78/209 (37.32%). No association between clinical and demographic characteristics, with the exception of age, and optimal HRQoL achievement was found. Patients reaching an optimal HRQoL differed in disease perception and mood. Asthma control was significantly associated with optimal HRQoL. (χ²=49.599; p<0.001) and well-controlled and totally controlled patients significantly differed in achieving optimal HRQoL. (χ²=7.617; p<0.006).

Conclusion: While the majority of asthma patients did not reach optimal HRQoL, it is achievable, in real life, independently from disease severity. Failure to achieve optimal HRQoL was related to unsatisfactory disease control. Patients reaching optimal HRQoL differ from others in disease illness perception and mood. Therefore, therapeutic plans should be directed toward achieving the best possible clinical control of asthma and comorbid rhinitis, but also incorporate individualized elements according to patient-related characteristics.

Nasal airway resistance and correlation with lower airway involvement in allergic rhinitis
Apurama Iyer, Amita Athahve. Chest Medicine and Environment Pollution Research Centre, Seth G.S. Medical College & King Edward Memorial Hospital, Mumbai, Maharashtra, India. Chest Medicine and Environment Pollution Research Centre, Seth G.S. Medical College & King Edward Memorial Hospital, Mumbai, Maharashtra, India.

Background: Allergic rhinitis often precedes onset of asthma. Nasal airflow obstruction is measured by rhinomanometry.

Aims and objectives: Determining nasal airflow obstruction by active anterior rhinomanometry. Correlating nasal resistance with clinical severity of rhinitis and incidence of latent lower airway involvement.

Materials and methods: 32 patients with allergic rhinitis underwent active anterior rhinomanometry to determine nasal airflow obstruction. Nasal airflow challenge test was performed.

Results: 56% of patients with mild rhinitis and 94% with moderate-severe rhinitis significantly raised nasal airway resistance values. (χ²=0.3 Pa/sec) 0.05)

Conclusions: Clinical severity of allergic rhinitis correlated with nasal airway resistance values measured by active anterior rhinomanometry.

Chronic rhino-sinusitis in severe asthma improves at high altitude
Lucia H. Rijssenbeek-Nouwens1, Karin F. Fieten1, Adriano O. Bron1, Els J. Veesink1, Elisabeth H. Beij1. 1High Altitude Clinic, Dutch Asthmacenter Davos, Davos, Switzerland; 2Department Respiratory Medicine Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Severe asthma and chronic rhino-sinusitis often coexist (Meltzer, JACI 2004). Patients with severe asthma have shown to benefit from high altitude treatment (Rijssenbeek AJRCCM 2010). It is unknown whether chronic rhino-sinusitis also improves at high altitude.

Aim: To investigate the effect of high altitude treatment on symptoms of upper and lower airways disease in patients with severe asthma and rhino-sinusitis.

Method: 137 patients with severe asthma treated at the Dutch Asthmacenter Davos were included. In 65 patients, using nasal steroids, sino-nasal symptoms (SNOT scores), asthma control (ACQ), exhaled Nitric Oxide (FeNO), use of oral and nasal steroids were analysed, as well as the relationship between parameters of upper and lower airways. Parametric and non-parametric tests were used where appropriate.

Results: The improvement in SNOT-20 correlated significantly with the improvement in ACQ (R=0.527, p<0.005), the improvement in SNOT-20 and ACQ correlated significantly with improvement in FeNO (R=0.489, p<0.005), and decrease in FeNO (R=0.426, p<0.005).

Conclusions: A simultaneous improvement in upper and lower airways symptoms and oral steroid use occurs at high altitude in patients with severe asthma and chronic rhino-sinusitis.

Implications: These beneficial effects on upper airways disease underscore the anti-inflammatory and steroid-sparing effect of high altitude treatment in patients with severe asthma.

P987

The relationship of gastroesophageal reflux with asthma quality of life and asthma control test in asthmatic patients
Bilun Ge McCormick, Sermin Börekçi, Asadullah Haiatullah. Department of Pulmonary Disease, University of Istanbul, Cerrahpasa Medical School, Istanbul, Turkey

Aim: In this study we aimed to investigate the relationship of gastroesophageal reflux with Asthma Quality of Life (AQLQ) and Asthma Control Test (ACT) in asthmatic patients.

Method: Between September – October 2010, total 50 patients followed with a diagnosis of asthma at outpatient clinic of Cerrahpasa Medical School Chest Diseases department were enrolled in this study. Patients' reflux symptoms in last one month were irrogated by using “Reflux Symptom Index” that consisting of 9 questions and graded from 0 to 5 (0: none; 1: very little, 2: low, 3: moderate, 4: severe, 5: very severe). ACT and AQLQ questionnaires were filled. Statistical analysis was done by sing SPSS 15.0 software.

Results: 34 patients (68%) were female and 16 (32%) were male, mean age was 42±14. The number of patients suffering from reflux was 23 (46%). The statistically very significant negative correlation was found between gastroesophageal reflux and AQLQ (r=-0.551; p<0.005). Between the presence of gastroesophageal reflux and ACT, the statistically significant negative correlation was found (r=-0.314; p<0.05) (Table 1).

Asthma severity and body mass index relationship

Emir Maden 1, Turgut Teke 1, Sebnem Yosunay 2, Durdu Mehneth Yavas 2, Mustafa Dinc 1, Rukiye Metiner 1, 1Pulmonary Medicine, Selcuk University Meram Medical Faculty, Konya, Turkey; 2Pulmonary Medicine, Byshehir State Hospital, Konya, Turkey

Obesity is considered as a risk factor for asthma; however the relationship between obesity and asthma control is being discussed. In this study we aimed to evaluate the relationship between obesity and disease severity in asthmatic patients. Asthma patients diagnosed in our clinic (453 patients) were enrolled to study. BMI (kg/m2) of the cases were analyzed. BMI was classified as low (BMI, <18.5 kg/m2), normal weight (18.5–24.9 kg/m2), overweight (25.0–29.9 kg/m2), and obesity (≥30 kg/m2). The patients were divided in to two groups; BMI >30 kg/m2 (obese) and BMI ≤ 30 kg/m2 (normal). The two groups were compared to age, sex, smoking history, comorbidities (gastroesophageal reflux, hypertension, diabetes mellitus, glaucoma, psychiatric disease, hipertirodi), allergy skin test positivity and pulmonary function test parameters by using statistical program SPSS 15.0 software.

Results: The mean age of the 169 patients was 39.5±17.1 years; 52% were male and 48% were women. The obese group included 31 patients. The two groups were compared. In the group with normal weight FEV1 and FVC values were significantly higher (p=0.05). In the obese group the proportion of women and men, presence of gastroesophageal reflux and the hypertension, the average age of patients were statistically significantly higher than in normal group (p<0.05). There was no statistically significant difference between the two groups in terms of smoking history, diabetes mellitus, glaucoma, psychiatric disease, hipertirodi, allergy skin test positivity FVC%, FEV1%, FEV/FVC% parameters (p>0.05).

Conclusion: The gastroesophageal reflux and hypertension comorbidities were more commonly seen in obese asthmatic than non obese asthmatics.

The effect of obesity or overweight on airway hyperresponsiveness and clinical features in patients with asthma

Jae-Woo Kwon 1,2,3, Tae-Wan Kim 1,2,3, Jae-Ryoung Kang 1,2,3, Jae-Bum Kim 1,2,3, Young-Sook Chang 1,2,3, Sang-Ho Chun 1,2, Hee-Bom Moon 1, Kyung-Up Min 1,2,3, COREA Research Group. 1Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; 2Institute of Allergy and Clinical Immunology, Seoul National University Medical Research Center, Seoul, Korea; 3Institute of Rheumatology, Seoul National University Bundang Hospital, Seongnam, Korea.

Background: Obesity is a risk factor of asthma in general population but the effect of obesity on airway hyperresponsiveness (AHR) or airway inflammation in asthma is not clear. This study attempted to evaluate the effects of obesity on asthmatics in the aspects of symptoms, AHR and severity.

Methods: The 852 asthmatics who were diagnosed based on clinical symptoms and AHR confirmed by methacholine bronchial provocation test were enrolled from COREA adult asthma cohort. The intensity of AHR was assessed by provocative concentration of methacholine causing a 20% fall in FEV1 (PC20). BMI was classified into 4 categories, underweight (<18.5 kg/m2), normal weight (18.5–24.9 kg/m2), overweight (25.0–29.9 kg/m2), and obesity (≥30 kg/m2).

Results: BMI was negatively correlated with FEV1 (L), FVC (L), and FEV1/FVC (%) in lung function test. The prevalence of wheezing was increased with the increase of BMI after adjustment for age, sex, smoking, medication history, and PC20 (<0.0001). AHI was higher in normal weight group than overweight group (P<0.001). The risk of moderate or severe AHR (PC20 ≤4 mg/ml) was increased when BMI increased after adjustment for age, sex, smoking, and medication history (P=0.035).

Conclusion: Obesity is a risk factor of asthma in general population but obesity in patients with asthma is negatively correlated with the intensity of AHR and not related with asthma severity. However obesity increases the prevalence of wheezing in asthmatics although obesity does not increase AHR.

The increased comorbidities in obese asthmatics

Nedjla Mazican, Sermin Boreci, Bilun Gemicioglu. Department of Pulmonary Disease, University of Istanbul, Cerrahpaşa Medical School, Istanbul, Turkey

Aim: Many studies have demonstrated an association between obesity and asthma, also the affects of obesity with airway inflammation were investigated. The aim of this study was to investigate the difference of age, sex, atopy, comorbid diseases and pulmonary function test parameters between obese and non obese asthmatics.

Method: The data files of 210 asthmatic patients who admitted to our outpatient clinic in 2010 were evaluated. 169 patients without atactic, with asthma control test over 20 and assessed BMI (body mass index) value enrolled in this study. The patients were divided in to two groups; BMI≥30 kg/m2 (obese) and BMI<30 kg/m2 (normal). The two groups were compared to age, gender, smoking history, comorbid diseases (gastroesophageal reflux, hypertension, diabetes mellitus, glaucoma, psychiatric disease, hipertirodi), allergy skin test positivity and pulmonary function test parameters by using statistical program SPSS 15.0 software.

Results: The mean age of the 169 patients was 39.5±17.1 years; 52% were male and 48% were women. The obese group included 31 patients. The two groups were compared. In the group with normal weight FEV1 and FVC values were significantly higher (p=0.05). In the obese group the proportion of women and men, presence of gastroesophageal reflux and the hypertension, the average age of patients were statistically significantly higher than in normal group (p<0.05). There was no statistically significant difference between the two groups in terms of smoking history, diabetes mellitus, glaucoma, psychiatric disease, hipertirodi, allergy skin test positivity FVC%, FEV1%, FEV/FVC% parameters (p>0.05).

Conclusion: The gastroesophageal reflux and hypertension comorbidities were more commonly seen in obese asthmatic than non obese asthmatics.

The role of inflammatory cells, adhesion molecules, intermediate filaments and chemokine receptors in the pathogenesis of nasal polyps

Metin Onerci1, Cagdas Elsunur1, Elif Guzel2, Atilla Dagdeviren2, 1Department of Otolaryngology Head and Neck Surgery, Hacettepe University Faculty of Medicine, Ankara, Turkey; 2Department of Histology and Embryology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Pathogenesis of nasal polyps is incompletely understood. This study investigates the role of inflammatory cells, adhesion molecules, intermediate filaments and chemokine receptors in development of nasal polyps. Totally, 35 patients were enrolled (Group 1, 10 patients with Samter syndrome; Group 2, 10 patients with diffuse polyps without signs of Samter syndrome; Group 3, 5 patients with solitary nasal polyps; Group 4, 10 controls). Expression of CD147, CD62E, CD4, CD8, CXCR4, CD147, CD90, CD104, BF45, vimentin, pancytokerin and MASA were determined. Expression of CD4, CD8 and CD104 were significantly higher in patients expressing vimentin in Group 1, Group 2 and Group 3 than in Group 4. Ratio of patients expressing vimentin in Group 1, Group 2 and Group 3 were significantly higher in all 3 groups than control group. Expression of CD147 in Group 3 and Group 4 was significantly higher than in Group 1 and Group 2. CD98 expression was higher in Group 1, Group 2 and Group 3 than in Group 4. Ratio of patients expressing CD98 antigen were significantly higher in all 3 groups than control group. Expression of CD147 in Group 3 and Group 4 was significantly higher than in Group 1 and Group 2. CD98 expression was higher in Group 1, Group 2 and Group 3 than in Group 4. Ratio of patients expressing CD98 antigen were significantly higher in all 3 groups than control group.
103. Respiratory epidemiology: genetics and modifiable risk factors

P993 European screening for α1-antitrypsin deficiency in subjects with lung disease Timon Greschko1, Helen Meters2, Bernard Budinger3, Gyorgy Losonczy4, Ludmilla Borsa5, Dalcius Vaiuciu6, Ivan Solovei7, Matjaz Flazer8, Marcela Vigdorovici9, Tatyana Martynenko9, Tetyana Pertseva10, Sandra Camprubi11, 1Department of Internal Medicine, Division for Pulmonary Diseases, Hospital of the University of Marburg, Marburg, Germany; 2Department of Pulmonology, District Dispensary for Pulmonary-Phthisis Diseases with Inpatient Hospital, Russe, Bulgaria; 3Department of Pulmonology, University Hospital for Lung Diseases Jandovance, Croatia; 4Department of Pulmonology, Semmelweis University, Budapest, Hungary; 5Department of Pulmonology, District Dispensary for Pulmonary-Phthisis Diseases with Inpatient Hospital, Russe, Bulgaria; 6Diagnostic Department of Internal Medicine, Vlahia University Hospital Sfantu Gheorghe Clinic, Vlahia, Romania; 7Department of Pulmonology and Physiology, National Institute for Tuberculosis, Lung Diseases and Thoracic Surgery, Hggy, Slovakia; 8Department of Pulmonology, District Hospital, Instituto Grifols, S.A., Barcelona, Spain; 9Department of Internal Medicine, Division for Pulmonary Diseases, Hospital of the University of Marburg, Marburg, Germany; 10Department of Pulmonology, University Hospital for Lung Diseases Jandovance, Croatia; 11Department of Pulmonology, Semmelweis University, Budapest, Hungary; 12Department of Pulmonology, Marius Nasta University Hospital Oradea, Oradea, Romania; 13Department of Pulmonology, Municipal Medical Institution City Hospital #5, Barnaul, Russian Federation; 14Department of Hospital Therapy, Dnepropetrovsk State Medical Academy, Dnepropetrovsk, Ukraine; 15Diagnostic Trials and Pharmacovigilance Department, Instituto Grifols, S.A., Barcelona, Spain

Introduction: Alpha1-antitrypsin deficiency (AATD) is a common hereditary disorder that predisposes to early-onset pulmonary embolism. Despite its prevalence, AATD is highly underdiagnosed. According to published guidelines for AATD, a diagnostic testing is greatly recommended in symptomatic adults with emphysema, COPD, or asthma with airflow obstruction incompletely reversible after aggressive bronchodilator treatment.

Aim: To investigate AATD presence in ten European countries targeting a cohort of symptomatic subjects.

Methods: Blood samples from adult subjects with lung disease were collected as dried blood spot (DBS). Detection testing algorithm consisted of 3 steps: first, all DBS specimens were analysed for α1-antitrypsin (AAT) levels by nephelometry; second, only samples with AAT levels below normal range (0.83 – 2.00 g/l) were genotyped for S- and Z-alleles by polymerase chain reaction; third DBS were phenotyped by isoelectric focusing in case of PS, PZ and non-S non-Z allele results.

Results: A total of 5396 subjects from Bulgaria, Croatia, Hungary, Latvia, Lithuania, Romania, Russia, Slovakia, Slovenia, and Ukraine were screened in 11 months. Seven hundred and eighty two (14.4%) had DBS AAT levels below the normal range. Among them, detection of S- and Z-alleles showed 16 PIZZ, 1 PISZ, 5 PSS, 38 PSZ, 79 PZ and 642 non-S non-Z variants. AAT genotyping of PIZ, PSS and non-S non-Z alleles revealed 1 PIZZrze, 38 PMZ, 78 PMZ, 579 PMIZ and 63 non allele. Detection rate of severe AATD in symptomatic subjects was 0.41%.

Conclusions: These data suggest a significant preventive approach in countries with a large number of symptomatic subjects but low awareness about this genetic condition.

In conclusion, inflammatory cells, adhesion molecules, intermediate filaments and chemokine receptors may play a role in pathogenesis of nasal polyps.

P994 Alpha1-antitrypsin deficiency in Italy: Analysis of the Italian registry disease

Ilaria Ferraroti, Stefania Ottaviani, Roberta Scabini, Marina Gorrini, Maurizio Lussetti. Center for Diagnosis of Inherited Alpha1-Antitrypsin Deficiency, IRCCS San Matteo Foundation Hospital, Pavia, Italy

Alpha1-antitrypsin Deficiency (AATD) is a rare hereditary disorder with a prevalence of about 1/5000 individuals in Italy. Deficient patients are at a higher risk to develop lung emphysema at an early age and liver cirrhosis. The low prevalence of AATD suggested the establishment of a registry with the aim to learn more details about the natural history and the quality of care of these patients. The Italian Registry of AATD was established in 1995. A total of 312 adult subjects with severe AATD were enrolled, namely 206 PIZZ, 48 PISZ, 3 PSS and 55 patients with, at least, one rare deficient allele (R). The frequency of 17.6% of PPRR is the highest so far recorded in national registries of AATD. Clinical data have been collected 253 were index-patients, mainly affected by lung and liver diseases (79% and 10%, respectively), and 55 were enrolled because of kinase with AATD patients. Mean age of enrollment was significantly higher (49.6 ± 14.4 years) than in non-index (43.5 ± 14.5 years). The mean interval between the onset of symptoms and the final diagnosis was 8 years for patients with lung diseases, and 13 years for liver diseases. Among index patients, most of them were former-smokers (63%). From 1999, 100 patients underwent augmentation therapy with purified AAT (Prolastin); they were mainly former-smokers (75%) with panlobular emphysema (34%). Interestingly, 10% of patients receiving augmentation therapy were non-index subjects. The data of the registry allow a detailed characterization of the natural course of the disease and the levels of the patient care, and confirm the usefulness of early detection of AATD.

P995 The polymorphisms of C-reactive protein gene modify the association between central obesity, asthma and lung function in Taiwan

Teng-Hui Huang, Tsu-Yu Yuan, Ru-Ling Hsiao, Tsu-Nai Wang, Department of Public Health, College of Health Science, Kaohsiung Medical University, Kaohsiung, Taiwan

Background: High-sensitive CRP concentrations and obesity are proposed to cause asthma and impaired lung function, but little has been reported to date on the association between CRP gene and asthma.

Objective: Three tagSNPs polymorphisms for CRP gene were selected from HapMap data, and genotyping by using TaqMan allelic discrimination assay. We studied the association of polymorphism in CRP gene and their interactions with central obesity on asthma and lung function.

Method: A total of 814 asthmatic adults and controls were recruited in southern Taiwan. All subjects underwent questionnaire interviews, pulmonary function tests and genotyping. We detected three single nucleotide polymorphisms of CRP gene, and analyzed gene-obese interaction on the risk of asthma.

Results: We found that BMI and WIR were associated with hs-CRP concentrations. Although CRP SNPs alone and haplotypes were not associated with asthma risk, the association of asthma with central obesity, measured as the waist-to-hip ratio (WHR), seemed to be stronger in subjects who carries A/T heterozygote (p=0.042) in index (49.6 ± 14.4 years) than in non-index (43.5 ± 14.5 years). The mean interval between the onset of symptoms and the final diagnosis was 8 years for patients with lung diseases, and 13 years for liver diseases. Among index patients, most of them were former-smokers (63%). From 1999, 100 patients underwent augmentation therapy with purified AAT (Prolastin); they were mainly former-smokers (75%) with panlobular emphysema (34%). Interestingly, 10% of patients receiving augmentation therapy were non-index subjects. The data of the registry allow a detailed characterization of the natural course of the disease and the levels of the patient care, and confirm the usefulness of early detection of AATD.

P996 DNA and fatty acids oxidative stress in respiratory diseases: Preliminary results from the GEIRD study

M. Elisabetta Zanolini1, Veronica Capra1, Paolo Degani2, Paolo Girardi1, Mario Olivieri1, Morena Nicosi1, Luigi Perbellini1, Anezzi Jaili1, Roberto de Marco1, 1Unit of Epidemiology and Medical Statistics, Dept Publ Health & Community Medicine, University of Verona, Verona, Italy; 2Dept Epidemiology, Prevention and Special Functions, National Institute for Cancer Research, Genova, Italy; 3Unit of Occupational Medicine, Azienda Ospedaliera “Istituti Ospitalieri di Verona”; Verona, Italy; 4Unit of Hygiene, Dept Publ Health & Community Medicine, University of Verona, Verona, Italy

Among the determinants of respiratory diseases, emphasis has recently been placed on oxidative stress, but its role on the occurrence of the respiratory diseases is only partially known. The aim of this study is to investigate the oxidative stress levels in people with respiratory diseases and controls. 8-OhdG, a DNA oxidation product, and 8-oxoproline, a lipid oxidation product, were measured in spot-urine samples collected in the frame of Genes Environment Interactions in Respiratory Diseases (GEIRD) study, a nested multi-case control survey. Controls and cases of COPD, current asthma, past asthma, non-allergic rhinitis, allergic rhinitis and other respiratory conditions (n= 239, 19, 122, 70, 58, 45 and 76 respectively) were analysed to test differences in levels of urinary creatinine-corrected 8-OhdG and 8-oxoproline, using quantile regression models adjusting for age, gender, smoking habits, BMI and other potential confounders. Adjusted 8-OhdG median concentrations were significantly higher in allergic...
value for obesity and SOD GG genotype is 2.68 (95%CI, 1.30-5.55). Compared with non-obesity and SOD AG/GG genotype, we found that the AOR was significantly higher than the controls. The activities of SOD and CAT in new SOD Ala16Val and CAT C-262T and asthma. The WHR of asthmatic patients in our study, we did not find any significant association between the SOD gene Ala16Val and CAT gene C-262T.

Introduction: Smoking is a risk factor for COPD but little is known about whether this risk differs by genetic ancestry. The few prior studies rely on self-reported race/ethnicity.

Methods: The Multi-Ethnic Study of Atherosclerosis (MESA) is a population-based study of adults without clinical cardiovascular disease in the United States. Principal components (PCs) of ancestry were derived from genome-wide data (Affymetrix 6.0) in MESA. Variance was measured by AT/ERS guidelines. We tested the interaction of PCs with packyears of smoking on FEV1, stratified by gender and adjusted for age, height, weight, and smoking in women. PCs did not modify the relationship of packyears to FEV1 (p=0.86). In men, the relationship was modified by PCs (p=0.01), specifically PC2 (tracking Asian ancestry) was associated with lower FEV1 in all groups (p<0.001). In women, PCs did not modify the relationship of packyears to FEV1 (p=0.086). In men, the relationship was modified by PCs (p=0.001), specifically PC2 (tracking Asian ancestry) was associated with less of a decrement in FEV1 per packyears smoking (p=0.001).

Conclusion: Variation between European and African ancestry did not modify the relationship between smoking and lung function in either gender, but this relationship may be modified by Asian ancestry in men.

The associations between the adult asthma, central obesity and gene polymorphisms and activities of superoxide dismutase and catalase

Rui-Ling Hsiao, Li-Ling Yang, Teng-Hui Huang, Tsu-Yu Yuan, Tsu-Nai Wang. Department of Public Health, College of Health Science, Kaohsiung Medical University, Kaohsiung, Taiwan

Background: Adult asthma is caused by interaction effects of genetic and environmental factors. Previous studies have indicated that obesity may increase the risk of asthma but not for central obesity. This would enable us to further investigate the mechanism of defective antioxidant enzymes for asthma pathogenesis.

Conclusion: The activities of SOD and CAT are significantly related to adult asthma but not for central obesity. This would enable us to further investigate the mechanism of defective antioxidant enzymes for asthma pathogenesis.

Birth mode and gut microbiota influence the risk of allergies and asthma – The KOALA birth cohort study

John Penders1,2, Rianne van Niniwegen2, Elen Stobberingh1, Dirkje Postma3,4,5, Naian Reijmerink6,7,8, Edward Dompeling,9 Piet van den Brand1,9, Monique Mommers6, Carol Thys9, Department of Medical Microbiology, School for Public Health and Primary Care (Caphri), Maastricht University Medical Center, Maastricht, Netherlands; 2Department of Epidemiology, School for Public Health and Primary Care (Caphri), Maastricht University, Maastricht, Netherlands; 3Department of Pulmonology, University Medical Center Groningen, Groningen, Netherlands; 4Department of Pediatric Pulmonology and Pediatric Allergology, Beatris Children’s Hospital, University Medical Center Groningen, Groningen, Netherlands; 5Department of Environmental Epidemiology and Biostatistics, University of Virginia, Charlottesville, VA, United States; 6Department of Pulmonology, School for Public Health and Primary Care (Caphri), Maastricht University Medical Center, Maastricht, Netherlands; 7Department of Epidemiology, School for Oncology and Developmental Biology (GROW), Maastricht University, Maastricht, Netherlands

Background: Gut microbiota (GM) composition and birth mode have been linked to allergies. However, results are inconsistent and the hypothesized intermediate role of GM in the association between birth mode and allergies has not been studied yet.

Aim: To study the relationship between GM composition, birth mode and allergic phenotypes.

Methods: The KOALA-study includes data on birth mode and on allergic symptoms from birth until age 6 years. Faecal samples were collected at age 1 month (n1=176) to determine GM composition using 16S rRNA. Blood samples were collected at ages 1, 2, and 6 years to determine specific IgE levels against common allergens.

Results: Infants born by caesarean (C-)section had lower numbers of bacteroides C. difficile prevalence was highest in infants born by C-section (42%), followed by infants born vaginally in the hospital (26%) and at home (19%). Colonisation by C.difficile was associated with an increased risk of eczema, wheeze and sensitisation throughout the first 6 years of life and with asthma (OR: 2.02, 95%CI: 1.15-3.56) at 6 years. Regarding mode and place of delivery, only children with atopic parents had an increased risk of asthma (2.06, 1.27-3.35) and sensitisation to food allergens (1.91, 1.29-2.84) when they had been vaginally delivered in hospital, when compared to vaginal delivery at home. C-section also increased the risk of sensitisation to food allergens (2.16, 1.21-3.86) compared to infants delivered at home.

Conclusion: Birth mode strongly influences the GM composition and both are associated with allergic manifestations, including asthma. More extensive microbial profiling is needed to examine whether C.difficile reflects other shifts in GM.
P1001
Patterson, sensitization in early childhood in farming environment: A French part of the PASTURE/FOREALL European birth cohort study
Annie Leydier1, Vincent Kaulie1, Amandine Chauveau1, Flora Metzger2, Erika von Mutius3, Dominique Angèle Vuitton4, Jean-Charles Dalphin5, Marie-Laure Dalphin1. 1Pediatry, University Hospital, Besançon, France; 2Respiratory Diseases, University Hospital, UMR CNRS 6249, Besançon, France; 3Pediatry, University Children’s Hospital, Munich, Germany; 4University of Franche-Comté, EA 3181, Besançon, France

Background: Cross sectional studies have repeatedly shown that children growing up on a farm had a significantly lower prevalence of atopic sensitization measured by specific IgE (IgEs) in serum but very little is known regarding sensitization tested by skin prick-tests (SPT).

Objective: To compare SPT-tested sensitization during the first 4.5 years of life in children born and living on dairy farms (F) and in children of families from the same rural area, but not born and not living on farms (non-F).

Methods: 168 children at 1 yr (49% F; 49% boys) and 155 at 4.5 yrs (52% F; 52% boys) were tested by SPT using a battery of 11 (1 yr) and 16 (4.5 yrs) age- and area-adepted antigens. Correspondent serum specific IgE were measured at both ages.

Results: Prevalence of at least one positive SPT was of 8.5% (1 yr), 9.6% (4.5 yrs) in F and 11.6% (1 yr), 19.5% (4.5 yrs) in non-F groups (p=0.05). In the whole population, positive SPT were mainly against food allergens at 1 yr (13/17, 12 for egg antigen) and against Aeroallergens in 4.5 yrs (24/26, 15 for seasonal antigens). At 1 yr, 17% of girls had positive SPT, versus 5.5% of boys, compared with 4.5 yrs (10.7% vs 17.5%). No relationship between IgE and SPT-tested sensitization was observed at 1 yr. Such a relationship was demonstrated at 4.5 yrs considering all antigens as well as categories (food, seasonal, perennial) but not for each single antigen.

Conclusions: The prevalence of positive skin prick tests is significantly lower in children growing up on a dairy farm than in their rural peers. At one year, there is no correlation between SPT and IgE-tested sensitizations.

P1002
Air pollution and development of respiratory system: A 19-year cohort study among children in Franche-Comté, France
Anne Leydier1, Vincent Kaulek2, Amandine Chauveau1, Flora Metzger2, Marie-Laure Dalphin1. 1Pediatry, University Hospital, Besançon, France; 2Pediatry, University Children’s Hospital, Munich, Germany; 4University of Franche-Comté, EA 3181, Besançon, France

Background: At follow-up while 47.1% of the adult group had severe nasal obstruction (flow <20%) at 1 yr and 17% of girls had positive SPT, versus 3.5% of boys, compared with 4.5 yrs (24/26, 15 for seasonal antigens). At 1 yr, 17% of girls had positive SPT, versus 5.5% of boys, compared with 4.5 yrs (10.7% vs 17.5%). No relationship between IgE and SPT-tested sensitization was observed at 1 yr. Such a relationship was demonstrated at 4.5 yrs considering all antigens as well as categories (food, seasonal, perennial) but not for each single antigen.

Objective: To examine the combined effect of weather, pollution and topography on the development of respiratory symptoms and function in schoolchildren

Methods: For one year, 52 subjects recorded daily respiratory symptoms. These correlations demonstrate a combined effect of certain weather conditions on acute exacerbations, especially those which result in airborne water droplets formation. The deleterious influence of pollution is also confirmed. Particles can serve as nuclei for airborne water droplets formation and an increased retention of particles and pollutants under these weather conditions is suggested.

Results: Statistically significant (p<0.05) relationships were recorded between altitude and exacerbations frequency (r=-0.33 to -0.44), relative humidity (r=0.19 to 0.43), temperature (r=-0.08 to -0.58), dew point (r=0.13 to -0.42), and the difference between temperature and dew point (r=0.19 to -0.46) showed predominately statistically significant relationships with symptoms. Particulates showed some of the strongest correlations with symptoms (r=0.11 to 0.44). Generally, an adjustment of data for infectious exacerbations led only to minor changes in the results.

Conclusion: Our study provides for the first time evidence of increased respiratory symptoms in lower altitude areas of river valleys. The correlation results demonstrate a combined effect of certain weather conditions on acute exacerbations, especially those which result in airborne water droplets formation. The deleterious influence of pollution is also confirmed. Particles can serve as nuclei for airborne water droplets formation and an increased retention of particles and pollutants under these weather conditions is suggested.

Spatial distribution of COPD in a rural population in India using geographic information system (GIS)
Veena MurdHALDAR1, Sundeep SalVI2, Jyoti LOnDHE2, Somnath SambHudas1, Vijendra Ingole1, Peter Barnes3, Sanjuy JEvucka2, Vida Rural Health Program, K.E.M Hospital Research Centre, Pune, Maharashtra, India; Respiratory and Clinical Research, Chest Research Foundation, Pune, Maharashtra, India; 1Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom

GIS mapping is a useful tool to study the spatial distribution of diseases and examine their association with geographic risk factors. We used GIS to determine spatial distribution of COPD in 22 rural villages spread across an area of 232 km², and study the association between proximity to highways and prevalence of COPD.

Methods: 3,952 randomly selected individuals were administered a respiratory health questionnaire and underwent pre and post bronchodilator spirometry (forced expiratory volume in one second) according to the ATS/ERS standards. COPD was defined as post-bronchodilator FEV1/VC<0.7. Each individual’s residence was mapped using Global Positioning system (Garmin eTrex, USA). Spatial distribution of all individuals and the association between proximity to highway and prevalence of COPD were performed using ArcGIS software version 9.3, USA.

Results: A significant cluster of COPD subjects were found residing <500m from the highway (Moran’s Index = 0.07; p<0.01). 90% of individuals residing <500m from the highway used liquified petroleum gas for cooking and in this population a strong positive correlation was found between proximity to highways and COPD prevalence (OR 2.39; 95% CI 1.04-5.54). Individuals who resided >500m from the highway had a higher prevalence of COPD and this was strongly associated with the use of biomass fuel (OR: 1.46; CI: 1.06-2.01; p<0.01).

Conclusion: Residing <500m from the highway was strongly and positively associated with COPD. The prevalence of COPD was three-fold higher amongst those living >500m from the highway and this was significantly associated with the use of biomass fuel.

P1005
Effect of urban vehicular traffic pollution on respiratory symptoms and pulmonary function in schoolchildren
Fabio Cibella1, Roberto Dell’Aggigolare2, Giuseppina Cuttitta1, Stefania La Manna3, Mario Merli1, Mario Bucchi1, Daniela Natale4, Giovanni Vegli1, 1Institute of Biomedicine and Molecular Biology, National Research Council of Italy, Palermo, Italy; 2Institute of Information Science and Technologies, National Research Council of Italy, Palermo, Italy; 3Health and Environment Unit, Regional Agency for Environment Protection, Palermo, Italy; 4Epidemiology Unit, Regional Agency of Public Health of Tuscany, Florence, Italy

Our aim was to evaluate the relationship between pollution from urban traffic on respiratory symptoms and function in adolescents. In 2005-2006 we performed a survey on 2,150 schoolchildren (10-17 yrs) from 16 junior high schools in the city of Palermo, Italy. Subjects fulfilled an ISAAC questionnaire and underwent spirometry and skin tests. The geographic location of each residence was geo-coded by Geographic Information System. A vehicular traffic model computed the daily average traffic of 2,561 road segments in the city and was used for estimating the amount of traffic close to each dwelling. We identified 3 areas with progressively increasing traffic: A (in the West side close to the hills around the city - 14.8% of subjects); B (central - 53.3%); and C (the outskirts in the North and South of Area B - 31.5%). Prevalence of respiratory symptoms was: wheeze ever (WE), 22.1% in Area A, 22.1% in Area B, and 23.3% in Area C (p=0.02); asthma ever (AE), 8.1%, 12.4%, and 13.0%, respectively (p=0.068); impaired lung function (ILF) was present in 1.7% of subjects, in 4.1%, and in 5.2%, respectively (p=0.037). In a logistic regression model, Odds ratios (OR) with 95% confidence intervals (CI) were calculated with Area A as reference and corrected for confounders: Area B was a significant risk factor for WE (OR 1.66, IC 1.17-2.36), AE (OR 1.83, IC 1.15-2.91), and ILF (OR 2.71, IC 1.06-6.89). The corresponding OR for Area C were 1.66 (IC 1.16-2.40), 1.72 (IC 1.06-2.80), and 3.42 (IC 1.32-8.84), respectively. Our results point out that children exposed to increased levels of urban vehicular traffic near the house of residence are at higher risk for asthma and impaired lung function.

Long-term effect of urban air pollution on lung function
Valérie Siroux1,2, Joëtana Lepape3, Caroline Arnoldi4,5, Anne Boudier4,5, Bénédict Jaccoud4,5, Isabelle Riscou, Claire Chappaz1, Xavier Moel1,2, Nino Künzli6, Francine Kaufmann1,4, Remy Slama1,2, Isabelle Pin2,7,8, INSERM, Grenoble, France; 3Institut Albert Bonnou, University Joseph Fourier, Grenoble, France; 4UNIVERSITÉ, INSERM, Villefranche, France; 5UMRS 1035, UMR Paris 11, Villefranche, France; 6ASCOPARG, ASCOPARG, Grenoble, France; 7Epidemiology and Public Health, Swiss Tropical and Public Health Institute, Basel, Switzerland; 8Pédriatric, Grenoble CHU, Grenoble, France.

Background: Long-term effects of air pollution on lung function remain uncertain particularly for adults.

Aims: To investigate the association between exposure to nitrogen dioxide (NO2) – used as a marker for local traffic-related pollution – and particulate matter <10 microns (PM10) in the urban area of Grenoble (France) and lung function in adults.

Methods: Lung function parameters (FEV1, FVC, %FEV1/FVC measured predicted) were assessed using the Stanojevic equations were assessed between 2001-2007 for 450 adults living in Grenoble (120 asthmatics and 330 non asthmatics), in the frame of the INTERMONITOR study and the NO2 database (1999-2003).

Results: Measurements (μg/m³) were 34 (IQR 31-38) for NO2 and 31 (IQR 29-33) for PM10. In non asthmatics, for a 10 μg/m³ increase in NO2 and PM10, FVC% predicted decreased by 3.7 (p=0.01) and 11.7 (p=0.03) and FEV1% predicted by 3.3 (p=0.02) and 9.0 (p=0.07) respectively. Similar but not significant negative trends were observed in asthmatics.

Conclusion: Results suggest negative associations of home outdoor NO2 and PM10 with lung function in non asthmatics.

Grant: region Rhône-Alpes (CIBLE).

Influences of smoking habits on annual change in FEV1 - A 12-year follow-up study
Hisamatsu Omo1, Ayumi Onoue1, Yayoi Funakoshi1, Hironori Yada1, Hisamitsu Omori1, Ayumi Onoue1, Yayoi Funakoshi1, Hironori Yada1, Kumamoto University, Kumamoto, Japan; Department of Public Health, Kumamoto Health Science University, Kumamoto, Japan; Department of Internal Medicine, Kumamoto Red Cross Hospital, Kumamoto, Japan; Department of Respiratory Medicine, Kumamoto University, Kumamoto, Japan.

Background: The rate of forced expiratory volume in 1 second (FEV1) decline is a marker of chronic obstructive pulmonary disease risk. To date, limited longitudinal data exist on airflow obstruction (COPD) and FEV1 decline in Japan.

Aims and objectives: The aim of this study was to investigate the rate of FEV1 decline by smoking habits over a 12-year periods in Japanese males.

Methods: The study included 913 male subjects, aged 30-76 years at baseline, whose lung function tests at a medical check-up in 1994 (baseline), 1999, and 2006. The study group consisted of 263 persistent never smokers, 296 early quitters (those who stopped smoking between 1994 and 2006), 117 late quitters (those who stopped smoking between 1999 and 2006), and 237 persistent smokers without airflow obstruction at baseline. Airflow obstruction (AO) was defined as FEV1/FVC<0.7 and 5th percentile lower limit of normal (FEV1/FVC<0.7). LOCP was defined as FEV1/FVC<0.7 and 5th percentile lower limit of normal (FEV1/FVC<0.7).

Results: Mean annual decline in FEV1 over a 12-years period was -35.0 ml/yr in persistent never smokers, -37.9 ml/yr in early quitters, -40.7 ml/yr in late quitters, and -44.8 ml/yr in persistent smokers. Mean annual decline in FEV1 over a 12- year periods defined using the fixed criteria and the LLN criteria were -34.6 ml/yr, -34.3 ml/yr in persistent never smokers without AO, -42.3 ml/yr, -42.3 ml/yr in persistent smokers without AO, -60.3 ml/yr, and -56.7 ml/yr in persistent smokers with AO, respectively.

Conclusions: Persistent smokers with AO had a significant reduced FEV1 decline compared with those in persistent never smokers and current smokers without AO. Our study confirmed that early cessation of smoking may reduce the FEV1 decline and prevent the development of AO among smokers.

Risk factors for obstructive lung function in morbidly obese patients
Aarnoud van Huijstede1, Jan Willems El2, Guido Mannaerts3, Eric Snoey4, Ronald Luijtwiler5, Erwin Bierrie6, Pietri Hiemstra7, Gert-Jan Braunstahl8, 1Department of Pulmonology, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 2Department of Internal Medicine, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 3Department of Surgery, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 4Department of Anesthesiology, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 5Department of Internal Medicine, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 6Department of Statistics, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 7Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands.

Background: Morbidly obese patients are not only at risk for asthma but also for pulmonary complications related to bariatric surgery.

Aim of the study: To calculate a risk score for obstructive lung function in morbidly obese patients as pre-surgical screening tool before bariatric surgery, and relating pulmonary complications to this score.

Methods: 39 of the 342 patients (11.4%) had an obstructive lung function. A history of asthma (adj OR 3.2; 95% CI 1.4-7.5), <5 pack years (adj OR 2.8; 95% CI 1.2-6.3) and abdominal circumference >120cm (adj OR 7.0; 95% CI 1.6-31.0) were associated with an obstructive lung function (multiple logistic regression). The risk of obstructive lung function was calculated (1, 1 and 2 points respectively).

P1006
Reduced body mass index is associated with the presence of airflow obstruction in a rural Indian setting
Biswaajit Chakrabartib, Sabita Parkuta1, Pramayrata Goom2, Vicky Moore3, Christopher Wurbarthen2, Peter Calvey4, Justin Zaman1, Rahul Mukherje2, 1Aintree Chest Centre, University Hospital Aintree, Liverpool, United Kingdom; 2Mostrik Swastha Kendra, Shramajibhi Swasthya Udhyog, Chengal, West Bengal, India; 3Department of Medicine & Physiology, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 4Epidemiology & Public Health, Div of Population Health, University College London, United Kingdom; 5Clinical Sciences Centre, University Hospital Aintree, Liverpool, United Kingdom.

Background: Respiratory conditions remain a significant source of morbidity globally. We wished to understand factors associated with the development of airflow obstruction (AO) within a rural Indian setting. We hypothesised that being significantly underweight (BMI less than 18.5) could be linked to the development of AO (FEV1/FVC less than 0.7).

Methodology: Patients greater than 35 years old attending a primary care outpatient clinic at Chengal, West Bengal, India underwent: 1. A structured questionnaire 2. Measurement of BMI 3. Spirometry (analysed by a Respiratory Clinical Physiologist for Global Initiative for Obstructive Lung Disease). Results: 416 patients (mean age 51 years; 47% male; 62% never smokers) completed the study; spirometry deemed valid for analysis in 286 (69%); 47 (16%) of all subjects were noted to exhibit AO; GOLD stage 1 (15%); GOLD stage 2 (49%); GOLD stage 3 (26%); GOLD stage 4 (10%). Never smokers comprised 43% (2047) of all AFO cases. On logistic regression, factors associated with AFO were: Increasing age (95% CI 0.004-0.011; p=0.005), smoking status (95% CI 0.07-0.17; p=0.006), male gender (95% CI 0.19-0.47; p=0.012), reduced BMI (95% CI 0.19-0.65; p=0.02) and occupation (95% CI 0.12-0.84; p=0.08). Mean BMI was significantly lower in the 47 patients with AFO (20.1 ± 21.6; p=0.02).

Conclusion: Our study suggests that being underweight is associated with the presence of AFO in a rural Indian setting.
prescribed in 35 patients, of whom 34% (97%) had a risk-score of ≥2 (p<0.000). Only 5 pulmonary complications occurred, however all pulmonary complications were in ≥2 group (p=0.225).

Conclusion: Abdominal circumference is a better predictor than BMI for obstructive lung function in morbidly obese patients undergoing bariatric surgery. Although the incidence of pulmonary complications after bariatric surgery is low, pre-surgical risk factor analysis could identify patients at risk for obstructive lung function and pulmonary complications.

P1011
Associations of different serum 25(OH)D levels to parameters of respiratory health in COPD patients
Louise Jeanette Pauline Persson1, Marianne Voll-Aanerud1, Per Bakke2, Jon Andrew Hardie1, Pieter S. Hiemstra1, Tomas Mikal Eagan1,2, 1. Dept of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 2. Institute of Internal Medicine, University of Bergen, Bergen, Norway; 3. Dept of Pulmonology, Leiden University Medical Center, Leiden, Netherlands

Recent studies show a high prevalence of vitamin D deficiency in COPD patients. Optimal vitamin D levels may differ for different physiological processes. There is no current consensus on the optimal level for respiratory health and lung function.

Methods: Serum 25(OH)D in 426 COPD patients. GOLD stage II-IV, aged 40-76, from the Bergen COPD Cohort study, were determined by liquid chromatography double mass spectrometry. Examinated explanatory variables were sex, age, body mass index (BMI), smoking habits, FEV1, exacerbation frequency, PaO2, respiratory symptoms, use of inhaled steroids, CRP, total white blood (WBC) count and seasonality. Vitamin D levels were categorised into 5 groups (A,B,C,D,E): A: <10ng/ml; B: 10-20ng/ml; C: 20-30ng/ml; D: 30-40ng/ml; and E: 40-52ng/ml. Associations were tested with chi-square and Kruskal Wallis.

Results: The prevalence of subjects in vitamin D categories, A to E, were 6.8%, 26.5%, 33.1%, 27.0%, and 6.6% respectively.

The percentage of daily smokers in group A through E were: 58.6%, 53.1%, 39.7%, 38.8%, and 58.6% (p=0.046).

Mean FEV1 was 43%, 43%, 51%, 51%, and 56% in group A through E (p<0.001).

Conclusion: Vitamin D deficiency (<20ng/ml) was common in COPD patients and significantly related to important disease phenotypes, but the critical cutoff level of vitamin D varied between the different respiratory health variables.

P1012
Microbial evaluation of proton pump inhibitors and the risk of pneumonia
Sabine Meijvis1, Marie Claire Cornips 2, Paul Voorn3, Patrick Souverein2

Recent studies suggested a possible risk of community-acquired pneumonia in patients using proton pump inhibitors (PPIs). This study aimed to identify colonizing gastrointestinal bacteria and the risk of pneumonia in patients using different PPIs.

Methods: This was a case-control study with 609 patients using PPIs from general practitioners. Risk factors for pneumonia were evaluated using logistic regression.

Results: Recent initiation of PPI treatment (<30 days) was associated with an increased risk of pneumonia (OR 2.2; 95% CI 1.0-4.6). The risk of pneumonia was not significantly different between different PPIs.

Conclusion: Recent initiation of PPI treatment may increase the risk of pneumonia. Further studies are needed to confirm these findings.

Department of Public Health and General Practice, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, Norway; 2. Department of Epidemiology and Community Medicine, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

Introduction: Measures of body mass index (BMI) and waist circumference (WC) define overall obesity and central obesity respectively. While high BMI has been established as a risk factor for asthma in adults, WC has seldom been investigated.

Aims and objectives: We conducted a prospective cohort study to investigate the individual and combined effect of central obesity and overall obesity on adult incident asthma.

Methods: A total of 23,245 adults without asthma, 19-55 years of age from the second Norwegian Nord-Trøndelag Health Study (HUNT), were followed for 11 years. WC and BMI were measured and categorised as central obesity (WC ≥88cm in women and ≥102cm in men) and overall obesity (BMI ≥30.0 kg/m²). Asthma incidence was self-reported during the follow-up. Odds ratios (OR) were calculated by logistic regression models adjusted for age, smoking status, education, family history, physical activity, social benefit, economical difficulty and sex.

Results: Of the 23,245 adults in the analysis, 12% (n=2,792) were overall obese, 13.6% (n=3,170) were centrally obese at baseline and 3.5% (n=818) had asthma during the 11-year follow-up. Central obesity in the absence of overall obesity was significantly associated with incident asthma (OR 1.44, 95% confidence interval (CI) 1.09-1.91). The OR for overall obesity in the absence of central obesity was 1.38 (95% CI 0.96-2.00), similar to central obesity alone. Central obesity combined with overall obesity (OR 1.81, 95% CI 1.48-2.23) is compatible with an additive effect of BMI and WC on asthma.

Conclusion: Central obesity and overall obesity seem to have an individual effect on incident asthma in adults and an additive effect when in combination.

P1014
Trends in co-morbidity in oxygen-dependent COPD
Magnus Ekstrom1, Claes Jorgeson1, Kerstin Strom1, 1. Department of Internal Medicine, Blekinge Hospital, Karlskrona, Sweden; 2. Department of Mathematical Science, Blekinge Institute of Technology, Karlskrona, Sweden

In recent decades, mortality from non-respiratory diseases has increased in patients on long-term oxygen therapy (LTOT) for COPD (Ekstrom, M.P. et al. AJRCCM. Epub 2011 Jan 7). This study tests the hypothesis that co-morbidity has increased over time in oxygen-dependent COPD.

Material and methods: Patients starting LTOT for COPD between 1 January 1992 and 31 December 2008 in the national Swedish Oxygen Register were included. All registered diagnoses within five years prior to initiating LTOT were collected retrospectively from the Swedish Hospital Discharge Register, which include about 99% of all public hospitalizations in Sweden. Odds ratios (ORs) for diagnosis entities per calendar year were estimated using logistic regression adjusted for age, sex, PO2 breathing air, FEV1, and smoking history.

Results: 6147 patients (55% women) with a mean age 71.6 ± 8.4 years were included in the analysis. Adjusted odds ratios per calendar year (OR; 95% confidence interval; P-value) increased for anaemia (1.07; 1.04-1.10; P<0.001), diabetes mellitus (1.04; 1.02-1.06; P<0.001), hypertension (1.14; 1.11-1.16; P<0.001), ischecmic heart disease (1.05; 1.04-1.07; P<0.001), pulmonary embolism (1.17; 1.12-1.23; P<0.001) and for renal failure (1.20; 1.14-1.26; P<0.001). There was no time-trend for cerebrovascular disease (P=0.141) or cancer (P=0.062).

Conclusion: Co-morbidity has increased over time, which could contribute to the increased mortality from non-respiratory diseases in oxygen-dependent COPD.

P1015
Coexisting cardiovascular diseases increase the risk of exacerbations in patients with COPD
Loes C.M. Bettens, Karel G.M. Moons, Arno W. Hoes, Frans H. Rutten. Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

Background: Few studies published prediction models with exacerbation of COPD as the endpoint, and the prognostic value of coexisting cardiovascular diseases has never been evaluated adequately.

179s
Purpose: To develop a prediction model for exacerbation of COPD.

Methods: Data from an existing cohort of 244 patients with COPD according to the GOLD criteria were used, with a follow-up of 4.2 (SD 1.2) years. The initial assessment was between 2001 and 2003. Exacerbation of COPD was defined as a period of worsening of COPD symptoms necessitating boosts of prednisolone therapy. Univariable and multivariable logistic regression analysis was used to construct a final, reduced prediction model. After bootstrapping, c-statistics were used to estimate the ability of the model to discriminate between patients who suffered from an exacerbation and whom not.

Results: In total, 115 (47.1%) patients experienced at least one exacerbation and more than half (57.4%) of the patients had ≥ 2 exacerbations during the follow-up. The final reduced model included body mass index, FEV1 (as predictor), smoking history, systemic steroid use in the year before initial assessment, use of corticosteroid inhalers, a history of stroke/TIA, and a history of ischaemic heart disease. The c-statistic after bootstrapping was 0.81 (95%CI 0.76 – 0.86).

Conclusions: Variables related to severity of pulmonary obstruction, smoking history, but also a history of cardiovascular diseases were independent predictors of an exacerbation of COPD. More attention should be paid to unmask coexisting cardiovascular disease, because adequate treatment of these diseases could reduce exacerbations, but probably also mortality in patients with COPD.

P1018
Fibrinogen and all-cause mortality in a nationally representative US cohort
Deepa Vaivli1, Hana Muellerova2, Ruth Tal-Singer1, David Mannino3
1Preventive Medicine, University of Kentucky, Lexington, KY, United States; 2Worldwide Epidemiology, GlaxoSmithKline, London, United Kingdom; 3COPD Clinical Discovery, GlaxoSmithKline, Upper Merion, PA, United States

Background: We aimed to study the association of lung function, fibrinogen and mortality.

Methods: We analyzed data from 8201 adults aged =25 years from the National Health and Nutritional Examination Survey (NHANES III). Hazard ratios were calculated to determine the risk of dying (all cause mortality) due to elevated fibrinogen values defined > 400 mg/dL (the top decile) and the interaction with lung function (determined using modified GOLD staging) and adjusted for age, sex, race-ethnicity, smoking, cardiac disease and diabetes.

Results: 3198 subjects (weighted%) 28 died during the follow-up of up to 18 years. The predictors of mortality are shown in the table (normal lung function with a fibrinogen level =< 400 mg/dL is the referent group for all the lung function categories).

Conclusion: Elevated fibrinogen values are important predictors of death and add to the predictive ability of impaired lung function to predict mortality.

P1019
COPD prevalence in chronic heart failure
Armine Minasian1, Richard Dekhuijzen2, Frank Van den Elshout1, Petra Vol1, Frank Willems1, Paul Van den Bergh1, Yvonne Heijdra1, 3Pulmonology, Rijnstate Hospital, Arnhem, Gelderland, Netherlands; 4Cardiology, Radboud University Nijmegen Medical Centre, Nijmegen, Gelderland, Netherlands; 5Preventive Medicine, University of Kentucky, Lexington, KY, United States; 6Worldwide Epidemiology, GlaxoSmithKline, London, United Kingdom; 7Clinical Discovery, GlaxoSmithKline, Upper Merion, PA, United States

Introduction: COPD frequently coexists with chronic heart failure (CHF) leading to impaired prognoses as well as diagnostic and therapeutic challenges. However, lung functional data on COPD prevalence in CHF are scarce and COPD remains to be widely undiagnosed or misdiagnosed. The aim of this study was to determine COPD prevalence in CHF.

Methods: In this cross-sectional study spirometry was performed in 220 CHF patients (78.2% male, median age 71 years [IQR 63-77] with left ventricular dysfunction history, systemic steroid use in the year before initial assessment, use of ACE inhibitors, peripheral edema, blood pressure, tachycardia, PaCO2, creatinine, neutrophil count, NT-proBNP, and infiltrate on chest radiograph. In a multivariable model, patient age, history of hypertension, tachycardia, creatinine, neutrophil count >11.5 x10^9/L, and NT-proBNP remained significantly associated (p<0.05) with hs-cTnT.

Conclusion: Multiple variables, including those reflecting heart failure, renal dys- function, and inflammation are predictive of hs-cTnT during AECOPD, suggesting that the mechanisms underlying hs-cTnT elevation are multifactorial.
Background: Several studies have shown that low lung function (even within normal limits) as well as respiratory symptoms are associated with increased cardiovascular mortality. In a case referent study we have compared sputum from patients hospitalised for acute myocardial infarction (AMI) with sputum from a random sample in the general population. The objective was to investigate the association between inflammatory cells in the airways and AMI.

Methods: The cases (N=58, mean age 58 years) had a confirmed diagnosis of AMI and performed induced sputum within 96 hours after the onset of chest pain. The referents (N=120) were selected by random sampling from the hospital’s catchment area. Subjects aged 40–74 years (mean age 55 years) were invited to participate. Results: Only six patients (10%) were females and 27 patients (47%) were current smokers. The corresponding prevalence of COPD was 5% (49%) and 27% (23%), respectively. The total number (mean SD of sputum cells was 3.9 x 10^6/mL (4.2) and macrophage count was 1.10 x 10^6/mL (1.2) among cases, and 3.1 x 10^6/mL (2.8) (p=0.12) and 0.72 x 10^6/mL (0.69) (p=0.011) among referents. The difference in total macrophage count between the cases and the references increased with declining cholesterol (p=0.028). There was also a negative association with increasing age, systolic blood pressure, and current smoking, although not significant. Conclusion: AMI is associated with a high macrophage count in induced sputum from patients with a low cardiovascular risk profile, suggesting multifocal inflammatory activity.

P1021
High blood pressure, antihypertensive medication and lung function in a general adult population
Eva Becker 1, Stefan Karrasch 1,4, Holger Schulz 1,4, Sven Glaser 2, Christa Meisinger 3,4, Annette Peters 5,6, SUNDAY, SEPTEMBER 25TH 2011
1Dept of Respiratory Medicine, Oslo University Hospital, Oslo, Norway; 2Dept of Respiratory Medicine, Ålesund University Hospital, Ålesund, Norway

Background: Several studies have shown that high blood pressure as well as antihypertensive treatment are associated with reduced lung function in a general adult population. Furthermore, we speculate that the negative effect of antihypertensive medication on lung function is mainly attributable to beta-blockers.

Conclusion: Our analysis indicates that both high blood pressure and antihypertensive treatment are associated with reduced lung function in a general adult population. Furthermore, we speculate that the negative effect of antihypertensive medication on lung function is mainly attributable to beta-blockers.

P1022
Prevalence of pulmonary arterial hypertension and right ventricular dysfunction in COPD patients in the Kirov region of Russia
Julia Chuyasova, Vasily Pryanov, Elena Popova, Division of Respiratory Diseases, Kirov State Medical Academy, Kirov, Russian Federation

Purpose: To estimate the prevalence of pulmonary artery hypertension (PAH) and right ventricular (RV) dysfunction in COPD patients in the Kirov region of Russia.

Material and methods: 1088 COPD patients (mean age 55±14 years, 97% men and 3% women) were studied. All the patients underwent physical examination, laboratory investigations and transthoracic echocardiography. RV end-diastolic diameter, RV wall thickness and right atrium (RA) area were measured. The systolic pulmonary arterial pressure (PAP) was measured by pulsed Doppler (systolic PAP = tricuspid regurgitation pressure gradient + estimated RA pressure). RA pressure was estimated based on the diameter and respiratory variation of the inferior vena cava. Mean PAP was calculated with formula: mean PAP = 0.61 x systolic pressure + 2 mm Hg. Global RV systolic function was estimated using RV myocardial performance index and RV fractional area change. RV diastolic function was assessed using tricuspid e/a ratio and E/E’ ratio.

Results: PAH (systolic PAP > 37 mmHg and mean PAP > 25 mmHg) was detected in 40.3% of cases (438 patients). Right ventricular (RV) remodeling and dysfunction were revealed in all COPD patients with PAH. Diastolic RV dysfunction was detected in 100% and systolic RV dysfunction in 12.8% of those cases. Conclusion: Our study confirmed high prevalence of PAH and RV dysfunction in COPD patients in the Kirov region of Russia. Prognosis of these patients is characterized by an increased risk of death. Physicians should detect PAH in COPD patients as early as possible and start treatment for prevention complications.

P1023
Prevalence of comorbidities in patients with COPD in south-Spain
Aurelio Amedillo 1, Mercedes Merino 2, Pilar Cordero 2, Imaculada Alfageme 3, José Luis López-Campos 2, Bernardino Alcacer 4, Francisco Daster 5, Pneumology Department, University U. Puerta del Mar, Cádiz, Spain; 2Pneumology Department, Hospital Infanta Cristina, Badajoz, Spain; 3Pneumology Department, Hospital U. Virgen del Rocio, Sevilla, Spain; 4Pneumology Department, Hospital U. San Cecilio, Granada, Spain

Objective: The prevalence of comorbidities in COPD is variable according to different publications. Our objective was to analyze the prevalence of comorbidities in stable COPD patients in our area, and its relation to other parameters.

Material and methods: Concurrent multicenter prospective study that included stable COPD patients from 6 hospitals at the South of Spain. We obtained demographic, epidemiologic and pulmonary function test variables, Charlson and Deyo/IRE index, British Medical Research Council (BMRC) Dyspnea scale, London Chest Activity of Daily Living Scale (LCADL), Hospital anxiety and depression scale (HAD) and St George’s respiratory questionnaire (SGRQ).

Results: We studied 164 patients (83.5% males), with a mean age of 65.7 years and mean FEV1 of 49.7%. According to GOLD classification, 4.9% were in Stage I, 38.4% in Stage II, 45.1% in Stage III and 11.6% in Stage IV. The prevalence of cardiovascular disease or diabetes mellitus was 6.1%, peripheral vascular disease 8.5%, isquemic stroke 4.9%, ulcer disease 7.9%, diabetes 12.8%, neoplasms 11%, hepatic disease 10.4% and renal disease 2.4%. Using the HAD scale 14% of the patients showed anxiety symptoms, and 15.2% depression symptoms. 30% of patients have 1 comorbidity, 16.6% have 2 comorbidities and 3.7% have 3 or more.

Conclusions: The prevalence of comorbidities didn’t correlate with the severity of COPD. There was statistical correlation between Charlson index and hospital admissions due to COPD exacerbation.

P1024
The evaluation of systemic inflammation in COPD patients comorbidized with cardiovascular diseases or diabetes mellitus
Yoko Yumino, Satoko Fuji, Naoki Takasaka, Jun Kojima, Hiromichi Hara, Takamori Nishita, Takeo Ishikawa, Makoto Kawashita, Keisuke Saito, Jun Araya, Katsutoshi Nakayama, Kazuyoshi Kuwano. Division of Respiratory Diseases, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

Background: COPD is one of so-called life-style related diseases and reported to show systemic inflammation, due to strong relationship to long-time tobacco smoking. Therefore, COPD patients often have a variety of comorbid diseases, in
cladding cardiovascular diseases (CVD), diabetes mellitus (DM), and other systemic diseases.

Purpose: To investigate smoking status and frequency of comorbid COPD among the patients with CVD, DM, or both, who had smoking history (≥ 10 pack-years), and also to investigate how CVD, DM or COPD is associated with systemic inflammation, oxidative stress and clinical disorders.

Method: Totally 83 patients, over 40 years with history of cigarette smoking, were recruited for this study. All the participants were examined for pulmonary function test with bronchodilator, urine 8-OHdG/Creatinine, plasma levels for TNF-α, hs-CRP and pentoxifylline as predictors of airway obstruction, oxidative stress and systemic inflammation.

Results: 11 in the 21 patients with CVD (52.4%) were diagnosed as COPD, 14 in 37 with DM (37.8%), and 9 in 23 with both (36.0%). Further analyses on the associations between each disease and systemic inflammation or oxidative stress were performed by logistic multivariable analyses adjusted with age, sex, smoking history, statin use, and each disease. As the results, Systemic inflammation evaluated by hsCRP was significantly higher in COPD patients. The risk of oxidative stress evaluated by 8-OHdG increased approximately 3 fold with COPD.

Conclusions: Because the smokers with DM or CVD seem to have much higher risk of COPD than smokers without them, they should be examined with pulmonary function test.

P1025
Use of a US population-based survey to describe the relationship of COPD and co-morbidities
Roy Pleasants1, Harry Herrick2, Winston Liao2, Janet Croft3, Jill Ohar4.
1 Pulmonary and Critical Care, Duke University, Durham, NC, United States; 2Chronic Diseases and Center for Health Statistics, NC Division of Public Health, Raleigh, NC, United States; 3Office of Public Health, Centers for Disease Control and Prevention, Atlanta, GA, United States; 4Pulmonary, Allergy and Critical Care, Wake Forest University, Winston Salem, NC, United States

The Behavioral Risk Factor Surveillance System (BRFSS) is a US state-based survey that includes 90+ questions on health issues primarily related to chronic diseases. In 2007 and 2009, 6 questions were added to the North Carolina (NC) BRFSS to describe the prevalence and impact of COPD. In the 2009 NC BRFSS, there were 12,337 adults who completed the survey and 993 reported they had been diagnosed with COPD. The age-adjusted prevalence of COPD was > 5%.

The age-adjusted relative risk (RR. 95% CI) for 7 chronic diseases were compared between COPD and non-COPD: arthritis (1.64, 1.46-1.84); diabetes mellitus (1.76, 1.39-2.24); myocardial infarction (2.58, 2.0-3.33); coronary artery disease (CAD) (3.49, 2.5-4.9); stroke (2.47, 1.9-3.2); kidney disease (2.85, 1.89-4.3); current asthma (7.5, 6.24-9.3); 3 of these co-morbidities (4.95, 3.9-6.3). About 1 in 5 persons with COPD had 3 or more of these co-morbidities compared to 1 in 40 persons without COPD. One of the 6 BRFSS questions in 2009 addressed the use of prednisone in the prior year in persons with COPD. The RR of prednisone use in COPD patients with any of the co-morbidities were: arthritis 1.15 (0.89-1.48); diabetes mellitus 0.73 (0.47-1.11); myocardial infarction 1.0 (0.66-1.68); CAD 1.86 (1.02-3.38); stroke 1.28 (0.67-2.43); kidney disease 1.77 (0.77-4.07); current asthma 1.48 (1.08-2.03); 3 of these co-morbidity 1.44 (0.95-2.2). Increased prednisone use in concurrent asthma and COPD is expected whereas increased likelihood of receiving prednisone in patients with concurrent COPD and CAD is an unexpected finding, possibly related to severity of disease in these patients.

P1026
Prevalence of anemia of chronic disease in patients with chronic obstructive pulmonary disease
Afroditi Bouto1, Erika Pedini1, Ioannis Stavropoulos1, Theodoros Kontakiotis1, George Kyriazis2, Panagiota Touskliki2, Nikolaos Chavouzis3, Lazaros Sickleftis1, Paraskevi Argyropoulou1, Respiratory Failure Unit, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Department of Pulmonology, Aristotle University of Thessaloniki, Thessaloniki, Greece; 3Immunology Laboratory, G Papanikolaou Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 4Laboratory of Applied Molecular Oncology, Thaegeion Anticancer Hospital, Thessaloniki, Greece

Background: Anemia of chronic disease (ACD) is a disorder occurring in subjects with chronic immune activation. Chronic Obstructive Pulmonary Disease is characterized by systemic inflammation, so it could be accompanied by ACD.

We recruited for this study. All the participants were examined for pulmonary function test with bronchodilator, urine 8-OHdG/Creatinine, plasma levels for TNF-α, hs-CRP and pentoxifylline as predictors of airway obstruction, oxidative stress and systemic inflammation.

Results: 11 in the 21 patients with CVD (52.4%) were diagnosed as COPD, 14 in 37 with DM (37.8%), and 9 in 23 with both (36.0%). Further analyses on the associations between each disease and systemic inflammation or oxidative stress were performed by logistic multivariable analyses adjusted with age, sex, smoking history, statin use, and each disease. As the results, Systemic inflammation evaluated by hsCRP was significantly higher in COPD patients. The risk of oxidative stress evaluated by 8-OHdG increased approximately 3 fold with COPD.

Conclusions: Because the smokers with DM or CVD seem to have much higher risk of COPD than smokers without them, they should be examined with pulmonary function test.

P1027
The association between asthma, atopic diseases and metabolic factors in a young population of southern Taiwan
Tsu Yu Yuan1, Li Yu Wang1, Teng Hui Huang1, Ru-Ling Hsiao1, Tsu-Nai Wang1, 1Department of Public Health, College of Health Science, Kaohsiung Medical University, Kaohsiung, Taiwan; 2Department of Medicine, Mackay Medical College, New Taipei City, Taiwan

Background: Previous studies have suggested that obesity and cholesterol may play a role in the susceptibility for asthma. The relationship between cholesterol concentrations, asthma and atopic diseases is still controversial.

Objective: The aim of this study was to investigate whether metabolic factors are associated with asthma and atopic disease.

Methods: The cross-sectional study sampled randomly 6838 subjects ≤ 18 years old from elementary, junior and senior high schools in southern Taiwan. All subjects completed questionnaire interview, weight and height data measurements and blood sample collection. Allergic disorders were determined by the subjects ever been diagnosed by a doctor. Body mass index (BMI), blood pressures, the levels of triglyceride and total cholesterol were measured.

Results: We found a significant association between high concentrations of cholesterol and dermatitis in girls (aOR = 1.56, p = 0.002) and rhinitis in boys (aOR = 1.31, p = 0.038) after adjusting for potential confounding factors. Obesity was statistically significant associated with dermatitis (p = 0.008) and rhinitis (p = 0.038). The interaction effect of cholesterol and obesity on dermatitis was significant (p = 0.032). We did not find that cholesterol and triglyceride concentrations were associated with asthma.

Conclusion: We found that high concentrations of cholesterol were associated with dermatitis in girls and rhinitis in boys. Obesity and high concentrations of cholesterol may increase the risk of dermatitis.

P1028
Epidemiology of allergic rhinitis in asthmatic patients in Greece
Angel Afroz, Florou Sofia, Vakali Fotini, Vlassou Christina, Gratziou, Asthma and Allergy Center, Pulmonary and Critical Care Dept., University of Athens, Evgenidion Hospital, Athens, Greece

Background: The co-morbidity of allergic rhinitis and asthma is a fundamental issue of common airway disease.

Objective: This study was designed in order to evaluate the co-existence of allergic rhinitis in asthmatic patients in Greece.

Methods: Data from 2700 patients with diagnosed asthma and nasal symptoms were recorded during a scheduled or an urgent visit to a specialized physician. The review was performed by respiratory physicians and allergologists. Recordings were based to a common study questionnaire.

Study population: A total of 2588 asthma patients were finally evaluated. The age range was 43.7 years with a small prevalence of female gender. One third of asthmatic patients were smokers.

Results: 62% of asthmatic patients were atopic and 53% of them had a positive asthma family history. 80.7% of asthmatic patients also had symptoms from allergic rhinitis. Nasal symptoms showed significant seasonal distribution with major peaks in spring (70%) and autumn (32%). In 60% of the cases the allergic rhinitis symptoms affect daily activities and in 72% they deteriorate asthma symptoms. Despite the use of appropriate treatment, asthma was not well controlled in 49% of the cases. 60% of the patients had at least one asthma exacerbation in the previous year and among them 85% had 1-3 exacerbations. In addition in well controlled asthmatics who were the 40.3% of total population, 77% of the patients had used medical therapy for managing allergic rhinitis.

Conclusion: The co-morbidity of allergic rhinitis in asthmatic Greek patients is high and needs to be always addressed and managed properly in order to achieve a better asthma control.

P1029
Asthma and obesity: Epidemiological data in young adults
Andrea Antunes Cetlin1, Manoel Romeu Gutierrez2, Heloisa Bertoti2, Marco Antônios Barbieri2, Elias Tha Atoua Viana2, 1Department of Medicine, University of São Paulo Medical School of Ribeirão Preto, Ribeirão Preto, São Paulo, Brazil; 2Department of Pediatrics, University of São Paulo Medical School of Ribeirão Preto, Ribeirão Preto, São Paulo, Brazil

In recent years, several studies have found an increase in the prevalence of asthma among obese patients, but the exact nature of this association has not been fully elucidated. The aim of this study was to assess the association between asthma and obesity in 23- to 25-year-old Brazilian adults.
This was a cross-sectional analysis of 1922 men and women. Subjects completed a translated questionnaire from the European Community Respiratory Health Survey and underwent spirometry and a bronchial challenge test. Weight, height and waist circumference were measured. Multiple logistic regression analysis was carried out to assess the association of variables related to obesity and asthma, defined by the presence of symptoms and bronchial hyperresponsiveness (BHR). A self-report of a previous physician diagnosis of asthma was separately analyzed as also were socioeconomic characteristics, schooling, physical activity, smoking status, anthropometry and spirometry.

No association was detected between asthma confirmed by BHR and obesity indicators: odds ratio (OR) = 1.076 (95% CI: 0.689 - 1.680) for obesity assessed by body mass index $\geq 30$ kg/m$^2$; OR = 0.947 (95% CI: 0.686-1.308) by abnormal waist circumference and OR = 1.019 (95% CI: 0.740-1.404) by waist-to-height ratio $\geq 0.5$. A previous diagnosis of asthma confirmed by BHR and obesity, but obesity was associated with self-report of a previous physician diagnosis of asthma.

Results: The pooled effect size for coal smoke as a lung carcinogen (OR=1.82, 95% CI 1.60 to 2.06) was greater than that from biomass smoke (OR=1.50, 95% CI 1.17 to 1.94). The risk of lung cancer for combined fuel was greater in women (OR=1.81, 95% CI 1.54 to 2.12) compared to men (OR=1.16, 95% CI 0.79 to 1.69). The pooled effect size were 2.33 (95% CI 1.72, 3.17) for adenocarcinoma, 3.58 (1.58, 8.12) for squamous cell carcinoma, and 1.57 (1.38, 1.80) for tumours of unspecified cell type.

Conclusion: These findings suggest that burning of both coal and biomass is consistently associated with an increased risk of lung cancer. The review defined inadequate detection of smoking in many studies (excluded from this review) and makes recommendations for factors which must be included in future studies in this area.

P1032 Impact of air pollution control measures and weather conditions on asthma during the 2008 summer olympic games in Beijing

Wen Wang, Yi Li, Kewu Huang. Department of Respiratory, Beijing Chao-Yang Hospital, Capital Medical University & Beijing Institute of Respiratory Medicine, Beijing, China Centre for Atmosphere Watch and Services, Chinese Academy of Meteorological Sciences, Beijing, China Department of Respiratory, Beijing Chao-Yang Hospital, Capital Medical University & Beijing Institute of Respiratory Medicine, Beijing, China

The alternative transportation strategy implemented during the 2008 Summer Olympic Games in Beijing provided an opportunity to study the impact of the control measures and weather conditions on air quality and asthma morbidity.

Methods: An ecological study compared the 41 days of the Olympic Games (8 August–17 September 2008) to a baseline period (1–30 June). Also, in order to understand the impact of weather conditions on air quality, a pollution linking meteorological index (Plam) was introduced to represent the air pollution meteorological condition.

Results: Our study showed that the average number of outpatient visits for asthma was 12.5 per day at baseline and 7.3 per day during the Olympics—a 41.6% overall decrease. Compared with the baseline, the Games were associated with a significant reduction in asthma visits (RR 0.58, 95% CI: 0.52-0.65). At 16 days visit per day, asthma visits were also significantly higher, during the pre-Olympic period (RR 1.32, 95% CI: 1.15-1.52). The study also showed that the RR of asthma events on a given day, as well as the average daily peak ozone concentration during the preceding 48–72 h, increased at cumulative ozone concentrations of 70 to 100 ppb and 100 ppb or more compared with ozone concentrations of less than 70 ppb (P<0.05).

Conclusions: We concluded that along with “good” weather conditions, efforts to reduce motor vehicle traffic in Beijing during the Olympic Games were associated with a Prolonged decrease in air pollution and significantly lower rates of adult asthma events. These data provide support for efforts to reduce air pollution and improve health via reductions in motor vehicle traffic.

P1033 Indoor PM2.5 levels in homes using different types of cooking fuels in a rural Indian population and it’s association with COPD

Utkarsh Mukkannawar 1, Somanath Sambhudas 2, Sanjay Jurekar 1, Ajay Ojha 3, Sundeep Salvi 3, Environmental Research, Chest Research Foundation, Pune, Maharashtra, India; 2Epidemiology, Vida Rural Health Center, King Edward Memorial (KEM) Hospital, Pune, Maharashtra, India; 3Environmental Technology, Technogreen Environmental Solutions, Pune, Maharashtra, India

50% of world’s population uses biomass fuel (BMF) for cooking and heating purposes, an important risk factor for COPD.

Aim: To measure indoor particulate matter diameter $<2.5 \mu m$ (PM2.5) levels in homes that use different types of cooking fuels in a rural population, and to study its association with COPD.

Methodology: 287 homes using different types of cooking fuels (Liquefied Petroleum Gas (LPG): 91, BMF: 101, LPG+BMF: MIX: 95) were randomly selected from 22 villages. All male and female individuals above the age of 55 years residing in these homes were invited to participate. After obtaining written consent, indoor PM2.5 levels were measured using “AirMetrix” low volume sampler over 24hrs and expressed as $\mu g m^{-3}$. All subjects performed pre and post bronchodilator spirometry. COPD was defined as post-bronchodilator FEV1/FVC <70%, and small airways obstruction (SAO) as FEV2<75% $<65$s predicted.

Results: 429 subjects (mean age 45±15 years; M: 217 and F: 212) consented to participate and 266 performed acceptable spirometry. Prevalences of COPD (OR SAO were 4.9% and 24.4%, and 100% and 92% respectively, were never smokers. 24hr mean levels of PM2.5 were significantly higher in homes that used BMF verses LPG (median (IQR): BMF 236.5 $\mu g m^{-3}$ (145-414) versus LPG 109.7 $\mu g m^{-3}$ (85-172); p = 0.0001). Use of BMF was strongly associated with SAO (OR: 2.39 p<0.02) and was also associated with COPD (OR: 3.28), although this did not reach statistical significance (CI 0.8-14.23).

Conclusion: In Indian village homes, individuals in homes that use BMF have significantly higher indoor PM2.5 levels and this is strongly associated with increased prevalence of COPD and small airways obstruction.
P1034
Effects of air pollution from biomass burning in nasal mucociliary clearance of Brazilian sugarcane cutters
Aline Di Ferrere, Ercy M.C. Ramos, Giovana N.B. Ferrari, Rafaeila F. Xavier, Luiz C.S. Carvalho Junior, Alessandra C. Toledo, Dionei Ramos. Physiotherapy, UNESP- Sao Paulo State University, Presidente Prudente, Sao Paulo, Brazil

Nasal mucociliary (NM) system is the first line of defense of the upper airways and it is responsible for the clearance of inhaled particles, including particulate matter (PM) from biomass burning. Several epidemiological studies have demonstrated a consistent association between levels of air pollution from biomass burning and increase in hospitalization for respiratory diseases and mortality. About 44.3% of the sugarcane is burned to facilitate the manual harvesting every year and the most exposed people are the sugarcane cutters. Nevertheless no previous reports studied respiratory effects of PM from biomass burning in these individuals. This study evaluated the effects of exposure to PM from biomass burning on NM transport after harvest. Twenty-five non-smokers (mean age = 25.7±4.5 years; BMI 23.9±2.6 kg/m²) workers in a Sugar and Ethanol Company located in Maringópolis, state of Sao Paulo, Brazil, in April 2010, were evaluated in two periods: pre-harvest season and three months after harvest. Mucociliary clearance by saccharin transit time test (STT) and nasal symptoms were assessed. STT was 7.9±3.4 min at pre-harvest and decreased significantly after harvest 3.9±2.2 min, p<0.001).

Nasal symptoms did not change following exposure. Our results suggest that acute exposure to particulate matter from sugarcane burned affects mucociliary clearance in non-smokers workers in the absence of symptoms.

P1035
The investigation of the relationship between respiratory exposures and the occurrence of the disease in patients with COPD
Sibel Gurses1,2, Ozer Selcuk Sommez1, Nilgun Denizem2, Atilla Ihsan Keyf2, Bebrail Simon2. 1Chest Diseases, Igdir State Hospital, Igdir, Turkey; 2Chest Diseases, Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Ankara, Turkey

We aimed to investigate the relationship with COPD and respiratory exposures. 711 patients admitted to our hospital with a diagnosis of COPD between May 2009-June 2010 were included. For the control group, 246 volunteer patients admitted to in-patient and out-patient clinics with any diagnosis other than COPD were included. Questionnaire including the questions according to socio-demographic characteristics, environmental and occupational exposures, patterns of tobacco use and passive-tobacco-smoke exposure of the patients was filled with face-to-face interview method.

The mean age was 62.7±10.8 for COPD and 64.9±10.9 for the control group (p=0.05). The average monthly-income-levels and educational-status of the patients for COPD group was significantly lower than the control group (p=0.015, p=0.002, respectively). In COPD group the number of people dealing with farming were greater than the people in the control group (p=<0.001) Tandoor and fireplace were more commonly used by women with COPD (p=0.034 and p=0.002, respectively). Smoking rates in both groups were similar. However, duration of smoking and the amount of cigarette-consumption in COPD group was higher than the people in the control group (p=0.018, p=0.001, respectively). In childhood-period, exposure to passive smoke and life-long-exposure-time in COPD group were statistically higher than the people in the control group (p=0.015, p=0.001, respectively).

For the development of COPD, except smoking, biomass-fuels and environmental exposures including passive exposure to tobacco smoke, environmental and occupational exposure to pollutants are also important risk factors, and prevention of exposure to these pollutants impede the development of COPD significantly.

P1036
Prenatal environmental tobacco smoke exposure and children's respiratory health
Lyudmila Jelenina1, Olga Lavrova2, Maria Petrenko2. 1Pediatrics, St. Petersburg State Pediatric Medical Academy, St. Petersburg, Russian Federation; 2Laboratory of Inherited Lung Disorders, St.Petersburg Pavlov State Medical University, St. Petersburg, Russian Federation

Background: Exposure to environmental tobacco smoke (ETS) is associated with respiratory symptoms. Prenatal ETS exposure is associated with impaired lung function and wheezing illnesses, particularly in preschool children. Although negative impact of prenatal ETS exposure on children is evident, ETS impact on respiratory system of infants is still poorly explored.

Purpose: To assess the possible effects of ETS exposure in utero on lower respiratory disease in children from infants up to seven years of age.

Methods: We evaluated the health impact of ETS in 117 infants born from asthmatic mothers. We also analyzed the onset of wheeze & asthma by the age of 7 with regard to the impact of ETS.

Results: The prevalence of wheeze during the first year of life was 4.7 times higher in infants who were prenatally exposed to ETS (OR-4.69 [CI:1.63-13.52]) compared to children without ETS exposure. However, no differences in allergic asthma prevalence by 7 years of age were found between the patient groups.

Conclusions: The research results provide strong evidence linking prenatal ETS to impairments in infants’ respiratory system.

P1037
Inhaled black carbon in the lower airways of London cyclists
Chinedu Nwokoro, Naseem Mushtaq, Clare Harrison, Mubin Ibrahim, Iain Dickson, Omar Hussain, Zoya Manzoor, Clare Evin, Isobel Dundas, Jonathan Grigg. Centre for Paediatrics, Barts and the London School of Medicine and Dentistry, London, Greater London, United Kingdom

Background: Inhalable elemental black carbon (BC) from fossil fuel combustion impacts lung health. We recently developed a novel method for assessing internal dose of BC using the ambient black carbon (BC) mass (BCm) obtained from a project (BCm). To date, the determinants of BCm in healthy individuals living in urban areas remain unclear. Personal external monitoring indirectly suggests that cyclists have high levels of BC exposure.

Aim: To compare BCm in healthy adult cycling (cyclist) and non-cycling (pedestrian) London commuters.

Methods: AM carbon was assessed in non-smoking urban commuters aged 18 to 40 yr. AM were sampled using a passive BC filter, e.g., Teflon filter (STT) and nasal symptoms were assessed. STT was 7.9±3.4 min at pre-harvest and decreased significantly after harvest 3.9±2.2 min, p<0.001).

Cyclists had significantly more AM carbon than pedestrians (Chart 1).
air pollutants exposure and lung obstruction was explored by logistic regression analysis.

**Results:** In both studies T-R air pollutants concentrations were statistically significant higher (p<0.05) in the vicinity of road in comparison to rural areas. The significant association between living close to a busy road and risk of obstruction was found. In the Warsaw study risk was 4.35 times higher (95% CI: 2.57-7.35) among non-smoking inhabitants of the city compared with rural area residents. The second study resulted in similar observations – the risk was 3.16 times higher (95%CI: 1.09-9.16). Amid smokers the difference in risk of obstruction between urban and rural areas was insignificant.

**Conclusion:** Presumably high T-R air pollutants concentration in the proximity of main roads is one of the significant reason of airways flow limitation. Therefore the risk of obstruction highly depends on place of living, particularly among non-smoking people.

**Effect of daily pollution exposure in the autonomic system in traffic workers of Sao Paulo**

Daniel Alves1, Milene Saccomani1, Felipe Mendes1, Paulo Saldiva2, Celso Carvalho1, *Physical Therapy, University of São Paulo, São Paulo, Brazil; 2Pathology, University of São Paulo, São Paulo, Brazil*

**Background:** Heart rate variability is used to quantify autonomic response and to detect cardiovascular diseases. Chronic pollution exposure is known to increase arterial pressure and the incidence of cardiac ischemia leading to cardiovascular diseases and death; however, the effect of variation of daily pollution in chronically exposed subjects remains poorly known.

**Objective:** To study the effect of acute pollution exposure in the autonomic system at rest and exercise in traffic workers.

**Methods:** Twenty-one male subjects were studied in 4 randomized working days (once a week) with distinct pollution exposure. The amount of pollution (ozone (O3) and nitrogen dioxide (NO2)) was measured 24 hours before the day test by a pollution analyzer. Activity of autonomic system response was measured during 8 minutes either at rest or during treadmill exercise (moderate intensity).

**Results:** The levels of pollution exposure were considered intermediate and ranged from 123.9 μg/m3 to 317.2 μg/m3 and 0.1 μg/m3 and 26.3 μg/m3 respectively (of NO2 and O3). In the days with higher levels of pollution, it was observed a reduction in the activity parasympathetic system (RMSSD) at rest (p<0.05). In addition, it was observed a linear correlation between the levels of pollution and a reduction in the RMSSD measure at rest (p=0.52; p=0.01). Interesting, during exercise, the parasympathetic response was increased in the most polluted days (p<0.05).

**Conclusion:** Our results suggest that even low changes in daily pollution exposure selectively modify the autonomic system to either rest of exercise. Supported by CNPq.

**Non-malignant abnormalities by chest radiography and high-resolution computed tomography in millers and miners with different levels of asbestos exposure**

Ericson Bagattini1, Luiz Eduardo Nery1, Gustavo Meirelles1, Reynaldo Rodrigues2, Luis Maria Napolis2, José Alberto Neder2, Mario Tetta-Filho3, *1Occupational Health Area, State University of Campinas, Campinas, Sao Paulo, Brazil; 2Division of Respiratory Diseases, Federal University of São Paulo, Sao Paulo, Brazil; 3Pathology, Federal University of São Paulo, São Paulo, Brazil; 4Pulmonary Division – Incor-HC, University of São Paulo Medical School, São Paulo, Brazil*

The diagnostic performance of high-resolution computed tomography (HRCT) and conventional chest radiography (CXR) has not been compared on a large sample of subjects with widely-different degrees of cumulative exposure to asbestos, i.e., with ample differences in pre-test likelihood of disease. We evaluated 1427 ex-workers in chrysotile mills and mines who were separated into 4 groups (Gr) of decreasing cumulative exposure (Groups I to IV). The prevalence of either parenchymal or pleural abnormalities were markedly reduced as exposure decreased (p<0.01). Assuming HRCT as the criterion standard, CXR was associated with increased false-positive and false-negative rates for parenchymal and pleural abnormalities, respectively. These findings were consistent across the groups of asbestos exposure (table).

**Acute respiratory effects in atopic humans exposed to short-term controlled exposure to diluted wood smoke**

Ingunn S. Riddervold1, Jakob H. Bønløkke1, Anna-Carin Olin2, Vivi Schlünssen1, Torben Sigsgaard1, *1Department of Occupational and Environmental Medicine, School of Public Health, Aarhus University, Aarhus, Denmark; 2Division of Occupational and Environmental Medicine, Sahlgrenska University Hospital and Academy, Öthenburg, Sweden*

Growing evidence suggests that particulate air pollution derived from wood stoves causes acute inflammation in the respiratory system and possibly increases the incidence of asthma and other respiratory diseases. The aim of this study was to evaluate acute respiratory effects from short-term wood smoke exposure in humans. A total of 20 non-smoking atopic subjects with normal lung function and without bronchial responsiveness completed the study. The subjects were monitored during three different experimental exposure sessions, aiming at particle concentrations of 200μg/ml, 400μg/ml, and clean air as control exposure. A balanced cross-over design was applied and the subjects were randomly allocated to exposure orders.

Diluted wood smoke were generated in a wood-burning facility and added to a full-scale climate chamber exposure lasted for 3 hours under controlled environmental conditions. Respiratory effects were evaluated at baseline and follow-up measurements during exposure in relation to changes in lung function and were assessed in relation to changes in airway inflammation status measures by fractional exhaled nitric oxide (FENO), exhaled breath condensate (EBC) and nasal lavage (NAL, samples). No statistically significant differences between the three exposures were found for any of the lung function outcomes. FEV1 (p=0.6283); and FVC (p=0.8364), or for FeNO (p=0.3578). Mild signs of airway inflammation were found in few of the analyzed markers of inflammation in the NAL and EBC samples. In conclusion, short term exposure with wood smoke causes only mild inflammatory response.

**Biodiesel usage in Austria: Improving or deteriorating respiratory health?**

Hans-Peter Hutter1, Michael Kundi1, Peter Wallner1, Bernd Knegger1, Irene Schicker1, Hanns Moshammer1, *1Inst. Environmental Health, ZPH, Medical University of Vienna, Vienna, Austria; 2Department of Meteorology, University of Natural Resources and Life Sciences, Vienna, Austria*

We estimated respiratory health outcomes for two scenarios for the fraction of biodiesel used in road vehicles: B10 a blend of 10% bio- and standard diesel; B100 biodiesel only.

Data of the composition of vehicle exhausts, vehicle frequency and exhaust volumes were entered into a dispersion model to obtain estimates for the change in particulate matter (PM10, PM2.5) and nitrogen dioxide (NO2) for Vienna and the surrounding region (Lower Austria). From established exposure-response relationships the health impacts (respiratory mortality and hospital admissions) of the scenarios were expressed as a difference to the reference scenario (year 2007). Impacts of B10 were very small. For B100 fine particles would decrease by 4% (countrywide) to 8% (city of Vienna) while NO2 would increase by 11% in Vienna. Based on effect estimates for chronic exposure the reduction of PM2.5 would lead to 53 less cardiopulmonary annual deaths. Effect estimates based on time series studies resulted in smaller numbers: Reduction of ambient PM10 levels were estimated to result in 8 less annual respiratory hospital admissions. Concerning respiratory mortality the increase of NO2 could result in additional 20 premature deaths per year, while the beneficial effect of the reduction in particles only would lead to a reduction of one case per year.

If health impacts of these air pollutants were independent, the increase in NO2 would strongly outweigh the reduction of PM2.5. However, dose-response relationships of PM and NO2 are not independent and NO2 is indicating traffic related exposures as is PM2.5. Therefore the adverse impact might be less pronounced than indicated by the net difference.

P1043

**Relation between fractional exhaled NO and lung function and exposure to ambient particulate matter from contrasting sources**

Maciej Strak1,2, Maake Stenhorst2, Krystal Godt3,4, Isse Gosens1, Flemming Cassese1, Ian Mudway1, Frank Kelly1, Roy Harrison1, Erik Lefebvre1, Bert Brunekreut2, Gerard Heek2, Nicole Janssen1, *1Centre for Environmental Health (MGO), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands; 2Division Environmental Epidemiology, Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands; 3MRC-IHPA Centre for Environmental Health, King’s College London, London, United Kingdom; 4Division of Environmental Health and Risk Management, University of Birmingham, Birmingham, United Kingdom*

Epidemiological studies demonstrated the adverse health effects of ambient particulate...
late matter (PM) but it is not clear which specific characteristics (size, components) or sources of PM are responsible for the observed effects. The aim of the RAPTES project is to establish which specific characteristics of ambient PM are responsible for health effects associated with PM. To address this we combined exposure of volunteers with real-world exposure conditions at sites with high contrast and low correlation between PM characteristics.

30 young, healthy volunteers were exposed multiple times at different sites in the Netherlands: two traffic sites, underground train station, farm and an urban background site. Exposure of volunteers and air pollution characterization took place on 30 consecutive occasions. Particle number concentration (PNP, ultrafine particles) and total oxidative potential were not associated with changes in FENO or lung function parameters. An increase in FENO and decrease in lung function were observed in young, healthy volunteers after five-hour exposure to ambient air pollution, specifically associated with high concentrations of ultrafine particles and not with other major PM characteristics.

P1044 Short-term effect of ozone in a panel study of asthmatics
Bertil Forsberg1, Peter Roman 2, Umeå University, Dept Public Health and Clinical Medicine, Umeå, Sweden

Introduction: Particulate matter, exhaust and ozone concentrations in ambient air have been associated with respiratory effects, and asthma is especially sensitive.

Aims: Our objective was to study short-term effects of particles (PM10), vehicle exhaust (NO2) and ozone in relation to lung function among adults with asthma residing in the two major Swedish cities Stockholm and Gothenburg.

Methods: 797 adults (17 females) with asthma recorded from the GAZLEN survey (aged 25-72 years) used a daily diary over a 10 week period (winter-spring) and recorded peak expiratory flow (PEF), forced expiratory volume in the first second (FEV1). We collected urban background concentrations of PM10, NO2 and ozone in the city centre, and adjusted for participant (intercept), time trend, day of week, temperature and humidity in the regression analysis. We evaluated the effect of the same day concentrations, and lagged one and two days, respectively.

Results: 37% of ozone lag 0, lag 1, lag 2 and lag 0-2 were seen in both cities, some significant. In Stockholm there was also a significant negative effect of ozone on PEF. No significant effects were seen for PM10 or NO2.

Discussion: We found the most consistent negative effects on lung function of ozone. Fluctuations in daily mean concentrations of PM10 and NO2 may be less well represented by a central monitoring station.

P1045 The effects of whole life arsenic exposure via drinking water on airway hyperresponsiveness in C57BL/6 mice
Kathryn A. Ramsey 1,2, Alexander N. Larcombe 1,2, Peter D. Sly 3, Graeme Miles 1,2,1Clinical Sciences, Telethon Institute for Child Health Research, Perth, WA, Australia; 2Centre for Child Health Research, University of Western Australia, Perth, WA, Australia; 3Queensland Children’s Medical Research Institute, University of Queensland, Brisbane, QLD, Australia

Background: Arsenic exposure via drinking water is a significant global environmental health issue. Epidemiological data suggest a relationship between arsenic exposure and the development of obstructive lung disease.

Aims: We aimed to determine if whole life arsenic exposure via drinking water impacts lung function and results in airway hyperresponsiveness.

Methods: Pregnant C57BL/6 mice were exposed to drinking water containing 0 (control) or 100μg/L arsenic from gestational day 8 to parturition. After birth, offspring were exposed to arsenic (or control) in breastmilk/drinking water until the next morning. PNC was also associated with an about 1% decrease in FEV1 and FVC at almost all measured time points. PNC, PM2.5 and total oxidative potential were not associated with changes in FENO or lung function parameters.

Discussion: Studies have shown that mice exposed to arsenic throughout life have impaired baseline lung function and airway hyperresponsiveness as adults. These findings support the notion that ingested arsenic is a novel respiratory toxin and may be an important risk factor for the development of obstructive lung disease in arsenic exposed populations.

P1046 Carbon content of airway macromolecules and lung function in children within the London low emission zone (LEZ)
Thomas Round 1, Dev Gadgil 1, Isobel Dundas 1, Iain Dickson 1, Naseem Mushtaq 1, Helen Wood 1, Jonathan Grigg 1, Chris Griffiths 1, Centre for Health Sciences, Barts and The London School of Medicine, London, United Kingdom; 2Environmental Research Group, Kings College, London, United Kingdom

Introduction: The London Low Emission Zone (LEZ) was introduced in 2008 with the aim of reducing traffic emissions to improve respiratory health. Increased airway macromolecule carbon (AM) content is associated with decreased FEV1.

Aims: Investigate the association between AM carbon and lung function as part of a larger study into impact of the LEZ on children’s respiratory health.

Methods: Cross sectional study of children aged 8-9 within schools. Sputum induction with nebulised 4.5% saline. Nebulisation extended from 15 to 20-30 minutes. Sputum processed with standard techniques. Images were obtained for 50 random AM per child. AM carbon was assessed using imaging software. Analysis of mean carbon area per cell with lung function and distance from main road was performed.

Results: 2008-10, 20 schools and 619 children taken part in LEZ study, with 59 (9.5%) attempting sputum induction. Standard 15 minute nebulisation led to a sample yield of 20%, compared to modified nebulisation (mean 22.55 minutes) with 52% yield. 15 samples so far have identified macrophages, 13 suitable for imaging.

Discussion: Spearman rank correlation for carbon area per cell were negative for% predicted FEV1 (r=-0.32) and distance from main road (r=0.1).

Conclusion: Sputum induction is practical and acceptable within schools. Prospective data suggests that modified nebulisation can improve sample yield. Further children will be recruited over the next 2 years to investigate this potential association and applicability to future research.

P1047 Copper nanoparticles generate reactive oxygen species (ROS) after air delivery to alveolar type-II cells in vitro
Peter S. Thorne 1, Jong Sung Kim 2, Andrea Adamcakova-Dodd. Occupational and Environmental Health, University of Iowa, Iowa City, IA, United States

Rapid screening methods for NP are needed that replicate in vivo toxicity. We assessed cytotoxicity and ROS generation from Cu NP using an in vitro dynamic exposure model (IVDEM) that overcomes limitations of submerged-cell methods and mimics in vivo exposure conditions by generating and depositing airborne NP directly onto cells grown at an air-liquid interface (ALI). A549 cells were exposed to particle-free air or Cu NP aerosols (12±1 μm) for 4 h at 0.4 μg/cm² after which cells were incubated for 4, 8, 12, or 24 h. Cytotoxicity was assessed by Alamar Blue assay of mitochondrial function and ROS using carboxy-H2DCF-DA as an indicator of steady-state levels of pro-oxidants. Aerosolized Cu NPs were 30 nm (σ=1.9) indicating that the system produced a nanoscaled distribution of NP. Direct exposure of cells at the ALI mimics agglomeration and retained inherent particle characteristics. Viability for cells exposed to particle-free air or Cu NPs for 4 h were no different than cells maintained in the incubator (controls) indicating no trauma associated with exposure in the IVDEM. The production of intracellular ROS in particle-free, air-exposed cells was the same as controls. However, intracellular ROS levels after Cu NP exposure increased at 4 and 8 h post-incubation (130% and 170% of control). ROS levels resolved to baseline at 24 h postexposure indicating that Cu NP-induced oxidative stress did not exceed the cells’ ability to neutralize ROS. Cu NPs generate significant intracellular ROS after air-delivery to human alveolar cells in this IVDEM. This in vitro test system using lung epithelial cells with an ALI has potential utility for NP toxicity assessment.

SUNDAY, SEPTEMBER 25TH 2011
from 2001 to 2003 daily records: of attendances at São Paulo Hospital Emergency Unit (SPHEU) with ICD 10th J01-J06, of levels of PM2.5, NO2, SO2, CO, and O3, of temperature and humidity.
GLM Poisson regression was adopted using daily number of AURTI visits as de- pending variables. Long-term trend was controlled by a semi parametric function. Linear terms were used for temperature and humidity. Effects were presented as percentage increase and 95% CI in AURTI SPHEU visits due to interquartile range increases in air pollutants daily levels. During the study period, 177,325 visits occurred in the SPHEU and 137,530 (72%) were due to AURTI.

In terms of age groups, emergency visits of children and younger than 13 years of age were the most frequent, followed by the groups 40 to 65 years, 30 to 39 years, older than 64 years and adolescents from 13 to 19 years old. PM2.5 presented effects at lag zero on daily visits due to AURTI and this pattern was observed for all age groups. Among those younger than 13 years of age this effect started at lag zero (2.1%; 95% CI 0.9- 5.8) and remained almost four days. NO2, SO2, and O3 presented effects at lag zero. URKI cannot be considered severe health outcomes. However, it is one of the most frequent groups of respiratory diseases and affects different age groups. Despite of the well-known respiratory symptoms, there are other age groups to present susceptibility enlarging the burden of air pollutants on health.

Conclusion: Symptoms of anxiety and depression are common among people with long term exposure to indoor air pollution and they usually go undiagnosed due to low accessibility to proper health facilities. They should be routinely screened for psychiatric morbidities.

P1051
The frequency and factors for occurrence of asbestos-related diseases in the rural of Sivas localised on central Anatolia (cross sectional epidemiologic study)

Isa Dongel1, Mehmet Bayram2, Huseyin Yalcin4, Sefa Gul turk4, Nur Dilek Bakan5.

Department of Internal Medicine, Sivas Numune Hospital, Sivas, Turkey; 4Thoracic Surgery, Sivas Numune Hospital, Sivas, Turkey; 5Chest Disease, Yeditepe Teaching Hospital for Chest Disease and Thoracic Surgery, Istanbul, Turkey

Objective: To determine the rate and affecting factors of asbestos-related diseases (ARD) in the villages close to ophiolitic units in the rural of Sivas, central Anatolia in Turkey.

Methods: Volunteers (age>35, >20 years resident) from villages close to ophiolitic units and from villages >20 km distant to ophiolitic units as control group were included. Chest X-rays and questionnaire for demographical data and respiratory symptoms were performed. A geological map was used to measure the distance between ophiolitic units and villages. Samples were taken from houses and soils and analyzed for asbestos with X-ray diffraction.

Results: 2947 volunteers (1148 male, 1839 female) from 48 villages close to ophiolitic units and 157 (91 male, 66 female) volunteers from 6 villages far to ophiolitic units were included. Mean age of study and control groups were 55.2 and 57.3 respectively. 292 patients (3 malignant mesothelioma, 289 pleural plaque) with ARD were identified from villages close to ophiolitic units. No ARD was identified in control group. Factors affecting ARD risk were male sex (OR 3.1;p=0.00), advanced age (OR 1.05 for every year of age;p=0.00), residency close to ophiolitic units (for each 1 km 12% increase) and, decrease in BMI (for each 1 unit 3.6% increase) in multivariate logistic regression analysis. Serpentinite was found in samples of villages close to ophiolitic units, no asbestos was found in control villages.

Conclusion: ARD rate is high in residents close to ophiolitic units in rural Sivas. Factors associated with ARD development were advanced age, male sex and living close to ophiolitic units.

P1052
The impact of residential proximity to ophiolitic units in the development of asbestos-related diseases

Mehmet Bayram1, Isa Dongel2, Nur Dilek Bakan3, Huseyin Yalcin4, Sefa Gul turk4, Cavit Bucak5, 6Thoracic Surgery, Sivas Numune Hospital, Sivas, Turkey; 7Chest Disease, Sivas Numune Hospital, Sivas, Turkey; 8Thoracic Surgery, Sivas Numune Hospital, Sivas, Turkey; 9Chest Disease, Yeditepe Teaching Hospital for Chest Disease and Thoracic Surgery, Istanbul, Turkey; 10Mineralogy and Petrology, Cumhuriyet University Geology Engineering, Sivas, Turkey; 11Physiology, Cumhuriyet University Faculty of Medicine, Sivas, Turkey; 12Chest Disease, Yeditepe Teaching Hospital for Chest Disease and Thoracic Surgery, Istanbul, Turkey

Objective: To determine the relation between risk of asbestos related diseases (ARD) and the proximity of birthplaces to ophiolitic units (OU) which contains serpentine in the province of Sivas, Turkey.

Method: Records between 2000 and 2010 of mesothelioma, pleural plaque (PP), prostate cancer and breast cancer patients from cancer registry were reviewed. Samples were obtained from indoor plasterers and source of plasters. Birthplaces of patients were marked on a map with OU modified from geological map (mesothelioma: red square, PP: black star and OU: green areas).
The distance between residential area of birthplace of the patients and OU were measured.

**Result:** Birthplaces of 100 mesothelioma, 133 PP, 161 prostate cancer and 139 breast cancer patients were included. Samples of plasters and soil were identified as 95% serpentine. Mean distance to OU of patients with ARD and control cases were 5.9 and 15.9 kilometers.

Logistic regression analysis after age adjustment between groups showed that risk for ARD increased with decrease of distance to OU (Odds ratio: 1.72 for every 5 km decrease).

**Conclusion:** The proximity of birthplace to OU increases the risk of ARD.

**P1053**

CO-diffusion capacity in asbestos-exposed workers with or without abdominal chest X-ray findings

Alexandra Mr M. Perel', Marcell Velasco Garrido1, Eva Sabine Goldenstein1, Schumann Gundrun1, Ulf Manuwal1, Dennis Wilken1, Xavier Baur2

1Department of Clinical Occupational Medicine, Institute for Occupational and Maritime Medicine, Hamburg, Germany; 2Gesundheitmanagement Hamburg, Vattenfall Europe Business Services GmbH, Hamburg, Germany

**Background:** Exposure to asbestos can cause a restrictive lung disorder with impaired pulmonary gas exchange. It is controversial, whether lung function impairments occur in the absence of radiological abnormalities.

**Aim:** To assess CO-diffusion capacity in asbestos-exposed workers according to radiological findings.

**Methods:** Medical surveillance of 63 male workers formerly asbestos-exposed included a comprehensive medical and occupational history. All subjects underwent spirometry and body plethysmography according to ATS/ERS quality standards. CO-diffusion capacity (DLco) was measured according to Machney et al. 2005. Results are reported as% predicted. Subjects were classified according to chest X-ray findings.

**Results:** Exposure varied widely across workers (2-420 fibre-years). Asbestosis (ILO: ≥1/1, ≥pleural fibrosis) was found in 4 workers, 18 had pleural fibrosis and 41 had normal chest X-ray findings. Pulmonary gas exchange was reduced in all three groups: DLco 51% (95%-CI 24%, 78%), 73% (95%-CI 65%, 81%) and 84% (95%-CI 79%, 89%), respectively. DLco was below the lower limit of normal in 37 cases. Mean DLco of never smokers (n=12), ex smokers (n=24), and smokers (n=3), all with normal chest X-ray, was 85% (95%-CI 77%, 93%), 84% (95%-CI 76%, 91%), and 84% (95%-CI 70%, 99%), respectively. We found no statistical association between DLco and fibre-years.

**Conclusions:** We detected significantly impaired gas exchange in all three groups: DLco 51% (95%-CI 24%, 78%), 73% (95%-CI 65%, 81%) and 84% (95%-CI 79%, 89%), respectively. We found no statistical association between DLco and fibre-years.

**Background:** Relationships between isolated parietal plaques and lung function in asbestos-exposed workers free from pleural fibrosis was found in 4 workers, 18 had pleural fibrosis and 41 had normal chest X-ray findings. Pulmonary gas exchange was reduced in all three groups: DLco 51% (95%-CI 24%, 78%), 73% (95%-CI 65%, 81%) and 84% (95%-CI 79%, 89%), respectively. DLco was below the lower limit of normal in 37 cases. Mean DLco of never smokers (n=12), ex smokers (n=24), and smokers (n=3), all with normal chest X-ray, was 85% (95%-CI 77%, 93%), 84% (95%-CI 76%, 91%), and 84% (95%-CI 70%, 99%), respectively. We found no statistical association between DLco and fibre-years.

**Conclusions:** We detected significantly impaired gas exchange in all three groups: DLco 51% (95%-CI 24%, 78%), 73% (95%-CI 65%, 81%) and 84% (95%-CI 79%, 89%), respectively. We found no statistical association between DLco and fibre-years.

**Methods:** The study population consisted of 2,743 subjects included in a large-scale pilot screening program for asbestos-related diseases in four regions of France between 2003 and 2005. All had been occupationally exposed to asbestos, and were free of interstitial disease on high resolution chest computed tomography (HRCT). The asbestos exposure was assessed with calculation of an individual cumulative exposure index (CEI) taking into account all job periods for each subject. Each included subject benefited from pulmonary function tests (PFT) and HRCT was interpreted by a panel of expert radiologists in thoracic imaging. In both univariate and multivariate analysis, variables were adjusted on tobacco status, body mass index (BMI), CEI to asbestos and the center where PFT were made.

**Results:** Isolated pleural plaques were associated with a significant decrease of TLC (p=0.049), FVC (p=0.001) and FEV1 (p=0.003). On the other hand, no significant relationship was observed between pleural plaques and FEV1/FVC ratio. FEF25-75% and RV. A significant correlation was found between the extent of pleural plaques and the reduction of FVC (p trend=0.0089) and TLC (p trend=0.0464). By contrast, thickness of pleural plaques was not related to any functional impairment.

**Conclusions:** Our results are in favor of a relationship between isolated parietal and/or diphragmatic pleural plaques and a trend to restrictive pattern.

**P1055**

Respiratory morbidity of children exposed to crocidolite at Wittenoom, Western Australia

Peter Franklin1, Alison Reid2, Latha Samuel3, Nicholas de Klerk4, Bill Musk2, 1School of Population Health, University of Western Australia, Perth, Western Australia, Australia; 2Respiratory Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; 3Western Australian Institute for Medical Research, University of Western Australia, Perth, Western Australia, Australia; 4Centre for Child Health Research, University of Western Australia, Perth, Western Australia, Australia

Little is known about the general respiratory health of people exposed to asbestos in childhood. This study investigated respiratory symptoms and lung function in subjects who lived in an asbestos mining town (Wittenoom) as children. Lung function (spirometry), chest x-ray, and respiratory symptom data from former Wittenoom children who participated in an Asbestos Review Program (ARP) were assessed. Symptom frequencies and predicted FVC, FEV1 and FEV1/FVC were calculated. Predicators of increased symptoms and poor lung function were assessed using linear and logistic regression. 186 individuals of the ARP had been children when living in Wittenoom. Of these, 8 had developed mesothelioma, 2 lung cancer, 14 radiographic asbestos and 3 diffuse pleural thickening. These participants were excluded from the analyses. The median age of arrival was 2.3 (95% CI 0.6 – 6.0) years and the median duration of residence was 24 (12 - 48) months. The mean age at assessment was 48.5 (SD 9.3) years. About 25% were past smokers and 22.7% still smoked at the time of the assessment. Reported symptoms included: cough (15.7%), phlegm (11.6%), dyspnea (18.3%), wheeze (20.1%) and asthma (20.8%). The main predictor for increased symptoms was current smoking. Mean (SD) predicted FVC, FEV1 and FEV1/FVC were 90.6% (21.4), 90.1% (20.4) and 79.5% (21.1), respectively. Age at time of test, age at 1st exposure and cumulative asbestos exposure were associated with both reduced FVC and FEV1. Age at time of test, being male and asthma were associated with decreased FEV1/FVC. Asbestos exposure as a child is associated with sub-clinical restrictive lung function decrements even in the absence of radiographic abnormalities.

**P1056**

The sociodemographic and clinical characteristics of Turkish workers with pneumoconiosis

Hilal Altinöz, Cengiz Celikkalkan, Fatih Hamsioglu, Nalan Cesniz, Hikmet Orbay, Istanbul Occupational Disease Hospital, Istanbul Occupational Disease Hospital, Istanbul, Turkey

Pneumoconois is an irreversible, preventable disease caused by dust inhalation. Although in other countries, by precautions the incidence decreased to 0.3–5%, it is still 10-15% in our country in pneumoconiosis causing occupations. We aimed to describe the characteristics of our 208 pneumoconiosis workers admitted to Istanbul Occupational Disease Hospital. Patient files between 01st Jan 2008 and 31st Dec 2010 are used for the descriptive study. All of the patients were male with 38,82±13 years of age. The most common workplace was Gaziosmanpasa with 27 cases. The mostly seen works were denim sandblasting, dental technicians, coal mining and casting (%50,5,%12,%6,7,%4,8). The most exposure material was silicium (86,5%). Mean exposure time was 9,9±8,9 years. Profusion according to the ILO classification was in the table. In 37 cases, there was an A opacity and B opacity in 28. The mean FEVI% was 67,27±23.3, FVC% 77,8±20,86, FEV1/FVC%85,1±16 and KeC 102,74±28,1. The period between exposure and

Radiographic profusion
symptoms were calculated at 10.48±8.7 years. Patients were mostly referred by a social security center, secondly by Sureyyapasa training hospital and thirdly, admitted by themselves. The most common symptoms were breathlessness, cough and exertional dyspnea. The exposure time in a workplace is very important but in our files there were no data showing this, so we planned to rearrange our patient files. Generally each paper in the literature discusses only one type of occupation causing pneumoconiosis. To our knowledge this is the first study concerning nearly all occupations causing the disease.

P1057
Respiratory symptoms, lung function impairment, and sensitization to metals in construction workers exposed to ashes, cement and ash-cement mixtures
Dragan Mijakoski1, Jovanka Karadzinska-Bislimovska2, Saso Stoleski, Jordan Minov2, Minosa Markova1, Aneta Atanasovska1, Allergy Center, Institute for Occupational Health of RM, WHO CC, GAZLEN CC, Skopje, Macedonia, The Former Yugoslav Republic of; 2Dpt for Functional Cardiorespiratory Diagnostics, Institute for Occupational Health of RM, WHO CC, GAZLEN CC, Skopje, Macedonia, The Former Yugoslav Republic of

Objective: To evaluate the prevalence of respiratory symptoms, lung function impairment, and sensitization to metals in construction workers exposed to ashes, cement and ash-cement mixtures.

Methods: We performed a cross-sectional study including 45 construction workers exposed to ashes, cement and ash-cement mixtures (mean age 43.1±6.8 yrs, mean job duration 19.5±7.1 yrs). In addition, 50 office workers (mean age 42.2±10.5 yrs, mean job duration 17.8±9.2 yrs) were examined as a control. Evaluation of examined subjects included completion of questionnaire on respiratory symptoms, lung function testing, histamine challenge test (PC20 ≤ 8 mg/ml), and patch testing.

Results: Compared with office workers, construction workers had more frequently respiratory symptoms (cough, phlegm, wheezing, and shortness of breath) in the last 12 months (40.0% vs. 16.0%, P<0.05). The difference was significant for cough (42.2% vs. 16.0%, P<0.05), wheezing (37.8% vs. 14.0%, P<0.05), and shortness of breath (44.4% vs. 14.0%, P<0.05). Lung function testing showed that construction workers had significantly lower FEV1 and significantly lower FVC/FVC. Significant association was registered between respiratory symptoms and BHR in both construction and office workers. Patch testing to chromium, cobalt and nickel was positive in 22.2%, 15.6%, and 8.9% of all construction workers, respectively.

Conclusion: Our data emphasize important role of specific occupational hazards in the development of respiratory symptoms, lung function impairment, and sensitization to metals in construction workers exposed to ashes, cement and ash-cement mixtures.

P1058
Cement dust exposure, respiratory symptoms and exhaled nitric oxide: A cross-sectional study
Alexander Tungu1,2, Magne Bråtveit2, Bente Moen2, 1Centre for International Health, University of Bergen, Bergen, Hordaland, Norway; 2Public Health and Primary Health Care-Section for Occupational and Environmental Medicine, University of Bergen, Bergen, Hordaland, Norway

Aim: To explore whether cement dust exposure is associated with increase in chronic respiratory symptoms and FeNO concentration among cement factory workers in Tanzania.

Methods: The exposed group comprised 171 cement production workers while 98 workers from a beverage factory served as controls. Personal total dust samples were collected from the breathing zone of workers in the cement factory (n=130) and the beverage factory (n=16). The information on chronic respiratory symptoms was collected by a questionnaire, and FeNO concentrations were measured by a NOx Mino monitor among 117 exposed and 24 controls.

Results: Geometric means of total dust exposure among control and exposed workers were 0.6 mg/m³ and 5.0 mg/m³, respectively (p<0.001). The exposed workers and controls had similar age and smoking habits. The prevalence of from being the major risk factor for lung cancer, may be a co-factor in the development of asbestos in lung disease. The Health and Safety Executive report mentions the high rate of smokers in asbestos related industry [1]. We reviewed our local population of asbestos workers to explore that.

Methods: Between 1994 and 2007, 268 workers were seen for clinical assessment, spirometry, health safety advice and smoking cessation. A retrospective analysis of records, spirometry, smoking habits, effect of smoking cessation advice, was undertaken.

Results: 268 subjects were seen, 65 on multiple occasions, 214 (79%) were involved with asbestos handling or removal. 42 (16%) worked in supervisory or managerial capacities. 12.5% were laboratory analysts. Current smoking rates for handlers was 67% (144/214), managerial group 36%, and analysts 33% (p=0.015). Ex smoking rates were 11% for removers, 38% for the supervisory and managerial group and 8% for analysts. Non-smoking rates were 22% for handlers and removers, 46% for supervisors and managers and 58% for analysts. The rate of decline in FEV1 for current smoking handlers/asbestos remover was 52.8 ml per year, and for supervisors 22.3 ml per year (p=0.0023). The mean FEV1 decline in non-smokers and ex-smokers was 37.5 ml/yr.

Conclusions: Workers with highest asbestos exposure are significantly more likely to be current smokers and to have greater decline in FEV1, conferring greater disease risk [2]. Smoking behaviour has not changed since 1983. Consultant advice on cessation was ineffective for the group most at risk.

References:
chronic respiratory symptoms was higher among exposed compared to controls; Wheezing (18% vs. 15.3%) Work related shortness of breath (15.8% vs. 6.1%), dyspnoea (13.5% vs. 9.2%), chronic spontaneous production (8.4 vs. 1.1%) and chronic cough (6.6% vs. 1.9%).

Exposed workers had higher mean FPaO2 concentrations (26.0 ppm) than controls (20.0 ppm), but the difference was not significant.

Conclusions: The prevalence of chronic respiratory symptoms and FPaO2 concentrations among exposed workers indicate an association between cement dust and airway inflammation.

P1065 Pulmonary asbestos fiber in an urban population in Spain
Maria-Isabel Velasco-García1, María-Jesús Cruz2, Carmen Diego3, Mª Angeles Montero1, Ferran Morell2, Jaume Ferrer2

Introduction: In this study, asbestos fibers in lung are characterized and quantified for the first time in an exposed and an unexposed Spanish population.

Material and methods: We studied samples from 47 autopsy specimens (25 unexposed subjects from Barcelona with no lung disease, and 22 asbestos-exposed subjects from El Ferrol), and 32 resected surgical specimens from lung cancer patients in Barcelona.

After eliminating organic material, the inorganic residue was analyzed by optic microscopy and electron microscopy. Results are expressed as the number of asbestos fibers or asbestos bodies per gram of dry lung tissue. To identify the type of fibers found, 38 samples were analyzed by scanning electron microscopy and energy dispersive x-ray analysis.

Conclusions: This study provides the first available data on the type of asbestos content in lung in the Spanish population. The exclusive retention of amphiboles was worthy of note and suggests elimination of chrysotiles following inhalation. Optic and electron microscopy were both reliable methods for pulmonary asbestos determination in our laboratory.

P1066 Serum cytokine spectrum in workers with occupational salt dust exposure in underground conditions
Nicodaj Denisiević1, Tatyana Rybina2, Elena Amelchenko2

Introduction: Cytokines are circulating cellular mediators of the immune response, hematopoiesis, inflammation and development. The aim of this study was to assess the level of cytokines in workers with occupational salt dust exposure in underground conditions.

Methods: We studied 49 workers with occupational salt dust exposure with mean age 39.7 ± 7.0 years, length of work in underground conditions 9.7 ± 5.5 years. The control group included 17 healthy men 46.9 ± 8.3 years without occupational hazards. Serum levels of IL-8, IL-2, TNF-α, INF-γ were measured by ELISA.

Results: The concentration of all studied cytokines in serum of workers with occupational salt dust exposure engaged in underground working conditions was lower vs the control group. We revealed a significant decrease in INF-γ values (p = 0.0226) (4.30 [0.30, 12.8] pg/ml vs 11.8 [3.80, 19.8] pg/ml). In our opinion, decreased cytokine values in workers engaged in underground working conditions could possibly relate from the reduced activation of T-lymphocytes and NK-cells.

Conclusions: Low bacterial and viral antigens exposure of underground workers, daily respiratory tract clearance during the work shift (bacteriostatic and bactericidal effect on microorganisms of the salt dust) probably contributes to the reduction of cytokine production.
P1067
Occupational and environmental determinants of exposure to asbestos in malignant mesothelioma cases
Soussan Salehpour1, Seyed Ali Azin2, Ali Cheraghi-Vali3, Mohammad Mehdi Heidari1, Sajedeh Mir Mohammad Saadeghi1. 1Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran; 2Social Medicine Department, Iran University for Health Sciences Research, The Academic Center for Education, Culture and Research, Tehran, Islamic Republic of Iran

Background: The relationship between pleural malignant mesothelioma and exposure to asbestos is currently known, but there is no accurate information regarding high-risk occupations and types of exposure in Iran.

Aim and objectives: As Asbestos is still used in Iran intake of ban in many other countries, in this study we specified high risk jobs for asbestos exposure and further intervention.

Methods: In this case-control study, 64 cases with diagnosis of pleural malignant mesothelioma who were admitted in Masih daneshvari hospital between 2001 and 2009 were studied. All the cases and 55 controls participated in a telephone interview for job history and occupational and environmental exposures to asbestos.

Results: Asbestos exposed occupations in mesothelioma group included corrugated asbestos cement sheet production 11 (%17.2), Insulation 6 (%9.4), and car brake shoe manufacturing 2 (%3.1). In control group the only exposed occupation was construction 8 (%13.79). Odds Ratio calculated for occupational exposure to asbestos was 5.51 (CI=2.26-13.47). Residency in neighbourhood of corrugated asbestos cement sheet production factory was the most prevalent cause for environmental exposure.

Conclusion: In 46.87% of mesothelioma cases, source of exposure to asbestos was corrugated asbestos cement sheet industry due to employment in the factory, residency in neighbourhood of the factory or use of its products.

P1068
Investigating of CEA, CA125, CA15-3, CA19-9, TF3, TF4, TSH, vitamin B12, folic acid and ferritin in malignant and benign diseases due to environmental asbestos exposure
Isa Donge1, Mehmet Bayram2, Semsettin Sahin3, Ismail Benli4. 1Thoracic Surgery, Sivas Namune Hospital, Sivas, Turkey; 2Chest Disease, Sivas Numune Hospital, Sivas, Turkey; 3Biochemistry, Gaziosmanpasa University Medicine School, Tokat, Turkey; 4Biochemistry, Gaziosmanpasa University Medicine School, Tokat, Turkey

Aim: To identify several biochemical marker levels in mesothelioma (MM), in subjects with pleural plaques (PP) due to environmental asbestos exposure (EAE) and in healthy subjects with EAE.

Method: 277 patients with PP from villages close to asbestos-containing units (OU) (serpentinite asbestos containing). 121 healthy subjects from villages close to OU, 118 healthy subjects without EAE and 24 MM patients were included to the study.

Table 1: Distribution of sex, age and biochemical findings according to the groups

107. Smoking cessation science and smoking-related disorders

P1070
Smoking cessation – What determines adherence to pharmacological treatment
Ana Castro, Júlia Valério, Albertina Correia, Miguel Guimarães, Ivone Pascoal.
Pulmonology, Centro Hospitalar Vila Nova de Gaia - Espinho EPE, Vila Nova de Gaia, Portugal

Introduction: Cigarette smoking is the 1st modifiable risk factor for premature morbidity and mortality. Treating smokers is the best cost-effectiveness health care intervention.

Objective: Assess adherence to pharmacological treatment and factors influencing it. Correlate variables determining adherence and results at the end of treatment and 12 months follow up.

Methods: Characterization of a patients sample whom was prescribed Varenicline or Nicotine Replacement Therapy (NRT). Analyse and correlate treatment adherence with factors affecting adherence (motivation, dependency, household smoking habits, side-effects,etc).

Results: 166 smokers were included, 71% male, 28% female, mean age 49 years. Mean tabagic burden: 45pack-years. Mean motivation 8.1–Richmond test (RT); mean dependence 5.1–Fagerström test (FT). Varenicline was proposed to 48% and NRT to 51%. 55% of patients followed the treatment correctly and the others discontinued therapy. Reasons given for non-compliance: unrecognized therapeutic effect, excessive self-confidence, price, side effects. The patients that completed treatment, 52% did not smoke at the end of treatment and 55% were nonsmokers at the end of 12 months follow up. There was a positive correlation (Spearman correlation)
Correlation,p<0.05) of adherence with: RT, educational level and NRT therapy. Negative correlation with: household smoking habits, FT.

Conclusion: Treatment adherence is a key factor for smoking abstinence. In our group, adherence was higher in patients treated with NRT, better-educated and more motivated. False expectations, side effects and price can influence adherence to therapy. The smoking habits of the household and the degree of dependency negatively affect adherence and abstinence.

**P1071**
Tobacco cessation quit line in Iran. Evidence based during one year.

**Aim:** To compare the effectiveness of different approaches for smoking cessation: acupuncture and combination of acupuncture and nicotine substituting therapy.

**Methods:** We use two main approaches - acupuncture and combination of acupunc-ture points with NRT therapy. Participants were divided into two groups of 25 people each. The participants who stopped smoking was 21.8% after 2 years.

**Conclusion:** The use of e-Cigarette substantially decreased cigarette consumption without causing significant side effects in smokers not intending to quit.

**P1075**
Acupuncture versus combined acupuncture and nicotine substituting therapy for the treatment of nicotineism

**Aim:** To compare the effectiveness of two different approaches for smoking cessation: acupuncture and combination of nicotine and cigarette substituting therapy.

**Methods:** We use two main approaches - acupuncture and combination of acupuncture and nicotine substituting therapy with Tabex (Cytisine, original Bulgarian product). The patients, 50 active smokers (mean age 45 years), highly motivated in smoking cessation, were divided into two groups of 25 people each. The participants in both groups had mean 25 years of smoking history and mean use of 20 cigarettes daily. Acupuncture was performed with standard and micro needles on acupunctural ear and nose points. Tabex was adminstered for 20 days, according to the following regimen: 1 tablet is sucked out in the morning, 1 tablet orally at 10th day, 20th day, 3rd and 6th month after onset.

The results showed that the combined method (acupuncture+Tabex) has more significant long lasting effect (depletion or significant reduction of abstinence, and smoking cessation in 65% of the mild and heavily nicotine dependent patients) at the end of the 6th month than the acupuncture separately (32%).

In conclusion we recommend the combined method of acupuncture and cigarette substituting therapy with Tabex for the treatment of mild and heavily nicotine dependent smokers.

**P1104**
Effect of an electronic cigarette on smoking cessation and reduction: A prospective pilot study

**Aim and objectives:** We designed a prospective proof of concept study to monitor possible modifications in the smoking habits of 40 regular smokers experimenting the most popular marketed e-Cigarette in Italy (Categoria) focusing on smoking reduction and smoking abstinence.

**Methods:** Study participants were invited to attend a total of 5 study visits: at baseline, week 4, week 8, week 12 and week 24. Product use, number of cigarettes smoked, and exhaled carbon monoxide levels were measured at each visit. Smoking reduction and abstinence rates were calculated.

**Results:** A mean of 2.0 cartridges/day was used at week-24. Sustained 50% reduction in the number of cig/day at week-24 was observed in 3/40 (32.5%) participants; their median of 25 cigs/day decreased to 6 cigs/day (p<0.001). Sustained 80% reduction was shown in 5/40 (12.5%) participants; their median 30 cigs/day decreased to 3 cigs/day (p=0.043). Sustained smoking abstinence at week-24 was observed in 9/40 (22.5%) participants. Mouth (20.6%) and throat (32.4%) irritation, and dry cough (32.4%) were common, but diminished substantially by week-24. Participants’ acceptance and acceptance of the product was good.

**Conclusion:** The use of e-Cigarette substantially decreased cigarette consumption without causing significant side effects in smokers not intending to quit.
P1076

The impact of education to healthcare professionals (HCPs) on smoking cessation in changing patient referral patterns

Ben Vikes, Alsenz Nazar, Chris Walsh, Sunjeet Agarwal, Dilip Nazareth, Paul Stockton. Respiratory Medicine, St. Helen’s and Knowsley Teaching Hospitals NHS Trust, Prescot, Merseyside, United Kingdom

Background: NICE (UK) recommends that every smoker should be advised to quit and referred to a smoking cessation service (SCS) for support. In a previous survey [1], 74% of patients had a missed opportunity for referral to SCS. The current survey evaluates the impact of a HCP education programme on referral patterns.

Method: HCPs including doctors, nurses and pharmacists completed an anonymous, voluntary questionnaire in January 2011.

Results: 58/65 HCPs completed the survey. 45% were aware of local smoking cessation guidelines. 50% had received information on smoking cessation in the last 12 months. 24% did not wish to receive training. 95% evaluated smoking cessation to be important, but only 79% considered that a hospitalization was a useful opportunity to stop smoking. Education by SCS did not alter the reasons given for not referring patients for smoking cessation [Fig 1] of HCPs, although awareness of, and referral to, SCS was higher in the group of HCPs who received education (64% vs 54%). 12% of respondents indicated that referring to SCS was not part of their role.

Conclusion: Education of HCPs did not alter overall attitudes towards smoking cessation in this group, but did result in increased awareness and positively influenced referral rate to the SCS.

P1077

Lung age in smokers – To tell or not to tell?

Kenji Miyamoto, Masayo Takase. Pneumologie, Pavlov State Medical University, Saint-Petersburg, Russian Federation

For smokers, lung age is a useful tool to make spirometry data easier to understand and to increase or maintain the motivation to quit smoking. However, only a quarter of smokers develop COPD. This suggests that many smokers are nonresponsive to tobacco smoking so far as the age-related decline in FEV1 is concerned. Many such smokers might have a lung age younger than their chronological age. We wondered whether, if the lung age is younger than the calendar age, knowing the younger lung age might encourage them to continue smoking.

Purpose: To compare smokers and nonsmokers whose lung ages were younger than their chronological ages when both have normal lung function with no respiratory symptoms.

Subject and methods: We performed spirometry for 353 volunteers who attended our “Lung Age Project” at the University Campus Festival.

Results: Among the subjects, 331 (M/F=158/173) of them had normal spirometry data (80%≤VC and 70%≤FEV1/FVC). In males, 25% of 48 smokers and the same percentage of 110 nonsmokers had a lung age younger than the chronological age. In contrast, in females, 71% of 24 smokers and 46% of 149 nonsmokers had a younger lung age. However, after age and height were matched between both groups, there was no significant difference of the ratio of those who had younger lung age between smokers and nonsmokers, 32% vs. 35% in males and 71% vs. 58% in females, respectively. After telling smokers their younger lung age, some of them happily said “I can continue to smoke for a while”, or “It is too early to quit smoking”.

Conclusion: Many nonsymptomatic smokers have a younger lung age than their chronological age, like nonsmokers. Therefore, we should be cautious about telling lung age to those smokers who want to quit smoking.

P1078

The influence of anxiety on smoking behaviour in patients with chronic hepatitis

José Marínucu, Lucian Negutniu, Stefan Mihaiucu, Ioan Iacobiciu, Nicoleta Bertici, Carmen Ardelen, Ioana Todir, Adriana Neghina, Cristian Oancea, Stefan Frent, Raul Neghina. Clinic of Infectious Diseases, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Clinic of Infectious Diseases, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Clinic of Infectious Diseases, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Clinic of Infectious Diseases, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Department of Pulmonology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania Department of Pulmonology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania Department of Psychology and Educational Sciences, December 1918 University, Alba Julia, Romania Clinic of Infectious Diseases, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Department of Parasitology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Department of Pulmonology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania Department of Pulmonology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; Department of Pulmonology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania

Objective: The study included 68 smokers with chronic hepatitis admitted to the Clinic of Infectious Diseases, Timisoara who answered the State Trait Anxiety Inventory-X2 (S.T.A.I-X2) anonymous test. The final scores allowed classification of patients by level of anxiety: minimal (score below 40), moderate (score 40-60) and severe (score over 60). Other variables were: sex, marital status, residence, number of cigarettes/day, family conflicts, alcohol intake etc.

Results: Most of the patients were male (63.2%, p=0.05). Of the study group, 63.7% had severe anxiety and 35.3% moderate anxiety (p=0.001). The number of cigarettes smoked/day ranged between 10-20 in 73.5% of cases whereas 26.5% of patients reported less than 10 cigarettes smoked/day (p<0.0001); the former group included 44 patients with severe anxiety and 6 cases with moderate anxiety. Patients who increased the number of cigarettes smoked/day after finding out the diagnosis predominated within the study group (67.6%) while only 32.4% of cases smoked less (p<0.0001). Most of the patients reported a positive history of familial conflicts (70.6%, p<0.0001) and alcohol intake (66.2%, p=0.0003).

Conclusions: Considering that severe anxiety in patients with chronic hepatitis leads to an increased number of cigarettes smoked/day, it becomes mandatory to establish a cognitive-behavioral therapy with anti-smoking counseling in these cases.

P1079

Influence of smoking intensity and smoking quitting on lung function parameters in COPD patients

Irina Pavlenko, Julia Ilkovich, Nina Sklarevich. Research Institute of Pulmonology, Pavlov State Medical University, Saint-Petersburg, Russian Federation

Aim: To evaluate dependence of changes in lung function parameters (LFP) from intensity of smoking in patients with moderate and severe COPD.

Materials, methods: 74 patients (63 male, 11 female) with COPD III-IV stages, FEV1 ≤ 0.70, FEV1/FVC% ≤ 50% and FEV1/FVC ≤ 70% were included in the study. Each patient was divided to 2 subgroups: low smoking intensity (less than 20 cigarettes per day) and high smoking intensity (20 and more cigarettes per day). LFP (FEV1 in liters, FEV1/FVC% of pred., “Lung Age” - LA) were measured in both subgroups. Smoking status - 31 current smokers, 33 ex-smokers vs. current smokers in subgroups with high intensity of smoking. Smoking status - 31 current smokers, 33 ex-smokers vs. current smokers in subgroups with low smoking intensity.

Results: LFP significantly improved in a year in ex-smokers vs. current smokers (p<0.05) in all groups. FEV1/FVC% significantly increased in ex-smokers vs. current smokers in subgroups with high intensity of smoking. FEV1/FVC% and FEV1/FVC significantly increased in ex-smokers vs. current smokers in subgroups with low smoking intensity. Other variables were: sex, marital status, residence, number of cigarettes/day, family conflicts, alcohol intake etc.

Conclusions: Smoking cessation has positive influence on lung function parameters in patients with severe and moderate COPD irrespective of smoking intensity. FEV1 in lites is the most sensitive indicator reacting on smoking intensity.

Evaluation of the antismoking therapy within two specialized medical practice – Arges county

Razvan Marmandiu1, Loredana Marmandiu2, Cristian Didilescu3. 1Pneumologie, Spitalul Județean de Urgență Pitești, Pitești, Arges, Romania; 2Pneumologie, Spitalul Leordeni, Leordeni, Arges, Romania Department of Psychology, Institutul “Marius Nasta”, Bucharest, Romania

Objective: Evaluation of the abstinence rate for 1956 people who were administered pharmaceutical treatment combined with psychological support within the
P1081 Behaviour of long-term weight following smoking cessation
Andreas Scherr1, Michael Tamm1, Bruno Steifert2, Martin Kuster3, Anja Meier1, Baiana Stolz4.
1Clinical of Pulmonary Medicine and Respiratory Cell Research, University Hospital of Basel, Basel, Switzerland; 2Industrial Health Service, F Hoffmann-La Roche AG, Basel, Switzerland; 3Industrial Health Service, Novartis Pharma AG, Basel, Switzerland

Weight gain often accompanies smoking cessation and is considered to be an important cause of unsuccessful quit attempts. We analyzed data from smoking cessation programs to identify risk factors of weight gain. 703 employees from University Hospital Basel, Switzerland, and two local health industry companies (Novartis Pharma AG, F Hoffmann-La Roche AG) absolved a structured smoking cessation program. This consisted of 10 visits with counseling and motivational support. Various modalities of both nicotine replacement therapy and/or bupropion were offered. The impact of factors on weight gain in long-term nicotine abstinence was analyzed by a linear mixed effect model. Smoking cessation at 24 months was associated with a weight gain of 2.76 kilogram (95% CI 1.85; 3.66; p=0.0001). Weight gain occurred independently from smoking cessation program to identify risk factors of weight gain.

Weight change after a quit attempt was not only affected by the outcome of smoking cessation, but also by baseline weight and the interaction of time and medication. Knowledge about individual risk factors for weight gain could help to resolve barriers to cessation smoking.

P1082 Tobacco smoke is a major source of indoor air pollution in Hungary's hospitality venues
Adam Domonkos Tamoki1, David Laszlo Tarnoki1, Mark J. Travers2, Andrew Hyland3, Katherine Dobson2, Laszlo Mechtler3, Ildiko Horvath4, Andrew Hyland2, Katherine Dobson2, Laszlo Mechtler3, Ildiko Horvath4, Anja Meyer1, Daiana Stolz1.
1Clinical of Pulmonary Medicine and Respiratory Cell Research, University Hospital of Basel, Basel, Switzerland; 2Industrial Health Service, F Hoffmann-La Roche AG, Basel, Switzerland; 3Industrial Health Service, Novartis Pharma AG, Basel, Switzerland

Tobacco smoke is a major source of indoor air pollution in Hungary's hospitality venues. Tobacco smoke is a major source of indoor air pollution in Hungary's hospitality venues. Tobacco smoke is a major source of indoor air pollution in Hungary's hospitality venues. Tobacco smoke is a major source of indoor air pollution in Hungary's hospitality venues.

Results: The TSI SidePak AM510 Personal Aerosol Monitor was used to measure the concentration of particulate matter less than 2.5 microns in diameter (PM2.5) measured in the ambient air of 6 public restaurants, 11 cafes and 21 other locations in Budapest and Zala karos between January and August 2008. Results: In the 27 places where smoking was observed the average PM2.5 level was 97.44 μg/m3 [range: 3.48-28 μg/m3] compared to 5.5 μg/m3 [range: 0.28-28 μg/m3] in the 16 places where smoking was not observed. Conclusions: The levels of indoor fine particle air pollution measured in public locations in Hungary where smoking was observed were times higher than the levels in locations where smoking was not observed and in nearly all instances exceeded the levels that the World Health Organization and US Environmental Protection Agency have concluded to be harmful to human health.

P1083 The tenth year preliminary results of smoking cessation polyclinics of Karadeniz Technical University medicine faculty
Funda Ortun1, Gunes Qadri2, Aykut3, Tuvik4, Ismail Yilmaz4, 1Chest Diseases, Karadeniz; Technical University, Medical School, Trabzon, Turkey; 2Public Health, Karadeniz; Technical University, Medical School, Trabzon, Turkey

Aim: Our outpatient smoking cessation clinic was opened in April 2000. Aim of this study was to create a database for our national long-term smoking cessation rates and to share our experience.

Method: We included 696 patients who had applied our smoking cessation clinic between April 2000-December 2010 years. After smoking habits and sociodemographic features of the people were asked, all the people attended to a suitable smoking cessation program. The results were analyzed by Chi-square test, Kaplan Meier survival analysis and Cox-regression analysis.

Results: It was observed that 696 people containing 408 (58.6%) men and 282 (40.5%) women visited the polyclinic during this period. According to duration without smoking, women did not smoke 24.36±6.83 months and men did not smoke 21.63±4.66 months. Success rates were not different between men and women (Log Rank p=0.729) at the end of tenth years. The success rates at the end of the first, the fifth and tenth years in patients who attended smoking cessation program were 58%, 40.6% and 31.7% respectively. We found that male gender, lack of regular income, low education level and the amount of cigarettes smoked per day were independent risk factors for restart smoking by Cox-regression analysis.

Discussion: In conclusion, our smoking cessation rates have decreased over the years. Especially, male gender, low educational level, lack of regular income and high amounts of daily cigarette were reduced success rates. We think that more close follow-up of these patients might positively affect on the success rates.

P1084 Smoking behavior of hospital staff
Yili VakefaII, Jul Bushi1, Dhmiraq Pritfi3, Ibruna Sokoli1, Josif Laçka4, Dhmiraq Arjeti1, Perlat Kapsys1, 1Pneumology, University Hospital “Sh. Ndreoi”, Tirana, Albania; 2Pneumology, Hospital of Pogradec, Pogradec, Albania; 3Pneumology, Hospital of Shkodra, Shkodra, Albania; 4Pneumology, Hospital of Berat, Berat, Albania

Aim: Evaluation of preventive actions at hospital and to measure the implication level of the hospital staff in tobacco prevention.

Method: From 658 hospital staff, 629 (95.6%) were in working place in the time of study, 573 (91.1%) have fulfilled the questionnaire in correctly manner. The questionnaire was articulated in the group questions, the aim of which was to explore the behavior of hospital staff and the level of their perception related to the "tobacco" problem.

Results: 22.5% of the hospital staff smoke, 6.2% smoke in presence of their patients, where the physicians make up the higher percentage (10.2%), in comparison for other healthcare workers (sanitary 5.6% and nurses 3.2%). 82.5% think that trying to convince people to stop smoking is part of their role; 90.2% consider that it has an exemplary role to play in front of patients. 93.4% have the right knowledge according to the damage of tobacco active use. Regarding to "World Day Without Tobacco" 66.1% thinks that this day is useful to rise the susceptibility on the problems related with tobacco using, 25% thinks that this day can help in making mindful the tobacco smoking people to leave it, 8.9% it is useless.

Conclusion: This underlines the need and the necessity to realize anti-tobacco campaigns among health care population. Moreover since the exemplary role they have to play, is very well accepted, preventive actions could rely on a good level of participation.

P1085 Smoking habit – Still a problem in workplace
Ghuliten Apti1, Hayat Memis1, Ana Maria Trailescu1, Cristian Didulescu1, 1Pneumology, Hospital of Pneumology Constanta, Constanta, Romania; 2Internal Medicine, University of Medicine C Davilla, Bucharest, Romania; 3Pneumology, Hospital of Infectious Diseases V.Bubes, Bucharest, Romania; 4Pneumology, National Institute of Pneumology M.Nasta, Bucharest, Romania

Despite the media effort to aware the population on dangerous effect of smoking on health and the laws prohibiting the smoking in workplaces still exist a lack in understanding and applying them.

Aim: To estimate the prevalence of smoking habit, smoker profile in workplace.

Method: Epidemiological study of prevalence;

Study population: 471 workers known to exposure to gas, fumes and mineral dust, aged between 25-65 years. The data were collected on basis of occupational and smoking history, self reported occupational exposure and nicotine dependence test.

Results: Medium age was about 40.6±7 years; 89,1% males. History of exposure: in 54,1% more than 20 years; high exposure in 48%.

194s
Prevalence of symptoms of chronic bronchitis in Murmansk, Russia

Also of smoking on the lung function.

in Soligorsk Central Hospital. The presumably positive effect of potash mine exemplify; 16% recognized the risk of smoking. Nicotinic dependence: extremely 72,2% from workers knew that smoking is harmful but only 26,6% knew to smoking influence on lung function characteristics of potash miners

Objective: Smoking habit: Prevalence, attitudes and behaviour among medical students in Casablanca in 2010

The aim of this study was to know the prevalence of smoking in medical students, and by the way to sensitize the habit and to know their attitudes and behaviour in their future exercise. We carried out a cross-sectional survey from February to March 2010 among 736 medical students enrolled in the university of Medicine and Pharmacy of Casablanca during the academic year 2009–2010. Ninety seven percent of students answered the questionnaire: 61.5% were female 61.5%, mean age 21 years. The prevalence of permanent or occasional smoking was 8% with little variation according to the study year. Smoking was significantly higher among male (16% versus 2.7% in female). The mean daily consumption of cigarettes was 8. The duration of smoking was 6 months or more for 82% and 70% of smokers were slightly or not addicted to nicotine according to the FAGERSTROM’s scale. More than half of the students (58%) had already tried to quit and 52% plan to do so within 5 years. The main triggering reason for quitting was the occurrence of symptoms (66%). Most students knew that smoking is harmful to health (92%). Among tobacco risks the respiratory ones were the best known. Only 39% of the students contemplate to systematically warn their smoking patients against tobacco’s risks. Majority of them (71%) were not aware about the existence of an antitobacco law. But they called for a ban on selling tobacco to children as well as training health workers to help smoking patients to quit. In comparison with some years ago, there is a significant decrease in smoking habit in medical students, may be thanks to a steady and continuing educational effort since the induction of a teaching program in 1983.

P1010
Smoking influence on lung function characteristics of potash miners

Hалина Baradzyна1, Неннад Hurевич2, Николай Denisевич3. 1Pulmonology, Republic Scientific-Practical Centre of Pulmonology and Phthisiology, Minsk, Belarus; 2Pulmonology, Soligorsk Central Hospital, Soligorsk, Belarus

There are known negative effects of smoking on the lung function. The impact of smoking on the lung function of the potash mines with different industrial work record of service has not been so far well investigated.

Objective: The influence of smoking on lung function characteristics of the miners potash mines with different industrial work record of service.

Methods: We examined 111 miners of potash mine in Soligorsk (all male, average age 33.7±11.3 years) with different industrial work record by spirometry: 1 gr. with the record of service less than 10 yrs, II gr. has the record of service from 10 to 20 yrs, and III gr. – more than 20 yrs. 74% of examined miners were smokers. Period of smoking was in average 1.3 year more than industrial work record of service.

Results: The miner’s lung function characteristics were in total very high and according to the normal significance. In I gr. of miners the lung function characteristics were equal to characteristics of smokers and nonsmokers. There were no significant differences in characteristics between the smokers and nonsmokers

Conclusion: Our investigation shows that smoking exerts more intensive negative influence on the lung function of the potash mine workers than industrial aerosols. Antismoking programs could be one of the main points of prophylactic strategy in Soligorsk Central Hospital. The presumably positive effect of potash mine microclimate neutralizes the negative impact not only of industrial aerosols but also of smoking on the lung function.

P1017
Prevalence of symptoms of chronic bronchitis in Murmansk, Russia

Pentti Nieminen1, Tuula Toljamo2, Mark Borskeno1, Yuri Payasov3, Sergei Lyalyushkin1, Arvid Nyberg4, Vuokko Kinnula5, Dmitry Panych6. 1Medical Informatics and Statistics Research Group, University of Oulu, Oulu, Finland; 2Department of Pulmonary Medicine, Lapland Central Hospital, Rovaniemi, Finland; 3Statistical Dept., Murmansk Region Health Ministry, Murmansk, Finland; 4City Emergency Hospital, Murmansk Hospital, Murmansk, Russian Federation; 5Pulmonology, Soligorsk Central Hospital, Soligorsk, Belarus

Incidence, morbidity and mortality of COPD in the Murmansk region of northwest Russia are high, but statistical figures do not probably reflect the whole problem. As much as 60% of the male population in Russia is smokers. We describe findings of a project which addresses prevention of COPD in Murmansk.

Aims and objectives: 1. What is the proportion of prolonged respiratory symptoms among adult subjects who visit a GP for primary care?

2. What is the distribution of nicotine-dependence among smokers?

3. How motivated they are to quit smoking?

Methods: A survey of 200 Murmansk region adult citizens was performed. Inclusion criteria: adult patient visiting a primary care GP for any medical reason. Venues were one polyclinic located in Murmansk city and one hospital polyclinic located in a mining area 200 km outside Murmansk.

Results: 200 outpatients were enrolled. Altogether 60.5% had symptoms of chronic bronchitis and 55 (33.0%) had prolonged dyspnoea and wheezing as well. Respiratory symptoms were more common in those subjects, who lived in the mining area. More than half (51.5%) of the subjects had been smokers at some stage of their adult life. A total of 63 (31.5%) were current smokers. The proportion of heavily dependent smokers (FTND 6-7) was 23.8%. Adults living in the mining area were more heavily nicotine dependent. 42.9% of the current smokers had a high motivation to quit smoking.

Conclusions: Significant numbers of primary care patients in Murmansk, Russia experience prolonged respiratory symptoms. Smoking is common in this northern city and there is an urgent need to identify efficient ways for smoking cessation. This study reveals that several smokers have high motivation to quit smoking.

Pulmonology, University Hospital Albacete, Albacete, Spain

Material and methods: Retrospective descriptive analysis of the results obtained from patients who were attended in a Tobacco Consulting Room from 1 January to 31 December 2008 and subsequent follow-up to complete a year.

108. Smoking rate: smoking cessation interventions
Results: 268 of 410 patients (56.3% male), mean age 46 years and mean cigarettes/day 27.1. Statistical significance between cigarettes smoked and sex, higher in males. Respiratory comorbidity: 15.7% COPD, 9% asthma, 10.8% OSAHS and 1% OCD. Cardiovascular comorbidity, 7.83%, and psychiatric, 32.46% 44.4% without treatment, 22.8% NRT, 6.3% bupropion and 26.5% varenicline. Overall of the 268 patients, treatment success in 45 (16.8%), 29 men and 16 women. Percentage rises to 29.6% if we don’t consider those who didn’t attend the second consultation. Success among respiratory patients was statistically significantly longer compared with cardiac (27.1% vs. 4.7%, p < 0.03) and among non-psychiatric compared with psychiatric ones (19.8% vs. 10.3%, p < 0.05). Those who were treated pharmacologically, statistically significantly greater success among who used varenicline than NRT or bupropion (35.2% vs. 21.5%, p < 0.001).

Conclusions: 1. 62.92% didn’t start treatment (34.64% and 28.28%, first and second appointment respectively). 2. Cigarette consumption by males was significantly higher than women (28.51 vs. 25.08, p < 0.02). 3. Overall treatment success 16.8%, amounting to 29.6% excluding those who don’t attend the second consultation. 4. Greater success among respiratory than cardiac patients (27.1% vs. 4.7%) and among non-psychiatric than psychiatric ones (19.8% vs. 10.3%). 5. Greater success among varenicline than NRT or bupropion-treated (35.2% vs. 21.5%).

P1091 Special characteristics of smoking cessation program participants in a large municipal hospital in Greece

Georgios Makrantoni, Marios Kougias, Evangelos Balis, Konstantina Kotsilias, Stavroula Bousia, Maroussia Kouvela, George Tatsis, Department of Pulmonary Medicine, Evangelismos Hospital, Athens, Attiki, Greece

Introduction: Greece is the European Union country with the highest rate of tobacco consumption (more than 40%) enforcement of laws forbidding consumption of tobacco products, combined with public awareness of the adverse effects of smoking, result in the need for efficient smoking cessation centers.

Aims: The aim of the present study is to demonstrate special characteristics of smokers addressing to the smoking cessation center of Evangelismos hospital, in Athens Greece, including dependence, motivation profile, special characteristics such as depression profile and pulmonary function testing values.

Methods: Three hundred (300) smokers of mean age of 48.74±11.42 years, smoking 38.97±22.87 packyears participated in Evangelismos Hospital smoking cessation program during the last two years. A thorough medical history was obtained focusing on dependence and motivation for quitting.Pulmonary function testing, including spirometry was performed in all individuals. Statistical analysis was performed using the non-parametric test for sign values.

Results: Men smoke more than women (47.52±26.61 vs 35.33±22.05). One the other hand Greek women present more motivated to quit smoking than men (16.26±11.32 vs 10.08±12.08).In addition pulmonary function testing reveals high percentage of abnormalities caused by smoking, such as small airway disease. Abandoning the cessation program is significantly ralated (p<0.05) with a depressive profile of the participant.

Conclusions: Smoking cessation programs reveal interesting profiles of the Greek population, concerning the smoking habit, pulmonary function testing abnormalities and factors related to abandoning a smoking cessation program.

Objective: To assess what factors are associated with a higher rate of smoking cessation.

Material and methods: Cross-sectional study of a sample of smokers. Of a total of 1545 patients were analyzed those patients on whom information is available smoking within 6 months of follow-up. We defined 2 groups: group 1 who do not attend all visits but answer phone calls to complete a period of 6 months of treatment; group 2, patients attending all follow-up visits.

Results: See table. The results of the quantitative variables are expressed as mean and standard deviation. The results of the qualitative variables are described as the absolute value and percentage.

Greater success among varenicline than NRT or bupropion-treated (35.2% vs. 21.5%).

P1094 Abundance of smoking cessation reasons in participants of smoking cessation clinic

Zahra Hessami, Mahshid Aryanpur, Gholamreza Heydari, MohamamadReza Masjedi, Shabnam Esampanah. National Research Institute Tuberculosis and Lung Disease Tobacco Prevention and Control Research Center, Shahid Beheshti University, Tehran, Islamic Republic of Iran

Introduction: Cigarette smoking is an important cause of respiratory and other health problems around the world. Stop Smoking at any age could be decreasing these problems. Smokers finally think about smoking cessation. Having Strong reasons to quit is important factor for attempt to quit.

Objectives: We aimed to investigate what their motivations to quit are?

Method: This cross-sectional study was done on the volunteers of smoking cessation clinic of tobacco prevention and control research center. Data from (345)
Low-income is a predictive factor of failure associated with smoking cessation at a public clinic in Brazil

Rafaela F. Xavier, Dionei Ramos, Giovana N.B. Ferrari, Juliana T. Ito, Fernando M.M. Rodrigues, Alessandra C. Toledo, Ercy M.C. Ramos. Physiotherapy, UNESP - Sao Paulo State University, Presidente Prudente, Sao Paulo, Brazil

Smoking cessation programs (SCP) are the main way to reduce tobacco related mortality and morbidity. The search for predictors of failure or success specific to a population with special characteristics, such as Brazilians, should be the first step in the development of SCP national. We evaluated the demographic characteristics and factors influencing the failure or success of quitting among participants in a SCP. This retrospective study was conducted from 2008-2009 in a SCP based on cognitive behavioral treatment associated or not with medication therapy consisted in 20 meetings during 12 months. After that the individuals were invited to answer a socio-economic questionnaire by telephone. A total of 15% of individuals were included in this study and 65 agreed to answer a socio-economic questionnaire (aged=49±10, pack-years index=35±24, women=63%). Regarding education level: 50% had primary education, 29% had high school and 21% had university education. According with sociodemographic questionnaire 14% of the individuals were at class A2, 21% at class B2, 54% at class C1 and 11% at class D. After the fourth meeting 47.7% of individuals attempt to quit but only 32% of this professional aid in smoking cessation intervention in national programs.

Knowledge about tobacco according to smoking habit and level of formal education

Paulo Gregorio, Bruno Lemos, Aline Moraes, Felipe Mattos, Marina Sampayo, Priscila Viveiros, Ierna de Godoy. Clinical Medicine, Botucatu Medical School, Botucatu, Sao Paulo, Brazil

Tobacco related illnesses are important public health issues worldwide. Population’s knowledge about smoking and awareness about health risks are keys for cessation. We aimed to analyze the knowledge about tobacco and how this is influenced by smoking habit and level of formal education. We interviewed citizens who took part in an event of preventive health in a town of the State of Sao Paulo, Brazil. We interviewed 190 subjects, with age 49.5 ± 18y, 59% males, 26.3% smokers, 49% non-smokers and 24.7% former smokers. A standard questionnaire was applied with the following main questions: 1) Is tobacco dependence a disease?; 2) Is low level of consumption safe?; 3) Do you receive any information about smoking cessation?; 4) Is tobacco a disease?; 5) Do you want to stop smoking? A total of 87% of the subjects interviewed received some kind of information about their health. However, 27% of them did not consider smoking a disease and 32% considered that a low level of smoking would not represent a danger or risk to their health.

In conclusion, the percentage of smokers in our sample is consistent with the prevalence of tobacco smoking in our country. The percentage of former smokers reflects the impact of Brazilian policies for tobacco control. Although anti-smoking campaign are designed to reach all social layers through an accessible language, we find that the knowledge about tobacco are still incomplete among general population.

Smoking prevalence and smoking behaviour among Portuguese physicians: A cross-sectional study

Soia Belo Ravara, Miguel Castelo Branco, Jose Manuel Calheiros. Health Sciences Research Centre (CICs), Faculty of Health Sciences (FCS), University of Beira Interior (UBi), Covilhá, Portugal

Background: Studies evaluating Portuguese physicians’ smoking behaviour are limited and applied different methodologies. Studies from the 70’s and 80’s show high prevalence rates, higher than the general population. Recent studies had reported decreasing smoking prevalence trends. However, it is not clear if physicians are smoking less than the general population and whether this decreasing trend has continued thereafter. In 2009, a survey was carried out to evaluate smoking prevalence trends and smoking behaviour among Portuguese physicians.

Methods: Questionnaire-based cross-sectional study, conducted during two main national medical conferences, using a convenience-sample methodology. Physician smoking behaviour was self-reported.

Results: Participants: 607 physicians; 57.6% primary care; 33.1% hospital-based specialists; 9.3% undergraduate students; 62.7% females; median age 34. Smoking prevalence was 29.6% in males, 15.3% in females (p < 0.001). Smoking prevalence was not related to medical specialty; 53.3% of the smokers reported being daily smokers, smoking in average 10 cigarettes a day; median of regular smoking age was 18 years. 46% of the smokers reported desire to stop smoking, 56.7% had already tried to quit but only 33.8% reported needing assistance on their quit attempt. Age-gender specific analyses revealed that the majority of younger physicians (aged≤44) reported being never smokers (males: 62.7%; females: 77.6%), in contrast to older smokers (p < 0.001).

Conclusions: Smoking prevalence among Portuguese physicians is decreasing and is lower than in general population. Physicians smoke less cigarettes and reported more occasional smoking than the general population.
Smoking cessation is associated with substantial health benefits. Nevertheless out-
coming of smoking cessation was often investigated on strongly selected populations.
We aimed to assess the influence of our smoking cessation programme on lung function under real life conditions.

703 smoking employees from University Hospital Basel, Switzerland, and two local health industry companies (Novartis Pharma AG, Hoffmann-La Roche AG) participated on a structured smoking cessation programme. The programme consisted of 10 visits with counselling and motivational support within 2 years of follow-up. Various modalities of both nicotine replacement therapy and/or bupro-

P1102 Exhaled carbon monoxide according to daily cigarette consumption in
healthy smokers
Juliana Zabatore1, Demétria Kovelis1, Mahara Pronça1, Karina Furlanetto1, Leandro Camões2, Filoñ Pinto1, Gabriela de Aquino em Fisioterapia Pulmonar (LFPF), Universidade Estadual de Londrina (UEL), Londrina, Brazil; 2Programa de Mestrado em Fisioterapia, Universidade Estadual Paulista Julio de Mesquita Filho (UNESP), Presidente Prudente, Brazil

Methods: To compare the exhaled carbon monoxide (CO) levels in apparently healthy smokers according to the intensity of cigarette consumption and verify its relationship with lung function and nicotine dependence.

Methods: Forty-four healthy smokers (20 male, 48±12 years, BMI: 27.4±4 kg/m²)
were influenced by BMI (p=0.017, β=0.358) and the number of cigarettes smoked per day (p=0.025, β=0.398). SOD was also negatively influenced by BMI and WC (p<0.05 for both). FEV1 was related negatively with WC (p=0.047, β=0.31).

Conclusion: There is an increased oxidative stress and chronic inflammation in heavy smokers with long smoking history. These processes are closely linked with obesity, which along with smoking increase the risk of early decline in lung function.

P1101 Active smoking negatively affects recovery of patients hospitalized due to
acute exacerbation of chronic obstructive pulmonary disease (COPD)
Andrea Schäfer, Noémi Eszes, Zsuzsanna Kováts, Veronika Mülter. Pulmonology, Semmelweis University, Budapest, Hungary

COPD is a progressive inflammatory airway disease most often caused by smoking. Significant proportion of COPD patients continues to smoke even in advanced stages, mainly as the result of severe tobacco dependence. COPD predisposes to depression making symptoms worse. Frequency and effects of active smoking and depression in patients hospitalized due to acute exacerbation of COPD is unknown. One hundred patients admitted to the Department of Pulmonology Semmelweis University with the diagnosis of COPD acute exacerbation were analyzed (men: women = 46:54). Detailed history, Fagerström nicotine dependence test (FNDT) and the Beck depression inventory scale were registered, expired CO was mea-

The outcome of a smoking cessation attempt as well as baseline lung function and medication significantly influenced FEV1 within 2 years of a quit attempt. These observations could be important in encouraging smokers to stop smoking.

References:

Results:
Significant correlation of 0.4 with the number of cigarettes smoked in the last 24h (p<0.05). In patients with FEV1<30% predicted, there was no significant decrease of FEV1 at baseline (p=0.056). The changes in FEV1 and in CO levels between G1 and G3 (p=0.013) but not between G1 and G2 (p=0.138). When analyzing the relationship between CO levels of smokers as a whole with smoking habits and nicotine dependence, moderate cor-
relations were found with number of cigarettes smoked in the last 24h (p=0.54, p<0.01), cigarettes/day (p=0.53, p<0.01), FTQ (p=0.33, p=0.02), pack-years (p=0.32, p=0.03) and time since last cigarette smoked (r = 0.31, p<0.04). These relationships were not found when assessing each group separately.

Conclusions: Exhaled CO levels are higher in heavy smokers in comparison to moderate and light smokers, whereas no difference was found between moderate and light smokers. Moreover, CO levels are related with smoking habits and nicotine dependence.

P1103 Effects of paternal tobacco use on different parameters of a newborn child
Seyed Ali Arsalan1, Aneel Roy Bhagwani2, Inzor Arif Farhan2, Sadaf Kanwal2, Haleema Hashmi3, Seyed Ali Abbas4, Seyed Arshad Hasain4. 1Pulmonology, Liaquat National Hospital Medical College, Karachi, Sindh, Pakistan; 2Medical College, Liaquat National Hospital and Medical College, Karachi, Sindh, Pakistan; 3Gynaecology and Obstetrics, Liaquat National Hospital and Medical College, Karachi, Sindh, Pakistan; 4Pulmonology, NHS Trust Tansell Bridge, Kent, United Kingdom

Introduction: There has been significant research done on the effects of maternal smoking on pregnancy but not much data is available regarding the role of paternal smoking and its effect on the vitals of a newborn child. We therefore tried to evaluate the effects of paternal tobacco use on newborn child.

Methods: A prospective study carried out in gynecology and obstetrics department of our hospital. A questionnaire based interview was conducted with the delivering females in the month of October 2010 in terms of tobacco use of their spouse during pregnancy. The neonatal vitals were assessed and previous abortion history was also inquired.

Results: Age of the delivering females was 28.34 years ±4.095 S.D. Females delivered was n=100. Tobacco use was found among spouses of n=25 females. Out of them n=14 were smokers and n=13 chewed tobacco whose husbands smoked (n=14) previous abortion history was found in n=6 (42.85%) females out of which n=2 females were exposed to tobacco smoke during those earlier pregnancies, as compared to females with non smoking husbands (n=38) previous abortion was noted in n=19 (20.09%). Among females whose husbands chewed tobacco (n=11) previous abortion history was found in n=3 females. Among n=2 preterm neonates n=1 had paternal smoking history. Of n=7 neonates with respiratory distress n=2 had paternal smoking history, n=1 (out of n=2) had delayed sucking and n=1 had delayed micturition.

Conclusions: Our results suggest that paternal tobacco consumption might have risks to the newborn child & ongoing pregnancy. Paternal smoking may have biological correlation with such outcomes. Further research should be carried out in this aspect.

P1104 Smoking cessation in tuberculosis and COPD patients
N.V. Yahorava, H.L. Hurvech, A.A. Ringa, M.A. Skrahna, T.M. Krytskaia. Clinical, RSFC for Pulmonology and Tuberculosis, Minsk, Belarus

The aim of this study was to investigate clinical, nicotine dependence status in smoking tuberculosis (TB) and COPD pts, efficacy of treatment of nicotine depen-
dence by nicotine acetylcholine receptor agonist (cytine), mexidol, behavioural intervention in TB and COPD pts.

Methods: 91 smoking TB and COPD pts (74m, 17w, age 41±8) were examined before and after 3 months of treatment. 50 Pts have been treated with 4-5 anti-
tuberculosis drugs, basic course of COPD (82-agonist, anticholinergic, corticoids, 02), cytine (1.5-5mg/dag-25days), mexidol (100mg/dag-25days), behavioursal intervention. 41 Pts have received 4-5 antibacterial drugs and basic course of COPD only (Gr2). Examination of clinical status, blood gases, pulmonary function tests, quiz pts about their smoking status had been performed in all pts.

Results: In TB and COPD pts was found low nicotine dependence, low moti-
vation to quit. After 3 months of treatment in TB and COPD pts clinical status was improved. Smoking cessation was achieved in 16% pts of Gr1, decrease of nicotine consumption-60% pts of Gr1. In 76% pts of Gr1, 71% pts of Gr2 was found improvement of chest X-ray. Sputum conversion was found in 80% pts of Gr1, 73% pts of Gr2. In Gr1 was found increase of forced expiratory volume in 1 second for predicted on 14%, p<0.05, peak expiratory flow for predicted on 13%, p<0.05, decrease of PCO2 on 14%, p<0.01, HCO3- on 8%, p<0.05. In COPD pts changes were not found.

Conclusions: In TB and COPD pts treatment of smoking, mexidol, behavioural inter-
tervention to antibacterial and basic course of COPD leads to decrease of level
of nicotine consumption, improvement of clinical, blood gases exchange status, pulmonary function.

P1105
Association between dopamine transporter, monoamine oxidases genotypes and tobacco smoking
Marina Smirnova1, Natalia Mitushkina2, Olga Suhovskaya1, Evgeniy Imyanitov1, 2
1Palmolivia, State Medical University, St. Petersburg, Russian Federation; 2Oncology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation

There are many polymorphisms of genes involved in metabolism of compounds contained in tobacco smoke (MAOA, MAOB, DATI and DRD2). Dopamine (DA) is critical for reward and its predictive signals, genetically driven variation in DA transmission may account for the observed differences.

The aim of study was to examine interactions between DATI and MAOA polymorphisms and nicotine dependence, number of cigarettes and successful quit smoking in healthy smokers, patients with COPD and asthma.

Methods: 99 smokers-males (36-78 years) were genotyped for polymorphisms of DATI, MAOA. CO breath testing has been made for cigarette smokers.

Information about current tobacco consumption was obtained using self-report measures and structured interviews.

Results: Age at initiation of smoking was assessed at age 12 and 22 years. Results suggest that age at onset of intensive consumption and nicotine dependence (ND) moderated the association of the DATI gene. Individuals with DATI 40 bp (6R, 7R, 8R) and DATI 30bp (5R) had lower nicotine dependence and they quit smoking more successful than smokers with DATI 40 bp (10R, 11R) p=0.038 and DATI 30bp (6R, 7R, p=0.029). ND patients with COPD p=2.54±0.36 (from 4 to 10), asthma 3.15±0.44 (from 3 to 8). Patients with COPD more often had DATI 40 bp (10R, 11R) than patients with asthma (p=0.039).

Have been revealed association between the MAOA polymorphism and smoking (p=0.48). Smokers with COPD and smokers with several nicotine withdrawal more often had 3R 4R MAOA.

Conclusion: These results support the hypothesis that the DATI and MAOA polymorphisms are associated with smoking cessation and can influence on smoking cessation in patients with COPD.

P1106
Smoking induced satellite associations in a rural population of south India
Rangananid Pajanjive1, Uma Natarajan1, 2Department of Respiratory Medicine, Indira Gandhi Medical College & Research Institute, Kadirkamam, Vadukchery, India; 1Department of Anatomy, Cytogenetics Division, Mahatma Gandhi Medical College & Research Institute, Vadukchery, India

A smoker is exposed to a variety of carcinogenic constituents present in cigarettes, making it essential to analyze the biological effects of these constituents as they may be a health hazard to the future generations1. Cytogenetic assay in peripheral blood lymphocytes was done to assess the incidence of Satellite Associations among 30 smokers and 30 non-smokers in a rural population of South India. Smokers were divided into three groups based on their Smoking Index (SI): I - SI less than 150, II - SI 150 to 300, III - SI more than 300. An equal number of matched control individuals were selected and Lymphocyte cultures were set up from heparinised blood. The mean frequency of satellite association in smokers belonging to group I, II and III were 45 (44.25±3.30), 53 (53±6.34) and 67 (67±6.22) respectively, whereas the mean frequency of satellite association in non-smokers was 29.83% (29.83±6.22) respectively.

The frequency of Satellite Associations in smokers I, II and III increased with the increase in the frequency of their smoking index than their non smoking counterpart. The students 1"t" test (SSP software) for satellite association was found to be highly significant at p ≤ 0.01 in all the three Smoker Group viz. I, II and III.

These findings confirm the genotoxic effect of cigarette smoke on the chromosomes and can be used as a Smoking Cessation Intervention tool.

Single-breath lung diffusion capacity for carbon monoxide in children and young adults born extremely preterm
Emile Sadath1, Ola Rokhsand2,3, Einar Thoresen1, Thomas Halvorsen1, 2
1Department of Clinical Medicine, University of Bergen, Bergen, Norway; 2Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 3Institute of Medicine, University of Bergen, Bergen, Norway

Introduction: Extreme preterm (EP) birth is associated with acinar developmental alterations, potentially influencing lung diffusing capacity (DLCO) and gas exchange. Techniques of measurement are complex and feasibility in children needs to be addressed.

Aims: To study repeatability of DLCO in children and young adults, and to compare results of subjects born EP and at term in two different decades.

Methods: Two area-based cohorts of subjects born at gestational age (GA) ≥28 weeks or with birth weight (BW) ≥ 1000 grams in the two periods 1991-1992 (n=35) and 1982-1985 (n=46) and matched controls born at term performed single-breath DLCO tests twice within two weeks. Mean ages (SD) were 10.6 (0.4) and 17.7 (1.2) years.

Results: The coefficient of variation for interession measurements of DLCO for subjects born preterm and at term in the 1991-92 and 1982-85 birth-cohorts were 8.2 and 7.7%, and 9.5 and 7.6%, respectively. EP birth was associated with significantly reduced height adjusted DLCO and with lower KCO**. Deficits were similar in the two birth-cohorts (test of interaction, p = 0.410).

P1108
Effect of prenatal exposure to tobacco on lung function of infants born preterm
Manuel Sanchez-Solis1,2, Luis Garcia-Marcos1,2, Virginia Perez3, Pedro Mondejar1, Maria Dolores Pastor1
1Pediatric Service, Universitary Hospital Virgen de la Arrixaca, Murcia, Spain; 2Pediatric Department, University of Murcia, Murcia, Spain

Introduction: The exposure of fetuses to tobacco during pregnancy, in otherwise healthy infants born at term, is associated to lower expiratory flows as measured both by means of the rapid thoracoabdominal compression technique (RTC) and by the raised-volume rapid thoracoabdominal compression technique (RVRTC).

The aim of the present study is to measure lung function by RVRTC in healthy infants born preterm exposed or non-exposed to tobacco in pregnancy.

Methods: Forced vital capacity (FVC), forced expiratory flows at 50%, 75%, 25-75% of FVC (FEV50, FEV75, FEF57, FEF25-75) and forced expiratory flow at 0.5 sec (FEV50), were obtained by RVRTC. These parameters were compared to controls born at term, at a corrected age of 7 months, without neonatal respiratory distress. A multivariate linear regression analysis adjusted for gender, gestational age, corrected age, length and prenatal tobacco exposure, was performed.

Results:

Conclusions: Infections born preterm, at a corrected age of ~7 months, prenatal tobacco exposure is significantly associated to a lower FVC, but does not change forced expiratory flows.

P1109
Acetazolamide for severe hyperventilation and apnea in a child with Pitt-Hopkins syndrome
Stijn Verbout1, Wilfried De Backer2
1Pediatrics, University of Antwerp, Wilrijk, Belgium; 2Respiratory Medicine, University of Antwerp, Wilrijk, Belgium

Case report: We present the case of a 9 year old boy with Pitt-Hopkins syndrome...
In view of the hyperventilation, we started the patient on 250 mg of acetazolamide once daily. The patient was reevaluated one and a half month later. The clinical picture was markedly improved: long lasting apneas and episodes of syncope were no longer observed. A blood gas showed a pH of 7.35 with a pCO2 of 32.9 mmHg and a base excess of -6.5 mmol/L. Polygraphic monitoring showed the presence of several short central apneas but with preserved oxygen saturation and a more stable CO2 curve.

Discussion: Pts-Hopkins syndrome is due to de novo mutations at the TCF4 locus and is characterised by distinct facial features, mental retardation and episodic hyperventilation with apnea while awake. Both the pathogenesis of these hyperventilation episodes as its treatment are unknown. This is the first report on the positive effect of acetazolamide on daytime hyperventilation and apnea in this syndrome. In this view; it would also be interesting to study the effects of acetazolamide in patients with similar syndromes including Rett and Joubert syndrome.

P1110
Peripheral airway function versus spirometry in childhood asthma
Sanna Kjellberg1, Paul Robinson2, Emilia Viklund1, Maria Strom1, Per Gustafsson1, Department of Paediatrics, Central Hospital, Skövde, Sweden;2Department of Respiratory Medicine, Children’s Hospital at Westmead, Sydney, New South Wales, Australia.

Background: Tests of peripheral airway function are rarely used in clinical studies of paediatric asthma. The relationships between FEV1 and indices of small airway function from inert gas washout and impulse oscillometry have not been directly compared and are largely unknown.

Methods: Scord and Sacin (inert gas indices of ventilation inhomogeneity in the conducting and acinar airway zones, respectively) were measured from mass spectrometer multiple breath SF6 washout. Frequency dependence of resistance (R5-R20Hz, a measure of small airway obstruction) was measured using impulse oscillometry (IOS). Both of these tests were performed prior to spirometry, both at baseline and post-bronchodilatation (BD) (400 mcg salbutamol inhalation) in 58 subjects aged 8-18 yrs with stable asthma of mild to moderate severity. Reference values for Scord and Sacin were obtained from 45 healthy subjects and for R5-R20Hz from 169 age matched controls. Spirometric reference values were taken from Staňojević et al 2009 [1]. Results were expressed as z-scores.

Results: FEV1 was normal (z score > 1.96) in 48/58 (83%) at baseline and 58/58 (100%) subjects post-BD. In those subjects with normal FEV1 abnormal (z score > 1.96) R5-R20Hz, Scord and Sacin were found in 38/48 (79%), 26/47 (55%), and 5/47 (11%) at baseline and 18/58 (31%), 15/56 (27%) and 4/45 (9%) of subjects post BD, respectively.

Conclusions: Peripheral airway dysfunction is common in school age asthmatics with normal FEV1. This abnormality persists in almost a third despite bronchodilatation. The most sensitive indices to detect this peripheral abnormality are R5-R20Hz and Scord.

P1111
Vocal cord dysfunction in adolescents
Johannes Schulze, Sarah Weber, Martin Rosewich, Olaf Eickemeyer, Markus Rose, Stefan Zieilen, Department of Allergy, Pulmonology and Cystic Fibrosis, Children’s Hospital, Goethe-University, Frankfurt, Germany.

Background: Vocal cord dysfunction (VCD) often presents with dramatic and abrupt symptoms. To diagnose VCD, visualisation by direct laryngoscopy is required and usually a specific method to provoke VCD is needed.

Objectives: Adolescents with clinical suspicion of VCD were invited to participate. The first objective was to diagnose VCD, second objectives were changes of pulmonary function test (PFT) and predictors of VCD before and after methacholine challenge test (MCT).

Methods: After an initial PFT, a direct laryngoscopy was performed. This was followed by the MCT; the endpoint was the methacholine dose causing a 20% drop of the forced expiratory volume in one second (PD20FEV1). After that a second laryngoscopy was conducted. PFT changes before and after MCT were compared with the data of 14 healthy controls (HC).

Results: Thirty-five patients (8-19 years) were investigated. Three failed to have a significant reaction to methacholine and three showed anatomical alterations. In the remaining 29 patients, 14 had VCD and 15 had bronchial hypersensitiveness (non-VCD). PD20FEV1 methacholine was significant lower in VCD compared with non-VCD (VCD 0.24 mg ± 0.4, non-VCD 0.73 mg ± 0.73; p= 0.001). VCD patients showed significantly lower PFT parameters after MCT; FEV1, VCD 58.5% ± 20.1, non-VCD 77.8% ± 18.4, and HC 98.7% ± 16.6 (p< 0.0001); inspiratory vital capacity (IVC); VCD 61.3% ± 20.9, non-VCD 75.7% ± 14.8, and HC 101.1% ± 15.4 (p< 0.0004).

Conclusions: The combination of MCT and laryngoscopy may be able to differentiate between VCD and non-VCD patients. VCD patients showed a positive reaction at lower methacholine doses and had a higher airway obstruction. PFT and MCT do not replace direct laryngoscopy in the diagnosis of VCD in adolescents.

P1112
Evolution of lung function in preterm infants with or without bronchopulmonary dysplasia
Manuel Sanchez-Solis1,2, Luis Garcia-Marcos1,2, Virginia Perez1,2, Maria Dolores Pastor1, Pedro Mondejar1,3, Pediatric Service, University Hospital Virgen de la Arrixaca, Murcia, Spain;2Pediatric Department, University of Murcia, Murcia, Spain.

Introduction: Healthy preterm infants do not catch-up lung function (LF) during the first two years of life. The aim of study is to compare the evolution of LF in infants born preterm, with and without BPD.

Methods: Forced vital capacity (FVC), forced expiratory flows at 50%, 75%, 25-75% of FVC (FEF50, FEF75, FEF25-75) and forced expiratory flow at 0.5 sec (FEF0.5) was obtained by raised volume rapid thoracoabdominal compression technique (RVRTC) in 14 (7 males) BDP+ and in 12 (6 males) infants born preterm BDP-. Measurements were repeated at 6 and 12 moths after baseline. A generalized estimating equations (GEE) adjusted for gestational age, length, corrected age and body mass index z-score (according OMS tables) was built for boys and girls separately.

Results:

Conclusions: FVC, FEF25-75 and FEF0.5 decrease among male infants with BPD as compared to those without BPD; however in female infants they tend to be similar, and FEF50, FEF25-75 and FEV0.5/FVC even improve.
Field test and an ergospirometry with maximal stress on a treadmill and study the correlation between the principle variables of both tests.

Methods: It is a descriptive transversal study carried out amongst obese children from 6 to 14 years old with a control group of normal-weight children. A 6MWTD and an ergospirometry on a treadmill with an incremental maximal stress protocol according to the ERS/ATS recommendations were carried out on the obese children. On the control group, the 6MWTD was carried out.

Results: A total of 28 obese children (17 male, 61% were studied, with an average age of 10.90 years old (±2.43) and a BMI of 27.61 kg/m² (±3.46). The average 6MWD was 539.4 m (±44.6), which makes up 92.94% (+11.27) of the theoretical. The HRmax in the 6MWT was 70.10% (±7.24) of the maximum and the perceived effort scale (PE) was 6.8 (±1.6). The VO2peak was 35.64 ml/kg/min (±5.86), placing itself at 83.21% (±5.86) of the theoretical. The HRmax was 192.84 bpm (±10.10) which makes up 92.05% (+5.17) of the maximum. The RER was 1.15 (±0.13) and the PE was 9.40 (±0.84). The correlation between the 6MWD and the VO2peak was not significant (p=0.05). In the group of normal-weight children, the 6MWD was 95.5% (±7.56) of the theoretical, the HRmax% was 60.75% (±7.96) and the average was 83.21% (±6.13). Significant differences (p<0.05) were found between the PE and the HRmax% reached between the group of normal-weight and the obese children.

Conclusions: The obese children are able to maintain the distance walked in the sub-maximal stress test at the expense of a greater maximal heart rate and a greater stress perception than the normal-weight children.

P1116 Respiratory impedance using forced oscillation technique in preschool children with a history of wheezing

Claudia Calogero1, Niccolò Parri1, Graziia Femii1, Peter Sty1, Barbara Cuomo1, Maximo Palumbo1, Emanuele Lombardi2, 1Section of Respiratory Medicine, “Anna Meyer” University Hospital for Children, Florence, Italy; 2Queensland Children’s Medical Research Institute, University of Queensland, Brisbane, Australia; 3Department of Paediatrics, “Anna Meyer” Hospital, Viterbo, Italy

Background: This study aimed to assess respiratory impedance using the forced oscillation technique (FOT) in preschool children with a history of wheezing. Methods: FOT respiratory resistance (Rs) and reactance (Xs) were assessed in children at 6, 10, 15, and 20 years of age, as well as resonant frequency (Fres), were measured in kindergartens. Children were labelled to have a history of wheezing (WZ) if, based on questionnaires, they had had a diagnosis of asthma, or >3 episodes of WZ, ever, or WZ during the previous year. All children had no respiratory symptoms or signs at the time of testing. Post-bronchodilator (BD) impedance was assessed 15 min after administration of salmeterol 200 mcg via MDI and a spacer.

Results: A total of 165 healthy (H) children (82 female; median age 4.8 yr, range 2.9-6.1) and 64 WZ children (25 female, median age 4.6 yr, range 2.7-6.0) were evaluated. Mean (SD) Rs, Xs and Fres are reported in the table. Post-BD changes were not significantly different in the two groups.

Conclusions: Rs, Xs and Fres were not significantly different in asymptomatic preschool children of a history of WZ and in controls. Other indices, such as the area under the curve of Xs, need to be investigated.

P1117 Detection of bronchodilator effect by spirometry in preschool asthmatic children

Daphna Vilozni1,2, Gilat Livnat1, Fahed Hakim1, Lea Bentur1, 1Pediatric Pulmonary Unit, Meyer Children’s Hospital, Rambam Health Care Campus, The Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel; 2Pediatric Pulmonary Unit, The Edmond and Lili Safra Children’s Hospital, Sheba Medical Center, Affiliated with Sackler Medical School, Tel-Aviv University, Ramat-Gan, Israel

Study objective: Measuring bronchodilator (BD) response in school children by spirometry is an integral part of asthma diagnosis and assessment. However, the applicability of the spirometry criteria to preschool age is questionable. We measured changes in forced spirometry indices to determine their ability to detect BD-response in asthmatic preschool children.

Patients and methods: Data of 288 children (aged 2.6-6.9y) were analyzed. Spirometry tests were carried out before and 15 minutes after BD-inhalation in 145 asthmatic children. Data was compared to that of 39 controls and to that after inhalations of saline (n=104 asthmatics)administered similarly. An increase above 12% from baseline FEV1 after intervention was considered significant. Response of other spirometry indices were related to change in FEV1.

Where there’s smoke there’s fire! What is the function?

Peggy Radford. Pediatric Pulmonary, Phoenix Children’s Hospital, Phoenix, AZ, United States

Morbidity and mortality from smoke inhalation occurs in victims of fire. This study’s purpose is to report infant pulmonary function (IPF) in children exposed to smoke from a building fire. The children received care in another facility and were referred to our center for IPF. IPL was performed on 45 children; 23 females, 22 males mean age of 114 weeks; range 50 to 173 weeks at the time of testing. Time to testing after the fire was 8.4 months (range 3-17 mos). Conscious sedation was used for raised Vocal than subglottal compression as the IPL technique. Pre-bronchodilator results were obtained on 45 children.

The low TLC group also had significantly lower FVC and FEV 1 than the normal TLC group. The results of 45 children showed low normal TLC and FVC. When the results compared abnormal TLC% versus normal TLC%, the low TLC% group also had significantly lower FVC and FEV 1 than normal TLC% group. These findings are similar to the decline in FVC found in World Trade Center workers. Mildly increased specific compliance of the respiratory system was also found. No restrictive pattern was detected. Serial IPFT assessments in our cohort is required to validate present data.

Longitudinal assessment of lung function in children and adolescents with sickle cell anemia

Alan Lunt1, Gerard F. Rafferty1, David Rees2, Sue Height2, Anne Greenough1. 1Division of Asthma, Allergy and Lung Biology, King’s College ‘London, London, United Kingdom; 2Department of Paediatric Haematology, King’s College Hospital, London, United Kingdom

Aim: Lung function studies in children with sickle cell disease (SCD) have not identified consistent abnormalities. The results, however, of two cross-sectional studies suggest restrictive abnormalities become more prominent with increasing age. Our aim was, by undertaking serial comprehensive assessments in SCD children, to further characterize any changes in lung function with increasing age.

Methods: Two cohorts of SCD children were recruited. Cohort 1: 21 children, mean age at baseline 8.1 (range 2.9-12.0) years and mean length of follow-up 9.0 (8.1-9.8) years. Lung function was assessed by spirometry and body plethysmography.

Results: Lung function declined significantly in both cohorts. The results are expressed as median (IQR) and percentage predicted for height.

Comparison of the data from the two cohorts demonstrates a faster decline in cohort one.

Conclusion: Children and adolescents with SCD suffer deterioration in lung function with increasing age; the speed of decline is greatest in young children.

P1120

Pediatric pulmonary function testing in infants and toddlers with perinatal burden

J.1,2,3 Vaclav Krehdab1, Jan Zikan1, Petr Kottak1, Jana Tovkova1, Petr Pohunek2, Pavel Kol1, Daniela Markova1, 1Dept. Paediatrics and Adolescent Medicine, General Teaching Hospital and Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 2Dept. Pediatrics, Charles University in Prague, 2nd Faculty of Medicine and University Hospital Motol, Prague 5, Czech Republic; 3Dept. Rehabilitation and Physical Medicine, Charles University in Prague, 2nd Faculty of Medicine and University Hospital Motol, Prague 5, Czech Republic

Methods of infant pulmonary function testing (IPPT) represent an important diagnostic tool for an assessment of chronic lung disease in infancy (CLDI). We assessed lung function in a cohort of children with a perinatal burden. We tested 74 infants and toddlers (birth weight 1.47±1.1 kg [mean±SD]; body length at birth 30±6.13 cm, with CLDI). Age at testing was 1.36±0.69 (median 1.35) yrs; body weight 9.0±2.2 kg; body length 76.0±9.7 cm. The whole-body plethysmography (to measure FRCp and sReff), tidal breathing analysis (IPPTE%e), baby resistance/compliance (specific Crs) and rapid thoraco-abdominal compression method (VmaxFRC) were performed. MS Baby Body, VIASYS, USA was used. Standard protocols [1] and proper reference values [2] were used.

IPPT equals 115±4.412% pred (P<0.02), sReff reached 134±6.938% pred (P<0.0005). The response of the control group to bronchodilators or to Saline was negligence.

Other indices increased by 23.4±2.1% (n=69%, 70%, and 74% of the group; p<0.001 for all). The response of the control group to bronchodilators or to Saline was negligence.

Conclusion: Infant pulmonary function testing (IPPT) represents an important diagnostic tool for an assessment of chronic lung disease in infancy (CLDI). We assessed lung function in a cohort of children with a perinatal burden. We tested 74 infants and toddlers (birth weight 1.47±1.1 kg [mean±SD]; body length at birth 30±6.13 cm, with CLDI). Age at testing was 1.36±0.69 (median 1.35) yrs; body weight 9.0±2.2 kg; body length 76.0±9.7 cm. The whole-body plethysmography (to measure FRCp and sReff), tidal breathing analysis (IPPTE%e), baby resistance/compliance (specific Crs) and rapid thoraco-abdominal compression method (VmaxFRC) were performed. MS Baby Body, VIASYS, USA was used. Standard protocols [1] and proper reference values [2] were used.

IPPT equals 115±4.412% pred (P<0.02), sReff reached 134±6.938% pred (P<0.0005). The response of the control group to bronchodilators or to Saline was negligence.

Comparison of the data from the two cohorts demonstrates a faster decline in cohort one.

Conclusion: Children and adolescents with SCD suffer deterioration in lung function with increasing age; the speed of decline is greatest in young children.

P1121

Validity of volumetric vest respiratory measurements in preterm infants with changes in posture

Sarah Kent1, Catherine Olden1, Heike Rabé2, Paul Seddon1. 1Respiratory Unit, Royal Alexandra Children’s Hospital, Brighton, United Kingdom; 2Trevor Mann Baby Unit, Royal Sussex County Hospital, Brighton, United Kingdom

Respiratory measurements in unsedated infants are problematic: applying a face mask causes arousal and changes respiratory pattern. We have previously validated a volumetric vest system (FloRight) in normal newborn infants. However, other calibrated chest wall measurements (eg Respirate) lose validity if posture or chest shape changes.

In order to assess whether this system remained valid with chest distortion and changes in posture, we measured tidal breathing in 11 preterm infants (median 30 weeks at birth) simultaneously by mask/ultrasonic flowmeter and FloRight, both in supine (S) and randomised right or left lateral position (L). The following tidal breathing parameters were compared over 20 breaths of stable breathing in quiet sleep: tidal volume (Vt), timing of peak tidal expiratory flow (vtpvfe (%) and expiratory inspiratory time ratio (tI/T).

FloRight measurements were closely correlated with mask measurements in both S and L. Vt S=0.99, L=0.99, vtpvfe (%) 0.94 and 0.96, tI/T 0.97 and 0.96. FloRight Vt measurements were slightly but significantly higher than mask, both in S (1±2ml, p<0.02) and L (1±4ml, p<0.001) but vtpvfe (%) and tI/T measurements were not significantly different.

FloRight accurately measures tidal flow timing parameters in small preterm infants both in supine and lateral posture. Tidal volume measurements are highly correlated but slightly overestimated compared to mask; especially in lateral lying: this could be due to the vest not fully conforming to chest distortion.
Aims: To study the usefulness of a supra-maximal stress protocol to confirm the achievement of a maximal oxygen consumption in cardiopulmonary stress tests amongst obese children.

Methods: It is a descriptive transversal study carried out upon obese children from 6 to 14 years old. An ergospirometry is carried out on them with a treadmill with an incremental maximal stress protocol and after 15 minutes of rest the supra-maximal stress protocol is applied with 105% of the intensity previously obtained.

Results: A total of 24 obese children (15 male, 62.5%) were studied, with an average age of 10.98 years old (±2.18) and an average BMI of 27.44 (±3.31).

A plateau was not found for the oxygen consumption in any instance. A total of the supra-maximal test, the VO₂peak was 2.15 l/min (±0.57), RER 1.16 (±0.58), RER 1.05 (±0.11) and HRmax% 91.5 (±3.18).

Conclusions: The execution of a supra-maximal stress test after a period of rest after a normal test is feasible amongst obese children. The classic criteria that define the success of the VO₂max can be inadequate for this group, thus, carrying out a supra-maximal stress test would be useful in order to verify it.

P1123

Prescription of physical exercise for obese children based on cardiopulmonary exercise tests

Laura Fidalgo-Marrón1, Estela Infanzón-Marrón2, Ester Cid-Parrís1, Alfonso Ortigado-Matamala1, Pilar Sevilla-Ramos1, Jose Maria Emeens-Bustos1, Pediatria, Hospital Universitario de Guadalajara, Guadalajara, Spain; 2Medicine Faculty, Universidad Complutense de Madrid, Madrid, Spain

Aims: To study the differences between the theoretical training zones and those obtained using a cardiopulmonary stress test for the prescription of slight-moderate intensity physical exercise amongst obese children. To correlate the exercise intensity in the theoretical zones and those obtained with the degree of perceived effort.

Methods: It is a descriptive transversal study carried out amongst obese children from 6 to 14 years old. An ergospirometry was carried out on a treadmill with an incremental maximal stress protocol according to the ATS/ERS recommendations. The anaerobic threshold (AT) was calculated using the V-slope method, collecting the HR reading at this point and assigning the perceived effort scale value (PCERT) obtained at that moment. The differences between the theoretical HR at AT and the collected one were subsequently studied.

Results: A total of 28 obese children (17male, 61%) were studied, with an average age of 10.90 years old (±2.43) and a BMI of 27.61 kg/m² (±3.46). The average HR at AT was 117.45 bpm (±15.67) which corresponds to 56.29% (±7.56) of the maximal. Theoretically, the threshold would be in an range around 75% of the maximum, which would make up an average difference of 48.96 bpm (±15.29) (p<0.0001) with the actual anaerobic threshold. The perceived effort value was between 1 and 2.

Conclusions: The prescription of physical exercise for obese children with varied controlled intensities must be personally carried out and based on a cardiopulmonary exercise test feasible amongst obese children. The classic criteria that define the success of the VO₂max can be inadequate for this group, thus, carrying out a supra-maximal stress test would be useful in order to verify it.

P1124

Effects of oral breathing and cervical postural alteration in respiratory mechanics and exercise capacity

Renata Tiemi Okuro1, André Moreno Morcello1, Maria Ângela G. Oliveira Ribeiro1, Edvalda Sakano2, Camila Isabel Santos Schiavon3, José Dirceu Ribeiro1, Pneumologia, Universidade Federal de Campinas, Campinas, São Paulo, Brazil; 2Physiotherapy, State University of Santa Catarina, Florianópolis, Santa Catarina, Brazil

Introduction: Although chronic and persistent mouth breathing has been associated with postural alterations, causing decreased muscle strength, reduction of thoracic expansion and pulmonary ventilation with consequences in exercise capacity, the relationship between these alterations have been little studied.

Objective: To evaluate exercise tolerance and respiratory muscle strength in relation to cervical posture and respiratory mode (oral breathing (OB) and nasal breathing (NB)) children.

Method: An analytical cross-sectional study included 8-11 years old children with clinical orthorharyngology diagnosis for OB. We excluded obese children, with asthma, chronic respiratory diseases, neurological and orthopedic disorders and cardiac patients. All participants underwent postural assessment, maximal respiratory pressures (maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP)) and six minute walk test (6MWT).

Results: There were 92 children (30 OB and 62 NB). In the OB group, there was no difference between the means of MIP, MEP and 6MWT between the group with posture alteration (severe and moderate) and normal cervical posture. In the RN group, the mean MIP (70.8±19.1 x 54.7±21.7 cmH2O, p=0.003) and MEP (67.7±22.1 x 50.5±19.5 cmH2O, p=0.002) were higher in the group with cervical postural alteration. The presence of OB determined the decrease of MIP, MEP and 6MWT. The presence of moderate cervical posture had positive relationship in MIP and MEP values.

Conclusion: Oral breathing affects negatively the respiratory biomechanics and exercise capacity. The head posture, altered moderately, acts as a compensation mechanism to improved respiratory muscle function.
110. Risk and detection of childhood asthma and allergy

P1127 Late-breaking abstract: Asthma through childhood; do children remit from their disease?
Vegard Howland1, Amund Risler1, Petter Mowinckel1, Kai-Håkon Carlsten1,2,3
Department of Pediatrics, Oslo University Hospital, Ullevaal, Oslo, Norway; 1Voksentoppen, Oslo University Hospital,
Rikshospitalet, Oslo, Norway; 2Faculty of Medicine, University of Oslo, Oslo, Norway

Background and aim: Around 50% of children with early wheeze outgrow their disease according to the literature. In a prospective birth cohort running through puberty, we assessed persistence, remission and relapse of asthma.

Methods: Time-course asthma phenotypes (figure below) were constructed from the 2-10-16 yrs investigations in the Oslo “Environment and Childhood Asthma” study, based on the presence/absence of recurrent ≥2 bronchial obstruction (rBO) 0-2 yrs, and asthma from 2-10 and 10-16 yrs defined as ≥2 of: doctor diagnosis/symptoms/asthma-medication use. Positive bronchial hypersensitivity (BHR) at 16 years required a PD20-metacholine <8 μmol.

Results: Of the 550 subjects (52% boys) attending all investigations, 228 children had rBO/Asthma in at least one time-period, 143 with rBO (figure below). Among rBO children at 16 yrs, 34% had asthma, whereas 51% of those in remission had symptoms, medication use and/or BHR, compared to 27% with never asthma (p<0.0001), thus 33% only were without signs of asthma.

Conclusion: Only one third of the early wheezers were in true clinical remission by 16 years. Thus early recurrent “wheeze” appears less benign than commonly reported.

P1128 Late-breaking abstract: Maternal genetic asthma predisposition affects pulmonary microRNA profiles in neonatal offspring
Stefan Dehmel1, Agnieszka Pastula1, Rabea Imker1, Nikola Schulz1, Oliver Eickelberg1, Adalbert Roscher2, Susanne Krauss-Etschmann1,2
1Department of Pediatrics, Oslo University Hospital, Ullevaal, Oslo, Norway; 2Department of Pediatrics, University Hospital, Ulm, Germany; 3Department of Pediatrics, University Hospital, Münster, Germany;

Methods: We asked if maternal genetic asthma predisposition affects pulmonary miRN profiles during an early developmental stage and might therefore influence lung development.

Aim: We asked if maternal genetic asthma predisposition is sufficient to affect pulmonary miRN profiles in offspring that do not bear the genetic asthma risk. To address this question, we used female mice with a heterozygous deficiency for Tbx21 as they develop spontaneous airway remodeling and airway hyperreactivity (Fitto et al., Science, 2002, 299:336).

Methods: Female C57BL/6-Th21+/- mice were mated with WT males. Neonatal lungs from male WT offspring of dams with (Tbx21+/-, n=5) and without genetic asthma predisposition (WT, n=3) were removed within 24h after birth and total mRNA including small RNAs was extracted. Duplicate pools of RNAs were subjected to miRNA expression profiling (ABI, TaqMan® Array microRNA cards). In silico target prediction was performed for miRNAs with a >1.5x change followed by pathway analysis (DEANA-nmapth, TargetScan).

Results: Male WT offspring of Tbx21+/- dams showed an up-regulation of 14 of 750 miRs (1.5-2.1x), while 17 miRs were down-regulated (1.5-4.7x) compared to male WT offspring of dams without genetic asthma predisposition. Pathway analysis showed a significant enrichment of target genes within the WNT pathway (49 of 154 genes). MiRs 27a* and 124 were found to target multiple genes (≥15) in the WNT pathway suggesting a key regulatory function for these miRs in WNT signaling.

Conclusion: These data show that maternal genetic asthma predisposition affects pulmonary miRN profiles during an early developmental stage and might therefore influence lung development.

P1129 Revisiting the September asthma epidemic
Conrad Capili, Robert Jacobson, Xujian Li, Young Juhn. Community Pediatric and Adolescent Medicine, Mayo Clinic, Rochester, MN, United States

Background: September asthma epidemic has been well documented. Whether a similar pattern of asthma exacerbation is observed in children returning to school from winter and spring break is unknown.

Objective: To assess whether the September asthma epidemic occurs in Olmsted County, Minnesota and determine whether similar asthma epidemics occur after winter and spring break.

Methods: The study included all asthmatic children ages 5-18 who had received medical care at our institution as of March 12, 2008 (n=3092). Asthma status was defined by physician diagnosis in the medical records. We compared the frequency of all asthma-related hospitalizations, ED visits, outpatient visits, and corticosteroid therapies for acute asthma symptoms between August and September of 2008 and 2009. Similarly we compared the frequency of all asthma-related visits or treatments between during and after spring break and between during and after winter break.

Results: The frequency of asthma-related visits and treatments in September of 2008 and 2009 was 2.1% per person-month, which was significantly greater than that in August of 2008 and 2009 (1.2% per person-month) (p<0.003). Similarly, the frequency of asthma-related visits and therapies during the period after spring break of 2008 and 2009 (1.1% per person-month) tended to be greater than that during spring break (0.75% per person-month) (p=0.063). There was no difference in asthma-related visits or therapies during and after winter break (p=0.59).

Conclusions: The September asthma epidemic does occur in our study setting, but this may not be a September-specific concern. Clinicians should consider a step-up therapy and reinforce medication compliance for asthma exacerbation-prone children returning to school.

P1130 Asthma symptoms in pediatric patients: Differences throughout the seasons
Ellen Koster, Jan Raaijmakers, Susanne Vijverberg, Anke-Hilse Maitland-van der Zee. Pharmacoepidemiology & Clinical Pharmacology, Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands

Background: Seasonal variation in asthma has been widely recognized. The aim of this study was to describe seasonal patterns of asthma symptoms and medication use in a cohort of pediatric asthma medication users and to study determinants of seasonal childhood asthma.

Methods: For this study, 602 children participating in the PACMAN (Pharmaco-genetics of Asthma medication in Children: Medication with Anti-inflammatory effects)-cohort were included. Parents were asked about their child’s respiratory symptoms and rescue medication use over the past year.

Results: There was a decline in asthma symptoms and medication use during the summer period and a peak occurred from autumn to spring. The prevalence of wheeze ranged from 3% in summer to 56% in autumn. The prevalence of respiratory symptoms and medication use was significantly lower during summer (p<0.0001). Oral steroid and antibiotic use and strong parental necessity beliefs were associated with uncontrolled asthma, regardless of seasonality. Allergic rhinitis was associated with an increased risk of uncontrolled asthma during spring (RR: 1.3, 95%CI: 1.1-1.6) and summer (RR: 1.2, 95%CI: 1.0-1.4). Eczema was associated with a higher risk of uncontrolled asthma during autumn (RR: 1.2, 95%CI: 1.0-1.4) and winter (RR: 1.2, 95%CI: 1.0-1.4).

Conclusions: We showed seasonal patterns in asthma symptoms and medication use. We showed associations between allergic rhinitis and asthma control during spring/summer and eczema was associated with uncontrolled asthma during au-
tumm/winter. Seasonality in asthma morbidity and health care use is most likely associated with atopic constitution and viral infections, which are common during fall, winter and spring.

P1131 Air pollution and asthma hospitalizations in children
Amne Iskandar1, Zorana J. Andersen2, Klaus Bønnelykke1, Klaus Andersen2, Hans Bisgaard1, 1Copenhagen Prospective Studies on Asthma in Childhood; COPSAC; Health Sciences, University of Copenhagen; Copenhagen University Hospital, Gentofte, Copenhagen, Denmark; 2Institute of Cancer Epidemiology, The Danish Cancer Society, Copenhagen, Ø, Strandboulevarden 49, Denmark

Introduction: Short-term exposure to air pollution can trigger asthma hospitalizations in children, but it is not known which components of air pollution are most important. There is no available evidence on the particular effect of ultrafine particles (UFPs) on admission for asthma.

Aim: To study whether short-term exposure to increased air pollution levels is associated with hospitalizations for asthma in children.

Hypothesis: 1) The association between asthma admissions and air pollution is stronger with UFPs than PM10, PM2.5, NOx. 2) Infants are more susceptible to the effects of exposure air pollution than older children.

Method: Daily count of hospital admissions for asthma in children aged 0-18 years were extracted from Danish National Patient Registry between 2003 and 2008, from hospitals located within a 15 km radius from the central fixed urban air pollution monitor in Copenhagen. Time-stratified case-crossover design was applied and data analyzed using conditional logistic regression to estimate the effect of air pollution on asthma admissions.

Results: We detected a significant association between asthma hospitalizations in children aged 0-18 years and NOx (ORs ratio: 1.11, 95% CI: 1.05-1.17), PM10 (1.07, 1.03-1.12), and PM2.5 (1.09, 1.04-1.13), and none with UFPs. Infants had higher risk of being hospitalized for asthma than older children, for all pollutants, but were not statistically significantly more susceptible.

Conclusion: A significant association showed between air pollution and hospitalization in children, with infants possibly most susceptible. Gases (NOx and NO2) originating from traffic showed strongest associations, while UFPs showed no effect.

P1132 Comparison of prevalence of childhood asthma in two different African-American communities in Columbus area. A pilot study
Shadid Sheikh1, Kevin Morris2, Karen McCoy1, 1National Center for Health Statistics, Hyattsville, MD, United States; 2Princess Amalia Children's Clinic, Isala Klinieken, Zwolle, Netherlands

Asthma prevalence is on the rise and children in minority communities have the highest prevalence.

Objective: Pilot study done at Mission Day School (private elementary school) and at New Salem Baptist Church (urban inner city neighborhood) in Columbus, OH, to understand asthma prevalence in two communities with same racial but different socio-economic status. All children were African Americans.

Method: Study was done using validated “Easy Breathing Survey (Hall CB et al. J Pediatr 2001;139:267-72)” with 4 questions. A positive response to any of the 4 questions has 94% sensitivity for asthma and specificity [95%CI] of each question between 66% - 86%.

Results: Questionnaire was sent to 105 families at both places. Fifty four families completed the survey. MF 28:26 and 27:26, family history of asthma 24 and 27, known asthma triggers in 16 and 18 children respectively. Nine (16%) children at both sites had previous diagnosis of asthma and among them, 8 at school and all nine at church still had positive responses to survey. Additional 27 children at school and 26 at church responded positively to questions on survey though none of them had a previous diagnosis of asthma and about one third of them at both sites had required acute care for asthma within a year.

Conclusion: Asthma prevalence is high in African American community irrespective of their socio-economic status. In the majority, symptoms are not well controlled. More than half of children at both sites had positive survey suggesting that they might have undiagnosed asthma.

P1133 Prevalence and risk factors of asthma in urban Canadian aboriginal children
Ming Ye1, Reintou Gemke1, 1Paediatrics, Rijnland Ziekenhuis, Leiderdorp, Netherlands; 2Princess Amalia Children’s Clinic, Isala Klinieken, Zwolle, Netherlands; 3Paediatrics, UMC Medical Centre, Amsterdam, Netherlands

Background: Clinical experience shows that wheeze is common in children with Down syndrome (DS), but that treatment with anti-asthmatic drugs is usually disappointing.

Aim: To compare the prevalence of current wheeze in children with DS, their siblings, and general population controls.

Methods: This was a case control study in which the International Study of Asthma and Allergy in Childhood questionnaire for respiratory symptoms was completed by parents for 130 children with DS and 167 of their siblings, and for 1/19 age and sex matched control subjects from the general population.

Results: Both wheeze ever and wheeze during the last 12 months was more commonly reported in DS than in their siblings or controls. The relative risk (RR) of current wheeze in DS was 2.8 (95% CI 1.42-5.51) compared to siblings, and 2.75 (95% CI 1.28-5.88) compared to controls. Children with DS were less likely to have received a doctor’s diagnosis of asthma (3.1%) than siblings (4.2%) or controls (6.7%, p<0.04). During 4 yr follow-up, the diagnosis of asthma was confirmed in none of the 24 DS children with current wheeze, and atopy was found in none of them. Chronic rhinitis occurred more frequently in children with DS (40%) than in their siblings (17.3%); eczema did not (14.6 vs 19.2%).

Conclusion: Wheeze is common in children with DS. This is likely to be related to factors specific for DS, and probably unrelated to asthma.

P1134 Nocturnal dry cough in early childhood is a risk for the development of asthma
Ise Boudewijn1, Olga Savenj1, Marjan Kerkhof1, Gerard Koppelman2, Henriette Smit1, Alet Wijga3, Dirkje Postma1, 1Department of Epidemiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 2Department of Pediatric Pulmonology and Pediatric Allergology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 3Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands; 4Centre for Prevention and Health Services Research, National Institute for Public Health and the Environment, Bilthoven, Utrecht, Netherlands; 5Department of Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands

Background: Wheeze in young children is an established predictor of the development of asthma later in life. Cough frequently occurs in childhood as well. So far, little is known about the role of nocturnal dry cough (NDC) in the development of asthma.

Objective: The aim of this study was to investigate the association of NDC at ages 1-7 years, in the presence or absence of wheeze, with doctor-diagnosed asthma at 8 years of age.

Methods: Data from the Prevalence and Incidence of Asthma and Mite Allergy (PIAMA) birth cohort were used, which consists of 3963 children born in The Netherlands. Children were followed from birth up to 8 years of age. Presence of NDC without having a cold, wheeze, and a doctor’s diagnosis of asthma ever with symptoms of asthma in the past 12 months (DDA) was reported yearly by the parents.

Results: The prevalence of NDC at age 1 to 7 years varied from 15.0% at age 7, to 23.3% at age 5. NDC without wheeze was significantly associated with DDA at age 8, except for the age of 1 year (range of Odds Ratios (OR) at age 2 to age 7: 1.82 (age 5) to 7.65 (age 7), range of p-values <0.001<0.048). NDC combined with wheeze showed the most strong association with DDA at age 8 (range of OR at age 1 to age 7: 3.96 (age 1) to 35.96 (age 7), all p-values < 0.000). Wheeze without NDC was also strongly associated with DDA at age 8 (range of OR at age 1 to age 7: 2.06 (age 1) to 29.12 (age 7), range of p-values <0.001<0.003).

Conclusion: These results show that NDC in early childhood is an independent risk factor for the development of asthma. The presence of NDC even increases the risk for asthma in children with wheeze.
P1136
Early childhood infections with rotavirus and norovirus are associated with risk of developing asthma
Monique Monnens1, Melanie Ogunyena1, John Penders1,2, Johan Reimerink1, Focke Stelma1, Marion Koopsman1,2, Carel Thijs1,2, Department of Epidemiology, School for Public Health and Primary Care (CAPHRI), Maastricht University, Maastricht, Netherlands; 3The Laboratory for Infectious Diseases and Screening, National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands; 4Department of Medical Microbiology, University Medical Centre (UMC), St Radboud, Nijmegen, Netherlands

Background: The role of early infections in asthma aetiology is not fully understood. Most research has focussed on respiratory infections and, although gastroenteritis has been associated with increased asthma risk, gastrointestinal viruses have thus far received little attention.

Aim: To investigate whether infection with gastrointestinal viruses during infancy is associated with the development of childhood asthma and related atopic manifestations.

Methods: In 591 children from the KOALA Birth Cohort Study, IgG seropositivity for rotavirus and norovirus (GGII.4 and GGL.1) was determined at age 1 year. Gastrointestinal symptoms during the first year were assessed by repeated questionnaires. Associations with childhood asthma at 6-7 years and eczema until age 6-7 years, atopic dermatitis at age 2 years and specific IgE at age 2 years and 6-7 years were analysed using multivariable logistic regression and GEE.

Results: Children seropositive for rotavirus at age 1 year had an increased risk for subsequent asthma (adjusted odds ratio 2.36; 95% Confidence Interval 1.00-5.62) and wheeze (1.90; 1.33-2.71), with the highest risk observed in children with rotavirus infection with intestinal symptoms (5.56; 2.78-7.48). Norovirus GGII.4 seropositivity at age 1 year was associated with decreased asthma risk (0.26; 0.08-0.85), and GGL.1 seropositivity was associated with decreased risk of wheeze until age 6-7 years (0.65; 0.42-1.00).

Conclusion: Early life rotavirus and norovirus infections are associated with wheeze and asthma development. Symptomatic rotavirus infection might reveal an underlying general susceptibility to wheeze and asthma or may be causal factor if viremia occurs.

P1137
Maternal asthma phenotypes and children’s allergy status
Maria Vakharlovskaya, Olga Lavrova, Maria Petrova, Laboratory of Inherited Lung Disorders, St.Petersburg Pavlov State Medical University, St. Petersburg, Russian Federation

Background: Asthma is a complex heterogeneous disease comprising a number of discrete phenotypes. Allergy status in children tends to differ according to asthmatic phenotype of parents, particularly mothers. Mother’s asthmatic phenotype stipulates for differences in structure and time of allergy onset in children.

Purpose: To study the influence of maternal asthma phenotype on children’s allergy status.

Methods: We evaluated the allergy status in children from birth to 7 years of age born from 117 asthmatic mothers with regard to their asthma phenotypes: 88 (75.2%) mothers had early onset asthma phenotype (defined as asthma developing before 16 years of age), 29 (24.8%) – late onset phenotype.

Results: The prevalence of allergic asthma and other allergic forms (allergic rhinitis and atopic dermatitis) in children by 7 years of life differed (p<0.001, binomial test) depending on the onset asthma phenotype of mothers. Children born from mothers with early onset asthma phenotypes will be at higher asthma and others allergic forms risk (OR=3.04 [CI 1.03-9.132]).

Conclusions: Maternal asthma phenotype influences the onset and structure of allergy in children. Understanding of underlying asthma genesis is needed for protective measures and prognosis of the diseases in children.

P1138
Maternal stress during pregnancy and childhood asthma: The KOALA birth cohort study
Ischa Kummeling1,2, Monique Monnens1, John Penders1,2, Caroline Bastaenenc1, Carel Thijs1,2, CAPHRI School of Public Health and Primary Care, Department of Epidemiology, Maastricht University, Maastricht, Netherlands; 4Clinical Trials Unit, Medical Research Council, London, United Kingdom; 4Department of Medical Microbiology, Maastricht University Medical Center, Maastricht, Netherlands

Introduction: Asthma is among the most common chronic diseases in children. The development of the immune system into an asthma-like makeup may begin in utero and maternal stress can drive immune responses. Increase in chronic stress during pregnancy can parallel the rising prevalence of asthma.

Aim: To investigate whether maternal perceived stress during pregnancy increases the risk of developing asthma in childhood.

Methods: Within the KOALA Birth Cohort Study, The Netherlands, maternal perceived stress was ascertained by using the 10-item version of Cohen’s Perceived Stress Scale at 14 and 30 weeks of pregnancy. Associations with parental reported wheeze and asthma (n = 1783), total and specific IgE (n = 360) and lung function (standardized FEV1 and FVC; n=417) at age 6-7 years were analyzed using multivariable regression analyses. Asthma was defined as ever doctor-diagnosed asthma with clinical symptoms and/or the use of prophylactic asthma medication in the last 12 months.

Results: Maternal perceived stress was not associated with asthma at age 6-7 years (stress in first trimester: adjusted OR 0.74; CI95% 0.36-1.51; third trimester: 0.82; 0.43-1.59; or both trimesters: 0.90; 0.43-1.87). Maternal stress was also not associated with allergic sensitization (first trimester: 0.50; 0.19-1.30; third trimester: 0.70; 0.28-1.72; or both trimesters: 0.39; 0.12-1.24). No statistically significant associations were found between perceived stress and FEV1 and FVC, nor between the level of stress (low, medium, high tertile) in the first or third trimesters and any outcome.

Conclusions: This study did not find evidence for an effect of maternal stress in pregnancy on asthma development at age 6-7 years.

P1139
Electronic auscultation of the lungs in children with asthma
Elena Strehzhina, Tatiana Filimonova, Galina Sharowskaya, Andrey Dmitriev, Pulmonology Department, Medical University Hospital Riasan, Riasan, Russian Federation Pulmonology Department, Medical University Hospital Riasan, Riasan, Russian Federation Pulmonology Department, Medical University Hospital Riasan, Riasan, Russian Federation

Aim: The aim of this study was to determine the quantitative characteristics of sounds by electronic auscultation in children with asthma.

Materials and methods: 112 children with moderate and severe persistent asthma and 41 healthy child, the control group, aged 7-18 years were included in this study. Sound phenomena recorded on the chest with an electret microphone SAFA (Korea) twice: at admission and on the third day of treatment. Data processing was carried out using Audacity 1.3 audio editing and Adobe Audition 1.5.

Results: The asthmatic children respirophonomogram’s curve didn’t show a smooth amplitude decrease in frequencies over 300-1200 Hz, had the persistence of the peaks in the range of more than 1100 Hz, the sawtooth shape of the curve. Sound characteristics do not depend on sex, age, level of physical development of children.

After treatment we noted the decrease of the respirophonomogram’s curve in amplitude at frequencies exceeding 500 Hz, with preservation of low-amplitude peaks in the range of the asthma frequency (1200 Hz). Thus, the air flow becomes less turbulent and severity of bronchial obstruction is reduced. Correlations between the parameters of respiratory sounds and spirometry and peak flow not revealed.

Conclusions: Asthmatic children characteristic respiratory sounds by the electronic auscultation allows to objectively establish the presence of obstruction in children.
Component-resolved allergy diagnostics identify phenotypes in problematic severe childhood asthma

Methods: This cross-sectional study included 56 children with problematic severe asthma, insufficiently controlled despite 80 μg daily inhaled corticosteroids (budesonide or equivalents). IgE antibodies against 131 individual allergen components from inhalant and food sources were analysed using immunosorbent-phase allergen chips. Airway inflammation (FeNO), lung function (FEV1), and bronchial hyperresponsiveness (methacholine challenge) were assessed in all subjects, and Health-Related-Quality-of-Life (HR-QoL) questionnaires and asthma control tests were completed.

Results: IgE antibodies were detected in 80% (n=45) of children tested. Airway inflammation was greater in these children (FeNO mean, 31 ppb vs 16 ppb, p=0.039) and lung function was reduced (FEV1 mean, 79% vs 92%, p=0.05) compared to children without detectable IgE (n=11, 20%). However, HR-QoL and asthma control test scores, and bronchial hyperresponsiveness, did not differ between these groups. Children (30%, n=20) with specific IgE to >3 (median value) mould/indoor components were more sensitized to specific food components (median 5.9 vs 2.2, p=0.026) compared to 45% (n=25) of children with specific IgE to fewer mould/indoor components. Also, children with IgE to >3 mould/indoor components had increased bronchial hyperresponsiveness (methacholine, dose response slope, 101% vs 31%, p=0.027) and lower HR-QoL scores (5.1 versus 5.7, p=0.011).

Conclusions: Polysensitization to indoor and mould allergens based on component-resolved diagnostics identifies a more severe subgroup of childhood asthma.

Iodine subsidy as a factor in prevention of bronchial asthma (BA) in infants

Object: to evaluate the effectiveness of the prevention of the atopic diseases and BA in babies with the use of the iodine drug. Methods: Evaluation of the health state of the babies having got the iodine with maternal milk in the lactation period from 3 to 6 months (n=117) were studied. 118 babies without iodine donation was the control group. Evaluation of the health state according to the anamnesis, examination, laboratory data and hereditary predisposition to allergic diseases was carried. The indices of median iodurea in state according to the anamnesis, examination, laboratory data and hereditary predisposition was estimated. The indices of median iodurea in basic group it was noted evident decrease (χ²=110.90, p=0.0001). Frequent respiratory infections, especially pneumonia, in the first year of life were less common in children with higher risk of iodine deficiency. Excretion of iodine with urine in babies of the iodine subsidy group was 2.9 times more than in control group (0.32; 3.7 < 3.7). The frequency of the acute respiratory infections in comparison with the control group (2.9±0.3; 3.7±0.5) is more significantly (p<0.05).

Conclusions: Iodine drugs can be recommended to breast feeding mothers (2.9 times of the frequency acute respiratory infections in comparison with the control group).

Corticosteroids as a promoter of T cell regulation in vivo in asthma patients.

Background: In asthma, Th1/Th2 ratio was correlated with vitamin D (r= 0.68; P = 0.0001). A positive correlation was found between FVC percent predicted and vitamin D (r = 0.35; P = 0.027). A negative correlation was observed between serum IL-17 and vitamin D (r = - 0.617; P = 0.001). Th1/Th2 ratios of controls were higher (27.2± 24.13%) than those of patients (13.4± 8.55%; P = 0.0001). In asthma, Th1/Th2 ratios were correlated with vitamin D (P = 0.045). The Th1/Th2 ratio was significantly decreased in asthmatic children. A positive correlation was observed between vitamin D and IL-10+ cells (r = 0.428; P = 0.008). A correlation was observed between the percentage of CD25+FoxP3+ Treg cells and vitamin D values in asthmatics (r = 0.368).

Conclusions: Asthma was associated with lower serum Vitamin D levels despite high levels of sun exposure. Our findings suggest that vitamin D is an important promoter of T cell regulation in vivo in asthmatic patients.
developing before 16 years of age) and later-onset asthma and in the group of pop-
ulation control. The genetic polymorphisms –590 C/T were studied by PCR-RFLP
analysis.
Results: The frequency of –590 C allele of the IL-4 gene was significantly higher in
the group of patients with asthma (p = 0.0366) as compared to the population
group. The analysis of distribution of the –590 C/T genotype showed significant
increasing of the frequency of this genotype in the group of patients with later-onset
asthma (p = 0.0231) as compared to the early-onset asthma group of patients.
Conclusions: Asthma is caused by genetic and environmental factors and this
chronic disease is genetically heterogeneous. Our data show that –590 C/T IL-4
polymorphism plays a role in disease formation and could be treated as a prognostic
gene marker of the risk of later-onset asthma.

111. Paediatric respiratory infection: signs, symptoms and sequelae

P1147 Effects of respiratory viral infections on the lower respiratory tract of
children, especially asthmatic children
Asako Fujisuka1, Mika Arakawa2, Kazuko Sugai3, Masahiro Noda4, Hirokazu Kimura5
1Department of Pediatrics, The Chuo Medical Center, Yokohama, Kanagawa, Japan; 2Public Health, Tochigi Prefectural
Institute, Utsunomiai, Tochigi, Japan; 3Pediatrics, National Hospital Organization Yokohama Medical Center, Yokohama,
Kanagawa, Japan; 4Virology III, National Institute of Infectious Diseases, Musashimurayama, Tokyo, Japan; 5Infectious
Disease Surveillance Center, National Institute of Infectious Diseases, Musashimurayama, Tokyo, Japan.

Aim: Recent studies strongly suggest that some respiratory viruses are associated
with exacerbation of asthma. We examined their characteristics and their effects
on children with acute lower respiratory symptoms and asthma.

Method: We examined some respiratory viruses in nasopharyngeal swabs using
the polymerase chain reaction (PCR) assay or RT-PCR and analyzed their clinical
data obtained from 107 children (M/F: 70/37, mean age 25.3±2.7 months) with
lower respiratory symptoms who were treated in our hospitals between January and
November 2010. From clinical records, we prospectively investigated the clinical
symptoms of the children.

Results: RSV was detected in 27 samples, HRV in 31, HRV and RSV together in 4,
HRV and HBoV together in 2, EV in 7, PV in 5, HBoV in 2, and Adv in 2, but no
virus was detected in 29. In the RSV group, asthmatic children numbered 10 and
non-asthmatic children, 17, (of whom 11 were inpatients and 6, outpatients).
The mean age of the inpatients (9.3±8.2 months) was significantly less than that of
the outpatients (26.2±14.2 months) (p=0.003). In the HRV group, the frequency of
severe respiratory symptoms was significantly higher in asthmatics than in non-
asthmatics (p=0.04). The mean age of the asthmatic inpatients tends to be
higher than that of the asthmatic outpatients.

Conclusion: Younger children are more susceptible than older children to severe
respiratory symptoms in RSV infections, while, asthmatic school-age children tend
to have severe asthmatic symptoms with HRV infections. These findings suggest
that asthma exacerbation in school-age children may be associated with HRV
respiratory symptoms in RSV infections, while, asthmatic school-age children tend
to have severe asthmatic symptoms with HRV infections.

P1148 CARESS: The Canadian registry of palivizumab (2005-2010)
Ian Mitchell1, Bosco Paes2, Abby Ly3, Krista Lanctot3. 1Pediatrics, University of
Calgary, Calgary, AB, Canada; 2Pediatrics, McMaster University, Hamilton,
ON, Canada; 3MORE, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Objective: To evaluate the current management of children at high-risk of RSV
infection who received palivizumab prophylaxis in tertiary care centers and com-
munity settings using a Canadian Registry Database.

Methods: A prospective, observational, registry of children who received ≥1
dose of palivizumab during the 2005-2010 RSV seasons across 29 sites. Data on
palivizumab utilization and compliance, and outcomes related to a respira-
tory infection were collected monthly until the full course of palivizumab was
completed.

Results: 7699 infants were enrolled, with an average age of 5.4±4.6 months.
Participants were typically male (56.4%), Caucasians (71.5%), with an average
gestational age (GA) of 32.2 (SD 6.0) completed weeks. 5237 (68.0%) infants
received palivizumab for prevention (435 completed weeks GA) only, 766 (9.9%)
for congenital heart disease, 646 (8.4%) for chronic lung disease and 1050 (13.6%)
for other risk factors (e.g., CNS disorders, airway anomalies and cystic fibrosis).
Participants received an average of 3.9 (SD 1.6) injections, with 30040 doses given
overall. 5.5% of patients withdrew from the study. No direct, drug related serious
adverse events were identified. 460 infants had a total of 541 hospitalizations
for a spectrum of respiratory tract illnesses resulting in a hospitalization rate of
6.0%. The overall RSV positive hospitalization rate was 1.47% with no mortal-
ity. Living with siblings was significantly correlated with a shorter time to first
RSV-positive hospitalization (B=0.615, df=1, p<0.046).

Conclusions: The RSV hospitalization rate observed in the 2005-2010 RSV sea-
sons was similar to that found in several published reports of infants receiving
prophylaxis (range 1.3%-5.3%).

P1149 Increasing immunosuppression despite high load of respiratory viruses:
Fludarabine as rescue treatment in alloreactive lung disease
Burt Rotter1, Martine Raphaelle2, Jan Iaap Boelema3, Beatrix Children’s Hospital,
University Medical Center Groningen, Groningen, Netherlands; 4Wilhelmina
Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands.

Background: Allo immune lung syndromes (alloLS) as Bronchiolitis obliterans
syndrome and idiopathic pulmonary syndrome are life threatening complications
after allogeneic hematopoetic stem cell transplantation (HSCT) or lungtransplan-
tation (LTX; rejection). Respiratory viral infections (HRV; HBoV) may trigger these alloLS. If
conventional treatment with corticosteroids is not effective, 2nd line therapy may
be needed.

Aim: To describe safety and efficacy of the T-cell depleting agent fludarabine to
treat allo immuneLS due to viral infections in the presence of viral infections.

Methods: We describe 5 patients (4 HSCT, 1 LTX) with steroid refractory alloLS
who were therefore treated with fludarabine. 30mg/m2 on a weekly basis. Viral
prevalence of respiratory viruses was monitored by quantitative PCR before and
during treatment.

Results: The five patients all initially had good engraftment, but developed res-
piratory complications. 4 patients were positive in BAL and/or nasopharyngeal
aspirate with cycle threshold (CT values <30 for rhinovirus (2), parainfluenza
and RSV (1) and adenovirus (1)). 4/5 patients had initial response after mean 2.4
(range 1-4) courses. The LTX patient improved clinically as well as for FEV1
for 2 months and then had a relapse with progression of the alloLS. One patient
died from aspergillosis after 2 months. 3 patients had sustained response. Viral
load (expressed in CT values) remained high in all patients, without occurrence of
systemic disease.

Conclusions: Fludarabine is feasible and an effective 2nd line treatment of steroid
refractory allo immune lung syndromes, without an increase in viral load. This
empirical treatment now deserves a controlled study.

P1150 Lung function of preschoolers with parapneumonic effusions complicating
community acquired pneumonia
Vasiliki Avramadou, Elpis Hatziairopou, Fotis Kivrassilis, Charalampos Antachopoulos, John X-ray, Thessaloniki, Greece

Background: Parapneumonic effusions as a complication of community acquired
pneumonia (CAP) in children show an increasing prevalence.

Aim: To monitor expiratory Inspiratory Resistance (Rint), Lung Clearance Index
(LCI) and chest X-Ray among preschoolers with parapneumonic effusions.

Methods: We evaluated children hospitalized with pleural effusion as a compli-
cation of CAP. Expiratory inspiratory resistance (Rint) and Lung Clearance Index
(LCI) were measured on the day of discharge and six months later.

Results: 13 preschoolers, aged 3.5±1.21 years were studied. In 1/13 (84.6%)
Streptococcus Pneumonia was isolated. 84.6% had chest drainage, intratracheal
urokinase was administrated in 69.2% of the children. Two children developed
broncho-pleural fistula and one pericarditis. Lung decortication was documented in
1 child. 38.4% of the patients had abnormal chest X-ray, 6 months later. Children
with pleural effusions had significantly higher Rint on day of discharge (1.12±0.34
pm 0.78±0.20 kPa L-1 second, p<0.001). Six months later Rint was reduced to
normal levels (0.77±0.31 kPa L-1 second, p<0.001). Children with pleural effu-
sion had significantly higher LCI compared to controls (mean difference [95% CI]
2.8 [1.9, 3.8], p<0.001). Six months later, 46.15% of the children had still
significantly high LCI compared to controls [95% CI] 2.2 [1.3, 3.3] p<0.01).

Conclusions: One third of preschoolers with pleural effusions had an abnormal
chest X-Ray, while half of the children had significantly high LCI six months later.
LCI is a sensitive marker that detects abnormal lung function and could be
used to monitor preschoolers with parapneumonic effusions complicating CAP.

P1151 Recurrent respiratory tract infections in the preschoolers and IgG3 deficiency
Joanna Vasilopoulou1, Ageliki Karatazi1, Fotini Palagianni1, Maria Trigkis1.
1Paed. Allergy Unit, Dept. of Paediatrics, 2Dept. of Microbiology, Patras University General Hospital, Patras, Greece

Introduction: Recurrent respiratory infections (RRI) are a common cause of
morbidity during childhood.

Materials and methods: We report four cases of otherwise healthy preschool
children who were referred to our paediatric allergy clinic for lower RRI with
wheezing, crackles, cough and rhinitis, mostly during the autumn and winter

208s
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
months, since they started attending kindergarten. They were being treated with antibiotics, inhaled beta-2 agonists and corticosteroids for the exacerbations. They were on prophylactic therapy with fluconazole 200g/day and montelukast 4mg/day, with no improvement. There was no history of atopy and the skin prick tests to common allergens were negative. Chest-x-ray and sweat test were normal. All patients underwent an immunologic screening that included CBC, ESR, CRP serum concentration of IgG, IgA, IgM, IgG1, IgG2, total IgG and IgG subclass levels. The major Ig isotypes and the IgG subclasses were quantified by rate nephelometry. The laboratory investigation results were all within normal limits except for IgG values which was in all patients below the 5th centile, based on published Greek normative data. IgG3 levels were: patient 1, aged 3.5: 10.5mg/dl (normal values 17-90), patient 2, aged 4.5: 20.7mg/dl (normal values 24-85), patient 3, aged 5.3: 16-3mg/dl (normal values 24-85), patient 4, aged 6: 14mg/dl (normal values 22-100).

Conclusion: IgG3 deficiency should not be ignored as a possible cause of RRI. Although it may be a transient phenomenon, it is prudent to follow these patients as some might evolve into common variable immunodeficiency. Moreover the use of increased doses of inhaled or systemic corticosteroids may delay the clearance of the virus from the respiratory tract.

P1152
Abdominal pain as a predictor of pneumonia in children
Ilija Kurovski, Vesna Vecevska, Lidija Sekova, Ljupco Nikoloski. Department of Pulmonology and Allergology, University Children’s Hospital, Skopje, Macedonia, The Former Yugoslav Republic of

Introduction: The abdominal pain may occur in children with pneumonia. When it is present, becomes an important symptom because it focuses attention on diagnostic evaluation to cause errors in diagnosis.

Methods: We prospectively studied 258 children aged 3 to 14 years who were admitted to the hospital with a diagnosis of pneumonia.

Results: The dominant initial clinical presentation in 22 (8.5%) of the patients was acute abdomen and the duration of the pain in patients before the diagnosis of pneumonia was established. Respiratory rate on admission >40 was in 14/22 (63.6%) of the patients. Seventy-three percent of the patients had temperature >38°C and 40°C WBC >17,000/mm³ was seen in 15/22 (68.2%). Auscultation abnormalities were present in 17/22 (77.3%) patients. The diagnosis was confirmed in all by chest radiography. It was observed that left-sided pneumonia is capable of mimicking appendicitis almost frequently as right-sided pneumonia. All abdominal symptoms disappeared in all children following the treatment of pneumonia, and no sequelae were observed.

Conclusions: In children presenting with acute abdominal pain, pneumonia must also be evaluated before a surgical procedure should be performed in a child with abdominal pain of unknown cause, especially if there are respiratory symptoms, fever and increased white cell count. Prompt diagnosis is essential, not only to avoid surgical intervention but also to start therapy early and to prevent possible complications of pneumonia.

P1153
Development a set of reagents for real-time PCR diagnostics and surveillance of infections caused by B. pertussis, B. parapertussis and B. bronchiseptica
Maria Praded, Tatiana Selezneva, Svetlana Yatsyshina. Bronhadenitis TB is the most common form of tuberculosis disease in childhood. In Bulgaria about 67% of all patients newly diagnosed children with this diagnosis. The purpose of this study was to determine the diagnostic capabilities of the T SPOT TB in this form of TB disease. In a period of one year were examined in 50 children ages 0-12 years treated in ower hospital with tuberculosis of lung lymph nodes. The diagnosis was set based on history, clinical, microbiological and radiological check you. TST and T SPOT TB test were performed simultaneously in the studied children. It was investigated the relationship between immunological samples TST and T SPOT TB compared contacted hectic age, BCG status and spatum smear microscopy. If no children with TST negative samples, 44% were normergichni reactions to 15 mm. 56% were hyperergic—a 15 mm. In a study with T SPOT TB 28% gave negative results and 72% positive. Most children 44% responded to both applied antigen, 20% of the CFP 10 and only 8% of ESAT 6. As a result of the study made the following conclusions: 1. T SPOT TB has in place in the diagnosis of tuberculosis especially in countries with compulsory BCG vaccination Bulgaria 2. T SPOT TB has a better diagnostic capabilities in major age groups 3. It was a good correlation between the two tests - the percentage of correlation 80%. 4. The sensitivity of the T SPOT TB was 70% and 90% in TST

P1154
Diagnostic capabilities of the T SPOT TB in children with tuberculous bronhadenitis: University Clinic for Lung Diseases – Sofia, Bulgaria
Svetlana Velizarova, University Clinic for Lung Diseases, Medical University, Sofia, Bulgaria

In order to evaluate the clinical manifestations, management and outcome of childhood lung abscesses in Sofia, Bulgaria, a retrospective chart review of 35 pediatric with LA from September 1995 to September 2010 was conducted. Among the 37 patients (20 males and 17 females), 51, 4% (18/37) were primary lung abscess and 49,6% (17/35) had underlying chronic diseases (secondary lung abscess). The predisposing factors of the primary group (n = 18) included 16 cases of respiratory tract infection and 2 with laceration wound. The underlying diseases in the secondary group (n = 17) included 11 cases of hematologic disorder (64,7%), 4 of congenital heart disease, and 2 each of hyperimmunoglobulin E syndrome. 14 patients underwent diagnostic tapping, including echo-guided aspiration (11 cases) and computed tomography-guided percutaneous needle aspiration (2 case). Positive yield rate from aspiration in a secondary group was 50% (7/14). Surgical intervention was performed in 10 of the secondary group and in 1 patient from the primary group. The pathogens were identified in 17 patients (49,6%): 5 with oral flora, 4 with Staphylococcus aureus plus other pathogens, 1 with St. aureus alone, 2 with Pseudomonas aeruginosa plus Proteus mirabilis, 4 with P. aeruginosa alone, and 1 with Aspergillus. The average duration of parenteral antibiotic use was 20 days. 2 cases (5,4%) died due to poor control of the underlying diseases, and 3 of the patients (10,8%) had sequelae (3 with bronchiectasis and 1 with lung fibrosis). Early percutaneous aspiration has an important role in identification of pathogens. Oral anaerobes and S. aureus are the core pathogens in primary lung abscess and gram-negative pathogens should also be considered in secondary LA.

P1155
Connective tissue disorders as the factor that changes clinical course of community-acquired pneumonia in children
Zoia Nestereenko1, Olena Ivanivna2. 1Department of Pediatrics, Faculty of Preclinical Studies, Lugansk State Medical University, Lugansk, Ukraine; 2Outpatient Department, Lugansk Municipal Children’s Hospital No.2, Lugansk, Ukraine

Aim: To study peculiarities of clinical course of community-acquired pneumonia in children.

Methods: 64 children with CAP aged 1-18 were studied during one year. Patients were divided for analysis by age groups (range 2-3 to 9-12 years) and gender. All cases were divided for following: children aged 1-3 (group A, n = 16), and aged 4-8 (group B, n = 48). All patients had manifestations of CTD. CAP was clinically and radiographically diagnosed with detection of serum antibodies (IgG and IgM) against atypical macromolecular pathogens measured by enzyme-linked immunosorbent assay (ELISA).

Results: All patients had CAP caused by atypical pathogens with indistinct clinical manifestations and symptoms. Recurrent course of CAP was in 54 (84,4%) patients. CAP caused by Chlamydia pneumonia (Cp) was more frequent in group A – in 15 (93,7% of the group) patients. CAP caused by Mycoplasma pneumonia (Mpm) was more frequent in group B - in 44 patients (91.6% of the group), in 6,8% - together with respiratory virus. Positive radiography should be performed in a child with abdominal pain of unknown cause, especially if there are respiratory symptoms, fever and increased white cell count. Prompt diagnosis is essential, not only to avoid surgical intervention but also to start therapy early and to prevent possible complications of pneumonia.

P1156
Clinical management and outcome of childhood lung abscess (LA): A 15-year experience
Oleksander Katliv, Dmitro Dmytriiev, Oleksander Marulov. Pulmonology, Vinnitsa National Medical University, Vinnytsia, Ukraine

In a study with T SPOT TB 28% gave negative results and 72% positive. Most children 44% responded to both applied antigen, 20% of the CFP 10 and only 8% of ESAT 6. As a result of the study made the following conclusions: 1. T SPOT TB has in place in the diagnosis of tuberculosis especially in countries with compulsory BCG vaccination Bulgaria 2. T SPOT TB has a better diagnostic capabilities in major age groups 3. It was a good correlation between the two tests - the percentage of correlation 80%. 4. The sensitivity of the T SPOT TB was 70% and 90% in TST

Clinical management and outcome of childhood lung abscesses (LA): A 15-year experience
Oleksander Katliv, Dmitro Dmytriiev, Oleksander Marulov. Pulmonology, Vinnitsa National Medical University, Vinnytsia, Ukraine

In order to evaluate the clinical manifestations, management and outcome of childhood lung abscesses in Sofia, Bulgaria, a retrospective chart review of 35 pediatric with LA from September 1995 to September 2010 was conducted. Among the 37 patients (20 males and 17 females), 51, 4% (18/37) were primary lung abscess and 49,6% (17/35) had underlying chronic diseases (secondary lung abscess). The predisposing factors of the primary group (n = 18) included 16 cases of respiratory tract infection and 2 with laceration wound. The underlying diseases in the secondary group (n = 17) included 11 cases of hematologic disorder (64,7%), 4 of congenital heart disease, and 2 each of hyperimmunoglobulin E syndrome. 14 patients underwent diagnostic tapping, including echo-guided aspiration (11 cases) and computed tomography-guided percutaneous needle aspiration (2 case). Positive yield rate from aspiration in a secondary group was 50% (7/14). Surgical intervention was performed in 10 of the secondary group and in 1 patient from the primary group. The pathogens were identified in 17 patients (49,6%): 5 with oral flora, 4 with Staphylococcus aureus plus other pathogens, 1 with S. aureus alone, 2 with Pseudomonas aeruginosa plus Proteus mirabilis, 4 with P. aeruginosa alone, and 1 with Aspergillus. The average duration of parenteral antibiotic use was 20 days. 2 cases (5,4%) died due to poor control of the underlying diseases, and 3 of the patients (10,8%) had sequelae (3 with bronchiectasis and 1 with lung fibrosis). Early percutaneous aspiration has an important role in identification of pathogens. Oral anaerobes and S. aureus are the core pathogens in primary lung abscess and gram-negative pathogens should also be considered in secondary LA.

Clinical characteristics of pediatric patients affected with H1N1/2009 pandemic influenza A virus who needed hospital admittance in the western region of Guatemala
Kenneth Escobar1, Adolfo Cuá2, Fabiola Moscoso3, Mario Mejía1, 3Pediatrics, Hospital Regional de Occidente, Quetzaltenango, Guatemala; 3School of Medicine, Universidad de San Carlos de Guatemala, Quetzaltenango, Guatemala; 2Central America and Panama Emergent Diseases Surveillance Program, Hospital Regional de Occidente –CDC/CAIP, Quetzaltenango, Guatemala

Introduction: A new variant of the H1N1 influenza A virus caused a pandemic from 2009 until the second semester of 2010.

Aim: To review the clinical characteristics of children who needed admission to our hospital due to a respiratory infection caused by H1N1/2009 influenza A pandemic virus.

Methods: We included in this review all pediatric patients who were admitted to our hospital due to H1N1/2009 influenza A pandemic virus infection, detected by a polymerase chain reaction test in a nasopharyngeal aspirate, sent to the CDC in the US, for accurate viral classification.

Results: We reviewed 40 clinical files. 24 were male; mean age 19 months. 47% were severe malnourished. Three symptoms were predominant in these patients: fever, cough and some degree of respiratory distress. 87.5% of these patients suffered from pneumonia, the main indication to be admitted to the pediatric ward. Hematotic biometries were normal. C reactive protein mean value of 30 mg.d.l in 26 cases. Only one patient received oseltamivir, but 87% (30 patients) were under antibiotics since admission. 10% required mechanical ventilation. An alveolar radiological pattern was seen in 70% of the chest X rays. Mean time hospitalization 7.5 days. The primary outcome of the study, mortality rate, was 7.5% (3 cases).

Conclusions: The mortality due to H1N1 2009 influenza A pandemic virus was low, even though most of our patients were malnourished, had pneumonia and did not receive antiviral treatment. This data correlates with data from other series in which mortality rate from this new pandemic influenza virus was lower than expected.

P1158
Outcome of H1N1 infection in hospitalised paediatric patients in a tertiary hospital
Department of Child Health, Department of Infectious Diseases, Sultan Qaboos University Hospital, Muscat, Oman

Introduction: In Oman, a total of 7040 cases tested positive for H1N1 with 31 deaths, till February 2010. We describe the clinical characteristics of children admitted to Sultan Qaboos University Hospital (SQUH) from September 2009 to February 2010.

Methods: The clinical data of all children with influenza like illness were reviewed. The diagnosis was confirmed in 38 cases by positive RT-PCR assay.

Results: A total of 243 children were admitted with influenza like symptoms, out of which 38 tested positive for H1N1. The mean age group was 4 years 1 month. The time between onset of symptoms and admission ranged from 1-22 days. The duration of admission from 1-22 days. LFT was abnormal in 2 children. None of the confirmed cases had been vaccinated. The number of children treated with peripheral anti-tussives (leodropropizine n=101) was higher than with central anti-tussives (codeine and cloperastine n=60).

Conclusions: The number of children treated with peripheral anti-tussives (leodropropizine n=101) was higher than with central anti-tussives (codeine and cloperastine n=60). Percentage of cough resolution was significantly higher with levodropropizine than with central anti-tussives (47% vs. 28% respectively, p=0.0012) (Fig 2). Percentage of no change or worsening was lower for levodropropizine vs. central drugs (3% vs. 18%, respectively).

P1160
Impact of cough on quality of sleep and effect of anti-tussive treatment in children: An observational study
Alessandro Zanzani1, Granulca De Danieli2, Luigi Lanata2, Rossella Balsamo1, Salvatore Cazzato3, Francesca De Blasio4, 1Respiratory Medicine, University of Bologna, S. Orsola Malpighi Hospital, Bologna, Italy; 2Medical Department, Dompi spa, Milan, Italy; 3Department of Paediatrics, University of Bologna, University of Bologna, S. Orsola Malpighi Hospital, Bologna, Italy; 4Respiratory Medicine and Pulmonary Rehabilitation Section, Clinic Center, Private Hospital, Naples, Italy

Background: Cough is one of the most frequent symptoms in children and is the most common symptom for which children are visited by primary care paediatricians.

Methods: We studied 433 children who required a paediatrician specific consultation for acute cough and analyzed quality of sleep and anti-tussive treatment.

Results: The mean age of the children was 6.1 years (DS 3.6). Cough disturbed sleep in 87.5% of children (Fig 1) and in 71% of parents.

Conclusions: Cough disturbed children and parents sleep. Both peripheral and central anti-tussives were effective in reducing cough intensity, with an advantage for levodropropizine in terms of higher cough resolution and lower unsuccessful treatment.
Primary ciliary aplasia as a cause of recurrent respiratory infections in an infertile young man

Mari Canciani1, Sura Bortotola2, Gioia N. Canciani3, Margherita De Santi1,
1Allergy and Pulmonology Unit, Department of Pneumology, University of Udine, Udine, Italy; 2Department of Pneumology, University of Udine, Udine, Italy; 3Noricch School of Medicine, Health Policy & Practice, University of East Anglia, Norwich, Norfolk, United Kingdom; 4Department of Human Pathology and Oncology, University of Siena, Siena, Italy.

We present a case of primary ciliary aplasia (PCA) a rare form of primary ciliary dyskinesia, characterised by the total absence of cilia in respiratory and sperm cells.

B.A. was born to healthy, first-degree related parents (first cousins). A few hours following birth, the patient developed the first of recurrent upper and lower respiratory tract infections. Cystic fibrosis, major immune deficiencies and allergic sensitization were excluded. Chest CT showed diffuse bronchiectasis of both middle lobes. Nasal and bronchial mucosa samples on transmission electron microscopy revealed total lack of cilia and basal bodies on columnar epithelial cells, despite displaying the morphological features of ciliated cells. At puberty, testicular volume and serum hormone levels were normal. Seminal fluid analysis revealed: ejaculate volume of 0.6 ml; pH 8; low sperm concentration (0.5-0.7 million of spermatozoa/ml); and asthenospermia-terathospermia (immotile spermatozoa and ejaculate volume of 0.6 ml; pH 8; low sperm concentration (0.5-0.7 million of spermatozoa/ml); and asthenospermia-terathospermia (immotile spermatozoa and motility). The clinical presentation at birth and the parents’ consanguinity make it unlikely that these changes are the result of infection or exposure to pollutants, thus supporting the hypothesis that PCA can be an inherited disorder.

A neonate with respiratory distress and unilateral pulmonary hyperinflation

Abdullah Yousef1,7, Ella Sugo2,6, Bruce Currie3,6, Pamela Palasanthiran4,6, Adam Jaffe5,6.

Introduction: Bronchial atresia is characterized by a mucus-filled bronchocoele in which fluid is trapped, distorting the normal bronchial architecture.

Case report: A 9-day old boy presented with history of increased work of breathing and cyanosis. Antenatal ultrasound at 22 weeks of gestation demonstrated marked pleural effusion and a right middle lobe bronchial atresia occurring with cCMV infection which may give further insight into the pathogenesis of this rare condition.

A girl with extensive dissemination of thoracic echinococcosis

Iris Grothus1, C.P. van de Ven1, A.W.P.M. Maal2, G. Palles3, J.C. de Jongste4.

A 10 year old girl from Iran was routinely screened for tuberculosis after immigration. She reported chronic cough and chest pain during the past year. A cystic lesion was detected on chest X-ray, and confirmed by a chest CT which also showed no suspicion of chronic lung disease, tuberculosis was excluded and Echinococcus serology was negative. Bronchoscopy showed no abnormalities, BAL cultures were negative and galactomannan was normal. Abdominal ultrasound excluded cystic lesions in the liver. She was treated with antibiotics and her symptoms disappeared. Surgery was scheduled to make a final diagnosis and because of the infection risk, with a diagnosis of infected CCAM and pleural adhesions. Before surgery we made an MRI scan which revealed a massive amount of cilia, occupying a large part of her left hemithorax. We now suspected dissiminated thoracic echinococcosis, and repeated serology, which was now positive. After alendroalcon prophylaxis and treatment of the cyst in the liver, the cystic lesion was resected. The excised tissue was histologically examined. We diagnosed the patient with a new form of thoracic echinococcosis, which might have been prevented by careful medical history taking, which could have detected cyst rupture.

Chronic nonspecific diseases of lungs (CNDL) and iodine deficiency diseases in children

Turidik Bobomuratov, Gulchehra Isakova, Dilshoda Akramova, Almardon Kuziev, Nurbakhaiz Habibullin, Almardon Kuziev.

During the chronic bronchopulmonary pathology as CNDL on children on background of iodine deficiency diseases, accompanied with the chain of unfavorable factors in immune system, metabolic processes which aggravate the clinical course, as well as make it ill effects.

Local cytokine production peculiarities in nasopharyngeal (adenoid) tissue of children with chronic lymph proliferative syndrome of different etiology

Elena Varyushina1, Marina Drudova2, Elena Tyrnova3, Andrey Simbirtsev1.

For estimation of iodine insufficiency degree we defined the concentration of the iodine in single portion of the urine by photometrical method. On 25% examined, median concentration of the iodine in urine was found the moderate iodine insufficiency degree (20-49 Mgl), on 55.8% light degree (50-99 Mgl), but on 19% iodine concentration in urine was above 100 Mgl. Thus, presence of iodine deficiency diseases in children with CNDL, has a definite significance during and outcome of chronic bronchopulmonary process, which requires additional and regular introduction of iodine-containing preparation and thyroid hormone.

Local cytokine production peculiarities in nasopharyngeal (adenoid) tissue of children with chronic lymph proliferative syndrome of different etiology

Elena Varyushina1, Marina Drudova2, Elena Tyrnova3, Andrey Simbirtsev1.

1Immunopharmacology, State Research Institute of Highly Pure Biopreparations, St. Petersburg, Russian Federation; 2Pediatrics, Research Institute of Ear, Nose, Throat & Speech, St. Petersburg, Russian Federation.

Proinflammatory cytokines can regulate local inflammatory and immune responses.
during infections of respiratory tract. Production of IL-1α, IL-1β, IL-6 and IL-8 was investigated in children with chronic lymph proliferative syndrome. Biopsies of adenoid tissue were taken in 42 children 3-8 years old during adenectomy or adenotonsillectomy. Cytokine production was detected in cryostat sections using non-direct immunohistochemistry. Neutrophils were stained histochemically. Cytokine-producing cells (mainly macrophages) were counted in sections, results were expressed in units (0 no reaction – 3 high intensity) and percent of positive cases was calculated. I group of children (n=16) had Epstein-Barr virus (EBV), cytomegalovirus (CMV)-infection (past-infection, PCR+DNA VEB, CMV), II group (n=15) – streptococcal infection (ASL=0–200mg/ml), III group (n=11) – unclear etiology. We detected IL-1α, IL-6 in 25-75%, IL-1β in 25%, IL-8 in 75% patients from I group, but at 94.100% cases in II or III groups. Intensity of all cytokines production was the highest in II group (IL-1α 4.00±0.40, IL-1β 1.40±0.35, IL-6 1.53±0.28, IL-8 1.73±0.32 units) and decreased in group I (IL-1α 0.25±0.23, IL-1β 0.25±0.23, IL-6 0.50±0.27, IL-8 0.93±0.36; p<0.05 vs II vs III (beside IL-8), IV vs III. The number of neutrophils infiltrated adenoid tissue showed local inflammation and did not differ significantly among three groups. We conclude that in children with VEB, CMV infection cytokine production is suppressed in comparison with groups with Streptococcal infection or unclear etiology.

Geographical variation in the risk of childhood pneumonia and relationships to socio-economic and health deprivation
Matthew Thomas1, Alasdair Blain1, Mark Shirley1, Clare Simmister1, Mohamed Elema12, Russell Goron1, Mark Pearce2, Julia Clark2, Stephen Rushon1, David Spencer1, 1Centre for Lifecycles Modelling, Newcastle University, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom; 2Department of Respiratory Paediatrics, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom; 3Department of Paediatric Infectious Disease and Immunology, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom; 4Regional Epidemiology Unit, Health Protection Agency North East, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom; 5Institute of Health and Society, Newcastle University, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom

Introduction: Socio-economic deprivation is a recognised risk factor for childhood pneumonia, while the relevance of health deprivation is unknown. The aim of this study was to establish whether there is significant spatial variation in risk of childhood pneumonia and whether this risk was determined by health and socio-economic deprivation.

Methods: Data on childhood hospital admissions in NE England from May 1997-April 2007 (n = 93,252) with a diagnosis of bacterial or lobar pneumonia were extracted from the Hospital Episode Statistics database. The spatial unit was a postcode district, which was linked with data from the health and socio-economic domains of the UK Child Wellbeing Index. Bayesian convolution models were used to model the association between standardised relative risk of admission to hospital with pneumonia in postcode districts and the deprivation indicators.

Results: There were 3874 admissions. From a total of 116 districts, 53 had a significantly different relative risk (RR) using a 95% Bayesian confidence interval (BCI) than that predicted by population alone (31 lower risk, 22 higher risk). The lowest RR was 0.32 and the highest 2.34. When the deprivation indices were included, the median effect of health deprivation was 0.43 (95% BCI 0.27-0.58). The model using only health deprivation provided the best explanation for the data (Deviance Information Criterion for null model 749.68 vs. 744.08 for health deprivation model).

Conclusion: There is substantial variation in the relative risk of pneumonia in different areas of NE England. Health deprivation better explains the spatial variation in risk than socio-economic deprivation.

P1167
Risk factors for recurrent wheezing following bronchiolitis: 3 yrs of follow-up
Giulia Cangiano1, Alessandra Pierangel2, Carolina Scagnolari2, Enea Bonci1, Corrado Molinari1, Paola Pagetti1, Jole Rabbal1, Marianna Ferrara1, Stefano Luciani1, Fabio Midulla1, 1Paediatrics, Sapienza University, Rome, Italy; 2Molecular Medicine, Sapienza University, Rome, Italy

We have previously demonstrated the association between bronchiolitis from Rhino virus (RV) and recurrent wheezing after one year of follow-up (Eur Respir J 2010; 36 (54) P2707). Our objective was to identify wheezing recurrence and related risk factors in infants with bronchiolitis from Respiratory Syncytial Virus (RSV), RV, Bovacivirus (hBoV), Influenza A and B, Parainfluenza 1-3, Metapneumovirus, Adenovirus and Coronavirus detected from nasals washes with RT-PCR. 208 infants (mean age ± SD 2.4±2.1, range 0.07-11.89 months, 89 males) hospitalized with bronchiolitis were evaluated for recurrent wheezing (RW) during 3 yrs of follow-up. Demographic and clinical data were obtained from parents with a structured questionnaire and patient’s medical files. Of the 208 infants, 152 (73%) answered to the phone call. 104 viruses were identified from 92 infants: RSV in 68 (33.9%), RV in 18 (16.3%), hBoV in 17 (18.5%), RSV+hBoV in 10 (10.9%), other viruses in 4 (4.3%). 34.9% of the infants with bronchiolitis had RW at the 3rd yr of follow-up. The related risk factors for RW were blood eosinophil counts > 400 cells/mm3 (OR 9.35; CI 0.95 1.98; 79.0), breastfeeding more than 2 months (OR 2.43; CI 1.20, 4.89) and bronchiolitis from RV (OR 3.17; CI 1.03, 9.79). At the 3rd yr of follow-up, 66.7% of the infants with bronchiolitis from RV have RW comparing to 75.1% of the infants with bronchiolitis from RSV, 30% of the infants with bronchiolitis from RSV+hBoV and 25% of the infants with bronchiolitis from other viruses. In conclusion infants with RW at the 3rd yr of follow-up after acute bronchiolitis seem to be those with atopic predisposition and a specific viral infection.

P1168
Making a bronchiolitis pathway work: If at first you don’t succeed ... Leo Thanikkel, Georgia Spentzou, Roona Amiapratong, Rob Ross Russell. Department of Paediatrics. Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Introduction: Last year we presented a poster asking why we were so poor at following bronchiolitis guidelines. A number of measures were introduced following last year’s poor performance. This year we re-audited the pathway.

Methods: In 2008 we developed a care pathway for bronchiolitis trying to reduce unnecessary investigations and treatments, and optimise support with triage. Over the first winter we failed to produce any impact [1]. Analysis showed that the problem lay in the first hours of admission, and with doctors unfamiliar with the pathway. Formal and informal feedback, and focused teaching was instituted. Monthly data on key targets were collated and disseminated to staff.

Results: Over the first 4 months of the 2010/11 season the use of unnecessary investigations and treatments fell considerably (see table). Median length of stay also fell, from 3 days to 2.0 days.

This translates to significant savings. The reduced length of stay saved 77.4 beddays (~£40,000 (£ 48,000), 0.63 beds) and approximately £1500 (£ 1800) in investigation costs over the 4 month period. There have also been considerable savings in treatment costs.

Conclusion: Our work shows that the introduction of a guideline has to be continuously followed up with clear aims, focused teaching, and careful analysis. We believe that engaging doctors at all levels and regular feedback about progress are essential. Perseverance is important in order for the pathway to pay off; especially in a system where at regular intervals doctors rotate into the department.

P1169
Respiratory syncytial virus (RSV) prophylaxis in special populations
Ian Mitchell1, 1Bosco Paes2, Abby Li3, Krista Lancot4, 1Paediatrics, University of Calgary, Calgary, AB, Canada; 2Paediatrics, McMaster University, Hamilton, ON, Canada; 3MORE, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Objective: To compare palivizumab utilization and compliance, and respiratory infection (RI) outcomes in subgroups of infants at high risk for RSV within the Canadian Registry Database.

Methods: A prospective, observational, registry of infants at 29 sites who received ≥1 dose of palivizumab during the 2006-2010 RSV seasons. Utilization and RI outcomes were collected monthly over the full course of palivizumab Infants <35 completed weeks gestational age without medical conditions who met standard approval criteria (Group 1) were compared to those at high risk of RI due to underlying medical illnesses (Group 2).

Results: There were more infants in Group 1 (n=4880, 84%) than Group 2 (n=9952, 16%). Group 2 included Down syndrome (20.2%), upper airway anomalies (18.5%), pulmonary disorders (13.3%), cystic fibrosis (12.5%), neuromuscular impairment (8.2%), multiple system disorders (6.1%), cardiac disorders (2.7%), immunocompromise (1.8%), and miscellaneous disorders (10.8%). From 2006-2010, the proportion of Group 2 infants increased 4-fold from 5.6% (691/2243) to 19.1% (662/4213). Group 2 was older at enrollment (10.2±9.2 vs 5.3±5.3 months, p<0.005), had more advanced gestational age (35.9±6.0 vs. 30.9±5.4 weeks, p<0.005) and had higher RI (9.0% vs. 4.2%, p<0.0005) and RSV hospitalization (2.3% vs 1.32%, p=0.003) rates. Group 2 infants tended to be less compliant with treatment (69.4% vs 72.8%, p=0.048). Group (p=0.015) was an independent

Furniture SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
Birth by caesarean section is associated with asthma and atopic allergies (OR 1.27, 95%CI 0.69-2.36) non-significant association was observed in children without a family history of atopy (p for effect modification=0.06) but not asthma. More specifically, having wheeze (OR 1.36, 95%CI 1.07-1.71) asthma diagnosis (OR 1.41, 95%CI 1.09-1.83) and atopic sensitization (OR 1.67, 95%CI 1.08-2.60). There was some evidence that family history of allergies may modify the effect of caesarean section delivery on atopy (p for effect modification=0.06) but not asthma. More specifically, children with a family history of allergies had double the odds of atopic sensitization if born by caesarean section (OR 2.34, 95%CI 1.20-4.54) whilst a non-significant association was observed in children without a family history of allergies (OR 1.27, 95%CI 0.69-2.36).

Conclusion: Birth by caesarean section is associated with asthma and atopic sensitization in childhood. The association of caesarean delivery and atopy but not asthma is more pronounced in children with family history of allergies.

Physical activity and asthma symptoms in a population-based cohort

Conclusions: Physical activity levels were comparable between children with and without asthma related symptoms, with small differences only seen mainly in children who cough at night. Further analysis will investigate whether this is due to insufficient asthma treatment, and determine potential long-term effects of physical activity on prognosis of symptoms and lung function.

Prevalence of asthma and allergies in the Greek (G/C) and Turkish (T/C) communities in Cyprus

The prevalence of wheezing among 8-8 year-olds was 8.7% vs 11.4% (OR=0.74, p<0.01). Family history of atopy and early nursery attendance were elevated amongst the G/C. Other favourable factors as projected in the hygiene hypothesis were more frequent in the T/C community, including higher proportion in less urban areas (60% vs 34%), bedroom sharing (52% vs 37%) and exposure to farm animals (4.7% vs 6.0%). The same picture emerged in the 13-14 year old group. Controlling for participants' characteristics did not overturn the observed pattern in terms of community in either age-group e.g. the adjusted OR for wheezing remained at 0.73 (p=0.03) in the younger age-group.

Conclusions: Observed differences in the prevalence of risk factors between the two communities did not account for the lower prevalence of asthma and allergies among G/C children, suggesting that other factors not related to the hygiene hypothesis might be at play.

Assessment of primary care doctor’s diagnosed bronchial asthma in schoolchildren

We aimed to assess, whether physical activity differs between children with and without asthma symptoms.

Methods: In a population-based cohort, we collected information on physical activity and respiratory symptoms (wheeze, cough without colds, night cough) by questionnaire at ages 4-8 (N=5212) and 6-10 years (N=4236). We compared prevalence of symptoms between inactive (0-1 hour/day of outdoor play) and active (>2 hours/day) children.

Results: At age 4-8, 4447 children (85%) were active, at age 6-10, 3686 (87%). In 4-8 years olds, 17% of active and 19% of inactive children had current wheeze (OR 1.39, 95%CI 1.04-1.87). 38% vs. 41% had cough without colds (p<0.01, OR 0.77 vs. 0.59) and atopic sensitization (OR 1.67, 95%CI 1.08-2.60). There was some evidence that family history of asthma the diagnosis was confirmed in 82 (44.8%) and 200 (41.5%), respectively.

Study Design: at the time of referral, 166 ((34.5%) were not. In the groups of suspected and established primary care doctor’s diagnosis of bronchial asthma the diagnosis was included in the survey. At referral and during a 6 months evaluation period patient characteristics, history, symptoms, signs and results of type 1 allergy tests, spirometry, post bronchial beta-2 agonist dilation tests, 4-weeks daily measurement of peak flow rates, corticosteroid reversibility trials and exercise challenge tests were entered into a pre-defined electronic form. The secondary centre diagnosis of asthma was based on these data.

Results: 665 consecutively referred children aged 5-18 (mean 8.1 years, 233 girls (35%) and 432 boys (65%), were included in the study. 183 (27.5%) children had a referral diagnosis of suspected asthma, 482 (72.5%) an established referral diagnosis of asthma. In the latter group 316 children (65.5%) were on inhaled steroids at the time of referral, 166 (34.5%) were not. In the groups of suspected and established asthma the diagnosis was confirmed in 82 (44.8%) and 200 (41.5%), respectively.

Conclusions: In more than half of schoolchildren with a suspected or established primary care doctor’s diagnosis of asthma referred to a secondary paediatric re-
ferral centre the diagnosis may not be confirmed. Sensitivity and specificity of the
diagnosis of asthma in schoolchildren established in primary care settings need
further improvement.

P1175
Evidence that children can assess their asthma medication devices
Katerina Papataxiarchou1, Nikolaos Grekas1, Katerina Athanasissiou1,
Athanasios Kadias2, Polytimi Panagiotopoulou-Gurtagani2,1 Clinical Research
Department, Elpen Pharmaceutical Co Inc, Pireas, Attica, Greece; 2 First
University Department of Pediatrics, Agia Sophia Childrens Hospital, Athens,
Greece
Introduction: The value of obtaining children’s reports about their health from
questionnaires is important in clinical paediatrics and child health research. FSI-10
questionnaire for asthma devices’ assessment has been developed and implemented
for adult patients. The reliable Greek version has also been used in adults for both
clinical practice and research.
Objectives: The aim of this pilot study was to examine the suitability of Greek
FSI-10 in asthmatic children in order to measure their satisfaction and the usability
of inhalers in daily practice.
Methods: This 8-week pilot study was designed and conducted as an open label,
single-centre, non interventional, notified to regulatory authorities. Patients have
consented in study participation by their legally authorised persons. 33 (15 female)
asthmatic school children aged between 6 and 16 years were on the same device
use at least two months before study enrollment. Four different breath activated
dry powder inhalers (AeroDuo17, Elipenhaler2, Diskin8, Turbahalder17) were used
by study subjects. Questionnaire’s items were child-reported and completed by the
two pediatricians who interviewed in details the selected patients at the end of the
study. All necessary clarifications and explanations were also given by the
physicians during interview.
Results: Evidence that school children can reliably assess their inhalers by us-
ing the Greek FSI-10 was concluded. The questionnaire was easily understood.
Reliability was very good as shown by Cronbach test (Cronbach’s α = 0.925).
Conclusions: Greek FSI-10 may be used in pediatric school aged population.
Minor modifications may improve its measuring properties and reliability. Further
work on this topic is needed.

P1176
Validation of history on atopy and childhood illness in a clinical birth cohort study
Nadjia Hawwa Vising, Signe Marie Jensen, Hans Bisgaard. Copenhagen
Proactive Studies on Asthma in Childhood, COPASC, Copenhagen University
Hospital Gentofte, Health Sciences, University of Copenhagen, Gentofte,
Denmark
Background: The longitudinal birth cohort study is the preferred design for studies
of childhood health, particularly asthma and other atopic diseases. Still, prospec-
tive data collection depends on recollection of the medical history representing
a potential recall-bias.
Aims: We aimed to ascertain completeness of data on atopic disease and other
health symptoms reported in a closely monitored birth cohort study. Possible bias
from questionnaire severity and socioeconomic factors was sought.
Methods: The Copenhagen study on Asthma in Childhood (COPASC) is a clinical
birth cohort study of 411 children. Child health is monitored at 6-monthly clinic
visits from birth till age 3 with a particular emphasis on asthma and other atopic
diseases. Cohort information of 260 children was compared with the records from
family practitioners as an external reference.
Results: A total of 6134 medical events were reported at the COPASC interviews.
Additional 586 medical events were recorded by family practitioners, but not
reported at the interview. None of these missed events were related to atopic
disease. Respiratory, infectious and skin related symptoms showed completeness
above 90%, other diseases showed lower completeness around 77%. There was
no meaningful influence from concurrent asthma or socioeconomic, including
household income, mother’s education or employment.
Conclusion: The COPASC study exhibited full completeness to the main study
objectives, atopic disease, and high completeness to respiratory, infectious and skin
related illness. Our findings support the validity of clinical interviews of parents
in longitudinal cohort studies investigating childhood illness and atopic disease in
childhood.

P1177
Psychogenic cough: Clinical and laboratory characteristics
Vasiliki Avramidou, Elpis Hatziagorou, Fotis Kirvassilis, Dimos Gidaris,
John Tsanakas. 3rd Paediatric Dept, Paediatric Pulmonology Unit, Hippokration
Hospital, Aristotle University, Thessaloniki, Greece
Background: A bizarre loud and hoking cough which increases with increased
attention and is absent at night in an otherwise well child suggests a psychogenic
origin.
Aim – method: Clinical and laboratory characteristics of children with psy-
chogenic cough were analyzed retrospectively. Children were followed up in a
Paediatric Respiratory clinic, over a nine year period.
Results: 114 children with psychogenic cough (46% boys) aged 4.5 - 18 years
were evaluated. Mean duration of the cough was 8.6±11.1 months. Clinical
characteristics of cough were: harsh and explosive (85%), coughing and barking
(14%), exacerbating in the presence of medical staff (62%), disappearing with
sleep (98%), not exacerbated with exercise (82%), not accompanied with wheeze
(98%). Fifty-three children (46%) appeared to be under psychological stress, in-
cluding school phobias, attention seeking, or anxiety (28%) and parental strife
(18%). Sixty-three children (55%) had been prescribed antitussive medication,
salbutamol, inhaled and oral steroids, or anti-histamines, with no response. Physi-
cal examination and lung function tests were normal. Among 21% of the children
flexible bronchoscopy was normal. Explanation and discussion of the problems
that appeared to be associated with the cough were beneficial for 81% of the
patients. 6% of cases with persistent symptoms despite reassurance were referred
for psychiatric consultation.
Conclusions: In children with chronic cough, the characteristics of the cough may
be suggestive of psychogenic cough. The physician’s awareness of the possibility
of psychogenic factors in the aetiology of persistent cough may help in early
diagnosis and thus unnecessary and expensive investigations may be avoided.

P1178
Tourette's syndrome manifest as chronic cough in children
Teh-Ming Wang1, Chin-Hua Su2 1 Pediatrics, Taichung Veterans General
Hospital, Taichung, Taiwan; 2 Pediatrics, Taichung-Veterans General
Hospital, Taichung, Taiwan
Background: Tourette’s syndrome (TS) is a neuropsychiatric disorder charac-
terized by the presence of involuntary motor and phonics tics. Some of the involun-
tary phonic tics may present as coughing, grunting, and wheezing. These symptoms
may easily be confused with the symptoms associated with the disorders causing
chronic persistent cough. The purpose of this study was to present our experience
of the clinical manifestation and treatment outcome of the TS.
Material and methods: Retrospective review studies were done from Jan 2008 to
Dec. 2010. There were 8 patients who initially present as chronic cough (cough > 4 weeks) in OPD.
Results: Their ages ranged between 6 and 17 years old. Of these patients, 6 (75%)
were boys, 2 (25%) were girls. The onset of motor tics. All cases showed simultaneously multiple tics. The
most common tics in TS were throat clearing (58%), facial grimacing (48%),mouth
opening (48%), barking cough (38%), head turning (28%), shoulder jerk (28). Two
patients were associated with the behavioral disorders, obsessive-compulsive
disorder (1/8), attention-deficit disorder (2/8). No known of positive familial his-
tory in our patients. All patients suffered from rhinitis more or less and 5/8 could fully remit after aggressive nasal
management except 3 cases.
Conclusion: We would like to point out that TS should also be considered in
children with chronic cough. This may help prevent the potential unwanted effects
of the drugs which are presumptively given to these patients.

P1179
Prognostic importance of congenital stridor occurred during the 1st year of life
in children of five years of age
Elena Striga, Olga Zaytseva, Yury Soklatsky. Paediatric, The Moscow State
Mediko-Somatological University, Moscow, Russian Federation
Introduction: Stridor usually manifests after birth or at the age of 1 month
and most commonly is a symptom of upper respiratory tract infections. But
stridor appears at 2-3 years of age may be suggestive of psychogenic cough. The physician’s awareness of the possibility
of psychogenic factors in the aetiology of persistent cough may help in early
diagnosis and thus unnecessary and expensive investigations may be avoided.
Objective: To evaluate the impact of congenital stridor in infants as a predictor of
chronic diseases.
Methods: We examined 114 1-year old patients with congenital stridor. 60 chil-
dren were included in 5-year catamnesis data. Our cohort consisted of children
with persistent congenital stridor, excluding children with stridor due to ARD or
tracheal intubation.
Results: On their admission to the hospital all children had stridor of various
degrees, 21,9% had regurgitation, 7% - choking, 7,9% - projectile vomiting, 5,3% were
short-winded, 4,4% had sleep apnea and voice change. All children underwent
thorough examination, rhinolaryngoscopy was performed in 94 patients. Laryngomalacia was diagnosed in 80%, accompanied by pharyngolaryngeal reflux
and gastroesophageal reflux in 93.3%. Reflux-spasmodic without inflammatory
changes was found in 53,3%. All patients had connective tissue dysplasia. Mitral
valve failure was present in 35%, PFO - in 16.7%, heart rate abnormalities - in
21,7%. Chest deformations were found in 45%, hypermobility of joints - in 38.8%.
Conclusions: Congenital stridor may serve as a predictor of chronic disorders of
gastrointestinal tract, ENT-system, dysplasia of connective tissue, cardiovascular
diseases. Children with congenital stridor need to undergo detailed examina-
tions and long-term regular medical check-ups in order to minimize the risk of
complications.
P1180
Factors associated and attack rate in adenovirus infection among children with chronic respiratory disease
Carlos Flores Berriozabal, Mireya Méndez, Bernardina Chateau, Claudia Astudillo, Hugo Cerda, Sandra Flores, Pontificia Universidad Católica de Chile, Hospital Josefina Martínez de Ferrari, Santiago, Chile; Facultad de Medicina, Universidad Andres Bello, Santiago, Chile

Background: In-hospital adenovirus infections spread easily causing a profound impact in morbidity and mortality associated with outbreaks.

Objectives: To identify the attack rate of adenovirus infection in a hospital for children with chronic respiratory diseases (CRDs) and to assess the factors associated to the infection.

Material and methods: Fifty children with CRD were evaluated between June 2010 and October 2010 at Josefina Martinez Hospital. They were exposed during the Winter Campaign to patients with respiratory infections admitted during that period. Case was defined as “Case”. Univariate and multivariate logistic regression models were used to calculate odds ratios and 95% confidence intervals for selected variables: gender, age, tracheostomy and gastrostomy.

Results: Twenty four of chronic patients (48%) were younger than 2 years old and nineteen of them (38%) were 2 to 5 years old. 68% of all children have tracheostomy and 50% of them have gastrostomy. The attack rate was 50% in three months. There was no mortality. Risk factor associated with adenovirus infection was age 0 to 23 months old (OR = 11.1, 95% CI 1.12 - 109.6, p = 0.039). There was no association with other variables.

Conclusions: It is important to strengthen prevention measures for adenovirus infection, and these should be kept as long as viral shedding is prolonged. Closed hospitals allow a rapid dissemination. Infants are highly vulnerable. Tracheostomy is not associated with increased risk of infection.

P1183
Pulmonary function abnormalities in Egyptian sickle cell disease patients
Amany Abou Zeid, Mona El Ghamarawy, Egypt Pediatric Hematology, Cairo University Hospitals, Cairo, Egypt

Background: Pulmonary complications account for significant morbidity and mortality in sickle cell disease (SCD) patients. Abnormal pulmonary functions (PFTs) in these patients include airway obstruction, restriction, abnormal diffusing capacity, and hypoxemia. This study was carried out to assess PFTs among SCD patients, and the effects of different clinical and laboratory variables on PFTs.

Methods: Forty five steady state SCD patients, previously diagnosed and followed up at the Hematology Outpatient Clinic of New Children Hospital, Cairo University, were included. They were homozygous for HbSS and 18 sickle β-thalassemia. Their mean age was 15.1 years with a range of 5-33 years. Clinical, laboratory and PFTs were performed.

Results: Abnormalities of PFTs were found in 57.8% of our patients (n=26, 23 having restrictive and 3 obstructive patterns). According to severity of affection, 44.4%, 8.9% and 4.4% had mild, moderate and severe abnormalities respectively. Patients’ age was the only clinical variable that showed a statistically significant difference between SCD patients with normal and abnormal PFTs (p=0.02) and between those with normal and restrictive patterns (p =0.05). Frequency of vaso-occlusive crisis and serum ferritin level showed a statistically significant relation with severity of pulmonary affection (p=0.01 and 0.01 respectively). No statistically significant difference in parameters of PFTs of patients on hydroxyurea (HU) and those not. Conclusion: Pulmonary function abnormalities, mostly mild and restrictive, were found among our SCD patients. These changes may be more prominent with increasing age. Severity of pulmonary affection was related to frequency of VOC.

P1182
Pulmonary function in children with inflammatory bowel disease do not differ from healthy population
Joanna Peradzynska, Katarzyna Krenke, Joanna Lange, Aleksandra Banaszakiewicz, Izabela Luzowska, Pediatric Pneumonology and Allergy, Medical University of Warsaw, Warsaw, Poland; Pediatra: Gastroenterology, Medical University of Warsaw, Warsaw, Poland

Crohn’s disease (CD) and ulcerative colitis (UC) are multisystem disorders. Besides inflammatory process in the mucosa of the gastrointestinal tract there is an increasing age. Severity of pulmonary affection was related to frequency of VOC.

Material and methods: Fifty patients with IBD (25 with CU and 25 with CD, mean age 14,19±3,2) and 39 healthy control subjects (mean age 13,97±3,47) were included in the study. All patients from study and control group underwent standard spirometry, whole body plethysmography, assessment of diffusion lung capacity for carbon monoxide (DLCO).

Results: There were no significant differences between study and control groups Lung volumes remain within normal limits. DLCO was abnormal in 9 (18%) and 6 (15.3%) children from study and control group, respectively. We found one (2%) with decreased vital capacity (restriction not confirmed by whole body plethysmography) and two (4%) with obstructive changes in IBD group. In two patients from control group (5.1%) airway obstruction was diagnosed. Small airways tests were abnormal in 13 (26%) subjects from study group and in 13 (33%) control patients.

Conclusion: Pulmonary function in children with inflammatory bowel disease do not differ from healthy population.

P1184
Peripheral airway function in adults with sickle cell disease
Alice Chubb, Alan Lunt, Moira Dick, David Rees, Sue Height, Siew Lay Thein, Gerrard F. Rafferty, Anne Greenough, Division of Asthma, Allergy and Lung Biology, King’s College London, London, United Kingdom; Department of Paediatric Haematology, King’s College Hospital, London, United Kingdom; Department of Molecular Haematology, King’s College Hospital, London, United Kingdom

Aim: Impulse oscillometry (IOS) requires minimal patient co-operation and assesses peripheral airway function. Our aim was to determine whether IOS indices were useful to identify lung function abnormalities in adults with sickle cell disease (SCD).

Methods: IOS measurements were performed on 36 adults, homozygous for sickle cell haemoglobin (HbSS), mean age 40.77±13.80 (± SD 13.80) years; the controls were 10 ethnically matched subjects. Respiratory system resistance (Rs) at oscillation frequencies of 3Hz (Rs3), 5Hz (Rs5), 10Hz (Rs10), 15Hz (Rs15) and 20Hz (Rs20), respiratory system reactance (Xrs) at an oscillation frequency of 5Hz (Xrs5), resonant frequency (fres) and reactance area (AX) were recorded. Frequency dependence of resistance between 3 and 20Hz (f-d) was also calculated.

Results: Rs was raised at all oscillometry frequencies in the SCD patients. Xrs5 and AX were increased in SCD patients (p=0.00091, p=0.0006 respectively). The slopes of the linear transformations of frequency dependence of resistance (f-d) curves were negative in SCD patients, but not in the controls (p<0.0001).

Conclusion: Peripheral airway function in adults with sickle cell disease is not associated with increased risk of infection.
PI1185
Assessment of tracheobronchomalacia in relapsing polyrhondritis using impulse oscillometry
Hirotaka Hanauda1, Hiroki Nishine1, Hirotaka Kida2, Takeo Inoue1, Masamichi Mineishi1, Noriaki Kirumoto2, Terumi Miyazawa3. 1Division of Respiratory and Infectious Diseases, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 2Division of Chest Surgery, Department of Surgery, St. Marianna University School of Medicine, Kawasaki, Japan

Results: Five patients developed into tracheobronchomalacia (TBM). R5-R20 and X5 showed a significant difference between patients with TBM and patients with only airway involvement (AI) (R5-R20/TBM 0.48±0.21kPa/l/s, AI 0.15±0.27kPa/l/s, p<0.005, X5: TBM -0.48±0.17 kPa/l/s, AI -2.2±0.25 kPa/l/s, p=0.013). IOS was measured before and after stenting in 1 patient and a marked improvement was seen after stenting (before: R5 0.95kPa/l/s, R20 0.5kPa/l/s, 0.66kPa/l/s, R5-R20 0.05kPa/l/s, after: R5 0.31kPa/l/s, R20 0.29kPa/l/s, 0.09kPa/l/s, Freq 9.13 Hz, R5-R20 0.02kPa/l/s).

Conclusions: IOS was useful in the evaluation of airway involvement in RP and R5-R20 and X5 were practical markers to differentiate patients with TBM.

PI1186
Diagnostics of loss in lung elastic recoil pressure using impulse oscillometry and body plethysmography
Larisa Kryukhina, Marina Kameneva. Lung Function Laboratory, Research Institute of Pulmonology I.P.Pivovar State Medical University, Saint-Petersburg, Russian Federation

Respiratory resistance at 20 Hz (R20) by impulse oscillometry (IO) characterizes airways resistance with inextensible walls. Airways resistance (Rtot) by body plethysmography reflects the total resistance of the first 8 - 10 bronchi generations. These indicators by different methods are close physiologically. The airways in patients with an emphysema are deprived of elastic support, so a lung compliance (CL) considerably increases. We have assumed that shortening of R20 increases with loss of lung elastic recoil.

Aim of the study is evaluation loss of respiratory resistance by IO with increasing of compliance and decreasing of lung elastic recoil.

Methods and materials: We compared Rtot and R20 in 67 healthy volunteers (32F/35M, 47±1 yrs) and in the patients with obstructive disorders - 41 patients with COPD (16F/25M, 56±1 yrs) and 52 patients with bronchial asthma (34F/18M, 47±2 yrs). We have used the relation Rtot/R20. All patients were performed investigation of lung elasticity using esophagus balloon.

Results: Rtot/R20 in healthy group was 0.79±0.03 and in patients with obstructive disorders it was 1.72±0.10 (p<0.01). The analysis Rtot/R20 in patients with obstructive disorders showed considerable difference of Rtot/R20 value in patients with normal lung elastic recoil and in patients with loss lung elastic recoil (1.24 and 2.08 respectively, p<0.01). The correlation analysis showed moderate dependence Rtot/R20 with CL and coefficient of retraction (CR) (r=0.57 and 0.38 accordingly, p=0.01).

Conclusion: The relation Rtot/R20 reflects loss in parenchymal elastic recoil pressure. In healthy and patients with obstructive disorders with normal lung elastic recoil it is less 1.24.

PI1187
Direct airway resistance response after deep inspiration in symptomatic asthmatics
Karin van der Velden-van Etten, Karin Nietzeman-Lammering, H.C. Hoogsteden. Dept. of Pulmonary Medicine, Erasmus Medical Center, Rotterdam, Netherlands

Introduction: Immediately after a deep inspiration there is a response in the airways resistance. In patients with asthma the response to deep inspiration (DI) is impaired compared with healthy subjects.

Aim: We want to investigate the airway resistance response after DI changes when subjects are exposed to a bronchoconstrictor.

Methods: All subjects were symptomatic asthmatics. They all performed a tidal breathing challenge test (Meth) with methacholine bromide from 0.039-39.6 mg/ml in doubling doses. After each inhalation the airway resistance was measured by impulse oscillometry (IOS/PFT, Care Fusion, Würzburg) during 60-80 seconds with a DI at 30s. At 90s FEV1 was measured. P-values <0.05 were assumed to be significant.

Results: We analyzed 24 tests. One patient was excluded because of spirometric induced asthma. In 12 cases we found a PC20 <16 mg/ml. In 11 patients there was no PC20 or a PC20 >16.

P20±16 p-value
mean at baseline
R5 (kPa/l/s) 0.37 0.28 0.072
R5-R15 (kPa/l/s) 0.08 0.06 <0.05
ΔR5 0.08 0.06 <0.05
ΔR5-R15 0.004 0.000 <0.05

At mean at baseline
R5 (kPa/l/s) 0.66 0.45 0.005
R5-R15 (kPa/l/s) 0.26 0.15 0.038
ΔR5 0.08 0.04 <0.05
ΔR5-R15 0.03 <0.05

ΔR5 is the difference in R5 before and after DI, ΔR5-R15 is the difference in R5 before and after DI. We found a significant difference in ΔR5 between baseline and the highest concentration both in cases and non cases (resp: p<0.024 and p=0.022).

Conclusion: When PC20 is reached there is still an overall decrease in airway resistance after DI. Compared to those who didn’t reach PC20 <16 the decrease is not significant but both groups had a high SE. The response to DI is highly variable in asthmatics.

P1189
Agreement of airway resistance measurements by two different techniques of body-plethysmography and impulse oscillmetry in asthmatic patients
Agha Sharifir, Khalid Ansarir. Tuberculosis and Lung Disease Research Center, Tabriz University of Medical Sciences, Tabriz, Azarbarjany Shahri, Islamic Republic of Iran, Tuberculosis and Lung Disease Research Center, Tabriz, University of Medical Sciences, Tabriz, Azarbarjany Shahri, Islamic Republic of Iran

Background: Airway resistance can be measured by different techniques of body-plethysmography and impulse oscillometry (IOS). So far there has been no systematic study comparing validity of these techniques in relation to clinical condition of the patients reported.

Aims and objectives: We investigated correlation between these techniques in assessment of airway resistance and asthma control test.

Methods: In 92 patients with asthma selected on the basis of ATS criteria for diagnosis of asthma and GINA asthma control test (ACT) questionnaire completed. Pulmonary function tests including body-plethysmography with airway resistance measurement and impulse oscillometry measuring total airway resistance at 5 Hz and 20Hz were done using IOS.

Results: ACT score has a significant correlation with a r value of - 0.34 with total airway resistance measured by body-plethysmography (p=0.003) and also significant correlation with r value of - 0.31 (p=0.002) with airway resistance measured by IOS at 5Hz but no significant correlation with airway resistance measured by IOS at 20 Hz. There is a significant correlation between airway resistance measured by body plethysmography and airway resistance measured by IOS at 5 Hz and at 20 Hz.

Conclusions: These finding indicates a good correlation of total airway resistance measured by body plethysmography and by IOS at 5 Hz as well as at 20 Hz which is stronger with the first. Also significant negative correlation between ACT score and airway resistance centered in peripheral airways measured by IOS at 5 Hz but not with the resistance at central airways measured mainly by IOS at 20Hz.

P1198
Sgaw as an alternative for FEV1 in the measurement of airway responsiveness to methacholine in patients experiencing chronic cough
Remco Borsel, Maria Habes, Reindert van Steenwijk. Lung Function, Academic Medical Centre (AMC), Amsterdam, Netherlands

Background: A drop of 5% in specific airway conductance (S Gaw) during a methacholine challenge test (MCT) is considered to be comparable to a drop of 20% in FEV1 to assess airway hyperresponsiveness (AHR). In our department patients with chronic cough tested with a MCT on a drop of FEV1 show an increase in cough without reaching a conclusive PC20.

Aim: To examine the correlation between drops in FEV1 and S Gaw during MCT in chronic cough patients.

Methods: 16 patients with history of chronic cough were included for a cross-sectional study. Inclusion criteria: episodic chest symptoms, chronic cough and post bronchodilator FEV1/FVC ratio ≥ 0.70. Each concentration in MCT was followed by measurement of S Gaw and FEV1. Linear regression was used to determine the correlation between PC20 FEV1 and PC50S Gaw.

Results: LogPC50S Gaw was significantly lower than log PC20FEV1 (p<0.004). 7 patients showed a positive response only to S Gaw (Figure 1).

We found that a decrease of 20% in FEV1 was accompanied by 65% decrease in S Gaw.
Conclusions: Patients with chronic cough show a larger response to methacholine by sGaw as compared to FEV1 than reported in the literature. This suggests that in this set of patients sGaw is relatively more sensitive in assessing AHR.

Implications: Chronic cough patients may exhibit AHR that remains unnoticed when performing MCT with FEV1.

P1190
Non-invasive measurement of respiratory impedance in conscious guinea pigs utilising impulse oscillometry
Carmen Claudia Klein1, Jens Thomas2, Norbert Mieskes3, Martin Hoffmann2, Hans-Juergen Smith3, 1Veterinary Clinic, fzm GmbH, Research Centre of Medical Technology and Biotechnology, Bad Langensalza, Germany; 2Medical Development, fzm GmbH, Research Centre of Medical Technology and Biotechnology, Bad Langensalza, Germany; 3Medical Development, Research in Respiratory Diagnostics, Berlin, Germany

Aim: Since rodents are often utilised as models in respiratory research, we investigated a newly constructed Impulse Oscillometry System (IOS) which was modified to allow non invasive measurements of respiratory impedance in conscious guinea pigs.

Material and methods: Five female guinea pigs (body weight 592.2±73.0 g) were included in the study. The animals were fixated manually in an extended supine position. a) Three consecutive IOS measurements, taken within a few minutes duration from each animal were used to evaluate short time variability. b) The results of measurements taken on three consecutive days at the same time of the day were used to assess long time variability. Coefficients of variation (CV%) were calculated for oscillometric resistance parameters between 5 and 35 Hz.

Results: Coefficients of variation (CV%) for Resistance parameters at selected frequencies are shown in table 1.

Appropriateness of ATS/ERS recommended lung volume reference values for contemporary Australasian children
Maureen Verheggen1,2, Karla Logie2, Chris O’Drea1, Barbara Dixon5, Maureen Swanney1, Graham Hall5,1, 1Respiratory Medicine, Princess Margaret Hospital, Perth, Australia; 2School of Paediatrics and Child Health, University of Western Australia, Perth, Australia; 3Respiratory Physiology, Christchurch Hospital, Christchurch, New Zealand; 4Paediatric Respiratory Physiology, Telethon Institute for Child Research, Perth, Australia; 5Respiratory Medicine, Sydney Children’s Hospital, Randwick, Australia

Introduction: There are only limited reference ranges for static lung volumes (LV) by Plethysmography (PLETH) or gas dilution (DIL) that encompasses the paediatric age range. International recommendations suggest the data from Zaplateel (PLETH) and Cook (DIL) be used pending appropriate data using modern equipment and most recent guidelines.

Aim: To assess the suitability of these recommended reference ranges to contemporary healthy Australasian children.

Methods: Healthy subjects performed LV measurements by DIL or PLETH according to the 2005 ATS/ERS guidelines. Data was compared to recommended reference ranges and expressed as% predicted.

Results: Measurements were obtained in 244 subjects aged 5 to 19 years (120 male) of which 121 and 144 performed LV by DIL and PLETH, respectively.

Lung volumes as %pred

FRC and RV measured by both methods were significantly lower than published values (p<.001). Individuals below the LLN for TLC and outside the 95% CI for FRC and RV ranged from 4% for TLC by DIL to 55% for RV by PLETH.

Conclusions: Measured TLC agrees well with both PLETH and DIL reference ranges. FRC and RV by either method were significantly lower than predicted. A proportion of these healthy subjects would be considered to have LV outside the normal range. The recommended reference ranges for RV and FRC are inappropriate for use in Australasian children. New reference ranges using modern equipment are needed for this population.

P1193
Spacer device selection may not impact bronchodilator responsiveness (BDR) in asthmatic children
Jeanette Langley3, Claire Shackleton1, Sunalene Devadason3, Graham Hall1, 1Department of Respiratory Medicine, Princess Margaret Childrens Hospital, Perth, Western Australia, Australia; 2Clinical Sciences, Telethon Institute for Child Health Research, Perth, Western Australia, Australia; 5Respiratory Medicine, University of Western Australia, Perth, Western Australia, Australia

Assessment of spirometry before and after bronchodilators is used in the diagnosis and management of asthma. The impact of spacer device selection on clinical BDR is poorly understood. ATS guidelines state 400μg of salbutamol should be used for BDR testing. The aim of this study was to investigate if spacer selection has an effect on BDR in asthmatic children and at what salbutamol dose BDR reached significance.

Methods: This study compared spirometry and BDR with a disposable spacer (Lite Aire; Thayer Medical) and a multi-patient use spacer (Space Pod; Medical
P1194 Feasibility and reproducibility of pulmonary function tests in preschoolers

Daniele Froman1, Docimar Marques2, Filipe Athayde3, Mercles Alceu4, Gilda Araujo5, Paulo Camargos1, Raquel Britto1, Verônica Parreira5

1Graduation Program in Rehabilitation Sciences, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; 2Department of Nursing, Faculdade Ciências da Vida, Sete Lagoas, Minas Gerais, Brazil; 3Department of Pediatrics, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; 4Department of Physical Therapies, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Relevance: Preschoolers present particularities that reinforce the importance of assessing their pulmonary function; however few studies have focused on pulmonary function tests in this population.

Purpose: To assess the feasibility of assessing breathing pattern through inductive respiratory plethysmography, spirometry and peak cough flow (PCF) in healthy preschoolers, as well as the test-retest reproducibility of these tests.

Methods: It was assessed the breathing pattern (tidal volume-Vt; respiratory frequency-f; inspiratory time -Tl; inspiratory duty cycle-Tl/Ttot, mean respiratory flow -Vm; peak and root mean-square (RMS) of bronchial flow), spirometry (forced vital capacity-FVC, forced expiratory (min) volume forced in one second (FEV1), FEV1/VC and FEV1/VC and PCF and 38 healthy children aged 4.8±0.6 years. To evaluate the test-retest reproducibility, 10 children (depending to sample size calculation) were reassessed after three weeks. The study was approved by Ethics Committee. Feasibility was defined as the rate of success achieved by the children. Test-retest reproducibility was evaluated by paired t-test, considering significant p<0.05, and Intraclass Correlation Coefficient (ICC).

Results: The results showed a rate of successes of 100% for breathing pattern, 84% for spirometry and 90% for PCF. Regarding the reproducibility, there were no significant differences between variables of any test and it was observed the following ICC values: Vt=0.74, f=0.87, Tl=0.80; Tl/Ttot=0.95, Vm=0.68; 4.6%. ICC of 0.66, FVC=0.92, FEV1=0.81, FEV1/VC=0.75, PCF=0.85.

Conclusions: These results suggest high rate of success in performing the pulmonary function tests and good test-retest reproducibility in healthy preschoolers.

P1195 Feasibility of spirometry-controlled chest magnetic resonance imaging (MRI) in children

Sandra de Lever1, Pierluigi Cinti2, Elis van der Wiel1, Pieter Wielopolski3, Harm Tiddens1,2,4,5

1Radiology, ErasmusMC-Sophia, Rotterdam, Netherlands; 2Acousticologia, ErasmusMC Sophia, Rotterdam, Netherlands

Standardization of inflation- and expiration level using a spirometer during chest-MRI is important to optimise image quality and interpretation. To perform the correct breathing manoeuvres in a MRI is a challenge for most children.

Aim of this pilot study: To evaluate the feasibility of spirometry-controlled chest-MRI.

Methods: A custom made MRI compatible spirometer (Masterscope, Carefusion) and a dedicated holder for the spirometer head was used. This allowed correct and child friendly positioning of the spirometer in the MRI.

Children practiced in supine position 4 hour prior to MRI with a lung function technician the following breathing manoeuvres: slow vital capacity (SVC); a breath-hold (13 sec) at Total Lung Capacity and at Residual Volume; and flow volume and coughing to obtain dynamic images of central arteries. During the MRI the lung function technician sat by site by the MRI technician and coached and monitored the child’s performance and instructed the MRI technician when to start the acquisition.

Results: 14 Children (age 5 – 17 years, 9 boys) had a MRI. Each child was able to perform the child prior to the MRI and coach the child during the MRI by a lung function technician.

Conclusion: Spirometry-controlled chest MRI is feasible in most children and improves the standardization and the image quality of chest MRI. We recommend training of the child prior to the MRI and coaching of the child during the MRI by a lung function technician.

P1196 Early lung function testing in infants with aortic arch anomalies identifies infants at risk for airway obstruction

Charles Rocke1, Hans Proquittè1, Bernd Opgen-Rhein2, Christoph Buehrer1, Gerd Schmalisch3,1, Neontology, 2Paediatric Cardiology, Cardiö Universitätsmedizin Berlin, Berlin, Germany

Aortic arch anomalies (AAA) (vascular rings) are rare anomalies (approx. 3% of all cardiac anomalies) that can obstruct the upper airway. The preferred strategies for diagnosis and treatment vary among institutions. The aim of this study was to investigate the degree of airway obstruction in infants with AAA by lung function testing (LFT).

Patients and methods: Sixteen patients born between 2005-2010 with echocardiographic: AAA (10 right sided (69%) and 6 double aortic arch (31%)) preoperative LFT was performed in the 39th (36th – 41th) postconceptional week (median (range)) body weight 3300 (2320 - 4360) g. Raw was measured by baby bodyplethysmography (Jaeger, Wurzburg, Germany). With the same equipment the maximal expiratory flow at functional residual capacity (V’maxFRC) was measured using the rapid thoraco-abdominal compression (RTC) technique, according to international guidelines. V’maxFRC was also expressed in standard deviation scores (Z-scores) based on sex-, age and high-specific reference values of healthy infants published by Hoo et al. AJRCMB 2002.

Results: Between Raw and the Z-score of V’maxFRC was a strong correlation (r=0.768, p<0.001). Most infants were within the normal range of V’maxFRC without statistically significant difference between right sided and double AAA. However, 3 infants (20%) were near or distinctly below the 10th percentile of V’maxFRC and had Raw >-1.41zH2O/L/s, indicating upper airway obstruction.

Conclusion: Most infants with AAA had no impairment of the upper airway conductivity. However, early LFT may help to indentify and to monitor patients who may be at risk for significant airway obstruction.

P1197 Forced expiratory tracheal noise time in diagnostics of hidden bronchial obstruction among spirometry negative asthma patients

Irina Pochekutova, Veronika Malavea, Vladimir Korzenbaum. Acaustical Tomography, V.I. Vavilov Pacific Oceanological Institute FEB RAS, Vladivostok, Russian Federation

Computer instrumentation (Korzenbaum et al., 2008) provides a precise estimation of acoustic tracheal forced expiratory noises time (FETa). The purpose was an estimation of FETa efficiency as diagnostic test of hidden bronchial obstruction (BO). The sample consisted of homogeneous groups: young male asthma (BA) patients as a BO model (71 persons with spirometry negative BO), control group (77 non-smoking healthy subjects and 44 smokers). FETa values were normalized by C – chest circumference, H – height, M – body mass. The FETa was divided by ROC-analyzis. Percentages of deviation from the norm, revealed by acoustic indicators in groups were evaluated.

Conclusions: The presence of BO in healthy non-smokers patients with spirometry negative is 0.01 re healthy non-smokers.

Diagnostic efficiency of FETa and its normalized indicators in spirometry positive BA is very close to efficiency of base-line spirometry. Moreover, bronchial obstruction is acoustically diagnosed almost in a half of patients with spirometry negative BA, whereas healthy are indistinguishable from young smokers. Thus, FETa seems to be important for diagnostics of hidden bronchial obstruction, at least, in young male subjects. The study was supported by Far Eastern Branch of Russian Academy of Sciences grants No. 09-1-P21-08, No. 09-3-A-06-231.

P1198 Dynamic hyperinflation in patients with severe COPD

Karin Kloosteen, Dirk-Jan Siesbo. Pulmonary Department, University-Medical Center, Groningen, Netherlands

Introduction: Dynamic hyperinflation (DH) is thought to be an important clinical feature in patients with COPD, but is difficult to measure.

 Aim: To investigate DH in patients with COPD referred for bronchoscopic lung volume reduction and to test the feasibility of using metronome paced hyperventilation (MPH).

 Methods: DH was measured by MPH using the breath-by-breath method (Oxycon Pro) in a 15-min protocol. After 3 baseline IC maneuvers, 3 MPH tests (40Hz for 60 sec, with 3 min rest in-between) were performed. Each MPH test was directly followed by an IC maneuver. DH was defined as IC/IC (decrease in IC/baseline IC) and calculated using the average of 3 ICs.

Groups Healthy patients non-smokers BA smokers BA patients with approved BO

FETa 16 27.3 41* 78.9* 78.9*
FETa/C 17 25 49.2* 87.8* 87.8*
FETa/H 18 27.3 47.4** 80.3* 80.3*
FETa/M 13 22.7 46.2* 83.9* 83.9*
FETa/VFRC >75% 2.6 0 0 74.6* 74.6*

*p<0.001; **p<0.01 re healthy non-smokers.

218s
Conclusion: All patients tolerated the MPH very well. IC variability was 4.6% (±4.0), and 8.6% (±4.4) after MPH. VE reached 28.8 L/min (±12.6), calculated maximal VE (FEV1% ±7.5) was 34.5 L/min (±15.5). MPH frequency was 39.7 Hz (±1.4). For the Gold-IV patient group the IC of 1.83 L (±0.47) decreased to 1.21 L (±0.42) after MPH with a ΔIC/IC of 34% (±12). In Gold-III IC decreased from 2.39 L (±0.93), to 1.79 L (±0.63) with a ΔIC/IC of 23% (±12). In the overall group ΔIC/IC correlated with TLC-He (r=0.45, p=0.03) and FEV1 (r=-0.38, p=0.04).

Conclusion: Measuring DH is feasible using MPH, and can be used in the routine clinical setting. DH is significantly present in patients with COPD and increases with disease severity.

Results: Good agreement was found between phase delay estimated by ACC and SI (r =0.98, p<0.001; Figure, panel a). Mean values were 219 s and -0.45 with delays at AUR significantly smaller than ALRI (r =0.985±0.2262 vs -1.941±0.2655; p=0.0002).

Discussion: The results show that novel methods for CO measurement in exhaled air can be used for non-invasive monitoring of CO exposure. The proposed method is simple, rapid, and requires no specialized equipment. It can be used in various clinical settings, including health monitoring, occupational health, and environmental exposure assessment. Future studies should focus on optimizing the sensitivity and specificity of the method for different CO sources and exposure scenarios.
P1203

Static lung volumes in lung transplant recipients with bronchiolitis obliterans syndrome
Therese Small1, Christopher Ward2, James Leodan1, Andrew Fisher2, Paul Corris1, John Gibson1, Sir William Leech Centre for Lung Research, Freeman Hospaial, Newcastle upon Tyne, United Kingdom; 2Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

The bronchiolitis obliterans syndrome (BOS), post lung transplantation, is defined as progressive, irreversible obstruction of the small airways leading to pulmonary hypertension and declining lung function. We studied 32 patients: post SLT and post sequential single lung transplantation (SSLT).

We studied 32 patients: 11 SLT (9 COPD; 2 OB) and 21 SSLT (6 COPD; 1 OB; 14 cystic fibrosis). The SSLT group were significantly younger (median 38 ± 5 years).

SLT median 52.8 ± 72.8 121 ± 156 0.48 1.64 0.77
SLT range 30.5-64.1 51.4-88.2 90.9-179.0 102-175 0.62-0.81 0.93-3.49 0.45-0.95

SSLT median 63.3 ± 82.6 89.9 ± 101 0.63 2.0 0.60
SSLT range 30-1-30.10 52.2-110 53.1-124.0 72.8-164.0 0.51-0.77 0.96-3.29 0.39-0.79

The SSLT group had larger TLC and FRC, while IC was similar in the two groups and, as a proportion of VC, was actually greater in the SLT group.

IC was relatively well preserved in the SLT patients with early BOS, despite the presence of a hyperinflated native lung. Longitudinal lung volume measurements might usefully evaluate the progress of BOS in both SLT and SSLT recipients.

P1204

Postoperative predictive value of lung function in patients with lung cancer – Fortune-telling or reality? Evaluation after surgical treatment
Monika Franczuk, Jerzy Usekieniewicz, Piotr M. Rudzinski, Stefan Wesołowski, Tadeusz M. Orlowski. Lung Function Lab, Thoracosurgery Department, Research Institute for Th and Lung Diseases, Warsaw, Poland

Lung function testing is important tool of the evaluation patients with lung cancer, candidates for surgical treatment. Based on the scope of the planned resection and the result of bronchofiberoscopy there is possible to calculate the expected postoperative value of lung function (ppoFEV1, pppoLCO), but reliability of such estimation is still under discussion. The aim of the study was to evaluate lung function in the postoperative out-patient observation and compliance with the result.

The analysis included 42 operated pts (mean age 64.3 ± 8.8 yrs, 23 M) who underwent spirometry before resection and after 3 and 6 months during the out-patient follow-up. The people undergoing additional chemotherapy and/or radiotherapy were excluded from the assessment.

Lobectomy was performed in 39 pts (28 upper, 11 lower) one pneumonia in 3 pts. Mean FEV1 value before surgery and 3 and 6 months after was 2.36±0.49 L (88.0±18.3%), 1.79±0.45 L (67.2±18.6%) and 1.84±0.47 L (68.9±18.1%) respectively. The significant correlation of pppoFEV1 (1.9±0.55 L, 73.1±18.3%) and measured values was revealed, amounting to 0.72 and 0.76 respectively for the study in 3 and 6 months after surgery. Detailed analysis showed that the correlation was higher in group of patients after lower than upper lobectomy: 0.85 vs 0.73 at 6 months after resection.

Conclusion: In studied group mean value FEV1 measured in the postoperative follow-up at 3 and 6 months after resection shown good agreement with pppoFEV1, however better for patients who underwent lower lobectomy, poorer for upper resection.

P1205

Maximal inspiratory pressures, lung volumes and flows in young rowers
Jana Krivastik1, Mati Arend2, Raul Ramon1, Jyrki Maestas1, Department of Physiology, University of Tartu, Tartu, Estonia; 1Institute of Exercise Biology and Physiotherapy, University of Tartu, Tartu, Estonia; 2Institute of Sport Pedagogy and Coaching, University of Tartu, Tartu, Estonia

Respiratory muscle training has demonstrated improvement in exercise performance in both healthy adults and in patients with chronic respiratory illnesses. Such programs often ask to perform respiratory efforts against a pressure load equivalent to a certain percent of maximal respiratory pressures. Portable devices are available to measure those maximal pressures, but it can be highly dependent on participant effort.

Our aim was to find out whether maximal inspiratory pressure (MIP) correlates with different flow-volume loop parameters in a group of college level rowers and to compare the data from athletes with reference values.

We studied 19-33 year-old rowers (n=14, two of them female) with height 173-202 cm. Spirometry was performed to determine FVC, FEV1, PEF and PIF. MIP was measured with a hand-held mouth pressure meter. All measured values were compared with reference data and correlations between MIP lung function and anthropometric indices were found.

Compared to reference population values of FVC and FEV1, from rowers were mostly above average (97-130% pred.), whereas PEF ranged from 85 to 126% of predicted. All 3 forced expiration indices correlated with height (r=0.01). When using MIP reference values depending on age only, we obtained values in a range of 88-212% pred (absolute values 98-234 cm H2O). The only significant positive correlation was found between MIP and PIF (r=0.05).

Relatively high lung volumes and flows compared to the predicted values indicate the increased functional capacity of respiratory system in rowers. We found a wide range of MIP values in young subjects with MIP and PIF did correlate with neither anthropometric nor spirometric indices (except for PIF).

P1206

Asthma diagnosis by the reversibility test of respiratory muscles power in asthmatics using the respiratory pressure meter
Omer Elbadie, Mohamed Elbarg Ali, Aamir Mazgoub, Omer Musa. Physiology, Faculty of Medicine, Nile Valley University, Artaha, Sudan Respiratory Medicine, Faculty of Medicine, National Ribat University, Khartoum, Sudan Physiology, Faculty of Medicine, National Ribat University, Khartoum, Sudan Physiology, Faculty of Medicine, National Ribat University, Khartoum, Sudan

Introduction: Intermittent and mild asthma types are difficult to diagnose during the symptoms free period. The respiratory muscles perform extra work in asthma and expected to be stronger than normal subjects. The respiratory pressure meter measures the respiratory muscle power as a function of the air volume expired or inspired by effort. The hypothesis was introduced that if the bronchiodilators are dilated by a bronchodilator the expired volume of air and consequently the pressure it exerts is expected to increase.

Objective: To perform a pilot reversibility test in asthmatic patients by spirometry and respiratory pressure meter.

Methods: This is a cross-sectional hospital based study carried out in Lung function tests clinic in Police hospital in Khartoum in 2010 –2011 to determine the reversibility of the respiratory muscle power after salbutamol inhalation using the respiratory pressure meter. Following informed consent, PEFR, FEV1/FVC, Maximum inspiratory pressure (MIP) and Maximum inspiratory pressure (MIP) were measured in 20 patients with asthma and the tests were repeated 15 minutes after salbutamol inhalation. All patients were not during an acute attack.

Results: 20 patients were included. FEV1 reversibility was 10.8% and PEFR reversibility was 13.1%. The MIP increased from 81.2 cmH2O to 91.2 cmH2O, with a reversibility of 12.3% while the MIP increased from 60.8 to 69.9 cm H2O, with a reversibility of 15%.

Conclusion: Respiratory muscles power reversibility could be a potentially sensitive diagnostic test for asthma.
FEV1 values were 4.1% larger than the predicted values in the whole group. For 31 subjects (58.5%) measured FEV1 values were outside the 95-105% interval of FEV1 predicted values.

Conclusions: A significant number of healthy adults have had spirometric values outside the confidence interval of predicted values (European equations in use). A larger study is needed in subjects with different ages and heights to verify the data obtained in our study. The opportunity of determining specific predicted values in a large population study is discussed, considering the necessary resources.

P1208
E-patient reported outcomes: Can you have reliance on compliance?
Aleck Harrison1, Grant Sommow2, Harlip KaurNagra2, Richard Woodward1
1Clinical Operations, AJH Partners, Wallingford, Oxon, United Kingdom; 2Clinical Trials, Vitalograph Ltd, Maida Vale, London, United Kingdom

Introduction: Consistent evidence is required to confirm the value of electronic Patient Reported Outcomes (e-PROs) for compliance in Usage and Quality of PEF manoeuvres in large clinical trials where these data are used as critical end-points [1].

Method: In an international asthma trial requiring twice daily symptom scores and three PEF manoeuvres over 105 days e-PROs were recorded using the Vitalograph PEV/PEF e-diary within a protocol specific program. Usage Compliance was assessed by the actual number of completed sessions made by patients as a percentage of the potential total. Quality Compliance assessed by Repeatability of the two highest manoeuvres of a session using the ATS/ERS standard of ≤3±3L/min.

Results: From 519 asthmatic patients at 78 sites a total of 103,198 diary sessions were made. Compliance during screening was 93.7%, treatment 88.4% and overall 89.8%.

Three manoeuvres were recorded in 99% of the sessions.

Repeatability Compliance of PEF for both screen and treatment periods was 88%. The difference in PEF between the two highest manoeuvres was 13.8±3 L/min.

There was no statistical difference between the morning and evening data.

Conclusion: These data concur with other previously published [2]. Thus e-PROs from asthmatic patients are consistent for both quantity and quality and have statistical reliance as the primary end-points for future trials.

The sponsors of this trial are thanked for the anonymous use of their data.

P1209
Comparison of referral patterns between a respiratory laboratory in the Republic of Ireland and Western Australia
Elizabeth Salamon1, Marina Stack2, Kevin Gain1, 1Respiratory Medicine Department, Royal Perth Hospital, Perth, Western Australia, Australia; 2Respiratory and Sleep Laboratory, Cork University Hospital, Cork, Ireland

Background: Respiratory diseases account for 13% of deaths in the Republic of Ireland (ROI), and 8% in Western Australia (WA) each year. County Cork has a population of 0.5 million and is served by Cork University Hospital (CUH), one other public, and one private hospital laboratory. CUH has 815 beds and is the principle teaching hospital. Located in the city centre, Royal Perth Hospital (RPH) is the largest teaching hospital (855 beds) in WA, which has a population of 2.2 million. This area is also serviced by three other teaching hospitals, and numerous private laboratories.

Diagnosis | CUH | RPH |
--- | --- | --- |
Asthma | 12.8% | 10.1% |
COPD | 16.9% | 20.3% |
ILD | 22.7% | 10.3% |
CF | 7.5% | 0.8% |
Cancer | 5.5% | 9.5% |
Connective tissue | 5.7% | 6.4% |
Other | 27.4% | 17.7% |
Not specified | 1.6% | 24.9% |

Test | CUH | RPH |
--- | --- | --- |
Spirometry | 2811 | 3054 |
DLCO | 1350 | 1266 |
Lung volumes | 1119 | 1208 |
Mouth pressures | 41 | 39 |
CPET | 5 | 35 |
Altitude simulation | Test not offered | 53 |
Skin allergen | | |
6 MWD | Physiotherapist role | 88 |
Bromchial challenge | 6 | 5 |
Total | 5360 | 5766 |

Aim: To compare test request profiles of two public respiratory laboratories in ROI and WA.

Method: Referrals to each laboratory between 1st November 2009 and 31st October 2010, were reviewed.

Results: CUH performed 5360 tests on 2104 patients, aged 5-90 years. 9% were repeat visits within the time frame. RPH performed 5766 tests on 2336 patients, aged 13-98 years. 14% were repeat visits. The results offered and diagnoses are presented.

Discussion: The number of patients seen, and number of tests per patient were comparable. Specialist nurses at CUH perform spirometry which is redirected in the reduced number of COPD and cancer patients seen in the laboratory.

P1210
How to diagnose restrictive ventilatory defect by spirometry, and reduce the number of lung volumes measurements?
Stefan Wieslowski, Piotr Borek, Lung Function Lab, Institute of TB & Lung Diseases, Warsaw, Poland

Diagnosis of restrictive ventilatory defect by a low FVC on spirometry is not accurate, even in non-obstructive patients. On the other hand TLC measurements are time-consuming and expensive. So it would be convenient to be able to predict or rule out the possibility of restrictive defect by spirometry and reduce the number of unnecessary TLC measurements.

Aim of the study: We have looked for a FVC value above which reduced TLC is very unlikely, and other FVC value below which it is highly probable.

Material: Consisted of pulmonary test results obtained from adult patients, who had undergone spirometry and lung volumes measurements at the same visit.

Results: From the whole 6538 test results, 4089 patients (53.2% females, 46.8% males; mean age 47.5±14.9 years) without airway obstruction were included into analysis. Restrictive ventilatory defect (TLC <50th percentile) was found in 955 (19.5%) patients, and reduced FVC (FVC <5th percentile) was found in 655 (13.4%) patients. Setting arbitrary the lower limit on 70% of FVC pred. to predict volume restriction had specificity 99%, and PPV 91%. Setting the upper limit at 95% of FVC pred. to exclude volume restriction had NPV 99%. Performing TLC measurements only in patients with FVC between 70 and 95% of pred., would reduce number of tests by 2/3 to 1/3.

Conclusions: Spirometry allows accurately rule out volume restriction in patients with FVC >95% of pred., and predict restrictive defect in patients with FVC <70% of pred. Performing TLC measurements only in patients with FVC between 70 and 95% of pred. reduces the number of tests and costs of diagnosis of restrictive defect.

P1211
Non invasive assessment of pulmonary shunt in adults with liver disease
Georgia Spentzos1, Sami Sanka1, Matt Rutter2, Nick Fung3, Robert Ross Russell3, 1Department of Paediatrics, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 2Department of Respiratory Physiology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 3Department of Engineering, Cambridge University, Cambridge, United Kingdom

Introduction: The oxygen dissociation curve charts the relationship between haemoglobin saturation (SaO2) and arterial pO2. Less well known is the relationship between the inspired oxygen (FiO2) and SaO2, which reflects aspects of the oxygen cascade that affect the transfer of oxygen into blood.

A number of models describe this cascade and this allows reconstruction of the curve from a number of data points, allowing estimation of the shunt and whole lung VQ ratio. Its value lies in the simplicity with which both FiO2 and SaO2 can be measured.

We are undertaking a “proof of concept” study evaluating shunt in adults undergoing assessment for liver transplantation, where pulmonary shunt is an important clinical problem.

Methods: Adults breathe an O2:N2 mix with an FiO2 between 0.14 and 0.35. After equilibration, SaO2 is recorded. At least 3 data points are collected, and analysed using previously validated methodology [1] recently adapted for MATLAB.

Results: To date (February 2011) we have studied 9 patients with this technique. All tolerated the procedure well. Studies were performed in our respiratory laboratory and took between 20 and 30 minutes to complete.

Shunt varied between 2% and 20% and VQ ratios between 0.78 and 1.5. Patients are also having shunt assessed by VQ scans, and these data will be compared.

Conclusions: This technique offers a very simple and well tolerated test that quantifies both shunt and VQ mismatch. It only requires an oximeter and a supply of nitrogen. Given that current methods for assessing these parameters require specialised equipment and are time consuming, it may provide an effective test for shunt or VQ matching in a wide range of patients.

P1212

Is obstructive lung disease correlated to age and smoking habit or is there more?
Saedna Lone, Remco Boksem, Reinbert Van Steenwijk. Lung Function, Academic Medical Center (AMC), Amsterdam, Netherlands

Background: On World Spirometry Day lung function measurements were done to identify obstructive patients without a previous diagnosis of an obstructive lung condition and to raise awareness on lung health and disease.

Aim: To establish the significance of the degree of obstruction in relation to reported symptoms and other characteristics.

Methods: 783 participants performed lung function and filled a standard questionnaire. The degree of obstruction in relation to smoking, shortness of breath, cough, age and BMI were investigated. Significance in relationships was measured with multivariate analysis with backward elimination.

Results:

In 15.8% an abnormal lung function was measured: 124 times obstruction based on FEV1/FVC and another 43 cases with a FEV1 below 80%.

In a linear regression model smoking (β = 0.015 p < 0.005) and age (β = -0.02 p < 0.005) were significant predictors in obstruction.

Conclusions: There was a positive correlation between age and smoking but no correlation with other characteristics. Amongst the older obstructive participants there is a large group of non-smokers who need further investigation.

Implications: In its current form the WSD cannot identify persons at risk for an obstructive lung disease. In case of a low FEV1 and/or a low FEV1/FVC the test should also be repeated after a bronchodilator. There has to be a good description of the target group and a questionnaire adapted to the group.

P1213

The correlation between lung function parameters, and level of activity in seropositive rheumatoid arthritis
Ghulien Apti1, Anamaria Trailescu2, 1Pneumology-Lung Function Testing Department, Hospital of Pneumology, Constanta, Romania; 2Pneumology, Hospital of Infectious Diseases V.Babes, Bucharest, Romania

Pulmonary involvement is one of the most frequent extra-articular manifestation of rheumatoid arthritis.

Aim: To assess the lung function (LFT) and diffusion capacity (DLCO) in non-smoker patients with rheumatoid arthritis (RA) and correlation with disease activity and rheumatoid factor positivity.

Methods: 55 patients non-smokers with a prior diagnosis of RA in rheumatology department, were subjected to lung function analysis. The various parameters - from spirometry, diffusion capacity, -were correlated with rheumatoid factor (RF) positivity (RA+/-) and disease activity score (DAS), C reactive protein (CRP) levels.

None of them had the diagnosis of lung interstitial disease prior the study.

Results:

30.9% had negative rheumatoid factor, and 69% positive; from them 12.7% were male;
FEV1, FVC, TLC were lower in RA+ group than in RA- and FEV1/FVC was higher in RA+ group (81.4% vs. 126.2%). Statistical significance was achieved for FEV1/FVC and TLC (4.6 vs. 1.6).

TLCO was lower than predicted values in 36.4%; 29.4% in RA- and 39.8% in RA+ (OR=1.4); corrected TLCO was 22.3 ± 4.8 in RA+ and 20.1 ± 3.6 in RA- (p=0.03) regarding level of activity, decreased TLCO was correlated (correlation factor=0.29) with RF positivity, CRP high levels (>8.9) and high DAS (>4.8).

Restrictive dysfunction had 23.6% RA+ (OR=2.5)and 11.7% RA- Decreased TLCO had 63.6% from those with restrictive dysfunction (71.4% in RA+ group). More than 50% from those with restrictive dysfunction and low TLCO had a DAS ≥5.

Conclusions: Restrictive dysfunction and decreased TLCO are correlated with RF positivity and with high level of disease activity in patients with RA.

P1214

Assessment of the suitability of filters for use in clinical studies with an HFA fluticasone propionate pressurized metered dose inhaler (pMDI) and a valved holding chamber (VHC)
Kurt Nikander1, Lois Slator2, Dirk von Holten1, Ross Hatley2. 1Philips Respironics, Respironics New Jersey, Inc., Parrygall, NJ, United States; 2Respironics Respiratory Drug Delivery (UK) Ltd, Chichester, United Kingdom

The assessment of delivered dose is an integral part of the development protocol for new aerosol delivery devices, especially in pediatric patients in which pharmacokinetic studies are difficult to perform.

The aim of this study was to evaluate the dose collection efficiency of a 3 M Filterte G-200 (G-200) filter in a low dead space filter holder for use in ex vivo testing using a preproduction OptiChamber Diamond VHC (Diamond; Philips Respironics). Two preproduction Diamond VHCs were tested over 10 runs. Five fluticasone propionate (Flonfenta HFA 220 μg) pMDIs were primed before use. The mouthpiece of the VHC was sealed to a filter holder containing two 67 mm G-200 filters. The pMDI was actuated into the VHC, followed by 20 s extraction (at 90 L/min), repeated 25 times. Filters and VHC deposits were analyzed using HPLC (Agilent 1100/1200). The percentage of total emitted dose deposited on the 2nd filters over 10 runs was calculated; where the amount of drug detected on the 2nd filter was below the Limit of Quantification (LOQ; 25 μg) the LOQ was used to calculate the total, and where the amount detected was zero the Limit of Detection (LOD; 2.5 μg) was used to calculate the total (overestimates the total amount on the 2nd filters significantly), the total was then divided by total recovered drug.

Desaturation during maximal exercise can be caused by several problems; decreased diffusing capacity, leading to an increased Alveolar-arterial problems; decreased diffusing capacity, leading to an increased Alveolar-arterial

Discussion: Despite the correlation and agreement between two methods for measuring inspiratory capacity, they can have significant variability within and between methods.

P1216

Can NO diffusion predict desaturation during maximal exercise?
Eline Oppersma1,2, W.J.C. van Beurden2, M. Brusse-Keizer 2, P.D.L.P.M. van der Valk3, F.H.C. de Jongh4,5, 1Technical Medicine, Twente University, Enschede, Netherlands; 2Pulmonary Department, Medisch Spectrum Twente, Enschede, Netherlands; 3Respironics Respiratory Drug Delivery (UK) Ltd, Chichester, United Kingdom

Introduction: Desaturation during maximal exercise can be caused by several problems; decreased diffusing capacity, leading to an increased Alveolar-arterial (A-a) oxygen gradient, or V/Q mismatch or a contact time problem. The present method to establish decreased diffusing capacity is the measurement of diffusing capacity for carbon monoxide (TLCO). We hypothesise that the diffusing capacity for nitric oxide (TLONO) is more accurate than TLCO.

Aim: The aim of this study is to find out whether diffusing capacity for NO, as a marker for the membrane component of diffusion, can be a more accurate predictor of the A-a gradient at maximal exercise, compared to diffusing capacity for CO, as a marker for the membrane and hemodynamic component of diffusion.

Methods: 15 patients with pulmonary complaints (mean age 38 years) performed a combined single breath TLONO/TLCO measurement and a maximal exercise test.

We constructed a model to predict the A-a gradient at maximal exercise.
Results: The A-a gradient at maximal exercise can be predicted by TLCO%R, and resulted in an R^2 (coefficient of determination) of 0.64. TLNO%R predicted the A-a gradient at maximal exercise with an R^2 of 0.81 (see figure).

Conclusion: The diffusing capacity for NO is a more accurate predictor of the A-a gradient at maximal exercise than the diffusing capacity for CO, and thereby a more accurate predictor of desaturation during exercise.

P1217
DLno; slave to a rhythm?
Antoinette Houtkooper, P.J.A.M. van Ooij, R.A. van Hulst. MMEC - Diving Medical Center, Royal Netherlands Navy, Den Helder, NH, Netherlands

Background: It is generally accepted that spirometry and diffusing capacity are subjected to a diurnal rhythm (CINKOTAI 1966, BORSBOOM 1999, MEDAROV 2008). Values for VC, for example, are lowest around noon and highest between 3.00 and 4.00 pm (MEDAROV 2008), while DLco is highest between 08.00 and 09.00 am and decreases during the day (CINKOTAI 1966, MEDAROV 2008).

Introduction: The aim of this study was to investigate the diurnal rhythm for DLno. The DLno is a relatively new method and for applying in studies it is important to know whether there is a diurnal rhythm or not.

Methods: Eleven male subjects were measured between 8 am and 10 pm. In this period DLno was measured six times using a Masterscreen PFT-Pro (CareFusion), each time with a pause of at least two hours (max 4 hours).

Statistics: The Shapiro-Wilk test was used to test for normality. To determine diurnal variance, within-day variations were tested using the one-way Analysis of Variance (Anova). The Bonferroni correction was used for multiple comparisons. However, as diurnal variations can be curve shaped we also tested this index with a fractional polynomial regression model.

Results: The Anova test with Bonferroni correction showed no significant diurnal variation in DLno (p=0.854). Also the fractional polynomial regression model to the 4th degree or lower did not show any significant relationship between time of the day and DLno (p=0.526).

Conclusion: In our study DLno does not have a diurnal rhythm. We would like to expand our group of subjects to confirm this statement. Further investigation is therefore necessary.

P1218
Intra- and intersession variability of the single-breath determination of carbon monoxide diffusing capacity
Kevin De Soomer, H. Vaerenberg, W. De Backer, E. Oostveen. Dept. of Lung Function and Pulmonary Medicine, Antwerp University Hospital, Antwerp, Belgium

Background: Some lung function laboratories perform 3 instead of 2 reproducible tests for the single-breath determination of the carbon monoxide diffusing capacity (DLCO) with the underlying assumption that the average of 3 values is more reliable than the average of 2. Recent ATS/ERS guidelines (Eur Respir J 2005) established lung function device MasterScreen (Jaeger Ltd, Hohburg, Germany). Ten healthy subjects performed 2 tests on each device, whereas 24 patients performed only one measurement on the EOP as a part of their routine testing and we compared the results using t-tests with Bland & Altman analysis.

Results: The results (Table 1) show that the differences in TLCO, KCO and VAeff although statistically significant (p<0.05) were lower than the expected clinical repeatability. Analysis of patient and healthy subjects showed similar results. The between device variation was greater than the within Jaeger device variation.

Conclusion: The Easy One Pro gives values comparable with established gas transfer systems.

P1220
How long does it take for supine gas transfer to become stable after sitting up?
Liam O’Reilly, Helen Ward, Brendan Cooper. Lung Function & Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, West Midlands, United Kingdom

Introduction: We are interested in using the change in gas transfer from sitting to supine in patients with various lung diseases, but were unable to find any published studies showing how long a subject should be supine before a stable representative measurement could be made. We looked at this in healthy subjects first.

Method: We measured single breath gas transfer (TLCO & KCO) using a MasterScreen lung function system (Jaeger Ltd, Hohburg, Germany) 3 times sitting at rest and then after approximately 10, 15, 20, 25 & 30 minutes respectively, lying supine in 14 healthy subjects (11F:3M; Ages: 22-51 years).

Results: The results (Table 1) show that TLCO and KCO increase by about 9% and 15% respectively and VAeff decreases by 5% from sitting to supine. Stability is reached after 15 minutes.

The determination of DLCO using 3 tests did not significantly reduce the within or between CV compared to the use of only 2 tests. Although adding the third test to estimate DLCO significantly reduced the value of DLCO (p<0.001), this reduction was not clinically relevant (~1% reduction in the value of DLCO). For the average healthy subject the DLCO varied as much as ±7% (2 tailed 95% confidence interval) during a 6 weeks period of time.

Conclusion: A DLCO determination based on 3 instead of 2 tests does not result in a more stable estimate of DLCO.

P1219
Comparison of two commercially available portable gas transfer devices
Lindsey Padddison, Maxine Jones, Brendan Cooper. Lung Function & Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, West Midlands, United Kingdom

Introduction: We compared a novel portable gas transfer device which uses ultrasound and mass flow technology on healthy subjects and patients with suspected lung disease attending a routine lung function department.

Method: We measured single breath gas transfer (TLCO & KCO) on 34 subjects (20F:14M) using the EasyOnePro (EOP) (idd, Zurich, Switzerland) with an established lung function device MasterScreen (Jaeger Ltd, Hohburg, Germany). Ten healthy subjects performed 2 tests on each device, whereas 24 patients performed only one measurement on the EOP as a part of their routine testing and we compared the results using t-tests with Bland & Altman analysis.

Results: The results (Table 1) show that the differences in TLCO, KCO and VAeff although statistically significant (p<0.05) were lower than the expected clinical repeatability. Analysis of patient and healthy subjects showed similar results. The between device variation was greater than the within Jaeger device variation.

Discussion: This comparison of gas transfer measurement between the EOP and Jaeger systems shows that across a wide range of values the differences between the 2 devices are within the normal repeatability (S.I units) for TLCO, KCO and VAeff of <1.00, <0.50 and <0.20 respectively.

Conclusion: The Easy One Pro gives values comparable with established gas transfer systems.

Values shown as Mean (SD). TLCO in mmol/4L/min/L, KCO in mmol/4L/min/L, VA in L/min.

Discussion: We have shown that changes in gas transfer when supine stabilise after 15 minutes. Unexpectedly, not all subjects showed an increase gas transfer, with 6 showing no increase or a slight decrease when supine. This result needs further explanation.

Conclusion: Supine gas transfer should be measured after 15 minutes lying supine. Not all subjects produced an increase in gas transfer when supine.
115. Exercise tests and emerging outcomes: defining the impact of pulmonary rehabilitation

P1222
Effect of COPD severity on hemodynamic responses to exercise in patients with GOLD stages I-IV
Maroula Vasilopoulou1, Ioannis Vogiatzis1,2, Ioannis Nasis1, Stavroula Maronian1, Eleni Kortianou1, Maria Koskolou1, Antonia Koutsoukou2, Manos Alchanatis2, Nikolaos G. Koumoutsos2, 1Respiratory and Sleep Medicine, Atenna General Hospital, Athens, Greece; 21st Department of Physical Education and Sports Sciences, National and Kapodistrian University of Athens, Athens, Greece; 31st Department of Respiratory Medicine, Pulmonary Rehabilitation Unit, Sotira Hospital, National and Kapodistrian University of Athens, Athens, Greece; 4Physiotherapy, Technological Educational Institution of Larnia, Larnia, Greece

Introduction: Exercise-induced dynamic hyperinflation and large intrathoracic pressure swings can compromise the normal increase in cardiac output (Q) during exercise in COPD. Therefore, it is anticipated that the greater the disease severity, the greater would be the impairment in Q during exercise.

Aim: Thus, the aim of the study was to investigate whether the Q response is more severely impaired in the more advanced stages of COPD.

Method: We studied sixty COPD patients (15 patients at each stage, 1 to IV). Patients undertook a constant load test (75% Wmax) and a six minute walking test (6MWT). Q at rest and during exercise protocols measured by biochemical (PhysioFlow, Enduro) to determine the kinetic response at the onset of exercise (On-transient) and during recovery (Off-transient).

Results: While Q kinetics (On & Off) was not different between the two exercise protocols, on-transient and off-transient time constants were slower the more severe the disease severity was (Table 1).

Table 1. Q Kinetics (On & Off)

</tbody>
</table>

Values are means ± SEM *Significant difference among stages.

Conclusion: The more advanced the disease severity the more impaired was the hemodynamic response to the 6MWT and the constant load test, possibly reflecting greater cardiovascular impairment in COPD or greater physical deconditioning. This study reflects, equally well as the constant load test, the degree of impairment in the hemodynamic response to exercise.

P1223
Electrocardiographic and echocardiographic abnormalities in COPD patients according to disease severity
Laura Caram, Cristiane Naves, Sílvia L. Zanini, Suzana Tanni, Liana Coelho, Renata Ferrari, Imao Godoy. Department of Internal Medicine, Botucatu Medical School - São Paulo State University – UNESP, São Paulo, District of Ribeirão Preto, São Paulo, Brazil

Epidemiological studies show high prevalence of cardiovascular disease (CVD) in COPD patients; however, few studies have assessed the prevalence of cardiac abnormalities in different stages of COPD. The aim of this study was to assess the prevalence of electrocardiographic and echocardiographic changes in 50 mild/very severe COPD patients (62% male gender, age= 67±9 years, FEV1= 56±23%). All individuals underwent to medical history and physical examination, electrocardiographic and Doppler echocardiography evaluations. Changes suggestive of ischemic heart disease occurred in 10% and mild left ventricular diastolic dysfunction in 88% independently of COPD stage. Mild/moderate COPD patients showed higher prevalence of anormalities in segmental contractility (p=0.01), while severe/very severe COPD patients showed higher prevalence of right ventricular overload (p=0.01) and increased right heart chambers (p=0.001). Age, male gender, systemic arterial blood pressure, C-reactive protein and BODE index were included in a multiple linear or logistic regression analysis with the left ventricular diastolic diameter/the size left atrium as dependent variables. Male gender and the BODE index were selected as predictors of left ventricular diastolic diameter/size left atrium as dependent variables. While Q kinetics (On-transient) and during recovery (Off-transient).

P1224
Effects of pulmonary rehabilitation (PR) on arterial stiffness in patients with COPD: The Brico study
Lowie Vanfleteren1, Martin Spruit2, Frans Franssen2, Martin Boorsma3, Jos Oep Rooij2, Miriam Groene3, Emiel Wouters1, 1Respiratory Medicine, Maastricht University Medical Center, Maastricht, Netherlands; 2Program Development Center, Ciro +, Centre of Expertise in Organ Failure, Horn, Netherlands; 3Research and Development, Astra Zeneca, Charnwood, United Kingdom

Background: Arterial stiffness, a strong predictor of cardiovascular mortality, is increased in patients with COPD. The effects of PR on arterial stiffness have been studied scarcely.

Methods: Pulmonary function, 6MWD, BML, SGRQ, mMSC dyspnea score, aortic pulse wave velocity (APWV), brachial pulse wave velocity (BPWV) and pulse wave analysis (SphygmoCor; AtCor Medical, Sydney, Australia) were determined in 102 patients (35 female; age: 64±7 years, FEV1= 53±17) with clinically stable COPD, prior and subsequently to a 35-session PR program including high-intensity interval and resistance training.

Results: 6MWD (+31,3 ±0.7, p<0.001), SGRQ (–2.4±1.8, p=0.001) and BMI (–0.5±1.1, p<0.001), and BMDP (+5.4±1.8 kg/m2, p=0.006) all improved, compared to baseline. Overall there were no changes in APWV, BPWV, central blood pressure and augmentation index (AI), while central and peripheral pulse pressure (PP) increased slightly. Peripheral PP increased by to a modest but significant reduction in peripheral diastolic blood pressure (DP). Also a significant, but clinically irrelevant reduction in heart rate (HR) was seen.

Conclusion: On average, pulmonary rehabilitation does not reduce arterial stiffness in patients with COPD.
Reproducibility of a time trial cycle ergometer test protocol in comparison to a constant work rate test protocol in patients with COPD

Willem Gossens1,2, Josse Oomen1, Alex van Hyl1, Matthijs Hesseling2, Lars Berkhoudt1,2,3, Erik de Groot1,4,5,6, Lars Borghouts1,2, Willem Gosens1,2, Joost Oomen1, Alex van Hyl1, Matthijs Hesseling2, Lars Berkhoudt1,2,3, Erik de Groot1,4,5,6, Lars Borghouts1,2.

Introduction: In cardiopulmonary rehabilitation programs (CPR), constant-load cycle endurance tests (CLET) protocols are used to evaluate the response to specific interventions. In healthy subjects CLET protocols show a much lower reproducibility of the CLET protocol and TTT protocol on a cycle ergometer in patients with COPD.

Methods: In 20 patients with COPD (GOLD II-IV, FEV1 of 56.1±5.5% exercise performance was measured. Patients were randomly allocated to a CLET protocol or TTT protocol. Patients performed the test protocol to which they were assigned, five times. In the CLET group exercise to exhaustion at 120% of the actual individual training workload attained in the during CPR training sessions. Patients of the TTT group were asked to perform a certain amount of work (120% * Wstarting + 420) as fast as possible.

Results: CLET protocol showed a significantly lower coefficient of variation (CV) (6.5±1.6) than the TTT protocol (22.9±4.8) (p < 0.001). Individual CV (time to completion) ranged from 9.0% to 36.9% in the CWRT protocol and from 3.4% to 16.3% in the TTT protocol. There was a significant difference between the mean exercise time of the CLET (59.1±18.5 s) and the TTT (367±122 s) (p < 0.005). There were no differences in mean work (p = 0.058), power (p = 0.463), RPM (p = 0.629), subjective assessments of breathlessness (P = 0.55) and leg fatigue (P = 0.15) between the CLET and de TTT protocol.

Conclusions: The TTT protocol reproducibility was sign. higher than in the CLET protocol in patients with moderate-to-severe COPD.

P1227

Estimation of peak work load based on 6-min walk distance and general demographics in patients with COPD: A new regression equation

Background: Estimating peak work load to estimate Wpeak using 6-min walk distance (6MWD) are not accurate enough to target training intensity during pulmonary rehabilitation (PR) in patients with COPD (Sillen et al ERS 2011). We aimed to develop a new regression equation to estimate Wpeak using 6MWD and general demographics in COPD patients entering PR.

Methods: Measurements of lung function, body composition, and peak and functional exercise capacity were obtained in 3000 patients with COPD (53% men, age: 63.0±9.4 yrs; FEV1: 44.1±18% pred.), referred to 4 PR centres in the Netherlands (all member of the Vereniging Asmastra gegen Nederland). A stepwise multiple regression analysis was performed to estimate Wpeak using 6MWD, gender, age, height, body weight, fat free mass and FEV1.

Results: On average, patients had a normal body composition (BMI: 25.8±5.5 kg/m2, FFM: 16.9±18.4 kg, and a peak power (59±13 Watts) and functional exercise capacity (6MWD: 399±120 metres). The VAN regression equation derived from the stepwise multiple regression analysis was as follows: Wpeak = -52.787+(0.319*gender, women=0 and men=1)-(0.229*age in yrs)/(0.108*height in cm) + (0.267*body weight in kg) + (0.182*FFM in kg)/(0.132*6MWD in m)+(23.528* FEV1* in litres)

This regression equation explained 67% of the variation. The mean difference between the actual and the predicted Wpeak was 0.9±19 watts. 26% of the COPD patients had a predicted Wpeak which differed less than 5 watts (±5) of the actual Wpeak.

Conclusions: The level of accuracy of this newly derived regression equation seems too low to be used in individuals with COPD to target training intensity during PR.

P1228

Inhibitory effect of SABA on exercise dynamic lung hyperinflation during 6-min walk test in stable COPD patients

Masahiro Satake1, Takaharu Shiraya, Hitomi Takahashi2, Keiyu Sugawara2, Chikage Kasai2, Noritaka Kiyokawa1, Toru Watanabe2, Sayaka Fujii3, Atsutoyo Kawagoshi2, Mitsubou Honma4,4, Physical Therapy, Akita University Graduate School of Health Sciences, Akita, Japan; 3Department of Respiratory Medicine, Maastricht University Medical Centre +, Maastricht, Netherlands; 4Department of Respiratory Medicine, Akita City General Hospital, Akita, Japan; 5Rehabilitation, Hyagi Ioannou Clinic, Akita, Japan; 6Pulmonary Medicine, Akita City General Hospital, Akita, Japan.

Aim: The purpose of this study was to evaluate the inhibitory effect of short acting β2-receptor agonist (SABA) on exercise dynamic lung hyperinflation during the 6-minute walk test (6MWT) in stable COPD patients.

Subjects and methods: We examined 14 patients with stable COPD (mean age: 76yr, mean FEV1: 57.9% pred) who were referred to our clinic between July 2008 and October 2009. 6MWT and lung function test were performed after the inhalation of SABA (proteracol hydrochloride, 0.5 mg) or placebo. The Borg dyspnea score increased with time during 6MWT and was confirmed during every walk. There was no effect of day (p=0.23) on energy expenditure. There was no significant difference (0.0 [-0.4 to 0.3] METS) in energy expenditure between the actual and the predicted Wpeak.

Results: Compared to the baseline assessment, 6MWD increased by a mean of 20.5m when measured after inhalation of SABA (512.4±90.7m vs. 532.9±79.8m; p<0.05). During the 6MWT, inspiratory capacity (IC) decreased significantly with time. The IC after inhalation of SABA was significantly higher than the placebo. The Borg dysnea score increased with time during 6MWT and was attenuated significantly after inhalation SABA.

Conclusions: In the present study, there was a significant attenuation in exercise dynamic lung hyperinflation, suggesting the important rescue role SABA in the management of COPD. It is therefore likely that most patients with COPD may derive considerable benefit from rescue bronchodilator therapy with SABA.

P1229

Energy economy of walking with a wheeled ambulatory aid (rolloator) in patients with chronic obstructive pulmonary disease (COPD)

Kimberly Hill1, Thomas E. Dolmage2, Lynda Woon3, Tina Brooks1, Roger Goldstein1, 1School of Physiotherapy and Curtin Health Innovation Research Institute, Curtin University of Technology, Bentley, Western Australia, Australia; 2Respiratory Diagnostic & Evaluation Services, West Park Healthcare Centre, Toronto, ON, Canada; 3Department of Respiratory Medicine, West Park Healthcare Centre, Toronto, ON, Canada; 4Department of Physical Therapy, University of Toronto, Toronto, ON, Canada; 5Department of Respiratory Medicine, West Park Healthcare Centre, Toronto, ON, Canada.

Background: Probst et al. (Chest 126: 1102, 2004) reported that, when using a rolator, patients with COPD increased their distance walked in 6 min along with increased oxygen uptake and ventilation. It was difficult to appraise economy (mechanical work to total energy expenditure) because the main determinant of the energy demand, speed, varied between conditions; hence, the authors concluded that rolator use improved distance by increasing ventilatory capacity and/or economy.

Objective: To determine whether walking with a rolator improved the energy economy in patients with COPD. The hypothesis was that oxygen uptake, at the same speed, would be lower (improved economy) when walking with a rolator.

Methods: Subjects completed 2 walks, (with and without a rolator) at individually set and constant speeds. At least 24 h later they repeated the session for a total of 4 walks. Energy expenditure was estimated from measured oxygen uptake using a telemetric system. Since mechanical work was kept constant (speed) during each walk, differences in economy were reflected in differences in energy expenditure in metabolic equivalents (METS).

Results: Ten subjects completed the study. Attainment of a steady state was confirmed during every walk. There was no effect of day (p=0.23) on energy expenditure. There was no significant difference (0.0 (-0.4 to 0.3) METS) in energy expenditure with (3.6 [2.9 to 4.3] METS) or without (3.6 [2.9 to 4.3] METS) the rolator.
Conclusions: Rollator use does not acutely affect walking economy in patients with COPD. A better understanding of how people with COPD benefit from rollator use may facilitate their design and prescription.

P1232
Characterization of balance impairments in individuals with COPD
Marla Beauchamp1,2, Kathryn Sibley1,3, Bimal Lakhan1,4, Julia Romano2, Sunita Mathur2,3, Roger Goldstein3, Dina Brooks1,4, 1Graduate Department of Rehabilitation Medicine, University of Toronto, Toronto, Canada; 2Rheumatic Medicine, West Park Healthcare Centre, Toronto, Canada; 3Physical Therapy, University of Toronto, Toronto, Canada; 4Mobility Team, Toronto Rehabilitation Institute, Toronto, Canada

Background: Balance deficits are increasingly recognized as an important secondary impairment in COPD, however little is known regarding the specific components of balance that are impaired.

Objectives: 1) To determine the specific components of postural control that are impaired in individuals with COPD compared to age-matched healthy controls; 2) To determine if deficits in balance in COPD are related to muscle strength or physical activity.

Methods: Balance, physical activity and lower extremity muscle strength were assessed in 37 patients with COPD and 20 healthy controls using the Balance Evaluation Systems Test (BESTest), the Physical Activity Scale for the Elderly (PASE), and an isokinetic dynamometer, respectively. A subset of subjects (20 COPD and 20 controls) underwent a second testing session in which postural perturbations were delivered using a lean-in-and-release system. Center of pressure data were collected from three force plates mounted in the platform.

Results: Subjects with COPD (age 71±7 yrs; FEV1 39±16 percent predicted) exhibited higher total, lower scores than controls (age 67±6 yrs) on all of the BESTest subscales (all p<0.001). The largest deteriorments in postural control were evident in biomechanics, transitions and gait. The PASE was a significant predictor of BESTest scores (p=0.034) in COPD. In response to anterior perturbations, subjects with COPD showed a longer time to foot-off (p=0.027) and foot-on (p=0.018) as well as a longer duration anticipatory phase (p=0.008) compared to controls.

Conclusions: Comprehensive balance assessment and management should be included in pulmonary rehabilitation. Deficits in balance in COPD appear to be related to decreased physical activity levels.

P1231
Comparison of maximal exercise capacity between patients with COPD from Brazil and United Kingdom
Rafael da Cruz Diniz1,2, Caroliny Capela1,2, Carolyn Sandland3, Nidia Aparecida Hernandez1,2, Vanessa Suziane Probst1,2, Sally Singh1, Fabio Pinta1, 1Laboratório de Pesquisa em Fisioterapia Pulmonar (LIEP), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil; 2Centro de Pesquisa em Ciências da Saúde (CPCS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil; 3Department of Respiratory Medicine, Glenfield Hospital, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

Background: Field exercise tests such as the incremental shuttle walking test (ISWT) have been used worldwide in order to assess exercise capacity of patients with chronic obstructive pulmonary disease (COPD). However, the responses to this test in patients from different world regions have not yet been compared.

Objectives: To compare the responses to the ISWT between patients with COPD from Brazil and United Kingdom (UK).

Methods: 20 patients with COPD from Brazil were matched to 20 patients from the UK concerning gender distribution, age, body mass index and FEV1. All patients performed the ISWT during the baseline assessment for admission to a pulmonary rehabilitation program in their respective country. The total distance walked was recorded and heart rate (HR), oxygen saturation (SpO2) and dyspnea scores (Borg scale) were assessed before and after the test in both centers.

Results: In both groups, SpO2 decreased and HR and dyspnea scores increased significantly after the test (p<0.05 for all). Brazilian patients walked farther and achieved higher% of their maximal predicted HR than patients from the UK (345±173 vs 209±116 meters [p=0.006] and 80±12 vs 64±10%pred [p<0.001], respectively). The increase in dyspnea sensation after the test tended to be higher in the Brazilian group (4 [2-6] vs 2 [1-4], p=0.06).

Conclusions: Brazilian patients with COPD seem to walk more and achieve higher effort during the ISWT than patients from the United Kingdom. This is in line with previous data showing that patients from South America (especially Brazil) are more active in daily life and have better functional exercise capacity in comparison to patients from Europe and United States.

P1232
The effect of pulmonary rehabilitation on the sit-to-stand test in COPD
Mehal Paul, Jane:int title="University of East London, Amy Cleary, Karen Dargan, Ria Fowler, Michael Polkey, William Man. Harefield Pulmonary Rehabilitation Team and Respiratory Biomedical Research Unit, Royal Brompton & Harefield NHS Trust, Harefield, Middx, United Kingdom

Background: The sit-to-stand (STS) test is a component of the Short Physical Performance Battery (SPPB), it measures the fastest time to stand from a seated position 5 times with folded arms. We hypothesised the STS may be a useful outcome measure in COPD and that it would improve after an 8-week outpatient pulmonary rehabilitation (PR) program.

Methods: In 83 COPD patients (43M: 40F) referred to PR, the following were measured before and after PR: STS, incremental shuttle walk test (ISWT), MRC Dyspnea score (MRC) and St George’s Respiratory Questionnaire (SGRQ). Modified BODE (ISW as the exercise component) and ADO scores were calculated as composite mortality indices. Spearman’s rank correlation was used to assess the relationship between STS and ADO scores. The correlation coefficients and Wilcoxon signed rank test to assess the effect of PR on STS. We estimated minimal clinically important difference (MCID) using an anchor based approach against a 5-point Likert scale and the MCID of ISW.

Results: 18 patients were unable to complete STS either pre- or post-PR. 6 were unable to perform STS pre-PR but improved sufficiently to do so after PR. STS at baseline correlated significantly with ISW (r=0.53), MRC (r=0.35), modified BODE (r=0.26) and ADO (r=0.35), but not with age, FEV1, predicted, BMI or SGRQ. In 65 patients with full pre- and post-PR data, median STS time improved from 13.8s to 12.0s following PR (p<0.0001). Median improvement was -1.8s in those feeling “much better” after PR and -2.4s in those achieving the MCID of the ISW.

Conclusions: Not all COPD patients referred to PR can complete a STS. The STS is sensitive to change following PR. The MCID for the STS is probably of greater than 2 seconds.

P1233
Age of loss of walking ability in patients with Duchenne muscular dystrophy: A marker for the elective use of mechanical ventilation
1Leonardo Augusto Tavares2, Marçal Alcides Moreira1, Maria Teresa Fontesca2, Laura Belisário Lasmar2, 1Neuromuscular Disease Program/Complex Disease Unit, John Paul II Child Hospital/Hospital Foundation of Minas Gerais State, Belo Horizonte, Minas Gerais, Brazil; 2Respiratory Disease Program, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Introduction: In adolescence of Duchenne muscular dystrophy (DMD) comes the cardiorespiratory restrictive impairment (hypoventilation, sleep breathing disorder and order respiratory effort), marked by the loss of ambulation. At that time, the institution may be required ventilatory support. The onset of this reducing need for tracheostomy and increasing quality of life in DMD. Public Program (Ventilator-VIP) in John Paul II Child Hospital/Hospital Foundation of Minas Gerais State (IPIC/HPMFGS) assist DMD patients.

Objective: To evaluate loss of ambulation and the need to VS in patients with DMD in VIP/IPIC/HPMFGS.

Methods and patients: Cohort study, between 2002-2010 in VIP. Group A: 16 (25%) VS users and group B: 46 (74.2%) nonusers of VS. Likelihood of VS was estimated by survival analysis of Kaplan-Meier.

Results: Medians for the entire sample (years): last visit: 15.6 (4.0 to 30.2), monitored by the VP: 4.5 (0 to 6.5). Median age (years) loss of ambulation: A 8.1 (5.1-13), B 10.6 (7.15 to 15) (p=0.05). Majoritily in A lost early ambulation. Significant difference between the two groups (p=0.05). Survival curve of cumulative probability of VS: age < 11 years: no patient needed VS, 16 years: 20%, 23 years: 36%, and 26 years: 100%. Statistically significant difference in the cumulative probability (p<0.001) in need of SV among patients with loss of ambulation before 10 years (group C) and with loss of ambulation after that age (group D). 15 years of age, 12% of patients in C required SV. 100% needed to SV in C, in D only after 23 years.

Conclusions: Age of loss of ambulation at age 10 is a marker for estimating the need of early VS in patients with DMD.

P1234
In which male patients with COPD participated in a pulmonary rehabilitation program should be evaluated for osteoporosis? Dicle Kayraz1, Pinar Ergin2, Gülseren Kayalı3, Fatma Sengül4, Nese Demir2
1Ankara Chest Diseases and Thoracic Surgery Training and Research Hospital, Pulmonary Rehabilitation and Home Care Unit, Ankara, Turkey; 2Neumome Training and Research Hospital, Physical Therapy and Rehabilitation, Ankara, Turkey

Osteoporosis is common in patients with COPD and an important risk factor for the development of hip, vertebral or long bone fracture which could add further disability and incapacity.

The aim of the study was to analyze the utility of different measures (age, smoking habit, daily dose of inhaled steroids, anthropometric measures of body composition, stage of COPD, dyspnea, health related quality of life, exercise capacity, comorbidities) for detecting the need for evaluation in male COPD patients who were participated in a PR programme.

Methods: Patients who were in a pulmonary rehabilitation programme with confirmed stable COPD and not on long-term oral corticosteroids (n=57) performed spirometry. They underwent nutritional assessment by midarm circumference,calculation BMI and FFMI. Dyspnea sensation was assessed with the MRC, where health related quality of life was assessed with the SGRQ,Exercise capacity was measured using the SWT.All had DXA assessment of Bone Mineral Density.
**Results:** A total of 57 COPD patients with the mean age of 62.07±7.7 years. Osteoporosis was found in 22 patients (38.6%) at both the total hip and total lumbar spine. After adjusting for all covariates (age, FEV1, daily dose of inhaled steroids and smoking pack years) COPD patients with a lower BMI was found to be at an increased risk of hip region osteoporosis. The adjusted odds ratio for BMI 0.51 (0.28-0.91), P=0.023.

The addition any of the other measurements was not found as a risk factor for osteoporosis. Comorbid nutritional assessment, incorporating a calculation of their BMI may confer benefit detecting those at risk of osteoporosis in male COPD patients.

The effectiveness of pulmonary rehabilitation in COPD outpatients with comorbidities
Nigel Mendil, Pinar Ergün, Dicle Kaymaz, Selma Aktaş, Ezgi Utku. Pulmonary Rehabilitation and Home Care Department, Anaturk Chest Disease and Chest Surgery Education and Research Hospital, Ankara, Turkey

**Aim:** Chronic obstructive pulmonary disease (COPD) is often associated with other chronic diseases. The aim of this study was to determine the frequency and prevalence of chronic comorbidities in patients with COPD and to assess their influence on the effects of pulmonary rehabilitation (PR).

**Method:** 183 patients were included multidisciplinary comprehensive PR program between July 2007 and September 2010 in our outpatient PR center. All patients were grouped according to the following comorbidity categories: 0 (absence of comorbidity), 1 and >2 (depending on the number of comorbidity). Incremental Shuttle Walking Test (ISWT) and Endurance Shuttle Walking Test (ESWT) was used to evaluate exercise capacity. Medical Research Council (MRC) for the perception of dyspnea, St. George’s Respiratory Questionnaire (SGRQ) for quality of life, Hospital Anxiety and Depression Scale (HADS) for psychological evaluation and BMI, fat-free mass (FFM), fat-free mass index (FFMI) analyzing for body composition.

**Results:** 131 patients reported at least one chronic comorbidity added to COPD. Metabolic (systemic hypertension, diabetes, dyslipidemia) and heart diseases (chronic heart failure, coronary heart disease) were the most frequently reported comorbid combinations (88 and 23, respectively).Statistically significant improvement was determined in ISWT and ESWT (p<0.01); statistically significant decrease was determined in MRC, SGRQ and HADS (p<0.001) for each comorbid categories.

**Conclusion:** Chronic comorbidities are very frequent in patients with COPD undergoing PR. Comorbidities does not preclude access to effectiveness of rehabilitation.

**P1236**

Comorbidities in COPD patients are not associated to higher disease severity
Laura Caram, Renata Ferrari, Cristiane Naves, Suzana Tanni, Liana Coelho, Simone do Vale, Irma Godoy. Department of Internal Medicine, Botucatu Medical School - Sao Paulo State University – Unesp, Distrito de Rabúpis Júnior, São Paulo, Brazil

The influence of disease severity on the prevalence of comorbidities in COPD patients is unclear. The aim of this study was to assess the prevalence of comorbidities in 25 mild/moderate COPD patients (68% male gender, age=65±8 years, FEV1=73±15%predicted) and 25 severe/very severity COPD patients (56% male gender, age=69±9 years, FEV1=40±18%). Comorbidities were registered based on medical charts diagnoses, on Charlson comorbidity index and on Hospital Anxiety and Depression Scale. Of the 50 patients evaluated, 70% had diagnosis of comorbidities, and 42% of these were cardiovascular diseases (40% hypertension, 10% coronary artery disease and 6% heart failure grade I). Depression was present in 20% of patients, dyslipidemia in 14% and diabetes mellitus in 14%. The prevalence of dyslipidemia (p=0.02), depression (0.008) and alcoholism (p=0.06) were higher in patients with mild to moderate disease. Charlson comorbidity index, systemic arterial blood pressure, diabetes mellitus, ischemic heart disease and chronic cardiac failure and the scores of the Hospital Anxiety and Depression Scale were similar between both groups. The majority of patients with diagnostic of dyslipidemia had concentrations of lipids (total cholesterol, HDL, LDL and triglycerides) within normal values and the lipid profile were similar between groups. In conclusion, comorbidities are highly prevalent in COPD patients regardless of the disease severity. Some diseases such as dyslipidemia, depression and alcoholism are even more prevalent in mild/moderate patients.

Late-breaking abstract: Effects of mucus clearance on the differences of rheological property, driving pressure and frequency during high frequency chest wall oscillation (HF CWV)
Tetsuo Miyawaga1, Tomomi Ichiba2, Masayuki Takahashi2, Robert Hansen4,1 Division of Respiratory Care, Showa University, Graduate School of Nursing and Rehabilitation Sciences, Yokohama, Kanagawa, Japan; 2Department of Physical Therapy, Kyorin University, Faculty of Health Sciences, Hachioji, Tokyo, Japan; 3Home Care Product Division, Tokibo Co. LTD, Shinagawa, Tokyo, Japan; 4Chairman/CEO, Electro Med, Inc.; New Prague, MN, United States

**Background:** HF CWO is commonly used for airway clearance. However the effect of mucus clearance on the rheological property, driving pressure and frequency during HF CWO is not clear. The purpose of this study is to clarify differences of airway clearance efficacy.

**Method:** 24 normal subjects participated in the study 1. Mucus stimulants (MS) were prepared using thicker 1, 2, 3 and 4% and the pressure controls of SmartVest™ were driven 20, 40 and 60 on the frequency 13Hz. MS rheological studied were measured using Rheometer. They were quiet breathing into the endotracheal tubes having internal diameter of 7mm during SmartVest™. We measured migration velocity of each MS, PEFR, Pmax and effortless breathing. Another 26 normal subjects participated in the study 2. MS were prepared using similar thicker were driven frequency 9Hz, 13Hz and 17Hz on the driving pressure 40.

**Measurement methods and items were carried out in a similar manner of Study 1.**

**Results:** The higher setting pressure and frequency controls drove, the more PEFR and Pmax increased (p<0.05). In the rheology of MS, the lower viscoelasticity of 1% MS had, the faster clearance velocity moved (p<0.05). However, the clearance velocity did not increase in the higher viscoelasticity of MS in spite of high driving pressure. The 13Hz oscillation was most reduced in viscoelasticity and yield value by comparison with 9Hz and 17Hz. The lower viscoelasticity of MS in the each frequency, the clearance velocity increased (p<0.05). The subjects were not tolerable on17Hz.

**Conclusions:** The oscillation of 13Hz and driving pressure 40 is the most effective for mucus clearance.

Assessment of nocturnal hypoventilation in patients with chronic respiratory failure: Role of transcutaneous PCO2 monitoring. An observational study
Daniele Nguyen-Baranoff, Claudio Kabec, Marjolaine Georges, Ameline Vagner, Numba Kabeya, Philippe Camus. Service de Pneumologie et Réanimation Respiratoire, Centre Hospitalier et Universitaire de Dijon, Dijon, France

Patients with nocturnal hypoventilation are at risk of developing daytime ventilatory failure. As a result, this finding has therapeutic implications. Currently, assessment of nocturnal hypoventilation is performed using nocturnal oximetry (NO) coupled to diurnal arterial blood gases (ABG). Even if theoretically useful, transcutaneous PCO2 (TcPCO2) monitoring is not routinely used. Therefore, its role should be defined.

**Objectives:** To compare NO coupled to ABG versus TcPCO2 for detecting alveolar hypoventilation in a cohort of chronic respiratory failure patients.

**Methods:** We performed 153 NO coupled to a TcPCO2 recording (91 under non invasive ventilation and 62 during spontaneous breathing) in 98 patients. In addition, ABG were performed during spontaneous breathing. Aetiologies of respiratory failure were: neuromuscular disorder (97 traces), thoracic cage abnormalities (35 traces) and lung disease (21 traces). Nocturnal hypercapnia was defined by a nighttime mean PaCO2 ≥ 50 mmHg, nocturnal hypoxemia as ≥ 30% of the night spent with a SaO2 <90% and diurnal hypercapnia as a PaCO2 ≥45 mmHg.

**Results:** Combined normal NO and normal ABG underestimated nocturnal hypercapnia in >50% of both spontaneously breathing and ventilated patients. Conversely, nocturnal hypoxemia was associated with nocturnal hypoventilation in 100% of non ventilated patients but only in 50% of ventilated ones.

**Conclusion:** Normal values of nocturnal oximetry and/or ABG do not allow to exclude nocturnal hypoventilation. Our results underline the interest of performing transcutaneous TcPCO2 monitoring to evaluate patients at risk of nocturnal hypoventilation.
P1239
Evaluation of home oxygen provision in east London: A study of appropriateness of ordering, and patient understanding and compliance
Robin Johns 1, Marc Rodriguez 2, Kara Remmo 3, Simon Lloyd-Owen 1
1 Respiratory Medicine, Bart's and the London NHS Trust, London, United Kingdom; 2Community Respiratory Team, Tower Hamlets Community Health Service, London, United Kingdom

Introduction: In the UK, commissioners fund home oxygen via a tariff based on flow rates, hours of prescribed usage, and mode of delivery; each specified on an oxygen order form (HOOF).
Aims: Over six months, records from the local supplier (Air Products) showed 130 patients were under-using oxygen by at least 75% of that ordered. This study aimed to evaluate why.
Methods: Diagnoses and reasons for oxygen provision were obtained from electronic records. Patients were telephoned to explore understanding of the need for oxygen, health benefits, and their individual order. Some were deceased (11), were children, or were not contactable. Data on contactable adults, who agreed to interview (45), are presented.
Results: Commonest reasons for oxygen provision were COPD and obesity hypoventilation/obstructive sleep apnoea. 47% (21/45) could not name their oxygen.

Conclusions: This study confirms the hypothesis that a LTOT “complex” service, may have greater effectiveness than a “complex”, in reducing the exacerbations rate, the number and the length of the hospitalizations of the COPD patients.

P1241
End of life in COPD: There may be no surprises!
Gail South 1, Orla Reddington 1, Lisa Hatfield 1, Alison Phillips 1, Hannah Wall 2
1BreathingSpace, The Rotherham Foundation Trust, Rotherham, South Yorkshire, United Kingdom; 2NHS Improvement, St John’s House, Leicester, Leicestershire, United Kingdom

Background: In the UK prognostic indicators have been developed for predicting end of life (EOL) in COPD.
We report on the prevalence of these indicators in patients admitted to a nurse led unit for people with acute exacerbations of COPD (AE-COPD).
Methods: Data on general and COPD specific prognostic indicators plus the surprise question were collected on all admissions Aug 2010 to Jan 2011.
Results: Total 199 patients (54/4%). Mean age 70 (37-93). In 86 (48%) cases the clinician would not have been surprised if the patient died in the next 6-12 months. In only 5 of these instances were no other prognostic indicators identified (positive predictive value of negative response 95%) 174 (87%) had at least 1 prognostic indicator identified at the time of admission.

Of the 15 deaths so far there was a negative response to the surprise question in 14 and in all at least 1 other prognostic indicator was present.
Conclusions: Prognostic indicators were present in 87% of patients admitted.
The surprise question should form part of admission assessment.
It is too early to say which prognostic indicators are important in predicting EOL.

P1242
Are COPD patients referred to palliative care?
Respiratory Medicine, Basildon & Thurrock University Hospital, Basildon, United Kingdom

Introduction: The consultation on a strategy for COPD in England suggests patients with COPD should be considered for end of life care particularly if they have the following markers of severity: 1. Severe airflow obstruction (FEV1 <30%) 2. Low BMI (<20) 3. Housebound 4. Two or more admissions in previous year 5. Respiratory failure or previous ventilation.
Method: A list of patients discharged in Jan 2007 with a diagnosis of COPD was obtained. Of 69 patients identified 40 were chosen at random and included. The case notes were investigated and the markers of severity met were recorded. It was also determined if the patients had survived to discharge, 3 months and 3 years.

Results:

Discussion: None of the patients had all 5 criteria measured during, or prior to the admission in question illustrating the importance of thoroughly assessing level of disability in COPD. When considering the patients alive at 3 years there was a trend towards fewer patients surviving the greater the number of severity criteria they met. However the patient who met 4 of the severity criteria, and survived to 3 years demonstrates the difficulty in precisely predicting the transition to the end of life in COPD and thus timing of involvement of palliative care. Only 3 of the 40 patients were considered for specialist palliative care, and this consisted of using
the Liverpool care pathway in the hours prior to death. More studies are needed to look into optimal timing for end of life care in COPD.

P1243

Readmission predictors in patients with chronic obstructive pulmonary disease due to an exacerbation

Naoyuki Yoshida1, Takashi Yoshiyama2, Satoshi Kosijima3, Misako Aoki1, Shoji Kudo1,2, Respiratory Care and Rehabilitation Center, Fukuyagi Hospital, Japan Anti-Tuberculosis Association, Kyossho-shi, Tokyo, Japan; 3Respiratory Diseases Center, Fukuyagi Hospital, Japan Anti-Tuberculosis Association, Kyossho-shi, Tokyo, Japan; 4Clinical Laboratory Department, Fukuyagi Hospital, Japan Anti-Tuberculosis Association, Kyossho-shi, Tokyo, Japan

Introduction: Hospitalizations for chronic obstructive pulmonary disease (COPD) exacerbations increase risk of readmission due to an exacerbation and lead to higher mortality.

Aims: To determine factors which may contribute to readmission due to a new episode of COPD exacerbation.

Methods: We reviewed medical charts of all patients with a discharge diagnosis of a COPD exacerbation admitted to Fukuyagi hospital, the secondary respiratory hospital serving the north-west of Tokyo, from October 2008 to March 2010. Data collected included age, sex, pack-year history of smoking, body mass index (BMI), previous FEV1, arterial blood gases at an emergency room, and incidence of long term oxygen therapy (LTOT). Comorbidities were measured with Charlson Comorbidity Index. Length of stay at this time as well as the number of hospitalizations for a COPD exacerbation in the previous 12 months were obtained. Readmission was defined as one or more hospitalization for an exacerbation within six months after discharge.

Results: 57 patients (57 men) were included in this study (mean FEV1 38.4% predicted). 19 of these patients (28.8%) were readmitted. Readmission was significantly associated with receiving LTOT (odds ratio [OR], 3.63 [95%CI, 1.18 to 11.2], p=0.04), hospitalizations for a COPD exacerbation in the previous 12 months (OR, 20.2 [CI, 4.58 to 88.1], p<0.001), and Charlson Comorbidity Index (≥1 vs 0 or 1) (OR, 7.56 [CI, 2.08 to 27.53], p=0.003).

Conclusions: Receiving LTOT, hospitalizations during the previous year, and comorbidities are strong predictors of readmission due to a new episode of exacerbation in our COPD patients.

P1244

A time-limited, six month program of community-based disease management, support and education following hospital admission for A/E COPD; outcomes from a pilot study

Myra Stern, Helen Broomfield, Angela Williamson, Catherine Potter, Clare Yeramesu, Respiratory Medicine, Whittington Hospital NHS Trust, London, United Kingdom

Introduction: Our specialist multidisciplinary respiratory team (MDRT) can successfully support COPD patients following A/E COPD admission (>1000 bed-days saved/year). Patient-dependency has made discharge difficult. The aim of this pilot study was to determine the efficacy/suitability of a time-limited (6/12) support program, focused on self-management.

Method: Patients admitted with A/E COPD ≥2/year or with first time with no previous diagnosis/education, were referred. Disease severity, anxiety/depression and admission frequency (year before/year after) were documented. A pre-determined program of self-management skills was assessed by the Bristol QoL (BQ).

Results: 23 COPD patients, mean (±SD) age 73.3±3.02 years; FEV1 0.79±0.07; MRCDS 4.1±1.0 were included in this pilot study for 6.4±0.9 months (mean±SE). 11/23 were discharged appropriately; 2 died; 23 required ongoing support. There was no significant difference in disease severity or HADS between those discharged and those requiring ongoing support. Admission rate significantly (p<0.02) decreased from 1.9±0.2/patient in 12/12 prior to MDRT to 1.2±0.3/patient in 12/12 after team input, in both groups with no significant difference in final BQ (39.3±3.9 vs 44.0±4.4) scores.

Conclusion: A time-limited program focused on self-management is appropriate for about 50% patients admitted with severe COPD. Further work needs to be done to determine specific factors that can predict which patients are suitable for this intervention.

P1245

Evaluation of contribution of high frequency chest wall oscillation treatment to medical treatment in patients with acute exacerbations of COPD

Tugba Goktalay, Selin Akbas, Fatma Yagci, Aysu Demir, Mert Eryilmaz, Kilis, Turkey

Vest TM device which applies high frequency chest wall oscillation has been approved by FDA for the clearance of bronchial secretions in 1988 and for the induction of sputum in 2000. It has been used in abroad but not in Turkey yet. The Vest TM device was applied to 16 of 30 patients. Basal BODE index of the study groups was not statistically different, also mean age was similar BODE index, PO2 and SO2 of the patients were statistically better both on the third and fifth days (Table). There was a 4% increase from basal FEV1 of Group1, while this difference was 6% in Group2 (p<0.002, p=0.002). Similarly the increase in 6MWT was 107m in Group 1 while it was 150m in VestTM group (p=0.000, p=0.000). Although MMRC dyspnea scale did not statistically different, the VestTM group reported decreased dyspnea perception (p<0.055) BODE index (p=0.801), p=0.595 and SpO2 (p=0.640, p=0.870) were not found different between the two groups.

Adding Vest TM to conventional treatment in COPD exacerbations did not result in any difference in BODE index, however exercise capacity and dyspnea perception were found to be improved more with Vest TM.

P1246

Hospital at home for patients with acute exacerbations of chronic obstructive pulmonary disease; will it be an effective home care model?

Dicle Kaymaz, Pinar Ergin, Evrim Gunay, Selma Akkas, Nilgun Mendil, Salihat Bastal, Ergu Uzlu, Pervin Demar. Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital, Pulmonary Rehabilitation and Home Care Unit, Ankara, Turkey

The current acute care model for COPD is, in general, insufficient for optimal management of the disease. Coordination of services is especially important at the time of the COPD exacerbation, which is characterised by high morbidity, high healthcare utilisation and even worse fragmentation of care. Home care services can offer a great potential for this aim, Hospital at home (HAH) care model is feasible, simple, and efficacious for certain patients with selected acute medical illnesses who require acute hospital-level care.

Aim: The aim of the present study was to analyze the effectiveness of HAH for patients with COPD exacerbation.

Methods: Two hundred and six patients who were admitted to our institution via the emergency department with the diagnosis of COPD exacerbation were included to HAH. Patients were followed up during the year after HAH practise.

Hospitalization rates, emergency department, home admnistration days, hospitalisation days when needed were evaluated before and after one year period of HAH

Results: After one year follow up period of HAH practise hospitalisation rates, emergency department and out patient clinic admnitions, length of hospital stay were decreased. Respectively 40.29% 21.84% and 46.35%. The decreases for all parameters were found statistical significant (p<0.01).

Conclusion: We conclude that integrated care services including home care using the HAH modalities are strongly needed to enhance both health and managerial outcomes. Clinicians should consider this form of management, especially as there is increasing pressure for inpatient beds in Turkey.

P1247

Hand grip strength in patients engaged in pulmonary rehabilitation program during COPD exacerbation

Ordun Ozdemirci-Taskan1,2, Zeynep Erden1, Nurdan Kokturk2, Gulcin Kaynak Karatas1,2 Department of Physical Medicine and Rehabilitation, Gazi University Faculty of Medicine, Ankara, Turkey; 1Department of Pulmonary Medicine, Gazi University Faculty of Medicine, Ankara, Turkey

Aims: To measure hand grip strengths and investigate related factors in COPD patients engaged in pulmonary rehabilitation program during exacerbation.

Material and methods: Grip strengths of both hands were measured using viconometry in 52 COPD patients.

Results: Mean hand grip strength were 0.41±0.14 bar. Patients were divided into two groups according to a cut-off point, 0.40 bar (54% ≤ 0.40, 46% >0.40), there was no significant difference in age, systemic diseases, FEV1/FVC, arterial blood gases between groups. Hand grip strengths were lower in women (p=0.003). In patients with lower strength, FEV1, FVC values (p=0.019 and p=0.002, respectively), hemoglobin levels, mini-nutritional scores and T scores at femoral neck were lower than that of patients with higher strength (p<0.05). The difference in 6 minute walk distance was not significant (p=0.087). However patients in the lower strength group had higher fatigue levels (p=0.039) and higher rest number during the walk test (p=0.032).

There was a moderate positive correlation between grip strength and 6-minute walk distance (r=0.511, p=0.001). There were negative correlations between strength and test duration and number (r=-0.339, p=0.03 and r=-0.664, p=0.002), saturation changes (r=-0.383, p=0.012), dyspnea and fatigue levels (r=-0.475, p=0.001) during the walk test.

Conclusion: Hand grip strengths of COPD patients in exacerbation showed good correlation with 6-minute walk test, indicator of functional capacity. Hand grip strength measurement which is simple to perform and has low cost may be a helpful indicator of muscle performance, especially when 6-minute walk test can be performed during exacerbation.
Effects of case management on hospitalisation and exacerbation rate in severe, complex COPD: A randomized controlled trial

Lommel Boer1, 2, Tiard Schomerus1, Ammenwerth2, Jeanette Peters1, 2, Yvonne Heijdra1, Jan Verrouwen1, 2, Erik van der Heijden2, 3, 4 Department of Medical Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 2Department of Pulmonary Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 3Department of Primary and Community Care, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Acute exacerbations have negative effects on lung function, physical performance, dyspnoea, and quality of life. Patients with severe COPD and co-morbidities are especially vulnerable to exacerbations.

Aim: We investigated if a case manager could reduce number and duration of hospital admissions due to exacerbations of COPD.

Method: In this RCT, 81 COPD patients GOLD stage 3–4 and co-morbid disease, with ≥1 reported exacerbation in the past 2 years were randomised to usual care or a case management care condition. In the usual care condition, patients visited the pulmonary nurse every 3 to 6 months. In the case manager condition, the pulmonary nurse started with a home visit, and contacted patients at least every 6 weeks by phone. Basic self-management techniques were taught and an exacerbation action plan was offered to the patient and all health care providers.

Results: Number and duration of hospital admissions were not lower in the experimental condition. The number of exacerbations reported by the general practitioner did not differ significantly. No differences were found between the two conditions with respect to health status measured by the CRQ. There was major drop out in both groups (42%), main reason was death (53%). Patients were more satisfied with the experimental condition, particularly because the case manager helped coordinating the complex care by many professionals.

Conclusions: Benefits on health status and hospital admission rates and duration were not found. However, patients with severe COPD and multiple co-morbidities benefit from a case manager by structuring care in a better way leading to increased patient satisfaction.

P249 The current situation and the perspective of respiratory care in Japanese COPD patients revealed by Japanese White Paper on home respiratory care 2010 – COPD subgroup analysis

Jun Ueda1, Michiaki Mishima2, Koichiro Tatsunami3, Kazunisha Takahashi3, Hideki Ishihara4, Hajime Kuroswa4, Keisaku Fujimoto5, Mariko Koyama6, Kazuko Toyama7, 8, 9, 10 Clinical Research Unit of Internal Medicine, School of Health Care and Nursing, Urayasu, Japan; 2Department of Respiratory Medicine, Graduate School of Medicine, University of Tokyo, Japan; 3Department of Primary and Community Care, Urayasu, Japan; 4The Japan Respiratory Society; 5Department of Respiratory Medicine, Tokyo Medical College, Tokyo, Japan; 6The Japan Federation of Pulmonary Rehabilitation Working Group, Tokyo, Japan; 7Department of Primary Care and Nursing, Urayasu, Japan; 8Department of Respiratory Medicine, Tokyo Medical College, Tokyo, Japan; 9Respiratory Care Committee, The Japan Respiratory Society, Tokyo, Japan; 10Committee, The Japan Respiratory Society, Tokyo, Japan

To assess the current situation and the perspective of respiratory care of outpatients with chronic respiratory diseases, the nationwide survey was conducted. In the patient survey, the questionnaires were sent to 3090 patients (JFPPORD) and the return rate was 27%. Of the 338 COPD patients, 73% were receiving LTOT (LTOT and HMV 24%). With regard to the pharmacological treatment, Tiotropium, LABAs, ICXs, mucolytic agents, macrolides were prescribed in 57%, 72%, 50%, 51%, and 20%, respectively. Those receiving pulmonary rehabilitation (PR) and nutritional guidance accounted for 65% and 42%, which was 60% and 28% in the 2002 White Paper respectively. Among the LTOT/HMV group, 31% had been hospitalized more than once in the past year due to exacerbation. Concerning wishes for medical staffs, the most common reply was they wanted to be taught more about the skills for self-management, which were 78% and 83% in 2010 and 2005, respectively. The most common concrete examples of this concerned PR. The three most common demands concerning LTOT were a wish for subsidy of electricity cost of the concentrator (45%), for distribution or rental of oximeters (41%), and better explanation of the response of the LTOT/HMV providers in the time of natural disaster (35%). It is suggested that there are demands regarding the needs of patients for more information about the self-management skills and an increase in opportunity to receive PR. To achieve anxiety-free respiratory care for handling of patients in the time of natural disaster. To consider the skills for self-management, which were 78% and 83% in 2010 and 2005, respectively. The most common concrete examples of this concerned PR. The three most common demands concerning LTOT were a wish for subsidy of electricity cost of the concentrator (45%), for distribution or rental of oximeters (41%), and better explanation of the response of the LTOT/HMV providers in the time of natural disaster (35%). It is suggested that there are demands regarding the needs of patients for more information about the self-management skills and an increase in opportunity to receive PR. To achieve anxiety-free respiratory care for handling of patients in the time of natural disaster.

P250 The "susceptibility to exacerbation" phenotype in COPD and response to pulmonary rehabilitation

J.L. Canavan1, K.A. Ingram2, R.P. Fowler2, P. Marns3, K. Dobson3, A.L. Clark4, C.M. Nolan5, M.I. Polkey1, W.D.-C. Man1, 2 Respiratory Biomedical Unit, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom; 2Royal Brompton Pulmonary Rehabilitation Team, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom

Introduction: Exacerbations are a key feature of COPD and are known to impact lung function, daily physical activity level, quality of life, survival, and health resource usage. Pulmonary rehabilitation (PR) is an effective treatment for disability in COPD, with previous research identifying improved outcomes for patients reporting no exacerbations (NE) when compared with patients suffering exacerbations (NE) (Rioardo-Sforza et al., 2005). A frequent susceptibility exacerbation phenotype (≥2 exacerbations in previous year) has been identified (Hurst et al., 2010) which may have implications for response to PR. We hypothesised that patients with frequent exacerbations (FE) would gain less benefit from an 8-week outpatient PR program.

Method: In 93 COPD patients reporting NE (n=28), one exacerbation (OE) (n=28) or FE (n=37) in the previous year, the following assessments were made before (T0) and after (T1) PR: fat free mass (FFM), incremental shuttle walk (ISW), self-report Chronic Respiratory Disease Questionnaire (CRQ-DQ-SR).Median(IQR) change in ISW, FFM, and CRQ-DQ-SR total score from T0 to T1 was compared between groups using Kruskal-Wallis tests.

Results: ISW distance and CRQ-DQ increased in NE (80 (13-148) m, 13.5 (1.5-23.8) OE (50 (0-110) m, 19.0 (2.0-32.0)) and FE (60 (20-270) m, 21.0 (8.0-28.0)) groups.FFM increased in NE (0.36 (-1.32-1.20)) kg) and OE (0.51 (0.85-1.33) kg) but not FE (0.07 (-1.38-2.99) kg).No significant differences were found between groups for any variables (ISW: p = 0.46, CRQ-DQ total p = 0.35, FFM: p = 0.94).

Conclusion: The "susceptibility to exacerbation" phenotype does not appear to affect improvements in exercise capacity, or health related quality of life gained during PR.

P251 Promoting excellence in COAD care – Through a community multidisciplinary team approach

D. Liu, K.M. Lo, Y.H. Leung, H.M. Ma, H.S. Chan, S.S. Ho, Medical, Alice Ho Miu Ling Nethersole Hospital, Hong Kong, Hong Kong

Background: It was estimated that the prevalence of COPD among the elderly Chinese living in Hong Kong was 25.9%.

Method: The COAD Alliance Community Program was designed and carried out by a community hospital in Hong Kong. It involves a multidisciplinary team of specialists via a community outreach approach. The highly dedicated team includes respiratory physicians, physiotherapists, occupational therapists, community outreach nurses, and others. High risk COPD patients with more than 3 emergency room or hospital admissions per year were invited and recruited into the program. They were then assessed by case manager who were responsible organizing the community based services for these patients. Services provided include advice and information provision, self care management at home, outreach nursing visits, outpatient physiotherapy sessions and emotional/counseling support. These patients’ “pre – program” and “post – program” emergency room admission rates, inpatient admissions and hospital inpatient bed-days were recorded and tabulated.

Results: 100 patients were recruited into the COAD Alliance Community Program. Six patients died during the study and 12 patients remaining for analysis. Reduction in AED attendance (mean number of admission of 2.38 pre program c.f 1.68 post program) and medical ward admissions (1.6 c.f 0.85) was evident. There is also a significant reduction in hospital inpatient bed-days (8.16 pre program c.f 4.42 days post program, p = 0.05). Total cost reduction is 215,028 Euros.

Conclusion: The multidisciplinary approach was effective in reducing emergency room attendances, inpatient bed–days and total health expenditure.

P252 Breathlessness and social cognition: The effect of social comparison on perceived breathlessness in asthma and COPD

Maayke Petersen, Omer Van den Bergh. Psychology, KU Leuven, Leuven, Belgium

Aim: The effect of context variables on the perception of breathlessness has been investigated extensively, but not in a social cognitive framework. Our aim was to test how findings in social cognition can be translated from general self-perception to research on dyspnea. We investigated the effect of social comparison on perceived dyspnea in an experimental study in asthma patients and in a field study in COPD patients in rehabilitation.

Methods: In Study 1, 50 asthma patients participated in an experiment with two sequences of resistive load breathing. Both sequences were preceded by the presentation of one of two social comparison standards. We measured reported dyspnea and persistence in load breathing. In Study 2, 48 patients with COPD completed measures on social comparison at the start and end of rehabilitation as well as on perceived dyspnea during activity. In both studies, we expected comparison standards to affect self-report of breathlessness. We controlled for functional parameters such as lung function (Study 1) and BODE index (Study 2).

Results: In both studies, we found an significant impact of social comparison on the report of breathlessness. In Study 1, we found social comparison to have an impact on persistence in load breathing. Furthermore, as moderator of the relationship of social comparison and dyspnea we identified perceived similarity with comparison standard.

Conclusion: Social cognitive processes can shape the perception of breathlessness. Particularly in settings with a strong social component such as group exercise training in rehabilitation, these social cognitive mechanisms might be important targets to improve exercise persistence.
P1253
Participants perspectives of living with COPD: The role of different groups of health professionals
Andrew Hardy1, Alison Coe2. 1Acute Medicine, Calderdale and Huddersfield NHS Foundation Trust, Halifax, West Yorkshire, United Kingdom; 2My Therapy Services (Respiratory Physiotherapy), Muld Huddersfield NHS Trust, Castleford, United Kingdom

Methodology: This is a qualitative research study of participants experiences of a pulmonary rehabilitation (PR) programme based in Wakefield, UK. 4 group interviews were carried out in spring 2010 involving 24 participants. 22 had a primary diagnosis of COPD (mean FEV1 1.1 litres, 42% predicted), 1 had lung cancer and 1 was a carer for a participant with COPD. A structured interview included discussion of the roles of different groups of health professionals - general practitioners (GP) and nurse specialists.

Results: Participants liked their GP to have good communication skills. Specific examples of good practice were describing illness in a manner which the participant could understand and allowing time to ask questions. Participants appreciated the amount of time they were able to spend with a doctor, liked regular contact with the same GP and the cleared waiting for appointments. Participants wanted to feel that something could be done to improve their situation, trusted doctors decision making and rarely asked questions regarding their treatments. Specialist nurses were considered to be more helpful in managing symptoms than GPs. Nurses had more time for patients, were more likely to involve patients in decision making, and showed greater empathy. Some nursing staff were considered to have more specialist knowledge than GPs. Participants described a high degree of trust in nurses decision making and were more comfortable discussing their condition with them.

Summary: Patients with COPD value good communication skills, expert knowledge, a positive approach and good time management in their health providers. Specialist nurses are able to deliver an effective patient-centred service.

P1254
The impact of depression in recovery and outcome of patients hospitalized for COPD exacerbation
Andreas Papamargaritis1, Konstantinos Bartziakos2, Stamatoula Tsirika1, Fotini Karakountaki1, Emmanuel Kastanakis1, Aikaterini Haniotou2, Vlassis Poluchronopoulos1, Konstantinos Kostikas3. 13rd Respiratory Medicine Department, Samanofegorion General Hospital, Athens, Greece; 2Respiratory Medicine Department, Anna Fleming General Hospital, Athens, Greece; 2nd Respiratory Medicine Department, University of Athens Medical School, Athens, Greece

Background: Depression has been associated with worsening of COPD symptoms and quality of life, more exacerbations and increased mortality.

Objectives: To evaluate prospectively the impact of depressive symptoms on patients with COPD exacerbation.

Methods: Twenty-one patients (VEF1: 46±10% predicted) were evaluated monthly for one year.

Results: Depression was diagnosed in 7 patients (33.3%) and a depressive symptom was present in 7 patients (33.3%). There was a significant reduction in MVIC after IET was observed just for MD at moments 10, 30, 60 minutes and it was recovered in 24h.

Conclusion: Muscle weakness and a susceptibility to develop muscle fatigue after walking occur in the patient and dorsi-flexor muscles in patients with COPD compared to controls.

Project supported by the Réseau en santé respiratoire du FRSQ

P1256
Upper and lower limbs muscle in patients with COPD: Similar muscle efficiency but differences in resistance to fatigue
Eduardo Foschini Miranda, Carla Malaguti, Paolo Marchetti, Simone Dal Corso. Rehabilitation Sciences, Nove di Julia University, São Paulo, Brazil

Background: It is still controversy whether the impairment of muscle function is homogeneous between the upper and lower limbs in patients with COPD.

Objective: To compare muscle function between quadriceps femoris (QF) and middle deltoid (MD) after a fatigue protocol and also the recovery time fatigue.

Methods: Twenty-one patients (VEF1: 46±10% predicted) performed for both muscles: maximum voluntary isometric contraction (MVIC) and post-exercise for either plantar-flexor (P1257) or dorsi-flexor muscles.

Conclusion: Muscle weakness and a susceptibility to develop muscle fatigue after walking occur in the patient and dorsi-flexor muscles in patients with COPD compared to controls.

P1257
How should we measure arm exercise capacity in COPD? A systematic review
Tanya Janaudis-Ferreira1,2, Marla K. Beauchamp3, Roger S. Goldstein1,2, Dina Brooks1,2. 1Respiratory Medicine, West Park Healthcare Centre, Toronto, ON, Canada; 2Department of Physical Therapy, University of Toronto, Toronto, Canada; 3Department of Medicine, University of Toronto, Toronto, Canada

Background: There are no recommendations on how to measure arm exercise capacity in individuals with chronic obstructive pulmonary disease (COPD). The objectives of this study were to: (i) synthesize the literature on measures of arm exercise capacity in individuals with COPD; (ii) describe the psychometric properties and the target construct of each measure and (iii) make recommendations for clinical practice and research.

Methods: Studies conducted in COPD that included a measure of arm exercise capacity were identified after searches of 5 electronic databases (MEDLINE, CINAHL, EMBASE, Physiotherapy Evidence Database and Cochrane Library) and reference lists of pertinent articles. One reviewer performed data extraction and two assessed quality of studies that described measurement properties using the Consensus-based standards for the selection of health measurement instrument.

Results: Of 654 reports, 41 met the study criteria. Five types of arm exercise tests were identified: arm ergometry, ring shifts, dowel lifts, proprioceptive neuromuscular facilitation, and activities of daily living (ADL) tests. Four studies assessed measurement properties of the Unsupported Upper Limb Exercise test (ULEX), 6-minute Pegboard and Ring test (6PBT), a test involving weight shifts and 231s

117. Rehabilitation, outcome measures and effects

P1255
Lower limb fatigue, during walking in patients with COPD
Philippe Gagnon1, Valérie Couta1, Laurent Bouyer2, Cynthia Broscorial1, François Malha1, Didier Sany1. 1Pneumologie, Centre de Recherche de l’Institut Universitaire de Cardiologie et de Pneumologie de Quebec, Quebec, QC, Canada; 2Centre de Recherche, Centre Interdisciplinaire de Recherche en Réadaptation et Intégration Sociale, Quebec, QC, Canada

Background: The contribution of quadriceps muscle fatigue to cycling exercise intolerance is well recognized in COPD. Whether muscle fatigue occurs in plantar and dorsi-flexor muscles during walking is still unknown in these patients.

Aim: To compare muscle strength and fatigue induced by walking exercise in plantar and dorsi-flexor muscles between COPD patients and healthy subjects.

Method: Eleven patients with COPD (FEV1 58±15% predicted) and 11 healthy subjects matched for age and BMI performed a 12-minute walking exercise. The speed and slope of the treadmill were adjusted to achieve a targeted 40 kcal energy expenditure for each subject. Maximal voluntary contraction (MVC) and twitch force (Tw) measured by magnetic stimulation were obtained for plantar and dorsi-flexor muscles prior to and 15 minutes after exercise.

Results: At rest, MVC and Tw tended to be lower in COPD patients compared to healthy subjects for plantar (51±12.8 vs 65±23.7 kg, p=0.08 and 10±9.4±3.7 vs 13±2.6 kg, p=0.09) and dorsi-flexor (24±4.10 vs 33±7.8±4.4 kg, p=0.06 and 4.2±1.4 vs 6±1.2±1.3 kg, p<0.05) muscles. In COPD patients both, MVC and Tw were significantly decreased by 15% after exercise for plantar-flexor (p<0.001), 15±21% (p<0.05) and for dorsi-flexor (4±11% and 31±19%, p<0.05). There was no difference in healthy subjects post-exercise for either plantar-flexor (1±10% and -4±14%), or dorsi-flexor muscles (1±3% and 4±7%).

Conclusion: Muscle weakness and a susceptibility to develop muscle fatigue after walking occur in the patient and dorsi-flexor muscles in patients with COPD compared to controls.

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30

Aim: The work of walking (WOW) can be a better outcome measure of functional capacity. The aims of this study were to compare WOW between patients with cystic fibrosis (CF) and healthy controls, and to determine the factors affecting WOW during 6-minute walk (6MWT) in patients with mild cystic fibrosis.

Materials and methods: Twenty-five mild CF patients (FEV1 88.6±19.2%, 12.6±3.3 years) and 20 healthy subjects (13.8±4.5 years) participated in this study. 6MWT was performed, and WOW calculated as body weight×6MWT distance. Peripheral muscle strength (knee extensors, shoulder flexors, hand grip) were assessed using a dynamometer. Inspiratory and expiratory muscle strength (MIP and MEP) were determined with a mouth pressure device. Fat free mass percent (%FFM) was assessed using skinfold method. Health status were determined with Childhood Health Assessment Questionnaire (CHAQ).

Results: Lung function, WOW, and quadriceps muscle strength were significantly lower in CF patients as compared to healthy subjects (p<0.05). The WOW in 6MWT was significantly related with knee extensor strength (r=0.71), shoulder flexor strength (r=0.65), hand grip strength (r=0.78), MIP (r=0.52), MEP (r=0.64), %FFM (r=-0.38), CHAQ activities of daily living (r=0.56) and total scores (r=0.47, p<0.05). Quadriceps muscle strength and MEP explained 82% variance in WOW in 6MWT.

Conclusion: Quadriceps muscle strength and WOW decrease in mild CF patients. The WOW performed during in a functional capacity test is related to peripheral muscle strength, health status and body composition in CF. Quadriceps muscle strength and MEP are the independent factors determining WOW in CF patients. The work of walking can be used as outcome measure in these patients.

Six minute walk test in obese children and adolescents

Mariana Simoes Ferreira, Roberto Teixeira Mendes, Maria Angela G. de Oliveira Ribeiro, Jose Dirceu Ribeiro. Pediatrics, Center for Investigation in Pediatrics, LAFESP/ICPESP, State University of Campinas Medical School, Unicamp, Campinas, Sao Paulo, Brazil

Background: Six minute walk test (6MWT) is an accessible tool to evaluate the submaximal physical capacity. There are few studies that evaluate the 6MWT in obese children and adolescents.

Aim: To compare the performance of obese and healthy children and adolescents in the 6MWT analyzing the walked distance (WD), the work (W) and the efficiency of the metabolic processes during the test.

Method: Comparative, analytical and cross sectional study including, eighty four subjects in the 6MWT analyzing the walked distance (WD), the work (W=body weight × WD) and the metabolic efficiency (%FFM). %FFM was defined according to CDC standards (IMC = body weight/height²). The 6MWT followed the ATS guidelines.

Results: The obese subjects walked a significantly shorter distance than the eu-obese group (p=0.00). There were similar differences between the groups in the PC (p=0.25), %FFM (p=0.32), W (p=0.17), and efficiency of the metabolic processes (%FFM) (p=0.41). The W in the eu-obese group was significantly higher than the healthy group (p=0.00). There were similar differences between the groups in the PC (p=0.25), %FFM (p=0.32), W (p=0.17), and efficiency of the metabolic processes (%FFM) (p=0.41).

Conclusion: The work rate increment during IST in 6MWT has determined a higher exercise tolerance, cardiopulmonary stress and perceived exertion at peak exercise were equivalent between CST and MIST.

Six minute walk test in obese children and adolescents

Mariana Simoes Ferreira, Roberto Teixeira Mendes, Maria Angela G. de Oliveira Ribeiro, Jose Dirceu Ribeiro. Pediatrics, Center for Investigation in Pediatrics, LAFESP/ICPESP, State University of Campinas Medical School, Unicamp, Campinas, Sao Paulo, Brazil

Background: Six minute walk test (6MWT) is an accessible tool to evaluate the submaximal physical capacity. There are few studies that evaluate the 6MWT in obese children and adolescents.

Aim: To compare exercise tolerance time, cardiopulmonary stress, and perception of effort between CST and a modified incremental step test (MIST).

Methods: Thirty-two patients with COPD (FEV1: 50±15% of predicted) underwent the CST and MIST at the same day, an hour apart, on a single step (20 cm of height). Both tests were externally paced by sonorous stimulus previously recorded on a CD. CST started with a rhythm of 15 steps/minute and increments of five steps were performed every two minutes, with a total time of ten minutes. MIST started with 10 steps/minute and increments of one step every 30 seconds until the limit of tolerance.

Results: CST had shorter duration than MIST (42.7±2 min versus 6.4±3 min, respectively; p<0.05) and also lower total number of steps (77.4±51 versus 103.6±30, p<0.05). However, similar cardiopulmonary stress, pulmonary impairment, exercise desaturation and leg fatigue was observed between both tests. Desaturation in both tests and non-desaturation in either tests were observed in five and seven patients, respectively. Among the metabolic and ventilatory variables measured at peak exercise, higher oxygen uptake and lower ventilatory equivalent for oxygen were observed for IST as compared to MIST (1.5±0.3 L/min versus 1.2±0.4 L/min and 33.5±7.4 vs 36.3±7.8; p<0.05). The recovery time was longer in MIST as compared to CST (1.1±0.2 min versus 0.5±0.2 min, p<0.05). The recovery time was longer in MIST as compared to CST (1.1±0.2 min versus 0.5±0.2 min, p<0.05). The recovery time was longer in MIST as compared to CST (1.1±0.2 min versus 0.5±0.2 min, p<0.05).

Conclusion: The desaturation was detected only during IST in 33% of patients. VO2 peak is higher, ventilatory demand is lower and desaturation more pronounced during stepping than cycling.

The modified version of the pulmonary functional status and dyspnea questionnaire: A valid measure to evaluate functional status in patients with COPD

Chris Burtn1,2, Daniel Langer1,2, Hans Van Remoortel1,2, Rik Gosselink1,2

Background: The modified version of the Pulmonary Functional Status and Dyspnea Questionnaire (PFSDQ-M) is a reliable tool which aims to evaluate perceived functional status in patients with chronic obstructive pulmonary disease (COPD).

Aim: To establish the MID of PFSDQ-M using different approaches.

Methods: 461 patients with COPD (FEV1 ≥ 42% predicted) completed the PFSDQ-M before and after a 3-month pulmonary rehabilitation program (ΔCRDQ +16±1.5points, Δ6MWD +45±8.9m, both p<0.001). The correlation between the ΔPFSDQ-M and the anchors ΔCRDQ and Δ6MWD was calculated. When r ≥ 0.3 linear regression analyses were performed to predict the MID from these anchors (i.e. establish the ΔPFSDQ corresponding with 10points ΔCRDQ, 2.5points Δ6MWD). The PFSDQ was also applied in the distribution-based Cohen’s effect size technique to confirm the MID.

Results: Anchor and distribution - based methods estimates are summarized in Table 1.

Conclusion: The MID of the PFSDQ-M ranged from -3 to -6 points in patients with moderate to very severe COPD. The estimate was similar with both statistical techniques.

ER is a fellow of CAFES 14/15/10-3.

P1265
The minimal important difference of the pulmonary functional status and dyspnea questionnaire – Modified version in patients with COPD

Eloisa Regueiro1,2,4, Chris Burtin1,2, Daniel Langer1,2, Hans Van Remoortel1,2, Paul Baten1, Valeria Pires Di Lorenzo1,2,3, Dirceu Costa1,2, Wim Janssens4, Marc Decramer1,2, Rik Gosselink1,2, Thierry Troosters1,2

Background: The modified version of the Pulmonary Functional Status and Dyspnea Questionnaire (PFSDQ-M) is commonly used in COPD to obtain information about their symptoms and functional status. It has been shown to be responsive to change following pulmonary rehabilitation. The minimal important difference (MID) of the PFSDQ has never been established.

Aim: To establish the MID of PFSDQ-M using different approaches.

Methods: 416 patients with COPD (FEV1 42±12points, Δ6MWD 45±8.9m, both p<0.001). The correlation between the ΔPFSDQ-M and the anchors ΔCRDQ and Δ6MWD was calculated. When r ≥ 0.3 linear regression analyses were performed to predict the MID from these anchors (i.e. establish the ΔPFSDQ corresponding with 10points ΔCRDQ, 2.5points Δ6MWD). We also applied the distribution-based Cohen’s effect size technique to confirm the MID.

Results: Anchor and distribution - based methods estimates are summarized in Table 1.

Conclusion: These findings add to the validity of the PFSDQ-M as a subjective tool to evaluate functional status in patients with COPD.

P1265
Anxiety and depression in patients referred for pulmonary rehabilitation

Karen Ingram, Jane Canavan, Ria Fowler, Philippa Morris, Amy Clarke, Claire Nolan, Michael Polkey, William Man. Harefield Pulmonary Rehabilitation Team and Respiratory Biomedical Research Unit, Royal Brompton & Harefield NHS Foundation Trust, Harefield, United Kingdom

Introduction: Psychological morbidity is well recognised in chronic respiratory disease, but the effect of uptake, completion and response to pulmonary rehabilitation (PR) is unknown.

Method: In 302 consecutive patients referred to an 8-week outpatient PR program, the Hospital Anxiety and Depression Score (HADS) was used to assess symptoms of anxiety and depression. A HADS domain score of ≥21 identified patients with moderate levels of anxiety and depression. Subsequent uptake and compliance with PR was recorded. Pre- to post-PR changes in incremental shuttle walk (ISW) and self-reported Chronic Respiratory Disease Questionnaire (CRDQ) were compared between those with moderate anxiety (ANX) or moderate depression (DEP), and those without, defined as HADS ≤ 7 (NA and ND).

Results: 71 (23.5%) and 59 (19.5%) patients had evidence of moderate anxiety and depression respectively. 22 (31%) of ANX and 21 (36%) of DEP either failed to start or complete PR. Despite similar FEV1% predicted, ANX had significantly impaired baseline ISW (median 100 vs. 180 m; p<0.01) and health status (CRDQ: SR 55 vs. 86) compared to the NA group. There was no significant difference in median pre- to post-PR change in ISW and CRDQ between ANX and NA completers. Similarly, the DEP group had comparable FEV1% predicted to ND, but had significantly impaired baseline median ISW (90 vs. 200 m; p<0.01) and mean CRDQ (53 vs. 84; p<0.01). However ISW and CRDQ response to PR was similar between DEP and ND.

Conclusion: Significant psychological morbidity is prevalent in patients referred to PR. Over 30% fail to start or complete PR. These patients also have impaired exercise capacity and quality of life, but completers respond normally to PR.

P1266
Breathlessness is associated with lower completion rates of pulmonary rehabilitation classes

Victoria Lord1, Melanie Thomas1, Joerg Steier1, Nicholas Hopkinson2

Background: It is important to develop specific approaches to improve completion rates in pulmonary rehabilitation (PR). Currently, it is not clear what parameters predict completion & non-completion. We hypothesised that specific demographic parameters are associated with completion rates of PR.

Methods: Respiratory patients who commenced PR classes at the Royal Brompton Hospital from September 2007 were included. At assessment we recorded age, MRC dyspnoea score, FEV1 (% pred), FVC & body mass index. Completion was defined as attendance of 12 or more out of 16 sessions. T-tests and logistic regression tests were performed on the variables.

Results: Data was available for 167 patients (77 females, mean (SD) age 66 (9.7) yrs, FEV1, 1.15 (0.6) litres (46.1% pred (21.3)), MRC 3 (1). We included a range of diseases (122 COPD, 16 bronchiectasis, 12 ashma, 14 restrictive disease and 3 normal sprirometry). The 105 patients who completed PR had a lower baseline MRC dyspnoea score, which was significant. The remaining tested parameters were not independent associated with completion rate. Of the non-completers 37% failed to attend classes and 21% stopped due to an exacerbation. Completion rates were not different in those with or without COPD.

Conclusion: A more tailored approach to improve completion rate of PR classes may need to focus on the more breathless & exacerbating patients.
Conclusion: NLR muscle training optimizes exercise and muscle training programs in patients with low FFM and more advanced COPD.

P1269 Pulmonary rehabilitation: Investigating the characteristics and use of a warm-up

Elizabeth Heywood, Gill Phillips. Rehabilitation Sciences, Leeds Metropolitan University, Leeds, West Yorkshire, United Kingdom

Background: Exercise training is recognised as an essential component of pulmonary rehabilitation (PR). Guidelines however do not detail a warm-up phase although evidence when prescribing any form of physical activity considers warming up as fundamental for optimal performance. Warm-up structure should relate to the subsequent tasks and consider individual capabilities. Particular attention is therefore required in PR that participants are warmed-up but not fatigued before exercise training.

Aims and objectives: To investigate current practice in PR, considering specific characteristics and use of a warm-up phase.

Methods: An online, prospective, cross-sectional survey using questionnaires disseminated through Physiotherapy networks in the UK.

Results: All 52 respondents reported use of a warm-up. The majority included upper and lower limb movements integrated with low intensity aerobic exercise. Marching on the spot was the predominant activity reported but also thoracic rotations (23%), walking (12%) and lateral trunk flexion (14%). Stretching was integrated into all programmes. Warm-ups lasted between 6-10 minutes for 51% (range: 3-15 minutes). Modified Borg Scale of Perceived Breathlessness was used by 12% to determine warm up intensity. However, 29% reported participants frequently failed to complete the warm-up, with 88% limited by breathlessness.

Conclusions: All surveyed PR programmes report the inclusion of a warm-up phase though with considerable variability regarding content, duration, and intensity. Individuals however may fail to complete due to breathlessness. Further research is required to determine how warm-ups in PR can be effectively structured for maximum participant benefit.

P1270 The effect of pulmonary rehabilitation programme in patients with pulmonary sarcoidosis

Katerina Neumannova1, Jakub Zatolok1, Vitezslav Kolek2. 1Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; 2Department of Pulmonary Diseases and Tuberculosis, Medical Faculty of Palacky University and University Hospital, Olomouc, Czech Republic

Background: Pulmonary rehabilitation (PR) has proven effective in treatment of COPD patients. The effectivity of PR in patients with pulmonary sarcoidosis remains unclear and therefore there is a need for further research.

Aim: To evaluate the effect of PR on breathing pattern and health-related quality of life (HRQL) in patients with pulmonary sarcoidosis.

Methods: There were 10 patients with pulmonary sarcoidosis recruited to the 6-week PR programme. The assessment included lung function tests, maximal inspiratory (MIP) and expiratory (MEP) mouth pressures, chest expansion (CE), 6-minute walking test (6MWT) and HRQL by Sarcoidosis Health Questionnaire (SHQ). The evaluation was performed at baseline and after six weeks. The PR programme consisted of respiratory physiotherapy, soft tissue techniques and regular physical activity.

Results: The mean age of patients was 45.9±14.1 years with stages I, II and III of the disease (2, 7 and 1 patient respectively). Six patients were undergoing PR programme simultaneously with corticotherapy. Lung function tests showed normal values in all patients at baseline and after PR.

Conclusion: Patients with pulmonary sarcoidosis can benefit from a PR programme, as it improves chest expansion and strength of breathing muscles, which plays an important role in the physical fitness level and is further reflected in an improved HRQL of the patients. Supported by Palacky University, FTK_2010_004.

P1271 The effect of an 8-week outpatient rehabilitation programme on chest expansion and ventilatory parameters in patients with COPD

Katerina Neumannova1, Jakub Zatolok1, Vitezslav Kolek2. 1Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; 2Department of Pulmonary Diseases and Tuberculosis, Medical Faculty of Palacky University and University Hospital, Olomouc, Czech Republic

Background: Dysfunction of the breathing mechanisms could lead to an increased
inspiratory effort and to a higher prevalence of breathing disorders during activities of daily living in patients with COPD.

Aim: To assess whether patients with COPD have different chest expansion (CE) in comparison with healthy controls and whether the rehabilitation programme (RP) can influence CE and ventilatory parameters in COPD patients.

Methods: The examined group consisted of 36 medically stable adults with COPD (aged 62.9±6.7 years, stage II) who have undergone an 8-week outpatient RP (breathing and postural control exercises, airway clearance techniques and soft tissue techniques) and 30 healthy controls (aged 63.3±3.0 years). Lung function test and CE were measured at baseline and after 8 weeks.

Results: COPD patients had significantly reduced CE in comparison with control group at baseline. CE was significantly higher after RP in patients with COPD and there was no significant difference among control group and COPD patients after RP.

There was an improvement of ventilatory parameters in COPD patients after RP, although the severity of the peripheral airway obstruction remained at the same level.

Conclusion: Our results show that physiotherapy treatment approaches can influence chest mobility and improve breathing mechanisms in COPD patients.

118. Respiratory physiotherapy in the intensive care unit and on the ward: breathing exercises and respiratory muscles

P1274
The inter-observer agreement of handheld dynamometry in critically ill patients
Johann Segers1, Goele Vanpee1, Pieter Wouters2, Helen Vanmechelen1, Greet Van den Berge3, Greet Hermans1, Rik Gosselink1, 1Department of Rehabilitation Sciences, University Hospitals, Katholieke Universiteit, Leuven, Belgium; 2Department of Intensive Care Medicine, University Hospitals, Katholieke Universiteit, Leuven, Belgium; 3Department of General Internal Medicine, University Hospitals, Katholieke Universiteit, Leuven, Belgium.

Objective: Muscle weakness is associated with increased risk of morbidity, mortality and limiting functional outcome. To assess muscle weakness reliable measurements are required. The objective is to determine inter-observer reliability of handheld dynamometry (HHD) in awake and cooperative critically ill (CI) patients.

Patients: A cross sectional, randomly selected sample of CI patients.

Measurements: HHD was performed in CI patients, who had at least a score of 3 on the Medical Research Council scale. 3 Upper limb and 3 lower limb muscle groups were tested at the right hand side. Patients were tested twice daily by 2 independent raters.

Results: 51 test-retests were performed in 39 CI patients. Strength was considerably reduced compared to the predicted value: shoulder abduction 43% pred (IQR: 35-56); elbow flexion 38% pred (IQR: 23-58); wrist extension 51% pred (IQR: 35-56).

P1273
Pulmonary rehabilitation: Are the effects similar in populations from different countries?
Carlos Augusto Camillo1,2, Chris Burtin3, Daniel Langer3, Vinicius Cavalheri1,2, Nilda Aparecida Hernandez1, Eirc Maia Cipulo Ramos2, Vanessa Probst1, Fabio Putta1, Rik Gosselink1, Thierry Troosters1, 1Laboratorio de Pesquisa em Fisioterapia Pulmonar (LFIP), Departamento de Fisioterapia, Universidade Estadual de Londrina, Londrina, Paraná, Brazil; 2Programa de Mestrado em Fisioterapia, Departamento de Fisioterapia, UNESP – Univ. Estadual Paulista, Presidente Prudente, São Paulo, Brazil; 3Pulmonary Rehabilitation and Respiratory Division, Universitaire Ziekenhuis Gasthuisberg, Leuven, Belgium.

Background: There are no studies investigating whether differences in socioeconomic, ethnic or climate characteristics could interfere with outcomes of pulmonary rehabilitation (PR) programs.

Objective: To compare the training effects of similar exercise training programs applied to two groups of patients with chronic obstructive pulmonary disease (COPD) living in different world regions: one from Western Europe (Belgium) and another from South America (Brazil).

Methods: 564 patients with moderate to severe COPD (45 in Brazil and 519 in Belgium) underwent similar high-intensity outpatient PR programs. Baseline values and their respective post-training changes of pulmonary function, exercise capacity, physical activities in daily life, respiratory muscle force, health-related quality of life (HRQoL) and functional status were compared between centers.

Results: Patients were matched for age, BMI and FEV1. Baseline differences were found in the 6-minute walking test (67.4±12%pred in Brazil vs 57±20%pred in Belgium; p<0.01), inspiratory muscle force (96±28cmH2O in Brazil vs 143±48cmH2O in Belgium; p<0.01) and functional status (all domains had better scores in Brazil in the Modified Pulmonary Functional Status and Dyspnea questionnaire; p<0.01). After 3 months of training, only the dyspnea domain of the Chronic Respiratory Disease Questionnaire showed significant difference between centers (0.50 [2 – 5] in Brazil vs 5 [2 – 8] in Belgium; p<0.01).

Conclusions: Similar PR programs applied in populations from different countries yield similar improvements in exercise capacity, respiratory muscle function, functional status and most HRQoL outcomes. Dyspnea was more enhanced in Belgian patients.

Effects noninvasive mechanical ventilation on muscle strength, ambulation, and functional performance in the intensive care
Sahveren Cakartas1, Farid Bazarri2, Caroline Jolley1, Lizzie Flude1, Victoria Lord1, Mike Polkey1, Nick Hopkinson2, Mike Polkey1, Nick Hopkinson2, Mike Polkey1, Nick Hopkinson2.
1Respiratory Research Unit, The Royal Brompton and Harefield NHS Trust, London, United Kingdom; 2NHR Respiratory Disease Biomedical Research Unit, The Royal Brompton & Harefield NHS Trust, London, United Kingdom.

Introduction: Patients with acute exacerbations of chronic respiratory disease are often too breathless to exercise leading to muscle deconditioning. Using NIV to assist exercise during an exacerbation might prevent this but it is not known if this is acceptable to patients.

Methods: 10-in-patients with an acute exacerbation (including COPD, Bronchiec-
tasis, CF) were recruited. If they were unable to cycle for 5 minutes at 20 watts unaassociated they then cycled with NIV for up to 20 minutes. NIV settings were ad-
justed to patient comfort. Oxygen was titrated to maintain SpO2 88-92%. Patients were asked to rate their level of distress and willingness to repeat the intervention.

Results: Mean age was 52.8 (15.9). 56% male: 67% used NIV at night. All were naive to NIV during exercise. NIV increased cycle time by 90 seconds (47.8%). All stated they would repeat this type of exercise and most (90%) reported it easier to exercise with NIV.

Conclusion: NIV is well tolerated, feasible and significantly increases exercise capacity in patients hospitalised with an acute exacerbation.

P1279
Is there a need for training when using an oscillatory positive expiratory pressure device?
Thibault Coppens1, Grégory Reyche1, Jean Rosselou1, Pierre Delguste1, Giuseppe Liistro2,1Physiological Medicine and Rehabilitation, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Pneumology Unit, Cliniques Universitaires Saint-Luc, Brussels, Belgium.

Introduction: Oscillatory positive expiratory pressure with Acapella® is routinely used to remove secretions. The system uses a counterweighted plug and a magnet to generate pressure and airflow oscillations. To be efficient, this pressure must be higher than 10 cm H2O. There is no recommendation about the instructions for the patient and the interface (mouthpiece or facemask) to use with the system. The aim of this study was to measure the pressure generated by subjects after basic instructions.

Material and method: Eight healthy subjects (28.7 yrs. ± 8.0) were recruited. They were instructed to breathe through Acapella® with two interfaces (mouthpiece and facemask) and with different resistance settings in a randomized crossover design. Continuous recordings of airway pressure and airflow were performed. Sequence was composed by 5 breathes at each resistance setting. Success rate was defined as an expiratory pressure higher than 10 cm H2O.

Results: Depending on interface, significant differences (mouthpiece vs face-
mask) were measured for Pe max (11.23 cm H2O±3.6 vs 10.3 cm H2O±2.52; p=0.001). Pe (6.67 cm H2O±1.58 vs 6.2 cm H2O±1.43; p=0.001), inspiri-
tory flow (3.04±0.94 vs 3.47±1.11; p=0.001) and expiratory flow (5.64±0.05 vs 6.23±0.01; p=0.001). Time spent with Pe ≥ 10 cm H2O (1.24±1.33 vs 236s)
P1280 Validation of a time-frequency wheeze detector in cystic fibrosis: A pilot study

Tomas Miguel3, Celedonia Igual Camacho 1, Juan Carlos Meléndez Moral 4, Jon Thomas Ellingsen4, Ola Røksund 3,5.

Objective: This pilot study aimed to validate a time-frequency wheeze detector (TF-WD) in the cystic fibrosis disease.

Methods: Recordings were made in a clinical setting from a stable cystic fibrosis adult outpatient with a digital stethoscope following the CORSA guidelines. Several TF-WD algorithms were tested and the best performance was obtained with the Taplidou et al. (2007) algorithm, which was validated in four sound files. The number, duration and type of wheezes were blindly analysed independently by three experienced respiratory physiotherapists. Their evaluation was then compared with the automatic method. The statistics accuracy of the wheezes detection was quantified through sensitivity, specificity and performance measures using Matlab. True positives/negatives and false positives/negatives were counted by comparing each point of the sound file.

Results: Inter-rater agreement between the physiotherapists was 96.9%. The sensitivity, specificity and performance of the automated method were 77.2%, 98.4% and 87.1% respectively.

Conclusion: The automated method tested shows sufficient reliability to continue the study and implement a future clinical validation with a larger sample. Wheezes detection through computerized analysis can provide an objective measure to assess and monitor cystic fibrosis patients, however further research is needed to validate the most robust algorithm.

P1281 Randomized clinical trial: Effects of controlled breathing exercises on respiratory muscle in the elderly

Maria Angeles Cebrià i Iranzo1, David Alan Arnall2, José Manuel Tomás Miguel3, Celedonia Igual Camacho1, Juan Carlos Meléndez Moral1, Jon Roger Web1.

Introduction: Respiratory muscle (RM) strength decreases with aging, and in most cases this decrease is associated with functional impairment and disabilities, particularly in the frail elderly. RM training has been shown to improve RM strength. The purpose of this study was to assess the effect of controlled breathing exercises on RM strength among elderly people with disabilities who are unable to engage in general exercise reconditioning. The hypothesis is that controlled breathing exercises will improve RM strength vs. a control group.

Methods: Forty-eight elderly were randomly assigned to a control group (n=24) or training group (n=24). A supervised training protocol, consisting of controlled Pranayama breathing exercises, was performed 5 times per week for 6 weeks. Maximum inspiratory pressure (MIP) and maximum expiratory pressure (MEP) were assessed at 4 time points: pre-test, intermediate, post-test and follow-up.

Results: The anthropometrics, pulmonary function and RM function data of participants did not showed significant differences between groups. ANOVAs revealed significant differences in MIP and MEP between the two groups after the training protocol. For MIP the effect was effective (F3,138=9.122, p<0.001, η²=0.165). Also for MEP is statistically significant (F3,138=9.02, p<0.001, η²=0.165).

Conclusions: This is the first controlled study in elderly people that report a significant gain in RM strength due to the Pranayama training program.

P1282 Laryngeal movements during mechanical insufflation-exsufflation

Tiina Andersen1-2, Astrid Sandès1, Ove Fonedens1, Thomas Halvorsen1,3, John Hjelm1, Magnus Hilland3, Tom Karlsen2, Thor-André Ellingsen2, Ola Roksund1,3.

Norwegian Centre of Excellence for Home Mechanical Ventilation, Thoracic Department, Haukeland University Hospital, Bergen, Norway; 1Department of Physiotherapy, Haukeland University Hospital, Bergen, Norway; 2Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 3Department of Otolaryngology/Head and Neck Surgery, Haukeland University Hospital, Bergen, Norway; 4Section for Pediatrics, Institute of Clinical Medicine, University of Bergen, Bergen, Norway; 5Institute of Surgical Science, University of Bergen, Bergen, Norway.

Introduction: Mechanical insufflation-exsufflation (MI-E) is the most effective approach to increase peak cough flow in patients with neuromuscular diseases, thereby potentially augmenting airway clearance. Co-ordinated movements of the vocal cords and laryngeal false and true vocal cords are crucial for effective coughing. Thus, laryngeal response patterns to MI-E have not been studied.

Objectives: To validate the laryngeal response patterns to MI-E in healthy subjects.

Methods: Ten healthy volunteers (21-26 years) were examined with video recorded flexibl transnasal fiberoptic laryngoscopy during MI-E (Cough Assist®, Respiration, USA) according to a standardized protocol at pressures of ±20 to ±50 cmH2O. Participants were instructed to inhale during insufflation and to cough or actively exhale during exsufflation. Laryngeal patency and movements during MI-E was assessed from video recordings according to a pre-set scheme.

Results: In all subjects and regardless of the applied pressure and instructions, the vocal cords ab ducted during insufflation and exsufflation. Coordinated glottic closure and opening on instruction to cough was found in 10/10. At exsufflation pressures of ±40 to ±50 cmH2O, hypopharyngeal obstruction was observed in 10/10. Cough presented as sequential glottic closures in the majority. Retroflex movement of the epiglottis, partially occluding the laryngeal entrance, was observed in three subjects during insufflation, irrespective of pressures.

Conclusion: The laryngeal response patterns to MI-E in healthy subjects was as described for spontaneous cough. Negative pressures may cause temporary hypopharyngeal obstruction, and retroflex movement of the epiglottis may obstruct airflow. The examination was well tolerated and may be considered for use in patients.
The assessment of the maximum inspiratory pressure (MIP) is used as an indicator of inspiratory muscle strength and may be useful in evaluating the success of weaning from mechanical ventilation. During this procedure it is common that a fall of saturation peripheral O2 (SpO2) occurs, leading to discontinuation of the maneuver, which can underestimate the value of MIP. The objective of this study is to verify whether the implementation of hyperoxegenation prior to the assessment can mitigate this decline of SpO2, increasing the measurement support time (t,), and generating a more reliable MIP.

The evaluation of the MIP, occlusion time (OT), SpO2, respiratory rate (RR) and heart rate (HR) was carried out randomly on 26 patients, with or without hyperoxegenation prior, maintaining the duration of occlusion of unidirectional valve for an indefinite period. Hyperoxegenation was defined as the use of inspired oxygen fraction (FiO2) to 100%, two minutes before the maneuver. The measurement was performed with the patient in the supine position and elevated head with an angle of 60°.

The value of MIP and OT were higher with previous hyperoxegenation (53.77±22.37 cmH2O vs 43.38±20.11 cmH2O; p<0.001; and 58.69±26.09 sec vs 37.04±15.07 sec;p< 0.001; respectively). In addition, there was a smaller drop in SpO2 after the measurement when the method was performed with hyperoxegenation (93.15±1.24% vs 84.58±9.73%;p<0.001). There was increase in RR and HR independently of the hyperoxegenation.

Implementation of hyperoxegenation prior to the assessment of MIP increase the values obtained, generating a more reliable MIP.
lung function in the postoperative period. Aiming to attenuate these negative effects, the preoperative IMT may be an alternative.

Objective: To determine whether preoperative IMT is able to attenuate the impact of surgical trauma on the diaphragmatic excursion in obese women undergoing OBS.

Methods: Thirty-two obese women (35.4±8.75 years and 41.78±3.84 kg/m²), undergoing elective OBS were randomly assigned to receive preoperative IMT (IMT group) (n=15) or usual care (Control group - CG) (n=17) 2.4 weeks before the surgery. The diaphragmatic excursion was evaluated using the digitalized image of the radiograph. The area was calculated of the right and the left dome of the diaphragm. The patients were assessed before and after training, and 1 day after surgery.

Results: The diaphragmatic excursion of the right and the left dome were not altered by training. In the first postoperative day, there was a significant decrease in both groups. However, the values of diaphragmatic excursion were higher in the IMT group, even though they were not statistically significant.

Conclusion: The preoperative IMT appears to attenuate the negative postoperative effects of open bariatric surgery in diaphragmatic excursion.

P1290
Effects of preoperative inspiratory muscle training (IMT) in obese women undergoing open bariatric surgery: Respiratory muscle strength

Marcelina Bahári-Boutin Moulin, Dirceu Costa, Gustavo Miguel, Flavio Campos, Eli Maria Forti. Physiotherapy Post Graduate, Federal University of São Carlos, São Carlos, São Paulo, Brazil Bariatric Surgery, Meridional Hospital, Cariacica, Espirito Santo, Brazil

Introduction: Patients undergoing open bariatric surgery have an impaired lung function in the postoperative period. Aiming to attenuate these negative effects, the preoperative IMT may be an alternative.

Objective: To determine whether preoperative IMT is able to attenuate the impact of surgical trauma on the respiratory muscle strength in obese women undergoing open bariatric surgery.

Methods: This study is a randomized controlled trial. Thirty-two obese women (35.4±8.75 years and 41.78±3.84 kg/m²), undergoing elective open bariatric surgery were randomly assigned to receive preoperative inspiratory muscle training (IMT group) (n=15) or usual care (UC group) (n=17) 2.4 weeks before the surgery. The respiratory muscle strength was carried out by using measurement the Maximal Inspiratory and Expiratory Pressures – MIP and MEP. The patients were assessed before training, before surgery and 1 day after surgery.

Results: After training, there was an increase in the MIP only in the IMT group (IMT=93.3±23.80 to 120.1±20.35 vs UC= 92.9±18.63 to 91.76±20.38 cmH2O – p<0.05). The MEP was not altered by training. In the first postoperative day, there was a significant decrease in MEP in both the groups. However, the MEP was higher in the IMT group (IMT = 63.3±21.60 vs UC = 48.8±19.32 cmH2O – p<0.05). The MEP was similar between the groups (IMT=49.66±22.71 vs UC= 49.70±39 cmH2O).

Conclusion: The preoperative IMT increased the inspiratory muscle strength (MIP) and attenuated the negative postoperative effects of open bariatric surgery in obese women for this variable, though not influencing the MEP.

P1291
Inspiratory muscle strength and endurance in patients with COPD: A propose outcome with manovacuometry and PowerBreathe®

Renata Basso1, Eloisa Regueiro1, Valéria Pires Di Lorenzo1, Mauricio Jamami1,2, Dirceu Costa1,2. 1Physiotherapy - Postgraduate Programme in Physiotherapy - Special Unit of Respiratory Physiotherapy, Universidade Federal de São Carlos, São Carlos, São Paulo, Brazil; 2Physiotherapy - Postgraduate Programme in Rehabilitation Sciences, Universidade Nove de Julho, São Paulo, Brazil

Background: Reduced respiratory muscle force and endurance are commonly observed in patients with COPD and contributes to dyspnea, oxygen desaturation and reduced exercise capacity, hence respiratory muscle assessment is clinically relevant.

Aim: To propose an assessment method of respiratory muscle endurance in patients with COPD and to verify it relationship with maximal inspiratory pressure (MIP) and maximal voluntary ventilation (MVV).

Method: 18 patients (GOLD I-4; 63±9years) performed the MIP and an incremental and constant respiratory muscle endurance test using the PowerBreathe® device. The incremental test started with 10cmH2O, increasing 10cmH2O each 2min, with 1min of rest between them, which determined the maximal pressure sustained (MPS). The endurance test was 80% of the MPS. The limit time (lim) was determined. Comparisons and correlations were determined using Paired t-test and Pearson correlation.

Results: The MIP was 52±20cmH2O, MVV (Spred) 44±15, MPS 48±23cmH2O, tim 10±8 min and 80%MPS 35±21cmH2O. The MIP and MPS were not different. Correlation was found between MIP and MPS (r=0.5; p=0.03) and MIP and MVV (r=0.6; p=0.03).

Conclusion: The MIP and MEP were similar in the endurance test and showed a relationship with MVV; with suggest to be a reasonable test to assess the respiratory performance in these patients.

P1292
Respiratory muscle function during and after a severe exacerbation of COPD – Preliminary results

Rafael Barreto de Mesquita1,2, Isabel Cristina Hilgert Genz3, Letícia de Castro1, Núbia Aparecida Hernandes4,5, Vanessa Suziane Probst1,2, Fábio Pinta1. 1Laboratório de Pesquisa em Fisioterapia Pulmonar (LFPF), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil; 2Centro de Pesquisa em Ciências da Saúde (CPCS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil

Background: It is known that peripheral muscle function (especially the quadriceps muscle function) is markedly reduced during the course of a severe exacerbation of chronic obstructive pulmonary disease (COPD). However, the function of the respiratory muscles has not been studied in depth in the same context.

Objectives: To investigate the respiratory muscle function during and after a severe exacerbation of COPD requiring hospitalization.

Methods: Twelve patients with COPD (7 male, 68±14 years, forced expiratory volume in the first second [FEV1], 37±22%pred) hospitalized due to an acute exacerbation of COPD were studied. Inspiratory and expiratory muscle strength (PImax and PEmax, respectively) were assessed at day 1 and day 3 of hospitalization and at hospital discharge, as well as at 1 month after discharge (1MD). Lung function was assessed at day 1, at discharge and at 1MD.

Results: PImax was significantly reduced at day 1, day 3 and at discharge in comparison to 1MD (p<0.05 for all), although it tended to improve overtime during the hospitalization period. PEmax improved significantly overtime during the hospitalization period, while lung function was not significantly altered. Delta PImax%pred (1MD minus day 1) correlated significantly with age (r=0.72), while delta PEmax%pred (discharge minus day 1) correlated significantly with PaCO2 assessed at day 1 (r=0.75).

Conclusions: These preliminary data suggest that the respiratory muscle function is markedly reduced at the onset of a severe exacerbation of COPD. However, unlike the quadriceps muscle, respiratory muscles markedly improve their function during the hospitalization period and during the following month.

Maximal sniff nasal inspiratory pressure in Brazilian healthy subjects: A multicentre study

Guilherme Augusto de Freitas Fregonez1, Polomma Russelly Saldanha Araújo1, Armele de Fátima Dornelas de Andrade1,2, Marlene Moreira1, Ester Silva1, Jasiel Frusanto Nascimento Jr.1, Lattesa de Andrade Carvalho3, Ana Gabriela Leal Cavalcanti1, Viviane Cerezo Silva1, Vanessa Resque1,2,3. 1Physical Therapy Department, Federal University of Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil; 2Physical Therapy Department, Federal University of Pernambuco, Recife, Pernambuco, Brazil; 3Physical Therapy Department, Piracicaba University, Piracicaba, Sao Paulo, Brazil

Objective: To propose reference values of SNIP for Brazilian population.

Methods: This study was conducted in three centers in Brazil, Natal-RN, Recife-PF and Piracicaba-SP. Subject were evaluated in relation to anthropometrics parameters, physical activity profile and maximal sniff nasal inspiratory pressure follow recommendations of ATS/ERS Statement on Respiratory Muscle Testing. SNIP

Background: Reduced respiratory muscle function and endurance are commonly observed in patients with COPD and contributes to dyspnea, oxygen desaturation and reduced exercise capacity, hence respiratory muscle assessment is clinically relevant.

Aim: To propose an assessment method of respiratory muscle endurance in patients with COPD and to verify it relationship with maximal inspiratory pressure (MIP) and maximal voluntary ventilation (MVV).

Method: 18 patients (GOLD I-4; 63±9years) performed the MIP and an incremental and constant respiratory muscle endurance test using the PowerBreathe® device. The incremental test started with 10cmH2O, increasing 10cmH2O each 2min, with 1min of rest between them, which determined the maximal pressure sustained (MPS). The endurance test was 80% of the MPS. The limit time (lim) was determined. Comparisons and correlations were determined using Paired t-test and Pearson correlation.

Results: The MIP was 52±20cmH2O, MVV (Spred) 44±15, MPS 48±23cmH2O, tim 10±8 min and 80%MPS 35±21cmH2O. The MIP and MPS were not different. Correlation was found between MIP and MPS (r=0.5; p=0.03) and MIP and MVV (r=0.6; p=0.03).

Conclusion: The MIP and MEP were similar in the endurance test and showed a relationship with MVV; with suggest to be a reasonable test to assess the respiratory performance in these patients.

was measured from FRC in the sitting positions using a catheter through a plug occluding one nostril during 10 maximal sniffs through the contra-lateral nostril. For each test the largest pressure measured in cmH2O was taken into account. Correlation and multiple linear regressions were used to predicted male and female SNIP equations. Results were compared with previous published studies. Results: We studied 244 subjects (114 male and 130 female) distributed in different age groups 20-80 years old. We found a significantly negative correlation between SNIP and age for male and female (p=0.05). In a multiple regression analysis age continued to have an independent predictive role with SNIP. The predicted equations found for male and females were respectively SNIP = –0.46 age + 135.5 and SNIP = –0.34 age + 109.6. Conclusion: The results of this study provide reference equations for SNIP for health Brazilian population from 20 to 80 years old. Financial support: CNPq.

P1294 Late-breaking abstract: Determination of the endurance capacity on resistance exercise – Physiological responses during load-duration relationship

Vivian Arakelian1,2,3, Nuno Frade de Sousa 1,3, Vanessa Borges 1, Camila Gomes Gatto 1, Markus Campos 1, Danilo Bertucci 1, Vilmar Baldissera 1,2, Audrey Boirghi-Silva 1,2,3,16. Interunits in Bioengineering, University of São Paulo, São Carlos, SP, Brazil; 2Department of Physiotherapy, Federal University of São Carlos, São Carlos, SP, Brazil; 3Department of Physiology Science, Federal University of São Carlos, São Carlos, SP, Brazil

Resistance exercise (RE) has been strongly encouraged, providing a favorable effect on muscular strength and endurance, cardiovascular function, metabolism and cardiovascular risk reduction. However, little is known about cardiovascular, ventilatory, and metabolic adjustments in the critical load (CL), which would allow the transition of moderate exercise for intense exercise. So, the objectives of the study were to: 1) determine the existence and intensity of critical load (CL) during RE; 2) determine the execution time of CL, and 3) evaluate the behavior of cardiovascular, respiratory and metabolic responses during RE at different intensities and at the CL. Fifteen healthy young men (23±2.5 years) carried out 1 repetition maximum (IRM) on the RE at different percentages of IRM (60%, 75% and 90% IRM) in order to obtain CL by linear regression: load X reverse of time until fatigue (Tlim). Heart rate (HR), blood lactate ([La]), metabolic and ventilatory parameters were measured all resistances loads. The execution time and number of repetitions was different amongst the resistance intensities (p<0.001). All exercises intensities significantly increased (p<0.001): HR, systolic blood pressure (SBP) (p<0.001) and [La] when compared to both rest and recovery. [La] corrected by Tlim was significantly higher during maneuvers at a greater resistance (p<0.0001). However, metabolic and ventilatory measurements were stable with IRM and the time until fatigue (p<0.05). Lastly, the CL during RE was approximately 54% IRM. In our study we characterize CL as the exercise intensity that shows peak values of 83% VO2max and 90% HRmax.

P1295 Late-breaking abstract: Evaluation and comparison of functional capacity to incremental shuttle walk test and maximal exercising test on treadmill in obese women

Soraya Pilon Jurgensen 1, Luciana Di Sousa 1,3, Vanessa Borges 1, Camila Gomes Gatto 1, Markus Campos 1, Danilo Bertucci 1, Vilmar Baldissera 1,2, Audrey Boirghi-Silva 1,3,16. Interunits in Bioengineering, University of São Paulo, São Carlos, SP, Brazil

The Incremental Shuttle Walk Test (ISWT) has been increasingly used and may constitute a method for assessing functional capacity in obese population. However, if ISWT represents maximal exercise effort and produces similar cardiorespiratory responses in obese women remains to be investigated. The aims was compare the cardiorespiratory responses between obese and eutrophic during the ISWT and the cardiopulmonary exercise testing (CPET). Twenty-nine women (17 obese), allocated in the obese group (OG) and eutrophic group (EG), performed two ISWT and a CPET on a treadmill (Bruce protocol). Heart rate (HR) was determined before and after each test. Ventilatory (VE) and metabolic (VO2; VCO2) measurements were collected breath by breath with a portable ergospirometer (Oxycon mobile; CareFusion-Germany). We considered the results of the second ISWT to statistical analysis. Oxygen uptake (ml/kg/min) as well as distance walked and time of the test were significantly lower in the OG in both tests (ISWT: p<0.001, <0.001, <0.001; CPET: p<0.001, =0.016, <0.001, respectively). Both tests showed correlation between distance and VO2 (ml/kg/min) and HR (ISWT: r=0.83, p<0.001; CPET: r=0.53, p=0.52, respectively). Comparing the methods the ISWT was able to elicit ventilatory, metabolic and cardiovascular responses in agreement with CPET. In addition, it was observed the agreement of both tests to identify relative VO2, VE and HR at the peak of exercise. The ISWT seemed to be an adequate method between obese women and promote ventilatory, metabolic and cardiopulmonary responses in agreement to the CPET. Grants: FAEPESP (09/01842-0, 10/03030-0).

P1296 Level of agreement between five asthma control questionnaires

Francois Vermeulen, Inge Myeyle, Isabelle De Meulder, Marie Bruyneel, Vincent Ninane. Chest Service, St Pierre Hospital, Brussels, Belgium

Introduction: The Global Initiative for Asthma (GINA) guideline outlines the importance of a total control of asthma. This control is assessed by questionnaires evaluating symptoms, reliever use and functional results. Our study compared 5 different questionnaires and evaluated the degree of agreement between them. Methods: Successive asthma patients with a more than 3 months diagnosis were recruited at our out-patient clinic. They were asked to complete consecutively 5 asthma control questionnaires (GINA, ACQ, ACT, ADAQ, RCP) in a random order. Spirometry and exhaled nitric oxide were also measured. The GINA score was considered as the reference test and compared to the four others using the kappa statistic. For comparison with the ACT and RCP questionnaire, the “partly controlled” level GINA questionnaire was considered as “uncontrolled”. Results: Eighty patients (1.61 female for 1 male) aged 41 ± 8.17 years-old were recruited between June and December 2010. The GINA questionnaire results agreed with the ACQ in 62.5% of cases (controlled 22.5%, partly controlled 12.5%, uncontrolled 27.5% - kappa 0.44, p<0.001), with the ACT in 62.5% of cases (controlled 25.0%, uncontrolled 47.5% - kappa 0.46, p<0.001), with the ADAQ in 45.1% of cases (controlled 26.3%, partly controlled 17.5%, uncontrolled 18.8% - kappa 0.45, p<0.001), and with the RCP in 81.3% of cases (controlled 18.8%, uncontrolled 62.5% - kappa 0.54, p<0.001). Conclusion: Despite the fact that most of these questionnaires have been validated, the agreement between them was moderate. The shortest questionnaire (RCP) showed the highest level of agreement with GINA.

P1297 Factors associated with asthma control in patients with stable asthma

Vivian Grammatopoulos1, Aikaterini Hanoutou2, Afroditi Evangelidou3, Nikolaos Tsamis1, Pavlos Myrianthefs3, George Baltopoulos1. 1Physical Therapy Department, Technological Educational Institute, Athens, Greece; 2Department of Respiratory Medicine, General Hospital I. Kallergis, Athens, Greece; 3Faculty of Nursing, National and Kapodistrian University, Athens, Greece

Introduction: Despite the Global Initiative for Asthma (GINA) guidelines for asthma management, the prevalence of uncontrolled asthma in Greece remains high and factors associated with asthma control unknown. Aim: To predict associated factors with asthma control in stable asthma Methods: 100 Greek patients with stable asthma were included in the study and classified as having controlled (>20) or uncontrolled (<20) asthma by the Asthma Control Test-AST cut-off points. Multiple logistic regression analysis was conducted to identify possible predictors of asthma control. All analyses were conducted with SAS statistical software, version 9.1. Results: Among study participants, those who had follow-up visits solely in emergency were at excess risk of having uncontrolled asthma (OR=3.79; 95% CI=1.21-11.91; p=0.02). Patients with higher levels of MRC were more likely to have their asthma uncontrolled (OR=3.47; 95% CI=1.21-11.91; p=0.02). Patients with higher levels of MRC were more likely to have their asthma uncontrolled by almost 50%. Lastly, no evidence of significant associations with asthma control and physical activity (p=0.47), age (p=0.53), gender (p=0.25), BMI (p=0.60), was noted. Discussion: Greek patients with stable asthma should have regular follow-up visits in order to improve dyspnea and pulmonary function and achieve adequate control and management of asthma.

P1298 Physical, social, and psychological function in asthma patients with and without analgesic tolerance

Denz Ilul-Ince1, Sema Savci2, Naciye Vardar-Yagli1, Ebru Calik1, Melda Saglam1, Hulya Arkan1, Metul Bonol-Gucu1, Gul Karakaya4, Fuat Kalyoncu4. 1Department of Physiotherapy and Rehabilitation, Hacettepe University, Ankara, Turkey; 2School of Physiotherapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey; 3Department of Physiotherapy and Rehabilitation, Gazi University, Ankara, Turkey; 4Department of Chest Medicine, Hacettepe University, Ankara, Turkey

Purpose: Ingestion of aspirin and similar drugs triggers severe bronchospasm in some asthmatic patients. The purpose of this study was to compare physical, social
and psychological function between analgesic intolerant and tolerant asthmatic (AIA and ATA, respectively) patients.

Methods: Twenty-seven AIA and 29 ATA patients participated in this study. Respiratory and quadriceps muscle strength (QMS) were measured. Asthma Control Questionnaire and Asthma Knowledge Test were applied. Six-minute walk test was performed, and physical activity level was determined using International Physical Activity Questionnaire (IPAQ). Dyspnea and fatigue perception was evaluated using modified Medical Research Council dyspnea scale and Fatigue Severity Scale, respectively. Psychological function was evaluated using Beck Depression Inventory. Immunology, Genetics and disease specific quality of life were determined using Nottingham Health Profile and Asthma Quality of Life Questionnaire, respectively.

Results: The FEV1, QMS, IPAQ walking score, and Asthma Knowledge Test score were significantly higher in AIA patients as compared to those of ATA patients (p < 0.05). No significant differences were found in asthma control, respiratory muscle strength, symptom perception, six-minute walk test distance, psychological function, and quality of life between the two groups (p > 0.05).

Conclusion: The AIA patients share similar characteristics with ATA patients except better airway function, peripheral muscle strength and physical activity level, and worse asthma knowledge. Presence of analgesic intolerance effects components of physical function in asthma.

P1299

Study of heart rate autonomic modulation in patients with asthma disease

Victor Francisco Souza1, Iver Perez1, Audrey Borgoh Silva2, Paulo Boso1, Roberta de Paula Lucía Álvares Santos3, Direce Costa1, Luciana Maria Malosá Sampão1, 1Rehabilitation Sciences Master’s Program, Nove de Julho University, São Paulo, Brazil; 2Physiotherapy, Federal de São Carlos University, São Carlos, São Paulo, Brazil; 3Physiotherapy, Beneficência Ribeirão Preto Hospital, Ribeirão Preto, São Paulo, Brazil; 4Santa Casa Hospital, Dept. of Pneumology, Santa Casa Hospital, São Paulo, Brazil.

Background: Evaluate the autonomic activity of patients with asthma in moderate supine and sitting positions.

Material/Methods: Twenty individuals with asthma and 10 healthy individuals had their heart rate and electrocardiographic R-R intervals (iR-R) were recorded for 360 seconds in the supine and seated positions. Heart rate variability was analyzed in the time domain (TM) (RMSD index, i.e., the mean square of the differences between successive iR-R records) and the SDNN index, i.e., the mean standard deviation of normal iR-R in ms) and in the frequency domain (FD), from the low-frequency (LF) and high-frequency (HF) bands in absolute units (au) and normalized units (nu), and the LF/HF ratio.

Results: In TD, the AG showed a significantly higher values for the RMSD and the SDNN in the seated position, compared with the control group (CG). In FD, the AG presented significantly higher values for HF components, in the supine position, and for LF components, and HF in the seated position.

Conclusions: Patients with asthma present reduced HRV when compared with healthy sex- and age-matched controls, with the reduction in sympathetic and vagal activity. Furthermore, both patients and healthy individuals with asthma do not present autonomic adjustments with front postural change. Future studies should examine the HRV as a useful tool to obtain parameters for the stratification of cardiovascular risk in this population, and in the evaluation of different physical therapy interventions designed to treat these patients.

P1300

The health-related quality of life of asthmatic patients according to the illness severity

Juliana Maria De S Pinto1, Ana Maria M. Noguera1, Jacinto R. González1, José Ignacio C. Arellanas1, 1Physiotherapy, University of Salamanca, Salamanca, Spain; 2Physiotherapy, University of Fortaleza, Fortaleza, Brazil; 3Medicine, University of Salamanca, Salamanca, Spain.

Aim: To evaluate the differences in the Health Related Quality of Life (HRQoL) of Asthmatic patients according to the illness severity using the Saint George Respiratory Questionnaire (SGRQ), an specific instrument for respiratory diseases.

Methods: A cross-sectional, descriptive and observational study with 103 outcomes with Asthma (65 women and 38 men) with mean age of 58.48 years (SD 18.30 years) recruited from the Respiratory Service of the University Hospital of Salamanca, Spain from January to July 2010. Socio-demographic and spirometric data (American Thoracic Society criteria) were collected. The HRQoL was evaluated by the SGRQ. Descriptive analysis, one-way analysis of variance and the t-test student were applied using SPSS.

Results: It was found that 30.1% had Intermittent (I), 35% had Moderate Persistent (MP), 25.2% had Moderate Persistent (MOP) and 9.7% had Severe Persistent (SP) asthma according to the Global Initiative of Asthma. The mean of the domains were: Symptoms 39.93 scores (SD 21.83 scores), Activity 43.50 scores (SD 28.10 scores), Impact 24.61 scores (SD 17.81 scores) and the Total 32.84 scores (SD 19.07 scores). There were significant differences (ANOVA) between the groups of severity and the forced expiratory volume in 1 s (FEV1), the Vital Capacity (VC) and all domains and the Total SGRQ. There were no significances in the FEV1, and the VC between I and MP groups (t-test student). Also there was no significations between the three contrast between the MP, MOP and MS groups in all domains and in the total SGRQ.

Conclusions: The HRQoL is related to the asthma severity in this studied sample due to higher differences between the Intermittent Asthma and the other groups.

P1301

Evaluation of lung function and deposition in the nebulization carried by heliox associated with positive end-expiratory pressure in stable asthmatics: Clinical trial

Luciana Alcoforado1, Catarina Rattes1, Daniella Brandão1, Cyda Reinaux1, Dirceu Costa1, Luciana Maria Malosá Sampaio1, 1Rehabilitation Sciences Master’s Program, Nove de Julho University, São Paulo, Brazil; 2Physiotherapy, Federal de São Carlos University, São Carlos, São Paulo, Brazil; 3Physiotherapy, Beneficência Ribeirão Preto Hospital, Ribeirão Preto, São Paulo, Brazil; 4Santa Casa Hospital, Dept. of Pneumology, Santa Casa Hospital, São Paulo, Brazil.

Introduction: The combination of positive end-expiratory pressure (PEEP) and heliox is an alternative to optimize aerosol.

Background: Assess the influence of nebulization with bronchodilators added by heliox associated with PEEP in lung function and deposition radioaerosol in stable asthmatics during.

Methods: Randomized controlled trial double-blind study involving 32 patients (mean age 47±10 years) divided into four groups: G1: Heliox PEEP + G2-Oxygen + PEEP; G3-Heliox, and G4-Oxygen-submitted to inhalation lung scintigraphy with bronchodilators. Spirometry and cardiopulmonary parameters were evaluated before and after intervention. The deposition index (DPI) was obtained by the ratio of counts in each region of interest (ROI) by the total counts of the right lung and inspiratory capacity (IC) regional obtained by multiplying the total by IC. Statistical analysis used Fisher’s tests, Kruskal-Wallis, Mann-Whitney, Wilcoxon and ANOVA considering p < 0.05.

Results: Post-intervention, the G1 had increased values of predicted FEV1 (p < 0.029) and IC (p < 0.004). In reviewing the DPI the groups, there was a higher DPI in the middle third (44.3%), p = 0.001 and intermediate region (40.2%, p < 0.01). In assessing the DPI between groups, no difference. The IC was higher in regional G1 and G2 (p < 0.05).

Conclusion: The nebulized bronchodilators and heliox combined with PEEP improved lung function. The deposition of drugs was higher in the middle third and intermediate portion of the lungs in all groups. In evaluating the IC regional groups associated with PEEP showed higher values independent of the gas used.

P1302

Effect of nebulization with heliox coupled with positive end-expiratory pressure on the regional chest wall volume variations: A clinical trial

Luciana Alcoforado1, Catarina Rattes1, Daniella Brandão1, Cyda Reinaux1, Vitoria Lima1, Larissa Feitosa1, Jacqueline Barcelar1, Andrea Alvizerti2, Armele Demelas de Andrade1, 1Departamento de Fisioterapia, Universidade Federal de Paranaíba, Recife, Pernambuco; 2Dipartimento di Biomeccanica, Politecnico di Milano, Italy, Milano.

Positive end-expiratory pressure (PEEP) and heliox are used separately to optimize the nebulization in asthmatic patients. We evaluated the efficacy of nebulizer bronchodilators carried by the heliox coupled to PEEP at the same time, in the distribution of volume variations into the different thoracoabdominal compartments and to correlate them with pulmonary function in stable asthmatic. Randomized controlled trial study involving 27 patients (mean age 46.5±11.67 years) divided into four groups: G1= Heliox PEEP, G2-Oxygen + PEEP, G3-Heliox, and G4-Oxygen-submitted to nebulization with bronchodilators. Spirometry, cardiopulmonary and chest wall volume by Opto-Electronic Plethysmography (OEP) parameters were measured before and after nebulization. For the OEP, 89 markers were attached to the trunk in a sitting position and three measures of slow vital capacity and quiet breathing were captured by six cameras. Statistical analysis used Fisher’s tests, Kruskal-Wallis, Mann-Whitney and Wilcoxon. Post-intervention, regarding to FEV1/FVC ratio, the G1 had increased values when compared to G3 (p=0.02) and G4 compared to G3 (p=0.02). None difference was found in the regional chest wall volume variations between groups and within groups in the initial and end expiratory volume. IC increased in the G1 (0.09L) and G2 (0.08L) when compared to G3 (0.06L) and G4 (0.06L), p < 0.05. There was a correlation between the change in FEV1 and end expiratory abdominal volume (r=0.411, p=0.033). In conclusion, nebulization coupled to PEEP can improve the IC in stable asthmatic patients and pulmonary function without changes the regional chest wall volumes.

P1303

Respiratory movements, chest mobility and sensitivity to pain in patients with sensory hyper reactivity (SHR) asthma and COPD

Ewa-Lena Johansson1, Ewa Ternesten-Hasséus2, Monika Fagevik-Olsén1, Eva Wenner-Hasséus2, Monika Fagevik-Olsén1, Eva Millennials2, 1Institute of Neuroscience and Physiology, 2Internal Medicine/Respiratory Medicine and Allergology, University of Gothenburg Sahlgrenska Academy, Gothenburg, Sweden.

Introduction: SHR is characterized of airway symptoms induced by chemicals, scents, cold air and exercise; it affects more than 6% of the Swedish adult population. The symptoms including chest tightness, difficulties to breathe and cough are suggestive for asthma but asthma-tests are negative and asthma medication has no effect.

Aim: To study SHR patients’ respiratory movements, chest mobility, and sensitivity to pain in comparison to patients with asthma, COPD and healthy controls.

241s
Methods: 37 patients with SHR, 32 with asthma, 19 with COPD and 28 controls were included. Chest expansion was measured with a measuring tape, thoracic and abdominal movements were measured with the respiratory movement-measuring instrument (RMMI). Pressure pain threshold (PPT) was assessed at five bilateral points.

Results: The Kruskal Wallis test showed that the groups differed significantly on the subject of lung function, respiratory rate and PPT but also regarding chest expansion and abdominal movements at quiet and deep breathing.

Analyzed with the Mann – Whitney U-test the SHR, asthma and COPD patients had decreased PPT compared to the healthy controls. Compared to the controls and the asthma group the SHR patients had reduced abdominal and thoracic movements. In the COPD group, but not among the asthmatics, abdominal and thoracic movements were reduced compared to the controls.

Conclusion: In SHR respiratory movements and chest mobility are impaired and the patients appeared to have most similarities with the COPD group where 15 out of 19 had severe or very severe COPD. SHR, asthma and COPD patients had all decreased PPT.

P1304
Neurophysiological and functional assessment in patients with difficult asthma control
Fabiana Canuto¹, João Corrêa¹, Luciana Sampao³, Roberto Sávio³
¹ Mestrando em Ciências da Reabilitação, Universidade Nove de Julho, São Paulo, Brazil; ²Ambulatório de Asma de Difícil Controle, Hospital da Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil

Introduction: Asthma usually responds to treatment with inhaled corticosteroids (with or without the addition of long-acting beta agonists or other drugs) and that means the symptoms and normal lung function or as close to normal as possible. Now, when asthma is inadequately controlled despite a therapeutic strategy adapted and tailored to the level of clinical severity, indicated by a specialist and at least six months duration is regarded Difficult Asthma Control (DAC).

Objective: To evaluate the functional and neurophysiological aspects of patients with DAC.

Method: We performed a cross-sectional study in three groups of patients: DACC (making use of oral corticosteroids), DACO (which makes use of smallmuls) and GC (healthy controls of similar age). The evaluation was made by testing six-minute walk. Sit-ups test, static balance with the pressure platform, monosynaptics reflexes (Fenwick and Achilles) and quadriceps strength of the dominant leg.

Results: Asthmatic patients have reduced functional capacity, seen testing the six minute walk test and sit-ups (p <0.05), and patients who use oral corticosteroids showed a reduction in the strength of the quadriceps compared to control (p <0.05).

P1305
Comprehensive spa treatment in the Czech Republic
Katerina Neumannova¹, Jakub Zatloukal¹, Vitezslav Kolek²
¹ Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; ²Department of Pulmonary Diseases and Tuberculosis, Medical Faculty of Palacky University and University Hospital, Olomouc, Czech Republic

Introduction: Patient with asthma (AB) can receive a comprehensive care treatment in specialized centres (Spa’s) in the Czech Republic.

Aim: To evaluate an effect of the comprehensive spa treatment (CST) on ventilatory parameters, chest mobility and posture in children with AB.

Methods: The examined group consisted of 50 medically stable children with AB (aged 11.6±2.5 years) who underwent a 4-week treatment in the Luhacovice Spa. The assessment was performed at baseline and after the treatment and it included lung function tests, maximal inspiratory (MIP) and expiratory (MEP) mouth pressure examination, chest expansion (CE) and kinesiological examination (muscle strength and length). The CST included respiratory physiotherapy, postural exercise and regular physical activity.

Results: Lung function tests showed normal values at the baseline and after treatment. A significant improvement was observed in all ventilatory parameters, respiratory muscle strength and CE at both levels. There was a lower presence of muscle imbalances (shortened and weakened muscles) after the treatment.

Conclusion: Children with AB can benefit due to the combination of physiotherapy approaches and physical activity not only in ventilation and breathing mechanism, but also in improved posture.

P1306
State of the respiratory physiotherapy in Spain: Map from online survey results
Daniel Martí¹, Ana Balakal², Elena Gimeno¹, Gerard Muñoz³, Jordi Vilardell³
¹Pneumology Department, Clinic Institute of Thorax, Hospital Clinic-IDIBAPS, Barcelona, Spain; ²Pneumology Department, Hospital del Mar: Parc de Salut Mar-IMIM-CIBERESP, Barcelona, Spain; ³CERAL-CIBERESP, Centre de Referència de l’Hospital del Mar-IMIM, Barcelona, Spain

Objective: To define the map of respiratory physiotherapy (RP) in Spain.

Design: Online questionnaire.

Setting: A 39 items online survey was allocated in a survey web during 4 months.

Direct contacts, professional colleges, physiotherapy services, universities and professional associations were invited to answer once every professional. The survey was about clinical, teaching and research profile questions and even it was posted on a web-side respiratory national society during the same period.

PARTICIPANTS: graduated physiotherapists living and working in Spain.

Results: 818 questionnaires were answered. The answers obtained had a heterogeneous territorial distribution; Galicia, Catalunya and Castilla- la Mancha were the most responder areas. 560 physiotherapists (69%) performed regular RP treatments. 123 (15%) were involved in respiratory research and 137 (17%) in RP teaching at the university or in post-graduate courses. However, RP was not homogeneously established over the country and only 21.5% of the physiotherapists were fully involved in RP. Physiotherapists involved in RP worked in private centres (25.2%) and at public hospitals (20.5%). Only 309 of the total (38%) obtained a RP post-graduate specialisation in respiratory physiotherapy.

Conclusions: The response rate allows to define the professional situation of RP across Spain. Our specialisation is not well established and its distribution is not homogeneous over the country. There is a need to increase the number of RP post-graduate trained professionals and researchers in order to improve the quality of Respiratory Physiotherapy over Spain.

P1307
OSCE as an evaluation method for graduate students in respiratory therapy
Cibele C.B. Marques da Silva, Adriana C. Lunardi, Felipe A.R. Mendes, Flavia Ferreira, Celsio R.F. Carvalho. Physical Therapy, School of Medicine of University of Sao Paulo, Sao Paulo, Brazil

Objective: The aims of this study were to assess the use of OSCE (objective structured clinical evaluation) as a tool to evaluate the abilities of graduate students in respiratory therapy and to verify the internal consistency of this exam.

Methods: Forty seven students were evaluated by two exams: traditional and OSCE. Each question (traditional) or station (OSCE) ranged from 0.0 to 2.0 and the total score of both exams was 10.0. The exams were prepared by independent educators that were blinded to the final grades. Internal consistency of OSCE stations was assessed by four experienced Respiratory Therapists.

Analysis: Internal consistency was tested by Cronbach’s Alpha. The relation between scores obtained in both exams was analyzed by Iland Altman and Pearson’s test.

Results: The average score of the students’ grades ranged from 4.5 to 9.1. The internal consistency of OSCE stations was considered good (0.7). The agreement between exams was estimated and it was observed that they are not comparable. It was also observed a low agreement between both exams (r=0.1; p=0.9; Pearson correlation). The correlation between two exams was moderate.

Conclusions: Our results showed that OSCE and traditional exams are not related. The OSCE exam had good internal consistency and assessed distincts aspects of traditional exam.

P1308
Management of dysfunctional breathlessness (DBY) – A retrospective service evaluation
Ashay Dwarkanath, Vera Davidson, Claire Taylor, Anthony Fennerty. Respiratory Medicine, Harrogate and District NHS Foundation Trust, Harrogate, Yorkshire, United Kingdom

Introduction: DBY has an incidence of about 10% and may pose a diagnostic and therapeutic challenge. We have established a physiotherapist run clinic to manage this condition.

Aim: To evaluate the outcome of a physiotherapist run DBY clinic.

Method: The diagnosis of DBY was made on the basis of exclusion with a normal clinical examination,lung function and echocardiogram,or with symptoms disproportionate to measurements of severity of their respiratory illness. Patients were assessed by the physiotherapist with regard to their breathing pattern and the Nijmegen (Ni) score,with a score over 23 being regarded as diagnostic of DBY. Consecutive patients referred to the clinic over 24 months were reviewed. The following parameters were analysed-underlying respiratory illness,breathing pattern,Ni score (Pre and Post Intervention),HAD scores and the intervention modalities.

Results: 51 patients (males-20) were referred to the clinic in 24 months. The mean age was 60.2 range, 20-84.26/51 patients had chronic cardiac respiratory illness.28/51 patients had an abnormal breathing pattern.
37 patients had a pre intervention Ni score over 23 (mean-29, range, 23-42). Interventions included patient education, cognitive behaviour therapy, breathing exercises and training. Post intervention the Ni score fell below the diagnostic threshold in 29/37 patients (mean reduction-14, range, 3-22). HAD scores was used to assess the degree of mood impairment and there was no linear correlation with the pre intervention Ni score.

Conclusion: A clinically significant improvement in symptoms as measured by the Ni score was achieved in 78% of the patients referred to our DYG clinic. There was poor correlation between HAD score and the Ni score.

P1309
Clinical outcomes of spinal cord stimulation (SCS) to restore cough
Anthony DiMarco1, Krzysztof Kowalski1, Robert Geertman3, Dana Hromyak4, Frederick Frost1, Gregory Nemunaitis1. 1Department of Physical Medicine and Rehabilitation, Case Western Reserve University and MetroHealth Medical Center, Cleveland, OH, United States; 2Department of Medicine, Case Western Reserve University and MetroHealth Medical Center, Cleveland, OH, United States; 3Department of Research, Case Western Reserve University, Cleveland, OH, United States

Background: In spinal cord injury (SCI), paralysis of the expiratory muscles often results in an ineffective cough and consequent inability to effectively clear airway secretions. SCS is an effective method of expiratory muscle activation.

Design: Clinical trial assessing the clinical outcomes and side effects of SCS to restore an effective cough in 12 SCI subjects.

Main outcome measure(s): Ease in raising secretions, requirement for trained caregiver support for secretion management and incidence of acute respiratory tract infections.

Results: Based upon questionnaire responses, the degree of difficulty in raising secretions improved markedly, and the need for alternative methods of secretion management lung function was observed in FVC: 3.6±0.9 vs 4.0±1.0 L, FEV1:3.0±0.7 vs 3.4±0.8 L, FEF25-75%: 3.4±0.8 vs 8.3±0.9 L/s, ERV: 0.35±0.4 to 0.66±0.4 L/min and MVV:103.4±22 vs 137.3±29 L/min, all to p<0.001 compared to pre-operative phase. We found an increase of 0.06 l in the FVC and 5.9 l/min in the MVV after SCS for each 1 cm of neck circumference decrease. For each 1kg/m² lost after the SCS FVC increase 0.03 l and MVV 2.74 l/min.

Conclusion: The loss of weight induced by BS provides an increase in the lung function and the reduction of fat around the neck appear to be more important to increase lung function than BMI. Financial support: CNPq-Brasil.

P1310
Influence of the loss of weight after bariatric surgery in the respiratory muscle endurance

Background: Weight loss induced by bariatric surgery (BS) in morbidly obese has effects on respiratory function, however the relationship between weight loss and respiratory muscle endurance is unknown.

Objective: To study relationship between weight loss and respiratory muscle endurance induced by BS.

Methods: We evaluated anthropometric parameters (waist circumference (WC), hip circumference (HC), waist-hip ratio (WHR), neck circumference (NC) and lung function tests (spirometry and respiratory muscle strength and maximal voluntary ventilation)) in 39 patients (29 F), mean age 35.9±10.9 years, without respiratory or heart diseases, before and after gastric bypass, Roux-en-Y surgery.

Results: After 10.8±7.7 months of BS we observed a decreasing in the anthropometric values (p<0.05) of weight:124.8±17.5 to 88.8±14.28 kg, BMI: 47.9±5.6 to 34.3±4.75 kg/m² and NC:43.5±3.9 to 37.2±4.7 cm. Significantly improved lung function was observed in FVC: 3.6±0.9 vs 4.0±1.0 L, FEV1:3.0±0.7 vs 3.4±0.8 L, FEF25-75%: 3.4±0.8 vs 8.3±0.9 L/s, ERV: 0.35±0.4 to 0.66±0.4 L/min and MVV:103.4±22 vs 137.3±29 L/min, all to p<0.001 compared to pre-operative phase. We found an increase of 0.06 l in the FVC and 5.9 l/min in the MVV after BS for each 1 cm of neck circumference decrease. For each 1kg/m² lost after the BS FVC increase 0.03 l and MVV 2.74 l/min.

Conclusion: The loss of weight induced by BS provides an increase in the lung function and the reduction of fat around the neck appear to be more important to increase lung function than BMI. Financial support: CNPq-Brasil.

P1311
Airway clearance techniques (ACT): A retrospective study in 188 patients, 96 of which with respiratory failure (RF)
Francesco Di Abensca1, Barbara Garabelli1, Lorenzo Appendini1, Gloria Savio1, Agnese Barison1, Nadia Baschini1, Paola Baraldi1, Bruno Banfi1. 1Divisione di Pneumologia Biabilitativa, IRCCS Fondazione Salvatore Maugeri, Veruno, Novara, Italy; 2Department of Statistics, Consorzio Valutazioni Biologiche Farmacocinetiche, Pavia, Italy

ACT comprise PEP-Mask and ELTGOL (PE) commonly used in our clinical practice and a recently introduced device, Temporary PEP (T-PEP®, UNIKO®).

The aim of this observational retrospective study was to compare the efficacy of T-PEP group on possible effects and specific indications of T-PEP compared with PE. We re-evaluated data from 188 patients (113 males, mean 70±10 years) including 96 patients with RF (i.e. in LTOT and/or mechanical ventilation, MV), 97 COPD and 75 COPD and/or bronchectasis patients, with or without exacerbation consecutively treated with ACT. 55 subjects were treated with T-PEP, 133 with PE. Demographic, clinical and physiological characteristics between ACT groups were similar. Repeated measures analysis of variance were used. After ACT, significant improvements in all physiological measures were found with no difference between groups: p<0.001 for FVC, FEV1, PEF, SaO2, PaO2, PaCO2/FiO2. Patients on LTOT showed that the need for O2 therapy decreased after ACT in T-PEP group (1.56±1.301 to 1.46±1.01 L/min – FiO2 0.245±0.048 to 0.260±0.041%) whereas increased in PE group (0.99±0.809 to 1.49±1.16 L/min – FiO2 0.242±0.028 to 0.273±0.088% p<0.029). Among patients not on MV, T-PEP group showed a trend to an increase of PaO2/FiO2 (p=0.078). ACT can improve physiological parameters with no difference between T-PEP and PE. In the T-PEP group, the reduction on needs of O2 therapy in LTOT patients and the trend of an increase of PaO2/FiO2 in patients not in MV seem to indicate that further studies are needed to target differently ACT in patients with RF Supported in part by MPR, Italy.

P1313
Change in erythrocyte aggregation during phototherapy in patients with COPD
Yulduzkhon Kayumova, Nigora Mukhiddinova. Ministry of Health of the Republic of Uzbekistan, Republican Specialized Scientific-Practical Medical Center of Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Introduction: Aggregation of red blood cells affects the efficiency of blood flow and oxygen delivery to tissues. This determines the importance of studying this parameter in patients with COPD and to seek correction in case of violations.

Aim: To study erythrocyte aggregation in patients with COPD during phototherapy with lamps with ceramic coating.

Methods: We studied 30 patients in stable phase of COPD (22 men and 8 women) aged 39-64 years, divided into 2 equal groups: 1st - after phototherapy for 10 days, 2nd - without phototherapy. Control group - 10 healthy men aged 40-58 years. Phototherapy was held with infrared light from ceramic-coated lamps of series KL, ZB and GI with wavelengths of 2-40 microns. Spontaneous aggregation of erythrocytes of venous blood was quantitatively evaluated by a special system of criteria for microphotographs of aggregates: the 1st group - before and after 10 days of phototherapy, while the 2nd and control groups - once.

Results: In the 1st group before the start of phototherapy erythrocyte aggregation...
The mean Modified Borg Scale was reduced from 2.88 to 2.02 (p < 0.05) showing that the number of emergency department attendance was reduced by 44.5% from 1.91 to 1.06 (p < 0.001) respectively. Together with a small increase in the use of propofol we observed a substantial reduction in the use of midazolam and morphine.

**Conclusion:**
Chronic Obstructive Pulmonary Disease (COPD) was ranked second among common respiratory diseases in Hong Kong. A pilot of Respiratory Nurse Clinic for COPD has been implemented since December 2009 in United Christian Hospital, Hong Kong, China. The Respiratory Nurse Clinic for COPD was run by qualified Respiratory Nurses and accredited locally since December 2009. Confirmed COPD patients who were high risk of hospitalization could be recruited. The key components of the program included patient registry, risk stratification, different models/levels of care with holistic approach, home non-invasive ventilator program, patient empowerment program and 24-hours hotline service.

**Results:**
The first 100 COPD patients were analyzed for their healthcare utilization for three months before and after joining the clinic. Their mean age was 74.6 ± 12.0 years (n = 100). The eclectic world of respiratory nursing

**P1314**
Can education and electronic prescription improve the use oxygen in acute clinical settings?

Gareth Ebbon, Ajit Thomas, Shiva Bikmalla, Asad Ali, Vikas Panamiyi, Ben Beauchamp, Rahul Mukherjee. Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

**Introduction:** Recent data on effects of hyperoxia in patients with coronary artery disease, brain injury [1] and post resuscitation patients [2] have shown increased mortality and morbidity. This calls for efforts to reduce unnecessary oxygen use in hospitals, which we instituted via targeted multidisciplinary education and widening the use of electronic prescription of oxygen between 2008 and 2010.

**Method:** Cross-sectional point prevalence of oxygen prescribing practice was audited at out patient hospital in November 2008 and November 2010 excluding Intensive care, paediatric and maternity wards. Between the 2 oxygen audits, we widened and improved electronic prescribing with a multidisciplinary training program on oxygen use for all caregivers.

**Results:** At the Nov 2010 point of data collection, 185/1267 (15%) patients were on oxygen. Of these a clear valid oxygen prescription was noted in 149 (81%); 46% of saturations documented were within target range. The proportion of patients in hospital receiving oxygen had reduced from 28% (191/666) since 2008; the prescription rate improved from 57% to 81%.

**Conclusion:** With the focus on education, increased awareness through local and national alerts and electronic prescriptions of oxygen, we have noted almost halving of in-hospital oxygen use and higher rates of oxygen prescription. There is however room for improvement in adherence to target saturation oxygenation.

**P1315**
Manage growing demand: Respiratory nurse clinic keeps people with COPD healthy

Shu Wah Steve Ng, Wai Yee Tsang, Chung Leung Penny, Lee Veronica Chan, Chung Ming Chu. Medicine & Geriatrics, United Christian Hospital, Hong Kong, China

**Introduction:** Chronic Obstructive Pulmonary Disease (COPD) was ranked second as a respiratory cause of hospitalization (14.6%) and inpatient bed-days (20.5%) among common respiratory diseases in Hong Kong. A pilot of Respiratory Nurse Clinic for COPD has been implemented since December 2009 in United Christian Hospital in Hong Kong. It focused on reducing the need for intensive medical care for COPD patients. This preliminary review aims to evaluate the effectiveness of the clinic.

**Methodology:** The Respiratory Nurse Clinic for COPD was run by qualified Respiratory Nurses and accredited locally since December 2009. Confirmed COPD patients who were high risk of hospitalization could be recruited. The key components of the program included patient registry, risk stratification, different models/levels of care with holistic approach, home non-invasive ventilator program, patient empowerment program and 24-hours hotline service.

**Results:** The first 100 COPD patients were analyzed for their healthcare utilization for three months before and after joining the clinic. Their mean age was 74.6 ± 12.0 years (n = 100). The mean Modified Borg Scale was reduced from 2.88 to 2.02 (p < 0.05). It is by 16.4% less than in the 2nd group, where the index was 8.5 ± 1.3. It is by 15.4% more than in the 3rd group, where the mean was 5.5 ± 1.3. But after testing the differences between all 3 groups, a statistically significant difference (p < 0.05) was detected only between the 2nd and control groups.

**Conclusion:** Erythrocyte aggregation increases in patients with COPD. During the 10-day course of treatment with infrared light from lamps with ceramic coating this indicator tended to normalize.

**P1316**
Practical nursing strategies in the management of pemphigus patients

Lynda Holsworth1, Trudi Miller1, Brownyn Levey1, Julian Goss1, Sanjiv Manjra2, Devika Williams1, 2, Glen Westall1, 2, Gregory Snell1, 2. Allergy, Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, Victoria, Australia; 2Cardiothoracic Surgery, The Alfred Hospital, Melbourne, Victoria, Australia

**Background:** In severe emphysema hyperinflation results in reduced quality of life and reduced exercise capacity. Portaero Inc. has developed a technique to create a permanent incision passage from the parenchyma of the lung through the chest wall (pneumostoma) to enable trapped air to vent. A pilot study demonstrated that the creation of a pneumostoma was feasible, safe and potentially beneficial to patients with severe emphysema.

**Objectives:** This report describes the nursing strategies developed in association with this novel device.

**Methods:** Pneumostomomas were created in a series of 8 patients. Tracts were created via a percutaneous incision and placement of an access tube which remained in place for 3-4 weeks. The pneumostomomas were maintained by a disposable tube changed daily by the patient.

**Results:** Early post operative complications included subcutaneous emphysema (8) and wound infection (1). Identified long term issues were problems with skin integrity (4), superficial granulation tissue (3), recurrent localised infection (2), bleeding and pain within the tract following activity (2). Inserting the daily tube was complicated by angulation and collapsibility of the tract, resistance entering between the ribs and anxiety. These problems were addressed with careful attention to skin integrity, treatment of granulation tissue with topical steroids and medical management of pain and infection. A bronchoscope was used to visualise the tracts, assess patency and identify tract direction or narrowing.

**Conclusion:** Continuous education and close support from nursing staff while the patients learned to deal with these issues enabled 6 of the patients to maintain a pneumostoma long term (between 6 and 18 months).

---

**P1317**
Daily weanscreen in mechanically ventilated patients: effects on sedation, analgesics and duration

J. van Rosmalen, F. van Beers, A. van Hees, P. Vos, P. van Berkom, J.A.H. van Oers. ICU, St Elisabeth Hospital, Tilburg, Netherlands

**Introduction:** The duration of mechanical ventilation (MV-duration) should be limited as much as possible to avoid complications.

**Objective:** The aim of the study was to find out the impact of a daily weanscreen on MV-duration.

**Setting:** A 20-bed mixed medical–(neuro-)surgical Intensive Care Unit.

**Methods:** In 2009 the sedation protocol was prescribed each day by the intensivist. In 2010 we introduced a 4 interventions weanscreenprotocol, including: Daily Spontaneous Awakening Trial (SAT), Rapid Shallow Breathing Index (RSBI), Spontaneous Breathing Trial (SBT) and MD enumerates reason to continue. From January to December 2010 we assessed all ventilated patients every day from Monday to Friday. The subsequent 4 steps of the weanscreen protocol were carried out by a ventilation practitioner (R.N.) to promote extubation. The amount of sedatives per year was divided by the number of ventilated patients, resulting in an average dose midazolam/propofol/morphine per patient. The MV-duration was evaluated and compared with 2009.

**Results:** The 672 patients in 2010 were compared to 594 patients in 2009. SAPSII was the same in both cohorts, Median MV-duration decreased from 42 to 38 hours (p < 0.001). Midazolam (mg/patient) was at 257 ± 393 mg/patient in 2009 and 262 ± 279 mg/patient in 2010. Morphine (mg/patient) was at 251 ± 200 mg/patient in 2009 and 251 ± 200 mg/patient in 2010. Conclusions: In our population we succeeded in reducing the use of midazolam and morphine by a daily 4 component–weanscreen, and a 10% decrease in MV-duration (statistically n.s.).

---

**P1318**
Home non-invasive ventilation service for patients with chronic respiratory failure

Shu Wah Steve Ng, Wai Yee Tsang, Yuen Yee Anna Chan, Lee Veronica Chan, Chung Ming Chu. Medicine & Geriatrics, United Christian Hospital, Authority Hospital of Hong Kong, Hong Kong, China

**Introduction:** There is increasing use of Non-Invasive Ventilation (NIV) in the management of patients with chronic respiratory failure such as Chronic Obstructive Pulmonary Disease (COPD). It was estimated that patients requiring home mechanical ventilation was 2.9 per 100,000 populations in 2004 in Hong Kong.
Most of them (94.8%) were treated by NIV. The domiciliary NIV program has been established in a local acute hospital to provide optimal and comprehensive care for the patients since 2004. Methodologies: The service was run by qualified Respiratory Nurses. The enhancement program has provided more structured, proactive and specialized NIV service. The key components of the service include patient registry, primary nurse model, clinical pathway, patient and carer empowerment, nurse clinic, quality assurance and 24-hours hotline. Results: There were 145 patients recruited since 2005. The gender ratio was about 4 to 1 (117.5% of male and 28, 19.3% of female) with mean age of 71.98±8.91. After receiving domiciliary NIV service, their attendance numbers in emergency department, unplanned admission and length of stay were significantly reduced. Conclusions: The domiciliary NIV service could provide holistic, continuous and cost-effective care for these high-risk patients with complex needs. It could reduce avoidable healthcare utilization of these patients.

PJ1319
Concept of caring – Family caregiver’s perspective on end-of-life care in advanced COPD
Betina Korn. Department of Respiratory Medicine, St. James’s Hospital, Dublin, Ireland

Background: Informal family caregivers provide the majority of care to patients with advanced COPD wishing to be cared for and die at home. Little is known about family caregiver’s perspective on end-of-life care.

Aims: This study aimed to conceptualise caregiver’s insight into caring for their family member with advanced COPD.

Methods: This sub analysis of data was part of a larger study and utilised an explorative descriptive qualitative design. Eight family caregivers that had cared for a loved one dying at home from COPD committed to semi-structured interviews about their experience. Transcripts of the interviews, field notes and reflective journal entries underwent a qualitative template analysis.

Results: The concept of “caring” was one of five themes identified. Seven subthemes within this theme describe the level of involvement caregivers had in the care of their family member. Carers understood complex care issues, describe the effect caring has on their own life and demonstrate organisational skills. They describe how family and kinship enables them to care and how they witness, recognise and respond to physical decline and suffering of their dying family members. Caring for their loved one was an all-encompassing, all-consuming affair and left them exhausted but gratified. A novel finding was the caregiver’s detailed knowledge about their experience. Transcripts of the interviews, field notes and reflective journal entries underwent a qualitative template analysis.

Conclusions: The key finding was family caregiver’s experiential knowledge. This knowledge is largely unrecognised by health care professionals. It remains a challenge to health care professionals to tap into this wealth of caregiver’s experiential knowledge in order to provide better end-of-life care in advanced COPD.

P1320
Clinical effectiveness of manual hyperinflation on atelectasis in patients with acute respiratory failure
Li Hsiang Yang1, Suh-Hwa Maa 2. 1Department of Nursing, Chang Gung Memorial Hospital, Taoyuan, Taiwan; 2Department of Somatics and Sports Leisure Industry, National Taitung University, Taitung, Taiwan

The literature and the clinical experience all demonstrate that manual hyperinflation (MH) in patients receiving mechanical ventilation may improve sputum clearance and ventilation. The purpose of this study was to examine the effectiveness of MH in patients with lung atelectasis associated with ventilation support. Twenty-eight patients with lung atelectasis associated with ventilation support, and stable vital signs were randomized into either an experimental group (n=14), or a control group (n=14) in the pulmonary intensive care unit of a Medical Center in northern Taiwan. The MH technique was carried out at a rate of 8–13 breaths per minute for a period of 20 minutes each session, 3 times per day until weaned from the ventilator. The control group received standard prescribed mechanical ventilation without supplemental MH. Sputum contents (wet/dry weight ratio, viscosity), respiratory system capacity (spontaneous tidal volume (VT), maximal (Pt-max.), index of rapid shallow breathing (IVT), dynamic lung compliance, chest x-ray signs and oxygenation ratio (PaO2/FiO2) were all measured just prior to the MH on Day 0 as baseline, and then each day for the next three days. The results showed significant improvements in the scores of the experimental group compared to those of the control group for sputum viscosity (p=0.011) and the index of rapid shallow breathing (p=0.008) after adjusting for covariates. Other outcome variables did not differ significantly between the experimental group and the control group.

P1321
Persistent symptoms of hospitalized COPD patients in the palliative phase
C.M. van Otteren, W.J.C. van Heusden. Pulmonary Department, Medisch Spectrum Twente, Enschede, Netherlands

Introduction: Literature shows that COPD will be the third cause of death worldwide and will lead to increasing health costs. Over time a great amount of severe COPD patients will demand different treatment and counseling with special attention for palliative care. Recently a new guideline has been developed in the Netherlands describing the palliative care for COPD patients. This guideline promotes more attention for quality of life, symptom control and psychosocial support. The first step in improving palliative care is measuring patient’s symptoms and impairments.

Aim: The aim of this study was to measure the incidence of persistent symptoms, fear and depression in admitted COPD patients in the palliative phase.

Results: 210 COPD patients in the palliative phase admitted to hospital with a COPD exacerbation were included. On day three the CCQ and HADS questionnaires were recorded. The rate of dyspnea, fatigue, fear and depression were scored on day 1 and 7 by means of VAS score (0-10).

Results: The median HADS score fear was 9.5 (1-19), depression was 7 (4-15). The median VAS score dyspnea day 1 was 3 (3-10), day 7 was 5 (1-9). The median VAS score fatigue day 1 was 7 (3-9), day 7 was 4.5 (1-10). The median VAS score fear day 1 was 3.5 (0-10), day 7 was 2 (0-10). The median VAS score depression day 1 was 5 (0-10), day 7 was 3 (0-10).

Conclusion: Fear and depression scores are high among patients with COPD in the palliative phase at admission in hospital and improve only partly during treatment of the exacerbation. There is no improvement in dyspnea score during admission.

P1322
A survey of nursing staff on intercostal drain (ICD) care in a tertiary centre
R. Nasser, R. Ahmed, A. Scott, M.E.J. Callister. Respiratory Medicine, St. James’s University Hospital, Leeds, West Yorkshire, United Kingdom

Introduction: A recent audit of ICD’s for pleural effusions in our 800 bedded tertiary centre revealed that in a 2 month period a significant proportion of drains were being managed on non respiratory wards (44% oncology & 16% other medical wards). Guidelines recommend that ICD’s are nursed on wards familiar with drains and their management.

Method: We carried out an anonymous survey of nursing staff to enquire about training, knowledge & comfort in managing ICD’s. The completed survey questionnaires were returned via internal mail.

Results: 110 questionnaires were distributed & 71 were returned (65%). 76% were Staff nurses, 22.5% Sisters & 1.5% were matrons. 77% had been qualified more than 3 years. 38% worked in general medicine, 20% in respiratory, 24% in Oncology & 18% in other specialties. A majority of the nurses felt they did not have adequate training, very few of them had any post registration training.

Conclusion: There is a clear need for education and training for nursing staff who are expected to look after patients with ICD’s. There is also a need for a trust wide chest drain observation chart.

P1324
Evaluation of health quality of patients with asthma and chronic obstructive pulmonary disease
Katarzyna Kiecicka, Anna Doboszyńska. Clinical Nursing Department, Medical University of Warsaw, Warsaw, Poland

Background: Bronchial asthma and chronic obstructive pulmonary disease (COPD) are characterized by inflammatory process in the airways, leading ultimately to their obstruction. Complex view on these diseases is associated with patients’ quality of life. Therefore, evaluation of the quality of life is of utmost importance, especially in the complex assessment of therapeutical process.

Objectives: This study aimed at evaluating and comparing life quality in two groups of patients, degree of dyspnea, and level of illness acceptance.

Aim: The study involved 100 patients with diagnosed bronchial asthma or COPD. Mean age of patients was 63 years. Investigative material was obtained with diagnostic poll with the aid of questionnaires based on: Saint George’s Respiratory Questionnaire, Medical Research Council dyspnea scale and Acceptance of Illness Scale. Collected data were analyzed statistically.
Results: In the group of asthmatic patients, total score of SGRQ was 54.9 ± 6.7 and was significantly lower than that in the group of patients with COPD - 67.9 ± p=0.0001. Strong negative correlation of life quality with illness acceptance was shown in both asthmatic and patients with COPD (R=-0.96, R=-0.98; p<0.001). Statistically significant relationship between respondents’ life quality and severity of dyspnea (F=11.71; t=0.83; p<0.000001).

Conclusion: 1. Statistically significantly lower quality of life is seen in patients with COPD in comparison with asthmatic patients. 2. Quality of life is worsening with more severe or uncontrolled disease. 3. Quality of life of examined patients is closely correlated with level of illness acceptance.

P1325
Nurse care for patients with chest drainage and creation of local procedural standards
Renata Sabo, Zuzana Taligov, Jan Platino, David Magula, Dalibor Petras.
2nd Pneumology, Specialized Hospital of St. Svoradus, Nitra, Slovakia (Slovak Republic)

Introduction: Drain is simple or complicated device or entire system, which serves to evacuate unwanted secretions or air from the pleural space. Today, the chest drainage (CD) is frequently used in pneumology. Its application is pathophysiological favourable, because the accumulation of fluid/air in body cavities prevents oxygenation of the cells, slows down mobilisation of collagen, prevents lymphatic drainage and creates a bounded space, resulting to delay the healing process.

Aims: Upon nurse assistance during CD to share own experience with formation of the local procedural standards.

Methods: From 2007 to 2009 CD was performed on 159 patients (pts). Empyema had 88 pts, malignant pleural effusion 58 pts and pneumothorax 13 pts.

Results: CD was without complications in 134 pts (84.3%). The complications occurred in 31 pts (19.5%). In 7 pts (4.4%) occurred trapped lungs; pain occurred in 31 pts (19.5%). In 7 pts (4.4%) collapse during CD was without complications in 134 pts (84.3%). The complications had 88 pts, malignant pleural effusion 58 pts and pneumothorax 13 pts.

Introduction: Upon nurse assistance during CD to share own experience with formation of the local procedural standards.

P1326
Obesity hyperventilation syndrome in the health area of the public company hospital Costa del Sol: Why do women have a higher prevalence? Juan Antonio Piña Fernández1, Ana Mochón Doña1, Juan Jose Santos Gonzalez2, Mar Sánchez Jimenez2, Pilar Fuentes Gala2, José Joaquin Cebrian Gallardo2, Luis Fernandez de Rota2, Francisco Linde de Luna2, Alicia Padilla Galo2, Ana Escobar Dueñas2, Pilar Cuellar2, 1VitalAire, Neumology, Empresa Publica Hospitalica Costa del Sol, Marbella, Malaga, Spain; 2Neumology, Empresa Publica Hospitalica Costa del Sol, Marbella, Malaga, Spain

Introduction: After detecting in a previous study on the prevalence of obesity hyperventilation syndrome (OHS) in the health area of the public company Hospital costa del sol that the prevalence of OHS in women was almost twice the rate of men (men 22.2%, women 56.81%), we try to find out what could be the factor or factors that determine these results.

Results: We analyzed 51 patients. Sex: Male (15), Women (36).

Phase 1: Underpinning theories. 1) The newly developed theory of CARe emphasizes the need for solution-focused nursing integrating a double goal: patient wellbeing and treatment efficacy. According to CARe, patients expect to be actively involved in the ongoing adjustment of the NIV treatment integrating their personal habits, preferences and expectations aiming at maximizing their overall wellbeing. 2) Experimental learning is learner-centred focusing on practical experience and learning by doing. Phase 2: Modelling the intervention. Skills of involvement, emotional attunement and monitoring NIV are central components of the intervention model. The teaching method is high-fidelity simulation. To evaluate learning outcome within the tree component areas we will use the Model of Practical Skill Performance.

Conclusion: We expect the learning outcome will be beneficial to both patients and nurses. The educational intervention is ready to test for feasibility.

P1329
A phenomenological study of pain in patients suffering from COPD
Marie Hustavenes1, Elise Austegaard1, Dagfinn Nåden2, Randi Andenæs2, 1Department of Medicine, Levienberg Diakonale Hospital, Oslo, Norway; 2Anaesthetic Ward, Randers Regional Hospital, Randers, Denmark

Introduction: Taking care of COPD patients in non-invasive ventilation (NIV) requires Complex Adaptiveness (CARe) from the involved nurses. Nurses are struggling to manage NIV and providing high quality nursing care for these patients requires plenty of practice.

Aim: To develop an intervention through high-fidelity simulation as a tool for less experienced nurses to advance their skills in providing NIV nursing care.

Method: We used the first two phases of the Medical Research Council framework. Firstly, in the preclinical phase we evolved the underpinning theories of the intervention. Secondly, in the modelling phase we identified the components of the intervention.

Results: Phase 1: Underpinning theories. 1) The life changiing pain, 2) the pain of dyspnoea attacks, and 3) the non-communicated pain.

Conclusion: Patients described various appearances of pain. Three major essences were identified: 1) The life changing pain, 2) the pain of dyspnoea attacks, and 3) the non-communicated pain. Regarding the first essence, pain was described as life changing since it implied a dramatic limitation on their lived life and the painful knowledge of progression. Concerning the second essence, dyspnoea attacks were experienced as physical pain in chest, head and muscles, as well as pain of acute fear of dying due to lack of air. Relating to the third essence, pain was not communicated to health care personnel due to lack of time, fear of not being taken seriously, or that they were never asked. Pain became private, and various methods of relieving pain were sought elsewhere.

Conclusions: Patients with severe COPD experienced pain at a level that interfered with their daily life, which had a negative impact on their quality of life.
1330
Caring for a family member with COPD: Exploring carers’ needs
Raquel Gabriel1, Cristina Jácome1, Daniela Figueredo1,2, Alda Marques1.
1School of Health Sciences, University of Aveiro, Aveiro, Portugal; 2Member of
the Research Unit UniFAI (Unidade de Investigação e Formação Sobre Adultos e
Idosos), University of Porto, Porto, Portugal.

Background: Research of the impact of Chronic Obstructive Pulmonary Disease
(COPD) on patients’ family carers is limited when compared to other chronic
diseases such as cancer, heart disease or dementia. The disease places a particular
burden on families but their support is crucial for the patient’s adjustment to the
disease. However, current knowledge on the specific needs of family carers living
with a patient with COPD is scarce.

Aims: This exploratory study aimed to contribute to a better understanding of the
family carers’ needs of patients with advanced COPD (stage III and IV).

Methods: Qualitative semi-structured interviews were conducted with ten carers
(females=8), with a mean age of 57.6 (SD=7.1) years old. The majority were spouses
(n=9) and were caring for more than 4 years (n=6). All interviews were
audio-recorded, transcribed and submitted to thematic analysis.

Results: Main results suggest carers’ needs for: i) information about the disease
To provide adequate care and to discern between kinds of attention needed to respond
to symptoms (e.g., difficulties in recognising when a exacerbation is occurring)
(n=8); ii) emotional support, like having someone trustworthy to talk about the
caregiving experience (n=4); iii) respite care, in order to allow carers to take some
time for their own (n=3); iv) instrumental support, as male carers reported
difficulties in providing housework or meal preparation (n=2).

Conclusions: The findings suggest that patients with COPD have significant
Concerns and fears about the irreversible process of their disease. Adequate knowl-
edge about these aspects will allow health professionals to adjust pulmonary
rehabilitation programs in the context of COPD. Understanding family needs pro-
ciding carers with education about the disease and emotional support is essential to the
management of COPD and to support carers in their caregiving role.

1331
Living with COPD: A perspective on patients’ concerns
Cristina Jácome, Raquel Gabriel, Alda Marques, Daniela Figueredo. School of Health
Sciences, University of Aveiro, Aveiro, Portugal.

Background: The World Health Organization has emphasized the need for a
patient-centred health care for the management of chronic conditions. COPD is a
highly incapacitating chronic disease and its non-pharmacological management has
been based on pulmonary rehabilitation programs. However, patients’ perspectives
regarding their own concerns have received little attention from these programs,
which is crucial to design adequate patient-centred interventions.

Aims: The aim of this study was to identify the specific concerns and fears of patients
with moderate-to-severe COPD, regarding their actual and future condition.

Methods: A qualitative, cross-sectional study was carried out with 18 COPD
outpatients. Data were collected using audiotaped semi-structured interviews to
capture patients’ detailed perceptions. A thematic analysis was performed by 2
independent judges.

Results: Participants were mostly male (n=11; 61.1%), with a mean age of 58.4
(SD=8.3) years old and a mean FEV1 percentage predicted of 43.1 (SD=17.7%). Patients
were mainly concerned about the progression of their condition (n=10; 55.5%) associated with the deterioration of their physical capacities (n=5; 27.8%)
and becoming older (n=3; 16.7%). Fears about being on their own (n=3; 16.7%)
and dying due to their respiratory disease (n=9; 50%), particularly dying of
asphyxiation (n= 6; 33.3%), were also reported by patients.

Conclusions: The results suggest that patients with COPD have significant
Concerns and fears about the irreversible process of their disease. Adequate knowl-
edge about these aspects will allow health professionals to adjust pulmonary
rehabilitation programs considering the patients’ emotional needs.

151. Mechanisms of allergic inflammation of the airways

1398
LSC 2011 Abstract: Different biochemical properties of house dust mite
induce divergent epithelial and inflammatory responses
S. Post, M. C. Nawijn, A. J. M. van Oosterhout, Irene Heijink. Pathology &
Medicine, Department of Allergology & Pulmonary Diseases, University Medical
Center Groningen, Groningen, NE.

Introduction: Allergic asthma is mainly caused by exposure to allergens like
house dust mite (HDM), when transepithelial delivery is facilitated by disruption of
the epithelial barrier.

Objective: We aimed to gain more insight in which biochemical property of
HDM is critical for the disruption of barrier function and initiates an inflammatory
response.

Methods: HDM extracts with different biochemical properties were analyzed for their
effects on airway/bronchial epithelial barrier function by measuring changes in
transepithelial resistance and immunostaining of the functional proteins ZO-1,
claudin and E-cadherin. Furthermore, we examined the induction of a pro-
flammatory phenotype of human bronchial epithelium by these HDM extracts, as
well as the epithelial remodeling and airway inflammation in vivo in a mouse model.

Results: We found that the different HDM extracts induced divergent responses. Importantly, the extract with lowest serine protease activity induced the most pro-
nounced effects on barrier function in vitro, and induced an increased production
of IL-25 in vivo. Remarkably, the same HDM extract induced HDM-specific IgE, a profound epithelial E-cadherin deelocalization, goblet cell hyperplasia, cellular inflammation and increased levels of CCL17 and IL-5 in vivo.

Conclusion: Together, these results indicate that the disruption in epithelial bar-
rier function is independent of serine protease activity, and is essential for allergic
sensitization and airway remodeling in vivo.

1399
2011 Abstract: The influence of glucocorticoid therapy on transcription
factor balance in asthma patients
Roxana Bumbacea, Stephen Durham, Carsten Schmitz- Weber. Respiratory
Medicine - Allergy, NHIF - Royal Brompton Hospital, London, GB. Allergy, Elias
Hospital Bucharest, Bucharest, RO. Allergy and Molecular Biology, Zentrums für
Allergie & Umwelt (ZAUM), Munich, DE.

Background: Transcription factors are important in T-cell subset differentiation as
well as clonal expansion and determine the polarization process towards different
T cell phenotypes. Glucocorticoids are important for asthma treatment, potentially
by modulating T cell differentiation. We hypothesize that the transcription factor
balance could be of predictive value in the treatment of asthma. Our study aimed to
profile T-cell transcription factors after 8 week GC-treatment of steroid naive
asthmatic patients and to test the steroid sensitivity of Th2 versus Th1 and Treg
transcription factors (TF) after a treatment period, which is known to control
Th2-cell activity and improve clinical symptoms.

Methods: Human CD4+ T-cells were isolated from steroid naive atopic asthmatic
patients. In vitro and after successful inhalative GC-treatment, TF mRNA levels
were determined using real-time RT-PCR. Additionally, CD4+ T-cells from healthy
donors were exposed to a serial dilution of GC in the presence of Th1, Th2 or Treg
polarizing conditions and analyzed for gene expression after 48h.

Results: After 8 week GC-treatment, RORC2, T-Bet and GATA-3 did not show
significant changes, FOXP3 was slightly higher. In contrast the Th2-gene Gfi-
1 was significantly more highly expressed in asthma patients compared to healthy
individuals and decreased significantly following GC treatment. In vitro analysis
revealed that Gfi-1 is abundantly expressed in Th2-polarizing conditions in asthma
and displays dose-dependent sensitivity to GCs.

Conclusion: The current study shows for the first time that Gfi-1 is involved in
allergic asthma and may represent a biomarker for assessing Th2-dependent
disease and GC-responsiveness.

1400
PGD2 biosynthesis in several human mast cell models is catalyzed by
cyclooxygenase-1
Jeong-Hee Choi1,2, Sven-Erik Dahlén2, Gunnar Nilsson3. 1Clinical Immunology
and Allergy Unit, Department of Medicine, Karolinska Institutet, Stockholm,
Sweden; 2Experimental Asthma and Allergy Research Unit, The National Institute
of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Background: Mast cells and eicosanoid mediators play an important role in
asthma. There are few studies comparing eicosanoid release from different human
mast cell models.

Objective: We characterized release of eicosanoids from the LAD2 human mast
line cell and primary cultured-human mast cells from cord blood (CBMC) and
peripheral blood (PBMC).

Methods: Mast cells were stimulated with anti-human IgE via cross-linking of IgE
antibodies for 30 minutes, and β-hexosaminidase, cysteinyl leukotrienes (CysLTs),
LTB4, prostaglandin D2 (PGD2) were measured, and expression of cyclooxygenase
(COX)-1 and COX-2 were studied by western blot.

Results: LAD2 released β-hexosaminidase and PGD2 after stimulation with
anti-human IgE in a dose-dependent manner, but not CysLTs or LTB4, CBMC and
PBMC showed significant increase of CysLTs and LTB4 in addition to β-
hexosaminidase and PGD2, after stimulation. IL-4 priming did not enhance CysLTs
release in any of the mast cell models. IL-4 primed LAD2 however showed signifi-
cant enhancement of PGD2 release. The PGD2 release from the three human mast
cell models was consistently abolished by the selective COX-1 inhibitor, FR222347
(10(-5) M), but not by the COX-2 inhibitor, etoricoxib. There was strong COX-1
expression in LAD2 which showed significant inhibition of PGD2 release after
treatment with COX-1 siRNA.

Conclusion: LAD2 is a good model for studies of PGD2 release, but not for
CysLTs. The PGD2 release from the isolated human mast cells is dependent on
COX-1, in line with recent in vivo findings in asthmatics (Daham K et al. Clin
Exp Allergy 2011;41:36-45).

Alpha-melanocyte stimulating hormone potentially inhibits basophil activation, indicating a novel function of this neuropeptide in airway allergy
Ulrike Raap1, Manuelo Gehring2, Thomas Lugert2, Alexander Kapp1

Methods: Human basophils of patients with allergic rhinitis to grass pollen only

Results: Human peripheral blood basophils expressed MC-1Rs at protein and mRNA level. The MC-1R was functionally active in isolated basophils as shown by α-MSH-mediated intracellular increase of calcium 2+, α-MSH significantly inhibited anti-IgE, FMLP or PMA induced release of IL-4 and IL-6 (p<0.05). Further, α-MSH suppressed IgE or grass pollen induced basophil activation assessed with CD63 surface expression (p<0.01). The effect of α-MSH on basophil activation was MC-1R-mediated as shown by blockade with a peptide analogue of agouti signaling protein.

Conclusion: Our data show that α-MSH inhibits the allergic immune response in human basophils, presenting a novel and promising anti-inflammatory function of this peptide in allergic airway diseases.

1402

Local and systemic inflammatory responses following bronchial instillation of house dust mite allergen (HDM) and HDM/lipopolysaccharide (LPS) in mild asthmatics
M. Berger1, J.D. de Boer2, P. Bresser2, T. van der Poel1, R. Lutter1, P.J. Sterk1, J.S. van der Zee1, Respiratory Medicine, Academic Medical Center, Amsterdam, Netherlands; 2Respiratory Medicine, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands

Rationale: Exposure to house dust, containing HDM and LPS, is associated with severity of allergic asthma. We hypothesized that adding LPS to bronchial provocation with HDM amplifies allergic inflammation in asthmatics on maintenance treatment with inhaled corticosteroids (ICS).

Aim: To assess the allergic inflammatory response in blood and bronchoalveolar lavage (BAL) fluid induced by provocation with HDM +/- LPS.

Methods: We included 39 mild asthmatic patients with HDM allergy. After 2 weeks run-in with fluticasone 100 μg bid, blood was drawn and subjects underwent bronchoscopy for instillation of saline in one lung followed by instillation of HDM +/- LPS in the contralateral lung. Six hours later, blood was drawn and BAL was performed. Statistical comparisons were made by Univariate Analysis.

Results: Additional instillation of LPS to HDM resulted in a significant increase in peripheral blood leukocytes and neutrophils, and a decrease of eosinophils. Provocation with HDM+LPS significantly increased total cell numbers, neutrophils, and Eosinophil Cationic Protein (ECP) in BAL fluid (p<0.04), and showed a trend towards an increase in eosinophils.

Conclusion: Additional instillation of LPS to a provocation with HDM in mild asthma decreases circulating eosinophils and increases pulmonary eosinophil influx and ECP-release, despite treatment with ICS.

1403

Poly(1-C)-induced responses in nasal and bronchial epithelial cells of patients with asthma and healthy controls
A.H. Wagener1, S. Luiten2, L.N. Venenkamp1, W.P. Kunsch1, P.J. Sterk1, C.M. van Drunen1, 1Dept. Pulmonology, Academic Medical Center, Amsterdam, Netherlands; 2Dept. ENT, Academic Medical Center, Amsterdam, Netherlands

Rationale: The majority of asthmatic exacerbations is associated with respiratory virus infection (Busse, Lancet 2010). Since airway epithelium is the primary site of a viral entry, we hypothesized that nasal and bronchial epithelia are equally responsive to respiratory viruses when measured as cytokine responses to poly(I:C).

Aim: We compared baseline cell activity and induced responses of primary human nasal and bronchial epithelial cells to poly(I:C) in allergic asthmatics and healthy controls.

Materials and method: This was a 2-group study in 8 allergic asthmatics (defined by GINA, PC20<8 mg/ml) with rhinitis (defined by ARIA) and 8 healthy volunteers. Both groups were instructed to take a controlled diet containing poly(I:C). Cytokine production was measured by Multiplex ELISA for 30 mediators and analysed by parametric analysis corrected for multiple testing.

Results: There were no significant between-group or within-group differences in baseline cell activity. Exposure to poly(I:C) induced up-regulation of several cytokines with no significant between-group differences. Asthmatics showed a higher activity for MIP-1β (p<0.009), MIP-1α (p<0.003), MCP-1 (p<0.038), and TNF-α (p<0.05) in nasal as compared to bronchial epithelial cells.

Conclusion: Expression is highly variable in individual subjects, and asthma- Nugenetic differences may explain these results. Further work is required to target peripheral lung inflammation in this patient group.

1404

Allergic mast cell expression of FcεRI differs between allergic asthma and rhinitis
Cecilia Andersson1, Ellen Tufvesson1, David Aronsson1, Anders Bergqvist1, Michiko Mori2, Leif Björner1, Jonas Erjefält2, Lund University, Respiratory Medicine & Allergology, Lund, Sweden; 2Lund University, Experimental Medical Science/Airway Inflammation, Lund, Sweden

Background: A significant proportion of patients with allergic rhinitis (AR) develop asthma. Our aim was to investigate expression of the high affinity IgE receptor (FcεRI) on alveolar mast cells in patients with AR with mild and uncontrolled asthma, AR with and without bronchial hyperreactivity (BHR) and non-atopic controls.

Methods: Bronchial and transbronchial biopsies from controls, patients with AR and patients with AR with concurrent asthma were processed for immunohistochemical identification of MC T and MC TC and their expression of FcεRI and bound IgE.

Results: The alveolar parenchyma in uncontrolled asthmatics had an increase in activities of both MCεRI (p<0.05) and MCεRI+ (p<0.003). In patients with AR with or without BHR and mild asthma no difference in tissue density of MCεRI or MCεRI+ was observed in central airways and alveolar parenchyma compared to controls. Mast cell expression of FcεRI was high in all groups in central airways. The expression of FcεRI on alveolar mast cells was increased in AR patients with concurrent mild (p<0.01) and uncontrolled (p<0.001) asthma compared to healthy controls. The asthmatics also had increased numbers of alveolar mast cells that expressed surface-bound IgE. A similar increase in mast cell FcεRI expression and surface-bound IgE was not seen in patients with AR with or without BHR.

Conclusions: Our data suggest that patients with atopic asthma have increased alveolar mast cell expression of FcεRI and surface-bound IgE compared to healthy controls and patients with AR with or without BHR. This might reflect a peripheral involvement of mast cells in the allergic asthma response and underscores the need to target peripheral lung inflammation in this patient group.

1405

Nlrp3/caspase-1-independent IL-1β production mediates diesel exhaust particles-induced pulmonary inflammation
Sharen Provoost1, Kurt Touwen1, Nele Pauwels1, Tom Vanden Berghe2, Peter Vandenabeele2, Bart Lambrecht3, Guy Foss1, Tania Maes 1, 1Department of Respiratory Medicine, Laboratory for Translational Research in Obstructive Pulmonary Diseases, Ghent University Hospital, Ghent, Belgium; 2Department for Molecular Biomedical Research, Unit for Molecular Signaling and Cell Death, Flanders Institute for Biotechnology, Ghent, Belgium; 3Department of Respiratory Medicine, Laboratory of Immunoregulation and Mucosal Immunology, Ghent University Hospital, Ghent, Belgium

Inhalation of diesel exhaust particles (DEP) induces an inflammatory reaction in the lung; however, the mechanisms are largely unclear. Interleukin (IL)-1β/IL-1RI signaling is crucial in several lung inflammatory responses. Typically, caspase-1 is activated in the Nlrp3 inflammasome, that recognizes several damage associated molecular patterns, which results in cleavage of pro-IL-1β into mature IL-1β. Here, we hypothesize that the Nlrp3/caspase-1/IL-1β pathway is critical in DEP-induced lung inflammation. Upon DEP exposure, IL-1RI KO mice showed reduced inflammation in the lung when compared to WT mice. In line, treatment with recombinant IL-1RI antagonist (anakinra) and IL-1β neutralization impaired the DEP-induced lung inflammatory response. Upon DEP exposure, Nlrp3 and caspase-1 KO mice, however, showed similar IL-1β levels and comparable inflammation in the lung compared to WT mice. In conclusion, these data demonstrate that the DEP-induced inflammation in the lung is mediated by IL-1β. This is in stark contrast with the inflammatory responses induced by LPS stimulation, where Nlrp3/caspase-1/IL-1β is critical.

248s
lungs acts through the IL-1/IL-1RI axis. In addition, DEP initiates inflammation independent of the “classical” Nramp3/caspase-1 pathway.

152. Dilemmas and progress in understanding childhood asthma

1406 Late-breaking abstract: MAGNETIC: a randomised, double blind, placebo controlled study of nebulised magnesium sulphate in acute asthma in children

Cecilia Powell, Department of Child Health, University of Cardiff, School of Medicine on behalf of the MAGNETIC Study Collaboration, Cardiff, Wales, United Kingdom

MAGNETIC is a double blind randomised placebo controlled study in acute asthma. Children between 2 and 16 years with acute severe asthma were randomised to receive standard care of three doses of nebulised salbutamol and intravenous ibuprofen every 20 minutes in the first hour with either placebo or nebulised magnesium (250mmol/L, 151mg/dose). Primary outcome was asthma severity score (ASS, 0-9) at 60 minutes post treatment; secondary outcomes were length of stay (LOS), need for intravenous (IV) bronchodilator therapy, need for PICU/intubation, stepping down of treatment at one hour, number of additional salbutamol administrations and serious adverse events.

506 children (median age 4.0 years; 58% male) were recruited from 30 centres. 251 children received treatment A and 255 children, treatment B. There were no clinical differences in baseline characteristics and no serious adverse serious events in either group.

</table>

There was no clinically significant difference in asthma severity score at 60 minutes post treatment. Treatment B significantly reduces the likelihood of intubation and need for intensive care admission.

1407 More airway smooth muscle in preschool children increases risk of future asthma

Ruth O’Reilly1, Tim Oates2, Jiayu Zhu3, Peter Jeffery3, Andrew Bush1, Sejal Saglani1.

1Respiratory Paediatrics, Royal Brompton Hospital, London, United Kingdom; 2Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 3Surgery, University Medical Centre Utrecht, Utrecht, Netherlands.

### Introduction

Accurate prediction of future asthma in preschool wheezers is not possible. Reticular basement membrane (RBM) thickness and airway smooth muscle (ASM) are increased in school-aged asthmatic children [Reganey AJRCM 2008], but nothing is known about ASM changes in preschool wheezers, or the relationship of early airway pathology to future asthma.

### Aims

1) To measure RBM thickness and ASM in severe preschool wheezers and age-matched controls; 2) To relate preschool RBM thickness and ASM to school age asthma.

### Methods

Endobronchial biopsies (EBx) were obtained from preschool wheezers (n=47, median age 26 months) and non-wheezers (n=21, median age 15 months) undergoing clinically indicated bronchoscopy between 2002-2005 [Saglani AJRCM 2007]. 5μm sections were stained with haematoxylin & eosin. ASM was expressed as a proportion of the subepithelial area. ASM and RBM thickness were quantified using computer analysis. Children were followed up age 6-11 years to determine asthma status.

### Results

**Asthma:** At preschool age, ASM thickness was increased in wheezers (n=37, median 4.3μm) compared to controls (n=16, median 3.0μm), p=0.01. ASM was similar between preschool wheezers (n=28, median 0.08) and controls (n=14, median 0.077), p=0.97. 5168 (75%) children were followed up at school age.

- **School age:** Children with and without asthma had similar RBM thickness in their preschool EBx, p=0.23. However, children with asthma (n=8, median age 9.1 years) had increased preschool ASM (median 0.10) compared to those without asthma (n=24, median age 7.3 years, median ASM 0.066), p=0.007.

### Conclusion

Preschool children whose EBx had a higher proportion (>10%) of ASM had a 10-fold increased risk of asthma at school age.

1408 Remodelling of the bronchial mucosa in very young children with high risk for developing asthma

Katarina Urbanova1, Petr Pohunek1, Jiri Uhlik1. 1Department of Paediatrics, 2nd Faculty of Medicine of Charles University and University Hospital Motol, Prague, Czech Republic; 2Department of Histology and Embryology, 2nd Faculty of Medicine of Charles University, Prague, Czech Republic.

Remodelling of the bronchial wall was thought to be a typical characteristic for asthma and the result of chronic inflammation. Structural changes were documented in bronchial mucosa of preschool children treated for asthma. We have very limited knowledge about the onset of immunological changes in very young children. The course of wheezing disorders in young age cannot be reliably predicted, so it is difficult to identify the most probable candidates for developing asthma.

The aim of our study is to identify abnormalities in the bronchial wall in children with high-risk of developing asthma. We examined endobronchial biopsies from 23 children under 4 years of age undergoing flexible bronchoscopy for clinical reasons others than recurrent wheezing. Twelve children fulfilled the criteria of Asthma Predictive Index, eleven children were in the control group. Thickness of the basement membrane was significantly higher in the high risk group than in the controls (on the average 4.14 μm vs. 3.5 μm respectively). On the other side, there seems to be no significant difference in the presence of neutrophil leucocytes and myofibroblasts between the two groups. This may correlate with the fact that all the patients were suffering from chronic or repeated respiratory problems for which they were indicated to bronchoscopy. However we suggest that first signs of remodelling like thickening of the basement membrane can be already present in children with high-risk of developing asthma in very early age. This may help us to improve therapeutic interventions in these children to prevent further development of irreversible morphological changes in later age.

Supported by GSA MH CR No. NT 11444 and NT 11459.

1409 Airway inflammation, lung function and wheezing phenotypes in preschool children

Kim D.G. van de Kant1, Marijn Jansen1, Ester M.M. Klaußnen1, Chris P. van der Grinten2, Ger T. Rijkers3,4, Jean W.M. Muris5, Onno C.P. van Schaayck3, Quirijn Jobin6, Edward Dompeling7, 1Paediatric Pulmonology, School for Public Health and Primary Care (CAPHRI), Maastricht University Medical Centre, Maastricht, Netherlands; 2Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 3Surgery, University Medical Centre Utrecht, Utrecht, Netherlands; 4Medical Microbiology and Immunology, Sant Antonius Hospital, Nieuwegein, Netherlands; 5General Practice, School for Public Health and Primary Care (CAPHRI), Maastricht University Medical Centre, Maastricht, Netherlands.

### Background

Wheeze is a common symptom in preschool children. Currently, it is difficult to predict whether wheezing symptoms will pass or will persist and develop into asthma in later childhood.

### Aims

To prospectively study whether inflammatory markers in exhaled breath condensate (EBC) and pre- and post-bronchodilator interrupter resistance (Rint) assessed at preschool age, are able to predict wheezing phenotypes at five years of age.

### Methods

Children (N=227) from the ADEM study [1] were included. At preschool age (median (IQR): 3.3 (2.8-3.8) years), pre- and post-bronchodilator Rint was assessed. EBC was collected using a closed-glass condenser system. Inflammatory markers (Interleukin (IL)-2, IL-4, IL-8, IL-10, sICAM) were measured using multiplex immunoassay. Wheezing phenotypes were determined at five years of age via annual questionnaires.

### Results

Children were classified as: never- (n=47), early-transient- (n=89), intermittent- (n=46), and persistent wheezers (n=45) [2,3]. Children with persistent- and intermittent wheezes who had elevated levels of all interleukins compared with never wheezers (p<0.05). Moreover, children in the never- and transient wheeze group had slightly lower levels of baseline Rint compared with persistent wheezers (Median (IQR): 3.3 (1.1-7.7) vs. 1.4 (1.2-6.0) cmH2O/L, p<0.10).

### Conclusions

Children of the intermittent- and persistent wheeze group at age 5 years already had elevated inflammatory markers at preschool age, indicating augmented airway inflammation in these children.

Airway inflammation is a continuous trait in children regardless of asthma symptoms

Ann-Marie M. Schoo, Bo L.K. Chawes, Klaus Bennelykke, Hans Bisgaard.
Copenhagen Prospective Studies on Asthma in Childhood; COPSAC, Health Sciences, University of Copenhagen, Copenhagen University Hospital, Gentofte, Denmark

Rationale: Elevated fractional exhaled nitric oxide (FeNO) and bronchial hyperresponsiveness are used as surrogate markers of asthma and children with persistent asthma.

Objective: To investigate the association between FeNO and bronchial responsiveness in a population of high risk children including the full spectrum from asymptomatic children to children with intermittent asthmatic symptoms and children with persistent asthma.

Methods: An unselcted group of 196 six-year-old children were included from the Copenhagen Prospective Study on Asthma in Childhood (COPSAC) birth cohort born of mothers with asthma. Bronchial responsiveness was assessed as the relative change in specific airway resistance after cold dry air hyperperventilation. FeNO measurements were performed prior to the hyperperventilation test. The association between FeNO and bronchial responsiveness was assessed by generalized linear models.

Measurements and main results: Bronchial responsiveness and FeNO exhibited a significant and linear association. A doubling of FeNO corresponded to an 8.4% increase in airway resistance after challenge (95% CI: 3.7-13.1, p=0.006). There was no evidence of interaction with current asthma and stratified analyses showed similar associations in children with and without asthma.

Conclusions: FeNO and bronchial responsiveness are associated and continuous traits in the population regardless of asthma. This suggests bronchial inflammation may be present subclinically, and caution against the use of these surrogates marks for asthma should be maintained. Childhood asthma remains a clinical diagnosis and surrogate markers may only be used cautiously as supportive evidence.

Randomized placebo-controlled study of ciclesonide in preschool children with recurrent wheeze and a positive asthma predictive index or atopy

Paul Brand1, Kannivelu Jagannath2, Maria Luz Garcia1, Adrian Morrison3, Jan Vermeulen4, Heinrich Weber5.
Princess Amalia Children's Hospital, Utrecht, The Netherlands; 2Thoracic Research Institute, Thoracic Research Institute, Chennai, India; 3Pediatrics, Hospital Universitario Severo Ochoa, Leganes, Madrid, Spain; 4Paediatrics, Victoriu Hospital, Cape Town, South Africa; 5Paediatrics, Panorama Medi-Clinic, Cape Town, South Africa

Rationale: To assess the efficacy and safety of ciclesonide, versus placebo, in preschool children with recurrent wheeze and a positive asthma predictive index (API) or atopic sensitization.

Methods: Children 2-6 yrs with recurrent wheeze episodes were eligible if they had a positive API, or were sensitized to aeroallergens. Children with exclusive episodic viral wheezing were excluded. After a 2-4 week baseline period, patients with ongoing symptoms/rescue medication use were randomised to once-daily ciclesonide 40, 80, 160 μg or placebo for 24 weeks.

Results: The number of wheeze exacerbations requiring systemic steroids was unexpectedly low in all groups: 25 (10.2%) in placebo group, as compared to 11 (4.4%), 18 (7.3%), and 17 (6.7%) in ciclesonide 40, 80, and 160 μg, respectively.

Conclusions: In preschool children with recurrent wheeze and a positive API, ciclesonide is safe and effective in reducing exacerbations.

Opposite effect of endotoxin exposure with different MD-2 genotypes on asthma in children

Blazenza Kljic Bukić1, Mario Blikic1, Neda Abarle1, Susana Marinho2, Angela Simpson3, Adhan Custovic4; 1Department of Pediatrics, General Hospital Dr Jure Dobravić, Split, Croatia; 2Thoracic Research Institute, University of Manchester, School of Translation Medicine, Manchester, United Kingdom

Background: Endotoxin exposure may play an important role in the development of asthma. MD-2 is a glycoprotein that assembles with TLR4 to form functional signalling receptor for endotoxin. We hypothesised that genetic variations in MD-2 may modify the relationship between endotoxin exposure and asthma.

Methods: Study population comprised 423 children with physician-diagnosed asthma and 414 non-asthmatic controls (age 6-18 years) recruited from the general hospital in Slavonski Brod, Croatia. We collected mattress dust sample and measured endotoxin content using kinetic limulus assay. We genotyped 9 haplotype-tagging SNPs in MD-2 (Sequence). Correction for multiple comparisons was carried out using Benjamin-Hochberg's False Discovery Rate (FDR) method.

Results: In the whole population, endotoxin exposure was associated with a decreased risk of asthma (aOR 0.75, 95%CI 0.58-0.98, p=0.03). None of the MD-2 SNPs was associated with asthma after FDR correction. For three SNPs, we identified a significant interaction between genotype and endotoxin exposure (G×E). The effect of endotoxin exposure on asthma may differ across children with different variants of the MD-2 gene.

Lessons learned from the epidemiology and natural history of asthma

Rationale: Patients with severe or difficult-to-treat asthma are an understudied population. The primary objective of The Epidemiology and Natural History of Asthma: Outcomes and Treatment Regimens (TENOR) study is to characterize the natural history of disease in the largest cohort of severe or difficult-to-treat asthma patients. We highlight the main findings of 25 research articles.

Methods: TENOR was a 3-year, multicenter, observational cohort study of 4,756 patients (n=3,489 adults ≥ 18 years; n=627 adolescents 12-17 years; n=637 children 6-11 years) Data was collected semi-annually and annually.

Results: Regardless of age, patients demonstrated high rates of HCU, despite receiving multiple long-term controller medications. Uncontrolled asthma, per the NHLBI guidelines, is highly prevalent and predictive of future asthma exacerbations in children and adolescents/adults. Children have an increased exacerbation risk and asthma burden compared with adolescents/adults. Increased weight is associated with worse asthma related outcomes. Aspirin sensitivity is associated with increased asthma severity and possible remodeling of both the upper and lower airways. Also, the phenotypes of persistent airflow are described. IGE and allergy play an important role in severe or difficult-to-treat asthma. Quantitative results not listed due to space constraints.

Conclusions: Patients with severe or difficult-to-treat asthma demonstrate an unmet need. The characterization of this cohort has improved our understanding of asthma control and exacerbations.

Flexible bronchoscopy in the diagnosis of paediatric lung diseases

Airway-related complications in preterm infants who were intubated at birth

Pedro Mondejar-Lopez1, M Dolores Pastor-Vivero1, Esther Bragado-Alcaraz2, Juan José Quesada-Lopez2, Virginia Perez-Fernandez2, Manuel Sanchez-Solís2, Luis Garcia-Marcos2, 1Paediatric Pulmonology Unit, Virgen de la Arrixaca University Children’s Hospital, Murcia, Spain; 2Neonatology, Virgen de la Arrixaca University Children’s Hospital, Murcia, Spain; 3Respiratory Health Institute, University of Murcia, Murcia, Spain

Background: Airway (AW) complications associated with intubation (IT) and mechanical ventilation (MV) have been observed in preterm infants (PTI). We describe their clinical manifestations (CM) and FB findings.

Methods: Fiberbronchoscopy (FB) was performed in symptomatic PTI who were intubated at birth. We describe their clinical manifestations (CM) and FB findings.

Results: AW complications in preterm infants who were intubated at birth (n=637 children 6-11 years). Data was collected semi-annually and annually.

Conclusions: Patients with severe or difficult-to-treat asthma demonstrate an unmet need. The characterization of this cohort has improved our understanding of asthma control and exacerbations.

Brachoscopic and high resolution CT findings in children with chronic wet cough

Kostantinos Dourou1, Ethfimia Alexeopoulou2, Aggeliki Nicopoulou2, Michael Anthracopoulos1, Panayotis Yiiallouras2, Andrew Frezayas1, Polintik Nicoladou1, Kostas Priftis1.1 Third Department of Paediatrics, Atikmon Hospital, University of Athens School of Medicine, Athens, Greece; 2Second Department of Radiology, University of Athens School of Medicine, Athens, Greece; 3Respiratory Unit, Department of Paediatrics, Medical School of the University of Patras, Patra, Greece; 4Department of Allergy-Pneumology, Penteli Children’s Hospital, Penteli, Greece; 5Cyprus International Institute for Environmental and Public Health in Association with Harvard School Public Health, Cyprus University of Technology, Limassol, Cyprus

Background: Chronic wet cough strongly suggests endobronchial infection which, if left untreated, may progress to bronchiectasis. Our aim was to compare the efﬁcacy of bronchoscopy CT (HCCT) and high resolution bronchoscopy (FB) in detecting airway abnormalities in children with chronic wet cough and to explore the association between radiological and bronchoscopic/bronchoalveolar lavage (BAL) ﬁndings.

Methods: We retrospectively evaluated 93 children (0.6-16.4 years) with wet cough for more than 6 weeks referred to a specialized center and deemed unlikely to have asthma. All patients were submitted to hematological investigations, chest x-rays, HCCT, and FB/BAL. HCCT scores were correlated with the Bhalla method and bronchoscpic findings of bronchitis were grouped into 5 grades of severity.

Results: Positive HRCT were found in 70 (75.2%) patients, respectively (p=0.76). A positive correlation was found between Bhalla score and duration of cough (p=0.23, p=0.026). FB/BAL was superior to HRCT in detecting abnormalities (p<0.001). The Bhalla score correlated positively with the type IIR (OR: 5.44, 95%CI: 1.92-15.40, p=0.001) and type IV (OR: 8.91, 95%CI: 2.53-15.42, p=0.001) bronchoscopic lesions; it also correlated positively with the percentage of neutrophils in BAL (p=0.23, p=0.036).

Conclusions: HRCT detected airway wall thickening and bronchiectasis and the severity of the ﬁndings correlated positively with the length of clinical symptoms and the intensity of neutrophilic inﬁltration in the airways. However, HRCT was less sensitive than FB/BAL in detecting airway abnormalities. The two modalities should be considered complementary in the evaluation of prolonged wet cough.

Foreign body aspiration in children: Single center experience during a 4 years period

Mohammadreza Modarei, Mojtaba Gorgi, Bahareh Ashaj, Sedareh Mamishi, Ebrahim Soltan, Nima Parvaneh. Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran

Introduction: Accidental Foreign Body Aspiration (FBA) is a cause of death in children. It requires early recognition and timely treatment to minimize the potentially dangerous side effects. The aim of our study was to determine the clinical spectrum, the demographic, and also the etiology of FBA in children.

Method: We retrospectively reviewed 188 pediatric patients with a history suggestive of foreign body aspiration over the 4 years from February 2007 to February 2011 in Children’s Medical Center affiliated to the Tehran University of Medical Sciences, Tehran, Iran.

Results: Foreign body was conﬁrmed in 112 children (59.5%) by rigid bronchoscopy. The mean age of the patients was 4 years, the 24 hours from the time of aspiration (early diagnosis). Fifty one of the patients had wheezing (24% unilateral, 27% bilateral), and 4% with no wheezing. Fifty ﬁve percent of foreign bodies were located in the right side, 35% in the left side, 8% in the trachea and 4.5% in the both sides. Of the 112 foreign bodies recovered, 87% were organic; 54% of these were sun ﬂower seeds. There was not any peanut among recovered foreign bodies in our series.

Conclusion: FBA should be excluded in children who have had a history of choking, persistent cough and chronic respiratory symptoms even in the presence of normal physical findings.

BAL eosinophil counts and speciﬁc clinical phenotypes of atmatic and/or atopic children

Deborah Snijders1, Erica Bazza2, Samuela Bugnin1, Laura Butottecha3, Elena Mutt1, Andrea Ballar1, Grazia Emi1, Simonetta Baralde-Nowak1, Marina Saetta1, Angelo Barbat1, 1Department of Pediatrics, University of Padova, Padova, Italy; 2Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy

Eosinophils play an important role in the inﬂammatory process of asthma and allergy, but their role is still unclear. This study aimed to investigate whether BAL eosinophils could identify speciﬁc clinical phenotypes of asthmatic and/or atopic children. We analysed BAL and bronchial biopsies from 107 children undergoing ﬁberoptic bronchoscopy for appropriate indications: 26 astatic asthmatics (AAS), 28 non-atopic asthmatics (NAAS), 22 atotics without asthma (ANAS) and 31 non-atopic non-atotic controls (C). Total and differential cell counts, ECP and IL-8 were analysed in BAL. Inflammatory cells were also quantified in bronchial biopsies by immunohistochemistry. Based on BAL counts we grouped children into non-eosinophilic (BAL eos <1%), 90 children: 16 AAS, 24 NAAS, 20 ANAS. 30 C) and eosinophilic (BAL eos ≥2%; 17 children: 16 AAS, 24 NAAS, 20 ANAS, 30 C) and eosinophilic (BAL eos ≥2%; 17 children: 16 AAS, 24 NAAS, 20 ANAS, 1 C) age was similar in the two groups (median 5 yrs). Eosinophilic children showed more frequent increases in IgE, ECP, IL-8, BAL neutrophils and tissue eosinophils (p<0.01 for all). When the eosinophilic group was divided in intermediate (2% ≤ BAL eos <4%) and severe (BAL eos ≥4%), both groups had increased IgE, ECP and tissue eosinophils. Instead, IL-8 and neutrophil counts were increased in intermediate but not in the severe group (p<0.005). Severe eosinophilia was seen more frequently in children with difficult asthma (p=0.039).

In conclusion, BAL eosinophilia in our study was observed in 15.8% of children and severe eosinophilia in 7.5%. AAS were more frequent in the intermediate and severe eosinophilic groups; NAAS were equally distributed in the three groups and ANAS were present in the non-eosinophilic and severe eosinophilic group.
Bacterial cultures in bronchoalveolar lavage fluid in children with chronic respiratory conditions

Pedro Mondejar-Lopez1, Mº Dolores Pastor-Vivero1, Esther Bragado-Alcaraz1, Virginia Perez-Fernandez2, Manuel Sanchez-Solís1, Luis Garcia-Marcos2, 1Paediatric Pulmonology Unit, Virgen de la Arrixaca University Children’s Hospital, Murcia, Spain; 2Respiratory Health Institute, University Marqués, Murcia, Spain

Background: The role of bacteria has usually been underestimated in children with chronic respiratory symptoms.

Aims: To describe the incidence of positive (+) bacterial cultures (BC) in bronchoalveolar lavage (BAL) fluid in children with chronic symptoms, and to assess differences between children with and without bronchectasis (BCE).

Methods: We carried out a review of all BAL performed from 2007 to 2010 in outpatients of our respiratory clinic. We defined 2 groups (gr: 1) BCE of unknown etiology, 2) Other chronic respiratory conditions with cystic fibrosis or receiving antibiotic treatment at the moment of the BAL were excluded. Chi2 test was used to assess differences between both gr and the association between gr 1 and the presence of purulent airway (AW) secretions. A multivariate logistic regression was built using gr as dependent variable; and gender, age, AW malacia and gastroesophageal reflex (GER) as independent ones.

Results: The final sample consisted of 70 children (56% male; gr 1: 23, gr 2: 47) who underwent a BAL at a median age 51.7±33.5 mo. BC was + in 48 (69%) children: 19 (83%) in gr 1 and 29 (62%) in gr 2 (p=0.077). Among + BC, the most common bacteria were H influenzae (n=28) and S pneumoniae (n=18), followed by S aureus (n=5), P aeruginosa (n=4) and K pneumo (n=2). A very significant association was found between gr 1 and purulent secretions (p<0.0001).

Conclusion: Although a + BC in BAL fluid is more common in children with BCE, the role of bacteria in other non-suppurative lung diseases should be taken into account.

1420 The role of transbronchial biopsy in pediatric patients

Ines de Mir, Antonio Moreno, Patricia Gorriz, Sandra Roviros, Alba Torrent, Silvia Garret, Carlos Martin, Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain Pediatric Pulmonology Unit, Hospital Maternonfantit Vall d’Hebron, Barcelona, Spain

Objective: To evaluate the use of transbronchial biopsies in pediatric lung diseases.

Methods: Retrospective review of transbronchial biopsies performed between 1998 and 2010. We analyzed the technique used, type of bronchoscope, complications, sample adequacy and diagnostic utility.

Results: We reviewed 137 biopsies, 25 were desimated for lack of information, so 112 biopsies from 47 patients were finally evaluated. Of these, 34 had received a lung or cardio-pulmonary transplant (age range, 6 months-22 years) and 13 were non-transplanted patients (18 months to 18 years). In 22 procedures, a 3.6 mm flexible bronchoscope was used (with forceps of 1.1 mm clips); in the rest we used a 4.9 mm bronchoscope (with 1.8 mm clips).

Conclusions: One hundred biopsies (90%) were adequate (91.2% of the biopsies performed with the 1.8 mm forcecs and 62.7% with the 1.1 mm forcecs). In the non-transplant population, biopsy was diagnostic in 75% (78% biopsied with the 1.8 mm, 11% with 1.1 mm forcecs; 11% unknown)

Cell acute rejection was diagnosed in 25% of the transplanted patients. Rejection was observed in 23% of all the biopsies and in 33% when we considered the symptomatic patients.

Complications included five pneumothorax (4.5%), three bronchospasms (2.7%) and nineteen bleeding (16.9%), 17 mild-moderate and 2 severe (1.8%), that stopped after instillation of cold saline and adrenaline

Conclusion: Transbronchial biopsy is a relatively safe and effective method for diagnosis and monitoring of lung diseases in selected children. We got a poor performance with the pediatric bronchoscope and forceps of 1.1 mm in our unit, so when possible the use of forceps 1.8mm might be preferable.
the mandibula measured just above the epiglottis correlated significantly with the change in upper airway resistance (R²=0.91, p<0.014). It could be concluded that stimulating the hypoglossal nerve changes the upper airway morphology. A relatively complex motion of the tongue base is observed with an enlargement of the airway lumen predominantly near the tongue base. Depending on the volume of the oral cavity, the enlargement is homogeneous or a decrease in cross-sectional area occurs at the palatal level. The distance between the tongue base and the mandibula appears to be a good surrogate for changes in upper airway resistance.

1424 Mechanical response to electrical- and neuro-stimulation of the genioglossus (GG) in propofol-sedated OSA patients
Yaniv Dotan1, Louis Gaitini2, Arie Oliver1, 1Medicine, Bnai-Zion, Technion, Haifa, Israel; 2Anesthesiology, Bnai-Zion, Technion, Haifa, Israel

Pharyngeal collapsibility during sleep is believed to increase primarily due to decline in dilator muscle activity. However, it is well documented that GG-EMG increases during apneas and hypopneas. The magnitude of increase is limited, however, as arousal terminates the respiratory disturbance. In the present study we prevented arousal by “drug-induced sleep” with propofol. We induced prolonged hypopneas in 17 patients with OSA by lowering CPAP after discontinuation of propofol, and monitored GG-EMG, flow and the area of (GAA) at the site of collapse (pharyngoscopy) until arousal. Prolonged hypopnea triggered a dramatic increase in GG-EMG. The mechanical response to this physiological drive to the GG was compared to baseline condition (after lowering CPAP from holding pressure), electrical stimulation (ES) of the GG, and after arousal.

Before arousal from sedation, flow remained unchanged despite the large increase in GG-EMG activity, while inspiratory CSA decreased. ES of GG, however, increased CSA and flow. Arousal resulted in fast enlargement of CSA and restoration of unobstructed flow, associated with marked reduction in GG-EMG. The mechanical response to this physiological drive to the GG was compared to baseline condition (after lowering CPAP from holding pressure), electrical stimulation (ES) of the GG, and after arousal.

Methods: We assessed resting sympathetic outflow and sympathetic neurovascular transduction in newly diagnosed OSA without comorbidities (N=10) and in age-matched (N=10) and young (N=10) healthy controls. Sympathetic activity was directly measured (microneurography) at rest and in response to sustained isometric handgrip exercise. Neurovascular transduction was derived from the relationship of sympathetic activity and blood pressure to leg blood flow during exercise.

Results: Sympathetic activity in OSA was almost 2x the age-matched and 3x the younger controls. Neurovascular transduction was not different between OSA and age-matched controls, but was lower in younger controls. Among all subjects, resting activity was related to transduction (R² 0.12, p=0.04), however this relation was much stronger without those with OSA (R² 0.55, p<0.01).

Conclusions: Greater sympathetic activity in OSA does not appear to derive solely from lesser neurovascular transduction. Hence, other potential mechanisms associated with OSA per se likely result in greater sympathetic outflow. However, elevated outflow without lesser transduction may underlie the prevalent development of hypertension in this population.

1426 Chronic intermittent hypoxia is a major trigger for non-alcoholic fatty liver disease
Judith Aron-Wisniewska1, 2, Caroline Minville3, 4, Joan Tordjman2, Patrick Levy1, 2, Jean-Luc Bousil1, Arnaud Basdevant5, Pierre Bedossa6, Karine Clement1, 2, Jean-Louis Pepin5, 4. 1Endocrinology and Nutrition Department, and Center of Human Nutrition (CRNH), Assistance Public-Hôpitaux de Paris, Clinique de Gastroentérologie-Hépatologie, Paris, France; 2INSERM, UMR5 872 Traum 7, Nortomique, Université Pierre et Marie Curie-Paris 6, Centre de Recherche des Cordeliers, Paris, France; 3INSERM U 1042, HP Laboratoire (Hypoxie: Pathophysiologie), Joseph Fourier University, Grenoble Cedex 09, France; 4INSERM U 1042, HP Laboratoire (Hypoxie: Pathophysiologie), Joseph Fourier University, Grenoble Cedex 09, France; 5Surgery Department, Assistance Publique-Hôpitaux de Paris, Hotel Dieu/Cochin Hospital, Paris, France; 6Cardiology Department, Assistance Publique-Hôpitaux de Paris, Beaujon Hospital, Centre de Recherche Bichat-Beaujon, Clichy, France

Backgrounds and aims: Morbid obesity is frequently associated with low grade systemic inflammation, increased macrophage accumulation in adipose tissue (AT), obstructive sleep apnea (OSA) and nonalcoholic fatty liver disease (NAFLD). It has been suggested that chronic intermittent hypoxia (CIH) resulting from OSA could be an independent factor for early stage of NAFLD in addition to other well-recognized factors (dyslipidemia, insulin resistance). Moreover, macrophage accumulation in AT is associated with local hypoxia in fat tissue. We hypothesized that the association between CIH and morbid obesity could exert additional specific deleterious effects both in liver and adipose tissues.

Methods: 101 morbidly obese subjects were prospectively recruited and underwent bariatric surgery during which a liver biopsy as well as subcutaneous and omental AT biopsies were obtained. Oxygen desaturation index (ODI) quantified the severity of nocturnal CIH.

Results: Liver biopsy analysis demonstrated that NAFLD lesions (ballooning of hepatocytes, lobular inflammation), NAFLD activity score (NAS) and fibrosis were more severe in patients with the highest ODI tertile (p values <0.001 for all hepatic lesions). In multivariate analysis, after adjustment for age, obesity and insulin resistance status, CIH remained independently associated with hepatic fibrosis, fibroinflammation and NAS. By contrast, no association was found between CIH, macrophage accumulation and adipocytes size in both subcutaneous and omental adipose tissue.

Conclusions: In morbidly obese patients, CIH was strongly associated with more severe liver injuries but did not worsen obesity induced macrophage accumulation in adipose tissue depots.

1427 The impact of obstructive sleep apnea syndrome on superoxide dismutase-1 activity in erythrocytes of high risk for type 2 diabetes (pre-diabetic) males Szczenz Nacosta1, 2, Edward Wysocka3, 2, Tomasz Piorunkiewicz1, Małgorzata Rywnikowska1, Lech Tolinski2, Halina Banara-Gabryel1, 1Department of Respiratory Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Clinical Biochemistry and Laboratory Medicine, Poznan University of Medical Sciences, Poznan, Poland

Introduction: The relationships between obstructive sleep apnea syndrome (OSAS) and cardiovascular risk factors are under wide-world interest.

The aim of the study was to analyze superoxide dismutase-1 activity in erythrocytes of high risk for type 2 diabetes (pre-diabetic) males, due to a severity of OSAS diagnosis.

Methods: OSA suspected males with no acute or severe chronic disease were enrolled. Non-smoking Caucasians aged 30-63, with BMI 25-39.9 kg/m², submitted clinical, biochemical and polysomnographic examinations. EMBLA device was used to test severity of OSA episodes. The results of oral glucose tolerance test allowed to select pre-diabetic males. Apnea/hypopnea index (AHI) categorized patients for: OSAS (n=14, aged 53±7, AHI 0-4.9), OSAS1 (n=14, aged 55±8, AHI 5-15), OSAS2 (n=14, aged 56±5.5, AHI 16-30); OSAS3 (n=14, aged 55±7, AHI >31). Plasma glycerol, fasting lipid profile (TC, HDL-C, LDL-C, TG), uric acid were estimated. Fasting serum insulin (ELISA BioSource, Sunrise

CPAP effects on leptin and visceral fat in patients with sleep apnea:
Double-blind, randomized, controlled trial
Peelin Lee1, Chih-Wei Yu2, Ming-Tzer Lin3, Tiffany Ting-Fang Shih4, Wen-Fei Shau2, Huey-Dong Wu5, Ching-Ting Tang1, Sandy Huey-Jen Hu6, Shieh-Chin Wang3, Chong-Jen Yu4, Pan-Chyr Yang3.
1Center of Sleep Disorder, National Taiwan University Hospital, Taipei, Taiwan; 2Dept. Medical Imaging & Radiology, National Taiwan University Hospital, Taipei, Taiwan; 3Division of Health Technology Assessment, Center for Drug Evaluation, Taipei, Taiwan; 4Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Rationale: Obstructive sleep apnea (OSA) is common in obesity. Leptin plays an important role in controlling appetite, energy expenditure, and body fat deposition. Studies investigating the effect of continuous positive airway pressure (CPAP) on leptin have conflicting results. The major confounder is the visceral obesity. 

Objectives: We tested the stored blood from a double-blind, randomized, placebo-controlled trial aimed to (1) determine the CPAP effect on leptin and visceral fat and (2) investigate if changes of visceral fat after CPAP correlated with leptin in OSA patients.

Methods: Ninety-six patients were randomized to 12-week therapeutic (n=48) or subtherapeutic group (n=48). CPAP was measured the levels of leptin from stored blood and measured visceral fat with abdominal MRI. Results were analyzed with the intention to treat. The multiple linear regression was used to measure correlation between changes of visceral fat with changes of leptin.

Results: Eighty patients completed the study and 16 withdrew. 12-week therapeutic CPAP did not modify leptin and visceral fat compared to subtherapeutic group although significant improvement of objective sleepiness. The regression analysis identified that changes of visceral fat independently correlated with changes of leptin (coefficient 1.531, P=0.001, 95% CI (0.056 to 2.95)).

Conclusions: 12-week CPAP treatment does not modify leptin and visceral fat and changes in visceral fat independently correlate with changes of leptin. CPAP therapy should be combined with other measures that can reduce visceral fat when managing OSA patients.

1429 Predictors of recurrence in patients undergoing cryoballoon ablation for treatment of atrial fibrillation: the independent role of sleep disordered breathing
Thomas Bitter1, Georg Nölker1, Jürgen Vogt1, Klaus-Jürgen Gutleben1, Thomas Bitter1, Georg Nölker1, Jürgen Vogt1, Klaus-Jürgen Gutleben1, Nina Westerheide1, Dieter Horstkotte1, Olaf Oldenburg1.
1Department of Pulmonary and Critical Care Medicine, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Introduction: In patients with atrial fibrillation (AF) undergoing pulmonary vein isolation, cryoballoon technique (cryoPVI) has been adopted in many centers. This study aimed to evaluate predictors of AF recurrence including impact of sleep disordered breathing (SDB).

Methods: In 82 patients consecutively assigned to cryoPVI cardiorespiratory screening for SDB, assessment of medical history, ECG, echocardiography, standard laboratory measurement, and blood gas analysis were performed prior to intervention. After 3 months blanking period 7-days Holter ECG was performed at 3, 6 and then every 6 months to determine AF recurrence.

Results: 75 patients (69 paroxysmal AF; 6 persistent AF, 22 female, age 60±9 years) completed at least 6 month follow-up. Median follow-up of 12 months (interquartile range 6 to 18 months) confirmed maintenance of sinus rhythm in 69.4% of these patients. Stepwise forward regression model revealed moderate to severe SDB (cut-off apnea-hypopnea-index (AHI) ≥ 15; Hazard Ratio (HR) 2.95, p=0.04), early recurrence of atrial fibrillation (HR 8.74, p<0.001), persistent atrial fibrillation (HR 7.16, p<0.001), pre-procedural class III-antiarrhythmic drug treatment (HR 3.63, p=0.02), but not SDB per se (AHI ≥5b) as independent predictors for AF recurrence.

Conclusion: Moderate to severe SDB is a treatable condition that independently predicts AF recurrence in patients undergoing cryoPVI. Screening for SDB and adequate treatment may improve long-term success of cryoPVI.
distribution, provide lobar Raw and pressure. The difference in lobar pressure and
tegogether with lobar inflow, provide lobar S.
Results: Results show that the lobar S profile has a similar shape and as the flow
profile: The lobar S profile is constant during expiration. During inspiration lobar
S does increase exponentially near the end of the inspiration. Furthermore it can
be seen that both Raw and S do vary significantly between the different lobes.
Conclusions: Lobar Raw and S can be obtained through 2D updated with CFD by
taking a CT scan and a simultaneous flow and peso measurement. Information on
these lobar properties can be used to predict the outcome non-invasive ventilation.

1432
HOT HMV UK: An investigation into mechanisms of action of home mechanical ventilation (HMV) following acute hypercapnic exacerbations of COPD
Patrick Murphy1, John Mosham1, Michael Polkey1, Nicholas Hart1, 1Asthma, Allergy & Lung Biology, King's College London, London, United Kingdom;
National Heart and Lung Institute, Respiratory Biomedical Research Unit, Royal Brompton Hospital and Imperial College, London, United Kingdom;
NIHR Biomedical Research Centre, Guy’s & St Thomas’ NHS Foundation Trust and Kings College London, London, United Kingdom

Introduction: HMV in COPD remains controversial. Current data indicates improvements in arterial carbon dioxide (PaCO2) are mediated by improved pulmonary mechanics and hypercapnic ventilatory response (HCVR). This hypothesis has yet been to test in a controlled trial and no studies have investigated changes in neural respiratory drive (NRD) measured by parasternal EMG (EMG para).

Method: Patients with persistent hypercapnia (PaCO2 > 7 kPa) 2-4 weeks after resolution of an acute exacerbation of COPD were randomised to home oxygen therapy (HOT) or HOT and HMV. Baseline studies included HCVR and EMG para.

Results: 20 patients have been recruited and randomised. There was a significant between group difference in HCVR and NRD.

Follow up data is presented on 9 patients. Ventilator settings were IPAP 28±1, EPAP 5±1, RR 15±1. Significant improvement in both PaO2 and PaCO2 only occurred in the HMV group.

There was a significant between group difference in HCVR and NRD.

Follow up data is presented on 9 patients. Ventilator settings were IPAP 28±1, EPAP 5±1, RR 15±1. Significant improvement in both PaO2 and PaCO2 only occurred in the HMV group.

Conclusions: These preliminary data suggest that the addition of HMV to HOT in this group is associated with improvements in gas exchange and this appears in part mediated by changes in HCVR and NRD suggesting “resetting” of central drive.

1433
Polysomnography (PSG) under NIV in stable COPD to reduce patient-ventilator asynchrony (PVA) and morning breathlessness
Dan Adler1, Stephen Perrig2, Hirotsuka Takahashi3, Fabrice Espar4, Daniel Rodenstein5, Jean-Louis Pepin6, Jean-Paul Janssens1, 1Division of Pulmonary Diseases, Geneva University Hospitals, Geneva, Switzerland; 2Sleep Laboratory, Department of Psychiatry, Geneva University Hospitals, Geneva, Switzerland; 3Division of Pulmonary Diseases, Clinique St Luc, Catholic University of Louvain, Woluwe, Belgium; 4Division of Pulmonary Diseases, University Hospital, Grenoble, France

Introduction: Patient-ventilator asynchrony (PVA) is frequent in COPD patients considered yet effectively treated by NIV.

Objective: To assess whether adjusting ventilator settings during polysomnography (PSG) might improve patient-ventilator synchronization, sleep quality and morning dyspnea (“deviation dyspnea”).

Methods: 8 consecutive severe COPD patients (6±1.8 yrs, FEV1 30.4±8.7% of predicted values) were recruited and treated with NIV after PSG recording. PSG was performed in 20 patients receiving NIV and in a subgroup of 10 patients during NIV and HMV. HMV and NIV were performed in 10 patients in 20% of time of recording. Each night the patient received 60 minutes of NIV (active valve circuit (AVC) or leak circuit (LC) with and without additional artificial leak (4mm I.D.) next to the fullface mask). PaO2 was measured at the site of oxygen (FiO2-ventilator) as well as mask (FiO2-mask) following expiration system (AVC or LC) and opened or closed artificial leak. Capillary blood gas analyses were performed at start and end of each measurement.

Results: Overall, FiO2-mask (29±5%) was lower compared to FiO2-ventilator (34±4%) with a mean (95% CI) difference of 5.1 (4.2 to 5.9, p<0.0001)%. With LC FiO2-mask decreased by 3.2 (2.6 to 3.9, p<0.0001)% compared to AVC (Figure). PaO2 tended to be 6.3±1.0 to 13.7±1.0 mmHg lower after 60 minutes of NIV comparing LC and AVC, p=0.08. Implementing an artificial leak FiO2-mask decreased by 5.7 (5.1 to 6.4, p<0.0001)% (Figure) with lowered PaO2 of 10.4 (3.1 to 17.1, p<0.0001) mmHg.

Conclusions: Leak circuits regularly used for exhalation during NIV and uninhibited air leaks significantly reduce FiO2 in patients receiving NIV and O2, which substantially deteriorates patients’ oxygenation.

1435
Monitoring of non-invasive ventilation: Is the strategy used in daily practice enough?
Marjolaine Georges, Claudio Rabec, Nnunha Kabeya, Daniele NGuyen, Ameline Vagner, Philippe Camus. Service de Pneumologie et Réanimation Respiratoire, Centre Hospitalier et Universitaire de Dijon, Dijon, France

Background: Non-invasive ventilation (NIV) is recognized as an effective treat-
ment in respiratory failure. However, empirically determined NIV settings may not achieve optimal ventilatory support. As a result, NIV should be systematically monitored. Current strategy used for this monitoring includes clinical assessment, arterial blood gases (ABG) and oximetry. Ideally, complete polysomnography should be done but actually this practice is infrequent. Simple tools such as capnography (TcPCO₂) or built-in ventilator software (VPA/P-Reslink) provide useful information but their role should be defined.

**Objectives:** To determine effectiveness of current strategy versus different simplified tools in assessing NIV effectiveness.

**Methods:** Efficacy of NIV was assessed in 95 patients. They underwent oximetry, TcPCO₂, Reslink and ABG during spontaneous ventilation. Subjective comfort of NIV was evaluated by questionnaire. Results: While the usual approach including oximetry and ABG considered 42 patients as correctly ventilated, only 10 patients (11%) are effectively treated as questioned, ABG, oximetry, TcPCO₂ and Reslink were normal. Therefore, current strategy gave a wrong estimate of NIV quality in 34% of patients. Adding Reslink to this strategy recognized 20 patients as inadequately ventilated whereas adding TcPCO₂ allowed to identify 8 patients.

An alternative non-invasive strategy combining Reslink and TcPCO₂ identified 21 patients with good NIV performance. Among them, 8 (9%) had pathological ABG and were badly classified.

**Conclusion:** The usual strategy overestimates quality of NIV. Combining Reslink and TcPCO₂ allows detecting NIV failure in 75% of patients without ABG.

**Impact of three back-up rate (BUR) on subjective quality of sleep (QoS) and residual events in obesity-hyperventilation (OHS) patients with three simplified tools**

**Aim of study:** To compare the impact of spontaneous ventilation (SV; BUR=0), low BUR (10.9±0.9/min) and high BUR (20.5±1.5/min) applied in random order during 3 consecutive nights in OHS patients. Main outcome: Sleep structure assessed PSG Secondary outcome: Hyperventilation and residual events.

**Methods:** Infusion of non-invasive ventilation (NIV) was performed for sleep structure, obstructive (OE), central (CE) and mixed (ME) respiratory events, % time spent with patient ventilator asynchrony (PVA) and nocturnal hyperventilation measured by TcPCO₂. Two questionnaires assessed subjective QoS.

**Results:** Ten stable OHS patients under long term NIV (mean±SD; aged 55.7±9.2 yrs; BMI 48.5±5.4 kg/m², PaCO₂; 5.5±0.7 kPa) were included. Table 1 depicts main results.

ODL, CE, ME and time spent with PVA were all much higher with SV than with either low or high BUR. Subjective QoS did not differ between SV and low BUR. However subjects with high BUR perceived more awakenings and a lower QoS than with low BUR whereas their Sleep efficiency was lower.

**Conclusion:** In stable OHS patients under long term NIV, SV was associated with a very high rate of ODL, CE and ME when compared to low and high BUR. High BUR was perceived as less comfortable than low BUR.

1437

**Diffusion weighted MR can improve preoperative lung cancer diagnosis**

**Johan Coolen 1, Frederik De Keyzer 2, Paul De Leyn 3, Johan Vansteenkiste 3, Walter De Wever 4, Herbert De Caluwe 2, Christophe Dooms 2, Eric Verbeken 4, Willy Coosemans 5, Dirk Vauzermont 6, Yolande Lievens 1.**

**Purpose:** Since diffusion-weighted MR (DW-MR) has shown promise in differentiating benign from malignant disease in several oncologic applications, we aimed to evaluate the potential role of this technique in differentiating benign from malignant lung lesions.

**Material and methods:** 50 patient staged with PET-CT and operated because of proven lung cancer or having a suspicious lung opacity were included. DW-MR was performed one day before surgery. PET-CT was evaluated first by visual inspection of all MR images by a chest radiologist and second by calculating the ADC values. Both PET/CT and DW-MR findings were correlated with pathology.

**Results:** Good correlation was found between DW-MR and pathology (κ=0.56, p<0.0001), whereas PET/CT performed worse (κ=0.20, p=0.1457). In total, 33 patients were diagnosed correctly with PET/CT, 7 incorrectly and 10 undetermined. DW-MR staged 45 patients correctly and 5 incorrectly. The 10 undetermined cases on PET/CT were correctly diagnosed on DW-MR. Pure ADC-average based diagnose showed an optimal threshold of 0.00152 mm²/s between benign and malignant lesions, with sensitivity and specificity of 91 and 57% respectively.

**Conclusion:** DW-MR could become an appropriate diagnostic instrument for preoperative lung cancer patients in the near future because it has a high accuracy for differentiating benign from malignant lung lesions.

**Comparison of four-dimensional (4D) CT ventilation imaging with SPECT/V/Q scans**

**Tokihiro Yamamoto 1, Sven Kabus 2, Jens von Berg 2, Cristian Lorenz 2, Michael Goris 1, Billy Loo 1, Paul Krafl 1.**

**Background:** A novel ventilation imaging method based on 4D-CT has advantages over existing methods. However, little validation has been performed.

**Purpose:** To compare 4D-CT ventilation imaging (VCT) with SPECT ventilation (VPECT) and perfusion (QPECT) scans.

**Methods:** VCT, VPECT and QPECT were acquired for 3 patients. VCT was compared with VPECT and QPECT. The spatial overlap of defects was assessed using the dice coefficient (DC). The defects were determined by (1) thresholding the SPECT images with 20%, 30% or 40% of the maximum value in the lung and (2) segmenting the same volume with lower values in VCT.

**Results:** VCT was of higher resolution than SPECT. Figure shows example images. Visually, regions of both agreement and disagreement were identified.
Table shows DCs (mean±SD) between the V_{QC} and V_{SPECT} or Q_{SPECT} defects. V_{SPECT} suffered from central airway depositions of aerosols, which drove extremely high correlations. There were moderate correlations with Q_{SPECT} in all patients. Lower thresholds yielded consistently lower DCs due to differences in low-value regions.

Conclusions: The 4D-CT ventilation moderately correlated with the SPECT V/Q. Ongoing studies focus on investigating more patients and spatial characteristics of the differences.

1439 Micro-CT and 18F-FDG micro-PET of pulmonary fibrosis in mice induced by adenoviral gene transfer of TGF-β1

Thomas Rose1, Christian van Falec1, Roman Halter2, Claudia Boehm3, Matthias Luepke1, Florian Laenger1, Jack Gauldie5, Juergen Borlak2, Frank Wacker1, Ulrich Maus6.1 Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; 2Pathology, Hannover Medical School, Hannover; 3Pathology, Hannover Medical School, Hannover, Germany; 4Pathology, Hannover Medical School, Hannover; 5Center for Computer Vision and Imaging Biomarkers, Sheffeild, Sheffield, United Kingdom; 6Pathology, Hannover Medical School, Hannover, Germany

Introduction: The morphological and functional information provided by micro-CT and micro-PET allows monitoring of acute and chronic disease states in small laboratory animals. We examined in-vivo micro-CT and micro-PET as non-invasive tools to assess pulmonary fibrosis in mice.

Material/Methods: Pulmonary fibrosis was induced in mice by intratracheal delivery of an adenoviral gene vector encoding biologically active TGF-β1. Respiratory gated and ungated micro-CT was performed in 18 mice at 1 to 4 weeks after pulmonary adenoviral gene delivery. In 5 additional mice 18F-FDG micro-PET and micro-CT was performed. Imaging was correlated to histopathology and findings in animals exposed to a control vector. Radiation doses were measured using thermoluminescence dosimeters.

Results: Significant correlation between Ashcroft histogram scoring and micro-CT was found for visual assessment scoring (p<0.001) and automated quantification by a region growing segmentation algorithm (p=0.004 for gated and p=0.006 for ungated exams). 18F-FDG micro-PET showed slight increase of glucose metabolism in the consolidated lung areas determined by micro-CT, which was coregistered to the micro-PET data using anatomical landmarks. Radiation doses for micro-CT ranged from 174 to 277 mSv. For micro-PET an expected dose of 140 mSv was calculated from the measurements.

Conclusion: Micro-CT and micro-PET allow valid visualisation of morphology and metabolism for the assessment of fibrosis in mice. The measured radiation doses allow serial examinations without deterministic radiation effects.

1440 Association of texture-based quantitative fibrotic patterns and pulmonary function test in a new validation set

Hyun Kim, Matthew Brown, Fereidoun Abtin, Peiyun La, Daniel Chong, Jonathan Goldin. Center for Computer Vision and Imaging Biomarkers, Department of Radiological Sciences and Thrombus Imaging Research Group, David Geffen School of Medicine, University of California-Los Angeles, Los Angeles, CA, United States

Background: Under non-volumetric CT scan, a texture-based quantitative lung fibrosis (QLF) score has been developed as a computer-aided diagnostic metric in a scleroderma-related interstitial lung disease (SSc-ILD) [1].

Objective: To test an association the QLF from CT score with pulmonary function tests in new study cohort.

Methods: From our anonymized research database, 119 subjects with SSc-ILD (mean age 48±10.6 years and 70.7% ±14.3 of FVC) underwent baseline CT scans with high-resolution, volumetric, 64 detectors in the prone position at full inspiration. The extents of fibrotic patterns were measured as a QLF score in 5 steps: 1) denoise images; 2) grid-sample at a fixed location; 3) convert the characteristics of intensities into texture features; 4) classify voxels as fibrotic or non-fibrotic patterns based on texture features and 5) report fibrotic voxels as percentages. Associations were tested by Spearman rank correlation.

Result: Correlations between pulmonary function test and QLF were similar in the previous study and this new cohort as shown below.

Conclusions: The quantitative fibrotic patterns in whole lung can be a useful prognostic metric of severity and the heterogeneity of distribution in fibrotic patterns in lobes can be used as an index.

1441 Transthoracic echocardiography and pulmonary artery pressure assessment in patients with COPD exacerbation

Seymon Stoezynski1, Katarzyna Mireta2, Grzegorz Brozek1, Ewa Sozanska1, Zbigniew Gasior2, Wladyslaw Pierzchala1. 1Department of Pulmonology SP CSR in Katowice, Medical University of Silesia, Katowice, Poland; 2R Department of Cardiology, GCM in Katowice, Medical University of Silesia, Katowice, Poland

Background: Transthoracic echocardiography (TTE) is accepted as screening tool for pulmonary hypertension (PAP), whereas it is rarely performed in COPD patients due to possible difficulties caused by hyperinflated lungs.

Aims and objectives: The aim of our study was to find out whether it would be possible to predict if TTE is capable to assess pulmonary artery pressure (PAP) in patients with COPD exacerbation.

Methods: 40 consecutive patients with COPD exacerbation were enrolled. TTE directed for diagnosis of RV dysfunction, pulmonary function tests, blood gases, six minute walking test and BORG scale were performed at baseline and after successful treatment.

Results: It was possible to perform TTE in 17 (42.5%) subjects on admission and in 26 (65%) at discharge. PAP was present in 88.2% pre-treatment, and in 80.8% post-treatment (PAP mean±±25 mmHg), and in 35.3% pre-treatment and in 52.9% post-treatment (RVSP±±35 mmHg). It was possible to measure PAP using RVSP in 94.1% patients pre-treatment, and in 96.2% post-treatment, whereas it was possible to measure RVSP in 58.8% patients pre-treatment before, and 65.4% post-treatment. Simple as well as multivariable analysis did not find predictive value (p<0.05) of the following parameters: FEV1, FVC, IC, RV/TLC, TLC, ITGV, TLCO/VA, pO2, pCO2, 6MWT distance, BORG scale, GOLD (BMI), pack-years, spumon purulence to prognose possibility of obtaining accurate TTE results.

Conclusions: TTE may be used as an ineffective tool in assessment of PAPmean and in much smaller extent in assessment of RVSP in patients with COPD exacerbation, but it still seems impossible to predict in which patients it would be possible to perform accurate TTE.

1442 Mean eccentricity index strongly reflects mPAP in patients with IPAH using CINE cardiac MRI

Andrew Swift1,2, Smitha Rajaram2, Robin Condliffe1, Helen Marshall2, Dave Capener2, Judith Hurdman3, Charlie Elliot3, David Kiel3, Jim Wild2. 1Cardiovascular Biomedical Research Unit, National Institute of Health Research, Sheffield, United Kingdom; 2Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom; 3Sheffield Pulmonary Vascular Disease Unit, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Introduction: Left ventricular systolic eccentricity index (eEI) measured at echocardiography has been shown to correlate with pulmonary artery pressure (PAP) in patients with pulmonary hypertension (PH). This study assesses the relationship of eEI, diastolic eccentricity index (dEI) and mean eccentricity index (mEI) with mPAP in patients with idiopathic pulmonary arterial hypertension (IPAH) using CINE cardiac MRI.

Methods: We studied 36 patients with IPAH who underwent RHC and MRI within

157. Epithelial cells: role in health and disease

1443 Late-breaking abstract: Activation of the macrophage inflammasome by TLR3 ligation potentiates release of IL-8 and IP-10 from alveolar type II epithelial cell cultures from asthmatic but not normal donors

Davide Grandolfo, Andrew Thorley, Teresa Tetley. Lung Cell Biology, National Heart & Lung Institute, Imperial College London, London, United Kingdom

Recognition of microbial ligands by Toll-like receptors is central to the innate immune response of the peripheral lung to infection. This study investigated the effect of TLR3 ligation on cytokine release by primary human alveolar type II epithelial (ATII) cells and macrophages (AMs) alone and in co-culture. We hypothesised that TLR3 ligation elicits a distinct cytokine profile in both cell types which is enhanced by co-culture. Monocultures and co-cultures of ATII cells and AMs were exposed to the TLR3 ligand PolyIC for 24h. Both cell lines released IL-8 and IP-10 in response to PolyIC; co-culture significantly potentiated their release 4- and 5.7-fold respectively (P < 0.0001). The potentiation was not ATII-AM cell contact dependent; addition of Poly IC treated AM conditioned medium to ATII monolayers maintained the response whereas conditioned medium from ATII cells did not induce potentiated release from AMs. To elucidate which macrophage-derived cytokines were responsible for the potentiated response, neutralising antibodies were added to conditioned medium from AMs prior to incubation with ATII monolayers. Results demonstrated that neutralization of inflammasome-related cytokines, IL-1β and IL-18, significantly inhibited release of IL-8 and IP-10 (Table 1).

In conclusion, our study demonstrates that TLR3 ligands activate the AM inflammasome, inducing release of IL-1β and IL-18 which potentiates the innate immune response of the alveolar epithelium.

1444 Compressive forces stimulate release of TGFβ2 from differentiated bronchial epithelial cell cultures from asthmatic but not normal donors

Christopher Grange, Patrick Dennison, Donna Davies, Peter Howarth. Division of Infection, Inflammation and Immunity, Southampton University School of Medicine, Southampton, Hampshire, United Kingdom

Bronchoconstriction induces mechanical stress in the airways and normal bronchial epithelial cells respond by inducing profibrogenic responses. No studies have examined whether these responses are similar in asthmatic and non asthmatic populations. We tested the hypothesis that primary bronchial epithelial cells from asthmatic and non asthmatic donors respond similarly to mechanical stress mimicking bronchoconstriction by release of TGFβ2.

**Methods:** Bronchial epithelial cells (from healthy (n=9) and asthmatic (n=9) volunteers were obtained at bronchoscopy, expanded and grown at an air liquid interface (ALI). These were apically compressed with 5% CO₂ in air (30cm water pressure) for 1 hour, or sham compressed. 24 hours later total TGFβ2 was measured by ELISA in the basolateral medium.

**Results:** After sham compression, TGFβ2 release was similar in ALI cultures from healthy (median (IQR) 203.4 (143.8-271.7) pg/ml) or asthmatic (245.5 (162.3-276.6)) donors (p=0.67). After active compression, TGFβ2 significantly increased in the asthmatic ALI culture medium (median (IQR) of 299.4 (205.4-365.0)) (p=0.68). This change amounted to a median (IQR) difference of 29.7 (14.8-57.0) pg/ml in the asthmatic group and 11.6 (-35.6-48.7) in the healthy group (p=0.04).

**Conclusions:** Bronchial epithelial cells from asthmatic patients respond differently from normal cells to compressive force in vitro that mimics bronchoconstriction. This new finding suggests that there are at least two abnormalities in the asthmatic airway: the initial bronchoconstriction, and the epithelial response to it.

1445 SIRT6-induced activation of autophagy inhibits CSE-induced bronchial epithelial cell senescence

Naki Takaoka1, Jun Araya1, Hironori Hara1, Satoke Fujii1, Yoko Yumino1, Takatori Munata1, Makoto Kawashir1, Jun Hiroma1, Makoto Ootaka2, Toshikazu Morikawa3, Katsumi Nakayama1, Kazuyoshi Kuwano1. 1Division of Respiratory Diseases, Department of Internal Medicine, Jikei University School of Medicine, Minato, Tokyo, Japan; 2Division of Chest Diseases, Department of Surgery, Jikei University School of Medicine, Minato, Tokyo, Japan

**Introduction:** Senescence has been implicated in the pathogenesis of COPD, and tobacco smoke is known to induce cellular senescence. SIRT6, a class III histone deacetylase (HDAC), has been demonstrated to potentially antagonize cellular senescence. Autophagy, a lysosomal degradation pathway, is associated with cellular senescence.

**Aim:** To elucidate the regulatory role for SIRT6 in autophagy activation in terms of tobacco smoke-induced cellular senescence.

**Methods:** Primary HBEFC were used for the experiments. Senescence associated beta-galactosidase (SA-b-gal) staining and western blotting of p21 were performed to evaluate cellular senescence. SIRT6 expression vector and siRNA were transfected into HBEFC. To characterize autophagy, fluorescence microscopic detection of LC3-EGFP dot formation and western blotting for LC3, p62 were performed. Results: CSE-induced cellular senescence was inhibited by SIRT6 overexpression, while SIRT6 knock down increased the percentage of SA-b-gal positive cells. SIRT6 overexpression increased autophagy activation as shown by formation of LC3-EGFP dot and increased conversion from LC3-I to –II at basal level after CSE treatment. In contrast, SIRT6 knock down repressed autophagy activation. Furthermore, SIRT6-induced autophagy potentiated the accumulation of p62 expression after CSE treatment. SIRT6-induced autophagy regulated CSE-induced cellular senescence, because autophagy inhibition by knock down of LC3 diminished anti-senescence effect of SIRT6 overexpression.

**Conclusion:** These findings suggest the pivotal regulatory role of SIRT6 in autophagy activation and CSE-induced cellular senescence. SIRT6 might be a target molecule for the treatment of COPD.

1446 A three miRNA signature regulates the CF transmembrane conductance regulator (CFTR) in cystic fibrosis airway epithelium

Irene Oglesby1, Shane ONeill1, Noel McElvaney1, Catherine Greene2. 1Respiratory Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; 2Respiratory Medicine, Beaumont Hospital, Dublin, Ireland

Expression profiling studies have identified altered miRNA patterns in several human diseases, however little is known of the role miRNA play in cystic fibrosis (CF). Here we examined the impact of altered miRNA expression in CF bronchial epithelium on CFTR expression.

We performed miRNA expression profiling on bronchial brushings taken from five CF and five non-CF individuals by qRT-PCR using Taqman Low Density Arrays (TLDA). Expression of altered miRNA was validated by qRT-PCR in additional brushings and in vitro in CF and non-CF bronchial epithelial cell lines. CFTR gene expression was also measured. miRNA inhibition and over-expression studies were performed in CFBE41o- and 16HBE14o- cell lines respectively in vitro and CFTR mRNA and protein was detected by qRT-PCR and western blot.

Of the 667 miRNA examined 56 were down-regulated and 36 up-regulated in CF. Here we examined the impact of altered miRNA expression in CF bronchial epithelium on CFTR expression.

1447 IL-17A induces glucocorticoid insensitivity in airway epithelial cells

Jan Zijlstra1, Nick ten Hacken2, Roland Hoffmann1, Antoon van Oosterhout1, Irene Heijink1. 1Pathology and Medical Biology, University Medical Center Groningen, Groningen, Groningen, Netherlands; 2Pulmonology, University Medical Center Groningen, Groningen, Netherlands

Glucocorticoids (GC) are the cornerstone of asthma treatment. However, a subset of asthmatic patients is insensitive, which is a problem in the management of asthma. Previous studies suggest that GC-insensitivity is associated with Th17 cells. Th17
cells act by producing inflammatory cytokines, including IL-17A. We aimed to assess whether IL-17A reduces GC sensitivity in airway epithelial cells and to elucidate the underlying mechanism.

We investigated the effect of IL-17A on the suppressive effect of budesonide (BUD) (10^{-5}-10^{-10} M) on TNF-α-induced IL-8 secretion and on Histone Deacetylase (HDAC) activity in the human bronchial epithelial cell line 16HBE with/without specific inhibitors for the ERK, p38 and PI3K pathways and upon overexpression of HDAC2.

We observed that IL-17A-induced IL-8 secretion is normally sensitive to GC in 16HBE, in contrast pre-treatment with IL-17A (2h) significantly reduces the sensitivity of TNF-α-induced IL-8 secretion to BUD. Immunodetection revealed that IL-17A activates the p38, ERK and PI3K pathways, but only inhibition of PI3K signaling reversed this GC-insensitivity. Our data suggest that IL-17A-induced GC-sensitivity is mediated by a reduction in HDAC2 activity, as IL-17A reduced HDAC activity, while overexpression of HDAC2 reversed IL-17A-induced GC-insensitivity. In contrast, IL-17A did not affect BUD-induced transcriptional activity, suggesting that IL-17A does not impair translocation of the ligated GC-receptor.

In conclusion, we show that IL-17A increases GC-insensitivity in bronchial epithelium which likely involves PI3K-dependent reduction in HDAC2 activity. IL-17A-induced GC-sensitivity may thus serve as a new target for therapeutic intervention in GC-insensitive asthma.

### 1448 Corticosteroid-dependent transcription is reduced by inflammatory stimuli in human airway epithelial cells: Rescue by long-acting β₂-adrenoceptor agonists

**Author:** Christopher Rider, Elizabeth King, Neil Holden, Mark Giemmbycz, Robert Newton. *Airways Inflammation Research Group, University of Calgary, Robert Newton; 2Childrens Hospitals and Clinics of Minnesota, Minneapolis, United States of America; 3Department of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, Minnesota, United States of America; 4Department of Medicine, University of Toronto, Toronto, Ontario, Canada; 5Framingham Heart Study, Framingham, MA, United States of America; 6Department of Epidemiology and Biostatistics, University of Toronto, Toronto, Ontario, Canada; 7Department of Medicine, University of British Columbia, Vancouver, BC, Canada.

**Rationale:** Inhaled corticosteroids (glucocorticoids) are the most effective treatment for inflammatory diseases such as asthma. However, in some patients with severe disease, or who smoke, or suffer from COPD, these drugs are less effective. While many investigators focus on the repression of inflammatory gene expression, corticosteroids also induce the expression (transactivation) of numerous genes to elicit anti-inflammatory effects.

**Results:** Using human bronchial airway epithelial, BEAS-2B, and pulmonary, A549, cells, we show that tumour necrosis factor (TNF) α, interleukin (IL)-1β, fetal calf serum (FCS), phorbol ester, cigarette smoke extract and a Gαδ-linked G-protein coupled receptor agonist, all attenuate simple glucocorticoid response element (GRE)-dependent transcription. With TNFα and FCS, this was not overcome by increasing concentrations of dexamethasone, budesonide or fluticasone propionate. Thus, maximal GRE-dependent transcription was reduced and this was confirmed for the glucocorticoid-induced gene, p57KIP2. Long-acting β₂-adrenoceptor agonists (LABAs), formoterol fumarate and salmeterol xinafoate, enhanced simple GRE-dependent transcription to a level that could not be achieved by glucocorticoid alone. In the presence of TNFα or FCS, which repressed corticosteroid responsiveness, LABAs restored corticosteroid-dependent transcription to that achieved by corticosteroids alone.

**Conclusions:** The transactivation of transactivation represents a mechanism to explain corticosteroid resistance and its reversal may explain the clinical benefit of LABAs as an add-on therapy in asthma and COPD.

**Funded by AstraZeneca.**

### 1449 Azithromycin fails to restore apoptosis in cystic fibrosis airway epithelium

**Author:** Erika Sutanto, Simone Caleo, Erika Sutanto2,3, Clara Foo1,2, Anthony Kicic1,2,3, Stephen Stick1,2,3, Erika Sutanto2,3, Clara Caleo1,2, Anthony Kicic1,2,3, Stephen Stick1,2,3, Wim Janssens1. *Funded by AstraZeneca.*

**Rationale:** Airway epithelium is primary target for respiratory viruses, especially human rhinovirus (HRV). Apoptosis as early host defense mechanisms is induced in response to viral infection. We have previously observed damped apoptotic & increased viral replication in cystic fibrosis (CF) airway epithelium compared to healthy controls. Azithromycin induces innate immune responses in non-CF epithelium. We hypothesize that addition of azithromycin to HRV-infected CF epithelium which likely involves PI3K-dependent reduction in HDAC2 activity.

**Conclusions:** The repression of transactivation represents a mechanism to explain corticosteroid resistance and its reversal may explain the clinical benefit of LABAs as an add-on therapy in asthma and COPD.

**Funded by AstraZeneca.**

### 158. Exercise training: new populations, new techniques

**1451 Preliminary results of pulmonary rehabilitation in interstitial lung diseases: A randomised controlled trial B32220095560**

Silvia Pérez Bogerd1, Wim Wuyts1, Veronica Barbier1, Daniel Lange1,2,3, Chris Burin1,2, Hans Van Remoortel1,2,3, Marc Decramer1, Thierry Troosters1,2,3, Wim Janssens1. *1Pulmonary Rehabilitation and Respiratory Division, UZ Gent/Ghent University, Ghent, Belgium; 2Faculty of Kinesiology and Rehabilitation Sciences, Katholieke Universiteit Leuven, Leuven, Belgium.*

**Background:** Pulmonary rehabilitation (PR) is an excellent therapeutic option in chronic lung diseases, however there are little data on PR in interstitial lung diseases (ILD).

**Aims:** To report preliminary 3month outcomes of a randomised controlled trial evaluating the effects of PR on exercise capacity (Six Minute Walking Distance, 6MWD; Peak Work Rate, Wmax), quality of life (SGRQ, CRDQ) and muscle force (QF) in 50 ILD patients over 1year.

**Method:** Patients were randomly assigned to receive a PR program or usual medical care. Mean changes in outcomes were compared between the study arms.

**Results:** 3month data are currently available in 34 patients (table 1). 6MWD and Wmax increased significantly in the PR group compared to the control group (mean differences 67m [95%CI 34 to 101m] (figure 1) and 16W [95%CI 5 to 26W]). An improvement in QOL was also observed (SGRQ -12.5 [95%CI 18 to -7] and CRDQ 17.5 [95%CI 12 to 23]). Improvements in QF between both groups did not reach statistical significance (p=0.06).

**Table 1. Baseline characteristics of patients. Data as mean ± SD**

**Conclusion:** Although CF are more susceptible to HRV1b infection, the damped apoptotic response seen in CF epithelium after HRV infection cannot be restored with pre or co-treatment with azithromycin. The increased production of IL-8 observed post viral infection was not ameliorated following macrolide treatment.

**Funding:** NHMRC, ARC, ACFRT.
in conventional training, which shows that this device can be used with a more accessible option for resistance training in COPD.

1454 Non-linear exercise training is the preferred training method in patients with severe COPD
Peter Klijn1, Henk van Steeg2, Ton van Keimpema1,3, Rik Gosselink4, 1Department of Pulmonology, Asthma Center Heidehuij, Hilversum, Netherlands; 2Jüts Center for Health Sciences and Primary Care, University Medical Center, Utrecht, Netherlands; 3Department of Pulmonology, Academic Medical Center, Amsterdam, Netherlands; 4Respiratory Rehabilitation, Katholieke Universiteit Leuven, Leuven, Belgium

Methods: COPD patients underwent exercise training 3-times/ wk for 12 weeks and were randomized to either NLE [N=36; FEV1, 31±9.2% pred, 61±7.1 yr, fat-free mass (FFM) index 15.4±2.6 (kg FFM/m²)] or combined endurance and progressive resistance training (Spruit et al EJR 2002) [EPR N=36; FEV1, 33±9.5% pred, 61±4.5 yr, FFM-index 15.2±2.3 (kg FFM/m²)]. NLE: resistance training with varying repetition zones based on maximum load (1RM): strength 1-3, 4-6, 8-10 reps, 50-85% 1RM; local muscle endurance 12-15, >20 reps, 30-50% 1RM; ergometer training with varying intensity zones (%maximum workload (Wmax) from maximum exercise test: 65%, 85%, 90%, 85%, 80%).

Results: After 12 weeks cycle endurance time at 75%Wmax increased in both groups with significant larger improvements with NLE training (387±158 to 1049±244sec) compared to EPR (384±268 to 631±364sec) p<0.001. The NLE group showed significant larger improvements compared to EPR for dyspnea 1,6±1.3 vs 0,1±0.1 and fatigue 1,4±1 vs 0.6±1.2 domains of Chronic Respiratory Questionnaire (p<0.01). Both groups showed similar improvements for emotional functioning 0.3±0.9 vs 0.8±1.1 and mastery 0.1±0.2 vs 0.1±1.2.

Conclusion: NLE is the preferred method of exercise training in patients with severe COPD compared to the present guideline based method because of better improvement of both endurance and health-related quality of life.

1455 Effects of whole body vibration in patients with COPD: A randomized study
Biyathy Sat, Eric Derron. Department of Respiratory Medicine, University Hospital Ghent, Ghent, Belgium

Introduction: Besides conventional resistance training (CRT), whole body vibration (WBV) has been shown to be effective. Effects of WBV in COPD patients have not been assessed so far.

Aim: To compare, the effects of WBV with those obtained by CRT on exercise capacity, muscle force and QoL.

Methods: Patients with COPD, referred for pulmonary rehabilitation, were randomized in one of two training groups. Patients in CRT group performed resistance training on multigym equipment and patients in WBV group trained on a FITVIBE.

Results: 70 patients with COPD, showed at baseline an impaired exercise capacity, muscle force and QoL, no significant differences were seen between groups. Both groups improved the exercise capacity, muscle force and QoL over time. There were no significant differences after training.

1456 Home-based rehabilitation program for lung cancer patients
Valentine Coats, François Maillais, Sébastien Simard, Éric Frechette, Didier Sacy. Pneumologie, Centre de Recherche de l’Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec, QC, Canada

Patients with lung cancer often experience a reduction in exercise tolerance and muscle weakness. Despite the well-recognized effectiveness of pulmonary rehabilitation, few researches have studied its impact in lung cancer patients, particularly among those awaiting for a lung resection surgery (LRS).

Objectives: To investigate the feasibility of a short home-based rehabilitation program (HHRP) in patients with lung cancer awaiting for a LRS and to determine its effectiveness on exercise tolerance and skeletal muscle strength.

Methods: Ten patients with lung cancer awaiting for a LRS were invited to a
159. Biomarkers and outcomes of community-acquired pneumonia

PI459 Does the serum C-reactive protein (CRP) predict adverse outcomes in patients admitted with community acquired pneumonia?
Gareth Walters, Hon Sum Liu, Monika Gemza, Farrukh Rauf. Respiratory Medicine, Worcestershire Royal Hospital, Worcester, United Kingdom

BTS guidelines on management of community acquired pneumonia suggest that failure of C-reactive protein (CRP) to resolve by ≥50% during admission predicts complication. We aimed to see whether a high CRP ≥50% at ≥24 days increases probability of effusion and death but is not a reliable marker of empyema or ITU admission.

In order to determine if some marker that can help us to predict complications in patients admitted with community-acquired pneumonia (CAP), we prospectively included 228 patients and studied leukocyte count (WBC), C-reactive protein (CRP), procalcitonin (PCT) and midregional proadrenomedullin (MR-proADM) in the first 24 hours of their admission. One hundred and forty six (64%) patients suffered 310 significant complications including 22 patients and studied leukocyte count (WBC), C-reactive protein (CRP), procalcitonin (PCT) and midregional proadrenomedullin (MR-proADM) in the first 24 hours of their admission.

In ROC analysis the best AUCs were PSI 0.729 and MR-proADM 0.706. The optimal cut-off to predict complications for MR-proADM was 0.833 mmol/L (sensitivity 67.3%, specificity 66.2%, positive likelihood ratio (LRH) 1.99 and negative likelihood ratio (LHR) 0.49. Findings for PSI class 4 and 5 were sensitivity 72.3%, specificity 62.3%, LRH 1.92 and LHR -0.44. Similar results were obtained when we compared patients with and without only respiratory complications. PCT and CRP, and especially MR-proADM and PSI score, appear to be useful in early identification of patients at risk for complications during hospitalization.
We studied the accuracy of white blood count (WBC) and 3 biological markers, C-Reactive Protein (CRP), Procalcitonin (PCT) and Proadrenomedulin (Pro-ADM) obtained in the admittance at Emergency Department, in predicting mortality of 224 patients hospitalized with Community Acquired Pneumonia (CAP).

ROC analysis showed that AUC for MR-proADM was significantly higher compared to those of PCT, CRP and WBC, and without significant differences when compared with PSI and CURB65.

Optimal cut-off to predict 30-day mortality for MR-proADM was 1.066 nmol/L. For 90 and 180-days mortality the optimal cut-off for MR-proADM was the same, 1.001 nmol/L, and for 1-year mortality, 0.998 nmol/L.

A logistic regression model combining MR-proADM levels with PSI score showed for 30-day mortality an optimal cut-off of 1.001 nmol/L, and for 1-year mortality, 0.998 nmol/L.

For 90 and 180-days mortality the optimal cut-off for MR-proADM was the same, 1.066 nmol/L, and for 1-year mortality, 0.998 nmol/L.

A threshold of PCT ≥ 0.5 rules out viral etiology with a very high negative predictive value. Legionella is associated with initial higher CRP. CPR and PCT do not allow to differentiate between viral or atypical etiology.

Background: Accurate severity assessment is important to guide initial management of patients with community-acquired pneumonia (CAP). Recognised severity scores may fail to recognise some high risk patients. Lactate is a powerful marker of sepsis but has not been studied in patients with CAP.

Methods: In a prospective study, arterial lactate was measured on admission in 855 patients with CAP. Recognised severity scores were calculated from admission data. The outcomes of interest were 30-day mortality and the need for mechanical ventilation or vasopressor support (MV/VS). The area under the receiver operator characteristic curve (AUC) and multivariable analysis adjusting for pneumonia severity were used to evaluate predictive markers.

Results: 30-day mortality increased with increasing arterial lactate level from 2.8% for lactate ≤2mmol/l, 17.9% for 2.1mmol/l-3.9mmol/l up to 30.8% in patients with lactate ≥4mmol/l (p<0.0001). Requirement for mechanical ventilation or vasopressor support increased with increasing lactate levels from 4.2% for lactate ≤2mmol/l, 15.6% for 2.1mmol/l-3.9mmol/l up to 36.4% in patients with lactate ≥4mmol/l (p<0.0001). Lactate had an AUC of 0.73 (0.70-0.77) for 30-day mortality, which was lower than that for CURB65-AUC 0.77 (0.74-0.80) and PSI-0.81 (0.78-0.84). Lactate had an AUC of 0.73 (0.70-0.77) for MV/VS which was equivalent to CURB65 and PSI.

Conclusion: A threshold of PCT ≥ 0.5 rules out viral etiology with a very high negative predictive value. Legionella is associated with initial higher CRP. CPR and PCT do not allow to differentiate between viral or atypical etiology.

P1463
Lactate is an independent marker of severity in hospitalised patients with community-acquired pneumonia
James D. Chalmers1, Aran Singanayagam2, Ahsan Akram2, Pallavi Mandal2, Gourab Choudhury3, Mavee Smuth1, Adam T. Hill2.
1MRC Centre for Inflammation Research, Queens Medical Research Institute, Edinburgh, United Kingdom; 2Department of Respiratory Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom

Background: Biometers - C-reactive protein (CRP) and procalcitonin (PCT) - in community-acquired pneumonia (CAP) could be useful to distinguish bacterial or viral etiology.

Objective: To analyse initial levels of PCT and CPR in hospitalised CAP according to etiological diagnosis.

Material and methods: Prospective observational study in 685 patients. The etiology of CAP was classified as bacterial, viral and atypical (Mycoplasma, Chlamydia, Chlamydia trachomatis and Chlamydia pneumoniae). We have calculated the cut-off points of PCT and CRP to differentiate bacterial or viral etiology and its diagnostic value through sensitivity (S), specificity (E), positive predictive value (PPV) and negative predictive value (NPV).

Results: An etiological diagnosis was reached in 295 (43%) patients: 203 (29.6%) bacterial - 118 S pneumoniae (51.1%) and 24 Legionella (11.8%), 12 (1.8%) virus and bacteria (2.3%) and 24 (3.5%) atypical. The comparison between Legionella vs S pneumoniae with a cut off PCT ≥ 2 and S:70%; E:59%; PPV:27%. NPP:90%. Atypical or Bacteria with a threshold of PCT ≥ 0.5 and S:89%; E:68%; PPV:22%. NPV:97%. Viruses vs Bacteria with a cut off PCT < 0.5 and S:8.9%; E:6%. PPV:12%. NPV:99%.

Conclusion: A threshold of PCT ≥ 0.5 rules out viral etiology with a very high negative predictive value. Legionella is associated with initial higher CRP. CPR and PCT do not allow to differentiate between viral or atypical etiology.
The aim of our study was to evaluate the impact of the inflammatory response on admission and time to reach clinical stability (TCS) in hospitalized patients with CAP. An observational, prospective study was performed on consecutive patients hospitalised for CAP from April to December 2010 at the Respiratory Dept., Policlinico Hospital, Milan, Italy. Cytokines were detected on blood samples collected within 24 hours from the admission with a high sensitivity immunoassay, and were classified as pro-inflammatory (IL6) and anti-inflammatory (IL4 and IL10). Gradients between the latter and the former were also calculated. Two groups of patients were identified: those who reached CS within 3 days from the admission (Group A) and the rest of the population (Group B).

A total of 43 subjects were prospectively enrolled (26 males; mean±SD age: 71±18 yrs). Cytokine values are shown in Table according to the two study groups.

Negative correlations were found between IL10/IL6 ratio and TCS (r = -0.372, p=0.014), as well as IL4/IL6 ratio and TCS (r = -0.312, p=0.042). An effective anti-inflammatory response seems to be a protective factor, whilst individuals showing unbalanced pro-inflammatory patterns take a longer time to recover. Further research is needed to assess the potential application of specific therapeutic agents in order to attenuate inflammatory damage.

**P1465** Biomarkers and community acquired pneumonia (CAP) severity

Ana Lasierra1, Sergio Fandos1, Elisa Mincholé1, Ana Lilian Simon1, Maria Angeles Ruiz2, David Nieto1, Elena Forcén1, Salvador Bello1. 1Pulmonology Department, Hospital Universitario Miguel Servet, Zaragoza, Spain; 2Clinical Biochemistry Department, Hospital Universitario Miguel Servet, Zaragoza, Spain; 3Microbiology Department, Hospital Universitario Miguel Servet, Zaragoza, Spain

To check if any biomarker can be useful to assess Community Acquired Pneumonia (CAP) severity, we studied white blood cells count (WBC), and levels of C Reactive Protein (CRP), Procalcitonin (PCT) and Proudenomedullin (MR-proADM), as well as PSI and CURB65 scores from 228 patients with CAP within the first 24 hours of their admission in our hospital.

MR-proADM correlated better with both severity scores than other biomarkers, and was the only biomarker able to distinguish among all different risk classes of PSI score (p<0.05 for every of the two groups comparisons, see figure 1 and 2). ROC analysis for discrimination between low risk (PSI 1-3) from high risk (PSI 4-5) CAP showed that MR-proADM had the best AUC (0.811) and could be considered a good predictor of CAP severity (see figure 1 and table 1). Optimal cut-off of MR-proADM of 0.646 mmol/L showed a sensitivity of 92.1%, specificity 55.1%, positive predictive value 76.2%, and negative predictive value 80.3% for severe CAP.

**MR-proADM can be helpful, together with validated clinical scores, to identify CAP severity in the first hours of patient’s management.**

**P1466** Biomarkers to discriminate bacterial, viral and mixed community acquired pneumonia (CAP)

Elsa Mincholé1, Ana Lasierra2, Ana Lilian Simon1, Sergio Fandos1, Maria Angeles Ruiz2, Virginia Moya1, Francisco De Pablo1, Salvador Bello3. 1Pulmonology Department, Hospital Universitario Miguel Servet, Zaragoza, Spain; 2Clinical Biochemistry Department, Hospital Universitario Miguel Servet, Zaragoza, Spain; 3Microbiology Department, Hospital Universitario Miguel Servet, Zaragoza, Spain

To find out if C Reactive Protein (CRP), Procalcitonin (PCT) and Proudenomedulin (Pro-ADM) are able to discriminate different CAP etiologies, we collected biological samples from 228 patients admitted in our hospital with CAP in the first 24 hours. Average age: 73 years, 61% males. We performed a complete microbiological searching, and found at least one pathogen in 155 (67.98%) patients. Fifty seven were typical bacterial CAP, 57 viral or atypical 41 were mixed (virus + bacteria).

**Results:**

- **PCT** was the only biomarker that showed significant differences (p<0.0001) between typical bacterial CAP (2.402 ng/mL) and viral/atypical bacterial CAP (0.272 ng/mL). Also, was the only biomarker that discriminated (p=0.007) viral pneumonia from mixed pneumonia (1.568 ng/mL).
- **PCT** and CRP levels in viral CAP showed significant differences (p<0.0001 and p=0.046 respectively) when compared to the other etiologies grouped together (typical bacterial + mixed).
- **A PCT cut-off of 0.255 ng/mL identified typical bacterial involved CAP (bacterial and mixed) from viral/atypical ones, with a sensitivity of 74.23% and a specificity of 50%.

**Conclusion:** CRP, and especially PCT, seem to be useful in early identification of typical bacteria-involved CAP, including those in association with viruses.

**P1467** The ability of pro adrenomedullin to predict severe sepsis in patients with community-acquired pneumonia

Ane Uranga1, Pedro Pablo España1, Alberto Capelastegui1, Inmaculada Gorordo1, Rosa Díez1, Amaia Bilbao2, Carmen Mar3, Edurne Bereciartu4, Edurce Bereciartu5. 1Pneumology, Hospital of Galdakao, Galdakao, Vizcaya, Spain; 2Basque Foundation for Health Innovation and Research, Basque Foundation for Health Innovation and Research, Sondeka, Vizcaya, Spain; 3Biochemistry, Hospital of Galdakao, Galdakao, Vizcaya, Spain; 4Microbiology, Hospital of Galdakao, Galdakao, Vizcaya, Spain

**Objective:** The aim of this study was to compare the ability that validated predictive rules (PSI and CURB65) and the new biomarker Pro adrenomedullin (proADM), had to predict severe sepsis.

**Methods:** We prospectively included patients over 18 years old for a period of one year. PSI and CURB65 scores were estimated to all of them on admission. Blood samples were collected at the time of diagnosis to determine proADM
Results: 685 patients were included: 40 of them with bacteremia. The medians of CRP, PCT, TNF-α and IL-6 were significantly higher in those with bacteremia (Table 1). PCT ≥36 to predict positive blood cultures showed sensitivity (S) of 85%, specificity (E) 42% and negative predictive value (NIVP) of 98% (ROC area 0.70). The threshold of IL-6 ≥ 150 for predicting bacteremic CAP showed: 60% sensitivity, 70% and 96% negative predictive value (ROC area 0.65).

Conclusions: Bacteremic CAP is associated with higher inflammatory cytokines systemic. PCT showed the highest diagnostic value. A cutoff ≥0.36 has high sensitivity. Lower initial PCT levels rule out bacteremic CAP with a high negative predictive value.

P1470

C-reactive protein (CRP) utility in severe community-acquired pneumonia (SCAP) prognosis

Alexander Makarevich1, Oksana Omelyanenko1, Elena Amelchenko2, Tatjana Rybina2,1

11st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus

Background: Among SCAP patients mortality is usually high, especially in those requiring invasive mechanical ventilation (IMV) or vasopressor support (VS). We aimed to assess CRP on admission and 6th day values association with mortality and adverse outcomes in SCAP patients requiring intensive care unit (ICU) admission.

Methods: 30 ICU patients with SCAP (CURB-65 class 3,4) were enrolled. Control group included 16 healthy volunteers. X-ray examination, CRP levels measurement were performed on admission and on day 8. The main endpoints were in-hospital outcomes (in-hospital mortality (IH), duration of ICU stay (DICUS), necessity of IMV and VS). Results: CRP values correlated with CURB-65 score (p=0.8, p<0.05 and r=0.76; p<0.05 respectively) and were statistically different in CURB-65 class 3 and 4 patients (p<0.05). CRP levels were higher in non-survivors vs survivors [median] [311 vs 24mg/ml, p<0.05 respectively] on the 1st and 8th days [249 vs 89 mg/ml, p<0.05 respectively], revealed correlation with IHM (r=0.64, p<0.05 and r=0.6; p<0.05 respectively). Longer DICUS was associated with higher CRP values on admission (r=0.43, p<0.05). CRP on the 1st day correlated with necessity of VS and IMV (r=0.79; p<0.05 and r=0.63; p<0.05 respectively), their values appeared to be higher in patients requiring VS and IMV vs those who didn’t need them [311 vs 244 mg/ml respectively, p<0.05]. Negative X-ray dynamics was associated with increased CRP levels on the 1st day (r=0.55; p<0.05).

Conclusions: Increased CRP values in SCAP patients requiring ICU admission are associated with disease severity, negative X-ray dynamics and could be used for identifying patients with high IHM risk, prediction of DICUS, necessity of VS and IMV.

P1471

Biomarkers in severe community-acquired pneumonia (SCAP) prognosis, complications and outcomes

Oksana Omelyanenko1, Alexander Makarevich1, Elena Amelchenko2, Tatjana Rybina2,1

11st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus

Background: Early prognostic assessment is crucial for SCAP patients management. We studied accuracy of C-reactive protein (CRP), interleukin-2 (IL-2), interferon-γ (INF-γ), free triiodothyronine (T3), free tetraiodothyronine (T4), thyroid stimulating hormone (TSH), total cortisol (TC) in predicting SCAP hospital mortality and disease severity, outcomes, complications, need for invasive mechanical ventilation (IMV) and vasopressor support (VS).

Methods: 30 ICU patients with SCAP CURB-65 class 3-5 were enrolled. Control group included 16 healthy subjects. X-ray examination, serum markers measurement were performed on the 1st day after admission.

Results: CAP severity was associated with enhanced CRP (r=0.8, p<0.05), IL-2 (r=0.64; p<0.05), TC (r=0.87; p<0.01), decreased T3 (r=-0.75; p<0.05) values. Non-survivors revealed higher CRP/L-2, TC, lower T3, TSH levels vs those in survivors [median: 11 vs 24mg/ml, p<0.05], [138 vs 8.9 pmol/l, p=0.03], [1377 vs 865 pmol/l, p=0.03], [2.8 vs 4.6 pmol/l, p<0.05], [0.89 vs 2.6 nmol/l, p=0.03]. Necrotising pneumonia developed in patients with decreased IL-2, T4 values (r=0.6, p=0.04 and r=0.48, p=0.03) pleural effusion - in those with enhanced INF-γ levels (r=0.8, p=0.01). IL-2/CRP/Tc values were higher in patients requiring VS [122 vs 19 pg/ml, p=0.04], [311 vs 232 mg/ml, p=0.05], [1377 vs 865 pmol/l, p=0.03]. Enhanced CRP, low T3 levels were associated with IMV requirement (r=0.63; p<0.05 and r=0.71; p<0.05). Duration of ICU stay correlated with TC, CRP values (r=0.89; p=0.01 and r=0.43; p=0.04) length of hospitalisation - with TSH, T4 (r levels 0.56, p=0.01 and r=0.14, p=0.05).

Conclusions: CRP, thyroid hormone, TC, IL-2, INF-γ can augment early prognostic assessment of SCAP pts.
Comparison of inflammatory response biomarkers to predict complications in hospitalized patients with community-acquired pneumonia

Anne Urga1, Pedro Pablo España1, Alberto Capelastegui1, Inmaculada Gorordo1, Rosa Diez2, Amaia Bilbao2, Carmen Mar2, Edurne Bereciartua1, 2*, Pneumology, Galdakao Hospital, Galdakao, Vizcaya, Spain; 2Basque Foundation for Health Innovation and Research, Basque Foundation for Health Innovation and Research, Sondika, Vizcaya, Spain; 3Biochemistry, Galdakao Hospital, Galdakao, Vizcaya, Spain; 4Microbiology, Galdakao Hospital, Galdakao, Vizcaya, Spain

Background: Recently, an extensive research has gone into identifying the predictive value of biomarkers for complications in community-acquired pneumonia (CAP).

Objective: The aim of this study was to evaluate the utility of inflammatory biomarkers measured on admission in hospitalized patients with CAP.

Methods: We prospectively included patients over 18 years old for a period of one year. Procalcitonin (PCT), C reactive protein (CRP) and Pro adrenomedullin (ProADM) were compared in predicting complications occurred in the follow-up of 30 days. Mortality, severe sepsis, ventilation and/or septic shock and ICU/ICU admission were the complications analyzed. For the comparison of biomarkers, the nonparametric Wilcoxon test was used, whereas AUC was used to measure the predictive ability of each biomarker.

Results: A total of 320 patients with diagnosis of CAP were included in our study and samples for biomarkers could be extracted in 258 of them. Table 1 shows the results of the comparison of the biomarkers according to each outcome, and the AUC values. Biomarkers are described as median and interquartile range.

Conclusions: ProADM is a powerful tool for the prediction of mortality and other complications in hospitalized patients with CAP. In addition, we found that PCT has the greatest predictive value for complications such as ventilation/shock or ICU/ICU admission.

P1474 Interleukin-2 (IL-2) and Interferon-γ (IFN-γ) in identifying severe community-acquired pneumonia (SCAP): clinical outcomes and complications

Alexander Makarevich1, Oksana Omelyanenko1, Elena Amelchenko2, Tatyana Rybina2.

11st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus

Background: Exaggerated and protracted proinflammatory response is associated with poor prognostic implications in SCAP. We assessed the diagnostic value of IL-2 and IFN-γ in identifying SCAP-in-hospital outcomes and complications.

Methods: 30 SCAP patients CURB-65 class 3-4 were enrolled. Control group included 16 comparable healthy volunteers. We performed X-ray examination, IL-2 and IFN-γ measurement within the first 24 hours after admission and on day 8. In hospital mortality (IHM), need for vasopressor support (VS), SCAP complications (necrotising pneumonia (NP), pleural effusion (PE)) were analyzed.

Results: Increasing CAP severity was associated with increased IL-2 values both on the 1st day (r=0,64; p<0,05).IL-2 on admission values correlated with IHM (r=0,67; p<0,05). Patients with poor clinical prognosis had higher IL-2 levels on the 1st day vs those who survived [median]138 vs 20,8 pg/ml, p<0,05 respectively]. IL-2 on admission correlated with need for VS (r=0,65; p<0,05) and revealed higher concentrations in patients requiring VS vs those with stable haemodynamics [122 vs 19pg/ml, p=0,05]. Patients who developed NP showed lower IL-2 levels vs those without destructive lung changes [16 vs 26 pg/ml, p<0,05]. PE in SCAP patients correlated with enhanced IFN-γ levels on the 1st and 8th days (r=0,8; p<0,01 and r=0,69; p=0,02). Patients with PE demonstrated higher IFN-γ values [41 and 20 pg/ml, p=0,031] vs those without PE [0,3 and 3,8 pg/ml, p<0,05].

Conclusions: IL-2 on admission values are reliable for mortality risk stratification, prediction of need for VS and NP development, IFN-γ could be helpful in identifying PE complication in SCAP patients.

P1475 Thyroid hormones implication in severe community-acquired pneumonia (SCAP): Relationship with survival, outcomes and clinical complications

Oksana Omelyanenko1, Alexander Makarevich1, Elena Amelchenko2, Tatyana Rybina2.

11st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus

Background: The low thyroid hormone levels in the absence of primary thyroid disease have proved to be predictive of outcomes and disease severity in critical illness. We aimed to assess thyroid function in SCAP patients requiring intensive care unit (ICU) admission and it’s association with in-hospital outcomes, SCAP complications, need for invasive mechanical ventilation (IMV) and vasopressor support.

Methods: 40 ICU patients with SCAP CURB-65 class 3-5 were enrolled. Control group included 16 healthy subjects. X-ray examination, free triiodothyronine (T3), free tetraiodothyronine (T4), thyrotropin (TSH) levels were compared in predicting complications occurred in the follow-up (necrotising pneumonia (NP), pleural effusion (PE)) were analyzed.

Results: FT3 initial values decreased with increasing severity of CAP (r=0,75; p<0,0007). FT3 and TSH levels were lower in non-survivors vs in survivors [median]138 vs 20,8 pg/ml, p<0,05 respectively]. IF-γ levels on admission were higher in non-survivors vs those with stable haemodynamics [122 vs 19pg/ml, p=0,05]. Patients who developed NP showed lower IL-2 levels vs those without destructive lung changes [16 vs 26 pg/ml, p<0,05]. PE in SCAP patients correlated with enhanced IFN-γ levels on the 1st and 8th days (r=0,8; p<0,01 and r=0,69; p=0,02). Patients with PE demonstrated higher IFN-γ values [41 and 20 pg/ml, p=0,031] vs those without PE [0,3 and 3,8 pg/ml, p<0,05].

Conclusions: Thyroid hormone levels in SCAP patients are reliable markers of diseases severity, high risk of IHM and NP development and can be helpful in identifying patients requiring IMV and predicting length of in-hospital stay.

P1476 Pro-adrenomedullin, procalcitonin and CRP levels to predict bacterial pneumonia in patients admitted to emergency room

Alicia Lacoma1,3,4, Cristina Prat1,3,4, Pere Tudela2,3, Montse Giménez1,3, Vicente Asuina1,3,4, Servi de Microbiologia, Hospital Universitari Germans Trias i Pujol, Institut en Ciències de la Salut “Germans Trias i Pujol”, Badalona, Spain; 2Unitat Curta Estada- Urgències, Hospital Universitari Germans Trias i Pujol. Institut en Ciències de la Salut “Germans Trias i Pujol”, Badalona, Spain; 3Universitat Autònoma de Barcelona, Badalona, Spain; 4CIBER Enfermedades Respiratorias, Instituto de Salud Carlos III, Badalona, Spain

Objectives: To assess if MR-proADM, PCT and CRP levels can distinguish
bacterial pneumonia from other kind of lower respiratory tract infections (LRTI).

Methods: Patients with fever and respiratory symptoms that were admitted in emergency room (ER) and from whom blood cultures were drawn. After retrospective analysis, patients were classified as: pneumonia (n=85), chronic obstructive pulmonary disease (COPD) exacerbation (n=25) and bronchial infection (n=52). Four patients were admitted to ICU and 9 died.

Results: PCT showed significantly higher levels in pneumonia when comparing with COPD exacerbation (p=0.003) and bronchial infection (p=0.002). CRP only showed significantly higher levels when comparing pneumonia group vs bronchial infection (p=0.002). Finally, MR-proADM showed statistically higher levels when comparing pneumonia group with COPD exacerbation (p=0.014) and bronchial infection (p=0.006). PCT and MR-proADM showed significantly higher levels in cases of definite bacterial diagnosis in comparison to other diseases (p-value < 0.001). PCT and MR-proADM are significantly higher in patients admitted to ICU (p=0.011 and p=0.001). Regarding mortality, no significant differences were found.

Conclusions: PCT and MR-proADM show significantly higher levels in pneumonia in comparison to other lower respiratory tract infections. PCT and MR-proADM levels are increased in confirmed bacterial infections. Biomarkers measurement can be helpful for the management of patients admitted in ER with clinical symptoms of respiratory tract infection.

LSC 2011 Abstract: Molecular interplay between inflammation and occurrence of proliferation: Role of cadmium

Subhadip Kanda. Department of Zoology, University of Calcutta, Kolkata, West Bengal, IN

Department of Environmental Science, University of Kalyani, Kalyani, West Bengal, IN

Introduction: Cadmium is one of the inflammation-related xenobiotics with potent carcinogenicity. The mechanism between inflammation and cell proliferation due to chronic cadmium exposure has not been studied yet (Lau KT, et al., Toxicol Appl Pharmacol 2006).

Objectives: The present study was undertaken to determine molecular mechanism of inflammation linked cell proliferation due to cadmium exposure in mice and lung cancer cell line.

Methods: Swiss albino mice and A549 cell line were chosen for experiments. Levels of different cytokines, expression level of cell cycle regulatory proteins estimated by ELISA, western blot and immunoprecipitation. Other techniques used scanning electron microscopy, histopathology and Cytotoxic assay. Cell cycle analysis, DNA fragmentation assay and RT-PCR experiments.

Results: Prolonged exposure of low concentration of cadmium resulted in up regulation of proinflammatory cytokines and cell cycle regulatory molecules both in vivo and in vitro. Swiss albino mice (n=9, 30 ppm of CdCl2 for 90 days) and A549 NSCLC cell line (n=6) were treated with 1 µM and 10 µM of cadmium chloride respectively. Levels of inflammatory cytokines TNF-alpha, IL-6 and IL-8 were significantly higher in cadmium treated mice and cells. Levels of cell cycle regulatory proteins cyclin D1 and cyclin E were also higher in treated samples.

Conclusion: Cadmium promotes inflammation and cell proliferation in vivo and in vitro due to cadmium toxicity.

P1478

LSC 2011 Abstract: Cigarette smoke-induced inflammation promotes melanoma cell metastasis in lung parenchyma

Sandrine Bekaeart, Natacha Rocks, Maud Gueders, Geneviève Paulissen, Agnès Noel, Didier Cataldo. Laboratory of Tumor and Development Biology, University of Liège, Liège, BE

It is only during the last decade that clear evidence has been obtained that inflammation plays a critical role in different stages of tumor development, including initiation, promotion, malignant conversion, invasion and metastasis. There is increasing evidence that an inflammatory microenvironment is an essential component of all tumors (Paula and Lyden, Nat Rev Cancer, 2009 Apr;9(4):283-93). In the present study, we assessed in vivo the impact of cigarette smoke (CS) on the tumor cell extravasation in lungs after tail vein injection of B16F10 melanoma cells. We first characterized airway inflammation obtained after smoke exposure (reference smokers 3R4F) for varied time periods (1, 2, 4, 8 and 12 weeks). Smoke exposure was performed 5 days a week. Neutrophils, alveolar macrophages, interstitial macrophages, dendritic cells, T cells and natural killer T (NKT) cells, were characterized in lung tissues of mice exposed to CS and AIR using flow cytometry. In vivo, the direct effect of cigarette smoke extract (CSE) on proliferation of B16F10 melanoma cells was determined for 1 to 5 days. In vitro, mice exposed for 2 weeks to cigarette smoke or air were injected with B16F10 melanoma cells in the tail vein. After 3 weeks, hematoxylin-eosin staining allowed quantification of lung metastasis (tumor area/totul lung area). An increase of metastasis and implantation site in lungs was observed in CS exposed group. Conceivably, CS constitutes significantly promote extravasation of melanoma cells in lung tissues. The mechanism or signaling pathway responsible for this dissemination needs to be further investigated.

P1479

SK-216, an inhibitor of plasminogen activator inhibitor-1, limits tumor growth and lung metastasis formation probably through the reduction of tumor angiogenesis

Takeshi Masuda, Noboru Hattori, Koukusei Hamai, Shin Akita, Tadasu Seno, Hiroshi Iwamoto, Shinichiro Ohshimo, Masashi Kanekura, Nobuishi Ishikawa, Kazumori Fujitaka, Yoshihito Harata, Hiroshi Murai, Nobuo Kohno. Molecular and Internal Medicine, Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan

Introduction: Plasminogen activator inhibitor-1 (PAI-1), the main inhibitor of plasminogen activators, is known to be involved in tumor progression.

Objectives: To investigate whether a PAI-1 inhibitor, SK-216, can limit tumor growth and lung metastasis formation.

Methods: C57BL/6 mice were subcutaneously inoculated with Lewis lung carcinoma (LLC) cells and tumor volume (mm3) was measured twice a week until 2 weeks after the inoculation. The numbers of lung tumors were also counted 21 days after the injection of LLC cells through the tail vein. The mice were given either water or SK-216 (500 p.p.m.) in drinking water. In addition, the sections of tumor were stained with CD31 antibody, and the number of CD31-positive vessels was counted in three random microscopic fields per section.

Results: The volumes of subcutaneous tumors 14 days after the inoculation of LLC cells were significantly smaller in SK-216-treated group than those in control group (mean ± SD, 1566±515.9 mm3 and 2235±353.0 mm3, respectively; p<0.01). The numbers of lung surface tumors were significantly lower in SK-216-treated group than those in control group (3.3±4.1 and 12.1±7.3, respectively; p<0.02). The numbers of CD31-positive vessels in subcutaneous or lung tumor sections were statistically significantly lower in SK-216-treated group (60.5±15.9/field and 78.7±21.8/field, respectively; p<0.004: lung tumor; 24.0±7.9/field and 44.8±4.4/field, respectively; p<0.002).

Conclusion: These results suggest that SK-216 limits tumor growth and lung metastasis formation probably through the reduction of tumor angiogenesis.

P1480

The long non-coding MALAT-1 RNA indicates a poor prognosis in NSCLC and induces migration and tumor growth

Lars Henning Schmidt1, Tilman Speck2, Steffen Koschmieder1, Julia Humberg1, Antje Hascher1, Eitmar Bulk1, Alessandro Marri1, Ludger Hilligensen, Wolfgang Berdel2, Carsten Müller-Tidow1, Rainer Wiwrodk3

1Department of Medicine A, Hematology, Oncology and Pulmonary Medicine, Westfälische Wilhelms University, Albert-Schweitzer-Straße 33, Münster, Germany; 2Institute of Pathology, Westfälische Wilhelms University, Albert-Schweitzer-Straße 33, Münster, Germany; 3Department of Thoracic Surgery, Niels-Stensen-Klinik, Oesterrapen, Oesterrapen, Germany

Introduction: The functions of large long non-coding RNAs (lncRNA) have remained elusive in many cases. MALAT-1 (Metastasis-Associated-in-Lung-Adenocarcinoma-Transcript-1) is a lncRNA, that is highly expressed in several tumor types.

Methods: Overexpression and RNA interference (RNAi) approaches were used for the analysis of the biological functions of MALAT-1 RNA. Tumor growth was studied in nude mice. For prognostic analysis MALAT-1 RNA was detected on paraffin embedded lung cancer tissue probes (n=352) using in-situ hybridization.

Results: MALAT-1 was highly expressed in several human non-small cell lung cancer cell lines. MALAT-1 expression was regulated by an endogenous negative feedback loop. In A549 NSCLC cells, RNAi mediated suppression of MALAT-1 RNA suppressed migration and clonogenic growth. Forced expression of MALAT-1 in NIH 3T3 cells significantly increased migration. Upon injection into nude mice, NSCLC xenografts with decreased MALAT-1 expression were impaired in tumor formation and growth. In-situ hybridization on paraffin embedded lung cancer tissue probes revealed that high MALAT-1 RNA expression in squamous cell carcinoma of the lung was associated with a poor prognosis.

Conclusion: These data indicate that MALAT-1 expression levels are associated with patient survival and identify tumor promoting functions of MALAT-1.

P1481

Expression of miR-126 and miR-126′ in primary tumors and metastasis of adenocarcinoma and squamous carcinoma of the lung

Lina Cavalcão1, Sofia Reis2, Sofia Silva1, Paula Santos3

1Anatomia Patológica, Faculdade de Medicina Universidade de Coimbra, Coimbra, Portugal; 2Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologias da Universidade de Coimbra, Coimbra, Portugal; 3Imunologia, Centro de Neurociencia e Cell Biology, Coimbra, Portugal

MicroRNAs are a family of small non-coding RNAs that negatively regulate gene expression at post-transcriptional level. Their expression has been proved to be associated to cancer but several aspects of this association remain elusive.
miR-126 and miR-126* are processed from the same precursor microRNA and are down-regulated in non-small cell lung cancer (NSCLC). However, information is lacking regarding their involvement in metastatic potential and differential expression in adenocarcinoma and squamous carcinoma of the lung. In this study, these questions were approached by comparing microRNA levels in 37 samples of matched adjacent lung parenchyma, primary tumour and lymph node metastasis (when present). Each kind of tissue was isolated by laser microdissection and, after RNA extraction, the two microRNAs were quantified by RT-qPCR. Both miR-126 and miR-126* were found to be down-regulated in primary tumour cells comparatively to matched normal tissue (p-value<0.001). On the contrary, no significant differences were found between primary tumour and lymph node metastasis cells or between tumour cells of metastatic and non-metastatic samples. Although overall expression was similar in adenocarcinoma and squamous carcinoma, in non-metastatic tumors miR-126 and miR-126* expression was lower in squamous carcinoma (p-value=0.037 and p-value=0.035, respectively). These results suggest that these microRNAs might act as tumor suppressors but are not involved in the metastatic process. In addition, their expression seems to relate to the type of NSCLC in non-metastatic tumors and might therefore be useful for their characterization.

P1482
Expression and significance of VE-cadherin and E-cadherin in non-small cell lung cancer
Hong Chen, Juan Tao, Makoto Suzuki, Yan Li, Yong Wang. Department of Pulmonary Disease, The First Affiliated Hospital, Chongqing Medical University, Chongqing, China Department of Pulmonary Disease, The First Affiliated Hospital, Chongqing Medical University, Chongqing, China Department of Thoracic Surgery, Kamamoto University Hospital, Kamamoto, Japan Department of Pulmonary Disease, The First Affiliated Hospital, Chongqing Medical University, Chongqing, China Department of Pulmonary Disease, The First Affiliated Hospital, Chongqing Medical University, Chongqing, China

Objective: The aims of our study were to assess the expression of vascular endothelial cadherin (VE-cadherin) and epithelial cadherin (E-cadherin) in human non-small cell lung cancer (NSCLC) tissues and to correlate these expression levels with clinicopathological characteristics of NSCLC.

Methods: The expression levels of VE-cadherin and E-cadherin were examined by immunohistochemistry in NSCLC tissues from 39 patients and in 30 adjacent non-neoplastic tissues that were at least 5 cm away from the tumor tissues.

Results: The positive rates of VE-cadherin and E-cadherin in NSCLC were 51.3% (20/39) and 43.6% (17/39), respectively. The positive rate of E-cadherin in NSCLC was lower than in adjacent non-neoplastic tissues (73.3,22/30, P<0.05). The VE-cadherin expression level inversely correlated with lymph node metastasis (P<0.05).

Conclusions: We demonstrated the aberrant expression of VE-cadherin in NSCLC and the downregulation of E-cadherin expression. Both of these proteins are associated with lymph node metastasis. These results indicate that both of these proteins may take part in the growth and metastasis of NSCLC and thus may be therapeutic targets for the treatment of NSCLC.

P1483
Transcriptional regulation of the human osteopontin promoter in non-small cell lung cancer
Min Kwang Byun, Jung Ar Shin, Hyung Jung Kim, Yoon Soo Chang. Internal Medicine, Yonsei University College of Medicine, Seoul, Korea

Background: Elevated osteopontin (OPN) transcription often correlates with increased metastatic potential of transformed cells, and OPN has been shown to enhance metastatic ability. We hypothesized that transcription determines OPN expression, tried to find out response element resided in the DNA sequence element and suppression molecules.

Methods: We investigated the transcriptional regulation of OPN in non-small cell lung cancer cell lines. These elements were treated with pp2 (src tyrosine kinase inhibitor), FTI (Farnesyl transferase inhibitor), and 2BP (2 bromo palmitate) in order that confirm suppress transcriptional expression.

Results: Deletion and mutagenesis analyses of the OPN promoter region identified a proximal promoter element (–123 to –89) relative to the transcription initiation site) that is essential for maintaining high level of OPN expression in the tumor cells. Proximal promoter elements (–123 and –89) were treated with pp2, FTI and 2BP, whether if transcriptional expression could be suppressed by these molecules. In case of FTI, OPN expression was suppressed, but statistical significance wasn’t meaningful.

Conclusion: The proximal promoter element (–123 to –89) was essential for maintaining high level of OPN expression in non-small cell lung cancer cell lines. Further investigation for searching material to suppress OPN expression is needed.

Inhibitor of DNA-binding (Id) – 1 and 3 proteins overexpression has impact on prognosis of lung adenocarcinoma
Leila Antonello1,2, Thayla Tuma3, Francisco Vargas1, Edwin Parra1, Ricardo Terra1, Milene Accenio1, Lisete Teixeira1, Vera Capelozzi1,2. 1Pulmonary Division - Piracicaba Laboratory, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, Brazil; 2LM 03 - Clinical Laboratory, Pathology Department, University of São Paulo Medical School, São Paulo, Brazil; 3Pathology Department, University of São Paulo Medical School, São Paulo, Brazil; 4Thomai Surgery Division, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, Brazil

The inhibitor of DNA-binding (Id) are involved in cell cycle regulation, apoptosis and angiogenesis. Many authors suggest participation of Id genes in development and progression of large number of human cancer, but their role in lung cancer has not been evaluated.

Objectives: To evaluate Id 1, 2 and 3 expressions in lung adenocarcinoma in correlation to age and survival.

Methods: Ids were quantified in tumoral and non-tumoral tissues from 43 patients who underwent lobectomy for lung adenocarcinoma. Their preoperative clinical stages were $T_1$-$N_0$-$M_0$ and the mean follow-up was 26.7 months. Immunohistochemistry was applied to analyze the intensity of Ids expression in nucleus and cytoplasm (quantitative scores performed in 500 cells). The impact of these markers was tested on follow-up until death from recurrent lung cancer.

Results: Distinct profile of Ids expression was observed between tumoral and the matched adjacent nonmalignant tissue. Ids were significantly more expressed in tumoral cells. Patients whose tumor cells expressed lower scores of cytoplasm Ids tended to present better long-term survival (p=0.05). The Cox model controlled for age, gender and type of NSCLC.
P1487

Adenovirus-mediated AP-2α down-regulates MnSOD expression in lung cancer A549 cells and its molecular mechanism
Rui Zhou1, Yi He1, Ping Chen1, Guang-Sen Zhang 2, Shih-Hai Zou1.
1 Departments of Respiratory Medicine, The Second Xiangya Hospital, Central South University, Changsha, Hunan, China; 2Departments of Hematology, The Second Xiangya Hospital, Central South University, Changsha, Hunan, China

Objective: MnSOD is potential therapy target for lung cancer and it is important to control MnSOD aberrant expression in lung cancer cells. In this study, we investigate the effect of AP-2α activation on MnSOD expression in lung cancer cell line and provide experimental evidence on the applications of AP-2 for lung cancer therapy.

Methods: A549 cells were transfected with the Adenovirus-AP-2α construct (AD-AP-2α) at multiplicities of infection (MOI) of 0, 10, 30, 50 MOI or with the adenovirus-lacZ reporter gene construct (Ad-lacZ). The MOI A549 cells were transfected for 0, 6, 12, 24, 48 hrs with Ad-AP-2α at 50 MOI and also were transfected for 24hrs with the dominant-negative mutant AP-2α construct with liposome-mediated method. The time- and dose-dependent effects of AP-2 on MnSOD expression were detected by RT-PCR and Western blot.

Results: (1) With increasing Ad-AP-2α titers, the expression of MnSOD is decreased. (2) Transfected with 50 MOI Ad-AP-2α and measured expression of MnSOD at 6, 12, 24, 48 hrs, we observed a concomitant decreasing in MnSOD expression. (3) Compared with the controls, the expression of MnSOD was declined after transfecting the dominant-negative mutant AP-2α construct into lung cancer (A549) cells.

Conclusions: The results suggest that AP-2 represses MnSOD expression in lung cancer cells and down-regulation of MnSOD may be related to DNA binding domain of AP-2α.

P1488

Telomerase (h-TERT) and targeting EGFR in non small cell lung carcinoma: A combined immunohistochemistry and chromogenic in situ hybridization study based on tissue microarrays
Anastassios Stamatsopoulos1, Evangelos Tsiambas2, Petros Michos1, Ioannis Gakidis1, Andreas Karameris 2, Dimosthenes Bourou3. 1 Thoracic Surgery; KAT General Hospital of Athens, Athens, Greece; 2Pathology Tissue Microarray Lab., NIMTS Hospital, Athens, Greece; 3Respiratory Medicine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan

Purpose: Our aim was the evaluation of EGFR gene and protein alterations in NSCLC and the potential role of telomerase in the regulation of its expression.

Methods: Using tissue microarray technology, forty (n=40) paraffin embedded histologically confirmed primary NSCLCs were cored twice at a diameter of 1mm and re-embedded into a recipient block. Immunohistochemistry was performed by the use of monoclonal antibodies anti-EGFR (31G7), and anti-telomerase/h-TERT (4F12). Also, a Chromogen in situ hybridization protocol was applied based on the use of EGFR gene and chromosome 7 centromeric probes. Computerized Image Analysis was performed for the evaluation of immunohistochemistry results.

Results: EGFR overexpression was observed in 23/40 (57.5%) cases correlating to stage (p=0.001) and histological type (p=0.04). Telomerase was overexpressed in all examined cases (high and moderate levels) correlating to stage (p=0.001). A significant value of concordance (kappa=0.686, 0.677±0.695) was assessed comparing telomerase and EGFR protein expression. EGFR gene amplification was identified in 2/40 (5%) cases associating to histological type (p=0.027) and chromosome 7 aneuscopy in 7/40 (17.5%) cases.

Conclusions: NSCLC is characterized by rare cases of EGFR gene amplification and this genetic event may affect the efficacy of targeted therapeutic strategies based on monoclonal antibodies. Also, the strong concordance between EGFR and this genetic event maybe affect the efficacy of targeted therapeutic strategies based on monoclonal antibodies.

Inhibition of B7-H4 gene expression by RNA interference (RNAi) in lung cancer A549 cell line
Suqing Sun1, Yong Lin1, Linen Huang2, Chenguang Jiang1, Yuelin Jin1.1 Medical Department, Southeast Hospital, Southeast University, Nanjing, Jiangsu, China; 2Department of Medicine, Southeast University, Nanjing, Jiangsu, China.

Background: B7-H4, a member of the B7 family, is involved in the regulation of antigen-specific immune responses. Here we addressed its expression in non-small-cell lung cancer (NSCLC) pathology and correlation to the number of CD3+ tumor infiltrating T-lymphocytes in invasive carcinomas. We also observe the effects of B7-H4 gene expression on cell proliferation and migration in the human NSCLC cell line.

Methods: B7-H4 expression was evaluated by immunohistochemistry in 102 patients with NSCLC who underwent surgical tumor resection. Expression data was correlated with clinicopathologic features and with the number of tumor-infiltrating T-cell. B7-H4 mRNA was cloned into pGCU6Neo plasmid and the product was transfected into A549 cells with Lipofectamine 2000.

Results: B7-H4 is transcribed in three cell lines. In tumor tissues, expression of B7-H4 in A549 is both in the cell membrane and in the cytoplasma of B7-H4 transfection vector-pGCaB7-H4 was successfully constructed. After transfected with pGC SHB7-H4, the expression of B7-H4mRNA in A549 cells was obviously decreased with an increased cell proliferation observably. Compared to cell lines without treatment, the proliferation of cell lines cultivated with decreased B7-H4 gene was increased, the cell cycle was blocked in the G0 as well, invasion and mobility abilities of cells in vitro were added.

Conclusion: Our observations also suggest that the B7-H4 gene is associated with A549 cell proliferation, migration and cell cycle distribution. RNAi recombinant of B7-H4 gene could effectively inhibit the expression of B7-H4 mRNA in A549 cells.

P1490

Novel functions of stanniocalcin-1 (STC1) through uncoupling protein 2 (UCP2) up-regulation: promoting survival of cancer cells under oxidative stress and inducing the uncoupling respiration (Warburg effect)
Shinya Okkuchi, Toshiaki Kakoki, Masahito Ehima, Toshiharu Nawai. Respiratory Medicine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan

We have demonstrated that multipotent stromal cells (MSCs) promote cell survival though upregulation and secretion of stanniocalcin-1 (STC1) (Stem Cells 2009; 27: 670-81). This study demonstrates that MSC derived STC1 promotes survival of lung cancer A549 cells through the uncoupling of oxidative phosphorylation, the reduction of intracellular reactive oxygen species (ROS) and concomitant shift towards a more glycolytic and more oxygen consuming metabolic profile (known as the Uncoupling Respiration). MSC-derived STC1 upregulated uncoupling protein 2 (UCP2) in injured A549s in an STC1 dependent manner. Knock down of UCP2 reduced the ability of MSCs to reduce cell death in the A549 population.

Our data suggest that MSCs promote cell survival by regulating the uncoupling respiration in an STC1 dependent manner. Furthermore, STC1 may provide promising avenues for treatment of reactive oxygen species and metabolic disorders.

P1491

TNF neutralization ameliorates urethane-induced lung carcinogenesis
Sophia P. Karabela, Georgios T. Stathopoulos. Thoracic Pulmonary Services, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Aim: To preclinically investigate the therapeutic potential of TNF blockade against lung neocarcinosis (TNF in the lung).

Methods: Long-term studies: Balb/c mice received urethane or saline followed by anti-TNFα or placebo during weeks 0-4 (early), 20-24 (late), or 0-32 (continuous) post-urethane. End-points were lung tumor number (and) diameter (δ) at 32 weeks. Short-term studies: Balb/c mice received weekly doses of infliximab 15 mg/kg, Amgen-Wyeth; 10 mg/kg) during weeks 0-4 (early), 20-24 (late), or 0-32 (continuous) post-urethane. End-points were lung tumor number (and) diameter (δ) at 7 days.

Results: Compared with controls (δ=16.2±1.6 δ=1.0±0.07mm), early sTNFRFc-treated mice had fewer lung tumors of equal size (p=0.01; 1.3, P<0.05; b=1.07±0.03mm, P>0.05), but late sTNFRFc-treated mice had equal numbers of smaller lung tumors (b=14.1±1.2, P>0.05; δ=7.1±0.07mm, P>0.01). Continuous sTNFRFc resulted in reduced lung tumor number and size (b=9.3±1.0, P<0.05; δ=7.6±0.03mm, P>0.05). sTNFRFc-treated mice had fewer macrophages, but higher IFN-γ and IL-10 levels in BAL; tumors from these mice showed slower proliferation and angiogenesis. In short-term studies, sTNFRFc inhibited urethane-induced macrophage influx and TNF expression, but enhanced IFN-γ and IL-10 expression in BAL. A possible source of IFN-γ and IL-10 in sTNFRFc-treated mice were macrophages, which responded to sTNFRFc by enhanced IFN-γ and IL-10 expression.
Conclusion: TNF blockade halts lung tumorigenesis in mice, and may be useful in lung cancer chemoprevention.

P1492
Krebgs von den Lungen-6 (KL-6) is a prognostic biomarker in patients with surgically resected non-small cell lung cancer
Sonosuke Tanaka1, Nobuhisa Ishikawa1, Noboru Hattori1, Hirohona Hamada2, Akihito Yokozawa3, Nobuoki Kohno3, 1 Department of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; 2Division of Physical Therapy and Occupational Therapy, School of Health Sciences, Hiroshima University, Hiroshima, Japan; 3Department of Hematology and Respiratory Medicine, Kochi Medical School, Kochi, Japan, Nankoku, Japan

Background: By immunizing mice with a lung adenocarcinoma cell line, we previously established a murine IgG1 monoclonal antibody that recognizes a sialylated sugar chain designated Krebs von den Lungen-6 (KL-6). KL-6 is a high-molecular-weight glycoprotein classified as a human MUC1 mucin. The aim of this study was to determine whether KL-6 expression in tumors correlates with circulating KL-6 levels and whether circulating KL-6 has any prognostic value in patients with surgically resected non-small cell lung cancer (NSCLC).

Method: Immunohistochemical analysis of KL-6 expression was performed on 103 NSCLC tissues, and its associations with serum KL-6 levels and survival were examined. We also evaluated whether KL-6 expression patterns and/or serum KL-6 levels could predict prognosis in these NSCLC patients.

Result: Immunohistochemical analysis of KL-6 in NSCLC tissues showed that a depalidized KL-6 expression pattern was associated with a high level of circulating KL-6 and a poor prognosis in NSCLC patients who underwent curative surgery. Furthermore, a high circulating KL-6 level was associated with both poorer progression-free survival (PFS) and overall survival (OS), and multivariate analyses confirmed its independent prognostic value for both PFS and OS (p=0.041 and 0.023, respectively).

Conclusion: Our data suggest that preoperative serum KL-6 level reflects KL-6 expression patterns in NSCLC tissue, and can serve as a useful prognostic biomarker in NSCLC patients who undergo curative surgery.

P1493
Potential therapeutic significance of CIK cells in gefitinib resistant NSCLC with EGFR mutations
Chen He1, Min Li2, Jingdong Meng3, Junli Wang1, Jun Xu1, 1Guangzhou Institute of Respiratory Disease, First Affiliated Hospital of Guangzhou Medical College, State Key Lab of Respiratory Disease, Guangzhou, Guangdong, China; 2Dept. of Respiratory, Bao’an People’s Hospital, Shenzhen, Guangdong, China

The gefitinib resistant limits its efficacy in the treatment of non-small cell lung cancer (NSCLC), thus, we tried to evaluate the drug-resistance reversal to gefitinib by the cytokine induced killer (CIK) cells. The gefitinib resistant cell line PC-9/GR was developed from a NSCLC cell line PC-9 harboring EGFR E746-A750 deletion by gefitinib selection. The effect of CIK cells alone or combination with gefitinib on PC-9/GR was determined by the cytotoxicity in vitro as well as growth inhibition of NSCLC in vivo. The effects of gefitinib on PC-9/GR cells were compared.

The induction of G0/G1 arrest and apoptosis was observed in PC-9/GR treated with CIK cells in vitro and vivo, however, there was no significant difference in the cytolytic activity of CIK cells against PC-9 and PC-9/GR targets. In addition, a synergistic cytotoxicity was obtained by the combination CIK cells and gefitinib in PC-9/GR through the inhibition of p-ERK and p-AKT activity by CIK cells. Finally, CIK cells inhibition could significantly increase the frequency and function of NK cells and decrease the frequency of Treg cells and level of TGF-β in patients with tumors. In conclusion, CIK cells have a strong cytotoxicity to PC-9/GR and a clinical immune modulation, thus it might be a favorable treatment of NSCLC with EGFR mutations.

Expression of immunohistochemical markers chromogranin A, Ki-67, CD99, EGRF in resected pulmonary neuroendocrine tumors
Yanina Slavova1, Dora Marinova2, Vladimir Maksimov3, Danail Petrov3, Elzar Goranov4, Vladimir Djambazov3, 1Institute of Mathematical Statistics and Actuarial Science, University of Bern, Bern, Switzerland; 2Department of Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom; 3Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; 4School of Social and Community Medicine, University of Bristol, Bristol, Bristol, United Kingdom; 5Institute of Mathematical Statistics and Actuarial Science, University of Bern, Bern, Switzerland; 6Department of Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom

Aims: Recurrent cough (RC) is common in childhood and an important cause of primary care visits. Despite that, data on the natural history of recurrent cough in unselected children are scarce.

Methods: In a population-based cohort in Leicestershire (UK) we measured recurrent cough (defined as chronic night cough + cough apart from colds + GP visits for cough) with repeated questionnaires. For non-wheezers, we computed frequency of recurrent cough at different ages, and determined predictors of RC in multivariative logistic regressions.

Results: We had data on 1247 children aged 1 year, and data on 1127, 1267, 1410, 825 aged 2, 4, 6, and 9 years respectively. Prevalence of RC at these ages was 17%, 19%, 21%, 16% and 12% respectively. Of all children with RC at age 1 year, 62% continued to report RC at age 2 years, and 46%, 35%, 28% at age 4, 6 and 9 years respectively. Factors associated with RC during the first 2 years of life were nursery care and possetting. In contrast, attendance to nursery care in infancy protected from RC at age 6 and 9 years. Associations with family history of atopy were marginal.

Conclusions: Recurrent cough is common and tracks strongly during childhood. At all ages, there are strong associations with upper respiratory symptoms. This might be explained by an increased susceptibility to upper respiratory infections.

P1495
Natural history of recurrent cough in children
Marie-Pierre F. Strippoli1, Anna M. Pescatore1, Ben D. Spycher2, Caroline S. Birdsmoore2, Michael Silverman3, Claudia E. Kuehni1, 1Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; 2Department of Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom

Aims: Many children have asthma-like symptoms in early life, but few develop asthma. Several models for predicting later asthma in symptomatic toddlers have been built, but some included factors that are difficult to assess, and methods used were prone to overfitting, leading to selection or exaggeration of irrelevant factors. We aimed to identify predictors for later asthma avoiding previous limitations.

Methods: In a population-based cohort, we selected 1-3 year-olds with respiratory symptoms (current wheeze or recurrent cough) and related healthcare visits. Asthma (current wheeze or recurrent cough) and related healthcare visits was assessed 5 years (N=1226) and 8 years (N=866) later.

The included factors are easy to assess in clinical practice: family history, symptoms at baseline, demographic and perinatal data. We used lasso penalized logistic

161. Paediatric epidemiology: predicting outcomes of wheeze, antenatal growth, early life exposures and outcome of premature birth

Robust prediction of later asthma in symptomatic toddlers: A novel approach
Anna Pescatore1, Ben Spycher2, Lutz Daebrem2, Marie-Pierre Strippoli1, Cristino Dogra3, Michael Silverman4, Claudia Kuehni1, 1Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; 2School of Social and Community Medicine, University of Bristol, Bristol, Bristol, United Kingdom; 3Institute of Mathematical Statistics and Actuarial Science, University of Bern, Bern, Switzerland; 4Department of Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom

Aim: Many children have asthma-like symptoms in early life, but few develop asthma. Several models for predicting later asthma in symptomatic toddlers have been built, but some included factors that are difficult to assess, and methods used were prone to overfitting, leading to selection or exaggeration of irrelevant factors. We aimed to identify predictors for later asthma avoiding previous limitations.

Methods: In a population-based cohort, we selected 1-3 year-olds with respiratory symptoms (current wheeze or recurrent cough) and related healthcare visits. Asthma (current wheeze and treatment) was assessed 5 years (N=1226) and 8 years (N=866) later.

The included factors are easy to assess in clinical practice: family history, symptoms at baseline, demographic and perinatal data. We used lasso penalized logistic
regression to select predictors. This minimizes the number of included predictors while maximizing area under ROC curve (AUC).

Results: Main predictors selected in the model for asthma 5 yrs later (AUC=0.76) were ≥4 wheezing attacks in the past 12 months (OR=1.65), wheeze causing breathlessness (3.1) and activity disturbance (2.4), eczema (1.5) and male sex (1.5). Other predictors (OR<1.5) were: non-viral triggers for wheeze or cough, parental history of asthma and atopy, and low birth weight. The results for asthma 8yrs later (AUC=0.72) were similar.

Conclusion: Among factors easy to assess in symptomatic toddlers, wheeze severity, eczema and male sex are main predictors of asthma in mid-childhood. Because our approach for variable selection avoids overfitting, the resulting prediction models should perform well with new data. However, external validation is needed.

Phenotypes of childhood wheeze: Early symptom pattern vs. long term disease course

Ben Spycher, Raquel Granell, Jonathan Steerne, John Henderson. School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom

Aim: Wheezing in childhood is phenotypically heterogeneous. We investigated how phenotypes defined by early symptom pattern are related to phenotypes based on later retrospective time course.

Method: We analysed data on wheeze-related symptoms (frequency and duration of episodes, shortness of breath (SOB), fever and triggers (chest infection, smoke, cold weather, “other”)) in children from a population based birth cohort (ALSPAC) at ages 6m (n=2261), 18m (2400) and 30m (1786). We used latent class analysis to identify phenotypes, which were compared to previously published phenotypes based on 7 measurements of current wheeze in the first 7yrs of life (Thorax 2008;63:974–980).

Results: We identified 5 phenotypes at age 6m and 6 at ages 18m and 30m. At each age, 3 phenotypes, each comprising 20-30% of children, were identified, one with episodes triggered mainly by infections and cold weather and one with “other” triggers predominating. Other phenotypes were characterised by moderate or mild symptoms and differed in patterns of triggers. Phenotypes were similar at different ages. Among children with mild wheeze, >60% were classified longitudinally as “transient early” or “prolonged early wheezers” while >34%, >46% and >63% of children in the severe groups at ages 6m, 18m, and 30m respectively were classified as “persistent wheezers”.

Conclusion: In children <3yrs from the general population, severe wheeze can be associated both with a viral and a multiple trigger pattern. Severe wheeze in early childhood is a strong predictor of wheeze persisting into school age, regardless of reported triggers.

Allergic females have the least chance of recovery following early wheezing

Emma Goksir, Maimor Amark, Bernt Alm, Göran Wennegren. Department of Paediatrics, University of Gothenburg, Gothenburg, Sweden

Background: We have previously reported on the outcome in childhood and adolescence in children hospitalized due to wheezing before the age of two. The aim of the present follow-up was to report on the prevalence of and risk factors for asthma at adult age.

Methods: We have prospectively studied asthma development in 101 children hospitalized due to wheezing before the age of two. The cohort was re-investigated 20 years later. We identified 5 phenotypes at age 6m and 6 at ages 18m and 30m. At each age, 3 phenotypes, each comprising 20-30% of children, were identified, one with episodes triggered mainly by infections and cold weather and one with “other” triggers predominating. Other phenotypes were characterised by moderate or mild symptoms and differed in patterns of triggers. Phenotypes were similar at different ages. Among children with mild wheeze, >60% were classified longitudinally as “transient early” or “prolonged early wheezers” while >34%, >46% and >63% of children in the severe groups at ages 6m, 18m, and 30m respectively were classified as “persistent wheezers”.

Conclusion: In children <3yrs from the general population, severe wheeze can be associated both with a viral and a multiple trigger pattern. Severe wheeze in early childhood is a strong predictor of wheeze persisting into school age, regardless of reported triggers.

First and second trimester fetal size and asthma outcomes at age ten years

Steve Turner, Nanda Prabhu, Rebecca Cutts, Keith Allen, Peter Helms, Anthony Seaton, Graham Devereux. Child Health, University of Aberdeen, Aberdeen, United Kingdom

Introduction: Childhood asthma is a common condition characterised by relapse and remission. Here we sought to identify the precision of physiological measurements made in 5-year-olds for predicting asthma outcome at 10 years of age.

Methods: As part of a cohort study, 5 year old children attended a clinical assessment which included skin prick reactivity, spirometry and bronchodilator response. A respiratory symptom questionnaire was completed at ages 5 and 10 years. Children were categorised as having persistent asthma, early remittent asthma, later onset asthma or being non-asthmatic.

Results: Of the 1924 originally recruited, questionnaire data were available in 808 children at both 5 and 10 years of age including 37 with persistent asthma, 30 with early remittent asthma and 33 with later onset asthma. Skin prick reactivity was determined in 483 5-year-olds, spirometry in 410, bronchodilator response (BDR) in 164 and FENO in 110. Asthma had sensitivity of 82% [95% CI 68, 92] and specificity of 57% [95% CI 42, 68] for predicting persistent asthma in symptomatic 5-year-olds and a sensitivity of 72% [95% CI 50, 87] and specificity of 79% [95% CI 78-80] for predicting later onset asthma in asymptomatic 5-year-olds. Regardless of asthma status at 5 years, FENO >10.7ppb had a sensitivity of 62% and a specificity of 89% for asthma at 10 years. Spirometry and BDR were not predictive of later asthma outcomes.

Conclusions: In this community-based cohort, objective physiological measurements taken in 5-year-olds were able to predict asthma outcome in later childhood. The absence of atopy or elevated FENO in a young child with asthma or asthma-like symptoms may be helpful in predicting low risk for future asthma symptoms.

P1501
Fetal and infant growth is associated with wheezing in preschool children.

The Generation R study Group, Erasmus Medical Center, Rotterdam, Netherlands; 2Pneumatics, Division of Respiratory Medicine, Erasmus Medical Center, Rotterdam, Netherlands; 3Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands; 4Pediatrics, Erasmus Medical Center, Rotterdam, Netherlands

Background: Birth size is associated with wheezing in childhood. Not much is
known about the role of longitudinal growth in fetal life and infancy on asthma symptoms. Our aim was to examine the associations of fetal and infant growth characteristics with wheezing in preschool children.

Methods: This study was embedded in a population-based prospective cohort study among 5,125 children. Information on second and third trimester fetal growth (fetal weight, head circumference, abdominal circumference, fetal estimated weight) was obtained by multiple ultrasounds during pregnancy. Infant growth (length, weight) was repeatedly measured at the Community Health Centres at the ages of 3, 6, and 12 months. All growth characteristics were converted into age and sex adjusted standard deviation scores (SDS). Parental report of wheezing until the age of 4 years was yearly obtained by questionnaires.

Results: Fetal growth characteristics were not associated with wheezing at all ages. Infant weight gain was associated with the risk of wheezing in the first 2 years (Odds ratios (OR) age 1 year: 1.23 (95% Confidence Intervals (CI): 1.02, 1.48); age 2 years: 1.42 (95% CI: 1.22, 1.66)) per SDS weight gain in the first 3 months of life. These effect estimates were higher for children who were fetal growth restricted from the 2nd trimester to birth (at age 1 year: 1.32 (1.10, 1.57), age 2 years: 1.26 (1.04, 1.54)).

Conclusions: Increased weight gain during the first 3 months after birth is associated with increased risk of wheezing in the first 2 years of life, especially after fetal growth restriction. Our results suggest that abnormal fetal and infant growth might influence the development of asthma in childhood.

Longitudinal development of lung function in extremely preterm infants

Maria Volta1, Olga Rotondi2, Grit Egger1, Teo Eustache1, Thomas Halvorsen1,2,3, Department of Clinical Medicine, University of Bergen, Bergen, Norway; 2Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 3Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway.

Introduction: With the advent of modern neonatal intensive care, survival after extreme preterm (EP) birth increased considerably. Large cohorts of subjects born EP are now approaching adulthood; their lifelong pulmonary prospects being basically unknown.

Aims: To construct spirometric growth curves to early adulthood for subjects born EP.

Methods: Two area-based birth-cohorts of subjects born in 1982-85 and 1991-92 at gestational age <28 weeks or with birth weight <1000 grams (n=81) and individually matched control subjects born at term (n=74) were examined in 2001 and 2009. Paired multiple linear regression models were constructed to assess growth patterns.

Results: Most measures of lung function were significantly reduced in subjects born EP over the full study period. Mean growth of FEV1 through puberty was 1.5 liters in both preterm and control subjects, and there was a small but not significant growth from age 18 to 25.

*Mean values (95% CI).

Conclusions: Lung function deficits after EP birth persists to adult life. Growth in lung function was parallel in subjects bornEP and at term, and no signs of age related decline was observed at age 25.

P1503
Factors for lower respiratory illnesses (LRI) in infants < 32 wks gestational age (GA): Do they differ by type of illness?

Francia Rusconi1, Monica Da Frè1,2, Valeria Chiandotto1, Virgilio Carnielli3, G.Salesi, Ancona, Italy; 2Child Health, University of Aberdeen, Aberdeen, United Kingdom.

Introduction: Factors present in infancy have been associated with respiratory outcomes in childhood. Risk factors for wheeze in adults differ from those in children, for example female gender and active smoking. Here we test the hypothesis that physiological outcomes measured in infancy are associated with persistent respiratory outcomes in eighteen year olds.

Methods: As part of a longitudinal birth cohort study, measurements of infant lung function and atopy were made in infancy. Participants were followed up with at ages 6, 12 and 18 years. Based on reported symptoms, individuals were categorised as remittent wheeze, later onset wheeze, persistent wheeze and no wheeze.

Results: Of the 253 individuals originally recruited, 148 were followed up at age 18 years including 13 with persistent wheeze, 13 with remittent wheeze, 23 with later onset wheeze and 99 with no wheeze. Compared to the no wheeze group, persistent wheeze was independently associated with reduced lung function at one month (mean reduction% predicted V’maxFRC 43 [95% CI 13, 74]), increased length at one month (40% increase risk per cm increase [95%CI 6, 187]), atopy in infancy (OR 5.2 [95%CI 1.1, 23.8]) and current smoking (OR 6.1 [95%CI 1.3, 30.7]). Later onset wheeze was associated with female sex (OR 4.0 [95% CI 1.5, 11.4]). Remittent wheeze was not associated with the risk factors considered in the analysis.

Conclusion: Although female sex and active smoking are risk factors for wheeze in adulthood, the presence of reduced lung function and atopy in infancy remain risk factors for ongoing respiratory symptoms in young adults.

P1504
Preterm birth and inhaled corticosteroid usage in 6-19-year-olds – A Swedish national cohort study

Hartmut Vogt, Karolina Lindström, Lennart Bräck, Anders Hjern. Clinical and Experimental Medicine, Division of Pediatrics, Linköping University, Linköping, Sweden Clinical Sciences and Education, Karolinska Institute, Stockholm, Sweden Occupational & Environmental Medicine, Department of Public Health and Primary Care, School of Medicine, University of Gothenburg, Gothenburg, Sweden National Institute of Public Health, Department of Clinical Epidemiology, Copenhagen, Denmark; 2School of Public Health, Copenhagen, Denmark.

Objective: To construct spirometric growth curves to early adulthood for subjects born EP.

Methods: Area-based birth-cohorts of subjects born between 1982 and 1992 in 2 Italian regions (ACTION study) and those born in weeks 24-28 were used to construct growth patterns.

Results: Degree of immaturity, expressed as completed gestational weeks at birth, had an inverse dose-response relationship with ICS usage. Compared to children born between 31 and 37 weeks gestation, the odds ratio for ICS usage increased with the degree of prematurity, from 1.10 (1.08-1.13) for children born in weeks 37-38, to 2.28 (1.96-2.64) for children born in weeks 24-28, after adjustment for socio-economic confounders and perinatal mediators.

The increase in ICS usage with decreasing gestational age at delivery was similar in boys and girls and declined with older age.

Conclusion: Preterm birth increases the risk of ICS usage in 6-19 year olds by degree of immaturity, all the way from extremely preterm to early term birth.

P1505
Early life antecedents of persistent wheeze in young adults

Dave Mullane1, Steve Turner1,2, Giancarlo Ciccarone2, Peter Le Souef3,4. 1School of Puediatrics and Child Health, University of Western Australia, Perth, Australia; 2Child Health, University of Aberdeen, Aberdeen, United Kingdom.

Introduction: Factors present in infancy have been associated with respiratory outcomes in childhood. Risk factors for wheeze in adults differ from those in children, for example female gender and active smoking. Here we test the hypothesis that physiological outcomes measured in infancy are associated with persistent respiratory outcomes in eighteen year olds.

Methods: As part of a longitudinal birth cohort study, measurements of infant lung function and atopy were made in infancy. Participants were followed up with at ages 6, 12 and 18 years. Based on reported symptoms, individuals were categorised as remittent wheeze, later onset wheeze, persistent wheeze and no wheeze.

Results: Of the 253 individuals originally recruited, 148 were followed up at age 18 years including 13 with persistent wheeze, 13 with remittent wheeze, 23 with later onset wheeze and 99 with no wheeze. Compared to the no wheeze group, persistent wheeze was independently associated with reduced lung function at one month (mean reduction% predicted V’maxFRC 43 [95% CI 13, 74]), increased length at one month (40% increase risk per cm increase [95%CI 6, 187]), atopy in infancy (OR 5.2 [95%CI 1.1, 23.8]) and current smoking (OR 6.1 [95%CI 1.3, 30.7]). Later onset wheeze was associated with female sex (OR 4.0 [95% CI 1.5, 11.4]). Remittent wheeze was not associated with the risk factors considered in the analysis.

Conclusion: Although female sex and active smoking are risk factors for wheeze in adulthood, the presence of reduced lung function and atopy in infancy remain risk factors for ongoing respiratory symptoms in young adults.

asthma/atopy, obstetrical and perinatal variables, breastfeeding and current envi-
ronmental factors (siblings, smoking/dampness at home, traffic) were assessed as possible predictors through multivariable regression analysis.

1009/1413 children had assessment-interview. Bronchitis/asthmatic bronchitis (18.8% of children) were significantly associated with lower GA, parental asthma (Odds ratio.OR 1.80) and day care (OR 2.00), while female sex and foreign mother were protective (OR 0.71 and 0.56). Risk of bronchitis/pneumonia (16.2%) was significantly reduced at higher GA, in twins (OR 0.45), and in infants discharged from NICU in april-september (OR 0.63). 14% of children were admitted to hospital for LRI; they were significantly more likely to have been exposed to maternal smoking in pregnancy (OR 1.67), have had birthweight <10° centile (OR 2.0) and BPD (OR 2.1); infants with LRI requiring O2 or ventilation (5.2%) had the same risk factors.

Wheezing and LRI admissions had different risk profiles: the former were similar to those in general populations studies, while the latter were associated with prenatal factors influencing lung growth (intrauterine growth restriction, smoke) and BPD.
Factors associated to an earlier wheezing episode during the first year of life in Europe and Latin America: The EISL study

Luis Garcia-Marcos1, Javier Maillo2, Dircua Solé3, Paul Brand4, Manuel Sanchez-Solís1, Virginia Perez-Fernandez1, EISL Study Group.
1Pediatric Respiratory and Allergy Units, Vigeo de la Arrixaca University Children’s Hospital, Murcia, Spain; 2Pediatric Respiratory Medicine, El Pino Hospital, Santiago, Chile; 3Pediatric Allergy, Clinical Immunology and Rheumatology, Federal University of Sao Paulo, Sao Paulo, Brazil; 4Princess Amalia Children Clinic, Isala Klinieken, Zooloe, Netherlands

Background: There is scarce information about what factors might influence the time to the first wheezing episode in infants.

Methods: The “Estudio Internacional de Sibilancias en Lactantes (EISL)” included 13,684 infants who wheezed at least once in the first year of life, recruited from 15 centers in 6 Latin American countries (n=12,045) and from 5 centers in 2 European countries (n=1,639). A multivariate Cox regression analysis was performed using as dependent variable the time to the first wheezing episode. The regression included the following factors: gender, parental asthma or rhinitis, infant exposure to second-hand smoking in pregnancy, colds (a wheeze in the first 3 mo), nursery school, breast feeding >= 3 mo, number of siblings, persons at home, mould stains on walls, university studies of mother, Afro-American ethnicity, and pets at home. An adjusted hazard ratio (aHR) of the pooled whole population and also separately for EU and LA was calculated.

Results: Adjusted hazard ratios (aHR) for an earlier episode of wheezing in the first year of life

Conclusions: Some factors usually shown to be a risk factor for wheezing are not associated to a shorter period of time to the first episode. Furthermore, some delaying or advancing factors are different in Europe as compared to Latin America.

Long-term evolution of virus-induced and multi-trigger wheeze in children of the EGEA study

Isabelle Pin1, Valérie Siroux1, Anne Boudier1, Lucile Vignal-Nicollet1, Jocelyne Jouven1, Françoise Karsenty1, Pélée1, CHU de Grenoble, Grenoble, France; 2INSERM U828, Institut Albert Buisson, Grenoble, France; 3Centre de l’Asthme de l’Allergie de l’Enfant, Hôpital d’Enfants Armand Trousseau EA6046, Paris, France; 4Équipe d’épidémiologie Respiratoire et Environnementale, CESP/P1018 Inserm, Villejuif, France

Background: Recent guidelines have proposed different phenotypes according to triggers (episodic/virus (EV) and multi trigger wheeze (MTW)) in preschool children. Studies aimed at characterizing asthma evolution according to these phenotypes are seldom.

Aims: To investigate lung function and asthma evolution up to adulthood between MTW and EVW in childhood.

Methods: 588 children, aged 10.9±3.0 years included in EGEA study were classified as non wheezer (n=265), EVW (wheeze only with viral infections and asymptomatic between episodes, n=131) and MTW (wheeze with viral infections and between episodes with triggers such as dust, tobacco smoke, exercise, and cold exposure in affecting the development of asthma in urban and rural settings.

To determine the relationship of indoor endotoxin and manifestations of respiratory symptoms in urban children in Hong Kong.

Methods: Random sample of schools for children aged 7 to 11 years were recruited through the school system. Parents completed the locally validated ISAAC questionsnaires with additional questions about the home environment. Random subgroup of subjects was recruited for SPTs and dust samples were collected according to the ISAAC Phase II protocol. Endotoxin levels were log-transformed before analysis.

Results: 3,546 primary schoolchildren were screened with a participation rate of 96%. A random subsample of 1,303 subjects has been skin-tested with 439 also provided mattress dust samples. Among them, 37 (8.4%) had at least one wheezing attack in the past year and 47 (10.7%) had a physician diagnose of asthma. The median (interquartile range) of endotoxin concentration (EU/m³) and log (EU/m³) were 12.9 (6.25) and 547 (230-1,137) in those without current wheeze; they were 34 (19-83) and 1,689 (853-3,301) in those with current wheeze. The differences were significantly different (p<0.01) adjusted for confounders.

Among those with a asthma diagnosis, higher endotoxin level was associated with use of asthma medication in the past year.

Conclusion: Higher level of endotoxin level in this urban sample of schoolchildren is associated with wheezing and increased use of asthma medication among known asthmatics. Further studies are needed to reveal the possible roles of microbial exposure in affecting the development of asthma in urban and rural settings.

Does maternal smoking play a role as an inducer, rather than trigger, of asthma and respiratory symptoms?

Mark Upton1, Alex McCaonnachie2, Carole Hart3, George Davey Smith4, Graham Watt5, 6General Practice and Primary Care, University of Glasgow, Glasgow, United Kingdom; 7Robertson Centre for Biostatistics, University of Glasgow, Glasgow, United Kingdom; 8Public Health, University of Glasgow, Glasgow, United Kingdom; 9MRC Centre for Causal Analyses in Translational Epidemiology, University of Bristol, Bristol, United Kingdom

Background: Asthma is a complex chronic disease arising from the interaction of genetic and environmental factors. In children, it is difficult to separate any role of maternal smoking in the antenatal induction of asthma from a later role as a symptom trigger, as most mothers who smoke in pregnancy continue to smoke after their child’s birth.

Aim: To estimate the association between parental smoking and asthma and respiratory symptoms in adults, and to compare findings with those for current exposure to environmental tobacco smoke (ETS).

Methods: The Midspean Family Study included offspring aged 30-59 years, whose parents reported their smoking habits as part of an epidemiological study 20 years earlier. Offspring completed a questionnaire and underwent spirometry. We used
