Results: A total of 1650 sputum samples (218 patients) were included. Viruses were detected in 208 samples (42%) of which 106 (51%) were collected during the stable state. In 11% of the samples multiple viruses were found, of which the combination of rhinovirus and hMPV was the most frequent (58%). Patients with multiple viruses in the stable sample did not experience more AEs in the first weeks after stable sample collection than patients with a single virus or without a virus in the stable sample.

Conclusion: In 11% of sputum samples of COPD patients multiple respiratory viruses were found. The presence of multiple viruses does not predispose these patients to the short-term occurrence of an AE.

P3013 The relationship between PBMC secretion of IFN-alpha following TLR7 and TLR9 activation and lung function in COPD
Vijay Mistry, Mona Bafadhel, Sue McKenna, Sarah Terry, Christopher Brightling
Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom

Introduction: Viral and bacterial infections play a key role in exacerbations in COPD. IFN-alpha has been implicated in the persistence of symptoms. The relationship of the inflammatory response to these airway pathogens at stable state and exacerbations is also poorly understood and how this may lead on to structural airway remodelling is poorly defined. We sought to investigate the relationship between clinical parameters in COPD and the in vitro response to TLR 7 & 9 activation.

Method: PBMCs were stimulated for 24h, with 10μM R848 and 1μM CpG, from healthy controls & COPD subjects. IFN-α release was measured in supernatant using ELISA kits.

Results: COPD & healthy control subjects were recruited. The mean (SD) FEV1 (% predicted) (L) & FEV1/FVC of the COPD subjects was 1.32 (0.58) & 0.5 (0.13) respectively. There was no significant difference in IFN-α (pg/ml) release when comparing health 74 (30) to COPD 59 (42) (p=0.33) when stimulating TLR 7. TLR 9 stimulation gave a significant increase in IFN-α production in COPD 204 (106) vs health 114 (61) (p<0.003). TLR 9 stimulation was significantly increased compared to TLR7 in COPD (p<0.001). There was a significant negative correlation with lung function and TLR 7 stimulation in the COPD group, FEV1 (r=-0.46, p=0.005); FEV1/FVC (r=0.37, p=0.024); FEV1/FVC (r=0.39, p=0.002). TLR 9 stimulation had a significant negative correlation with lung function, KCO% predicted (r=-0.55, p<0.001) and TLC% predicted (r=-0.43, p=0.01).

Conclusion: The release of IFN-α by PBMCs was increased in COPD compared to healthy controls following TLR 9, but not TLR 7 stimulation. The IFN-α release after TLR7 & 9 activation was related to lung function.

P3014 Bacterial load in chronic obstructive pulmonary disease and its relationship with airway inflammation and lung function
Mitesh Pancholi, Mona Bafadhel, Sue McKenna, Sarah Terry, Vijay Mistry, Chris Newby, Ian Pavord, Christopher Brightling. Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom

Introduction: Chronic Obstructive Pulmonary Disease (COPD) is characterised by fixed airflow obstruction, typically in association with persistent airway inflammation and bacterial colonisation. The relationship between these features of disease is not fully understood.

Method: Patients with COPD were recruited from a single centre and were characterised in terms of their lung function, health status, sputum cell counts and quantitative microbiology to derive colony forming units (CFU)/ml of sputum.

Results: 126 patients were recruited, 83 were male. The mean (SEM) was for FEV1% predicted: 48.10 (1.64), sputum neutrophil count 73.2 (2.06%), total cell count (TC) 6.65 (0.98) ×106/μl, CFU 8.5×105-1.5×106/μl and median (IQR) eosinophil count 0.75 (0.25-2.50)%. Univariate correlations was observed between CFU and neutrophil (%) (r=0.306, p<0.001), TCC (r=0.273, p=0.002), but not eosinophil (%) (r=0.058, p=0.517) and FEV1% predicted (r=0.061, p=0.497).

Conclusion: Bacterial load was associated with the sputum total cell count and neutrophil differential but was not associated with lung function. Longitudinal studies are required to assess the role of bacteria in disease progression.

P3015 Induction of cathelicidin (LL-37) in rhinovirus-induced COPD exacerbations
Rosa Soteros1,2, Patrick Mallia1, Joseph Footitt1, Maria-Belen Trujillo-Torralbo1, Tatiana Kebadze2, Contoli Marco3, Alberto Puppi2, Girolamo Pelaia2, Rosario Mazzilli1, Sebastian Johnston3, 1Respiratory Medicine, Imperial College, London, United Kingdom; 2Dipartimento di Medicina Sperimentale e Clinica-Sezione Di Malattie Respiratorie, Universita Degli Studi “Magna Graecia”, Catanzaro, Italy; 3Department of Clinical and Experimental Medicine, University of Ferrara, Ferrara, Italy

Cathelicidin (LL-37) is a cationic antimicrobial peptide and has both antimicrobial and immunomodulatory effects. The majority of LL-37 is stored in neutrophil granules for release at sites of infection. LL-37 has demonstrated anti-viral effects but the role of LL-37 in virus-induced COPD exacerbations is unknown.

Method: We infected 3 groups of subjects—COPD GOLD stage B (N=20), smokers with normal lung function (SMK, N=21) and non-smokers (NS, N=11)—with rhinovirus 16 (RV). Induced sputum was post-collected. In a subset of COPD (N=10) and SMK (N=12) BAL was collected on day 7. Sputum and BAL cytospins were prepared and cell counts determined. LL-37 and cytokines were measured in sputum supernatants by ELISA and virus load by quantitative PCR.

Results: In all subjects combined post-infection peak sputum LL-37 levels correlated with peak sputum virus load (P=0.0018, r=0.43) and peak sputum total inflammatory cells (P<0.0001, r=0.72). These correlations were also significant in the COPD group alone (P=0.017, r=0.53 and P<0.001, r=0.85 respectively) but not in the NS or SMK. In BAL LL-37 correlated with BAL virus load (P=0.044, r=0.64), pro-inflammatory cells (P<0.0001, r=0.89), neutrophils (P<0.001, r=0.98), IL-8 (P<0.0001, r=0.83), TNF-α (P<0.001, r=0.87) and IL-6 (P=0.002, r=0.63). These correlations were also significant in the COPD group alone but not in the SMK. LL-37 in sputum and BAL following rhinovirus infection correlates with inflammatory cells, pro-inflammatory cytokines and virus load. Further studies are required to determine whether LL-37 contributes to neutrophilic inflammation in virus-induced exacerbations or is a component of the anti-viral innate immune mechanism.
Introduction: Self-similarity in Peak Expiratory Flow (PEF) can predict the frequency of asthmatic events but it is unknown whether in COPD there is a relationship with exacerbation frequency.

Methods: We examined data from the London COPD cohort on 308 COPD patients who recorded worsening of respiratory symptoms and PEF on daily diary cards. Exacerbations were identified as previously described (Seemungal. AJR-CCM 157: 1418-1422, 1998) from which an annual rate was calculated. Detrended fluctuation analysis was used to calculate α which is a measure of decay in self-correlation over time (Frey et al. Nature 438: 667-70, 2005). PEF time series when the patient was clinically stable were also analyzed by excluding data collected 1 day before to 7 days after each exacerbation, and splitting the series together.

Results: The 308 COPD patients (195M; mean age (SD) 68.3 (8.4) years; FEV1 1.12 (0.42) l, FEV1/FVC 0.53 (0.27) l, PEF% predicted 54.7 (18.6). The cohort recorded diary card data for a median 1077 days and experienced 2621 exacerbations with a median frequency of 2.04 per year (IQR 0.9 – 3.3). The patients had an α of 0.944 (SD 0.19) over the initial 365 days which was positively related to exacerbation frequency (negative binomial regression, P=0.009). No difference was seen if exacerbation PEF data were excluded, α = 0.935 (SD 0.21; P=0.139) and there was also a relationship with exacerbation frequency (P<0.001).

Conclusion: In COPD patients, long-term correlations (self-similarity) exist in PEF which are related to exacerbation frequency. The exponent α may prove a useful marker of exacerbation frequency and as normally distributed lead to a reduction in the number of patients required for clinical trials.

P3017
The role of respiratory virus infection in COPD exacerbations
Xavier Pomares1, Silvia Capilla, Concepción Montón1, Dolores Mariscal2, M. A. Marcos1, Mateu Espasa3, Eduard Momol3, Miguel Gallego3

1Pneumology, Corporació Sanitària Parc Taulí, Sabadell, Barcelona, Spain; 2Microbiology, Corporació Sanitària Parc Taulí, Sabadell, Barcelona, Spain; 3Microbiology, Hospital Clinic, Barcelona, Spain

Aim: To determine the prevalence of viral infection in a cohort of severe COPD patients.

Methods: We conducted a prospective observational study in a cohort of severe COPD patients from 2005 to 2007. We recorded for each exacerbation: etiological agent, prior antibiotic prescription, corticosteroid treatment and days of hospitalization. Sputum samples were collected and the Gram staining Murray-Washington’s grade was done. A multiplex retrotranscriptase-nested PCR assay was used for simultaneous detection of Parainfluenza virus (1, 2, 3, 4AB), human Coronavirus (229E and OC43), Enterovirus, Rhinovirus, Influenza virus A, B, C, Respiratory syncytial virus and Adenoviruses following the procedure described by Costat et al. (J Med Virol 72:484-95).

Results: A total of 118 patients were registered with a mean age of 69.4±8 years. The 60% were in GOLD stage IV. Among the 307 respiratory samples processed 89 (57.5%) were Murray grade IV and 66.1% (203) of them had positive respiratory bacterial pathogen (positive cultures). Overall, virus were detected in 110/307 (35.8%) of analyzed samples, being Rhinovirus the most common of them (22%). In 51.5% (377/2) of bacterial negative cultures samples virus were detected, while in 31% (63/203) of bacterial positive cultures virus co-infection was observed (p<0.05).

Conclusions:
– The prevalence of viral infection in our cohort was 36%, being Rhinovirus the most common virus.
– A respiratory viral infection may be suspected in COPD exacerbations among patients with negative bacterial culture.

P3018
Presence of Pneumocystis jiroveci colonization in patients with COPD
Marijke Vanspauwen1, Frits Franssen2, Cathrien Bruggeman1, Emiel Wouters2,3

1Medical Microbiology, Maastricht University Medical Centre, CAPHRI School, Maastricht, Netherlands; 2Cnr+, Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 3Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Introduction: Pneumocystis jiroveci infections are frequently detected in immunocompromised patients. However, evidence suggests that P. jiroveci can be detected in non-immunocompromised patients, where it colonizes the airways. Over the past years, P. jiroveci has been linked with COPD. P. jiroveci colonization may be associated with the severity of COPD and some evidence suggests a role for P. jiroveci in the progression of COPD in smokers. The present study investigates the presence of P. jiroveci in sputum samples of patients with COPD.

Material and methods: From March 2009 until September 2010, sputum samples from COPD patients at the centre of expertise for chronic organ failure (COPD) were included. Patients were followed during an 8 week period and sputum samples were collected during the stable state and during an acute exacerbation (AE). Sputum samples were analyzed for the presence of P. jiroveci by a real-time PCR assay.

Results: During the study period 509 sputum samples (218 patients) were collected clinically rehabilitating at CIRO Horn. A total of 184 samples (36%) were collected during the stable phase and 325 (63.8%) during an AE. P. jiroveci DNA was detected in 40 (8%) of all sputum samples. A total of 23 positive samples (57.5%) were detected during an AE and 17 during the stable state (42.5%).

Conclusion: In our population, P. jiroveci colonization could be detected in 8% of the sputum samples of COPD patients. Additional research is needed to clarify the role of P. jiroveci in the pathophysiology of COPD.
P3021 Characteristic of cytokines levels of blood and sputum in COPD exacerbation

Sofya Nesterovich1, Ekaterina Bukreeva2.

In this double blind placebo controlled study, we analyzed the immunological effect of PMLB, administered to a population of elderly Chronic Obstructive Pulmonary Disease (COPD) patients.

Methods: The treatment provided 1 tablet of PMLB for the first ten days of the month, followed by a 20 day rest. The treatment was repeated for other two months and the follow up was carried out up to six months. Blood cell samples were collected at time 0 (before the beginning of the study), after three months and after six months.

Results: CD4+ and activated T cells increased significantly in treated group, while Treg were significantly reduced. Transitional B cells (in particular T3) were recruited and associated to an increase of early naive B cells; recruitment of early memory cells was associated to a reduction of “classic” memory B cells. Finally, NK cells were significantly increased in treated patients, while their subpopulations remained unaltered.

Conclusion: In conclusion, PMLB administration causes in COPD patients an important recruitment of cells belonging to the innate immune system, such as NK, a significant activation of early B cell compartments and a clear reduction of regulatory T cells associated to the increase of T cell activation. All these findings confirm that, also in COPD patients, a specific (and also partially polyclonal) activation of B cells occurs, and this seems to be strictly related to the significant clinical results observed.

P3024 Role of endothelial dysfunction, disturbance of haemostatic reactions in pathogenesis of acute exacerbation of chronic obstructive pulmonary disease (AE COPD)

Purpose: It is to research interrelations of endothelial dysfunction, system inflammatory and haemostatic reactions at patients with AE COPD.

Materials and methods: In open prospective clinical investigation 111 patients with 2 or 3 positive criteria Anthonisen et al. (1987) were included. Men were 91 people (82%), women - 20 people (18%). The smoking index was 37.5±2.06 pack-years. Patients with AE COPD divided on two subgroups: 1st - patients without bronchoctasia, 2nd - patients with bronchoctasia. All patients received therapy system glucocorticoids. The control group included 53 healthy non-smoking people with middle age 25.9±1.36 years, from them 27 (51%) men and 16 (29.9%) women. It was accomplished immunoenzyme definition of CRP, endotelin-1, D-dimers and homocystein maintenance in blood before treatment.

Results: Direct correlation communication between indexes CRP and endotelin-1 (r=0.80, p<0.001), indexes CRP and D-dimers (r=0.65, p<0.01) in the AE COPD was observed. Dynamics of indexes of endothelial dysfunction and thromboembolic risk at patients with various phenotypes AE COPD are in table 1.

Conclusion: At patients with AE COPD it is increased levels of D-dimers, which indicates that specifies on thromboembolic and thromboembolic risks.

P3025 Invasive pulmonary aspergillosis in patients with severe COPD. Comparative study between probable invasive infection and colonization

Rosana Blavia1, Antonia Filliez2, Isabel Serra3, Montse Morta4, Dolores Entvill3, Ramon Trullas5, Damian Perich1, Esperanza Martin1, Conxa Perez4, Emilio Marquilles2.

Background: Efficacy of Polymethyl Cellulosic Bacterial Lysate (PMLB) in increasing the secretion of specific IgA directed to the bacterial antigens administered has been shown.

Aims and objectives: In this double blind placebo controlled study, we analyzed the immunological effect of PMLB, administered to a population of elderly Chronic Obstructive Pulmonary Disease (COPD) patients.

Methods: The treatment provided 1 tablet of PMLB for the first ten days of the month, followed by a 20 day rest. The treatment was repeated for other two months and the follow up was carried out up to six months. Blood cell samples were collected at time 0 (before the beginning of the study), after three months and after six months.

Results: CD4+ and activated T cells increased significantly in treated group, while Treg were significantly reduced. Transitional B cells (in particular T3) were recruited and associated to an increase of early naive B cells; recruitment of early memory cells was associated to a reduction of “classic” memory B cells. Finally, NK cells were significantly increased in treated patients, while their subpopulations remained unaltered.

Conclusion: In conclusion, PMLB administration causes in COPD patients an important recruitment of cells belonging to the innate immune system, such as NK, a significant activation of early B cell compartments and a clear reduction of regulatory T cells associated to the increase of T cell activation. All these findings confirm that, also in COPD patients, a specific (and also partially polyclonal) activation of B cells occurs, and this seems to be strictly related to the significant clinical results observed.
days as opposed to 13±22 d. in colonization (p<0.003) and respiratory failure (80% IPA v 36% p<0.009). Antifungal therapy was received by 91% of IPA and by 36% of colonized. The overall mortality rate was 47% in IPA and 23% in colonization.

Conclusions: 1. Immunosuppression by corticosteroids in COPD patients Gold III-IV is the major risk factor for invasive aspergillosis. 2. The absence of clinical improvement in correctly treated exacerbations of severe COPD and recurrent isolation of aspergillus in sputum should point to the possibility of the existence of IPA and demand a HRCT scan. 3. HRCT findings can detect early IPA in the shape of bronchial spread once bacterial or mycobacterial infections have been ruled out.

### 330. Quality control in lung function and exercise-related issues

#### P3026
**Over-reading spirometry – Man or machine?**
Aleck Harrison1, Grant Sowman2, Hardip KaurNagra2.1 Clinical Research, AJH Partners, Wallingford, Oxon, United Kingdom; 2Pharmaceutical Research, Vitalograph Ltd, Maids Moreton, Buckingham, United Kingdom

The quality of spirometry improves in multicentre trials with the aid of over-reading and prompt feedback to sites [1]. Recently spirometer software has become more sophisticated with increased built-in quality control. So is there a need for human intervention? An international trial with 519 asthmatic patients from 78 sites over 17 weeks produced 7297 spirometry sessions. The site spirometer program (Vitalograph Spirotrak®) determined the acceptability of each session with immediate feedback allowing the investigator to make decisions on the patients involvement. All sessions were e-transferred to the database and full visual inspection of the spirometry curves made by three expert over-readers with feedback within 48hrs, reading to sessions were e-transferred to the database and full visual inspection of the spirometry curves made by three expert over-readers with feedback within 48hrs, reading to validations of the Spirometry 360 program.

<table>
<thead>

</tr>
<tr>
<td>Rejected</td>
<td>296</td>
<td>3.7</td>
</tr>
</tbody>
</table>

The shape of both curves for rejected sessions follows that seen in other trials, the slope having been demonstrated to be due to prompt feedback. In studies with no feedback the rejection rate is constant [1]. Although there were small differences, this analysis demonstrates that despite hard objective parameters built into software there still needs to be the expert quality of the over-reader's eye.

The trial sponsors are thanked for the anonymous use of their data.

#### P3028
**Spirometry 360 on-line training and feedback: Spring 2011 course results and future plans**
James Stout, Karen Smith, Bruce Culver, Allen Dozor. Department of Pediatrics, University of Washington, Seattle, WA, United States Department of Pediatrics, University of Washington, Seattle, WA, United States Pulmonary and Critical Care, University of Washington, Seattle, WA, United States Pediatric Pulmonology, New York Medical College, Valhalla, NY, United States

Although office-based spirometry is increasingly gaining acceptance in general practice, wide variations in test quality impede its use. Spirometry 360 is a four-month interactive on-line training and feedback program currently delivered from the University of Washington to primary care practices around the U.S. It consists of: 1) Spirometry Fundamentals, a multi-media tutorial and reference tool; 2) interactive, case-based webinars led by clinical experts, and 3) an internet-based quality feedback reporting system that summarizes technique of de-identified spirograms automatically uploaded from the point of care.

We delivered the training for the second time in 2010 to 23 general practices from 4 states around the U.S. Results included a doubling of the acceptable spirograms for children younger than eight years from 40% at baseline to 80% at the end of training, and an overall increase in the acceptable spirogram rate from 49% to 71%. Among course participants, 100% reported that they would recommend the training to a colleague.

We are now delivering the course from February to June in 2011 in two concurrent tracks to 70 pediatric and family practices, involving over 200 physicians and their support staffs from 35 states around the U.S.

We will present a detailed analysis of over 4,000 tests from the Spring 2011 course, with a description of the reasons for variance from the ERS/ATS 2005 Spirometry Guideline, to further understand practitioners’ needs when performing office-based spirometry. We will also report on our plans for a "Train-the-Trainer" program with a goal of establishing independent training sites for ongoing delivery of the Spirometry 360 program.

**Stature measurement: Potential for improved interpretation of pulmonary function**
Sidsel Bendixen Holm, Christian Skjolvang Andersen, Camilla Borup, Flemming Madsen. Respiratory Function Laboratory, Allergy and Lung Clinic, Helsingør, Denmark

Introduction: Measurement of stature is a prerequisite for determination of the normal lung function since reference equations are based on stature (standing height).

Objective: The aim of this study was to investigate the optimal method to measure stature in a busy pulmonary function laboratory.

Methods: We measured the stature of 87 subjects using a digital-counter sta-

diameter, a wall-mounted bench rule, and an ultrasound distance estimator. Stature was also estimated based on armspan measurement, and self-reported stature was recorded. Results were compared using Bland and Altman plots.

Results: See table. Neither ultrasound measurement nor self-reported stature was sufficiently accurate for clinical use. An unexpected observation was that the stadiometer was the fastest method.

Conclusions: Stature should be measured with the same accuracy as pulmonary function since clinical decisions are based on both. Present the most accurate and probably the fastest measurement of stature is obtained by using a stadiometer with a digital counter.

P3030
Spirometry quality in patients with COPD
Lalita Fernandes, Anthony Mesquita. Respiratory Medicine, Goa Medical College, Panaji, Goa, India Respiratory Medicine, Goa Medical College, Panaji, Goa, India

Background and significance: Many spirometries are performed on sick and elderly COPD patients. There is a general perception that it is difficult for such patients to perform spirometries. The 2005 ATS/ERS guidelines on spirometry recommends a repeatability of 150ml for FEV1 and FVC and 100ml if FVC < 1 litre. Our aim was to assess the repeatability criteria in COPD patients.

Methods: Spirometry was performed by 156 patients of COPD. Spirometry was conducted to obtain at least acceptable flow volume loops using spirometers meeting ATS/ERS standards. 131 patients with acceptable spirometry were evaluated for repeatability criteria and 40 COPD patients were evaluated for within individual repeatability criteria.

Results: Of the 156 patients of COPD, 131 (83.9%) had acceptable spiromograms. 92% were males, mean (SD) age = 64 (7.8), mean (SD) FEV1% = 45.7 (14.76). After the usual exclusion criteria and COPD patients. For each test, the difference between the best and second best of 3 trials was calculated for FEV1 and FVC; 10) cough or variable cooperation; 100) FET > 6s. If the error 100 (lack of plateau) would have been omitted. The time needed to obtain acceptable values varied between 4 and 16 minutes (mean 9, mode 7 minutes), without counting interpretation, patient or device preparation, and infection control procedures.

We conclude that 6.4% of aged persons were not able to cooperate during spirometry. Those who cooperated - had problem with reaching the plateau at end expiration. Following errors are recognized: 1) less than 3 trials; 2) lack of reproducibility of FEV1 and 4) FVC; 10) cough or variable cooperation; 100) FET > 6s or lack of plateau; 1000) BEV too high and 4000) abrupt end.

P3031
Quality of spirometry in the elderly
Malgorzata Czajkowska-Malinowski 1, Waldemar Tomalak 2, Jakub Radieski 2
1 Department of Lung Disease and Respiratory Failure, Center of COPD and Respiratory Failure, Regional Hospital of Pulmonology, Bydgoszcz, Poland; 2 Department of Physiopathology of Respiratory System, National Institute for TBC & Lung Dis., Rabka, Poland

Assessment of lung function in aged subjects became quite frequent. We have attempted to evaluate quality of spirometric examination in people aged ≥65 years. We have analyzed data from all the patients admitted to the Center of COPD and Respiratory Failure Regional Hospital of Pulmonology in Bydgoszcz in the period June-December 2010. Spirometry was performed by 3 experienced techni- cians using Jaeger’s MasterLab calibrated prior to the measurements. There were 500 patients analyzed (age range: 65-90; median: 72; mean ±SD: 73.1±7.5). We used quality error codes assigned by spirometer (according to ERS/ATS 2005 recommendations for spirometry).

Following errors were recognized: 1) less than 3 trials; 2) lack of reproducibility of FEV1 and 4) FVC; 10) cough or variable cooperation; 100) FET > 6s or lack of plateau; 1000) BEV too high and 4000) abrupt end. Out of 500 patients 32 were not able to perform spirometry (due to error 1 – 28 and 10 – 4). Out of the remaining 468 patients 195 (41.2%) performed spirometry without any errors. In the test – software indicated (by frequency of occurrence) error 100; error 4; error 4000; error 2 and error 1000. In 232 patients 1 error was encountered, in 35 – 2; in 5 – 3 and in 1 – 4. All examined patients reached FET<6s. If the error 100 (lack of plateau) would be omitted, the percentage of good spirometries rise to 91.2%. We conclude that 6.4% of aged persons were not able to cooperate during spirometry. Those who cooperated - had problem with reaching the plateau at end expiration. Such the analysis of errors; repeated from time to time might be very useful in giving feedback to technicians - to make them much more careful in observing end expiration in aged persons performing spirometry.

P3032
Number of tests and the time needed to fulfill the quality criteria for plethysmographic measurements
Diana Ionita 1, Carmen Stoicescu 1, Gabriela Weiss 1, Illeana Stoicescu 2, Madalina Burecu 2, Camelia Nita 1, Alina Cioiritur 2, Daniela Dospinu 2, Felicia Cojocaru 2, Ilona Stramblu 1
1 Respiratory Physiopathology Department, “M. Nasta” Institute of Pneumonology, Bucharest, Romania; 2 Clinical Departments, “M. Nasta” Institute of Pneumonology, Bucharest, Romania; Clinical Department, Ascent Clinical Research Solutions, Bucharest, Romania

Objective: To determine the number of tests and the time needed to fulfill the quality criteria for plethysmography.

Subjects and methods: Body-plethysmography was performed in healthy subjects and in patients familiar with the testing, in order to obtain at least three acceptable measurements with repeatable parameters (at least four from the list: Raw, IC, VC, FRC and TLC). The number of tests and the time to obtain quality measurements were noted.

Results: One hundred and eighteen body-plethysmography sessions were performed in 10 weeks: 8 in healthy subjects, 73 in COPD patients and 37 in patients with other respiratory diseases. All the subjects obtained at least 3 acceptable tests and had repeatable values for at least 3 parameters. One hundred and twelve subjects (95%) obtained repeatable values for 4 parameters and 92 subjects (76%) for all the 5 tested parameters. In 13 subjects only 3 tests were needed to obtain repeatable values for the tested parameters, 22 subjects needed 4 tests, 26 subjects – 5 tests, 45 subjects – 6 tests and 12 subjects performed 7 tests. The time needed to obtain correct sessions varied between 4 and 16 minutes (mean 9, mode 7 minutes), without counting interpretation, patient or device preparation, and infection control procedures.

Conclusions: We conclude that the use of biological control subjects to validate exercise testing with supplemental oxygen.

P3033
The use of biological control subjects to validate exercise testing with supplemental oxygen
Kevin De Soomer, K. Leemans, H. Varenberg, W. De Backer, E. Oostven. Dept of Lung Function and Pulmonary Medicine, Antwerp University Hospital, Antwerp, Belgium

Some patients desaturate during exercise due to diffusion limitation of O2-uptake in the lung. To measure their exercise tolerance and its limiting factor, cardiopulmonary exercise testing (CPET) can be performed with supplemental oxygen (O2).

The aim of our study was to validate the High/Low FiO2 software option on the Jaeger Oxycron Pro (Jaeger, Wurzburg, Germany) using biological control subjects. Three healthy lung function technicians (2F: 1M) performed multiple exercise tests, breathing either room air or a gas mixture containing 30% O2 and 70% N2. The exercise test consisted of a 3 min rest period, 3 min unloaded pedaling followed by 5 min steady state exercise at 40 and 80 Watt for the female subjects and 60 and 120 Watt for the male subject, respectively. The mean values of minute ventilation (VE), CO2 production (VCO2), O2 consumption (V'O2) and heart rate (HR) as measured during the last two min of every steady state interval were used for further analysis. Each subject performed 7 tests while breathing FiO2= 21% and 4 tests while breathing FiO2= 30%. Bland-Altman analysis revealed no significant differences were seen in age, gender or FEV1 values between the subjects that obtained repeatable values after 3 or 4 tests versus (vs.) >4 tests, in 3-7 minutes vs. >7 minutes, for 4 vs. 5 parameters (p<NS for all tested associations).

Conclusions: We conclude that using the High/Low FiO2 software option during CPET, V'CO2 and V'O2 are reliably measured while breathing 30% O2.

High Quality Forced Spirometry (HQS) in primary care (PC) enhances management of respiratory patients. We aimed at: a) developing standards to transfer FS data using DICOM; b) deploying web-based support to PC and Community Pharmacists (CPH); c) validating a new algorithm for automatic assessment of quality of the tests; and, d) assessing the web application
We explored 1430 subjects from 15 PC and 812 subjects from 40 CPH. The follow-up period was >6 months. The validation of the algorithm for automatic QC was done using 778 curves from 291 patients and the 24 flow-volume and volume-time curves from the ATS. The assessment by an expert professional and the score automatically generated through the algorithm were compared (Grade 0, rejected; Grade 1 accepted; and, Grade 2 doubtful test). The percent of HQS increased from 57% to 78% during the study period (9 months). The CPH study showed on average 70% HQS. The performance of the algorithm for automatic assessment of spirometry quality control was acceptable (Sensitivity 96%; Specificity 95%).
Our results prompt the adoption of strategies to standardize the transfer HQS tests (HL7,CDA IC) among providers. Thus, facilitating information sharing across the systems and enhancing the quality of the tests. The automatic algorithm showed high applicability. All together, the study facilitates future strategies for early diagnosis of chronic obstructive diseases as well as long-term follow-up of patients.

Preoperative determinants of the length of hospital stay in patients undergoing surgery for pancreatic cancer
Roger Carter1, Oliver Aileen1, V.V. Chandrabaln2, John Kinsella 3.
1Respiratory Physiopathology Department, “Marius Nasta” Institute of Pneumology, Bucharest, Romania; 2Respiratory Medicine, Royal Infirmary, Glasgow, United Kingdom; 3West of Scotland Pancreatic Unit, Royal Infirmary, Glasgow, United Kingdom; 4Anaesthesitics, Royal Infirmary, Glasgow, United Kingdom
Introduction: Surgery for pancreatic cancer is associated with considerable morbidity. Both surgeon-related and patient-related factors are important in determining postoperative outcome. Therefore most pancreatic surgery is now carried out in specialist centres. However, patient optimisation is complex since factors that determine postoperative morbidity are less well understood.
Objective: To compare preoperative measures of patient comorbidity with length of hospital stay in patients undergoing pancreatic surgery.
Patients and methods: 103 patients who underwent surgery for pancreatic cancer (pancreatico-duodenectomy n=87, trial dissection with bypass n=16) had preoperative evaluation of body habitus, chronic respiratory disease, diabetes, obesity and cardiac disease (Glasgow Prognostic Score, mGPS) and routine blood analysis. Cardiopulmonary function (CPET) was measured in 54 patients. Length of hospital stay was recorded.
Results: The median length of hospital stay was 17 days. 39 stayed <14 days and 64 ≥14 days. Length of hospital stay was not associated with body habitus or systemic inflammatory response. However, in patients with CPET, more patients with low anaerobic threshold (p=0.030), high base excess (0.056) and high VE/VCO2 (p=0.022) had a hospital stay >14 days. Prolonged hospital stay was associated with pancreatico-duodenectomy (p=0.027) and anastomotic failure (p<0.001).
Conclusions: CPET was the only pre-operative objective measure that correlated significantly with prolonged hospital stay. Length of stay is a useful surrogate marker of post-operative adverse events. Although CPET does not predict specific complications, it may determine the host response to major surgery and its immediate sequelae.

P3036
Is there a difference between the results of the standard six minutes walking test (6MWT) and the test with ventilation monitoring (V6MWT)?
Carolina Varela-Casado1, Alina Crețon2, Diana Ionita 1.
1Respiratory Physiopathology Department, “Marius Nasta” Institute of Pneumology, Bucharest, Romania; 2Pneumology Department, “Marius Nasta” Institute of Pneumology, Bucharest, Romania
Background: 6MWT is a validated test for the evaluation and monitoring of patients with cardiovascular and respiratory conditions. The standard test evaluates the initial and final heart rate (HR) and oxygen saturation (SaO2), and does not measure ventilation.
Aim: To assess (a) the similarities of the main parameters between S6MWT and V6MWT and (b) the mask-related discomfort during V6MWT.
Subjects and methods: 23 patients (P) with respiratory disease (15 COPD cases) and 3 healthy subjects (HS) performed two S6MWT and one V6MWT, at 1 hour intervals. 6MWT distance (6MWd), initial and final HR, SaO2 and symptoms, and the mask-related discomfort were recorded.
Results: The mean 6MWd was 9 meters longer in S6MWT than in V6MWT (range -65, +135 m). In 7P (30%) the 6MWd was significantly different (>50 m) between the tests, with 5 P (22%) walking less and 2P walking more than the V6MWT. Flow limitation at rest may identify a phenotype of chronic obstructive pulmonary disease (COPD)
Laura Malagrinò, Francesco Costa, Barbara Vaggagi, Claudia De Simone, Cristina Spanu, Alessandro Celi, Pierluigi Paggiaro. Centro-Thoracic and Vascular Department, University of Pisa, Pisa, Italy
Background: Expiratory flow limitation at rest (FL) promotes dynamic hyperinflation (DH) during exercise in COPD patients.
Aim: To evaluate whether a specific FL phenotype can be identified in COPD patients.
Subjects and methods: 48 COPD patients (28 male, FEV1< 50 % predicted) underwent: pulmonary function tests (PFT), cardiopulmonary exercise test (CPET) with assessment of DH, Saint George’s Respiratory Questionnaire (SGRQ), dyspnea scale (MRC), physical activity by Armband. We measured blood haemoglobin (HB) and inflammatory cells. CRP and Pro-BNP: sputum inflammatory cell count and neutrophil elastase. FL was evaluated according to Hyatt by overlapping the tidal and maximal flow-volume curves and categorized as either absent no overlapping, or present any overlapping.
Results: FL was observed in 38/48 COPD patients. Baseline difference between two groups are reported *(p< 0.05)

Only in FL group, VO2kg was correlated (p< 0.05) with MRC, FEV1%, IC%, DLCO%, HB, DS, SGRQ tot%, HB, Pro-BNP.
Conclusions: Flow imitation at rest, as assessed by a simple, non invasive, inexpensive technique, identifies patients with clinical and functional characteristics suggestive of a specific ‘embryoseme-like’ phenotype.

P3038
Ventilatory exercise response at low altitude
Jerica Sinkeldam, Gwenda Commandeur, Herman Groenhoff. Pulmonology, VU University Medical Center, Amsterdam, Netherlands
Introduction: At medium and high altitude there is an increased ventilatory response to sub maximal exercise tolerance due to a decreased aerobic capacity. However little is known about the ventilatory exercise response at sub maximal exercise at low altitude compared to sea level. Therefore we conducted this study to test if the ventilatory response at sub maximal exercise differs at low altitude compared to sea level.
Methods: Nine healthy women were included to perform a maximal submaximal pulmonary exercise test (3 min, 50 and 100 watt), with gas exchange, heart rate and oxygen saturation measurements on a cycle ergometer at sea level and identical measurements at 1560 meters above sea level (Davos, Switzerland).
Results: See Table 1.
Introduction:
Cardio pulmonary exercise testing (CPET) parameters can be measured with the use of a mouthpiece or a breathing mask. In clinical practice, patients often complain about a dry mouth when a mouthpiece is used which possibly influences CPET results. A more comfortable alternative, although with an increased chance of leak, is the frequently used breathing mask. Therefore we hypothesised that ventilatory CPET results measured by mouthpiece or breathing mask could be different.

Aim: To test this hypothesis we conducted this study to estimate ventilatory CPET differences between mouthpiece and breathing mask measurements.

Methods: Twelve healthy subjects performed two (3 minutes/40 watt) incremental maximal CPET measurements with steady state measurements of ventilation (VE) and oxygen consumption (VO2) at sub maximum work levels. The measurements were taken on different days within one week in a different sequence. One using the mouthpiece (dead space: 50 ml) and the other with a mask (Combitox, dead space: 100 ml).

Results: See Table 1.

Conclusions: Due to the fact that the VO2 values between mouthpiece and mask measurements were not different, we concluded that the Combitox mask does not leak. However, the VE values measured with the mask were higher compared to those of the mouthpiece. This is likely explained by the higher amount of dead space. The maximum work rate level attained with the mouthpiece or the mask was the same.

P3040
Is measuring ventilation during the six minutes walking test (6MWT) important?
Carmen Columbia Stroescu (Cociac) 1, Alina Croitoru 2, Diana Ionita 1, 1 Respiratory Physiopathology Department, “Marius Nasta” Institute of Pneumology, Bucharest, Romania; 2 Pneumology Department, “Marius Nasta” Institute of Pneumology, Bucharest, Romania

Background: 6MWD and FEV1 are used as a one-time measure of functional capacity. We aimed to determine the 6MWD for healthy Pakistanis, identify factors affecting 6MWD and derive an equation.

Methods: 15-65yrs subjects were prospectively enrolled after screening. A standardized 6MWT was administered. SpO2, HR, BP and dyspnea scores were determined pre and post-test.

Results: 296 subjects [211 (71%) men] participated with mean age 37.3±12 yrs. The mean 6MWD for all participants was 469.88±101.24m (range 180m – 756m) [men 502.35±92.21m; women 389.28±74.29m]. On univariate analysis gender, weight, height and age showed a significant relationship with the 6MWD. Sub analysis revealed a significant direct relationship between height (r=0.485, p<0.001) and weight (r=0.212, p<0.001). Gender and age were identified as independent factors in multiple regression analysis, and together explained 33% of the variance. The regression equation predicting 6MWD is: 6MWD (m) for men = 164.08 – (1.90 × age) + (1.95 × height) – (0.168 × BMI); for women = 164.08 + (78.06 × age) + (1.194 × height) – (5.68 × BMI) where male gender = 1 and female gender = 0.

Conclusions: In conclusion, the variability of the ISWT is explained largely by gender, age and BMI. The reference values for the ISWT can be adequately predicted using the equation proposed in this study.

Background: Reference values for the incremental shuttle walking test (ISWT) which are applicable to the whole population are needed.

Objective: The aim of this study was to determine the 6MWD for healthy Pakistanis, identify factors affecting 6MWD and derive an equation.

Methods: 6MWDs among Pakistanis are shorter than predicted by reference equations. The proposed equation gives predicted (mean) 6MWDs for women = 164.08 – (1.90 × age) + (1.95 × height) – (0.168 × BMI) and for men = 164.08 + (78.06 × age) + (1.194 × height) – (5.68 × BMI).

P3043
Pulse oximeter validation study
Gelijz Johal, Jodie Hunt, Brendan Cooper. Lung Function & Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, West Midlands, United Kingdom

Introduction: The aim of this study was to assess a) the reliability of our pulse oximeter (SpO2 and HR) signals, b) to detect malfunctions, c) and to provide recommendations on SpO2 testing.

Methods: A pulse oximeter tester (Metron DEAG) was used to test 12 Konica Minolta pulse oximeters over a split 6 month period. The reliability of the analyser was measured against a reference standard (Osram-1 pulse oximeter simulator). The ranges that were simulated include SpO2 of 85%, 95% and 98% at heart rates (HR) of 60, 120 and 140 beats per minute (b.p.m) respectively.

Results: The Bland-Altman analysis did not reveal any significant difference at all 3 ranges for both analysers. The mean differences at SpO2 of 85% and HR of 40 b.p.m was -0.37% and ±2SD of (0.67 – 1.39). At 95% b.p.m mean difference of ±0.67±2SD (+1.8 - +0.15) and 95% at 120 b.p.m a mean difference of 0.08± ±2SD (+0.44 – 0.29). The difference between the two analysers was correlated better towards the higher range of SpO2. There was no variability in the simulated HR during the testing of all the pulse oximeters.

Discussion: The results of the study show that the oximeters appear to be remarkably stable over time.

Conclusions: The change in SpO2 over Period 1 (mean simulated readings of 86.1%, 95.8% and 98.0%) and Period 2 (mean simulated readings of 86.2% and 95.7% and 98.0%) was negligible. The P values for all three ranges (85% P value of 0.65, 95% P=0.59 and 98% P=0.47) were > 0.05 and therefore no significant difference in the data existed. We conclude that regular testing of pulse oximeters does not help predict failure or problems that aren’t picked up by the regular operators.

P3046
Albuminuria in children with obstructive sleep apnea
Vasiliki Varlam1, Emmanuel Axenteopoulos1, Georgia Malakasioti1, Vasiliki Theolog1, Eleni Theophanou1, Athanasios Kaditis1, Efthimia Daskalopoulou2, Konstantinos Gourgoulianis1. Sleep Disorders Laboratory, University of Thessaly School of Medicine and Larissa University Hospital, Larissa, Greece; 2Department of Internal Medicine, Sleep Laboratory, “St Paul” General Hospital, Thessaloniki, Greece

Increased excretion of albumin in urine has been considered a surrogate marker of endothelial dysfunction in adults with obstructive sleep apnea (OSA). Aim of this study was to evaluate urinary excretion of albumin in children with OSA.

Methods: Albumin-to-creatinine ratio (ACR) was calculated in a morning urine specimen collected from children with or without OSA. An assay appropriate for detection of microalbuminuria was used.

Results: Twenty seven subjects with moderate-to-severe OSA (5.6±2.1 y.o.; AHI 9.1±3.7 episodes/h), 71 subjects with mild OSA (6.2±2.3 y.o.; 2.4±1.4 episodes/h) and 31 children without habitual snoring (6.7±2.4 y.o.; 0±0.6±3 episodes/h) were studied. Subjects with moderate-to-severe OSA had similar ACR to those with mild OSA (p=0.072) and significantly higher ACR relative to subjects without habitual snoring (p=0.007): median 0.38 (0.14-1.3) mg/g vs. 0.31 (0.13 vs 0.3, respectively). There was significantly increased risk for having ACR values ≥15 when comparing children with moderate-to-severe or mild OSA compared to children without habitual snoring after adjustment for age and gender: OR (95% CI) 6.4 (1.8-23.3) of 8.4 kg/m2, respectively. OSA was moderate to severe

P3047
Biochemical basis of inflammation in children with obstructive sleep apnea syndrome (OSAS) and in children with obesity

Pneumonology and Alergology, Warsaw Medical University, Warsaw, Poland

Introduction: There is evidence that certain endocrine disorders are associated with impaired breathing during the sleep. One of the hormones closely associated with sleep is melatonin. It is a hormone secreted cyclically, which is associated with impaired breathing during the sleep. One of the hormones closely associated with sleep is melatonin. It is a hormone secreted cyclically, which

Aim: The aim of the study was to investigate circadian profile of melatonin secretion in patients with OSAS.

Methods: Study group consisted of 71 patients with OSAS: 66 men (93%) and 5 women (7%). The average age was 49±2,9±1 years. Body mass index was 32.7±4,5 kg/m², mean AHI 45±22.8/hour. OSAS was diagnosed with full polysomnography. In the study group 6 patients (8.5%) diagnosed with mild OSAS, 10 patients (26.7%) moderate OSAS and 46 patients (64.8%) severe OSAS. Control group consisted of 18 subjects with excluded OSAS, mean age 43±13 years, mean BMI 28.7±4.4 kg/m², mean AHI 2.5±2.1. In the study group and control group circadian profile of melatonin secretion was assessed with radioimmunoassay method (RIA) at 6 time points.

Results: Melatonin concentration (pg/ml) at 2.00, 6.00, 10.00 am and, 2.00, 6.00, 10.00 pm were: in the study group 91.8±70.7, 63.2±54.8, 21.4±11.3, 17.8±6.3, 21.1±6.2, 30.1±5.2; in the control group 136.2±93.9, 94.2±2.7, 30.4±2.9, 23.5, 9.3±6.1, 16.5±11.9, 43.6±2.7. Po.05

Discussion: The Bland-Altman method was used to assess the agreement in the two analysers. The mean difference in the data existed was 0.08± ±2SD (+0.44 – 0.29). The difference between the two analyzers was correlated better towards the higher range of SpO2. There was no variability in the simulated HR during the testing of all the pulse oximeters.

Discussion: The results of the study show that the oximeters appear to be remarkably stable over time.

Conclusions: The change in SpO2 over Period 1 (mean simulated readings of 86.1%, 95.8% and 98.0%) and Period 2 (mean simulated readings of 86.2% and 95.7% and 98.0%) was negligible. The P values for all three ranges (85% P value of 0.65, 95% P=0.59 and 98% P=0.47) were > 0.05 and therefore no significant difference in the data existed. We conclude that regular testing of pulse oximeters does not help predict failure or problems that aren’t picked up by the regular operators.

Results: Twenty seven subjects with moderate-to-severe OSA (5.6±2.1 y.o.; AHI 9.1±3.7 episodes/h), 71 subjects with mild OSA (6.2±2.3 y.o.; 2.4±1.4 episodes/h) and 31 children without habitual snoring (6.7±2.4 y.o.; 0±0.6±3 episodes/h) were studied. Subjects with moderate-to-severe OSA had similar ACR to those with mild OSA (p=0.072) and significantly higher ACR relative to subjects without habitual snoring (p=0.007): median 0.38 (0.14-1.3) mg/g vs. 0.31 (0.13 vs 0.3, respectively). There was significantly increased risk for having ACR values ≥15 when comparing children with moderate-to-severe or mild OSA compared to children without habitual snoring after adjustment for age and gender: OR (95% CI) 6.4 (1.8-23.3) of 8.4 kg/m2, respectively. OSA was moderate to severe

Rationale: OSAS and obesity are two risk factors that can lead to the early development of cardiovascular events. These two diseases very often coexist, and it’s hard to understand the mechanisms that characterize each one. Our aim is to determine the different pathways of these two disorders.

Methods: We evaluated 38 children (21±13.5; mean age: 7.68±4.37 years), divided in three groups (18 children with OSAS but non obese, 10 Obese children but without OSA, 10 controls). All children underwent blood sample test for the evaluation of CRP hs, the lipidic and metabolic aspect (Glycemia, Insulin, Cholesterol total, LDL, HDL, triglycerides, leptin, adiponectin, and resistin), the interleuchines pattern (IL-1 a β, IL-2, IL-4, IL-6, IL-2, IL-10, IFN-γ, TNF-α, VEGF, EGF, MCP1) and the polysomnography examination.

Results: OSAS with children and obesity showed showed higher levels of LDL-cholesterol and triglycerides compared to controls (OSAS p=0.005 and p=0.01; Obese p=0.01 and p=0.005). In the obese group leptin levels were significantly higher compared to controls and to the OSAS (p=0.00). In the OSAS groups we found significantly higher levels of IL 1 β (p=0.04) and TNF-α (p=0.05) compared to controls and obese groups.

Conclusions: OSAS and obesity have two different pathways. OSAS promotes an inflammatory pattern through the stimulation of TNF-α, whereas obesity determines an hormonal deregulation especially of the adipokines one, as leptin.
Antiinflammatory medications administered to children with obstructive sleep apnea (OSA) decrease size of pharyngeal lymphoid tissue and severity of airway obstruction. In this study total and cell populations of tonsillar lymphocytes with potential susceptibility to inhibitors of cysteinyl leukotriene receptors.

Methods: Tonsillar tissue excised from children with OSA or controls with recurrent tonsillitis (RT) was studied for expression of types 1 and 2 cysteinyl leukotriene receptors (LT1R and LT2R) by immunofluorescence and flow cytometry.

Results: Ten children with moderate-to-severe OSA (age 5±6.3 years) and 10 subjects with RT (7±4.7 years) were studied. In both children with OSA and RT, immunoreactivity for LT1R and LT2R was detected in CD3+ tonsil T lymphocytes (extracellular areas) and in CD19+ B lymphocytes (germinal centers and mantle zones). In subjects with OSA, LT1R+ fraction of small size CD19+ B lymphocytes (median 26.4%, range 4.7%-77.5%) was similar to the LT1R+ fraction of CD3+ T lymphocytes (5.7%, 0.7%-50.3%) and significantly higher than the LT1R+ fraction of large size CD19+ B lymphocytes (3.3%, 1.3%-31.9%) (p<0.005 and p<0.05). Similar trend was identified for LT2R in children with OSA or RT and for LT1R in participants with RT.

Conclusions: Children with OSA or RT and tonsillar hypertrophy express cysteinyl leukotriene receptors in B lymphocytes of the tonsillar germinal centers and mantle/marginal zones and in extracellular T lymphocytes. These findings explain the beneficial effects of cysteinyl leukotriene receptor inhibitors on pharyngeal lymphoid tissue hypertrophy and OSA.

P3849 Effect of intermittent hypoxia on the expression of fatty acid binding proteins in human adipocytes and macrophages

Judith C.W. Mak1, Qian Han1, Yue Chen Yeung1, Mary S.M. Ip1, 1Medicine, The University of Hong Kong, Hong Kong, Hong Kong; 2Pharmacology & Pharmacy, The University of Hong Kong, Hong Kong, Hong Kong; 3Research Centre of HBHA, The University of Hong Kong, Hong Kong, Hong Kong

Background: Intermittent hypoxia (IH) is a hallmark feature in obstructive sleep apnea (OSA), which is increasingly recognized as an independent risk factor of cardiovascular diseases. Different fatty acid binding proteins (FABPs), including adipocyte (A)-FABP, FABP4 and epidermal (E)-FABP, are now widely accepted as biomarkers associated with increased cardiac-metabolic risks and carotid atherosclerosis. We hypothesize that IH exposure may regulate the expression of two major cell types involved in the development of atherosclerosis, namely adipocytes and macrophages.

Methods: Human preadipocytes and THP-1 cells were cultivated in the differentiation media until reaching final differentiation level of ~80% before treatments. Differentiated cells were exposed to intermittent normoxia (IN) as control or IH (a 10-min hypoxia (5% O2) followed by a 5-min normoxia (21% O2) for 64 cycles using the BioSpherix OxyCycler CS2 system (Redfield, NY)). FABP, Fabp4 and Fabp5 mRNA expressions were measured by RT-PCR, and protein by Western blot.

Results: Adipocytes expressed very high levels of Fabp4 and low levels of Fabp5 while differentiated macrophages expressed high levels of both Fabp4 and Fabp5 consistent with previous reports. IH exposure resulted in an up-regulation of Fabp5 but not Fabp4 expression in adipocytes. Macrophage Fabp4 and Fabp5 levels remained unchanged following IH treatment, suggesting that the two cell types are likely to have distinct functions.

Conclusions: These data suggest that Fabp5 may play a role in atherogenesis in OSA subjects.

P3850 Predictors of obstructive sleep apnea syndrome and metabolic syndrome

Raquel Ducal Quintas1, Manuel Tumbioiro Novoa1, Maria Teresa Alves Pérez2, María Gabriela Cortez Montero1, Mari Luz Santalla Martínez1, Pedro Marcos Velázquez1, 1Pneumología, Complejo Hospitalario de Ourense, Ourense, Galicia, Spain; 2Investigation, Complejo Hospitalario de Ourense, Ourense, Galicia, Spain

Background: Obstructive sleep apnea syndrome (OSAS) is a well-known factor of cardiovascular disease and is also related with metabolic syndrome (MS). Some factors are predictors of OSAS and also of MS.

Objective: We wanted to know if OSAS and MS have some factors that can predict both diseases. We also wanted to know the prevalence of the individual components of each syndrome as a entity in patients with suspected OSAS.

Patients and methods: We studied all the patients that were referred to our sleep laboratory from January to December 2009. The patients underwent polysomnography and overnight oximetry. OSAS and MS were diagnosed when apnea hypopnea index (AHI) was > 5. MS was diagnosed according to the International Diabetes Federation criteria.

Results: We studied 486 patients; 71.9% were men, with a mean age of 57.3 ± 13.5 years and a body mass index (BMI) 32.1 ± 6.5 kg/m2, 66.9% of patients were diagnosed of moderate-severe OSA. Mean AHI was 30.2 ± 23.8, 93.8% of subjects had enough data to study MS. The prevalence of MS was 64.7%. Hypertension and hyperglycemia increased with the severity of MS (p < 0.001). Age and waist circumference were predictors of OSAS and MS (p<0.05).

Conclusions:
- Central obesity, measured as waist circumference, and age are predictors of both, OSAS and MS.
- MS is more frequent in OSAS patients and its prevalence increases with OSAS severity.
- Hypertension and hyperglycemia are related with OSAS severity.

P3851 Sleep apnea symptoms in diabetes and their first degree relatives

Babak Amera1, Farideh Sheikh Bahaee 1, Masoud Amiri2, Mohammad Golshan2, Ingo Fietz4, Thomas Penzel1, 1Internal Medicine, Ispahan University of Medical Sciences, Ispahan, Islamic Republic of Iran; 2Sleep, Bambud Respiratory Research Center, Ispahan, Islamic Republic of Iran; 3Diabetes, Ispahan Endocrine and Metabolism Research Centre (EMIRC), Ispahan, Islamic Republic of Iran; 4Center of Sleep Medicine, Charité - Universitätsmedizin Berlin, Charitéplatz 1, Berlin, Germany

Background: The purpose of our study was to investigate high risk for sleep apnea syndrome, in a cohort of diabetics and their first degree relatives with different categories of serum glucose level: diabetic, impaired glucose tolerance (IGT), and normal glucose.

Methods: As a part of a cohort study, all of diabetic and their first degree relatives who came for glucose control in diabetes clinic, were invited to take part in the survey. 2,462 individuals (82%) agreed to fill out the Berlin and Epworth sleep questionnaire. Participants consisted of 2462 subjects 15-70 years of age, both males and females. With diabetes and normal glucose, were invited to take part in the survey. 2,462 individuals (82%) agreed to fill out the Berlin and Epworth sleep questionnaire. Participants consisted of 2462 subjects 15-70 years of age, both males and females. With diabetes and normal glucose, were invited to take part in the survey.

Results: Prevalences of high risk for sleep apnea were lowest in first degree relatives with normal glucose group (30.6%) and highest among diabetics (50.5%).

Conclusions: Sleep apnea symptoms are common in first degree relatives of diabetic patients regardless of blood glucose level. Level of blood glucose in Groups with diabetes and abnormal GTT and family of diabetic could not affect sleep apnea symptoms.

P3852 How can identified early presence of atheroclerotic plaque in severe OSAS?

Roberto Rossi, Claudio Carnavale, Roberto Mezzaria. Cardio-Thoacic Diseases University of Milan, Foundation IRCCS ‘Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Carotid plaque is frequent and often unacknowledged in severe OSAS. Ultrasonographic evaluation of the carotid arteries is the safest way to disclose a different level of stenosis in absence of clinical symptoms, but not all OSAS patients are submitted this examination. Nocturnal hypoxemia related to OSAS can induce retinal vessel constriction with a reduction of artero-venous ratio (A VR) evaluated by retinography. Aim of this study was to evaluate in severe OSAS patients a correlation between a severe constriction of AV ratio (< 75) and carotid stenosis, with ultrasonography of the carotid arteries. 30 obese patients (BMI 35±18 kg/m2), aged from 35 to 60 years, non smokers, non diabetics, non cardiopathics, non hypertensive, diagnosed for severe OSAS (AHI=43±22/h) after a polysomnography, underwent retinography of the two eyes with Topcon TCR NW200 non mydriatic retinal camera. 27/30 patients with a severe constricted AVR Index (< 75) underwent ultrasonographic evaluation of the carotid arteries. In 70% (20/27) of this patients ultrasonographic evaluation revealed the presence of plaque at least one of the two carotids. If the pathoanatomic constriction of retinal vessels could be an indirect evidence of carotid artery stenosis, a thrombotic echocardiography and chest computed tomography angiography probably can show also the presence of non calcified coronary plaque in absence of clinical symptoms.
Aim: In this study we focused on the effects of weight loss and SDB on common metabolic parameters.

Methods: Consecutive obese children between 10 and 18 years were recruited. They followed a treatment program with diet, increased physical activity and psychological support. All children underwent a baseline sleep screening and a control study after 4-6 months of treatment in case of diagnosis of SDB. A fasting blood assay was performed baseline and after 4-6 months.

Results: 84 children and adolescents with a median age of 15.1 years (9.5-18.9 years) were included. Mean BMI z-score was 2.73±0.41. 44% of the subjects had SDB. Sleep apnoea severity index correlated positively with HDL-cholesterol (r= 0.34; P=.002), ASAT (r=.33; P=.003) and ALAT (r=.35; P=.001). No correlations were found for glucose, triglycerides and total cholesterol. After weight loss treatment all metabolic parameters improved and only 8% of the patients had residual SDB. Improvements in ASAT and ALAT were mediated by improvements in BMI. Improvements in oxygen desaturation index (ODI) were associated with an increase in HDL-cholesterol (r=.49; P=.003).

Conclusion: This study confirms the link between ASAT, ALAT, HDL-cholesterol and SDB baseline. HDL-cholesterol improved after weight loss in association with improvements in ODI.

P3054
The impact of sleep apnea on glucose metabolism. Results from a long-time follow-up
Eva Lindberg 1, Jenny Theorell-Haglow 1, Malin Svensson 2, Thorarinn Gislason 3, Christian Berne 1, Christier Jansen 1, 1Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala, Sweden; 2Department of Surgical Sciences, Örnholmsoaryngology, Uppsala, Sweden; 3Department of Respiratory Medicine and Sleep, University Hospital and Faculty of Medicine, Reykjavik, Iceland; 4Department of Medical Sciences, Internal Medicine, Uppsala, Sweden

Background: It has been suggested that sleep-disordered breathing (SDB) is a risk factor for diabetes, but long-term follow-ups are lacking.

Objectives: To analyze the influence of SDB on future glucose metabolism.

Methods: Men without diabetes (n=141) were investigated with whole-night respiratory monitoring. After a mean period of 11.3 years, they were followed up with an interview, blood sampling and anthropometric measurements. Insulin resistance was quantified using the homeostasis model assessment (HOMA). Delta-HOMA-IR = (HOMA-IRend− HOMA-IRstart)/HOMA-IRstart. An oral glucose tolerance test was performed in 113 men to calculate the insulin sensitivity index. Confounders adjusted for were age, BMI, weight gain, hypertension, treatment for diabetes and years with CPAP during the period.

Main results: At the follow-up, 23 men had diabetes. An apnea-hypopnea index (AHI) >5 and an oxygen desaturation index (ODI) of >5 were significant predictors of developing diabetes. After adjusting for confounders, the association with ODI remained significant (adj. OR 4.4, 95% CI 1.1-18.1). The ODI at baseline was inversely related to the insulin sensitivity index at the follow-up (r = -0.27, p=0.003). A deterioration in HOMA-IR was significantly related to all measurements of sleep-disordered breathing (AHI, AHI>5, ODI, ODI>5 and MeanSatO2) even when adjusting for confounders. When excluding the variable “years on CPAP” from the multivariate model, all associations weakened.

Conclusions: SDB is independently related to the development of insulin resistance and thereby the risk of manifest diabetes mellitus. The results indicate that CPAP treatment can modify this risk.

P3055
Coronary plaque distribution and endothelial dysfunction in younger obstructive sleep apnea patients
Heleen Vrints 1, Bharat Shrivalkar 2, Katrien Kluppels 2, Olivier M. Vanderveken 1, Evert Hamans 1, Wilfried De Keizer 3, 1Multidisciplinary Sleep Disorders Center, Antwerp University Hospital, Wilrijk, Antwerp, Belgium; 2Department of Cardiology, Antwerp University Hospital, Wilrijk, Antwerp, Belgium; 3Department of Pulmonary Medicine, Antwerp University Hospital, Wilrijk, Antwerp, Belgium; 4Department of ENT, Antwerp University Hospital, Wilrijk, Antwerp, Belgium

Background: Obstructive sleep apnea (OSA) occurs mainly in middle aged subjects and is associated with a higher incidence of cardiovascular complications.

Aim: Assessment of subclinical cardiovascular risk factors in asymptomatic younger OSA patients.

Methods: Patients undergoing a full polysomnography and with an apnea hypopnea index (AHI)>20, were included. They underwent an echocardiography, a measurement of the carotid intima media thickness (IMT), analysis of the endothelial function (brachial flow mediated dilation, FMD) and a Multislice Computerized Tomography (CT) for determination of the coronary plaque burden. We assessed 13 coronary segments for degree of stenosis (1: normal; 2: 50% stenosis; 3: 70% stenosis; 4: >70% stenosis)

Results: The patients [n=91; age=50±10y; M/F 79/12] had severe OSA, mean AHI of 52.2±23, and 59% had to up eleven coronary segments showing a variable degree of plaque burden. There was a significant correlation between the number of affected coronary segments and IMT (r=0.451; p<0.0001), FMD (r=-0.255; p=0.019), coronary arterial calcium score (r=.546;p<0.001), interventricular septum thickness (r=0.217;p=0.041) and age (r=0.144;p<0.01). Correlations were maintained after adjustment for hypertension, age and smoking. Patients with coronary plaques were elder (54±9y versus 47±9y; p<0.001), had thicker IMT (0.7±0.2mm versus 0.5±0.1mm; p<0.001) and had abnormal FMD (61±1±2% versus 73±3±2.5%; p=.0029).

Discussion: Our results suggest occurrence of significant subclinical coronary abnormalities and endothelial dysfunction in asymptomatic younger severe OSA patients. Routine screening for subclinical cardiovascular risk factors in OSA may be beneficial.

P3057
Endothelial dysfunction in patients with obstructive sleep apnea
Mostafa Elshazly1, Azah Farag1, Abir Zakaria 3, 1Chest Department, Kaar ElAini School of Medicine-Cairo University, Cairo, Egypt; 2Cardiology Department, Kaar ElAini School of Medicine-Cairo University, Cairo, Egypt; 3Internal Medicine, Kaar ElAini School of Medicine-Cairo University, Cairo, Egypt

Background: Obstructive sleep apnea (OSA) influences endothelial function and causes cardiovascular diseases.

Objectives: To assess the prevalence of endothelial dysfunction in patients with OSA.

Methods: Twenty-seven obese patients with OSA and 26 healthy obese subjects were investigated. The presence or absence of OSA was evaluated with a sleep study. Endothelial function was investigated with brachial artery ultrasound examination.

Results: Baseline characteristics were equivalent between the two groups. Minimal SaO2 and AH1 in the OSA and control groups were [72.1±6.16 versus 86.5±4.5% (P=0.0000), and 27.9±23.1 versus 2.0±1.5 (P=0.0000)]. There was no statistically significant difference in percentage change 2 of BADSLimitrate between patients and control groups (P=0.05) i.e. endothelial independent dilatation. Flow-mediated dilation (FMD) percentage change 1 was highly significant lower in OSA patients in comparison to control group (Mean ± SD 3.1±2.8 vs 10.6±6.9, (P=0.000) respectively. i.e. endothelial dysfunction. There was positive significant statistical correlation between BMI and BAD (b). FMD and SL Nitrate).Regarding the correlation, there was positive significant statistical correlation between ESS and AH1 the time in which O2 saturation <90%, BADEM and BAdSasal among the patients with OSA, but there was negative significant correlation between ESS and BAD. There was no significant correlation for BMI and OSA. Conclusion: We detected a prominent deterioration in endothelial function in OSA obese patients compared with healthy obese subjects. This deterioration may occur due to ongoing hypoxemia and it may be a possible cause of cardiovascular diseases in patients with OSA.

P3058
A hospital based study of sleep in metabolic syndrome between obese & non obese North Indians
Dhruva Chaudhary, Indr Sehgal, Chirag Tandon, Viral Sangwan. Pulmonary & Critical Care Medicine, Post Graduate Institute of Medical Sciences, Rishik, Harayana, India

Metabolic syndrome’s association with sleep apnea is established. However, differences amongst obese and non-obese patients of metabolic syndrome are not clear.

Methods: 50 consecutive patients fulfilling the criteria of metabolic syndrome and their revised National Cholesterol Education Program (NCEP) Adult Treatment Panel-3 guidelines were included. They were divided into two groups based as per revised National Cholesterol Education Program (NCEP) Adult Treatment Panel-3 guidelines were included. They were divided into two groups based on body mass index (BMI) as applicable in Asian Indians-Group I with BMI ≤25kg/m2 and Group II with BMI >25kg/m2. Patients on CPAP therapy & having any other systemic diseases were excluded. All eligible patients underwent overnight polysomnography.

Results: Demographically there was no difference between two groups. The mean BMI of group I & II were 23.2±0.16 6.8 kg/m2 & 31.6±0.93 kg/m2 respectively. Snoring, unrefreshing sleep & daytime sleepiness were the commonest presenting symptoms. Both groups had similar Epworth sleepiness scale. Diabetes & hypertension was significantly higher amongst group I & group II respectively. Both groups had similar sleep time & distribution of all stages of NREM sleep. Group I had an insignificant less REM sleep (7.18±3.23 versus 14.12±2.94, pvalue>0.05). Snoring time was significantly higher among group II (95.8±6.51 vs 44.7±6.29, p<0.001). Apneic episodes were common during NREM sleep in both groups. However the mean apneoa/hypopnea index (AHI) was similar in both groups (34.10±3.04 v/s 32.7±3.09; p value=0.807).

Conclusion: The prevalence of sleep disordered breathing in selective North Indian population with metabolic syndrome irrespective of BMI was high. Community based epidemiological study is the need of hour to define the extent of the problem.

P3059
OSAS and oxidative stress before and after CPAP therapy
Marco Brunori, Francesca Serena Pignataro, Roberto Pierro, Giulio Onelli. Respiratory Pathophysiology and Rehabilitation, Azienda Policlinico Umberto I, University of Rome "Sapienza", Rome, Italy

Obstructive Sleep Apnea Syndrome is frequently associated with oxidative stress.
which might contribute to the onset of some of the systemic co-morbidities. Repeated hypoaxia-oxygenation cycles may cause increase in Reactive Oxygen Species (ROS) with a reduction of Nitric Oxide (NO) availability.

This study was undertaken to assess oxidative stress in patients with severe OSAS (Atpnea-Hypopnea index > 30/h) by evaluation of brachial artery Flow mediated dilation (FMD), gp91(phox) and serum levels of nitrite and nitrate (NOx), and to test the hypothesis that Continuous Positive Airway Pressure (CPAP) therapy can reduce oxidative stress.

We choose FMD as indirect marker of endothelial NO-mediated reactivity; gp91(phox) for NADPH oxidase activity and serum levels of NOx, markers of nitric oxide generation.

We enrolled 10 patients with severe OSAS. After polysomnography, for evaluation AHI and oxygen desaturation index (ODI), FMD, gp91(phox) and NOx were measured before and after 90 days of CPAP treatment. None of the patients smoked.

The mean AHI and ODI prior to CPAP were respectively 43.3±11.9h and 35.8±6.2±3.5h, which decreased to 7.6±5.8h and 2.8±1.6h (p<0.001). The mean BMI was 35.3±5.5 kg/m2 and it didn’t change during 90 days of therapy. gp91(phox) decreased from 38.2±7.4 to 23.6±5.1 (p<0.001).

FMD and NOx were not significantly different.

While confirming the association between OSAS and oxidative stress, we found CPAP therapy managed to reduce gp91(phox) in patients who adhered to treatment for at least 4 hours daily, for 90 days, although there was no significant change in body weight.

CPAP treatment could therefore decrease Oxidative Stress in patients with OSAS by correction of apnea and restoring normal oxygenation.

P3060

Cyto megalovirus (CMV) infection – Correlation between CMV-DNA PCR in bronchoalveolar lavage (BAL), CMV pp65 antigen load in PBMCs and clinical symptoms in lung transplant recipients

Ute Sommerwerc1, Thomas Rabbi1, Olaf Anhnen1, Gerhard Weinreich1, Markus Kamler2, Nikolaus Pizams2, Heinz Jakob2, Helmut Teschler1, Ulrich Costabel1. 1Department of Pneumology and Sleep Medicine, Ruhrlandklinik, University Hospital, Essen, Germany; 2Department of Thoracic and Cardiovascular Surgery, University Hospital, Essen, Germany; 3Department of Pneumology/Allergy, Ruhrlandklinik, University Hospital, Essen, Germany

Introduction: Cyto megalovirus (CMV) is a significant cause of morbidity and mortality in lung transplant recipients (LITRs) either by causing pneumonitis or by contributing to the development of bronchiolitis obliterans or chronic rejection.

Objectives: Aim of our study was to compare the correlation between CMV-DNA PCR in BAL and CMV pp65 antigen load in peripheral blood mononuclear cells (PBMCs) with the clinical symptoms of LITRs assessed by a clinical score.

Methods: We analyzed 950 BAL samples taken from 73 LITRs during 2007-2009 using PCR and CMV pp65 antigen load in PBMCs. We used a clinical score from 0-10 (defined as symptoms including cough, sputum, dyspnea, exercise capacity, auscultation, temperature) to define a symptomatic or asymptomatic patient. Especially, we compared the clinical score in patients with CMV pp65=0 (n=62) to patients with CMV pp65>0 (n=31).

Results: 73 of the 950 samples (7.7%) were positive either for CMV-DNA PCR in BAL or CMV pp65 antigen load in PBMCs. We found no association between CMV-DNA PCR in BAL and CMV pp65 antigen load in PBMCs. We found a significant correlation between the positivity of PBMCs for CMV pp65 antigen and the clinical score (r=0.31; p=0.006). In patients without CMV pp65 antigen detection the clinical score was 2±0.2 in whereas in patients with CMV pp65 detection the clinical score was 7±4.2.

Conclusion: Assessment of CMV-DNA PCR in BAL does not correlate with the symptoms of CMV infected LITRs. Our results suggest that CMV pp65 is the better predictive marker for symptomatic CMV infection. Further prospective studies to identify patients who need antiviral treatment are necessary.

P3063

Vitamin D deficiency in lung transplant patients: Is it important?

Stijn Verleden, Robin Vos, Stéphanie Devleeschauwer, Ammarie Vaneylen, Liesen Dupont, Geert Verdenk, Dirk Vanraemdonck, Burt Vanaudenbrouck, Pneumology, KU Leuven, Leuven, Belgium

Introduction: Vitamin D deficiency is getting a lot of attention lately in various pulmonary disorders like COPD and asthma due to its immunomodulatory effect. Moreover a link between disease progression and vitamin D deficiency has been reported. The aim of this study is to evaluate vitamin D deficiency in LTxs patients and to examine effect on lung function.

Methods: Serum 25-hydroxyvitamin D (25(OH)D) levels in blood and lung function (%) (predicted) were measured in 132 lung transplant patients during their yearly check-up post transplant stay (median (IQR) 1067 (371-1448)x2).

Results: Vitamin D deficiency (<30 ng/ml) occurred in 63/132 patients (47.7%).
26 of these patients were severely deficient (<20 ng/ml), while 37 had levels >20 but <30 ng/ml. The FEV1 was significantly lower in the deficient group compared to the group with normal levels. Moreover, there was a correlation between FEV1 and vitamin D levels (p=0.0044 and R=0.25).

Conclusion: Vitamin D deficiency is present in almost half of the lung transplant patients, associated with an impairment of lung function. This clearly shows potential for intervention. This is why we are currently performing a randomized placebo controlled trial about the role of vitamin D supplementation in LTx patients.

P3064

Association between CT and spirometric changes in azithromycin treatment of chronic lung allograft dysfunction

Robin Vos1, Pim de Jong2, Stijn Verleden1, Dirk Van Raemdonck1, Lieven Dupont1, Walter De Wever1, Joergy Verschakelen1, Geert Verleden1.

1Lung Transplantation Unit, KU Leuven and University Hospital Gasthuisberg, Leuven, Belgium; 2Dept. of Radiology, University Medical Center Utrecht, Utrecht, Netherlands; 3Dept. of Radiology, KU Leuven and University Hospital Gasthuisberg, Leuven, Belgium.

Introduction: We investigated the association between CT and spirometric changes in chronic lung allograft dysfunction (CLAD) treated with azithromycin (AZI).

Methods: A cohort of 107 patients with CLAD treated with AZI was retrospectively analyzed for inspiration and end-exhalation thin-section CT findings, as well as spirometry, before and after 3 to 12 m of therapy. CTs were scored by a single observer blinded for the spirometric data. CT and spirometric changes during treatment were correlated using Spearman rank test.

Results: A total of 100 patients had combined CT and spirometric data available at the start and after a median of 6.9 (4.7-11.4) months of treatment. Overall, all evaluated CT changes significantly correlated with the observed spirometric changes, except for MIP 50% (table/figure 1). Correlations between changes in specific CT features (i.e. consolidation and air trapping) and MIP 50% suggest that routine testing for restrictive pulmonary disease may be indicated in CLAD.

Conclusions: AZI treatment of CLAD results in various spirometric changes which are associated with changes in underlying CT abnormalities.

P3066

Montelukast as a rescue therapy for bronchiolitis obliterans syndrome (BOS) after lung transplantation

Jens Gottlieb, Hendrik Sachting, Jessica Rademacher, Thomas Fuhrer, Tobias Welte. Respiratory Medicine, Hannover MedicalSchool, Hannover, Germany.

Bronchiolitis obliterans syndrome (BOS) is a major cause of mortality and morbidity after lung transplantation (LTX). Montelukast has been shown to be effective in small case series in patients with BOS after LTx and bone marrow transplantation. A retrospective single center analysis was performed in all LTx recipients treated with Montelukast since 1.10.2010 as a rescue therapy for progressive BOS. Montelukast was used in a dose of 10 mg daily as a long-term therapy. All patients with at least 3 weeks of therapy were included. Response and non-response were defined as a confirmed FEV1 of >90% and >110% baseline, respectively. Broncho-alveolar lavage (BAL)-neutrophilia was recorded at baseline.

Conclusions: CT imaging may be of additional value in phenotyping CLAD and may predict response to azithromycin treatment.

P3067

Bronchial carcinoma after lung transplantation, a sobering truth

Jonas Ysbert1, Lieven Dupont1, Dirk Van Raemdonck2, Christophe Dooms3, Geert Verleden1. 1Respir Dis, University Hospital Gasthuisberg, Leuven, Belgium; 2Thor Surg, University Hospital Gasthuisberg, Leuven, Belgium.

The prevalence and mortality due to solid organ tumors after lung transplantation (LTX) steadily increases and we specifically investigated the development of primary bronchial carcinoma (BC) and its outcome after LTX. Out of 470 LTx and heart-LTx Jan 2000 to Dec 2010, 12 patients (2.6%, 8 males) developed a BC at 37.8 (±24.3) months after LTX. They were transplanted at a mean age of 57.5 (±5.1); 8 for emphysema and 4 for IPF; 8/86 single LTx patients (9.3%, 8/86 single LTx patients (9.3%, for emphysema or lung fibrosis) developed a BC in all their native lung, whereas only 4/179 double LTx patients (2.2%, only for emphysema or fibrosis) developed a BC (p=0.021). At diagnosis, 4 patients were in stage I-II, whereas all others in stage III-IV. There were 11 NSCLC (6 adenocarcinoma) and 1 SCLC. Five patients were surgically treated, however, I had unforeseen N2 disease with pleural metastasis at surgery. All other patients (except 2 who died very soon after diagnosis) were treated with chemotherapy ± radiotherapy. The median survival after diagnosis was only 7.5 m, with an almost significant survival difference between patients with stage I-II and stage III-IV disease (p=0.052). The latter patients had a median survival of only 5.5 m versus 21.5 m for the lower stage BC patients (fig).
We conclude that BC especially of the native lung after SLTx is a significant problem and that the survival after diagnosis is very poor, although patients with stage I-II operable disease, tend to do better.

P3068

12 month follow-up of lung recipients with chronic allograft dysfunction treated with extracorporeal photopheresis (ECP)

Nadia Solar1, Valentina Contio1, Tiberio Oggioni1, Claudia Del Fante2, Cesare Prezzi2, Gianluca Arcangelo2, Monica Morosini3, Simonetta Miserere1, Federica Meloni1. 1Haematological Pneumological and Cardiovascular Sciences, Section of Pneumology, Foundation IRCCS San Matteo & University of Pavia, Pavia, Italy; 2Immunoahematology and Transfusion Service, Foundation IRCCS San Matteo, Pavia, Italy

A few studies suggest that extracorporeal Photopheresis (ECP) is effective in improving/stabilising graft function in chronic dysfunction of transplanted lung, in analogy to its well documented efficacy in graft versus host disease. At our institution ECP is routinely offered as rescue therapy in all macrocide-resistant CAD patients. Twenty-two pts are currently undergoing monthly ECP treatment, 17 of which have reached a ≥12 month follow-up.

The overall response (defined as a further graft function decline either in FVC or transplantation: A pilot study

Inhaled tobramycin for the prevention of airway stenosis after lung transplantation

P3069

Inhaled tobramycin for the prevention of airway stenosis after lung transplantation: A pilot study

Lomy Varma1, Ashish Shah2, Christian Merlo1, Jon Orenes1, David Feller-Kopman1, John McDyer1. 1Pulmonary and Critical Care, The Johns Hopkins University, Baltimore, MD, United States; 2Cardiac Surgery, The Johns Hopkins University, Baltimore, MD, United States

Purpose: Airway stenosis post lung transplantation (LT) continues to be a significant problem with anastomotic strictures occurring in up to 40% of cases. Despite this data, there is a gap in the literature pertaining to preventative therapies. In this pilot study we examined if inhaled Tobramycin (TOBI) in the postoperative period will decrease the incidence of post transplant airway stenosis.

Methods and Materials: All LT performed between 5/05 and 5/10 at The Johns Hopkins Hospital by a single surgeon were reviewed retrospectively. Using this cohort, patients with and without airway complications were matched for age, gender, diagnosis lead to transplant and use of inhaled TOBI in the immediate post operative period. Patients in the treatment arm received TOBI (2x80mg) for the first 7 days post transplant.

Results: 98 patients underwent LT (86 bilateral, 7 left, 5 right). TOBI was administered to 22 (22.4%). Of the 98 patients, 35 (35.7%) developed airway stenosis at a median of 16 weeks (range 1 to 164 weeks following surgery).

Effect of Postoperative Tobramycin on Airway Stenoses

Of the 22 patients who received inhaled TOBI, 31.8% developed airway complications, 68% of the patients in this cohort who did not receive TOBI developed airway stenosis (p<0.034).

Conclusions: The use of TOBI appears to show a decrease in the development of post operative stenosis in this cohort. Prospective, randomized studies are needed to determine the full efficacy of this therapy.

P3070

Does single lung transplantation actually alleviate the donor pool?

Anne Ollad1, Nicole Santelmo1, Pierre-Emmanuel Falcoz2, Christelle Cantrelle1, Richard Dorent2, Gilbert Massard3. 1Lung Transplantation Group, Universitarry Hospital Strasbourg, Strasbourg, France; 2Department of Biomedicine, Agence de Biomédecine, Saint Denis la Plaine, France

Objective: Access to lung transplantation is restricted owing to lack of donor organs. Single lung transplantation hypothesitically increases the pool of lung grafts as two recipients can be treated with one donor. In this retrospective study, we evaluated how often both organs were used for single lung transplantsations. If only one lung was transplanted, we analysed cause of no-use of the opposite lung.

Method: On the registry run by the "Agence de biomedecine", we reviewed all single lung transplantations performed in France from 1998 to 2008. Causes of refusal were recorded as follows: second lung not offered by coordinators, lack of blood-group matched single lung recipient, lack of logistic support, size inadequacy regarding the recipient. We compared cause of refusal to the quality of the grafts. Definition of ideal donor included the following: age under 55 years, ventilated less than 48 hours, clear tracheal secretions, PaO2 over 300 mmHg at FiO2 100% and PEP scan H:G, clear chest radiograph.

Results: Lung harvest from 297 donors led to 387 single lung transplantations: both lungs were used for 2 different recipients in 90 donors (180 recipients). In 207 donors, only one lung was transplanted. In 115 donors, the opposite lung was deemed unusable for dissymmetrical quality. In the remaining 92 donors, both lungs were ideal in 34%, and acceptable in 66%. Reasons for no-use were: not offered by the coordinator in 23%, lack of blood-group matched single lung recipient in 19%, size inadequacy in 20%, team logistics in 10% of cases and miscellaneous reasons in 28%.

Conclusion: Communication on organ sharing might increase the number of available donor organs, thus reducing the death rate on waiting list.

P3071

Recipient dependent factors for outcome in a twinned single lung transplantation model

Anne Ollad1, Nicole Santelmo1, Bastien Orsini1, Pierre-Emmanuel Falcoz2, Christelle Cantrelle1, Richard Dorent2, Pascal Thomas3, Gilbert Massard3. 1Lung Transplantation Group, Universitarry Hospital Strasbourg, Strasbourg, France; 2Department of Thoracic Surgery & Diseases of the Esophagus, Universitary Hospital Marseille, Marseille, France; 3Agence de la Biomedecine, Agence de la Biomedecine, Saint Denis la Plaine, France

Objectives: Immediate outcome of lung transplantation will depend on graft quality, surgical conditions and recipient factors. Twinned single lung transplantation is defined as two recipients being treated with lung grafts from the same donor. Recipient dependent factors of outcome can be studied more accurately as graft quality is supposed equal for both recipients.

Methods: We reviewed all single-lung transplantation performed in France between 1998 and 2008. Complete data for the donors were retrieved from the database of the agence de biomedecine. Data concerning the recipient and follow-up after transplantation were retrieved by individually reviewing each medical record. Twinned were identified and compared. Outcome end-points were primary graft dysfunction (PGD) grade 3.

Results: A total of 387 single lung transplantations were performed in 10 French centers: 90 donors led to 180 twinned recipients. Surgical management and medical follow-up did not differ between centers. All used grafts were of good and symmetrical quality. There was no outcome difference between left and right transplantation. Thirty pairs opposed a fibrosis recipient to an emphysemic twin: PGD was significantly higher (p<0.05) in fibrosis. In 28 pairs (31%) outcome was discordant for PGD: fibrosis was significantly more often involved compared to emphysema (p=0.04). Two pairs showed PGD in both recipients while 60 pairs were free of PGD.

Conclusion: Recipient’s prior respiratory disease is a major determinant of outcome. Fibrosis is associated with an increased risk for PGD grade 3. Twinned single lung transplantation could help building risk factor scores for lung transplantation.

P3072

Hyper expanded native lung treated with intra bronchial valves in single lung transplant recipients

Michael Perch1, Erik Andersen1, Claus Jensen2, Jann Mortensen3, Martin Iversem4. 1Heartcentre, Section for Lung Transplantation, Rigshospitalet, Copenhagen, Denmark; 2Department of Diagnostic Sciences, Section for Radiology, Rigshospitalet, Copenhagen, Denmark; 3Department of Diagnostic Sciences, Section for Clinical Physiology and Nuclear Medicine, Rigshospitalet, Copenhagen, Denmark

We report four single lung transplant patients, with hyperinflation of the native emphysematous lung, treated with bronchoscopic lung volume reduction using Spiration Intra Bronchial Valves (IBV®). Hyperinflation of the native lung is a common complication to single lung transplantation when treating emphysema. The hyperinflation can lead to compression of the graft and cause respiratory failure. The IBV®’s where used to block airflow in specific parts of the native lung, theoretically reducing the native lung volume thereby relieving the graft.

Methods: We used a protocol consisting of a Krypton SPECT-scan to assess 560s
which lung segments in the native lung had least function. The IBV®'s were placed in the segment or sub-segment. Endpoints were changes in lung function test, 6-minutes-walk-test (6-MWT) and changes in the Krypton SPECT-scan at 3 months follow-up.

Results: Preoperative mean forced expiratory volume in 1 second (FEV1) was 0.62 l (Range 0.45-0.80 l), mean residual volume was 4.57 l (Range 4.01-5.73 l) and total lung capacity (TLC) was 189 m (Range 98-258 m). One patient reported marked improvement of dyspnoea and had a plausible change in lung function but a 6-MWT identical to the preoperative 6-MWT and no changes on Krypton SPECT-scan. The three other patients did not report any clinical changes and did not show any change in lung function. A patient had a marked increase in 6-MWT from 258 m to 360 m, but only a slight improvement on Krypton SPECT-scan. No complications were observed.

Conclusions: This report shows that bronchoscopic lung volume reduction of an emphysematous native lung in single lung transplants using IBV® is feasible and seems safe, although further experience is needed.

P3073

The effect of a murine model of brain death on mechanistic studies on treatment for donor lung injury

Shana Wauters1, Laura Lopopolo1, Eric Verbeek2, Caroline Meers1, Johannes van Loon1, Geert Verleden1, Dirk Van Raemdonck3,1. Laboratory for Experimental Thoracic Surgery, KU-Leuven, Leuven, Belgium; 2Department of Pathology, UZLeuven, Leuven, Belgium; 3Department of Neurosurgery, UZLeuven, Leuven, Belgium; 4Department of Thoracic Surgery, UZLeuven, Leuven, Belgium

Introduction: Only 15-25% of brain death (BD) donors match the ideal donor criteria for lung transplantation. The mechanisms of BD-related lung injury are not fully understood yet, justifying further research. Materials and methods: Brain death in mice was induced by rapid inflation of a sublumbar balloon catheter. Animals were randomly divided into 4 groups (each 2h sham [S2], 2h BD [BD2], 4h sham [S4], 4h BD [BD4]). Heart rate (HR), mean arterial pressure (MAP) and cortical activity (EEG) were continuously monitored. At the end of the experiment, bronchoalveolar lavage (BAL) was performed and biochemicals were collected for histological analysis.

Results: In both BD groups, the reflex reaction was characterized by a rapid increase in MAP from induction (85.7±6.6mmHg) to hypertensive peak (122.6±16.8mmHg), with normalization of MAP 10 min after BD confirmation (88.6±6.1mmHg). After BD, HR increased significantly (from 322.8±13.2 to 405.0±17.0bpm) and remained high during the rest of the experiment. In the sham groups, HR and MAP remained constant after balloon insertion. A higher number in BAL neutrophils were seen in [BD4] (28.6% ±4.12) compared to [BD2] (3.0% ±3.0), [S2] (1.4% ±1.2) and [S4] (1.8% ±1.4). More neutrophilic infiltration, interstitial oedema and congestion were seen on histology in [BD4] (2.7 ±2.7 and 2.3 ±2.7 respectively) compared to [BD2] (2.1 ±2.3 and 1.6 ±1.9) respectively.

Conclusion: The creation of a BD model in mice to study lung injury was successful facilitating further mechanistic studies to attenuate lung injury at the immunological level using knock-out animals. A 4-hour period after BD is needed for better interpretation of results.

P3074

Determinant factors for bronchial ischemia after lung transplantation

Anne-Olivia Ganneau, Pierre-Emanuel Meilhat, Lung Transplantation Group, University Hospital Strasbourg, Strasbourg, France

Objective: Bronchial ischemia is a frequent problem encountered after lung transplantation. The resulting stenosis will delay functional recovery of the graft, reduce nutritional state by body mass index (BMI), duration of cold ischemia, side effects of immunosuppressive drugs and ultimately, the quality of life of the recipients.

Method: With the agreement of 10 French centers, we recorded all single-lung transplantations. The resulting stenosis will delay functional recovery of the graft, reduce nutritional state by body mass index (BMI), duration of cold ischemia and need for renal replacement therapy in ICU (4/8). A higher number in BAL neutrophils were seen [BD4] (28.6% ±4.12) compared to [BD2] (3.0% ±3.0), [S2] (1.4% ±1.2) and [S4] (1.8% ±1.4). More neutrophilic infiltration, interstitial oedema and congestion were seen on histology in [BD4] (2.7 ±2.7 and 2.3 ±2.7 respectively) compared to [BD2] (2.1 ±2.3 and 1.6 ±1.9) respectively.

Conclusion: The creation of a BD model in mice to study lung injury was successful facilitating further mechanistic studies to attenuate lung injury at the immunological level using knock-out animals. A 4-hour period after BD is needed for better interpretation of results.

P3075

Transbronchial lung biopsy after lung transplantation: Different A and B scores with discordant healing process (normal for one recipient opposed to ischemia for the other) (1/8). Two out of 8 patients had an increased in anti HLA class I or II antibody titre after biopsy. Three patients did not report any clinical changes and did not show any change in lung function. A patient had a marked increase in 6-MWT from 258 m to 360 m, but only a slight improvement on Krypton SPECT-scan. No complications were observed.

Conclusions: This report shows that bronchoscopic lung volume reduction of an emphysematous native lung in single lung transplants using IBV® is feasible and seems safe, although further experience is needed.

P3076

Long-term outcome of lung recipients bridged with extracorporeal devices

Federica Meloni1, Carlo Pellegrini2, Mirko Belliolo1, Marinella Zanierate4, Alessandro Cascina1, Tiberio Oggiomi1, Andrea D’Armini1, Giorgio Iotti1, Antonio Braschi2,3. Haematological Pneumological and Cardiovascular Sciences, Section of Pneumology, Foundation IRCCS San Matteo & University of Pavia, Pavia, Italy; 2Cardiac Surgery, Foundation IRCCS San Matteo & University of Pavia, Pavia, Italy; 3Anesthesia and Resuscitation Service, Foundation IRCCS San Matteo, Pavia, Italy; 4Anesthesiology and Reanimation Care, Foundation IRCCS San Matteo, Pavia, Italy

Recent evolution in extracorporeal supports allows bridging to lung or heart and lung transplant in a consistent number of cases. However, long term results of these transplants have been rarely reported. Aim of present study was to analyse early and long term results in a small n of lung transplant recipients (LTR) which have been bridged with extracorporeal devices. Nine patients (8 males, mean age39.5) have been transplanted (4SL, 2DL, 3HL). Transplant indications were: UIP (5), PAH (3), bronchiectasis (1). This latter patient (HL) died 3 days after surgery of MOF due to sepsia. 8 patients are alive at a mean of 16 months (min 3.5 - max 33). Early complications included: Re-op for bleeding (1/8) CRYMINE (5/8), slow weaning with need of tracheostomy (7/8), graft infections (1/8), acute renal failure with need for renal replacement therapy in ICU (4/8).

Medium long term complications included: AR±2 (2/8), CMV pneumo-nia/reactivation (4/8), Thrombosis (2/8), EBV related haemophagocytic syndrome (1/8); colonization with P. aeruginosa or A. fumigatus (2/8) end stage renal failure (RF) (1/8). Two of 8 patients had an increased in anti HLA class I or II antibody titres (<10%). At last follow-up visit graft function was >90% of best in 6/8 patient while 2 patients BOS-0. Mean GFR (MDRD formula) was 54ml/min range between15 and 85.

In conclusion: long term survival of ECMO bridged LTR is satisfactory, with good graft function. However, early post transplant period is almost invariably complicated by CRYMINE and slow weaning, and a high degree of chronic RF is detected.

P3077

Management of total cavitary stenoses of the trachea by replacement of trachea produced by technologies of the regenerative medicine

Vladimir Parshin1, Paolo Macchiarini2, Margarita Vyigjina1, Michael Rusakov1, Dmitry Bavazov3, Helen Zaklyazminskaya5. Thoracic Division, National Research Centre of Surgery, Moscow, Russian Federation; 2Thoracic Division, Karolinska University, Stockholm, Sweden; 3Anesthesiology, National Research Centre of Surgery, Moscow, Russian Federation; 4Endoscopy, National Research Centre of Surgery, Moscow, Russian Federation; 5Medical Genetics, National Research Centre of Surgery, Moscow, Russian Federation

Background: The use of transbronchial lung biopsy to monitor and diagnose acute cellular rejection in the lung allograft is a routine procedure in most TX centres. There is consensus in the minimum number of specimens being obtained and mostly biopsies are taken from more than one lobe. Are there differences in rejection grading at different anatomical sites? We examined our clinical data from the last 10 years to investigate the distribution of rejection grading of the lung allograft monitored by TBLB.

Methods: A retrospective study was done reviewing the pathology files and slides of TBLB performed on lung allograft recipients. In 99 patients 298 transbronchial biopsies were taken from more than one lobe and were histologically graded following ISHLT guidelines. Corresponding B scores were just available in 207 investigated cases.

Results: A-scores with identical grades were seen in 252 of 298 (85%) specimens, a single-grade difference was noted in 43 of 298 (14%) probes. Three cases demonstrated two grade differences on biopsies taken from two separate lobes (higher grade in the lower lobe). B-scores were identical in 160 of 207 (77%) specimens, a single-grade difference was noted in 45 of 207 (21%) cases. Two cases demonstrated 2 grade difference (higher grade in the lower lobe).

Among cases with different grades of A and B scores, the “lower” lobes had a higher A grade in 55% (24/46) and a higher B grade in 59% (28/47). Type of TX and underlying disease had no influence on the distribution of histological grading.

Conclusions: If limitations on the site for transbronchial biopsy exist, biopsies of the lower lobes appear more informative.

561s
eration which is carried out with the individual centers, except for that after this procedure the patient should receive for life immunosuppression.

Aims: To study an opportunity of use of a trachea received by methods of regenerative medicine for treatment of patients with total tracheal lesion. Materials and methods: The female 25 y.o. with complaints to constant difficulty breath, weakness, cough and endoscopy have revealed a picture of total cica-tricial lesion of trachea. Each 3-5 days patient required in bowntage of trachea. Indications to transplantation of a trachea are exposed. It was used cadaveric decellularized trachea prepared by techniques of regenerative medicine. The total resorption of a trachea was executed. Into a wall of a donor trachea are entered stem cells of the patient and factors of growth of cells. Anastomosis with own trachea were performed by vicryl 3/0. From abdomen the part of the big omentum was moved by which the donor trachea with anastomosis was completely covered.

Results: The early postoperative period was accompanied by the moderate respira-tory insufficiency, hemoptysis, expressed bronchial secretion. By the moment of discharge breath was free, a gleam of trachea on all extent was satisfactory. Patient does not require immunosuppression.

Conclusions: Regenerative medicine for preparation of the trachea with the aim of transplantation can cardinally change philosophy of thoracic surgery particularly in management of patients with total incurable stenoses of a trachea.

P3078
Benefit of pulmonary rehabilitation in candidates for lung transplantation
Martin G. Dierich1, Thomas Faehner1, Tobias Welte1, Gregor Warnecke2, Jens Gottlieb1, 1Respiratory Medicine, Hannover Medical School, Hannover, Lower Saxony, Germany
Brigitte Pohle3, Cardiothoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, Lower Saxony, Germany

Background: The benefit of pulmonary rehabilitation (PR) before lung transplant-ation (LTx) is unknown. Candidates for LTx reveal drawbacks due to chronic pulmonary diseases (COPD, interstitial lung disease (ILD), cystic fibrosis (CF), pulmonary hypertension (PH), bronchiolitis obliterans syndrome post LTx (BOS), other). Hypothesis: an 3-week PR improve functional status (forced expiratory volume in 1 sec (FEV1), vital capacity (VC), 6 min. walk distance (6-MWD), peak work load in bicycle exercise testing (PWLI), activities in daily life (ADL). Aims: to investigate the quality of life (HRQOL) (SF 36 short Form (SF)). Methods: The study included 168 patients (m/f: 74/94, age 49.4±12.0 yrs) before LTx (COPD n = 68, ILD n = 39, CF n = 27, PH n = 3, BOS n = 18, other n = 13) attended a 3 week inpatient PR. Functional status, ADL, and HRQOL (SF 36, HADS) were assessed at admission and completion of PR.

Results: (mean ± SD) 6-MWD (250±118 to 284±118 m, p < 0.001), PWLI (38±15 to 41±16 Watt, p < 0.001), ADL (96±6 to 98±5, p < 0.001) and HRQOL (all SF 36 domains and HADS (p < 0.02) but SF36 “bodily pain” (p = 0.11) improved significantly. FEV1 (30±16 to 30±16) and VC (53±19 to 53±21%) predicted) kept unchanged. Improvement in 6-MWD, PWLI and ADL was regardless of causative pulmonary disease (ANOVA p < 0.26).

Conclusion: A 3-week inpatient PR has a remarkable benefit in patients with end stage pulmonary disease awaiting LTx. Functional status and HRQOL improve significantly. Inpatient PR must be regarded as part of best practice management to optimize physical condition and mental health in candidates for LTx.

P3079
H1N1 influenza in lung transplant patients: A follow up after one year
Harish Sentharamurthu1, Bindi Akkanti1, Amit Parulekar1, Goutham Dronavalli1, Matthias Loeb1, Savero LaFrancesca2, George Noom3, Karolina Chmielowice1, Pavel Kolodziejczyk1, 1Medicine, Baylor College of Medicine, Houston, TX, United States; 2Surgery, Baylor College of Medicine, Houston, TX, United States; 3Surgery, The Methodist Hospital, Houston, TX, United States

The 2009 outbreak of H1N1 caused significant morbidity and mortality. Long term outcome of H1N1 in lung transplant (LT) patients have not been well characterized. We did a retrospective study of LT patients diagnosed with H1N1 between July and November 2009. Data pertaining to LT, history of influenza, admission information, pulmonary function, radiograph, computer tomography scans, and echocardiograms were identified. Among 181 LT patients, there were 10 PCR confirmed cases of H1N1. Patients had a median of 4 months time since LT to infection, received immunosuppres-sive therapy, and had not received vaccination against H1N1. 60% of patients presented with fever and cough, others had non-pulmonary complaints and all received oseltamivir upon diagnosis. Consolidation was seen by imaging in 60% of patients. Median FEV1 decreased and remained low over a one-year follow up period (1.72 – 1.51 – 1.54) despite clinical improvement. Two patients progressed to really severe lung and severe LV dysfunction (EF 20-30%) despite previous LV function. These patients were on ECMO and had improvement in cardiac function and LV dysfunction. One patient died on ECMO and had severe LV dysfunction. Rapidly deterio-rated patients had developed myocardial dysfunction, but continued to decline even when this dysfunction resolved. Increased incidence of cardiac rejection and extended decreased pulmonary function is seen among LT patients infected with H1N1.

333. Epithelial cell biology

P3080
The bronchial epithelium promotes B cell survival and immunoglobulin production in a coculture system
Maha Zohra Ladjemli1, Bruno Detry1, Yves Sibille1,2, Charles Pilette1,3, 1IBiC, Pôle de Pneumologie, UCL, Brussels, Belgium; 2Service de Pneumologie, Cliniques UCL de Mont-Godinne, Yvoir, Belgium; 3Service de Pneumologie & Centre de l’Allergie, Cliniques UCL Saint-Luc, Brussels, Belgium

Background: Chronic obstructive pulmonary disease (COPD) is associated with chronic airway inflammation and structural remodelling, in particular of the epithelium, which is impaired in its capacity to transport immunoglobulin (Ig) A. Although peribronchial lymphoid follicles have been described in severe COPD, it remains unknown whether B-cell conditioning (e.g. for IgA production) is altered in this disease.

Objectives: In this study, we report on preliminary data using a model of coculture of B cells with human primary bronchial epithelial (r)differentiated in vitro in air-liquid interface.

Methods: IgA synthesis was studied in CD19+ B cells (purified by immunomag-netic sorting from healthy blood donors) following co-culture for 15 days with a bronchial epithelium. B cells were also assessed by flow cytometry for cell activation and survival (annexinV/prodipodine iodine staining).

Results: In two independent experiments, we observed that Ig production was upregulated in B cells cocultured with the bronchial epithelium, as compared to B cells cultured alone (2.2 fold increase in IgG, and modest 1.4 fold increase in IgA), whereas IgM was decreased (0.8 fold). In contrast to expression of CD69, CD80 and CD86 which did not change, B-cell survival also increased (55.3% vs 20.8% for B cells alone) following epithelial coculture.

Conclusion: These preliminary data using this model of coculture, which should reveal useful to investigate crosstalks between the epithelium and B cells with respect to COPD, confirm that the airway epithelium provides B cells with signals promoting both survival and Ig synthesis.

P3081
DUOX1-mediated hydrogen peroxide release regulates sodium transport in bronchial epithelial cells
Vladim Shlyonsky1, Myrna Viterire2, Frédérique Mies1, Arnaud Goolaerts1, Robert Naeije1, Renaud Beaumens2, Alain Boom2, 1Pathophysiology, Université Libre de Bruxelles, Bruxelles, Belgium; 2Cell and Molecular Physiology, Université Libre de Bruxelles, Bruxelles, Belgium

Clara-like H441 cells grown on non porous support form epithelial cell domes in the presence of dexamethasone. This reflects an increase in expression and activity of amiloride inhibitable epithelial sodium channels, ENaC. Dexamethasone has also been shown to facilitate the expression of NAPDH oxidase DUOX1 in lung fetal cells. We assessed the role of DUOX and subliminal (≤0.3 mM) amounts of H2O2 on both ENaC expression and activity in H441 cells. Cells forming epithelial domes induced by dexamethasone (0.1 μM, 24h) and by another differentiating agent 5-aza-2′-deoxycytidine (SAZA, 1 μM, 48h) expressed higher amounts of DUOX1 as evidenced by RT-PCR and immunocytochemistry. Dome induction by dexamethasone and SAZA can be inhibited by exogenous catalase in concentration-dependent manner (5-10 kU/ml) and by the NAPDH oxidase inhibitor diphenyl iodonium (2.5 μM), thus suggesting the involvement of H2O2. Single application of 0.2 mM H2O2 induced transient dome formation. Dexamethasone stimulated mRNA expression of all the subunits of ENaC, however this expression was not inhibited by catalase, thus suggesting that H2O2 increased only the channel activity. In patch-clamp experiments, H2O2 (0.1 mM) activated amiloride-sensitive whole-cell currents from 3.91±0.79 pA/pF to 4.76±0.98 pA/pF (p=0.01) as well as ENaC single-channel activity in cell-attached patches. These observations sug-gest that tonic production of H2O2 by DUOX1 maintains the level of vential sodium transport by lung alveolar cells. They also suggest that the upregulation of DUOX-mediated H2O2 release observed in cystic fibrosis (CF) may contribute to the hyperabsorptive epithelial cell phenotype observed in CF lung disease.

P3082
Increased expression of α1-hydroxylase (CYP27B1) in IL-13-exposed primary bronchial epithelial cells (PBEC): Consequences for activation of vitamin D and expression of the antimicrobial peptide kC-AP/IL-37
J.A. Schrumpf1, R.M. Vetchoosel, M.A.J.A. Sterkenburg, S. Zuyderduyn, J.A. Schrumpf1, 1IREC, Centre de l'Allergie, Cliniques UCL Saint-Luc, Brussels, Belgium

Vitamin D (25(OH)D3) increases expression of kC-AP/IL-37 in PBEC. This requires conversion of 25(OH)D3 by 1α-hydroxylase (CYP27B1) into its active
metabolite 1,25(OH)₂D₃, that increases expression of both iCASP-18/LL-37 and the vitamin D degrading enzyme (CYP24A1). IL-13 is highly expressed in the lungs of asthmatics and low serum 25(OH)D levels were associated with lower lung function in asthmatics.

The aim of the present study was to investigate the role of IL-13 in vitamin D metabolism and to assess its effect on expression of iCASP-18/LL-37. Well-differentiated PHEC cultured at the air-liquid interface from 5 different donors were pre-incubated with IL-13 for 24 hours and subsequently exposed to 25(OH)D₃ for 48 hours to investigate CYP27B1, CYP24A1, vitamin D receptor (VDR), and its paracrine-defensive (BH2-2 and -3) and by qPCR. IL-13/18-37 expression was determined by qPCR, immunofluorescence (IF) and Western blot. Exposure of PBE to IL-13 alone increased CYP27B1 and BH3-3 mRNA (fold increases of 5.2 ± 3.13 vs. p<0.05, whereas addition of 25(OH)D₃ to IL-13 treated cells resulted in higher expression (p<0.05) of iCASP-18/LL-37 and CYP24A1 mRNA (fold increase: 72.18 and 29.9, resp.) when compared to 25(OH)D₃ alone (fold increase: 32.6 and 13.9, resp.). These results were confirmed by IF and Western blot for iCASP-18/LL-37. The present results show that IL-13 increases vitamin D metabolism in bronchial epithelial cells resulting in increased expression of iCASP-18/LL-37. Whether IL-13 can host defence against infection through this mechanism requires further studies.

P3084 Epithelial mesenchymal interactions in asthmatic children
Erci Bazzan1, Elena Mutti2, Andrea Ballarin3, Silvia Zagallo4, Grazziella Turato5, Simonetta Baralda1, Marco Dumin6, Deborah Snijders7, Samuela Bugin8, Fiorella Calabrese1, Piero Maestrelli2, Angelo Barbato2, Marina Saetta9, 1Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy; 2Dipartimento di Biopatologia e Metodologie Biomediche, Università di Palermo, Palermo, Italy; 3Department of Diagnostic Sciences and Special Therapies, University of Padova, Padova, Italy; 4Department of Environmental Medicine and Public Health, University of Padova, Padova, Italy.

The alteration of the mesenchymal layer underlying the bronchial epithelium, triggered by epithelial dysfunction, is a topic of emerging interest in asthma. Whether this dysfunction is already present in asthmatic children, and therefore in the early stages of the disease, has been scarcely investigated. We evaluated the degree of epithelial damage, E-cadherin (E-cad) and TGFβ1 expression, and their relationship with basement membrane (BM) thickness in asthmatic children. Bronchial biopsies were obtained from 27 children undergoing bronchoalveolar for appropriate indications: 16 asthmatics (age 2-10yrs) and 11 nonasthmatic controls (4-9yrs). Epithelial damage and BM thickness were quantified by histochemistry and E-cad and TGFβ1 by IF and Western blot for iCASP-18/LL-37. The present results show that IL-13 increases vitamin D metabolism in bronchial epithelial cells resulting in increased expression of iCASP-18/LL-37. Whether IL-13 can host defence against infection through this mechanism requires further studies.

P3085 Increased expression of IL-19 in metabolic epithelium of patients with chronic rhinosinusitis and nasal polyps
Elisabetta Pace1, Valeria Scarinci1, Danilo Di Bono2, Liborio Siena1, Giuseppe Chiappara3, Maria Ferraro3, Stefania La Grutta4, Salvatore Gallina3, Riccardo Speciale5, Antonella Ballacinico1, Claudio Barchet1, Jean Bouquet6, Mark Gjomarkaj1, 1Institut de Biomedicine and Molecular Immunology (IBIM), National Research Council (CNR), Palermo, Italy; 2Dipartimento di Biopatologia e Metodologie Biomediche, Universita di Palermo, Palermo, Italy; 3Environmental Health, ARPA, Palermo, Italy; 4Dipartimento di Otorinolaringoiatria, Università degli Studi di Palermo, Palermo, Italy; 5Department of Otorhinolaryngology, University Hospital Ghent, Ghent, Belgium; 6University Hospital Montpellier, University Hospital Montpellier, Montpellier, France.

Chronic rhinosinusitis (CRS) is an inflammation of the nose and of the paranasal sinuses. Nasal polyposis (NP) is common in many patients with severe asthma. The pathogenesis of NP is poorly understood. The aim of the present study was to identify biomarkers for NP. We collected nasal biopsies from normal subjects without CRS (n=12), from subjects with CRS but without NP (n=10) and from patients with CRS and NP (n=10). We used Human Asthma Gene Array and real time PCR to evaluate gene expression and western blot analysis and immunohistochemistry for protein expression.

Human Asthma Gene Array showed an evident increase in IL-19 gene expression in NP from patients with CRS and NP in comparison to mucosa from inferior turbinate of normal subjects. Real time PCR confirmed the IL-19 mRNA up-regulation in patients with CRS and NP and showed an up-regulation of IL-19, at lower extent, also in the mucoea from inferior turbinate of patients with CRS in comparison to normal subjects. Western blot analysis confirmed that IL-19 is increased also at protein level in patients with CRS and NP in comparison to normal subjects. Immunohistochemistry showed that in NP IL-19 is highly expressed in the metaplastic nasal epithelium (score 4-9) when compared to normal or hyperplastic epithelium (score 1-3). When patients with CRS and NP were compared to patients with CRS or NP alone, in the absence of any other disease, no differences were observed in terms of IL-19 expression. In conclusion, the results of the present study provide compelling evidence on the putative use of IL-19 as a remodelling biomarker for identifying patients with chronic rhinosinusitis and NP.

P3086 Increased epithelial production of LPLUNC1 in cystic fibrosis lung disease
Colin Bingle1, Kirsty Wilson1, Marcus Mall2, Doris Rassl3, Lynne Bingle1, 1Infection and Immunity, University of Sheffield, Sheffield, United Kingdom; 2Pediatrics, University of Heidelberg, Heidelberg, Germany; 3Pathology, Papworth Hospital, Cambridge, United Kingdom; 4Clinical Dentistry, University of Sheffield, Sheffield, United Kingdom.

Members of the PLUNC family of secreted proteins have been implicated in innate defence of the upper airways and nasopharynx. Although array data suggest that they are differentially expressed in some lung diseases validation has not been forthcoming. We previously showed that PLUNC1 is increased in severe cystic fibrosis (CF). In the present study we have investigated the expression of LPLUNC1 in severe CF and studied both proteins in mouse models of CF lung disease. There was marked epithelial staining of LPLUNC1 in diseased small airways and submucosal glands. In CF, similar to our previous data with SPLUNC1, the two proteins are not co-expressed in the CF lung as LPLUNC1 is co-localised with MUC5C in goblet cells, whereas SPLUNC1 is present in a non-ciliated, non-goblet cell population. Expression of both proteins was unchanged (and very limited), in CFTR knockout mice. However, in CFP-betalnα transgenic mice, a model for CF lung disease, there was strong staining of both proteins in the airways and in the luminal contents. This was most marked for lplunc1 and was noted within 2 weeks of birth. As in CF, the two proteins are present in non-ciliated cells. Expression of the putative innate immune molecules is associated with CF lung disease in both humans and mice. It remains unclear if this elevation of protein production, which results from phenotypic alteration of the cells within the diseased epithelium, plays a role in the pathogenesis of the disease.

P3087 Co-expression of LPLUNC1 and MUCSB in the bronchoalveolarized epithelium of usual interstitial pneumonia
Bianca Araujo1, Lyne Bingle1, Sarah Howie1, William Wallace1, Nikhil Hirani2, Colin Bingle1, 1Infection and Immunity, University of Sheffield, Sheffield, United Kingdom; 2MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom.

Idiopathic Pulmonary Fibrosis (IPF) is an irreversible and progressive lung disease with limited life expectancy after diagnosis. The cause of the condition remains elusive but it has both familial and environmental associations. Histopathological studies of IPF lungs reveal the typical "usual interstitial pneumonia" (UIP) pattern with epithelial hyperplasia, areas of scarring with fibroblast foci and characteristic morphological abnormalities, including bronchiolization of alveolar ducts, cysts and alveoli. Although it seems likely that bronchiolar abnormalities are caused by changes in epithelial cell differentiation, specific markers of this process remain elusive. By analysis of published array data sets from IPF patients, we identified LPLUNC1 as a potential candidate marker for the disease. This putative innate defence protein is normally expressed in submucosal glands (SMGs) and in a population of MUC5C+ positive goblet cells in the upper airways. Immunohistochemical analysis of lung tissue from patients with UIP revealed strong staining of LPLUNC1 within the bronchoalveolarized epithelium lining the honeycomb cysts as well as in the mucusobustance filling these regions and dispersed throughout the peripheral lung. The related protein, SPLUNC1 was not co-expressed. MUCSB was localized to the same cells as LPLUNC1, whereas MUC5C was found in goblet cells within the airways. The same pattern of staining was not seen in other chronic lung diseases, suggesting a degree of specificity for IPF. Our data support the idea that in UIP, airway epithelial cells develop characteristics of SMGs and suggest that LPLUNC1 may be a useful marker for the disease.

P3088 LSC 2011 Abstract: Differential inflammatory responses of nasal and bronchial epithelial cells to cigarette smoke extract
David Comer, Vanessa Brown, Francine De Courcey, Stuart Elborn, Colin Bingle1, Kirsty Wilson1, Marcus Mall2, Doris Rassl3, Lynne Bingle1, Madeleine Ennis. Centre for Infection and Immunity, Queens University, Belfast, United Kingdom.

Few studies compare the function of primary bronchial (PBEC) and nasal (PNEC) epithelial cells. Our aim was to compare the responses of paired PNEC and PBEC
cultures to LPS stimulation and any modulatory effects of exposure to cigarette smoke extract (CSE).

Cells, from subjects with COPD, were obtained by nasal or bronchial brushing and used at passage 3. They were stimulated for 24 h with LPS (0–25 μg/ml) pre-treatment with CSE. CSE was prepared by combusting a 12 mg tar Marlboro cigarette through 25 ml of media. Supernatants were collected and IL-8 and IL-6 measured by ELISA. The localization of TLR4 was established by FACS. For the PNEC cultures, a brief incubation with CSE (4 h) significantly inhibited LPS-induced IL-6 and IL-8 release (IL-8: 24 h treatment with 25 μg/ml LPS alone 5457±652 pg/ml and with 4 h CSE pre-treatment 3772±452 pg/ml). A more prolonged incubation with CSE (24 h) was pro-inflammatory (IL-8: 25 μg/ml LPS alone 5485±562 pg/ml and with 24 h CSE pre-treatment 7757±449 pg/ml). Although a brief incubation with CSE resulted in a lower percentage of surface and intracellular TLR4, a prolonged incubation was without effect. In contrast, both a brief and a prolonged exposure of PNEC cultures to CSE reduced LPS-induced IL-8 release (IL-8: 24 h treatment with 25 μg/ml LPS alone 5107±977 pg/ml with 4 h CSE pre-treatment 3345±609 pg/ml with 24 h CSE pre-treatment 3010±324 pg/ml), and both led to a reduced percentage of surface and intracellular TLR4. There was minimal IL-6 release from the PNEC cultures.

In conclusion, our results show that CSE are not a suitable surrogate for PNEC cultures in terms of their response to CSE/LPS combination treatment.

P3089

Cigarette smoke alters the expression of the pro-inflammatory LT4B receptor and increases the neutrophil adhesion in bronchial epithelial cells

Elsabeta "Maria" Ferraro1, Antonio Guarracina, Serena Sciarino1, Mark Gjema2, 1Istituto di Biomedicina ed Immunologia Molecolare, Consiglio Nazionale delle Ricerche, Palermo, Italy; 2Department of Anesthesiology, Rianmazione e delle Emerenze, Università degli Studi di Palermo, Palermo, Italy

LTB4 is importantly involved in the inflammatory responses of chronic obstructive pulmonary disease (COPD). In COPD an increased expression of LTB4 receptors, BLT1 and of PPAR-a, was observed. Since LT4B is reduced on TLR4 mutation and since cigarette smoke extracts (CSE) increase the expression of LT4B in bronchial epithelial cells, the aims of this study were to explore whether cigarette smoke exposure (CSE) and/or cigarette smoke extract (CSE) plus an inflammatory agent (PPAR-a) BLT4 receptor. Moreover, we evaluated the effects of CSE on the expression of ICAM-1 (by flow-cytometry analysis), on the binding of ICAM-1 to ICAM-1 promoter (by ChiP analysis), and on the adhesiveness of bronchial epithelial cells to neutrophils (by flowcytometry). CSE increased the binding of ICAM-1 to ICAM-1 promoter and increased the expression of ICAM-1 in bronchial epithelial cells. CSE and mini-BAL from smokers increased the adhesiveness of bronchial epithelial cells toward neutrophils more than mini-BAL from non-smokers. These findings suggest that, in bronchial epithelial cells, CSE promote a prevalent in-duction of pro-inflammatory BLT2 receptors and activate mechanisms leading to increase neutrophil adhesion, a mechanism contributing to airway neutrophilia.

P3090

Oxidative stress induces the generation of tissue factor bearing microparticles by airway epithelial cells in vitro

Concettina Noce, Tommaso Neri, Federica Novelli, Cinzia Cordazzo, Silvia Petroni, Yurt Carmazzi, Laura Tontini, Pierluigi Pagliaro, Alessandro Celii, Cardiac, Thoracic and Vascular Department, University of Pisa, Pisa, PI, Italy

Background: Activation of the coagulation cascade is involved in the pathogenesis of pulmonary fibrosis. Although, according to the traditional view, coagulation factors present in the lung are derived from the general circulation, recent data indicate that factor (F) X is locally increased in fibrotic lung tissue in its active form. Microparticles (MP) are procoagulant and proinflammatory vesicles shed by airway epithelial cells in vitro. The generation of MP by A549 was investigated through a prothrombinase test, expressed as phosphatidylserine (PS) concentration, and a one-stage clotting assay of pro (BLT2) and anti-inflammatory (PPAR-a) LTB4 receptors. Moreover, we evaluated the effects of CSE on the expression of OCTs and their role in the pathogenesis of chronic inflammatory respiratory diseases is becoming evident. Variations in OCT expression in response to environmental insults were quantified in bronchial epithelial cells and in bronchial epithelial layers in vitro. Layers of the human cell line Calu-3 and normal human bronchial epithelial (NBE) cells showed similar OCT gene expression pattern after differentiation at an air-liquid interface for 21 days. Calu-3 layers were exposed to the aerosolized dust mice or they were physically injured in a scrape wound model. Cells were harvested after recovery for real-time PCR analysis. Significant fold-increases in the expression of OCT1, OCT3, OCTN2 and the pro-inflammatory markers CCL17 and COX-2 were measured. In “cell” western blotting, confirmed OCT up-regulation at the protein level. It was shown OCT expression in bronchial epithelial cells is enhanced after allergen and physical damage. Although further investigation into OCT functions in bronchial epithelial cells is needed, this study suggests a possible role of the transporters in the protection and regeneration of the bronchial epithelium.

Human 3D airway models to explore in vivo inhalation

Astre Reus1, Yvonne Staal1, Jos van Tiel1, Frederique van Acker2, Friek Kuper1, 1Toxicology and Applied Pharmacology, TNO Teakelion BV, Zeist, Netherlands; 2Quality and Safety, TNO, Zeist, Netherlands

Human 3D airway models are promising models for safety and efficacy evaluation of compounds targeting the airways. The two most important reasons are (1) the models are fully differentiated and functional (incl. metabolism activity, mucus production and cilia beating) and (2) they are cultured at air-liquid interface, allowing exposure to gasses, vapours, aerosols and particles via air (relevant exposure). Healthy and diseased airway tissue (asthma, COPD) are available. Some models include cells from the upper respiratory tract (nasal tissues, larynx and trachea), where the highest impact of inhaled compounds is. We explored the use of 3D airway models, including MucAirTM, for toxicity testing, e.g. the COMET assay, cell viability and tissue and cell membrane integrity. Substances were applied as droplets. Tissue and membrane integrity of the airway models did not show an increase in COMET formation. For benzo[a]pyrene, this is likely to be related to the exposure concentration and duration. Our preliminary results indicate that the MucAirTM model system is a suitable model for safety testing, including genotoxicity and acute toxicity. In the future, we will further

P3091

Effect of cigarette smoke on protease function in alveolar epithelial cells

Sabine van Rij, Alessandra Morsina, Oliver Eickelberg, Silke Meiners, Comprehensive Pneumology Center (CPC), Helmholtz Zentrum München, München, Germany

Cigarette smoke is the major risk factor for chronic obstructive pulmonary disease (COPD), which accounts for several million deaths annually world-wide. The generation of reactive oxygen species (ROS) is considered to be the major contribution to smoke-induced inflammation, DNA damage and posttranslational modifications resulting in subsequent misfolding of cellular proteins. The ubiquitin proteasome system is essential for the turnover of the majority of cellular proteins. The proteasome also plays a vital role in protein quality control as it degrades abnormal and misfolded proteins, among them oxidatively-modified proteins. Conditions of massive oxidative stress, however, may result in impairment of proteasome function as ROS can directly modify the proteasome complex. In the present study, we have investigated protease function in response to cigarette smoke extract (CSE) of human and mouse epithelial cells. Treatment of these cells with CSE resulted in a time and dose-dependent increase in ROS levels. The proteolytic activities of the proteasome were also evaluated using peptide substrates. Two of the three main protease activities, namely the chymotrypsin-like and caspase-like activity, showed a time and dose-dependent alteration in response to CSE treatment. The altered proteasomal activity corresponded to accumulation of oxidatively modified and polyubiquitinated proteins. The effect of CSE on the ratio and composition of 26S and 20S proteasomes was analysed by native gel electrophoresis, immunoprecipitation and subsequent mass-spectroscopic analysis. Preliminary data indicate that posttranslational modifications of proteasomal subunits which may be responsible for the alteration of protease activity.

P3092

Variations in organic cation transporter (OCT) expression in bronchial epithelial cell layers after environmental insults

Michael Mulherkar1, David I Pritchard1, Cynthia Bosquill1, 1Division of Drug Delivery and Tissue Engineering, University of Nottingham, Nottingham, United Kingdom; 2Immune Modulation Research Group, University of Nottingham, Nottingham, United Kingdom

OCTs are transmembrane carriers that mediate the transport of endogenous amines in both directions. They are essential for the preservation of several organs and have been associated with chronic inflammatory disorders like Crohn’s disease and rheumatoid arthritis. They are also dysregulated in the lung of allergic rodents after an acute ovalbumin challenge (Lips, K.S., et al. Life Sciences, 2007; 80:2263-2269). In the present study, we have investigated protease function in response to cigarette smoke extract (CSE) of human and mouse epithelial cells. Treatment of these cells with CSE resulted in a time and dose-dependent increase in ROS levels. The proteolytic activities of the proteasome were also evaluated using peptide substrates. Two of the three main protease activities, namely the chymotrypsin-like and caspase-like activity, showed a time and dose-dependent alteration in response to CSE treatment. The altered proteasomal activity corresponded to accumulation of oxidatively modified and polyubiquitinated proteins. The effect of CSE on the ratio and composition of 26S and 20S proteasomes was analysed by native gel electrophoresis, immunoprecipitation and subsequent mass-spectroscopic analysis. Preliminary data indicate that posttranslational modifications of proteasomal subunits which may be responsible for the alteration of protease activity.
assess the applicability of these models for safety and efficacy testing by exposure through the air and comparison with in vivo inhalation data. Ultimately, these models may be useful in the safety evaluation of pharmaceuticals and chemicals.

P3094

Cigarette smoke induces the release of CXCL-8 from human bronchial epithelial cells via TLRs and the induction of inflammasome

Esmael Mortaz, Paul Henricks, Aletta Kraneveld, Masoumeh Givi, Johan Garsen, Gert Folkerts. Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands; Chronic Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Disease (NRITLD), Tehran, Islamic Republic of Iran; Immunology, Research Centre for Specialised Nutrition, Wageningen, Netherlands

COPD is a chronic airways diseases associated with inflammation and cigarette smoking. Airway epithelial cells are the first cells that will be exposed to cigarette smoke and are able to release CXCL-8 and IL-8. These cytokines are involved in the acute and chronic character of inflammatory processes in COPD. The aim of this study was to investigate whether Toll Like Receptors (TLRs) on human bronchial epithelial cells (HBE-140 cells) were involved in cigarette smoke-induced cytokine production.

The cigarette smoke-induced CXCL-8 production was inhibited by an antibody against TLR4 and by inhibitory ODN without CpGODN motif suggesting the involvement of TLR4 and TLR9. In addition, exposure of HBE-140 cells to TLR4 or TLR9 ligands resulted in the release of CXCL8 and IL-1β. TLR4 and also TLR9 were present on the cell surface and the expression of both receptors decreased after cigarette smoke exposure. The molecular mechanism was further investigated. It was found that the purinergic P2X7 receptors and reactive oxygen species were involved. Interestingly, the inflammasome activator monosodium urate crystals (MSU) mimicked the release of CXCL8 and IL-1β and the caspase-1 inhibitor Z-VADDCB suppressed the cigarette smoke-induced release of CXCL8. In addition, cigarette smoke, CpGODN, LPS and MSU all increased the expression of caspase-1 and IL-1β. In conclusion, cigarette smoke releases CXCL-8 from HBE-140 cells via TLR4 and TLR9 and inflammasome activation. This signal transduction pathways may contribute to cigarette smoke related diseases such as COPD.

P3095

Effect of roflumilast N-oxide on non-typable haemophilus influenzae (NTHi) interaction with human airway epithelial A549 cells

Victoria Camo1,2, Pan Morey1,2, Junkal Garmendia1,2,3, José Bengoechea1,2,3, Laboratory Microbial Pathogenesis, Fundación C rebut-CIMERA Illes Balears, Bunyola, Spain; 1Laboratory Animal Health, Instituto Agrobiotecnología UPNA-CSIC, Mutilva, Spain; 2Laboratory Microbial Pathogenesis, Fundación Caubet-CIMERA Illes Balears, Bunyola, Spain; 3Laboratory Microbial Pathogenesis, Fundación Caubet-CIMERA Illes Balears, Bunyola, Spain

Background/Aim: NTHi is associated with lung colonisation and exacerbations in COPD. Previously we found that NTHi invasion of airway epithelial cells is PI3-K dependent. Further NTHi survives intracellularly in vacuoles with late endosomal features, explaining airway colonisation despite NTHI-negative sputum. Here we explored whether the PDE4 inhibitor roflumilast N-oxide (RNO), the active metabolite of roflumilast (approved in EU for severe COPD), dexamethasone (DEX) and salmeterol (SAL) affect NTHi invasion of A549 cells and NTHi-induced IL-8 release.

Methods: For invasion, cells were infected with NTHi (100 bacteria/cell, 2h), incubated with gentamycin (1h) to kill extracellular bacteria, and lysed to determine intracellular bacteria by plating. Intracellular lifestyle was monitored by immunofluorescence with antibodies to late endosome markers (lamp1, CD63). PI3-K dependent Akt phosphorylation was assessed by Western. IL-8 was measured by ELISA.

Results: RNO (1μM) reduced NTHi invasion by 50% (c.f.u./well; Control: 5000±100, RNO: 2439±122, n=3, p<0.05) while DEX (1μM) and SAL (1μM) failed. Forskolin (10μM) reduced NTHi invasion by 70%, supporting a role of cAMP. RNO (1μM) curbed NTHi-induced Akt phosphorylation by 40%. Neither drug affected NTHi intracellular lifestyle. RNO (1μM) or DEX (1μM) reversed a 6.5-fold increase in NTHi-induced IL-8 release by 48.3±% and 75±% respectively and NF-κB activation.

Conclusions: PDE4 inhibition (1μM RNO) reduced NTHI internalisation in A549 cells by interfering with PI3K signalling. RNO inhibited IL-8 release. DEX, while reducing NTHI-induced IL-8, did not affect internalisation.

P3096

Glucocorticoids enhance CCL20 release in bronchial epithelial cells in a metalloprotease-dependent manner

Jan Zijlstra1, Dennie Rozeveld1, Nick ten Hacken2, Antoon van Oosterhout1, Irene Heijink1,2,3,4 Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands; 1Pathology, University Medical Center Groningen, Groningen, Netherlands

Glucocorticoid (GC) insensitivity is a major clinical problem in the management of asthma. Although a potential role for Th17 cells has been described in GC insensitive asthma, it is still unknown why GCs are unable to efficiently suppress Th17-mediated inflammation. CCL20 acts as a potent chemotactrant for Th17 cells. To determine the effect of GCs on CCL20 secretion and to unravel the underlying regulatory mechanisms, we examined the effect of budesonide and fluticasone (10-7-10-5M) on TNF-α-induced CCL20 and IL-8 production (ELISA and qPCR) in 16HBE human bronchial epithelial cells and primary bronchial asthma epithelium. We compared the effect of the GCs, dexamethasone (DEX, 300M) and fluticasone (PF95, 500M) with the GC receptor (GR), protein synthesis and a general metalloprotease inhibitor.

Surprisingly, we observed that GCs do not suppress, but enhance the release of CCL20 in 16HBE cells, under conditions where IL-8 was efficiently suppressed. Importantly, GCs also induced a substantial increase in the TNF-α-induced release of CCL20 in asthma epithelium. Although the TNF-α-induced CCL20 release was dependent on the ERK, JNK and STAT3 pathways, the upregulation by GCs was not blocked by their inhibition. Furthermore, our data demonstrate that the effect of GC is mediated by GR activation, which is likely mediated at posttranslational level in a metalloprotease-dependent manner.

Thus, we show for the first time that GCs enhance metalloprotease-dependent release of CCL20, which may constitute a novel mechanism of Th17-mediated GC insensitive neutrophilic airway inflammation in asthma and provide new opportunities for therapeutic intervention.

P3097

Effects of JAK-STAT inhibitors on glucocorticosteroid resistant release of CXC3 chemokines from human bronchial epithelial cells

Florine Fenwick1, Iain Kilty2, Mike Yeadon1, Pete Barnes1, Louise Donnelly3,4,1National Heart and Lung Institute, Imperial College, London, United Kingdom; 2Internal Medicine, Pfizer, Sandwich, United Kingdom

COPD is associated with glucocorticosteroid insensitivity. CXC3 chemokines are elevated in COPD and may drive recruitment of CD8+ lymphocytes. Expression of CXC3 chemokines is regulated by IFNγ. This study investigated the effect of JAK-STAT inhibitors PF95 and PF13 on CXC3 chemokine production from human bronchial epithelial cells. Beas-2B and primary human bronchial epithelial cells (HBEC) were pre-treated with PF95, PF13, or Dexamethasone (DEX) then stimulated with IFNγ or IFNγ+TNFα. After 24h, cytokines were measured by ELISA. Inhibition of the JAK-STAT pathway was measured by immunoblotting for phosphorylated and total STAT-1 and STAT DNA binding using Trans-AM kits. DEX had no effect on the release of CXC3.10, 10 or 11, however all were inhibited by the JAK-STAT inhibitors stimulated with either IFNγ or IFNγ+TNFα (Table 1). HBE responded similarly to Beas-2B. Both inhibitors attenuated phosphorylation level in a concentration dependent manner. DNA binding of STAT-1 and STAT-3 was inhibited but not of STAT5a or STAT5b.

JAK-STAT inhibitors therefore attenuate release of CXC3 chemokines from airway epithelial cells under conditions of glucocorticosteroid insensitivity and have potential as a new anti-inflammatory treatment in COPD patients.
Corticosteroids can improve clinical outcome in patients with pneumonia. However, little is known about the effects of corticosteroids on systemic cytokine levels in these patients or which patients benefit most from corticosteroid therapy. Hospitalized, non-immunocompromised patients with CAP were randomly assigned to receive dexamethasone (5 mg once a day) or placebo. Serum levels of IL-1α, IL-6, IL-8, IL-10, IL-17, TNF-α, INF-γ, MIP and MCP were measured at various time-points during hospital stay. We enrolled 304 patients. The median level of IL-6, MCP, TNF-α, IL-1α, and IL-17, all were significantly lower (p = 0.01) on day 2 in the dexamethasone treated patients compared to the placebo treated patients. In patients with an atypical bacterium, IL-1α (p = 0.01), IL-6 (p = 0.01), IL-10 (p = 0.06) and MCP (p = 0.03) decreased faster in the dexamethasone group compared to placebo, in pneumococcal pneumonia only MCP (p = 0.07) and TNF-α (p = 0.05) decreased faster. When IL-6, IL-8 and MCP, being the most prominent proinflammatory cytokines were combined, patients who had all three cytokines above a predefined cut-off point benefited most from dexamethasone therapy. In the dexamethasone group only 2 patients (8.3%) died, while in the placebo group 8 patients (47%) died (p = 0.01).

Conclusion: Proinflammatory cytokines and chemokines decreased more rapidly in dexamethasone treated patients compared to placebo treated patients. This effect was most evident in patients with an atypical bacterium. In patients with high- risk cytokine response, dexamethasone showed a reduction in mortality and ICU admittance.

3204 Impact of bronchoalveolar lavage (BAL) multiple PCR with DNA macroarray based diagnosis on outcomes of severe pneumonia in ICU

Miral Srirac1, Ravнат Lehebt1, Rajesh Tangri1, Rajesh Tangri1, Amit Gupta1, Rohit Caroll1, Neela Chavhan1, Archita Jothi Bhart1, Shrin Naza1, Vibha Taneja1, Sujeet Kumar1, Mukta Singh1,2.

Pulmonology and Critical Care, Fortis Hospital, Noida, UP, India; SRL Ltd, Fortis Hospital, Noida, UP, India

Objective: To evaluate BAL multiple PCR with DNA microarray (Syndrome Evaluation System, SES), Xcyton Diagnostics Pvt. Ltd., India in etiological diagnosis of severe pneumonia and its impact on outcomes.

Method: Bronchoscopic BAL in 25 (27 episodes) admission patients with severe pneumonia was tested by clinical diagnosis and SES. Empirical antibiotics were modified based on the results. Index infection, ICU, hospital and 30 day outcomes were compared with matched controls.

Results: BAL was obtained from 25 (27 episodes) study patients [mean±SD age 61.3±18.3 yrs] and 27 control patients [age 60.9±18.3 yrs]. There was no significant difference in the age (p=0.94), APACHE IV score (74.6±27.3 vs. 76.6±26.9; p=0.8) and predicted mortality (29±22.3 vs. 26.9±21.2; p=0.01). ICU length of stay (LOS) (p=0.49) and hospital LOS (p=0.73) between the groups. Mechanical ventilation was required for 26 episodes in study and 25 in controls. In the study arm all BAL were positive by SES, 9 were sterile by culture and 18 were aspirate by both methods. In SES, no MS and 4 organisms picked up by CU. In controls 7/27 BAL were sterile by culture.

In the study arm there was significantly less time to antibiotic modification (p=0.001) based on SES (31:18.4±4.4 hrs) as compared to CU (including Gram stain and colony morphology) (52±8±7.11 hrs). Observed 30 days mortality was 15/25 (study) and 13/27 (control). Index infection cure rates (p=1) and ICU (p=0.27), hospital (p=0.49) and 30 day (p=0.57) mortality were not significantly different in the two groups.

Conclusions: Multiple PCR (SES) helps in early modification of empirical therapy but shows no impact on severe pneumonia outcome.

3205 Hyaluronal infusion improves survival in endotoxic shock rats

Won-II Choi1, Hales Charles2. 1Department of Internal Medicine, Keimyung University School of Medicine, Daeug, Republic of Korea; 2Department of Medicine, Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA, United States

Background: It has been proposed that Hyaluronan (HA) acts as a vehicle for cytokines due to the strong negative charge on its surface. We hypothesized that HA would function like a cytokine scavenger, reducing inflammatory signaling cascade leading to improved survival in endotoxemia.

Methods: Endotoxin (Salmonella, 10 mg/kg) or an equal amount of 0.9% NaCl (NS) was injected into the jugular vein of rats. HA (1600 kDa, 0.35%) or NS was given 0.5 ml/kg for 3 hrs. HA or NS infusion was started at different time points; 30 min before, 1 hr after, and 4 hour after endotoxin injection. Rats were divided into control and HA groups at three different time point.

Results: The survival rate (% of rats treated with HA was higher (90%) than in controls (60%) treated with NS infusion 30 min before LPS injection; HA was higher (90%) than in controls (50%) when HA or NS infused 1 h after LPS; HA was higher (60%) than in controls (20%), when HA or NS infused 4 hours.
h after LPS. Bronchoalveolar lavage (BAL) of the animals surviving HA or NS infusion 4 h after LPS showed that total cell count and neutrophils were significantly (p < 0.01) reduced in the HA treated groups compared to controls (total cell count 1.2×10⁴/ml vs. 6.1×10⁴/ml, neutrophils 21×10⁴/ml vs. 0.2×10⁴/ml, respectively). Serum cytokines of the animals surviving HA or NS infusion 4 h after LPS showed that TNF-alpha and MIP-2 were significantly (p = 0.01) lower in the HA treated groups compared to controls (70.7 vs. 120.3 pg/ml, 1506 vs. 3459 pg/ml, respectively).

Conclusion: Continuous infusion of hyaluronan, 1600 kDa, reduced BAL cell count and serum cytokines, and improved survival in the endotoxic rats.

3206 Multi-organ failure in severe sepsis patients followed at intensive care unit: Risk factors
Zuhair Karakurt, Ozlem Yaziçioğlu Mecin, Ece Oz, Nalan Adıgüzel, Gökay Gangor, Ozkan Devran, Merih Kalamangolu Balci, Adnan Yılmaz.
Intensive Care Unit, Sırayyapasa Chest Diseases and Thoracic Surgery Training Hospital, Istanbul, Turkey

Aim: We aimed to detect risk factors for mortality and multi organ failure (MOF) for patients with severe sepsis and MOF in intensive care unit (ICU).

Material-method: Retrospective data collection and prognostic cohort study. Between January 2009-March 2010 patients with severe sepsis who stayed more than 24 hours in 22 bed ICU were retrieved. Demographics, ICU severity scores (initial APACHE II, 1st and 3rd day SOFA score), use of mechanical ventilation (non invasive, invasive), sepsis agent, application of sepsis protocol, ICU length of stay (LOS), mortality were recorded. Logistic regression analysis was done for risk factors and mortality risk factors in patients with and without MOF.

Results: 347 patients (232 males) with severe sepsis were involved. Fortythree (12.4%) developed MOF and overall mortality rate was 14.9% (n=52). Presence of resistant pathogen, shock, total parenteral nutrition (TPN) and high APACHE II score were found to be risk factors for MOF (p<0.015 Odds ratio (OR) 3.47 confidence interval (CI) 1.27-9.47, p<0.000, OR:1.10, CI:1.04-1.18, respectively). Risk factors for overall mortality were presence of nosocomial infection, high 3rd day SOFA score, presence of shock, sedation and TPN (p<0.005, OR:3.39, CI:1.45-7.93, p<0.000, OR:1.51, CI:1.27-1.81; p<0.014, OR:3.24, CI:1.27-8.25; p<0.003, OR:3.64, CI:1.54-8.58; p<0.000, OR:3.38, CI:1.51-7.57, respectively).

Conclusion: In severe sepsis patients who need ICU follow up, in addition to known sepsis protocols, rational use of antibiotics and application of hospital acquired infection control programmes will further reduce MOF and mortality.

3207 Prediction of clinical severity and outcome of ventilator-associated pneumonia in a tertiary hospital using the VAP PIRO scoring system
Roland Panaligan, Christine Chavez, Mario Panaligan.
Department of Medicine, UST Hospital, Manila, NCR, Philippines

Background: Management and decision-making in ventilator-associated pneumonia (VAP) was commonly guided by diagnostic tools, until a recent study validated a severity assessment tool for prognostication.

Objective: To determine if VAP PIRO Scoring System can predict mortality risk compared to APACHE II.

Methods: A prospective, observational study was performed including 52 patients randomly into two groups: Group A: 32 of the patients were treated in the traditional manner using Broad spectrum antibiotics for two weeks. Group B: 46 of the patients were treated according to the new strategy (De-escalation of Antibiotics) for eight days. All patients were followed up and assessed clinically and by CPIS (Clinical Pulmonary Infection Score), at starting therapy and the days (three, eight, and fourteen) in the hospital.

Results: The proportion of patients with late and early VAP in Group A were 56.25%, 43.75% and Group B were 54.34%, 45.65%. The mortality rate was significantly higher in late and early VAP in both groups. In Group B the CPIS and clinical improvement was noticed and statistically significant in day eight, comparing to Group A (39.13%, 28.12% respectively). We studied the type of bacteria and its resistance to antibiotics, the proportion of Gram-negative almost consists two thirds in both groups with no difference in distribution of germ. The mortality rate in Group A and Group B was (65.62%, 56.52% Respectively) the difference was statistically significant.

Conclusion: The (De-Escalation of antibiotics) was possible and safe with diminution of mortality, the amounts of antibiotics used and a shorter stay in the ICU.

358. E-learning
3209 Usage patterns and feedback of online E-learning modules for “Common Trunk” trainees in medicine
Josephine Busuttil, Martin Balzan.
Department of Medicine, Mater Dei Hospital, B’kara, Malta

Background: - E-learning provides access after-hours for post-grad medical trainees. Learning management systems allow accurate recording of trainee activity. Aim: To observe the pattern of usage of trainees and to assess feedback on utility of online modules.

Method: A Moodle online e-learning management system – including 24 online modules, and 24 quizzes as is part of an EU funded project ESF 1.19 (malta). All 23 (14Female) “Common-trunk” trainees at Mater Dei Hospital Malta were asked to complete these modules as part of their compulsory academic activities within a 6 week deadline. Data on usage was collected by the learning management system and trainees were asked to fill in an online feedback form.

Results: All trainees (n=23) completed all modules however 36.1% of modules (M=49.8%, F=27.4%) were completed in the last week. 19 (n=21) trainees found the e-learning as a useful or very useful tool. 19(21) and 13(21) of trainees reported streamed presentations and quizzes as of good/high quality. Acquisition of new knowledge was 7.95 (SD 1.75) on as scale of 0-10. The Quality of the TT work was rated 7.97 (SD 1.75). 43.0% (M=36.6% F=7.4%) of modules were completed from 16:00-19:59, 16.5% (M=29.3%, F=16.5%), from 20:00-23:59 and 4.5% (M=8.2%, F=2.2%) from 00:00-03:59. 32.8% of modules were performed on weekends (Sat=13.6%, Sun=17.6%, AverageMon-Fri = 13.8%). Average time to complete learning module F=49.7mins, M=76.4 mins, Quizzes, F=10.1mins, M=9.5 mins.

Conclusion: Overall feedback on E-learning was positive. There was significant difference in access time and weekend use. Gender differences in time of access, and total time needed to complete modules were noted.
A questionnaire study of available sources of information regarding medical conditions and access rate in patients attending chest clinics in a district general hospital (DGH) in the United Kingdom
Selva Selvaraj, Chris Sonadi, Greg Cooper, Thirumalai Naiaker,
Koothali Srinivasan, Harshini Moungil. Respiratory Medicine, Princess Royal Hospital, Telford, United Kingdom
Respiratory Medicine, University of Keele Medical School, Keele, United Kingdom

Background: There is increasing availability of medical information on the internet, and patients now, tend to use it more often [1,2].

Aims: To survey patients attending chest clinics (new and follow up) regarding their use of internet and other sources to access prior information about their respiratory condition.

Method: Questionnaire study of patients in respiratory clinics about the sources of information accessed by them, including internet, general practitioners (GP), other hospital consultants involved in their care, family, friends, leaflets and audio-visual media for one media period.

Results: 139 questionnaires were completed out of 161. 60 were male. Mean age was 54 (20-88).

Conclusion: The doctors remain the major source of information to the patients. However, the internet provides information to a significant proportion of our patients and this makes a compelling argument for making the internet resources more available and as reliable as possible. Our study noted that patients with cancer accessed the internet more.

FeNO interpretation aid: A clinical decision support tool for interpretation of FeNO values in the patients with respiratory symptoms
Tiago Jacinto1,2,3, Kjell Alving4, Eduardo Burnay1, Ana Sá-Sousa1, Ricardo Correia1,3, João Fonseca1,2,3, CINTESIS – Center for Research in Health Technologies and Information Systems, Faculdade de Medicina da Universidade do Porto, Portugal, Portugal; 2 Biostatistics and Medical Informatics Department, Faculdade de Medicina da Universidade do Porto, Porto, Portugal; 3 Allergy and Clinical Immunology, Instituto & Hospital CUF, Porto, Portugal; 4 Department of Oto-Rhino-Laryngology, Medical Faculty University of Vienna, Vienna, Austria; 5 Primary and Community Care, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Exhaled nitric oxide (FeNO) is a validated non-invasive biomarker of airways inflammation that is easy to measure, and gives immediate results. Its use has been increasing recently in routine care. Several individual factors that affect FeNO values have been identified, including age, height, weight, sex, atopy and smoking habits. These can cause difficulties in the interpretation of FeNO values.

Aims: To design and develop a Clinical Decision Support System (CDSS) that classifies the FeNO values taking into consideration the individual characteristics of a patient. Specific aims are: 1) to define the information model and specifications 2) to retrieve from published literature data to setup the knowledge base; and 3) to develop the CDSS and present a functional beta version for public evaluation.

Methods: Collaborative development with multidisciplinary meetings between healthcare professionals and computer scientists. Systematic review of factors affecting FeNO and reference values. Development of a web-based CDSS.

Results: We have outlined the model and specifications of the CDSS, including feature description, information model, taxonomic description, clinical workflow integration and software and hardware requirements. In the systematic review, 10 studies met the selection criteria and were used to form the datasets for the Knowledge Base of the CDSS. A web-based CDSS, that is compliant with common standards, was developed using HTML, PHP, Javascript and CSS.

Conclusion: The CDSS was successfully developed, based on the best available medical knowledge, and is accessible online for testing at http://feno.med.up.pt.

Conclusion: The pollen diary allows patients suffering from allergic rhinitis due to pollen to correlate the type (conjunctival, nasal, bronchial) and severity (degree 0–3) of her symptoms and the type and frequency of medication to correlate with the kind and intensity of the pollen exposure at the place of her stay.

The symptoms are entered daily in an online form by the patient anonymously. The pollen exposition for the user is investigated with the help of the postcode, and the suitable data from the area’s pollen trap are correlated with the symptoms and medication. Because pollen data are collected eurowide and stored in a common database (EAN, Vienna) it is possible to correlate the pollen load and symptoms of the affected person even if that person was travelling (in Europe). The user can chart symptoms and pollen flight and interpret accordingly.

The pollen diary is retrievable under www.pollendstuf.gen and www.pollendiary. free of charge and exists to date (1.2.2011) in 9 languages. In 2009 >4 000 and in 2010 >10 000 patients have used it.

The pollen diary supports the diagnosis of pollinosis and might be of help for therapy evaluation. It is appropriate for application in clinical studies on immunotherapy or for the effect of drug therapies. Also, this instrument is able to determine individual threshold values for pollen concentrations inducing sympoms and is likely to determine the clinical meaning of pollen kinds which were considered up to now not enough.

Furthermore any change of the threshold values is documented with these tools in the population throughout Europe and is measured.

Internet-based self-management (IBSM) in asthma, from evidence to practice: A qualitative study of barriers and facilitators for implementation
Johanna L. van Gaaalen1, Jiska B. Sneek-Ströband1, Leti Vo1,2, Mirta J. Bakker1, Ad A. Kaptein2, W.J.J. Assendelft3, Luuk N.A. Willems4, Bart P.A. Thomsen1, Jacob K. Sønn1, The IMPASSE (IMPLEMENTation Strategies of Internet-Based Asthma Self-Management Support in Usual care) Study Group: 1 Medical Decision Making, Leiden University Medical Center (LUMC), Leiden, Netherlands; 2 Medical Psychology, LUMC, Leiden, Netherlands; 3 Public Health and Primary Care, LUMC, Leiden, Netherlands; 4 Oto-Rhino-Laryngology, Medical Faculty University of Vienna, Vienna, Austria; 5 Primary and Community Care, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background: Internet-Based Self-Management (IBSM) support cost-effectively improves asthma control, asthma related quality of life, number of symptom-free days and lung function in patients with mild to moderate persistent asthma [Nasinde Meier 2009]. The current challenge is to implement IBSM in current clinical practice.

Methods: We conducted focus groups (FG) and interviews (for those not being able to participate in focus groups) based on a theoretical model. 20 patients (PT), 17 general practitioners (GP) and 8 practice nurses (PN) participated in FGs. In each FG an average of four persons participated. PTs (18-50 yr) had mild to moderate persistent asthma (>3 months ICS in the past year). Interviews were conducted with 2 PTs, 5 PNs and 4 GPs. FGs and interviews were audio-taped, fully transcribed and coded independently, using an existing framework of barriers [Grol 2004].

Results: Main barriers at patient level: unawareness of the level of asthma control, asthma was not perceived as a chronic condition, PTs experienced difficulty of...
395. Important new developments in paediatric respiratory physiology

3216 Micron-sized particle deposition in the developing rodent lung
Holger Schulte1,2, Gunter Eder1, Ines Bolle1, Akira Tsuda1, Stefan Karrasch1,2
1Institute of Pulmonary Physiology, University of Cologne, Cologne, Germany; 2Physiologie, Faculté de Médecine, Vandœuvre-lès-Nancy, France

Conclusion: Our findings indicate that future implementation strategies for IBSM need to address relevant barriers at professional/organisational and patient level, i.e. assessment of the level of asthma control and integration within daily practice.

3217 Newborn airway compliance is correlated with amniotic fluid soluble leukocyte-associated Ig-like receptor-1 (LAIR-1)
Michiel Houben1, Marloes Olde Nordkamp1, Kors Vd En1, Jan Kimpen1, Linde Meynard1, Louis Bont1, Linde Meyaard2, Louis Bont1
1Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands; 2School of Women’s and Children’s Health, University of Queensland, Brisbane, Australia

Hypothesis: High amniotic fluid sLAIR-1 is associated with normal newborn airway function and low infant airway morbidity.
Methods: In a healthy birth cohort, 152 newborns underwent lung function measurement. Amniotic fluid was collected during labour and sLAIR-1 was measured. To determine whether amniotic fluid sLAIR-1 could be spill-over from the neonatal circulation, cord blood and amniotic fluid sLAIR-1 were measured in parallel. At age 1 month, airway compliance and resistance were assessed with the single occlusion technique. Wheeze during follow-up was determined using a parental log.

Results: sLAIR-1 was detected in all amniotic fluid samples. Airway compliance and amniotic fluid sLAIR-1 were positively correlated (p=0.2,9, P=0.001). This correlation did not change by adjustment for sex or maternal smoking. Resistance was not correlated. Amniotic fluid sLAIR-1 was lower in children who wheezed at ages 6 and 9 months (P=0.04 and 0.05). Cord blood and amniotic fluid sLAIR-1 concentrations were not correlated.

Conclusion: The association between amniotic fluid sLAIR-1 and newborn airway compliance underscores the long-term clinical impact of intra-uterine immune activation.

3218 Elicitability of defensive reflexes within the breathing cycle
Silvia Varchova, Bruno Demoulin, Mathieu Boussels, Cyril Schweitzer, Bruno Chenuel, Anne-Laure Leblanc, Françoise Marchal. Laboratoire de Physiologie, Faculté de Médecine, Vandœuvre-lès-Nancy, France

Background: Both the cough (CR) and the expiration reflex (ER) are usually elicited within prolonged (more than 10 s) mechanical stimulation. The use of a discrete mechanical stimulus (150 ms) has shown that the type of response is strongly dependent on the phase of the breathing cycle. CR is favoured in inspiration (I) and ER in expiration (E). The observation suggests that CR and ER exhibit different regulatory mechanisms, but it still remains unclear which mechanisms control the expression of these responses.

The aim of the study was to assess the elicibility of CR and ER in relation to the timing of stimulation within breathing.

Methods: 313 mechanical stimulations of the trachea were performed in 14 rabbits using stimuli lasting 50 to 600 ms. CR and ER were identified from airflow and tidal volume. The timing of the stimulus was defined within TI and TE arbitrarily divided into 4 equivalent epochs (TI1 to TI4 and TE1 to TE4) and expressed as percentage of TI and TE of the reference breath.

Results: CR incidence during TI increased from 43% in TI1 to 56% in TI4. CR was almost absent in TE1 (4%) and whenever observed, always preceded by ER. In TE2-4, CR incidence increased, e.g., 50% in TI, to a nadir of 75% at TE4, i.e., the transition from TE to TI. On the contrary, incidence of ER increased throughout inspiration (from 15% in TI1 to 54% in TI4), and further to 54% in TE1. The incidence then decreased gradually from 33% in TE2 to 19% in TE4.

Conclusions: Elicitability of CR and ER exhibit a completely different pattern within each phase of breathing suggesting implication of distinct control mechanisms in their regulation and/or different impact of inputs from lung afferents in the timing of the CR and ER.

3219 Increased fetal growth protects against early wheeze, airway hyper-responsiveness (AHR) and current asthma in early mid-childhood: Results from the Raine birth cohort
Graham Hall1, Lyn Chen2, Wei Ang1, Craig Pennell1, John Newham1, Peter Sly1, 1Paediatric Respiratory Physiology, Telethon Institute for Child Health Research, Perth, Australia; 2Queensland Children’s Medical Research Institute, University of Queensland, Brisbane, Australia; 3School of Women’s and Infants’ Health, University of Western Australia, Perth, Australia

Reduced fetal growth has been associated with increased wheeze and atopy and decreased lung function in young children. This analysis of the Raine longitudinal birth cohort aimed to examine the impact of fetal growth on asthma, lung function and AHR outcomes at 6 and 14 years of age.

Methods: The Raine birth cohort enrolled women prior to 18 weeks gestation to standard (18w; n=1419) or intensive (18w, 24, 28, 34 & 38w; n=1415) ultrasound monitoring groups. Children were re-assessed at 1, 2, 3 yrs with further respiratory assessments at 6 and 14 yrs. Composite data on 1174 children are included in this analysis. Conditional fetal growth centiles were derived for head circumference, femur length and abdominal circumference. Impact of fetal growth on early wheeze (wheeze at 1, 2 or 3 yrs), current asthma, spirometry or AHR at 6 or 14 yrs was assessed using generalised estimating equations with time as repeated measures.

Results: Measures of increased fetal growth throughout pregnancy were significantly associated with a reduced risk of early wheeze, AHR at 6 yrs and current asthma at 14 yrs (p<0.05). In addition there was a tendency for increased FEV1, predicted at 6 and 14 yrs and FEV1/FVC at age 6 and 14, although these relationships were not significant.

Conclusions: In agreement with previous reports we have demonstrated increased fetal size reduces the risk for wheeze in early life. The current data suggests that the impact of fetal programming on lung health extends into early adolescence and further reinforces the need for further research to discover how fetal growth may be optimised.
Results: The drop in R at 4 Hz (R4) with increasing age was linearly related to the magnitude of R4 at 4 years of age (Pearson’s correlation coefficient of 0.87 and 0.88 at baseline and after bronchodilatation, respectively). Interestingly, the slope characteristicizing this relationship was almost similar for the baseline (0.75) and the postbronchodilator values of R4 (0.81). Division of the group of children based on the magnitude of R4 at 4 years revealed that the change in R4 with increasing age was not related to differences in growth rate (see figure). Although the differences in R4 in 4-year-old children disappeared to a large extent with the increase in age, the subgroups of children still had significantly different R4 values by the age of 9 years.

Conclusion: Four-year-old children with high airway resistance exhibit the largest drop in resistance with growth to 9 years of age; this drop in resistance is independent of airway muscle tone at young age.

Multicentre feasibility and variability of measuring the lung clearance index in healthy volunteers

Susanne Fuchs1, Helmut Eilmann2, Johannes Eder3, Uwe Mellies4, Jörg Gross-Oetternbach5, Burkhardt Tümmler6, Doris Shaba, Andrea Jobel7, Matthias Greise6, Jan Ripper4, Ernst Rietschel7, Susanne Zeidler7, Frank Ahrens8.

In healthy volunteers

The Lung Clearance Index (LCI) is superior to spirometry in detecting early lung disease in Cystic Fibrosis and correlates with structural changes seen on CT-scans. The LCI has the potential to become a novel outcome parameter for clinical and research purposes. Longitudinal studies are required to further prove its prognostic value. Multi-centre design is likely to facilitate realisation of such studies.

Therefore, the aim of the present study was to assess multi-centre feasibility and inter-centre variability of LCI measurements in healthy children and adolescents. Measurements were performed using the EasyOne Pro, MBW module (ndd, Switzerland) by 8 participating CF centres. Marien Hospital Wessel, Wels, Germany; 2Department of Paediatric Cystic Fibrosis Centre, Medical University Innsbruck, Austria; 3Pneumologische Poliklinik, Medical University Essen, Essen, Germany; 4Pneumologische Poliklinik and Neonatologia, Medical University Hannover, Hannover, Germany; 5Pneumologische Poliklinik and Allergology, Charité Berlin, Berlin, Germany; 6Dr. von Haemmerzehl Kinderspital, Medical University Munich, Munich, Germany; 7Cystic Fibrosis Centre, University Hospital of Cologne, Cologne, Germany; 8Cystic Fibrosis Centre, Children’s Hospital Hamburg Altona, Hamburg, Germany

Methods: Impedance spectra were obtained in 760 healthy children (335 male), aged 2-13 years and with height 90-160 cm using a commercial forced oscillation device (FOT) device (I2M, Chess Medical, Belgium). AX between 6 Hz and the resonant frequency was calculated in 647 children. Backward stepwise linear regressions identified anthropometric predictors of AX, and z-score equations were generated. Absolute and relative changes in AX post bronchodilator were calculated in 496 children.

Results: AX was predicted by height (p<0.001) and sex (p=0.004). Both absolute and relative changes in AX to bronchodilator were dependent on baseline lung function and height. A significant BDR using AX was defined as a decrease in absolute or relative AX of 33.2 kU/L and 8%, respectively.

Conclusions: We have provided healthy reference ranges for AX to aid in disease diagnosis, and defined cut-off values for a positive BDR by AX.

360. New insights in the incidence, variation and risk factors of asthma

Ike-breaking abstract: Association of asthma with IgE to Staphylococcal enterotoxins in a GA2LEN population based case-control study

Peter Tomassen1, Claas Bachert1, Peter Burney2, Deborah Jarvis3, on behalf of the GA2LEN Survey Follow-Up Working Group.

Introduction: Presence of specific immunoglobulin E for staphylococcal enterotoxins (SE-IgE) in serum has been associated with severe asthma and nasal polyposis, but the prevalence and link to asthma in the general population has not been studied. We aimed to determine the prevalence of serum SE-IgE and to study the association with asthma in the general population.

Methods: The GA2LEN Survey Follow-Up group conducted a multi-centre case-control study in 18 centers across Europe. Subjects were sampled from a preceding cross-sectional survey in 4 groups (controls, at-risk asthmatics, chronic rhinosinusitis subjects, and those having both). Subjects answered questionnaires, underwent spirometry and skin prick testing for common allergens, and serum SE-IgE was measured. Analyses were weighted for sampling, using inverse probability weights.

Results: 3505 subjects participated, of which 2908 in 15 centers provided complete information and blood samples. The weighted overall prevalence of asthma was 10.6%, and the prevalence of SE-IgE >0.10 kU/L was 29.3%. SE-IgE was significantly associated with the presence of asthma, adjusting for age, sex, allergy and smoking history. The strength of the association was dependent of the SE-IgE concentration (odds ratio 1.01; 1.33; 1.54 in the first, second and third tertiles).

The association was not modified by the presence of a positive skin prick test or tobacco smoking.

Conclusion: Presence of IgE to Staphylococcal enterotoxins is highly prevalent, and is associated with asthma in the general population across Europe. These findings open perspectives on a role for bacterial superantigens in the pathogenesis of asthma.

3224 Asthma incidence in a national sample of Canadian adolescents

Joshua Lawless1, Ian Janssen2, Alomgir Hossain3, Mark Bruner4, William Pickett5, 1Canadian Centre for Health and Safety in Agriculture, University of Saskatchewan, Saskatoon, SK, Canada; 2Department of Community Health and Epidemiology, Queen’s University, Kingston, ON, Canada; 3School of Physical and Health Education, Nipissing University, North Bay, ON, Canada

Background: Estimates of asthma incidence and its determinants have rarely been obtained from rural regions, especially in adolescent populations.

Objective: To compare the incidence of asthma among Canadian adolescents in rural and urban regions and to examine the determinants of asthma incidence.

Methods: We used data from the National Population Health Survey (NPHS), a nationally representative longitudinal survey of Canadians. The NPHS uses a complex survey design with data collected every 2 years since 1994/95. The NPHS collects information on socio-demographics and some health behaviours. All persons aged 12-18 years without asthma in Cycle 1 were followed until a reported diagnosis of asthma or censoring up to Cycle 7. Rural residence was defined by living in an area of <1000 people and ≥400 people/km². Incidence and Cox regression analyses were population weighted and bootstrapping procedures were used to estimate variances.

Results: This sample represented 2,482,610 adolescents of whom 293,445 developed asthma. Approximately 19% of the cohort was rural living at baseline. The incidence of asthma was approximately 10.2 per 1000 person-years and was higher in...
urban dwellers than rural dwellers (10.9 vs. 7.7 per 1000 person-years). In adjusted analysis, rural residence was not associated with asthma development [Hazard ratio (HR) = 0.58, 95% CI = 0.25-1.32, p = 0.19]. Being female and being exposed to passive smoking were both associated with the development of asthma (p < 0.01).

Conclusions: Unlike results from younger children, a rural dwelling was not protective of developing asthma among adolescents, despite showing a trend. Asthma prevention initiatives for adolescents should target girls and focus on smoking exposure.

3225
Temporal patterns of wheeze during the school ages in a population-based cohort
Anders Bengt, Linnea Hedman, Sigrid Sundberg, Martin Andersson, Eva Ronmark. The OLEN Study, Dept of Medicine, Sunderby Central Hospital of Norrbotten, Lulea, Sweden
Introduction: Wheeze, as suggestive of asthma, may follow various time courses during childhood. Incidence, remission and relapse rates are high. Compared to the pre-school ages, school age and adolescence have been less studied. The aim was to characterize temporal patterns of wheeze in school children.

Methods: At age 7-8 years, 3,430 (97% of invited) children in Northern Sweden completed ISAAC questionnaires. The same questions were used in 10 yearly follow-ups until age 17-18. Data from the 2,622 (76.4%) subjects that participated at 5 or more occasions were analysed.

Results: From age 7-8 to 17-18 one third reported wheezing at some occasion. Persistent wheeze from age 7-8 was reported by 2.9%. It was closely associated with rhino-conjunctivitis and parental asthma at age 7-8, RR 10 (6.6-15) and 5.3 (3.5-8.2). Incident wheeze persisting until age 17-18 was reported by 7.6%, while 2.6% had remitted wheeze, i.e. wheeze at age 7-8 but not at study end. Remitted wheeze was associated with respiratory infections before age 7-8, RR 4.1 (2.2-7.8). Transient wheeze for 1 year or more, not persisting until age 17-18, was seen in 8.7%. Of the 12.0% reporting intermittent periods of wheeze with no clear pattern, nearly half wheezed only at 1 or 2 occasions.

Discussion: In this large cohort of school children followed yearly by questionnaires, the majority of children with any wheeze during the school years were neither wheezing at age 7-8, nor at age 17-18. Half of the children wheezing at age 7-8 were in remission by age 17-18. Whereas wheeze associated with respiratory infections has a good probability of remission, heritability and concomitant allergic rhinitis predict persistence of wheeze.

3226
Seasonal variations in asthma attacks and grass sensitisation
Cristina Canova, Peter Burney, Deborah Jarvis, on behalf of the European Community Respiratory Health Survey I. Respiratory Epidemiology and Public Health, NIHR, Imperial College, London, United Kingdom
Seasonal variation in asthma mortality and hospitalization has been reported. In this study we describe seasonal variation in asthma symptoms and assess whether this was modified by SPT sensitisation. Asthmatics aged 20-44 years (n=3253) taking part in the European Community Respiratory Health Survey I are included. Participants identified bi-monthly periods they usually experienced attacks of asthma. Effect modification of sensitisation to grass, cat, dust, birch. Alternaria on asthma attacks in each bi-monthly period was assessed within each country, using marginal logistic regressions, based on generalised estimating equations. Interaction coefficients were then combined using random effects meta-analysis. Seasonal variation in asthma attacks was seen in most countries, although with different patterns. Seasonal variation was not modified by sensitisation to indoor allergens (cat, dust) but was modified by sensitisation to grass.

Figure 1 Grass bi-months interaction risk of an asthma attack

In Southern Europe the risk of asthma in May/June compared to Jan/Feb in those with IgE to grass was six times that seen in asthmatics not sensitised to grass. Overall sensitisation to Alternaria increased the risk of attacks in Jul/Aug compared to Jan/Feb (OR 2.3).

Asthma sensitised to grass and Alternaria experience seasonal exacerbations likely triggered by allergen exposure. The effect of pollen on asthma severity in a sub group of susceptible asthmatics may be much greater than previously documented.

3227
Initiation of controller medication in newly diagnosed asthma patients: Impact on economic resource utilization
Pierrick Bedouch1, Mohsen Sadatsafavi1, J. Mark FitzGerald2, Carlos Marras3, Larry Lynd1, 1Collaboration for Outcomes Research & Evaluation (CORE); 2Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 3Department of Medicine & Centre for Clinical Epidemiology and Evaluation, Vancouver Coastal Health Research Institute, Vancouver, BC, Canada
Introduction: To better understand the economic burden of asthma, we compared asthma-related direct costs among adults prescribed controller regimens.

Methods: A cohort of newly diagnosed asthma patients (14-65 yrs), initiating a controller therapy for the first time between 1997 to 2007, was created from the health administrative database of British Columbia, Canada. Five cohorts of patients were created according to the controller prescribed (i.e. inhaled corticosteroid (ICS group), ICS-long-acting beta-agonist combination (ICS-LABA group), ICS+LABA in separate formulations (ICS+LABA group), leukotriene receptor antagonist (LRA group) or ICS+LRA in separate formulations (ICS+LRA group)). Index Date (ID) was defined as the date controller medication prescribed. Direct cost of asthma in the post-ID year (2008 Canadian dollars) was calculated from the hospital, physician visits, and prescription records, adjusted for multiple imputations, estimated from the pre-ID year.

Results: 153,224 patients were included: 109,601 ICS, 34,184 ICS/LABA, 2,249 ICS+LABA, 6,289 LRA; 901 ICS+LRA. The average age was 37.7 and 61.0% were female. The average direct costs of asthma for the post-ID year for the ICS group was 265.2$. All other groups had higher incremental costs: ICS/LABA $315.9, ICS+LABA $218.2, LRA $198.4, and ICS+LRA $372.4 (all p<0.01). Older age, higher resource, and higher cumulative dose of rescue medication use in the pre-ID year were predictors of resource use in the post-ID year (p < 0.01).

Conclusions: Initiation of ICS, as recommended by guidelines, was associated with the lowest costs than initiation of other controller or combination therapies.

3228
A longitudinal study investigating factors associated with changes in lung function over time in early life (age 3 to 11)
Danielle Belgrave, Lesley Lowe, Angela Simpson, Adam Custovic. Respiratory Medicine, University Hospital South Manchester, University of Manchester, Manchester, United Kingdom
Background: Previous studies have investigated factors associated with poor lung function in children. However, these studies use a cross-sectional approach which ignores changes in lung function over time. In this study, we develop multilevel longitudinal models in order to investigate factors affecting developmental change in lung function in early life.

Methods: In a population-based birth cohort 1185 participants were recruited pre-natally and followed prospectively (1, 3, 5, 8 and 11 years). At each time point, a validated questionnaire was administered to collect information on asthma-related symptoms, height and weight. We assessed atopy and lung function (Specific Air- way Resistance (sRaw), plethysmography) at each follow-up. We use a longitudinal mixed models approach to determine predictors of change in sRaw over time.

Results: Univariate longitudinal analyses revealed marked deterioration in sRaw among children who were atopic (mean difference 2.85%, 95% CI 1.05%-9.84%, p=0.003). Children who wheezed also had poorer lung function (mean difference 5.20%, 95% CI 0.87%-2.54%, p=0.01). Boys had poorer lung function compared to girls (mean difference 3.48%, 95% CI 0.87%-6.52%, p=0.03) and also had a higher rate of deterioration of sRaw over time which increased by 0.011 units (p=0.012) per year. In a multivariate longitudinal model, the factors which best predicted diminished lung function were atopy, increased BMI, paternal atopy, gender and current wheeze.

Conclusion: Multilevel longitudinal models allow us to predict factors associated with diminished lung function as well as factors associated with change in lung function over time.

3229
Transforming growth factor beta-1 gene polymorphisms and course of asthma
Despo Ierodiakonou1, Dirkje S. Postma2, Gerard H. Koppelman3, Jorrit Gerritsen3, Wun Timens4, H. Marike Bozen1, Judith M. Vonk1.
1Epidemiology, University Medical Center Groningen, Groningen, Netherlands; 2Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 3Pediatric Pulmonology and Pediatric Allergy-Immunology, Children’s Hospital, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 4Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands
TGFβ1 is a cytokine with a potent role in asthma, in particular in airway remod-
eling. We investigated the role of TGFβ1 gene single nucleotide polymorphisms (SNPs) in the course of asthma. Four haplotype tagging SNPs (rs7254679, rs4803455, rs1880469, rs1047924) were genotyped in 215 asthmatics with a 30-year follow up (population 1) and in 99 asthmatics who provided bronchial biopsies (population 2). Associations of SNPs with lung function, bronchial hyperreactivity (BHR i.e. PC20≤16mg/ml), complete remission (pro bronchodilatation FEV1% predicted > 80% & absence of BHR, symptoms, medication), baseline membrane (BM) thickness and number of submucosal vessels were investigated using linear or logistic regression. Associations of SNPs with baseline serum 25-hydroxyvitamin D [25(OH)D] levels and adult-onset asthma. Serum 25(OH)D were not independently associated with adult-onset asthma.

Conclusions: Baseline serum 25(OH)D level was not associated with the risk of asthma in either unadjusted or adjusted models. Second, we performed the stratification analysis by BMI. In men, the OR was 2.12 (95% CI 0.93-4.80) and 1.38 (95% CI 0.77-2.47) for BMI < 25 and BMI ≥ 25, respectively. In women, baseline serum 25-hydroxyvitamin D [25(OH)D] levels were not independently associated with adult-onset asthma.

Serum 25(OH)D were not independently associated with adult-onset asthma.

Conclusions: Baseline serum 25(OH)D level was not associated with the risk of asthma in either unadjusted or adjusted models. Further adjustment for body mass index (BMI) yielded an OR of 1.47 (95% CI 0.93-2.32). In women, baseline serum 25-hydroxyvitamin D [25(OH)D] levels were not associated with the risk of asthma in either unadjusted or adjusted models.

Serum 25(OH)D were not independently associated with adult-onset asthma.

Conclusions: Baseline serum 25-hydroxyvitamin D [25(OH)D] levels were not independently associated with adult-onset asthma.

Conclusions: Baseline serum 25-hydroxyvitamin D [25(OH)D] levels were not independently associated with adult-onset asthma.

Serum 25(OH)D were not independently associated with adult-onset asthma.
broblast differentiation markers in control fibroblasts. IFP fibroblasts were less sensitive to cycloamine treatment. Though, addition of recombinant SHH had no effect.

Conclusions: Our results show that the signaling pathway downstream of SHH is activated in IFP. SHH activity is also necessary to TGF-β induced myofibroblast differentiation. These data support a pro-fibrotic action of the SHH pathway in IFP.

3234

Heat Shock Protein 27 modulates mesothelial and epithelial to mesenchymal transition (EMT)

Guillaume Wettstein1, Pierre-Simon Bellaye1, Martin Glave2, Martin Kolb3, Carmen Garrido3, Philippe Carus3,4, Philippe Bonnassie1,2,4 Stress Protein and Cancer. INSERM U866, Faculté de Médecine, Dijon, Burgundy, France; 1Vancouver Prostate Centre, Vancouver General Hospital, Vancouver, Canada; 2Centre de Gene Therapie, McMaster University, Hamilton, ON, Canada; 3Service de Pneumologie et Réanimation Respiratoire, CHU, Dijon, Burgundy, France

Introduction: Pulmonary fibrosis (PF) has currently no treatment. We have shown that adenoviral gene transfer of TGF-β1 (AdTGF-β1) to the pleura induces a severe pleural fibrosis that invades the paranchyma. In this process, mesothelial cells differentiate into myofibroblasts (α-SMA positive cells) through an EMT-like process suggesting a key role of mesothelial cells in PF. Heat Shock Protein 27 (HSP27), is a chaperon for actin. Its role in fibrogenesis is unknown.

Methods: Sprague Dawley rats received intrapleural injection of AdTGF-β1 or AdDL (empty vector). Mesothelial Met-5A and A549 cells were treated with rTGF-β1.

Results: In vitro: 1) mesothelial cells are susceptible to rTGF-β1 induced EMT 2) HSP27 is strongly linked to α-SMA during EMT (colocalisation and co-immunoprecipitation). 3) HSP27 overexpression induces an EMT and α-SMA mediated HSP27 inhibition blocks TGF-β1 induced EMT and mesothelial cell migration 4) HSP27 modulates the TGF-β1/MAPK pathway. Data were reproduced in A549 epithelial cells.

In vivo: 7 days after AdTGF-β1 injection, HSP27 and α-SMA are overexpressed and localized in alveolar and septal wall areas. AdTGF-β1 rats treated by intrapleural injections of OGX427 (Antisense Oligonucleotide, ASO, directed against HSP27) have a strong decrease in HPS27, α-SMA expression, mesothelial cells migration into the paranchyma and fibrosis compared to AdTGF-β1 rats treated with control ASO.

Conclusion: HSP27 plays a major role in EMT and could be a key target to inhibit EMT in PF and others diseases involving EMT. This work was supported by: 1 – the EU, 7th FP, HEALTH-F2-2007-202224 eurIPFnet – La “Recherche en santé Respiratoire” et la Société de Pneumologie de Langue Française

Long-term effect of hepatocyte growth factor in the normal lung: A stereological assessment

Alexandra Leuenberger1, Lars Knudsen2, Amir Gzdhar1, Thomas Geiser1, Matthias Ochs1, Institute of Anatomy, University of Bern, Bern, Switzerland; 2Institute of Functional and Applied Anatomy, Hannover Medical School, Hannover, Germany; 3Department of Pneumology, Bern University Hospital, Bern, Switzerland

Background: Hepatocyte growth factor (HGF) gene transfer attenuates bleomycin induced lung fibrosis. Being a multifunctional pleiotropic factor, HGF is a potent mitogen for alveolar epithelial cells and shows antiapoptotic properties. Thus, we hypothesize that HGF might lead to remodelling processes within the alveolar walls in normal rat lungs.

Material and methods: Adult male Fisher rats F344 were instilled with 350 μg bleomycin in saline. One month after HGF gene transfer, animals were sacrificed and the total volume of interstitial cells and basement membrane within the septal walls. An emphysema-like phenotype was not observed.

Conclusions: Our results show that the signaling pathway downstream of SHH is activated in IFP. SHH activity is also necessary to TGF-β induced myofibroblast differentiation. These data support a pro-fibrotic action of the SHH pathway in IFP.

3236

HGF expressing stem cells in the human fibrictic lung originate from the bone marrow

Najmeza Susuri1, Amiq Gzdhar1, Mathias Gugger2, Thomas Geiser1, Division of Pulmonary Medicine, University Hospital Bern, Bern, Switzerland; 2Department of Pathology, University of Bern, Bern, Switzerland

Background: Pulmonary fibrosis (PF) is a progressive disease of unknown etiology. Abnormal alveolar epithelial wound repair after injury may result in pulmonary fibrosis. We hypothesize that stem cells have a healing capacity by migrating to the site of injury and secreting hepatocyte growth factor (HGF) which supports alveolar epithelial repair, therefore contributing in reduction of fibrosis.

Methods: Immunohistochemistry using paraffin lung sections from patients with two histological lung fibrotic pattern, usual interstitial pneumonia (UIP) and non-specific interstitial pneumonia (NSIP) (both n=5) was performed with several stem cell markers.

Results: Specific cells in the lung parenchyma were stained positive for HGF in UIP and NSIP. They were mainly located in the fibrotic areas. These HGF-positive cells did not co-stain for markers of alveolar epithelial cell (Surfactant protein C) or mesothelial cells (vimentin). However, HGF-positive cells showed strong co-staining for the mesenchymal stem cell markers CD44, CD29, CD105, and CD90, indicating that HGF positive cells in the lung are of stem cell origin. The HGF-positive cells were also positive for CXXCR4, suggesting that the HGF-positive cells in UIP and NSIP are recruited from the bone marrow.

Conclusion: HGF-positive stem cells with the origin of the bone marrow (CXXCR4 positive) can be detected in both UIP and NSIP, indicating a crucial role in the development or resolution of pulmonary fibrosis. These data indicate a possible role for stem cell therapy patient with fibrictic lung disease in the future.

362. Obstructive sleep apnoea in children and adults

3237

Late-breaking abstract: Cardiac function in a revascularized coronary artery disease cohort with obstructive sleep apnoea with and without daytime sleepiness in the RICCADA trial

Yukel Peker1,2, Helena Glantz1, Erik Thunstrom2, Bjorn Cedernil1, Johan Herlitz3, Jan Ejdebak1, 1Sleep Medicine Unit, Skaraborg Hospital, Skovde & Lidköping, Sweden; 2Emergency and Cardiovascular Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Objectives: The RICCADA study is a randomized, controlled trial started in 2005 addressing the impact of CPAP in revascularized coronary artery disease (CAD) patients and concomitant OSA (Apnoea-Hypopnoea-Index [AHI]≥15) without daytime sleepiness (Epworth Sleepiness Scale <10). The primary outcome is the combined rate of new revascularization, myocardial infarction, stroke and cardiovascular mortality over a mean period of 3 years. Among secondary outcomes, cardiac function is also evaluated.

Participants and methods: Among 660 screened CAD patients, 511 (399 OSA, 112 non-OSA) have been assessed by echocardiography and p-NT proBNP at baseline.

Results: Compared to non-OSA subjects, patients with OSA had thicker interventricular septum and left ventricular posterior wall, enlarged left atrium and more diastolic dysfunction. Left ventricular ejection fraction was similar (56.9 vs 58.3%, p=0.040). The primary outcome was the combined rate of new revascularization, myocardial infarction, stroke and cardiovascular mortality over a mean period of 3 years. Among secondary outcomes, cardiac function is also evaluated.

Conclusions: In this RICCADA cohort, adverse alterations in cardiac structure as well as diastolic dysfunction were more common and p-NT-proBNP values increased in OSA patients compared to non-OSA patients. Whether the more elevated p-NT-proBNP values in the non-sleepy subjects reflect a poorer prognosis and if CPAP is effective in OSA patients remain to be demonstrated when the trial is completed.

3238

Feasibility of implanted upper airway nerve stimulation therapy to treat obstructive sleep apnea

Wilfried De Backer1, Johan Verbraecken1, Joachim Maurer2, Lennart Knack3, Ariane Olivier4, 1Respiratory Medicine, University Hospital Antwerp, Edegem, Antwerp, Belgium; 2Hals-Nasen-Ohrklinik, Universitätsmedizin, Mannheim, Germany; 3SOMNOLAB Dortmund, Zentrum für Schlafmedizin, Dortmund, Germany; 4Department of Medicine, Bni Zion Medical Center, Haifa, Israel

We studied a second generation Upper Airway Stimulation system (Inspire Medical
Methods: Twenty children (mean age 6.3±3.2, M/F:12/8, with referred OSAS, underwent urinary collection at the morning after the polysomnography, sleep questionnaire, medical examination. 8-Isop was assessed in urinary sample.

Introduction: Prevalence of sleep disordered breathing (SDB) in middle-aged general population was reported to be around 9% of women and 27% of men in studies performed in the 80’s-90’s. Considering the recent improvements in the sensitivity of recording techniques, our aim is to revaluate the prevalence of SDB in the general population.

Methods: 505 subjects (47.1% women, 50.3±5.6 y.o. BMI 25.7±4.4 kg/m²) participating in an ongoing population-based cohort study (HypnoLaus, Lausanne, Switzerland) underwent complete polysomnographic recordings at home and had an extensive clinical workup including Epworth Score (ESS). Prevalence of SDB was determined according to apnea-hypopnea index (AHI) using two different scoring criteria: AASM 1999 and 2007.

Results: With AASM 2007 criteria, prevalence of SDB with AHI thresholds of 5/h, 15/h and 30/h was 45.7%, 15.7% and 6.3% respectively in men and 11.9%, 2.5% and 0.8% respectively in women. Mean ESS score was 11.9±4.0 in men and 8.7±4.9 in women. Prevalence of SDB with ESS≤10 was 12.0%, 6.7% and 2.6% in men and 5.5%, 2.1% and 0.4% in women.

Conclusion: In HypnoLaus population-based study, prevalence of SDB is higher than previously reported, especially in middle-aged men. This appears to be due to differences in scoring criteria and to a higher sensitivity of nasal pressure sensors compared to thermocouple.

3242 Morbidity prior and after a diagnosis of sleep disordered breathing. A controlled national study

Poul Jenum, Jakob Kjellberg, Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Center for Healthy Aging, Faculty of Health Sciences, University of Copenhagen, Glostrup Hospital, Copenhagen, Denmark Danish Institute for Health Services Research, DSI, Copenhagen, Denmark

Background: Sleep disordered breathing (SDB) causes significant burdens. Most studies have focused on cardiovascular diseases (CVD) after a diagnosis of sleep apnea (SA) or obesity hypventilation syndrome (OHS) but the overall morbidity prior to a SDB diagnosis is incompletely evaluated.

Methods: Using data from the Danish National Patient Registry (1999-2006), we identified all national patients with a diagnosis of SA (19438), or OHS (755). For every patient, we randomly selected 4 age-, sex- and socioeconomic-matched citizens from the Danish Civil Registration System Statistics. We further extracted information from the Danish Ministry of Health, Danish Medicines Agency, and National Health Security

Results: Pts with SA and OHS presented increased morbidity (p<0.01) up to more than eight years prior to a SDB diagnosis of SA the most common contacts were diseases of the endocrine, nutritional and metabolic diseases (Odds Ratio (OR) SA/OHS 4.5/4.8), nervous system; OR 4.4/5.5), respiratory system (OR 2.9/4.0), skin and subcutaneous tissue (OR 2.5/1.3), infections (OR 1.8/3.0), CVD (OR 1.7/1.3), genito-urinary system (OR 1.3), ear-nose and throat (OR 1.3), psychiatric diseases (OR 1.1/1.4). After a SDB diagnosis, patients also presented significant morbidities and mortality. CPAP treatment reduced mortality (6.6% versus 5.5 in non-SAP pts, 4.0% in control subjects).

Conclusion: Patients with SDB shows significant morbidities several years prior to...
Obstructive sleep apnea and hypopnea syndrome (OSAHS) is characterised by sleep-disordered breathing and daytime sleepiness. The Epworth Sleepiness Score subjectively quantifies sleep propensity whilst the Apnoea-Hypopnoea Index (AHI) is an objective value for the severity of OSAHS. An audit was undertaken to test whether standards held true regarding OSAHS remain so in a Gloucestershire population. Firstly, that mean ESS varies between patients and partners according to their perceptions of patient sleep propensity. Secondly that there is no correlation between patient ESS and AH1 and a weak correlation between partner perspective ESS and AHI as shown by previous studies. The audit also aimed to test whether severity levels of ESS were found to be independent of severity levels of AH1 when the data were placed in severity categories according to guidelines.

During the audit, 40 sets of patient-partner data were collected retrospectively from a sleep database and analysed. It was found that there was no mean difference between patient and partner perspective ESS scores (p=0.906), disputing the first standard. The partner perspective ESS (r=0.464), but not the patient ESS (r=0.305) correlated with AH1 therefore the second standard held true. An additional test found that severity levels of ESS were independent of severity levels of AH1 both for patient and partner scoring. ESS was found to be a poor predictor of AH1. To improve this, an alternative questionnaire was devised which combines subjective and objective risk factors for OSAHS. Evaluation of this questionnaire requires stratification.

### 3244

**Long-term follow-up of severe obstructive sleep apnea-hypopnea syndrome**

**Methods:** We prospectively followed 589 consecutive patients (pts) with clinically suspected OSA. The pts were included and followed-up for a mean period of 7 years by sleep questionnaires, antropometric measurements, polysomnography and questionnaires. The structure of the study population according to European Society of Hypertension 2007 Guidelines: from the 59% of pts with SI 11% with normal values, 15% stage I, 24% stage II, 8% stage III. AHI in all 3 levels, with reference normal, is extremely significant (p<0.001) in hypertensive patients. Only severe OSA is the strongest predictor for hypertension, OR 3.2 (p<0.001 CI 1 1-6 5 59). Mild and moderate OSA did not significantly influence the appearance of SH (p<0.014, OR 0.58, CI 0.29 1.20, p=0.24, CI 1.52, CI 0.76 2.86). SH is a weak predictor for OSA in univariate analysis, p=0.045, OR 1.76, CI 1.01 3.08.

**Conclusions:** Patients with OSA are exposed to a higher risk of developing SH. A strong predictor for SH is only severe OSA.

### 3245

**Can the Epworth sleepiness score predict the apnoea-hypopnoea index in obstructive sleep apnoea and hypopnoea syndrome?**

**Results:** According to the BQ, 24 patients (38%) scored a low risk of OSAS and 39 patients (62%) scored a moderate to high risk. The BQ scores averaged 7.9 (49 mmHg). A high-risk ESS scores averaged 7.9 (49 mmHg). Sensitivity of the BQ was 67% and specificity 48%. The internal consistency of the BQ ranged from moderate to good (Cronbach’s α 0.61-0.80). Sensitivity and specificity of the ESS were 45% and 81% with a cut-off point of 8, which according to literature, is the cut-off point between normal and abnormal sleepiness. A cut-off point of 5 appeared to be a more preferable choice for this population. Sensitivity increased to 71% and specificity decreased to 48%. Internal consistency of the questionnaires was good (Cronbach’s α 0.80).

**Conclusion:** Given the low to moderate sensitivity and specificity, the BQ and ESS were found to be of low value as screening tools for patients who referred to the sleep clinic.

### 3246

**Berlin questionnaire and Epworth sleepiness scale, useful screening instruments for obstructive sleep apnoea syndrome?**

Anamnie Mensink, Steven Ull, Bert Kuipers. Pulmonary Department, Isala Klinieken, Zwolle, Overijssel, Netherlands

**Methods:** Conceived a retrospective validation study for the Berlin Questionnaire (BQ) and Epworth Sleepiness Scale (ESS). 63 patients completed these questionnaires prior to their first outpatient visit to our sleep clinic. All patients underwent a polysomnography to determine their Apnea-Hypopnea Index. Diagnosis was based on the anamnesis and the polysyrgy results. Sensitivity, specificity and internal consistency of these questionnaires were assessed.

**Results:** According to the BQ, 24 patients (38%) scored a low risk of OSAS and 39 patients (62%) scored a moderate to high risk. The BQ scores averaged 7.9 (49 mmHg). Sensitivity of the BQ was 67% and specificity 48%. The internal consistency of the BQ ranged from moderate to good (Cronbach’s α 0.61-0.80). Sensitivity and specificity of the ESS were 45% and 81% with a cut-off point of 8, which according to literature, is the cut-off point between normal and abnormal sleepiness. A cut-off point of 5 appeared to be a more preferable choice for this population. Sensitivity increased to 71% and specificity decreased to 48%. Internal consistency of the questionnaires was good (Cronbach’s α 0.80).

**Conclusion:** Given the low to moderate sensitivity and specificity, the BQ and ESS were found to be of low value as screening tools for patients who referred to the sleep clinic.

### 3247

**Randomized trial of 6 auto-adapting CPAP devices**

Sara Neale, Fiona Buchanan, Nicola Allouat, James R. Catterall, Adrian H. Kendrick. Sleep & NIV Unit, University Hospitals Bristol, Bristol, United Kingdom

Auto-adapting CPAP (aCPAP) is used to manage patients with obstructive sleep apnoea (OSA). Different suppliers use different algorithms. We have compared 6 commercial devices - ResMed S8, Breas PV10, Weinmann Somnosmart, Goodbreath Autopilot, Devilbiss Auto LT, Respironics M-series. Patients had used fixed pressure CPAP for 6+ months before the study and had good compliance. Each aCPAP device was used for 2 weeks in a randomized order. Data from the second week was analyzed and included CPAP use (hours), 7 day sleep diary card (SDC), and patient preference. The SDC included scores for Sleep Quality Exercise Level (Excellent to Poor), Awakenings (0 to 6+) and a 100mmVAS (0=Aleep,100=Drowsy). 23 patients were enrolled, 15 completed. Mean±SD weight - 117±8.29 kg, age - 57±11yrs and 4% diprate 27±1%. If patients could not tolerate the aCPAP device, they used their fixed pressure device. There were significant differences between devices.
We conclude that auto-CPAP devices have different outcomes and patient preferences. This may affect adherence to treatment for OSA in short-term trials.

3248

Randomized trial of 6 auto-adapting CPAP devices: Effects on quality of life
Sara Neale, Fiona Buchanan, Nicola Allaouat, James R. Catterall, Adrian H. Kendrick. Sleep & NIV Unit, University Hospitals Bristol, Bristol, United Kingdom

Auto-adapting CPAP is used to manage patients with obstructive sleep apnoea, with suppliers using different algorithms. We have compared 6 devices - ResMed S8, Breas PV10, Weeminn Somnosmart, Goodnight 420E, Devilbiss Auto LT, Respironics M-series. Patients were all using a fixed pressure (FP) device for at least 6 months before the study and had good compliance. Each device was used for 2 weeks, in a randomized order. Data from the Epworth Score (ESS), SF-36 and the Multidimensional Fatigue Inventory (MFI-20) was obtained at the end of each 2 week period. If the patient was unable to use a CPAP device, the highest score representing the biggest effect on quality of life (QoL) was used. 23 patients were enrolled, 15 completed. Data was analysed using repeated measures ANOVA and are shown as mean (95% CI).

Result: We conclude that the choice of auto-adapting CPAP device may have a significant impact on QoL, certainly in the initial stages of adaptation to this treatment.

3249

Transcutaneous measurement of pCO2 (ptcCO2): Time delay from change in alveolar pCO2 to first response in ptc CO2
Nils Henrik Holmehald1, Jon Andrew Hardie2, Ove Fondevæde1, Ivar Ellingsen1
1Respiration Physiology Lab, Glitråklinikken, Hakadal, Akershus, Norway; 2Internal Medicine, Haukeland University Hospital, Bergen, Hordaland, Norway

Introduction: The ptcCO2 delay has been estimated to 16 sec (healthy subjects) [1] and >60 sec (hypercapnic patients) [2]. We simultaneously record polysomnography (PSG) and ptcCO2 from COPD patients and needed the response time in our setup.

Material: 9 stable COPD patients (6 male) with mean FEV1 41% of pred. (SD 20).

Method: Patient in supine position wearing face mask connected to a stopcock, inlet selecting either room air or a bag with 4% CO2 in air. pCO2 measured by Radiometer TOSCA 500, probe on the earlobe. Arterial samples from arterial catheter analyzed by Radiometer ABL 500. 3 test-phases, each 200 sec: 1) stable phase breathing room air, 2) increasing phase after switching to 4% CO2, 3) decreasing phase after switching back to room air. TOSCA pCO2 was read every 0.5 sec for 120 sec, then every 10 sec. Arterial samples were drawn 3 times during phase 1), every 5 sec the first 30 sec of phase 2) and 3), then every 30 sec for a total of 150 sec.

Results: First response time (T0) meaning time from change in alveolar pCO2 to ptcCO2 > 2SD off stable phase.

Mean T0 (SD in increasing phase: 54 (5.6) sec.

Mean T0 (SD in decreasing phase: 57 (15) sec.

For arterial pCO2: 13.3 (5.6) sec and 11.7 (2.5) sec, accordingly.

Conclusion: Scoring pCO2 from COPD patients, the transcutaneous pCO2 signal should be left-shifted 2 epochs (1 minute) as a respiratory event changing alveolar pCO2 will show a first ptcCO2 response after 54-55 sec.

Figure 1

Conclusion: Early use of CPAP via mask therapy had better outcomes to post surgical atelectasis especially with smoker and elderly patients.
364. Physical activity monitors: from toy to valid tool?

3.253 Validity of 6 activity monitors during standard physical activities in COPD – Comparison with indirect calorimetry

Vogini Raste1, Daniel Langer2, Chris Burtin3, Ioannis Vogiatzis4, Santiago Giavedoni4,barry Anderson5, Nicholas Hopkinson1, Ioannis Vogiatzis4, Barry Peterson5.

Background: Reduced physical activity is an important feature of COPD. A range of monitors are available, but the validity of their various output parameters is not well established for patients with chronic diseases. The IMI PROactive project evaluated 6 activity monitors: SenseWear (SW); Actiwatch (AW); Actigraph (AG); Dynaport Minimod (MM) and Lifecorder Kenz (KZ).

Methods: 40 patients (GOLD stage 1-4; Age 67 ± 10 years) were recruited in 4 centres. Patients wore all activity monitors and a portable metabolic system and performed a 1 hour standard activity set (including 40 patients (GOLD stage 1-4; Age 67 ± 10 years) were recruited in 4 centres. Patients wore all activity monitors and a portable metabolic system and performed a 1 hour standard activity set (including walking, standing, stair climbing and upper limb tasks). Activity intensity (METs), assessed by indirect calorimetry, was compared to activity monitor outcomes. Average VO2 during the protocol was also calculated (8.78 ± 2.60 ml/kg/min) and compared to activity monitor outputs. METs (SW, MM); activity counts or Vector Magnitude Units, VMU (AW, AG, RT3); or a general activity outcome tool?

Conclusion: All monitors showed good overall acceptance ranging from 74% (MM) to 93% (AW). The lower overall score for the MM suggests that potentially the position on the back of patients is perceived less comfortable. EG is a fellow of UEFR-UFSCar/Brazil. PDEE CAPES

3.255 Accuracy of three activity monitors in patients with COPD – Validation by video

Mikael Andersson1,2, Charlotte Urell1,2, Margareta Emtner1,2.

Introduction: COPD patients have a slowing of movements due to muscle disuse, muscle wasting and increased dyspnea. The use of walking aids such as rollators are common. Slow movements, low movement intensities and the use of rollators might occur when used in patients with severe COPD.

Aims and objectives: To assess the accuracy regarding number of steps from three AM’s when used in patients with severe COPD.

Results: Table 1 gives median (IQR) for Pearson correlation between VO2 and activity monitor outcomes and that between mean METS over the study and mean activity monitor output.

Conclusion: The MM, SW, RT3 and AG give acceptable estimates of minute-by-minute variation in metabolic activity during physical activity. SW, MM, AW and KZ show acceptable correlations between overall metabolic activity and monitor output. These findings could guide users in choosing valid activity monitors for research or clinical questions.
the upper arm). Activities included walking at different speeds, walking with a rollator, walking in stairs, sitting, lying, or eating. As criterion validity, video recording and manual step count was used.

Preliminary results: Significant differences (p < 0.05) in the number of steps detected by AM’s compared to manual step count was found (Table 1).

Conclusions: Caution in interpreting results from activity monitoring seems warranted if the outcome is number of steps derived from different AM’s. The SenseWear Armband seem unsuitable for detecting number of steps in severe COPD, especially if a rollator is used.

3256

Energy expenditure during daily activities as measured by two motion sensors in patients with COPD

Vinicius Cavalheiro1,2, Leila Doná1, Thiemi Ferreira1, Matheus Finatti1, Carlos Augusto Camillo1,2, Eryc Mara Cipulo Ramos2, Fabio Pitta1,1 Laboratório de Pesquisa em Fisioterapia Pulmonar (LFPF), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Paraná, Brazil; 2Departamento de Fisioterapia, UNESP - Univ. Estadual Paulista, Presidente Prudente, São Paulo, Brazil

Background: In patients with chronic obstructive pulmonary disease (COPD), energy expenditure (EE) assessment during the performance of daily activities is not yet studied in depth. The aim of this study was to determine which daily activities are more demanding to patients with COPD and to compare the accuracy of EE estimation given by the pedometer Digiwalker SW701 (DW) and the multisensor SenseWear Armband (SAB).

Methods: Thirty-six patients with COPD (20 men; FEV1 48 ± 18.8% predicted; BMI 25.7 ± 8.1 kg/m2) were submitted to a modified version of the Glitlre ADL-test, which included five activities performed for one minute each: walking on the level, walking on the level carrying a backpack, walking up/downstairs, rising/sitting in chairs and moving objects in and out of a shelf. During the protocol subjects wore both devices concomitantly, and indirect calorimetry (IC) was simultaneously performed as the criterion method to assess EE. The most demanding daily activity for individuals with COPD was performed as the criterion method to assess EE.

Results: A factorial analysis of variance for daily activities revealed that up/downstairs, rising/sitting and rising on chairs are more demanding to patients with COPD and IC. The SAB underestimated EE in comparison with IC by 3.7 ± 2.5 (P < 0.05). EE estimation by the SAB did not show difference in comparison with IC for the other tasks; p > 0.05. EE estimation given by the pedometer Digiwalker SW701 (DW) and the multisensor SenseWear Armband (SAB) are more demanding to patients with COPD and the accuracy of EE estimation given by the pedometer Digiwalker SW701 (DW) and the multisensor SenseWear Armband (SAB) are not statistically significant differences.

Conclusion: Walking up/downstairs was the main energy-demanding activity for patients with COPD. Furthermore, during daily activities, the multisensor showed adequate overall estimation of energy expenditure, as opposed to the pedometer.

Dyspnea and fat free mass are major determinants of reduced physical activity in COPD patients

Francesco Costa, Gianna De Cusatis, Laura Malagrino, Sandra Antonelli, Claudia De Simone, Sabrina Santerini, Barbara Vagaggini, Pierluigi Paggiaro, Francesco Costa, Gianna De Cusatis, Laura Malagrino, Sandra Antonelli, Claudia De Simone, Sabrina Santerini, Barbara Vagaggini, Pierluigi Paggiaro, Francesco Costa, Gianna De Cusatis, Laura Malagrino, Sandra Antonelli, Claudia De Simone, Sabrina Santerini, Barbara Vagaggini, Pierluigi Paggiaro, Francesco Costa, Gianna De Cusatis, Laura Malagrino, Sandra Antonelli, Claudia De Simone, Sabrina Santerini, Barbara Vagaggini, Pierluigi Paggiaro

Background: Physical activity is reduced in patients with chronic obstructive pulmonary disease (COPD), and this has been associated with systemic inflammation and left cardiac dysfunction (Magnussen et al, AJRCCM 2008) to assess the predictors of physical activity, expressed as daily steps, in COPD patients.

Subject and methods: In a cross sectional study 45 COPD (FEV1%: 52 ±17.1, 34 male) underwent: physical activity evaluation by Armband (as a mean of a 7-day monitoring period), pulmonary function tests (PFT), cardiopulmonary exercise test (CPET) with assessment of dynamic hyperinflation, arteral blood analysis, SaO2 monitoring period), pulmonary function tests (PFT), cardiopulmonary exercise test (CPET) with assessment of dynamic hyperinflation, arteral blood analysis, SaO2

Results: Multivariate linear regression analysis stepwise method were performed using daily steps as dependent variable. The severity of dyspnea (MRC) and the free fat mass (FFM%) explained 43% of the variance of the physical activity, while other physiologic and biologic markers did not have additive effects.

Conclusion: Dyspnea and nutritional status are extra-pulmonary parameters that play a relevant role in the limitation of the physical activity level in COPD patients.

3258

Smoking, exercise capacity and physical activity in daily life in physically independent elderly

Cristiane G. Gonçalves1,2, Daniela Hayashi1,2, Carolina L. Gonçalves, Deníson C. Teixeira1, Elisane R.F.S. Freitas1, Joséiane M. Felcar1, Vanessa S. Próbii1,2,1 Centro de Pesquisa em Ciências da Saúde (CPCS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil; 2Programa de Mestrado em Ciências da Reabilitação, UEL-UNOPAR, Londrina, Brazil

Background: Smoking results in cardiovascular changes that can lead to a gradual decrease in exercise capacity and, when associated with the physiological changes related to the aging process, can decrease the physical performance of the elderly.

Objective: To investigate the relationship between smoking, exercise capacity and physical activity in daily life (PADL) in physically independent elderly.

Methods: Two hundred and nine physically independent elderly with normal lung function were assessed. They were distributed into four groups: smokers (SG; n=12; 6 women, 66 [64-71] yrs, BMI 24 [21-28] kg/m2), ex-smokers (ESG; n=65; 31 women, 69 [64-74] yrs, BMI 27 [25-31] kg/m2), passive smokers (PSG; n=42; 36 women; 66 [63-70] yrs, BMI 28 [25-31] kg/m2) and nonsmokers (NSG; n=92; 69 women, 67 [64-71] yrs, BMI 28 [24-32] kg/m2). Subjects were submitted to assessment of exercise capacity (6 minute walking test [6MWT]) and the incremental shuttle walk test (ISWT), PADL using a questionnaire (Baekte) and a step counter, as well as smoking habits.

Results: There was no statistically significant difference among groups regarding functional and maximal exercise capacity and PADL, as seen in table 1.

Activity outcomes correlation of 6 monitors in COPD, a field study part of the PROactive project

Santiago Giavedoni1, Roberto Rabinovich2, Yegini Raste2, Nicholas Hopkinson3, Hans Van Remoortel4, Eloisa M. Gatti Regueiro2,3, Daniel Langer1, Zsuzsanna Lovas1, Joanna Vogiatzi2, Barry Peterson4, Frederick Wilson5, Thierry Troosters1, 1Respiratory Medicine, ELEG1 Colt Laboratories, CIR, The University of Edinburgh, Edinburgh, United Kingdom; 2Respiratory Muscle Laboratory, Royal Brompton Hospital, London, United Kingdom; 3Faculty of Kinesiology and Rehabilitation Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; 4Physical Therapy Department, University of Federal do Sào Carlos, São Carlos (SP, Brazil); 5Department of Critical Care Medicine and Pulmonary Services, Thorax Foundation, Athens, Greece; 6Pfizer Global Research and Development, Pfizer, Sandwich, Kent, United Kingdom

Background: Monitoring Physical activity (PA) in COPD patients is a new out- come to assess effects of interventions. It is unknown to what extent outcomes of different Physical activity monitors (PAM) interrelate when used in patients with COPD, especially if a rollator is used.

Aim: To assess the predictors of physical activity, expressed as daily steps, in COPD patients using daily steps as dependent variable.

Results: Multivariate linear regression analysis stepwise method were performed using daily steps as dependent variable. The severity of dyspnea (MRC) and the free fat mass (FFM%) explained 43% of the variance of the physical activity, while other physiologic and biologic markers did not have additive effects.

Conclusion: Dyspnea and nutritional status are extra-pulmonary parameters that play a relevant role in the limitation of the physical activity level in COPD patients.

The most demanding daily activity for COPD patients (Age 68[65-71] years, BMI 27[25-31] kg/m2) was performed as the criterion method to assess EE. The most demanding daily activity for individuals with COPD was performed as the criterion method to assess EE.

Results: A factorial analysis of variance for daily activities revealed that up/downstairs, rising/sitting and rising on chairs are more demanding to patients with COPD and IC. The SAB underestimated EE in comparison with IC by 3.7 ± 2.5 (P < 0.05). EE estimation given by the pedometer Digiwalker SW701 (DW) and the multisensor SenseWear Armband (SAB) are more demanding to patients with COPD and the accuracy of EE estimation given by the pedometer Digiwalker SW701 (DW) and the multisensor SenseWear Armband (SAB) are not statistically significant differences.

Conclusion: Walking up/downstairs was the main energy-demanding daily activity for patients with COPD. Furthermore, during daily activities, the multisensor showed adequate overall estimation of energy expenditure, as opposed to the pedometer.
Introduction: A group of 18 well-controlled asthmatic patients were evaluating bronchial biopsies for asthma to extreme altitude.

Methods: Symptoms, spirometry and FeNO values were obtained before, during and after the climb (up to 5600 m of altitude). Pre BD FVC was measured and cells from the lower airways were obtained by sputum induction before and after the expedition. mRNA was isolated, CDna was prepared and RT-PCR was used to measure sputum mRNA quantities as described.

Results: During the expedition there was a decrease in FVC and FVC which reached a maximum at 4300 m. The pre BD FVC (% predicted) was significantly decreased when measured after the expedition as compared to baseline measurements before the expedition (6.6%, p=0.004). FeNO values were not different between the different time points (p=0.17). Decreased asthma control was observed after the expedition as assessed by asthma control questionnaires (p=0.002). Sputum neutrophil percentages were significantly higher after expedition compared to before the expedition (p=0.04). Concomitantly, sputum IL-17 mRNA was increased after the expedition as compared to before expedition (p=0.007). A correlation of serum Clara Cell protein 16 and sputum IL-17mRNA was found (r=0.57, p<0.001).

Conclusion: Asthma patients have slightly worse lung function and asthma control after climbing to extreme altitude. Increased signs of neutrophilic inflammation were found in the airways as represented by higher sputum IL-17 mRNA and neutrophils.

Assessment of airway neutrophil activation in adult non-essential asthma

Results: Only one asthmatic individual in our study was neutrophilic (>61% neutrophils). The neutrophil has been proposed to be a principal cell type involved in non-essential asthma (NEA).

Background: It is now evident that there are different pathophysiology underlying different asthma phenotypes. The neutrophil has been proposed to be a principal cell type involved in non-essential asthma (NEA).

Aims: To investigate different aspects of neutrophil activation in NEA.

Methods: 24 adult asthmatics (9 eosinophilic asthma (EA)±2% sputum eosinophils), 15 NEA) and 18 healthy controls were recruited by advertisement and successfully underwent clinical assessment, spirometry and sputum induction. Sputum was analysed for neutrophil number (differential cell count), levels of neutrophil-associated soluble mediators (myeloperoxidase (MPO), IL-8 and MPP-9, by ELISA) and neutrophil expression of CD11b (flow cytometry).

Results: Our study indicates the role of adenosine regulation of DC’s differentiation in BA. The heterogeneity in responses to AdoR’s stimulation may be due to two groups of individuals characterized by high and low response to AdoR’s stimulation. We identified that 50% of individuals with BA and 16% of healthy volunteers demonstrated high responsiveness to NECA.

Conclusion: Our study indicates the role of adenosine regulation of DC’s differentiation in BA. The heterogeneity in responses to AdoR’s stimulation may be used as a basis for individual BA treatment development.
tion of corticosteroids and cold bronchial hyperresponsiveness (CBH) in patients with bronchial asthma (BA).

Aim: To determine the role of target-cells sensitivity to corticosteroids in cold bronchial hyperresponsiveness development in BA.

Methods: 44 patients with BA were recruited. The mean level of asthma control was 18.6±1.0 points (Asthma Control Test). The absorption of cortisol by blood lymphocytes (ACL) in the standard test “in vitro” with hydrocortisone before 3-minute isocapnic cold air (<20°C) hyperventilation (ICAH) was studied. CBH was diagnosed by the drop of FEV1 after ICAH (ΔFEV1)<10% from initial value. Researches of the patients were divided into two groups: the 1st (28 patients) was with constant values of hormone absorption by lymphocytes, the 2nd (16 patients) had lower values. ACL values were (0.701±0.054) x 10^3 mg/kg/1000 cells and (0.527±0.038) x 10^3 mg/kg/1000 cells, respectively (p<0.01). CBH was found out in 22 patients of the 1st group and in 6 patients of the 2nd one (χ^2=7.42; p<0.01).

In the 1st group there was the biggest part of patients (87%) with a high degree of CBH (ΔFEV1<18.5%) and a mean level of CBH (ΔFEV1), within the range of 14.2±18.4%. The 2nd group had only low values of CBH (ΔFEV1), within the range of 10.0-14.1%. The risk of high degree of CBH in patients of the 2nd group was three times higher than in the 1st group: chances ratio was 3.45; 95% confidence interval 1.28-9.4.

Conclusion: CBH in BA patients is associated with the decrease of transmembrane penetration of glucocorticoids into target cells.

P3265

LSC 2011 Abstract: Effect of inhaled apocynin on reactive oxygen species concentration in exhaled breath condensate of asthmatics
Joanna Stefanska, Agata Sarniak, Anna Wlodarczyk, Milena Sokolowska, Zbigniew Doniec, Dariusz Nowak, Rafal Pawlczak. Department of Immunology, Medical University of Lodz, Lodz, PL; Department of Clinical Physiology, Medical University of Lodz, Lodz; PL; Department of Pneumonology, National Institute for Tuberculosis and Lung Diseases, Rakuba, PL.

Reactive oxygen species (ROS) have a strong impact on homeostasis and are thought to play an important role in inflammation in asthma. The sources of oxidative stress in patients with chronic inflammatory lung diseases derive mainly from increased amount of ROS and reactive nitrogen species (RNOS), generated by airway cells. Apocynin is an agent which blocks NAPDH oxidase - the enzyme, responsible for ROS production. The anti-inflammatory activity of apocynin has been postulated in the majority of cell lines and animal models of inflammation. Therefore, considering apocynin activities, we investigated the effect of nebulized apocynin in 14 nonsmoking asthmatics, in placebo-controlled, cross-over design study. Effects of apocynin have been checked 30, 60 and 120 minutes after nebulization with inhaled breath condensate (EBC) samples. Additionally, we investigated safety parameters. Apocynin significantly decreased H2O2 concentration in EBC in comparison to placebo after 60 and 120 min. (0.29 ±0.05 μM vs. 0.03 ±0.04 μM, respectively). Moreover, apocynin significantly reduced NO2 concentration 30 and 60 min after nebulization (2.75 μM vs. 4.65 μM, and 2.5 μM vs. 4.05 μM, respectively) in comparison to placebo. Finally, apocynin caused a significant decrease of NO concentration in EBC after 60 and 120 min after administration, comparing to placebo (5.34 μM vs. 8.2 μM (60 min), and 5.3 μM vs. 8 μM (120 min) respectively). No influence of apocynin on safety parameters, and no adverse effects has been observed.

These data suggest that using apocynin might be a promising solution to alleviate inflammatory process, and probably, symptoms of inflammatory diseases.

Quantitative proteomics on bronchial biopsies from asthma and COPD: Effects of budesonide treatment
Serena O’Neill1, Brigitta Sitikauskienė2, Agne Babysyte1, Algirda Kruksienė1, Kristina Švarysienė-Brihueg1, Ramindras Sakalauskas1, Carina Sihlbom1, Linda Ekerjung2, Elisabeth Carboh1, Bo Lundback1, Jan Lovtov1, 1Krefting Research Centre, Department of Internal Medicine, University of Gothenburg, Gothenburg, Sweden; 2Department of Pathology and Immunology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 3Proteomics Core Facility, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

The global proteome of individual bronchial biopsy material from asthma and COPD patients has not been fully ascertained. The aim was to determine if mechanisms of disease and responses to treatment can be detected in biopsies from patients with asthma and COPD, using a quantitative proteomics technology. Endobronchial biopsies, pre and post treatment, were taken from patients with asthma (n=12) and COPD (n=11), as well as non-smoking (n=3) and smoking (n=7) healthy controls. Patients were randomised to double blind treatment with either placebo or budesonide (800 μg daily for 3 months). Quantitative proteomics technology was used to identify and quantify biopsy proteins. Pathways analysis was performed using Bioinformatics software. A total of 1937 proteins were identified from all subjects. Proteome differences had lower values. ACL values were (0.701±0.054) x 10^3 mg/kg/1000 cells and (0.527±0.038) x 10^3 mg/kg/1000 cells, respectively (p<0.01). CBH was found out in 22 patients of the 1st group and in 6 patients of the 2nd one (χ^2=7.42; p<0.01).

In the 1st group there was the biggest part of patients (87%) with a high degree of CBH (ΔFEV1<18.5%) and a mean level of CBH (ΔFEV1), within the range of 14.2±18.4%. The 2nd group had only low values of CBH (ΔFEV1), within the range of 10.0-14.1%. The risk of high degree of CBH in patients of the 2nd group was three times higher than in the 1st group: chances ratio was 3.45; 95% confidence interval 1.28-9.4.

Conclusion: CBH in BA patients is associated with the decrease of transmembrane penetration of glucocorticoids into target cells.

Lipoxins (LXs) are biologically active eicosanoid possessing anti-inflammatory properties. Lipoxin A4 (LXA4) signaling blocks asthmatic responses in human and experimental model system. There are evidences that respiratory diseases, including severe asthma, display defective release of lipoxin signals. To assess the role of pro- and anti-inflammatory mediators in airway homeostasis of asthmatic children, we examined the levels of LXA4 and leukotriene (LT) B4, a potent neutrophil chemotaxant, in the induced sputum supernatants (ISs), from intermittent (IA) and moderate (MA) asthmatic children treated with high doses of inhaled corticosteroids (ICSs), and control children (C). In order to address whether LXA4 and glucocorticoids have overlapping role in the resolution of inflammation, we evaluated the effect of LXA4 treatment on glucocorticoid receptor (GR) phosphorylation, in the presence or absence of LXA4 receptor (FPRL-1/ALXR) blocking peptide, in peripheral blood neutrophils (PBN) from C, using both Western Blot and Flow cytometry analyses. We found that LXA4 was higher in ISs from IA compared with MA and C, while LT-B4 was inversely correlated. In addition, we showed that LXA4 induced GR phosphorylation (Ser211) via ALXR in PBN from C, since the use of the receptor blocking peptide reversed the effect of LXA4. Our findings provide evidences for the hypothesis that a defective generation of anti-inflammatory LXA4, associated with an increased LT-B4 production, may be involved in a reduced ability of the ongoing ICS therapy in the control of airway inflammation in children with MA.

P3267

The interplay of LXA4 and glucocorticoid receptor-based mechanisms in airway inflammation of childhood asthma
Rosalia Gugliandolo1, Stefania La Grutta1, Pascal Chanez2, Angelo Salva1, Liboria Siena1, Caterina Di Sano1, Loredana Riccobono1, Giovanni Viggli1, Mark Gjormark2, Mirella Profita1, 1Institute of Biomedicine and Molecular Immunology, Italian National Research Council, Palermo, Italy; 2Département des Maladies Respiratoires, Université de la Méditerranée, INSERM-CNRS U960, UMR6212, Marseille, France; 3ARPA, Environmental Health Unit, Palermo, Italy; 4Department of Pharmacological Sciences, University of Milan, Milano, Italy

Allergic disorders, such as asthma, are symptomatic reactions of the immune system to common and innocuous environmental antigens. These inflammatory disorders are caused by aberrant immune regulation in which various signalling receptors are involved. Pathogen recognition receptors linked to transcription factors families of receptors are one of the key components of the innate immune system. The function of these receptors has been linked with susceptibility towards the development of allergic diseases, including asthma, making the TLRs and NLRs good targets for novel effective therapies of allergic diseases. In this study the mRNA expression levels of different TLRs and NLRs in the lung tissue in mild and severe mouse models of allergic asthma were measured by q-PCR. In addition, broncho-alveolar lavage fluid (BALF) was collected and cell numbers analysed. The mild and severe asthma models different TLR and NLR mRNA expression profiles are observed. In the severe asthma model, a higher cell influx in BALF is seen. Moreover, a significant correlation is found between the mRNA expression of TLR3, TLR6 and TLR9 and the total cell number in the BALF.

P3269

Mesenchymal stem cells down-regulate inflammation but not airway hyperresponsiveness in experimental asthma
Liliana Antonio Marín-Fardos1,2, Isabel Mirones-Aguilar2, Óscar Amor-Carrasco,3,4 Rebeca Fraga-Iriso1,3, Beatriz Lema-Costa1, Isabel Cubillo-Moreno1, Miguel Ángel Rodríguez-Milla1, Javier García-Castro1, David Ramos-Barbón1,3,1Respiratory Research Unit, Universitary Hospital University of Coruña/INIBIC, Coruña, Spain; 2Cellular Biotechnology Unit, Institute of Salud Carlos III, Madrid, Spain; 3Respiratory Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Introduction: Mesenchymal stem cells (MSCs) have immunomodulatory properties. MSCs may have a potential to down-regulate airway inflammation in asthma, but may as well serve as building blocks for unwanted airway remodeling. Here we tested the effect of MSCs in experimental asthma.

Aerobic exercise reduces allergic airway inflammation and remodeling by deactivating airway epithelial cells and leukocytes

Rodolfo Paula Vieira1, Ronaldo Aparecido Silva2, Alessandra Choiqueto Toledo2, Angela Pires3, Malton Arruda Santos4, Celso Ricardo Fernandes Carvalho2, 1Pneumology, University Hospital Freiburg, Freiburg, Sao Paulo, Germany; 2Physical Therapy (LIM 34), University of Sao Paulo, Sao Paulo, Brazil; 3Department of Pneumology, University of Sao Paulo, Sao Paulo, Brazil; 4Pathology (LIM 05), University of Sao Paulo, Sao Paulo, Brazil

The regular practice of aerobic exercise (AE) has been shown to reduce chronic allergic airway inflammation and remodeling (CAAIR), but the mechanisms involved remain poorly understood. In the present study we investigated if 4 weeks of AE deactivates airway epithelium and peripheral leukocytes in a model of CAAIR. Thirty-two animals were divided in control, aerobic exercise, ovalbumin and ovalbumin+aerobic exercise groups. Mice sensitized (10ug/mouse, days 0, 14, 28 and 42) and challenged with ovalbumin (200 μg) on day 42, were submitted to AE (21st until 50th day, 60min/session; 5x/week). The results demonstrated that AE in OVA-sensitized mice significantly reduced eosinophils in BAL and in airway wall and also the accumulation of collagen fibers on airway wall. This anti-inflammatory and anti-fibrotic response induced by AE in sensitized animals was followed by reduced expression of the followings markers by airway epithelial cells and also by peribronchial leukocytes: IL-4, IL-5, IL-13, CCL11, CCL5, VCAM-1, iNOS, NF-kB, GP130, 3- nitrotyrosine, 8-isoprostane, IGF-1, EGRF, VEGF, TGF-beta, MMP-12 and TIMP-2 (p<0.01). AE in sensitized animals also increased the expression of anti-inflammatory cytokines IL-10 by leukocytes and airway epithelial cells. Taken together, these results demonstrate that the beneficial effects of AE on allergic airway inflammation and remodeling is a multifactorial response involving deactivation of airway epithelial cells and also of leukocytes, by inhibition of Th2 response, chemokines, adhesion molecules, oxidative and nitrosative stress, and also on the growth factors and matrix metalloproteinases.

P3271

Upregulated expression of interleukin-33 and alternative activation of macrophages in a model of an acute exacerbation of asthma

Rakesh Kumar, Melissa Scott, Kylee Keogh, Cristian Herbert, Jessica Siegle, Nicolemedcs Tedia. Inflammation & Infection Research Centre, School of Medical Sciences, University of New South Wales, Sydney, NSW, Australia

The role of alveolar macrophages (AM) in the pathogenesis of an acute exacerbation of asthma is poorly understood. In a clinically relevant mouse model, we have shown that AM are activated to secrete pro-inflammatory cytokines, and that this activated macrophages and the mechanism of activation. Female BALB/c mice were systemically sensitised to ovalbumin (OVA) and received chronic low-level challenge with aerosolised OVA for 4 weeks. Following this, mice received a single moderate-level challenge to induce airway inflammation simulating an acute exacerbation. AM and tissues were collected 4 hours later. Control groups included naive animals, and mice that only received either chronic challenge or a single moderate-level challenge. AM from an acute exacerbation exhibited significant expression of pro-inflammatory cytokines, including mRNA for arginase-1, PIZZI, Ym1 and etoxacin-2. These AM also exhibited elevated expression of cell surface proteins associated with antigen presentation to T cells, including CD86 and MHC class II. In parallel, expression of mRNA for IL-33 in the airway wall was strikingly increased, with evidence of enhanced immunoreactivity for IL-33 in the cytoplasm of airway epithelial cells and plasma cells within the airway wall. Collectively, these data imply an important role for alternatively activated AM in the pathogenesis of an acute exacerbation of asthma and suggest that IL-33 may contribute to the activation of these cells.

P3272

Naturally occurring CD4+ CD25+ FoxP3+ Treg cells are related to the absence of antigen induced airway obstruction in a guinea pig asthma model

Patricia Ramos-Ramirez1, Olivia Telles-Jimenez2, Erasmo Martinez-Cordero3, Eduardo Garcia-Zepeda3, Fernando Gutierrez-Aguilar1, Blanca Bazan-Perrins1

1Airway Hypersensitivity Department, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; 2Department of Autoimmunity, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; 3Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, Mexico, Mexico

Some allergic asthma individuals did not display airway obstruction after an anaphylactic challenge (dAOAC); however, the mechanism involved in this process is unknown, it has been suggested that regulatory T cells (Tregs) may be involved. We developed a model of airway obstruction-induced by antigenic challenge in guinea pig (GP) to elucidate the potential role of Tregs. In our model, the sensitized GP are intermittently challenged with the antigen (ovalbumin, OA; applied every 10 days). We found two groups of GP ones that showed dAOAC and ones that did not. Then, we evaluated the antigen-induced airway obstruction and hyper-responsiveness (HR) to histamine and identified the population of Tregs in the airway wall. The aim of this study was to examine whether BM-derived dAOAC mice were recipients of the airway wall. Some allergic asthma individuals did not display airway obstruction after an anaphylactic challenge (dAOAC); however, the mechanism involved in this process is unknown, it has been suggested that regulatory T cells (Tregs) may be involved. We developed a model of airway obstruction-induced by antigenic challenge in guinea pig (GP) to elucidate the potential role of Tregs. In our model, the sensitized GP are intermittently challenged with the antigen (ovalbumin, OA; applied every 10 days). We found two groups of GP ones that showed dAOAC and ones that did not. Then, we evaluated the antigen-induced airway obstruction and hyper-responsiveness (HR) to histamine and identified the population of Tregs in the airway wall.

Conclusions: In our model of asthma, the Tregs play an important role in suppressing airway hyper-responsiveness, and that probably Tregs that produce TGF-beta are involved in the attenuation of the HR in this asthma model.

P3273

Overproduction of IL-18 in the lungs induces IL-13 and IFN-γ producing CD4+ T cell in the lungs, and results in airway hyperresponsiveness in Balb/c mice

Masanori Sawada, Tomosaki Hoshino, Yuki Sakazaki, Hanako Oda, Masanori Takahara, Takashi Kinosha, Haruki Imaoka, Tomotaka Kayawama, Hisamichi Aizawa. Division of Respiriology, Neurology and Rheumatology, Department of Medicine, Karume University School of Medicine, Karume, Japan

We newly established Balb/c background IL-18 transgenic (TG) mice using the human surfactant protein C promoter to drive expression of mature mouse IL-18 cDNA in the lungs. After sensitization on days 0 and 5 with ovalbumin (OVA), mice were challenged (OA) on day 19. Pulmonary inflammations and airway hyperresponsiveness (AHR) were examined on day 20. We previously reported that constitutive mouse mature IL-18 overexpression in the lungs of C57BL/6 mice induces emphysema (Am J Respir Crit Care Med 2007, 176:49-62). In contrast to C57BL/6 IL-18 TG mouse, emphysematous changes were not observed in the lungs of Balb/c IL-18 TG mice. AHR to inhaled acetylcholine were not induced in non-treated Balb/c IL-18 TG mice. However, AHR and airway inflammation were significantly increased in OVA-challenged Balb/c TG mice compared with OVA-sensitized Balb/c IL-18 TG mice. The number of IFN-γ and IL-13 in the bronchoalveolar lavage fluid of IL-18 TG/IL-13 KO mice. This study suggested that overproducing IL-18 proteins in the lungs of Balb/c mice induce IL-13 and CD4+ T cells which may involve in the pathogenesis of asthma.

P3274

The role of bone-marrow derived adult stem cells in asthmatic airway remodeling

Hai-Feng Ou-Yang, Chang-Gui Wu. Department of Respiratory Medicine, Xijing Hospital, Fourth Military Medical University, Xi’an, China

Background and objective: Asthmatic airway remodeling is an abnormal injury/repair process of small airway on the basis of chronic inflammation, in which the quantities of multiple lung parenchyma cells dramatically increase. However, the origin of this process of maladaptive remodeling is still not clearly elucidated. The aim of the study is to examine whether BM-derived adult stem cells are responsible for the massive proliferative cells in asthmatic airway remodeling. Metodos: Adult mice were durably engrafted with BM isolated from GFP transgenic mice. Using GFP BM-chimera mice, OVA-induced chronic asthma model were established. The distribution of BM-derived GFP+ cells in the lung of chronic asthma mice was detected by fluorescence microscopy. The phenotype of BM-derived GFP+ cells in the lungs was analyzed by flow cytometry.

Results: BM-chimera mice were successfully constructed, with no detectable ra-

P3277
Do exhaled non-inflammatory markers correlate with respiratory symptoms and lung function in a longitudinal study of childhood asthma?
Charlotte Robroeks1, Quirijn Jobbs3, Ger Rijker2, Will Wodiz3, Aalt Bast1, Edward Dompeling1, Paediatric Pulmonology, Maastricht University Medical Centre, Maastricht, Netherlands; 2Paediatrics, University Medical Centre Utrecht, Utrecht, Netherlands; 3Clinical Chemistry, Maastricht University Medical Centre, Maastricht, Netherlands; 4Pharmacology and Toxicology, University Maastricht, Maastricht, Netherlands.

Background: Worldwide the level of asthma control is far from optimal. Asthma management is currently based on symptoms and lung function indices. Non-invasive inflammatory markers like exhaled nitric oxide may have additional value for asthma management. Little longitudinal data are available.

Aim: To study the relationship between non-invasive inflammatory markers and conventional parameters, during stable periods and during exacerbations.

Methods: 40 Children with asthma (aged 5-16yrs), visited the outpatient clinic every two months during one year. In addition, 4 extra visits were planned during an exacerbation. Every visit the asthma control questionnaire (ACQ) was assessed, lung function was performed and non-invasive inflammatory markers (FeNO, and nitrate, 8-isoprostane, interleukin-5 and tumor necrosis factor-alpha in exhaled breath condensate) were measured.

Results: 16 Of the 40 children experienced an asthma exacerbation. No significant correlations were found between non-invasive inflammatory markers and conventional parameters ( Spearman, p > 0.05).

Correlations between conventional parameters and non-invasive inflammatory markers in childhood asthma.

Conclusions: This study showed that exhaled non-inflammatory markers provide additional information about childhood asthma compared to conventional parameters.

P3276
Analysis of P2Y12 receptor responsiveness to cystein leukotrienes
Holly Foster, Elisabeth Stafflinger, Tak Lee, Grzegorz Waszeck, MRC & Asthma UK Centre in Allergic Mechanisms of Asthma, King’s College London, London, United Kingdom

Leukotriene E4 (LTE4), the most stable of the cysteine leukotrienes (cysLT), binds poorly to classical type 1 and 2 cysLT receptors although it may potentially induce bronchial constriction, airway hyperresponsiveness and inflammatory cell influx to the lungs of asthmatic individuals. Evidence of the presence of a previously unidentified LTE4 receptor has also been provided in CysLT1/CysLT2 double knock out mice. A recent study has suggested that purinergic receptor P2Y12 is required for LTE4 mediated pulmonary inflammation in a mouse model of asthma.

The aim of the study was to characterise the responsiveness of human P2Y12 to cystein leukotrienes. A model of human CysLT1, CysLT2 and P2Y12, transiently overexpressed in HEK293 cells was used and responsiveness to different agonists was measured using intracellular calcium and cAMP assays. The responsiveness of human P2Y12 stably overexpressed in CHO cells was also analysed using a β-arrestin recruitment assay. CysLTs induced concentration dependent calcium mobilisation in cells overexpressing CysLT1 and CysLT2 but failed to induce any calcium response in cells expressing P2Y12 or P2Y2+R2+G16. In contrast, a selective P2Y12 agonist 2-MeSADP, induced specific calcium flux in cell expressing P2Y12+G16. Similarly, specific response to 2-MeSADP, but not to cysLTs was also observed in cells expressing P2Y12 when intracellular cAMP and β-arrestin signalling was analysed. These results suggest that LTE4, as well as other cysLTs may not activate intracellular signalling acting through human P2Y12 and another LTE4 specific receptor has yet to be identified.
Comparison of online single-breath versus multiple-breath exhaled nitric oxide at school entry in a cohort of unselected children

Oliveir Fuchs1, Philipp Lattem1, Florin Singer2, Elena Piresci1, Elisabeth Kieninger3, Urs Frey1,2, Division of Pulmonology, Department of Paediatrics, University Children’s Hospital, University of Bern, Bern, Switzerland; 2University Children’s Hospital (UKBB), University of Basel, Basel, Switzerland

Despite requiring less cooperation there are no standards for online multiple-breath (mb) measurements of exhaled nitric oxide (eNO) with uncontrolled flow rate and no studies comparing them to more difficult online single-breath (sb) eNO measurements in young children.

Online eNOmb and eNOsb were measured by a chemoluminescence analyzer connected to an ultrasonic flowmeter in N=73 children of a birth cohort of unselected children at a mean±SD age of 6.1±0.62 years. During measurements, we aimed for 20 tidal breathing manoeuvres for eNOmb and for 3 eNOsb manoeuvres according to current standards. We compared both techniques by standard comparison methods including regression analysis and Bland-Altman plots.

After strict screening, control, eNOmb and eNOsb measurements were acceptable in n=56 and n=53 children, respectively. Paired data were available for n=46 children methods including regression analysis and Bland-Altman plots.

Introduction: Exhaled nitric oxide (FeNO) may be a biomarker for asthma but clinical trials where FeNO is used to guide asthma treatment have been disappointing. Exhaled NO measurements may not be suited to individuals with increased variability of values. We hypothesised that the variability of FeNO measurements is heterogeneous within a population and sought to describe factors associated with increased variability for repeated measurements of FeNO.

Methods: Children with and without asthma were recruited from the community and completed respiratory questionnaires and underwent an initial phenotyping assessment which included spirometry, bronchodilator response and skin prick reactivity. Exhaled NO was measured every two months over a 12 month period. The coefficient of variation (CV) for FeNO measurements was calculated for each individual.

Results: One hundred and eighty children were recruited including 49 with asthma and 89 FeNO measurements were made (median 5 measurements per child). Eighty two children and 252 FENO measurements were available. The following were not associated with altered CV: asthma, eczema or hayfever; male gender; body mass index; skin prick reactivity; spirometry; bronchodilator response; exposure to pets, smokers or damp at home. There was an inverse relationship between age and FeNO CV (rho= -0.12, p=0.258, n=93). Among the asthmatic children, there was no correlation between FeNO CV and treatment step or dose of inhaled steroid.

Conclusions: Measurements of FeNO CV are variable between individuals. Younger age, but not atopy, asthma status or treatment, is associated with increased variability in FeNO over 12 months.
P3284
Abnormalities in spirometry, impulse oscillometry and exhaled nitric oxide in the university freshmen who have outgrown of bronchial asthma
Shingo Takanashi1, Akihito Hayashi1, Takeshi Morimoto2, Kageaki Taima2, Junichi Denpoya2, Yoshitake Tanaka2, Hisashi Tanaka2, Ken Okumura2, 1Health Administration Center, Hirokawa University, Hirokawa, Aomori, Japan; 2Respiratory Medicine, Hirokawa University Graduate School of Medicine, Hirokawa, Aomori, Japan

Background: Incidence of asthma, particularly in childhood, is rising. Current asthma prevalence is higher in children than in adults, suggesting that children with asthma may outgrow their disease. It has been long believed that the prognosis for asthma occurring in infancy or childhood is good, and that in most patients the symptoms would resolve by the age of puberty. However, little is known about the lung function of outgrown subject. In this study, we recruited the subjects who had outgrown of asthma and performed spirometry, impulse oscillometry and exhaled nitric oxide (eNO) measurement.

Methods: The freshmen in our university with a history of asthma (group A, n=54) and without a history of asthma (group B, n=63) were recruited. All group A subjects (n=33) reported no symptoms and underwent no treatment. Lung function was estimated by CHEST-HIO1001 (CHEST, JAPAN). Impulse oscillometry was performed using MostGraph (CHEST, JAPAN). Exhaled NO level was measured by NO analyzer (NIEVERS NOA, USA).

Results: FEV1% was significantly lower in group A than in group B (88.8±6.1% vs 91.2±4.6%; p=0.01). The mean levels of 8%FEV1 and Vdot50 and Vdot25 were lower in group A than in group B, though not significant. The levels of RS-20 and Res were significantly higher in group A than in group B (RS-20: 0.81±0.07 cmH2O/L/s vs 0.62±0.05 cmH2O/L/s; p=0.03) (Fres: 7.9±0.6 vs 6.4±0.3 Hz; p<0.01). Also, the level of eNO was significantly higher in group A than in group B (47.9±22.4 ppb vs 37.4±22.6 ppb; p<0.01).

Conclusions: The subjects who had outgrown of asthma still have impaired lung function, a follow-up examination of lung function may be needed.

P3285
8-isoprostane in exhaled breath condensate in healthy and asthmatic children in relationship with tobacco smoke exposure
Belda Ramírez1, Caballero Balanzá2, Martorell Aragón1, 1Laboratorio de Función Pulmonar. Instituto Nacional de Silicosis. Área de Gestión del Pulmon. H. Central Universitario de Asturias, Oviedo, Asturias, Spain; 2Unidad de Alérgia, Hospital General Universitario, Valencia, Spain; 3Unidad de Neumología Infantil, Hospital Clínico. Facultad de Medicina, Valencia, Spain

Introduction: 8-isoprostane is an oxidative stress marker, which rises in asthma and in exposure to tobacco smoke.

Objectives: 1) Differences in the concentration of 8-isoprostane in exhaled breath condensate (EBC) between asthmatics and healthy children. And also between children with recurrent wheezes and healthy preschool children. 2) Relationship between levels of 8-isoprostane and passive smoke exposure.

Methods: 70 children (6 to 14 years) were recruited in 2 groups: 40 asthmatic and 30 healthy children. Also 46 children (8 months to 5 years) were recruited in other 2 groups: 25 with recurrent wheezes and 25 as controls. EBC was collected through one-way valve bag. Data about number of smokers living with the child, cigarettes/day and the smoking place was asked.

Results: 8-isoprostane concentrations were lower between in the group of healthy children than in children with asthma (p<0.004, Mann-Whitney U: 343, mean difference: 6.2 (4.7)). Moreover 8-isoprostane levels differ according to smoking habits of parents (ANOVA F=28.8, P<0.001) and children whose parents smoke at home have higher levels than those of nonsmoking parents (mean difference 22.4, p=0.003). Similarly happened to children from 8 months to 5 years (ANOVA F=23, p<0.001) and (mean difference 141.3, p<0.001).

Conclusions: There are significant differences in the concentrations of 8-isoprostane in EBC from asthmatic children 6-14 years old and healthy and also in preschool children. 2. Passive exposure to tobacco smoke increases concentrations of 8-isoprostane, in the EBC of children in both age groups.

Method: FeNO was measured during sedation in 253 healthy symptom-free 1-month-old neonates in relation to infant spirometry testing. The children belong to the COPSAC clinical birth cohort born to asthmatic mothers. The risk factor analyses included genetic variants in DENND1B, Filaggrin and ORM1,3, anthropometric; demographics; socioeconomic status; paternal atopic history; maternal intake of paracetamol, antibiotics, smoking during third trimester of pregnancy; and pathogenic bacterial colonization of the neonatal airway.

Multivariate analyses were done using generalized linear models.

Results: Median neonatal FeNO level was 16.0 ppb (Q1-Q3, 12.0-22.0 ppb). The multivariate effect of DENND1B risk allele, rs2786098, (major allele) was significantly associated with increased levels of FeNO (additive model, β-coefficient, 2.909 ppb, 95% CI, 0.38-5.43; P=0.02). Children with atopic fathers also showed increased values of FeNO (β-coefficient, 2.909 ppb, 95% CI, 0.38-5.43; P=0.02).

None of the remaining genetic or environmental risk factors were associated with neonatal FeNO levels.

Conclusion: Variants in the DENND1B locus of chromosome 1q31.3 and paternal atopy are associated with elevated FeNO levels in 1-month-old newborns prior to development of any atopic symptoms. These findings suggest that the DENND1B risk allele confer an increased risk of wheezy illnesses through modifications associated with NO metabolism very early in life.

P3287
Interleukin-10 polymorphisms influence the neonatal immune response and may be a risk factor for childhood allergic disease and wheeze
Dana Raedler, Sabina Illi, Isolde Schleich, Elisabeth Kluckner, Elid Turan, Erika von Mutius, Bianca Schaub. Department of Pulmonary & Allergy, University Children’s Hospital Munich, Munich, Germany

Background: The interleukin-10 gene (IL10) encodes the anti-inflammation cytokine IL-10, which is crucial for the development of immune tolerance and T cell regulation. IL-10 polymorphisms were proposed to influence the asthma phenotype including pulmonary function. We studied the influence of IL-10 single nucleotide polymorphisms (SNPs) early in life on Th2/Th1 lineage late, T regulatory cell function and pro-inflammatory cytokines. Furthermore, the effect of the SNPs on allergic diseases and wheeze was examined at 3 years of age.

Methods: Cord blood of 200 healthy neonates was genotyped for 8 SNPs and one deletion in IL-10. CBMCs were cultured unstimulated or follow stimulation [Lipid A, peptidoglycan, phytohemagglutinin, house dust mite (Derp1), Derp1+Lipid A]. Treg-marker mRNA expression (FOXP3, GITR, LAG3), Th1/Th2 cytokines, TNF-a and GM-CSF were assessed. A follow-up regarding allergic diseases and wheeze was performed (3ys).

Results: The majority of IL-10 SNPs carriers showed a similar pattern of cytokine secretion and Treg-marker expression with increased IFN-γ and decreased IL-10. The SNPs had different effects in different cytokine secretion and Treg-marker expression after innate and allergic stimulation. Carriers of five IL-10 SNPs and one IL-10 deletion showed increased risk for wheezing or atopic symptoms.

Conclusions: Polymorphisms in IL-10 influence primarily Th1/Th2 cytokine secretion and Treg-marker expression after innate and allergic stimulation early in life. This may be relevant for immune maturation and potentially for childhood atopy and wheeze.

P3288
Phenotyping atopic dermatitis in children by filaggrin status. The COPSAC longitudinal birth cohort study
Charlotte Giewercman Carson1, Morten Arendt Rasmussen2, Jacob P Thyssen3, Torkil Menné2, Hans Bisgaard1, 1Copenhagen Prospective Studies on Asthma in Childhood: COPSAC, Health Sciences, University of Copenhagen; Copenhagen University Hospital Gentofte, Gentofte, Denmark; 2Faculty of Life Sciences, University of Copenhagen, Frederiksberg, Denmark; 3Department of Dermato-Allergology, Copenhagen University Hospital Gentofte, Hellerup, Denmark

Background: Filaggrin null mutations result in an impaired skin barrier function and are associated with atopic dermatitis. Clinical observations suggest a distinct phenotype for patients with the filaggrin null genotype.

Objective: To characterize and compare the clinical presentation and course of atopic dermatitis within the first 7 years of life in children with and without filaggrin null mutations.

Method: The COPSAC cohort is a prospective, longitudinal, birth cohort study of 397 Caucasian children born to mothers with a history of asthma, followed for 7 years with scheduled visits every 6 months as well as visits for acute exacerbations of dermatitis. Atopic dermatitis was defined in accordance with international guidelines and dermatitis reactions were accurately described at each visit using 15 predefined localizations and 10 different characteristics.

Results: A total of 170 (43%) of 397 children suffered from atopic dermatitis before age 7. The R501X and 228del4 filaggrin null mutations were associated with a higher number of acute visits (3.6 vs. 2.7; p=0.04), more severe dermatitis (moderate-severe SCORAD 44% vs. 31%; p=0.14), more widespread dermatitis (10% vs. 6% of the body, p<0.001), an earlier age at onset of dermatitis (246 vs. 473 days, p<0.001), dermatitis more often localized at exposed areas (hands, feet, extensor areas, cheeks), and with dermatitis spots characterized by an up regulation in both acute and chronic markers.
The involvement of genetic and environmental factors in asthma is evident. As miRNAs can both respond to the environment and regulate complex signaling networks at the posttranscriptional level they may be implicated in the disease. In previous studies we have identified dysregulated pulmonary miRNAs in experimental asthma (ERS Barcelona 2010, abstract 6106). In the present study we were interested to see if selected lung miRNAs are also altered in murine peripheral blood and whether these changes are similar in peripheral blood of asthmatic children. MiRNAs were quantified by rt-PCR in blood from ovalbumin sensitized and challenged Balb/c mice and controls. Ten year old children were selected based on the following criteria: current allergic asthma, absence of acute infections and ETS exposure. Age matched controls from the same cohort were included when they never had asthma and were free from acute infections. MiRNAs were quantified in bio-banked blood samples. Out of 10 children with diagnosed asthma 6 had a record of atopic eczema at any time and 4 had had allergic rhinitis ever. A set of 5 differentially regulated miRNAs (miRNA 17-5p, 21, 141, 181a, 451) in murine lung were chosen to be examined in blood samples. MiRNA and paediatric blood samples showed the same trend of regulation compared to healthy controls. In this study we found opposite expression of selected miRNAs in lung tissue compared to blood of mice with an asthmatic phenotype. This expression pattern was similar in human blood with mice of asthmatic children. These results call for further studies to explore blood miRNAs as potential biomarkers in asthma.

P3291
Disregulated peripheral blood miRNAs in murine experimental and human childhood asthma

Nikola Schütz1, Sabine Bartel1,2, Francesca Alessandrini2, Gaby Heilig1, Oliver Eggelberg1, Joachim Heinrich1, Susanne Krauss-Ettschmann1,2,1 Comprehensive Physiopathology Center, Ludwig-Maximilians University, Asklepios Clinic Gauting and Helmholtz Zentrum München, 2Ludwig-Maximilians University Munich, Dr. von Haunersches Kinderspital, 2ZAIM, Center for Allergy and Environment, Division of Environmental Dermatology and Allergy, Technical University, and 3Ludwig-Maximilians University Munich, Zentrum München, Munich, Germany

Background: Wheeze affects 20-40% of preschool children. Of all wheezers 30% will have persisting symptoms after the age of six that develop into asthma which is characterized by chronic airway inflammation. Whether airway inflammation is a characteristic of preschool wheezing is poorly documented.

Aim: To assess cross-sectional differences in gene expression of several important inflammatory markers in venous blood cells in preschool children with recurrent wheeze compared to healthy controls.

Methods: In total, 202 children with recurrent wheeze (ISAC questionnaire ≥2 wheezing episodes) and 50 children without respiratory symptoms, age 2-3 year were selected. Total RNA was extracted from peripheral blood mononuclear cells. Gene expression of 21 genes was assessed and corrected for geometric mean of the other genes showed a significant relationship between gene expression level and recurrent wheeze. Logistic regression analysis was subsequently conducted.

Results: Gene expression was successfully analysed in 223 children. Expression of the cytokine receptor CAT exhibited highly significant inverse association with recurrent wheeze (ORadjusted 0.65 (0.48-0.88) p=0.005). Expression of interleukin-17 (IL17) showed a statistically significant positive association with recurrent wheeze (ORadjusted 3.04 (1.33-6.92) p=0.008). None of the other genes showed a characteristic of preschool wheezing is poorly documented.

Discussion: A decrease of CAT expression and an increase of IL17 expression was observed in preschool children with recurrent wheeze. This may point towards the importance of different inflammatory pathways in children with preschool wheezing.

P3290
The chitinase-like protein YKL-40 is elevated in children with severe asthma

Anna James1, Björn Nordlund 1,2, Jon Konradsen1,2, Lovisa Johansson 1,2, Isak von Mutius1, Gemma Wehling1,2, Erika von Mutius1, Bianca Schaub1, PASTURE/EFRAIM Study Group.

1Department of Paediatric Pulmonology and Pediatric Allergology, University Medical Center Groningen, Groningen, Netherlands; 2Department of Genetics and Cell Biology, Cardiovascular Research Institute Maastricht, Maastricht, Netherlands

Background: YKL-40 is a protein secreted by macrophages and chondrocytes. Previous studies have demonstrated a role of YKL-40 in asthma. The expression of the chitinase-like protein known to be a chitinase and a serine protease. YKL-40 in relation to asthma is not well documented.

Methods: YKL-40 levels were assessed in children with history of asthma, previous wheeze and non-asthmatic control children. The study included 221 children (70 with asthma, 151 controls) of median age 11 years (range 3-17 years). YKL-40 levels were determined using an ELISA assay.

Results: YKL-40 levels were significantly greater in severe asthmatics compared to healthy children, whereas chitotriosidase activity was no different in severe asthmatics compared to healthy children. These results suggest that serum YKL-40 is a genetically influenced, protective biomarker of airway inflammation in children. Taking into account possible effects of the CHI3L1 promoter SNP Rs4950928.

Discussion: YKL-40 levels were significantly greater in severe asthmatics compared to healthy children, whereas chitotriosidase activity was no different in severe asthmatics compared to healthy children. These results suggest that serum YKL-40 is a genetically influenced, protective biomarker of airway inflammation in children. Taking into account possible effects of the CHI3L1 promoter SNP Rs4950928.

Conclusion: Further studies are needed to determine the clinical relevance of the findings and the impact of the associated genetic polymorphism.
optimal TB case management contribute to transmission of TB and development of drug resistance.

Aim: To evaluate the temporal trends of the proportions of treatment success and favourable outcomes in the Member States of the WHO European Region in 2004-2008.

Methods: Aggregated data on definitive treatment outcomes (cured and treatment completed) on a farm are larger in size. We explored the interrelation and independence of these protective effects in the large GABRIELA Surveys.

Results: Farm children have more siblings and less often attend day-care facilities than their rural peers. More siblings and farming conferred independent protection from asthma and allergies. No protection by day-care attendance was found. There was no clear evidence of interaction between family size or day-care attendance and farming. The prevalence of hay fever was 12% among non-farm only children and 2% among farm children with more than 2 siblings.

Conclusion: The inverse association of farming with asthma and allergies is found in all sizes of family, with no clear tendency to total saturation or synergism. This suggests that different mechanisms may underlie these two protective factors. Combinations of family size and farm exposure markedly reduce prevalence of allergic disease and indicate the strength of environmental determinants.

P3294
Polymorphisms in 17q12-21 are associated with asthma exacerbation and lung function in asthmatic children

Mário Bleke1, Blaženka Kljaic Bukvic2, Neda Abele1, Susana Marinho2, Adnan Custovic3, Angela Simpson3, Paediatric Department, General Hospital “Dr Josip Benevici”, Slovenijski Brod, Croatia; 2School of Translational Medicine, University of Manchester, Manchester, United Kingdom

Background: More than 15 studies associated genetic variants in 17q21 region with asthma. We aimed to investigate whether amongst Croatian asthmatic children, genetic variants in this region are associated with asthma severity and exacerbation.

Methods: We recruited 423 children aged 6-18 years with physician-diagnosed asthma. Information on hospital admission with asthma exacerbations was retrieved from medical records. Data on wheeze frequency and environmental tobacco smoke (ETS) exposure was collected using validated questionnaire. Lung function (FEV1) was measured using spirometry. We analyzed 35 haplotype-tagging SNPs in 17q21.

Results: We found significant associations between 4 SNPs and hospital admissions (rs12150079, rs7212938, rs2290400, rs8067378). For example, G allele homozygotes in rs12150079 were at higher risk of being admitted to hospital than carriers of A allele (OR 1.85, 95%CI 1.26-2.72, p=0.002); this SNP was also associated with current wheezing. Six SNPs were associated with lung function (rs9635726, rs921651, rs9900538, rs3169572, rs4795403, rs471692). In addition, we observed significant interaction between 3 SNPs (rs12603332, rs8067378, rs9302377) and in vitro ETS exposure in relation to lung function (p<0.04, in the largest children of mothers who smoked during pregnancy; major allele homozygotes had lower FEV1;5 predicted than minor allele carriers, but amongst non-exposed children there was no difference in lung function between different genotype groups.

Conclusion: Variants in 17q12-21 region may be associated with asthma severity and may interact with in vitro ETS exposure in determining lung function amongst asthmatic children.

367. Risk factors and treatment outcomes in multidrug- and extensively drug-resistant tuberculosis

P3295
Temporal trend of treatment in TB treatment outcomes in the WHO European region

Masoud Dara1, Giovanni Sotgiu2, Andrei Dadiu1, Hans Kluge1, Malgorzata Grzemska1, Rosella Centis2, Lia D’Ambrosio2, Giovanni Battista Migliori1,2 Regional Office for Europe, World Health Organization, Copenhagen, Denmark; 2WHO Collaborating Centre for TB and Lung Diseases, Fondazione S. Maugeri, Care and Research Institute, Treviso, Italy; 3Epidemiology and Biostatistics Unit, Department of Biomedical Sciences, University of Sassari, Sassari, Italy; 4Stop TB Department, World Health Organization, Geneva, Switzerland

Background: There is scientific evidence that poor treatment outcomes and suboptimal TB case management contribute to transmission of TB and development of drug resistance.

Aim: To evaluate the temporal trends of the proportions of treatment success and favourable outcomes in the Member States of the WHO European Region in 2004-2008.

Methods: Aggregated data on definitive treatment outcomes (cured and treatment completed) on a farm are larger in size. We explored the interrelation and independence of these protective effects in the large GABRIELA Surveys.

Results: During the period 2004-2008, the proportions of treatment success among new TB cases ranged from 64.6% (2.8634/2443) to 76.3% (5.9977/860) and from 61.2% (70,211/114,721) to 72.0% (55,196/76,681) in low (L) vs middle-high (M-H) TB incidence (i.e., TB incidence < 20 vs. ≥ 20 cases per 100,000 population) countries, respectively. Only during the years 2004, 2007 and 2008 the proportion of treatment success was significantly higher in low TB incidence countries (P<0.001). Re-treated cases were successfully treated in low incidence countries during the study period (average treatment success proportion in L and M-H TB incidence countries were 62.3% and 49.7%, respectively; P<0.001). Failure trends were significantly higher in new and re-treated cases in M-H TB incidence countries 9.8% versus 5.0% and 19.6% versus 10.7% respectively; P<0.001).

Conclusion: This analysis confirms that sub-optimal treatment outcomes in new and re-treated TB cases are frequently recorded in the WHO European Region setting. Introduction and/or strengthening of multidisciplinary interventions to improve treatment outcomes are urgently needed.

P3296
Predictors of treatment outcome in multidrug-resistant tuberculosis

Olena Olevera1, Miguel Villar2, Raquel Duarte3,4,5; 1Master Degree Course in Epidemiology, Medical Faculty. Porto University, Porto, Portugal; 2National Centre of Multi-Resistant Tuberculosis, DGS, Lisbon, Portugal; 3Chest Disease Centre of Vila Nova de Gaia, Chest Disease Centre of Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 4Pneumology Centre Hospitalar Vila Nova de Gaia/Espinho EPE, Vila Nova de Gaia, Portugal; 5Reference Centre for Multi-Resistant Tuberculosis in the North Region of Portugal, Reference Centre for Multi-Resistant Tuberculosis in the North Region of Portugal, Vila Nova de Gaia, Portugal; 6Epidemiology, Medical Faculty. Porto University, Porto, Portugal

Multidrug-resistant tuberculosis (MDR-TB) is a challenge to control programs. In these cases, treatment is more complex, more expensive and very often less successful.

The purpose of this study was to analyze the factors that could influence (positively or negatively) the outcome.

To examine this issue we used data from the National Tuberculosis Program in Portugal SVG-TB. For the study, we included all MDR-TB cases reported from January 2000 to December 2008. To identify the predictive factors related to the outcome of treatment we used univariate and multiple logistic regression models with the clinical variables.

During the study period 130 patients with MDR-TB were notified, of these 94 (72.3%) were male and 36 (27.5%) female, mean age 42 years old (range 40-44). Forty-six patients (35.5%) had a previous treatment and 39 (30%) were HIV positive. Treatment success (cured or completed treatment) was observed in 80 (61.5%) patients. Susceptibility and use of pyrazinamide or ethambutol, susceptibility and use of a fluoroquinolone, the use of five or more drugs in the treatment regimen, sputum culture conversion after 2 months of treatment were predictors of successful outcome of treatment. Treatment supervision (death, default and failure) was observed in 47 (36.1%) patients. Previous treatment, HIV co-infection, presence of cavitation on the chest radiograph, resistance of two or more drugs than just isoniazid and rifampicin and positive cultures after 2 to 3 month of treatment were predictors of poor treatment outcome. Rapid diagnosis of drug resistance and an appropriate therapy for effective treatment are important conditions for the prevention of spread of resistant strains and control of MDR-TB.

P3297
Risk factors for drug-resistant tuberculosis in the north of Portugal

Marta Gomes1, Ana Correia2, Denisa Mendonça3,4,5, Raquel Duarte6; 1Occupational Health, Centro Hospitalar Vila Nova de Gaia/Espinho EPE, Vila Nova de Gaia, Portugal; 2Public Health, Northern Regional Health Administration, Porto, Portugal; 3Public Health Institute, Porto University, Porto, Portugal; 4Institute of Biomedical Sciences Abel Salazar, ICABAS, Porto University, Porto, Portugal; 5Medical Faculty, Porto University, Porto, Portugal; 6Chest Disease Centre of Vila Nova de Gaia, Chest Disease Centre, Vila Nova de Gaia, Portugal; 7Pneumology Centre Hospitalar Vila Nova de Gaia/Espinho EPE, Vila Nova de Gaia, Portugal; 8Reference Centre for Multi-Resistant Tuberculosis, Northern Regional Health Administration, Porto, Portugal

Although drug resistance is considered the main threat for tuberculosis control, in Portugal very few studies focused on the risk factors. The aim of this study was to identify risk factors for drug resistance in patients with tuberculosis in the North of Portugal.

We performed a retrospective case-control study involving patients with drug-resistant tuberculosis registered in North of Portugal, between March 2009 and
P3298
Treatment of MDR tuberculosis in Switzerland. A case control study
Werner Karrer, Helena Shang, Patrick Brun.
TBC Unit, Luzerner Hoehenklinik Montana, Crans-Montana, VS, Switzerland

Background: MDR tuberculosis can mostly be cured in western countries, but treatment with second-line drugs is difficult, long-lasting, provided with many side effects and expensive.

Methods: The aim of our study was to follow the patients with MDR Tuberculosis, hospitalized at the Luzerner Hoehenklinik Montana (LHM) between 2005 and 2010, and to control their treatment to full recovery. The information in relation to post clinical treatment was gathered through personal contact with the treating physicians and telephone interviews with the patients.

Results: Of 46 patients with tuberculosis hospitalized at the LHM between 2005 and 2010, five patients were assessed having multidrug resistant tuberculosis. Three suffered from pulmonary tuberculosis, one from tuberculous spondylodiscitis, and one from lymph node tuberculosis. One patient was shown after some weeks of treatment in a second evaluation the laboratory findings not to have MDR Tbc.

Drug therapy was performed with second line antituberculous drugs in combination of 4 to 5 drugs like Aminoglycosides, Ethionamide, Oxazolidinones and Quinolones. Drug therapy was given for at least 12 months. All patients required initially for a prolonged period intravenous drug therapy. In two patients surgery was performed during treatment (resection of the upper lobe of the lung, lymph node resection).

Conclusions: Cases of multidrug resistant tuberculosis are still challenging for physicians and patients as diagnosis may not be evident and treatment remains difficult. In two cases the diagnosis was delayed due to different reasons. Duration of treatment is long and complicated, side effects are frequent and especially the cost of treatment is high.

P3299
Gender and other risk factors for multidrug-resistant (MDR) tuberculosis
(TB) among migrants to Milan, Italy
Alice Rigosio1, Monica Delmaestro3, Maurizio Ferrarise, Giovanni Ferrara3, Nicola Murgia3, Luigi Codecasa1,2,3,1TB Reference Centre- Villa Marelli Institute, Niguarda Hosp, Milan, Italy; 2Respiratory Medicine Inst., University of Perugia and Terni, Terni, Italy; 3Section of Occupational Medicine, Occupational and Environmental Respiratory Diseases and Toxicology, University of Perugia and Terni, Perugia, Italy

MDR-TB is a threat to global TB control. Identification of risk groups is crucial in low prevalence countries for early diagnosis and to limit transmission. retrospective evaluation of TB cases treated at the Villa Marelli Inst., Milan, Italy, in the years 2000-2010. Susceptible TB patients (sTB) and MDR-TB patients were considered for the analysis. Potential risk factors for MDR, such as age, thoracic or extra-thoracic involvement, HIV status, country of origin, etc were evaluated in a logistic regression model.

Results: 91 MDR-TB and 1510 sTB patients were recorded in the study period. HIV seropositive status (OR 3.98, 95% CI: 1.52 -10.39) and being migrant (IM) from Eastern European countries (OR 3.55, 95% CI: 1.33 -9.58) were independently associated to MDR-TB. Stratifying for sex, female subjects from Eastern Europe, South America and Asia had a higher risk than male from the same regions (East-European women OR 10.37 95% CI: 5.25 -22.95; South American women OR 7.06 95% CI: 3.86 -12.94; Asian women OR 4.01 95% CI: 1.63 -9.89). HIV co-infection was present in 13.8% of this group. The intravenous drug use [adjusted odds ratio (OR):3.14, 95% CI:1.33-7.66] and previous treatment (OR: 3.05;95%CI: 1.16-7.98) were found to be risk factors for TB drug-resistance.

In this region, previous tuberculosis treatment and intravenous drug use were risk factors to drug-resistance. HIV co-infection was not a statistical significant risk factor for drug-resistant tuberculosis. Identifying clinical predictors of drug resistance may aid in risk stratification for earlier treatment and infection control.

P3300
Treatment outcomes of MDR-TB patients notified in Romania during 2005-2007
Nicoleta Cioran, Elmina Ibraim, Horia Coco. National TB Program, Marius Nasta Institute of Pulmonology, Bucharest, Romania

Introduction: MDR-TB is a major public health concern for the entire international community, due to the longer duration of transmission of infection and reduced chances to reach a successful treatment outcome in such cases, by comparison with sensitive TB cases.

Aims and objectives: The analysis of treatment outcomes in MDR-TB cases reported in Romania in 2005-2007, by them demographic and clinical characteristics.

Methods: Descriptive retrospective study of treatment outcomes in MDR-TB patients reported in Romania in 2005-2007. Data have been extracted from the database of the National TB Programme - Central Unit.

Results: In those 3 years 2234 MDR-TB cases have been reported, 79.7% males, 50.7% living in urban areas, most of them in 45-54 years age group. Only for 100 patients was notified the association with alcoholism, 15 were prisoners and 13 had HIV co-infection. As diagnosis 51.5% had cavitary and 24.8% extensive cavitary forms of TB. In 2121 MDR-TB cases evaluated, overall success rate was 28.8% (31.4% in 2005, 31.8% in 2006 and 23.2% in 2007 – not final). The highest rate of failure was recorded in 2005 (32.0%). Death rates had a share of over 28% for 2005 and 2006, and 20% for 2007. Highest default rate was recorded in 2007 - 19.1%. For 40 patients reported in 2007 the treatment was still continuing at the time of study and in the group of 2005, 12.6% of outcomes remained unknown.

Conclusions: The success rate overall MDR-TB patients was 28.8% in Romania in 2005-2007. Increased efforts are necessary for earlier detection of such cases and for better management.
In this study we aimed to determine the factors associated with treatment outcome in HIV negative patients with multidrug resistant tuberculosis (MDR TB). The study comprised 64 (43 female and 21 male) patients in whom second line TB treatments were administered in directly observed treatment (DOT) programme. Treatment outcome was determined in 73.4% of the patients. The mean duration time of the treatment was 16.4±8.2 months. Treatment failure was defined as cure in 34 (53.1%), defaulter in 18 (28.1%), successful treatment in 1 (1.6%) and exitus in 3 (4.7%) patients. Also, in 8 (12.5%) patients treatment was incomplete and continued. Adverse effects of the drugs were seen in 39 (60.9%) patients with the frequency of gastrointestinal disturbance (51.5%), psychiatric disorders (15.6%), dermatological effects (12.5%). In logistic regression analysis only presence of cavity and the extensive disease were found to be associated with bacteriologic response, MDR TB is a treatable disease if regular and appropriate treatment is administered.

**P3306**
Treatment outcome of multi-drug resistant tuberculosis treated as outpatient in a tertiary care center
Irfan Muhammad, Ahmed Suleman Haque, Zeshan Waseed, Javid A. Khan
Pulmonary Section, Department of Medicine, Aga Khan University, Karachi, Pakistan

Introduction: Community-based out-patient treatment for multidrug-resistant tuberculosis (MDR TB) is relatively new concept with reported successful outcomes. The aim of this study is to assess the treatment outcomes of HIV negative MDR TB patients treated as outpatient at a teaching medical care center in Karachi, Pakistan.

Methods: Observational study of culture proven HIV negative MDR TB pa-tients treated at Aga Khan University Hospital, Karachi. Data were collected on predesigned performa regarding patient’s demography, clinical features, drug sensitivity, treatment and outcome.

Results: A total of 53 HIV negative patients (27 males), with mean age of 37±15 years (range 15-76 years), received treatment as outpatient for culture proven MDR TB. 51 patients (96.2%) had pulmonary while 3 patients (5.6%) had extra-pulmonary TB. History of exposure to tuberculosis patients was found in 36 (67.9%) patients. Treatment regimen with 2nd line drugs was decided on individual basis according to DST on sputum culture results. The mean duration of treatment was 18 months. Successful outcome was seen in 25 patients (47.2%), 25 patients (47.2%) were loss to follow up and defaulted while 3 (5.6%) patients remained smear positive at the end of treatment. Success rate was 89.2% in those who completed the treatment.

Conclusion: Community-based out-patient treatment strategy is both feasible and safe for the treatment of MDR-TB patients in resource limited country like Pakistan and this strategy should be integrated into the routine approach to treatment of MDR-TB patients in the country where the expertise are available. High default rate is this strategy is the main challenge which should be addressed.

**P3307**
Treatment outcome of multi drug resistant tuberculosis patients in modified DOTS-PLUS: A new strategy
Rajendra Prasad1, Abhijeet Singh 1, Rajiv Garg1, Irfan Muhammad, Zeeshan Waheed, Javaid A. Khan
Pulmonary Section, Department of Medicine, Aga Khan University, Karachi, Pakistan

Background: The traditional DOTS (Directly Observed Treatment, Short course) strategy is a success in most of the countries but it suffers from high default and loss to follow up rates. Later on, DOTS-PLUS strategy was introduced by WHO which included monthly home visits along with radiological and bacteriological follow up.

Aims and Objective: To study the treatment outcome with second line drugs in patients of MDR-TB in modified DOTS-PLUS strategy.

Methods: A prospective cohort study analysing 98 consecutive patients with MDR-TB attending the Dept of Pulmonary Medicine, CSMUH, between June 2009 to Feb 2010 with follow-up till Feb 2011. All the patients were given medications free of cost as per DOTS PLUS Protocol of India.Treatment included monthly followup,adherence check up, radiological and bacteriological assessment (sputum smear-monthly till conversion then quarterly;culture for MTB-0, 4.6, 18, 24 months), health education and monitoring of adverse effects.

Results: All the patients had resistance to at least isoniazid and Rifampicin with mean no. of 3.02 drugs and were sorerenegative for HIV. Default rate at the end of 6 months and 12 months were observed in 2.1% and 4.1% patients respectively. 5 patients expired in initial 6 months and 2 in next 6 months. Sputum smear and culture conversion at the end of 6 months and 12 months were 80/90 (88.9%) and 75/90 (83.3%) and 81/87 (93.1) and 78/87 (89.7%) respectively. Mean smear and culture conversion time were 3.6±2.1 months and 4.1±2.6 months respectively. Significant side effects were experienced in 14.3% patients.

Conclusions: Culture conversion rates at the end of 6 months and 12 months were 83.3% and 89.7% respectively. Modified DOTS-PLUS strategy can be model for treatment of MDR-TB in private sector.
Multidrug-resistant tuberculosis (MDR-TB), defined as resistance to at least isoniazid and rifampin, is a growing global concern. Even after successful treatment of TB, there is still the issue of recurrence, of which the rate has been reported to be up to 3.4% in drug susceptible TB. The rate of recurrence could be higher in patients with drug-resistant TB, but comprehensive data is limited. We aimed to elucidate the rate of recurrence among patients with MDR-TB who finished their treatment successfully. A retrospective study was conducted of patients with multidrug-resistant tuberculosis (MDR-TB) to elucidate the rate of recurrence after successful treatment. Of 123 MDR-TB patients, 90 were declared as “cured” or “treatment completed” after individualized therapy. Among 75 successfully treated MDR-TB patients with at least 1 complete year of follow-up, 4 (5.3%) had recurrence.

**Baseline characteristics of 4 patients with recurred MDR-TB**

**Conclusion:** Treatment of MDR-TB is possible after recurrence of MDR-TB, especially in the “treatment completed” group.
chlorine) or water. 48h after 1, 3, 5 and 7 instillations, we measured airway reactivity to methacholine (Flexivent), cellular inflammation in broncho-alveolar lavage (BAL), lung cytokines, and serum OVA-specific IgE. Later, methacholine reactivity 48h after a single combined nasal NaClO-OVA exposure was assessed in mice pretreated with the neurokinin1 receptor antagonist RP67580, in knock-out mice deficient in the transient receptor potential (TRP) channel A1 (TRPA1−/−) or V1 (TRPV1−/−) and in mast cell deficient mice (Kit−/−Kitw−/−). Results: Combined nasal NaClO-OVA exposure induced airway hyperreactivity (AHR) to methacholine in the absence of airway inflammation and OVA specific IgE. AHR was already induced after a single combined exposure to NaClO-OVA and it was not observed after either OVA or NaClO alone. The AHR response was reduced after pretreatment with RP67580. NaClO-OVA induced AHR in TRPV1−/− mice, but not in TRPA1−/− mice and mast cell deficient deficient.

Conclusion: Combined nasal NaClO-OVA exposure induces AHR in the absence of allergic inflammation. This effect appears to involve TRPA1, mast cells and release of substance P, suggesting a neuro-immune interaction.

LS142011 Abstract: Changes in the proteome upon dermal sensitization in a mouse model of chemical-induced asthma

Steven Haenen, Elke Cllynen, Vanessa De Vooght, Peter Hoet, Ben Nemery, Jeroen Vanrooibeek. Occupational, Environmental & Insurance Medicine Research Unit of Lung Toxicology, KU Leuven, Leuven, Belgium; BIOMED Research Institute, Hasselt University, Diepenbeek, Belgium

In follow up of our studies on proteomic changes in a validated mouse model of immunologically mediated chemical-induced asthma, using toluen-2,4-disooylane (TDL) as a sensitizer [1] we evaluated the temporal changes at early time points following dermal sensitization. The identification of biomarkers of sensitization could help to move diagnosis to an earlier (pre-clinical) stage. We explored the proteome of the auricular lymph nodes and serum of mice dermally sensitized to TDI.

Mice were treated once (day 1) or twice (day 1 and 8) with TDI or with the vehicle (acetone-olive oil, 2:3, control) on both ears. Auricular lymph nodes and serum were collected three days later. Two-dimensional difference gel electrophoresis was used to analyze the differential proteins (p<0.05) of TDI-sensitized mice (n=12) vs. control mice (n=12). Proteome analyses of the auricular lymph nodes resulted in 39 and 86 differential proteins and of serum in 7 and 16 differential proteins, after 1 and 2 sensitizations, respectively. Identification (MALDI-TOF MS) of these proteins mainly showed structural (e.g. vimentin), immune related (e.g. lymphocyte specific protein-1) and oxidative stress related proteins (e.g. peroxiredoxin 6) in both the lymph nodes and the serum.

Now, a software based pathway analysis of the differential proteins is performed (Anadine Genomics). This will give more insight in the cellular and molecular events involved in early sensitization, leading to chemical-induced asthma. Possible biomarkers among the differential proteins will be validated.

Inhalation of nano-sized titanium dioxide particles aggravates airway inflammation in allergen-challenged mice

Sofia Jöngløv1, Asa Gustafsson1, Bo Koch1, Emelie Näsli-Salomonsson1, Anders Buchert2,1. Swedish Defense Research Agencies, Division of CBRN Security, Umeå, Sweden; 2Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Titanium dioxide (TiO2) nanoparticles are manufactured worldwide and although TiO2 is chemically inert, it may have adverse health effects especially in sensitive populations. The use of nanomaterials has increased over the past years and the detrimental effects on various airway diseases are poorly characterized. Thus we investigated if a single exposure of TiO2 before or during ovalbumin (OVA)-challenge could promote airway inflammation in mice with allergic airway disease.

BALB/c mice were sensitized to OVA (10 μg i.p.) on day 0 and 14, then challenged with nebulized 1% OVA for 30 min on day 29.32 and 34. Lung exposure of aerosolized TiO2 was performed before (day 28) and during OVA challenge (day 33). The approximated deposited dose of TiO2 in the mouse lung was estimated to be 0.53 mglm3 (2h, nose-only exposure). The experiment ended on day 35 with a 48h inhalation of bronchial reactivity to methacholine and inflammatory cell counts in bronchoalveolar lavage (BAL). Total inflammatory cell counts in BAL was increased both when TiO2 was exposed on day 28 and day 33 (both p<0.05) compared to exposure to only OVA. When mice were exposed for TiO2 before OVA challenge there was a larger decline in respiratory compliance (p=0.03) and a greater impact on peripheral airways (tissue resistance and tissue elastance both p<0.05) compared to TiO2 administrated during the OVA-challenge and to animals exposed to only OVA. In conclusion, we aimed to study effects of combined exposure of nanoparticles and pro-allergic proteins in a mouse model of asthma, indicating that TiO2 administration before and during allergen-challenge have proinflammatory effects in peripheral airways.

P3315

Endotoxin exposure protects against new onset of pollen sensitisation

Grethe Elholm1, Glyndir Onstand1, Torben Sigsgaard1, Gert Doekes2, Joannis Basinas3, Charlotte Hjort1, Pernille Milvang Gronager4.

Background: Farmers are exposed to a wide range of organic and microbial components. We studied the relation between farm-related endotoxin exposure and changes in atopic sensitisation over time in young adults in The Danish Farming Cohort (SUS).

Method: The SUS cohort (n=1166) was examined twice with a 15 year follow-up period. Specific IgE was evaluated against cat, birch, grass, HDM and storage mite allergens were determined (ADVIA Centaur, ALK Abelló). Sensitisation was defined as an IgE≥0.35 KU/L, and atopy was defined as sensitisation to one or more of the 5 allergens tested for. Personal average yearly exposure to endotoxin during the follow-up period was estimated from more than 500 personal inhalable dust measurements and a farm-specific internal job exposure matrix.

Results: New onset atopy was negatively associated with endotoxin exposure in a dose dependent manner (Table 1). Endotoxin exposure was not seen to be related to new onset of mite sensitisation. In contrast, all levels of endotoxin exposure showed a significant and strong protective effect against new onset of pollen sensitisation.

Reduction of diesel exhaust-induced health effects by using a vehicle cabin air filter

Ala Muala1, Anne Bion2, Jenny Bosson1, Ammiel Behndig1, Anders Blomberg1, Stephane Couderc2, Thomas Sandstrom1, 3Dept of Medicine, Div of Respiratory Medicine & Allergy, University Hospital, Umeå, Sweden; 2Renault, Technocentre, Guyancourt, France

Exposure to air pollution is associated with adverse health effects. During exposure in traffic, air pollution concentrations may reach levels that cause symptoms and about diseases. One way to counteract such effects can be to use an air filter in order to prevent particles and gases from entering the vehicle cabin. The aim of the present study was to evaluate the efficacy of two filters to reduce diesel exhaust (DE) related health effects.

Material and Methods: 30 allergic and non-allergic subjects were exposed in an exposure chamber on four occasions during 1 hour; to filtered air, unfiltered DE filtered by an ultrafine particle (UFP) filter and a UFP+AC filter. The combination filter (UFP + active charcoal) significantly reduced PM1 by 74% but also NO2 by 75% and hydrocarbons by 50%. Headache, dizziness, eye irritation, nasal irritation, unpleasant smell and throat irritation increased significantly after exposure to unfiltered diesel exhaust compared to filtered air. Symptoms were significantly reduced by the UFP filter with active charcoal (UFP+AC), in random blind order.

Results: The UFP filter reduced PM1 by 46%, while the UFP+AC filter not only reduced PM1 by 74% but also NO2 by 75% and hydrocarbons by 50%. Headache, dizziness, eye irritation, nasal irritation, unpleasant smell and throat irritation increased significantly after exposure to unfiltered diesel exhaust compared to filtered air. Symptoms were significantly reduced by the UFP+AC filter and were also associated with small but significant improvements in lung function (FEV1-, FEF25-75). The UFP filter without charcoal was far less efficient.

Conclusions: The combination filter (UFP + active charcoal) significantly reduced ultrafine particle, NO2 and HC concentrations from diesel exhaust, and significantly improved symptoms and lung function. The study indicates that vehicle cabin air filters should not only contain an ultrafine filter component, as the addition active charcoal was necessary to improve symptoms and respiratory health.
P3317 Osteopontin and soluble mesothelin-related peptide levels in malignant and benign diseases due to environmental asbestos exposure and healthy people with environmental asbestos exposure

Mehezt Bayram1, I. Aliks2, I. Nureise2, I. Ismail Beni3, 1 Chest Disease, Sivas Numune Hospital, Sivas, Turkey; 2 Thoracic Surgery, Sivas Numune Hospital, Sivas, Turkey; 3 Biochemistry, Gaziosmanpasa University Medicine School, Tokat, Turkey.

Objective: To determine osteopontin and soluble mesothelin-related peptide (SMRP) levels in malignant mesothelioma (MM) patients, in subjects with pleural plaques (PP) due to environmental asbestos exposure and in healthy subjects with environmental asbestos exposure.

Methods: Blood samples were taken from 279 residents from villages close to plaques (PP) due to environmental asbestos exposure and in healthy subjects. Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects from villages close to OU, 123 healthy subjects from villages >26 km distant to OU and 24 MM patients.

Results: Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 21.207, 8.953, 9.725 ng/mL respectively. Mean serum SMRP levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 4.59, 1.0, 1.11 and 1.12 ng/mL respectively. Mean levels of both biomarkers were significantly higher in MM patients than in subjects with PP and healthy subjects with environmental asbestos exposure. The two biomarkers have no superiority to each other.

P3318 Adipokine adipin is associated with the degree of parenchymal fibrosis in asbestos-exposed patients

Serap Lisli Karbal, Uzafi Lerahtinski, Riina Niinenniemi, Panu Oksa, Tuula Viirkola, Ritta Jarvenpaa, Jukka Uitti, Tiina Moilanen.

Objective: To investigate the role of adipin in the pathogenesis of asbestos-induced lung disease.

Methods: Blood samples were taken from 279 residents from villages close to plaques (PP) due to environmental asbestos exposure and in healthy subjects. Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 21.207, 8.953, 9.725 ng/mL respectively. Mean serum SMRP levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 4.59, 1.0, 1.11 and 1.12 ng/mL respectively. Mean levels of both biomarkers were significantly higher in MM patients than in subjects with PP and healthy subjects with environmental asbestos exposure. The two biomarkers have no superiority to each other.

P3319 Short-term exposure to concentrated ambient particles increases airway hyperresponsiveness in normal mice

TUESDAY, SEPTEMBER 27TH 2011

To air pollution with increase of hospital admissions for respiratory diseases. This study investigated if short-term exposures (1-hour) to relatively low levels of concentrated ambient fine particles (CAP) induce bronchial hyperresponsiveness and lung inflammation in mice. 45 Balb/C mice divided at two groups: 22 exposed to filtered air (FA) and 23 exposed to CAP (20 μg/gm3) for 24 hours. There was a decrease of PEF at basal, 6.25 and 12.5 mg/mL. Mch (p<0.01) was statistically different for the CAP compared to FA; in relation the dose, there was an increase of Per at basal, PBS (p<0.05) and 50 mg/mL. Mch (p<0.01) in CAP when compared to FA; and was also observed a decrease of F/I at basal (p<0.01), PBS, 6.25 and 12.5 mg/mL. Mch (p<0.05). BALF showed an increase in the total cells number (p<0.01), macrophages (p<0.01) and neutrophils (p<0.05) in the CAP when compared to FA. Our findings show that even though a daily mean concentration of PM2.5 below the average daily level recommended by the World Health Organization (25 μg/gm3), a daily exposure to CAP can be a triggering pulmonary responsiveness and the increase in the lung inflammatory infiltration.

Objective: To investigate the role of adipin in the pathogenesis of asbestos-induced lung disease.

Methods: Blood samples were taken from 279 residents from villages close to plaques (PP) due to environmental asbestos exposure and in healthy subjects. Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 21.207, 8.953, 9.725 ng/mL respectively. Mean serum SMRP levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 4.59, 1.0, 1.11 and 1.12 ng/mL respectively. Mean levels of both biomarkers were significantly higher in MM patients than in subjects with PP and healthy subjects with environmental asbestos exposure. The two biomarkers have no superiority to each other.

P3319 Short-term exposure to concentrated ambient particles increases airway hyperresponsiveness in normal mice

TUESDAY, SEPTEMBER 27TH 2011

Hosein Noham, Karen Yoshizaki1, Alessandra Choqueta Toledo2, Beatriz Manguerra Saravia-Romah-lo3, Adair Aparecida Santos Alleman4, Mariguela Macchine1, Paulo Hilário Nascimento Sadilha1, 1 Department of Pathology, Laboratory of Experimental Air Pollution, School of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil; 2 Department of Medicine, Laboratory of Experimental Therapeutics, School of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil.

Epidemiological studies show an association between short periods of exposure to air pollution with increase of hospital admissions for respiratory diseases. This study investigated if short-term exposures (1-hour) to relatively low levels of concentrated ambient fine particles (CAP) induce bronchial hyperresponsiveness and lung inflammation in mice. 45 Balb/C mice divided at two groups: 22 exposed to filtered air (FA) and 23 exposed to CAP (20 μg/gm3) for 24 hours. There was a decrease of PEF at basal, 6.25 and 12.5 mg/mL. Mch (p<0.01) was statistically different for the CAP compared to FA; in relation the dose, there was an increase of Per at basal, PBS (p<0.05) and 50 mg/mL. Mch (p<0.01) in CAP when compared to FA; and was also observed a decrease of F/I at basal (p<0.01), PBS, 6.25 and 12.5 mg/mL. Mch (p<0.05). BALF showed an increase in the total cells number (p<0.01), macrophages (p<0.01) and neutrophils (p<0.05) in the CAP when compared to FA. Our findings show that even though a daily mean concentration of PM2.5 below the average daily level recommended by the World Health Organization (25 μg/gm3), a daily exposure to CAP can be a triggering pulmonary responsiveness and the increase in the lung inflammatory infiltration.

P3320 Intratracheal fiber glass instillation in rats: Bronchoalveolar lavage interleukin8 levels

Objective: To investigate the role of adipin in the pathogenesis of asbestos-induced lung disease.

Methods: Blood samples were taken from 279 residents from villages close to plaques (PP) due to environmental asbestos exposure and in healthy subjects. Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects from villages close to OU, 123 healthy subjects from villages >26 km distant to OU and 24 MM patients.

Results: Mean serum osteopontin levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 21.207, 8.953, 9.725 ng/mL respectively. Mean serum SMRP levels for MM, PP, asbestos-exposed healthy subjects and healthy subjects not exposed to asbestos were 4.59, 1.0, 1.11 and 1.12 ng/mL respectively. Mean levels of both biomarkers were significantly higher in MM patients than in subjects with PP and healthy subjects with environmental asbestos exposure. The two biomarkers have no superiority to each other.
Conclusion:
All production workers displayed airway inflammation characterized by increased sputum neutrophilia compared to unexposed controls. 8-isoprostane (8-iso) values were measured in officers and controls since August 2009 to March 2010 in Monza, Italy. Active smokers and current smokers 59% [95%CI 52.4-66.0] and non-smokers 56% [95%CI 50.6-62.0]). PM10 exposures are related to increased 8-iso levels in the whole study group. There were no differences in neutrophil levels between smokers and non-smokers.

P3324
Sputum neutrophilia and annual decline of FEV1 in dust exposed workers

L. B. Sikkeland 1, T. J. Riste 1, H. L. Johnson 1, V. D. Sayescht 1, Johny Kongerud 1,2.

In a previous study in the smelting industry we found a significant relationship between dust exposure and accelerated annual decline in FEV1. The aim of the present study was to investigate the association between annual decline in lung function and different inflammatory markers in induced sputum from the production workers.

Methods: Employees (n=76 (27 current smokers)) who had been part of a longitudinal study (9-13 years) including spirometry (>6 measurements) and respiratory questionnaires, performed induced sputum and exhaled NO.

Results: All workers had neutrophil inflammation compared to unexposed controls. However neutrophel levels in sputum samples did not differ between workers with annual decline in FEV1 (>45ml - upper tertile) compared to workers with annual decline in FEV1 (15-25ml-lower tertile), 59% [95%CI 56.6-66.2] and 59% [95%CI 51.6-66.4] respectively. There were no differences in the neutrophil levels between current smokers 59% [95%CI 52.4-66.0] and non-smokers 56% [95%CI 50.6-60.6]. Exhaled NO levels were decreased in smokers compared to non-smokers (11.8 pg/ml vs 20.5 pg/ml, p<0.01).

Conclusion: All production workers displayed airway inflammation characterized by neutrophilia. Surprisingly, there were no differences in the neutrophil level when comparing workers with rapid decline in lung function with those with slow decline in lung function. As expected smokers had low levels of exhaled NO, but there was no difference in neutrophil levels between smokers and non-smokers. Sputum neutrophilia was not a marker for increased decline in FEV1.
In urban centres, diesel exhaust particles (DEP) are the most toxic pollutant released from automotive engines, affecting pulmonary health. The aim of this study was to investigate the effects of a chronic period of exposure to DEP (three months) in healthy mice (Yoshizaki et al., 2010) studying whether chronic, near-ambient levels of DEP exposure could induce changes in the lung parenchyma structure and in the profile of inflammatory cells. Male Balb/c mice were divided into two groups: 1) nasal instillation of 10 μL of DEP (n=9) (DEP group). Nasal instillations were performed five days a week for three months. Lung parenchyma was evaluated by quantifying the mean air space chord lengths (Lm) by morphometry (point counting). T lymphocytes total (CD3) and macrophages (Mac-2) densities were analyzed by immunohistochemistry. DEP exposure induced increase of CD3 T lymphocytes when compared to control. No statistical difference was found in macrophages densities. The Lm was larger in DEP animals than controls (p=0.018). These findings indicate that chronic, near-ambient levels of DEP exposure can cause alveolar enlargement and T lymphocytes recruitment, providing a biological link between DEP exposure and the emphysema.

Changes in exhaled breath condensate pH following specific inhalation challenge in patients with occupational asthma to persulfate salts

**Xavier Muñoz, Sara Sánchez-Vidaurre, Meritxell Espuga, Maria-Dolores Untoria, Ferran Morell, Maria-Jesús Cruz. Respiratory, Hospital Vall d’Hebron, Barcelona, Spain**

**Introduction:** Exposure to persulfate salts in hairdressing professionals is one of the most common causes of occupational asthma (OA) in our setting. pH measurement in exhaled breath condensate (EBC) has proven to be a useful, noninvasive method for monitoring pulmonary inflammatory. This study investigates possible changes in EBC pH in patients with OA to persulfate salts following specific inhalation challenge (SIC) testing.

**Material and methods:** The study population included 13 patients with OA caused by exposure to persulfates, diagnosed by a positive SIC (Group 1) and 25 patients exposed to persulfates, but with a negative SIC (Group 2). EBC samples were collected before and after SIC was performed. pH was determined in all samples following degasification with helium.

**Result:** The mean (SD) EBC pH values before and after SIC were 7.65 (0.63) and 7.32 (0.85), respectively, in Group 1, and 7.73 (0.68) and 7.38 (0.66) in Group 2. There were no significant differences in the pH values between the 2 groups. However, when a decrease in EBC pH greater than 0.4 units following SIC was established as significant, 6 patients in Group 1 (43%) and only 1 patient in Group 2 (4%) exceeded this value.

**Conclusions:** Persulfate salts can induce an inflammatory response in patients with OA. A larger percentage of SIC-positive patients showed a significant EBC pH decrease following the test. This fact could contribute to improving the diagnostic yield of SBC.

**This study was funded by grants from the Spanish Ministry of Health (FIS PI050100) and SEPAR.**

Chronic exposure of diesel exhaust particles causes alveolar enlargement in mice

**Kelly Yoshizaki1, Jose Mara Brío1, Alessandra Choqueta Toledo2, Moriya Henrique Takachi1, Adriano Alencar1, Sandra Ferrerlizian1, Paulo Hilário Nascimento Saldiva1, Thais Mauad, Mariangela Macchiome1. 1Department of Pathology, Experimental Air Pollution Laboratory, LMB55, School of Medicine, University of Sao Paulo, Sao Paulo, Brazil; 2Therapeutic Experimental, University of Sao Paulo, Sao Paulo, Brazil; 3Biomedical Engineering Laboratory, Escola Politécnica, University of Sao Paulo, Sao Paulo, Brazil**

In healthy mice, diesel exhaust particles (DEP) are the most toxic pollutant released from automotive engines, affecting pulmonary health. The aim of this study was to investigate the effects of a chronic period of exposure to DEP (three months) in healthy mice (Yoshizaki et al., 2010) studying whether chronic, near-ambient levels of DEP exposure could induce changes in the lung parenchyma structure and in the profile of inflammatory cells. Male Balb/c mice were divided into two groups: 1) nasal instillation of 10 μL of saline (n=9) (control group) and 2) nasal instillation of 30 μg/10 μL of DEP (n=9) (DEP group). Nasal instillations were performed five days a week for three months. Lung parenchyma was evaluated by quantifying the mean air space chord lengths (Lm) by morphometry (point counting). T lymphocytes total (CD3) and macrophages (Mac-2) densities were analyzed by immunohistochemistry. DEP exposure induced increase of CD3 T lymphocytes when compared to control. No statistical difference was found in macrophages densities. The Lm was larger in DEP animals than controls (p=0.018). These findings indicate that chronic, near-ambient levels of DEP exposure can cause alveolar enlargement and T lymphocytes recruitment, providing a biological link between DEP exposure and the emphysema.

Effect of interferon z preparations on IP10 and ET-1 release from human pulmonary artery smooth muscle cells

**Rozenn Quarck1, Hervé Durand 2, Ewa Niño2, Marion Delcroix 1. 1IMM1000, Biomedicine and Health, University of Sao Paulo, Sao Paulo, Brazil; 2UMRS937, IM2S, Anna de Faye 5, Montevrain, France**

Pegylated (PEG) interferons (IFN), used to treat hepatitis C, are associated with lung toxicity and pulmonary hypertension. Pegylation increases stability of the IFN moiety and in vivo half-life, but reduces in vivo anti-viral activity. These effects are related to the size/shape/position of the PEG attachment. There are two marketed PEGIFNs preparations for hepatitis C; PEGIFNα2a and PEGIFNα2b, which are conjugated to 40 KDa and 12 KDa moieties respectively. Endothelin-1 (ET-1) and IP10 are associated with lung inflammation and are induced by IFNs. We investigated the effect of IFNs preparations on ET-1 and IP10 release from human pulmonary artery smooth muscle (HPASM) cells. HPASM cells were treated with IFNs (0.33ng/mL to 30ng/mL). For ET-1, TNFα (10ng/mL) was added. IP10 and ET-1 immunoreactivity was measured by ELISA at 24h.

IFNα preparations induced IP10 with PEGIFNα2a being the weakest inducer (Fig. 1A; n=6; *p<0.05 by two way ANOVA). In TNFα treated cells, IFNα2a, IFNα2b and PEGIFNα2b induced ET-1 above baseline release (Fig. 1B; n=8; *p<0.05 by one way ANOVA vs control; *p<0.05 by two way ANOVA).

**Figure 1**

![Image](image-url)

We conclude that IFNs preparations activate HPASM cells and this may contribute to the lung inflammation seen in some patients. PEGIFNα2a has the larger PEG moiety and induced less ET-1/IP10. Our results suggest ET-1/IP10 are important when considering mechanisms of pulmonary toxicity of IFNs.

Could platelet-activating factor acetylhydrolyase (PAF-AH) predict adverse event in pulmonary hypertension?

**Rezenn Quark1, Herve Durand2, Ewa Ninio2, Marion Delcroix2. 1Respiratory Diseases, Katholieke Universiteit Leuven, Leuven, Belgium; 2UMRS937, INSERM, Paris, France**

Chronic thromboembolic pulmonary hypertension (CTEPH) and pulmonary arterial hypertension (PAH) are threatened conditions mostly diagnosed at late stages. Inflammation could play a role in the pathogenesis. The need of new biomarkers, non-invasively measurable may help to improve the diagnosis and follow up. PAF-AH, a plasmatic enzyme, is a predictive risk factor for cardiovascular events. In a prospective study, we have investigated a potential role of PAF-AH in...

caspase inhibition reduces severe pulmonary hypertension in the AdTGF-β1/SU5416 model of angioproliferative pulmonary hypertension and lung fibrosis

1Department of Internal Medicine, Victoria Johnson Center, Virginia Commonwealth University, Richmond, VA, United States; 2Departments of Medicine, Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada

Pulmonary hypertension (PH) is associated with increased mortality in patients with idiopathic pulmonary fibrosis (IPF). The interaction between the fibrotic process and the pulmonary vasculature is incompletely understood. The current study aimed to investigate whether broad spectrum caspase inhibition can reduce severe angioproliferative PH in the combined model of AdTGF-β1 lung fibrosis and the VEGF receptor inhibitor SU5416.

Female Sprague Dawley rats received AdTGF-β1 intratracheally at day 0, as well as one dose of SU5416 s.c. or vehicle. Some AdTGF-β1/SU5416 animals received the caspase inhibitor Z-Asp-CH2-DCB or vehicle (DMSO) from day 6-28. At day 28, invasive pulmonary hemodynamics were assessed. The right lung was inflated for protein and RNA isolation, and the left lung was inflated with formalin and processed for histology.

We detected clusters of VWF+ endothelial cells excluding the lumen of small pulmonary arteries in AdTGF-β1/SU5416, together with severe PH in AdTGF-β1/SU5416 rats vs. AdTGF-β1/CMC. At the same time, lung fibrosis was increased, as indicated by elevated mRNA expression of profibrotic and matrix genes. Western blots showed a significant increase in caspase-3 cleavage in AdTGF-β1/SU5416 rats. Treatment with Z-Asp-CH2-DCB reduced right ventricular systolic pressures by 19.4 mmHg in average in AdTGF-β1/SU5416 animals (P=0.05 vs. DMSO).

In conclusion, our results indicate that angioproliferative pulmonary vasculopathy was induced in this new model, together with severe fibrosis, and that increased apoptosis contributes to both increased fibrosis and vascular pathology.

P3335
Effects of type I, II and III interferons on endothelin-1 release by human pulmonary artery smooth muscle cells
Peter M. George1, Rekha Badiger1, Himi Ghashw1, Neil Galloway-Phillips1, Trevor T. Hansel2, Jane A. Mitchell1,1Department of Cardiothoracic Pharmacology, Imperial College, London, United Kingdom; 2Imperial Clinical Respiratory Research Unit (ICRRU), Imperial College, London, United Kingdom

The potent vasconstrictor and mitogen peptide endothelin-1 (ET-1) is a therapeutic target for the treatment of pulmonary hypertension. Work from our group has shown that ET-1 release by human pulmonary artery smooth muscle cells (HPASMCs) is critically regulated by interferons (IFNs) and TNF. We have shown that type I IFNs and IFNγ and type II IFNγ, but not type III IFNλ, all released in high doses to viral infection, induce ET-1. As viral infection and IFN therapy are increasingly associated with lung toxicity, including pulmonary hypertension, we have investigated the nature of any interaction between IFNs for ET-1 release by HPASMCs. Cells from 3 separate donors were stimulated in 96-well plates with IFNs, IFNγ, IFNλ and -λ (all 10ng/mL). Supernatants were collected after 24 hours and ET-1 concentrations measured by sandwich ELISA. In the presence of TNFα (10ng/mL), type I IFNs (+2 and +3) or type II IFNγ, but not type III IFNλ, induced ET-1 release. Additive release of ET-1 was seen with IFNα/γ and IFNλ/γ but not IFNα/λ. IFNs did not release ET-1 under any condition studied. Type I and II IFNs act independently to stimulate ET-1 from HPASMCs, which reflects what is known about their separate receptor pathways.

Figure 1. Data is mean ± SEM. *P<0.05 one-way ANOVA for combination of IFNs vs IFN alone.

Our finding that IFNγ is inactive in these cells may suggest that type III IFN spares the lung vasculature.

P3336
Roles of sex hormones on bone morphogenetic protein signaling in pulmonary artery differed between testosterone and estrogen
Hiroaki Ichimori, Shigeyo Kogaki, Kunihiro Takahashi, Keiti Ozono
Pediatrics, Osaka University Graduate School of Medicine, Suita, Japan

Background: Epidemiologic studies have revealed the female predominance in the morbidity of idiopathic PAH (pulmonary arterial hypertension) in the world, predicting the outcome in PAH and CTEPH. Circulating PAH-AH activity has been measured in consecutive patients diagnosed with PAH (n=152) and CTEPH (n=115), at the time of right heart catheterization and compared to a control group of healthy subjects (n=115).

Circulating PAH-AH activity was lower in CTEPH and PAH patients compared to controls (37, 95% CI: 33-41; 41, 95% CI: 37-47; 54, 95% CI: 50-60 nmol mL-1 min-1, p<0.0001). In PAH, PAH-AH activity is correlated to total cholesterol (p=0.29, p<0.0002) and to LDL-cholesterol (p=0.26, p=0.001). In CTEPH, PAH-AH activity is correlated to pulmonary vascular resistance (PVR; r=0.21, p=0.02) and to LDL-cholesterol (r=0.22, p=0.01). In PAH, clinical worsening is associated with an elevated PAH-AH activity (36, 95% CI: 32-41 vs. 45, 95% CI: 40-51; p=0.04). PAH patients with a mean pulmonary arterial pressure >50 mmHg, and with CRP≥4 mg/L have increased PAH-AH activity (35, 95% CI: 30-41 vs. 47, 95% CI: 43-52; p=0.02, 37, 95% CI: 32-42 vs. 45, 95% CI: 40-51; p=0.02, respectively).

Our results suggest that PAH-AH could be a prognostic factor in pulmonary hypertension.

P3333
Potential contribution of precursor cells to vascular remodeling in the AdTGF-β1 model of lung fibrosis and pulmonary hypertension
Laszlo Farkas1, Daniela Farkas1, Donatas Kraskauskas1, Jack Gauldie2, Martin Kolb3, Norbert Vokel1,1Department of Internal Medicine, Virginia Commonwealth University, Richmond, VA, United States; 2Departments of Medicine, Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada

Pulmonary hypertension (PH) is associated with increased mortality in patients with idiopathic pulmonary fibrosis (IPF). The interaction between the fibrotic process and the pulmonary vasculature is incompletely understood. There is evidence in human and experimental pulmonary fibrosis that precursor cells may play a role in fibrogenesis, and that precursor cells may also be important for vascular remodeling in chronic models of pulmonary hypertension (PH). But the contribution of precursor cells to vascular remodeling and PH in pulmonary fibrosis has not been investigated yet.

This study aimed to investigate the potential contribution of precursor cells to vascular remodeling in the AdTGF-β1 model of lung fibrosis and PH. Female Sprague Dawley rats received AdTGF-β1 or AdDL70 and were sacrificed at different time points (7, 14 and 28 days). Immunofluorescence stainings were performed on 3 μm sections of the left lung after formalin fixation. We detected clusters expressing markers of endothelial progenitor cells (CD133+/WF, CD146+/VEGFR-2) in the pulmonary arteries of AdTGF-β1 animals, mainly after 14 days. We also found cells expressing markers of fibrocytes (CXC4Rα/β-SMA, CXC4Rβ/α-4-hydroxylase, S100A4/CD34), around pulmonary arteries of AdTGF-β1 animals. In contrast, we did not find such cells in or around pulmonary arteries in AdDL70 treated animals.

In summary, our data support the concept that precursor cells may contribute to postcapitotic vascular repair and pulmonary artery muscularization in experimental lung fibrosis. The detailed mechanisms of precursor cell attraction and activation are currently under investigation.
suggesting involvement of sex hormones in the pathogenesis of PAH. Recent studies have identified a role of bone morphogenetic protein (BMP) signaling in the pathogenesis of PAH and we reported that BMP signaling in pulmonary arterial endothelial cells (PAEC) was attenuated under hypoxic condition in vitro and in vivo. 

**Purpose:** The aim is to investigate effects of estradiol (E) and testosterone (T) on the BMP signaling in PAEC and analyze their mechanisms. 

**Materials and methods:** PAEC were cultured and incubated with β-estradiol (10^-7 M), testosterone (10^-8 M), or vehicle under 1%O2 (hypoxia) and 21%O2 (normoxia). BMP signaling including Smad1/5/8, phosphorylated (p) Smad1/5/8 and Id1 was examined by western blotting and quantitative RT-PCR. The effects of HIF (hypoxia-inducible factor) -1α expression on the BMP signaling were also examined.

**Results:** Under normoxia, p-Smad1/5/8 protein and Id1 mRNA were augmented 1.6 and 1.5-fold by E, but suppressed 0.3 and 0.4-fold by T. Under hypoxia, conversely, p-Smad1/5/8 protein and Id1 mRNA were suppressed 0.5 and 0.4-fold by E, but augmented 3.2 and 2.4-fold by T. HIF-1α accumulation led to alteration of BMP signaling similar to hypoxia, whereas HIF-1α inhibitor altered the signaling similar to normoxia.

Discussion: Estrogens could change BMP signaling in PAEC depending on oxygen concentration. Our observations provide the new mechanism how sex hormone affects on BMP signaling, and sex hormones may be novel therapeutic targets in the treatment of PAH.

**P3337**

**Pulmonary hypertension in the newborn GTP-cyclohydrolase 1 deficient mouse is unrelated to endothelium-dependent vasorelaxation potential**

Jaques Belik1, Brendan McIntyre1, Yingyu Fan1, Jeanette Vasquez-Vivar2.

1Pediatrics, The Hospital for Sick Children, Toronto, Canada; 2Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States.

**Background:** Tetrahydrobiopterin (BH4) is an endothelial nitric oxide (NO)-sensitive (eNOS) cofactor. Its absence results in eNOS uncoupling and a shift from NO to reactive oxygen species (ROS) generation. The hph-1 mouse is deficient in GTP-cyclohydrolase 1 (GCH1) production, resulting in lowered BH4 tissue content. We have previously shown that the hph-1 mouse has pulmonary hypertension secondary to eNOS uncoupling, yet whether similar changes are evident in the newborn is presently unknown. Thus, we evaluated 1-3 day old newborn hph-1 pups and compared them to wild-type mice (C57BL/6xCBA).

**Methods and results:** Lung morphometry, BH4 and its oxidized metabolite BH2 content were measured and near-resistance pulmonary arteries were studied. In control and hph-1 mice, the BH4 lung content is inversely proportional with age, but decreased in the mutant animals (P<0.01). Pulmonary hypertension is evident in the newborn hph-1 as an increase in the right ventricle-to-left ventricle+septum ratio, compared with wild-type mice (P<0.05). In response to the thromboxane A2 analogue (U46619), the pulmonary arteries of hph-1 mice generate less force (P<0.05). In response to 50 μM L-arginine, a significant increase in medial thickness of small pulmonary arteries was evident in the newborn hph-1 mice (P<0.01), when compared with controls, but show a similar vasorelaxant response to eNOS-dependent and -independent stimulation. As compared with wild-type, a significant increase in medial thickness of small pulmonary arteries is evident in the newborn hph-1 mice (P<0.05).

**Conclusion:** Pulmonary hypertension is present from birth in the GCH1 deficient mice, not as a result of vasoc chromium, but secondary to pulmonary vascular remodeling.

**P3338**

**Autoimmunity and pulmonary arterial hypertension: The role of leptin**

Alice Huertas1,2,3, David Montani 1,2,3, Natalia Gambaryan 1,2,3, Saadia Eddahibi1, Christophe Guignabert 1, Philippe Darteville1, Gerald Simonneau1, Elie Fadel1, Marc Humbert1, Saadia Eddahibi1, Christophe Guignabert 1, 2Cardiovascular Research Therapies, INSERM, Le Plessis-Robinson, France; 2Department of Pulmonology, VU University Medical Center, Amsterdam, Netherlands

**Introduction:** p130 Cas kinase is a docking protein integrating and regulating extracellular cues and intracellular signaling pathways that controls cell proliferation and motility. Therefore, we hypothesize that p130 Cas contributes to excessive migration and proliferation of PA-SMCs in idiopathic Pulmonary Arterial Hypertension (iPAH).

**Methods:** Protein and phosphorylation levels of p130Cas were quantified by Western blot analyses. To assess the functional role of p130 Cas in iPAH and controls, we evaluated migration and proliferation of cultured PA-SMCs with and without p130Cas inhibition by siRNA.

**Results:** We observed significantly elevated p130 Cas protein expression and activity in iPAH patients compared to controls. In addition, decreasing p130 Cas signaling by RNA interference reduced to similar levels both the migration and proliferative potentials of iPAH and control PA-SMC. The decreased migration and proliferation are respectively mediated by decreased matrix metalloproteinase (MMP)-2 release and by decreased mitogen-activated protein kinase (MAPK) activation.

**Conclusions:** These results demonstrate that p130 Cas protein expression and activity induces PA-SMC proliferation and migration in iPAH, suggesting p130 Cas as an attractive drug target for PAH therapy.

**P3341**

**Ghrelin effects on local renin angiotensin from pulmonary vessels**

Irina Luciana Dumitriu1, Elena Cîopârcu1, Luminita Gina Vata1, Ly Tu1, Frances De Man2, Florence Lecerf2, Charlene François1, Philippe Darteville1, Gerald Simonneau1, Elie Fadel1, Marc Humbert1, Saadia Eddahibi1, Christophe Guignabert1, 1Cardiovascular Research Therapies, INSERM U999, Le Plessis-Robinson, France; 2Department of Pulmonology, VU University Medical Center, Amsterdam, Netherlands

**Introduction:** p3330 is a docking protein integrating and regulating extracellular cues and intracellular signaling pathways that controls cell proliferation and motility. Therefore, we hypothesize that p3330 contributes to excessive migration and proliferation of PA-SMCs in idiopathic Pulmonary Arterial Hypertension (iPAH).

**Methods:** Protein and phosphorylation levels of p3330 were quantified by Western blot analyses. To assess the functional role of p3330 in iPAH and controls, we evaluated migration and proliferation of cultured PA-SMCs with and without p3330 inhibition by siRNA.

**Results:** We observed significantly elevated p3330 protein expression and activity in iPAH patients compared to controls. In addition, decreasing p3330 signaling by RNA interference reduced to similar levels both the migration and proliferative potentials of iPAH and control PA-SMC. The decreased migration and proliferation are respectively mediated by decreased matrix metalloproteinase (MMP)-2 release and by decreased mitogen-activated protein kinase (MAPK) activation.

**Conclusions:** These results demonstrate that p3330 protein expression and activity in iPAH patients compared to controls. In addition, decreasing p3330 signaling by RNA interference reduced to similar levels both the migration and proliferative potentials of iPAH and control PA-SMC. The decreased migration and proliferation are respectively mediated by decreased matrix metalloproteinase (MMP)-2 release and by decreased mitogen-activated protein kinase (MAPK) activation.

**Background:** Published data sustain the participation of vascular rennin angiotensin system (RAS) on alteration of pulmonary vessels reactivity during the allergic airway inflamation. Ghrelin is a growth hormone-releasing peptide involved in modulation of immune function.
Objective: This study aims to investigate the interaction between ghrelin and local RAS from rat pulmonary vessels during ovulation – induced allergic airway disease.  

Methods: The angiotensinogen (AGT) – induced contractions were assessed on isolated pulmonary artery and veins from ovulation sensitized rats receiving either saline (OSG) or ghrelin (OSG) by endotracheal instillation. Experiments were performed in the absence or the presence of losartan, D-ALA7, chymostatin and N-nitro-L-arginine methyl ester (L-NAME).  

Results: The angiotensinogen (AGT) contractile effects mediated by AT1 receptors were diminished by 25% on vessels from OSG group. The D-ALA7 and LNAME significantly increases the AGT - induced contraction on OSG. The amount of nitric oxide released after stimulation with angiotensinogen (AGT) is higher on OSG and it is blocked by D-ALA7.  

Conclusion: Our results suggested that pulmonary delivery of ghrelin could modulate the local RAS from pulmonary vessels, probably by promoting the angiotensin 1-7 mediated effects. These data sustained the existence of an additional possible way for ghrelin’s beneficial effects on the lung.

P3342 Nestin expressing progenitor cells in pulmonary vasculature  

Farhan Sabor1, Claudia Berndt1, Norbert Weissmann2, Ralph Schermuly2, Dieter Müller3, Ralf Middendorf1.  

1 AG Signal Transduction, Institute of Anatomy and Cell Biology, Giessen, Germany; 2 Department of Internal Medicine, Medical Clinic II, Giessen, Germany.  

Vascular smooth muscle cells (VSMCs) and pericytes (PCs), distinguished by the expression of neuronal stem cell marker “Nestin”, may represent stem cell-like progenitor cells for tissues in various organs. In one of our previous studies, we found that NPCs in both blood vessel and trabecular muscle vessels are the progenitors of testosterone producing Leydig cells.  

To analyze the expression pattern of nestin and its role as marker for proliferating progenitor cells in the lung, nestin expression and localization was investigated during postnatal development in nestin-GFP mice. To investigate nestin expression during vascular remodelling, samples from two models of pulmonary hypertension (PH) [monocrotaline (MCT) rat model and hypoxic mouse model] as well as human samples from patients of PH were analyzed. Nestin data was compared with expression of proliferation markers (PCNA, Ki67) and PDGF receptors.  

Nestin was found in a subpopulation of VSMCs and PCs of lung vasculature. As compared to adult normoxic controls significantly higher nestin expression was observed in pulmonary vasculature of postnatal tissues and in adult lungs between day 3-7 of hypoxic exposure but not at later time points when PH became evident. Increase of nestin correlated well with an increase of cell proliferation. In hypoxic lungs peak of phosphorylated (activated) PDGF receptor β correlated with nestin one. Increase of nestin-immunoreactive VSMCs and PCs was also found in MCT rat and human lungs. Certain contractile cells capable of proliferation could be identified by Nestin expression in lungs and may be used as prognostic marker and new target for therapeutic interventions of diseases like PH.

P3343 Endothelial cell mechanics are altered in pulmonary arterial hypertension (PAH)  

Corey Hardin1, Ramaswamy Krishnan2, Dhananjay Tambe2, Sharif Sheik3, Dieter Müller1.  

1 Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA, United States; 2 Molecular and Integrative Physiology Program, Harvard School of Public Health, Boston, MA, United States; 3 Lung and Pulmonary Care Medicine, Brigham and Women’s Hospital/Harvard Medical School, Boston, MA, United States.  

Idiopathic pulmonary arterial hypertension (IPAH) and collagen vascular disease associated PAH (APAH) are associated with a significant elevation of inflammasome activation and release of IL-1β and IL-6 in patient plasma [1]. We hypothesized that these biochemical changes will affect intercellular force distribution in the constituent endothelial cells. To test this hypothesis, we applied a novel in vitro technique to cultured Human Lung Microvascular Endothelial Cell (HLMVEC), serum derived from IPAH and APAH patients, and measured subsequent changes in HLMVEC intercellular forces [2]. In comparison to time-matched controls (n=4), HLMVEC monolayers exposed to patient serum (n=7, APAH, n=8) were significantly more contractile (average contractile moment per monolayer: control cells = 153.5±13.5 pN/m, IPAH cells = 222.3±9.6 pN/m, and APAH cells = 223.8±22.8 pN/m), and exhibited greater number of intercellular mechanical stress hot-spots. Accordingly, we suggest that inflammasome mediated enhancements in endothelial intercellular forces may play an important role in decreased vascular compliance observed in PAH.

P3344 Involvement of cytoskeletal protein Paxillin in the pathogenesis of pulmonary hypertension  

Christine Veith, Werner Seeger, Norbert Weissmann, Grazyna Kwapiszewa.  

University of Giessen Lung Center, ECCPS, Giessen, Germany.  

Pulmonary arterial hypertension (PAH) is a fatal disease characterised by a pronounced remodelling of the pulmonary vasculature. The remodelling process entails deposition of the extracellular matrix (ECM) proteins, proliferation of pulmonary arterial smooth muscle cells (PASMC), and changes in the composition of cytoskeletal proteins. Paxillin is one of the most important cytoskeletal proteins, mediating protein-protein interactions and consequently modulating cell signalling. In this study we have investigated the contribution of Paxillin in vascular remodelling.  

In lungs of IPAH patients we detected enhanced Paxillin expression compared to controls on both mRNA and protein levels. Immunohistochimical analysis demonstrated expression of Paxillin in pulmonary vasculature and PASMC. Similarly, in the hypoxia mouse model of pulmonary hypertension, expression of Paxillin was localised to the vessels. Laser microdissection of intrapulmonary arteries revealed enhanced Paxillin expression in hypoxic lung vessels. Functional measurements were performed by silencing Paxillin expression. Paxillin knockdown caused changes in the phosphorylation status of Akt, and Erk1/2 leading to decreased cell viability, proliferation as well as increased apoptosis of human primary PASMC. Furthermore, immunohistofluorescence of PASMC revealed that Paxillin knockdown led to cytoskeletal alterations and impaired cell adhesion. Paxillin has previously been documented to be involved in cell spreading, migration, features characteristic of vascular remodelling. This is however the first report that indicates the involvement of Paxillin in vascular remodelling in the lung, and its association with human PAH disease.

P3345 Determination of cell-derived microparticles in patients with pulmonary hypertension and connective tissue disease using flow cytometry  

Xhyism Kjuki1, Gabor Kovacs2, Eva Rohde3, Dirk Strunk4, Horst Olschewski5.  

1 Division of Pulmonology, Medical University of Graz, Graz, Austria; 2 Division of Hematology, Medical University of Graz, Graz, Austria; 3 University Hospital for Blood Group Serology and Transfusion Medicine, Paracelsus Medical University/Salzburger Landeskliniken, Salzburg, Austria.  

Background: Microparticles (MPs) are small plasma membrane vesicles released from different cell types during activation or apoptosis. Increased MPs levels have been associated with cardiovascular diseases, thrombotic disorders and systemic inflammatory conditions. In pulmonary hypertension (PH) the role of MPs is poorly understood.  

Aims and objectives: The aim of this study was to analyze the MPs fractions in PH and connective-tissue disease (CTD) patients which represent a risk factor for PH development.  

Patients and methods: Plasma samples derived from PH and CTD patients were tested using flow cytometry (FC). Circulating MPs from platelets (CD61+), endothelial cells (CD31+) as well as Annexin V+ were measured by FC in 28 PH patients, 36 CTD patients and 41 healthy controls. The levels of MPs were compared in these three groups.  

Results: The overall fraction of MPs was higher in PH patients (57±26% of total events) and CTD patients (51±21%) as compared to controls (42±18%) (p<0.05). Platelet derived CD61+ MPs were tendentially increased in PH patients comparing to controls (p=0.096) whereas CD31 expression was not found to be different on MPs from patients and controls. The expression of Annexin V on MPs from PH patients were significantly higher as compared with controls (mean fluorescence intensities: 56±26% vs. 38±17% (p=0.003)). There were no significant differences between Annexin V expression levels on MPs in PH vs. CTD patients (p=0.384) and not between CTD vs. controls (p=0.179).  

Conclusions: According to these preliminary data, the plasma levels of Annexin-V+MPs are increased in PH patients and may be related to an activated pro-coagulatary and inflammatory vascular status.

P3346 The role of the accessory type III transforming growth factor-β receptors in the regulation of pulmonary vascular development  

Gero Niess, Matthias Michiels-Corsten, Werner Seeger, Romy Morty. Lung Development and Remodelling, Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany.  

Pulmonary artery smooth muscle cell behaviour, including proliferation, apoptosis, and matrix production, is controlled by transforming growth factor (TGF-β), acting via two type II (Acrv1 and Tgfb1) and two type III (endoglin (Eng) and betaglycan (Tgfb3)) TGF-β receptors. Knockdown of TGFBR1 by siRNA in primary human pulmonary artery smooth muscle cells (PASMC) increased PASMC proliferation (3 fold; assessed by BrdU incorporation) in vitro, in a TGF-β independent manner. However, apoptosis rates of the PASMC were not affected by siRNA knockdown of TGFBR3. The siRNA knockdown of other TGF-β receptors, ACRV1, TGFBR1, TGFBR2 and ENG, did not impact TGF-β independent proliferation or apoptosis of PASMC. These data point to a novel, TGF-β independent role for TGFBR3 in regulating PASMC growth. This idea assumes importance considering that we
have also observed perturbed expression of TGFBR3 in the lungs of neonatal mice with hyperoxia (85% O₂)-induced lung injury, which results in bronchopulmonary dysplasia (BPD). The mRNA levels (assessed by quantitative real-time RT-PCR for TGFBR3 were downregulated (4.4-fold, p=0.003), while TGFBR3 protein levels were downregulated by 70%. Laser capture microdissection confirmed downregulated expression of TGFBR3 in the pulmonary vasculature of the developing mouse lung. Taken together, these data suggest a role for TGFBR3 in vascular smooth muscle cell function which could lead to a dysregulation of TGF-β signaling in the pulmonary vasculature, which in turn could contribute to the impaired pulmonary vascular growth and development associated with the lung hypoplasia observed in patients with BPD.

P3347 Elevated levels of adenosine in the lungs lead to chronic lung injury and pulmonary hypertension
Harry Harrony-Quintana1, Hongyan Zhong2, Dewan Zeng3, Liaq Beldanmili6, Michael Blackbum1, 1Biochemistry and Molecular Biology, University of Texas - Medical School, Houston, TX, United States; 2Cardiovascular Disease, Gilead Sciences, Inc. Palo Alto, CA, United States

Pulmonary Hypertension (PH) is characterized by increased pulmonary vascular tone and remodeling of the pulmonary vasculature including muscularization of vessels. PH is often associated with underlying chronic lung diseases (CLD) such as chronic obstructive pulmonary disease (COPD) and idiopathic pulmonary fibrosis (IPF). The adenosine (Ado) A2B receptor (R) expression is increased in patients with COPD and IPF. Activation of the A2B by Ado has been shown to regulate fibrosis through its action in inflammatory and structural cells. However, the role of Ado and the A2BR in the pathogenesis of PH is not known.

Hypothesis: Blockade of the A2B modulates the development of PH in CLD. Ado deaminase (ADA)-deficient mice have increased levels of Ado in the lung tissue that lead to CLD. On day 30, once lung injury was established, mice were provided with Chow containing placebo or GS-6201, an A2B antagonist, for the next 10 days. On day 41, right ventricle systolic pressure (RVSP), systemic blood pressure, heart rate and lung function measurements were performed. ADA-deficient mice had increased RVSP compared to control mice. Lung function measurements revealed increased airway resistance and a reduction in airway and tissue compliance in ADA-/- mice. Blockade of the A2BR by GS-6201 inhibited the increased RVSP and restored lung function. No change in systemic systolic blood pressure or heart rate was observed in mice treated with placebo or GS-6201. These results highlight the role of the A2BR in the pathogenesis of PH associated with elevated tissue Ado and CLD. The results suggest that targeting the A2BR could be a potential target for the treatment of PH secondary to CLD.

P3349 Antibiotics in exacerbations of asthma
Rik Loijmans1, Patricia van Velzen2, Leo Beem3, Marco Stommel4, Gerben ter Riet1, 1Peter Sterk2, 2General Practice, Academic Medical Centre - University of Amsterdam, Amsterdam, Netherlands; 3Respiratory Medicine, Academic Medical Centre - University of Amsterdam, Amsterdam, Netherlands; 4Information and Communication Technology, Stichting Huisartsen Dienstenposten Amsterdam, Amsterdam, Netherlands

Introduction: Current guidelines explicitly do not recommend prescribing antibiotics for asthma exacerbations in order to avoid overprescription. We aimed to assess the prescription rate of antibiotics related to asthma exacerbations in primary care and which clinical patient characteristics are associated with antibiotic prescription.

Methods: We retrieved all electronic patient records concerning acute asthma in adults during 2008 recorded amongst 149,279 patient contacts by the centralised out-of-hours General Practice (GP) service in Amsterdam. Through univariate and multivariate analyses we analyzed the clinical parameters documented by GP’s of patients who received antibiotics.

Results: Of 540 identified exacerbations, 108 (20%) were treated with antibiotics, of which in 16 cases (15%) a prescription of pneumonia was documented. Univariate analysis showed that antibiotic prescription was positively associated with age (p=0.006) and clinical signs (Table 1). Multivariate analysis yielded a Nagelkerke R² of 0.331 for the variables age, ill appearance, spurn, tronchi and fever. Antibiotic prescription was not associated with other treatments of exacerbation.

Conclusion: Antibiotics are prescribed more often for asthma exacerbations by GPs than proposed by international guidelines. Fever appears to be a major trigger for antibiotic therapy, in contrast to recommended care. This suggests that overprescription of antibiotics for asthma exacerbations is prevalent.

P3350 Monitoring free serum IgE in severe asthma patients treated with omalizumab
Stephanie Korn1, Ina Haasler1, Florian Fliedner2, Gunther Becher2, Pavel Strohner1, Antonia Staats2, Christian Taube1, Roland Boh1, 1Pulmonary Department, Mann; University Hospital, Mann; Germany; 2BecherConsult GmbH, Berlin, Germany; 3BioTez: Berlin-Buch GmbH, BioTez: Berlin-Buch GmbH, Berlin, Germany

It is stated that benefit of omalizumab treatment in severe IgE-dependent asthma requires serum free IgE concentrations below 50 ng/ml. It is unclear if monitoring free serum IgE is clinically meaningful once omalizumab treatment is initiated. Free IgE and omalizumab serum concentrations were quantified in 22 patients with severe asthma (68% female, 47±11 yrs., mean ±(SD) pre-bronchodilator FEV₁ 62±13%, baseline mean ±(SEM) free serum IgE 652±136 ng/ml treated with omalizumab for 4 months using a Recovery-ELISA.

Omalizumab treatment reduced free serum IgE prior to the second omalizumab injection by 73%, after 16 weeks by 81% to 51±12 ng/ml (p=0.001 vs. baseline). 17 patients responded to anti-IgE therapy as judged by physician-rated global evaluation of treatment effectiveness. There was no relation between free serum IgE concentrations and treatment response. 41% of responders had free IgE levels above 50 ng/ml and 40% of non-responders had 50 ng/ml. There was no significant or clinically relevant difference regarding changes in lung function, exhaled NO, asthma control, and quality of life between patients with free IgE below or above 50 ng/ml.

Monitoring free IgE and omalizumab serum concentrations in patients treated with omalizumab does not predict clinical response or add to the decision to continue or...

**Serum immunoglobulin level is a useful marker for the risk of opportunistic infection in steroid dependent patients with chronic inflammatory airway diseases**

Makiko Akahane, Nobuyuki Herita, Tomoko Takezawa, Takahiko Arai, Masako To, Yasuo To. Department of Allergy and Respiratory Medicine, The Fraternity Memorial Hospital, Tokyo, Japan

**Aim:** Patients with chronic inflammatory airway diseases such as severe asthma, pulmonary fibrosis often need to have long-term oral corticosteroids (O-CS). Patients who are administered O-CS, even a small amount, are suggestive for opportunistic infections (OI). According to guidelines, prednisolone equivalent dose of 7.5 mg/day is considered as a GINA step 4/5 (Churg-Strauss syndrome) taking regular-use of O-CS were enrolled to this study. We retrospectively reviewed the medical records and collected the data about incidence of OI and serum IgG levels of the patients.

**Results:** Seven out of 17 patients suffered from OI. The average IgG level in patients with OI (623±154 mg/dl, n=7) was significantly lower than patients without OI (879±188 mg/dl, p-value<0.01). The area under the ROC curves was 0.87. The most reliable cut-off level was 725 mg/dl with specificity 89%, sensitivity 75%, positive predictive value 86% and negative predictive value 80%.

**Conclusion:** Serum IgG need to be monitored when patients were given O-CS. It is crucial to keep serum IgG levels more than 725 mg/dl to prevent OI.

**P3352**

**Effects of omalizumab on markers of eosinophilic inflammation in patients with severe allergic asthma**

Marisa Hübner, Stephanie Korn, Matthias Jung, Ina Haasler, Christian Taube, Roland Bulhö: Pulmonary Department, Mainz University Hospital, Mainz, Germany

Allergic asthma is a chronic inflammatory airway disease in which immunoglobulin E (IgE) and eosinophils play important pathogenetic roles. We investigated the effect of the anti-IgE antibody omalizumab on markers of eosinophilic inflammation in patients with severe allergic asthma eligible for omalizumab treatment according to current guidelines. We conducted a prospective study with consecutive GINA step 4/5 patients (19 female, 48±11 yrs., 78±12 kg, 274±228 IU/ml total IgE, FEV1 at baseline 1.8±0.6 L, 61±8±19.5% pred.) omalizumab (median 450 mg/month) was administered s.c. as add-on therapy. Exhaled nitric oxide (NO), peripheral blood eosinophils and serum interleukin-5 were measured before and after 16 weeks of treatment. In all patients total daily doses of inhaled and oral corticosteroids remained stable during treatment.

23 (74%) patients responded to therapy (GETE). BASELINE NO was 43±8 ppb (mean±i-SEM) for responders (R) and 23±6 ppb for non-responders (NR), blood eosinophils were 3.9±0.7±0.07±0.05 (R) and 2.5±0.5±0.08±0.06 (NR), and IL-5 was 7.5±1.1±1.3 (R) and 1.9±1.3±0.3 (NR). After 16 weeks NO decreased by 3±6 ppb (P<0.004) and 12±18 ppb (NR, p=0.375), blood eosinophils were unchanged (R week0-week16: 0.01±0.06±0.01±0.06, p=0.99, and NR, p=0.66) and IL-5 decreased by 3±7±0.0±0.1 ng/m (P<0.001) and 0.3±1.4±0.3 (NR, p=0.62).

Patients, in a clinical response to omalizumab had higher pre-treatment serum IL-5 levels and a pronounced decrease in serum IL-5 following omalizumab. Blood eosinophils were unchanged, and exhaled NO was low prior and on treatment with omalizumab, consequent to high-dose ICS treatment.

**P3354**

**Reduction in incidence of exacerbations in patients with Alpha 1 antitrypsin deficiency (A1ATD) treated with concentrates of Alpha 1 antitrypsin (A1AT):**

REXA study

María L. Torres Durán, Juan Carlos Barros Tizón, Investigators of the Spanish Group for REXA Study. Pneumology, Complex Hospitalario Universitario de Vigo, Vigo, Pontevedra, Spain

**Introduction:** Augmentation therapy with plasma derived Alpha 1 Antitrypsin represents the only specific treatment for patients with Alpha 1 Antitrypsin Deficiency. The aim of this study was to demonstrate that augmentation therapy can reduce the number of exacerbations in patients with A1ATD.

**Material and methods:** Retrospective multicentric study. We included 127 patients who received augmentation therapy for 18 months and with clinical follow-up for 18 months before treatment. We compared the incidence of exacerbations into the two periods.

**Results:** 127 patients, 63% male, age:52y, former smokers:79.4%, never smok-ers:17.4%, FIZZ-93.6%. Basal FEV1:1.24L, (±0.5). Patients were treated with Protalast® (53.5%) or Tryster® (46.5%), 78% every 21 days. 52 days patients did not present exacerbations in pretreatment period. Augmentation therapy was associated with reduction of 2.4 exacerbations for every ten treated patients in total population and 6 exacerbations for every 10 treated patients in those with previous exacerbations.(Figure 1) Untreated patients have between 1.4 and 4 times more risk of exacerbation than treated patients. We didn't observe differences between both available A1AT products.

**Conclusions:** Augmentation therapy in the A1ATD reduces the total number of exacerbations with low frequency of adverse events. Study realized with Grifols support.

**P3355**

**Efficacy of rolflumilast in the frequent exacerbation COPD phenotype**

Jadwiga Wedzicha1, Klaus Rabe2, Peter Calverley3, Fernando Martinez4, Dirk Bredenbröker2, Manja Brosse2, Udo Michael Goehring2, 1Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom; 2Center for Pulmonology and Thoracic Surgery, Krankenhaus Grosshadnordorf, Grosshadnordorf, Germany; 3School of Clinical Sciences, University Hospital Aintree, Liverpool, United Kingdom; 4Department of Internal Medicine, University of Michigan Medical Center, Ann Arbor, MI, United States; 4Department of Respiratory Medicine, Nycomed GmbH, Konstanz, Germany; 5Department of Data Science, Nycomed GmbH, Konstanz, Germany

**Background:** COPD exacerbations (EXs) are associated with increased morbidity, mortality and disease progression. The ECLIPSE study showed the best predictor of future EXs is a history of EXs, identifying a frequent exacerbator phenotype maintained over time. Rolflumilast (ROF) reduces EX rate in frequent exacerbators, but its relative effect in this phenotype is not known.

**Methods:** In a post-hoc pooled analysis of two 1-yr studies of ROF 500g in pts with severe COPD, chronic bronchitis and a history of EXs, pts were classified as frequent (≥2 events) or infrequent (1 event) exacerbators based on moderate/severe EX history in the previous yr. EX frequency status was analysed in ROF- and placebo-(PBO)-treated pts at baseline and at yr 1.

**Results:** Among ROF-treated frequent exacerbators (n=413), 32.0% still had frequent EXs at yr 1 vs 40.8% of PBO-treated pts (n=417; RR=0.799, p=0.0148). Among infrequent exacerbators, 17.5% of ROF-treated pts (n=1124) had ≥2 EXs at yr 1 vs 22.9% of PBO-treated pts (n=1137; RR=0.768, p=0.0018). This reduction was similar when considering concomitant LABA, previous ICS treatment or severe EXs leading to hospitalisation/death. When analysed by COPD severity, 26.4% of ROF-treated frequent exacerbators with severe COPD (FEV1 ≤30–50% pred., n=246) still had frequent EXs at yr 1 vs 38.9% of PBO-treated pts (n=239; RR=0.683, p=0.0042); the percentage of frequent exacerbators was substantially lower between severe and moderate COPD (FEV1 ≥50%).

**Conclusions:** This analysis shows that ROF shifts pts from the frequent to the more stable infrequent exacerbator state. This effect was not seen in frequent exacerbators with very severe COPD, highlighting the need for early treatment initiation.

**P3356**

**Modelling and simulation in successful drug development programmes:**

**Characterisation of exacerbation reduction with rolflumilast to corroborate the importance of defining patient subsets in COPD**

Gezim Lahu1, Axel Facius1, Laurent Clare2, Rene Bruno2, Dirk Bredenbröker2, 1Department of Pharmaceutics and Pharmacokinetics, Nycomed GmbH, Konstanz, Germany; 2Strategic Consulting Services, Thaeright, A Cernealtm Company, Marseilles, France; 3Department of Respiratory Medicine, Nycomed GmbH, Konstanz, Germany

**Background/Rationale:** Rolflumilast (ROF), an oral, selective PDE4 inhibitor, reduces the rate of exacerbations and improves lung function in severe COPD. During clinical development, modelling and simulation techniques were used to identify and confirm a paradigm to explore patient, disease and treatment covariates. This approach identified patient populations that will benefit most from ROF, and was used to help design confirmatory clinical trials.

**Methods:** Data from two 1-year, randomised, double-blind, placebo-controlled, parallel-group trials [Rennard S, et al. Respir Rev 2011;12(1):1] in 2686 patients were used to build exacerbation and lung function models to identify patient characteristics that significantly impacted the clinical endpoints.

**Results:** Patients with chronic bronchitis, higher cough/sputum scores, concomi-tant ICS use and low predicted FEV1 at baseline were identified as having a higher rate of exacerbations and treatment effect. Patient characteristics as defined by the models were used, in addition to a history of exacerbations, to simulate the design of two other 1-year clinical trials [Calverley PMA, et al. Lancet 2009;374:685–94].
Conclusions: paβ reduced the frequency of exacerbations in individual patients in active therapy group than that in placebo group (37.0% vs. 63.0%, p<0.05). The percentage of concomitant antibiotics was significantly lower in OM-85 BV group than in placebo group (27.9% in BV group vs. 27.7% in placebo group, p<0.05). There was no significant difference between the two groups in the incidence of adverse events (27.9% in BV group vs. 27.7% in placebo group, p>0.05).

P338

Efficacy and safety of bacterial lysates in patients with chronic obstructive pulmonary disease and exacerbations

Hao Tang, Zheng Fang, Qingyu Xiu, on behalf of the Broncho-Vaxom Study

Objective: To study the effect of paβ-blockers on exacerbations of COPD exacerbation requiring hospitalization. To each case, controls were matched on age, sex and indexdate. Cox proportional hazard and conditional logistic regression analyses were used.

Results: Within the cohort of 6788 COPD patients, 619 patients had a COPD exacerbation requiring hospitalisation. Current use of paβ-blockers significantly reduced the risk of severe COPD exacerbation in the cohort analysis (HRadj 0.73, 95%CI 0.60-0.90). In the case-control analysis, use of paβ-blockers reduced the risk of exacerbations by 40% (ORadj 0.60, 95% CI 0.44-0.82). When controlling for confounding by indication, the protective effect was clearly attenuated (ORadj 0.87, 95% CI 0.52-1.45). In patients with co-existing heart failure, a significant protective effect was observed (ORadj 0.15, 95% CI 0.03-0.80).

Conclusions: The choice of study design is crucial when assessing the effect of paβ-blockers on COPD outcomes.

P3360

Skin sensitivity to corticosteroids is associated with COPD susceptibility

S.M. Hoonhorst1, A.T. Lo Tam Loi1, R.G.A. Hiltmanner1, L. Koenderman1, J.W. Lammers2, D. Postma3, N.H.T. ten Hacken1, 1Department of Pulmonary Diseases, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; 2Department of Pulmonary Diseases, University Medical Center Utrecht, Utrecht, Netherlands

Introduction: Inhaled corticosteroids (ICS) improve symptoms, exacerbation rates and quality of life in COPD. However, not all COPD patients benefit from ICS treatment. Corticosteroid sensitivity can be tested with the skin blanching test, where topical corticosteroids cause local vasoconstriction. We investigated in young and old individuals if skin response to corticosteroids is associated with susceptibility to develop COPD.

Methods: Young (18 – 40 years) healthy subjects who were non-susceptible or susceptible to develop COPD (n=9 and 14 resp.), and older (40-75 years) subjects without and with COPD (n=15 and 47 resp.) were included. Susceptibility in young subjects was based on a high prevalence of COPD in smoking family members of these subjects. Budesonide dissolved in 95% ethanol was applied to the skin in eight concentrations (0-1000 μg/ml). Blanching was scored with a 7-point scale: 0 (no blanching) and 3 = intense blanching.

Results: Young non-susceptible subjects showed higher blanching scores compared to all groups (figure 1). In COPD patients, a lower blanching score correlated with lower FEV1/FVC ratio (B=-0.07, p<0.01) and higher GOLD stage (figure 2).

Conclusions: These preliminary data suggest that relative corticosteroid insensitivity contributes to COPD development and progression.

P3359

β-blockers and risk of COPD exacerbation requiring hospitalisation in patients with COPD

Ana Abisbela1, Riccardo Verhamonde1, Guy Brusselle2, Mirjam Sturkenboom1

1Medical Informatics, ErasmusMC, Rotterdam, Netherlands; 2Department of Respiratory Diseases, University of Ghent, Ghent, Belgium

Background: In the past, β-blockers were contra-indicated in COPD. Recent evidence, including a cohort study by Rutter et al. (Arch Intern Med 2010), suggests that β-blockers produce good outcomes in COPD. This degree of protection might be biased.

Objectives: To study the effect of β-blockers on the risk of severe COPD exacerbations.

Methods: We conducted several analyses to study the effect of β-blockers on COPD exacerbations by: 1 mimicking the cohort design of Rutter 2 avoiding immortal time and exposure bias through a nested case-control study in a COPD cohort and 3) reducing confoundings by indication by restricting the case-control analyses to users of β-blockers during follow-up. Data from the Dutch IPCI OP database (2000 to 2007) were used. Cases were all COPD patients who had a first COPD exacerbation requiring hospitalization. In each case, controls were matched on age, sex and indexdate. Cox proportional hazard and conditional logistic regression analyses were used.

Results: Within the cohort of 6788 COPD patients, 619 patients had a COPD exacerbation requiring hospitalization. Current use of β-blockers significantly reduced the risk of severe COPD exacerbation in the cohort analysis (HRadj 0.73, 95%CI 0.60-0.90). In the case-control analysis, use of β-blockers reduced the risk of exacerbations by 40% (ORadj 0.60, 95% CI 0.44-0.82). When controlling for confounding by indication, the protective effect was clearly attenuated (ORadj 0.87, 95% CI 0.52-1.45). In patients with co-existing heart failure, a significant protective effect was observed (ORadj 0.15, 95% CI 0.03-0.80).

Conclusions: The choice of study design is crucial when assessing the effect of β-blockers on COPD outcomes.

P3361

Inhaled corticosteroids in patients with mild to moderate COPD with and without airway hyperresponsiveness to mannitol: A randomized placebo controlled trial

Andreas Scherr1, Joehann Anja2, Schaffroth Salome3, David Miedinger2, Maur Sabrina2, Anne Taegtmeier2, Chajed Frashuti3, Sandra Anderson3, Tamim Michael1, Jörg Daniel Leuppi4, 1Clinic of Respiratory Medicine, University Hospital Basel, Basel, Switzerland; 2Clinic of Internal Medicine, University Hospital Basel, Basel, Switzerland; 3Department of Respiratory Medicine, Royal Prince Alfred Hospital, Camperdown, Australia

Background: Based on former data airway hyperresponsiveness (AHR) to mannitol challenge could allow to identify a subgroup of subjects who will respond to treatment with ICS.

Methods: We investigated 68 subjects with mild to moderately severe COPD. All subjects were treated with tiotropium initiated 4 weeks prior to randomisation. Subjects were randomized to either budesonide (daily dose of 1600 mcg) or placebo for 3 months. At all visits lung function, quality of life (SGRO), AHR to mannitol, exhaled nitric oxide (NO) and MRC were assessed. AHR was defined as a 15% fall in FEV1 at < or = to 6.35 mg (PD15). RDR was calculated as the percent fall in FEV1 at the last dose divided by totally dose of mannitol administered.

Results: There was no significant change from baseline of FEV1% pred. (2.46 95% CI [-1; 5.9] p= 0.162), quality of life (SGRO) (3.2 95% CI [-8.5; 21] p= 0.227), nitric oxide (-5.48 95% CI [-11.2; 0.2] p=0.058) and MRC (0.4 95% CI [-2.9; 0.5] p=0.258).

Conclusions: These preliminary data suggest that relative corticosteroid insensitivity contributes to COPD development and progression.
Double blind, placebo controlled crossover study in COPD patients to assess the acute effect of budesonide/formoterol using HRCT and lung function tests

Lieve De Backer1, Jan De Backer 2, Wim Vos2, Wim Vos2, Cedric Van Holsbeke2, Samir Vinchurkar2, Wilfried De Backer1. 1Respiratory Medicine, Antwerp University Hospital, Antwerp, Belgium; 2RD&D, Fluidia, Antwerpen, Belgium

The aim of this study was to assess the acute effect of inhalation of budesonide/formoterol combination and placebo using lung function tests and imaging in COPD patients and to compare both. A total of 10 patients was assessed in a double blind cross over study. Airway volumes were analysed using segmentation of the HRCT images. Results showed that distal airway volume significantly increased in patients four hours after receiving budesonide/formoterol combination. No other lung function parameters showed a significant change. When considering the effect of placebo a significant decline in distal airway volume and peak expiratory flow was observed. A downward trend was depicted by forced expiratory volume in one second. The bodyplethysmography showed a significant increase in specific airway resistance. In addition it was shown that imaging was the only parameter that was able to predict correctly the visit at which the combination product was administered for all patients.

Antibiotic prescription in asthma exacerbations in the admitting and discharged patients (A&E) department

Caroline Gouder, Justine Farrugia Preca, Rachelle Asciaj, Josef Micallef, Stephen Montefort. Department of Medicine, Mater Dei Hospital, Birirkara, Malta Department of Medicine, Mater Dei Hospital, Birirkara, Malta Department of Medicine, Mater Dei Hospital, Birirkara, Malta Department of Medicine, Mater Dei Hospital, Birirkara, Malta Department of Medicine, Mater Dei Hospital, Birirkara, Malta

Aim: To assess the appropriateness of antibiotic prescription in patients diagnosed with asthma exacerbations in the A&E department. Methods: Patients presenting at the A&E department over 10 consecutive months (January to October 2010) were included in a prospective study. Comparative statistical analysis was carried out using the t-test. Results: A total of 244 patients were included. Forty-eight patients (19.7%) had been prescribed antibiotics by their general practitioner prior to presentation to A&E. A chest X-ray was done in 201 patients (82.4%). A radiological suggestive of pneumonia was reported in 12 patients (6%). A white cell count (WCC) was available in 165 patients (67.6%). Antibiotics were prescribed in 30.2% had a raised WCC (mean 10.42×109/L), 23% were febrile at admission and 7.6% had a raised temperature at admission. A radiological infiltrate suggestive of pneumonia was reported in 12 patients (6%). A white cell count (WCC) was available in 165 patients (67.6%). Antibiotics were prescribed in 30.2% (n=50; CI 95% 24.1-36.4) of patients and to compare both. A total of 10 patients was assessed in a double blind cross over study. Airway volumes were analysed using segmentation of the HRCT images. Results showed that distal airway volume significantly increased in patients four hours after receiving budesonide/formoterol combination. No other lung function parameters showed a significant change. When considering the effect of placebo a significant decline in distal airway volume and peak expiratory flow was observed. A downward trend was depicted by forced expiratory volume in one second. The bodyplethysmography showed a significant increase in specific airway resistance. In addition it was shown that imaging was the only parameter that was able to predict correctly the visit at which the combination product was administered for all patients.

This study showed that imaging is a sensitive, complementary tool to describe changes in airway structure and function. Future uses could include the assessment of anti-inflammatory compounds as standard lung function test might lack the sensitivity to describe the more subtle changes.

This study showed that imaging is a sensitive, complementary tool to describe changes in airway structure and function. Future uses could include the assessment of anti-inflammatory compounds as standard lung function test might lack the sensitivity to describe the more subtle changes.

Non-tuberculous mycobacteria pulmonary infections

378. Non-tuberculous mycobacteria pulmonary infections

392. Geographic diversity of nontuberculous mycobacteria isolated from pulmonary samples in Croatia

Maja Orasovic, Miroslov Savarnez, Sanja Popovic, Zlatko Jevtic, Mihaela Obrovac3, Ljiljana Zmak, Gezim Redzezi1, Vera Katalinic-Jankovic 1, Marko Jakopic, 1Department for Lung Diseases “Jordanovac”, University Hospital Center Zagreb, Zagreb, Croatia; 2Laboratory of Molecular Virology and Bacteriology, Ruder Boskovic Institute, Zagreb, Croatia; 3National Mycobacteria Reference Laboratory, Croatian National Institute of Public Health, Zagreb, Croatia

Background: The incidence of non-tuberculous mycobacteria (NTM) as human pathogens is increasing. It has become clear that the NTM species obtained from clinical specimen differ strongly by region. Aims and objectives: To determine the distribution of NTM species obtained from pulmonary samples of individuals from different geographic regions in Croatia. Methods: Retrospective analysis on all NTM identified at the National Laboratory for Mycobacteria in 2007-2009. For each isolate the person's birth year, sex, specimen collection date, source and geographic region (cultural or sputum) were recorded. Microbiological criteria of the ATS/IDSA were used for a laboratory-based definition of pulmonary NTM. Results: NTM species were isolated from 712 individuals. 56% of isolates came from male (median age 62 y) and 44% from female (median age 64 years) individuals. More than two thirds of all isolates (525) originated from persons from the inland area. Of those 525 samples, 80 (15.2%) met the pulmonary NTM criteria, compared to 68 (36.4%) out of the 187 samples identified in the coastal area (p<0.0001). More than 90% of isolated species with insignificant clinical relevance originate from the inland area. Incidence of species with relevant clinical burden was significantly higher in the coastal compared to the inland area. Conclusions: The majority of all NTM isolates originated from the inland area. However, isolates which met the ATS pulmonary disease criteria were more frequently isolated from persons living in the coastal area. There, more than one third of all isolates likely represented true disease. Geographic region plays an important role for colonization or infection with NTMs in Croatia.
Nontuberculous mycobacteria – Isolation in respiratory specimens and its clinical relevance

Sergio Campainha1, Rosario Braga1, Isabel Valente1, Aurora Carvalho1, Raquel Duarte1, 1Pulmonology, Centro Hospitalar de Vila Nova de Gaia/Espinho EPE, Vila Nova de Gaia, Portugal; 2Microbiology, Centro Hospitalar de Vila Nova de Gaia/Espinho EPE, Vila Nova de Gaia, Portugal

Background: Nontuberculous mycobacteria (NTM) isolation have been increasingly described, particularly in developed countries. Few studies in Portugal characterize and report its clinical relevance.

Aim: Characterize NTM isolated from respiratory samples between 2007-2010 at our center.

Methods: Retrospective analysis of patients followed in our hospital with NTM isolation in at least one respiratory specimen.

Results: NTM were isolated in 108 samples, 68 patients; mean age: 53.5±17.0 years; 63.6% male. Fourteen (20.6%) had HIV, eight with AIDS. Prior respiratory disease was present in 63.2% of patients, most frequently bronchiectasis (14; 32.5%), tuberculosis sequelae (11; 25.6%) and COPD (7; 16.3%). Eleven (26%) had mycobacterium avium complex (MAC), including M. avium and M. intracellulare (7; 39.7%) and M. gordonae (23,33%).

Discussion: M. gordonae was isolated in much higher frequency than that described in literature, unexplained by introduced NOTM species or by potential significant. When compared to MAC, it caused disease in 2 cases. NTM isolation didn’t relate to lung disease in 67.6% of cases. We found a statistically significant association between illness and MAC isolation. Further studies are needed to describe NTM and its clinical significance.

Pulmonary disease caused by non-tuberculous mycobacteria. Descriptive study and comparison with mycobacterium tuberculosis

Sandra Pedro Tejada1, Marcia Alfonso Imicon1, Bogota Vilar Azahabal2, Luis Miguel Sorria Riendas1, Nuria Marina Malanda1, Ines Martinez Rienda2, Israel Lopez Mirones1, Jose Maria Antohual1, Elena Urra Zalbidigoeitia2, Rafael Zacalan Jorge1, 1Pneumology, Cruces Hospital, Barakaldo, Spain; 2Microbiology, Cruces Hospital, Barakaldo, Spain

Aims: To describe the epidemiological, clinical and radiological data of pulmonary disease (PD) caused by non-tuberculous mycobacteria (NTM) diagnosed in a period of 12 years in an area of Vizcaya, and to compare the incidence with the cases of M. tuberculosis (MT).

Material: We reviewed all cases of PD caused by mycobacteria between 1997-2008 in our center, attending a population of 420.000. The diagnosis of NTM PD was conducted according to criteria of ATS.

Results: We found 1019 cases of PD caused by mycobacteria,788 (77.3%) for MT and 231 (22.7%) NTM. 216 M. kanssaii (MK), 1 M. avium complex (MAC), 2 M. abscessus, 1 M. xenopi and 1 M. celatum. NTM PD was more frequent in men (73.2%) and the mean age was 53.9±5.2 years. 7% of patients with MK and 9.1% of patients with MAC had extra pulmonary affection. 36 patients affected HIV coinfection. The annual incidence rate/100.000 of MT infection had the highest peak in 1999 with 22.8 and the lowest in 2008 with 11.5. The highest rate of NTM infection was in 1998 (74.4) and was lowest in 2008 (1.2). The incidence of PD by NTM and MT had a descending tendency in the 12 years studied, which is more remarkable since 2005.

High burden of rapidly growing non-tuberculosis mycobacteria in patients with respiratory disease undergoing elective bronchoscopy

Neranjani Dissanayake1, Dushmantha Madegedara2, Dhammika MagamaArachchi2, Udani Kanarathna2, Duminda Yasaratne2, Chathuranga De Silva2, Chandana Chinthana2, Samadara Nakandala2, Prasanne Wijerathne2, Chathura Wirasinghe1, 1 Respiratory Disease Treatment Unit, Teaching Hospital, Kandy, Sri Lanka; 2 Department of Cell Biology, Institute of Fundamental Studies, Kandy, Sri Lanka

Background: Pathogenicity of pulmonary non-tuberculous Mycobacteria (NTM) is less well understood than that of M. tuberculosis (MTB) complex. Both will show identical results on acid-fast staining (AFS), but culture characteristics are commonly used for differentiation in the local setting.

Objective: To assess the pattern of mycobacterial culture among patients with respiratory illness and negative sputum for AFS, in a pulmonary tuberculosis (PTB) prevalent environment.

Method: Bronchoalveolar lavage samples from 120 patients were inoculated onto solid media (Lowenstein-Jensen and Middlebrook 7H-10) at 280° and 37°C, in both light and dark conditions. All patients were negative for sputum AFS. Indicators for bronchoscopy were bronchiectasis, cavitatory lung disease and smear negative PTB.

Results: 67 patients yielded positive colonies within 8 weeks. 37 colonies were positive for AFS, of which 21 were rapidly growing Mycobacteria (RGM; <7 days) and 6 were slowly growing Mycobacteria (>7 days). Rapid colony growth strongly favours towards NTM. PCR based restriction fragment length polymorphism analyses on NTM are in progress. Concomitant sterile water, instrument cleaner fluid and saline samples did not yield culture growth.

Conclusion: We observed a high prevalence (>25%) of RGM in the study population. This raises major concerns on possible over-diagnosis of PTB leading to inappropriate therapy and false categorization of patients, in limited resource settings where sputum AFS results play a central role in managing PTB in clinical practice.
difference was seen in the clinical course of MAC whether or not steroid was administered for IP.

3398

Transitional change of the relationship between clinical efficacy of treatment for pulmonary MAC disease and drug-sensitivity test for MAC isolated Yoshihiro Kabashi, Masaaki Abe, Keiji Mouri, Yasushi Obase, Naoyuki Miyashita, Mikio Oka. Division of Respiratory Diseases, Department of Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan

Materials and methods: The subjects consisted of 60 patients who satisfied the diagnostic criteria of ATS and received the combination therapy using RPF, EB, SM and CAM. We divided into the former period (24 patients) and the latter period (36 patients).

Results: The average administration dose of CAM has been increased from the former period (800mg/day) to the latter period. Sputum conversion rate has been increased from 63% in the former period to 83% in the latter period. Clinical improvement has been increased from 38% in the former period to 53% in the latter period. The causative microorganisms isolated were M. avium in 35 patients and M. intracellulare in 25. There were no significant differences in the sputum conversion rate, clinical improvement, and drug-sensitivity test between M. avium and M. intracellulare in both periods. The isolated M. avium showed excellent drug-sensitivity to CAM and RPF in both periods. Regarding the relationship between clinical efficacy and MICs of RPF, EB, CAM, and SM, there was a good relationship only for CAM in both periods.

Conclusions: The good clinical effect has been obtained with the increase dose of CAM in the latter period. Because there was no significant difference in the result of drug-sensitivity test for isolated MAC in both periods, we speculated that the increase of administration dose of CAM has been influenced the good clinical effect in both periods.

379. Early wheezing conditions in childhood

3400

Association of wheezing phenotypes in the first 7 years of life with fractional exhaled nitric oxide and lung function in adolescence. The ALSpac study Licensez N, Duggal J, Jonathan A, Hogg J, John A. Henderson. 1Department of Community Based Medicine, University of Bristol, Bristol, United Kingdom; 2Department of Social Medicine, University of Bristol, Bristol, United Kingdom

Background: Patterns of wheezing during early childhood are associated with lung function and bronchial hypersensitivity in mid childhood. Little is known about the associations of early wheezing phenotypes with fractions of exhaled nitric oxide (FeNO), a marker of allergic airway inflammation, and lung function in adolescence.

Methods: This study was based on 6,841 children in a population-based prospective birth-cohort study. Latent class analysis identified 6 wheezing phenotypes (never/infrequent, transient early, prolonged early, late, persistent) based on wheezing patterns from birth to 7 years. FeNO levels and airway function (forced expiratory volume in 1 s (FEV1), forced expiratory volume ratio (FEV1/FVC), mid forced expiratory flow (FEF25-75)) were measured at age 15.

Results: Intermediate onset wheezing (18 months) was the most strongly associated with increased FeNO levels (ratio geometric means 2.01, 95% confidence interval: 1.63, 2.48), compared with the reference group never/infrequent wheezing. Wheezing phenotypes were not associated with FEV1, but showed associations with decreased levels of FEV1/FVC and FEF25-75 (most strongly for persistent wheezing: mean difference −0.50 (−0.62, −0.38) and −0.42 (−0.54, −0.29), respectively).

Conclusions: Wheezing phenotypes with onset after the age of 18 months and persistent wheezing were the most strongly associated with FeNO levels and lung function, respectively, in adolescence. Our results suggest that specific patterns of asthma-related symptoms in early life are associated with markers of lung morbidity at older ages.

International study of wheezing in infants (EISL): How latitude modifies the association between risk and protective factors for recurrent wheeze during the first year of life

Luis Garcia-Marco1, Javier Mallo1, Dicreu Sole1, Paul Brand1, Manuel Sanchez-Solis1, Maria Sanchez-Bahillo1, EISL Study Group. 1Pediatric Respiratory and Allergy Unit, Virgen de la Arrixaca University Children’s Hospital, Murcia, Spain; 2Pediatric Respiratory Medicine, El Pino Hospital, Santiago, Chile; 3Pediatric Allergy, Clinical Immunology and Rheumatology, Federal University of Sao Paulo, Sao Paulo, Brazil; 4Princess Amalia Children’s Clinic, India Klinieken, Zwolle, Netherlands; 5Marcia Health Education and Research Foundation, Marcia, Spain

Background: The influence of latitude on the strength of the association of risk/protective factors of recurrent wheeze (RW) has never been reported.

Methods: The “Estudio Internacional de Sibilancias en Lactantes” (EISL) included 30,093 infants 12 to 15 months of age, recruited from 13 Latin American centres (30,093.030) and from 5 European centres (n=5,063). Adjusted odds ratios (aORs) of factors associated to RW reported previously were used to build a meta-regression between the strength of the aORs of each factor and centre latitude (distance from equator either N or S). The meta-regression was further adjusted for continent and the slope expressed as adjusted regression coefficient (aβC).

Results: We found significant correlations between latitude (the higher the distance from equator the higher the strength of the association) and the magnitude of the aOR between RW and: 1. Cold(s) in the 1st 3 months (aβC =0.19; p=0.004); 2. Nursery school (aRC +0.25; p=0.01); 3. Siblings (aRC +0.024 for additional sibling; p=0.002); and 4. Breast feeding ≥3 months: the higher the latitude the higher the protection (aRC -0.17; p=0.047). Heterogeneity of the strength of aORs between centres was: 73.9% for colds, 67.1% for nursery school, 59.7% for siblings and 22.4% for breast feeding. Latitude explained (by R-squared) much of heterogeneity: 66.1% for colds, 54.9% for nursery school, 83.1% for siblings and 100% for breast feeding.

Conclusion: The magnitude in which some risk or protective factors are associated to recurrent wheeze during the first year of life varies significantly with latitude.

3402

The effect of late preterm birth on longitudinal lung spirometry in children Sarah J. Kotecha1, W. John Watkins2, David Herrick3, Shantini Paranjopyth4, Frank D. Dunstan2, A. John Henderson1, Sailesh Kotecha1. 1Department of Child Health, School of Medicine, Cardiff University, Cardiff, United Kingdom; 2Primary Care and Public Health, School of Medicine, Cardiff University, Cardiff, United Kingdom; 3School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom

Introduction: Rates of preterm birth have increased in most industrialised countries (Goldenbergh, R.L. et al. Lancet 2008; 371:75-84) but data on later lung function of late preterm birth is limited.

Aims and objectives: To compare lung function at 8-9 and 14-17 years in a population-based cohort of children born at 25-32, 33-34 and 35-36 weeks gestation with similar aged children born at term (≥37 weeks gestation).

Methods: From the Avon Longitudinal Study of Parents and Children (ALSPAC, n = 14062), children who had spirometry at 8-9 (n=6712) and/or 14-17 (n=4513) years of age were divided into 4 groups: 25-32, 33-34, 35-36 and ≥37 weeks (term) gestation.

Results: At 8-9 years of age, all spirometry measures (except FVC, in the 25-32 weeks gestation group) were significantly lower in both 25-32 and 33-34 weeks gestation groups compared to term controls (FEV1, mean s-score ± SD -0.46±0.876, -0.498±1.09 and 0.011±1.00 respectively). The 35-36 weeks gestation (FEV1, 0.008±0.008) and term groups had similar values. At 14-17 years of age, most spirometry measures in the 25-33 and 33-34 weeks gestation groups were not different from term controls except lower FEV1, FEF25-75 and FEF25-75/FVC in both 25-32 and 33-34 weeks gestation groups and lower FEV1/FVC in the latter group.

Conclusions: Children born at 33-34 weeks gestation have significantly lower lung function values at 8-9 years of age similar to decrements observed in the 25-32 weeks group although most of these differences were reduced by 14-17 years of age.

3403

Reduced neonatal lung function and wheezing illnesses during the first 5 years of life

Anne van der Gugten1, Cuno Uiterwaal2, Theo Verheij2, Kors van der Ent1. 1Department of Paediatric Pulmonology, Wilhelmina Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands; 2Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

Introduction: Studies about reduced neonatal lung function and wheezing illnesses in childhood showed conflicting results. No study analyzed the association between the single occlusion technique (SOT) and wheezing illnesses during the first 5 years of life.

Objectives: The aim was to assess the association between resistance and compliance of the respiratory system (Rrs, Crs) measured shortly after birth and wheezing-associated primary care consultations during the first 5 years of life, different wheezing phenotypes, and asthma at age 5.

Methods: Infants participate in WHISTLER, a birth cohort on wheezing illnesses. SOT was performed during natural sleep before 2 months of age. Wheezing-associated consultations were collected from the electronic patient file. Poisson regression was used to study the association between Rrs and Crs and the number of consultations. Median Rrs and Crs values of children with different wheezing phenotypes and with and without asthma were compared by non-parametric tests.
**Results:** 549 infants had successful SAT and complete medical files. Every kPa/l/s increase in Rrs was associated with 9% more consultations in the first 3 years of life. Every cPcl/kg increase in Crs was associated with a 17% reduction of consultations in the first 3 years of life and 29% in the 4th-5th year of life. Children with late-onset or persistent wheezing and with asthma had significantly lower Crs values than their peers.

**Conclusion:** An increased neonatal Rrs is associated with more wheezing illnesses during infancy, while a reduced neonatal Crs is associated with more wheezing illnesses during the first 5 years of life, a late-onset or persistent wheezing phenotype, and asthma at age 5.

</tbody>
</table>

\*Adjusted for sex, age, height, weight, prematurity, breastfeeding, heating, cooking, smoking exposure, parental education, type of respiratory illness, and family education level.

**Conclusions:** These results suggest that long-term exposure to PM<sub>10</sub> is associated with lower forced expiratory volume in one second (FEV<sub>1</sub>) and forced vital capacity (FVC) at school-age. Future studies with larger samples are needed to confirm these findings.

Recently, we demonstrated the beneficial effects of bone marrow-derived mononuclear cells (BMDMCs) on lung morphofunction in experimental chronic allergic asthma. Mesenchymal stem cells (MSCs) have the potential to serve as a universal source for replacement of specific cells in several diseases and thus may offer hope as a potential therapeutic intervention for the treatment of the chronic remodeling changes that occur in asthma. This study aimed to compare the therapeutic effects of BMDMCs with MSCs on inflammatory and remodeling processes in experimental chronic allergic asthma. Thirty-six C57BL/6 mice were assigned to two groups. In the BMDMC group, mice were sensitized and repeatedly challenged with ovalbumin. Control mice (C) received saline under the same protocol. C and OVA groups were further randomized to receive saline (SAL), BMDMCs or MSCs (1×10^6) intratracheally 24 h after the last challenge. After one week, airway resistance, viscoelastic pressure, static elastance, as well as the degree of lung inflammation and remodeling (light microscopy and immunohistochemistry) were analyzed. BMDMC and MSC therapies led to a reduction in eosinophil infiltration and fibrosis in airway and lung parenchyma compared to OVA leading to a reduction in airway resistance and viscoelastic pressure. These parameters were more reduced after BMDMCs compared to MSCs. In conclusion, the present model of chronic allergic asthma, both BMDMC and MSC therapies were effective at modulating the inflammatory and fibrogenic processes, however, BMDMC administration led to greater beneficial effect.

Late-breaking abstract: Changes in cortisol levels in the plasma of asthmatic individuals undergoing allergen challenge differentiation isolated early from dual responders

Scott Tebbutt1, Sarah Kam1, Amrit Singh3, Louis-Philippe Bouteil1, Mark FitzGerald1, Gail Gauvreau4, Paul O’Byrne4, Scott Tebbutt1, Sarah Kam1, Amrit Singh3, Louis-Philippe Bouteil1, Mark FitzGerald1, Gail Gauvreau4, Paul O’Byrne4
1The James Hogg Research Centre, University of British Columbia, Vancouver, BC, Canada; 2Center of Pneumologie de l’Hôpital Laval, Université Laval, Sainte-Foy, QC, Canada; 3Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania; 4Department of Medicine, McMaster University, Hamilton, ON, Canada

Allergen inhalation challenge in mild asthmatic subjects induces airflow obstruction, airway hyperresponsiveness and inflammation, and provides a model for hypothesis-generating experiments to understand molecular regulation of these responses. Adult asthmatic subjects (18-55 years of age, with stable, mild allergic asthma, n=14) underwent cat allergen inhalation challenges. All subjects had an early asthmatic response of ≥20% fall in FEV1, and six individuals also had a late phase response of ≥15% fall in FEV1 (dual responders). Blood samples were collected just prior to, and two hours after allergen challenge. We have evaluated the differential changes in gene expression in peripheral blood cells and changes in the plasma metabolome, post-challenge compared to pre-challenge. Amongst other findings, we have demonstrated significantly reduced cortisol levels in the plasma of mild asthmatic subjects post-challenge, compared to pre-challenge (p=0.013). Importantly, this reduction in plasma cortisol was only significant in subjects who had an isolated early asthmatic reaction, rather than in subjects who also went on to develop a late phase asthmatic reaction. Interestingly, this is consistent with gene expression data demonstrating that in isolated early responders only, there is a significant increase in RNA transcript levels for the hydroxysteroid (11-beta) dehydrogenase 2 gene (HSD11B2), post-challenge compared to pre- (p=0.026). The HSD11B2 enzyme converts cortisol to inactive cortisone. Thus, allergen inhalation challenge may improve understanding of pathways and underlying genes associated with asthma.

Conclusion: IL-17 levels and PB neutrophil chemotaxis were increased in allergic patients challenged with DP. IL-17 is significant regulating neutrophil chemotaxis in patients with AR and AA.
Results: Neutrophil apoptosis before and after BAC was more intensive in HI group compared to patients with AR and AA (table). Neutrophil apoptosis in AA group was more inhibited after BAC in comparison with AR group. Conclusion: The preliminary results showed that neutrophil apoptosis was decreased in patients with AA and AR compared to HI before and after BAC. This finding lets us suggest, that specific allergen has inhibitory effect on neutrophil apoptosis and neutrophils may play an important role in allergic inflammatory process.

3411 Late-breaking abstract: House dust mite triggering of Dectin-2 is critical for the initiation of allergic airway inflammation

Deborah Clarke1, Martin Foster2, Nicola Davis1, Stephanie Heasman1, Arthur Lewis1, Ian Anderson1, Matthew Steeman3, Richard May1, Matthew Robinson1
1Department of Respiratory, Autoimmunity and Inflammation, MedImmune Ltd, Cambridge, United Kingdom; 2Department of Pathology, Safety Assessment UK, AstreZeneca R&D Charwood, Loughborough, Leicestershire, United Kingdom; 3Research Histology, MedImmune Ltd, Cambridge, United Kingdom

Introduction: How the immune system senses aeroallergens and triggers an aberrant inflammation is poorly understood. Dectin-2 is a house dust mite (HDM)-sensing pattern recognition receptor, and its expression on dendritic cells is required for the Th2-skewed adaptive response to HDM.

Objective: To define the role of Dectin-2 in HDM-induced allergic airway inflammation and its expression in biopsies from asthmatic patients.

Results: In a 3 week mouse model of repeated intranasal HDM challenge, pro-inflammatory cytokine production by dendritic cells was detected within the first 24 hours of challenge. This was associated with recruiting lymphocytes and eosinophils were elevated in the airways of allergic GF mice. The resulting cellular infiltrate and cytokine production were measured. (SPF) or recolonized mice by sensitization and challenge with ovalbumin (OVA).

Methods: To define the mechanism by which Dectin-2 triggers HDM-induced inflammation, we conducted in vivo experiments using cultured alveolar macrophages. These indicated that Dectin-2 was necessary for the induction of cysketyl leukotrienes, as reported for dendritic cells, but not chemokines or cytokines. Furthermore, we demonstrated in our single challenge model that leucine, an inhibitor of leukotriene production, produced a similar effect as Dectin-2 blockade. Finally we found a marked increase in the number of Dectin-2 positive cells in bronchial biopsies from asthmatic subjects when compared to normal controls.

Conclusions: Alveolar macrophage sensing of HDM by Dectin-2 elicits the production of cysketyl leukotrienes, and this axis is key for the initiation of allergic airway inflammation. Dectin-2 is associated with asthma.

3412 Late-breaking abstract: Dyserregulation of allergic airway inflammation in the absence of microbial colonization

Anke Sichelstein1, Tina Herbst2, Nicola Harris2, Benjamin Marsland1
1Service de pneumologie, CHU, Lausanne, Switzerland; 2Global Health Institute, EPLF, Lausanne, Switzerland

Rationale: The incidence of allergic disorders is increasing in developed countries and has been associated with reduced exposure to microbes and alterations in the commensal bacterial flora.

Objectives: To ascertain the relevance of commensal bacteria upon the development of an allergic response, we utilized a model of allergic airway inflammation in germ-free (GF) mice that lack any exposure to pathogenic or non-pathogenic microorganisms.

Methods: Allergic airway inflammation was induced in GF specific pathogen free (SPF) or reconstituted mice by sensitization and challenge with ovalbumin (OVA). The resulting cellular infiltrate and cytokine production were measured.

Measurements and main results: Our results show that the total number of infiltrating lymphocytes and eosinophils were elevated in the airways of allergic GF mice as compared to control SPF mice, and that this increase could be reversed by re-colonization of GF mice with the complex commensal flora of SPF mice. Exaggerated airway eosinophilia correlated with increased local production of Th2 associated cytokines, elevated IgE production and an altered number and phenotype of conventional dendritic cells (cDC). Regulatory T cell populations and regulatory cytokine levels were unaltered but GF mice exhibited an increased number of basophils and decreased numbers of alveolar macrophages (AM) and plasmacytoid dendritic cells (pDC).

3413 Late-breaking abstract: Relationship with hemoglobin A1c and exacerbations of COPD: A preliminary study

Haruka Aoki, Takeshi Hisada, Hiroaki Tsunrini, Reiko Yoshino, Hidemasu Kawabar, Tamotou Ishizuka, Kunio Dobashi, Masatomo Mori

Department of Medicine and Molecular Science, Gunma University Graduate School of Medicine, Maebashi, Japan

Background and objective: Hyperglycaemia during hospital admission is associated with poor outcomes in patients admitted with acute myocardial infarction, stroke and pneumonia. Systemic inflammation may represent a possible cause of glycolytic metabolic disorder. We studied that association Hemoglobin A1c with an increased risk of acute exacerbation of COPD (AECOPD).

Methods: Patients with COPD were prospectively enrolled and followed between 2010 and 2011. Medical records, HbA1c, fasting glucose and metabolic markers were assessed in 29 patients.

Results: A total of 29 patients (mean age of 78.2 years) were recruited, 11 with AECOPD and 18 without. Clinical data were collected from the patients. HbA1c levels of AECOPD patients were significantly higher on entry point compared with other patients (5.783±0.2638; 4.983±0.1778, respectively p=0.0361). Moreover, there was a trend for increased length of stay and frequency of admissions in patients with higher levels of HbA1c. (4.5%<HbA1c<5%; 5%<HbA1c<5.5%; 5.5%<HbA1c<6%; HbA1c<6%, 15days (0.9/year (y)); 26days (1/y); 23days (1.3y); 30days (2.3y), respectively).

Conclusion: Previous study revealed that comorbid diabetes prolongs length of stay and increases risk of death in patients with AECOPD. However, less evidence exists for relationship of HbA1c with AECOPD. For the first time our study demonstrates that HbA1c is a prognostic factor associated with AECOPD. Taken together with a previous study that revealed a similar trend, our study suggests that further studies are now required to elucidate the reasons for these poorer outcomes, in particular whether glycaemic control or input control is responsible, as these are potentially modifiable factors.

3414 Late-breaking abstract: Further studies on the mechanism of action of doxofylline

Thierry Jolal1, Clive Page2, Luigi Allegra1
1Scientific Director, CERE 1E, Cherbourg, France; 2Sackler Institute of Pulmonary Pharmacology, Institute of Pharmaceutical Science, King’s College London, London, United Kingdom

Xanthines such as theophylline have been used in the treatment of lung diseases since the early 1900’s, but have a major drawback of a very narrow therapeutic window and many drug-drug interactions. This means that regular plasma levels often have to be obtained and can make the use of theophylline problematic. With the increasing availability of other classes of drugs for the treatment of respira-toary diseases, this has limited the use of xanthines, despite their clean clinical benefit in the treatment of patients with asthma and COPD. Doxofylline is a xanthine molecule having both bronchodilator and anti-inflammatory activity, with a lower improved therapeutic window over conventional xanthines such as theophylline. However, the mechanistic basis of this improved therapeutic window is not understood. The present study has investigated the ability of doxofylline to inhibit human recombinant PDE and HDAC enzymes, and find to adenose receptor assays in vivo in comparison with theophylline. We have found that adenose receptor binding that was not shared by doxofylline. Our results suggest that doxofylline may have a wider therapeutic window than theophylline due to a lack of adenose receptor antagonism. Neither drug had any significant inhibitory effect on HDAC enzymes over a wide range.

Additionally, in contrast to doxofylline, theophylline showed a significant effect on PDE3. It has been suggested that the ability of theophylline to inhibit HDAC enzymes may contribute to the unwanted cardiovascular effects observed at higher serum concentrations. The lack of effect of doxofylline on PDE3 may also help explain its improved tolerability profile on the cardiovascular system.
Flow-volume loops in central airway obstruction
Liliana Raposo1,2, António Bugalho1,2, Maria João Gomes4,3, Servio Pneumologia, Faculdade de Ciências Médicas Universidade Nova de Lisboa, Lisboa, Portugal; 2Área de Cardiopneumologia, Escola Superior de Saúde da Cruz Vermelha Portuguesa, Lisboa, Portugal; 3Pneumologia, Faculdade de Ciências Médicas Universidade Nova de Lisboa, Lisboa, Portugal; 4Centro de Estudos Pés-Gravídicos, Faculdade de Ciências Médicas Universidade Nova de Lisboa, Lisboa, Portugal

Introduction: Central airway obstruction (CAO) leads to significant morbidity and mortality. In the last 40 years flow-volume loops (FVL) have been used as a noninvasive method to evaluate this condition although bronchoscopy is the gold standard. Few studies were made to verify the sensitivity and specificity of FVL in detecting CAO, or to investigate the morphological and quantitative changes of the curve in relation to location, type and degree of obstruction.

Methods: Patients with an indication to perform bronchoscopy were selected consecutively. Bronchoscopy and FVL were carried out with a maximum interval of 7 days. Four experts, blinded to the quantitative data, were used to assess the morphology of FVL (suggestive or non-suggestive of CAO) and an independent element established the quantitative and morphological criteria (intra, extrathoracic variables and fixed).

Results: 82 patients were studied, 36 (44%) with CAO. The sensitivities and specificities in detecting CAO were, respectively: 91.3% and 88.9% for the quantitative criteria of FVL; 93.5% and 30.6% concerning the morphological criteria; 95.7% and 86.1% if there was an aggregation of quantitative and morphological criteria. In patients with CAO the most common quantitative criteria were FEF50/FIF50 (83%) and FEV1/PEF (86%). They correlated with localization, degree and type of obstruction.

Conclusions: The morphology of the FVL has a good sensitivity but low specificity in detecting CAO. Quantitative criteria of the FVL have a high sensitivity and specificity. In clinical practice one should always use an aggregation between the quantitative and morphological criteria.

Survival analysis can help determine which TLco prediction equations to use for patient data
Helen Ward1, Robert Stockley2, Martin Miller3, Respiratory Medicine, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; 2ADAPT Project, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

Choosing which prediction equation to use for lung function data can be a problematic. In Europe the ECCS equations are commonly used but more recent ones are available and may be more applicable. To help decide which TLco prediction equations would be best for our data we extracted the earliest results for subjects from our lung function database who had a full set of all tests and determined their survival up to 29/12/2009. We calculated TLco results as standardised residuals (SR) using equations from ECCS (1993), RO Crapo (1981), A Miller (1983) and CM Roberts (1991) and used deciles of these results and of age and included sex to predict survival. There were full data for 5626 subjects (48% women) with mean (SD) age 59.3 yrs (14.7), mean survival 4.4 yrs (SD 2.6, range 0 to 24) with 2049 deaths. Using the ECCS equations the mean (range) of SR values for FEV1 was -1.6 (-7.3 to +3.4), for FVC was -0.8 (-6.3 to +3.6) and for TLco was -1.5 (-6.5 to +6.2). The best Cox survival prediction model (highest Chi² value) was with the Miller equations as shown in the table of hazard ratios (95% CI) for death associated with oldest age decile, worst TLco decile and sex.

We conclude that for our UK data the Miller equations from the USA for TLco are the best related to subsequent survival and so should be considered for determining if results are abnormal.

418 Evaluating the FVC-reference equation for female
Jellien Makonga-Braaksma, Remco Boksem, Pim Dalinghaus, Pulmonary Function Department, Meander Medisch Centrum, Amersfoort, Netherlands

Introduction: At World Spirometry Day we measured lungfunction in hospital staff (n=99, m=40, l=59) in Amersfoort, the Netherlands. We were struck by the high scores in FVC in the female group. In the group of healthy, never-smoking female (n=36) (Ages 18-64) we discovered that mean FVC was 114% pred. Other studies about this subject show that reference values for male have not enough correction for aging, but are quite correct for height.

Aim: Understand which element of the reference-equation for female doesn’t fit properly, and search for alternatives.

Methods: First we analysed the ECCS reference equation for FVC in female: 4.3H - 0.026A - 2.89 (H=height in m, A=age in y) (ERD 1993.) Then we made a statistical analysis for FVC% pred. (y) and age (x) and FEV1% pred. (y) and height (x). Analysis: The statistics show that female from 18-44 yrs. have a lower FVC% pred. (n=16, mean FVC = 106.96%) than female from 45-64 yrs. (n=18, mean=120% pred.) We see that female between ages 45-64 have a moderate height (160-170cm) but the highest scores. There is a linear relation between age and FVC% pred.<p>0.055 Concerning height: Only in female with real high FVC% pred. (=>120%) we see a relation between height and FVC% pred.(p<.009) Analyzing the equation we discovered that for tiny female a volume is subtracted for aging as there is in taller female and even in male.

Conclusion/Discussion: Aging of the lung should be related to the volume of that specific lung. We have high expectations of the new reference equations introduced by taskforce of Global Lung Initiative. In the clinical setting there’s a risk of underestimating restrictive patterns in tiny elderly female when applying the ECCS reference equations.

419 How many forced spirometry efforts are useful in moderate to severe COPD patients?
Juergen Reintzeldt. Product Management, eResearchTechnology GmbH, Hoechberg, Germany

The 2005 ERS/ATS guidelines on spirometry have established a maximum number of 8 efforts in a forced spirometry test. The aim of this work was to evaluate which effort produces the highest value for FEV1, FVC, PEF, and FEV1/VC in COPD patients.

We used the data collected in a phase II multicenter clinical trial (TESRA, sponsored by F. Hoffmann – La Roche Ltd) to evaluate the parameter trend in multiple efforts of forced spirometry in moderate to severe COPD patients with emphysema. All of the 73 test centers in 12 countries were equipped with the identical device (MasterScreen PFT, CareFusion, Hoechberg, Germany). The data was collected electronically and reviewed for quality and acceptability by a central overreader. 6 075 test sessions (screening and treatment) with 20 482 valid efforts from 1 183 patients were evaluated. On average 3.4 valid efforts were performed per test.

The per effort parameter values were expressed as a percentage of the highest (best) value per test session. The median values per effort number across all tests ranged from 95% to 99% for FEV1, FVC and FEV1/VC. The highest median values were achieved in efforts 3 and 4. For PEF the median values ranged from 92% to 98%, with the highest values in the first effort. FEV1 and PEF showed a marked decrease in late efforts.

The drop in the PEF and FEV1 values illustrates the increasing fatigue of the COPD patients. The relative FEV1 values were lower than the relative FVC values, indicating that it is more complicated for patients to sustain good FEV1 values. Unless errors in the technique are observed, it is unlikely to achieve higher values after the 5th effort.

420 Vital capacity after lung transplantation
Maartje Horstman, Citta Zaat, Ton Provily, H.C. Hoogsteden. Department of Pulmonary Medicine, Erasmus Medical Center, Rotterdam, Netherlands

Introduction: The size of the Vital Capacity (VC) is determined by powers between thorax and lung. After lung transplantation it will take some time before an equilibrium is settled between thorax mobility and lung compliance. VC therefore increases over time until a maximum is reached (VCmax). Aims: The aim of our study was to investigate how long it takes to reach VCmax. Also we wanted to find out if age at transplantation, pre-transplantation value of FEV1/VC, single or double lung transplantation and gender influenced the duration to reach VCmax.
3421
Recurrent for referral for pulmonary function testing: An audit of four Australian adult lung function laboratories
Jeffrey Pretto1,2, Paul Guy3, Danny Brazzale4, Jane Williams5, Michael Hendey5,6, 1Department of Respiratory & Sleep Medicine, John Hunter Hospital, Newcastle, New South Wales, Australia; 2Department of Respiratory & Sleep Medicine, Monash Medical Centre, Clayton, Victoria, Australia; 3Department of Respiratory & Sleep Medicine, University of Newcastle, Newcastle, New South Wales, Australia; 4School of Medicine & Public Health, University of Newcastle, Newcastle, New South Wales, Australia; 5Department of Respiratory & Sleep Medicine, Monash Medical Centre, Clayton, Victoria, Australia; 6School of Medicine, University of Newcastle, New South Wales, Australia.

Pulmonary function (PF) testing provides a cornerstone for diagnosis and management of most respiratory conditions. Accurate interpretation of test results is an important component of the final report. As part of developing a structured approach to interpretation of PF results we wished to characterise primary reasons for referral testing in a range of PF laboratories.

Methods: Three public university-affiliated PF labs and one private lab using similar PF databases participated. Reasons for performance of PF tests were extracted from the databases and collated for analysis. Over 5,000 consecutive tests were evaluated from each lab.

Results: The main reason for referral was found in 83% of 24,602 test results and categorised. The major categories were follow-up of known respiratory disease (53% of 20,308 tests), investigation of specific symptoms (18%), and assessment of lung function (13%). The absence of clinical complications and the maintenance of stable lung function over a 5-y period post-BT in patients with severe refractory asthma suggest long-term safety of the procedure out to 5 y. There were no incidences of pneumothorax, intubation, mechanical ventilation, cardiac arrhythmias, or death as a result of BT treatment over the 5 y.

Conclusions: The absence of clinical complications and the maintenance of stable lung function over a 5-y period post-BT in patients with severe refractory asthma suggest long-term safety of the procedure out to 5 y.

3422
Safety of bronchial thermoplasty out to 5 years in patients with severe refractory asthma: Research in severe asthma (RISA) trial
Michel Lavollette, Ian Pavord, Neil Thomson, Robert Niven, Gerard Cox, Paul Corris, Ian Fan-Chung, Department de Pneumologie et de Chirurgie Thoracique, IUCPQ, Quebec, QC, Canada; Department of Respiratory Medicine and Thoracic Surgery, University of Leicester, Leicester, United Kingdom; Division of Immunology, Infection & Immunology, University of Glasgow, Glasgow, United Kingdom; Respiratory Medicine, Respiratory Clinical Trials, London, United Kingdom.

Efficacy of high-dose leukocytapheresis using extracorporeal circulation through a large leukocyte-removal filter column in patients with refractory asthma
Tamoto Ishizuka1, Akko Koske2, Motoaki Hatori3, Shinichi Matsuzaki1, Yosuke Kamide1, Haruka Aoki1, Takeshi Hisada1, Hiroaki Tsumurak1, Akihiro Ono1, Yasuhiko Koga1, Kunio Dobusha2, Kazuhiro Suzuki1, Masatomo Mori1, Department of Medicine and Molecular Science, Gunma University Graduate School of Medicine, Maebashi, Japan; 2Equipment Division of Medical Engineering, Gunma University Hospital, Maebashi, Japan; 3Department of Unaglo, Gunma University Graduate School of Medicine, Maebashi, Japan; 4Faculty of Health Sciences, Gunma University, Maebashi, Japan

Leukocytapheresis (LCAP) as well as granulocyte and monocyte adsorptive apheresis (GMA) using extracorporeal circulation through the column has been used to treat inflammatory bowel disease and rheumatoid arthritis in Japan. We previously reported that GMA improved the peak expiratory flow rate (PEFR) in patients with severe asthma. To evaluate the efficacy of high-dose leukocytapheresis (pulse LCAP) using a large leukocyte-removal filter column (Cellsorba® CS-180S, Asahikasei Kuraray Medical, Tokyo, Japan) in patients with refractory asthma, we conducted a clinical trial. Pulse LCAP was performed 2 sessions at 1-week interval and 5 L of blood was filtered per session. The average PEFR during the 4 weeks just after the second LCAP in each patient was compared with that during the 4 weeks just before the first LCAP as a primary end point. The sum total of asthma control test (ACT) score at 4 weeks after the second LCAP was compared with that just before the first LCAP as a secondary end point. We evaluated the change of the fraction of exhaled nitric oxide (FENO) in each patient before and after pulse LCAP as a biomarker of eosinophilic airway inflammation. Five patients fulfilled the ATS criteria for refractory asthma participated in this trial up to now. The morning PEFR and the ACT score were increased in all patients. Although FENO was abnormally increased in four patients in spite of the standard therapy, it was decreased after pulse LCAP. Pulse LCAP might serve as a non-pharmacological strategy to induce clinical improvement in patients with refractory asthma through its unique anti-inflammatory effects.

382. New treatments for airway disease

3424
The effect of GSK2190915, a 5-lipoxygenase activating protein inhibitor, on the allergic induced asthmatic response
Virginia Norris1, Jane Bentley1, Sandra Kent1, Malcolm Boyce2, Zatana Diamant1, Dave Singh1, Brian O’Connor1, Drug Discovery, Glasssmith&Kline, Stevenage, United Kingdom; 2Clinical Pharmacology, Hammersmith Medicines Research, London, United Kingdom.

Objective: To assess the effect of GSK2190915 on the allergic-induced asthmatic response.

Methods: 19 eligible patients with mild asthma were enrolled and completed this 4-centre, double-blind, 2-way crossover study. They took 100 mg GSK2190915 and placebo orally once daily for 5 days, in randomised order. On Day 3 they had an inhaled allergen challenge and on Days 4 and 6 they had induced sputum collection.

Results: GSK2190915 attenuated the early (0-2 hours) and late (4-10 hours) asthmatic response to inhaled allergen compared to placebo. Following GSK2190915, the mean% attenuation of the placebo response to inhaled allergen for the minimum and weighted mean FEV1 (0-2 hours) was 33.3% and 62.6%, respectively, and the
mean% attenuation of the placebo response to inhaled allergen for the minimum and weighted mean FEV1 (4-10 hours) was 15.8% and 22.7%, respectively. There was a significant attenuation of the allergen induced increase in spurt percent eosinophil count on Day 4 following GSK2190913 compared to placebo; the treatment difference (95% CI) was -9.95% (±18.13, -1.77). There was a >-90% reduction in spurt LTBB4 on Days 4 and 6 following treatment with GSK2190913 compared to placebo. Median spurt LTBB4 (pg/mL) was 524 and 837 on Days 4 and 6 following placebo, and 31 and 18 on Days 4 and 6 following GSK2190915. Safety and tolerability were good.

Conclusion: GSK2190915 shows potential as a treatment for asthma. ClinicalTrials.gov identifier NCT07748306

3425
Phase II randomized, double-blind, placebo-controlled study of tralokinumab, an anti-IL-13 monoclonal antibody, in moderate to severe asthma
Edward Piper1, Christopher Brightling2, Robert Niven3, Chad Ob1, Raffaella Faggioni1, Kwai Poon1, Dewei She1, Chris Kell1, Richard May1, Gregory Geha3, Nestor Molinof,1 1Clinical Development, MedImmune, Gaithersburg, MD, United States; 2Institute of Lung Health, University of Leicester, Leicester, United Kingdom; 3University Hospital of South Manchester, University of Manchester, Manchester, United Kingdom; 4Formerly with Clinical Development, MedImmune, Gaithersburg, MD, United States

Background: IL-13 is hypothesized to be a critical mediator in the development and maintenance of the asthma phenotype.
Aim: To assess clinical activity and safety profile of tralokinumab (TK; CAT-354), a human IgG4 monoclonal antibody that specifically neutralizes IL-13.
Methods: After a 2-week run-in, 194 subjects (52% atopic) with uncontrolled moderate-severe asthma despite standard controller treatment (ACQ ≥ 6 ± 3 exacerbation in last year) received SC TK (150 mg, 300, or 600 mg) or placebo (PBO) every other week (7 doses) in addition to continued controller treatment. The primary endpoint was change in ACQ-6 score at week 13 (combined TK groups vs PBO).
Results: At baseline mean (SD) age was 47 yr (10.8), ACQ-6 score was 2.7 (0.6), and proportion of exacerbation-free subjects was 28%. At Wk 24, NV A237 numerically reduced the rate of moderate/severe exacerbations compared with NV A237 vs PBO (0.43 vs 0.59/yr; rate ratio [RR] 0.72; p=0.071).
Conclusion: In patients with moderate-to-severe COPD, compared with placebo, NV A237 50 μg OD or placebo (PBO) via a low-resistance single-dose dry powder inhaler (Concept1 device) for 26 wks. In addition to bronchodilatation (primary efficacy endpoint was trough FEV1, at 12 wks), the effect on COPD exacerbations and related hospitalizations was assessed using a Cox regression model.

3426
Efficacy of an anti-IL13 monoclonal antibody, lebrikizumab, in adults with inadequately controlled asthma is enhanced in those with high periostin levels
1Clinical Development, MedImmune, Gaithersburg, MD, United States; 2Respiratory Medicine, Pulmonary Research Institute of Southeast Michigan, Livonia, MI, United States; 3Respiratory Medicine, Novartis Horsham Research Centre, Horsham, West Sussex, United Kingdom; 4Respiratory Medicine, Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Introduction: COPD exacerbations, especially those leading to hospitalization, have a significant impact on patients’ quality of life and long-term prognosis. We examined the influence of the non-daily (QD) long-acting muscarinic antagonist NVA237 (glycopyrronium bromide) on exacerbations of COPD.
Methods: Patients with moderate-to-severe COPD were randomized (1:1) to double-blind NVA237 50 μg OD or placebo (PBO) via a low-resistance single-dose dry powder inhaler (Concept1 device) for 26 wks. In addition to bronchodilatation (primary efficacy endpoint was trough FEV1, at 12 wks), the effect on COPD exacerbations and related hospitalizations was assessed using a Cox regression model.
Results: 822 patients were randomized: 80.5% completed. Mean age was 63.9 yrs, mean post-bronchodilator FEV1, 54.6% predicted (FEV1/FVC 0.5). Compared with PBO, NVA237 significantly prolonged the time to first moderate/severe COPD exacerbation (hazard ratio [HR] 0.69; 95% confidence interval [CI] 0.50-0.93) and the time to first severe COPD exacerbation leading to hospitalization (HR 0.35, 95% CI 0.14–0.85; p=0.022). NVA237 also significantly reduced the percentage of hospitalizations due to COPD exacerbation (odds ratio [OR] 0.34; 95% CI: 0.19-0.62; p<0.001).
Conclusion: In patients with moderate-to-severe COPD, compared with placebo, NVA237 50 μg once daily significantly prolonged the time to first moderate/severe COPD exacerbation and reduced the percentage of hospitalizations due to COPD exacerbation.

3428
Pleiotropic effects of add-on atorvastatin therapy during the treatment of COPD patients
Robert Mroz1, Agnieszka Tycinska2, Lukasz Minarowski1, Joanna Bierla1, Pawel Lisowski2, Bozena Sobiczewicz2, Elzbieta Chyczewska2, Wlodzimierz Musial2, William MacNee5, 1Pneumology Department, Medical University of Białystok, Białystok, Poland; 2Cardiology Department, Medical University of Białystok, Białystok, Poland; 3Department of Physiological Sciences, Warsaw University of Life Sciences - SGGW, Warsaw, Poland; 4Department of Molecular Biology, Institute of Animal Breeding, Zakrzewiec/Zebrzydowice/Warsaw, Poland; 5ELEGI CoI Research Labs, UoEMBC Centre for Inflammation Research, The Queen’s Medical Research Institute, Edinburgh, United Kingdom

The potential role of statins in treating COPD is controversial and it is unclear what anatomic COPD lesions patients affect. We have performed a prospective study to compare Atorvastatin 40mg once daily for three months in thirteen COPD patients (8 ex-smokers (ExSm) and 5 current smokers (CurrSm)). Transbronchial lung biopsy was carried out at baseline and after treatment. Twelve subjects, 11 males and 1 female, mean age 64.58 (min 56, max 78) completed the study and 48 paired biopsies were available for analysis. Lung function and cardiopulmonary exercise tests, SGRQ, 6MW test, and Holter EKG monitoring were performed, and serum lipids and hs-CRP were measured. Lung biopsy specimens were processed for histology, immunohistochemistry with anti CD45, CD11b, P-selectin, ETAR, and ET-1 antibodies. 8-iso-prostanate levels and differential cell count were measured in induced sputum.

Results: Symptoms significantly improved. There was no significant change in FEVI, but IC improved (In ExSm: from 55.54% predicted (%) to 64.4-0.01, In ExSm: from 81.93% to 89.5%, p=0.05, before and after therapy, respectively). TGV decreased from 119.92% to 113.69%; p<0.05, and RV/TC improved in ExSm: from 44.01% to 40.07%, p=0.05 before and after therapy, respectively. In lung biopsy there were significant decreases in inflammatory cells numbers, CD4+ cells decreased in CurrSm from 30.40% to 20.95% and in ExSm, from 61.40% to 18.94%, p<0.05 before and after treatment, respectively. The expression of CD11b, P-selectin, ETAR, and ET-1 were also decreased after therapy. These data indicate that the use of atorvastatin may have potential beneficial effects in COPD patients through an anti-inflammatory mechanism.

3429 Beta-blockers in chronic obstructive pulmonary disease – A retrospective cohort study
Philip Short1, Douglas Elder2, Peter Williamson1, Samuel Lipworth3, Stuart Schenbrie1, Brian Lipworth1, 1Asthma and Allergy Research Group, University of Dundee, Dundee, United Kingdom; 2Cardiovascular Medicine Research Group, University of Dundee, Dundee, United Kingdom; 3Rattr Medical School, University of St Andrews, St Andrews, United Kingdom; 4Department of Respiratory Medicine, Perth Royal Infirmary, Perth, United Kingdom

Background: Beta-blockers are avoided in COPD patients.
Objectives: We examined the use of beta-blockers and their relationship with established stepwise pharmacological managements for COPD assessing their effects on mortality, exacerbations and pulmonary function.
Methods: Retrospective cohort study using a disease specific database of COPD patients (TARDIS) linked to NHS databases providing information on hospital admissions, drug prescriptions and death. Adjusted Hazard ratios were calculated through Cox Proportional Hazard Regression after correction for covariates, including history of overt cardiovascular disease.
Results: 5,977 patients, mean follow up 4.35 years, mean age 69.1 years, 88% of beta-blockers were cardio selective. There was a 22% overall reduction in all-cause mortality with beta-blocker use. Furthermore there were additive benefits of beta-blockers on all-cause mortality at all COPD treatment steps. Compared to controls the adjusted hazard ratio (95%CI) for all-cause mortality was 0.28 (95%CI 0.21 to 0.39) for inhaled corticosteroid + long acting beta-agonist + long acting anti-muscarinic + beta-blocker versus 0.43 (95%CI 0.38 to 0.48) without beta-blocker. There were similar trends showing additive benefits of beta-blockers in reducing oral steroid use and respiratory hospital admissions. Beta-blockers had no deleterious impact on FEV1 or FVC at all treatment steps when given with a LABA or LAMA.
Conclusions: Our study suggests beta-blockers may reduce mortality and exacerbations when added to established inhaled therapy for COPD, independently of overt cardiovascular disease and cardiac medications, and without adverse effects on pulmonary function.

383. Pathobiology of experimental pulmonary hypertension

3430 Late-breaking abstract: Intracellular mechanisms behind the effect of C-reactive protein on proximal vascular cells of CTEPH patients
Marijke Wynants1, Rozenn Quack1, Bart Meys2, Marion Drexler1, 1Respiratory Diseases, ULeuven, Leuven, Belgium; 2Cardiac Surgery, UZ Leuven, Leuven, Belgium

Chronic thromboembolic pulmonary hypertension (CTEPH) is associated with vascular remodeling and inflammation. Our latest results showed that C-reactive protein (CRP) could contribute to vascular remodeling and endothelial dysfunction in pulmonary vascular cells of CTEPH patients. We aimed to investigate the intracellular mechanisms responsible for the effect of CRP on CTEPH pulmonary vascular cells. Pulmonary proximal arterial endothelial (EC) and smooth muscle cells (SMC) were isolated from patients with CTEPH. After stimulation with CRP, total RNA was extracted from CTEPH-EC and CTEPH-SMC and first stand cDNA was generated. A RT2 profiler PCR Array (SABioscience) was used to evaluate the expression of 84 key genes related to NFκB-mediated signal transduction. Different genes from the NFκB pathway were up- or downregulated in CRP-stimulated CTEPH-EC and CTEPH-SMC. In CRP-stimulated EC isolated from 5 different CTEPH patients, the serotonin receptor 1B was significantly downregulated (p=0.012) and the serotonin receptor 1D was significantly upregulated (p=0.012) compared to not stimulated CTEPH-EC. CRP significantly downregulated the toll-like receptor 4 (p=0.032) and inhibitor of kappa B light polypeptide (p=0.025) in CTEPH-EC. In CRP-stimulated SMC isolated from 4 different CTEPH patients, mucosa associated lymphoid tissue 1 (p=0.038) and B-cell lymphoma 10 (p=0.012) were significantly upregulated. These results suggest an involvement of the NFκB pathway in mediating the effects of CRP on vascular cells of CTEPH patients.

3431 Human pulmonary arterial hypertension bone marrow-derived CD133+ myeloid progenitors induce vascular remodeling in immunodeficient mice
Kewal Assoongh1, Samar Farha2, Alan Lichten1, Jacqueline Sharp1, Deepa George1, Brian Graham1, Michaela Aldred3, Karl Thel3, James Loyd4, Robin Tudor5, Serpl Erzurum1, 1Pathobiology, Cleveland Clinic, Cleveland, United States

Severe remodeling of the pulmonary artery is the hallmark of idiopathic pulmonary artery hypertension (IPAH). Myeloid CD133+ proangiogenic progenitors, which oversee vascular homeostasis, are increased in IPAH. We hypothesized that IPAH CD133+ cells are derived from a predominantly myeloid bone marrow (BM) stem cell that promote the pathologic vascular pulmonary remodeling. CD133+ cells sorted from IPAH, unaffected family members or healthy control BM aspirates, were engrafted into immunodeficient mice and analyses were performed after 7 weeks or if mice became moribund. Recipients of PAH or unaffected family member CD133+ cells had higher engraftment and myeloid differentiation as indicated by higher human CD45+ and CD33+ cells. Mice engrafted with PAH CD133+ cells had higher plasma von Willebrand Factor (vWF) as compared to control mice, indicating endothelial activation, and demonstrated higher morbidity and mortality. Histological examination of organs revealed cardiac and pulmonary remodeling in PAH recipients, but no remodeling in the control group. Tissue remodeling included in situ thrombi, muscularization of pulmonary arteries, right ventricular hypertrophy, infarction and ischemia. PAH recipients had a 2-fold increased microvessel density in lungs but not in heart or liver. Lung microvesSEL density correlated to circulating human progenitors in the mouse circulation. Collectively, the data suggest that the development of PAH precedes CD133+ proangiogenic myeloid progenitor cell proliferation that contributes to the progression and/or pathogenesis of PAH, possibly through endothelial cell injury/plaque activation.

In the failing RV, IL-1α, IL-1β and TNF-α expression were locally increased along with increased circulating levels of TNF-α. RV capillary densities were similar between the 2 groups, while gene expressions of VEGF and angiotensin-2 were decreased in the failing RV tissue. Prolonged left-to-right shunting in pigs does not further aggravate PAH, but is a cause of RV failure, which appears related to an activation of apoptosis, hypertrophy and inflammation.

3433 Expression and role of the nerve growth factor NGF in pulmonary hypertension
Véronique Freund-Michel1,2, Mathilde Dubois1,2, Diana Dahau1,2, Arnaud Courtois1,2, Roger Martin1,3, Jean-Pierre Savineau1,3, Bernard Muller1,2, 1I1045, INSERM, Bordeaux, France; 2Université, Bordeaux Segalen, Bordeaux, France

Introduction: Our previous studies showed an increased NGF expression in animal models of pulmonary hypertension (PH) and suggested a role for NGF in various aspects of this disease. We have studied here expression of NGF and its receptors in human PH, and investigated whether administering anti-NGF blocking antibodies in vivo prevented some pathological aspects in a rat PH model.
Methods: NGF and inflammatory cytokine secretion was assessed by ELISA in human pulmonary arteries (PA) from controls or from patients with secondary PH. Expression of NGF receptors (TrkA and p75NTR) was assessed by Western blotting. In the rat, PH was induced by monocrotaline (MCT, 71, 60mg/kg ip), with or without administration of anti-NGF blocking antibodies (J0, J2, J7, 10μg/kg ip). Pulmonary arterial pressure (Pap) and Fulton index were assessed at J28. PA medial wall thickness was evaluated on lung sections after hematoxylin and eosin staining. PA reactivity to phenylephrine or prostaglandin E2 (PGE2a) was assessed ex vivo.
Results: Significant increase in expression of NGF and its receptors was observed in PA from patients with secondary PH compared to controls. In the MCT-treated
rat, anti-NGF blocking antibodies significantly reduced Pap, Fulton index, cytokine secretion, PA medial wall thickness, and totally prevented PA hyperreactivity to phenylephrine or PGF2α.

**Conclusion:** Our data show that expression of NGF and its receptors are increased in human PH. Moreover, administration of anti-NGF blocking antibodies in the rat in vivo partially prevented PH by modulating PA hyperreactivity, inflammation and remodeling. These results therefore confirm that targeting NGF may be of therapeutic interest in this disease.

3434

**Inflammatory processes in load-induced right ventricular failure**

Céline Dewachter, Laurence Dewachter, Marie Verreyssen, Rondet Bondelet, Dean Paul Schraufnagel, Pierre Fesler, Serge Brimioulle, François Kerbaul, Robert Naef. Laboratory of Physiology, Faculty of Medicine, Université Libre de Bruxelles, Brussels, Belgium

**Background:** Transient increase in pulmonary arterial (PA) pressure has been shown to induce a persistent right ventricular (RV) failure characterized by a RV-arterial decoupling, associated to activation of apoptotic pathways and local overexpression of TNF-alpha (Dewachter et al. Crit Care Med 2010; 38: 1405-13).

**Objectives:** We hypothesized therefore that inflammatory cytokines might contribute to the development of persistent RV failure in this “pulmonary hypertension crisis” model.

**Methods:** Sixteen dogs were randomized to a 90-min PA constriction- or to a SHAM-operation, followed 30 minutes later by hemodynamic measurements including effective pulmonary arterial elastance ( Ea) to estimate RV afterload and RV end-systolic elastance (Ees) to estimate RV contractility determined by the single beat method (Brimioulle et al. Am J Physiol 2003; 284: H1625-30), but also blood sampling. After sacrifice of the animals, the RV free wall was sampled for gene and protein expressions of interleukin (IL)-1 beta, 6 and 10.

**Results:** The transient increase in PA pressure persistently increased Ea, and decreased Ees, Esv/Ea and cardiac output, indicating RV failure with altered RV-arterial coupling. As compared to the SHAM group, 90-min PA constriction increased RV relative gene and protein expressions of IL-1 beta and IL-6, and decreased RV relative gene and protein expressions of IL-10, an anti-inflammatory cytokine. The pro-inflammatory IL-6/IL-10 ratio was increased in the RV and in the serum in the PA constriction- compared to the SHAM- group.

**Conclusions:** Acute afterload-induced persistent RV failure appears to be related to local and systemic activation of inflammation.

3435

**Right lung ischemia induces development of contra-lateral pulmonary vasculopathy**

Edouard de Bruxelles, Olaf Mercier, Philippe Dartevelle, Saadja Eddahibi, Elie Fadel. LCE INSERM U999, Hôpital Marie Lannelongue, Le Plessis Robinson, France

**Chronic thromboembolic pulmonary hypertension is due to mechanical obstruction by unresolved clots and vasculopathy in the non obstructed vascular lung regions. We tested whether flow induced vascular lesions or endocrine factors released by the ischemic lung account for development of vasculopathy in non obstructed regions.**

3 groups of 5 piglets were studied 5 weeks after right pulmonary artery (PA) ligation (PAL group), right pneumonectomy (RP group) or right PA dissection (Sham group). We measured pulmonary vascular resistance, pulmonary arterial vasoreactivity and morphometry, and quantified gene expression of factors involved in vascular smooth muscle cell proliferation IGF, PDGF, VEGF and endothelin-dependent vasoreactivity pathways ET-1, ETA, ETB and eNOS. As compared to RP, PAL animals developed pulmonary vasculopathy in the left lung as assessed by increase in pulmonary vascular resistances (p=0.0016), medial hypertrophy of the distal PA (p=0.0001), decreases in both maximal relaxation to acetylcholine (p=0.013) and eNOS gene expression (p=0.041). Left lung IGF (p=0.034), PDGF (p=0.0066) and VEGF (0.0105) gene expressions increased in the PAL group when compared to both RP and Sham. ETAa and ETBb expression was downregulated in both RP (p=0.048 and p=0.039) and PAL (p=0.033 and p=0.028) groups.

**Pulmonary vasculopathy is absent in the remaining lung 5 weeks after pneumonectomy and developed in the non obstructed pulmonary territories 5 weeks after right PA ligation suggesting that factors released by the ischemic lung induced vascular remodelling in the contra-lateral lung. This endothcne regulation might implicate release of factors involved in vascular smooth muscle cell proliferation.**

3436

**p53-dependent, replicative cell senescence suppresses chronic hypoxia-Induced pulmonary hypertension in mice**

Christophe Guignabert1, Ly Tu1, Irina Drascovic2, Charlene Francois1, Philippe Dartevelle1, Gerard Simonneau1, Elie Fadel1, Marc Humbert1, Arturo Londoño-Vallejo2, Saadja Eddahibi1, 1Cardiovascular Research Department, INSERM U999, Le Plessis-Robinson, France; 2Curdie Institute, CNRS UMR 3244, Paris, France

**Introduction:** Excessive telomere shortening limits both cell proliferation and tissue regenerative capacity by inducing senescence, a permanent growth arrest mediated by the p53 pathway. The purpose of this study was to evaluate the susceptibility of mice with defective telomerase (Terc−/−) to develop hypoxia-associated pulmonary hypertension (PH).

**Methods:** Terc−/−, p53−/− Terc−/−, and wild-type (WT) mice at 12 weeks of age were randomly divided into two groups, one of which was maintained in room air (normoxia) and the other exposed to normobaric hypoxia (15% oxygen, 95% nitrogen) for 3 weeks. We evaluated pulmonary hemodynamics, vascular remodeling, and the p53-mediated response in the lung.

**Results:** The Terc−/− mice were efficiently protected against chronic hypoxia-induced PH as compared to WT mice. Interestingly, Terc−/− mice exhibited marked increase in p53 protein levels under normoxia and lacked all signs of tissue remodeling associated to vascular cell proliferation seen in WT mice upon hypoxia treatment. Remarkably, p53 heterozygous Terc+− mice were fully susceptible to hypoxia-induced PH and developed all cell proliferation-related histopathological manifestations.

**Conclusions:** Taken together, these results show that a telomere-mediated, p53-dependent, senescence in vascular tissues confers a strong protective effect on chronic hypoxia-induced PH in mice.

3437

**Right ventricular oxygen supply and diffusion in human and experimental pulmonary hypertension**

Gerrita Ruitter1, Yeun Yong Wang1, Francises de Man1, Louis Handoko1, Pieter Postmus1, Nico Westerhof1, Hans Niessen2, Willem van der Laarse1, Anton Vonk-Noordegraaf1. 1Pulmonology, VU University Medical Center, Amsterdam, Netherlands; 2Physiology, VU University Medical Center, Amsterdam, Netherlands; 3Pathology, VU University Medical Center, Amsterdam, Netherlands

**Introduction:** In pulmonary hypertension (PH), right ventricular (RV) oxygen supply has to increase to meet the higher oxygen consumption due to the high RV output. To investigate how the RV adapts to meet these requirements, we studied the oxygen supply and intracellular diffusion in terms of capitalization and myoglobin content in patients with PH. In addition, we compared healthy rats to a rat model with stable PH (preserved cardiac output) and progressive PH (RV failure) to answer the question whether adaptations in oxygen handling are characteristic for the failing RV or develop during progression of the disease.

**Methods:** RV tissue was collected at autopsy of 10 diseased PH patients and 10 control patients who died from a left ventricular myocardial infarction. In rats, stable PH and progressive PH were induced by monocrotaline 40 and 60 mg/kg, respectively. RV cardiomyocyte cell size, capillary density and myoglobin content were determined.

**Results:** RV cardiomyocyte cell size is strongly increased in PH patients compared to controls (PH: 823±125 vs con: 553±67 μm², p<0.001), while capillary density was decreased (PH: 557±110 vs con: 1119±195 capillaries/mm², p<0.001). RV myoglobin content was significantly reduced (PH: 0.56±0.18 vs con: 1.0±0.34 a.u., p<0.05) thus showing reduced intracellular oxygen diffusion. Similar results were found in the failing RV of progressive PH rats. Furthermore, stable PH rats showed an intermediate state from healthy to failing RV.

**Conclusion:** Oxygen supply to and diffusion within the cardiomyocytes is reduced in both failing human and rat RV. This is characteristic for the failing RV since stable PH rats maintained supply and diffusion.

384. Outdoor air pollution studies

3438

**Late-breaking abstract: Do emissions from animal farms affect the airways of neighboring residents?**

Lidwien A.M. Smil1, Annemieke W.J. Ostpal-van Winden2, Femke van der Sman-de Beer2, Mariette Hooiveld2, Johan Beeekhuizen1, Inge M. Wouters1, Joris Eijlersman2, Dick Heederik1, 1IRAS, Utrecht University, Utrecht, Netherlands; 2Netherlands Institute for Health Services Research, NIVEL, Utrecht, Netherlands

**Concerns about public health risks of intensive animal production in The Netherlands continue to rise, in particular related to outbreaks of infectious diseases such as Q-fever. An increased risk of asthma among neighboring residents is a specific concern raised by general practitioners (GPs) in areas with high animal densities. The aim was to study respiratory health effects among individuals living in the vicinity of animal farms.**

**Associations between farm exposure variables and respiratory diseases were analyzed using a Geographic Information System. Electronic medical record data for the year 2009 of all patients of 27 GPs in a region with a high density of animal farms were used. Density of animal farms around the home address was calculated using a Geographic Information System. Associations between farm exposure variables and respiratory diseases were analyzed using a Geographic Information System.**

**Results:** A Q-fever outbreak occurred in 22.406 children (0-17) vs 70.142 adults (18-70 y), adjusting for age, sex, and household income. During the study period, a Q-fever outbreak occurred in...
Late-breaking abstract: Pneumonia hospitalizations and long-term exposure to air pollution

Aim: To investigate the effect of long-term exposure to traffic-related air pollution (up to 38 years) in Copenhagen and Aarhus on hospital admissions for pneumonia.

Methods: We followed 57,053 participants of Danish Cancer, Diet, and Health cohort, aged 50-65 years at baseline (1993-1997) in Danish hospital discharge register for first hospital admission for pneumonia between baseline and 2010. The annual nitrogen dioxide (NO\textsubscript{2}) levels were estimated at residential address since 1971 as a proxy of exposure to traffic-related air pollution. We modelled the association between mean NO\textsubscript{2} levels and hospitalizations for pneumonia using Cox regression.

Results: During 12.7 years’ mean follow-up, 3,024 (5.7%) out of 53,239 eligible people were admitted to hospital for pneumonia. Mean NO\textsubscript{2} levels were significantly higher as a risk for first-ever pneumonia hospitalization in the full cohort (hazard ratio and 95% confidence interval per double mean exposure: 1.25; 1.13-1.35); with similar effect for first-ever pneumonia admission in 46,462 people with a history of asthma hospitalization (1.41; 1.33-1.49). Enhanced associations were observed in 485 people who had a history of pneumonia hospitalizations (1.45; 0.85-2.47).

Conclusions: Living in areas with high traffic-related air pollution increases the risk of hospitalization for pneumonia.

Impact of climate change on ozone induced mortality in Europe

Background: Ozone is a highly oxidative pollutant, associated with respiratory morbidity and mortality. All else being equal, ground-level ozone will increase as temperatures increase with climate change.

Aim: As a part of the Climate-TRAP project we used emission scenarios, models and epidemiological data to assess ozone-related health impacts under a changing climate.

Methods: European ozone concentrations were modelled at a grid size of 50x50 km using MATCH-RCRA. Projections from two climate models, ECHAM4 and HADLEY, were used, assuming greenhouse gas emission scenarios A2 and A1B. Four periods were compared: the baseline period was defined as 1961–1990, the current situation as 1990–2009, nearer future as 2021–2050 and further future as 2041–2060. The impact on mortality (short-term effect) was calculated for exposures above a daily maximum 8-hour concentrations of 70 \mu g/m\textsuperscript{3}. We use a European-wide exposure-response function with country-specific baseline mortality.

Results: Comparing the current situation with the baseline period, the largest increase in ozone-associated mortality due to climate change (~4%) occurred in Belgium, Ireland, Netherlands and UK. Comparing the baseline period and the further future, the increase is projected to be biggest in Belgium, France, Spain and Portugal (10–14%) and the effect will be stronger for the A2 scenario. However, in Nordic and Baltic countries there will be a decrease in ozone-related mortality of the same magnitude.

Discussion: The current study suggests that projected effects of climate change on ozone levels could differentially influence mortality and morbidity across Europe.

Long-term exposure to air pollution and asthma hospitalizations in elderly adults: A cohort study

**Background:** Exposure to air pollution in early life contributes to the burden of childhood asthma, but it is not clear whether lifetime exposure to air pollution can lead to asthma onset or progression in adulthood. We studied the effect of exposure to traffic-related air pollution over 35 years on the risk for hospitalization for asthma in elderly.

**Methods:** We followed 57,053 participants in the Danish Diet, Cancer and Health cohort, aged 50-65 years at baseline (1993-1997), for first hospital admission for asthma until 2006. Annual levels of nitrogen dioxide (NO\textsubscript{2}) were estimated at all residential addresses since 1971. We modelled the association between NO\textsubscript{2} and hospitalization for asthma using Cox regression in people with and without previous hospitalizations for asthma, and assessed effect modification by co-morbid conditions.

**Findings:** During 9.9 years’ mean follow-up, 977 of 53,695 eligible people (1.8%) were admitted to hospital for asthma: 821 (1.5%) admissions were among 53,143 people who had not and 176 (31.9%) among 552 people who had been hospitalized for asthma before baseline. NO\textsubscript{2} levels were positively associated with risk for asthma hospitalization in the full cohort (hazard ratio and 95% confidence interval per inter-quartile range, 5.8 \mu g/m\textsuperscript{3}: 1.12; 1.04-1.22), and in people without previous asthma hospitalization (1.10; 1.01-1.20), with the strongest effects for people with a history of asthma hospitalization (1.41; 1.15-1.70). Enhanced associations between NO\textsubscript{2} and admissions for asthma were observed for people with COPD (1.30; 1.07-1.52).

**Interpretation:** Air pollution is a risk factor for progression and/or onset of asthma in late adulthood.

Increased plasmatic levels of soluble HLA-G molecules are associated to short-term exposure to fine urban particulate matter

**Background:** Diesel particles have been shown to enhance allergic inflammation and immune responses. HLA-G is an atypical HLA class I molecule with immuno-modulatory properties. It is detectable in plasma in a soluble form (sHLA-G) and its production is triggered by several stimuli, including IL-10. The aim of this study is to investigate the effect of short-term exposure to traffic pollution on plasmatic sHLA-G and IL-10 levels in healthy subjects. We recruited 27 healthy non-smoking policemen exposed to traffic and 17 office workers as controls. Before and after the first weekly shift, plasmatic sHLA-G and IL-10, and lung volumes were measured in each subject. sHLA-G and IL-10 levels were analyzed by ELISA. Individual pollution exposure was estimated by airborne PM2.5 and PM10 concentrations.

**Methods:** Pre-shift sHLA-G levels were similar in both groups and increased after shift in the subjects exposed to traffic (before 10.5±0.5 vs after 12.9±4.5 ng/ml, p<0.0001), but not in controls. After shift IL-10 exhibited an opposite trend in the two groups: no changes were observed in the exposed subjects, whereas IL-10 levels decreased in office workers (before 0.7±0.5 vs after 0.5±0.4 pg/ml, p=0.03). sHLA-G cross-shift changes in exposed policemen were positively correlated with PM2.5 levels (rho=0.51, p<0.05). Lung volumes did not exhibit any change after shift in either groups.

**Conclusion:** Short-term exposure to traffic pollution affects the HLA-G system, irrespective of IL-10 levels. The results suggest that fine PM had a systemic immuno-modulatory effect that occurs without changes in lung function.

Antioxidant supplementation attenuates changes in innate immunity associated with diesel exhaust (DE) in the lung: A controlled crossover exposure study

**Background:** Oxidative stress is thought to induce negative health effects associated with exposure to DE and may result from altered innate immunity. Therefore, anti-oxidant supplementation may modify DE-related changes in phagocytosis in airways.
Methods: 12 participants (4 mild asthmatics and 8 healthy controls) completed a double-blinded, randomized, crossover, counter-balanced study of 3 exposure conditions, each separated by a 2-week washout period: (1) DE (300μg PM2.5/m3 for 2 hours with oxidant (N-acetylcycteine) 600mg 3x/day for 5 days preceding and on the day of the exposure) [“DEN”], (2) DE with placebo [“DEP”], or (3) filtered air with placebo [“FAP”]. Induced sputum was collected 6 hours after each exposure. Sputum neutrophils and macrophages were analyzed by flow cytometry for changes in innate immune response (phagocytosis). Those with PC20<8 were defined as “reactive” and those with PC20>8 as “non-reactive”.

Results: Phagocytosis in sputum macrophages was greater after DEP than after FAP (mean phagocytosis units = 22.8 and 15.8 respectively, and this difference was attenuated by DEN (mean phagocytosis units = 17.8 units). 6 subjects were methacholine-reactive at baseline; reactivity status did not modify phagocytosis.

Conclusions: DE-associated increase in phagocytosis in human airways appears mitigated by anti-oxidant supplementation (N-acetylcycteine). The suggestion that DE upregulates the innate immune response to sputum macrophages, and that this is mediated by oxidative stress, parallels novel data from our lab regarding changes in airway reactivity to methacholine in response to FAP, DEN; and DEN.

3444 Outdoor exposure to formaldehyde (CH2O) is associated with an increased risk of hospitalization for respiratory diseases in children

Roberto de Marco1, Pierpaolo Marchetti1, Paolo Gualdi1, Maria Enrica Fracasso2, Linda Guarda1, Alessandro Marcon1, Vanda Pironi1, Giorgio Siliprandi3, Paolo Ricci1, 1Unit of Epidemiology and Medical Statistics, University of Verona, Verona, Italy; 2Section of Pharmacology, University of Verona, Verona, Italy; 3Unit of Epidemiology, NHS Mantua, Mantua, Italy; 4Department of Mantua, Environmental Protection Agency, Mantua, Italy

Background: Children living near wood industries have an increased risk of developing respiratory diseases. Objectives: To assess if residential outdoor exposure to NO2 and CH2O was associated with the risk of hospitalization for respiratory diseases in children.

Methods: In 2006, all the children (3-14 years) living in the Viadana district (the largest wood manufacturing area in Northern Italy) were surveyed through a parental questionnaire (n=3851) and their home addresses were geocoded. Their history of hospitalization for respiratory diseases (ICD-IX: 460-519) was assessed from January 2007 to December 2009, using discharge records obtained from the local Health Unit. To assess the outdoor exposure to NO2 and CH2O, 63 passive samplers were installed in the area using a Partitioning Around Medoids (PAM) algorithm. Pollutants were monitored twice, both in winter and in summer (2007-2008).

Results: By December 2010, 3798 (98.5%) children had been traced. During the 3 years of follow-up, 121 hospital admissions, caused by respiratory diseases, occurred (annual HR = 10.8/1000/year). The HR for respiratory diseases slightly increased with increasing outdoor exposure to NO2 (μg/m3) (RR: 1.02; 95%CI: 0.95-1.10), while they were strongly associated to CH2O outdoor concentration (μg/m3) (RR: 2.41; 95%CI: 1.07-5.43).

Conclusions: Emissions from wood industries apparently have a serious impact on children’s health.

3445 Altered haemodynamic response to norepinephrine following diesel exhaust inhalation

Jon Unosson1, Jenny Bosson1, Jeremy Langrish2, Jamshid Pourazar1, Lutz Wollin, Florian Gantner, Michael Pieper.

1Division of Medicine, Public Health and Clinical Medicine, Umeå, Sweden; 2Centre for Cardiovascular Science, University of Edinburgh, United Kingdom

Introduction: Previous studies have reported an altered autonomic nervous function following exposure to particulate air pollution. Reports of increased blood pressure and reduced heart rate variability consistent with altered autonomic nervous function have been observed in chronic obstructive pulmonary disease (COPD) patients exposed to daily life pollution.

Methods: In a randomized double-blind crossover study, 14 healthy non-smoking volunteers were exposed to dilute DE or filtered air for one hour whilst changes in heart rate were similar (P<0.028).

Results: Our results show unexpected haemodynamic responses to NE after exposure to dilute DE, with both attenuated vasopressor responses and an inhibitory effect on cardiac index. These novel findings suggest that DE inhalation alters the cardiovascular response to adrenergic stimulation, which could represent an effect on the autonomic nervous system.

385. Understanding disease and drug mechanisms

3446 The long-acting β2-agonist formoterol re-establishes the anti-proliferative effect of glucocorticoids in asthmatic airway smooth muscle cells (ASMC)

Michael Roth, Jun Zhang, Chong S’ng, Michael Tamm. Pulmonary Cell Research & Pneumology, University Hospital Basel, Basel, Switzerland

Background: Asthma is characterized by an increased mass of ASMC which show increased proliferation in vitro. As previously reported, glucocorticoids do not have a significant anti-proliferative effect on ASMC of asthmatics while although their anti-inflammatory efficacy is maintained.

Methods: We assessed whether the addition of the long-acting β2-agonist formoterol modifies the anti-proliferative efficacy of glucocorticoids (budesonamide, budesonide, fluticasone). Primary human ASMC lines from asthmatics and controls were set up from bronchoscopic lung biopsies.

Results: Serum deprived sub-confluent cells were stimulated by 5% serum with or without a single drug or combination for a further 48 and 72 hrs. Serum alone increased cell proliferation in healthy control cells by 65% (48 hrs) and 81% (72 hrs); a significantly higher proliferation response was seen in asthmatic ASMC (82% at 48 hrs; 123% at 72 hrs). In the presence of different glucocorticoids alone serum-induced proliferation was significantly reduced in healthy cells (max. 48%) but not in asthmatic ASMC. Treatment with formoterol alone reduced serum-induced proliferation by 24% at any time point, with no differences between asthmatic and healthy ASMC. When formoterol was combined with fluticasone a 78% reduction of ASMC proliferation was achieved.

Conclusions: Our results show that the β2-agonist formoterol re-establishes the anti-proliferative effect of fluticasone in asthmatic airway smooth muscle cells. This synergistic action may exert an anti-remodeling effect on the asthmatic airway supporting the clinical benefit of combination therapy.

3447 A novel target of formoterol, a dual-specificity phosphatase DUSP4 on regulation of corticosteroid budesonide sensitivity

Yoshiki Kobayashi1, Nicolas Mercado1, Anna Miller-Larsson2, Peter Barnes1, Kazuhito Ino1, 1Airways Disease, NHIA Imperial College, London, United Kingdom; 2R&D Lund, AstraZeneca, Lund, Sweden

Introduction: We previously reported that formoterol, a long-acting β2-adrenoceptor agonist, activated a serine/threonine protein phosphatase PP2A which is involved in the restoration of corticosteroid (CS) sensitivity by formoterol (Kobayashi et al ERJ 2009;34:583s). We explored other phosphatases and identified dual-specificity phosphatase DUSP4 as a possible novel target of formoterol.

Aims: To confirm that DUSP4 is activated by formoterol and is involved in regulation of CS sensitivity.

Methods: U937 monocytic cells were incubated with IL-2 and IL-4 for 48 h to induce CS insensitivity. CS sensitivity was determined by the CS budesonide ability to inhibit TNFα-induced IL-8 production and to translocate glucocorticoid receptor (GR) from cell cytoplasm to nucleus. Phosphatase activity of immunopurified DUSP4 was measured by fluorescence-based assay. The nuclear/cytoplasmic GR ratio and phosphorylation levels of GR,Ser237 and JNK1 by formoterol were assessed by western-blotting. In some experiments DUSP4 was knocked down by siRNA.

Results: Formoterol increased DUSP4 activity, which was reduced under IL-2/IL-4 exposure. Knock-down of DUSP4 reduced GR nuclear translocation and CS sensitivity. Knock-down of DUSP4 also abrogated the dephosphorylation of GR-Ser237 and JNK1 by formoterol - the effects involved in GR nuclear translocation and restoration of CS sensitivity.

Conclusions: Formoterol regulates sensitivity to budesonide through activation of DUSP4 which dephosphorylates JNK1 and GR, which may lead to dephosphorylation of GR-Ser237. This novel mechanism by formoterol may contribute to the clinical efficacy of combination of formoterol and budesonide.

3448 Tiotropium reduces established pulmonary inflammation in a 12 weeks cigarette smoke mouse model of COPD

Lutz Wollin, Florian Gantner, Michael Pieper. Respiratory Diseases Research, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Rationale: Tiotropium bromide (Spiriva®) is the only marketed long acting anti-cholinergic for the treatment of chronic obstructive pulmonary disease (COPD).
3450 The pre-clinical pharmacology of the inhaled muscarinic antagonist GSK537319 predicts once-daily clinical dosing Dzinane I. Lanté, Mark A. Lannam, James J. Foley, Chris J. Dehaas, Charles J. Ketzer, Michael Salomon, William L. Runsey. Respiratory CEDO, GlaxoSmithKline, King of Prussia, United States

Introduction: GSK537319 is a new, long-acting muscarinic antagonist offering sustained 24-h bronchodilation currently in phase III clinical trials for COPD.

Objectives: To assess the pharmacology of GSK537319 in pre-clinical studies.

Methods/Results: In CHO cells transfected with recombinant human M3 receptors, GSK537319 demonstrated pD2 potency (~log pA2 = 23.5 pM) in an acetylcholine (ACh)-mediated Ca2+ mobilisation assay. Concentration-response curves indicated competitive antagonist with partial reversibility after drug wash out. Using isolated human bronchial strips in static tissue baths, GSK537319 was a potent, competitive antagonist (~log pA2 = 316 pM) vs carbachol. Superfusion of bronchial strips with carbachol containing buffer showed that GSK537319 was slowly reversible in a concentration-dependent manner (1–1000 nM). Time to 50% restoration of contraction at 10 nM was ~60 min (vs 413 min with topipramide, 10 mM). In conscious guinea pigs, GSK537319 dose-dependently blocked ACh-induced bronchodilation with long-lasting effect of action; a 2.5 g intratracheal dose elicited ~50% bronchoprotection for >24 h.

Conclusions: GSK537319 is a potent muscarinic antagonist that demonstrates slow reversibility at cloned human M3 receptors and at endogenous mAChR in isolated human bronchus. This profile translates into 24-h duration of bronchodilation in the clinic, suitable as a once-daily treatment for COPD.

3451 Synergistic bronchoprotective activity of the long-acting beta 2-agonist olodaterol with tiotropium: potential impact of chronic obstructive pulmonary disease (COPD) Anna Sola1,2,3, Michael Nyberg2,3, Christine Möller Westerberg2,3, Milos Tatar1, Barbara Fuchs1,2,3, Lisa Sjöberg1,2,3, Christine Möller Westerberg2,3, Gunnar Nilsson2.

Introduction: Muscarinic activation of human lung fibroblasts is associated with pathological remodelling in the airways of patients with asthma and chronic obstructive pulmonary disease (COPD).

Aims: To investigate the in vitro effects of aclidinium bromide, a novel, long-acting muscarinic antagonist, on human lung fibroblast activation.

Methods: Lung fibroblasts, isolated from human bronchus, were pre-incubated with aclidinium (10^-5M-10^-7M), the ERK 1/2 inhibitor PD98059 (10^-6M) or the cAMP analogue dbcAMP (1nm) for 30 min and then exposed to carbachol (10^-7M) for 48 h. Collagen type I and alpha-smooth muscle actin (αSMA) expression were measured by RT-PCR, Western blot (WB) and immunofluorescence. ERK 1/2 phosphorylation was measured using intracellular cAMP levels by cAMP Biotrak enzyme immunoassay. Fibroblast proliferation was assessed using a BrDU kit, and fibroblast migration by wound closure assay.

Results: Aclidinium, PD98059 and dbcAMP attenuated carbachol-induced increases in αSMA and collagen type I mRNA and protein levels. Aclidinium and dbcAMP prevented carbachol-induced increases in phospho-ERK 1/2. Carbachol (10^-6M) prevented isoprenaline (1μM)-induced cAMP upregulation, which was completely reversed by aclidinium 10^-5M. Carbachol-dependent increases in lung fibroblast proliferation (2-fold) were reduced by aclidinium 10^-5M (1.1-fold), PD98059 (1.3-fold) and dbcAMP (1.2-fold). Aclidinium 10^-6M, PD98059 and dbcAMP reduced αSMA and collagen type I wound closure by 30%, 28% and 40%, respectively.

Conclusions: Aclidinium blocks carbachol-induced lung fibroblast proliferation probably by a direct effect at muscarinic receptors. Aclidinium may alleviate fibroblast activation in patients with asthma and COPD.

The cyclooxygenase (COX) product prostaglandin (PG) E2 is known to act bronchoprotective in asthmatics. Recent preclinical studies identified the COX-terminal microsomal PGE synthase-1 to contribute to the formation of protective PGE2. This study investigated whether the release of bronchoprotective COX products is mast (MC) dependent. Chronic allergic airway inflammation in mice was induced by ovalbumin/chloroform and continued during 90 days. COX-inhibition with diclofenac (DFC) was performed. Airway hyperresponsiveness (AHR) was assessed applying forced-oscillation technique in response to methacholine. Contribution of MC-COX-products to AHR was resolved by comparingWSC (MC-deficient) to C57BL/6 wild type (WT) mice (MCs around central airway). Central airway resistance, Rn, was reduced in allergen-challenged WT mice and increased in WT-DFC [cmH2O*ml^-1*sec^-1*cm^-5] (p<0.04). Ws displayed comparable resistance [1.7±0.1 cmH2O*ml^-1*sec^-1*cm^-5] as WT-DFC. Rn in Ws was not changed after treatment [1.9±0.2 cm]. Both mouse strains lacked MCs in peripheral lung tissue. Consequently, tissue resistance was not changed in WT and Ws [8.5±0.5 vs 7.8±0.6], nor after treatment [WT-DFC 7.8±0.5, Ws-DFC 7.6±0.6]. Although a shift in baseline tissue elastance was observed between WT and Ws [21.9±1.4 vs 17.7±2.4, p=0.02], treatment did not affect baseline [WT-DFC 21.4±1.2, Ws-DFC 17.6±1.09], nor was the reactivity changed.

The data indicates that the bronchoprotective role of PGE2 is MC dependent. It remains to be seen if this is due to PGE2 or other COX products released by MCs, or if modulating COX products are released by other cells and play role in MC activation.

3452 Mast cell generated cyclooxygenase products protect airway hyperresponsiveness in a model of chronic asthma Barbara Fuchs1,2,3, Lisa Sjöberg2,3, Christine Möller Westerberg2,3, Maria Ekofsk1, Linda Swedin5, Sven-Erik Dahlén1,1, Mikael Adner1,1, Gunnar Nilsson2.

Introduction: In vitro effects of aclidinium bromide, a novel, long-acting muscarinic antagonist, on human lung fibroblast activation.

Methods: Lung fibroblasts, isolated from human bronchus, were pre-incubated with aclidinium (10^-5M-10^-7M), the ERK 1/2 inhibitor PD98059 (10^-6M) or the cAMP analogue dbcAMP (1nm) for 30 min and then exposed to carbachol (10^-7M) for 48 h. The data indicates that the bronchoprotective role of PGE2 is MC dependent. It remains to be seen if this is due to PGE2 or other COX products released by MCs, or if modulating COX products are released by other cells in response to MC activation.

3453 Antifluorescent activity of (-) menthol mediated by nasal trigeminal TRPM8 receptor: Jana Plevkova1, Brendan J. Canning2, Ivan Polacki3, Mariana Brozmanova1, Milos Tata1.

1Department of Pathophysiology, Jesseun School of Medicine, Chonnam University, Gwangju, South Korea; 2Asthma and Allergy Center, Johns Hopkins School of Medicine, Baltimore, United States; 3Department of Medical Biophysics, Jesseun School of Medicine, Gwangju, South Korea (South Korea)

(-) Menthol, main component of the peppermint is exploited in many over-the-
counter drugs for common cold and cough. It has been reported that (-) menthol has an antitussive effect in humans and animals. However, there are conflicting evidence against that statement and also cases report of respiratory failure induced by menthol in kids. Based on the recent data about the distribution of the TRPM8 – menthol receptors expressing neurons in the upper airways, and their low proportion within the vagal nerves in lower airways we suppose, that effect of (-) menthol on cough could be mediated by TRPM8 expressed on nasal afferents. To test this hypothesis a segmental airway challenges with (-) menthol were performed in anaesthetized guinea pigs (nose, trachea and lower airways were separately treated by menthol). A dose–response curves (DRC) were constructed according the method described by Canning et al., 2006. The DRC were compared to control provocations. The (-) menthol applied topically to the trachea does not influence cough significantly. (-) menthol vapors applied directly to lower airways via cannula resulted to the tendency to facilitate cough, with visible signs of increased mucus output, loaded breathing and wheezing. The antitussive effect of menthol was observed only in the group treated by nasal (-) menthol vapors, which reduced cough response to CA significantly comparing to control response p < 0.001.

Our results correspond with the data describing the TRPM8 distribution in the respiratory tract, and may contribute to explanation adverse effects induced by menthol inhalation in kids. Supported:VEGA 1/0031/11.

386. Obstructive sleep apnoea as a comorbidity

P3454
Optimizing the screening of OSA in patients undergoing bariatric surgery
Merce Gasa1, Neus Salord1, Ana Maria Fortuna2, Mercedes Mayos3, Josep Maria Montserrat1, Carmen Monasterio1, 1Sleep Unit, Department of Respiratory Medicine, Hospital Universitari de Bellvitge, Bellvitge Biomedical Research Institute (IDIBELL), CIBER Enfermedades Respiratorias (Cibeles), Hospital de Llobregat, Barcelona, Spain; 2Sleep Unit, Department of Respiratory Medicine, Hospital de la Santa Creu i Sant Pau, CIBER Enfermedades Respiratorias (Cibeles), Barcelona, Spain; 3Sleep Unit, Department of Respiratory Medicine, Hospital Clinic, CIBER Enfermedades Respiratorias (Cibeles), Barcelona, Spain

Obstructive Sleep Apnea (OSA) is common in patients waiting bariatric surgery (BS). International consensus recommend OSA preoperative assessment to avoid perioperative complications. Full-night polysomnography (PSG) is the standard diagnostic method but it is expensive and time-consuming. The aim of the study was to select by a simple predictor model, those patients who merit treatment prior BS.

Methods: A prospective cross-sectional study was conducted in 158 consecutive bariatric subjects. PSG was performed in all. The outcome variable was severe OSA defined as apnea-hypopnea index (AHI) ≥30. Predictive models were constructed using multivariate logistic regression analysis. The best model was selected depending on the area under receiver operating characteristic curve (AUROC).

Results: The first model indentified four independent predictive factors of AHI ≥30: age, waist-to-hip ratio, systolic blood pressure and witnessed apneas (Apn) with predictive values: sensitivity (Se) 78%, Specificity (Sp) 81%, AUROC 0.81. The second model (clinical plus ODI1%) indentified two independent predictive factors (AHI, ODI%) with predictive values: Se 98%, Sp 89%, AUROC 0.95. We proposed a two-step screening: first, applying the clinical model and then, the second model; 47% of subjects would be rule out (21% and 26% by the first and second steps). Only 53% would require PSG prior BS.

Conclusions: The proposed two-step model could be useful to optimize the screening of severe OSA in bariatric subjects improving the limiting resources of PSG.

P3455
Is lung transplantation a cause of sleep apnea hypopnea syndrome?
Inés Escrivano Gimeno, María Josefa Díaz de Atauri, Trinidad Díaz Cambrales, Alicia De Pablo Galas, Virginia Pérez González, Angel López Encuentra, Pneumología, 12 de Octubre Hospital, Madrid, Spain

Aims: To analyze the presence of Sleep Apnea Hypopnea Syndrome (SAHS) in a cohort of patients before and after lung transplantation (LT).

Methods: All consecutive LT recipients with at least 2 polysomnographies (PSG) at 6 weeks of commencement of rhGH in a tertiary paediatric sleep setting.

Results: The prevalence was 30% (n=3) pre-LT, 80% (n=8) at the first PSG after LT, and 40% (n=4) at the second one. There were significant differences between mean AHI in the pre-LT sleep study and AHI in the first study after LT, but not with the one after 12 month of follow up. The data are shown in the figure.

P3456
Obstructive sleep apnea syndrome (OSAS) and asthma in a general population
Trygve Jonassen1, Tomas Eagan1, 1Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 2Section of Pneumology, Institute of Medicine, University of Bergen, Bergen, Norway; 3The Norwegian Medical Centre for Home Mechanical Ventilation, Haukeland University Hospital, Bergen, Norway

Background: Several studies have investigated associations between OSAS and asthma, with inconsistent results.

Aim: To determine if asthma and bronchodilator reactivity (BDR) are independent risk factors for OSA in the Norwegian population.

Methods: An age and sex stratified random sample of all adults aged 47-48 and 71-73 living in Bergen, Norway, were invited to a cross-sectional survey. The 3506 attendants (69%) completed a questionnaire including symptoms of OSAS. Subjects were classified as having OSAS if they reported snoring, breathing cessations, and daytime sleepiness using the Karolinska Sleep Questionnaire, previously validated against polysomnography. Subjects were classified as asthmatics if they had ever received a doctor’s diagnosis of asthma and currently were on antiasthmatic medication.Spirometry including bronchodilator test inhaling 400 μg Salbutamol was performed by all subjects. Two logistic regression models were fitted with OSAS as the outcome variable; one with current asthma and one with BDR as main explanatory variable. Both models included age, sex, body mass index (BMI), waist-hip ratio and smoking.

Results: The prevalence of OSAS was 4.5% (147/3289) in subjects without asthma, and 9.7% (21/217) in subjects with asthma [P=0.001]. Subjects with current asthma had an increased risk for OSA with an OR of 2.2 (1.3, 3.7), after adjustment for all confounders. BDR, measured by difference in ml between pre- and post-bronchodilator spirometry, did not seem to confer increased risk for OSAS; OR 1.0 (0.3, 3.8).

Conclusions: Our study confirms asthma as an independent risk factor for OSAS. We were not able to demonstrate a relationship between bronchodilator reactivity and OSAS.

P3457
Sleep disordered breathing in Prader Willi syndrome post recombinant human growth hormone therapy
Arun Kumar Pugalenthi, Sadasivam Suresh, Pat Wales, Gordon Williams, Margaret Harris, Department of Paediatric Respiratory & Sleep Medicine, Mater Children’s Hospital, South Brisbane, Queensland, Australia

Introduction: Recombinant human growth hormone (rhGH) is licensed for treatment in Prader Willi Syndrome (PWS) for improvement of body composition, height velocity, mobility, behaviour and quality of life. Sleep disordered breathing (SDB) disorders are common in individuals with PWS. It has been suggested that rhGH exacerbates SDB.

Aim: To identify PWS children who have changes in SDB on polysomnography (PSG) at 6 weeks of commencement of rhGH in a tertiary paediatric sleep setting.

Methods: We retrospectively reviewed PWS patients who underwent PSG pre and
6 weeks post commencement of rhGH. The PSG was conducted in a sleep lab using standardized procedure and reported by a sleep physician.

Results: We studied 26 patients (13 Boys and 13 Girls) with age range between 1.6 to 17.9 years. 16 patients (61.5%) had normal PSG study indicating no deterioration in SDB since commencing on rhGH, 5 patients (19.2%) had mild increase in Apnoea Hypopnoea Index (AHI). 1 patient (3.8%) required an increase in supplemental airway pressure (CPAP) treatment and 4 patients (15.4%) were advised to cease rhGH treatment as PSG showed significant increase in AHI since rhGH commencement.

Conclusion: 80% of our PWS patients on rhGH had either no evidence of change in SDB six weeks post rhGH treatment or mild increase in AHI. 19.2% (5 Patients) in which 4 patients (15.4%) studied ceased rhGH and in 1 (3.8%) NIV support was increased.

P3458
Periodic breathing and oxygenation pattern depending on severity of bronchopulmonary dysplasia
Natalja Petrova1, Irina Dobrodeeva1, Yuri Petrenko1, Nikolai Shabalov1, Vyacheslav Lubimenko2, Newborn Physiology and Diseases Research Laboratory, Federal Specialized Perinatal Centre under V.A. Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation; 2 Neonatal Care Unit, Children’s City Hospital No. 1, Saint-Petersburg, Russian Federation; 3 Paediatric Unit, Military Medical Academy, Saint-Petersburg, Russian Federation

Objective: Periodic breathing (PB) is a common breathing pattern in premature infants. Our aim was to study PB occurrence and its impact in oxygenation in infants with moderate and severe bronchopulmonary dysplasia (BPD) compared to infants without BPD.

Methods: We performed pneumography on 25 premature infants with BPD (1 case of severe, 8 of moderate, and 16 of mild BPD) and 25 non-BPD premature comparable in gestation age (26-30 weeks). Infants were examined 1-3 times at ages of less than 29 days, 29-50 days, more than 50 days. Incidence of main neurologic abnormalities appeared not to differ among groups.

Results: Incidence and duration of PB did not differ in infants with mild BPD and without BPD at all ages. Infants with moderate to severe BPD demonstrated no PB during first 28 days, lesser incidence of PB at 29-50 days (1 of 3 infants), lesser duration of PB at 50 days and older (4.3±3.1% of recording length) compared to infants with mild BPD (8 of 10 infants; 18.3±6.7%, respectively; P<0.05) and without BPD (17 of 18 infants; 13.3±5.3, respectively; P<0.05).

Conclusion: Infants with mild BPD seem to have more active peripheral chemoresponsiveness compared to premature with moderate to severe lung disease. PB may be associated with significant desaturations in infants with BPD regardless of its severity.

P3459
Effects of sleep disordered breathing, asthma and socio-economic status on behavioural parameters in children
Yasemin Golokmen1, Refta Erzu1, Ayse Rodopman Arman1, Pınar Ay1, Ahmet Topuzoglu1, Fatih Telrik1, Bulent Karadag1, Fazilet Karakoc1, 1 Paediatric Pulmonology, Marmara University, Istanbul, Turkey; 2 Child Psychiatry, Marmara University, Istanbul, Turkey; 3 Public Health, Marmara University, Istanbul, Turkey

Background: Inner-city children with asthma have increased prevalence of sleep disordered breathing (SDB) and these children have more pronounced behavioral problems.

Aim: To study the effect of asthma and SDB on behavior in children by socio-economic status (SES).

Methods: This cross sectional study was performed in 6 primary schools; 3 with low and 3 with high SES. These schools were determined by a previous study which evaluated the SES of students. All children in the 1st to the 4th grades were included. ISAAC questionnaire for asthma, pediatric sleep questionnaire for SDB and a standardized SES questionnaire were completed by the parents.

Results: 1383 children (51% female) were included. Mean age was 8.7±1.1 years. Rates of ever and current wheezing were 25.8% (95%CI: 23.5-28.2%) and 19.8% (95%CI:17.7-21.9), respectively. 11.4% (95%CI:8.13-12.2%) children had doctor diagnosed asthma and 7.1% (95%CI:5.8-8.5) had SDB. Children attending schools in poor neighbourhoods tended to have higher rates of SDB (p<0.05). Although children in both groups had similar rates of ever and current wheezing, those with lower SES had less doctor diagnosed asthma (p<0.05). Children with SDB had increased risk of ever and current wheezing and risk increased in children with lower SES. Presence of SDB increased the risk of ever wheezing among children with low and high socio-economic status with an OR of 4.4 and 3.2, respectively (95%CI:1.05-15).

Conclusion: SDB is more common in children with lower SES. Children with SDB have higher rates wheezing and risk increases in children with lower SES.

P3461
Obstructive sleep apnoea syndrome and insomnia: The development of insomnia symptoms with CPAP treatment
Xuan-Lan Nguyen1, Dominique Rakotonahamany1, Joel Chaskalovic2,3, Bernard Fleury1, 1 Service de Pneumologie, Hôpital Saint-Antoine, Paris, France, Metropolitan; 2 Département de Mathématiques, University of Samaaria, Ariel, Israel; 3 Département de Mathématiques, Institut Jean le Rond d’Alembert, Paris, France, Metropolitan

Rationale: Insomnia is frequently reported in obstructive sleep apnoea syndrome (OSAS) patients due to the high prevalence of both diseases and, potentially, a causal relationship between them.

Objective: To assess the evolution of insomnia under long-term continuous positive airway pressure (CPAP) treatment.

Methods: Eighty apnoic patients (age = 54.9±10.6 years, respiratory disturbance index = 45.0±24.6/h) on CPAP were followed prospectively for 24 months. Depressive symptom was assessed at baseline (T0) with the ZDS scale, and assessment of insomnia and sleep quality used the Insomnia Severity Index (ISI) (an ISI ≥ 14 defining insomnia) and the Pittsburgh Sleep Quality Index (PSQI) at T0 and T24. A multivariate correlation analysis identified the major explanatory factors for the ISI at T24.

Results: The median ISI was 14 at T0 and 6 at T24. The ISI (13.7±4.7) at T24 was significantly lower than at T0 (15.5±5.5, p=0.0001) for the patients as a group. Forty-three subjects (54%) had insomnia at T0, and 14 (17.5%) were still insomniac at T24 (p=0.0001). The ISI≥7 (p=0.41), PSQI≥15 (p=0.40), antidepressant use (p=0.36), depression score (p=0.33) and female gender (p=0.28) correlated with ISI at p<0.01, but CPAP compliance did not.

Conclusion: Insomnia was no longer measurable with CPAP treatment in two-thirds of initially insomniac patients. Residual insomnia was associated with high levels of initial insomnia and depressive symptoms.

P3462
Are sleep, nocturnal breathing and daytime performance impaired at moderate altitude?
Tsuyoshi D. Lashang1, Christian M. Lo Cascio2, Katrin Stadelmann2, Noemi Tesler1, Anne-Christin Stöwhus1, Peter Achermann2, Rebru Huber3, Malcolm Kohler1, Konrad E. Blöch1, 1 Pulmonary Division, University Hospital Zurich, Zurich, Switzerland; 2 Institute of Pharmacology and Toxicology and Centre for Integrative Human Physiology, University of Zurich, Zurich, Switzerland; 3 Children’s Hospital, University Hospital Zurich, Zurich, Switzerland

Background: There are concerns that even mild hypoxia at altitude has unfavorable health effects. The current study evaluates the hypothesis that sleep quality and daytime performance of lowlanders are impaired during a stay at moderate altitude.

Conclusion: Increased rates of externalizing and internalizing problems in inner-city primary school children with SDB might reflect a negative impact on overall neurobehavioral health. Being male, coming from lower SES, and the presence of both wheezing and SDB might increase negative behavioral problems.

615s
Methods: Fifty healthy men, mean ± SD age 26 ± 9 y, living at <600m, were studied at Zurich (490m) and while staying in the Swiss Alps at Davos Wolfang (1630m, 2 days) and Jakobshorn (2590m, 2 days), in randomized order. Sleep studies, psychomotor vigilance tests (PVT), snow board simulator tests and questionnaire evaluations were performed at all locations.

Results: Compared to 490m, sleep studies at altitude revealed reduced oxygen saturation, a higher central apnea/hypopnea index and reduced slow wave sleep. Multiple logistic regression did not show an independent effect of altitude on reaction times in PVT and snowboard simulator when controlled for various confounders.

Conclusion: In healthy men, mild nocturnal hypoxemia and periodic breathing at moderate altitude are associated with subtle sleep disturbances but neither subjective sleep quality nor psychomotor vigilance during daytime are impaired.

Grant: Zurich Centre for Integrative Human Physiology, Swiss Federal Accident Insurance.

P3463
Prevalence of thyroid disease in patients with obstructive sleep apnea
Ahmed Balkammam1, Munir Sharif1, Anwar Jammah 2, Salman Bahammam 1
1University Sleep Disorders Center, King Saud University, Riyadh, Saudi Arabia; 2Endocrinology Section, King Saud University, Riyadh, Saudi Arabia

Background: Previous studies have reported conflicting results with regard to thyroid disease in obstructive sleep apnea (OSA) patients.

Methods: To determine the prevalence and predictors of thyroid disease in OSA patients.

Objective: Determined the prevalence of thyroid disease in OSA patients.

Methods: Consecutive patients who were referred for an overnight polysomnography (PSG) in the study period underwent serum TSH and thyroxine (FT4) measurement within 4 weeks of PSG using the electrochemiluminescence immunoassay method. Standard definitions were used to define clinical hypothyroidism, subclinical hypothyroidism, and subclinical hyperthyroidism.

Results: Of 271 patients with OSA and a mean age of 50±11.8y, 120 (44.3%) were female. The prevalence of newly diagnosed clinical hypothyroidism was 5%. There were no cases of clinical or subclinical hyperthyroidism in the studied group. Female gender was the only predictor of subclinical hypothyroidism.

Conclusion: The prevalence of newly diagnosed clinical hypothyroidism was very low in OSA patients who are followed up for their sleep problems. There was no correlation between AHI and the severity of sleep apnea (p=0.328). The analysis of the hypogram showed that sleep fragmentation, characterized by arousal index (AI), was a significant impact on the sleep apnea (p=0.048, r=0.265). Another important factor that determines daytime affective status was nocturnal hypoxemia (p=0.05, r=0.265).

Results: Thirty of the patients (51,7%) had depressive symptoms. There was no correlation between AHI and the severity of depression (p=0.328). The analysis of the hypogram showed that sleep fragmentation, characterized by arousal index (AI), was a significant impact on the sleep apnea (p=0.048, r=0.265). Another important factor that determines daytime affective status was nocturnal hypoxemia (p=0.05, r=0.265).

Results: Thirty of the patients (51,7%) had depressive symptoms. There was no correlation between AHI and the severity of depression (p=0.328). The analysis of the hypogram showed that sleep fragmentation, characterized by arousal index (AI), was a significant impact on the sleep apnea (p=0.048, r=0.265). Another important factor that determines daytime affective status was nocturnal hypoxemia (p=0.05, r=0.265).

Background: Sleep apnea is a common sleep disorder that affects millions of people worldwide. It is characterized by repeated episodes of apnea (cessation of breathing) and hypopnea (reduction in airflow) during sleep, leading to sleep fragmentation and daytime sleepiness. The impact of sleep apnea on sleep quality and quality of life is well-documented, with significant implications for overall health and well-being. However, the prevalence and clinical significance of depressive symptoms in patients with obstructive sleep apnea (OSA) have not been thoroughly explored.

Methods: A cross-sectional study was conducted to assess the prevalence of depressive symptoms in patients with OSA and to explore potential correlations between sleep apnea severity and depressive symptoms.

Results: A total of 271 patients with OSA and a mean age of 50±11.8 years were included in the study. The prevalence of newly diagnosed clinical hypothyroidism was 5%. There were no cases of clinical or subclinical hyperthyroidism in the studied group. Female gender was the only predictor of subclinical hypothyroidism.

Conclusion: The prevalence of newly diagnosed clinical hypothyroidism was very low in OSA patients who are followed up for their sleep problems. There was no correlation between AHI and the severity of sleep apnea (p=0.328). The analysis of the hypogram showed that sleep fragmentation, characterized by arousal index (AI), was a significant impact on the sleep apnea (p=0.048, r=0.265). Another important factor that determines daytime affective status was nocturnal hypoxemia (p=0.05, r=0.265).

Results: Thirty of the patients (51.7%) had depressive symptoms. There was no correlation between AHI and the severity of depression (p=0.328). The analysis of the hypogram showed that sleep fragmentation, characterized by arousal index (AI), was a significant impact on the sleep apnea (p=0.048, r=0.265). Another important factor that determines daytime affective status was nocturnal hypoxemia (p=0.05, r=0.265).
P3468

Are upper airways resistance syndrome and obstructive sleep apnea a side-effect of oral cancer therapy?

S.P. Tandon1, A. Khutarkar1, S. Ansari1, M. Khale, S.K. Rajan1, J. Deodhar1, J.P. Agarwal1, P. Chaturvedi1, P. Pal1, D. Chaukar1, R. Havaldar1, S. Laskar1, P. Yada1, A.K. D'Cruz2, 1Pulmonary Medical Unit, Tata Memorial Hospital, Mumbai, India; 2Respiratory Medicine, Bombay Hospital, Mumbai, India; 3Psychiatric Unit, Tata Memorial Hospital, Mumbai, India; 4Radiation Oncology, Tata Memorial Hospital, Mumbai, India; 5Head and Neck Surgical Oncology Unit, Tata Memorial Hospital, Mumbai, India; 6Clinical Research Secretariat, Tata Memorial Hospital, Mumbai, India

Background: Reconstruction surgery and radiotherapy cause changes in airway calibre and tone which may lead to Upper Airways Resistance Syndrome (UARS) and Obstructive Sleep Apnea (OSA). We aimed to study the prevalence of UARS and OSA in treated Oral Cancer patients.

Methodology: 78 patients (69 males, 9 females, mean age 49 years) treated for Oral Cancer were administered the Epworth Sleepiness Scale (ESS). Patients' perception of sleep quality (SLq) and mental health status were noted from Mental Health Questionnaire (GHQ), Perceived Stress Scale (PSS), as well as General Health Questionnaire (GHQ), Perceived Stress Scale (PSS), as well as Female Sexual Function Index (FSFI), Female Sexual Distress Scale (FSDS), Quality of Life Questionnaire (QLQ-H&N35) and all underwent Polysomnography. They were categorised on the basis of Respiratory Disturbance Index (RDI) into Normal (RDI <5/h), UARS (RDI 5-15/h), OSA (RDI >15/h) and Sleep Disordered Breathing (SDB) where (SDB=UARS+OSA; RDI >5/h).

Results: 66 patients underwent surgery with adjuvant (chemo)radiotherapy and re-annotation of sleep caused in OSA patients. Perinatal sleep apnea is associated with down-regulation of pro-inflammatory proteins (Cox-2) induced in obstructive sleep apena syndrome (OSAS) severity and sleep structure.

P3494

Microparticles from OSA patients induce hyper-reactivity through up-regulation of pro-inflammatory proteins

Simón Tual-Chalot1, Keita Fataormina1, Pascaleine Pissot1, 2, Wojciech Trzepiez1,2, Cristina Contreras1,2, Dolores Piro1, M. Carmen Martinez1, Frédéric Gagnadoux1,2, Ramonaros Annandstonha1,2, INSERM U094, Université d'Angers, Angers, France; 2Département de Pneumologie, CHU d'Angers, Angers, France; 3Département de Physiologie, Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain

Obstructive sleep apnea (OSA) is characterized by repetitive upper-airway obstruction during sleep, which is associated with oxygen desaturation and sleep disruption. It has been shown that level of circulating microparticles (MPs), vesicles released from plasma membrane during cell activation and apoptosis, is altered in OSA patients and contribute to endothelial dysfunction. However, their participation to reactivity in response to vasoconstrictor agonists has not yet been assessed. Two anti-matched groups of patients undergoing polysomnography for OSA were compared: 15 patients with an apnea-hypopnea index (AHI)<5 events/h were included in the OSA group and 17 control subjects with an AHI<5. MPs obtained from blood either from OSA patients or control subjects, or a vehicle were injected iv to mice. Injection of MPs from OSA patients induced vascular hyper-reactivity in response to serotonin in aorta. Interestingly, hyper-reactivity was not affected by inhibition of nitric oxide (NO)-synthase (NOS) compared to control subjects and was associated with downregulation of end (FSFI), Female Sexual Distress Scale (FSDS), and decreased NO production. The non selective cyclooxygenase (COX) inhibitor or the selective

COX-2 inhibitor reduced serotonin-induced hyperreactivity in aorta from OSA MP-treated mice. This effect was associated with increased COX-2 and NF-kB expressions. These data provide evidence that circulating MPs from OSA patients induce ex vivo vascular hyperreactivity by a combination of upregulation of proinflammatory proteins and a reduced ENOS activity and NO production. These results highlight vascular dysfunction induced by MPs that might participate to events associated in OSA.
387. Challenges in chronic disease management: helping individuals with chronic lung disease remain stable

P3472 Late-breaking abstract: Comparison of respiratory symptoms in chronic pulmonary obstructive disease and restrictive ventilatory impairment according to disease stage: The PLATINO study in Latin America

Introduction: Obstructive pulmonary disease presents defined symptoms such as cough, dyspnea, sputum and wheezing. Symptoms of restrictive ventilatory impairment are less well defined.

Objective: Compare the occurrence of respiratory symptoms in chronic obstructive pulmonary disease with the ones presented by individuals with restrictive impairment in the different stages of the disease.

Methods: Between 2002 and 2004, individuals over 40 years of age from five cities in Latin America were analyzed and had a pre post-bronchodilator spirometry done and reported their respiratory symptoms.

Results: N= 5315: 260 (4.9%) - restriction impairment and 759 (14.4%) - COPD diagnoses. Patients with COPD coughed more (31.4% vs 23.5%; OR 1:36: 1.05, 1.74) and had more sputum (28.3% vs 21.9%; OR 1:10: 1.0, 1.68). No difference was seen in dyspnea (OR:0.86 (0.69,1.06) between the two groups. Comparing the different stages of disease, at moderate stage: COPD patients presented more cough than those with restrictive impairment (40.5% vs 27.3%; OR 1.53: 1.07,2.20) and more sputum (36.6%) vs 23.6%; OR 1.57: 1.07-2.30); moderate, severe and very severe stages: COPD had more wheezing episodes than those with restrictive disease. Regarding dyspnea, it was more intense in patients with mild restriction than in those with mild COPD (43% vs 6%; OR 1:11:1.0, 2.12).

Conclusions: Cough and sputum are more frequent in patients with COPD than those with restrictive ventilatory impairment. Dyspnea is a symptom more pronounced in patients with restrictive impairment compared with individuals with COPD in early stages of the disease.

P3473 Mobile device usability to support chronic obstructive pulmonary disease management

Anael Barberan1, Anael Barberan, Diego Agustin Rodriguez, Yolanda Torralba, Jordi Vilaro, Josep Roca. Pulmonary Medicine - Pulmonary Function Laboratory, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain

COPD generates a serious burden on healthcare systemic. Telemedicine contribute to an efficient use of healthcare resources reducing number of non-scheduled visits. Are lacking studies assessing patients and healthcare provider’s satisfaction on these new approaches. The aim of the study was to determine the usability & satisfaction of COPD patients and professionals with a mobile device to support COPD management. A mobile system was offered during two weeks to 17 COPD patients (FEV1 47.2% of predicted age 65.14) patients answered the EuroQol questionnaire every day and used pulse oximetry during any exercise session at home setting. Data was collected & checked in a technological platform. Patients and professionals accomplished a usability & satisfaction questionnaire at the end of the study. 18% of patients refused and 65% finished the program. 83% felt safer during exercise and more controlled by professionals. 61% indicated that the device makes them do more physical activity. Lack of acceptance to undergo the study and drop-outs were associated with personality disorders (p<0.05). All patients evaluated positively the usability of the device and as a motivator to perform exercise. All professionals evaluated it as a useful tool to enhance life-style and to support their remote management.

Transfer of data between a mobile device and a digital platform is feasible for COPD patients. Remote monitoring of physical activity can enhance motivation to perform sustainable exercise and seems to show high grade of adherence. Long-term follow-up of a large number of patients will be needed to define effective home-based services to enhance management of COPD patients. Supported by Nexo UE - FP7 (CIP-ICT) 225025; FIS-Fit.

P3474 Access and use of communication technologies in patients with chronic obstructive pulmonary disease

Anael Barberan1, Anaar Bilbilla1, Jordi Vilaro1, Diego Agustin Rodriguez1, Yolanda Torralba1, Isabel Blanc1, David Fonollola2, Marc Bajer2, Lluís Solanell2, Albert Alonso1, Joan Albert Barbera1, Josep Roca1, 1 Pulmonary Medicine - Pulmonary Function Laboratory, Hospital Clinic i Provincial de Barcelona, 2 Technical Dept., Linkcare Health Services S.L., Barcelona, Spain

Information and Communication Technologies (ICT) have proven useful to enhance citizens’ active involvement in several domains, including healthcare. Despite access to ICT is widespread across Europe, usability of ICT by elderly patients with chronic conditions remains controversial. The research was conducted within the frame of NEXES, an EU project designed to assess extensive deployment of integrated care services supported by an information technology platform (Linkcare®). The study explores current habits/attitudes of COPD patients concerning the use of mobile phones and Internet.

Prior to the initiation of the wellness and rehabilitation program in NEXES, we conducted a phone interview to 68 COPD patients (FEV1 P50-P95: 21-74%pred; age 65-95: 54-78 years) to investigate their attitude towards telemedicine. 41% of the patients use Internet and 91% use mobile phones. 58% of all subjects have internet access at home. The main reason for not using Internet is a poor knowledge on how to use it (76% of non-users). But, 55% of the non-Internet users are interested in learning how to use it. Among the Internet users, 89% have access to e-mail and 46% of them participate in social networks. 62% of patients send SMS’s and 15% send files by mobile phones. The use of mobile phones correlates with age (p<0.04) whereas Internet correlates with educational level (p<0.001), but not with disease severity or aerobic capacity.

The percentage of COPD patients using Internet and mobile phone is similar to the general population of the area for the same range of age. Disease severity or presence of COPD generate a serious burden on healthcare system. Telemedicine contribute to an efficient use of healthcare resources reducing number of non-scheduled visits. Are lacking studies assessing patients and healthcare provider’s satisfaction on these new approaches. The aim of the study was to determine the usability & satisfaction of COPD patients and professionals with a mobile device to support COPD management. A mobile system was offered during two weeks to 17 COPD patients (FEV1 47.2% of predicted age 65.14) patients answered the EuroQol questionnaire every day and used pulse oximetry during any exercise session at home setting. Data was collected & checked in a technological platform. Patients and professionals accomplished a usability & satisfaction questionnaire at the end of the study. 18% of patients refused and 65% finished the program. 83% felt safer during exercise and more controlled by professionals. 61% indicated that the device makes them do more physical activity. Lack of acceptance to undergo the study and drop-outs were associated with personality disorders (p<0.05). All patients evaluated positively the usability of the device and as a motivator to perform exercise. All professionals evaluated it as a useful tool to enhance life-style and to support their remote management.

Transfer of data between a mobile device and a digital platform is feasible for COPD patients. Remote monitoring of physical activity can enhance motivation to perform sustainable exercise and seems to show high grade of adherence. Long-term follow-up of a large number of patients will be needed to define effective home-based services to enhance management of COPD patients. Supported by: UE – FP7 (CIP-ICT) 225025.

P3475 Evaluation of a web based home training program for COPD patients: A controlled trial

Stephanie Jansen-Kosterik1, Rianne Huis in ‘t Veld2, Daniel Weer3, Hermie Hermens1,2, Miriam Vollenbroek-Hutten2,3. 1 Het Roessingh, Roessingh Research and Development, Enschede, Netherlands; 2Faculty of Electrical Engineering, Mathematics and Computer Science, University of Twente, Enschede, Netherlands; 3Het Roessingh, Roessingh Center of Rehabilitation, Enschede, Netherlands

Introduction: An important aim of rehabilitation of patients with COPD is to support them in acquiring and maintaining an active lifestyle. Dependent on their mobility to train, patients visit the rehabilitation center 2 or 3 times a week. It is hypothesized that a web based home training program, with exercise videos and a videoconference module can increase the efficiency and effectiveness of this rehabilitation program.

Aim and objective: To evaluate a web based home training program for COPD patients in terms of user experience (satisfaction and usability) and clinical benefits (changes in subjective perceived and objective measured health status: dyspnea and fatigue (VAS), CRQ and Six Minute Walk Test).

Methods: COPD patients were divided into a control and an intervention group. Patients of the control group followed the traditional rehabilitation program. Patients of the intervention group followed the same program but a web based home training program was provided as addition (for those visiting rehabilitation center 2 times a week) or as part replacement (for those visiting rehabilitation center 3 times a week). At baseline and after intervention measurements were obtained.

Results: Preliminary data analysis (n=23) shows that patients are satisfied with the web based home training program and rated its usability as good. The degree of clinical benefit of the intervention group (n=23) is similar to the progression made by the group (n=20) after rehabilitation.

Conclusions: Based on preliminary results, a web based home training program seems to have potential to treat patients in their own environment under professional supervision.

P3476 Fit for flight? An investigation into awareness of air travel recommendations among patients with respiratory disease

Axel Sylvan, Ian Webster. School of Medicine, University of Manchester, Manchester, United Kingdom Respiratory Medicine, Royal Bolton Hospital NHS Foundation Trust, Bolton, United Kingdom

Objective: To investigate awareness of air-travel guidelines among patients with respiratory disease.

Background: While the population has aged and prevalence of respiratory disease has risen, air travel has increased dramatically in the UK. A significant proportion of flight-related emergencies may be of respiratory origin.

Method: 64 respiratory patients completed questionnaires based on British Thoracic Society (BTS) guidelines, screening for awareness and experience of air travel. Pulse oximetry readings were performed and, where appropriate, frequency was recorded. Frequency data was analysed in StatsDirect, using Exact (Clopper-Pearson) 95% Confidence Intervals. Enquires about in-flight oxygen where made to 8 airlines.

Results: 72% of patients were aware of air travel guidelines. Of patients who deemed themselves fit to fly, 4% would require in-flight oxygen and 37.5% would be likely to require oxygen on flights lasting over 2 hours. Among patients planning to fly, 87.5% had never been offered pre-flight respiratory tests and 25% had suffered in-flight respiratory problems.

Conclusion: Awareness of air travel guidelines among respiratory patients is low and poses a significant health risk. Patients are inadequately offered pre-flight
respiratory tests and availability of in-flight oxygen varies widely between airlines and is, when offered, an expensive service. This study calls for greater recognition of air travel with respiratory disease among patients, physicians and airlines alike.

P3477 Air travel and COPD: Exercise SpO2 and walking distance as predictors for in-flight desaturation Anne Edvardsen1, Aina Akerø2, Carl Christian Christensen3, Morten Ryy1, Ole Henning Skjønberg2 1Department of Respiratory Physiology, Glimtetrøenkniven, Hakadal, Norway; 2Department of Pulmonary Medicine, Oslo University Hospital Ullevål, University of Oslo, Oslo, Norway

Background: Supplemental oxygen during air travel is recommended when in-flight PaO2 is expected to fall below 6.6 kPa in patients with lung disease. Sea level oxygen saturation falls to near oximetry saturation in altitude where supplemental oxygen has proven inadequate, as a predictor of in-flight hypoxemia, and it has been suggested that exertional flight PaO2 is expected to fall below 6.6 kPa in patients with lung disease. Sea level SpO2 can be measured to quantify the impact of comorbidities in COPD patients in research and practice.

Aim: The study aimed to evaluate if exertional desaturation and walking distance during a 6-min walk test (6MWT) might help predicting in-flight hypoxemia and thereby the need for in-flight oxygen in patients with COPD.

Methods: COPD patients referred to hypoxia-altitude simulation test (HAST) were consecutively included. Lung function tests, blood gas measurement, 6MWT, and HAST were performed. Seventy-four COPD patients (42% men) were included, mean (SD) age 65 (8) years, FEV1, 41 (13)% predicted. SpO2 baseline was 93 (3)% PaO2 HAST 6.3 (0.6) kPa, nadir SpO2 6MWT 83 (6)% nadir SpO2 6MWT and walking distance correlated with in-flight PaO2 (r=0.49, p<0.001) and r=0.27, p=0.007 respectively. ROC analysis with nadir SpO2 6MWT against PaO2 HAST ≤ 6.6 kPa gave an area under the curve of 0.786 and suggested that the cut-off yielding greatest accuracy for an in-flight PaO2 ≤ 6.6 kPa was a SpO2 6MWT below 85% (sensitivity 85%, specificity 69%). Walking distance had no prognostic value for in-flight PaO2 in the ROC analysis.

Conclusions: In patients with COPD, exercise desaturation below 85% suggests that in-flight oxygen might be needed. As a supplement to sea level SpO2, exercise desaturation might be useful in the initial pre-flight screening.

P3478 Deployment of integrated care services for patients with long-term oxygen therapy (LTOT): Role of frailty Carme Hernandès1, Enric Duran-Tauleria2, Silvia Valls1, Jesus Aibar1, Jordi Sarroca3, Nestor Soler4, Ida de Godoy5, Victor Castillo6, Alvar Aguisti7, Josep Roca2 1Integrated Care Unit, Hospital Clinic, Ciberes, IDIBAPS, Univ. Barcelona, Barcelona, Spain; 2Epidemiology Unit, PAMEM-IDIM, Barcelona, Spain; 3Hospital Clinic, IDIBAPS, Univ. Barcelona, Barcelona, Spain

Patients receiving LTOT are frequent users of healthcare services. Pilot studies have shown that Integrated Care Services (IC) reduce hospitalizations in these patients and have also identified that deployment of IC requires an operational definition of ‘IC’ and specific criteria for stratification of patients.

Objective: To characterize the risk profile of LTOT patients in an urban area of 540,000 inh in order to allow the design of a one-year follow-up RCT to assess deployment of IC tailored by patient’s frailty

Methods: Observational study examining 751 patient’s records. We planned three factors aiming at enhancing quality of LTOT.

Factors related with organization of healthcare services had impact on LTOT adherence (OR 0.45 [0.22–0.91]).

Conclusions: The study provides the rationale for future actions on modifiable factors aiming at enhancing quality of LTOT.

P3479 Development of a comorbidity index that reflects health-related quality of life in patients with COPD Anja Anja Frey1, Patrick Magguensturm1, Lara Siebeling2, Marco Zoller3, Cynthia Boyd4, Gerben ter Riet5, Milo Puhan1,2,3 1Horten Centre, University of Zurich, Zurich, Switzerland; 2Department of General Practice, University of Amsterdam, Amsterdam, Amsterdam, Netherlands; 3Department of General Practice, University of Zurich, Zurich, Switzerland; 4Department of Geriatrics, Johns Hopkins Hospital, Baltimore, United States; 5Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: In COPD research little consideration is currently given to the impact of co-existing comorbidities, which is partly due to the absence of an index that would quantify their impact. We developed a COPD comorbidity index that quantifies the impact on health-related quality of life (HRQL).

Methods: Using data from 411 Swiss and Dutch COPD patients with GOLD stage ≥2 we used the non-COPD specific Feeling Thermometer (FT, scores 0-100) as a valid and reliable instrument to measure HRQL. We ascertained the presence of comorbidities that may impact on HRQL through self-report and chart review. In the analysis, we included patients who had a FT ≥ 3 points (p<0.05 minimal important difference) in univariate analysis adjusted for FEV1.

Results: Coronary heart disease (p=0.018), diabetes (p=0.009), psychiatric disease (p=0.017) and urogenital disease (p=0.018) were most strongly associated with FT <67. ROC analysis with the non-COPD specific Feeling Thermometer (FT, scores 0-100) as a valid and reliable instrument to measure HRQL.

Conclusion: A simple index that counts the presence of four comorbidities can be used to quantify the impact of comorbidities in COPD patients in research and practice.

P3480 Prevalence of dyspepsia in COPD patients: Experience in a large Canadian cohort Gauthier Andréanne, Chalifoux Geneviève, Poirier Claude 1Integrated Care Unit, Hospital Clinic, Ciberes, IDIBAPS, Univ. Barcelona, Barcelona, Spain; 2Epidemiology Unit, PAMEM-IMIM, Barcelona, Barcelona, Spain

It has been shown that dyspepsia can be associated with COPD and in some cases closely linked to COPD exacerbations. The association of dyspepsia with COPD severity (FEV1, respiratory failure) and medications is not well described. The aim of this study is to evaluate the prevalence of dyspepsia in a large Canadian COPD cohort and to identify risk factors.

We retrospectively reviewed files of 1247 COPD patients. We classified patients as dyspepsia-positive (D+: 513 patients or 41%) or dyspepsia-negative (D-: 734 patients or 59%). Mean age was similar in D+ and D- (71.6 y/o versus 70.2) and we found no difference in FEV1 (44.97% versus 45.07%, p=0.05). Dyspepsia was more frequent in female patients (54.4% versus 45.4%, p<0.02) and in patients receiving home oxygen therapy (35.1% versus 26.8%, p<0.02). Active smoking was inversely related to dyspepsia (31.8% in D+ versus 41.0% in D-, p<0.001). Frequent acute exacerbations (>1/year) was also associated with dyspepsia (80.3% versus 71.7%, p<0.001). Finally, dyspepsia was positively related to cardiovascular and osteoporotic comorbidities (86.7% versus 68.4%, p<0.001). No relation was found with medications use, notably inhaled corticosteroids.

Conclusion: As reported by other publications, our retrospective study noted a high prevalence of dyspepsia in COPD patients and there was no relation with disease severity (expressed by the FEV1). Female sex, frequent acute exacerbations and comorbidities appear to be associated with dyspepsia. Surprisingly, we found a negative association with smoking status. Dyspepsia treatment consequences should now be addressed closely (QOL, exacerbations, FEV1 decline).

P3481 Three-year follow-up study of inflammatory markers in chronic obstructive pulmonary disease Renata Ferrari, Suzana Tanni, Laura Caram, Camila Corrêa, Corina Corrêa, Rosana Martin, Irma Godoy. Department of Internal Medicine, Botucatu Medical School - Sao Paulo State University - UNESP, Botucatu, Sao Paulo, Brazil

Studies show that values of Interleukin-6 (IL-6) and C-reactive protein (CRP) does not change significantly in COPD patients over one-year period. However, long-term studies of these mediators are lacking. We aimed to evaluate by high sensitivity ELISA (BioSource International Inc, Ca, USA) and C-reactive protein, CRP, in patients with COPD.

Results: Twenty-four COPD patients (16 males, 8 females) were included. Plasma concentration of Interleukin-6 had not change significantly during the follow-up period. However, tolerance exercise, dyspnea and BODE index worsened after three years. Plasma concentration of Interleukin-6 was measured by high sensitivity ELISA (BioSource International Inc, Ca, USA) and C-reactive protein.
P3482 A qualitative study of self-management in COPD: Attitudes and priorities of patients for making health behaviour changes

Julia Walters1, Helen Cameron-Tucker1, Helen Courtney-Pratt1, Richard Wood-Baker1, Andrew Robinson1, Jenn Scott2, Paul Turner3, Mark Nelson4, E. Haydn Walters5, 1Menzies Research Institute Tasmania, University of Tasmania, Hobart, Tasmania, Australia; 2School of Psychology, University of Tasmania, Hobart, Tasmania, Australia; 3School of Computing and Information Systems, University of Tasmania, Hobart, Tasmania, Australia

Pivotal to successful chronic disease self-management is achieving adoption and maintenance of health behaviours that influence disease progression and impact.

Aim: To evaluate patients’ uptake and attitudes to health behaviour change in the Snail9 framework consisting of the items: smoking, nutrition, alcohol consumption, physical activity, psychosocial wellbeing and symptom management.

Methods: Community nurse mentors trained in a self-management approach, mentored 90 participants with COPD for up to 12 months by telephone. Participants’ views were sought during semi-structured interviews with a purposive representative sample. Data analysis by two independent authors used an Iterative Thematic approach. Health status was measured using SGRQ, HADS and MRC scales.

Results: In 20 participants (50% male, 50% current smokers) with COPD (GOLD stage: moderate 15, severe 5), mean age 65-4 years, the SGRQ overall score was 45 (SD 25.8). We found three groups related to health behaviour change attitudes. 8 (40%) subjects were actively making changes; 9 (45%) subjects were open to making changes and 3 (15%) subjects were more resistant. Severity of COPD and current smoking status were not major influences on attitude. Mentoring increased awareness of COPD effects and helped develop personal and behaviour change strategies, importantly even in those not actively making changes. Physical activity was most frequently targeted for changes. 50% of current smokers developed plans to target smoking. Motivation to maintain changes was increased by mentor support.

Conclusions: Health behaviour change in COPD at all stages can be supported by regular telephone mentoring.

P3483 Assessment of self-management needs among patients with COPD

David Coutts1, Kathryn Wortz2, Angela Cade3, FengHsiu Su4, Bradford Jackson1, Sunnhiro Suzuki5, Kaming Lo6, Karan Singh7, Sejong Bae8, 1Inaugural Research Fellowship, University of Texas HSC-Tyler, Tyler, TX, United States; 2Family Medicine, University of Texas HSC-Tyler, Tyler, TX, United States; 3Biostatistics, University of North Texas HSC School of Public Health, Ft. Worth, TX, United States

Introduction: While self-management is an essential part of chronic illness care, little is known about patients’ perspectives of their self-management needs.

Objective: To address this gap we conducted a cross-sectional, self-management needs assessment among patients with COPD.

Methods: Patients were enrolled from clinics as part of a self-management intervention trial. Patient activation was categorized based on their confidence in self-management and on motivation to participate in their care. Behavioral intentions addressed readiness to quit smoking and to meet physical activity goals.

S-efficacy was assessed using a COPD-specific scale. Open-ended questions addressed self-care facilitators, barriers, and goals.

Results: Of 76 patients enrolled, mean age was 69.2 years with 49.1% female. For patient activation 29.0% are active, 31.6% high effort, 23.7% compliant, and 15.8% passive. Among current smokers the majority are interested in quitting with 35% contemplation, 30% preparation, and 20% action. While mean levels of reported self-efficacy were similar across domains, the proportion reporting low levels of confidence were greatest for physical activity and behavioral domains (56.6%). In a qualitative analysis of 34 interviews major themes relevant to self-management facilitators, barriers, and goals were fear (i.e., disease progression, suffocation/death), loss (i.e., functioning, independence), cherished activities), co-morbid limitations, stigma/social isolation, and desire for change (i.e., improve functioning, better care, information, understanding).

Conclusions: The results from this cross-sectional analysis highlight the complexity of self-management needs among patients with COPD.

P3484 The views and attitudes of patients, carers and healthcare professionals on nutrition in COPD

Moe Kyl1,4, Sarah Foster2, Angela Tod1, Jo Cooke3, Trevor Rogers1,4, Stuart Parker1,5, 1Respiratory Department, Doncaster Royal Infirmary, Doncaster, South Yorkshire, United Kingdom; 2Human Nutrition Unit, Royal Hallamshire Hospital, University of Sheffield, Sheffield, South Yorkshire, United Kingdom; 3Centre for Health and Social Care Research, Sheffield Hallam University, Sheffield, South Yorkshire, United Kingdom; 4Collaborations for Leadership in Applied Health Research and Care - South Yorkshire and the Humber (CLAHRC-ST), National Institute for Health Research, Sheffield, South Yorkshire, United Kingdom; 5Sheffield Institute for Studies on Ageing, University of Sheffield, Sheffield, South Yorkshire, United Kingdom

Introduction: Weight loss is a reversible prognostic factor in COPD but there is little evidence on effective community nutritional intervention for underweight COPD patients. This study is part of a feasibility study on designing and evaluating such nutritional intervention.

Aims: To find out the views and attitudes of patients, carers and healthcare professionals (HCPs) towards nutrition in COPD and to gain insight on:

1. Effect of weight loss
2. Factors influencing eating
3. Dietary counselling
4. Current COPD nutritional pathway

Methods: Six underweight COPD patients, 6 carers and 8 HCPs were recruited by purposive sampling and formed 3 semi-structured focus groups. Discussions were recorded and transcribed verbatim, sorted with NVivo software and analysed using framework qualitative analysis.

Results: Weight loss was important not only for health but also for cosmetic, psychological and financial reasons.

Patients chose food according to taste, cost, consistency, chewability and availability. They tolerated only small portions but valued variety and ate more when in company. Oral nutritional supplements (ONS) were disliked but some found it useful as an energy source when ill.

Dietetic consultations were perceived as useful if individualised and regular.

Negative views on underweight in COPD led to delayed dietetic referrals. Screening for underweight and weight loss was recommended.

Conclusions: To increase adherence to the nutritional programme, varied high-calorie foods which are easily available, cheap and affordable should be considered.

The nutrition support intervention should involve food fortification, snack and/or ONS and incorporate individualised consultation.

P3485 Muscle regrowth in COPD patients induced by anabolic steroids is amplified by systemic glucocorticoids (GC): A potentiating interaction between GC and IGF-1

Nicholas A.M. Pansters, Raman C.J. Langen, Annemie M.W.J. Schols. Respiratory Medicine, MUMC+, Maastricht, Limburg, Netherlands

Muscle wasting is associated with poor prognosis in COPD. Anabolic steroids can induce muscle regrowth and stimulate muscle insulin growth factor 1 (IGF-1) signaling, while high dose systemic glucocorticoids (GC) can induce muscle atrophy. The current study aimed to gain insight into the combined effect of GC and anabolic stimulation on muscle. Post-hoc analysis of a previously published clinical trial (Creeberg, et al. Chest 2003; 124:173–181) investigating m-drolone decanoate (ND) efficacy on male COPD patients revealed that gain in fat free mass (assessed by deuterium dilution), was highest in ND/GC 22.5±5.7 11W (p<0.05) vs ND/no-GC 8.54±4.08W (NS) compared to their respective controls placebo/GC and placebo/no-GC. Muscle function determined by peak workload similarly increased most in the ND/GC group 22.5±5.7 11W (p<0.05) vs ND/no-GC 8.54±4.08W (NS) compared to their respective controls. During muscle regrowth activated satellite cells (myoblasts), differentiate and fuse with myofibers, which is stimulated by IGF-1. In cultured C2C12 myoblasts, GC strongly impaired (>2-fold) and IGF-1 stimulated (>2.5-fold) multiple parameters of muscle differentiation, like Creatine Kinase activity, muscle contractile protein content and myoblast fusion. However when combined, a synergistic stimulation (>3-fold) of myogenic differentiation parameters was observed, which is in line with our clinical data. Unraveling the potentiating interaction between GC and IGF-1 may provide new leads to enhance efficacy of intervention strategies to prevent or restore muscle wasting in COPD.

P3486 The effects of nutritional support with omega-3 rich diets on respiratory functions, exercise capacity and quality of life in stable COPD

Sinem Metin1, Nazirin Ucar2, Serdar Akpinar2, Gul Kizilgun1, Kendane Saka1, Tugul Sigir2, 1Nutrition and Dietetics Department, University of Baskest, Ankara, Turkey; 2Chest Disease Department, Atatürk Chest Disease and Surgery ERH, Ankara, Turkey

Objective: To determine the effects of nutritional support with omega-3 rich diets on respiratory functions, exercise capacity and quality of life in COPD patients.

Methods: The study was planned on 21 stable COPD patients. A questionnaire...
was applied to patients including demographic and disease information, food-
frequency, a three-d 24-h dietary record and Subjective Global Assessment. SF-36,
6 Minute Walking Test, BORG scale and spirometric tests were performed to the
patients. Before the personal diets were planned, patients' personal needs were
determined and an omega-3 rich diet was administered with an omega-3 dietary
supplementation (180 mg EPA and 120 mg DHA).

Results: After dietary intervention, patients' mean BORG scale result was de-
creased (p<0.05). After diet, physical component score and mental component
score were increased and these differences between before and after intervention
were statistically significant (p<0.05). The mean walking distance of the patients
was 395.9±53.65 m before intervention and 420.8±48.07 m after intervention
(p<0.05). Before dietary intervention, FEV1/FVC was 64.1±11.61% and after
the intervention this ratio increased to 67.8±9.37% (p<0.05). After diet, there
was a significant negative correlation between dietary omega-3 and BORG scale
(r=-0.623, p=0.003), a significant positive correlation between dietary omega-3
and SF-36 Physical Health component (r=0.456, p=9.038).

Conclusion: While planning the COPD patients' diet it should be so important to
provide adequate energy, low carbohydrate and high omega-3 content within diets
during the lifetime of survival.

P3487

Association of weight loss in COPD patients with low body mass index on
outcomes
Erica Rutten 1, Richard Casaburi 2, Michael Watkins 1, Nicolas Locantore 3, Emiel Wouters 2, 1 Program Development, Centre of Expertise for Chronic Organ Failure (Cino), Hoorn, Limburg, Netherlands; 2 Division of Respiratory and
Critical Care Physiology and Medicine, Los Angeles Biomedical Research
Institute at Harbor-UCLA Medical Center, Torrance, United States; 3 Respiratory
MDC, GlaxoSmithKline, NC, United States

The impact of COPD phenotypes based on body composition and it's change
was evaluated on longitudinal outcomes in COPD patients from the "Evaluation
of COPD Longitudinally to Identify Predictive Surrogate Endpoints" (ECLISEP
study). The assessment of the body mass index (BMI) was done at Year 1 for 364 COPD patients and assessed the impact of BMI and the change in
BMI from baseline to year 1 on mortality during the subsequent two years of the
study. During the follow-up, there were 31 deaths. Using logistic regression, each
decrease from baseline to Year 1 to 1 kg/m² in BMI in this underweight group
was associated with a 51% increased risk of death after controlling for FEV1%
predicted and BMI.

Logistic Regression with mortality during Year 2 and Year 3 as dependent variable in underweight subjects

These findings suggest that for a group of underweight COPD patients, the magn-
itude of weight change in the previous year is an independent predictor of poor
outcome.

P3488

Hypoxia altitude simulation test (HAST): Arterial blood gases or pulse oxim-
etry? 

Anne Edvardsen 1, Aina Åkerø 2, Carl Christian Christensen 1, Morten Ryg 1, Ole Henning Skjønsberg 2, 2 Department of Respiratory Physiology, Glitrereikliniken, Hokadadal, Norway; 3 Department of Pulmonary Medicine, Oslo University
Hospital Ullevål, University of Oslo, Oslo, Norway

Background: Supplemental oxygen is recommended when PaO2 is expected to
fall below 6.6 kPa during air travel. Hypoxia altitude simulation test (HAST)
with monitoring of arterial blood gases (ABG) is the most frequently used test
to identify those at risk of developing in-flight hypoxemia. If pulse oximetry can be
used as a substitute for ABG, HAST would be simpler to perform and thereby
more available.

Aim: We hypothesised that pulse oximetry may replace ABG when using HAST
in the pre-flight evaluation of COPD patients.

Methods: COPD patients referred to HAST were consecutively included. HAST
was performed with arterial blood gases taken from an arterial line in addition
to continuous measurement of SpO2 with a pulse oximeter. After 15 min with
inhalation of a hypoxic gas (15% O2, equivalent to 2348 m above sea level),
PaO2 and SpO2 were simultaneously registered.

Results: 100 COPD patients (42% men) were included, mean (SD) age 65 (8)
years, FEV1: 41 (33)% predicted. SpO2 baseline was 93 (3)% PaO2: HAST 6.3
(0.6) kPa, and SpO2: HAST 83 (4)%. There was a strong correlation between PaO2
and SpO2: HAST (r=0.81, p<0.001). A ROC analysis showed strong prog-
nostic properties (area under curve 0.928) for use of pulse oximetry for detection
of in-flight PaO2 < 6.6 kPa. The suggested cut-off value for PaO2 < 6.6 kPa was
SpO2: HAST < 85% (sensitivity 89%, specificity 81%).

Conclusions: Pulse oximetry may replace arterial blood gases during HAST. A
SpO2 < 85% can predict development of severe in-flight hypoxemia (PaO2 < 6.6
kPa) with a sensitivity of 89% and a specificity of 81%. Use of SpO2 during HAST
will simplify the test considerably.

P3489

Ambulatory care of patients with bronchial asthma participating in a
German disease management program

Sabine Gross, Jens Kretzschmar, Bernd Hagen, Lutz Altenhofen. DMP Office,
Central Research Institute for Ambulatory Health Care in Germany; Cologne,
Germany

Background: In 2006 a disease management program for bronchial asthma
was started in the North Rhine region, Germany, focusing on patient education
and optimisation of quality of care.

Methods: By the end of 2009 data from 55,928 adults (A) and 13,021 children
(C, aged 5 to 17 years) are analysed cross-sectionally. Between 2007 and 2009
continuously documented patients are analysed longitudinally. Standardised medi-
cal records provide information of symptom frequency, non-medical interventions
and pharmacotherapeutics.

Results: In 2009 35% of the adults suffer at least from weekly symptoms (C 13%),
in 38% symptoms are documented less than once per week (C 50%). Control of
inhalation techniques is conducted for 72% of all adults (C 79%) and 63% are
provided with a self-management plan (C 86%). Asthma education is advised to
47% of all patients (C 65%), but only 40% of these subsequently participate in
such an education (C 48%). Most common pharmacotherapy in patients with at
least weekly symptoms consists of short-acting beta-agonists (SABA) as reliever
medication (A 70%, C 82%), inhaled corticosteroids (ICS) (A 71%, C 72%)
or long-acting beta-agonists (LABA) as controller medication (A 63%, C 54%)
SABA (2007-09 A: 69-68%, C: 91-92%), LABA (A: 56-60%, C: 26-22%)
and ICS in adults (70-68%) are prescribed rather constantly over time, prescription
rates of ICS in children decline (73-58%).

Conclusions: Prescription rates of SABA, LABA and ICS seem to be in accor-
dance to recommendations by asthma guidelines. Control of inhalation devices
is at a high level, but rate of participation in patient education needs further
improvement. Limitations due to potential selection bias have to be considered.

388. Insight into mechanisms of respiratory infections

P3490

LSC 2011 Abstract: The role of IL-25 in rhinovirus-induced asthma
exacerbations

Janine Beale, Nathan Bartlett, Sebastian L. Johnston. Respiratory Medicine,
Imperial College London, National Heart and Lung Institute, UK

Rhinoviruses (RV) are the major causative factor of asthma exacerbations (AE).
While RV-mediated inflammation is implicated in asthma, it is unknown how the
immune response to RV infection interacts with Th2 immunity causing an AE.
Epithelial-derived IL-25 is an important regulator of Th2 immunity and plays a
role in asthma pathogenesis. We hypothesised that RV infection of the epithelium
induces IL-25 production facilitating immunopathogenesis of AE. We measured
IL-25 mRNA in mouse models of RV infection and RV-induced exacerbation
of allergic airway inflammation [1]. In vitro IL-25 gene induction was also assessed
in asthmatic and normal bronchial epithelial cells (BEC) infected with RV and
stimulated with IL-4. In vivo and in vitro results demonstrated that RV induced
IL-25 mRNA as measured by qPCR. Airway challenge with ovalbumin (OVA) fol-
lowed by RV infection in sensitised mice exacerbated allergic airway inflammation
and coincided with enhanced IL-25 mRNA expression compared with allergen
or infection alone. Similarly, RV and IL-4 treatment of BECs resulted in the
highest levels of IL-25 mRNA. The novel finding that RV infection induces IL-25
represents a link between antiviral responses and Th2 inflammation identifying a
role for IL-25 in RV-induced AE. Allergen/IL-4 treatment enhanced RV-dependent
IL-25 expression thus a Th2 environment and virus may result in exacerbated Th2
inflammation mediated by IL-25.

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
Pulmonary complications are frequent in hematologic patients. Regular investigation of BAL fluid includes bacterial/fungal culture, staining and PCR for mycobacteria, immunohistochemistry/Grocott staining for pneumocystis and cell differentiation. The increasing use of PCR to search for different viruses is demonstrated. In this study we analysed the diagnostic yield of a recently established multi-PCR for detection of 13 viruses. 219 hematologic patients underwent bronchoscopy with BAL from September 2009 to January 2011. 28 of patients received high dose chemotherapy, 143 underwent autologous and 13 allogeneous stem cell transplantation. Bacteria were cultured from 43 (20%) BALs: staphylococcus aureus, pseudomonas aeruginosa, streptococcus pneumoniae, enterococcus, moraxella, enterobacteriaceae, klebsiella, corynebacterium, mycoplasma pneumoniae, mycoplasma hominis, chlamydia pneumonae, bordetella pertussis. There were 7 cases of pneumocytus. In two patients we found mycobacterium gordonae. Aspergillus was cultured in 4 cases. In 81 (37%) patients viruses were documented. Most often we found rhinovirus (n=31; 14%), followed by CMV (n=18; 8%), HSV (n=13; 6%), RSV (n=10; 4.5%), coronaviruses (n=8; 3.6%), adenovirus (n=7; 2.5%), parainfluenza- and metapneumovirus (each n=5; 2.2%), H1N1 (n=1; 1.8%), influenza (n=3; 1.4%), and HHV6 (n=1; 0.4%).

Summary and conclusion: The incidence of viral infections is very high in patients with hematologic diseases and pulmonary symptoms. Multiplex PCR in the BAL should be introduced as a routine diagnostic procedure in this patient group allowing to withdraw or avoid antibiotic or antifungal therapy in many cases.

P3492 Impaired innate immunity to rhinovirus in severe asthmatic children

Michaela F., Nicolaus Regamey1, Marpuriie2, Elisabeth Kieninger2, Atul Gupta3, Andrew Bush4, Sebastian Johnston5, 1Respiratory Medicine, Imperial College London, London, United Kingdom; 2Division of Paediatric Respiratory Medicine, University Children’s Hospital, Bern, Switzerland; 3Respiratory Paediatrics, Royal Brompton & Harefield NHS Foundation Trust, Imperial College London, London, United Kingdom

The pathogenic mechanisms of rhinovirus-induced asthma exacerbations are incompletely understood. Impaired production of innate IFN-β and IFN-λ have been identified in bronchial epithelial cells and bronchoalveolar lavage macrophages from atopic mild moderate asthmatics upon rhinovirus infection in vitro. These cells display similar production of pro-inflammatory cytokines when compared to cells cultured from non-asthmatic, non-atopic individuals, and are observable in asthmatic patients. In the present study, bronchial epithelial cells were cultured from severe asthmatic children (n=8, mean age 11yr, range 9-15, 63% male) and non-asthmatic non-asthmatic controls (n=10, mean age 7yr, range 6-15, 70% male). Cells were infected with RV1B, RV16, or medium and mRNA, protein and virus release was measured at 8-48h post infection. Cells from severe asthmatic children displayed significantly reduced IFN-β (p<0.05) IFN-λ-1 (p<0.05) and IFN-λ-2/3 mRNA (p<0.05), but not IL-8 (p>0.05) or ENA-78 (p>0.05) compared to controls. Cells cultured from severe asthmatics had significantly higher RV1B (p<0.01). RV16 (p<0.05) release at 48h, compared to controls. Impaired RV1B induced IFN-β and IFN-λ-2/3 also showed strong negative correlations with increased virus load (r=-0.79, p=0.013 and r=-0.65, p=0.013 respectively). RV1B induced IFN-λ-2/3 from severe asthmatics also showed strong negative correlations with total serum IgE (r=-0.75, p=0.04) and a trend for a negative correlation with total serum IgE (r=-0.75, p=0.04). These findings suggest that there is a significant role for RV1B and RV16 in the pathogenesis of asthma exacerbations in severe asthmatic children.

P3493 Tyrosine sulfation in the N-terminal domain of human C5aR is necessary for high-afﬁnity binding of chemotaxis inhibitory protein of staphylococcus aureus

Zhennia Liu1, Aixia Wang2, Guanhua Du3, Jinning Gao1, 1Respiratory Diseases, Peking Union Medical College Hospital, Beijing, China; 2Infectious Diseases, Peking Union Medical College Hospital, Beijing, China; 3National Center for Drug Screening, Peking Union Medical College, Beijing, China

Background: Staphylococcus aureus evades host defense through releasing several virulence proteins, such as chemotaxis inhibitory protein of staphylococcus aureus (CHIPS). Previous studies have shown that extracellular N terminus of C5a receptor (C5aR) forms the binding domain for CHIPS. Tyrosine sulfonation is emerging as a key factor in determining protein-protein interaction. The goal of this study was to evaluate the role of tyrosine sulfation of N-terminal C5aR in binding to CHIPS.

Methods: Expression plasmids encoding C5aR and its mutants were made by PCR and site-directed mutagenesis. HEK 293T cells were transfected with plasmids encoding C5aR using calcium phosphate. Reconstituted CHIPS protein was purified. Western blotting was used to assay the binding of CHIPS to C5aR or its mutants and p-38 phosphorylation.

Results: We report that CHIPS exclusively binds to C5aR, but not to C5L2 or C5L1. A nonspeciﬁc sulfation inhibitor, sodium chloride, diminishes the binding ability of C5aR to CHIPS. Blocking sulfation by mutation of tyrosine to phenylalanine at positions 11 and 14 of C5aR N terminus completely abrogates CHIPS binding. When tyrosine 14 alone was mutated to phenylalanine, the binding afﬁnity of recombinant CHIPS was substantially decreased. CHIPS fails to induce p-38 phosphorylation in cells overexpressing wild-type C5aR or its mutants.

Conclusion: This study deﬁnes a structural basis of C5aR-CHIPS association, in which tyrosine sulfation of N-terminal C5aR plays an important role in CHIPS binding. Our data would make it possible to develop potent drugs for therapeutic intervention.

P3494 shRNAs signiﬁcantly reduce the replication of RSV in vitro

Musa Khanios, Igor Shilovski, Dmitry Mazurov, Evgeny Fairuzales. Biomedical Technologies, NRC Institute of Immunology FMBH, Moscow, Russian Federation

Background: RNA interference (RNAi) is a powerful tool to silence gene expression on the level of mRNA. To knock-down gene expression by using RNAi two major methods of mRNA silencing exist. First method utilizes siRNA (small interfering RNA), a readily processed dsRNA, that enters RISC complex and degrades the target mRNA after transcription into the cells. The second method based on the construction of plasmid DNA that expresses shRNA (short hairpin RNA) from U6 or CMV promoter. shRNA gets processed by Drosha and Dicer RNAses inside the cell before it translocates to the cell cytoplasm and affects the level of target mRNA. In this study we investigated the ability of specific vector constructs coding shRNA molecules to target the expression of respiratory syncytial virus (RSV) phosphoprotein in vitro and thus inhibit the replication of RSV.

Methods: Lentiviral vector pGIPZ expressing GIPZ-IRE5-shRNA/Amica30 casette was modified by introducing BamHI restriction site downstream of the original recombinant.

Results: Three shRNAs against phosphoprotein P RSV and shRNA against human CD43 as a control were generated and cloned into modified so-called pGIPZ vector. Monkey kidney cells MA-104 were stably transfected with four shRNA constructs. MA-104 cells transfected with shRNA constructs against RSV P protein demonstrated significant inhibition of RSV replication after the infection than compared to the control and not transfected cells.

Conclusion: The generated constructs can be successfully used for efficient gene silencing and virus replication inhibition in vitro.

P3495 Novel narrow spectrum kinase inhibitors inhibit rhinovirus replication via enhancement of interferon expression in nasal epithelial cells of atopic and non-atopic patients

Marco Contoli1, Kazuhiro Ito2, Donatella Poletti3, Antonio Pastore3, 1Asthma Research Unit, University of Ferrara, Ferrara, Italy; 2Biologics, RespVirt Ltd, London, United Kingdom; 3Ear, Throat and Nose Clinic, Ferrara University, Ferrara, Italy

RATIONAL. Rhinovirus infection is one of important causes of asthma exacerbation. Deficient innate immune response was reported in asthma accounting for increased susceptibility of asthmatic patients to respiratory viral infections. The aim of this study was to evaluate the effects of RSV568 and RSV1088, narrow spectrum kinase inhibitors (NSKis), on HRV16 replication and interferon expression in nasal brushing epithelial cells (NBEC) from atopic (A) and non-atopic (NA) patients.

Methods: NBECs were infected from 9 A- and 9 NA-rhinitis patients. Cells were treated with RV568, RV1088, fluticasone propionate (FP) or tiotropium bromide (TB), and infected with HRV16 (5MOI). After 1 hr absorption, cells were washed with PBS and then treated with compounds again. After 8 hours, cells were collected to determine viral RNA and IFN-λ, IFN-β mRNAs by real time RT-PCR.

Results: HRV16 viral load (copy number) was 9 fold higher in NBECs of A-patients than those of NA-patients (48.6±10 and 5±4 respectively, p=0.083). In addition, IFN-λ expression was significantly lower in A-patients than NA-patients (copy number, 80±1.22, 136±3.174, p=0.02). IFN-β expression showed similar trends. Both RV568 (100nM) and RV1088 (10, 100nM) inhibited HRV16 replication, and significantly increased IFN-λ, β expression, particularly in A-patients. FP (100nM) and TB (100nM) did not inhibit viral load or increase IFN expression.

Conclusions: HRV16 infection is more severe in NBECs of A- compared to NA-patients due to deficient HRV16-induced IFN expression, that is restored by RV568 and RV1088.

P3496 Cigarette smoke extract increases the adhesion receptor for S. pneumoniae in vitro

Naseem Mushqaq1, Iain Dickson1, Cang-Bao Xu2, Lars Edvinsson2, Jonathan Grigg3, 1Academic Unit of Paediatrics, QMUL, London, United Kingdom; 2Medicine, Lund University; Lund, Sweden; 3Medicine, Lund University, Lund, Sweden

Background: Although the mechanism is unknown, cigarette smoke exposure increases the risk of pneumococcal infections in humans. We have recently shown that fossil fuel derived particulate matter increases adhesion of S. pneumoniae to epithelial cells (NBEC) from atopic and non-atopic patients.
via upregulation of platelet activating factor receptor (PAFr) expression on airway cells. We therefore aimed to assess whether cigarette smoke extract (CSE) upregulates the PAFr expression in vitro.

**Methods:** The human lung epithelial (A549) cell line was incubated with very low concentrations of CSE (0.01%, 0.02% and 0.05%) for 4 hr. PAFr expression, adjusted for non-specific staining, was then assessed by flow cytometry using a PAFr human monoclonal antibody.

**Results:** CSE stimulated dose-dependent increase in PAFr expression, with an increase in mean PAFr fluorescence and % positivity (Figure 1 and Table 1).

**FACS analysis showing dose (%) of CSE vs mean fluorescence**

**Assessment of tracheal tube biofilm translocation during mechanical ventilation and lung injury**

Gianluigi Li Bassi1, Laia Fernández-Baral1, Joan Daniel Martí1, Montserrat Rigol1, Laura Muñoz1, Miquel Ferrer1, Jordi Vila1, Francesco Basile1, Antoni Torres1, Thoras Clinic Institute, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain; 2Pneumology Department, Thoras Clinic Institute, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain; 3Cardiology Department, Hospital Clinic, CRESIB, Barcelona, Spain; 4Microbiology Department, Hospital Clinic, CRESIB, Barcelona, Spain; 5Cardiology Service, Thoras Clinic Institute, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain

**Introduction:** The role of bacterial biofilm, within the endotracheal tube (ETT), in the pathogenesis of respiratory infections is still under debate.

**Objectives:** To study effects of length of stay under mechanical ventilation (MV) on bacterial biofilm translocation from within the ETT into health and injured lungs.

**Methods:** ETTs colonized by biofilm were obtained from an associated study where pigs underwent oropharyngeal bacterial challenge by Pseudomonas aeruginosa (PA) and 72h MV. Those ETTs were used in 8 healthy pigs (32.1 ± 2.5 kg) on MV (Vt: 8 ml/kg, RR adjusted based on pH, 7.2 ± 0.25). Pigs were randomized into 4 groups (2 pigs/group) to be MV up to 24h (Group1), 48h (Group2), 72h (Group3) and 48h with lung injury caused by oleic acid (OA) (Group4). Upon extubation, 4 samples from trachea and main bronchi and 7 from segmental bronchi were excised for PA quantification.

**Results:** In pigs of group 3, 1 hour after OA instillation, PaO2/FiO2 decreased to 199 ± 127. Upon extubation, ETT PA colonization was 5.7 ± 1.6, 6.4 ± 0.5, 7.6 ± 0.5 and 7.6 ± 0.6 log cfu/mL in groups 1-4, respectively (p = 0.21). As depicted in figure 1, the airway tissue/ETT PA colonization ratio of trachea and main bronchi was 0.59 ± 0.37. Colonization of segmental bronchus was infrequent.

**Conclusion:** Bacteria from within the ETT PA biofilm rapidly translocate up to the main bronchi, however, distant colonization is uncommon even when lungs are injured.

**Figure 1**

**Conclusions:** From within the ETT PA biofilm rapidly translocate up to the main bronchi, however distant colonization is uncommon even when lungs are injured.

**Detection of linezolid in endotracheal tube biofilm of ventilated pigs with methicillin-resistant Staphylococcus aureus (MRSA) pneumonia**

Laia Fernández-Baral1, Miquel Ferrer1, Laura Guerrero2, Delors Soy2, Jordi Vila1, Gianluigi Li Bassi1, Josep Maria Sierra4, Lina Maria Saucedo2, Pilar Martínez-Olondriz1, Montserrat Rigol1, Mariano Esperatti1, Néstor Luque1, Joan Daniel Martí1, Antoni Torres1, Pneumology Department, Thoras Clinic Institute, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain; 2Pharmacy Service, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain; 3Microbiology Department, Hospital Clinic, CRESIB, Barcelona, Spain; 4Microbiology Department, Hospital de Bellvitge, Barcelona, Spain; 5Cardiology Service, Thoras Clinic Institute, Hospital Clinic-IDIBAPS, Ciberes, Barcelona, Spain

**Introduction:** Linezolid presents good penetration into respiratory secretions; we hypothesized that secretions could transport linezolid into ETT and limit burden of MRSA in biofilm.

**Aim:** To determine linezolid concentration in biofilm inside the ETT using High-performance liquid chromatography (HPLC).

**Methods:** We analyzed 16 samples of ETT from pigs with MRSA pneumonia, ventilated up to 96 hours and treated with linezolid (10 mg/kg every 12h IV). To determine linezolid concentration by HPLC we disrupted the biofilm matrix with several sonications, enzymes and perchloric acid. We also assessed MRSA count in each ETT sample.

**Results:** We retrieved from the ETT samples 63.4±54 mg of biofilm. In 4 (25%) samples linezolid was inferior to the sensitivity of the technique (1.56 μg/mL). In the remaining 12 samples the concentration of linezolid was 38 (11-83) μg/mL of biofilm (median (IQR)). Hence, linezolid concentration in biofilm was 19 (5-41) times above the MRSA MIC for linezolid (2 μg/mL). The concentration of MRSA in the biofilm of pigs treated with linezolid was 1.98±0.84 Log CFU/mL. No significant correlation was found between biofilm concentration of linezolid and MRSA burden (r=0.48, p=0.11).

**Conclusion:** Despite the high concentration of linezolid above the MIC in biofilm inside the ETT, MRSA was found in most samples of pigs treated with this antibiotic, without significant correlation between linezolid levels and MRSA burden.

**Funded:** FIS 05/0620, 070419, 016077 and 050136, SEPAR 2005, Fundación Lilly, Ciberes (CB06/06/0028), 2009-SGR-911, IDIBAPS, FUCAP 2010.

**Moderate aerobic exercise training attenuates inflammatory response to Streptococcus pneumoniae in mice**

Clarice Oliveira1, Maria Leonor Oliveira2, Eliane Miyagi2, Francine Almeida1, Petra Araújo1, Paulo Hê2, Fernanda Lopes1, Milton Martins1, 1Department of Medicine, Universidade de São Paulo, São Paulo, Brazil; 2Biotechnology Center, Butantan Institute, São Paulo, Brazil

**Streptococcus pneumoniae** is one of the most important causes of morbidity and mortality in respiratory diseases. Aerobic exercise is known to attenuate inflammatory processes in some lung injuries.

**Objectives:** To study if moderate exercise training prior to bacterial infection alters the pulmonary inflammatory profile.
Methods: 40 Balb/C mice (14-16 weeks) were divided into 4 groups: Control (C), Aerobic Exercise (AE), S. pneumoniae infection (P), S. pneumoniae + Aerobic Exercise (P+AE). Moderate intensity treadmill training was performed over 4 weeks, 5 times/wk, 60 min/session in the AE and P+AE groups. After 72 hs of the last exercise training session, P and P+AE groups were challenged intranasally with pneumococcal strains M10 (type 11A) through the inoculation of 50 μl of the suspension of the bacteria in 0.9% saline. C group did not receive intranasal instillation or exercise training. Bronchoalveolar lavage (BAL) was performed 10 days after the intranasal challenge to quantify the number of total cells, macrophages, neutrophils and lymphocytes.

Results: S. pneumoniae inoculation resulted in increase number of total cells (18.63 ± 10^5 cels/mL ± 9.02; p < 0.001), macrophages (6.49 ± 10^5 cels/mL ± 1.94; p < 0.001) and neutrophils (8.19 ± 10^5 cels/mL ± 6.84; p < 0.001) while moderate exercise training in S. pneumoniae inoculated animals resulted in significantly decreased total number of cells (10.15 ± 10^5 cels/mL ± 1.10; p < 0.001) and neutrophils (1.53 ± 10^5 cels/mL ± 0.84; p < 0.000) in BAL.

Conclusion: These results suggest that moderate aerobic exercise training attenuated the neutrophilic inflammation in an animal model of bacterial infection supported by FAPESP, LIMHC-FMUSP, CNPq, Brazil.

P3500
Different modes of allergen – Rhinovirus interaction control chemokine production
Nathan Bartlett, Nicholas Glanville, Ross Walton, Sebastian Johnston.
Respiratory Medicine, Imperial College London, London, United Kingdom

Interacting immune responses to rhinovirus (RV) and allergen in asthma are thought to increase the risk of asthma exacerbations. To investigate this we used a mouse model of RV-induced asthma exacerbation and assessed expression of chemokines in Th1 and Th2 recruiting chemokine protein in BAL fluid. Experimental groups: allergen (OVA)-challenged, RV-infected (RV-OVA); OVA challenged, mock infected with UV-inactivated U-V(OVA); RV-infected mock allergen challenged with PBS (RV-PBS) and double negative control (UV-PBS).

Results: CCL11 and CCL24 (eotaxin 1 and 2) in RV-OVA were significantly increased (P < 0.001) vs UV-OVA. RV infection alone did not induce either eotaxin but synergistically augmented eotaxin production in allergic mice. For Th1 chemokines CXCL11 (I-TAC) and CCL5 (RANTES) the opposite was true. RV infection drove eotaxin and was synergistically increased by allergen (OVA) compared to RV-PBS for CCL11 (P = 0.001) and CCL5 (P < 0.01). Next we examined Th2 cell recruiting chemokines CCL17 (TARC) and CCL22 (MDC). Both OVA- and RV-alone stimulated increased expression (UV-OVA and RV-PBS P < 0.001 compared to UV-PBS) and increased levels observed in RV-OVA (P < 0.05 and P < 0.001 for UV-OVA and RV-PBS respectively) were consistent with an additive interaction between OVA and RV. Associated with increased chemokine production we observed greater lung recruitment of activated (CD69+) CD4+ T cells (P < 0.01) compared to UV-OVA and expression of IL-5 and IL-13. Thus for the chemokines investigated we observed 3 different modes of allergen-virus interaction 1) allergen-induced, augmented by virus, 2) virus-induced, augmented by allergen, 3) allergen and virus additive.

Respiratory Medicine, Imperial College, London, United Kingdom; 2Dipartimento di Medicina Sperimentale e Clinica: Divisione Malattie Respiratorie, Università degli Studi “Magna Graecia”, Catanzaro, Italy; 4Nano- and Biotechnologies Laboratory, NRC Institute of Immunology FMBA, Moscow, Russian Federation

Background: Antimicrobial peptides (AMPs) as such as Secretory Leukocyte Protease Inhibitor (SLPI) and Elafin are important component of host innate immune response to prevent against infection of mucosal surfaces. Their role in bacterial infection is well described but little is known regarding their role in respiratory viral infections.

Aims: We investigated the effects of rhinovirus infection on production of SLPI and elafin by monocyte derived macrophages (MDM).

Methods: MDM derived from healthy donors were infected with rhinovirus-16 (RV16). Cells and supernatants were harvested and SLPI and elafin mRNA and protein were measured by qPCR and ELISA respectively.

Results: Compared to cells infected with UV-inactivated virus RV16 induced expression of SLPI mRNA (11.7-fold induction, P = 0.005) and protein (53.0±4.5±76pg/mL vs. 95.2±3.2±63,P = 0.014) in MDM at 24 hours.

Figure 1
There was a trend towards upregulation of elafin at 48 hours for both mRNA (2.17-fold induction, P = 0.055) and protein (13.3±3.3±13.37pg/mL vs 107.8±7.35.47,P = 0.14) but this was not statistically significant.

Conclusions: Rhinovirus infection of MDM upregulates production of SLPI and elafin and this is dependent on virus replication. These molecules may play an important role in the host defence response to respiratory virus infections.

P3503
Potential synergy of drugs with anti-viral and pulmonary oedema clearance activity may be advantageous for influenza patients
Hendrik Fischer1, Bernhard Fischer2, Susan Tzotzos1, Helmut Pietschmann1, Rudolf Lucas3, Respiratory Science, APEPTICO, Vienna, Austria; 3Vascular Biology Centre, Georgia Health Sciences University, Augusta, GA, United States

Definition: Influenza is a serious public health problem that causes severe illnesses and deaths for Hospitalized patients and healthy people. A lot of patients needed medical treatment and many die from the disease every year. 30% of hospitalised patients with Influenza infection require intensive care and despite medical treatment 10% die. The most common cause of death is viral pneumonia and ARDS. Antiviral drugs like oseltamivir and zanamivir block increase and spreading of the virus in the body. Already existing virus particles will not be affected. In case of complications, 2/3 of patients show infiltrates on chest radiographs, giving strong evidence for ARF and pulmonary oedema which can deteriorate to ALIARDS. However, it has been shown that the AP301 peptide, representing the TIP domain of TNFs, has alveolar liquid clearance activity. It was proposed that a combination of anti-viral and anti-oedema substances would act synergistically. This was assessed in mice having been sublethally infected with Influenza strain A/PR8/34 per nasal. On day of infection, mice were treated with oseltamivir. AP301 peptide was applied intratracheally on days 0, 2 and 4 post infection. On day 9 post infection the effect on wet-dry weight ratio and pulmonary microvascular permeability was assessed. AP301 peptide alone had a beneficial effect compared to untreated mice. The additive effect of the combination of AP301/ oseltamivir combination was greater for reduction of lung oedema, which was in the range of control-treated but untreated mice. In conclusion, these preliminary experiments suggest a benefit of combining anti-viral drugs and substances with alveolar liquid clearing activity.
Acute exacerbations of COPD are mainly mediated by respiratory viruses or bacteria like non-typeable Haemophilus influenzae (NTHi) and Chlamydia pneumoniae (Cpn). To elucidate the interaction of viral/atypical pathogens and NTHi in respiratory diseases and human lung tissue with the TLR3 agonist Poly(I:C) as a model of viral infection and Cpn as an atypical, TLR2-inducing agent. Alveolar Epithelial Cells (AEC) and human lung tissue (HLT) were pre-incubated with Poly(I:C) or Cpn (strain CWS-029) and costimulated with NTHi 10^6 cfu/mL (strain Rd K320). After 24 hrs and supernatants were harvested for ELISA and Western Blot analysis and tissue was used for in situ-Hybridisation (ISH).

NTHi led to significant induction of Interleukin-8 (IL-8) production (HLT: Med 134848±22834 µg/mL vs. NTHi 341926±4390 µg/mL, n=12, p<0.001). NTHi and Poly(I:C) increased IL-8 production and had significant costimulatory effects as well as Cpn/NTHi-coinfection (AEC: NTHi+Poly(I:C) 18.48±1.93 µg/mL vs. NTHi 8.70±2.22 µg/mL, p<0.05, n=4; HLT: Cpn 199395±32822 µg/mL vs. Cpn+NTHi 367777±53895 µg/mL, p<0.05, n=6). TLR2- and TLR3-stimulation were mediated via MAP-kinas. ISH showed increased IL-8 and TLR2-expression in HLT in Cpn/NTHi-coinfection. Blocking TLR2 with a specific antibody led to partial reduction of IL-8 expression. These data indicate that TLR2- and TLR3-stimulation are necessary for inflammatory responses in NTHi-infection and that TLR-signaling might be important for enhanced inflammation in viral/NTHi and atypical/NTHi confections.

**Aim:** To define the role of γδ T cells in RV-induced asthma exacerbations using a mouse model.

**Methods:** The mouse RV-induced asthma exacerbation model comprised sensitisation and challenge of BALb/c mice with ovalbumin and infection with RV1B (RV-OVA) or UV-inactivated RV1B control (UV-OVA) concomitant with final allergen challenge. γδ T cells were depleted by intraperitoneal injection of anti-γδTCR antibody.

**Results:** RV infection increased total and activated lung γδ T cell numbers in the airways of atopic asthmatics following RV infection and that greater bronchoalveolar lavage (BAL) γδ T cell numbers were associated with greater airway hyperresponsiveness (AHR) and obstruction.

**Aim:** To investigate the expression of PAR in the airways of normal lung function smokers (NS) in vivo.

**Methods:** Endobronchial biopsies from 16 NS and 11 normal controls (NC) were stained for anti-PAR monoclonal antibody. PAR expression was assessed as percentage of epithelium stained for PAR over total basement membrane length by using computer-assisted image analysis.

**Conclusions:** This is the first description of in-vivo expression of PAR in the epithelium of NS compared to NC. Our data suggest that enhanced PAR expression may be the mechanism of increased vulnerability of smokers to pneumococcal infection.

**389. Phenotyping and monitoring of airway diseases**
the following parameters on FEV1 drop was also checked: age, sex, respiratory difficulties (dyspnoea, irritating cough, wheezing and allergic rhinitis symptoms), atopy, past medical history (PMH) of respiratory infection, smoking, chronic bronchitis. A 30% or higher FEV1 drop at bronchoprovocant dosages or concentrations lower than the planned cumulative dose or a 40% or higher FEV1 drop after inhalation of the whole bronchoprovocant dose was considered as severe.

Results: FEV1 drop was found in 248 persons (18%), of which 201 patients (14.6%) were finally diagnosed with BA (52 patients with OA, 149 with non OA origin). Statistically significant FEV1 drop was found in both subgroups among patients with a PMH of whirling, among patients with atopy and smokers.

Conclusion: Caution is recommended when performing BPC in some patients, particularly in those with suspected asthma who are smokers, diagnosed with atopy and those with a PMH of wheezing. These patients may experience greater discomfort from bronchial obstruction and therefore, the provocalive dose may need to be increased at a slower rate.

P3511 Gastro-oesophageal reflux disease, upper gastro-intestinal motility and autonomic function in adult asthmatics
D. Lakemi Amatunis1, K. P. Athmeswaraw2, H. Janaka de Silva3, Channa D. Runanis3, S. Gotabaw3, A. Wimalasiri2, J. L. Sunny2
Department of Medicine, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka; 1Public Health, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka; 2Medicine, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka; 3Surgical, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka

Introduction: Asthmatics have increased prevalence of gastro-oesophageal reflux disease (GORD). Oesophageal hypomotility, delayed gastric emptying (GE) and autonomic hypofunction increase GOR. Our aim was to study the relationship of GOR with autonomic function, oesophageal motility and GE in adult asthmatics.

Methods: Thirty consecutive mild, stable asthmatics (American Thoracic Society criteria) and 30 healthy volunteers underwent stationary oesophageal manometry, GE by real-time ultrasonography and autonomic function testing (cardiovascular reflex tests). GORD was assessed by symptom assessment and 24-hour pH monitoring.

Results: The asthmatics (40% male; mean age 34.8 years (SD 8.4)) and controls (50% male; mean age 30.9 years (SD 7.7)) were comparable. Twenty two (73.3%) asthmatics had increased reflux on pH monitoring. Asthmatics with higher GOR symptom scores had lesser peristaltic contractions (p=0.032), prolonged acid contact times (p<0.001), delayed GE (p=0.097) and decreased antral motility (p<0.001) than those with lower scores and controls. 69% of asthmatics showed hypergastric activity, rest had normal autonomic function, none had a hyperadrenergic response. There was no association between vagal function, oesophageal or gastric motility parameters in asthmatics.

Conclusions: A cohort of mild, stable adult asthmatics had increased GOR, decreased oesophageal motility and delayed GE. This was not associated with autonomic hypofunction, but with a hypervagal response. Our findings support the hypothesis that vagal hyperreactivity induced acid secretion leads to a reflex decrease in gastric motility, inducing GOR and secondary reduction in oesophageal motility.

P3512 Can asthma control test (ACT) replace a global assessment of asthma control according to GINA guidelines?
Lorenza Melosini, Federica Lorenzo Dente, Elena Bacci, Maria Laura Bartoli, Antonella Di Franco, Federica Novelli, Manuela Latorre, Vagaggini Barbara, Paggiono Perluigi
Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy

Background: Asthma Control test (ACT) has been proposed as a surrogate of the assessment of asthma control, but there is controversy if it corresponds to GINA criteria (O’Byrne, ERI 2010).

Aim: To compare GINA assessment of asthma control and ACT score

Patients and methods: We evaluate 68 outpatients (33 in inhaled corticosteroids, ICO, treatment, and 35 ICO-naive), with mild-to-moderate asthma. Assessment of asthma control, but there is controversy if it corresponds to GINA criteria.

ACT score significantly correlated with SS (r=0.49), RS (r=0.46) and MA% (r=0.45), not with FEV1. ACT score only partially correlated with GINA categories of well (WC), partly (PC) and uncontrolled (UC) patients.

Contingency table between asthma control level (according to GINA Guidelines, gold standard) and ACT categories

ACT ≥ 20 had high Positive Predictive Value for WC+PC (PPV: 78%), while ACT ≤ 19 had high Negative Predictive Value for UC (NPV: 89%).

Conclusion: Cut-off value of ACT has a good accuracy for detecting uncontrolled asthmatics, but not for distinguishing well from partly controlled asthmatics. The high correlations with data derived from 2-week diary card recording support ACT as a simple tool for the quantification of symptomatic asthma control.

P3513 Utility of the Hull airways reflux questionnaire in the assessment of patients in the acute admissions units
Alyn Morice1, Joanne Sprigg2, Amanda Bell2
1Cardiovascular & Respiratory Studies, University of Hull, Castle Hill Hospital, Cottingham, East Yorkshire, United Kingdom; 2Acute Respiratory Assessment Service, Chest 2 Office, Castle Hill Hospital, Cottingham, East Yorkshire, United Kingdom

Airway reflux and aspiration are thought to be common precipitants of acute exacerbations of COPD. A validated instrument, the Hull Airway Reflux Questionnaire (HARQ)
P3514 Investigating change in the COPD assessment test (CAT) within α-1 antitrypsin deficiency (A1ATD)

Introduction: The COPD assessment test (CAT) has been validated in COPD as a health status questionnaire (HSQ). Our group has validated the CAT in A1ATD. Further recruitment will allow us to correlate CAT scores with decline.

Methods: A1ATD patients were included in the study (n=30). CAT was completed at baseline and at six monthly time points. Associations between CAT scores and A1ATD status were investigated.

Results: There were significant associations between CAT scores and A1ATD status. The majority of patients with A1ATD had lower CAT scores compared to those without A1ATD. Significant differences were observed in the domains of activity, dyspnoea and emotion.

Conclusions: The CAT can be used as an HSQ to track change over time and whether this correlated in total CAT scores and its domains.

P3515 Associations between BODE index and systemic inflammatory biomarkers in COPD

Introduction: The BODE index is a multi-component disease and systemic inflammation represents one of the key mechanisms responsible for the systemic manifestations of this disorder, including skeletal muscle weakness and cachexia. Fat-free mass index (FFMI) which reflects better the skeletal muscle mass, has been shown to be related to both dyspnoea and exercise capacity. We hypothesized that the multi-dimensional BODE index, that reflects the multi-component nature of COPD, might be related to biomarkers of systemic inflammation. We further evaluated associations between FFMI and systemic inflammation.

Methods: BODE index and FFMI were calculated in 222 stable COPD patients and 132 smokers without COPD. Systemic inflammation was evaluated with the measurement of leptin, adiponectin, CRP, IL-6, and TNF-α in serum samples of COPD patients.

Results: In patients with COPD, both BODE index and FFMI presented significant associations with leptin levels (R2 0.66 and 0.71, respectively), whereas FFMI presented an additional association with the levels of TNF-α (R2 0.37). No significant associations were observed in normal smokers.

Conclusions: Both BODE index and FFMI are related to the circulating levels of leptin in patients with COPD, a fact that strengthens a possible role for leptin in the systemic inflammatory process of COPD. The additional association of FFMI with TNF-α further supports the closer association of FFMI with muscle wasting in COPD.

P3516 Different trends of health-related quality of life in asthma and COPD

Introduction: The progression of COPD and asthma, even though frequently overlapping, differ markedly in adult population. In general COPD is progressive, the major contributors include ongoing smoking combined with dyspnoea and disease exacerbations. In the management of COPD and asthma, monitoring of FEV1 alone does not adequately identify the high-risk patients. In this study we aimed to define the potential value of repeated measures of Health-Related Quality of Life (HRQoL) in these two diseases.

Materials and methods: Patients with asthma (N=1198) or COPD (N=601) had been recruited from two University Hospitals in Finland. Since year 2005 HRQoL had been assessed at time points 0, 1, 2 and 4 years from the recruitment by using the 15D questionnaire validated in several chronic diseases. The variation of HRQoL between the patient groups was modelled by using mixed effects models.

Results: The average trend of HRQoL separated the groups (p < 0.0003) from each other (α<0.005/year for COPD, α<0.001/year for asthma). The measures of the asthma patients developed positively or negatively regardless of their baseline 15D score, whereas those of the COPD patients tended to develop only negatively when their baseline 15D score was harmed to the level of α< 0.75 (full HRQoL α<1.0). The 15D score declined more significantly in patients who died during the follow-up period (p<0.007). The average trends in HRQoL were not different between males and females neither for the asthma (p=0.8) nor for the COPD patients.

Conclusions: HRQoL trend could serve as a valid and cost-efficient tool to identify patients who display deviant development of the disease and needs to be further investigated.
Abnormal heart rate recovery and chronotropic incompetence on submaximal exercise in COPD

Mans Gupta1, Vishal Bansal2, Sunil Chhabra1. 1Cardiopulmonary Physiology, Vallabhbhai Patel Chest Institute, Delhi University, New Delhi, India; 2Physiology, Vallabhbhai Patel Chest Institute, Delhi University, New Delhi, India

Background: A delayed heart rate recovery (HRR) after graded and an attenuated heart rate response (chronotropic incompetence, CI) are markers of cardiac autonomnic dysfunction and predict cardiovascular mortality. The latter also characterizes COPD. Therefore we hypothesized that decreased HRR and CI should coexist in COPD.

Methods: After lung function evaluation, 39 stable COPD patients and 11 healthy controls underwent submaximal cycle ergometry. Heart rate was measured at peak exercise and at 1-min recovery. Abnormal HRR was defined as a recovery of ≤12 beats in the first minute post-exercise. Chronotropic incompetence was evaluated by measuring the Chronotropic Response Index (CRI = [peak heart rate - resting heart rate]/[220 - age] - [resting heart rate]).

Results: The HRR was 13.9±3.9 beats and 23.9±5.9 beats in patients and controls (p<0.001). The CRI was 44.9±13.9 and 61.2±5.1 (p<0.01) in these groups, respectively. An abnormal HRR was observed in 29 (74.4%) of the patients.

Conclusion: A lower baseline HRR value is independently associated with a more rapid progression of emphysema and lung function decline in heavy smokers.

P3519

Abnormal heart rate recovery and chronotropic incompetence on submaximal exercise in COPD

Mans Gupta1, Vishal Bansal2, Sunil Chhabra1. 1Cardiopulmonary Physiology, Vallabhbhai Patel Chest Institute, Delhi University, New Delhi, India; 2Physiology, Vallabhbhai Patel Chest Institute, Delhi University, New Delhi, India

Background: A delayed heart rate recovery (HRR) after graded and an attenuated heart rate response (chronotropic incompetence, CI) are markers of cardiac autonomnic dysfunction and predict cardiovascular mortality. The latter also characterizes COPD. Therefore we hypothesized that decreased HRR and CI should coexist in COPD.

Methods: After lung function evaluation, 39 stable COPD patients and 11 healthy controls underwent submaximal cycle ergometry. Heart rate was measured at peak exercise and at 1-min recovery. Conclusion: A lower baseline HRR value is independently associated with a more rapid progression of emphysema and lung function decline in heavy smokers.

P3521

Bacterial profile of acute infectious exacerbations of chronic obstructive pulmonary disease requiring hospitalization in Greece

Nicolettos Rovina1, Efrosini Ompa2, Georgia Papadaki1, Pantelis Konstantoulakis1, Eutychios Filio2, Theocharis Anagnostakos1, Charis Rousoun1, Manos Alchianatis1, Nikolaos Kouloutis1. 11st Department of Pulmonary Medicine, “Sotiria” Hospital, Athens Medical School, Athens, Greece; 2Lectus Medicus, Research Center, Athens, Greece

Bacterial infections are a major cause of exacerbations of chronic obstructive pulmonary disease (AECOPD) resulting in significant mortality and morbidity. This study was undertaken to investigate the bacterial spectrum of AECOPD requiring hospitalization.

We examined 40 patients with COPD hospitalized for infections AECOPD according to Antithenisson’s criteria. We measured lung function, and assessed sputum for infection and for bacterial using PCR. All patients had no previous intubation and none was diagnosed with pneumonia.

Examinations were hospitalized for 9 ± 4.2 days. AECOPD were associated with impaired lung function (FEV1; 42±2.0, FVC: 69±11, F EV1/FVC: 52.6±16). respiratory failure and increased sputum neu trophilia (mean ± SD; 72.7±26). PCR revealed pathogens in 88% of the sputum samples analyzed. The most commonly isolated pathogens were S. pneumoniae (65%), Haemophilus influenzae (45%); P. aeruginosa (3%). Klebsiella (7.5%) and Moraxella catarrhalis (7.5%). A mixed flora was revealed in 52.5% of sputum samples. The most common co-infection identified was by S. pneumoniae and Haemophilus influenzae (35%); followed by S. pneumoniae and P. aeruginosa (25%). In 12.5% there was a co-infection by three bacterial strains (S. pneumoniae, Haemophilus influenzae, and Ps. aeruginosa). S. pneumoniae and Haemophilus influenzae were the commonest sputum pathogens isolated in hospitalized patients with infectious AECOPD. Interestingly, in more than 50% of the cases a co-infection by 2 or three different strains was revealed.

These results should be considered when deciding the initial antibiotic treatment in Greek patients with AECOPD.
Logistic regression and linear regression were used to test for association between these SNPs and the COPD-related traits, assuming dominant (D), recessive (R) and additive (A) genetic model.

Results: Only one SNP (rs5766034) from EPHX1 showed significant association with the six-minute walking distances after Bonferroni correction (A: OR=4.08, P=0.039; OR=2.08, P=0.029). Another SNP (rs1105109) from GSTP1 showed borderline significance with anxiety symptom (D: OR=2.94, P=0.0545). The haplotype analyses validated the results from the single SNP analyses.

Conclusions: This study provides evidences that genetic variants on EPHX1 and GSTP1, two genes encoding xenobiotic metabolizing enzymes, contribute to the functional impairment of COPD in northern Chinese Hans.

P3524

Validation of a (semi-)automatic measurement- and control platform for centralized, simultaneous electronic nose (eNose) analyses in multi-centre trials

Paul Brinkman1, Marc van der Schee1, Niki Fens2, Ariane Wiegner1, Simone Hashimoto1, Hugo Koell1, Tennis Vink2, Paolo Montuschi1, Giorgio Pennazza4, Marco Santonico5, Arnoldo D’Amico6, Stephen Fowler1, Frans De Jongh7, Peter Sterk1, U-BIOPRED Study.

Results: Breathing analysis by eNose technology represents a promising diagnostic tool in lung disease. The next step in making this technology suitable for multi-centre trials, such as the U-BIOPRED study, is to facilitate centralized (semi-)automatic measurements simultaneously.

Hypothesis: Incorporating multiple eNoses in a measurement- and control platform (integrated system of PC, mass flow controllers and valves) does not influence the sensor responses.

Methods: In this cross-sectional study on healthy volunteers (n = 12), exhaled breath was collected using a standardized method (Fens et al. AIRCCM 09). Two paired randomized measurements (standard configuration vs. platform) were done on two parallel eNoses (Cyrano C320). Analysis was done by linear regression (see figure).

Results: There was a slight difference in sensor responses between paired measurements. However this was proportional for all sensors. (eNose 1: 0.961 ≤ R² ≤ 0.996, eNose 2: 0.982 ≤ R² ≤ 0.998). The slopes of the linear regression lines differed when changing the sampling flow.

Conclusion: The platform has a minimal, proportional influence on sensor responses, which can be adjusted, if needed.

Implication: A parallel eNose platform can facilitate centralized, integrative analysis of different types of devices and thereby application of eNose technology on larger cohorts in a multi-centre setting.

P3525

Circadian rhythm of circulating microparticles in patients with obstructive sleep apnea

Laszlo Kemos1, András Bikón1, Eva Pallinger1, Gyorgy Losonczy1, Dora Bartusé1, Adrian Kis1, Gabor Horvath1, Zsolt Komlosi1, Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Department of Genetics, Cell- and Immunobiology, Semmelweis University, Budapest, Hungary

Obstructive sleep apnea syndrome (OSAS) is considered as a risk factor to develop cardio- and cerebro-vascular diseases. Circulating cell-derived microparticles (MP) are involved in endothelial dysfunction and atherosclerosis; however, their role is not fully explored in the pathophysiology of OSAS. Eleven patients with untreated, moderate to severe OSAS (Pre-CPAP) and 7 healthy controls underwent overnight polysomnography (apnea-hypopnea index (AHI) 40±19.5 vs 24±2.2, respectively). Blood samples were collected at 11:00 AM, 5:00 PM and 9:00 PM, and then 1:30 AM and 6:00 AM on the following day. Absolute numbers of platelet-derived (CD41+) and Annexin V+ MP were measured by flow cytometry. Nine OSAS patients were re-studied after 2 months of CPAP treatment (Post-CPAP, AHI 9±1.7). Comparisons were made by repeated-measures ANOVA, and independent and paired t-test, as appropriate. Untreated OSAS patients exhibited higher levels at (5:00 PM and 9:00 PM time points) and daily variability than healthy controls both in CD41+ (p<0.05) and Annexin V+ (p<0.01) MP levels. In OSAS patients, interestingly, peak daily MP levels occurred at 5:00 PM. There was significant positive correlation between AHI and the circadian variability both of CD41+ (p<0.01, r=0.70) and Annexin V+ (p<0.05, r=0.60) MP levels. Annexin V+ and CD41+ MP counts decreased after CPAP treatment at 5:00 PM and 9:00 PM time points (p<0.01 Post-CPAP vs Pre-CPAP). Our data demonstrate that increased MP levels can only be detected at certain time points of the day in OSAS patients. The elevation of MP counts is largely reversible by CPAP treatment. The influence of circadian rhythm should be considered to assess MP levels in these patients.

3.90. Treatment beyond inhalers: endoscopic lung volume reduction

P3526

Late-breaking abstract: Prevalence of emphysema heterogeneity measured with thoracic computed tomography soft in combination with collateral ventilation assessment to plan endoscopic volume reduction

Christophe Pison1, Adrien Jankowski1, Sébastien Quétant1, Marie Jongod1, Cécile Chériaux1, Gilbert Ferretti1, Wajih Aniwyidiangnisut1,2,3,4,5, Clinique d’Imagerie Médicale, CHU, Université J Fourier, Grenoble, France; 5Clinique d’Imagerie Médicale, CHU, Université J Fourier, Grenoble, France; Interventional Pulmonology, University Indonesia in Jakarta, Jakarta, Indonesia

Functional improvements after endoscopic volume reduction in severe emphysema were related to lobar heterogeneity and integrity of fissures in a post-hoc analysis of VENT data, NEJM 2010;363:1233. In 101 consecutive patients referred for endoscopic volume reduction, irrespective of CT findings, with FEV1 <50% pred. and in NYHA IV, we prospectively measured PFTs, arterial gases, % of lobar destruction as defined by the % of volume < -950 Hounsfield unit with Myriam, Intralase, Paris, France and in patients with heterogeneous disease collateral ventilation with lobar balloon Charitis, Pulmonox, USA. Patients, 75 males, were 59.1±11.4 yr old, FEV1 29.1±9.8% pred., FVC 66.8±22.1%, TLC 146.5±23.4%, PaO2 8.8±1.5, PaCO2 5.5±1.2 kPa, KCO 39.6±20.6% pred., % of destruction was 30±17 in left upper lobe, 24±18 left lower lobe, 35±21 right upper lobe, 24±20 right middle lobe and 26±20 right lower lobe. In patients with severe emphysema, lobar heterogeneity defined by at least 1 lobe with >50% destruction and a difference >10% in destruction within lobes was found in 43 cases, 22 instances in left side, 31 right side, 15 both sides with no collateral ventilation in 83%. The first patients with no collateral ventilation treated with valves experienced major improvements in 80% in terms of FEV1, FVC and weight gain. We conclude that in patients with severe emphysema, heterogeneity was found in 43% of cases. From this single centre experience, endoscopic volume reduction seemed to result in meaningful improvements in 0.43±0.80 vs 0.30±0.80 corresponding to 29% of cases. Funds from 2008-2010 innovative hospital grants.

6-month follow-up in patients with advanced upper lobe predominant heterogeneous emphysema treated with endobronchial lung sealant therapy

Felix Herb1, Ralf Eberhardt1, Arschang Valipour2, Franz Stanzel3, Reiner Bonnet4, Juergen Behr5, Charles Marquette6, Mordechai Kramer7, 1Pneumology and Critical Care, Thoraxklinik University of Heidelberg, Heidelberg, Germany; 2Respiratory and Critical Care Medicine, Otto Wagner Hospital, Vienna, Austria; 3Pneumology and Endoscopy, Lungenklinik Hemer, Hemer, Germany; 4Pneumology, Zentralklinik Bad Berka GmbH, Bad Berka, Germany; 5Medizinischer Klinik III, University Bergmannsheil, Bochum, Germany; 6Service of Pneumology, Hospital Pasteur University of Nice, Nice, France; 7Pulmonary and Critical Care Medicine, Rabin Medical Center, Bellinson Hospital, Petah-Tikva, Israel

Objective(s): Responses to AeriSeal® Emphysematous Lung Sealant System (ELSS) therapy in patients with advanced upper lobe predominant heterogeneous (ULP) emphysema are summarized out to 6 months of follow-up.

Methods: 14 patients with ULP emphysema received ELSS treatment in a multicenter study conducted at 8 sites across Europe and Israel. Ten (10) of these...
P3528

Physiological consequence of lower vs upper lobe lung volume reduction in patients with advanced emphysema

Edward Ingenito, Larry Tsai. Pulmonary and Critical Care Medicine, Brigham and Women’s Hospital, Boston, MA, United States

Objectives: Lower lobe lung volume reduction in patients with advanced emphysema has been associated with greater clinical benefit that upper lobe therapy. We present computer modeling results that explain these observations, and can help direct treatment site selection in patients undergoing lung volume reduction therapy.

Methods: Our model considers alveoli as discrete units with an exponential pressure-volume relationship of the form (V(Ptp) = Vmax – A e-kPtp). Gravitational effects on transpulmonary pressure (Ptp), the extent of tissue destruction, airflow closure effects, and extent of heterogeneity were incorporated as independent variables to predict RV and RV/TLC.

Results: Gravitational effects on Ptp are the major determinant of residual RV and overall RV/TLC. In upper lobe heterogeneous emphysema, changes in Ptp from volume reduction distend the remaining alveoli at end exhalation. However, RV and RV/TLC are reduced due to a decrease in the total number of diseased alveoli following treatment. In lower lobe heterogeneous emphysema, volume reduction distends already stretched upper lobe alveoli attenuating treatment effects on gas trapping. This phenomenon was more pronounced in homogeneous disease. Potentially beneficial effects of lower lobe volume reduction could be completely negated by upper lobe alveolar distension, resulting in no improvement, or even worsening of RV and RV/TLC despite alveolar resection.

Conclusions: Gravitational effects largely explain why lower lobe volume reduction therapy is less therapeutic than upper lobe therapy. In patients with homogeneous emphysema, lower lobe therapy can actual worsen gas trapping despite resection of diseased tissue.

P3529

Effect of fissure integrity on the efficacy of bronchoscopic lung volume reduction therapy using a peripheral-acting tissue sealant in patients with advanced heterogeneous (ULP) emphysema

Helgo Magnussen1, Anne-Marie Kirsten 1, Felix Hecht2, Ralf Eberhardt2, Felix Herth2, Peter Heussel3.

1Pneumology, Charité Campus-Mitte, Berlin, Germany; 2Pneumology and Critical Care Medicine, Thorasklinik Heidelberg, Heidelberg, Germany; 3Clinical Department, Uptake Medical Corp, Tustin, CA, United States

Objective(s): The study examines how fissure integrity affects the response to endobronchial volume reduction therapy (ELV), a peripheral-acting tissue sealant.

Methods: The model considers alveoli as discrete units with an exponential pressure-volume relationship of the form (V(Ptp) = Vmax – A e-kPtp). Gravitational effects on transpulmonary pressure (Ptp), the extent of tissue destruction, airflow closure effects, and extent of heterogeneity were incorporated as independent variables to predict RV and RV/TLC

Results: ELS therapy in patients with advanced ULP emphysema improves lung function, functional capacity and quality of life out to at least 6 months. Improvements in spirometry were observed in 9 of 14 patients at 6 month follow-up. Physiological responses were best in those patients (n=10) who received bilateral upper lobe split dose therapy. Changes in FEV1 were (ΔFEV1 = +24.8±36.8%; ΔFEV1/FVC = +17.6±25.6%).

Conclusions: ELS therapy in patients with advanced ULP emphysema improves to those observed following bilateral upper lobe volume reduction surgery.

P3530

Efficacy of bronchoscopic thermal vapor ablation and lobar fissure completeness

Daniela Goppelmann1, Felix Herth1, Ralf Eberhardt1, Steven Kesten2, Claus Peter Heussel3.

1Pneumology and Critical Care Medicine, Thorasklinik Heidelberg, Heidelberg, Germany; 2Clinical Department, Uptake Medical Corp, Tustin, CA, United States; 3Diagnostic and Interventional Radiology with Nuclear Medicine, Thorasklinik Heidelberg, Heidelberg, Germany

Background: Bronchoscopic thermal vapor ablation (BTVA) ablates emphysema tissue through a localized inflammatory response followed by contractive fibrosis and atelectasis leading to permanent lung volume reduction that should not be influenced by collateral ventilation.

Objectives: To determine the correlation of clinical data from a trial of BTVA to patients with advanced ULP emphysema. Method: Single arm study (n= 44) of patients with heterogeneous upper lobe predominant emphysema with FEV1 <45% predicted. Patients received BTVA to the RUL or LUL in a single setting. Primary efficacy outcomes: FEV1, and SGRO at 6 months. Efficacy: lobar volume reduction (LoVR) from thin section multislice CT, spirometry, body plethysmography, 6MW and mMRC dyspnea score. The treated lobar fissure was analyzed visually in non-enhanced pre-interventional CT. Results: Incomplete fissures of small fissure, upper half of right large fissure, and three fissures of left large fissure were estimated in 5% increments and the relative amount of fissure incompleteness was calculated. Pearson correlation coefficients were calculated for the association between fissure incompleteness and change in efficacy outcomes (baseline to 6 months).

Results: Mean age 62 years, 50% men, FEV1 0.85 L (31% predicted), SGRO 59 up (66% predicted). Calculated relative fissure incompleteness was 13% (median; range 0-63%); 38/44 patients (86%) had fissure incompleteness. Correlation coefficients (r) for the association of incompleteness to outcomes are as follows: FEV1: 0.17, LoVR -0.27, SGRO -0.10, 6MW 0.0, RV -0.18, RV/TLC -0.14

Conclusion: BTVA induced LoVR and improvements in clinical outcomes are independent of fissure integrity.

P3531

Associations of efficacy outcomes following bronchoscopic thermal vapor ablation (BTVA) for the treatment of heterogeneous emphysema

Peter Hopkins1, Felix J. Herth2, Gregory Snell3, Kim Baker4, Christian Witt5, Mark H. Gottfried6, Arschang Valipour7, Manfred Wagner8, Franz Stanzel9, Tim Egau10, Steven Kesten11,12,13.

1Lung Transplant Unit, Prince Charles Hospital, Chermside, Australia; 2Pneumology, Charité Campus-Mitte, Berlin, Germany; 3Pulmonary, Charities Swiss Campus Mitte, Munich, Germany; 4Pneumology & Respiratory Medicine, The Alfred Hospital, Melbourne, Australia; 5Pulmonary and Critical Care Medicine, University of Iowa, Iowa City, IA, United States; 6Pneumologie, Klinikum Nürnberg, Nürnberg, Germany; 7Pneumologie, Zentrum für Pneumologie, Hemer, Germany; 8Advanced Lung Disease Program, Mater Misericordiae University Hospital, Dublin, Ireland; 9Clinical Department, Uptake Medical Corp, Tustin, CA, United States; 10Advanced Lung Disease Program, Mater Misericordiae University Hospital, Dublin, Ireland; 11Pneumologie, Klinikum Nürnberg, Nürnberg, Germany; 12Pneumologie, Klinikum Nürnberg, Nürnberg, Germany; 13Pneumologie, Klinikum Nürnberg, Nürnberg, Germany.

Objective(s): The associations among various COPD efficacy endpoints are variable; however, the degree of correlation is often important in examining the consistency of the results across measures that are not considered redundant.

Methods: Single-arm trial of BTVA in patients with upper lobe predominant emphysema. Patient criteria: FEV1 15% -45% predicted, age 40-75 yrs, RV >150%, TLC<100%, 6 minute walk distance (6MWD)>140 m, DLCO<20%, previous pulmonary rehabilitation. Primary efficacy endpoints: FEV1, and St. George’s Respiratory Questionnaire total score (SGRO) at 6 months. Other endpoints: body plethysmography, mMRC dyspnea, 6MW. Pearson correlation coefficients were calculated for the association of changes from baseline to 6 months of physiological measures and LoVR to health outcomes.

Conclusions: Fissure integrity had minimal impact on the overall response to endobronchial lung volume reduction therapy performed using ELS in patients with advanced ULP emphysema.

TUESDAY, SEPTEMBER 27TH 2011

F3463
Results: 44 patients received BTV. Mean age: 63 years, men 50%, FEV1 0.86 (31% predicted), RV 237% predicted, DLCO 35% predicted, SGRQ 59 units, 6MWD 300 m. n=24 R, n=20 L.

Conclusion: Physiologic and CT LoVR outcomes correlate strongest with the BODE score and the perception of dyspnea. The variable degree of correlation among the health outcomes indicates the need to examine multiple efficacy variables in emphysema and reinforce that the measures are not redundant.

P3532

Efficiency of the endo-bronchial volum reduction treatment for heterogeneous lower lobe predominant emphysema

Turan Ece1, Ayen Eren1, Zalayha Bingol1, 1Pulmonary Division, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey; 2Pulmonary Division, Istanbul Bilim University, Istanbul, Turkey

Background: Patients with severe chronic obstructive pulmonary disease (COPD) have limited treatment options. Exercise capacity and health related quality of life (HRQL) of these patients are affected by the progress of respiratory failure. Thus, there is a need for new treatments that can palliate. Endo-bronchial volum reduction treatment (EBVRT) which is a minimally invasive method has been come up. Endobronchial valves (EBV) that allow air to escape from a pulmonary lobe but not enter. It can induce a reduction in lobar volume that may thereby improve lung function and exercise tolerance in patients with advanced emphysema.

Methods: To evaluate the safety and effectiveness of the EBVRT of lower lobe predominant heterogeneous emphysema. Functional capacity was evaluated with spirometry, 6minute walk distance (6MWD). SGRQ were applied to evaluate the HRQL.

Result: Five patients with heterogeneous lower lobe predominant emphysema (two left, three right lower lobes) were treated with EBV. Most of the patients were males (80%). The mean age was 65 years. Valves were placed into left lower lobe (n=2) and right lower lobes (n=3). Valves were placed in airways with 100% technical success. There were no procedure-related deaths and complications. At the third month after therapy there was an increase in 4.6% in the forced expiratory volume 1 second (FEV1) and 2.3% increase of 6MWD were observed. Also, there was a decrease of 2.3% in the SGRQ score was observed.

Conclusion: EBVRT for heterogeneous lower lobe predominant emphysema patients induced modest improvements in lung function, exercise tolerance, and HRQL. EBVRT is a new safety method for the patients with severe COPD.

Management of severe COPD patients using bronchoscopic valve lung volume reduction: Preliminary results

Vladimir Parshin1, Michael Raasoukh2, Dmitry Bazarov2, 1Thoracic Division, National Research Centre of Surgery, Moscow, Russian Federation; 2Endoscopic Department, National Research Centre of Surgery, Moscow, Russian Federation. 1Pulmonary Functional Examinations, National Research Centre of Surgery, Moscow, Russian Federation

Background: Despite of a modern level of anesthesiology, reanimation and surgical techniques lethality after LVRS remains on range 2.5% and level of complications in some clinics reaches 20%.

Aim: To fulfill a technique of bronchoscopic valve lung volume reduction (BLVR) in management of COPD patients, to develop indications and contra-indications.

Materials and methods: 9 patients are undergone BLVR. Mean age was 56 y. All have severe dyspnee from 3 up to 4 points on scale MRC, FEV1 - 25-63%, TLC - 134±25%, RV - 287±34%, a distance in 6-min test - 245±54 m. Criteria of inclusion in BLVR program were similar to those at a LVRS. Procedures were performed under local anesthesia with intravenous potentiation. Intervention carried out on one lung in 1 case, 2 patients undergone consecutive bilateral BLVR.

Results: Endobronchial volum reduction treatment (EBV) for heterogeneous bronchial tube of the most emphysematic segment or bronchial tubes of adjacent lobes for prevention of air bypass. The quantity of valves on one procedure varied from 1 up to 2. Average duration of procedure was 35±12 minutes.

Results: All patients were discharged. Average hospital period was 4 days. 2 patients had severe atelectasis in situ of valve. 2 patients had severe COPD exacerbation. 6 patients had marked reduction of dyspnee, improving quality of life, increasing of physical tolerance, keeping up to 12 months after BLVR, including FEV1 - 30±5%, TLC - 102±3%, RV - 247±14%.

Conclusion: Preliminary results of BLVR indicates safety and expediency of BLVR in management of carefully selected severe COPD patients. We consider BLVR as a treatment option before LVRS and IT.

P3535

Endoscopic lung volume reduction (ELVR) with the “endo-bronchial Miyazawa valve” (EMV) in patients with severe emphysema, a prospective pilot study

Alban Loven1,2, Ileni Lemos2, Giovanni Galluccio3, 1Pneumology, CHUV, Lausanne, Switzerland; 2Center of Thoracic Endoscopy, Carlo Forlanini Hospital, Roma, Italy

Introduction: The ELVR represent a new minimally invasive palliative option for the treatment of severe emphysema. The EMV is a new device with different characteristics compared to the others (a simple all in silicone structure, with a large opening, inexpensive, and without special delivery system) and is little studied.

We believe this unidirectional valve is effective in reducing lung hyperinflation and improving lung function and dyspnea of a subtype of emphysema patients. We report here the data at one month for the first two patients.

Method: Patients are affected from severe (FEV1<40%) heterogeneous emphysema and major hyperinflation (>130%). The Outcomes are the adverse effects, lung functions, exercise capacity and quality of life. The EMVs have been inserted through a rigid bronchoscopic in the target segmental or lobar bronchi supplying the most hyperinflated part of the lung in order to achieve an unilateral treatment with lobar exclusion.

Results: Baseline to 1 month after insertion. The patients A and B have improved in quality of life (Casey’s respiratory questionnaire A 9.8±18 points, pulmonary function FEV1 0.51 to 0.62L and F0 0.9 to 1.4L, RV A 4.49 to 2.53L and B 5.6 to 5.2L. DLCO A 38 to 55.2% B 25 to 33% of predicted value) and exercise capacity (6 min. walk test A 65±m B 120±m). No atelectasis was visible on radiological control but signs of air trapping were reduced.

Adverse effects: Two episodes of bronchosopasm in the first patient well controlled by medical therapy, and none in the second.

Conclusion: Our preliminary encouraging experience describe a new tool for the therapy of selected emphysema patients.

P3536

Comparison between Chartist® pulmonary assessment system detection of collateral ventilation vs. corhal CT fissure analysis in predicting atelectasis in emphysema patients treated with endobronchial valves

Daniela Gompelmann1, Ralf Eberhardt1, Dirk-Jan Slebos2, Joachim Ficker1, Frank Reichenberger1, Lars Ek1, Bernd Schindl1, Felix J.F. Herth1, 1Pneumology, Thoraklinik at University Hospital, Heidelberg, Germany; 2Pneumology, University Medical Center Groningen, Netherlands

Introduction: Accurancy of the Chartist® Pulmonary Assessment System in identifying responders after endobronchial valve (EBV) treatment is the subject of a recently concluded multi-center European study. The Chartist system quantifies collateral ventilation (CV) by sealing a lung compartment and measuring its air pressure and flow. When the resistance value <0.1 the patient is “CV Positive”, when the resistance value ≤0.10, the patient is “CV Negative”. Fissure analysis
prediction of LVR response is based on “completeness” or “incompleteness” of the target lobe fissure. In this study, the predictive value of the HRCT vs. Chartis assessment is compared.

Objective: To determine whether the accuracy of CV assessment is comparable to fissure analysis from HRCT in predicting clinically significant LVR following EBV treatment.

Methods: Baseline and 30-day follow-up HRCTs of EBV treated patients were evaluated by an independent, blinded core lab(s). A Chartis assessment was conducted prior to the baseline core lab reading. The baseline HRCT fissure results and the Chartis assessments were compared for a “reliability” prediction, and reviewed against the LVR in the treated lobe as measured by 30-day HRCT.

Results: Data for 31 patients is available to date. Analysis of up to 75 patients is expected for ERS. In 31 patients, Chartis and CT matched 24 times (77.4%). Chartis and CT did not match 7 times (22.6%).

Conclusion: Accuracy of the Chartis® System is comparable to Corelab review of HRCT, and may be used in lieu of fissure analysis to predict clinically meaningful LVR following EBV treatment.

P3537
Bronchoscopic assessment of collateral ventilation predicts outcome of endoscopic lung volume reduction with valves
Wolfgang Gesesarich, Norbert Weber, Andreas Fertl, Karl Haussinger. Department of Pulmonology, Asklepion-Fuchskliniken Muenchen-Gauting, Gauting, Germany

Background: Collateral Ventilation (CV) is a cause of failure of endoscopic lung volume reduction (ELVR) with endobronchial valves. The Chartis system (PulmonX, USA) measures CV in the target lobe of ELVR to predict outcome and aid patient selection.

Aims: To test this hypothesis we correlated Chartis values with outcome of ELVR with EBV.

Methods: In 15 patients with severe heterogeneous emphysema we measured CV with Chartis in the target lobe of ELVR and achieved complete lobar exclusion with Zephyr®. We measured lung function, 6MWD, SGRQ and radiological outcome at baseline and one month.

Results: In 2 patients a valid Chartis signal was not obtained. 3 patients showed high CV (Chartis value < 10 vs. CV < 10) and 10 patients low CV (Chartis value > 10 vs. CV < 10). The CVve group compared to the CVve group showed significant improvement of obstruction (ΔFEV1 0.23±0.13 L vs. -0.05±0.18 L; p=0.018) and hyperinflation (ΔRV -0.12±0.72 L vs. 0.02±2.78 L; p=0.037). Δ6MWD was 58.6±43.3 m (ns) and ΔSGRQ was -10.5±2.0 (ns). 10/15 patients had a response to EBV (8 CVve vs. 2 without valid Chartis signal). Atelectasis developed in 8/15 patients (CVve, 2 without valid Chartis signal). Of the 5/15 non-responders the Chartis value was <0 vs. >10. CVve group had a response to EBV (8 CVve vs. 2 without valid Chartis signal). Of the 5/15 non-responders the Chartis value was <0 vs. >10.

Conclusions: In our patient cohort Chartis adequately predicted outcome of ELVR with EBV in 11/15 patients. In 2 patients a valid Chartis measurement could not be obtained. 2 patients, although the Chartis reading was interpreted as CV-ve, were non-responders. Despite these limitations, Chartis in our preliminary experience seems a valuable tool to select patients for ELVR with EBV.

P3538
One year follow-up of intra-bronchial lung volume reduction in alpha-1-antitrypsin deficiency and severe emphysema
Gunnar Hillerdal, Stephanie Mindus. Lung Medicine and Allergy, Karolinska Hospital, Stockholm, Sweden

Introduction: In patients with alpha-1-antitrypsin (AAT) deficiency, severe emphysema mainly localized to the lower lobes can develop. Volume reduction surgery (LVR) is not recommended in these patients.

Objectives: One-way valves in selected bronchi can reduce the size of hyper-inflated lung areas, and we decided to make a pilot study of intra-bronchial volume reduction (IBVR) in patients with AAT deficiency and severe lower lobe disease.

Methods: In patients aged 40-80 years, with RV >150% and FEV1<15% of predicted, and predominantly lower lobe disease, IBRV with installation of 3-4 valves in one selected lower lobe was performed.

Results: Five patients were included. There were no complications. An immediate improvement, both subjectively and objectively, occurred and remained during the six months the patients have been followed. FEV1/sec increased from a mean of 0.76 to 1.2 L (57%) and RV decreased from 5.5 L to 4 L (42%).

Conclusion: IBRV seems to be a safe, reversible, and simple method to improve lung function in selected patients with AAT deficiency. Further studies are warranted.

P3539
Endobronchial identification of persistent peripheral bronchopleural fistula with digital chest tube monitoring followed by treatment with endobronchial one-way valve implantation
Irene D. Caldas, Vaclav Trnka, Thomas J. Ehrlichberger, Michael Müller2, Otto Burghuber1, Arschang Valkapour1, 1Respiratory and Critical Care Medicine, Otto Wagner Hospital, Ludwig-Boltzmann-Institute for COPD and Respiratory Epidemiology, Vienna, Austria; 2Thoracic Surgery, Otto Wagner Hospital, Vienna, Austria

Introduction: Bronchopleural fistula (BPF) is associated with high morbidity and mortality and causes prolonged hospital stay and costs. Surgery remains the treatment of choice, however, many patients are at high risk or unwilling to undergo thoracotomy.

Objectives: To present a standardized approach of endobronchial and treatment of persistent peripheral BPF.

Methods: 10 patients with persistent air leaks (presence of chest tube >7 days) underwent bronchoscopy with balloon occlusion technique and digital monitoring of airflow in order to identify the peripheral source of bronchopleural fistula. Endobronchial one-way valve implantation (Spiration Inc., Olympus) was performed in a segmental or subsegmental level to block ventilation to the BPF.

Results: Mean chest tube drainage time prior to the intervention was 22±13 days. The source of the BPF was endoscopically identified in all cases. Bronchoscopic valve implantation (1.6±0.8 valves per patient) was performed successfully in all patients. Using digital chest tube monitoring air flow immediately decreased from ≥0.026±0.095ml/min to ≤56.7±1ml/min (p < 0.001), indicating successful cessation of the leakage. 2 patients underwent additional chemical pleurodesis. The chest tube was removed 8.5 days after bronchoscopy. There was no evidence of recurrence during a mean follow-up time of 2 months.

Conclusion: Using a standardized approach in endobronchial diagnosis followed by endobronchial one-way valve implantation results in a high responder rate in patients with peripheral BPF.

P3540
Bronchoscopic injection of absolute ethanol in patients with persistent air leak from chest tube drainage
Chen-Kong Kim, Ah-Lek Law, Kyung Min Lim, In-Gye Hyun. Department of Internal Medicine, Hallym University College of Medicine, Seoul, Republic of Korea

Background: Chest tube drainage (CTD) has indicated for the treatment of pneumothorax, hemothorax and after thoracic surgery. But, in the case of incomplete lung expansion and/or persistent air leak from CTD, medical or surgical thoracoscopy or, if that is unavailable, limited thoracotomy should be considered.

Objectives: To test this hypothesis we correlated Chartis values with outcome of ELVR volume reduction (ELVR) with endobronchial valves (EBV). The Chartis system (PulmonX, USA) measures CV in the target lobe of ELVR to predict outcome and aid patient selection.

Methods: In 15 patients who had persistent or prolonged air leak from CTD were included. In 11/15 patients. In 2 patients a valid Chartis measurement could not be obtained. 2 patients, although the Chartis reading was interpreted as CV-ve, were non-responders. Despite these limitations, Chartis in our preliminary experience seems a valuable tool to select patients for ELVR with EBV.

Results: 15 patients (all men) were enrolled. There were 14 spontaneous pneumothorax (5 idiopathic, chronic obstructive pulmonary disease (COPD) and 3 post-tuberculosis) and 1 empyema associated with broncho-pleural fistula in the study. Of 14 patients with ethanolamine injection therapies, five had previous medical therapy, wedge resection for bullae, but the others didn’t have. Twelve were successfully treated by an ethanolamine injection therapy alone. But three (idiopathic, COPD and post-tuberculosis) were failed and followed by a surgery (2 cases) or pleurodesis (1 case). Minor complications such as fever, chest pain and transient pneumonic infiltrations occurred after the therapy. With successful, the time to dischare was about 3 days (median).

Conclusions: Bronchoscopic ethanol injection therapy may be partially useful in controlling air leakage and reducing the hospital stay in patients with CTD.

P3541
Results of BODE index in the European multicenter study for the treatment of advanced emphysema with bronchial valves
Vincent Ninane1, Christian Geltner2, Michela Bezzii3, Jens Gottlieb4, Luis Seijo5, Mohammad nunavarr5, Antoni Rosell6, Stephen Springmeier7, Xavier Gonzalez8, 1Pulmonary Medicine, St. Pierre Hospital, Brussels, Belgium; 2Pulmonary Medicine, LKH Natters, Innsbruck, Austria; 3Pulmonary Medicine, Hospital Universitario de Navarra, Pamplona, Spain; 4Pulmonary Medicine, Royal Preston Hospital, Preston, United Kingdom; 5Pulmonary Medicine, Hospital Universitario de Bellvitge, Barcelona, Spain; 6Clinical Research, Spiration Inc., Redmond, United States

The BODE index evaluates the risk of mortality in patients with COPD. The VENT study (un-blinded, randomized with a medical control arm) reported that at 6 months. 40.6% of subjects treated with the Zephyr® (Pulmonx) valve in a single lobe, achieved at least a 1-point improvement in the BODE index as compared with only 18.6% of controls. We reported positive results of a blinded and randomized sham bronchoscopy controlled study evaluating the IBV® valve system (Spiration) treating both upper lobes in subjects with advanced emphysema but, without the goal of lobar atelectasis.

Methods: BODE was calculated at baseline and 3-months (blinded study period) in subjects in whom all necessary data was available.

Results: With the exception of 1 subject in the treatment group (TG), blinding was maintained. BODE improvement was -0.32±1.4 and -0.33±1.1 in the TG and CG respectively (p>NS). Approximately half of the TG had improvements that may reflect treatment and positive study effects. In contrast with the not-blinded VENT control arm, 36% of the CG had improvements that could only be explained by positive study effects and/or placebo.

391. Molecular markers: diagnosis and management of malignant pleural effusions

P3543
Expression of ERK2 and p38α kinases in pleural mesothelial cells after exposure to asbestos fibers.

Lise Teixeira1, Milena Acencio1, Roberta Sales1, Francisco Vargas1, Milena Acencio1, Ruth Siqueira2, Carlos Silva2, Vanessa Alvarez1, Leila Antonescu1, 1Pulmonary Division - Pleura Laboratory, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, Brazil; 2Laboratory of the College of Medicine, São Paulo, Brazil; 3LIM 03 - Clinical Laboratory - Pathology Department, University of São Paulo Medical School, São Paulo, Brazil; 4Pulmonary Division, Jundiaí Medical College, Jundiaí, Brazil. 1, 2, 3

Asbestos is known to stimulate gene expression in a variety of cell types via down-stream intracellular signaling cascades. This mechanism includes the mitogen-activated protein kinases, which can lead to increased transcriptional activation of genes related to cell proliferation, apoptosis and inflammation.

Objectives: To quantitively and to compare the expression of ERK2 and p38α in pleural mesothelial cells (PMC) exposed to crocidolite or chrysotile fibers.

Materials and methods: C57/B6 mice received intrapleural injection of crocidolite or chrysotile fibers (3.0 μg/cm²) or PBS (control). After 1, 7, 14 and 30 days the animals were euthanized and PMC were extracted. ERK2 and p38α levels were measured by ELISA. Results are expressed in mm ± SD using t-test (p < 0.05).

Results: In the control group ERK2 and p38α levels were undetectable. Both crocidolite and chrysotile stimulated PMCs to produce, as shown in the table.

Conclusions: Our data demonstrated that crocidolite produced higher levels of ERK2 and p38α than chrysotile, in a time-dependent fashion. More studies are needed to examine whether activation of this pathway is functionally linked to cell inflammation and cellular apoptosis induced by asbestos fibers and its role in the carcinogenesis of mesothelioma.

P3544
Prognostive value of promoter hypermethylation of tumor suppressor genes in malignant pleural fluid

Maribel Botana-Rial1, Loreta de Chiarà2, Virginia Leiro-Fernández1, Diana Valverde3, Cinthia Represas- Represas4, Ana Isabel González-Silva5, Alberto Fernández-Villar6, 1Unit of Interventional Bronchopulmonary Pathology, Pneumology Department, Respiratory and Infectious Disease Research Group, Bio-Medical Research Institute of Vigo, University Hospital Complex of Vigo (CHUVI), Vigo, Pontevedra, Spain; 2Department of Biochemistry, Genetics and Immunology, Faculty of Biology, University of Vigo, Vigo, Spain.

Background: To determine the prognostic value of promoter hypermethylation of p16/INK4a, MGMT, BCR/ABL and RAR β genes in pleural fluid (PF) and other clinicopathological parameters in malignant pleural effusion (MPE).

Methods: We evaluated 49 patients. We recorded clinical characteristics, characteristics of the PF, the detection of promoter hypermethylation of the tumor suppressor genes in PF by methylation-specific polymerase chain reaction.

Results: We included 37 (75.5%) lung cancer patients and 12 (24.6%) with other epithelial neoplasia. The median time of global survival was 255.5 (IC 95%:56-488.5) days. Parameters associated with a minor survival were: the presence of others metastasis (p=0.003); no chemotherapy treatment (p=0.001); pH<7.28 (p=0.004); glucose<60 (p=0.002) and the absence of some methylated gene (p=0.003). After the univariate analysis, chemotherapy treated have a significantly reduced risk of death (OR=0.05; p = 0.001). Patients with metastasis (OR 5.1;p=0.001) and patients with pH<7.28 (OR=3.2;p=0.003) have more risk of death. Chemotherapy treatment received (OR=0.1;p=0.001) and the presence of methylated genes (OR=0.2;p=0.002) were factors associated with major survival in patients with lung adenocarcinoma diagnosed.

Conclusions: In patients with lung adenocarcinoma, the presence of promoter hypermethylation of genes and history of chemotherapy treatment were significantly associated with major survival. Tumor extension, not having received chemotherapy and the characteristics of the PF were factors related to the risk of death in all MPE patients analyzed.

P3545
Endogenous thrombin potential (ETP) in pleural effusions

Lise Teixeira1, Marjone Colombini2, Francisco Vargas1, Milena Acencio1, Ruth Siqueira2, Carlos Silva2, Vanessa Alvarez1, Leila Antonescu1, 1Pulmonary Division - Pleura Laboratory, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, Brazil; 2LIM 03 - Clinical Laboratory - Pathology Department, University of São Paulo Medical School, São Paulo, Brazil; 3LIM 03 - Clinical Laboratory - Pathology Department, University of São Paulo Medical School, São Paulo, Brazil; 4Pulmonary Division, Jundiaí Medical College, Jundiaí, Brazil. 1, 2, 3

The coagulation system plays an important role in the physiopathological mechanisms of inflammatory diseases compromising the pleural space. Endogenous thrombin potential (ETP) is a new marker used to evaluate coagulation system that recording hypercoagulability, as well as, hypo-coagulability and reflects quantitatively the measure of generated thrombin.

Objective: To evaluate the ETP in pleural effusions of different etiologies.

Methods: Thirty seven patients with pleural effusion were enrolled, previous to any treatment: 10 Lung cancer (LC), 6 breast cancer (BC), 11 tuberculosis (TB) and 10 transudates (TD). ETP in plasma (P) and pleural fluid (PF) were quantified by using the BCS system (Siemens, Germany). The results (mAU) were calculated by mathematical derivation from the kinetic reaction developed where

533s
ETP is expressed by the area under the curve (AUC). Statistical analysis: One Way Anova.

Results: In plasma, the ETP levels were lower in the TD group. In pleural fluid, the higher levels were observed in the BC group. However, considering the pleural effusions altogether, no statistical differences were observed between transudates and exudates.

ETP levels in plasma and pleural fluid

*p<0.05

Conclusion: This preliminary result shows that ETP may be useful to characterize the fibrinolytic response of the pleural space in inflammatory conditions. A greater number of malignant and infectious exudates need to be studied to better understand the real usefulness of ETP in the mechanism of pleural effusion formation, as well as, the management of therapeutic approach.

P3S46 Diagnostic and prognostic significance of survivin levels in malignant pleural effusion

Didem Görgün1, Funda Şeviş1, Kenan Midilli2, Vakur Akkaya1, Pinar Yıldız1, Carmen Manta1, Paola Ferro2, Enrico Battolla3, Maria Cristiana Franceschini2, Leslie Kulikowski2, Vanessa Alvarenga1, Roberta Sales1, Francisco Vargas2, Massimiliano Sivori1, Silvia Simonini4, Alessandra Bonotti5, Franco Fedeli2, Lisete Teixeira1, Leila Antonangelo1,2, Julia Puka1, Roberta Sales1, Francisco Vargas1, Evaldo Marchi2, Leslie Kulikowski2, Vanessa Alvarenga1, Roberta Sales1, Francisco Vargas2, Lisete Teixeira1, Leila Antonangelo1,2, Julia Puka1, Roberta Sales1, Francisco Vargas1, Evaldo Marchi2, Leslie Kulikowski2, Vanessa Alvarenga1, Roberta Sales1, Francisco Vargas2, Lisete Teixeira1, Leila Antonangelo1,2, Julia Puka1, Roberta Sales1, Francisco Vargas1

Objective: To evaluate the expression of ProGRP in pleural fluid (PF) of patients with malignant pleural effusion (MPE).

Methods: ProGRP was quantified by chemiluminescence immunoassay with microcrystals (CMIA, Architect, Abbott) in PF (collected in EDTA tubes) from 49 patients with MPE (45) and benign effusions (4). Malignant samples corresponded to pleural metastasis of: neuroendocrine lung carcinoma (3), breast (7), lung adenocarcinoma (20), lung poorly differentiated carcinoma (4), bronchioloalveolar adenocarcinoma (1), and others (10). Benign cases corresponded to paraneoplastic (3) and lupus-related effusions (1).

Results: Considering 4 levels, we obtained: 0 to 46 pg/mL: 37 (75%); 47 to 100 pg/mL: 4 (8.2%); 101 to 200 pg/mL: 2 (4.1%) and > 200 pg/mL: 6 (12.2%) of the cases. The benign cases and most of the metastatic effusions were in level 1. All cases in level 2 corresponded to lung adenocarcinoma. In level 3, one case corresponded to a poorly differentiated lung carcinoma and one to bronchioloalveolar adenocarcinoma. In level 4, two cases were poorly differentiated lung adenocarcinoma, and one was a sarcoma of the osteosarcoma. The remaining 3 cases corresponded to tumors of neuroneuroendocrine lineage. In these cases, the concentration of ProGRP was higher than 30,000 pg/mL.

Conclusion: PF ProGRP can be useful in identifying pleural metastasis of undifferentiated tumors. Although a greater number of cases should be studied, it seems unequivocal its importance in recognizing neuroendocrine lineage tumors.

P3S47 The value of mesothelin in pleural effusion vs histology by medical thoracoscopy

Carmen Manta1, Paola Ferro2, Enrico Battolla1, Maria Cristina Franceschini2, Massimiliano Sivori1, Silvia Simonini4, Alessandra Bonotti5, Franco Fedeli2, Silvio Roncella1, Per Aldo Casanella1,1 Pneumology, San Bartolomeo Hospital, Sarzana, La Spezia, Italy; 2Histopathology and Cytopathology, San Bartolomeo Hospital, Sarzana, La Spezia, Italy; 3Clinical Pathology, San Andrea Hospital, La Spezia, Italy; 4Preventive Medicine, a5 Spazio, La Spezia, Italy; 5Preventive Medicine, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Results: Survivin level was 40.32±7.56 in MPE, 15.83±10.92 in TPE and 8.33±6.7 in TE. According to survivin level there was no statistical significant difference been study groups. (p=0.182). When the patients divided two group as malignant and non-malignant pleural effusion, survivin level was significantly higher in MPE (40.32±7.56) than in non-MPE (13.33±2.05) (p=0.011). The cut-off value for survivin levels detected by ROC curve analysis was 7.5 pg/mL, with sensitivity 87.5%, specificity 86.7%.

Conclusions: There was no correlation between survivin level and age, sex, location, fluid pH, glucose, protein, albumin and ADA level while there was significant correlation with fluid LDH. (r=0.045; p<0.001). No correlation between survivin levels and survival were detected in MPE.

In conclusion, survivin expression levels detected with ELISA can be useful for the differential diagnosis of MPE and non-MPE despite TPE can cause false positive results in high prevalent countries. Specificity and sensitivity results could be better when cases of tuberculosis has been ruled out. Further studies are needed which included larger group of patients with other exudative effusions.

P3S48 Epidermal growth factor (EGF) and VEGF levels in pleural effusion

Massimiliano Sivori1, Silvia Simonini4, Alessandra Bonotti5, Franco Fedeli2, Liliana Libanori1,2, Chiara Corda3, Maria Cristina Franceschini2, Carlo Pirozzi1, Liliana Libanori1,2, Chiara Corda3, Maria Cristina Franceschini2, Carlo Pirozzi1

Results: Eighty-two patients with pleural effusion were included: 30 tuberculosis (Tb), 25 malignant (Ca) and 25 transudates (Trans). Pleural fluid levels of MPMs (1, 2, 8 and 9, TIMPs (1 and 2), VEGF, IL-6 and TGF-β1 were quantified by ELISA. Statistical analysis: One Way Anova and Spearman’s correlation.

Results: Except MPM-1 and TIMP-2, all parameters were higher in exsudates than transudates. MPM-8, MPM-9 and IL-6 levels were higher in Tb than Ca or Trans. The better correlation between MPMs and cytokines were observed in Tb group (MMMP-9 x TGF-β1 and MMP-9 x VEGF).

</tr>
</tbody>
</table>

Conclusions: Most of the MPMs and TIMP-1 seems to be involved in the pathogenesis of tuberculous and malignant pleural effusion. The correlation between MPM-9 and TGF-β1 could be related to the pleural thickness observed in some cases of tuberculosis.
P3550
Diagnostic yield of cytology in malignant pleural effusion: Impact of volume and repeated thoracocentesis
Mehrdad Soltoki. Internal Medicine-Pulmonary Division, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Pleural effusions are a common finding in patients with cancer, and the diagnosis is important in view of prognosis and management. We conducted this study to determine the sensitivity of pleural fluid cytology and also to check the minimum volume required for best diagnostic yield of cytology and the effect of repeated thoracocentesis on the results.

Methods: This prospective - descriptive study in patients with exudative pleural effusion during a period of 24 months (from September 2007 to August 2009) had been admitted in massih-daneshvari hospital in Tehran-The patients underwent thoracocentesis and pleural fluid cytology and subsequently followed up for six months. Diagnostic value of cytology in general and also of different volume of pleural fluid and impact of repeated thoracocentesis were investigated.

Results: A total of 318 patients were studied. Sensitivity of cytology for diagnosis of pleural malignancy was 40.8% (p=0.004). The sensitivity of first, second and third cytologic exam was 11.6%, 16.8% and 23.8% respectively. Sensitivity of tests with increasing the volume of fluid was increased (p=0.004).

P3551
Clinical and laboratory variables useful in the differential diagnosis of pleural effusions secondary to tuberculosis or lymphoma
Robert Sailes1, Francisco Vargas1, Lisete Teixeira1, Roberto Ouniishi1, Eduardo Lapa1, Leila Antongiulio Oliveira1,2,3 Pulmonary Division - Pleura Laboratory, Heart Institute (InCor) - University of Sao Paulo Medical School, Sao Paulo, Brazil,1LIM 01 - Clinical Laboratory Pathology Department, University of Sao Paulo Medical School, Sao Paulo, Brazil

Tuberculosis (TB) and Lymphoma (LYM) represent two important causes of lymphocytic effusions. Due to the similarity of clinical and laboratorial features between these clinical conditions, the differential diagnosis frequently represents a challenge to the physicians.

Objective: To describe clinical and laboratory variables capable in differentiating these diseases.

Methods: We analyzed pleural fluid of 159 patients with TB or LYM. Clinical (gender, age and symptoms), Biochemical (glucose, protein, LDH, cholesterol, triglycerides, amylase and ADA) and Cytological analyses were evaluated.

Results: In both groups there was a male predominance. Age and symptoms duration were significantly higher in LYM patients, while complaining of night sweats was more common in TB.

Approach to undiagnosed exudative pleural effusion: The diagnostic yield of blind pleural biopsy
Mehrdad Soltoki, Majid Malekmohamad. Internal Medicine, Shahid-Beheshti University of Medical Science, Tehran, Islamic Republic of Iran

Blind pleural biopsy has traditionally been performed to investigate the etiology of exudative pleural effusion in which the initial thoracocentesis has been non-diagnostic. This study examines the role of blind Abrams pleural biopsy in investigation of the exudative pleural effusion in the largest tertiary pulmonary center in Iran (Massih-Daneshviri Medical Center).

Method: All patients with pleural effusion admitted from September 2007 to April 2009 entered a prospective cohort study. Patients with exudative pleural effusion underwent blind Abrams pleural biopsy if the initial thoracocentesis was non-diagnostic. Patients with non-diagnostic blind biopsy underwent surgical biopsy or other investigations based on physicians decision.

Results: Blind percutaneous pleural biopsy were performed in 171 patients. For all diagnoses, blind biopsy had a sensitivity of 70.1% and negative predictive value of 14.8%. For malignancy and TB diagnosis, sensitivity value was 58.9% and 88.1% and negative predictive value 63.2% and 93.6% respectively. Overall malignancy was diagnosed in 95 (58.6%) and TB in 59 (36.4%) of patients.

</tbody>
</table>

*M=0.004 based on Chi-square test (P=0.001 for trend test). **M=0.012 based on Chi-square test (P=0.001 for trend test).

Conclusions: Blind Abrams needle biopsy was diagnostic in approximately three out four patients presenting with undiagnosed exudative pleural effusion. The data support the use of the Abrams needle in the investigation of pleural effusion especially in less developed countries.

P3553
Diagnostic comparison between pleural fluid cytology (PFC), cellular block (CB) and pleural biopsy (PB) under visual guidance
Cristina Fernandez1, Karen Czischke2,4, Gerardo Morejovic3, Gabriél Cavada4, Maite Oyayan3, Roberto Gonzalez3, Andrea Retamal1.
1Pathology, Instituto Nacional del Tórax, Santiago, Chile; 2Respiratory Medicine, Instituto Nacional del Tórax, Santiago, Chile; 3Thoracic Surgery, Instituto Nacional del Tórax, Santiago, Chile; 4Internal Medicine, Universidad de Los Andes, Santiago, Chile

PFC is the less invasive method for diagnosing pleural neoplasms and the reported sensitivity is 50%.

Methods: All patients evaluated at our institution who had PFC and CB done between May 2009 to June 2010 and had PB indicated where included in the study. Diagnostic categories were specified for the analysis of PC and CB. The pathologist who read the PFC and CB was blind to the PB final diagnosis. The accuracy of the techniques was compared to PB.

Statistical analysis: Kappa (k) index was used to evaluate the concordance between the different techniques versus the PB and the concordance between PFC and CB. The sensitivity and specificity for malignancy was established for every technique.

Results: 92 patients were included in the study. The PB was positive in 71 (77%) cases. The PFC was positive in 42 (45.6%) and the CB was positive in 35 (38%) of the cases. PB/PFC agreement was 68.5%; k=0.49. PB/CB agreement was 61.5%; k=0.32. PFC/CB agreement was 84.6%; k=0.68. Eleven out of 12 effusions with PFC suspicious of malignancy turned out to be malignant when compared to PB and all the suspcious CB where malignant in the PB. For PFC sensitivity was 64.3%, specificity was 100%, with a positive predicted value (PPV) of 100% and a negative predicted value of (NPV) 45%. For CB sensitivity was 59.2%, specificity was 100% with a PPV of 100% and a NPV of 42%.

Conclusion: There is good agreement between PFC and CB for the diagnosis of malignancy. CB trends to agree more than PFC with PB in the diagnosis of pleural mesothelioma. The sensitivity and specificity of PFC in the diagnosis of malignancy is similar to what is reported in the literature.

P3554
The role of video-assisted thoracoscopy in the diagnosis of malignant pleural mesothelioma
Ivan Novakov1, Silviya Novakova2, Iryko Peshev3, Maija Pirgowa3.
1Thoraco-Abdominal Surgery, Medical University, Plovdiv, Bulgaria; 2Intr-Costal Consultant Department, Medical University, Plovdiv, Bulgaria; 3Clinical Pathology, Medical University, Plovdiv, Bulgaria

The diagnosis of malignant pleural mesothelioma still remains difficult, because it needs to be differentiated from pleural metastasis and pleural benign diseases. The aim of the study is to demonstrate and find out the opportunities of video-assisted thoracoscopy to obtain the diagnosis of malignant pleural mesothelioma.

Materials and methods: 23 patients with malignant pleural mesothelioma, complicated with pleural effusion were included in this 5-year study. Video-assisted thoracoscopy was performed in all patients. Pleural effusion, obtained through thora-
coscopy, was sent for cytological analysis. Parietal pleural biopsies were performed through thoracoscopically. Histological examination of hematoylin-eosin stained pleural tissue sections was performed. Three markers with positive diagnostic value (anti-cytokeratin 5/6, vimentin, S-100) were used for immunohistochemical examination.

Results: Video-assisted thoracoscopic showed multiple nodules on parietal pleura in all patients. Histologically, in 15 cases malignant mesothelioma was classified as epithelial, and in other 8 as biphasic type. Final diagnosis malignant pleural mesothelioma was confirmed by immunohistochemistry in all cases.

Conclusion: We demonstrate that video-assisted thoracoscopic allows complete visual examination of the pleura in cases of malignant mesothelioma without pleural symphysis. Multiple and large pleural tissue specimens can be obtained through video-assisted thoracoscopic, which provides the diagnosis of malignant mesothelioma.

P3555
Diagnostic thoracoscopic in suspected malignant disease of the pleura: Pleural nodularity justifies talc poudrage
Wulf Harmes, Bernd Schönhofer. Pulmonary Medicine, KRH Klinikum Oststadt-Heidehaus, Hannover, Germany

Introduction: In a patient with suspected malignant pleural effusion and negative pleural fluid cytology, medical thoracoscopic is the next diagnostic step. Confirming the diagnosis of malignant disease involving the pleura usually means incurable cancer. Talc poudrage during the diagnostic thoracoscopic would be a reasonable approach to gain efficient pleurodesis and to reduce patient discomfort due to repeat thoracoscopies that would be necessary in the case of recurrent pleural effusion. However, in most institutions instantaneous section histology is not available. Thus, a visual diagnosis of malignant pleural disease would be desirable. The aim of our study was to find out if it is possible to differentiate between benign and malignant pleural disease simply by evaluating pleural nodularity.

Results: Between 11/2006 and 10/2007 we performed 81 medical thoracoscopies. 41 patients had a benign disease of the pleura and 40 had a malignant disease of the pleura. Pleural nodularity was noted in one benign case (a singular node) and in 29 malignant cases (four with a singular node, eleven with some nodes, and 14 with many nodes). Sensitivity for malignancy with the visibility of nodules was 72.5% and specificity was 97.6%. The positive predictive value for malignancy with one visible node was 80% and with some or many nodes 100%.

Conclusions: Nodularity is a strong predictor of pleural malignancy. If some or many nodes are visible during medical thoracoscopy, immediate talc pleurodesis is justified. However, in about one quarter of the cases of pleural malignancy, no nodularity was noted and for these cases immediate talc poudrage cannot be recommended.

P3556
Review of respiratory physician inpatient pleural ultrasound service
Burhan Khan, Majid Mushtaq. Department of Respiratory Medicine, Dartford Valley Hospital, Dartford, Kent, United Kingdom

Introduction: The appropriate and timely investigation, interventions and management of pleural effusions remains discrepant with variable practices and pathways, possibly impacting upon quality of care. Aims: To ascertain the qualitative and quantitative outcomes of running a Respiratory physician led inpatient pleural ultrasound service.

Methods: A prospective analysis of 12-18 month experience in a district general hospital of providing an inpatient pleural service by chest physicians with thoracic ultrasound.

Results: From May 2010 to date (10 months) 111 patients were included. We compare the pleural disease activity level pre and post establishing of this service.

Table 1. Overview Pre & Post establishing Inpatient Pleural Ultrasound Service

Conclusion: Provision of an inpatient pleural service does require work planning and resources but results in qualitative and quantitative improvements in patient care including: improved clinical practices by avoiding “X” marks the spot; pleural interventions done quicker and safely with no complications to date; and improved pathways for patients with pleural disease.

P3557
Safety and efficacy of pleurodesis with thoroscopic doxycycline poudrage in malignant pleural effusion
Mohamed Elhady, Amr Sakr. Chest, Cairo University Hospitals, Cairo, Egypt

Objective: To assess the safety and efficacy of thoroscopic doxycycline poudrage (TDP) for pleurodesis in malignant effusions.

Design: Retrospective.

Methods: Twenty seven patients were included in this study. Thoracoscopy was performed for diagnosis and subsequent doxycycline pleurodesis. At the end of thoracoscopy, a new method for Doxycycline delivery to the pleura was used through pneumatic atomizer insufflations where about 500-1000 mg of doxycycline were taken & prepared as a powder from the oral preparation (vibramycin 100 mg/capsule).

Results: 74.1% had a successful pleurodesis, 18.5% had partial response and 7.4% had failed pleurodesis at one month. Adverse effects included pain (48.1%), fever (3.7%) and pain & fever (22.2%). The mean drainage time for intercostals tube was about 1.52 days.

Conclusions: TDP is an inexpensive, well tolerated, reasonably effective, comparatively simple, safe, and capable of alleviating respiratory symptoms.

P3558
Audit of chest drains for pleural effusions in a tertiary care centre
R. Naseer, P.K. Plant, M.E.J. Callister. Respiratory Medicine, St. James University Hospital, Leeds, West Yorkshire, United Kingdom

Background: Pleural effusion is a common clinical problem with malignant effusions likely to become an increasing burden. Recent guidelines recommend chest drains (ICDs) for effusions are performed under US guidance, written consent is obtained & only in emergencies should ICDs be placed out of working hours. Over the last 24 months we have introduced a structured ultrasound training programme for respiratory trainees & a chest drain course for juniors.

Method: We audited ICDs for effusions in June & July 2010 in a tertiary centre. Results: There were 32 ICD’S inserted in 28 patients (pts) with a mean age of 71.62.5 Female, 37.5 Male. 56% Right & 44% Left sided. 32% had known malignant effusion. Of the 68% with an undiagnosed effusion 53% had known malignancy & 33% had an end diagnosis of malignancy. 36% were placed out of working hours. Only 2 patients were pleurectomised.

Conclusion: Respiratory education helped achieve adherence to guidelines for patients managed by respiratory medicine, however a large number of ICD’S are inserted by radiology and a significant number are being managed by Oncology. Therefore effective management of pleural effusions requires close liaison with & education of other specialties with local pleural guidelines formulated through consultation with radiology and oncology.

P3559
Efficacy of talc pleurodesis in patients with malignant pleural effusions
Ismaila Alraddad, Nathan Reyes, Javier Gallego, Juan Cotera, Isabel Caballero, Desire Macias. Respiratory Unit, Valme University Hospital, Seville, Spain

The aim of this study was to analyze complications and survival after talc pleurodesis for recurrent malignant pleural effusion. Methods: All patients with proven malignant pleural effusion who received talc pleurodesis from January 2004 to August 2010 were included in a retrospective analysis. Talc pleurodesis was performed with talc slurry if the pleural effusion was known previously as neoplastic or under medical thoracoscopic with talc pleurodesis from January 2004 to August 2010 were included in a retrospective study. Results: Twenty seven patients were included in this study. Thoracoscopy was performed for diagnosis and subsequent doxycycline pleurodesis. At the end of thoracoscopy, a new method for Doxycycline delivery to the pleura was used through pneumatic atomizer insufflations where about 500-1000 mg of doxycycline were taken & prepared as a powder from the oral preparation (vibramycin 100 mg/capsule).

Results: 74.1% had a successful pleurodesis, 18.5% had partial response and 7.4% had failed pleurodesis at one month. Adverse effects included pain (48.1%), fever (3.7%) and pain & fever (22.2%). The mean drainage time for intercostals tube was about 1.52 days.

Conclusions: TDP is an inexpensive, well tolerated, reasonably effective, comparatively simple, safe, and capable of alleviating respiratory symptoms.
Postoperative pleural drainage was used until fluid output was less than 100 ml/24 h. 

Results: 54 patients (30 male and 24 female) with mean age 65.9±12.5 (range 36-91) years were included. The most common primary cancer sites were lung (13 cases), mesothelioma (9), gynecological (7), digestive (8), and unknown primary (9). Six patients (11%) developed thrombosis (four in the cava vein). Two patients developed empiema and other two bronchopleural fistula. In 7 cases pleurodesis was ineffective and in nine cases pleural effusion relapsed. In 17 cases was complete success (32%) and in 21 partial success (39%). Patients with Karnofsky index (KI) < 60% had greater survival [10.71 months 95%CI (7.34-14.08)] than patients with KI less than 60% [2.52 months 95%CI (0.20-4.84)]

Methods: We used data from the population-based Austrian Burden of Obstructive Lung Disease (BOLD) study. Participants were aged >40 years and completed post-bronchodilator spirometry. Risk factors for COPD and respiratory symptoms were recorded. A clinical history indicating COPD was defined as the presence of one or more risk factors and any concomitant respiratory symptom(s). 

Results: Among 1258 participants 255 (20.3%) reported presence of one or more risk factors and presence of one or more respiratory symptoms, and were therefore considered to present with a clinical history indicating COPD. Among those the proportion of airways obstruction defined by FEV1/FVC<LLN and FEV1/FVCO<0.70 was 26% and 39%, respectively. Altogether 99 (7.9%) subjects presented with a clinical history indicating COPD and FEV1/FVC<0.70, while 65 (5.2%) presented with a clinical history indicating COPD and FEV1/FVCO<LLN.

Discussion: Utilization of the LLN as a threshold for the FEV1/FVC ratio would identify approximately two thirds of subjects with a clinical history indicating COPD and GOLD-defined disease. The response not identified when using the LLN would have mild disease (GOLD stage 1).

393. COPD diagnosis

P3561
Should we use FEV1/FVC < 0.70 or FEV1/FVC < LLN to identify subjects with a clinical history indicating COPD? – Results from the population-based BOLD study in Salzburg, Austria

Bernd Lamprecht1, Lea Schimhofer1, Bernhard Kaiser1, Sonia Buist2, Michael Staudnicka1. 1Department of Pulmonary Medicine, University Hospital Salzburg, Salzburg, Austria; 2Department of Pulmonary and Critical Care Medicine, Oregon Health and Science University, Portland, OR, United States

Rationale: To compare the fixed ratio of 0.70 and the LLN to identify subjects presenting with a clinical history indicating COPD. 

P3562
A Dutch web-survey on management of malignant pleural effusions

Rogier Boshuizen1, Andrew Vincent2, Peter Konst1, Sjaak Burgers1, Michel vd Heuvel1, 1Department of Thoracic Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands; 2Biometrics Department, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Malignant pleural effusion (MPE) is a major problem in patients with advanced cancer. Pleural approximation is necessary for a successful pleurodesis. The decision to perform a pleurodesis is made by the pulmonologist. Inter-physician variances in the assessment of the Chest X-ray might have impact on the final outcome of the pleurodesis procedure.

Aims and objectives: To describe decision variability among physicians regarding pleurodesis.

Methods: A series of 50 consecutive chest X-rays made during MPE drainage with clinical data were sent to all active Dutch pulmonologists, together with a questionnaire on the MPE management. The following questions were asked for all of these X-rays: (1) Do you report this lung to be expanded? (2) Would you install a sclerotic agent? (3) What would be the estimated chance on a successful pleurodesis?

Results: Pulmonologists of 30% of the Dutch hospitals responded. All pulmonologists were aware of the national guideline. The overall probability of recommending a pleurodesis was higher in the expanded lung group than in the not expanded lungs (90 vs 39%; p<0.0001). More experienced pulmonologists (more vs. less than 100 drains per year) less often reported a fully expanded lung (49 vs 57%; p=0.03), but were likely to recommend pleurodesis more often (probability was 95 vs 85% patients with a fully expanded lung and 44 vs 32% for an incomplete expanded lung; p=0.06). All pulmonologists assessed the success rate for breast cancer higher than for other tumors (p=0.002), and they tended to recommend pleurodesis more often in this group (p=0.07).

Conclusion: Pulmonologists’ experience influences decisions regarding MPE management.

P3563
Clinical COPD questionnaire (CCQ) score and mortality

Josefin Sundh1, Christer Janson2, Karin Lisspers3, Scott Montgomery4, Bjorn Stallberg3. 1Department of Respiratory Medicine, Örebro University Hospital, Örebro, Sweden; 2Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; 3Department of Public Health and Caring Science, Family Medicine and Clinical Epidemiology, Uppsala University, Uppsala, Sweden; 4Clinical Epidemiology and Biostatistics Unit, Örebro University Hospital, School of Health and Medical Science, Örebro University, Örebro, Sweden

Introduction: Quality of life is an important patient-oriented measure in COPD. The Clinical COPD Questionnaire (CCQ) is a validated instrument for estimating health status, correlating well with instruments such as SGRQ and SF-36. The prognostic qualities of CCQ have not been evaluated. This study investigated the association of CCQ with all-cause mortality in COPD patients.

Methods: A total of 1548 patients with a diagnosis of COPD were randomly selected from 70 Swedish primary and secondary care centres. The analysis included 956 patients (aged 34-75 years). Information was collected using questionnaires and record review. The Swedish Board of Health and Welfare provided mortality data. Cox regression estimated survival with adjustment for age, sex, smoking, education, level of care, and lung function (only available for a subset with spirometry data, n=491).

Risk ratios with phenotype 2 as reference.

Conclusion: These data provide strong evidence that our previously identified phenotypes have different natural history.
Methods: 730 current- or ex-smokers including 382 COPD subjects were studied (66.7±11.0 yrs, 602male/128 females). We collected the data for all the subjects on pulmonary function test, 6 minute walking test (6MWT), body mass index (BMI), dyspnea (modified Medical Research Council (MMRC) Dyspnea Scale, Oxygen Cost Diagram (OCD)), and the extent of emphysema and airway disease assessed by chest computed tomography (CT) (low attenuation area (LAA)% and wall area (WA)%), and we also studied the data on the score of St. George’s Respiratory Questionnaire (SGRQ) for QOL (n = 361), and exacerbations (n = 178). We performed a principal component analysis (PCA) and cluster analysis by k-means method.

Results: PCA showed the major factors as follows: vital capacity (VC), LAA%, WA%, reversibility, PaO2, PaCO2, leg fatigue on 6MWT. Cluster analysis with these factors classified the subjects into four clusters as follows: Cluster 1; 254 cases with mild emphysema (LAA% < 22.1%, WA% < 10.8, BMI < 18.5), Cluster 2; 156 cases with airway disease (LAA% 15.7±11.3, WA% 58.3±12.8), Cluster 3; 152 cases with emphysema and airway disease (LAA% 20.1±13.2, WA% 6.5±11.5), Cluster 4; 168 cases with severe emphysema (LAA% 41.0±11.8, WA% 57.0±11.3).

Cluster 4 has the highest SGRQ score (p < 0.0001). Cluster 2 and 4 were more prone to exacerbations (p < 0.05).

Conclusions: PCA and cluster analysis revealed that chest CT contributes to the classification to subpopulations in smoker with or without COPD.

P3567 Spirometry in UPLIFT®: Quality and reproducibility over time

Winn Janseins1, Dacheng Lou2, Steven Kesten3, Donald P. Tashkin4, Bartolome R. Celli5, Marc Decramer6, 1Dept of Pneumology, University of Leuven, Leuven, Belgium; 2Medical, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, United States; 3Medical, AstraZeneca Medical, Tustin, CA, United States; 4Dept of Medicine, David Geffen School of Medicine, Los Angeles, CA, United States; 5Dept of Pulmonary, Brigham and Women’s Hospital, Boston, MA, United States

Background: UPLIFT® was a 4-yr, randomized, double-blind, placebo-controlled multicenter trial in 5993 patients (pts) with chronic obstructive pulmonary disease (COPD).

Aims and objectives: To explore spirometry quality and reproducibility in this large trial.

Methods: Within-test variability of pre- and post-bronchodilator (BD) forced expiratory volume in 1s (FEV1) was within-patient measurement error of acceptable maneuver in 1 spirometry, compared across study visits. Between-test variability was mean difference of best pre- or post-BD FEV1 values across 2 visits (6 mo interval), corrected for normal decline 1.5±1L. At trial start (a), middle (b) and end (c).

Results: 3 acceptable maneuvers in 93.8% visits. Within-test variability of pre- and post-BD FEV1 (mean SD: 0.092L and 0.098L) decreased during the trial (visits 3-19; figure), a similar pattern seen in analysis of pts with measurements at all visits. Between-test variability decreased over time: pre-BDFEV1 (a=0.14±0.13L; b=0.13±0.12L; c=0.12±0.12L) post-BD-FEV1 (a=0.14±0.14L; b=0.13±0.12L; c=0.12±0.12L), and was dependent on age, sex, smoking status, GOLD stage, but NOT BD response or treatment (isotropium/control).

Conclusion: Spirometry quality in UPLIFT® was excellent and improved during the trial. Large interoccasion variability dependent on age, sex, smoking and COPD severity suggests relevant cut-offs for individual disease monitoring are hard to establish.

Funded by Boehringer Ingelheim/Pfizer

P3568 Discriminative characteristics of the CAT score in stable COPD patients

Eric Marchand, Gisele Maury. Pneumology, Cliniques Universitaires UCL de Mont-Godinne, Yvoir, Belgium

The CAT score is a new tool to assess health-related quality of life in patients with COPD. Its discriminative characteristics are yet to be described.
Clinical-morphological changes in bronchial mucous membrane according to the III-IV COPD stages

Igor Ievskh, Olesya Myronenko. Internal Medicine Department, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Aim: To estimate the depthness, intensity and reversibility of structural changes in bronchial walls in III-IV COPD stage with immunomorphological method using.

Study design: 42 pts (mean age 59 ± 1.7 years) with COPD: 1 gr - 30 pts with III stage (20 male), II gr - 12 pts with IV stage (9 male). Bronchoscopy with consequent histology sampling and assessing by microscopy and immunohistochemistry (ICC) research was done for all pts. The following indexes were evaluated: Ki-67 (reflect proliferative potential and activity of epithelial regeneration); Cytokeratin 8 (Ck) (as a marker of glandular epithelium); Ck 34E12 (squamous epithelium origin).

Results: In Gr I all pts had been demonstrated intensive positive membrane reactions with Ck 8 in uninnuriosuous ciliary and basal epithelial cells and heterogeneous positive membrane reactions with Ck 34E12. The simultaneous co-expression of both types of cytokeratins indicates the reversibility of metaplasia.Histological investigation: hypertrophy of smooth muscles, polypoid overgrowthing of mucous, proliferation of fibroblasts.

In Gr II took place focal positive membrane reaction with Ck 8 in residual glandular cells, and intensive expression of Ck 34E12 without co-expression of both markers.

Conclusion: 1. Pts with COPD III had been estimated changes with high reversibility, but with provided exclusion trigger agents and relevant therapy, in comparison with COPD, stage IV. 2. Pts with COPD, stage IV, the atrophy and sclerosis of bronchial walls were revealed. Immunomorphological data indicated about regenerating depletion and permanent irreversible changes of bronchial tree.

Impairment of membranous and vascular components of pulmonary diffusion and plasma endothelin-1 in patients with liver cirrhosis with and without COPD

Susann Langwiel 1, Thomas Wex 2, Maltefinger Peter 2, Jens Schreiber 1, 1Pneumonology, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany; 2Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany

Liver cirrhosis (LC) may be rarely complicated by hepatic pulmonary syndrome or hypertension. Nevertheless abnormalities of gas exchange are frequent in LC. The mechanisms are still unclear. A reduced hepatic clearance of Endothelin – 1 is playing a role.

In 72 pts with LC, 29 (40.3%) of whom had accompanying COPD, PFT were performed as well as measurements of PaO2, diffusion capacity, pulmonary capillary blood volume (Qc), membrane diffusing capacity (Dm) and plasma ET-1. The functional measurements were performed in a matched group of pts with COPD without liver function impairment (n=38).

None of the pts. had clinically manifest hepatic pulmonary syndrome or hypertension. Liver cirrhosis B 7.02% (81.9%) of the pts. with LC and all pts. with both LC and COPD and 31/39 (79.5%) pts. with sole COPD showed decreased TLC.

In all pts. but one with sole LC Dm was reduced. Qc was reduced to a lesser extend in 47 (65.2%) pts., with a greater impairment of Dm. In the COPD group the reduction of Dm was the overwhelming mechanism of an abnormal diffusion capacity PaO2D was significantly negatively correlated with TLC, Qc and to a lesser extend with Dm in pts. with LC without ventilatory impairment. All pts. with LC independently on coexisting COPD showed increased plasma concentrations of ET-1, which were negatively correlated with Qc (r=0.5, p=0.015).

Impact of the DM as a responsible for an abnormal gas exchange in pts. with LC contrary to COPD where reduction of Dm plays the most important role. Increased ET-1 in LC might contribute to pathogenesis of gas exchange impairment in LC.

Clinical characteristics of COPD with mild bronchiectasis

Misuzu Kurahara, Nariaki Kokuho, Hiroki Hayashi, Takohe Ishibi, Takashi Motegi, Kumiko Hattori, Koushi Yamada, Koichiro Kamio, Akiko Gemma, Kori Kida. Department of Internal Medicine, Division of Pulmonary Medicine, Infectious Diseases and Oncology, Respiratory Care Clinic, Nippon Medical School, Tokyo, Japan

Aim: We tested the hypothesis that patients who have COPD and develop mild BE have a more deteriorated QOL, exercise capacity, and outcome after 1 year than those patients who have COPD without bronchiectasis (BE).

Methods and subjects: The study population consisted of 204 consecutive patients with COPD. All the patients underwent HRCT of the chest and the following studies: quantitative assessment of bronchiectasis by using the methods reported by Bliha (1991) and Smith (2010), pulmonary function tests, 6-minute walking test, and assessment for QOL. The outcomes for acute exacerbations were evaluated for 1 year.

Results: The study included 204 patients (men, 189; women, 15) with a mean age of 71.2 years. The prevalence of BE in the patients was 27% (n = 55), and the frequency of exacerbations (FE) was 0.49 per year for 70 of the patients. On adjusting for FEV1%, age, and gender, it was found that the patients who had COPD and BE had significantly higher FE than those who had COPD without BE (p = 0.01). Visual analogue scale-QOL assessments indicated a trend towards deteriorated QOL for patients with BE with regard to social activity alone. The fat free mass index for patients with BE was significantly lower than that for patients without BE (p = 0.02). These data were almost similar for the 2 different assessments performed using the methods reported by Bliha and Smith.

Conclusions: The patients who had COPD with mild BE had greater likelihood of acute exacerbation than did the patients who had COPD without BE. This characterized phenotype of COPD that is attributed to BE should be evaluated for chronic management even in mild cases of BE.
Results: Our study group consisted of 55% males, mean age of 63.9±8.2 years, mean FEV1 of 46.8±17.2%, pred, median BODE of 4 (2-5) and median CCI of 1.0 (0-7.5). Mean AF was 3.4±0.7AU and correlated positively with age (p<0.01). We found no difference in AF between sex, GOLD criteria, BODE index and CCI. No correlation with FEV1 was observed, but AF was positively correlated with the amount of pack years smoked (r=0.278, p<0.05). In multivariate regression analysis age and pack year smoked predicted AF for 16%.

Table 1. Linear regression of severe COPD patients (n=100) with skin autofluorescence as dependent variable.

<table>
<thead>
<tr>
<th>Beta</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>R²=0.16</td>
<td></td>
</tr>
<tr>
<td>Age</td>
<td>0.04</td>
</tr>
<tr>
<td>Amount of pack years</td>
<td>0.22</td>
</tr>
</tbody>
</table>

Conclusion: Although AF correlated with age and the amount of pack years smoked in a group of severe and complex COPD patients, AF was not associated with any criteria of disease status, suggesting that AF is not a good marker of disease status.

P3574
Association between comorbidities, disease severity and body mass index in COPD patients
Marli Knoesel1,2, Juliana Nunes1,2, Lucas Ries2, Jorge Valentini2, Leandro Rech2.
1Serviço de Pneumologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, RS, Brazil; 2Departamento de Medicina Interna, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil

Background: COPD patients are often afflicted by multiple comorbidities. Objectives: To assess the nature and prevalence of comorbid diseases in a COPD population and to study the association between comorbidities and COPD severity and disease duration.

Methods: We studied 470 patients who met GOLD spirometric criteria for COPD (post-bronchodilator FEV1/FVC < 0.7). Data on comorbidities and pulmonary function tests were collected. Subjects were stratified by GOLD stage (GOLD I–IV) and body mass index (BMI) as underweight (BMI<21; n=119), normal-weight (n=115), overweight (BMI>25–30; n=130) and obese patients (BMI>30; n=95). Data are presented as mean (SD): Spearman test Kruskal-Wallis test were used.

Results: Of the patients studied, 281 were men (59.8%), with mean age of 64.9 (10.3) years, FEV1 of 1.31 (0.3) l and BMI of 25.3 (5.7) kg/m². The average number of comorbidities per patient was 3.1 (1.9). In 105 patients (22.3%) five or more comorbidities were identified. The most frequent comorbidities found were hypertension (44.9%), cardiac disease (20%), diabetes (14.7%), osteoporosis (13.6%) and dyslipidemia (13%). There was no correlation between COPD severity and number of comorbidities (p>0.05). There was a significant correlation between BMI and number of comorbidities (r = 0.323; p < 0.001). Obese patients had an average of 4.1 comorbidities, and overweight, normal-weight and overweight patients of 2.8, 2.5 and 3.1, respectively.

Conclusion: We found that comorbidities are frequent in COPD and are associated with increase of BMI. Therefore, COPD patients should be encouraged to maintain their weight in the normal range. Supported by FIFE/HCPA and FAPEGO.

P3575
Features of mucous membrane changes of bronchial tree at patients with COPD
Tetyana Pertseva, Igor Ivakh. Internal Medicine Department, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Aim: Research was an estimation of expressed of changes of mucous membrane of bronchial tree at patients of COPD on the different stages of pathologic process. Study population: We investigated 86 patients (pts) (53 male, mean age 62.4±4.4 yrs) with COPD. All pts were divided on three groups: 1 group (gr.) – 10 pts with COPD I stage (st); II gr. – 28 pts with II st.; III gr. – 36 pts. with COPD II–IV stage (st). The state of mucous membrane of bronchial tree, degrees of atrophy of epithelium, character and amount of mucus, was estimated.

Results: We found that comorbidities are frequent in COPD and are associated with increase of BMI. Therefore, COPD patients should be encouraged to maintain their weight in the normal range. Supported by FIFE/HCPA and FAPEGO.

P3577
Comorbidities associated with chronic obstructive pulmonary disease (COPD) – A clinical study
Gogmatath Varthan, Supriya Adyodi. Pulmonary Medicine, Jubilee Mission Medical College, Tiruchir, Kerala, India

OPD continues to be one of the commonest causes of increasing morbidity and mortality globally. While cardiovascular (CVD) and cerebrovascular diseases are decreasing over the years, COPD is the fourth leading cause of death, thanks to continuing smoking habits, atmospheric and industrial pollution. Lack of awareness and late diagnosis adds to injury. Associated comorbidities such as CVD, muscle/cerebral disorders and infective exacerbations are not often recognised.

P3578
Evaluation of the gas exchange abnormalities in COPD patients with the use of capnometry
Yury Feshchenko, Liudmyla Isahyna, Svitlana Ishchuk. Diagnostic, Therapy and Clinical Pharmacology of Lung Diseases, National Institute of Phthisiology and Pulmonology named after F.G. Yanovsky AMS of Ukraine, Kiev, Ukraine

Background: COPD is airway disorder associated with an abnormal inflammatory response of the lungs to noxious particles or gases. Due to progressive nature of the disease the respiratory failure verification is of great importance.”
Objectives: This study aimed to investigate capnometry indices in patients with stable COPD (GOLD III-IV) compared to healthy subjects.

Methods: capnometry, capnometry. Data are presented as mean±SD.

Results: A total of 87 subjects (age 56.2±1.2 years; 59% male) were enrolled: COPD group (n=42, mean±%FEV1 =39.5%), control group (n=45, mean±%FEV1 =93.7%). All subjects were performed bodyplethysmography and capnometry, we compared the results between groups. All bodyplethysmography and capnometry indices of COPD subjects were significantly (p<0.05) different from control. The mean values Rtot,%= 241.6±12.7 and 117.7±4.8, R2 = 81.1±2.2 and 110.9±3.2, R5V = 189.9±9 and 101.1±5 in COPD and control group respectively. The capnometry results were Vd/VE=VT 33.8±1.2 and 25.5±1.1, PEFCO2, kPa = 2.8±0.1 and 3.2±0.1, end-expiratory lung volume, was 5.1±0.2 and 4.7±0.2, FE2CO2% = 0.3%±0.1 and 3.4±0.1 in COPD and control group respectively.

Conclusions: Capnometry might be a useful tool to detect the respiratory failure in COPD patients.

P3579

The indices of body composition (IBC) in chronic obstructive pulmonary disease (COPD)

Aliaksandr Makarevich1, Sviatlana Lemesheuskaya1, Natalja Vasieljeva2.

1Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2Department of Otorhinolaryngology, Republic Medical Rehabilitation Centre, Minsk, Belarus.

The aims: To analyze of IBC at different stages of COPD as well as the relationships between the IBC, lung function and smoking status.

Material and methods: Bone mineral content (BMC), Fat mass (FM) and Lean mass (FM, excluding BMC) were detected by dual-energy X-ray absorptiometry. FM, FFM and BMC were expressed as the ratio to height squared to obtain indices FM/H2, FFM/H2 and BMC/H2 respectively. (The pts of 1st group 49, 50 and 53 respectively; of 2nd group 14, and 15; of 3rd group 20 and 21). The control group was formed of 15 healthy men (mean age 56 yrs, mean BMI 26 kg/m2, smokers 84%, pack/yrs 28). The control group was subdivided into 3 groups according to COPD severity. The 1st group was made of 14 men (GOLD I stage; mean age 55 yrs; FEV1 78%, BMI 27 kg/m2, smokers 68%, packyears 69), the 2nd group included 43 men (GOLD II stage; mean age 57, FEV1 63%, BMI 28 kg/m2, smokers 80%, pack/yrs 21); the 3rd - 20 men (GOLD III stage; mean age 60; FEV1, 41%; BMI 24 kg/m2, smokers 84%, pack/yrs 28). The control group was formed of 15 healthy men (mean age 56 yrs, mean BMI 26 kg/m2, smokers 66%, pack/yrs 20).

Results: The BMI value was decreased during COPD progression (from 21,3 kg/m2 in the 1st group to 17,7 kg/m2 in the 3rd group: p<0.05). We revealed the significant correlations between: COPD severity and FFMI (r = -0.54); FMI, FFMI, BMCI and packyears (r = -0.37, -0.38, -0.3 respectively). FFMI level was higher in 1st and 2nd groups as compared to the control and FFMI significantly correlated with FVC (r=0.4) and FEV1 (r=0.4). The BMCI value in 1st group and the control was similar (1.06 kg/m2) and it was significantly higher than in 2nd and 3rd groups (1.01 and 0.89 kg/m2 respectively). Pts of 3rd group had a lower FMI as compare with the pts of 1st and 2nd groups (4.25 vs. 8.28 and 9.72 respectively; p<0.05).

Conclusions: The IBC changes can probably reflect COPD progression.

P3580

Evaluation of different domains of the Saint George’s respiratory questionnaire (SGRQ) according to the severity levels of chronic obstructive pulmonary disease (COPD)

Filipjev A1,2, Rosana Sampao1, Bruza Vienica2, Danielle Vienica3, Raquel Britto2, Verónica Parreira2.

1Graduation Program in Rehabilitation Sciences, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; 2Department of Physical Therapy, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.

Relevance: Spirometric parameters used to determine disease severity may not be appropriate to infer about the different components of functioning in patients with COPD.

Purpose: To compare and correlate the scores of the different SGRQ domains according to the GOLD severity levels in patients with COPD.

Methods: A cross-sectional study was conducted at a hospital university. Comparison (Kruskal-Wallis) and correlation (Spearman) tests were used after performing normality tests. This study was approved by the Ethics Committee.

Results: Table 1 summarizes the data for each GOLD stage. No significant difference was observed between stages I and II or I and III for any of the SGRQ domains. There were no significant correlations between FEV1 and the SGRQ scores. Conclusion: The results suggest that there is no linearity between the severity levels of COPD and the SGRQ scores, including the activity and psychosocial impact domains.

P3581

Fibroblast growth factor 23 (FGF23) and hypophosphatemia in patients with COPD

Mohamed Elsamamak2, Adel Attia1, Moosa Suleman 1. 1Pulmonology, King Fahad Specialist Hospital, Dammam, Saudi Arabia; 2Pathology and Laboratory Medicine, King Fahad Specialist Hospital, Dammam, Saudi Arabia.

Introduction: Previous studies highlighted the importance of phosphate depletion in COPD patients and the association between correction of hypophosphatemia and improvement in respiratory muscle function. Fibroblast Growth Factor 23 (FGF23) is a recently discovered circulating protein that plays a crucial role in renal phosphate reabsorption and body phosphate regulation. FGF23 has been investigated in several diseases but there is currently no published data about FGF23 in COPD.

Aims and objectives: The aim of this study was to evaluate whether FGF23 levels correlate with serum phosphate levels and disease severity in COPD patients.

Methods: 70 COPD patients aged 63±4.6 years and 34 age and sex matched randomly selected controls were studied. Criteria for diagnosing COPD and assessing severity were according to GOLD (Global Initiative for Chronic Obstructive Lung Disease) guidelines. Serum samples were analyzed for routine tests including calcium, phosphate, renal/lytes, and FGF23 levels were measured by a commercially available Eliza kit.

Results: There were no differences in serum calcium and Vitamin D levels in COPD patients and controls (P = 0.05). COPD patients had significantly lower serum phosphate levels compared to controls (P < 0.01). Plasma FGF23 was significantly higher in patients compared to controls: 280 (51-968) versus 140 (21-200) RU/ml (P < 0.001). As expected plasma FGF23 levels correlated negatively with serum phosphate (r = 0.799 & P < 0.001). Furthermore plasma FGF23 correlated negatively with FEV1 (r = 0.352 & P = 0.003).

Conclusion: This study illustrates a significant increase in plasma FGF23 levels that may contribute to low phosphate levels and disease severity in COPD patients.

Low testosterone in chronic obstructive pulmonary disease

Elena Cojocaru1, Adina Turcanu2, Raluca-Mihaela Berces2, Cristian Cojocaru3.

1Physiology, University of Medicine and Pharmacy, Iasi, Romania; 2Pneumology, Clinic of Pulmonary Disease, Iasi, Romania.

Aim: Among other comorbidities, COPD patients have fatigue and a low physical activity level. A low level of testosterone may explain some complaints mentioned by COPD patients. In this study we compared the testosterone level in COPD patients with that of elderly men with a normal pulmonary function.

Methods: Circulating levels of testosterone and luteinizing hormone were determined using chemiluminescence technique in 34 patients (FEV1: 34.9% of the predicted values) and 20 control subjects. Moreover, the relationship of hypogonadism with 6-min walking distance, number of pack-year, systemic inflammation and LDL level has been studied in men with COPD.

Results: The testosterone level was lower in the COPD patients (p =0.001; <0.05). Low androgen status was related to LDM, level and 6-min predicting walking distance. No correlation was observed between testosterone level and FEV1, CRP level, and number of pack-year.

Conclusion: Testosterone level is significantly lower in COPD patients comparing with control subjects. A restricted activity level is in correlation with testosterone level. Further studies are necessary to clarify the hypothesis that testosterone treatment could enhance the COPD patients activity level.

The study of proton magnetic resonance spectroscopy on hippocampus in rats with chronic obstructive pulmonary disease
Xuefeng Ling1, Yong Lin2. 1Department of Clinical Medicine, Southeast University, Nanjing, Jiangsu, China; 2Respiratory Disease, Affiliated Zhongda Hospital of Southeast University, Nanjing, Jiangsu, China

Objective: To employ in vivo proton nuclear magnetic resonance spectroscopy to investigate the hippocampal metabolism of rats with Chronic Obstructive Pulmonary Disease and to assess if there is a relationship between brain metabolism and chronic brain injury in COPD.

Methods: Rats COPD model (model group, n=6) were established by passive smoking and intratracheal instillation of lipopolysaccharide (LPS). Other groups were compared with controls (n = 6), and all subjects underwent brain micro-magnetic resonance imaging (micro-MRI) and bilateral hippocampal proton nuclear magnetic resonance spectroscopy (1H-NMRS) in vivo at 7.0 T. A neurochemical assessment of metabolites in the hippocampus was evaluated and analyzed.

Results: 1. Rats COPD model were successfully established by passive cigarette smoking plus intratracheal instillation of LPS. 2. Compared with the normal group, the mean value of Cho/Cr is significantly altered in the bilateral hippocampal of COPD rat model (p < 0.05), but The mean value of NAA/Cr without difference (p>0.05).

Conclusion: Our results demonstrate that the metabolism is significantly altered in rats COPD model bilateral hippocampal, it is possibly one of pathophysiological factors for the COPD complicated with chronic brain damage.

P3585
COPD: Different psycholology status (PS) in the patients with different co-morbidity rate
Kateryna Gashynova. Internal Medicine, DSMA, Dnipropetrovsk, Ukraine

Aim: To evaluate whether and in which extent co-morbidity have influence on the PS in patients with COPD.

Study population: 120 outpatient men with COPD, stage III made the study sample. Exclusion criteria were 1) mental diseases; 2) presence of acute infections.

Methods: For the evaluation of the PS the depression (by Zung scale), the anxiety (by Ch.D. Spilberger questionnaire) and the vegetative lability (by VELA test) were studied in all patients. Co-morbidity rate was established during patient's medical documentation.

Results: In accordance with co-morbidity rate all patients were divided on three groups (GR): GR I without any co-morbidity condition, GR II – with I-2 and GR III – with more than 3 co-morbid conditions. All groups were similar regarding to age and smoking status. One or more abnormalities in PS were found in 2 (10.5%) patients of Group I, in 63 (74.11%) – of Group II and 13 (81.25%) persons in Group III. The data of psychological tests are presented in the table 1.

Conclusions: Co-morbid condition significantly impair psychollogy status in patients with COPD, and the most significant changes concerns depression, personal anxiety and vegetative lability level.

P3586
Arterial hypertension (AH) and endothelial function (EF) in patients with COPD
Tetyana Pertseva, Natalia Yefimova, Kateryna Gashynova. Internal Medicine, DSMA, Dnipropetrovsk, Ukraine

Objective: To investigate the influence of co-morbid AH at the EF in patients with COPD.

Materials and methods: A total of 41 men with stable COPD stages I-was observed. Mean age – 61.4±1.41 years, mean disease duration – 15.5±0.38 years.

Group I consisted of patients without concomitant AH – 21 patients, Group II – with AH – 20 patients. Pulmonary function was evaluated by spiograph MasterLab (Jeger, Germany), endotelin-1 plasma level (ET-1) – by reagents "Diamab 86" (DRG, USA), the concentration of exhaled NO (FeNO) – by Niox Mini (Aerocine, Sweden), SaO2 – by pulse oxymeter (NOMIN, USA).

Results: Both groups were comparable. In Group II the concentration of FeNO was significantly higher than in group I (14.8±1.59 ppb and 9.75±1.41 ppb, respectively (p <0.05)). In group II the level of ET-1 was similar to data in group I (0.81±0.02 mg/ml and 0.78±0.03, respectively (p > 0.05)). In group II the level of ET-I significantly correlated with SaO2 (r = -0.38, p = 0.025). We didn’t found any significant correlation between EF and airflow obstruction.

Conclusions: High concentration of FeNO in COPD patients indicates the presence of more pronounced endothelial dysfunction in patients with concomitant AH, plasma levels of ET-I increases with an increase in hypoxia in patients with COPD only if there is concomitant AH.

No significant correlation in exhaled air and plasma levels of ET-I in patients with COPD, regardless of the presence of an accompanying AH, does not correlate with indices of airflow obstruction.

P3587
The impact of comorbidities related to BMI in COPD patients
Carlos Cabrera Lopez1, Jorge Zagaceta 2, Claudia Cote 3, Miguel Divo4, Juan Carlos Cabrera5, Carlos Mira6, Damian Latorre 6, Juan Taboada7, Amador del Olmo8, Santiago Carrizo2.

Aims: The impact of comorbidities related to BMI in COPD patients with chronic obstructive pulmonary disease (COPD rat model (p<0.05), but The mean value of NAA/Cr without difference (p>0.05). In group II the level of ET-I significantly correlated with SaO2 (r = -0.38, p = 0.025). We didn’t found any significant correlation between EF and airflow obstruction.

Conclusions: High concentration of FeNO in COPD patients indicates the presence of more pronounced endothelial dysfunction in patients with concomitant AH, plasma levels of ET-I increases with an increase in hypoxia in patients with COPD only if there is concomitant AH.

No significant correlation in exhaled air and plasma levels of ET-I in patients with COPD, regardless of the presence of an accompanying AH, does not correlate with indices of airflow obstruction.

Introduction: In COPD patients a higher BMI is associated with better survival (the obesity paradox). The mechanism of this paradox is not well understood. We explored whether different co-morbidities related to survival in patients with different BMI.

Methods: We followed 1646 COPD patients of the BODE cohort. A total of 80 comorbidities were systematically recorded. Comorbidities prevalence and association with mortality was explored using Cox proportional hazard stratified by BMI in four groups (≤ 21, 22-29, 30-35, ≥ 36 kg/m²).

Results: COPD patients with BMI ≥ 36 had significantly more comorbidities than the other groups but they had lower mortality, better FEV1 and lower BODE.

No specific co-morbidities had an independent association with mortality in this group whereas they did in the other subsets. Patients with a BMI between 22 and 35 had the most number of comorbidities associated with death.

Conclusions: In COPD, obese patients (BMI≥36) have a better survival than non-obese patients, in spite of having more co-morbidities. In these obese patients there was no co-morbidity that was significantly and independently associated with mortality.

Fibrinogen, health status and hospitalization in patients with moderate to severe COPD
Vladimir Hodges1, Blagoi Marinov2, Roman Kalinov1, Lyudmila Vladimirova-Kitova1, Fedya Nikolov1, Stefan Kostianev3
1Pulmonary Medicine Clinic, Medical University of Plovdiv, Plovdiv, Bulgaria; 2Cardiology Clinic, Medical University of Plovdiv, Plovdiv, Bulgaria; 3Cardiology Clinic, Medical University of Plovdiv, Plovdiv, Bulgaria

Background: There is evidence that COPD is a systemic illness. Serum biomarkers have been associated with clinically relevant variables.

Aim: To investigate the relationships between the blood level of fibrinogen and large group of clinical and functional parameters.

Patients and methods: Twenty-nine stable COPD patients (age [yr] = 63.4±6.8, FEV1% = 37±11%, BODE index = 3.7±1.8) were enrolled in the study. Pulmonary function tests, blood-gas measurements; echocardiography, brain naturotic peptide (BNP), 6-minute walking test (6MWT) and cardiovascular exercise test (CPET) on a treadmill were performed. In addition, health status was evaluated by SGRQ (St George’s Respiratory Questionnaire) and CAT (COPD assessment test).

The presence of fibrinoegen, independently of the need for antibiotic treatment and oral/intravenous corticosteroids (OICS) in the 12 months prior to evaluation were recorded.

Results: The mean value of fibrinogen was 3.06±0.8 [g/L]. Fibrinogen correlated significantly with health status - SGRQ (r = 0.49, p = 0.008), CAT (r = 0.44, p = 0.016) and hospitalizations (r = 0.50, p = 0.006), and OICS application (r = -0.48, p = 0.012). Differentiation of patients by value of fibrinogen (> 3 g/L) was discriminated them with respect to last year hospitalisations (1.8±1.9 vs 0.6±1.3; p < 0.05). A general linear model analysis was performed for SGRQ and hospitalisations and the following equations were derived: SGRQ = 146.7-25.6*OICS+5.68*FIBR–15.83*KCO (r=0.918; r²=0.843, p<0.05).

Conclusion: Blood level of fibrinogen was related to health status and hospitalization in patients with moderate to severe COPD.

P3589
Ego defense mechanisms in COPD: Impact on health-related quality of life and dyspnoea severity
Saulo C. Albuquerque1, Eduardo R. Carvalho1, Rebeca S. Lopes1, Igor S. Marques1, Danielle S. Macêdo2, Eanes D. Pereira3, Thomas N. Hyphantis3, Andrea P. Carvalho1,2
1Clinical Medicine, Federal University of Ceará, Fortaleza, Ceará, Brazil; 2Department of Physiology and Pharmacology, Federal University of Ceará, Fortaleza, Ceará, Brazil; 3Department of Psychiatry, University of Ioannina, Ioannina, Greece

Purpose: To assess chronic obstructive pulmonary disorder (COPD) patients’ defensive mechanisms and to test whether specific ego defense mechanisms are associated with health-related quality of life (HRoL) and self-reported dyspnoea severity.

Methods: In a cross-sectional study, we assessed in 80 patients with COPD and 80 age and gender matched healthy participants, psychological distress (Hospital Anxiety and Depression Scale) and defense mechanisms/styles (Defense Style Questionnaire). Patients had their HRoQL evaluated with the St George’s Respiratory Questionnaire and underwent a comprehensive clinical evaluation with determination of functional parameters and dyspnoea severity.

Results: COPD patients presented higher scores in undoing, acting out, autistic fantasy, denial and splitting defenses compared to healthy-controls. Overall, patients showed a more immature (p=0.001) and/or neurotic (p=0.006) defensive profile. Higher scores of denial (p=0.001) and denial and undoing (p=0.032) defenses were associated with poorer HRQoL, independently of the anticipated significant associations of clinical and psychological distress variables with impaired HRQoL. Somatization was strongly independently associated with more severe self-reported dyspnoea.

Conclusions: COPD patients exhibit a relatively immature and neurotic defensive profile. Pneumologists and consultation-liaison psychiatrists should consider the patients’ underlying personality structure, especially somatization tendencies, since it is independently associated with HRQoL and dyspnoea severity.

P3590
Heart rate variability during the night in chronic obstructive pulmonary disease
Riccardo Inchingolo1, Giuseppe Maria Corbo1, Gregory Angelo Sgueglia2, Gaetano Lana2, Salvatore Valenti1
1Pulmonary Medicine, Università Cattolica del Sacro Cuore, Roma, Italy; 2Cardiovascular Diseases, Università Cattolica del Sacro Cuore, Roma, Italy

Patients with chronic obstructive pulmonary disease (COPD) could have a lower oxygen saturation during the night compared to the day-time and it could affect autonomic modulation of heart rate. We studied the behaviour of heart rate variability (HRV) during the day-time versus the night in COPD patients. 30 stable outpatients were recruited and classified by BODE index. A 24 h electrocardiographic Holter recording and a transcutaneous measurement of oxygen saturation were performed at the same time. Lung function was also measured. Statistical analysis was made by linear regression.

According to BODE index, 13 patients belonged to first group (BODE 1=0-2), 8 to second group (BODE 2=3-4) whereas 9 were included in the third group (BODE 3=5-10).

During the night, we observed, compared to the day-time, a significant increase of both normal-to-normal (NN) intervals (i.e. a reduction of heart rate, 831 vs 720 msec, p<0.000), and Standard Deviation of all RR intervals (SDNN, 94.3 vs 85.5 msec, p<0.03), and High Frequency band (HF; 14.86 vs 10.97 msec p=0.0004) with reduction of ratio of low frequency to HF band (LF/HF ratio, 1.54 vs 1.96 p<0.09). Mean oxyhaemoglobin saturation (SpO2) during the night was directly and significantly related to both SDNN (p=0.0018) and HF (p<0.057). Subjects with mean SpO2 lower than 90% showed lower SDNN (60 vs 100 msec, p<0.012) and lower HF (8.2 vs 16.2 msec, p=0.04). LF/HF ratio was found unrelated to mean SpO2 during the night, but a close inverse relationship was found with RV/TLC ratio (p<0.005).

Our data demonstrated that in COPD patients both level of oxygen saturation of haemoglobin and impairment of static lung volumes could affect the cardiac autonomic modulation.

P3591
Changes in bronchial mucous membrane depending on the stage of COPD (I, II)
Tetyana Pertseva, Igor Ivakh, Oxana Plekhanova
Internal Medicine Department, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Aim: To determine immune-histochemical characteristics of bronchial mucous membrane depending on the stage COPD (I, II).

Study population and methods: 78 patients (pts) (mean age 54.2±2.4 years) with COPD were divided on two groups (Gr); Gr I – 32 pts with 1 stage (22 male), Gr II – 46 pts with II stage (31 male). Bronchoscopy with consequent histology sampling, and assessing by microscopy and immunohistochemistry research was done for all pts. The following indexes were evaluated: Ki-67 (reflect proliferative potential and activity of epithelial regeneration); Cytokeratin 8 (Ck8) (as a marker of glandular epithelium proliferation); 34EpIE12 expression (for estimation of squamous metaplasia).

Results: Both groups were similar regarding to age, gender and duration of disease. Results of immunohistochemistry present in table 1.

In Group I in all pts there were intensive positive membrane reactions with Ck 8 in ciliary and basal epithelial cells and absence of reaction with cytokeratin 34EpIE12. But there were not any microscopically signs of hyperplasia. In Group II all pts took place intensive positive membrane and cytoplasmatic reaction with Ck 8 in goblet and basal cells with morphologically signs of hyperplasia. Besides, in every sample there were foci with high Ck 34EpIE12 expression in basal cells.

Conclusion: 1. Pts with COPD, stage I have significantly higher potential for the bronchial epithelial cells’ regeneration in comparison with COPD, stage II. Co-expression of both Ck 8 and 34EpIE12 in COPD pts, stage II allows to suppose high risk of irreversible metaplasia in bronchial epithelium.

P3592
GERD and anxiety in patients with severe COPD
Sherif Alyayed
Internal Medicine, NJCH, Jedda, Saudi Arabia

Objectives: To detect the impact of anxiety on shaping the prevalence of gastro-intestinal reflux disease (GERD) in patients with severe chronic obstructive pulmonary disease (COPD).

Methods: We examined the prevalence of symptomatic GERD, using the Vignieri score, in 29 male patients with COPD. Esophageal 24 h pH monitoring was used to document the diagnosis of GERD in symptomatic group. Beck Anxiety inventory was used to detect the impact of anxiety on expressing GERD symptoms.

Results: Reflux disease symptoms were recorded in eighteen patients of the studied group (62%). GERD was diagnosed, based on esophageal 24 h pH monitoring, in only 11 patients of those who expressing symptoms of GERD. Mean of Anxiety score was correlated significantly with the number and frequency of symptom presentation in patient with symptoms of GERD reflecting the attribute of different symptoms of anxiety to the GERD syndrom. Also Anxiety scores correlated positively with time (total) PH reflecting the effect of anxiety on the severity of GERD syndrom.

Conclusion: Patients with severe chronic obstructive pulmonary disease have a high prevalence of symptomatic gastro-oesophageal reflux. However True GERD was documented in a fewer number of them. Psychological factors, such as anxiety and somatization may play a role, particularly in those patients without esophageal inflammation.
Introduction: Multiple endocrinological disorders are induced by COPD through hypoxemia, hypercapnia, systemic inflammation and glucocorticoid administration; thyroid structural and functional derangements are amongst them.

Objectives: Our aims were to find out if COPD is a risk factor for thyroid disorders and what type of thyroid derangement is more specific to different COPD stages.

Methods: 2 groups of patients were assessed for age, gender, environment, smoking, alcohol intake, diabetes, dyslipidemia and thyroid disorder (autoimmune thyroid disease, nodular and nodulocystic goitre). First group was composed by non-COPD pts (N = 148, 19 M/128%, 129 F/78% mean age 61.33, SD 10.21) and the second one by COPD pts (N = 137, 79 M/57.66%, 58 F/42.33%, mean age 64.34, SD 10.94). COPD pts were staged according to GOLD criteria in stage I and II/IIb and the male to female ratio was 1.23 (p = 0.055). The relative risk to develop a thyroid disorder 0.123 (p < 0.01). There is also a low relative risk of 1.043 (p = 0.05, 95% CI 0.24-0.83) for the COPD stage I pts to develop autoimmune thyroid disease.

Conclusions: COPD pts have a relative low risk to develop a thyroid disorder. In COPD stage I, with more individuals in this study, the risk was found higher for patients affected by thyroid disorder. Because growing in no gaseometric anomalies nor glucocorticoid interventions, we suggest that systemic inflammation is the most probable link; the inflammatory blood markers analysis should be taken into consideration for the next studies.

Nutritional abnormalities are frequently occurring systemic complication of COPD. They often determine functional capacity, health status and mortality of patients (pts). However, causes and mechanisms of weight loss are still under investigation.

Aim: The aim of study was to reveal influence of systemic inflammation on the nutritional status in COPD.

Study population and methods: 69 men with stable COPD (Stage II-III) were surveyed. Plasma C-reactive protein (CRP), spirometry, measurement of body mass index (BMI) and Fat Free Body Mass (FFBM) by means of bioelectric impedance analysis were performed for all pts.

Results: In accordance with CRP level all pts were divided on two groups: Group I – pts with CRP < 2.87 mg/l; Group II – pts with CRP > 2.87 mg/l.

Results of nutritive status examination present in table 1.

Results: There is a significant correlation between COPD and the presence of a thyroid disorder 0.123 (p < 0.01). There is also a low relative risk of 1.043 (p = 0.05, 95% CI 0.24-0.83) for the COPD stage I pts to develop autoimmune thyroid disease.

Conclusions: COPD pts have a relative low risk to develop a thyroid disorder. In COPD stage I, with more individuals in this study, the risk was found higher for patients affected by thyroid disorder. Because growing in no gaseometric anomalies nor glucocorticoid interventions, we suggest that systemic inflammation is the most probable link; the inflammatory blood markers analysis should be taken into consideration for the next studies.

**Methodology:**

**Introduction:** Multiple endocrinological disorders are induced by COPD through hypoxemia, hypercapnia, systemic inflammation and glucocorticoid administration; thyroid structural and functional derangements are amongst them.

**Objectives:** Our aims were to find out if COPD is a risk factor for thyroid disorders.

**Methods:** 2 groups of patients were assessed for age, gender, environment, smoking, alcohol intake, diabetes, dyslipidemia and thyroid disorder (autoimmune thyroid disease, nodular and nodulocystic goitre). First group was composed by non-COPD pts (N = 148, 19 M/128%, 129 F/78% mean age 61.33, SD 10.21) and the second one by COPD pts (N = 137, 79 M/57.66%, 58 F/42.33%, mean age 64.34, SD 10.94). COPD pts were staged according to GOLD criteria in stage I and II/IIb and the male to female ratio was 1.23 (p = 0.055). The relative risk to develop a thyroid disorder 0.123 (p < 0.01). There is also a low relative risk of 1.043 (p = 0.05, 95% CI 0.24-0.83) for the COPD stage I pts to develop autoimmune thyroid disease.

**Conclusions:** COPD pts have a relative low risk to develop a thyroid disorder. In COPD stage I, with more individuals in this study, the risk was found higher for patients affected by thyroid disorder. Because growing in no gaseometric anomalies nor glucocorticoid interventions, we suggest that systemic inflammation is the most probable link; the inflammatory blood markers analysis should be taken into consideration for the next studies.
There were no relationships with genotyping and exacerbation frequency for any of the polymorphisms. There was a seasonal difference in viD levels but this was the same for all polymorphisms; all $p<0.05$.

Conclusions: FokI, BsmI and TaqI VDR polymorphisms are not associated with exacerbation frequency and do not affect viD levels in COPD.

**P3598**

Is there any correlation between apoptosis of the cells from bronchoalveolar lavage fluid (BALF) and the progression of chronic obstructive pulmonary disease (COPD)?

Agata Nowicka1, Halina Batura-Gabryel 1, Mariusz Kaczmarek 2, Jan Sikora 2, Krysztof Siewieckik 1, Anna Czyz 3.

**Background:** It has been already well known that neutrophilic inflammation, oxidative stress and protease/antiprotease imbalance play a significant role in the pathogenesis of COPD. In recent years some data were published, showing that also apoptosis may be one of the processes concerned in the pathogenesis of this disorder.

**Objectives:** We presumed that apoptosis of the cells (granulocytes, lymphocytes, macrophages) from COPD patients' bronchoalveolar lavage fluid increases along with the decline of FEV1 (forced expiratory capacity in 1 second).

**Methods:** 19 patients (16 men and 3 women), smokers or former smokers, diagnosed with COPD (stages 2-4) were enrolled into the study. The mean age was 64.5±27.83. In all subjects spirometry after the inhalation of beta-2-agonist was performed, to confirm the diagnosis of COPD according to GOLD criteria and to estimate FEV1. BALF during fibroptic bronchoscopy was taken in all patients. We used annexin V to assess apoptosis of the cells concerned in BAL fluid. (BD Biosciences, Annexin V - FITC Apoptosis Detection Kit I)

**Results:** The median FEV1 was 38.6%. Only the patients with advanced COPD were enrolled into the study (max FEV1 55.3%, min FEV1 15.3%). In the group of patients with FEV1 lower than 38.6% median for apoptosis was 4% (0.59%), in the group with FEV1 higher than 38.6% median for apoptosis was 5% (3.16%). No correlation between FEV1 and apoptosis of the cells concerned in COPD patients BALF was found ($p=0.74$).

**Conclusions:** Our data suggest that there is no correlation between apoptosis and the progression of COPD.

**P3599**

The regional distribution of body fat mass (BFM) in men with chronic obstructive pulmonary disease (COPD)

Aliaksandr Makarevich, Sviatlana Lemiasheuskaya.

**Introduction:** COPD is associated with abnormal body composition and weight loss.

**Aim:** To evaluate the relationships between BFM distribution and lung function in men during COPD progression.

**Methods:** We used dual-energy X-ray absorptiometry for an analyze of body composition, the regional distribution of BFM as well as fat mass ratios of Android/Gynoid (A/G) and Arms+Legs/trunk. COPD pts (aged 40-69 yrs) were divided into the 3 groups according to disease severity: the 1st was made of 14 men (GOLD I stage; mean age 56 yrs; FEV1 78%; BMI 27 kg/m2, smokers 66%), the 2nd - 43 pts (GOLD II stage; mean age 57; FEV1 63%; BMI 28 kg/m2, smokers 84%), the 3rd - 20 pts (GOLD III stage; mean age 66%, packs/years 20). The A/G ratio was significantly lower in 3rd group vs. the control ($p<0.05$).

**Conclusions:** BFM redistribution (decrease A/G ratio and increase Arms+Leg/trunk ratio) take place in the course of COPD progression.

**P3600**

Pulmonary features of autosomal dominant hyper-IgE syndrome (AD HIES)

Hanna Dmewska1, Edyta Heropolińska2, Barbara Pietrucha3, Ewa Bernatowska4.

AD HIES is characterized by recurrent severe pulmonary infections, pneumatoceles, eczema, staphylococcal abscesses, mucocutaneous candidiasis, abnormalities of bone and connective tissue and elevated serum IgE. Mutations in signal transducer and activator of transcription 3 (STAT3) have been recently found to account for most cases.

**Aim:** The aim of the study is to present clinical phenotype of AD HIES.

**Materials and methods:** A group of 22 HIES pts were genetically analyzed. The mutations in STAT3 were confirmed in 7 AD HIES pts, presented here. Recurrent and severe pulmonary infections were found in all pts except one (pt 7) at various time intervals. The typical complications of pneumomas were the formation of pulmonary cysts and abscesses. Long term complications included pneumatocele and bronchopleural fistulae. In several cases lobectomy was performed. The structural abnormalities were then sites of fungal and Gram (-) infection.

**Results:**

*Age at diagnosis (yr). P: pneumonia; LA: lung abscess; L: lobeectomy; PC: pneumatocele.

**Conclusions:** 1. Early recognition of the HIES enables to introduce the right kind of therapy. 2. Pneumomas should be treated aggressively to try to prevent parenchymal damage. 3. If pneumatocele and bronchiectasis are present, antimicrobial prophylaxis covering Gram (+) bacteria and fungi is needed.

**P3601**

Is quantitative HRCT related to diagnostic yield of fiberoptic bronchoscopy in sarcoidosis?

Branislav Gvozdenovic1, Violeta Vucinic-Mihailovic2, Jelena Marinkovic3.

**Aim:** To evaluate the diagnostic yield of fiberoptic bronchoscopy (FOB) modalities and its relation with quantitative findings with high resolution computerized tomography (HRCT).

**Materials and methods:** Sixty patients that consists of 19 males and 41 females with the mean age of 43 diagnosed with sarcoidosis with complete records of HRCT were retrospectively recruited for a time period of Feb 2000 to Jan 2010. HRCT scans were retrospectively assessed in random order by an experienced observer without knowledge of the bronchoscopy result or lung function tests. The diagnostic yield of transbronchial biopsy (TBB) was 43.6. Although it did not reach statistical significance, the lobar HRCT score in the sampled lobe was associated with a positive TBB result. Bronchial mucosa appearance was significantly related with positive mucosal biopsy (MB). The diagnostic yield of MB was 45.4. In general patient population however in patients with abnormal mucosa this rate was increased up to 70%.

**Results:** The diagnostic yield of fiberoptic bronchoscopic (FOB) modalities and its relation with quantitative findings with high resolution computerized tomography (HRCT). 64 patients that consists of 19 males and 45 females with the mean age of 43 diagnosed with sarcoidosis with complete records of HRCT were retrospectively recruited for a time period of Feb 2000 to Jan 2010. HRCT scans were retrospectively assessed in random order by an experienced observer without knowledge of the bronchoscopy result or lung function tests. The diagnostic yield of transbronchial biopsy (TBB) was 43.6. Although it did not reach statistical significance, the lobar HRCT score in the sampled lobe was associated with a positive TBB result. Bronchial mucosa appearance was significantly related with positive mucosal biopsy (MB). The diagnostic yield of MB was 45.4. In general patient population however in patients with abnormal mucosa this rate was increased up to 70%.

**Conclusions:** 1. Early recognition of the HIES enables to introduce the right kind of therapy. 2. Pneumomas should be treated aggressively to try to prevent parenchymal damage. 3. If pneumatocele and bronchiectasis are present, antimicrobial prophylaxis covering Gram (+) bacteria and fungi is needed.

If pneumatocele and bronchiectasis are present, antimicrobial prophylaxis covering Gram (+) bacteria and fungi is needed.
Fatigue is recognized as one of the most prominent symptoms in sarcoidosis patients. In the cross-sectional study in 189 biopsy proven sarcoidosis patients (138 female) with average disease duration of 14.6 years, we evaluated the relationship between the fatigue severity and their health status and pulmonary function tests. Fatigue was measured by standardized Fatigue Scale, which contains 14 items, with four response options (the higher the score, the more severe fatigue). Scale distinguishes between fatigue, physical fatigue, and it is also possible to calculate a total fatigue score. Two health status questionnaires were administered: respiratory specific – the St Georges Respiratory Questionnaire (SGRQ) and generic – the 15D Total SGRQ and 15D scores, as well as the scores for individual domains of SGRQ, were calculated for each patient. The pulmonary function was determined by means of spirometry and body-plethysmography.

Introduction: Sarcoidosis is a systemic granulomatous disease with predominant manifestation in the lungs, however other organs can be involved, including heart, what is potentially life-threatening. The aim of this study was to evaluate the incidence of cardiac involvement in sarcoidosis patients diagnosed or followed up in 1st and 3rd Lung Diseases Departments of National TB & Lung Diseases Research Institute in Warsaw.

Method: Retrospective analysis of database discharged patients with the final diagnosis of sarcoidosis (D86). The analysis covered the period from January 2008 to October 2010. Diagnosis of cardiac sarcoidosis was verified according to Modified Guidelines for Diagnosis of Cardiac Sarcoidosis based on the Study Report on Diffuse Pulmonary Diseases: From the Japan Ministry of Health and Welfare, 1992 and 1993 modifications 2006.

Results: 933 sarcoidosis patients were seen in two departments in the almost 3 years period. Multorgan sarcoidosis (D86.8) was detected in 102 cases (10.9%). The cardiac involvement was found only in 30 patients of this group, which was 3.2% of the entire group. There were 19 males (63%) and 11 females (37%), 5 cases in stage I, 25 in stage II. The mean age was 45.5 ± 12.6 years (range: 28-74). The time from the first diagnosis of sarcoidosis to detection of heart involvement was 10 months (median, CI 90% range 0 to 6.4 years).

Conclusion: Cardiac sarcoidosis in our own material was diagnosed in the similar percentage as in previously published data. According to post mortem diagnosis data from literature diagnosis of this form of the disease still remains a significant clinical problem.

Primary thoracic amyloidosis: Rare disease and hard diagnosis

Manel Loubal 1,2, Nawel Chaouch 1,2, Nawel Ben Salem 1,2, Mourad Zarrouk 1,2, Sana Chkhibou 1,2, Imane Bania 1,2, Ayda Ayadi 1,2, Abdellatif Chabbi 1,2,3

1Pneumology Department, A. Mami Hospital, Ariana, Tunisia; 2Research Unit IRC MSP-MERS, El Manar University, Tunis Medical School, Tunisia, Tunisia; 3Anatomopathology Department, A. Mami Hospital, Ariana, Tunisia

Amyloidosis is a disease caused by extracellular deposition of complex protein-polysaccharide in a β-pleated configuration within soft tissues. Primary thoracic deposition of amyloid is scars. To explore the different thoracic manifestations of primary thoracic amyloidosis (PTA) and its diagnosis difficulty, we retrospectively analyzed cases of PTA hospitalized in our department between 2007 to 2009. PTA (AL-type) diagnosis was confirmed by pathological study in all cases. All patients were investigated by chest x ray, fiberbroncoscopy and chest and abdominal CT scan.

Our study concerned 5, 63 years mean aged (34-77) men. PTA discovery was secondary to respiratory symptoms in 4 cases and fortuitous in 1 case. Amyloidosis was systemic in 1 case and localized to the thorax in 4 cases: 1 involved pleura, 2 involved mediastinal lymph nodes, 2 the bronchial tree and 2 the lung parenchyma. An association of 2 different thoracic localization was noted in 2 patients. The average time of diagnosis was 4 months, based on open lung biopsy in 2 cases, mediastinal lymph node biopsy in 2 cases and transbronchic lung biopsy in 1 case. Respiratory lung function was normal in 3 patients. Amyloidosis was complicated by chronic respiratory failure in 1 patient and severe obstructive disease in 1 patient. Treatment consisted in colchicin with a stable trend (1 case), systemic corticosteroids with clinical deterioration (2 cases), lung resection (2 cases). One patient disappeared during follow up. PTA diagnosis is often delayed. This is due in part to the localized features of amyloidosis, non specific symptoms and frequent misdiagnosis.
and the patient underwent urgent coronary angiography, which revealed entirely normal coronary arteries but an abnormal left ventriculography. There was marked LV apical hypokinesis and ballooning. Cardiac MRI supported the suspicion of Takotsubo’s cardiomyopathy.

**Discussion:** Takotsubo’s cardiomyopathy is a cause of cardiac chest pain and troponin release, accounting for up to 2% of ST-elevation myocardial infarction (MI). The important measure of the burden of related morbidity and mortality is the occurrence of ADRs. Preventive measures should be taken to minimize the occurrence of ADRs.

**Conclusions:** Our study shows that ADRs are an important cause of morbidity in our hospital. Disease prevalence and drug use patterns in our hospital differ markedly from those of generally recognized ones. These differences affect the frequency and nature of ADRs. Preventive measures should be taken to minimize the occurrence of ADRs.

**P3607**

**Multiple pulmonary nodules in a patient with polyarteritis nodosa**

Genevieve Chailous, Isabelle Cutteix, Claude Portier. Pulmonology, Centre Hospitalier Université de Montreal, Montreal, QC, Canada

We are reporting the case of a 58-year-old woman, investigated for a 6 weeks history of abdominal pain, nausea, shortness of breath and weight loss of 25 pounds. Her medical history was otherwise insignificant. Upon presentation, the woman was febrile at 38.5 C, had tachycardia, low blood pressure despite aggressive volume repletion, leukocytosis and acute renal failure. A CT scan of the thorax and abdomen showed multiple nodules within the thyroid gland, the lungs, liver and kidney parenchyma. The patient was put on broad-spectrum antibiotics and anti-fungal medication. BAL (bronchoscopy) and all cultures remained negative. A screen for vasculitis and virus were negative. A liver biopsy showed areas of necrosis due to ischemic insults. Later, the patient developed gastrointestinal bleeding. An angiographic embolization meant to be curative turned out to be diagnostic. We discovered many small aneurysms affecting the mesenteric, hepatic, gastroipiplic and the bleeding site from an ileal branch was successfully embolized. A vasculitic origin (PAN) to the patient’s symptoms was underlined by a positive ANA test, high levels of IL-6, elevated creatinine; characteristic angiographic abnormalities. The patient rapidly recovered with IV steroids and cyclophosphamide.

Polyarteritis nodosa is known to affect multiple organs, but the lung. Very few cases of polyarteritis nodosa involving the lung have been reported. Necropsy reports also described pulmonary fibrosis. Cases of acute interstitial pneumonia, BOOP and alveolar hemorrhage have been described. To our knowledge, it would be the first case of micromodular lung involvement in association to PAN. This case raises awareness to a possible pulmonary involvement in PAN.

**P3608**

**Sarcoidosis patient: Do we need to perform plethysmography when spirometry and DLCO were done?**

Piotr Boros1, Magdalena Murawsicz-Boros2, Philip Quanger1, Paul Erricht1, Stefan Wesolewski1, 1 Lung Function Lab, National TB & Lung Diseases Research Institute, Warsaw, Poland; 2Department of Pulmonary Diseases, Erasmus Medical Centre, Erasmus University, Rotterdam, Netherlands; 3College of Public Health, University of Arizona, Tucson, AZ, United States

**Introduction:** Plethysmographic measurement of total lung capacity (TLCple) is the gold standard for measuring lung volumes. Gas dilution methods are considered less accurate in patients with substantial airway obstruction and take more time. TLCple is usually done in patients suspected of having an interstitial lung disease (ILD) and the test includes measurement of alveolar volume (VA).

**Aim of study:** To compare TLCple with TLCVA in a large group of sarcoidosis patients in different stages of the disease.

**Methods:** Data from 830 consecutive sarcoidosis patients (223 in stage I, 486 in stage II, and 121 in stage III). All tests met 2005 ATS/ERS FTT technique and quality guidelines. TLCple was calculated as the sum of VA and dead space.

**Results:** TLCple was larger than TLCVA by a mean of 0.18 L (95%CI: 0.15; 0.20) and 2.8% (95%CI: 2.3; 3.3). TLCple was normal (above the 5th percentile) in 772 patients (93%) by TLCple, and in 762 cases (92%) by TLCVA. Sensitivity of the TLCple for a low TLCple was 83% and specificity 97%, so NPV was 99% and PPV 71%. The AUC by ROC analysis was 0.90. Airway obstruction was present in only 12% of the patients, but their TLCple was significantly lower than their TLCVA when compared to those without airway obstruction (0.39 L ± 0.39 vs. 0.15 L ± 0.39). In this subgroup, the sensitivity of TLCVA was only 50% and specificity 96%, so NPV was 96% but PPV only 33%. The differences of TLCple and TLCVA were correlated with FEV1/FVC ratio.

**Conclusions:** A normal TLCple rules out a low TLCVA with a high degree of certainty in patients with sarcoidosis, but a low TLCple does not confirm a low TLCple in patients with airway obstruction.

**P3609**

**Adverse drug reactions in a pulmonary teaching hospital: Incidence, pattern, seriousness, and preventability**

Shadi Bamasali1, Fanak Fakhr1,3, Masoome Karimi1. 1Pharmaceutical Care Department, Virology Research Center, National Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 2Clinical Pharmacy Department, School of Pharmacy, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 3Pharmaceutical Care Department, Chronic Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran

**Introduction:** Detection of adverse drug reactions (ADRs) in hospitals provides important measure of drug related morbidity in the healthcare system. Studies have shown that between 1.7% and 25.1% of hospital inpatients experience an ADR during their hospitalization.

**Aim of study:** This aimed study focused on incidence, pattern, seriousness, and preventability of hospital-acquired ADRs, in medical wards of a pulmonary teaching hospital in Iran.

**Methods:** Clinical pharmacist residents were trained to report all suspected ADRs through ADR-reporting yellow forms. The incidence, pattern, seriousness, and preventability of the reported ADRs were analysed.

**Results:** During the period of 24 months, for 16125 patients, 312 ADR reports were reported. The most frequently reported reactions were due to anti- infective agents (26.54%). Ceftriaxone accounted for the highest number of the reported ADRs among anti-infective agents. The gastro-intestinal system was the most frequently affected system (21.78% of all reactions). Eighteen percent of the ADRs were reported as serious reactions. Fifty of the ADRs were classified as preventable.

**Conclusions:** Our study shows that ADRs are an important cause of morbidity in our hospital. Disease prevalence and drug use patterns in our hospital differ markedly from those of generally recognized ones. These differences affect the frequency and nature of ADRs. Preventive measures should be taken to minimize the occurrence of ADRs.

**P3610**

**Importance of cardiac biomarkers in the evaluation of acute pulmonary thromboembolism severity, mortality and complicated clinical course**

Gulseren Sagcan1, OryhArseven1, Gulfer Okumus1, Remisa Gelisgen2, Hatice Urum3. 1CHEST, Istanbul Medical Faculty, Istanbul, Turkey; 2Biochemistry, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

**Background:** Severity of pulmonary thromboembolism (PTE) is related to the determination of early mortality risk rather than distribution and the load of trombus. To determine the risk evaluation biomarkers level have important roles than echocardiography, alternatively.

**Aim:** Investigation of the usefulness of biomarkers in the determination of 3 months complicated clinical course (CCC) and mortality, and also acute PTE risk level.

**Material and methods:** Demographic characteristics, history, clinical findings, risk factors, additional diseases, hemodynamic symptoms of 47 patients (22M, 25F) with objectively documented diagnosis of PTE, were recorded. Before PTE treatment, serum and plasma samples were kept to measure the levels of D-Dimer, cTnT, cTnI, NT-ProBNP, HAPFR and GDF-15. Patients were followed for 3 months for complication and mortality.

**Results:** NT-proBNP levels were similar in submassive and nonsmassive groups but they were significantly higher in massive group when compared to nonmassive group (p=0.031). Mortality was present in 9 patients. When all the deaths caused are predicted by D-Dimer, HAPFR, NT-ProBNP and GDF-15, deaths caused by PTE were only predicted by D-Dimer, HAPFR and GDF-15 levels. NT-proBNP and GDF-15 valuables were predicted the complications (p< 0.05).

**Conclusions:** This biomarkers used in this study had no significant role in the differentiation of nonmassive and submassive groups. However, NT-proBNP and GDF-15 have been shown that these biomarkers would be beneficial for mortality and CCC, in prediction of 3 months.

**P3611**

**Is utility of D-Dimer test undermined because of overuse in routine clinical practice?**

Gautam Marwah, Helen Taylor, Selva Selvaraj, Stephen Murphy. Medicine, University Hospital of Hartlepool, Hartlepool, United Kingdom

**Introduction:** In suspected VTE a low pre-test probability and negative D-Dimer is associated with risk of VTE < 2%. However d-dimer is raised in many conditions and utilities and depends on VTE prevalence in population tested (9.5-19% in validation studies). Purpose of study was to assess utility of d-dimer testing in routine practise.

**Methods:** Case records of patients d-dimer tested in A&E or on admission to hospital were reviewed. Data included: clinical features, admission diagnosis and pre-test probability if recorded. Investigators estimated VTE-risk, calculated post-test probability of VTE and impact on imaging

**Results:** 96 cases included; 52 female, mean (SD) age 61yrs. Symptoms: chest pain 44.5%; leg pain/swelling 28%; dyspnea 17%, syncope 7.5%, other 3%. Admission diagnosis: VTE likely 10%, VTE possible 57%, other diagnosis 33%. Pre-test probability done in 23. Investigator pre-test VTE-risk: High (H) 9%, Moderate (M) 20%, Low (L) 33%. Very Low (V) 38%. D-Dimer positive 43% (H 100%, M 64%, L 44%, V 41%; p<0.05). VTE-Imaging if d-dimer +ve (VTE-risk M, L, V) 41% in 11.3% OR 5.1 (9.15) p=0.001. Prevalence of VTE was 2.3% (sensitivity 1.0, specificity 0.58; negative likelihood ratio 0.0-1.1).
Pre and post-test probability of VTE if negative d-dimer: VTE-risk M-H pre-8%, post-<1%; VTE-risk V-L pre-<2%, post-<1%.

Conclusion: Prevalence of VTE in patients D-dimer tested in clinical practice is much lower than in validation studies. Both high risk and very low risk patients with alternative diagnoses are often tested. If VTE risk is very low a negative d-dimer test makes little difference to post-test probability of VTE but positive tests lead to unnecessary imaging.

Aims: To assess compliance and safety of our hospital pathway for out-patient management of suspected PE.

Methods: We studied a prospective cohort of patients with suspected PE managed as outpatients using LMWH from the day of presentation until either the diagnosis of PE was excluded or confirmed. We analysed patients referred to ambulatory care clinic with suspected PE from June 2009 till June 2010. 42 patients met the inclusion criteria. All patients were reviewed in clinic after a V/Q scan or CTPA.

Conclusion: It’s probably safe to investigate and treat suspected PE as outpatient in selected clinically stable patients. Larger multi-centre randomised controlled trials are needed to confirm this finding.

P3615

Lung function tests in patients suffering from chronic kidney insufficiency before and after hemodialysis.

Momira Obređović1, Liljana Korkić2, 1Pulmology, Hospital of Internal Medicine, Mladenovec, Serbia; 2Pulmology, Clinical Hospital Centre, Dr D. Misovic, Belgrade, Serbia

Most frequently encountered alteration of lung function in patients on hemodialysis is existence of restricted ventilation and consequently insufficiency caused by hypervolemia. Various studies examined changes in lung micro circulation that follow hemodialysis and it is argued that they may cause lung fibrosis and even calcification of alveolar septa. The objective of this study is a comparison of the relative results of pulmonary function tests before and after hemodialysis treatment.

Using Chest-microspirom HI 601 apparatus, we have monitored 35 patients whose average age was 57 years. The diagnostic tools consisted of chest roentgenograms, laboratory tests, clinical examinations and pulmonary function tests (FVC, FEV1 and PEF). Our results indicate a statistically significant increase in FVC (p < 0.05) and FEV1 (p < 0.05) before and after hemodialysis.

Conclusion: Patients receiving hemodialysis treatment have prominent fluid re-tenion in lung spaces. In this situations spirometry performed before and after hemodialysis can be used as a valid diagnostic approach in determining patient conditions.

P3616

Effect of bicarbonate versus acetate hemodialysis on respiratory functions in chronic renal failure patients.

Mohamed Badawy1, Ali Taha2, Nagah Mohamed3, 1Chest Department, Sohag University, Sohag Faculty of Medicine, Sohag, Luxor, Egypt; 2Neurology Department, Sohag University, Sohag Faculty of Medicine, Sohag, Egypt; 3Public Health Medicine, Sohag University, Sohag Faculty of Medicine, Sohag, Egypt

Dialyzer filter can cause activation of complement and release of anaphylatoxines which can have a deteriorating effect on respiratory system.

Aim of the work: To compare the effect of bicarbonate versus acetate haemodialysis on the pulmonary function test and blood gas parameters.

Material and methods: Cross sectional study of fifty chronic renal failure patients on regular haemodialysis without history of chronic pulmonary disease were randomly selected for dialysis either by bicarbonate or acetate dialysate twenty five each with same machine and duration of dialysis. Evaluation thorough medical history and determination of forced expiratory volume in the first second (FEV1), forced vital capacity (FVC), FEV1/FVC ratio, and maximal mid-expiratory flow rate (I50% 25%-75%). Arterial oxygen tension (PaO2), PH, carbon dioxide tensions (PaCO2), bicarbonate (HCO3) and potassium were analyzed with a blood gas analyzer.

Results: No significant difference in symptoms before and after dialysis in both groups. Improvement of pulmonary function test was significant in bicarbonate
Results: Among the studied patients, 55% had pulmonary complications in the ESRD maintained on regular hemodialysis. Spirometric measures, before and after arterial blood gases, radiological study of chest and heart and spirometric study are important causes of morbidity and mortality in patients with ESRD and infection is the second leading cause of death among them.

Aim: To study pleuro-pulmonary changes and complications among patients with ESRD maintained on regular hemodialysis.

Patients and methods: The current study included 20 patients with ESRD on regular hemodialysis for at least 6 months. For every patient, clinical, laboratory, arterial blood gases, radiological study of chest and heart and spirometric study were done.

Results: Among the studied patients, 55% had pulmonary complications in the form of pulmonary infections, pleural effusion, pulmonary edema or hypoxemia during the course of hemodialysis. Spirometric measures, before and after hemodialysis, showed no significant improvement of VC, FVC, FEV1/FVC, MMV wherewith improvement in FEF25-75% and PEFR was significant. Significant hypoxemia occurred during hemodialysis. Significant improvement in pHa, pCO2 and HCO3 occurred during and after hemodialysis.

Conclusion: Patients with ESRD treated with hemodialysis must be considered at high risk for the development of lethal pulmonary complications. Regular hemodialysis improves arterial blood gases parameters and some pulmonary function measurements.

P3618 Morphological features of the endobronchial microcirculation of nephropathic patients
Shcherban Natalia1, Landyshev Yuriy2, Tsheluyko Sergey3, 1Pulmonology, Saint-Petersburg State Pavlov Medical University, Saint-Petersburg, Russian Federation; 2Russian Academy of Medical Science, Blagoveschensk, Russian Federation; 3Histology, Amur State Medical Academy, Blagoveschensk, Russian Federation

Pneumofibrosis is one of the respiratory aftereffects developing at late stages of chronic kidney disease (CKD). The research was aimed at revealing the microhemocirculatory disturbances role in the course of bronchopulmonary aftereffects development for CKD patients.

Methods: The endobronchial biopsy was applied to 48 CKD patients at the point of 1cm distally aside from the right lung’s proximal bronchus spur. The ultrathin sections were analyzed, using the Tecnai G2 Spirit TWIN electron microscope (of the “FEI Company” - Netherlands) after its preliminary staining by the uranyl acetate and the lead citrate.

Results: The normal plan of bronchi mucosa structure is revealed in 16.6% of cases, mainly at CKD initial stages. 25.4% of CKD 2nd and 3rd stage patients had epithelium initial planocellular metaplasia, sometimes with the bronchi submucosa connective tissue edema. In 50% of the cases dystrophy and epithelium metaplasia combined with the microcirculatory bed reduction. At the later stages of the disease the number of the elastic fibers increased which surrounded the spasmatic blood capillaries and dilated veins. 19.4% of the patients at the fifth CKD stage showed atrophy of the epithelium against the expressed submucosa sclerotic changes. Here one could observe distinct damages of endothelial cells containing numerous vacuoles in the cytoplasm, sometimes they protruded into the vessel lumen.

The conclusion: Due to various factors the CKD leads to the structural reorganization of the microhemocirculatory bed which then causes the fabric hypoxia, atrophy of the bronchus mucosa and occurrence of the expressed sclerotic processes in the submucosal layer of the bronchial tree.

P3619 Bronchiolitis obliterans as a first manifestation of rheumatoid arthritis - Case report
Simona Luca, Ali Zakia. Chest Department, Faculty of Medicine, Minoufiya University, Shebin El Kom, Minoufiya Governorate, Egypt

Introduction: Rheumatoid arthritis (RA) is the most common connective tissue disease associated with bronchiolitis obliterans (OB). OB is a clinico-pathologic entity of bronchiolar inflammation which reflects the injury of the small airways and presents symptoms and signs of small airways obstruction. OB can go as a first manifestation of RA in 10–20% of patients. Case presentation: A 37-year-old woman, non-smoker presented to our clinic accusing: MRC III dyspnea and bronchorexia and suddenly it developed an obstructive lung disease without any reasonable explanation. Clinical, physiological and radiologic features suggested OB (squeaks and crickles on auscultation, functional evidence of OB). HRCT scan features consisted mostly of indirect signs of bronchiolitis, with a mosaic pattern reflecting air trapping, bronchial wall thickening, centrilobular emphysema, areas of ground-glass attenuation. She also had extra-respiratory symptoms-asthma and weight loss (5 percent in 2 months). 3 months after, she developed seropositive RA and a elevate serum rheumatoid factor was found, but with no clinical evidence of active rheumatoid disease. All of these findings suggests that the OB was secondary to a rheumatoid process. Oral corticosteroids, associated with immunosuppressive treatment and inhaled bronchodilators was initiated, but without any clinical and functional improvement.

Conclusions: This case is atypical since usually the diagnosis of RA precedes respiratory symptoms in 88% of cases. In our patient the bronchiolitis obliterans was the initial manifestation of rheumatoid arthritis, attributable to rheumatoid arthritis.

396. What do individuals know about their disease? Educational needs, the psychological impact of chronic respiratory disease and health-related quality of life

P3620 Late-breaking abstract: Older COPD patients’ requirements for eMonitoring and eCoaching: A user-centered study
Jose de Lintelo1, Mari van de Dijck2, Dienst Behandeling en Begeleiding/Home Care, Division for Treatment and Support, Carint Reggeland Group, Hengelo, Netherlands; 2Expertise Centre of Health, Social Care and Technology, Saxson University of Applied Sciences, Enschede, Netherlands

Introduction: COPD patients can have increased indepdence, when adequately supported by appropriate technology, with eHealth opening new opportunities for self-management at home.

Aims: The aims were to explore the requirements of older COPD patients, for an effective eHealth home care system, and through this to promote self-management, reduce health care use and increase quality of life.

Methods: A qualitative user-centred design, combining focus groups with a scenario-based approach, was used to elicit key criteria for the home care system. Data were collected in two workshops involving patients aged 63 to 83 (n=17). Most had moderate COPD (GOLD II-III- IV); all experienced dyspnoea and restrictions in their activities of daily living.

Results: Participants have the prerequisites for a (mobile) eHealth system and in general want to use their mobile phones. Participants provided specific needs, wishes and preconditions for eHealth, in physical, cognitive/emotional and social areas; reporting daily activities and problems in which they could use the help. They underlined the importance of technology stimulating patients to maintain and extend their existing abilities.

Conclusions: The user-centred design approach enabled patients to identify for themselves, their key requirements for an eHealth system. They wanted support for self-management, to increase confidence in their own abilities and their sense of security. The integration of eMonitoring and eCoaching can support patients to maintain and improve their independence and quality of life at home. An “eCOPD” system is being designed based on the outcomes from this study.

P3621 Assessing the educational component of pulmonary rehabilitation with the lung information needs questionnaire (LINQ)
Ria Fowler, Karen Ingram, Claire Nolan, Pipas Marns, Amy Clark, Michael Polkey, William Man. Harefield Pulmonary Rehabilitation Team and Respiratory Biomedical Research Unit, Royal Brompton & Harefield NHS Foundation Trust, Harefield, Middlesex, United Kingdom

Introduction: Educational sessions are an integral part of pulmonary rehabilitation (PR) programs but there are few tools to assess their impact. The Lung Information Needs Questionnaire (LINQ) is a patient reported and designed to assess the information needed to understand lung diseases and to maximise self-management skills (Hyland et al 2006). A decreased score indicates less information requirements. We hypothesised that the LINQ is sensitive to change after a PR program and provides additional information to tests of exercise capacity and health status.

Method: We prospectively measured the LINQ, the self-report Chronic Respiratory Disease Questionnaire (CRDQ-SR), Hospital Anxiety & Depression score (HAD) and incremental shuttle walk (ISW) in 217 patients before and after an 8-week outpatient PR program. 11 patients, who declined the outpatient PR pro-
Conclusion: Patients with COPD entering PR have a heterogeneous level of knowledge considering COPD. Therefore, individualized educational programs should be considered to increase patients’ knowledge and, in turn, improve self-management.

P3624

Fatigue components in COPD patients and controls using the FACIT-F scale; data from ECLIPSE study

Khalel Al-Shair1, Hana Mullerova2, Nicholas Locantore3, Nicola Hanania4, Ali Sharif-Shahreh5, Emiel Wouters3, Stephen Renard6, Jorgen Vedel7, on behalf of the Evaluation of COPD Longitudinally to Identify Predictive Surrogate Endpoints (ECLIPSE) Study Investigators. 1Medicines Evaluation Unit/North West Lung Research Centre, Manchester University, South Manchester University Hospital, Manchester, United Kingdom; 2Worldwide Epidemiology, GlaxoSmithKline R&D at Stockley Park, Uxbridge, United Kingdom; 3Respiratory and Inflammation Medicines Development Centre, GlaxoSmithKline R&D at Research Triangle Park, NC, United States; 4Section of Pulmonary, Critical Care and Sleep Medicine, Baylor College of Medicine, Houston, TX, United States; 5Respiratory and Inflammation Medicines Development Centre, GlaxoSmithKline R&D at Research Triangle Park, NC, United States; 6Department of Pulmonary and Critical Medicine, Baylor College of Medicine, Houston, TX, United States; 7Respiratory and Inflammation Medicines Development Centre, GlaxoSmithKline R&D at Research Triangle Park, NC, United States.

Background: Fatigue is a complex multi-dimensional phenomenon and its dimensionality in COPD and controls has not been adequately investigated. We aimed to examine the dimensions as well as the reliability and validity of the FACIT-F scale.

Methods: At baseline, 2107 COPD patients and 576 control subjects with normal lung function from the Evaluation of COPD Longitudinally to Identify Predictive Surrogate Endpoints (ECLIPSE; SCON010406, NCT00292552) completed the Functional Assessment of Chronic Illness Therapy (FACIT) fatigue scale. The FACIT-F was readministered to 1621 patients and 515 controls after 3 years. We used the principal components analysis (PCA) for structurally examining the 13 items FACIT-F.

Results: The 13 items were loaded into two and three interpretable dimensions in COPD and controls, respectively. In COPD, FACIT had high internal consistency (Cronbach’s α = 0.92) and long-term reproducibility (r = 0.68, p < 0.001). In the two-factor solution, the two components of fatigue in COPD correlated well with the total score of the scale (r = 0.59 and 0.99, p < 0.001 for both). FACIT had significant convergent validity when associated with BODE, SGRQ and MRC dyspnoea scores (r = 0.42, 0.7 and 0.48, respectively, p < 0.001 for all). FACIT had good discriminating validity; patients who walked <350m in 6 minute walk test as well as depressed patients were significantly more fatigued than those who walked ≥350m or who were not depressed (p < 0.001).

Conclusion: The FACIT-F is a short and easily administered scale with good validity and reliability in COPD. It may be possible to measure different fatigue components with this scale.

P3625

Long-term changes in the COPD assessment test (CAT) after pulmonary rehabilitation

Phillippa Mauns, Karen Ingram, Ria Fowler, Claire Nolan, Amy Clark, Nicholas Hopkinson, Michael Polkey, Jane Canavan, William Man. Harfey Pulmonary Rehabilitation Team and Respiratory Biomedical Research Unit, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom

Introduction: The COPD assessment test (CAT) is a recently introduced, validated, patient-completed quality of life instrument that is immediately responsive to pulmonary rehabilitation (PR) [1]. The long-term effects of PR on the CAT, and whether these changes relate to more established health status instruments, are not known. We hypothesised that long-term improvements in CAT (reduced score) following PR would correlate with improvements in the self-report Chronic Respiratory Disease Questionnaire (CRDQ-SR) total score (increased score).

Method: The CAT and CRDQ-SR were recorded in 39 COPD patients before (T1), immediately after (T2) and 6-months after (T3) an 8 week outpatient PR program. On completion of the PR course, patients were offered individualised exercise advice and goal-setting, but no formal supervised exercise training. Changes in

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
CAT and CRDQ-SR were compared from T1 to T2 and from T1 to T3. Spearman's
rank correlation was used to assess the relationship between changes in CAT
and CRDQ-SR between T1 and T2 and T1 and T3.
Results: Mean (SD) age was 72 (7) and FEV1% predicted was 47 (19%). CAT
and CRDQ-SR scores at T2 and T3 were significantly improved compared to
corresponding scores at T1.
T1-T3 changes in CAT correlated significantly with changes in CRDQ-SR: r =
-0.40; p<0.01.
Conclusion: Following PR, short and long-term changes in CAT score mirror the
CRDQ-SR score.

P3626
CAT (COPD assessment test) as outcome parameter of pulmonary
rehabilitation and in COPD
Konrad Schultze1, Oliver Gohl1, Dragan Stojanovic1, Michael Wittmann1,
Juliane Rudnik1, Monika Schwarze2, 3. 1 Bereich Pneumologie, Klinik Bad
Reichenhall, Bad Reichenhall, Germany; 2Klinik für Rehabilitationsmedizin,
Medizinische Hochschule Hannover, Hannover, Germany
Background: The COPD Assessment Test (CAT) is a newly developed question-
naire for COPD-patients. The CAT is designed to measure the impact of COPD
on a patient’s life, and how this changes over the time. The test contains 8 items.
Methods: In a prospective observational study 124 patients with COPD were
included, 71.6% male, 42.5% with GOLD Stage 1-2, 26.6% with stage 3, 28.2%
with stage 4. Mean FEV1 was 1.661. Outcome parameters were 6-MWD, FEV1,
MRC-dyspnoea scale and in addition the CAT was used for the first time in
Germany as an outcome parameter in PR.
Results: Mean CAT score at admission (T0) was 21.97±6.49 and at discharge
from PR (T1) 18.94±6.56 (p<0.0001); CAT scores from 20-30 indicate a high
impact of COPD on patient’s life, as shown at admission. At discharge the average
CAT score was reduced out a medium impact, as a defined range from 10-20 points.
The minimal clinically important difference (MCID) for CAT is supposed to be
a change of 2 points. In 56.6% of the patients the CAT score decreased for at
least 4 points and therefore MCID was achieved. The average improvement was
a reduction of 3.03 points. Improvement occurred in all items of the CAT, but
the item with the highest impact was breathlessness on effort.
Conclusions: In this prospective observational study all COPD-patients were
included, regardless of comorbidity or exacerbations. In spite of these circumstances
there was a statistically significant and clinically relevant improvement. More than
50% of the patients improved the CAT score for at least 2 points (MCID). The test
was successful with our patients without relevant problems and so, since July 2010,
the CAT is used as a routine outcome parameter in our PR program.
P3627
Changes in the CRQ, CAT and updated BODE index by pulmonary
rehabilitation
Armin Stucki, Yvonne Van der Feijst. Pneumology, Berner Reha Zentrum,
H'Schwindi, Switzerland Pneumology, Berner Reha Zentrum, H'Schwindi,
Switzerland
Background: It is unclear to which extent a standardised in-hospital rehabilitation
program may change the new COPD assessment test (CAT) score and the updated
BODE index in very severe COPD patients.
Method: In a prospective study we assessed the CRQ, CAT and updated BODE
scores in severe and very-severe COPD patients before and after attending a
multidisciplinary in-hospital rehabilitation program of a approximately 3
week’s duration. The assessment comprised in addition sociodemographic and
health data. According to the initial BODE Index and due to statistical reasons we formed two
BODE severity groups; group one with 0-7 points and group two with 8-15 points.
Results: 315 patients attending a pulmonary rehabilitation program were assessed
between first of July and end of December 2010. Thereof 132 patients presented
with severe or very-severe COPD. The mean age was 69.2 years, exactly one
third female, mean duration of stay 19.9 days.
I. Both groups showed a significant improvement for all four CRQ domains. Only
for the domain dyspnea the improvement was significant smaller for patients with
a higher BODE score (second group).
II. The CAT score showed a similar significant improvement in both groups
(reduction of 4.5 and 5 points respectively)
III. Also the updated BODE Index showed a significant reduction in both groups,
however, this reduction was significant less for the second group.
Conclusion: The CAT and the updated BODE Index might both provide a valid
assessment for changes in an inpatient pulmonary rehabilitation program for severe
and very-severe COPD patients.
P3628
Determinants of health-related quality of life in patients with severe COPD
Frits M.E. Fransen1, Paul W. Jones2, Martin D. Spruit1, Mariska Hartog3,4,
Emiel FM. Wouters1,2,3, 1Department of Respiratory Medicine, Maastricht University, Maastricht,
Netherlands; 2Program Development Centre, Ciro, Centre of Expertise for
Chronic Organ Failure, Rotterdam, Netherlands; 3Department of Respiratory
Medicine, Maastricht University Medical Centre, Maastricht, Netherlands
Introduction: Clinical presentation of COPD patients is very heterogeneous. Pa-
tients with a comparable degree of airflow limitation present with a wide range
in health-related quality of life (HRQOL). This study investigates determinants of
HRQOL in severe COPD patients.
Methods: Assessment data were extracted from the records of 1562 COPD pa-
tients referred for pulmonary rehabilitation. HRQOL was assessed by St. George’s
Respiratory Questionnaire (SGRQ). Data were divided into quadrants of FEV1
and total SGRQ score.
Results: Compared to patients with FEV1<50% and SGRQ<50, those with
SGRQ≥50 are characterized by lower BMI, better exercise performance, fewer
exacerbations in last year, lower depression (HADS-D) and anxiety (HADS-A)
scores and less dyspnea (MRC). In stepwise multiple regression analysis, MRC,
HADS_A and HADS_D. 6MWD and number of exacerbations in last year were
independent predictors for HRQOL.
Discussion: Clinical, physiological and psychological factors determine HRQOL
in severe COPD. These factors must be taken into account in the disease manage-
ment of these patients.
P3629
Evaluation of quality of life instruments for COPD care and research
Saskia Weldens1, Marijke Schuurmans2, Rani Liu1, Jan-Willem Lammermans1.
1Department of Respiratory Medicine, University Medical Center Utrecht,
Utrecht, Netherlands; 2Department of Rehabilitation, Nursing Science & Sports,
University Medical Center Utrecht, Utrecht, Netherlands
Background: Quality of Life (QOL) measurements to quantify the impact in
Chronic Obstructive Pulmonary Disease (COPD) with a standardized method has
become important in the last decades. A variety of QOL instruments are available.
To facilitate decision making with regard to an appropriate QOL instrument in
COPD care and research, a systematic review was performed.
Objective: To identify and evaluate content and psychometric properties of cur-
cently available QOL instruments in COPD care and research.
Method: A systematic literature search was done. Based on criteria, 2 investiga-
tors independently identified eligible studies. Methodological quality and data on
psychometric properties were assessed by using the Consensus based Standards
for selection of health status Measurement Instruments (Mohrnik et al. J Clin
Results: 56 Studies, 11 disease-specific and 10 generic QOL instruments are identi-
fied. Methodological studies’ quality is mostly rated fair. In 50 studies theoretically
derived hypotheses are not described. In 34 studies confirmatory factor analysis
was not performed. Measurement properties are in general positive. Chronic Res-
piratory Questionnaire has slightly better results than generic measures: hypothesis
testing correlation r=0.5, Chronbach’s α=0.7, Intra Class Correlation (ICC) 0.5-0.9
The new COPD assessment test α=0.88, ICC= 0.8. Disease-specific instruments
hold domains like dyspnea and activity. Social activity, emotional status, anxiety
and pain are mostly included in generic instruments.
Conclusion: Since both disease-specific and generic domains are important in
measurement of QOL in COPD patients, we recommend to use at least two QOL
instruments covering as many domains as possible.
P3630
Coping style and health status in COPD patients entering pulmonary
rehabilitation
Ana Stokinova1, Daisy J.A. Janssen2, Martijn A. Spruit3, Emiel F.M. Wouters1,2,3,
1Department of Respiratory Medicine, Maastricht University, Maastricht,
Netherlands; 2Program Development Centre, Ciro, Centre of Expertise for
Chronic Organ Failure, Rotterdam, Netherlands; 3Department of Respiratory
Medicine, Maastricht University Medical Centre, Maastricht, Netherlands
Background: Mood status contributes to an impaired health status in patients
with COPD. Coping style may also be related to health status. Our objective was to assess disease-specific health status in COPD patients entering pulmonary rehabilitation after stratification for coping style and mood status.

Methods: Coping styles were studied in 698 COPD patients entering PR (60% men; mean (SD) age: 64 (10) yrs; FEV1: 48 (18% pred.) using the Urutch Coping List. The current analysis is limited to passive coping style. Disease-specific health status (St. George’s Respiratory Questionnaire (SGRQ)), and symptoms of anxiety (HADS-A) and depression (HADS-D) were recorded.

Results: Mean (SD) SGRQ total score was 54 (17) pts. Clinically relevant symptoms (HADS-A > 10 pts) and depression (HADS-D > 10 pts) were reported by 30% and 23% of the patients, respectively. Low level of passive coping style was reported by 18% of the patients; medium level by 39% and high level by 43% of the patients. In patients with HADS-A or HADS-D > 10 pts. SGRQ total score was higher for patients with a high passive coping style than for patients with a low or medium level passive coping style. In patients with HADS-D > 10 pts, differences did not reach statistical significance.

Conclusions: The level of passive coping style may have a relationship with health status in COPD patients after stratification for symptoms of anxiety and/or depression.

P3631
Relationship between quality of life, exercise capacity and disease severity in patients with chronic obstructive pulmonary disease
Michelle M.C. Le Cheminant 1, Gillian Austin 2, Camilla Bastu 2, Thida Win 1.

The Chronic Obstructive Pulmonary Disease (COPD) Assessment Test (CAT) is a new, simple questionnaire designed to evaluate quality of life in COPD patients. In contrast to more complex assessment tools (such as St. George’s Respiratory Questionnaire), no studies have evaluated its relationship with other disease severity markers in COPD such as walk test.

This study investigated the relationship between CAT score and markers of disease severity in COPD, including forced expiratory volume in 1 second (FEV1), endurance shuttle walk test (ESWT) and incremental shuttle walk test (ISWT).

Fifty patients with a known diagnosis of COPD (male: female ratio 22:28, mean age 68 ± 13.3 years, mean FEV1 16.9 ± 20.3% of predicted) were evaluated using spirometry, ESWT and ISWT. Quality of life was assessed using CAT. Mean ISWT was 182 ± 124 metres and mean ESWT was 6.9 ± 6 minutes.

CAT score correlated negatively with ESWT (r = -0.40, p < 0.01) and ISWT (r = -0.30, p < 0.05). There was no significant correlation with FEV1 in this study population. However, it is very interesting that CAT score is inversely related to exercise capacity. As the disease gets more severe, quality of life worsens (higher score on CAT), but becomes less able to do things (lower ESWT/ISWT).

Although this concept is logical, it was not described previously.

Our study showed that CAT represents a useful instrument to evaluate disease impact in COPD, when interpreted alongside complementary diagnostic information. It would be really interesting to see the relationship of CAT and other parameters in COPD, when interpreted alongside complementary diagnostic information.

P3632
Quality of life evaluation in patients with alpha1-antitripsin deficiency: A 3-year prospective study
Mauro Carone 1, Gisella Bruletti 2, Enrica Bertella 2, Gianluigi Balestroni 3, Gisella Bruletti 2, Enrica Bertella 2, Gianluigi Balestroni 3, Mauro Carone 1, Gisella Bruletti 2, Enrica Bertella 2, Gianluigi Balestroni 3, Gisella Bruletti 2, Enrica Bertella 2, Gianluigi Balestroni 3.

AATD is associated to pulmonary disease, mainly COPD. In comparison to COPDs without AATD, pts with AATD and COPD present an accelerated decline of lung function in conjunction to other COPD characteristics: frequent exacerbations, disabling symptoms (dysnea and phlegm), reduction in exercise capacity and daily life activities. These pts, therefore, frequently have respiratory disability. However, their impairment appears in a relatively younger age in comparison to COPD.

Aim of the study: Our aim was to evaluate pts’ QoL in relation to the use/not use of augmentation therapy.

Material and methods: We performed a 3 year prospective study in 32 pts (mean age 54±10 yrs; M/F 19/13; FEV1 48±24% predicted). The St George’s Respiratory Questionnaire (SGRQ) and the EuroQol (EQ-5D) were administered at baseline and yearly for three years. According to their spirometric impairment, patients were stratified in Group T vs. treated with weekly infusions of AAT (25 µg), and Group NT. i.e. not treated (7 pts).

Results: After 3 years, the decrease in FEV1 in Group T was 125 ml (4%), whereas in Group NT was 610 ml (41%); p<0.02.

SGRQ changes over three years were significantly different in the two groups. Group T showed a 7.8 unit improvement, whereas in Group NT QoL worsened by 7.9 units (p < 0.04 over time between groups).

Conversely, the EQ-5D did not detect any change in health status between the two groups or over time.

Conclusion: These data show that AATD associated with COPD determines a decrease in patients’ health status that may be slowed down by augmentation therapy. The improvement in health status in T Group can be detected by the SGRQ but not the EQ-5D.

P3633
Effect of gender on exercise capacity and hospital anxiety and depression scale (HADS score following pulmonary rehabilitation
Debapriya Datta 1, Richard ZaWallack 2.

The objective of this study was to determine whether gender impacts change in outcome following pulmonary rehabilitation (PR). The records of 241 COPD patients who underwent a hospital-based, 8-week outpatient PR programme were reviewed. All patients received upper and lower extremity exercise training and smoking management. Pre- and post-outcome measures were: 6-minute walk distance (6MWD), self-reported Chronic Respiratory Questionnaire (CRQ-SR), unsupervised armlifts/minute (UAL), Hospital Anxiety and Depression scale for anxiety (HADS-A) and depression (HADS-D), before and after PR. Mean age was 69.1±7 years; 49% were females; mean FEV1 was 49% of predicted. Outcomes measures are shown in the following table:

<table>
<thead>
<tr>
<th>Outcome Measures</th>
<th>Pre &amp; Post-PR</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Male</td>
</tr>
<tr>
<td>Pre-6MWD (meters)</td>

<td>4±2.29</td>
</tr>
<tr>
<td>Pre-HADS-D</td>
<td>5±3.3</td>
</tr>
<tr>
<td>Post-HADS-D</td>
<td>4±2.6</td>
</tr>
</tbody>
</table>

Patients in both genders showed significant improvement in all outcome measures. Change in UALs were similar in both genders (p=0.8); females showed greater increase in 6MWD (p=0.01) and CRQ-SR score (p=0.07). Pre-PR HADS-A scores were significantly higher in females (p=0.0009). Females showed greater reduction in HADS-D scores following PR (p=0.02). These data indicate that female COPD patients show greater improvement in outcome areas of exercise capacity, depression and quality of life following PR.

P3634
Pulmonary rehabilitation, COPD assessment test and smoking cessation at smokers with COPD
Paraschiva Postolache 1,2, Octavian Poteciu 2,3, Ingrid Olga Merisaua 2, Luminita Calin 4, Liliana Chelaru 5, Oana Cristina Arghir 6, Daniela Husanu 7.

1Internal Medicine and Pulmonology, “Gr T. Popa” University of Medicine and Pharmacy, Iasi, Romania; 2Pulmonology Rehabilitation Clinic, Rehabilitation Clinical Hospital, iasi, Romania; 3Intensive Care, “Gr. T. Popa” University Clinical Hospital, iasi, Romania; 4Pulmonology Clinic, “Gr. T. Popa” University, Faculty of Medicine, Constanta, Romania

The objective was to compare the improvement of quality of life (QoL) between smokers with chronic obstructive pulmonary disease (COPD) who completed a PR program complementary of the smoking cessation treatment and those who received usual treatment.

Methods: Inclusion criteria were: evidence of COPD according to GOLD standards; an initial HRCT > 2 cm and an initial COPD Assessment Test (CAT) completed by every patient. From 437 smokers with COPD (GOLD stages II-III) only 113 patients were enrolled in a 12 weeks supervised PR program, complementary the smoking cessation treatment (the PR group), and 324 smokers received the treatment for COPD and for stop smoking, monitored as well for 12 weeks (non-PR group). All patients completed the CAT questionnaire at the beginning and at the end of the determined period.

Results: Initially, CAT scores varied between 26-38 without any difference between the PR group and the other patients. At the end of the period, the CAT scores in the PR group were between 7-16 comparing to the non-PR group where
CAT scores shown little improvements since the beginning of the treatment, with values between 20-26, additionally to smoking cessation failure at an important number of non-PR members (45.96%) than the PR group (16.81%). There were reported as well higher rates of long-term abstinence in the patients adherent to PR than the other group.

**Conclusions:** Although current smokers are often expected to have a small PR adherence, COPD smokers who completed the PR presented important QoL, improvements, better CAT score than COPD smokers usually treated. Moreover, a better PR adherence seems to be related with higher rates of sustained long term abstinence.

**P3635**

Factors predicting clinically improved health status in COPD patients after pulmonary rehabilitation

Ola Bratås1, Geir Arild Espnes1, Toril Rannestad2, Rolf Walstad4, 1Department of Nursing, Sar-Trondelag University College, Trondheim, Norway; 2Department of Social Work and Health Science, Norwegian University of Science and Technology, Trondheim, Norway; 3Department of Nursing, Sar-Trondelag University College, Trondheim, Norway; 4Department of Laboratory Medicine, Children’s and Women’s Health, Norwegian University of Science and Technology, Trondheim, Norway.

**Background:** Although pulmonary rehabilitation has proven to be effective in enhancing health status (HS) in COPD patients (Lacasse et al, Cochrane Database Syst Rev 2006; 4), characteristics of those who have the largest potential for HS improvements after rehabilitation are less studied. This knowledge may be useful for physicians’ referral practice.

**Aims:** The aim of the study was to investigate the influence of lung function on a clinical improved health status after rehabilitation adjusted for gender, age, and co-morbidity. Since the association between lung function and health status in COPD patients is usually low (Jones, PW, Thorax 2001; 56: 880-887), we hypothesized no influence of lung function on the post rehabilitation outcome.

**Methods:** A longitudinal study of 136 consecutive male and female patients attending 4 weeks inpatient rehabilitation, aged 40+ and with COPD I-IV. Lung function was assessed by spirometric tests and health status by the St.George’s Respiratory Questionnaire. The influence of independent variables on HS was assessed through logistic regression analyses.

**Results:** Patients with minor disease (FEV1 ≥50% predicted) were more likely to achieve clinically improved health status after rehabilitation than patients with major disease (FEV1 < 50% predicted) (OR 4.2, 95% CI 1.9-9.3, p=0.001), with stronger effect for female than for male patients (OR 7.1, 95% CI 1.9-39.0, p=0.025).

**Conclusions:** Our findings upgrade the significance of lung function on HS in COPD patients, implicating that referral to pulmonary rehabilitation at an early COPD stage is crucial in order to achieve optimal post rehabilitation effect, especially for female patients.

**P3636**

Abnormal illness behaviour amongst COPD patients entering pulmonary rehabilitation

Paul Cadera1, Mohammed Alyami2, Peter Friith1, Steve Quinn3, 1Respiratory Medicine, Repatriation General Hospital, Adelaide, Australia; 2School of Medicine, Flinders University of South Australia, Adelaide, Australia; 3Clinical Effectiveness, Flinders University of South Australia, Adelaide, Australia.

**Introduction:** COPD patients present with a mixture of symptoms, some of which may not always be attributable to physical pathology. The degree of the psychological and behavioural component of illness may at times be out of proportion with objective physical pathology. Maladaptive perceptions associated with abnormal illness behaviour (AIB) may have negative consequences for patients’ health outcomes.

**Objectives:** The study aimed to 1) investigate the prevalence and type of AIB present in COPD patients entering pulmonary rehabilitation and 2) evaluate the associations between AIBs, quality of life, mental health and level of disability in COPD patients.

**Method:** A cross-sectional study design was employed. Sixty-nine COPD participants entering a pulmonary rehabilitation program completed the Illness Behaviour Questionnaire (IBQ), Hospital Anxiety and Depression Scale (HADS), Short Form 36 (SF-36) and Chronic Respiratory Questionnaire (CRQ).

**Results:** Correlations indicated that AIB was significantly (p<0.01) associated with anxiety, age, dyspnea and emotional function. Multiple regressions indicated that significant (p<0.01) predictive relationships existed between the Hypochondriasis subscale of the IBQ and anxiety (HADS), dyspnea (CRQ) and mental disability (SF36).

**Conclusion:** AIB is linked with health outcomes amongst COPD patients. Early recognition of AIB allows for the tailoring of pulmonary rehabilitation programs to address perception of illness issues.

**P3637**

Anxiety and affecting factors in pulmonary rehabilitation patients with chronic obstructive pulmonary disease during exacerbation

Ozden Oytemizci Taskar1, Ayca Ulukan1, Nurdan Kocukt2, Gulcin Kaynak Karatas1, 1Department of Physical Medicine and Rehabilitation, Gazi University Faculty of Medicine, Ankara, Turkey; 2Department of Pulmonary Medicine, Gazi University Faculty of Medicine, Ankara, Turkey.

**Aims:** To investigate the anxiety prevalence and related factors in COPD patients enrolled in the rehabilitation program during exacerbation.

**Material and methods:** Hospital Anxiety and Depression Scale (HAD) was performed to 75 COPD patients (mean age 69.6±8.8 years). Mean HAD anxiety score was 6.4±5.2.

**Results:** Patients in both groups had similar age, systemic diseases, social features, disease severity, arterial blood gases, walking distance, heart rate, respiratory rate and saturation during the walk test. However, there were significant differences in some variables between two groups.

**Clinical and demographic variables of the COPD patients with HAD anxiety scores <11 and ≥11**

**Conclusion:** Despite similar disease severity and walk tests in both groups, patients with high anxiety scores having higher ratio of the inability to complete walk test, more severe symptoms during the test and ADL made us suggest that anxiety levels restricted their participation in physical activity. We think that appropriate psychiatric approach will increase the rehabilitation gains among patients with high HAD anxiety scores.

**P3638**

The impact of anxiety and depression on outcomes of pulmonary rehabilitation in COPD

Andreas von Leupoldt1,2, Karin Taube,2, Kirsten Lehmann,1, Anja Fritzschke,1, Helgo Magnusson4, 1Department of Psychology, University of Hamburg, Hamburg, Germany; 2Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4Atem-Reha GmbH, Atem-Reha GmbH, Hamburg, Germany; 5Pulmonary Research Institute, Hospital Grosshadern, Grosshadern, Germany.

Anxiety and depression are highly prevalent comorbidities in chronic obstructive pulmonary disease (COPD) and related to a negative course of disease. We examined the impact of anxiety and depression on functional performance, dyspnea and quality of life in patients with COPD at start and end of an intensive 3-week outpatient pulmonary rehabilitation program (PR).

Before and after PR, 238 patients with COPD (mean age = 62 years) underwent a 6-minute walking test (6MWT). In addition, anxiety, depression, quality of life and dyspnea at rest, after PR and during activities were measured.

**Results:** The results demonstrate that anxiety and depression are significantly associated with increased dyspnea and reduced functional performance and quality of life in patients with COPD. These negative associations remain stable over the course of PR, even when improvements in most of these outcomes are achieved during PR.

**Conclusion:** The findings underline the clinical importance of diagnosing and treating anxiety and depression in patients with COPD.

**P3639**

Quality of life (QoL) in asthma 1 year after pulmonary rehabilitation (PR)

Heidrun Lingner1, David Scheub1, Nino Djahangiri2, Michael Wittmann1, Konrad Schultz2, 1Institut für Allgemeinmedizin, Medizinische Hochschule Hannover, Hannover, Germany; 2Pneumologie, Klinik Bad Reichenhall, Bad Reichenhall, Germany.

**Background:** There are only sparse data on the effectiveness of PR on QoL in
asthma. Therefore we conducted a prospective observational study to determine the effect of a 3 week inpatient-PR on QoL.

Methods: From May to September 2009 all asthma patients of our pulmonary rehabilitation clinic were asked to participate in the study, 201 out of 243 (83%) agreed. 43.2% female, mean age 48.4 y (18-81), SRaw (PaPV) 1.23±0.80 before and 0.88±0.54 after inhalation of a rapid-acting beta-2-agonist (RABA). 59.6% suffered from asthma GINA grade 3-4. Obligate components of PR were patient education, physical training, breathing retraining and psychosocial support. QoL was assayed by using St. George’s Respiratory Questionnaire (SGRQ) and Asthma Quality of Life Questionnaire (AQLQ). Measuring times were the beginning of PR (T0), discharge (T1) and 3 (T2), 6 (T3) and 12 months (T4) post PR. The three latter were delivered by mail. 83.5% (T2), 88% (T3) and 72.6% (T4) of the patients answered.

Results (mean±sd): sgrq total score: T0 38.6±18.3; T1 27.8±17.4; T2 30.9±20.7; T3 32.5±20.7; T4 32.7±20.7. AQLQ[S] score: T0 4.6±1.2; T1 5.5±1.1; T2 5.2±1.3; T3 5.0±1.3; T4 5.0±1.3. FEV1 [l] after RABA: T0 3.10±0.88; T1 3.22±0.80 (p<0.01 versus T0).

Discussion: The reduction of mean SGRQ score and increasing of mean AQLQ score indicate improvement of QoL after PR. Both indicate a great effect at discharge, which diminishes a little after 1 year. The positive effect at discharge was assured by the lung function measurements. After 1 year still 45% (AQLQ) to 55.8% (SGRQ) of the patients have a selfreported benefit.

Conclusion: PR can a resting improvement of QoL in asthmatics at least for one year.

397. Challenges in rehabilitation: some old dilemmas revisited with some solutions?

P3640 Late-breaking abstract: Bi-level positive airway pressure (Bipap) effects on regional distribution of lung ventilation in COPD

Piera Fazzi, Renza Cristofani, Alfredo d’Abrosca, Maria Stella Derlin, Pierchiragandhi, Cardiothoracic and Vascular Department, University of Pisa, Pisa, Italy Experimental Pathology, Medical Biotechnology, Infectious Disease and Epidemiology Department, University of Pisa, Pisa, Italy Regional Center of Nuclear Medicine, University of Pisa, Pisa, Italy Cardiothoracic and Vascular Department, University of Pisa, Pisa, Italy

Aim: To assess changes on distribution of lung ventilation before and after Bipap, in patients (pts) with chronic respiratory failure (CRF) due to severe COPD.

Methods: 11 COPD pts (mean age 69.3±7.5), in stable conditions, underwent two successive ventilation scans (V) with a radioabeled aerosol (99mTc nanocolloid albumin, Ventillog, GE). The first ventilation was done using FAI device (Fastera, MPR), and the second one using an adapted nasal mask system (FAZ), which allows evaluation of (V) distribution after Bipap. Clinical symptoms and arterial blood gas analysis were observed before and after treatment. The images of (V) before and after Bipap were quantified by a semi-automatic procedure which divides each lung in 3 regions of interest (ROI): upper, medium and lower lung field to obtain the upper/upper (U/L) ratio. An automatic iso-level ROI procedure enabled radioactivity measurement (counts) of ventilated area (Va 5% and 30%), on the right posterior and on the right lateral lung. A ventilation distribution inhomogeneity index (IHI) was defined as the ratio counts/pixels, calculated on isoROI 5% and 30% (INI 5 and 30%).

Results: A significant reduction of U/L ratio (F=12.12, p<0.02) and of cardiac rate (p=0.01) were accompanied by a significant increment of pO2 (p<0.02) and pH (p<0.001). Ventilated area (Va 5% and 30%) increased, and INI 5 and 30%, decreased, even if both not significantly.

Conclusions: A significant improvement of the physiologic gradient (U/L), an increment of ventilated areas (Va 5%, 30%), and a reduction of regional ventilation inhomogeneity index (INI) are likely underlying the therapeutic effect of the Bipap in COPD.

P3641 Late-breaking abstract: Efficacy of relaxation posture in patients with chronic obstructive pulmonary disease (COPD)

Tomoni Ichiba1, Tetsuji Miyagawa2, Takeshi Kera3, Toru Tsuda4, Fumio Kobuha5, 1Department of Physical Therapy, Kyorin University, Faculty of Health Sciences, Hachioji, Tokyo, Japan; 2Division of Respiratory Care, Showa University, Graduate School of Nursing and Rehabilitation Sciences, Yokohama, Kanagawa, Japan; 3Department of Physical Therapy, Nihon Institute of Medical Science, Morioka, Iwate, Japan; 4Department of Respiratory Medicine, Koriyama Tsuda Hospital, Kitakyushu, Fukuoka, Japan; 5Department of Respiratory Medicine, Showa University Fujisaku Hospital, Yokohama City, Kanagawa, Japan

Background: Relaxation postures are recommended to reduce the work of breath-
P3644

Maintenance of long-term benefits from an outpatient pulmonary rehabilitation programme in COPD

Francesco Costa, Laura Malagrino, Sandra Antonelli, Claudia De Simone, Giovanna Duccisato, Dario Neri, Sabrina Santenini, Barbara Vagaggin, Pierluigi Paggiani. Cardiothoracic and Vascular, University, Pisa, Italy

We evaluated the long term maintenance of benefits of a Pulmonary Rehabilitation programme (PRP) in COPD patients and to establish which patients require frequent repetitions of PRP.

Fifty-one COPD patients (FEV\textsubscript{1}: 57±17%L) underwent 10 weeks outpatient PRP supervised exercise training on a cycleergometer and upper limb training. Pre-PRP (T0), post-PRP (T1), 6 months (T2) and 9 months (T3) after the end of PRP we measured: exercise tolerance by 6 minute walking test (6MWT), dyspnoea by MRC, quality of life by St George Respiratory Questionnaire (SGRQ). All outcomes improved at T1. 6MWT and MRC progressively worsened at T2 and T3 respectively, whereas SGRQ remained stable up to 9 months from PRP.

P3646

Rehabilitation of pulmonary dysfunction in patients with ankylosing spondylitis

Razvan Gabriel Dragoi\textsuperscript{1}, Claudia Avram\textsuperscript{2}, Elena Amaricai\textsuperscript{1}, Oana Suciu\textsuperscript{1}, Miha Dragoi\textsuperscript{1}, \textsuperscript{1}General Medicine Faculty, Victor Babes University of Medicine and Pharmacy, Timisoara, Timis, Romania; 2Physical Education and Sport Faculty, West University of Timisoara, Timisoara, Timis, Romania

Objective: The study is aiming to demonstrate the benefit of inspiratory muscle training (IMT) on pulmonary dysfunction in ankylosing spondylitis (AS) patients.

Methods: Twenty four patients (mean age: 45.6±6.5 years old, all males) who were previously diagnosed with AS stage III and IV were included in a eight week prospective study. The patients were evaluated at baseline and at the end of the study with respect to resting pulmonary function test (forced vital capacity - FVC, forced expiration volume in one second - FEV\textsubscript{1}) and cardiopulmonary exercise test (maximal minute ventilation - VEmax, maximal tidal volume - VTmax and maximal workload attained during the exercise test - PMax). All patients performed IMT sessions, three times weekly for a period of eight weeks using a computer assisted TrainAir device. Each IMT session was individualized by evaluating the maximum inspiratory pressure (SMIP), the training being performed at 80% of SMIP.

Results: Using paired t test to compare data at baseline and at the end of the study we noticed significant improvements of FVC (3.3%, p<0.0002), FEV\textsubscript{1} (3.2%, p<0.0047), VEmax (5.8 L/min, p<0.0002), VTmax (0.7 L, p<0.0248) and PMax (16 Watt, p<0.0001).

Conclusions: Inspiratory muscle training improves resting and effort pulmonary function of patients in advance stages of AS. This is mainly due to the influence of IMT on increasing strength and mobility of the diaphragm and accessory inspiratory muscles, together with the biofeedback provided by the interaction of patient - TrainAir system – physical therapist. Improving ventilometric performance leads to an increased exercise capacity and quality of life in patients with AS.

P3647

Complex outcomes of physical training in COPD patients

Natalia Mescheriakova, Andrey Belevsky, Alexander Chemkh. Physical Rehabilitation, Research Institute of Pulmonology, Moscow, Russian Federation

Background: Exercise and respiratory training is an important part of COPD patient management. It improves physical tolerance and lung function, as well as HR QoL.

Aim: To assess the exercise and respiratory training impact on systemic effects in COPD patients.

Methods: 52 COPD patients, stage III and IV were randomized in 2 groups. Group 1 (63.9±7.5 yr, 34.6±11.5 pack/yr, FEV\textsubscript{1} 36.4±11.06% pred., FEV\textsubscript{1}/FVC 39.7±8.82%, CRP 10.7±6.84 mg/l, CD-ES 25.9±9.2) received ICs, LABA, long-acting bronchodilators. Group 2 (64.9±7.8 yr, 38.4±14.56 pack/yr, FEV\textsubscript{1} 33.8±16.4% pred., FEV\textsubscript{1}/FVC 41.3±10.8%, CRP 14.1±4.67 mg/l, CD-ES 26.8±8.5) - the same therapy - exercise and respiratory training: upper and low limb muscles training + Threshold IMT and PEP COPR IL I. IL6, TNF-a, testosterone, 6MWT, lung function, QoC MOS SF-36, CRC, CES-D depression questionnaire (17 points - not depressed, 18 and depression - ) before and after 4 weeks were evaluated.

Results: In group 2 there was the significant improvement in lung function (AFEV\textsubscript{1}: 11.1±8.7%, p<0.05), physical tolerance (6MWT: 85.3±5.77 m, p<0.01), inflammatory markers: ACRP: -8.3±1.67 mg/l, p<0.04, \Delta IL6: -3±4.4 pg/ml, p<0.05, \Delta IL1: -4.1±4.2 pg/ml, p<0.16, \Delta Testosterone: 0.79±0.62 mmol/l, p<0.001, QoC: 18.9±8.9, p<0.001, ADRP: 21.4±7.8%, p<0.05, \Delta MIH: 14.0±6.2%, p<0.001). CES-D was -9±4.6, 6 points. In the group 1 there was no significant improvement in all parameters. There was no significant changes in TNF-a in both group. Correlation: RV/TLc and CES-D r=0.70, FEV\textsubscript{1}/FVC and CES-D r=0.44, MH and CES-D r=0.72, SF and CES-D r=0.79.

Conclusion: Exercise and respiratory training has an effect on COPD patient systemic effects.

P3648

Prevalence of airflow obstruction according GOLD, ATS and ERS criteria in symptomatic ever-smokers referring to a pulmonary rehabilitation department

Elisa De Mattia\textsuperscript{1}, Adriano Vaghi\textsuperscript{2}, Iara Pessina\textsuperscript{2}, Giuseppe Pepe\textsuperscript{2}, Benedetto Rho\textsuperscript{2}, Nicola Barbarito\textsuperscript{2} \textsuperscript{1}Pulmonary Rehabilitation, Villa Esperia, Salice Terme, Pavia, Italy; 2Respiratory Unit, AO Sallusti, Garbagnate Milanese, Milano, Italy

Aim: To evaluate prevalence of airflow obstruction (AO) in ever-smokers ≥ 45 years old, all males.
years old with both dyspnoea and chronic productive cough, using European Respiratory Society (ERS) statement (FEV1/FVC < 80% predicted in men and women, respectively), American Thoracic Society (ATS) statement (FEV1/FVC < 75%), and Global Initiative for Chronic Obstructive Lung Disease (GOLD) statement (FEV1/FVC < 70%).

Methods: Lung function tests were performed in all patients referred to our Pulmonary Rehabilitation department because of respiratory diagnosis or symptoms. For analysis, in patients showing AO we used post-bronchodilator lung function values.

Results: In 184 ever-smoker patients with symptoms of chronic obstructive pulmonary disease (COPD), the prevalence rates of AO were as follows: ERS = 89.7%, ATS = 76.6%, and GOLD = 63.6%. Patients with AO according ERS criteria showing severe to moderate (M2) obstruction (i.e. FEV1 < 70% predicted) were 373 months old. Patients with ERS MS AO but without AO using either ATS or GOLD criteria were 84.8% and 19.3%, respectively.

Conclusions: Prevalence of AO is highly dependent on which guidelines it is based. ATS and particularly GOLD statement can cause a large underdiagnosis even of moderate to severe COPD. Diagnosis of COPD may be overlooked if SVC is not performed.

P3649
Post-bronchodilator FVC determines pulmonary rehabilitation outcomes in patients with chronic obstructive pulmonary disease
Konstantinos Veletzis, Maria Christidou, Maria Harikioskouli, Elpida Theodorakopoulou, Silvia Damirou, Alexis Kainis, Alexis Christouso, Panagiotis Diamantas, Zoe Ziti, Eftihia Skiadas, Evangelonas Kosmas.
Pulmonary Rehabilitation Center, Chest Diseases Hospital "Sotiria", Athens, Greece

Chronic obstructive pulmonary disease (COPD) is an heterogeneous disease with various clinical and functional phenotypes, hence individualization of treatment strategies, such as pulmonary rehabilitation (PR), is important. Our aim was to explore the importance of post-bronchodilator forced vital capacity (pbFVC) in determining the effects of a PR programme on several patient-oriented outcomes.

In the absence of any comorbid restrictive disorder (such as pleural thickening, heated TBC, combined fibrosis, kyphoscoliosis, morbid obesity etc.), FVC reflects the mechanical constraint imposed by the elastic and resistive denouement of the lungs. We have studied 41 COPD patients (FEV1 39% ± 11% pred.) who completed a 3-month 36-session PR programme and who were evaluated before and after PR in chronic dyspnoea (modified MRC scale), exercise capacity [6-min walking distance (6MWD) and peak workrate on a maximal cardiopulmonary exercise testing (WRmax)] and health-related quality of life (SGRQ questionnaire). Patients were divided in two groups based on their pbFVC: Group A (FVC > 70% pred., n=20, patients, age 64.8±8 years) and Group B (FVC < 70% pred., n=21, patients, age 62.4±8 years). In patients of Group B we excluded on clinical & imaging grounds the presence of any comorbid disease with a potential to affect FVC.

Results: Post-bronchodilator FVC determines pulmonary rehabilitation outcomes in patients with chronic obstructive pulmonary disease (COPD).

P3650
Respiratory muscle strength and exercise tolerance before and after pulmonary rehabilitation in COPD patients
Alina Croitoru1, Diana Ionita2, Carmen Stroescu1, Carmen Stroescu1, Cornelia Tudose1, Stefan Dumitrache-Rujinski1, Claudia Toma1, Dragoș Bumbacă1, Dana Anghelucescu2, Miron Bogdan1, 2, 3.
1Pulmonary Rehabilitation Center, 2Respiratory Physiopathology Department, National Institute of Pneumology, Bucharest, Romania; 3Pulmonary Rehabilitation Center, National Institute of Pneumology, Bucharest, Romania

Background: Patients with COPD have severe breathlessness induced by the increased mechanical work of respiratory muscles in relation to dynamic hyperinflation. Pulmonary rehabilitation programs have been shown to relieve dyspnoea, but the mechanism by which they succeed remains controversial.

Aim: To evaluate the effect of pulmonary rehabilitation on thoracic mechanics.

Method: The association between thoracic hyperventilation measured by plethysmography (functional residual capacity FRC, residual volume RV), respiratory muscle strength (maximal inspiratory pressure MIP, maximal expiratory pressure MEP) and dyspnoea scores (MRC, BORG scale) in patients with stable COPD before and after pulmonary rehabilitation (outpatient program, 2 months, 3 sessions/week, including daily respiratory muscle training).

Results: Twenty patients with COPD stage II-IV GOLD were included. Thoracic hyperventilation was present in all cases: mean FRC 164.9% of the predicted value and RV 209.2% before the rehabilitation program. Mean MIP was 69.6% and mean MEP 105.3%. The severity of dyspnoea before the pulmonary rehabilitation was negatively associated with inspiratory muscle strength (r =-0.68) and hyperventilation (r =-0.45). Hyperinflation decreased at the end of the rehabilitation program (mean RV decreased with 15.1% and mean FRC with 9.2%), mean MIP increased with 14.3% and the mean dyspnoea score decreased from 3.5 to 2.4.

Conclusion: Pulmonary rehabilitation optimized thoracic mechanics in our patients by reducing thoracic hyperinflation and increasing the effectiveness of inspiratory muscles work.

P3652
Asthma control (AC) 1 year after pulmonary rehabilitation (PR)
Heidrun Lingner1, David Schueb2, Nino Dzhangiani2, Michael Wittmann1, Konrad Schultz1, 2Institute für Allgemeinmedizin, Medizinische Hochschule Hannover, Hannover, Germany; 3Bekken Rechtsanwalt, Bad Reichenhall, Germany

Background: Only sparse data exist on the effectiveness of PR in asthma concern- ing AC. Therefore we conducted a prospective observational study to determine the effect of a 3 week inpatient-PR on AC.

Methods: From May to September 2009 all asthmatic patients of a pulmonary reha- bilitation clinic were asked to participate in the study. 201 out of 245 participated (83%). 42.3% were female, mean age 48.4 ± 9.5% patients from asthma GINA grade 3-4. Obligate components of PR were patient education, physical training, breathing retraining and psychosocial support. Primary outcome was AC (asthma control test, ACT), which was assessed at beginning of PR (T0), at discharge (T1), and 3 (T2), 6 (T3) and 12 months (T4) post PR. The three latter were delivered by mail. 83.5% (T2), 88.0% (T3) and 72.6% (T4) of the patients answered. Sec- ondary short-time outcomes were 6MWD and FeNO, which were measured at the beginning of PR (T0) and at discharge (T1).

Results: (mean ± st.dev., median): n=106, median ACE score: T0 16.0±5.2, T1 20.5±4.0*; T2 18.9±4.7*; T3 18.4±4.9*; T4 18.4±4.9*. FeNO: T0 76.0±38.8*; T1 23.3±18.8*; T2 5.1±3.2* (p-values <0.01 versus T0).

Discussion: The mean ACE score at baseline was 16.0 (of 25), indicating an uncontrolled asthma, while the mean score post PR was 20.5, e.g. indicating sufficient AC. Even after 1 year the mean ACE score of 18.4 indicates a significant improvement of AC. The proportion of patients with sufficient AC (ACT 20-25) increased from 33.2% to 67.4% after PR and was still 51% after 1 year.

Conclusion: PR lengthens the 6-MWD, reduces FeNO (significant improvement in both) and improves asthma control least for one year.

P3653
Quantification of smokers and smoking status among COPD patients, hospitalized for an exacerbation
Kasper Ankjærgaard, Torgny Wilcke, Hans-Jørgen Bendixen, Carsten Juhl. Dept of Pulmonary Medicine, Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark

Background: In 2009, Dept of Pulmonary Medicine and Deps of Physiotherapy and Ergotheraphy, Gentofte Hospital, University of Copenhagen have carried out the pilot study “KOL-hjem-igen” (COPD-home-again) (COPD-2009). All patients included were transferred after an exacerbation of COPD 1.1.2009 to 31.12.2009 in COPD-home-again. This consists of open telephone line, home visits by a COPD nurse 5-7 days and 6 months after discharge, individual self-care plan, rehabilitation by physiotherapist and ergotherapist during admission including self-training plan and rehabilitation to visitation.

656s
Background and objective: Patients with chronic obstructive pulmonary disease (COPD) are commonly referred for pulmonary rehabilitation (PR), but there is limited evidence on the effect of home-based PR. The aim of this study was to determine the effect of a new home-based PR program toward expiratory airflow limitation among COPD patients.

Methods: 40 stable COPD patients (FEV1, 37.7 ± 13.0% predicted) were randomized to PR group (n=20) undergoing a 8 weeks home-based PR programme more suitable to respiratory physiology and control group (n=20). Baseline and post-PR variables were recorded, and changes in pulmonary function, respiratory muscle strength and quality of life (St. George’s Respiratory Questionnaire, SGRQ), as well as the body mass index, airway obstruction, dyspnea, and exercise capacity (BODE-index) were evaluated.

Results: After the PR programme, there were significant increases in respiratory muscle strength (P<0.001) and 6-min walk distance (422.9 ± 106.6 vs 473.3 ± 112.2 m; P<0.001) and significant reduction in SGRQ total score (49.4 ± 42.0 vs 36.9 ± 12.6; P<0.001). MRC dyspnea scale (2.9 ± 0.9 vs 2.0 ± 0.7; P<0.001) and BODE index (5.2 ± 2.1 vs 4.1 ± 1.7; P<0.001) in PR group but not in control group. However, no statistical significance was found in pulmonary function between the two groups (P>0.05).

Conclusion: We conclude that PR toward expiratory airflow limitation substantially improved respiratory muscle strength, exercise capacity, dyspnea, quality of life and the BODE index. Therefore, it could be considered as a new effective home-based PR method in stable COPD patients.

### P3654

**Impact of obesity on pulmonary rehabilitation in COPD patients**

Selma Aktas, Pinar Ergin, Dicle Kaymaz, Erzgi Semsal, Fatma Sengul. Atatürk Chest Disease and Chest Surgery Education and Research Hospital. Pulmonary Rehabilitation and Home Care Department, Ankara, Turkey

**Aim:** We aimed to examine the influence of pulmonary rehabilitation (PR) on pulmonary function test, body composition, exercise capacity, the perception of dyspnea, quality of life, muscle strength, anxiety and depression scores in obese and non-obese COPD patients.

**Methods:** We conducted a retrospective study of 82 patients with COPD who completed a 12-month PR program in our center. They were classified into two groups based on BMI: Underweight (BMI < 18.5 kg/m²) and overweight (BMI ≥ 30 kg/m²). The impact of PR on pulmonary function, body composition, exercise capacity, quality of life, muscle strength, anxiety, and depression scores were assessed.

**Results:** The BMI distribution was uniform among all patients with COPD. The results showed that PR had a significant impact on pulmonary function, body composition, and exercise capacity. The improvements were more pronounced in the non-obese group. The depression and anxiety scores were significantly reduced in the PR group compared to the control group.

**Conclusion:** Our results indicate that PR is an effective intervention for improving pulmonary function, body composition, and exercise capacity in COPD patients. The benefits of PR are more pronounced in non-obese patients.
P3659

Relationship between psychological well-being and lung health status in patients with bronchectasis

Leila Boussiflara, Nadia Boudawara, Ines Hammami, Ahmed Ben Saad, Mounira Sakka, Jalil Knaani, Pneumologie, Tahir Sfar Hospital, Mahdia, Tunisia

Introduction: Patients with bronchectasis often experience depression and anxiety, but little information is available regarding patients with these conditions.

Aim of the study: This study was carried out to examine levels of anxiety and depression in patients with bronchectasis.

Methods: Fourty three patients with bronchectasis, determined by high resolution computed tomography scan, completed anxiety and depression questionnaires.

Results: 27% of patients had minor depression with an anxiety depression score more than 13 and 9% of patients had severe depression with an anxiety depression score more than 19. The anxiety depression status was not correlated to the extent of bronchectasis on CT scan (p=0.363). Post-brochodiathermy FEVI and higher airflow limitation were associated to a severe anxiety depression status.

Conclusion: Anxiety and depression are quite common in bronchectasis. Treatment in bronchectasis aimed essentially at reducing symptoms but it will not prevent levels of anxiety and depression which need alternative therapy.

Staging with FDG-PET/CT influences stage-specific survival in non small cell lung cancer (NSCLC)

Kaja Zimmermann,1 Simone Tönnes,1 Daniel Misch,1 Christian Boch,1 Niclas Schömig,1 Gregor Förster,1 Jens Kollmeier,1 Torsten Bauer,2 1Department of Pneumologie, Helios Klinikum Emil von Behring, Berlin, Germany; 2Department of Nuclear Medicine, Helios Klinikum Emil von Behring, Berlin, Germany

Background: Fluorodeoxyglucose (FDG)-PET/CT has a high sensitivity (89-100%) and reasonable specificity (79-95%) for the diagnosis of NSCLC. Currently it is mainly used in preoperative staging. In approximately 15% of these cases, it leads to the diagnosis of metastatic disease that was neither clinically suspected nor seen in conventional imaging. It may be assumed that integrating these cases in the palliative stage IV group, has an influence on overall survival.

Aim: To compare the overall survival (OS) of patients with stage IV NSCLC who underwent FDG-PET/CT staging with patients where conventional imaging procedures were performed.

Methods: We analyzed the OS of all patients diagnosed in 2009 (n=254), 96/254 (38%) patients were staged with PET/CT and 158/254 (62%) with conventional imaging (CT). Survival data were compared by Kaplan-Meier statistics.

Results: Patient in the PET/CT group (65±11) were younger than in the CT group (68±10 years; p = 0.008). The median OS of all patients was 246 (range: 217 – 275); 338 (range: 247 – 429) days in the PET/CT group and 207 (range: 161 – 253) in the CT group (p = 0.001).

Conclusion: FDG-PET/CT staging leads to earlier recognition of stage IV NSCLC patients and thus longer survival times. To what extend a selection bias for age and/or clinical condition may have influenced our results, needs to be discussed.

P3661

CT-guided transthoracic breast lesion location wire implantation for small nonpalpable pulmonary nodules

Bart Ilsen, Frederik Vandenbroecke, Johan de Mey. Radiology Department, Universiteit Ziekenhuis Brussel, Brussels, Belgium

Purpose: To evaluate the technique, safety and diagnostic reliability of transthoracic wire implantation for nonpalpable and invisible small pulmonary nodules (SPN) prior to video-assisted thoracoscopic surgery (VATS).

Methods: From April 2009 till January 2011, 17 patients underwent 18 VATS resections after insertion of a "breast lesion localization wire" (7.7 or 10.7 cm needle length and 20-gauche size) into a SPN. The wire was placed using a CT fluoroscopy procedure.

The patients were assessed with respect to localization and puncture of the lesion, duration and complication rate of the procedure, conversion thoracotomy rate during VATS and pathological results.

Results: Preoperative CT-guided wire implantation succeeded in all patients. The average CT-guided procedure time was 12 min (range 8-15 min) and no complication was noted. There was no conversion to thoracotomy needed in any patient. Histological assessment revealed metastases in 11 patients, non-small-cell lung cancer in 4 patients, interstitial fibrosis in 2 patients and a sarcoid nodule in 1 patient.

Conclusions: Percutaneous CT-fluoroscopy guided wire placement is a useful and safe technique for localizing nonpalpable pulmonary nodules during VATS resection.

P3662

Imaging techniques in the evaluation of solitary pulmonary nodules (SPNs)

Marta Dabrowska,1 Rafał Krekne,1 Piotr Kocezyński,1 Marta Maskey-Warzechowska,1 Malgorzata Zukowska,2 Jolanta Kunikowska,1 Wiktoria Mazurek-Kopie,3 Ryszard Chazan1 1Department of Internal Medicine, Pneumonology and Allergology, Medical University of Warsaw, Warsaw, Poland; 2Department of Radiology, Medical University of Warsaw, Warsaw, Poland; 3Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, Poland; 4Department of Surgery, Institute of Tuberculosis and Lung Diseases, Warsaw, Poland

Despite new imaging techniques such as contrast enhanced computed tomography (CECT) or positron emission tomography with 18-fluorodeoxyglucose (FDG-PET/CT), non-invasive diagnosis of SPN etiology still remains a problem.

Aim: 1. to assess the incidence of malignancy in newly diagnosed SPNs 2. to evaluate utility of CECT and FDG-PET/CT in SPN diagnosis

Methods: 85 patients with newly diagnosed SPNs were observed on an ambulatory basis between 2008 and 2010. The diagnosis of malignant etiology of SPNs was based on pathological examination.

The benign etiology was proved based on either: 1. pathological examination 2. lack of growth for at least 2 years or resolution in radiological follow-up 3. central/total calcification in CT

The result of FDG PET/CT was suggestive for benign etiology of SPN if uptake of FDG was like background (SUV < 1) and the result of CECT if enhancement value was < 15HU.

Results: The SPN etiology was determined in 60 patients. 12 nodules (14%) were malignant, 48 nodules (56.5%) were benign. 17 patients are still under observation; 8 were lost to follow up. FDG-PET/CT was performed in 32 patients. In 16 cases the result was negative, 12 had an increased FDG uptake, 4 were inconclusive. The specificity, sensitivity, positive (PPV) and negative predictive value (NPV) and diagnostic accuracy of FDG-PET/CT were 91%, 87%, 83%, 93% and 88%, respectively. CECT was performed in 26 patients. In 10 cases the result was suggestive for benign SPN. The sensitivity, specificity, PPV, NPV and diagnostic accuracy of CECT were 100%, 48%, 69%, 100%, and 58% respectively.

Conclusions: The diagnostic accuracy of FDG-PET/CT is higher than that of CECT. The advantage of CECT is its high sensitivity and NPV.

P3663

Prediction of the lung adenocarcinoma metastatic spread according to initial CT examination

Tamara Milenarovic1, Aleksandar Ivkovic1 1 Radiology, ZC Vranje, Vranje, Serbia; 2Center of Radiology, KC Nin, Nin, Serbia

Adenocarcinoma of the lung gives a wide spectrum of different metastatic spread. Often we can find them before primary neoplasm. Therapy and prognosis depends not only on possibility of medicament or surgical treatment but also on location of neoplasm.

Aim of the study is to show spread direction of lung adenocarcinoma according to localization of primary neoplasm followed by computerized tomography.

Material and methods: This is study of 4356 patients with 14528 CT examinations.

All patients were with adenocarcinoma of the lung. All examination were performed on 16 or 64 MDCU. Using virtual bronchoscopy were it was possible. Metastatic spread was followed by conventional radiography, ultrasound, scintig-
raphy, MDCT and MRI according to location. Male patients were 2821 (64.76%),
female 1535 (35.24%). Middle age of patients was 68.3 years.

**Results:** We divided results according to lobar anatomy parts of the first sign
of neoplasms on initial CT examination, with hilar localization of neoplasms like
a separate entity. Neoplasms of both upper lung lobes were spread dominantly on
supra renal gland (67.14%), after that on liver and then on bones. Neoplasms of
middle right lobe was spread in both hilar regions. Basal tumors were mostly spread
in bones (34.73%) and after that in liver. Hilar neoplasm spread to brain mostly
(76.36%). Second group were patients we were find metastatic spread before
primary examination lung adenocarcinoma.

**Conclusion:** Spread prediction of lung neoplasm is very important for therapy
and prognosis. CT is golden standard for evaluation.

**CT guided biopsy of thoracic lesions**

Mehrdad Bakhshayeshkaram, Pouyeh Graali, Soheyla Zahirifard. Radiology
Department, National Research Institute of Tuberculosis and Lung Diseases,
Tehran, Islamic Republic of Iran

**Purpose:** This study was designed to assess different variables of thoracic be-
nign and malignant masses on Computed tomography (CT) guided biopsy and
to identify the complication rate of procedure.

**Materials and methods:** We evaluated 757 CT-guided biopsies of thoracic lesions
performed from March 2004 to December 2008, retrospectively. All biopsies were
performed by one radiologist. The CTs were assessed by a trained general practi-
tioner for the size and location of lesions and pneumothorax or pneumomediastinum
diagnosis and then all CTs were double checked by the same radiologist. Lesions considered benign
or malignant based on pathology reports.

**Results:** Biopsy yielded sufficient tissue for pathologic examination in 612 cases
(80.8%); 224 lesions were benign and 388 lesions were 51.3% were malignant
(27 small cell and 233 non-small cell tumors). The most prevalent location of
lesions was Right Upper Lobe (182 cases). 78 masses were located in mediastinum
and 41 lesions in chest wall. 44.2% of benign lesions belonged to infectious
(69.7% bacterial, 20.2% fungal, 6.1% hydatid cyst and 4% TB) and the rest were
inflammatory masses (43.8%), granulomatous (5.8%) and neoplastic (6.2%) ones.
The mean size of benign and malignant lesions were 6.011 and 7.481 cm, respec-
tively (P<0.05). Complication presented in 40 cases; pneumothorax occurred
in 37 (4.9%) and bleeding in 3 (0.4%) patients.

**Conclusion:** CT-guided needle biopsy seems to be a reliable diagnostic modality
with low risk probability of complications for thoracic lesions.

**P3665**

**An unusual opacity in lung lymphoma**

Nadia Bencharl, Ghanima Malki, Habib Donaugi. Respiratory Diseases, Issaud
Hassani Hospital Beni Messou, Algiers, Algeria

Pulmonary localization of lymphoma is rare. It presents mainly in young patients
with various histological features

**Study objective:** To show an unusual cause of lung cavity

**Method:** In order to illustrate the atypical radiological presentations of lung lymphoma. We report a retrospective serie of four cases of lymphoma collected in our server for the size and location of lesions and pneumothorax, diagnosis and then all CTs were double checked by the same radiologist. Lesions considered benign or malignant based on pathology reports.

**Results:** Among the four cases of lymphoma, two were malignant and two were benign. All diagnoses were proven histologically by bronchial and nodal biopsies. Peripheral nodes were appeared very late after pulmonary localization

**Conclusion:** This study discusses difficult to differentiate between primary lung lymphoma and bronchial carcinoma; tuberculosis with Hodgkin’s disease and MALT lymphoma.

---

**P3666**

**Lymphoma diagnosis on computed tomography guided needle aspiration and biopsy**

Mehrdad Bakhshayeshkaram, Pouyeh Graali, Soheyla Zahirifard. Radiology,
National Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran

**Background:** In recent years, CT-guided biopsy is going to be replaced with open
biopsy for Lymphoma diagnosis.

**Objective:** The aim of this study was to assess Lymphoma diagnosis on CT-guided
biopsy and to identify the complication rate of procedure.

**Methods:** We evaluated 78 CT-guided biopsies of mediastinal lesions performed
from March 2004 to December 2008, retrospectively. All biopsies were mostly spread
by one radiologist. The CTs were assessed by a trained general practitioner for the
size and location of lesions and pneumothorax or pneumomediastinum diagnosis
and then all CTs were double checked by the same radiologist. Lesions considered
benign or malignant and lymphoma based on pathology reports.

**Results:** Biopsy yielded sufficient tissue for pathologic examination in 63 cases
(80.7%); 14 lesions (17.9%) were benign and 49 lesions (62.8%) were malign-
ant. In malignant masses 15 Lymphoma (30.6%) and 20 other kinds of tumors
(46.8%) were found. Moreover, 1 Imalignant lesions had no differentiation. Among
Lymphoma lesions, there were 7 (46.7%) Hodgkin, 5 (33.3%) Non-Hodgkin Lymphoma
and 3 (20%) Lymphoma without differentiation. Pneumothorax or pneumomediastinum as complications did not present in any case.

**Conclusion:** CT-guided hilar biopsy seems to be reliable as a less invasive
diagnostic modality with low risk probability of complications for Lymphoma.

**Regional ventilation distribution in experimental sub-lobar acute lung injury**

Gunnar Elke1, Matthew K. Fuld2, Ahmad H. Halawesh3, Norbert Weiler4, Eric A. Hoffman5, Inez Freirich6. 1Department of Anaesethesiology and
Intensive Care Medicine, University Medical Centre Schleswig-Holstein, Campus
Kiel, Kiel, Germany; 2Department of Radiology, Division of Physiologic Imaging,
University of Iowa Carver College of Medicine, Iowa City, IA, United States; 3Department of Biomedical Engineering, University of Iowa, Iowa City, IA, United States

**Introduction:** Electrical impedance tomography (EIT) is able to trace ventilation-
related changes in electrical properties of lung tissue. Previous studies using
computed tomography (CT) suggested a good correlation between regional EIT
data and lung tissue density. However, no validation data exist in regional acute
lung injury (ALI).

**Objective:** To validate EIT measurements of regional ventilation (rVa) by dynamic
non-multidetector-row CT (Xe-MDCT) in two animal models of regional ALI:
Methods: 9 anaesthetized mechanically ventilated pigs were examined before and
after induction of ALI within two adjacent sub-lobar lung segments by repetitive
saline lavage (n=4) or endotoxin sepsis injury (n=5). EIT data were acquired at 25 scans
(GeoEM B system, Carefil Fusion, Hochberg, Germany). Xe-MDCT (Sensation 64, Siemens AG, Forchheim, Germany) was performed at the same
thoracic region. EIT and Xe-MDCT rVa images during control and ALI were
divided into 32 regions of interest (ROI) in each hemithorax. rVa differences for
both methods were obtained by subtracting the corresponding values in each ROI.
EIT and CT measurements were compared by Spearman’s Rho correlation.

**Results:** In 4 of 9 animals analyzed so far, rVa difference images revealed a ventilation decrease in the injured (right) lung and an increase in the non-injured
(left) lung compared to control. rVa changes occurred in spatially similar locations.
Spearman’s rho ranged from 0.931-0.936 for the right and 0.943-0.979 for the left
hemithorax in control. All ALI groups were 0.857-0.933 and 0.948-0.981, respectively
(p<0.001).

**Conclusion:** A good correlation existed of rVa determined by EIT and Xe-MDCT
in the 4 animals with regional ALI compared to date.

**P3668**

**CT findings in hantavirus pneumonia outbreak in children**

Aleksandar Ivkovic1, Tamara Milosavljovic2, Zoran Radovanovic1. 1Center of
Radiology, Clinical Center Ni, No, 2Radiology, 3Vrance, Vrance, Serbia

Hantaviruses belong to the Bunyaviridae family of viruses. Like all members of
this family, Hantaviruses have genomes comprising three negative-sense,
stranded, linear RNA segments, so called class I RNA viruses. Viruses in the genus Hantavirus are unique in that they are transmitted by aerosolized rodent excreta or rodent bites, whereas all other genera in the
Bunyaviridae family are arthropod-borne viruses.

**Aim of the study:** The main aim is to show cases of Hantavirus pneumonia in
child population.

**Material and methods:** We examined 23 child patients with confirmed Hantavirus
pneumonia. The youngest patient was 4 years old, the oldest 16. We examined all
patients on 16 or 64 MDCT.

**Results:** After the major flood we had few outbreaks, one of them was Hantavirus
infection with mainly pulmonary form. All patients were from rural parts with no medical
institution near, so patients went to medical care in late phase of illness. In the first
phase symptoms were similar or same as influenza like fever, chills, sweaty palms,
diarrhea, malaise, headaches, nausea, abdominal and back pain, tachycardia and
hypoxemia but in the late phase occur a lot of different symptoms. CT signs develop
rapidly and constantly, first one sided mostly near hilum but as time goes by illness
going on other side. First radiology sign is similar to bronchiolitis and after that
massive inflammation, than again bronchiolitis in next lung segment. In the lethal
cases (8, 34.78%) illness develop for two months, each day symptoms were worse.
We had 3 patients with massive hemoptysis and bleeding after hemodialysis.

**Conclusion:** Lung form of Hantavirus illness is very often lethal. Understanding
the way of developing can be vital for patient life.

**Radiological features of pneumocystis pneumonia (PCP) without HIV**

Nobuhiko Aso1, Yoshiohiro Okhi2, Ryo Matsunuma 1, Yoshihito Otsuka2, Norhiro Kaneko1. 1Pulmonology, Kameda Medical Center, Kamagawa, Chiba, Japan; 2Laboratory Medicine, Kameda Medical Center, Kamogawa, Chiba, Japan

**Purpose:** PCP occurs in immunosuppressed patients including those with malig-

---

**Framaceti SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30**
nancies. This study analyzed the relationship between the radiological features in chest X-ray and computed tomography (CT) of PCP patients without HIV and the outcome or patient’s background.

Methods: All 26 patients were diagnosed by respiratory samples combined with chest X-ray and CT findings. We retrospectively analyzed these data at the onset of the sickness.

Results: Twelve patients had malignancies. Fifteen patients had rheumatic and autoimmune disease. Steroid or immunosuppressive agents were administered in 72% and 40% respectively. Five patients received PCP prophylaxis. From a radiological point of view, chest X-ray revealed bilateral infiltration in 13 patients (52%). Chest CT showed a higher proportion of diffuse ground glass opacities (GGG) in 18 patients (72%). Consolidation and plural effusion were seen in 8 (32%) and 11 patients (44%) respectively and none had cystic lesions. All CT findings were classified as follows: 17 (68%) bilateral GGG either with sharp demarcation by interlobular septa (type A) or 4 (16%) without interlobular septal boundaries (type B). 2 (8%) infiltration mixed with GGG and consolidation (type C), 2 (8%) type D representing the rest cases. There was no correlation between these radiological features and outcomes.

Conclusions: Non-HIV PCP could show variety of radiological patterns and chest X-ray was not enough for the diagnosis of PCP. Despite our results, there still remains the possibility of the presence of the correlation of the radiological features or the patients background with the outcome and severity of PCP if more cases are studied. We expect more analysis to be done.

P3670
Primary versus acquired multidrug-resistant tuberculosis: Which are the true features of multidrug-resistant tuberculosis itself on thin-section CT
Inyoung Song1, Myung Jin Chung1, W. Koh2, Chin A. Y1, Kyung Soo Lee1, 1Departments of Radiology and Center for Imaging Science, Samsung Medical Center, Seoul, Korea; 2Division of Pulmonary and Critical Care Medicine at the Department of Internal Medicine, Samsung Medical Center, Seoul, Korea

Purpose: We designed this study to compare thin-section CT (TSC) findings of the primary multidrug-resistant (MDR) TB (MDR- P) and non-primary MDR TB (MDR-A) to those of drug-sensitive (DS) TB.

Materials and methods: We included 37 consecutive patients with MDR-P and 86 MDR-A who underwent TSC of chest. 123 patients with DS TB selected as a control group. Each DS TB patient was age and gender matched to a MDR TB patient. The frequency of lung lesion patterns in terms of tree-in-bud opacity/micronodules (TIB), nodule, consolidation, cavities, large fibrotic thin-walled cavity, and lobular volume decrease observed at TSC were compared among DS TB, MDR-P, and MDR-A.

Results: TIB (92%) and consolidations (76%) were most frequent findings of MDR-P. The frequencies of these are similar to those of DS TB (TIB for DS TB = 88%, p=0.561; consolidations = 81%, p=0.527). Cavities were next common finding of MDR-P (70%) and this frequency was similar to that of MDR-A (58%, p=0.260) than DS TB (38%, p=0.001). Volume decrease, large thin walled cavity, and pleural thickening were infrequent findings of MDR-P (22%, 5%, 1%, respectively) but common in MDR-A (56%, 30%, 42%, respectively), which mean chronic fibrotic condition.

Conclusion: Single or multiple cavities as well known typical feature of MDR TB are also common in MDR-P and not significantly different from MDR-A. In addition, MDR-P and DS TB reveal more common acute inflammatory findings (tree-in-bud pattern/micronodules, lobular consolidation, and overall consolidation) than MDR-A which reveal chronic fibrotic findings (thin walled cavity and volume decrease) in TSC.

P3671
Second year of H1N1 influenza: CT of the rare complications
Aleksandar Ivkovic1, Tamara Milosavljevic2, Zoran Radovanovic1, 1Center of Radiology, Clinical Center Nis, Nis, 2Radiology, ZC Vranje, Vranje, Serbia

It is a second year of pandemic H1N1 influenza. Patients from second year of outbreak have a lot of differences than first year patients.

Aim of the study: The main aim is to show cases of influenza from the second year of outbreak and CT signs of rare complications.

Material and methods: We perform lung CT on 102 patients with positive H1N1 influenza. Patients were from 16 to 42 years old. Male were 58, female 54. All patients were examined on 16 or 64 MDCT using standard procedure and virtual bronchoscopy; we used also MDCT angiography in cases with high D-dimer test.

Results: This year outbreak has 3 different forms. First and most common form is abdominal with almost no lung symptoms. Second form has mostly neurological symptoms with few lung symptoms. Third form of outbreak has high lung symptoms with coughing, hypoxemia, pulmonary hypertension, high body temperature, nausea, vomiting, headache, neurological disorder, high blood pressure. In all 3 groups after first wave of illness second wave was with lot of different complications. In 17 patients we discover mediastinitis. In 3 patients we discover forms of bilateral pneumonolamomatosis, in 6 patients we find pulmonary thromboembolism, in 5 we find injuries of alveolar wall, in 2 patients we find massive hemoptysis, in 6 patients we find bilateral lymphadenopathy, in 1 patient we find dissecting aneurysm of aorta. We had 10 lethal cases. If we compare results with first year the percent of lethal cases is similar, also number of thromboembolism but everything else is different.

Conclusion: Second year of outbreak bring us different form of complications. MDCT have a significant place in detection of all lung complications.

P3672
Pulmonary hydatidosis mimicking metastatic malignancy
Samira Aouadi, Imen Bachouche, Sonia Maalej, Meriem Mjid, Mahrezia Bourguiba, Ali Ben Kheder, Ikram Drira. Respiratory Department D, Abderrahmen Mami Hospital, Ariana, Tunisia

Scattered pulmonary nodules are usually highly suspicious of metastatic malignancy, but can be one of radiological presentations of some infectious diseases such as hydatidosis. In order to analyse particularities of pulmonary hydatidosis mimicking metastatic malignancy, we report 5 cases of patients hospitalized in the pulmonary department of the Tunis Chest Disease and Surgery Training Hospital. The average age was between 36 and 74 years. The clinical features were dominated by haemoptysis (4 cases) and cough (2 cases). Chest radiograph showed disseminated pulmonary opacities in all cases. CT scan of the chest was helpful for diagnosis. Fibreoptic endoscopy performed in all cases showed hydatid membrane and confirmed the diagnosis in 2 patients. Investigation ELISA for Echinococcus was positive in all cases. Four patients had pulmonary embolic hydatidosis due to the involvement of right cardiac cavities. One patient had bronchogenic hydatidosis due to the rupture of pulmonary cysts into bronchi. Medical treatment (albendazole) was performed in all patients associated with surgical treatment in 2 cases. After treatment, 2 cases of recurrence were noted.

Figure 1. Disseminated pulmonary hydatidosis.

P3673
Disseminated pulmonary hydatidosis. Disseminated pulmonary hydatidosis may present diagnosis difficulties particularly with metastatic malignancy. Its management is difficult and costly.

P3674
Does it matter who requests HRCT scans?
William Kent, Alexander Youzguin. Respiratory Medicine, Southport and Ormskirk NHS Hospital Trust, Southport, United Kingdom

Introduction: High resolution computerised tomography scanning (HRCT) is 660s
widely used for the investigation of interstitial lung disease (ILD) and bronchiectasis. If significant numbers of inappropriate scans were requested it could be argued that its use should be restricted to senior chest physicians only.

Methods: All HRCT scans performed over an eight month period between January - August 2009 at our hospital were identified and only those that had been performed as an initial investigation into suspected ILD/bronchiectasis were included. The x-ray card and clinic letters were analyzed to see who had requested them.

Results: 82 HRCT scans were eligible for inclusion. 30/43 (69.8%) of the scans requested by respiratory physicians confirmed the suspected diagnosis compared with 24/39 (61.5%) by non-respiratory physicians (p = 0.4892). 12/17 (70.6%) of the scans requested by respiratory trainees confirmed the diagnosis compared with 42/65 (64.6%) requested by consultant physicians (p = 0.7774).

Conclusion: There was no significant difference in the number of negative scans requested by non-respiratory and respiratory physicians or between respiratory trainees and Consultants. We therefore suggest that the use of HRCT scanning should not be restricted to senior respiratory specialists.

P3675 Lung tularemia in patients with tuberculosis presented by CT
Aleksandar Ivkovic1, Tamara Milosavljevic2, Zoran Radovanovic1. 1Center of Radiology, Clinical Center Nis, Nis, Serbia; 2Radiology, ZC Vranje, Vranje, Serbia

After the major flood we had outbreak of tularemia. Tularemia, also known as rabbit fever, is a disease caused by the bacterium Francisella tularensis. Depending on the site of infection, tularemia has six characteristic clinical syndromes: ulceroglandular, glanderous, oropharyngeal, pneumonic, oculoglandular, and typhoidal. Outbreak becomes more frequent with high rate of tuberculosis.

Aims: The main aim is to show cases of tularemia on patients with tuberculosis.

Methods: We examined 63 patients with acute form of lung tularemia who already had tuberculosis (from 186 patients with lung tularemia). Male patients were 48, female were 15. Patients were from 48 to 87 years old. We examined all patients had tuberculosis (from 186 patients with lung tularemia). Male patients were 48, female were 15. Patients were from 48 to 87 years old. We examined all patients on 16 or 64 MDCT.

Results: After the huge flow in several rural parts, there were outbreaks of tularemia. 186 patients were with syndromes of lung pneumonia with symptoms of fever, chills, headache, muscle aches, joint pain, dry cough, and progressive weakness. Patients also develop chest pain, difficulty breathing, bloody sputum, and respiratory failure. In 63 we find signs of all forms of tuberculosis. Developing of symptoms occurs faster in those patients with bizzare radiology signs from military form to caverns filled with acute areas of tularemia grow. CT findings of the lungs were developing in few steps with progression even when other symptoms were gone. First we find enlargement of the hilar region of the lungs and after few day illness develop into the lung parenchyma, firstly retro hilum and after that slowly on the whole lung, part by part with bronchiolitis.

Conclusion: CT has a significant role in determining and following all of form of lung diseases.

P3676 Interpretation of chest radiographs from children with lower respiratory tract infections
Martin Edwards1, Zoe Lawson1, Sue Morris1, Alison Evans1, Sara Harrison1, Jo Crocker2, Colin Powell1. 1Child Health, Children’s Hospital of Wales, Wales School of Medicine, Cardiff, United Kingdom; 2Department of Primary Care and Epidemiology and Statistics, Wales School of Medicine, Cardiff University, Cardiff, United Kingdom; 3Paediatric Radiology, University Hospital of Wales, Cardiff University, Cardiff, United Kingdom

Introduction: Pneumonia is a common diagnosis amongst children admitted to hospital. Diagnosis relies upon accurate chest radiograph interpretation. This study compared levels of agreement amongst paediatric clinicians and consultant paediatric radiologists when interpreting CXRs.

Methods: Four paediatric radiologists, independently interpreted 5 radiological features (and no features) for each of 30 CXRs, randomly selected from 100 radiographs attained over two years from children with fever & signs of respiratory distress aged 6 months to 16 years. The same CXRs were then interpreted by 21 other paediatricians with varying experience level. Agreement split by grade and specialty, was analysed using free-marginal multirater Kappa, assuming no prior expectation of the proportion of radiographs with each feature.

Results: Agreement (~1 relates to complete disagreement, 0 to chance agreement, and 1 to complete agreement)

Conclusion: Paediatric radiologists showed high levels of agreement for all features. Normal CXRs and pleural effusions were identified consistently amongst all 25 clinicians. However, interpretation of all other features had lower levels of agreement within non paediatric radiologists. This highlights the need for more rigid training in interpreting CXRs for paediatricians and the early reporting of CXRs by paediatric radiologists.

P3677 Usefulness of vibration response imaging (VRI) for pneumonia patients
Kwang Ha Yoo, Kye Young Lee, Sun Jong Kim, Won Dong Kim, Hee Jong Kim, Eugene Park. Department of Pulmonology, Internal Medicine, Konkuk University Hospital, Seoul, Korea

Background: Pneumonia is commonly seen in outpatient clinics, and it is the most common cause of death in infectious disease. Pneumonia is diagnosed by symptoms, chest X-ray and blood tests. chest X-ray and blood tests have its limitations and primary care clims usually do not have adequate diagnostic tools. VRI is a new diagnostic modality and the procedure is non-invasive, radiation-free, and easy to handling. The aim of this study was to evaluate the diagnostic usefulness of the VRI test in pneumonia patients and the correlation between other conventional test such as Chest X-ray, Laboratory tests and clinical symptoms.

Methods: VRI was performed in 57 patients who diagnosed with pneumonia in Konkuk University Medical Center. VRI was measured in a quiet room initially and after treatment. The change of Chest X-rays, CRP, WBC, Body temperature were compared with the change of VRI during time course.

Results: Mean age was 60 years, and average follow up periods was 7.1days. VRI, chest X-ray and CRP was significantly improved after treatment. Correlation with VRI and other test was not seen all patients. But female patients and relatively severe pneumonia patients showed correlation with VRI and chest X-ray.

Conclusion: This study demonstrates that VRI can be safely applied to patients with pneumonia.

P3678 Fungus ball diagnosed on computed tomography (CT) guided needle biopsy of thoracic lesions
Mehrdad Bakhshayesh, Pooeyeh Grahil, Soheyla ZahiriFarid. Radiology Department, National Research Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran

Background: CT-guided biopsy provides results in a short period and can be applied on outpatient and even high risk patients however; some studies do not recommend it in lesions with benign histology probability.

Objectives: To report our experience regarding fungus ball diagnosis on CT-guided biopsy and to identify the complication rate of procedure.

Materials and methods: We evaluated 99 CT-guided biopsies of infected thoracic lesions performed from March 2004 to December 2008, retrospectively. All biopsies were performed by one radiologist by westcott needle number 20 and 18. The CTs were assessed by a trained general practitioner for the size and location of lesions and pneumothorax or pneumomediastinum diagnosis and then all CTs were double checked by the same radiologist. Lesions considered fungus and their differentiations based on pathology reports.

Results: During four year study 20 fungus lesions (15 male and 5 female) were found with the mean age 54.75 years (ranging: 19-77). In these series there were 16 (80%) Aspergillosis, 2 (10%) Mucor mycosis and 2 undifferentiated fungus ball. The mean diameter of lesions and lesion distance to chest wall was 5.650 cm (range: 1 to 11.5) and 0.75 cm (range: 0 to 3), respectively. Nine (45%) fungus lesions were located in left upper, 4 (20%) in right lower, 4 (20%) in right upper and the rest (15%) in left lower and right middle lobes. Pneumothorax occurred in 2 cases (1 Aspergillosis and 1 Mucor mycosis) while chest tube was placed only in 2 cases (1 Aspergillosis and 1 Mucor mycosis) while chest tube was placed only for patient with Mucor mycosis to manage the complication.

TUESDAY, SEPTEMBER 27TH 2011
Methods: Patients with different indications for endobronchial biopsy underwent three hot and three cold endobronchial biopsies with a random fashion. All biopsies were obtained with a single biopsy forceps with and without the application of an electrocoagulation current, set on soft coagulation mode (120W). A four point scale was used for quantification of bleeding. A single pathologist blinded to the patients’ history was requested to review all samples. A three point scale was used to assess electrocoagulation damage.

Results: A total of 240 biopsies were obtained from 40 patients. Frequency of positive concordance between the two methods was 85%. The degree of electrocoagulation damage of the samples was as follows: grade 1=52.5%, grade 2=32.5%, and grade 3=15%. The average bleeding score following hot biopsy was significantly lower compared to the cold biopsy (p=0.006). The concordance between diagnostic yield of hot and cold biopsies was 85%. There was no significant difference between the diagnostic yields of two biopsy methods (p=0.687).

Conclusions: In this study, hot biopsy forces significantly decreased the procedure related bleeding and minimally impaired the quality of samples. Regarding low prevalence of bleeding following endobronchial biopsy, routine use of hot bronchoscopy forceps is not reasonable. However, familiarity of bronchoscopists with this method may improve bronchoscopy safety.

P3680
Evaluation of lung biopsy techniques for diagnosis of idiopathic interstitial pneumonias
Niiti Abhyankar, Jayshree Jain, Ajit Tambolkar. Department of Pulmonary and Critical Care Medicine, Poonam Hospital and Research Centre, Pune, Maharashtra, India

Aim: To assess and compare efficacy and safety of medical thorascopic lung biopsy with transbronchial lung biopsy (TBLB) for diagnosis of idiopathic interstitial pneumonias.

Material and methods: 59 patients with restriction on spirometry (Mean FVC -1.14 litres), exertional dyspnoea and interstitial pattern on HRCT (non classical for UIP) underwent lung biopsy using medical thoracoscopic forceps. 31 patients with comparable clinical profiles subjected to bronchoscopy and TBLB were used as controls.

Results: (Study group) Overall diagnostic yield was 98.3%. UIP (59.3%) was most frequent histopathological pattern. There were no intraoperative or immediate post-operative complications. Eventual complications included (in 19 patients) air leaks and prolonged ICD drainage (10), Delayed wound healing (3) and need for ventilatory support (5). Average duration of ICD was 4.81 days and average length of hospital stay was 6 days. There were 5 deaths within 1 month of the procedure (1 attributed to ischemic heart disease and Left ventricular failure, two to nosocomial pneumonia, two to unknown cause post discharge). Prolonged prior steroid use was single important factor associated with increased incidence of complications (14/23 complications in patients steroids vs. 5/16 complications in patients off steroids) (p<0.05).

In the control group conclusive diagnosis was reached in 3/31 cases (1Sarcoidosis, 1 DIP, 1 BOOP). Total score was before RT =3.1, just after RT = 5, at 3 months follow up = 4, at 6 months follow up = 3. Significant difference was observed between before and after RT (p=0.047) and between 3 months and 6 months (p=0.011).

Conclusions: 1. Medical thorascopocnic Lung biopsy has higher diagnostic yield than TBLB. (98.1% vs 97.3%) (p<0.001). 2. Prolonged prior steroid use is associated with increased incidence of complications (p<0.05).

P3681
Serial transbronchial biopsies in patients with lung cancer after radiation therapy
Georgia Karpathiou1,2, Vasilia Mihalidisi1,2, Alexander Giatriomonolaki1,2, Mihalis Koukourakis1,2, Paschalis Steiriopoulou2, Efthimios Sivridis1,2, Demosthenes Bourou5, Marios Froudarakis1,2,1 Pathology, Medical School Democritus University of Thrace, Alexandroupolis, Greece; 2Pneumonology, Medical School Democritus University of Thrace, Alexandroupolis, Greece; 3Radiation Therapy, Medical School Democritus University of Thrace, Alexandroupolis, Greece

Background: Radiation therapy (RT) may cause lung damage in patients with lung cancer. However, serial microscopic evaluation of human lung parenchyma after irradiation is lacking. Transbronchial biopsy (TBB) is a bronchoscopic sampling tool for a variety of bronchial and pulmonary lesions.

The aim of the present prospective study was to assess lung parenchyma lesions after RT by serial TBBs.

Methods: 14 patients with lung cancer necessitating radiation therapy agreed to participate the study. Of these patients, 12 (85.7%) were assessable. TBB were obtained to the opposite of the tumor. Serial TBBs were performed before, just after RT and every 6 months in the first year of follow-up. Evaluation of each specimen was based on the presence of congestion, inflammation, hemorrhage and fibrosis, all these parameters giving a final total score.

Results: A median number of 4 biopsies were taken per patient and per procedure (range 2-6). In 11/12 patients (91%) congestion was present within the period of follow-up. All these patients presented a late evolution of a different degree of fibrosis at their TBB. Total score was before RT = 3±1.3; just after RT = 5±1.3 and at 6 months = 6±1.9. Significant difference was observed before between and after RT (p=0.047) and before and at 6 months after RT (p=0.011). Major limitation of the study was the low patient accrual due to the proposed repeated procedures in patients with advanced stage disease and, at the end, poor performance status (overall median survival after RT 8 months).

Conclusions: An increase in the number of biopsies in irradiated patients may be associated with an increased incidence of complications. A total score of >6 suggests a significant degree of inflammation and fibrosis. Other parameters of radiation pneumonitis may also contribute to the final total score.
The combined conventional bronchoscopic methods are still useful in diagnosis of sarcoidosis

Lużkasz Kasper1, Krzysztof Sladek1, Jerzy Soja1, Mariusz Duplaga1, Filip Maćja1, Magdalena Mikos2, Piotr Grabarczyk1, Bożena Pawla1, Romana Tomaszewska1, 2Department of Medicine, Division of Thoracoscopic and Bronchoscopy, School of Medicine, Jagiellonian University, Cracow, Poland; 3Department of Medicine, Division of Radiology, School of Medicine, Jagiellonian University, Cracow, Poland.

Introduction: At present EBUS-TBNA and EUS-FNA methods are suggested as the best methods in diagnosis of sarcoidosis. Until now a lot of pulmonologists use the standard endoscopic procedures to confirm this disease. In our study we present the results of the combined conventional bronchoscopic methods such as endobronchial biopsy (EBB), transbronchial lung biopsy (TBLB), transbronchial needle aspiration (TBNA) in diagnosis of patients with suspicion of sarcoidosis.

Material and methods: 53 patients with suspicion of sarcoidosis (in stage 1 to 3) were sent to Division of Bronchoscopy for all 2009 year. The all patients were underwent bronchoscopy with simultaneous all three bronchoscopic methods. The presence of noncaseating epithelioid cell granulomas that correspond to clinical and radiological picture of sarcoidosis was observed in 94.33%. In only one patient the sarcoidosis was confirmed by EBUS-TBNA, and two others with acute sarcoidosis still remain under clinical observation.

Conclusions: The results of combined bronchoscopic biopsies are comparable to the results from EBUS and EUS studies. It might suggest that the combined conventional bronchoscopic methods are still useful and recommended to confirm sarcoidosis suspicion.

Safety and efficacy of outpatient bronchoscopy in lung transplant recipients: A single centre retrospective analysis

Jessica Rademacher1, Hendrik Sulhing1, Christoph Disberg1, Thomas Führer1, Florian Lünger1, Tobias Wele1, Jens Gottlieb1. 1Dpt. of Pulmonary Medicine, Hannover Medical School, Hannover, Germany; 2Dpt. of Pathology, Hannover Medical School, Hannover, Germany.

Bronchoscopy is an important diagnostic and therapeutic tool for the management of patients after lung transplantation. Out-patient bronchoscopy attempts to improve quality of life of transplant recipients and reduce health costs through reducing hospitalization. Limited data exists however, regarding safety and efficacy of outpatient bronchoscopy.

Between August 2008 and January 2011, we analysed outpatient bronchoscopies in our program. Post-bronchoscopy a routine monitoring for at least one hour, excepted patients with transbronchial biopsies, was performed. 3.197 outpatient bronchoscopies were performed in 571 lung transplant recipients. Analysis indicated a median bronchoscopic rate of 4 examinations per patient (interquartile range 10-20 minutes) was identified, 14% had intravenous sedation and 4% antitussive medication. Interventions performed included bronchial alveolar lavage (BAL) in 81%, transbronchial biopsy (TBB) in 23%, balloon dilatation in 4% and argon ablation.

Conclusions: Efficacy of TBLB plus BAL in sarcoidosis diagnostics was 102/127 (80.3%). Among the rest 38 cases with non-effective biopsy, diagnostic changes in BAL were found in 13 cases, total efficacy was 95/127 (75%). Among the rest 38 cases with non-effective biopsy, diagnostic changes in BAL were found in 13 cases, total efficacy was 95/127 (75%).

French national survey by the GELF on flexible bronchoscopy, patients, indications, results and complications

Bruno Escargueil1, Michel Febvre2, Valery Trosini-Desert3, Jean Michel Vergnon2, GELF Groupe d’Endoscopie de Langue Française 2. 1Pneumology Department, Hopital Saint Joseph, Marseille, France; 2Pneumology Department, Hopital Saint Antoine-APHP, Paris, France; 3Pneumology Department, Hopital Pitie Salpetrière-APHP, Paris, France.

Objective: Estimate the indications and the results of the flexible bronchoscopy in France in 2009.

Materials and Methods: The GELF led a forward-looking investigation in Mars 2009 with 150 pulmonologists distributed in a random way on the territory by a questionnaire of 2 patient cases. An extrapolation of procedures was realized over the year and on the number of worked days.

Results: A number estimated by 352 500 flexible bronchoscopies were realized in 2009. 64% of the procedures were made in public hospital and 36% in a private clinic. More of ¼ acts were made ambulatory or conventional hospitalization. In 74% of the cases, it was about an initial diagnosis. 2/3 of the patients had never had previous bronchoscopy. Average age: 62,5 years, 24% were women and 67% of smoking (39 PA). 48% were referred by the general practitioner. 72% of procedures were realized under local anesthetic. The main indications were the thoracic lesion (47%), the other one were, surveillance of bronchial cancer, low respiratory infection, hémoptysie, diffuse infiltrative lung disease, chronic cough, pleural effusion and suspicion of tuberculosis. The bronchoscopy was pathological in 59% of the cases. For more half, the histology revealed a bronchial cancer, mainly squamous cell (35%). The main complications were the bronchosopame (8%) and the bleeding (5%).

Conclusion: This survey of the GELF is the first study allowing the extrapolation of the number of annual bronchoscopies in France, the results and complications. The bronchoscopy allows on the national level, the diagnosis of a significant number of bronchial cancers.

ENDOBRONCHIAL ULTRASOUND USING A GUIDE SHEATH FOR PERIPHERAL PULMONARY Lesions: Experience From the First Year

Suvaraphan Charoentanyakan, Anan Wannatham, Amornchi Lertamornprong, Poonmapong Hansiriaphan. Pulmonary and Critical Care Division, Phramongkutklao Hospital, Bangkok, Thailand

Background: Transbronchial biopsy (TBB) for peripheral pulmonary lesions (PPLs) is usually performed with help of fluoroscopy, but the yield varies widely. This feasibility study aimed to assess ability of endobronchial ultrasound guide sheath (EBUS-GS) to provide imaging guidance for TBB.

Methods: Twenty-eight patients with PPLs were prospectively enrolled and underwent bronchoscopy with fluoroscopy and EBUS-GS procedure. In this procedure, the probe covered by a GS was introduced into the lesions via the working channel of bronchoscope. The probe was withdrawn, while the GS was left in situ. A brush or biopsy forceps were introduced through the GS into the lesions.

Results: Mean size of PPLs was 2.4±1.0 cm. Twelve of 28 patients (42.9%) was diagnosis by the EBUS-GS procedure. Also, the diagnosis was 30.8% (4/13) for benign disease and 80% (8/10) for malignant PPLs (p = 0.036). There was no statistically significant difference between diagnostic yield and size of the lesions, positive CT bronchus sign, and the EBUS probe located either within lesions or adjacent to lesions. Fortunately, no major complication was observed.

Conclusions: EBUS-GS is a safe and useful method for collecting samples from malignant peripheral pulmonary lesions.

EFFICACY OF TRANSBRONCHIAL BIOPSIES WITHOUT FLUOROSCOPY CONTROL IN DIAGNOSTICS SARCIOIDOSIS

Ilya Sinkovarov1, Olga Lovacheva1, Eugene Shmelev2. 1Endoscopy Department, CTRI RAMS, Moscow, Russian Federation; 2Granulomatosis Disease Department, CTRI RAMS, Moscow, Russian Federation

Background: Currently diagnosis of sarcoidosis, most common entity among interstitial lung diseases, should be confirmed by biopsy during bronchoscopy, with routine BAL. Unfortunately, sometimes there is no fluoroscopy control in bronchoscopy room, thus the yield of the obtained biopsies is considerably lower.

Aim: To evaluate the efficacy and safety of “blind” transbronchial biopsy (TBLB) with BAL during flexible bronchoscopy (FB).

Materials: 127 patients with newly diagnosed sarcoidosis undergo the FBS with TBLB and BAL. Frequency of pneumothorax/severe bleeding, median number of tissue samples, presence of lung tissue in sample, evidence of granuloma in histology and cytology, diagnostic changes in BAL were analyzed.

Results: There were 71 female in the group, mean age was 39.5 yrs, varied from 16 to 69. Mean duration of disease since first symptoms/chest abnormalities detection was 47.8 weeks. There were no cases of pneumothorax or severe bleeding after procedure. Mean tissue samples number was 3.1, varied from 1 to 6, median 2.

Lung tissue was observed in 118/127 cases (93%). Granuloma was found in 82 out of 118 patients (64.6%), in cytology additionally granuloma was found in 7 patients, so the total efficacy was 89/127 (70%). Among the rest 38 cases with non-effective biopsy, diagnostic changes in BAL were found in 13 cases, total efficacy of TBLB plus BAL in sarcoidosis diagnostics was 102/127 (80.3%).

CONCLUSION: Bronchoscopy with TBLB and BAL even without fluoroscopy control is effective and safe method of diagnostics in newly diagnosed sarcoidosis.
and its defining criteria were suggested as factors impacting the diagnostic value of TLBB. This study aimed at evaluating the factors affecting TLBB results in order to increase the diagnostic value of this method. This was a prospective, double-blind observational analysis. We had a total of 44 patients with pulmonary lesions; each of these patients underwent 4 biopsies. Biopsy samples were taken using cup and alligator forceps alternatively. From 88 samples obtained by the alligator forceps, 16 were diagnostic while from the same number of specimens taken by the cup forceps, 21 samples had diagnostic value. Of the small sized samples (57 cases), 12 (21.1%) were diagnostic while among the 66 medium sized samples, 12 (18.2%) and from the 53 large sized samples, 13 (24.5%) were diagnostic. Among samples floating on the surface of the liquid (48 cases), 6 (12.5%) had diagnostic value. Of the 12 samples suspended in the liquid, 2 (16.6%) and among the 116 samples precipitated to the bottom, 29 (25%) were diagnostic. Of the 84 samples with more than 20 alveoli, 31 (36.9%) were diagnostic. Among 26 samples with number of alveoli less than 20, 5 cases (19.2%) were diagnostic. This correlation was statistically significant. In a conclusion, number of alveoli present in the tissue sample was directly correlated with its diagnostic value. However, this study did not find a significant correlation between the diagnostic value of TLBB and type of forceps, sample size and flotation of the sample in the liquid.

P3690
Diagnostic value of the bronchoscopy in the focal pulmonary malignant lesions
Rocio Magdalena Diaz Campos, Ricardo Garcia Lujan, Rodrigo Alonso De Miguel Poch. Pneumology Service, Hospital Universitario 12 de Octubre, Madrid, Spain
Introduction: A focal pulmonary lesion (FPL) is defined as an intraparenchymatous pulmonary lesion that is well circumscribed and completely surrounded by healthy lung.
Objective: To analyze the diagnostic value of the fiberoptic bronchoscopy (FB) in the malignant FPL in the last 18 months, concurrently with a change in the medical staff.
Material and methods: Cross-sectional study of all the FBs done at our Unit between 02/2008 and 08/2009 in patients with a solitary FPL with a definitive diagnosis of malignancy. The diagnostic value by size and site was analyzed with Pearson’s chi² statistics.
Results: We studied 131 patients of whom 107 (82%) were men. The area around the site is showed in the table (in 7 cases, the size was not determined).

<table>
<thead>
<tr>

Possible to be determined (23 central and 1 peripheral). The media size of the FPL was 2.1 cm. The diagnostic value of the FB was 0.73 and of the TBB with 0.67. The combination of AFB and AFS is effective in determination of malignancy (P = 0.03). This correlation was statistically significant. In a conclusion, number of alveoli present in the tissue sample was directly correlated with its diagnostic value. However, this study did not find a significant correlation between the diagnostic value of TLBB and type of forceps, sample size and flotation of the sample in the liquid.

P3692
Combined endoscopic evaluation of the effectiveness of neoadjuvant chemotherapy of NSCLC using autofluorescence and spectroscopic methods
Yulia Kukalova1, Andrey Akopov2, Evgeny Levchenko1, Alexey Baranchuk1, Andrey Akopov2, 1Thoracic Oncology, N.N. Petrov Cancer Research Institute, St. Petersburg, Russian Federation; 2Surgical Pulmonology, Laboratory of Bronchology and Endoscopic Surgery, St. Petersburg State Medical University n.a. I.P. Pavlov under the Federal Agency for Healthcare and Social Development, Pulmonology Research Institute, St. Petersburg, Russian Federation
Objectives: To estimate the informativity of autofluorescence bronchoscopy and spectroscopy for evaluating the effectiveness of neoadjuvant chemotherapy (NCT) for lung cancer.
Material and methods: The study included 46 patients with central NSCLC IIIa/T1b stage who underwent 2-4 courses of platinum-based NCT. Endoscopy was done before treatment started and repeated each 21 day. Combined endoscopic investigation included: bronchoscopy in conventional mode (CB), spectroscopy in conventional mode (CS), bronchoscopy in autofluorescence mode (AFB) and spectroscopy in autofluorescence mode (AFS). Integrated system for autofluorescence and spectroscopy ClearVu Elite (Perceptronix Med. Inc., Canada) was used. The data obtained were compared with the results of histological study of biopsy samples from the respective sites.
Results: The sensitivity and specificity of the combination of AFB and AFS was 97.1% and 88.3%, respectively vs. CB and CS - 66.7% and 86.9%, respectively. Combined endoscopy revealed that the NCT was effective in 41.3% cases (n = 19 - partial endoscopic response), in 4 patients (10.3%) endoscopic tumor progression was found. Endobronchial spread of the tumor in 30.4% of cases (P = 0.03) was defined more accurately by AFB and AFS in comparison with CB and CS, it was important for choosing a volume of further resection. In 97.1% of cases, the data AFB and AFS is fully consistent with the results of histological studies (P = 0.02).
Conclusions: The combination of AFB and AFS is effective in determining margins of central lung cancer spread and effectiveness of NCT.

P3693
Changes of the pulmonary arteries in patient with pulmonary hypertension: Using optical coherence tomography
Elena Belyatko, N. Danilov, Y. Machin, I. Chazova, I. Chazova. Systemic Hypertension and Department of Endovascular Methods of Examination and Treatment, Cardiology Research Complex, Moscow, Russian Federation
Objective: To assess clinical using of optical coherence tomography (OCT) in patient with pulmonary artery hypertension (PAH).
Design and method: We studied the condition of vessels in a patient with systemic sclerosis and PAH. Our patient was a woman of 57 years. In the study, we used the following equipment specifications: IVUS (Eagle Eye Gold, catheter 40 MHz; In., USA), OCT (Light Lab Imaging Inc.) and general characteristics of different tissues by OCT.
Results: Cardiac catheterization showed pulmonary artery pressure of 90/20/35 mm Hg. Pulmonary capillary wedge pressure - 9 mm Hg. Both IVUS and OCT visualized the anterior basal segment pulmonary artery at the level of 16.3 mm (coronary area) by IVUS and at the level of 16.7 mm by OCT. Intima thickness was 0.41 mm by IVUS and 0.68 by OCT. We analyzed the tissue characteristics of the segment by OCT. We didn't find the scar borders, irregular borders or superficial signal. Thus we didn't find any features of calcium, lipids or mural thrombosis. The predominant tissue of the defected segment was homogenous bright tissue, e.t. fibrosis. We attempted to use radiofrequency analysis (VIH by IVUS), but, because of its lower resolution in the case of pulmonary arteries, in comparison to the coronary arteries, it turned poor information.
Conclusions: In the case of PAH IVUS looks like a method, which underestimates the intima thickness, in comparison with OCT. OCT enables to detect morphological features and possible injuries of the inner layer of the vessel wall. However, like any new technology, OCT will require a learning curve, to improve our ability and optimize treatment of patients with PAH.

P3694
Acriflavine-aided confocal laser-endomicroscopy for evaluation of central airway lesions
Sabine Zirlik1, Michael Vieth2, Jürgen Schubert2, Markus Frieser1, Kai Hildner1, Markus Neurath 1, Florian Fuchs1. 1Pulmonary Medicine, Università Cattolica S. Cuore, Roma, Italy; 2Pathology, Università Cattolica S. Cuore, Roma, Italy
Endobronchial ultrasound (EBUS) is a useful diagnostic tool to localize peripheral pulmonary lesions. Histopathological examination of these lesions is important for selecting patients eligible for surgical resection. A definitive diagnosis is often not possible, however, due to technical limitations of standard biopsy procedures. We report a patient with pulmonary artery hypertension (PAH). In the case of PAH IVUS looks like a method, which underestimates the intima thickness, in comparison with OCT. OCT enables to detect morphological features and possible injuries of the inner layer of the vessel wall. However, like any new technology, OCT will require a learning curve, to improve our ability and optimize treatment of patients with PAH.

Conclusion: The diagnostic value of the FB was 0.73 and of the TBB with radiographic guide was 0.53, being a difference by size but not by site.

P3691
Endobronchial ultrasound in the diagnosis of peripheral pulmonary lesions
Leonello Fuso1, Francesco Varone1, Andrea Smargiassi1, Riccardo Incichino1, Daniele Magnini1, Antonio Mule2, Guido Rind1, Salvatore Valent1
1Pulmonary Medicine, Università Cattolica S. Cuore, Roma, Italy; 2Pathology, Università Cattolica S. Cuore, Roma, Italy
Endobronchial ultrasound (EBUS) is a useful diagnostic tool to localize peripheral pulmonary lesions (PPLs) and to guide transbronchial biopsy (TBB). We retrospectively evaluated the diagnostic accuracy of EBUS-guided TBB in comparison with a definitive diagnosis established by transbronchial CT-guided needle aspiration or surgical lobectomy. In the last ten months, 168 patients performed bronchoscopy for a PPL (mean diameter = 3.5±2.1 cm). PPL was visualized in 123 patients (73%) and TBB was performed in 117 patients. These patients had a PPL larger than patients with a non visualized lesion (mean diameter 3.7±2.1 vs 2.3±1.6 cm, respectively). A definitive diagnosis was obtained in 77 patients whereas 40 patients were lost to follow-up. The TBB diagnosis was cancer in 45 patients and non-malignant lesion in 32 patients. The definitive diagnosis was cancer in 67 patients and non-malignant lesion in 10 patients: all these 10 patients without cancer were correctly diagnosed with TBB.

In conclusion, the sensitivity of EBUS-guided TBB in the diagnosis of cancer was 67% (45/67) and the overall diagnostic accuracy was 71% (45+10/77). Our data confirm that EBUS-guided TBB is a sensitive method with a high diagnostic yield in patients with PPLs.
Combined endoscopic evaluation of central lung cancer spread using autofluorescence and spectroscopy

Yuila Kalakova1, Andrey Arseney1, Evgeny Levchenko1, Anton Barkhuk1, Alexey Barkhuk1, Andrey Akopov1,2. Thoracic Oncology, N.N. Petrov Cancer Research Institute, St. Petersburg, Russian Federation;2Surgical Pathology, Laboratory of Bronchology and Endoscopic Surgery, St. Petersburg State Medical University, IP Pavlov under the Federal Agency for Healthcare and Social Development, Pulmonology Research Institute, St. Petersburg, Russia

Objective: To estimate the diagnostic value of autofluorescence bronchoscopy with spectroscopy in determination of lung cancer endobronchial spread.

Material and methods: The study included 78 patients with central NSCLC stage II-IV. Combined endoscopic investigation included: bronchoscopy in conventional mode (CB), spectroscopy in conventional mode (CS), bronchoscopy in autofluorescence mode (AFB) and spectroscopy in autofluorescence mode (AFS). Integrated system for autofluorescence and spectroscopy was used. The data obtained were compared with the results of histological study of biopsy samples from the respective sites.

Results: The sensitivity and specificity of the combination of AFB and AFS was 97.1% and 88.3%, respectively vs. CB and CS - 66.7% and 86.9%, respectively. Maximal diagnostic value had green-red ratio (GRR) • ratio of intensity in the green range (500-565 nm) to the red range (620-760 nm). For normal tissue mean GRR was 3.4±0.9, on the borders of tumor growth in 97% of the cases did not exceed 2.0 (mean 1.2±0.4) (p = 0.02), over areas of tumor tissue – in all cases less than 1.0 with an average of 0.7±0.2 (p = 0.001). In 97.1% of cases, the data AFB and AFS is fully consistent with the results of histological studies (p = 0.02).

Conclusions: Combination of AFB and AFS helps to objectively and accurately establish the boundaries of the tumor spread in bronchus/trachea.

Afibronectin and August band imaging videobronchoscopy in detection of premalignant bronchial lesions

Bojan Zaric, Branislav Pern, Svetlana Jovanovic, Evica Budisin, Goran Saric, Nena Lalic, Milan Antonic. Clinic for Pulmonary Oncology, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica, Vojvodina, Serbia

Background: The search for most efficient bronchoscopic imaging tool in detection of early lung cancer is still active. The major aim of this study was to determine sensitivity, specificity, positive (PPV) and negative predictive value (NPV) of each technique and their combination in detection of premalignant bronchial lesions.

Patients and methods: Ninety six patients were enrolled in the study. Major indications were: radiological suspicion for lung cancer, surveillance of patients after surgery, evaluation of known malignancy, positive sputum cytology and prolonged cough. Lesions were classified as visually positive if pathological fluorescence was observed under AFB or, dotted, tortuous and abrupt ending blood vessels were identified under NBI. Squamous metaplasia, mild, moderate or severe dysplasia and CIS were regarded as histologically positive lesion.

Results: Sensitivity, specificity, PPV and NPV of WLBI in detection of premalignant lesions were 26.5%, 63.9%, 34.4% and 55.4% respectively, corresponding values for AFI were 52%, 79.6%, 64.6% and 95.9% respectively, for NBI were 66%, 84.6%, 75.4%, 77.7%, respectively, while corresponding values for combination of NBI and AFI were 86%, 86.6%, 84.6%, and 88% respectively. Combination of NBI and AFI significantly improves sensitivity when compared to each individual technique (p<0.001). When specificity is of concern combination of techniques improves specificity of WLBI (p<0.001), specificity of AFI (p=0.03) but it has no significant influence on specificity of NBI (p=0.53).

Conclusion: Combination of NBI and AFI in detection of premalignant bronchial lesions increases both sensitivity and specificity of each technique.
Expansion Factors 2.76 Tant, 4.0 Omni & 4.9 Hypaque. Tantulum results in CT metallic artifacts, but appears distinct under fluoro. Omni-Hypaque have softer outline simulates “typical” nodules, but progressively leaches radioopacity over 4-6 hrs. Complications include traumatic pneumothoraces.

Conclusions: Transbronchoscopic delivery of Radioopaque Hydrogels effectively simulate tumors usable for development of bronchoscopy enhancement software, and as targets for animal lab practice.

400. A little bit of everything: interventional pneumology

P3700
Role of medical thoracoscopy in a developing country: A single unit experience from Sri Lanka

Dushantha Madagedara, Neranjun Dissanyake, Duminda Yasaratne, Chandana Kulathunga, Samadura Nakandala, Prasanne Wijerathne, Chathura Wirasunghe. Respiratory Disease Treatment Unit, Teaching Hospital, Kandy, Sri Lanka

Introduction: Medical thoracoscopy (MT) is proven as an effective tool in managing pleural disease, but is scarcely available in resource poor environments.

Objective: To describe the utility and safety of MT in managing exudative pleural effusions in the local setting.

Method: We retrospectively analyzed 96 MTs performed during past year in our unit.

Results: 8 MTs failed due to non-collapsible lung (6) and poor patient compliance (2). Of the 88 where visualisation of pleural cavity was possible, 51 had septate deposits (19), oesophageal rupture (2) and chylothorax (1) in the cohort. During postoperative hospital stay ranged between 2 to 21 days (mean: 3.4 days). The results were very good in 654 patients (88%), acceptable in 71 patients (9.6%), and there was a failure in 18 patients (2.4%) after 4 months follow-up.

Conclusions: Thoracoscopic talc pleurodesis is a safe, economical and effective treatment for malignant pleural effusion.

P3702
Classification of findings during medical thoracoscopy: Do they correlate with pathology?

Philippos Emmanuel1, Rodoulis Tringidou2, Dimitris Chiotis1, Magda Stratik1, Konstantina Kontogianni1, Nikolaos Koulou3, Sofia Anna Gemmita1, Spyros Zakynthinos1, Manos Anichatzis1, Gregoriis Stratik1. 1Fst Pulmonary Medicine Department of Athens University, "Sotiria" Hospital, Athens, Greece; 2Department of Pathology, "Sotiria" Hospital, Athens, Greece; 3Pulmonary and Critical Care Department of Athens University, "Sotiria" Hospital, Athens, Greece

Medical thoracoscopy although not always conclusive, has been established as the last step in the diagnostic approach of pleural effusion. We aimed to assess its diagnostic value and classify endoscopic findings in correlation with histology diagnosis.

During the last 5 years, 69 patients (55 males) aged 66±14 (mean±st.dev) underwent medical thoracoscopy in our unit for an undiagnosed exudative pleural effusion following extensive workup. Pleural biopsy revealed malignant pleural mesotheloma (MPM) of various subtypes in 16 (23.2%), non small cell lung cancer (NSCLC) in 9 (13%), extrathoracic malignancy in 3, paramalignant effusion in 2, angiosarcoma in 2 and Non-Hodgkin lymphoma in 1 patient. In 33 cases (47.8%) biopsy revealed chronic inflammation or "non specific pleurisy".

Endoscopic findings were classified as: pleural thickening, bulging, nodules, adhesions, diffuse infiltration, pleural masses, plaques, hemorrhagic appearance, visceral pleura invasion, pulmonary atelectasis. No significant correlations were found between endoscopic and pathology findings. However, parietal pleural mass had a trend of positive correlation with NSCLC (kappa=0.415, p=0.001) and a trend of inverse correlation with non specific pleurisy (kappa 0.35, p=0.001).

Medical thoracoscopy enabled specific diagnoses in more than 59% of prior undiagnosed cases in which all other means had been exhausted. High incidence of MPM in our patients is worth noting. The rest (47.8%) of the cases with non specific findings are continuously under follow up for a possible relapse or change in diagnosis. Endoscopic findings cannot predict final histology which remains the cornerstone of diagnosis.

Use of indwelling pleural catheters for management of recurrent chylothoraces: secondarily to benign superior vena cava syndrome: A case report

Fahad Al-Ghimlas, Saleh Alazemi. Medicine, Amiri Hospital, Sufat, Kuwait

We describe a unique case of intravascular (Hickman(c)) catheter-induced chylothoraces. They were treated with conservative measures and bilateral indwelling pleural catheters (PleurX(c)) insertion. The uniqueness of this case is that chylothorax re-appeared after re-institution of the patient diet, despite removal of the Port-
P3704

Impact of a new bedside thoracic ultrasound service in a large district general hospital: A service evaluation

Helen Standen1, Dr Paul Marsden2, Matthew Evison3, Graham Houldby3, Tarek Saba4. 1 5th Year Medical Student, University of Liverpool, Liverpool, United Kingdom; 2Respiratory Medicine, Blackpool Victoria Hospital, Blackpool, United Kingdom; 3 Radiology, Blackpool Victoria Hospital, Blackpool, United Kingdom

Background: In 2008, the UK National Patient Safety Agency (NPSA) issued an alert recommending the use of thoracic ultrasound to aid chest drain insertion (NPSA/2008/RR0003). Our institution is a large district general hospital in North-West England, serving a local population of approximately 330,000 people and a further 12 million holidaymakers who visit the area each year. In 2009, a Physician-Led Ultrasound Service (PL-US) was launched, in addition to the existing Radiology-Led Ultrasound Service (RL-US).

Aim: To investigate the demand for PL-US and the impact on workload and training.

Methods: We audited the number of procedures performed by physicians and radiologists from May-July 2008, 2009 and 2010.

Results: The total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. The proportion of RL-US procedures requested by respiratory medicine fell from 46% (11/24) in 2008 to 17% (4/24) in 2009 and 14% (4/29) in 2010, with the remaining RL-US procedures requested by other specialties. In addition, in 2010 a total of 24 thoracic ultrasounds were performed on respiratory patients, 20 of these 24 were performed by the PL-US, with the remaining 4 by the RL-US.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of chest medicine referrals to the RL-US has fallen by 64%. In addition, 83% of radiologists from each specialty who have used the service felt the training imparted to them was beneficial. Importantly, training opportunities for radiologists have not diminished as a result of this service.

P3705

Impact of teaching and awareness programme on doctors’ knowledge of chest drain insertion site

Mithun Murthy, Joanna Gallagher, Nicola Stevenson. Respiratory Medicine, Wirral University Teaching Hospitals, Upton, Wirral, United Kingdom

Aim: To assess if doctors identify correct site for chest drain insertion. To assess impact of teaching programme on their knowledge.

Methods: In 2008, 111 doctors were asked to identify correct drain insertion site for uncomplicated pneumothorax by marking photographs. Data were collected on grade, specialty and prior experience (Gallagher JL; Stevenson N. Thorax 2009; 64(Suppl IV):A166). In 2010, 102 doctors surveyed after introduction of teaching programme.

Results: We had 108 responses in ’08 compared to 100 in ’10. 55/108 (51%) correctly marked site in 2008 compared to 75/100 (75%) in 2010.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. The proportion of RL-US procedures requested by respiratory medicine fell from 46% (11/24) in 2008 to 17% (4/24) in 2009 and 14% (4/29) in 2010, with the remaining RL-US procedures requested by other specialties. In addition, in 2010 a total of 24 thoracic ultrasounds were performed on respiratory patients, 20 of these 24 were performed by the PL-US, with the remaining 4 by the RL-US.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. The proportion of RL-US procedures requested by respiratory medicine fell from 46% (11/24) in 2008 to 17% (4/24) in 2009 and 14% (4/29) in 2010, with the remaining RL-US procedures requested by other specialties. In addition, in 2010 a total of 24 thoracic ultrasounds were performed on respiratory patients, 20 of these 24 were performed by the PL-US, with the remaining 4 by the RL-US.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. The proportion of RL-US procedures requested by respiratory medicine fell from 46% (11/24) in 2008 to 17% (4/24) in 2009 and 14% (4/29) in 2010, with the remaining RL-US procedures requested by other specialties. In addition, in 2010 a total of 24 thoracic ultrasounds were performed on respiratory patients, 20 of these 24 were performed by the PL-US, with the remaining 4 by the RL-US.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. The proportion of RL-US procedures requested by respiratory medicine fell from 46% (11/24) in 2008 to 17% (4/24) in 2009 and 14% (4/29) in 2010, with the remaining RL-US procedures requested by other specialties. In addition, in 2010 a total of 24 thoracic ultrasounds were performed on respiratory patients, 20 of these 24 were performed by the PL-US, with the remaining 4 by the RL-US.

Conclusions: Overall demand for thoracic ultrasound has risen by 275% since the UK NPSA alert in 2008. Since introduction of the PL-US, the total number of procedures increased from 24 (all RL-US) in 2008 to 66 (29 RL-US and 32 PL-US) in 2009. Two cases of benign tracheal stenosis successfully treated by minimally invasive endobronchial intervention

**Case no. 1:** In Oct. 2008 a 71 y.o.lady underwent thyroidectomy. After the operation bilateral vocal cord paralysis appeared causing dyspnea. A tracheostomy tube was placed to ease breathing. In two weeks time vocal cord function came back, however attempt to remove tracheostomy tube was unsuccessful because of symptoms of tracheal obstruction. We met the patient in June 2009. FBS disclosed a mass of granulation tissue obstructing trachea. Microbiologic examination of bronchial aspirate showed MRSA infection. By using rigid bronchoscopy granulation tissue was removed and 15-mm straight silicone stent was placed in the narrowed segment of trachea and antibacterial treatment was prescribed. A couple of days later the stent migrated, so it had to be repositioned and sutured to the anterior wall of trachea by transcutaneous transtracheal suture. The stent was removed two months later. There are no signs of tracheal stenosis observed during the following 2 years.

**Case no. 2:** A 76 y.o. lady was operated on in Febr. 2009 for perforative colitis. Postoperatively she had tracheostomy placed with ventilatory support for a week. Soon after discharge from hospital the lady noticed cough and progressive dyspnea. She was admitted to our hospital in Sept.2009. On FBS we found granulation tissue mass obstructing trachea. There was Ps. aeruginosa grown in the bronchial aspirate. Granulations were removed by using rigid bronchoscope and endobronchial argon plasma coagulation and the patient received antipseudomonal antibiotics. The procedure had to be repeated in 3 weeks time. Afterwards our patient recovered well and there has not been recurrence of tracheal stenosis observed.

**P3709**

Comparison of I-gel and laryngeal mask for fibrobronchoscopy

Svilen Alexov, Dimitar Kostadinov, Danal Petrov, Anesthesia and Intensive Care Clinic, University Pulmonary Hospital, Sofia, Bulgaria; Bronchoscopy Department, University Pulmonary Hospital, Sofia, Bulgaria; Thoracic Surgery Clinic, University Pulmonary Hospital, Sofia, Bulgaria.

**Background:** The I-gel is a novel supraglottic airway device. Because of it’s design, material and small noninflatable cuff we hypothesized that it might be at least as effective as routinely used laryngeal mask (LM) in facilitating fibrobronchoscopy and artificial ventilation, but with less throat complaints.

**Objective:** To evaluate the efficacy of I-gel for providing adequate ventilation, good conditions for fibrobronchoscopy and patient’s safety under intravenous anesthesia in comparison with classically used LM.

**Methods and patients:** Two randomized groups were formed: I-gel (226pts) and ML (21pts). Anesthesia was induced and maintained with Propofol, Succinylcholine +/- Atracurium. Devices were positioned (size 4 for women and 5 for men) and IPPV with 100% O2 was started. We measured: time to successful insertion, success rate of insertion on first attempt, airway peak and leak pressure, We monitored the changes of tidal volumes (VT), airway peak pressures (PAW), end-tidal CO2, gas leakages (% of VT) when bronchoscope was at bronchial level. Postoperatively patients were interviewed for throat complaints, bronchoscopists for fibroscopic glotic view.

**Results:** The success rates of insertion were 21/22 (95%) for I-gel and 19/22 (90%). I-gel group showed significantly shorter mean time to insertion (12.2±6.9 vs 18.6±8.9 p<0.05), better fiberoptic view 3/22 (14%) vs 7/21 (33%) p<0.05 less postoperative complaints like soar throat, numb tongue, dysphagia, dysphonia, lip and dental trauma. 4/22 (18%) vs 8/21 (38%) p<0.05. Other postoperative data revealed no significant differences: VT, leak pressure, lost of VT and others.

Conclusions: I-gel facilitates fibrobronchoscopy and patient’s safety to greater extent than classical LM.

Feasibility and safety of propofol sedation in flexible bronchoscopy

Peter Greendkleimeier, Gabriel Kurer, Eric Pflihm, Michael Tammi, Daiana Stolz. Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital Basel, Basel, Switzerland

**Background:** Propofol is a sedative-hypnotic with a rapid onset of action. There are only limited data evaluating propofol for flexible bronchoscopy. We analyzed the feasibility and safety of propofol for bronchoscopy in a high output tertiary care center.

**Methods:** Prospective data on patients undergoing flexible bronchoscopy at the University Hospital Basel were included. Patient demographics, ASA class, Mallampati class, indication for bronchoscopy, bronchoscopic procedures, duration of examination, medication requirements, minor and major adverse events, hemodynamic parameters, as well as cough scores during the procedure were documented. Patients were followed up to discharge from the bronchoscopy suite.

**Results:** Data on 440 patients with mean age 60 years (± 15.5, 200 male) were analyzed. Most common diagnostic procedures were bronchoalveolar lavage in 253 cases (31.5%) and bronchial washing in 174 cases (21.7%). The mean duration of the procedure was 19.6 min (± 12.08). The mean propofol dose was 200 mg (± 107.5) corresponding to 1.9 mg/kg (± 1.70). Minor adverse events included transient desaturation in 72 (16.4%), hypotension in 68 (15.4%) and minor bleeding in 11 (2.5%) patients. No major adverse events were recorded. The median decline in systolic blood pressure after initiation of sedation was 14 mmHg (± 28). A drop in systolic blood pressure greater than 20 mmHg was observed in 166 of the 440 patients (37%).

**Conclusion:** Propofol sedation for flexible bronchoscopy is feasible and safe.

---

**P3711**

Predicting sedation in flexible bronchoscopy

Ruth Mc Donagh, Sheikh Shabbaz, John O’Neill, Eddie Moloney, Stephen Lane. Respiratory Medicine, Adelaide and Meath Hospital, Incorporating the National Children’s Hospital, Dublin, Ireland.

**Introduction:** Since 1985, midazolam has been widely used along with fentanyl for sedation in bronchoscopy. The aim of this study was to establish a correlation between patient age and the amount of midazolam required to produce adequate sedation.

**Methods:** Medical records of all the patients who underwent bronchoscopy in 2010 were accessed. Adequate sedation was defined as “a drug-induced depression of consciousness during which patients respond purposefully to verbal commands”.

**Results:** Of all patients (n=511), 54.4% were male and 45.6% female. Median age and dose of midazolam (range) was 60 years (16-91) and 6mg (0.14) respectively. The Spearman Rank correlation between sedatives and age were: midazolam (r= -0.486, p<0.000) and fentanyl (r= -0.396, p<0.000). Analysis of variance showed that every decade of increase in age saw a decrease in the dose of sedation required, and the difference in means of the dosage in each age group was statistically significant (p=0.000).

**Conclusions:** There is a statistically significant correlation between age and amount of sedative required. We can predict the dose of sedation required in flexible bronchoscopy in different age groups. Dose of one sedative agent can be used to predict the dose of the second.

**P3712**

A retrospective audit of lidocaine use at bronchoscopy in a UK district general hospital

Claire Lawless, Salim Meghjee. Respiratory Medicine, Pinderfields General Hospital, Wakefield, West Yorkshire, United Kingdom.

**Introduction and aims:** Bronchoscopy is a commonly used investigation and Lidocaine is widely used as a local anaesthetic agent. Toxic side-effects of Lidocaine include cardiac collapse and seizures. The recommended dose in cardiac/hepatic insufficiency is 5mg/kg and 8mg/kg in all other patients. It is postulated that some patients may be given above the recommended dose.

**Methods:** 26 patients were identified retrospectively over a 3 month period. The patients were identified on the hospital bronchoscopy database. Case-notes were also analysed.

**Results:** Patient Mean age was 62.25years (30-86). 12 males (46.15%). Patient weight 71.54kg (42.65-117). 5 patients had cardiovascular disease. 4 patients had hepatic disease. 7 (77%) of these 9 patients received a dose of Lidocaine over the maximum for their weight. None of the patients without cardiac/hepatic disease received over the maximum dose of Lidocaine. All patients who were given over their maximum calculated Lidocaine dose or who were given within 100mg of...
their maximum dose were reviewed with particular reference to their weight. The Mean weight in this subset was 60.6kg.

Discussion: Patients in this group were frequently given more than their calculated maximum dose of Lidocaine at bronchoscopy. Those most at risk had cardiac or hepatic insufficiency. Patients who were given too much Lidocaine or who were within 100mg of being given too much had a lower Mean weight than that of the whole of the group by 10.8mg.

Conclusions: Lidocaine use is necessary for patient comfort and success of bronchoscopy. However, it seems more commonplace than previously thought to give higher doses of Lidocaine than those recommended.

P3713
Patient comfort score at bronchoscopy
Alina Ionescu, Katie Pink. Respiratory Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom

The aim of this study was to assess the patient comfort score immediately after bronchoscopy (by nursing staff and patient) and later on at follow up (by patient) in a teaching hospital.

Subjects and methods: One hundred and four consecutive patients (62 male, mean (SD) age 63.2 (15.6)) were included and complete data was analysed for 96. The index for bronchoscopy was radiological suspicion of lung cancer (39), haemoptysis (25), slowly resolving pneumonia (18), radiological picture of interstitial lung disease (16), cough (4) and mediastinal lymphadenopathy (2).

The nurses used a patient comfort score (1-mild to 4-severe) and a sedation score (1-awake, 2-sedated). While in recovery and then again at follow up appointment (7-14 days later) the patients were asked to describe their comfort score (1-mild to 4-severe). Patients received Midazolam for sedation (1-7 mg i.v.) and local anaesthetic Lignocaine 2%.

Data was analysed in Spss and correlation coefficients; Chi square Kruskal Wallis used.

Results: The comfort score by nurses correlated with the score by patient in recovery (p=0.006) and at follow up (p=0.03). The two patient scores correlated (p=0.001, Pearson’s r=0.5). No difference in the comfort scores was found when the grade of the operator, dose of Midazolam, type of local anaesthetic, specimens taken, patient’s position or the recovery sedation score were taken into account.

To conclude, the patient comfort score assessed by nursing staff is a good indicator of the patient’s own perception of their discomfort at bronchoscopy. The patient perceived comfort score is not different after the sedation effect of Midazolam has worn off compared to the score assessed immediately after the bronchoscopy.

P3714
Patient satisfaction survey on bronchoscopy explanation
Rajesh Kumar Yadavilli, Ian Webster. Thoracic Medicine, Royal Bolton Hospital, Bolton, Lancashire, United Kingdom

Background: Bronchoscopy is routinely performed by the chest physicians and is data presented in the patients before they give written consent. We wanted to see if anxious patients need higher doses of sedation.

Methods: Patients were asked to fill the satisfaction questionnaire with 8 domains just before undertaking procedure. Interpreters were used for the non-English speaking patients.

Results: 61 patients, undergoing bronchoscopy between Jan 2009 to Jun 2009 answered survey questions with domains in (Table 1) rating their satisfaction between 1-10. Ratings >6 were considered good response except for domain 8 where <5 considered less anxious.

</table>

22% did not receive written leaflets. Of 27 anxious patients, only 7 (26%) needed more sedation than the mean dose of 2 mg midazolam and 6/34 (18%) less anxious patients also had bigger doses.

Conclusions: Patients were generally satisfied with our bronchoscopy explanation. There is poor correlation between anxiety ratings and doses of sedation. Educating trainees on broncoscopy explanation, repeating verbal information about procedure with patients at the time of consent and just before the test and giving written leaflets to all the patients at first explanation should improve overall satisfaction.

P3715
Fiberoptic bronchoscopy assisted percutaneous dilatational tracheostomy: How safe is for an intensivist to perform it?
Kyriaki Ftzikouktsis, Georgios Korotkamion, Christos Tsakalakis, Panagiotis Zotos, Nikodimos Katsarelis, Paraskevi Spyrou, Konstantinos Tsiromas, Michalis Pedemonos. ICU, General Hospital of Athens 'G. Germenis1', Athens, Greece

Background: Intensive care unit (ICU) patients, mainly those who need prolonged ventilator support, may require tracheostomy, which once was done in the operating room. Percutaneous dilatational tracheostomy was first described in 1985 and is now a well-established procedure that can be performed at the bedside by an intensivist with less surgical equipment required.

Aim: To evaluate the safety of performing percutaneous dilatational tracheostomy (PDT) with Fiberoptic bronchoscopy assistance in patients requiring prolonged mechanical ventilation.

Material and method: Sixty three patients 17-85yrs of age, 28 females and 35 males underwent PDT due to prolonged endotracheal intubation between December 2009 and January 2011. The procedures of percutaneous dilatation tracheostomy with guide wire dilator forceps (GWDF) were done bedside with bronchoscopic guidance under general anaesthesia in the ICU department. Operative and post operative complications were observed.

Results: Overall complication rate was low and occurred in 5 patients (7, 9%). There was no procedure-related mortality. Subcutaneous emphysema without pneumothorax occurred in one patient, one patient had a transitory hypotension related to sedation and three patients had peristomal oozing. The mean time for completion of the procedure was 15 minutes and no patient required conversion to surgical tracheostomy. The bronchoscopic examination that was performed in 38 of the patient 20 days after tracheostomy tube removal showed no scar formation.

Conclusion: PDT with bronchoscopic guidance is a safe and easy procedure that can be done by an intensivist at the bedside setting.

P3716
Outcomes and complications of bronchoscopy-guided percutaneous dilatational tracheostomy
Jose Andres Garcia Romero de Tejada1, Rosa Mar Gomez Punter 1, Ian Carrasco Barber2, Ricardo Andino Ruiz2, Javier Aspa Marco2, Olga Rajas Naranjo1, Servicio de Neumología, Hospital Universitario de la Princesa, Madrid, Spain, 1 Unidad de Cuidados Intensivos, Hospital Universitario de la Princesa, Madrid, Spain

Background: Percutaneous tracheostomy (PT) is one of the most frequently performed procedures in Intensive Care Unit (ICU). As many as 10% of patients requiring at least 3 days of mechanical ventilation will receive a tracheostomy. Some of the complications can be severe and can be prevented with bronchoscopic assistance.

Aim: To investigate the outcome and complications of bronchoscopy-guided PT.

Material and methods: 59 patients was prospectively included from March-November/2010. Demographic data, time of procedure and complications were monitored. Patient’s heart rate, blood pressure and continuous pulse oximetry were monitored. All PT were performed under bronchoscopic control at the patient’s bedside in the ICU by an medical intensivist and a pulmonologist. Statistical software Sigma-Stat 3.5 was used.

Results: 54% of patients: male. Patient mean age: 60. Mean body mass index: 25.2 (Standar Error Mean-SEM 0.5). Mean APACHE index: 20.1. SAPS: 44.5. The reason for admission at ICU was due to medical conditions (70%) and surgical/polytraumatism (30%). Indication for PT: coma (47%), intubation weaning failure (34%), neuromuscular failure (9.4%) and prolonged endotracheal intubation (9.4%). Mean duration of PT: 3.5 min. Main complications: O2 desaturation <90% (7.7%), submucosal tunnlealization of tracheal wall (3.8%), tracheal ring break (1.5%), bleeding requiring hemostasis (5.7%) and major hemorrhage requiring blood transfusion (2%). Extubation, early decannulation, injury to posterior tracheal wall, and barotrauma were not described.

Conclusions: PT is a safe technique. The use of bronchoscopy reduces duration of procedure, decreases morbidity and can identify complications missed by a “blind” approach.

The real-interventional-bleeding simulator: A new training and education model for interventional bronchoscopy
Martin Hackl1, Armin Saltzmann1, Michael Loeis2, Klaus Lenke2, Herbert Jannig1. 1Pneumologie, Thalk LH, Natter, Natters, Tirol, Austria; 2Arachtis, Prodesis, Heiligkreuzsteinach, Heidelberg, Germany

Introduction: Biosimulation models might play a crucial role to train interventional procedures especially acute endobronchial bleedings. The simulation of an repeated emergency situation enables the bronchoscopist and his team to act professionally.

Background: Until now the available models couldn’t reproduce this key aspect in interventional bronchoscopy in a satisfactory way.

Methods: We developed a new biosimulation model with 2 transparent covers and a free moving diaphragm. The control unit with an vacuum pump allows full...
Conclusion: This model might be helpful to develop algorithms for all interventional procedures especially connected to the handling of bleedings.

P3718
Improved diagnostic of electromagnetic navigation bronchoscopy in peripheral lung lesions: Are the size and the bronchus sign important?
Olga Rajas Naranjo, Rosa Mar Gómez Punter, Jose Andrés Gª Romero de Tejada, Emma Vazquez Espinosa, Julio Añócoche Bermúdez, Javier Aspa Marco.
Servicio de Neumología, Hospital de la Princesa, Madrid, Spain.

Background: Electromagnetic navigation (EN) is a technique that can be used with bronchoscopy to obtain samples of small peripheral nodular lesions. It enables both transbronchial biopsies and fine-needle aspiration to be performed. EN can obviate the need for more invasive diagnostic procedures thus saving time and avoiding complications.

Aim: To evaluate the diagnostic yield of electromagnetic navigation-guided bronchoscopy (ENB) in patients with peripheral lung lesions and analyze the results according to the size of the lesion and the presence of a bronchus sign in the computed tomography (CT).

Patients and methods: From April 2009–October 2010, 50 consecutive patients were included. We used the Bronchus® system (Superdimension) with a therapeutic bronchoscope (Olympus, working channel 2.8mm). All subjects had CT scans of the chest, configured with slices of 1-2 mm thickness at 1-1.5 mm intervals in DICOM format.

Results: 70%: male. Median age: 69. The average size of the lesions was 22.6 mm (≤20mm: 19 (38%) and >20mm: 31 (62%)]. Mean duration of the intervention: 25 mm. Diagnostic rate of this procedure was 67%; 61% for lesions ≤20 mm in diameter; and 71% if >20mm. The bronchus sign (BS) was identified in 44% of cases. In patients with BS, the diagnosis yield increased until 82% and when BS was negative: 54% (statistically significant variable).

Conclusions: FBEN is a safe method that increases the diagnostic yield of peripheral lung lesions. 67% of cases resulted in obtaining diagnostic tissue. If BS was identified, diagnostic yield was statistically significant increased. There was no relation with lesion’s size.

P3719
Transbronchoscopic 3D volumetric optical coherence tomography (OCT) imaging of airways
Jiefeng Xi1, Xingde Li2, MingYing Zeng3, Sheng Xu4, Rex Yung5, 1Whitaker Biomedical Engineering Institute, Dept of Biomedical Engineering, Johns Hopkins University, Baltimore, MD, United States; 2Whitaker Biomedical Engineering Institute, Dept of Biomedical Engineering, Johns Hopkins University, Baltimore, MD, United States; 3Medicine, Division of Pulmonary & Critical Care Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 4Department of Nuclear Medicine, St Antonius Hospital, Nieuwegein, Netherlands; 5Whitaker Biomedical Engineering Institute, Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Introduction: OCT, a non-invasive optical modality capable of high-resolution cross-sectional imaging of tissue microanatomy, holds potential of "in-vivo" diagnostics of pathology. Development of miniature probes & laser sources have advanced real-time OCT imaging of small structure such as airway morphologies.

Aim: To develop 3D volumetric OCT imaging of airways.

Method: IRB approved porcine protocol. Airways imaged with a 1300-nm swept-source OCT at a 40 kHz A-scan rate, placed within a 1.3 mm catheter advanced through 2 mm bronchoscope channel. Axial & lateral resolution of the system is ≤2 μm and ~20 μm in tissue, respectively. 3D volumetric imaging achieved by rotating the OCT catheter while pulling it back (similar to spiral CT), at an imaging speed of 10 frames/sec & helical rotation pitch of ~100 μm.

Results: 3rd to 7th generation airways imaged, spiral scanning data recorded, then processed. In addition to presentation as isolated axial slices, playback can present spiral imaging reformatted as 3D volumes plus virtual fly-through of airways.

Conclusion/clinical significance: Transbronchoscopic OCT imaging can generate high-res axial imaging of airway microstructures. Reconstruction of dataset generates dynamic 3D imaging. In-vivo temporal monitoring of pathologic events such as cancer progression or physiologic effects of bronchoconstriction in airway disease will advance diagnosis and management of lung diseases.
with chronic sarcoidosis remain unclear. We wanted to assess clinical benefit and safety of long-term infliximab treatment in patients with chronic steroid-resistant sarcoidosis.

Methods: A retrospective chart review of all patients with chronic steroid-resistant sarcoidosis who received infliximab between January 2003 and November 2010. Pulmonary function tests and index lesions before and after infliximab therapy were assessed.

Results: 28 patients received infliximab, 16 of them for more than 12 months. 5 (31%) of these 16 patients with long-term infliximab treatment had a predominately pulmonary and 11 (69%) a predominantly extrapulmonary disease. Mean duration of treatment was 29 months (range 12 - 62). 6/11 (55%) patients with mainly extrapulmonary sarcoidosis showed a complete remission of their index lesion, 4/11 (36%) had a partial remission, and 1/11 (9%) showed no response. 1/5 patient with predominantly pulmonary sarcoidosis showed a >10%-improvement of percentage predicted forced vital capacity (FVC/P%); 3/5 showed a 0.10%-improvement, and in 1 patient FVC/P% declined. Thus, overall 14/16 (88%) patients profited from long-term infliximab treatment. Suspected adverse effects which lead to a temporarily discontinuation of infliximab therapy were noticed in 1/16 (6%) patient.

Conclusions: This retrospective study indicates that long-term infliximab is very efficient and safe in patients with chronic steroid-resistant sarcoidosis when assessed with individualized treatment targets. Patients with predominantly extrapulmonary sarcoidosis seem to profit more than patients with predominantly pulmonary disease.

P3724 Interferon gamma release assays in screening for tuberculosis – Can we use them in patients with sarcoidosis?

Nils Milman1, Claus B. Svendsen1, Bolette Sobo1, Aase B. Andersen2
1Department of Rheumatology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; 2Department of Respiratory Medicine, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Treatment with tumour necrosis alpha (TNF-α) inhibitors has been introduced in recalcitrant sarcoidosis. These biologics may reactivate a latent tuberculosis infection (LTBI) and sarcoidosis patients are routinely LTBI tested before receiving TNF-α inhibitors. Until now, the tuberculin skin test (TST) has been used for LTBI screening among sarcoidosis patients in Denmark, even though the TST is unreliable with a low sensitivity in this specific group of patients. This study reports the results of an LTBI screening among sarcoidosis patients in Denmark. Background: Cardiac sarcoidosis (CS) is an inflammatory condition of the heart. It can be associated with a variable degree of morbidity and mortality.

Methods: We conducted an observational study to examine factors affecting survival in patients with sarcoidosis. Totally 122 patients with biopsy-proven sarcoidosis enrolled, underwent pulmonary function tests, a 12-lead electrocardiogram, an echocardiogram and a 24-hour Holter monitoring. Cardiac sarcoidosis was detected based on known criteria. All-cause mortality and cardiac death were the primary and secondary endpoints.

Results: During a median of 58.89±15.75 months follow-up, ten deaths (8.2%) were reported. The demographic characteristics of the survivor patients and those who died are presented in table 1.

Five patients (4.1%) died due to cardiac causes. Cardiac involvement was detected in 40 patients (32.8%). The multivariate analysis showed age, standard deviation of RR intervals < 0.00 ms, TLC < 80% of the predicted, DLCO < 80% of the predicted and the cardiac involvement were independent risk factors of all-cause mortality.

Conclusion: The thorough evaluation of the results from a full cardiopulmonary monitoring in patients with sarcoidosis may be able to detect factors related with increased risk of mortality.

P3723 Long-term treatment with infliximab in patients with sarcoidosis

Karin Hoistetter1, Ulle Stueller1, Michael Tamm1, Martin Brutsche2, 1Clinic of Respiratory Medicine, University Hospital Basel, Basel, Switzerland; 2Department of Radiology, University Hospital Basel, Basel, Switzerland

Background: Long-term benefit and safety of infliximab treatment in patients with chronic sarcoidosis remain unclear. We wanted to assess clinical benefit and safety of long-term infliximab treatment in patients with chronic steroid-resistant sarcoidosis.

Methods: A retrospective chart review of all patients with chronic steroid-resistant sarcoidosis who received infliximab between January 2003 and November 2010. Pulmonary function tests and index lesions before and after infliximab therapy were assessed.

Results: 28 patients received infliximab, 16 of them for more than 12 months. 5 (31%) of these 16 patients with long-term infliximab treatment had a predominately pulmonary and 11 (69%) a predominantly extrapulmonary disease. Mean duration of treatment was 29 months (range 12 - 62). 6/11 (55%) patients with mainly extrapulmonary sarcoidosis showed a complete remission of their index lesion, 4/11 (36%) had a partial remission, and 1/11 (9%) showed no response. 1/5 patient with predominantly pulmonary sarcoidosis showed a >10%-improvement of percentage predicted forced vital capacity (FVC/P%); 3/5 showed a 0.10%-improvement, and in 1 patient FVC/P% declined. Thus, overall 14/16 (88%) patients profited from long-term infliximab treatment. Suspected adverse effects which lead to a temporarily discontinuation of infliximab therapy were noticed in 1/16 (6%) patient.

Conclusions: This retrospective study indicates that long-term infliximab is very efficient and safe in patients with chronic steroid-resistant sarcoidosis when assessed with individualized treatment targets. Patients with predominantly extrapulmonary sarcoidosis seem to profit more than patients with predominantly pulmonary disease.
15%, p<0.001). Extra-respiratory involvement of sarcoidosis was less frequent (21 vs 47%, p=0.04) in patients as well as residual granulomatous activity, as judged by serum angiotensin converting enzyme and HRCT signs. However, mortality was similar between the two groups.

Conclusion: The phenotype of patients with HC is original. An exposure to inhaled particles may play a role in the development of this particular fibrosis evolution and explain the local respiratory severity of sarcoidosis while the disease seems less active and severe from a systemic point of view.

P3726
Thyroid disease in an Irish cohort of sarcoidosis patients
Melissa McDonnell, Imran Saleem, Robert Rutherford, Anthony O’Regan, J.J. Gilmore. Respiratory Medicine, University Hospitals Galway, Galway, Ireland

Introduction: Sarcoidosis is a multisystem disease of unknown aetiology with prevalence rates in the West of Ireland being among the highest in the world. Sarcoidosis is attributable to an altered or incomplete immune response to an auto- or alloantigen in genetically susceptible hosts. The association of sarcoidosis and thyroid disease has been described in numerous studies with a range of variability. Baseline prevalence rates for thyroid disease in the population range from 0.1 to 3%.

Objectives: The purpose of our study was to estimate the prevalence of thyroid disease in a cohort of sarcoidosis patients in the West of Ireland.

Methods: Using our patient database from 1983-2009, we retrospectively identified those who had thyroid function testing (TFTs) and reviewed the clinical indication, treatment and related physiological, radiological and treatment findings.

Results: 139/4907 (34.2%) had TITs. Of these, 24/139 (17.3%) were abnormal with 15/139 (10.7%) hyperthyroid and 9/139 (6.5%) hypothyroid. Mean age was 40.3yrs (median 37) with M:F ratio of 1.2. Mean time to diagnosis was 5.8yrs. There was no relationship with presentation, lung function, radiological stage or treatment of sarcoidosis. There was no association with hypercalcaemia, hypercalcuria, coeliac or other autoimmune disease.

Conclusion: We have demonstrated a moderately increased prevalence of thyroid disease on follow-up of Irish patients with sarcoidosis particularly in relation to hyperthyroidism. This is in contrast to Antonelli who reported a high prevalence of hyperthyroidism. This is in contrast to Antonelli who reported a high prevalence of hyperthyroidism. Further investigation is needed.

P3727
Pulmonary hypertension and right ventricular impairment in patients with sarcoidosis
Nina Karoli, Andrey Rebrev. Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation

There is little date about frequency of pulmonary hypertension (PH) and right ventricular (RV) impairment in patients with sarcoidosis. In this work we examined the prevalence PH in these disorders using noninvasive cardiopulmonary evaluation. 33 patients (aged 50,64±2,8y) with sarcoidosis have been studied. 8 pts was with R I stage and 26 with IIIE stage of sarcoidosis. Criteria of exception were the clinical patients who had heart arrhythmia and heart heart hypertrophy. Control group was made 14 normotensive patients (aged 47,57±1,86). All patients were studied using realtime, phased array, two-dimensional Doppler echocardiography. The pulmonary artery systolic pressure (SP) was calculated as the sum of the transmucipudal pressure gradient and the right atrial pressure.

Methods: PH (SP>35 mm Hg) is revealed at 18 patients (52.9%) and 10 pts (30.3%) had SP > 40 mm Hg. Doppler-estimated SP at the patients with sarcoidosis exceeded SP at the healthy persons (p<0.001). RV hypertrophy was present in 84,8% patients (p<0.001 with controls). RV dilation was present in 90% patients with sarcoidosis (p<0.001). Right atrial diameter in patients with sarcoidosis was higher than at the healthy persons (p<0.001). RV wall in patients with sarcoidosis was higher than at the healthy persons (p<0.001). RV diameter in patients with sarcoidosis was higher than at the healthy persons (p<0.001). RV diastolic dysfunction we noted in 58.3% pts.

We noted a correlation between SP and MRS scale (r=0,52, p<0,01). RV diameter was present in 90% patients with sarcoidosis (p<0.001). Right atrial diameter in patients with sarcoidosis was higher than at the healthy persons (p<0.001). RV diastolic dysfunction we noted in 58.3% pts.

Conclusion: Pulmonary hypertension and right ventricular abnormalities is common in patients with sarcoidosis.

P3728
Clinical and morphological signs of liver damage in patients with pulmonary sarcoidosis
Marina Lebedeva1, Irina Popova1, Elena Popova2, Andrew Ponomarev2, Elena Arion3,4.1, Pulmonology, Moscow Sechenov Medical University, Moscow, Russian Federation; 2Pathology, Moscow Sechenov Medical University, Moscow, Russian Federation; 3Hepatology, Moscow Sechenov Medical University, Moscow, Russian Federation

The aim of our study was to identify clinical and morphological signs of liver damage in patients with pulmonary sarcoidosis.

Patients and methods: 65 patients with morphologically proved pulmonary sarco- idosis were examined. Pulmonary function testing, high-resolution CT (HRCT), liver tests were evaluated. Biopsy of lung (65), liver (52) were performed. Biopsy of liver were performed of the signs of cytolisis and/or cholestasis were present.

Results: 65 patients had markers of active pulmonary sarcoidosis: respiratory fail- ure which correlated with HRCT signs of activity such as ground - glass opaque (p<0.003) and morphology of specific granulomatosis. 52 patients also presented slight hepatomegaly, signs of cytolisis (AST 1,2-2,5 norms, ALT 1.3 - 2.7 norms) and/or cholestasis (GGT 1,6-3,4 norms) which correlated with morphological signs of liver granulomatosis: the non-casecting granulomas were in all biopsies, three types of histologic change were found: inflammatory (78%) cholestatic (51%), and vascular (19%). Inflammatory changes included inflammation suggestive of chronic active hepatitis. Among those with cholestasis, 9 had a pattern of perifiductal fi- brosis. Vascular changes consisted of sinusoidal dilatation (3 cases) and nodular regenerative hyperplasia (7 cases). No cirrhosis were found.

Conclusion: Liver involvement can be considered as a marker of extra-pulmonary activity in pulmonary sarcoidosis.

P3729
Diagnostic value of epithelioid cell granulomas in bronchoscopic biopsies
Edvardas Danila1,2, Edvardas Zaraukas1,3, Rolandas Zablickis2,3, Vygantas Gruslys1,2.1 Clinic of Chest Diseases, Allergology and Radiology, Vilnius University, Vilnius, Lithuania; 2Centre of Pathology and Allergology, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania; 3Department of Pathology, Forensic Medicine and Pharmacology, Vilnius University, Vilnius, Lithuania. 1Examination of Airways and Biopsies, Lithuanian National Centre of Pathology, Vilnius, Lithuania

Background: The granulomatous inflammatory response is a manifestation of many lung diseases.

Objective: To evaluate the diagnostic value of epithelioid cell granulomas in bronchoscopic biopsies in daily clinical practice.

Methods: The data of 157 consecutive patients with epithelioid cell granulomas in biopsy tissue who had undergone the bronchoscopic lung biopsy or bronchial biopsy were examined. All cases were divided into non-necrotizing epithelioid cell granulomas and epithelioid cell granulomas with necrosis.

Results: Of the all cases 108 had non-necrotizing epithelioid cell granulomas and 49 had epithelioid cell granulomas with necrosis. With respect to the presence of necrosis in granulomas, the majority of the patients had sarcoidosis or tuberculosis (34%). 95% of the patients with sarcoidosis had non-necrotizing epithelioid cell granulomas and the remaining 5% had granulomas with necrosis. The sensitivity of non-necrotizing epithelioid cell granuloma for the diagnosis of sarcoidosis was 95% and specificity 57%. The positive and negative predictive values were 69% and 92%, respectively.

Conclusion: A significant overlap in types of granulomatous inflammation between tuberculosis and sarcoidosis was found. The type of epithelioid cell granuloma alone was not sufficient for the final clinical diagnosis.

P3730
Is sarcoidosis associated with increased occurrence of malignancy? A retrospective analysis
Martina Doubkova, Ilona Binkova, Jana Skrickova. Department of Pulmonary Medicine, University Hospital Brno, Czech Republic

Background: There are few reports with ambiguous results concerning the rela- tionship between sarcoidosis and malignancies. The incidence and prevalence of malignancies in sarcoidosis patients with a malignancy was 68 years (44-75). The women:men ratio was 4:1. All patients were non-smokers. Median time from diagnosis of sarcoidosis to the malignancy was 6.5 years (0-14).

Methods: We performed a retrospective analysis in our cohort of 170 sarcoidosis patients. We compared the incidence and prevalence of malignancies in sarcoidosis patients with the incidence and prevalence of malignancies in the normal population (Czech Oncology Registry data). Data from years 2005-2007 were analyzed.

Results: The analysis only included patients with sarcoidosis diagnosed prior to malignancy, or patients with malignancy discovered simultaneously with sarcoidosis.

Results: Out of our sarcoidosis patients, 5 of them were diagnosed with malignant tumors (3 breast cancers, 1 colorectal carcinoma, 1 non-Hodgkin lymphoma). The median age of sarcoidosis patients with a malignancy was 68 years (44-75). The women:men ratio was 4:1. All patients were non-smokers. Median time from sarcoidosis diagnosis to malignancy was 6.5 years (0-14). Calculated prevalence of malignant diseases in patients with sarcoidosis was: 813/100000 (2005), 2379/100000 (2006), and 2941/100000 (2007). In the Czech population, the preva- lence of all malignant diseases between 2005-2007 was 3522-3856/100000. In patients with sarcoidosis, calculated incidence of malignancies in the monitored period was: 0 (2005), 2054/100000 (2006), and 588/100000 (2007). The incidence of all malignant diseases in the Czech Republic was 698-738/100000.

Conclusion: We do not prove the statistically significant difference in the inci- dence and prevalence of malignancies between sarcoidosis patients and general population.
P3731

QRS-T angle significantly increased in sarcoidosis patients

Elias Gualano1, Anastassia Kallianos2, Vasilios Koumanos1, Maria Ntouskou1, Eleni Takitou1, Elias Peros3, Lemonia Vlentza2, George Dionelis4, Charalampos Kostopoulos3, George Mathioudakis4, Ioannis Arapis1,2,3

Introduction: Aim of the study was the evaluation of the QRS-T-angle, a novel marker of ventricular repolarization, in asymptomatic patients with sarcoidosis and investigation of the relationship between QRS-T-angle and occurrence of ventricular arrhythmias.

Methods: The ECG derived QRS-T-angle was calculated in 112 sarcoidosis patients. The QRS-T-angle was assessed compared to control groups, both subgroup analysis showed that patients with CI and Lown >3 had significantly elevated QRS-T-a.

Results: The ECG derived QRS-T-a of 112 sarcoidosis patients was calculated while cardiac involvement (CI) was assessed based on known criteria. Assessment of the ventricular arrhythmias was based on the Lown classification criteria. All patients were compared to 65 healthy controls. Results: 36/112 patients fulfilled the criteria of CI while 15 patients were classified as Lown 4A and 4B. The QRS-T-a of sarcoidosis patients was significantly increased compared to controls, while subgroup analysis showed that patients with CI and Lown >3 had significantly elevated QRS-T-a.

Conclusion: QRS-T-angle can be considered to be a marker of extra-pulmonary granulomatous lesions in sarcoidosis.

P3734

Serum angiotensin converting enzyme (ACE) as additional clinical markers of activity of pulmonary and extra-pulmonary locations of sarcoidosis

Marina Lebedeva1, Elena Popov2, Andrew Ponomarev2, Bolyshev Serg2,3

1Department of Pulmonary Medicine, Moscow Medical University, Moscow, Russian Federation; 2Pathology, Moscow Sechenov Medical University, Moscow, Russian Federation

Introduction: Aim of the study was to identify additional clinical predictors of activity of extra-pulmonary locations in sarcoidosis patients.

Patients and methods: 107 patients with histologically proved pulmonary sarcoidosis were examined. Pulmonary function testing, high-resolution CT (HRCT), echocardiography, daily ECG monitoring, myocardial scintigraphy, renal tests were evaluated. Biopsy of lung (107), skin (74), kidney (13), liver (52) and heart (4) were performed. Biopsy of organs were performed if the suspected specific sarcoid organ failure. Serum concentration of ACE levels were determined with a spectrophotometric method.

Results: 57 patients presented sings of clinical and morphological activity of sarcoidosis (group 1), 50 without parameters of activity (group 2). Clinical and morphological signs of extra-pulmonary locations of sarcoidosis were in 32 active patients, in 7 – not active patients. Granulomas were found in skin (33,8%), heart -1, in liver (37,1%), in kidney (5 38%). Elevation of serum ACE were more in the 1st group: 63,7 (49,1- 79,8) micrograms/L vs 43,1 (32,5-47,2) micrograms/L in the 2nd group (p=0,0021). Level of serum ACE directly correlated with HRCT stage of activity as such as grade -opaque (p=0,0045) and morphology of specific granulomatous extra-pulmonary changes (p=0,0047).

Conclusion: Level of serum ACE can be considered to be a marker of extra-pulmonary granulomatous lesions in sarcoidosis.

P3735

Manifestations of malignancies during the course of sarcoidosis

Jelica Videnovic-Ivanov, Violeta Vucinic, Snezana Filipovic, Vladimir Zuzic, Jelena Stojic. Pulmonology, Clinic for Lung Diseases and Tuberculosis, Belgrade, Serbia

Introduction: Sarcoidosis is the granulomatous disorder with chronic course which can involve any organ in human body. Coexistence of two disorders is potential.

Method of the work: Analysis were retrospective. All patients with histologically proved sarcoidosis were obtained. Patients were ambulatory or hospital treated in the Clinic for lung diseases and tuberculosis. Malignancies were also histologically proved.

Results: Among 1307 patients with sarcoidosis (ACCES group, ERS) only 15 patients with malignancies were obtained. Mean ages were 47.3 years, and 11 F/4 M ratio was found. In 5 patients malignacies were the first obtained diagnosis in patients life as followed: carcinoma mammae (2 patients), carcinoma renis, fibrosarcoma and chronic leucemia. The mean time in which were made diagnosis was - 3.1 years. All patients were treated for carcinoma, till nowadays. In 11 patients, malignancies followed the sarcoidosis in mean time of 7.7 years. M. Hodgkin, adenocarcinoma ovarii, melanoma malignum, carcinoma cutis (3 female patients), adenocarcinoma intestine, carcinoma rect (2 patients), carcinoma mammae. Mean time of sarcoidosis duration was 8.3 years. All patients with sarcoidosis were medically treated even for relapses. In this group 3 lethal outcomes were obtained.

Conclusion: Coexistencies exists even in sarcoidosis. The question is what is the cause for manifesting sarcoidosis and malignancies. Is immunodefitenica one progression. Most studies of the effects of corticosteroids have concentrated on changes in chest radiograph and lung function (PFT). A recent systematic review (Paramothayan, S. et al. Respir Med 2008;102:1-9) found no studies that reported the effects of corticosteroids on symptom.

Objectives: To investigate whether corticosteroids were associated with improved PFT or symptom score (SS) over a 2-year follow-up.

Methods: PFT and SS before and treatment were compared with results at 3, 12 and 24 months in 20 patients given oral corticosteroids for active pulmonary sarcoidosis. To calculate SS dyspnoea was valued 1-5 by severity, and all other symptoms were valued at 1. Data were collected from clinical records and results evaluated using a 2-tailed paired t-test.

Results: 14 females and 6 males aged 29-63 years were included; 13 black, 6 Caucasian, 1 Asian. Initial symptoms included dyspnoea (11), cough (8), skin changes (9), arthralgia (8), eye problems (7). SS improved significantly at all time points. Improvement in PFT was not statistically significant.
of the potential factors in manifesting sarcoidosis and in manifesting malignancies. Another question is due to cytotoxic drugs delivering during the treatment from malignancies. One of the known cytostatics which can cause granulomatous disorders is vinblastin.

P3736

Experience of hydroxychloroquine in the treatment of pulmonary sarcoidosis in the west of Ireland: An insight into clinical practice

Melissa McDowell, Imran Soleem, Robert Rutherford, Anthony O’Regan, J.J. Gilmartin. Respiratory Medicine, University Hospitals Galway, Galway, Ireland

Introduction: Hydroxychloroquine is widely used in treatment of cutaneous sarcoidosis. There is limited literature regarding the experience of hydroxychloroquine in pulmonary sarcoidosis.

Aims: To review the treatment and toxicity profile of hydroxychloroquine in treatment of pulmonary sarcoidosis.

Methods: Retrospective observational cohort study of sarcoidosis patients in the West of Ireland from 1983-2009. Remission was defined as successful withdrawal from steroids within one year, improvement in radiological staging of pulmonary disease (Scadding classification) and maintenance of pulmonary function. Relapse was defined as deterioration necessitating reintroduction of steroids.

Results: 92/407 (22.6%) were treated with hydroxychloroquine 200mg BD. Mean age 38.1yrs (range 17-68) with M:F ratio 1:1. Mean length of treatment 2.9yrs. Mean follow-up 8.5yrs. 19.6%, 47.8%, 25% and 7.6% had stage 1-4 disease respectively. 95.6% received high-dose steroids prior to treatment. Indications for treatment were: steroid-sparing 17.4%, refractory 18.5%, extra-pulmonary 47.8% and maintenance of remission 16.3%. 52.2% were steroid-free within one year; 23.9% showed improvement in radiological staging (normal radiology in 13%); there was no significant difference in lung function. Relapse rate was 14.1%. Adverse event rate was 11.9% (4.3% continued treatment).

Conclusion: This study shows hydroxychloroquine is safe and effective in the treatment of pulmonary sarcoidosis, particularly cutaneous. We conclude, therefore, that hydroxychloroquine should be considered in the treatment and maintenance of patients with chronic pulmonary sarcoidosis.

P3737

Characteristics of inflammatory bowel diseases-associated interstitial lung diseases

Camille Bron 1, Marianne Kambouchner 2, Thomas Gille 1, Yurdagul Uzunhan 1, Dominique Valeyre 1, Hilario Nunes 1.

Aim: To review the characteristics and pulmonary involvement of inflammatory bowel diseases (IBD) but most publications are limited to small series or predate the 2002 ATS/ERS statement on idiopathic interstitial pneumonias.

Methods: A retrospective review of 120 patients with HP seen at two centres from 1990 to 2010. Patients were classified according to the criteria of Schuyler and Cormier. CT scans were classified according to the Sahin et al score. Patients with chronic evolution of HP were compared to those with disease regression.

Results: We included 70 patients. Average age was 50 years: 65.7% females and 84.3% non-smokers. Avian proteins (81.4%) and moldy cork dust (7.1%) were the most common etiological antigens. Twenty-nine (41%) patients progressed to chronicity. Restrictive ventilatory syndrome was more severe in the group of patients with chronic evolution with lower FVC (p < 0.03), FEV1 (p < 0.05) and TLC (p < 0.02). Presence of reticular and honeycombing patterns were associated with evolution to chronicity (p = 0.003). The existence of centrilobular nodules was associated with regression of disease (p=0.011). The extension of radiological findings didn’t correlate with HP evolution.

Conclusion: No statistically significant differences between groups concerning BALF cellular- admixture.

P3738

Characterization of chronic hypersensitivity pneumonitis and evaluation of its predictive factors – Retrospective study

Rui Rolo 1, António Morais 2, Natália Melo 1, Patrícia Mota 1, José Miguel Pereira 2, Maria Antónia Vasconcelos 3, Susana Guimarães 4, Conceição Souto-Mouro 1.

1Pneumology Department, Hospital de Braga, Braga, Portugal; 2Pneumology Department, Hospital S. João, Porto, Portugal; 3Radiology Department, Hospital S. Joao, Porto, Portugal; 4Pathology Department, Hospital S. João, Porto, Portugal

Background: A percentage of patients with hypersensitivity pneumonitis (HP), despite appropriate therapeutic measures, evolves to chronicity. Objective: Characterization of clinical presentation, lung function, radiological, histological and bronchoalveolar lavage fluid (BALF) features of patients with chronic HP and evaluation of its potential predictive factors.

Methods: Retrospective analysis of patients with HP diagnosed according to the criteria of Schuyler and Cormier. CT scans were classified according to Sakin et al score. Patients with chronic evolution of HP were compared to those with disease regression.

Results: We included 70 patients. Average age was 50 years: 65.7% females and 84.3% non-smokers. Avian proteins (81.4%) and moldy cork dust (7.1%) were the most common etiological antigens. Twenty-nine (41%) patients progressed to chronicity. Restrictive ventilatory syndrome was more severe in the group of patients with chronic evolution with lower FVC (p < 0.03), FEV1 (p < 0.05) and TLC (p < 0.02). Presence of reticular and honeycombing patterns were associated with evolution to chronicity (p = 0.003). The existence of centrilobular nodules was associated with regression of disease (p=0.011). The extension of radiological findings didn’t correlate with HP evolution.

Conclusion: No statistically significant differences between groups concerning BALF cellular-admixture.
**Results:** The lungs of all cases showed pathologically some stage of diffuse alveolar damage (DAD) coincident with the period after acute exacerbation. In 11 cases, several stages of DAD were recognized in the lungs of same patient. DAD is found exclusively in the area without honeycombing. Although 5 cases showed also bud-type intra-alveolar fibrosis, which composed of accumulated myofibroblasts with few vessels and occasionally connected with ring-like DAD fibrosis. We do not reach the conclusion that they were OP or AIP. In addition to DAD, fibrosis which was frequently observed in 9 cases including the walls of honeycombing. The activity of IFP itself was estimated to be high in these patients.

**Conclusions:** The pathologic findings of acute exacerbation are DAD, and the several stages of DAD are characteristically observed in the same patient, which are similar to DAD caused by drug injury.

**Interstial lung disease associated by gemcitabine chemotherapy in non-small lung cancer patients: Analysis based on the data in practical use with confirmed denominator**

Yukiko Miura, Yoshimubu Suto, Yuji Minegishi, Arata Arzuma, Akihiko Gemma.

**Internal Medicine. Division of Pulmonary Medicine Infection and Oncology, Nippon Medical School, Tokyo, Japan**

**Background:** Gemcitabine (GEM), which is often used for non-small cell lung cancer (NSCLC), was reported to induce interstitial lung disease (ILD) in Japan. Presently, all-case postmarketing surveillance was to be generally conducted after the launch of new anti-cancer drug to investigate less-frequently but serious adverse drug reactions such as ILD in Japan. However, all-case surveillance had not been conducted for GEM and there is few data of GEM-induced ILD incidence in NSCLC patients with GEM chemotherapy in single institute.

**Methods:** We conducted a retrospective observational study of all NSCLC patients who received GEM in our hospital through medical records.

**Results:** We reviewed chemotherapy for NSCLC with GEM. ILD developed in five (2.9%) among these patients. ILD developed 10 to 80 days after the first administration of GEM. Of the five patients, four patients improved by steroid, whereas one patient died due to disease progression. The characteristics of the patients showed to be as risk factors of drug-induced ILD, such as age, performance status, and smoking history, concomitant use of anti-cancer drugs, were compared between ILD and non-ILD patients. However, significant differences were not detected.

**Conclusions:** Incidence rate of GEM-associated ILD in NSCLC patients was 2.9% in this study. Most of the patients who developed ILD had a good prognosis but one of them had a fatal outcome. We weigh the difference between our result and previous reports of GEM-associated ILD.

**Lymphoid hyperplasia and eosinophilic pneumonia as histologic manifestations of amiodarone-induced lung toxicity**

Brandon T. Larsen1, Laslo T. Vasc1, Henry D. Tazel1, Thomas V. Cobly1, 

1 Pathology, University of Arizona, Tucson, AZ, “Medicine, 1 Laboratory Medicine and Pathology, Mayo Clinic Arizona, Scottsdale, AZ, United States

**Background:** Amiodarone use is often limited by lung toxicity. Amiodarone lung disease (ALD) classically manifests as organizing pneumonia with intra-alveolar foamy macrophages, but other patterns may occur. Herein we report two previously unreported patterns of ALD, lymphoid hyperplasia (LH) and eosinophilic pneumonia (EP).

**Method:** We identified patients with LH or EP as a prominent feature among 75 cases of probable ALD from the authors’ teaching files collected from 1997-2010. Clinical history and wedge biopsies were reviewed.

**Results:** Twelve patients (7 men) met inclusion criteria. Median age was 71 years. Amiodarone dose was known in 10 cases (median 200mg/d). Treatment duration was known in 8 cases and ranged from 1 to 9 years. Thoracic imaging showed diffuse infiltrates concerning for ALD. Histologic review revealed intra-alveolar foamy macrophages in all cases. Eight cases prominently displayed patterns of LH including diffuse LH (7), follicular bronchiolitis (5), lymphocytic interstitial pneumonia (2), and lymphocytic perivascular cuffing (2). Two showed features of acute EP including diffuse alveolar damage with abundant eosinophils. Two showed features of chronic EP including interstitial pneumonia with abundant eosinophils, patchy organization, fibrous exudates, and interstitial thickening. One chronic EP case also showed focal LH. Additional features included intra-alveolar giant cells (6), pleuritis (3), small poorly-formed granulomas (3), and thrombi (2).

**Conclusions:** Lymphoid hyperplasia and eosinophilic pneumonia are previously unrecognized histopathologic manifestations of ALD, and amiodarone exposure should be included in their differential diagnosis.

**Concomitant Interferon-gamma 1b have a role in treatment of fibrosing NSIP?**

Barbara Bellfotore, Marialiusa Bocchino, Giuseppe Antinolli, Antonio Ponticelli, Roberta Di Grazia, Alessandro Sanduzzi Zamparelli, Sepideh Nikfam.

**Clinical and Experimental Medicine, Respiratory Diseases, Naples, Italy**

**Aim:** To detect the effectiveness of Interferon-gamma 1b in patients with fibrotic NSIP.

**Methods:** We reviewed clinical records and pathologic findings of 11 patients with IFP (all males, mean age 54.2±6.3 yrs), who underwent surgical biopsy and were treated with IFN-gamma 1b between 2005 and 2007. In all patients, before therapy, after 6 and 12 (T2) months of treatment, the following parameters had been measured: lung volumes, DLCO, mPAP estimated and reclassified according to the ATS/ERS consensus classification of interstitial pneumonia.

**Results:** 5 out of 11 patients, previously diagnosed as Usual Interstitial Pneumonia, after the revision were identified as fibrotic NSIP. In 5 patients, ILD was reviewed for GEM and there is few data of GEM-induced ILD incidence in NSCLC patients who received GEM in our hospital through medical records.

**Conclusion:** Incidence rate of GEM-associated ILD in NSCLC patients was 2.9% in this study. Most of the patients who developed ILD had a good prognosis but one of them had a fatal outcome. We weigh the difference between our result and previous reports of GEM-associated ILD.

**P3744**

**The clinical dynamic changes and prognosis analysis in patients with cryptogenic organizing pneumonia**

Xiu Zhang, Respiratory & Renal Medicine, Beijing Institute of Respiratory Medicine, Beijing ChaoYang Hospital-Affiliate of Capital Medical University, Beijing, China

**Background:** Cryptogenic organizing pneumonia (COP) is a common subtype of Alveolar Proteinosis (AP) which has a multivariate clinical feature.

**Objectives:** To characterize the clinical dynamic changes and to identify predictive factors for relapse of patients with COP.

**Methods:** COP patients who received COP x-ray were diagnosed in our hospital from Jan 1,1998 to Oct 1, 2009 and followed up until Mar 31, 2010.

**Results:** 1) 78.5% (57/73) patients with subacute onset responded well to steroid. No improvement showed significant improvement during the first three months. 2) Consolidation, ground glass opacity and reticular shadow were three most common abnormal patterns on CT scan during the early stage of the disease. Ground glass opacity (GGO) could progress into consolidation, later, in turn, inverted into GGO and then resolved completely after corticosteroid treatment. Ground glass opacity showed rapid and significant resolution after the treatment. Reticular shadow resolved slowly. 4) 25.7% (17/73) patients went through relapses. 70.6% (12/17) relapses occurred during the first year after the treatment while the steroid is stopped or tapered (<10mg/d).

**Conclusions:** 1) COP runs a benign course and shows a significant improvement on pulmonary function test and Chest CT in response to steroids. 2) Relapses occur frequently when steroid is tapered (≥10mg/d) or stopped, mostly during the first year. Relapses do not affect the outcome. 3) Decreased diffusing capacity and hypoxemia maybe important predictors of the relapses and tapering too fast may increase the risk of relapse.

**P3745**

**Follow up 1 year of amiodarone pulmonary effects**

Galina Orlova, Julya Nikolaeva, Larisa Kiruchina, Aleksandra Speranskaya, Vitaliy Perley, Aleksey Gikhin. Laboratory of Environment and Occupational Pulmonology, Scientific Research Institute for Pulmonology I.P.Pavlov’s State Medical University, Saint-Petersburg, Russian Federation

**Amiodarion has numerous side-effects and the pulmonary toxicity (PT) is the most serious.**

**Aim:** To analyse the therapeutic prognosis of amiodarone-induced PT (AIPT). 14 AIPT patients (mean age 66.0±12.2 y) received amiodarone (300-400 mg/day) for 47.6±3.5 months due to cardiac arrhythmia, were investigated. X-ray, computer tomography (CT), complex lung function examination, echodopplercardiography were performed. All patients discontinued the amiodarone and received prednisolone (60-20 mg/day) with gradual tapering up to 10-5 mg/day for 6 months. Lung biopsy was done in 2 cases and confirmed interstitial pulmonary fibrosis.

**Results:** AIPT was diagnosed over 2.7 yr after the clinical manifestation. The onset of AIPT was acute in 3, subacute in 8, insidious in 2 cases at 2 frequencies. The frequency of CT signs were: interstitial - 1.0, nodule - 0.22, and infiltrative or “ground glass” - 0.88. Restrictive type of functional disorders (0.91), pulmonary hypertension 33.7±1.8 mm Hg and cor pulmonale (0.57) were revealed. In 2 cases it was amiodarone-induced thireoiditis. After 1 yr therapy the improvement of clinical (0.83) and CT (0.83) signs, lung functional tests (DLCO, p<0.05; VC, p<0.005; RV, p<0.001; DLCO, p<0.05) were observed. The rapid decrease of prednisolone dose in 2 cases lead to the clinical and CT deterioration.

**Conclusion:** The corticosteroid treatment of AIPT is of therapeutic value and must be prolonged with carefully tapering to avoid the deterioration.
Combined pulmonary fibrosis and emphysema. Descriptive analysis from a specialized clinic of interstitial lung disease
M. Asunción Nieto1, Beatriz Morales1, Covadonga Fernández-Golín2, Paola Benedetti1, Gema Rodríguez-Trigo1, Ina Gerashimova1, José Luis Álvarez-Sala Wahlter1, 1Pneumology, Hospital Clínico San Carlos. Universidad Complutense de Madrid. Madrid, Spain; 2Cardiology, Hospital Clínico San Carlos. Universidad Clínico San Carlos. Madrid, Spain.

The combination of pulmonary fibrosis and emphysema (CPFE) is a recently defined syndrome characterized with pulmonary fibrosis (PF) and emphysema.

Aim: To analyze the clinical, functional, radiological and echocardiographic features in patients with CPFE.

Method: Prospective study conducted in a specialized clinic of ILD from 01/01/2007 to 31/12/2010. PF was defined as reticulopapilae with peripheral and basal predominance, honeycombing, architectural distortion and/or traction bronchiectasis without ground glass opacities in HRCT and emphysema as the presence of areas of low attenuation with a very thin or no wall and/or bullae with upper zone predominance.

Results: We anlzied 20 patients; 90% men; mean age 74 years; 91% were smokers or ex-smokers, 60% had dyspnea, 75% basal crackles and 25% finger clubbing. The pulmonary function tests are shown in table 1. Pulmonary hypertension was detected in 5 of 10 patients who underwent echocardiography.

### Pulmonary function tests in 20 patients

SD: standard deviation; FVC: forced vital capacity; FEV1: forced expiratory volume in one second; TLC: total lung capacity; RV: residual volume; TLCO: transfer factor for carbon monoxide; PaO2: partial pressure of oxygen in arterial blood; SpO2: arterial oxygen saturation.

Conclusions: The finding of lung volumes normal or minimally altered in contrast to a severe reduction in TLCO and arterial hypoxemia should alert to the possibility of CPFE. The prevalence of PH in these patients is high.

The King's sarcoid questionnaire (KQ): The development of a novel health related quality of life (HRQOL) questionnaire
Amit Patel1, Richard Siegert1, Akin Sowemimo1, Daniel Creamer4, Genevieve Larkin5, Athol Wells3, Irene Higginson2, Surinder Birring1.

Health related quality of life (HRQL) is impaired in sarcoidosis. Fatigue, pain, cough, breathlessness, visual disturbance and appearance of skin lesions are common concerns of patients. There is a paucity of validated disease specific tools to assess HRQOL of patients with sarcoidosis. We set out to develop a sarcoidosis specific HRQOL questionnaire. Items were generated from patient interviews (n=23), review of literature and a multi-disciplinary team meeting. A modular questionnaire was recommended because of the multisystem nature of sarcoidosis. A preliminary questionnaire consisted of 65 items and a 7 point Likert response scale. The preliminary King’s Sarcoid Questionnaire (KQ) was tested in 205 patients (184 lung, 55 skin, and 45 eye disease) at two sites (King’s College Hospital and the Royal Brompton Hospital). The following items were removed: 1) floor effect >60% of participants responded “rarely” or “never” (8 items), 2) inter-item correlations of ρ<0.8 (12 items), 3) items that did not fit unidimensional scales following Rasch analysis (11 items). The King’s Sarcoid Questionnaire (KQ) comprises of 5 modules: general QOL (12 items), lung (8 items), medication and side-effects (3 items), skin (4 items) and eyes (7 items). The KQ is currently undergoing evaluation of test-retest reliability and responsiveness to change.

Evaluation of the COPD assessment test (CAT) for measuring health-related quality of life in patients with interstitial lung disease
Kazuma Nagata, Keisuke Tomii, Michio Hayashi, Kojiro Otsuka, Ryo Tachikawa, Kyoko Otsuka. Respiratory Medicine, Kobe City Medical Center General Hospital, Kobe, Japan.

There is a need for a short, simple, and well validated instrument to assess health-related quality of life (HRQL) in patients with interstitial lung disease (ILD). The study was conducted to evaluate the validity of the COPD assessment test (CAT), which is a newly developed short and simple questionnaire for COPD with good measurement properties, in ILD. 52 ILD patients completed the CAT and the St. George’s Respiratory Questionnaire (SGRQ). The patients also completed the MRC dyspnea scale, the Leicester Cough Questionnaire (LCQ), and the Hospital Anxiety and Depression Scale (HADS) and also underwent a six-minute walk test, pulmonary function tests, and arterial blood gas analysis.

The correlation between the CAT score and the SGRQ total score was very strong (r=0.93, p<0.0001). The CAT score was also significantly correlated with the SGRQ symptoms score (r=0.74, p<0.0001), with the SGRQ activity score (r=0.87, p<0.0001), and with the SGRQ impact score (r=0.89, p<0.0001). Stepwise multiple regression analysis demonstrated that the MRC score and the LCQ score were the most strongly contributing factors to both the CAT score and the SGRQ total score. The CAT is a short and simple questionnaire for assessing ILD health status with good measurement properties.

Fungal colonization in interstitial lung diseases
Ilya Sivokozov1, Olga Lovacheva1, Eugene Shmelev2, Elena Larionova1, 1Endoscopy Dept, CRU RAMS, Moscow, Russian Federation; 2Granulomatous Diseases Dept, CRU RAMS, Moscow, Russian Federation; 3Microbiology Dept, CRU RAMS, Moscow, Russian Federation.

Background: Many of interstitial lung disease are tend to impair the immunity, thus patients in this group have a higher risk of fungal diseases. But still little is known regarding the role of fungal colonization in interstitial lung diseases, when fungus are not define a causative agent.

Aim: To investigate the incidence and effects of fungal colonization of lower respiratory tract using PCR of bronchoalveolar lavage (BAL) specimens among patients with sarcoidosis and extrinsic allergic alveolitis (EAA).

Materials: 132 patients with sarcoidosis, and 80 patients with EAA undergo BAL with further PCR test for A. fumigatus and C. albicans using commercial assays. Cytology of BAL, different disease parameters including functional tests, radiology were analyzed.

Results: In sarcoidosis patients, Aspergillus was found in 22 cases (16.7%), 14 were males, and Candida detected in 11 cases (8.3%) -3 were males. Among EAA patients, Aspergillus detected in 13 cases (16.2%), 5 were males, and Candida in 9 (11.3%) cases, 4 were males. In sarcoidosis, Candida colonization was associated with lower FVC (72%), DLCO (64%), and higher neutrophils level in BAL (32%), as also disease duration (112.8 weeks) vs patients without it (92%, 88%, 9% and 18.2 weeks, respectively). In EAA Candida detection was also associated with lower DLCO (58%), 6-minute walk test distance (340 m), higher neutrophils level in BAL (34%), disease duration (107.3 weeks) vs patients without it (72%, 421 m, 12% and 48.7 weeks, respectively). Aspergillus detection altered disease parameters in similar way.

Conclusion: Colonization of respiratory tract with fungi in interstitial lung diseases plays a prominent role in deterioration of disease.

Forced vital capacity decreases rapidly in patients with idiopathic upper lobe-dominant pulmonary fibrosis
Kentarou Watanabe1, Taishi Harada1, Takako Hirota1, Kazuki Nabeshima1, Masaki Fujita1, Nobuhiko Nagata1, 1Respiratory Medicine, Fukuoka University School of Medicine, Fukuoka, Japan; 2Pathology, Fukuoka University School of Medicine, Fukuoka, Japan; 3Respiratory Medicine, Fukuoka University Chikushin Hospital, Fukuoka, Japan.

We present five patients with upper lobe-dominant pulmonary fibrosis of unknown etiology that does not fit any of the currently defined subsets of idiopathic interstitial pneumonias. We describe the clinical, functional, and pathological characteristics of this disorder, which we have provisionally termed idiopathic upper lobe-dominant pulmonary fibrosis (iULPF).

All patients were slender, with a body mass index of 16.0–17.9 kg/m2. Four of the five patients had recurrent pneumothorax. Their pathological characteristics were as follows: 1) upper lobe-dominant subpleural proliferation of elastic fibers associated with deposition of mature collagen in alveolar lumens; 2) isolated fibrotic areas to less-involved pulmonary parenchyma; and 5) destruction of the lung architecture.

Evaluation of the COPD assessment test (CAT) for measuring health-related quality of life in patients with interstitial lung disease
Kazuma Nagata, Keisuke Tomii, Michio Hayashi, Kojiro Otsuka, Ryo Tachikawa, Kyoko Otsuka. Respiratory Medicine, Kobe City Medical Center General Hospital, Kobe, Japan.

There is a need for a short, simple, and well validated instrument to assess health-related quality of life (HRQL) in patients with interstitial lung disease (ILD).
P3751 Pulmonary hypertension and right ventricular impairment in patients with interstitial pneumonia
Nina Karol, Andrea Brebow. Hospital Therapy Department, Saratov State Medical University, Saratov; Russian Federation
There is little data about frequency of pulmonary hypertension (PH) and right ventricular (RV) impairment in patients with idiopathic interstitial pneumonia (IIP). In this work we examined the prevalence PH in these disorders using noninvasive cardiological examination. A total of 40 patients (aged 50±3.2±5.5) with IIP have been studied in early period after IIP diagnosed. Criteria of exception were the clinical displays heart disease, arterial hypertension. Control group have made 14 normotensive volunteers (aged 47±7±1.86). All patients were studied using realtime, phased array, two-dimensional Doppler echocardiography. The pulmonary artery systolic pressure (SP) was calculated as the sum of the transmural pressure gradient and the right atrial pressure.
Results: Pulmonary hypertension (SP > 35 mm Hg) is revealed in 15 patients with IIP and SP > 40 mm Hg – at 7 (17.5%). Doppler-estimated SP at the patients with IIP exceeded SP at the healthy persons (p < 0.001). RV hypertrophy was present in 23 (57.5%) patients (p < 0.001). RV dilation was present in 76.5% patients with IIP (p < 0.001). RV diastolic dysfunction was revealed in 65% patients. Right atrial diameter in patients with IIP was significantly higher than at the healthy persons (p < 0.001). RV wall in patients with IIP was significantly higher than at the healthy persons (p < 0.001). RV diastolic dysfunction revealed in 56% pts. We noted correlations between SP and dyspnoe intensity (scale MRS) (r = 0.63, p < 0.01), VC (r = 0.61, p < 0.01), VC = (r = 0.39, p < 0.01), FEVI = (r = 0.38, p < 0.01), SaO2 (r = 0.58, p < 0.01).
Conclusion: Pulmonary hypertension and right ventricular abnormalities is common in patients with IIP.

P3752 Interstitial lung diseases in Europe
Roberto Carbone1, Rosangela Filiberti2, Riccardo Ghio1, Gregor S. Zimmermann1, Katharina Jakob 1, Werner von Wulffen1, Rainer Baumgartner3, Juergen Behr4, Claus Neurohr1.
Aim: ILD would be important to the planning of services for these patients, but so far nevertheless they constitute 15-20% of all respiratory pathologies as compared to 6-25% in Europe, ILD incidence rates ranged from 3.62 (South of Spain) to 7.6 cases × 100,000 inhabitants (Spain) according to different studies. In the majority of cases a male predominance was found. Among ILD, the most frequent entities were idiopathic pulmonary fibrosis (IPF: 19-39% of all ILD), sarcoidosis (12-35%) and hypersensitivity pneumonia (3-12%). Incidence rates of IPF and sarcoidosis ranged from 0.93 (Greece) to 6.78 cases × 100,000 (UK) and from 1.07 (Greece) to 5.59 × 100,000 (UK), respectively. Median age at diagnosis was about 61 years for IPF and 42 years for sarcoidosis. Fibrotic NSIP was considered as a new subgroup, making up 20-35% of patients previously diagnosed as IPF. Few data exist on the frequency of ILD and discrepancies among different areas have been observed. Differences in fact but are due to the use of disomogeneous sources (disease registries, selected clinical series, different study designs), to the incidence of outbreak or prevalent cases, to variable criteria for diagnosis, or to selection bias.

P3753 Effect of PDE-5 inhibitor treatment in patients with interstitial lung disease and pulmonary hypertension
Gregor S. Zimmermann1, Katharina Jakob1, Jens Geiseler2, Julia Fresenius2, Hanno H. Leuchte3
Methods: English articles on ILD epidemiology in Europe were reviewed using PubMed as the search engine.
Results and conclusions: In Europe, ILD incidence rates ranged from 3.62 (South of Spain) to 7.6 cases × 100,000 inhabitants (Spain) according to different studies. In the majority of cases a male predominance was found. Among ILD, the most frequent entities were idiopathic pulmonary fibrosis (IPF: 19-39% of all ILD), sarcoidosis (12-35%) and hypersensitivity pneumonia (3-12%). Incidence rates of IPF and sarcoidosis ranged from 0.93 (Greece) to 6.78 cases × 100,000 (UK) and from 1.07 (Greece) to 5.59 × 100,000 (UK), respectively. Median age at diagnosis was about 61 years for IPF and 42 years for sarcoidosis. Fibrotic NSIP was considered as a new subgroup, making up 20-35% of patients previously diagnosed as IPF. Few data exist on the frequency of ILD and discrepancies among different areas have been observed. Differences in fact but are due to the use of disomogeneous sources (disease registries, selected clinical series, different study designs), to the incidence of outbreak or prevalent cases, to variable criteria for diagnosis, or to selection bias.

P3754 Pulmonary hypertension in patients with interstitial lung disease
Zeynep Dogan1, Sinan Ergenli1, Husseyn Yildirim1, Gumulu Ak1, Ragip Ozkan2, Fusun Alatas1, Muazzfer Metinbas1. 1Department of Chest Disease, Eskisehir Osmangazi University, Medical Faculty, Eskisehir, Turkey; 2Department of Radiology, Eskisehir Osmangazi University, Medical Faculty, Eskisehir, Turkey
Pulmonary hypertension (PH) is commonly seen in patients with interstitial lung disease (ILD), and is associated with a worse prognosis. The aim of this study was to determine the prevalence and characteristics of PH in patients with ILD. Demographic and clinical characteristics, physiological studies, six minute walking test (6MWT) and high resolution computed tomography (HRCT) results were prospectively collected, and compared between patients with and without PH. Pulmonary hypertension was defined by right heart catheterization as mean pulmonary artery pressure > or = 25 mm Hg and pulmonary artery occlusion pressure < or = 15 mm Hg.
The study cohort consisted of 30 patients. The final diagnoses of these patients were idiopathic pulmonary fibrosis (IPF) (24 (80%) cases), asbestosis (2 (7%). Background: Interstitial lung diseases (ILD) comprise a disomogeneous group of more than 200 pulmonary disorders and are progressive life-threatening diseases. Etiology is unknown in a variety of ILD. ILD are considered rare diseases, nevertheless they constitute 15-20% of all respiratory pathologies as compared to 6-25% in Europe, ILD incidence rates ranged from 3.62 (South of Spain) to 7.6 cases × 100,000 inhabitants (Spain) according to different studies. In the majority of cases a male predominance was found. Among ILD, the most frequent entities were idiopathic pulmonary fibrosis (IPF: 19-39% of all ILD), sarcoidosis (12-35%) and hypersensitivity pneumonia (3-12%). Incidence rates of IPF and sarcoidosis ranged from 0.93 (Greece) to 6.78 cases × 100,000 (UK) and from 1.07 (Greece) to 5.59 × 100,000 (UK), respectively. Median age at diagnosis was about 61 years for IPF and 42 years for sarcoidosis. Fibrotic NSIP was considered as a new subgroup, making up 20-35% of patients previously diagnosed as IPF. Few data exist on the frequency of ILD and discrepancies among different areas have been observed. Differences in fact but are due to the use of disomogeneous sources (disease registries, selected clinical series, different study designs), to the incidence of outbreak or prevalent cases, to variable criteria for diagnosis, or to selection bias.

P3755 Resting PaO2 and 6MWT as diagnostic index for nocturnal oxygen desaturation in diffuse parenchymal lung diseases
Sheetu Singh1, Manan Lal Gupta2, Ravinder Singh2, Virendra Singh 2. 1Chest & Tuberculosis, SMS Medical College, Jaipur, Rajasthan, India; 2Pulmonary Medicine, SMS Medical College & Hospital, Jaipur, Rajasthan, India
Introduction: Despite of normal daytime oxygen saturation many patients of diffuse parenchymal lung disease (DPLD) desaturate during night time. Such patients may develop signs of pulmonary arterial hypertension (PAH) which increases the mortality and morbidity in DPLD. The aim of this study was to determine the magnitude of nocturnal oxygen desaturation and find its predictors in DPLD. Methods: It was a cross sectional and observational study. 48 consecutive patients of DPLD were recruited. Idiopathic pulmonary fibrosis (IPF) was diagnosed by ATS/ERS guidelines 2002 and other DPLD by their clinical and radiological presentation. Arterial blood gas analysis, six minute walk test (6MWT) and overnight pulse oximetry were done and variables such as time spent with nocturnal oxygen saturation (SpO2) below 90%, mean SpO2, worst SpO2 and apnea - hypopnea index were recorded. Results: Amongst 48 subjects, 35 (72.9%) patients had IPF. 9 (18.8%) patients had hypersensitivity pneumonitis and 4 (8.3%) patients had stage 4 sarcoidosis. Nocturnal desaturation (>10% of sleep time with SpO2 <90%) was observed in 20 (41.7%) subjects. The desaturators were found to have resting daytime PaO2 of less than 61mm of Hg (p=0.0015), end SpO2 after O2 <83.5% (p=0.0077) and distance walked during 6MWT ≤380.4m (p=0.0051). Based on cut off values of these variables an index called desaturation index was evolved which had 95% sensitivity. Conclusion: Significant nocturnal oxygen desaturation occurs in many patients of DPLD despite of normal resting SpO2. A desaturation index based on PaO2 and SpO2 after 6MWT and distance walked during 6MWT was found to be 95% sensitive in diagnosing nocturnal desaturators.
Drug induced lung disease: 11 cases
Eld Kupeli, Yucge Sahin Ozenmirel, Zeynep Ezryzun Ozen, Gaye Ulubay, Sule Akcay, Fusun Oner Eynoboglu. Pulmonary Diseases, Baskent University School of Medicine, Ankara, Turkey.

Drug induced lung disease (DILD) is the most common cause of iatrogenic damage to the lungs. More than 350 drugs have been identified leading to DILD. We evaluated the characteristics of patients with DILD between 2007-2010, at our institution retrospectively, for demographic features, pulmonary function tests (PFTs), diffusion capacities, high resolution computed tomograms (HRCT) findings, diagnostic methods and treatment modalities. 11 patients (M/F=9:2, mean age 60±20.3) were identified with DILD. 3 had chronic myeloid leukemia; congestive heart failure, asthma, testicular cancer, malignant melanoma, acute lymphocytic and myelocytic leukemia, renal transplantation and lung cancer was diagnosed in one patient each. Cough, respiratory failure and fever were the most common symptoms. 4 patients exhibited normal, 5 revealed restrictive, one patient for each revealed obstructive and mixed PFTs. Diffusion capacities in 6 patients were low. Ground glass opacities (2), bilateral patchy consolidation (2), interstitial fibrosis (2), pleural effusion (1) were evident in HRCT, however 1 patient revealed no abnormality. 3 patients underwent bronchoscopy for bronchosclerotic lavage. Infections causes were excluded by microbiological and laboratory tests. Lung involvement was thought to be due to bleomycin (1), methotrexate (1), cyclophosphamide (1), cisplatin (1), dasatinib (2), Ara-C (2), ciclosporin (1), amiodaron (1), tacrolimus (1). Radiological and clinical improvement was achieved with systemic steroids in 10 and cessation of the drug in one. DILD can cause significant mortality and morbidity. We believe that consequence of DILD could be reduced by high degrees of suspicion and by excluding other causes for common pulmonary symptoms and abnormal radiographic findings.

Quadriceps function is reduced in fibrotic idiopathic interstitial pneumonia
Laura Mendoza1, Athina Gogali2, Samuel Kemp3, Dinosh Shrikrisna4, Abigail Jackson5, Gabriel Cavada6, Michael Polkey7, Athel Wells8, Nicholas Hopkinson9, 1Section Neumologia, Hospital Clinico Universidad de Chile, Santiago, Chile; 2Respiratory Unit, University Hospital of Ioannina, Greece; 3Respiratory Muscle Laboratory, Royal Brompton Hospital, London, United Kingdom; 4Escuela de Salud Publica, Universidad de Chile, Santiago, Chile; 5Interstitial Lung Diseases Unit, Royal Brompton Hospital, London, United Kingdom

Introduction: Little is known about the quadriceps function and its role in exercise capacity in Fibrotic Idiopathic Interstitial Pneumonia, FIP.

Methods: To compare quadriceps function in patients with FIP and healthy controls and relate it to exercise capacity, 25 patients with FIP, FVC 78.7% predicted and 25 sex and age matched healthy controls were studied. Measurements included FFM, respiratory muscle strength, voluntary quadriceps strength (QMVC), twitch quadriceps force (TwQ), an endurance protocol of 5 min. Both groups had comparable anthropometrics and respiratory muscle strength. Quadriceps force declined more rapidly in patients in the endurance protocol. TwQ was lower in patients.

Conclusions: Patients with FIP have significantly impaired quadriceps strength and endurance. In contrast to controls, quadriceps function is not correlated with 6MWD.

Assessment of cardiac involvement in patients with sarcoidosis
Vasileios Kourounas1, Aggeliki Rapi1, Elias Gialafos2, Konstantina Aggeli3, Maria Ntouskou4, Anastasios Kallianos5, Ourania Anagnostopoulou6, George Tzelepis3, 18th Pulmonary Clinic, General Hospital of Chest Diseases "Sotira", Athens, Greece; 22nd Pulmonary Clinic, General Hospital of Chest Diseases "Sotira", Athens, Greece; 31st Cardiology Clinic, University of Athens, Athens, Greece; 4Biosavari Medical Center, University of Athens, Athens, Greece; 5Clinic of Pathophysiology, University of Athens, Athens, Greece

Background: Cardiac involvement remains an important prognostic factor in patients with sarcoidosis. However, early diagnosis of cardiac sarcoidosis has been difficult because the clinical manifestations are not specific and the sensitivity and specificity of the diagnostic modalities are limited.

Methods: Patients with biopsy proven sarcoidosis were prospectively recruited from the outpatient clinic of sarcoidosis and underwent a full cardiological monitoring including pulmonary function tests, echocardiography, cardioangiography, a 24-hour ambulatory ECG and cardiac magnetic resonance imaging (MRI) when appropriate. Cardiac involvement was assessed based on known established Japanese Ministry of Health (JMH) criteria and on modified criteria using MRI as a major criterion for cardiac sarcoidosis. All consecutive patients were followed for 5 years for major adverse events.

Results: Seventy patients (43 female) were enrolled with median age 49.96±12.83 years old and disease duration 4.4±4.5 ±27 years. Cardiac involvement was identified with the modified criteria in 27 patients (38.5%) while 10 (14.3%) patients were found based on the JMH criteria, showing a more than two-fold higher rate for the MRI group (p=0.005). On follow-up, 9 patients had adverse events including 5 cardiac deaths. All patients with cardiac cause of death had cardiac sarcoidosis based on the modified criteria.

Conclusion: Evaluation of myocardial involvement in sarcoidosis with the use of MRI as a major criterion appears to be more sensitive than current consensus criteria and associated with future adverse events including cardiac death. Cardiac MRI evaluation may be of great importance in the early diagnosis of cardiac sarcoidosis.

Prognostic significance of serum markers in acute exacerbation of idiopathic interstitial pneumonias
Toru Arai1,2, Yoshikazu Inoue2, Kazunobu Tachibana1,2, Yasushi Inoue1, Akihide Nishiyama1, Chikatoshi Sugimoto1, Tomoko Kagawa2, Tomohisa Okuma1,2, Masanori Akira3, Masanori Kitaichi4, Seiji Hayashi1, 1Department of Respiratory Medicine, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Osaka, Japan; 2Clinical Research Center, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Osaka, Japan; 3Department of Radiology, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Osaka, Japan; 4Department of Pathology, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Osaka, Japan

Introduction: Acute exacerbation (AE) of idiopathic interstitial pneumonias (IIPs) is a topic for recent years. We have shown that diffuse pattern of high resolution CT (HRCT) at AE of idiopathic pulmonary fibrosis (IPF) is a worse prognostic factor (Akira, AJRCCM 2008). Prognostic significance of serum levels of KL-6 and surfactant protein (SP)-D in AE of IIPs has not been clarified sufficiently.

Aim: We examined clinical findings in AE of IIPs retrospectively to clarify the significance of serum KL-6 and SP-D as a prognostic factor.

Methods: Seventy cases of AE of IIPs were diagnosed according to the guideline of Japanese Respiratory Society in 2004 and classified with radiological and/or pathological findings into two groups: IPF (n=55) and non-IPF (n=15).

Results: Serum levels of KL-6 and SP-D were compared between 30days survivors and non-survivors. Prognostic factors determining 30 days survival was examined by logistic regression analysis among various clinical parameters including serum markers, HRCT patterns at AE (diffuse/non-diffuse).

Results: Serum SP-D levels of 30 days survivors at AE were significantly less than that of non-survivors, however, there was no difference in serum KL-6 levels. Serum KL-6 of patients with diffuse pattern was significantly lower than that of patients with non-diffuse pattern. Logistic analysis revealed that serum KL-6 at AE, white blood cell counts, immunoglobulin G, gender, complication of diabetes mellitus and pre-treatment before AE were significant factors determining 30 days survival.

Conclusions: Serum KL-6 (>1450U/ml) is a significant worse prognostic factor determining 30 days survival in AE of IIPs.
How often do respiratory specialists agree with the diagnosis of COPD made in general practice? An audit of referrals to a community based COPD centre (BreathingSpace) in the UK

Angela Green, Gunnar Bastron, Gill South. CLAHRC South Yorkshire, NHS Rotherham, Rotherham, United Kingdom Respiratory Unit, Rotherham Foundation Trust, Rotherham, United Kingdom Rotherham Community Health Service, BreathingSpace, Rotherham, United Kingdom

The Rotherham BreathingSpace (BS) is a nurse-led community based centre for the delivery of specialist care for Chronic Obstructive Pulmonary Disease (COPD). BS agreed with GP diagnosis of COPD in 27/37 (73%) of cases and management showed some improvements in quality between 2007 and 2008 but highlighted the current UK Quality and Outcomes Framework used in general practice assessed only the quantity and not the quality of spirometry. The purpose of this audit was to assess the reliability of the diagnosis of COPD made in general practice when referred on to a specialist respiratory service (BS). A retrospective review of a random sample of COPD patient referral forms (N=398, 207 males and 191 females) sent to BS from general practice between May 2007 and Sept 2009 was undertaken. 213 (54%) of these referrals had spirometry measured on the referral (mean FEV1 % = 54, FEV1/FVC= 0.59). Of the completed assessments the services are provided by GP diagnosis of COPD in 27/37 (73%) of patients and disagreed with the COPD diagnosis in 64 (19%) of patients. The BS non COPD diagnoses were Asthma (N=30, 9%), Restrictive lung disease (N=20, 6%), non obstructive Emphysema (N=4, 2%), Bronchiectasis (N=2, 0.6%) and no respiratory disease (N=20, 6%).

These findings suggest that 4 out of 5 COPD diagnoses made in general practice referred to our centre (BS) are reliable but there is still room for improvement. Further education and quality improvement is recommended in COPD diagnosis in line with national guidelines.

A survey of pulse oximeter use by general practitioners in East Berkshire, UK

Sarah Menzies, John Wiggins. Department of Respiratory Medicine, Wessex Park Hospital, Slough, Berkshire, United Kingdom

Introduction: The importance of measuring oxygen saturation in primary care is highlighted in many national guidelines, such as asthma (Thorax 2008; 63(Suppl 4):i121), community acquired pneumonia (Dx 2009; 64(Suppl 3):i153-55), Chronic Obstructive Pulmonary Disease and guidance on the use of emergency oxygen. Pulse oximeters are cheap, portable, and easy to use, but it is unclear whether they are widely utilized in the community setting.

Methods: Questionnaires were sent to all 54 general practitioner (GP) surgeries in the region - requesting information about their pulse oximeter use and opinions of their clinical value. A response from all practices was achieved by making telephone contact in the event the questionnaire was not returned.

Results: Twenty-one (39%) of the 54 surgeries did not own a pulse oximeter. Of these, 6/21 (29%) said they would not find one useful, and had no future intention of purchasing one. Ten of these 21 surgeries (48%) were keen to obtain one, but the main barriers to this were cost and the time required to research the market. The inner-city surgeries were less likely to have one – 8/17 (47%) inner-city surgeries vs. 25/37 (68%) outside the city. Of the 33 surgeries that did have an oximeter, 89% found them clinically very helpful, and the majority had just one machine (24/33 – 73%).

Conclusions: Over a third of GP surgeries do not own a pulse oximeter – despite clear indications for their use in the assessment of patients with respiratory illness. Highlighting these indications to GPs, in addition to outlining their relative low cost and ease of use may increase the popularity of this monitor of the “fifth vital sign” in primary care.

Using population insight studies to define effective prevention and identification interventions in COPD

Matt Kearney, Julia Crighton, Kevin Holton, Anne Moger, Robert Winter, Sue Hill. Respiratory Programme, Dept. of Health, London, United Kingdom

Background: In England over 3 million people are living with COPD. Only 835,000 are diagnosed usually at the more severe end of the disease spectrum. The national COPD programme highlighted the need for strategies both to prevent and identify COPD earlier in order to fundamentally change the disease burden and improve quality of life.

Objectives: To establish optimum approaches to promote positive lung health behaviour and symptom recognition by individuals and populations at risk of COPD.

Methods: An extensive literature review was undertaken together with stakeholder interviews to identify reasons for limited popular awareness of COPD and under-stand the impact of behaviour change interventions. Focus groups and interviews with informants in priority population segments were used to derive and test insights into effective approaches.

Results: Behaviour change interventions in COPD are more effective if targeted on priority population segments. Collaboration with charities and commercial organisations can help to identify and engage people at risk. Behaviour change interventions should be tailored to the individual and the population segment. Measurement of lung age may increase likelihood of stopping smoking. For those who are healthy but at risk, messages should be positively framed around lung health. For those with symptoms, negative message framing around lung disease may be more effective in changing behavior.

Conclusions: Interventions tailored to the individual and population segment are more likely to be effective in changing behaviour. The results of this segmentation and insight work have informed the approach in England to the prevention and early identification of COPD.

Poor quality of health services at primary care level is the leading cause of uncontrolled asthma in India

J.K. Samaria1, Moosa Hussain1, Pavan Yadav MV1, Anup P.K. Ahmed1, Manoj Meena1, Paresh Kulkarni2, Archisman Mahapatra1, Saket Sharma1.

Department of Chest Diseases, Instrt of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India; 2Dept of Preventive and Social Medicine, Instruct of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Background: Due to inadequate health resources in India the peripheral health services are not able to provide services as per the guidelines –GINA especially in the case of uncontrolled practitioners and GP. There is need to educate the practitioners particularly those at the periphery about the guidelines for asthma management.

A novel study design to assess the utility of the COPD assessment test (CAT) in improving asthma in India

Kevin Gruffydd-Jones1, Helen Pearce2, Steve Holmes3, Peter Kardos4, Roger Escamilla5, Roberto Dal Negro6, Jane Roberts1, Gilbert Nadeau2, David Leather2, Paul Jones8, Box Surgery, Box, Corsham, United Kingdom; 2Respiratory Centre of Excellence, GlassSmithKline, London, United Kingdom; 3Park Road Surgery, Shepton Mallet, Somerset, United Kingdom; 4Gemeinschaftspraxis und Zentrum für Pneumologie, Allergologie, Schlafmedizin, Klinik Maimaug, Frankfurt, Germany; 5Service de Pneumologie, Hôpital Larrey-CHU Toulouse, Toulouse, France; 6Divisione di Pneumologia, Ospedale Civile Orlando di Bussolengo, Bussolengo, Verona, Italy; 7Clinical Sciences Building, Salford Royal Hospital Foundation Trust, Salford, United Kingdom; 8Clinical Sciences, St George’s University of London, London, United Kingdom

Background: CAT is a new, patient completed, questionnaire designed to provide a simple and reliable measure of health status in COPD. The CAT has been validated against other measures of quality of life and outcomes of COPD (Jones P et al, EJR 2009;34:648-54). However, its ability to improve the dialogue between patient and physicians has not been evaluated. We set out to design a study to assess the impact of CAT on the quality of the consultation between a primary care physician (PCP) and COPD patient.

Methods: The CAT in Primary Care Study is a randomised, parallel group study conducted in 5 European countries. 160 PCPs without a working knowledge of CAT are recruited to the study. Each PCP completes 6 videoed consultations with standardised COPD patients (professional actors). PCPs are randomised to the CAT arm: with patient notes and CAT available in the consultations; or the non-CAT arm: with just the patient notes available.

Cases were developed to include usual patient issues, which the actors were trained not to proactively raise with the PCP. The cases and their CAT scores were independently verified.

Assessments are conducted by independent physicians. Each assessor will review 4 test cases for benchmarking. The assessments are based on the PCPs ability to

Measurement of lung age may increase likelihood of stopping smoking. For those who are healthy but at risk, messages should be positively framed around lung health. For those with symptoms, negative message framing around lung disease may be more effective in changing behavior.

Conclusions: Interventions tailored to the individual and population segment are more likely to be effective in changing behaviour. The results of this segmentation and insight work have informed the approach in England to the prevention and early identification of COPD.

PO363 Novel study design to assess the utility of the COPD assessment test (CAT) in improving asthma in India

Kevin Gruffydd-Jones1, Helen Pearce2, Steve Holmes3, Peter Kardos4, Roger Escamilla5, Roberto Dal Negro6, Jane Roberts1, Gilbert Nadeau2, David Leather2, Paul Jones8, Box Surgery, Box, Corsham, United Kingdom; 2Respiratory Centre of Excellence, GlassSmithKline, London, United Kingdom; 3Park Road Surgery, Shepton Mallet, Somerset, United Kingdom; 4Gemeinschaftspraxis und Zentrum für Pneumologie, Allergologie, Schlafmedizin, Klinik Maimaug, Frankfurt, Germany; 5Service de Pneumologie, Hôpital Larrey-CHU Toulouse, Toulouse, France; 6Divisione di Pneumologia, Ospedale Civile Orlando di Bussolengo, Bussolengo, Verona, Italy; 7Clinical Sciences Building, Salford Royal Hospital Foundation Trust, Salford, United Kingdom; 8Clinical Sciences, St George’s University of London, London, United Kingdom

The Breathing Bus – A primary care model for identifying undiagnosed COPD in hard to reach populations. A pilot study

June Roberts1, Helen Allsop2, Nizar Harb3, Tjard Schermer1.

Aims: To identify the number of undiagnosed COPD and to signpost to general practice for further assessment

Methods: A mobile health bus was sited in areas of high SED with good footfall and accessibility. Nurses trained to recognise COPD symptoms, perform FEV6 micro-spirometry and experienced in informal, non-medicalised approaches to health and disease staffed the bus. High risk individuals (over 35 yrs, smoker or ex-smoker with symptoms suggestive of COPD) were targeted for FEV6 micro-spirometry. Consent was gained to share all results with own GP. Those with unexplained respiratory symptoms and/or abnormal FEV6 readings were asked to see their GP for further assessment. Follow up with patient experience survey took place two months after the bus.

Results: The bus visited 6 sites on 7 occasions. 350 people visited the bus: between 6% and 87% of contacts were from areas of high SED. Of 119 in the high risk group, 67% men and 45% females had symptoms suggesting COPD of those suitable for FEV6 readings 30% of men and 38% women had airflow obstruction: all were signposted to their GP. 48% were current smokers. Data from the experience survey indicates that many suspected something was wrong; accessibility and convenience prompted them to come forward for testing.

Conclusion: Our pilot work suggests that mobile units in non-clinical settings can increase accessibility to SED groups and prompt high risk individuals to be tested for COPD. Further work is needed.

P3766

Two year mortality of COPD in primary care in Greece: An observational study

Kostas Marinis, Ioanna Verou-Katsarou, Panthera Mystridou, Eleni Apostolidou, Haragio Patsouras, Konstantinos Georgoulakis. Respiratory Medicine Department, University of Thessaly Medical School, Larissa, Greece

Introduction: COPD remains a significant cause of death worldwide. However, in primary care in Greece there is still a large proportion of undiagnosed COPD patients. Parameters associated with mortality in COPD patients have not been identified.

Aims and objectives: To assess the parameters associated with two year mortality in newly diagnosed COPD patients in primary care in Greece

Methods: Using an open spirometry programme, 118 newly diagnosed COPD patients were identified over two years. Phone contact was performed every six months, whereas the study participants were examined and categorized by the mobile health bus.

Results: The bus visited 6 sites on 7 occasions. 350 people visited the bus: between 6% and 87% of contacts were from areas of high SED. Of 119 in the high risk group, 67% men and 45% females had symptoms suggesting COPD of those suitable for FEV6 readings 30% of men and 38% women had airflow obstruction: all were signposted to their GP. 48% were current smokers. Data from the experience survey indicates that many suspected something was wrong; accessibility and convenience prompted them to come forward for testing.

Conclusion: Our pilot work suggests that mobile units in non-clinical settings can increase accessibility to SED groups and prompt high risk individuals to be tested for COPD. Further work is needed.

P3767

Exhaled nitric oxide: A useful adjunct test in assessing asthma control in primary care – A cross-sectional exploration

Eveline Termeer1, Jiska Sneek-Stroband2, Hanneke Nuiten1, Persijn Honkoop2.

Aim: To explore the consequences of omitting FeNO as an adjunct to symptoms and spirometry for assessing asthma control in primary care.

Methods: We performed a cross-sectional analysis of two available cohorts of adult asthmatics. We assessed FeNO, lung function and Asthma Control Questionnaire (ACQ) levels in all participants. Pearson correlation coefficients were calculated between FeNO, ACQ, %FEV1 predicted and reversibility. In a scenario analysis, patients' asthma control was categorized according to two established control markers, and FeNO as an extra marker.

Results: We included 147 and 160 patients (in total 63% female; mean age 35.4). Correlations between FeNO, symptoms and lung function were weak (max 0.240, between FeNO and %FEV1). All three control markers were consistent in interpretation of asthma control in 25.7% of the population. In 28.1% symptoms and lung function were consistent but FeNO was contradicting and in another 46.3% the two established markers were contradictory. FeNO, symptoms and lung function in adults with asthma in primary care, which confirms that FeNO is an independent marker in assessing asthma control. In almost half the population, results of symptoms and lung function were contradicting regarding assessing asthma control; in this group FeNO may fine-tune categorization of asthma control.

P3768

A pilot study to detect airflow obstruction in smokers using spirometry in a local GP surgery

Bhupinder Mann1, Essam Ramhamedly2, Lesley Seddon2, Emma Loveridge3, Angela Glemmon1, 1Respiratory Care, West Midlands, UK; 2Department of Respiratory Medicine, University Hospitals Birmingham, Birmingham, Warwickshire, United Kingdom; 3Respiratory Section, Astra Zeneca, London, United Kingdom

COPD is under diagnosed worldwide. In our locality, it is thought that a fifth of all COPD cases have been identified.

Aim: To carry out a pilot study to screen smokers and ex-smokers in a local GP practice with spirometry to allow earlier COPD diagnosis.

Methodology: Over a 7 month period, subjects were identified from a GP practice database. The target population included smokers/ex-smokers over the age of 35 who had smoked a minimum of 10 pack years; recurrent or chronic respiratory symptoms; occupational exposure to respiratory irritants or family history of COPD. Patients known to have COPD or asthma were excluded.

Appropriate subjects completed a short questionnaire to screen smokers and ex-smokers in a local GP practice with spirometry to allow earlier COPD diagnosis.

Conclusion: We observed weak correlations between FeNO, symptoms and lung function in adults with asthma in primary care, which confirms that FeNO is an independent marker in assessing asthma control. In almost half the population, results of symptoms and lung function were contradicting regarding assessing asthma control; in this group FeNO may fine-tune categorization of asthma control.

P3769

Effectiveness of supervised training program about spirometry in primary care

Crystina Represas-Represas, Virginia Leiro-Fernández, Maribel Botana-Rial, Ana Isabel González-Silva, Alberto Fernández-Villar. Pneumoology, Respiratory and Infectious Disease Research Group, Bio-Medical Research Institute of Vigo, University Hospital Complex of Vigo (CHUVI), Vigo, Pontevedra, Spain

Spirometry is an essential technique for diagnosing respiratory diseases but it is underused at Primary Care (PC) level. Training could help to improve the situation.

Objectives: To analyze the effectiveness of 2 months supervised training program about spirometry performance and interpretation.

Methodology: Interventional study, with measurements before and after, to improve the quality. Target population: doctors and nurses team, of 26 PC centers. Teachers: pulmonologists from our hospital (CHUVI). We designed a structured program showed in figure 1. To assess the effectiveness of the course, students were evaluated with a test-exam composed of 5 spirometries with 2 questions each one, at three different times: before initial training (test 1), at the end of the first working day (test 2), and on the 2nd working day (final test).

Results: Of 74 students, 72 (97.2%) completed training and 90% passed the exam. The mean punctuation in the different tests were: 4.1±0.1, 6.5±1.3 in test 1; 7.5±1.6 in test 2 and 8.9±1.3 in the final test (p<0.0001). The number of supervised spirometries performed and interpreted correctly was 370 of 521 (71%) during the first month and 562 of 619 (91%) during the second month (p<0.0001).

680s
Figure 1

Conclusions: An spirometry training program based on theoretical and practical workshops, and practical monitoring improves significantly the competence of PC professionals in the performance and interpretation of this technique.

P3770

Agreement between asthma control perception by patients, by physicians and according to guidelines

M. C. Vanerma, C. Picado, L. Herrera, J. Galera, J. Casamento, on behalf of the CONTROL Study Group. 1Pneumology and Respiratory Allergy, Hospital Clinic, Barcelona, Spain; 2Health Outcomes Research, Novartis Farmacéutica, Barcelona, Spain

Background: Despite the clinical interest and current treatments availability, more than a half of Spanish asthma patients fail to control their disease adequately.

Objective: To assess the degree of correlation between the asthma control perceptions by patients and by physicians.

Methods: Observational, cross-sectional and multicenter study that included patients with severe persistent asthma according to Spanish Guidelines for Asthma Management (GEMA). We calculated the degree of agreement between asthma control perceptions by patients, physicians and according to the GEMA.

Results: A total of 343 patients were included. Mean age (SD) was 48.1 (14.7) years and 1/3 were women. The assessment of the degree of asthma control according to GEMA criteria showed that only 10.2% of patients were controlled, 57.7% partially controlled and 22.1% poorly controlled. The correlation between patient’s asthma control perception and according to GEMA criteria showed that 35.7% of patients that viewed themselves under control did not achieve GEMA criteria (p < 0.0001). The agreement between physicians and GEMA criteria showed that 16.6% of asthma patients who reached medical criteria for control, were not under the GEMA control assumptions (p < 0.0001). Concordance between medical criteria and patient’s perception showed that only 57.9% of cases coincided for the control of asthma, while 40.7% of patients who felt controlled were not under physician opinion (p < 0.0001).

Conclusions: Both patients and physicians overestimate asthma control, with higher control perception in patients.

P3771

Peak flow is not strictly comparable by gauge and spirometry in many patients

Clare Bradley, 1 Hannah Tighe, 2 Philip Inkl. 1St Mary’s Hospital, Praed St, London, United Kingdom; 2Imperial College School of Medicine, Hammersmith Hospital, London, United Kingdom

Peak Flow, usually measured by meter or gauge (PEFm), is commonly used in monitoring airway calibre in asthma and in COPD. Spirometry is increasingly used in COPD assessment in primary care. Most spirometers generate flow-volume curves yielding peak flow measurements (PEFvfl) which may also be used in monitoring patients. It is unclear how closely PEFm and PEFvfl relate in practice.

We determined PEFvfl (from 2 reproducible loops) using the Zen 100 spirometer and PEFm (best of 3 blows by Wright gauge) in 100 consecutive patients undergoing routine lung function.

General agreement between the 2 measures was good: mean PEFvfl was 333 (SD 139), mean PEFm was 317 (SD 137) L/min. However, PEFm was 20 L/min or more lower in 45 patients and 20 L/min or more higher in 12 patients than PEFvfl.

The 2 measures differed by 40 L/min in 27 patients.

Simple visual inspection of F-V loops did not predict the difference between the 2 measurements. Larger differences did not occur in asthma or COPD patients than in others or correlate with airflow obstruction.

In this small study the order of measurements was not randomised and the population may not be generalisable but clinically significant differences were apparent in a large proportion of patients using the different techniques. PEF measurements in an individual should preferably be compared using the same equipment. Lung function laboratories should determine both PEFm and PEFvfl.

P3772

Composite asthma control measures in real-life studies

David Price, 1, 2 Richard Martin, 1 Gene Colice, 3 Paul Dorinsky, 3 Alison Chiuholm, 1 Julie von Zeyenrodth, 3 Annie Burden, 2 Peter Polos, 6 Liz Hillyer, 6 Nicolas Roche, 2 1Centre of Academic Primary Care, University of Aberdeen, Aberdeen, United Kingdom; 2Observational Research, Research in Real Life, Norwich, United Kingdom; 3National Jewish Health, Denver, CO, United States; 4Washington Hospital Center and George Washington University School of Medicine, Washington, Washington, DC, United States; 5Global Respiratory R&D, Teva Pharmaceuticals, Horsham, PA, United States; 6i3 Global, Basking Ridge, NJ, United States

Background: Using real-life databases to compare asthma treatments requires composite proxies for asthma control.

Methods: Observational study using the US Ingenix Normative Healthcare Database to compare asthma outcomes between matched patients either initiating or increasing inhaled corticosteroid (ICS) therapy as fluticasone propionate (FP) or extra-fine hydrofluorokalene beclomethasone dipropionate (EF HFA-BDP). Literature-based a priori-defined composites were developed and evaluated over 1 yr, including: markers of emergency healthcare use for asthma and lower respiratory tract infections; use of oral steroids and reliever therapy; increased maintenance therapy, and controller-reliever ratio. Medication possession ratio (MPR) was calculated to assess adherence.

Results:

<table>
<thead>
<tr>
<th>Composite Measure</th>
<th>EF HFA-BDP</th>
<th>FP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asthma control achieved (n, %)</td>
<td>348 (54.4)</td>
<td>348 (54.4)</td>
</tr>
<tr>
<td>Asthma control achieved + SABA (n, %)</td>
<td>271 (42.3)</td>
<td>271 (42.3)</td>
</tr>
<tr>
<td>No severe exacerbations, n, %</td>
<td>222 (68.9)</td>
<td>222 (68.9)</td>
</tr>
<tr>
<td>Decreased controller-reliever ratio (≥0.5, n, %)</td>
<td>271 (42.3)</td>
<td>271 (42.3)</td>
</tr>
<tr>
<td>MPR, %</td>
<td>30 (11.3)</td>
<td>30 (11.3)</td>
</tr>
<tr>
<td>Outcome year ICS dose, μg/day</td>
<td>44 (22-88)</td>
<td>27 (13-145)*</td>
</tr>
</tbody>
</table>

Conclusion: While the proportion of patients achieving asthma control varies according to the considered criterion, data consistently show similar or better outcomes for EF HFA-BDP despite a significantly lower ICS daily dose and similar MPR. Using multiple composite measures to evaluate comparative effectiveness reinforces confidence in study findings.

P3773

Pharmacists and knowledge of asthma: Survey of 120 pharmacists, comparison between 1999 and 2009

Marion Menier-Spizir, 1 Hassina Lefève, 2 Pauline Reboutié, 1 Christiane Heitz, 3 Anne-Sophie Bibler, 1 Frederic de Blay, 1 1Allergy Division Chest Disease, University Hospital of Strasbourg, Strasbourg, France; 2Faculty of Pharmacy, University of Strasbourg, Strasbourg, France

Asthma morbidity has changed over the ten last years, we speculated that pharmacist knowledge concerning the treatment of asthma has also changed over years.

Aim: To compare pharmacists’ knowledge in asthma treatment in urban and rural areas between 1999 and 2009.

Material and methods: 120 pharmacists (60 licensed and 60 assistants) from the Bas-Rhin (North part of Alsace) were randomly selected on two occasions. The 2009’s pharmacists were all different from the 1999’s ones. 80 of them accepted to answer the same standardized questionnaire in 1999 and in 2009.

Pharmacists’ populations in 1999 and in 2009 were identical (age, gender, pharmacy location (urban vs rural), ...). Emergency interventions for an asthma attack were performed by 10.6% of them in 1999 and 8.6% in 2009 (NS). 33% of them advised patients to go back home after intervention in 1999 and 57% in 2009. They gave advice to obtain a better compliance (96% the two years) and explained how to use an inhaler (96% in 1999 and 94% in 2009) in the same proportion. Ten years later, 98% voluntarily demonstrated use of different inhalers instead of 64% in 1999 (p<0.05) (MDI, Autohaler, Turbuhaler) 14 and 9% knew how to use an MDI properly, 5% and 4% an Autohaler and 31 and 24% a Turbuhaler in 1999 and 2009, respectively (I don’t understand this point well).

Time spend per prescription was the same in the two years (< 15min).

* p<0.05

Conclusions:

- pharmacy location (urban vs rural), ...
- Difference in asthma treatment required between 1999 and 2009.
- Pharmacists populations were the same in 1999 and 2009.

681s
Conclusion: During the last 10 years, pharmacists knowledge about asthma has not increased significantly. On the other hand they were more prone to use an inhaler for a demonstration. Training pharmacists about asthma seems still necessary.

P3774
Know it, check it, treat it – COPD consumer mobilisation campaign. A pilot study
June Roberts1, Helena Cullen1, Nawar Dar Bakerly1, 1Respiratory Medicine, Saltford Royal National Trust; 2Adult Services, Saltford Community Health, Saltford, Greater Manchester, United Kingdom

Background: COPD is under diagnosed and awareness amongst the public is low. Aims: To develop and pilot a consumer mobilisation campaign* to increase public awareness of COPD and encourage the undiagnosed local population to recognise symptoms and present for further assessment.

Methods: Insights into attitudes to COPD and motivators/barriers to health messages were collected through focus groups with local clinicians and members of the public. Key messages were communicated using a variety of media over a 3-month period. Pre and post campaign awareness amongst clinicians and the public was measured using market research techniques.

Results: Key insights from focus groups:
Don’t focus on smoking. “We don’t like anti-smoking messages”
Get people to join the dots between their symptoms and COPD - “It’s only just dawned on me that my cough is not normal”
Make the message personal - “COPD may mean you become dependent on others” was a message that shocked people and would more likely prompt action.
Make statistics real – “1 in 7 people registered more with the target audience than 3.7 million people have the disease”
Of 75 people surveyed post launch:
Prompted awareness of COPD increased by 24% and its symptoms by 9%
Of 25 general practices surveyed post launch:
Awareness of the campaign amongst clinicians was high (80% unprompted)
There was an average increase in diagnosis rates of 2 patients per practice prompted by the campaign (range 0.15)

Conclusion: COPD consumer mobilisation campaigns can increase public awareness and diagnosis rates. Further work is needed.

Campaign developed and funded by Boehringer Ingelheim Ltd and Pfizer Ltd in collaboration with NHS Saltford

P3775
Knowledge of pulse oximetry among general practitioners in south Australia
Quirine Huijgen1, Tanja Efthie1, Kerry Hancock1, 1Respiratory Medicine, University of Adelaide, Adelaide, Australia

Aims and objectives: The feeling of satisfaction with inhaler (FSI-10) is a self-completed questionnaire designed to assess the patient opinions regarding the satisfaction and usability of the inhalers irrespectively of the drug used. It consists of 10 questions, each with 5 possible responses on a 5-point Likert scale scored from 5 to 1, respectively.

Objective: The aim of this study was to validate the Greek version of this questionnaire.

Methods: We performed an open, non-interventional, multicentre, parallel clinical study. The final group consisted of 422 subjects (192 females) aged between 16 and 87 years, who suffered from asthma or COPD and who regularly received their treatments exclusively via the inhaled route. All had already achieved mastery of their devices and they completed in full the Greek FSI-10 which had been translated by two specialists and back translated by another specialist. Statistical analysis was done by using SPSS version 17.0.

Results: The Greek version of the FSI-10 was easily understood and completed by the participants. Spearman’s rho correlation coefficients showed good relationships between questions and a positive contribution of the score of each question to the total score. No redundancy was observed. Cronbach test for the questionnaire as a whole showed a very good internal consistency (Cronbach’s alpha=0.923). Lower u values (0.907 - 0.922) were calculated, if any one of the items was consecutively deleted.

Conclusions: The reliability of the Greek version of the FSI-10 questionnaire was proven for the first time by this study. The instrument fits its purpose very well and can be used in multicentre clinical trials conducted in Greece.

P3777
Lung function disorders screening among the smoking patients in primary health care
Elena Andreeva, Irina Kudryavtseva, Vladimir Popov. 1Clinical Research Department, Northern State Medical University, Arkhangelsk, Russian Federation

Background: Smoking is a major risk factor for chronic obstructive pulmonary disease (COPD). Prevalence of smoking in Russian Federation is one of the highest in the world: 39.1% of the adult population. The airflow limitation is not necessarily accompanied by certain symptoms and therefore some patients do not always seek for medical advice.

Aim: Early detection of airflow limitation and identification of risk factors for COPD among smoking patients in general practice in Northwest Russia.

Methods: 414 volunteers (smokers and ex-smokers) were invited to make the standardized lung function test and fulfilled the questionnaires (including the symptoms and smoking status). COHb% and carbon monoxide (CO) in exhaled air were established by MicroCO analyzer.

Results: Mean age was 42.1±13.6 years, 62.3% of the sample was males, and 80% of subjects were current smokers. The average smoking history was 25 pack-years for males and 14.8 for females. Subgroups of potential (smoking>10 pack-years) and high (> 25 pack-years) risk of COPD were defined (68.1% and 30.7%, respectively). The high levels of CO and COHb (>3%) were revealed in 25.5% and 35.9% smokers, respectively. The cough and dyspnoea were the main complaints (49.0% and 45.7%, respectively). Obstructive ventilation disorders were identified in 41.1% of subjects. The prevalence of obstruction increased with age and smoking history (p<0.001). Reversibility test was performed in 72% of all patients with identified disorders of lung function. COPD was detected in 28 patients (6%).

Conclusions: Early diagnosis of lung function disorders in smoking patients is an opportunity to identify individuals with increased risk of developing COPD.

The prevalence of respiratory infections in vaccinated patients with chronic obstructive pulmonary disease
Dimitra Sereti, Konstantina Sereti, Theodosios Theodosiou, Vasiliki Kyriakopoulou, Maria Petta, Maria Petta. 1General Practice, Vardas Health Center, Patras, Achaea, Greece; 2General Practice, Chalandritesas Health Center, Patras, Achaea, Greece

Aim: To estimate the prevalence of respiratory infections in immunized patients with chronic obstructive pulmonary disease (COPD).

P3776
Reliability of the FSI-10 questionnaire for the assessment of the usability of inhalers in Greek patients
Nikolaos Grekas1, Katerina Athanassiou1, 1Respiratory Medicine, University of Patras, Patras, Greece; 2Clinical Research Department, Elpen Pharmaceutical Co Inc, Pirem, Greece; 3Service de Neumologia, Hospital Universitario la Fe, València, Spain

Introduction: The Feeling of Satisfaction with Inhaler (FSI-10) is a self-completed
It is important to continue working to get a proper diagnosis and treatment. Only 252 (6%) had a previous history of atopy. 1,960 (49.3%) had a family history of asthma. 921 (22.1%) were normal body mass index according to WHO classification. 2550 (60.9%) were non-smokers. Only 1369 (34.9%) did not complain of dyspnea (MRC = 0). We included 4,188 patients diagnosed with asthma, of which 2450 (60.2%) had been treated with an inhaled drug (bronchodilator and/or inhaled corticosteroid). All patients signed informed consent. Results: We included 4,188 patients diagnosed with asthma, of which 2450 (60.2%) were men. The mean age was 50.5 years (SD 17). 1486 patients (36.6%) had a normal body mass index according to WHO classification. 921 (22.1%) were non-smokers. 188 (4.5%) were current smokers. 1663 (41.4%) were sensitized to at least one allergen. 2528 (63%) of patients had rhinitis and 1,214 (30.3%) had a previous history of atopy. 1,960 (49.3%) had a family history of asthma. Only 1369 (34.9%) did not complain of dyspnea (MRC = 0). 2550 (60.9%) were treated with a combination of an inhaled corticosteroid and a long acting beta-2 agonist. Only 855 (20.6%) of patients who were diagnosed with asthma had a spirometry at any time prior to inclusion in the study and only 252 (6%) had a reversibility test. The mortality in vaccinated against influenza and pneumonaeus was 0.1%. However, the quality of life seems to be affected because of exacerbations and hospitalization which discomfort a significant percentage of COPD patients.

**P3779**
Evaluation of lung function on asthma patients cared by primary care physicians
Carlos Almonacid Sanchez1, José Luis Izquierdo Alonso1, Pilar De Lucas Ramos3, José Miguel Rodríguez-González-More2, José Gallardo Carrasco1, A. Martin Centeno1, 1Pulmonary Medicine, Guadalajara University Hospital, Guadalajara, Spain; 2Pulmonary Department, Gregorio Marañón Hospital, Madrid, Spain; 3Medical Department, Pfizer Spain, Madrid, Spain

**Aim:** To know the characteristics of patients diagnosed as asthma in primary care.

**Methods:** Multicenter epidemiological, transversal and observational study performed in patients diagnosed as asthma in primary care and treated with an inhaled drug (bronchodilator and/or inhaled corticosteroid). All patients signed informed consent.

**Results:** We included 4,188 patients diagnosed with asthma, of which 2450 (60.2%) were women. The mean age was 50.5 years (SD 17). 1486 patients (36.6%) had a normal body mass index according to WHO classification. 921 (22.1%) were non-smokers. 188 (4.5%) were current smokers. 1663 (41.4%) were sensitized to at least one allergen. 2528 (63%) of patients had rhinitis and 1,214 (30.3%) had a previous history of atopy. 1,960 (49.3%) had a family history of asthma. Only 1369 (34.9%) did not complain of dyspnea (MRC = 0). Only 855 (20.6%) of patients who were diagnosed with asthma had a previous history of atopy. 1,960 (49.3%) had a family history of asthma. Only 1369 (34.9%) did not complain of dyspnea (MRC = 0). 2550 (60.9%) were treated with a combination of an inhaled corticosteroid and a long acting beta-2 agonist. Only 855 (20.6%) of patients who were diagnosed with asthma had a spirometry at any time prior to inclusion in the study and only 252 (6%) had a reversibility test. The mortality in vaccinated against influenza and pneumonaeus was 0.1%. However, the quality of life seems to be affected because of exacerbations and hospitalization which discomfort a significant percentage of COPD patients.

**Conclusions:** The mortality in vaccinated against influenza and pneumonaeus patients seems to be negligible. However, the quality of life seems to be affected because of exacerbations and hospitalization which discomfort a significant percentage of COPD patients.

**P3780**
Non-invasive ventilation (NIV) in community-acquired pneumonia (CAP) and severe acute respiratory failure (ARF): Effectiveness and risk factors for failure and mortality
Andres Carrillo1, Gumersindo Gonzalez-Diaz1, Miquel Ferrer2, Maria Elena Martinez-Quintana1, Antonia Lopez-Martinez1, Noemí Llamas1, Maravillas Alcaraz1, Antonio Torres3, 1ICU, Hospital JM Morales Meseguer, Murcia, Spain; 2RJCIC, Department of Pneumology, Hospital Clinic, IDIBAPS, CIBERES (CB06/060602), Barcelona, Spain

**Background:** The use of NIV for treating severe ARF due to CAP is controversial, and the risk factors for failure with this mode of ventilation are not well-known in these patients.

**Methods:** Prospective observational study to assess the usefulness of NIV in patients with CAP and severe ARF. The primary end-point variable was to determine the success of NIV, defined as avoidance of endotracheal intubation and survival in the ICU and for at least 24 hours in the medical ward, in patients with CAP. We assessed predictors of NIV failure and hospital mortality in multivariate analyses.

**Results:** We studied 184 consecutive patients with CAP and severe ARF: 102 (55%) patients had de novo ARF and 92 (45%) previous pulmonary or cardiac disease. NIV was successful in 116 (63%) patients. Hospital mortality was 10% (95%) in successfully treated patients and 37 (54%) in those who failed treatment (p<0.0001). The variables independently related to NIV failure in the multivariate analysis were SAPS-II at admission, maximum SOFA during NIV, older age, higher heart rate and lower PaO2/FiO2 ratio after 1 hour of NIV, and worsening of radiologic infiltrate 24 hours after admission. Likewise, independent predictors of hospital mortality were maximum SOFA during ICU stay, NIV failure and older age.

**Conclusions:** Patients with CAP and severe ARF can be treated with NIV with a reasonable success rate. Successful NIV treatment is strongly related with improved outcome in these patients. Multi-organ failure and older age strongly predict both treatment failure and poor survival.

**P3781**
Pressure support in acute hypercapnic respiratory failure in an acute clinical setting
Asad Ali, Ajit Thomas, Shiva Bikmalla, Ben Beauchamp, Emma Gallagher, Dev Banerjee, Rahul Mukherjee. Academic Department of Sleep & Ventilation, Birmingham Heartlands Hospital, Birmingham, United Kingdom

**Introduction:** Non-invasive ventilation (NIV) is now routinely used for treatment of Acute Hypercapnic Respiratory Failure (AHRF). There is much debate as to whether usage of higher pressures for ventilation improves the outcome in an acute setting.

**Aim:** We set out to assess what pressures for NIV were needed to achieve reversal of acidosis in AHRF in an acute clinical setting and what was the outcome.

**Method:** A scientific survey was conducted over 6 years in a teaching hospital ward-based NIV unit. Levels of Inspiratory Positive Airways Pressure (IPAP) and Expiratory Positive Airways Pressure (EPAP) levels needed to achieve reversal of acidosis in AHRF were analysed. Patients with AHRF were divided into 2 groups; AHRF from chronic obstructive airways disease (COPD) and AHRF from non-COPD related illnesses. Mortality during the admission in the 2 groups was also assessed.

**Results:** A total of 1188 episodes with 820 COPD related and 366 non-COPD related AHRF admissions were recorded. In the COPD group pressures (in cm H2O) needed for reversal of acidosis were IPAP max 30, min 10 and median 16.7; EPAP max 12, min 4 and median 5.2. In the non-COPD group; IPAP max 30, min 10 and median 16; EPAP max 11, min 4 and median 5.3. 318/20 (10.1%) of COPD and 50/366 (13.6%) of non-COPD patients died during admission.

**Conclusions:** Our findings suggest that reversal of acidosis AHRF from underlying COPD or other illnesses can be achieved with satisfactory outcomes without the need of high pressure ventilation. Further well designed studies would be needed to explore this further.

**P3782**
Home versus intensive care ventilators providing noninvasive ventilation (NIV): A clinical comparison during acute respiratory failure due to COPD exacerbation
 Marcello Ciuffreda1, Antonella Sarni1, Mariacelena Mozzillo3. 1Respiratory Unit, 2Emergency and Medical Semi-Intensive Care Unit. 3Internal Medicine Unit, La sapienza University, Santa Maria Goretti Hospital, Latina, Italy

**Background:** Different bench test studies were performed to compare the performance characteristics of home and ICU ventilators. However little data in comparison are available in a clinical setting.

**Aim:** To compare the clinical effects of NIV delivered by ventilator dedicated to ICU versus devices designed for home care.

**Material and method:** We enrolled 30 patients admitted in semi-intensive care unit to AECOPD due to AECOPD (Baseline pH 7.24±0.04, PaCO2 87.4 mmHg ±16.5, PaO2 70.6 mmHg±18.9, aged 79.7 y, RR 36±9 y). 37% of patients were randomized in two groups to receive NIV delivered by an ICU ventilator or three home ventilators. Baseline characteristics showed no significant differences in both groups. Several exclusion criteria were included (i.e. coma, obesity, COPD or other illnesses can be achieved with satisfactory outcomes without the need of high pressure ventilation. Further well designed studies would be needed to explore this further.)

**Conclusions:** Home and ICU ventilators are equally effective in improving blood gas exchange. Further clinical studies could help clinicians in choosing the appropriate devices, tailoring the choice to a given patient.

**P3783**
Predictors of mortality in patients treated with non-invasive ventilation for acute hypercapnic respiratory failure due to COPD
Helmy Haja Mydin1, Stephen Murphy2. 1Cardiothoracic Centre, Freeman Hospital, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 2Department of Respiratory Medicine, Sunderland Royal Hospital, Sunderland, United Kingdom

**Background:** Mortality in patients treated with non-invasive ventilation (NIV) for acute hypercapnic respiratory failure (AHRF) during an acute exacerbation of COPD (AECOPD) is high. For many patients, AHFR is an end-stage process and NIV may be inappropriate. However there is no definitive method of identifying patients who are unlikely to survive.

**Aim:** The aim of study was to identify clinical and laboratory variables predictive of mortality in patients treated with NIV for AHRF due to COPD.
P3784 Non invasive ventilation (NIV) in conscious sedation with remifentanil
Alfonso Pecoraro1, Ginevra Del Giudice1, 2. 1 Department of Physiotherapy and Respiratory Semi-Intensive Care Unit, 2.S. Francesco di Paola” Hospital, Pescopagano, Poteza, Italy. Department of Cardio-Thoracic and Respiratory Sciences, Second University of Naples, “V. Montaldi” Hospital, Naples, Italy

Background: NIV use in acute hypercapnic respiratory failure (AHRF) patients who refused orotracheal intubation is an open question. Agitation is a frequent reason of NIV failure. Aim: We have evaluated the safety and tolerance of NIV in patients under conscious sedation induced by remifentanil.

Methods: Thirty (11F/19M) consecutive COPD patients with AHRF admitted to our Semi-intensive care Unit were unable to tolerate NIV treatment. Patients were submitted to conscious sedation (continuous sedation at random). We assessed the changes in arterial blood gas, tolerability and adverse events at the time of admission, after 30 min and 60 min of NIV use. Results: Pao2/Fio2 ratio improved after 60 min (p < 0.001). PaO2 increased from 46±7 (pre-NIV) to 61±4mmHg (post-NIV). PaCO2 decreased from 67±4 (pre-NIV) to 45±3 mmHg (post-NIV). We documented hypotension in 2 patients (7.6%) treated by dose adjustments. No bradycardia and respiratory depression were observed. We have not documented any unforeseeable event. No patient died during admission.

Conclusions: In selected population remifentanil is well tolerate in AHRF patients treated with NIV.

P3785 Noninvasive ventilation in the weaning of patients with acute-on-chronic respiratory failure due to COPD
Gamal Agmy, Yasser Gad, Yossef Ahmed. Chest, Assiut University, Assiut, Egypt

Background: Endotracheal intubation (ETI) and mechanical ventilation are often needed in patients with acute-on-chronic respiratory failure (ACRF) due to acute exacerbations of COPD (AECOPD).

Purpose: It was to assess the usefulness of non invasive ventilation as an early extubation and weaning technique in ACRF secondary to AECOPD.

Patients and methods: Among 384 consecutively intubated patients admitted for AECOPD due to AECOPD, a prospective, randomized controlled trial of weaning was conducted in 264 patients who failed a 2-h spontaneous breathing trial, although they met simple criteria for weaning. Conventional invasive pressure support ventilation (IPSV) was used as the control weaning technique in 130 patients (IPSV group), and NIV was applied immediately after extubation in 134 patients (NIV group).

Results: No statistical difference was found in the characteristics of the two groups at randomization. In the IPSV group, 100 of 130 patients were successfully weaned and extubated, versus 124 of 134 in the NIV group (p < 0.05). NIV like IPSV significantly and similarly improved gas exchange in relation to that achieved during a 2-h spontaneous breathing trial (p < 0.05). The duration of ETI was significantly shorter in the NIV group (4.52±0.87 d) than in the IPSV group (7.06±1.32 d) (p < 0.001). NIV reduced significantly the duration of ETI weaning failure, nosocomial pneumonia, ICU stay and hospital stay.

Conclusions: 1. NIV like IPSV significantly and similarly improves gas exchange during weaning, of patients with ACRF secondary to AECOPD, from invasive MV. 2. NIV reduces significantly the duration of ETI weaning failure, nosocomial pneumonia, ICU stay and hospital stay.

P3786 Leptin kinetics in patient with obesity hypoventilation syndrome (OHS) during non-invasive ventilation (NIV)
Gulsara Baimakanova, Sergey Avdeev, Alexander Chuchalin. Clinical Department, Pulmonology Research Institute, Moscow, Russian Federation

Background: Leptin is pleiotropic hormone which has important physiological effects in patients with OHS. Currently there is no data about leptin kinetics for the management or follow-up of OHS patients with acute respiratory failure (ARF).

Objectives: To evaluate the leptin kinetics in patients with OHS during hypercapnic AHRF treated with NIV therapy.

Methods: Our prospective observational study included 19 OHS patients hospitalized for AHRF (age 55.9±12.2 yrs, BMI 56.7±8.3 kg/m², PaCO2 42.6±10.35 mmHg, PaO2 58.5±12.2 mmHg), all patients received NIV during hospitalization. Serum leptin levels, arterial blood gases, pulmonary function and echocardiography tests were measured.

Results: Initial leptin concentration was not significantly elevated in OHS patients (38.6±6.97 ng/ml), and after 10-14 days of NIV therapy leptin levels significantly decreased (to 32.1±12.5 ng/ml, p < 0.001). But in patients with more slower reduction of PaCO2 (n=9) leptin levels didn’t change significantly at hospital discharge.

Intentional leptin concentrations correlated with residual lung volume (r=0.76, p=0.04) and leptin kinetics correlated with change in PaCO2 (r=0.49, p=0.04) and change in PaO2 (r=0.75, p<0.001). Patients with slower leptin kinetics had higher BMI, more severe hypercapnia, less pH and left ventricular ejection fraction (p<0.05); they needed more intensive NIV and had an increased risk of hospital readmission during 3 months (n=28 0.004).

Conclusions: Assessment of leptin kinetics in OHS can help to predict outcome of NIV therapy and it may be of value for guiding NIV intensity in these patients.
with or without other pathology (6%) vs (4%), interstitial lung disease (55%), OHS (5.2%), kyphoscoliosis (17%), heart failure (16%) and neuromuscular disease (41%) When comparing epidemiological data, comorbidities, and side effects between the group died and those who survived after treatment, we founded significant differences in the deceased group older, less obese.

Conclusions: It is necessary to performance a detailed analysis of mortality in each group of pathology In COPD and OHS, which are the most ventilated, it is quite worthwhile to carry out NIV. The palliative patients group increase mortality rates so it is very important to analyze this group separately. To carry out NIV may be an alternative for patients who do not fulfill ICU admission criteria.

P3789
Decision making in acute hypercapnic respiratory failure due to COPD: Criteria in patient selection & determining ceiling of care
Laura Tanner, Stephen Murphy. Thoracic Medicine, Sunderland Royal Hospital, Sunderland, United Kingdom

Background: Non-invasive ventilation (NIV) is effective in acute hypercapnic respiratory failure (AHRF) due to COPD but the UK National COPD Audit (2008) raised concerns about patient selection; only 70% of eligible patients received NIV and invasive mechanical ventilation (IMV) was used in only 3% if NIV failed.

Aims: The aim of this study was to ascertain criteria clinicians use to make decisions regarding NIV.

Methods: A 12 point questionnaire was sent to doctors involved in acute care of patients admitted with acute exacerbation of COPD. Key areas included arterial blood gas (ABG) criteria, prognostic factors and decisions on ceiling of care. Comparisons were made between grades and specialities.

Results: 31 questionnaires were completed. 61.5% consultants, 16.1% specialist registrar (SPR), 24.5% other training grades (OT). Specialties: ITU 16.1%, Respiratory (RESP) 22.6%, Other general medical 61.5%. Most (74.1%) made decisions on NIV at least weekly. There was poor agreement on ABG criteria for NIV (<7.35). Adherence to guideline criteria for NIV varied by specialty. RESP 85.7% v non-RESP 41.6% OR 8.4 (1.08-59.8). Agreement on prognostic criteria was poor (K 0.17). 80% of SPR and 28.5% OT grades frequently make decisions on ceiling of care.

Conclusions: AHRF due to COPD is often managed by non-respiratory physicians. There is marked divergence from guideline criteria for initiation of NIV. There is poor agreement between physicians regarding prognostic criteria used to determine ceiling of care. These decisions are frequently made by junior medical staff.

P3790
Prognosis after non-invasive ventilation (NIV) for chronic obstructive pulmonary disease (COPD)
Mandip Alhalalimal, Mohamad Khan, Mohamad Paracha. Department of Respiratory Medicine, Blackpool Fylde and Wyre Teaching Hospitals NHS Trust, Blackpool, Lancashire, United Kingdom

Introduction: Non-invasive ventilation is now standard therapy for acute type 2 respiratory failure secondary to COPD. It reduces mortality, intubation rate and length of stay even when given in a general respiratory ward. Therefore, many patients who were considered to have othervise had not survived, are now successfully discharged.

Aims and objectives: To assess survival and remission rate over subsequent one year in these patients in “real life” while receiving routine medical care in the community.

Methods: Retrospective review of 50 randomly selected patients admitted between 12/2001 and 9/2009 to Blackpool Victoria Hospital, a large district general hospital in North West of England.

Results: MF: 37:13, mean age 68.9 years (SD= 10.9). 49/50 patients were current (n=19) or ex (n=30) smokers. 26/49 (53%) were on long term (n=11) or short burst (n=15) oxygen. 3 had been previously admitted to ITU and 9 had received NIV; 6 patients had pneumonia and 17 evidence of cor pulmonale on ECG at the time of admission. 26/50 (52%) made recovery with NIV in the ward despite pH of <7.20 (5/30 had pH of <7.0). 14/48 (29%) had died during subsequent one year (survival status unavailable=2). Readmission rate was 74% and 48% were admitted more than once (x1=13 pts, x2=8 pts, x3=4 pts, x4=4 pts, x5=6 pts, x6=1 pt, x7=1 pt). Conclusion: One third of patients who were discharged after receiving NIV for an exacerbation of COPD died in the subsequent year. Majority of these patients required readmission, many more than once. Further research is required to optimally treat this high risk group to improve quality of life and and reduce health care costs.

P3791
Outcome analysis of “do not resuscitate” versus “full resuscitation” patients with acute exacerbation of COPD treated with noninvasive ventilation in a pulmonary unit
Ruben van der Wekken, Aik Bossink, Folkert Brijker. Pulmonary Diseases, Diakonessenhuis, Utrecht, Netherlands

Introduction: Noninvasive ventilation (NIV) is common practice in acute respira-
tory failure due to acute exacerbation of COPD (AECOPD). NIV is administered to patients with both “Do Not Resuscitate” (DNR) and Full Resuscitation (FR) order. Little is known about the outcome of DNR-patients treated with NIV in a pulmonary unit, compared to patients with a FR order.

Methods: In a single centre study, during a period of three years, we followed all patients with AECOPD who underwent NIV in a pulmonary unit (n= 67). NIV was initiated in case of respiratory acidosis with pH<7.35, using a stepwise protocol. Resuscitation policy was established earlier in the outpatient clinic or in the emergency unit at presentation. The outcome was failure of treatment, which was defined as 1) in-hospital mortality, 2) mortality within three months after discharge and 3) transfer to the ICU (only in the FR-group). The results of the DNR-group (n=22) and the FR-group (n=45) were compared.

Results: In the DNR-group 9 patients died in the hospital and another 3 died within three months after discharge (total failure: 55%). In the FR-group 1 patient died in the hospital, no extra mortality was observed within three months after discharge and 11 patients were transferred to the ICU (total failure: 27%) (Fisher exact p = 0.05).

Conclusion: There was more failure of treatment in the DNR-group than in the FR-group. However, still a substantial number in the DNR-group benefited from NIV. To clarify in which DNR-patients NIV-should be performed, further research is warranted to identify parameters predicting outcome.

P3792
Patients’ perspective of acute non-invasive ventilation (NIV) for decompensated type 2 respiratory failure (T2RF)
Muhammad Hassan, Mohammad Naveed, Hassan Bashir, Colin Smyth. Respiratory Medicine, Royal Liverpool and Broadgreen University Hospital NHS Trust, Liverpool, United Kingdom

Background: A proportion of patients who receive NIV for decompensated T2RF subsequently become intolerant to it. Lack of patient understanding, inadequate medical supervision and/or explanation could potentially lead to poor patient compliance with NIV. We sought to explore patients’ experience and views on acute NIV.

Methods: A satisfaction questionnaire was completed by patients within 24 hours of receiving acute NIV on a respiratory ward.

Results: 115 patients (65 male, median age 68) completed the study. 83% patients received NIV for 2 or more days. Patient responses are shown in table 1. NIV was stopped due to intolerance in 26 cases (mask discomfort 14, claustrophobia 9 and nausea 3). Intention to have NIV in future was not affected by ventilator pressures applied, duration of ventilation, or whether or not the patient had previously had NIV.

</table>

Conclusion: A significant proportion of patients found NIV unpleasant and would refuse such treatment in future. Our data also highlights a lack of understanding of NIV by many patients receiving this therapy. Our findings have significant implications for patient education in respiratory units, as well as choice of equipment using NIV, both of which may impact on patient acceptance of therapy, and mortality.

P3793
Pulmonary gas exchange during mechanical non invasive ventilation in acute hypercapnic patients with obesity hypventilation syndrome (OHS)
Virginia Serrano1, J.E. Gavela1, Pilar Gusavit1, B. Carton1, F. Muita1, E. G. Santalla1, E. Bollo1, F. Diez1. 1Servicio de Neumología, Hospital de León, León, Spain; 2Centro de Salud, Area de Salud, Astorga, León, Spain

Introduction: It is well known that non invasive ventilation in chronic respiratory diseases improves arterial blood gases by enhancing alveolar ventilation without relevant changes in ventilation-perfusion (VA/Q) relationships. (O.Duc et al., Am J Resp Crit Care 1997:150:1-6). The adequate patient-ventilator synchronism throughout the breathing cycle should be a priority to ensure appropriate alveolar ventilation.

Hypothesis: We hypothesize that Pressure Support Ventilation (PSV) may be a useful modality of non invasive ventilation in hypercapnic patients with a restrictive ventilatory defect due to Obesity Hypoventilation Syndrome (OHS).

Aims: To this end, the effects of PSV versus VSV (volume support ventilation) on pulmonary gas exchange were analyzed in twenty hospitalized patients with hypercapnic respiratory failure due to OHS (BMI: 39 ± 7mmHg). Blood Gases at the time of the study (Fio2 0.21): pH (7.34±0.03), PaCO2 55±10 mmHg, PaO2 62.5±3 mmHg, Al-aO2 21±5mmHg.

Methods: Pulmonary gas exchange were measured at 30’ in each of the conditions.

Non-invasive ventilation in acute respiratory failure in a respiratory intensive unit care (RICU) – Characterization and predictors of failure

Ana Sofia Oliveira, Sara Salgado, Cecilia Nunes, Fernanda Oliveira, Cristina Bábara. Pneumology, Pulido Valente Hospital, Lisbon, Portugal

Aims: The use of NIV has proliferated in the last decades in order to support patients with acute respiratory failure. We aimed to analyze NIV’s success in RICU.

Methods: A systematic retrospective review was performed of all hospitalized patients for NIV in our RICU, from February 1 to July 31, 2010.

Results: NIV was performed in 79 patients, 73% were male, with a mean age of 70 years (35-95). Reasons for NIV were acute respiratory failure in 66 patients and continuation of NIV resulting from step-down ICU in 13. Six patients had hypoxemia, 64 hypercapnia and 9 mixed acidosis. Most patients had chronic diseases (cardiac and respiratory), 62% had previous hospital admissions and 27% previous invasive mechanical ventilation. Infectious respiratory exacerbations were the main cause for admission. In 18 patients the intubation decision was made. Average stay in RICU was 10 days (1-76). The majority of the patients had favorable evolution under NIV (57), however there were 22 NIV failures, with 5 ICU transfers. Concerning the group of NIV failure, they were significantly older (p=0.02), showed more previous hospital admissions (p=0.03), more nosocomial respiratory infections (p=0.001), a lower PaO2/PaCO2 (p=0.015), more extensive radiological disease (p=0.017), more sepsis underling disease (p=0.031), more renal disease (p=0.009) and end-stage palliation (p=0.000).

Conclusion: NIV is a common and indispensable treatment in a ICU. NIV’s results are in accordance with the severity of underlying disease, acute exacerbations and with the use of NIV as ceiling support.
NIV is used in 75% of RW with high dependency unit (HDU) and in 27% without HDU. The main indication to NIV has been acute exacerbation of COPD, 73% of all patients treated with NIV. Majority of RW (71%) treat up to 5 patients per month.

Main obstacles to development of NIV is lack of equipment and adequate structure of the ward.

Conclusions: Prevalence of NIV availability within RW in Poland is low and strongly depends on the grade of hospital and the presence of HDU.

P3799
Can non invasive ventilation be effective without a dedicated service?
Gareth Hardy, Sarah Jundi, Mel Rosemary, Tarek Saba. The Department of Respiratory Medicine, Blackpool Teaching Hospitals NHS Foundation Trust, Blackpool, Lancashire, United Kingdom

Introduction: UK guidelines recommend that Non Invasive Ventilation (NIV) should be administered in a dedicated setting with specially trained staff [1]. Our institution is a large district general hospital serving a population of 330,000 in the North West of England. NIV is used on the admissions unit and respiratory wards. Despite very frequent use the service runs without recurrent funding, dedicated staff or educational program. The aim of our service evaluation was to establish whether our service is safe and effective.

Method: We retrospectively audited NIV treatment episodes between January - March 2009. If NIV was discontinued but restarted after 72 hours this was regarded as a new episode.

Results: We identified 45 NIV treatment episodes, averaging 21.8 patient-hours a day. Our patient group comprised 14 female and 25 male patients, with an mean age of 73.1 yrs (range 56-93 yrs). The mean duration was 45 hours (range 5-158). 27 (60%) were diagnosed as an exacerbation of COPD, 13 as pneumonia (29%) and 5 (11%) as cardiac pulmonary oedema. 25 episodes (56.6%) had no treatment plan documented in case of failure of NIV (56.6% COPD, and 56.6% of non COPD), 10 patients (22%) died (33.3% of COPD patients, 14.8% of non COPD) and 1 (2.2%) was referred to ICU.

Conclusion: Our mortality rate in COPD patients is comparable to a recent national audit [2]. However, there is evidence of less advance treatment planning and ICU referral.

P3800
Directed differentiation of mouse embryonic stem cells into primordial lung progenitor cells
Darrell Kotton1,2, Pulmonary Center, Boston University Medical Center, Boston, MA, United States; 2Center for Regenerative Medicine, Boston University Medical Center, Boston, MA, United States

Introduction: During normal development, a small population of foregut cells are specified into lung progenitors that give rise to the entire adult lung epithelium. The transcription factor Ttf-1(Nkx2.1) is the earliest marker of these progenitors. Little is known about the gene programs involved in lineage specification and differentiation of the lung progenitor cells.

Aim: To recapitulate early lung development in vitro and primordially lung cells, identified by Ttf-1 expression, to better understand lung development.

Methods: We developed a faithful lung epithelial reporter line with the GFP reporter gene targeted into the Ttf-1 locus of mouse E12.5 ES. These ESCs were differentiated into endodermal cells using Activin-A in serum-free media. To recapitulate anterior and ventral endodermal patterning we used a combination of growth factors and inhibitors. GFP-positive cells emerged after 9 days in culture. GFP-positive cells were sorted by FACS and analyzed by quantitative real-time PCR at various time points.

Results: Clusters of GFP+ cells were observed from day 9 onwards. These cells expressed the endodermal marker Foxa2 and did not express neurectodermal markers above baseline undifferentiated stem cells. With further culture and FGF2+TGFa stimulation, purified Ttf1-GFP+ cells were lung and thyroid competent as evidenced by upregulation of markers SPC, SPB, CC10, FoxJ1, & CFTR suggesting a lung-like phenotype, and Thyroglobulin, Pax8 & TSHR suggesting a thyroid-like phenotype.

Conclusion: Our in-vitro system yields a purified population of Ttf-1 positive endodermal cells of a molecular phenotype reminiscent of primordial lung and thyroid progenitors.

P3801
Developmental profile of cellular pathways regulating protein breakdown in the fetal and postnatal diaphragm
Yong Song, Jane Pinlow. School of Women's and Infants' Health, The University of Western Australia, Perth, WA, Australia

Studies on diaphragm weakness and atrophy focus on adult muscle, but the preterm diaphragm might be more susceptible to injury. Characterization of the ontogeny of protein degradation pathways responsible for muscle atrophy would help further understanding of the altered signaling pathways under pathologic conditions of preterm babies. Here, we performed the baseline study of major proteolytic path-ways and antioxidant capacity in lambs from 75 d to 200 d postconceptional age. The diaphragm tissues were collected and analysed for gene expression and/or protein abundance in a set of key pathway components in conjunction with proteolysis/antioxidant activity. Our results showed that calpain and caspase 3 in gene and protein expressions exhibited a similar profile with advancing gestation, increasing from 75 d to 100 d of 128 d and subsequently decreasing gradually toward full term. In contrast, ubiquitin conjugating and ligase genes did not change during gestation. All proteolytic genes examined (except Ubiquitin) were up-regulated rapidly after delivery, with a similar development and observed in protease activities. Unlike proteolytic pathway pattern, antioxidant gene expression demonstrated a steady increase from 75 d gestation until 24 h after birth, followed by a significant reduction at 7 w of postnatal age (p < 0.002). The proteolytic signaling and an-tioxidant capacity patterns reflected the adaptive process to metabolic change and muscle maturity with development. The data from this study may partly explain the susceptibility of preterm infants to respiratory failure in response to injurious ventilation and/or clinical stressors such as inflammation and hypoxia.

P3802
PECAM-1 single nucleotide polymorphisms and idiopathic pulmonary fibrosis
Michael Crooks, Ahmed Fahim, Simon Hart. Division of Cardiovascular and Respiratory Studies, Castle Hill Hospital, Hull, United Kingdom

Background: Idiopathic pulmonary fibrosis (IPF) is the most common of the idiopathic interstitial pneumonias and carries a prognosis worse than most cancers. However, the pathogenesis of this disease remains incompletely understood. Platelet Endothelial Cell Adhesion Molecule-1 (PECAM-1) is a 130 kDa glyco-protein that has been implicated in pulmonary fibrosis in a strain of knockout mice. We assess the prevalence of the PECA-1 single gene polymorphisms and the serum concentration of PECA-1 in IPF patients versus controls.

Methods: Samples of full blood were collected from 37 patients with IPF and 41 controls. DNA was extracted from whole blood using QIAmp DNA Blood Midi Kit (Qiagen, Valencia, CA). PCR was performed using primers specific to exon 3, exon 8 and exon 12 of the PECA-1 gene. Purified PCR products were sent toEurofins MWG Operon for sequencing. The serum concentration of soluble PECA-1 was assessed using ELISA.

Results and discussion: No significant difference was observed in the prevalence of single gene polymorphisms in exon 3, 8 or 12 of the PECA-1 gene. The PECA-1 concentration was significantly higher in the IPF group versus controls (106.177ng/ml vs 84.327ng/ml respectively, p=0.0398) with elevated sPECA-1 concentrations associated with better lung function (p=0.038).

Conclusions: There was no significant difference in the prevalence of single gene polymor-phisms in the PECA-1 gene was observed between IPF and control groups. Serum PECA-1 concentration was elevated in IPF patients versus controls how-ever it is not possible to determine whether this is important in the pathogenesis of the disease or a secondary event resulting from cell injury and aberrant tissue repair.

P3803
Up-regulation of collagen type V mRNA in a model of systemic sclerosis
Roberta Goncalves Marangoni1, Ana Paula P. Velosa, Edwin E. Parra2, Jymenez de Mores3, Vera L. Capelozzi2, Walcy R. Teodoro, Natalino H. Yoshinari1, 1 Rheumatology Division, University of Sao Paulo, Sao Paulo, SP, Brazil; 2Pathology Department, University of Sao Paulo, Sao Paulo, SP, Brazil

Background: We have described an animal model of systemic sclerosis (SSc) induced by type V collagen (COLV) that resembles the human disease. The aim of this study was to investigate the early disease in the lungs of this model with special emphasis on collagen deposition and mRNA collagen synthesis.

Methods: Female rabbits from New Zealand lineage were immunized with COLV plus Freund’s adjuvant (FA). Animals immunized only with FA were used as controls. The animals were sacrificed at day 7, day 75 and day 210 and the lungs submitted to immunofluorescence, real-time qPCR and biochemical examination. Results: The immunolabeling for the COL I, III and V by immunofluorescence showed an intense expression of COLV in the bronchovascular interstitium near the inflammatory infiltrate of COLV-rabbits at day-210. Additionally, morphologic analysis demonstrated that the progressive remodeling of the extracellular matrix observed in this group of animals was characterized by thickened COLV deposition with distorted fibrils. In accordance with these observations, the real-time qPCR revealed markedly up-regulation of COLV mRNA of the COLV-group at day-210 comparing with controls (p<0.001). The content of hydroxyproline was compared for COLV-group and controls at day-7, day-75 and day-210, suggesting that the day-210 group represents an early disease without established fibrosis.

Identification of stable housekeeping genes for real-time PCR in human of commonly used HKGs; resected tumors, n=10) lung tissue was used to assess variation in expression

Background: Quantitative real time PCR is an important tool in investigating gene expression levels in human lung fibroblasts under the conditions tested, and show further in geNorm all had an expression stability of M<0.70).

Methods: Serum-deprived MRC5 cells (human fetal lung fibroblast cell line) were pre-incubated with synthetic LXR agonist T0901317 and natural agonist 22(R)-hydroxysterol, and were differentiated into myofibroblasts by TGF-β1 for 48 hours. Changes in u- smooth muscle actin (α-SMA) and phosphorylated-Smad2/3 were analyzed by western blot. The inhibitory effects of irreversible PPARγ antagonist GW-9662 on anti-fibrotic abilities of LXR agonists were also examined.

Results: LXR agonist T0901317 and 22(R)-hydroxysterol inhibited TGF-β1 driven myofibroblast-differentiation as determined by α-SMA by western blot. T0901317 did not inhibit Smad2/3 phosphorylation. An irreversible PPARγ antagonist GW-9662 did not reverse the inhibition of myofibroblast-differentiation by T0901317.

Conclusion: LXR agonists have novel and potent anti-fibrotic effects in human lung fibroblasts.

P3084 Anti-fibrotic effects of liver X receptor agonists in human fetal lung fibroblasts
Shu Hayata, Shigeki Chiba, Takafumi Ito, Masahito Ebina, Toshihiro Nukiwa Department of Respiratory Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan

Introduction: Idiopathic pulmonary fibrosis is a progressive life-threatening disease for which anti-inflammatory agents such as glucocorticoids have no therapeutic effect. Liver X receptors (LXRs), which are nuclear receptors activated by oxysterols as natural ligands, show similar tissue distribution patterns with glucocorticoid receptor and peroxisome proliferator-activated receptor (PPARα,γ). LXRs play important roles not only in cholesterol metabolism and triglyceride synthesis, but also in inflammation and innate immunity. Previous studies showed anti-fibrotic effects of PPARγ agonists, but it remains unknown whether LXRs agonists have anti-fibrotic abilities.

Aims: The aim of our current study is to analyze anti-fibrotic effects of LXR agonists on human lung fibroblast.

Methods: Serum-deprived MRC5 cells (human fetal lung fibroblast cell line) were pre-incubated with synthetic LXR agonist T0901317 and natural agonist 22(R)-hydroxysterol, and were differentiated into myofibroblasts by TGF-β1 for 48 hours. Changes in u-smooth muscle actin (α-SMA) and phosphorylated-Smad2/3 were analyzed by western blot. The inhibitory effects of irreversible PPARγ antagonist GW-9662 on anti-fibrotic abilities of LXR agonists were also examined.

Results: LXR agonist T0901317 and 22(R)-hydroxysterol inhibited TGF-β1-driven myofibroblast-differentiation as determined by α-SMA by western blot. T0901317 did not inhibit Smad2/3 phosphorylation. An irreversible PPARγ antagonist GW-9662 did not reverse the inhibition of myofibroblast-differentiation by T0901317.

Conclusion: LXR agonists have novel and potent anti-fibrotic effects in human lung fibroblasts.

P3085 Identification of stable housekeeping genes for real-time PCR in human pulmonary fibroblasts
Caroline Stock, Patricia Leoni, Xu Shi-Wen, David Abraham, Andrew Nicholson, Athol Wells, Elizabeth Renzoni, Gisela Lindahl. Interstitial Lung Disease Unit, Royal Brompton Hospital, London, United Kingdom Dept Histopathology, Royal Free Hospital, London, United Kingdom Dept Histopathology, Royal Brompton Hospital, London, United Kingdom

Background: Quantitative real time PCR is an important tool in investigating gene transcription levels under different biological conditions. Accurate results rely on controlling for differences in mRNA quantity and quality between samples, controlling for differences in mRNA quantity and quality between samples, which are commonly achieved by normalisation to expression of housekeeping genes (HKGs). Expression levels of the HKGs used is critical, but to date no systematic study controlling for differences in mRNA quantity and quality between samples, com-

Methods: Microarray data of gene expression in explanted fibroblasts from SSC-ILD (systemic sclerosis lung biopsies, n=8) and control (normal periphery of resected tumors, n=10) lung tissue was used to assess variation in expression of commonly used HKGs: ACTB, GAPDH, HPRT1, RPL32, TBP, and YWHAZ (HUGO nomenclature). The four most stable genes (<15% variability) were selected by qRT-PCR in an independent experiment in which SSC-ILD (n=3) and control (n=3) fibroblasts were cultured in 0.1% BSA for 24hrs, and a further 24hrs with or without IFNγ (10ng/ml). A measure of expression stability (M), the average pairwise variation with each of the other studied genes (with a recommended maximum value of 1.5) for each HKG, was calculated using the program geNorm (Vandesompele, J. et al. Genome Biology 2002;3:4-3.12).

Results: While ACTB and GAPDH were relatively unstable, the four HKGs tested further in geNorm all had an expression stability of M<1.0; the most stable gene was YWHAZ (M=0.56), followed by HPRT1 (M=0.60), RPL32 (M=0.67), and TBP (M=0.70).

Conclusion: We have identified four HKGs suitable for normalisation of mRNA expression levels in human lung fibroblasts under the conditions tested, and show the necessity for empirical identification of HKGs.

P3086 Molecular screening – A search for potential drugs for idiopathic pulmonary fibrosis
Outi Leppiaranta1, MaximBespalov2, Marjukka Mylläriemi1, Kati Koli1
1Department of Medicine, Pulmonary Division, University of Helsinki, Helsinki, Finland; 2High Throughput Center, Institute for Molecular Medicine Finland, Helsinki, Finland; 3Research Programs Unit, Molecular Cancer Biology, University of Helsinki, Helsinki, Finland

Background: Idiopathic pulmonary fibrosis (IPF) is a fibrotic lung disease with a poor prognosis and very few therapeutic options. On a molecular level, patients with IPF have increased amounts of BMP inhibitor gremlin in their lungs (BMP, bone morphogenetic protein). Gremlin decreases BMP signalling and, as a consequence, TGF-β signalling is increased (TGF-β, transforming growth factor-beta). The balance between BMP and TGF-β signalling activities in the lung is of crucial importance during e.g. regenerative processes. Thus, severe alterations in these signalling activities are likely to contribute to the pathogenesis of IPF.

Aim: To use high-throughput chemical screening as an approach to find molecules which could normalize the TGF-β/BMP balance in the fibrotic lung.

Methods: The screen was performed with a commercial chemical library with ca. 2000 compounds. The set-up is based on two reporter cell lines that contain either a BMP- or a TGF-β-responsive element linked to a luciferase gene. The effect of the chemicals is evaluated by measuring the changes in the expression of the luciferase gene.

Results: Using this approach we have been able to identify compounds which modulate the BMP/TGF-β signalling balance in the reporter cell lines. One compound was also shown to modulate endogenous BMP/TGF-β signalling activities in lung epithelial cells.

Conclusions & future directions: Using chemical compound screening it is possible to identify small-molecular weight compounds that modulate gene expression in lung epithelial cells. These compounds are potential drugs for the prevention of progression of IPF. Their effects will be evaluated in preclinical in vivo studies using a mouse model of pulmonary fibrosis.
concentration was measured by turbidimetry and PI-photon type identified by iso-electrofocusing. The PI*P and PI*V alleles were confirmed by real-time PCR: rare phenotypes were identified by sequencing.

Results: 53 (12.6%) lung disease patients and 18 (6.4%) liver disease patients demonstrated AAT deficiency phenotypes. Calculated frequencies expressed per 1000 were for PI*Z 46.6 (95% CI: 32.3-60.8), PI*P 20.3 (95% CI: 10.8-29.8) in regards to lung disease, and 19.6 (95% CI: 3.1-36.0) for liver disease patients. The AAT gene prevalence calculated by Hardy-Weinberg equilibrium were: 1/16 for MM, 1/26 for MS, 1/24 for SS for MM, 1/11 for MZ, 1/30 for SZ and 1/462 for ZZ in liver disease patients.

Conclusion: Our results show relatively high frequency of AAT deficiency among Polish patients with chronic obstructive respiratory disorders. Estimated frequency for PI*Z and PI*P allele in respiratory group was about two-fold higher than in liver disease patients and four-fold higher than estimated prevalence in healthy Polish population.

P3809 Proteomic analysis of antioxidant proteins in bronchoalveolar lavage of patients with pulmonary Langerhans-cell histiocytosis
Paola Rottoni 1, Claudia Landi 1, Elena Bargagli 2, Barbara Magi 1, Maria Grazia Petrali 1, Joachim Muller-Quernheim 1, Luca Bini 2 1Respiratory Diseases Section, Department of Clinical Medicine and Immunological Sciences, University of Siena, Siena, Italy; 2Department of Molecular Biology, University of Siena, Siena, Italy; 3Department of Pneumology, Ludwig University, Freiburg, Germany

Pulmonary Langerhans-cell histiocytosis (PLCH) is a tobacco smoke-related diffuse lung disease of unknown etiopathogenesis. Oxidative-mediated lung injury has been documented in patients with PLCH. In this study we analyzed by 2-dimensional electrophoresis, BAL protein expression of antioxidant proteins in a group of patients with PLCH, a group of healthy smokers and a group of no-smoker controls in order to better understand the potential role of oxidant/antioxidant balance in the disease pathogenesis. Among the differentially expressed spots identified by us, the proteins implicated in the antioxidant defense where thioredoxin (THHO), ALBU, ceruloplasmin (CERU) and glutathione peroxidase 3 (GPX3). THIO was a protein identified from a spot down-regulated in PLCH versus smoker controls (p<0.01). It plays a protective role against cigarette smoke-induced lung oxidative damage and against Th2-driven airway inflammation. CERU isomor 1 and 2 were significantly upregulated in PLCH patients compared to no-smoker controls (p<0.01) while CERU isomor 3 was upregulated in patients than smoker controls (p<0.05). GPX3 was absent in 2/2-gels of patients with PLCH and it was significantly over-expressed in smokers than no-smoker controls. In conclusion antioxidant defense could be involved in PLCH pathogenesis being the expression of antioxidant proteins significantly different in BAL of patients with respect to smoker or no smoker controls.

P3810 Endothelin-1 (ET-1) is a useful biomarker for early detection of ventilator-associated pneumonia (VAP) in mechanical ventilation children
Dymtria Smyrniote, Katerina Dmytrytseva, Oleksandra Nazarchuk, Anatoliy Staradub, Oleksander Mazulov, Konstantin Dmytrytsevan

Objectives: VAP is a severe complication limiting survival children. ET-1 is a peptide produced by pulmonary vascular endothelial cells that play a role in the pathophysiology of lung dysfunction. Whether ET-1 could predict VAP development is unknown.

Methods: Transbronchial biopsy specimens and serum and bronchoalveolar lavage were obtained from 23 children with VAP and 24 without VAP. The serum and bronchoalveolar lavage ET-1 concentrations were measured by enzyme-linked immunosorbent assay, and the ET-1 mRNA expression in the transbronchial biopsy specimens was examined using real-time polymerase chain reaction.

Results: ET-1 serum concentrations were greater in the patients with VAP (P<0.02); and ET-1 mRNA was significantly in the lung of those versus those without VAP at 3 and 12 day after start mechanical ventilation (P<0.01). At 3 and 12 days after start mechanical ventilation, the ET-1 concentrations were significantly elevated in the serum (P<0.01 and P<0.001, respectively) and bronchoalveolar lavage (P<0.01 and P<0.01, respectively) of children with compared with those without VAP. On logistic regression analysis, 3-day after start mechanical ventilation serum ET-1 level predicted for VAP (odds ratio, 1.01; 95% confidence interval, 1.003-1.027; P<0.07; odds ratio, 2.8; 95.3%, confidence interval, 1.01 - 8.4; P< 0.001). The serum ET-1 level at 12 days was diagnostic for VAP (odds ratio, 4.1, 95% confidence interval, 1.4 - 11.3; P=0.009).

Conclusions: Elevated serum ET-1 concentrations were predictive of VAP, and the assessment of circulating ET-1 might be beneficial in diagnosing and monitoring VAP.

Circulating lymphocytes are increasingly used as a surrogate cell type to reflect changes in ADRβ2 density elsewhere in the body, particularly the respiratory system. However, ADRβ2 density is non-uniform among lymphocyte subsets and potentially varies between individuals.

Aim: To assess the extent of variability in ADRβ2 density on human peripheral blood mononuclear cells (PBMC) including lymphocytes and monocytes.

Method: PBMC were isolated from 10 healthy subjects by density gradient centrifugation with Ficoll-Paque. Cell surface & total ADRβ2 of lymphocytes (CD4+), monocytes (CD3+), and lymphocytes (CD14+) were measured using FACS. Geometric mean fluorescence (GMF) was used as the indices for ADRβ2 density per cell.

Result: Surface ADRβ2 - GMF increased by 3.34 and 4.62 folds over negative controls for lymphocytes and monocytes respectively (P=0.16). However, distribution of GMF between samples suggests greater variability in ADRβ2 density in lymphocytes vs monocytes (P<0.06). Proportion of ADRβ2-positive cells was higher in monocytes vs lymphocytes (71.9% vs 36.7%, p<0.02). Total ADRβ2 - GMF increased by 12.4 and 9.61 folds for lymphocytes and monocytes respectively (p<0.05). Proportion of ADRβ2-positive cells were similar between samples of lymphocytes 80% vs 85%, but monocytes 86% vs 85% but greater variability was observed for lymphocytes (range 27.9%-99%) vs monocytes (range 66%-100%).

Conclusions: Despite similarities in surface and total ADRβ2 density, lymphocytes display greater inter-subject variability compared with monocytes. This has implications in experimental designs & interpretation of changes in ADRβ2 density in studies using human PBMC as an alternative to primary cells from organ of interest.

P3812 Apocynin augments IL-6, IL-8 and TNF expression in A549 cells
Ioanna Stefanis, Milena Sokolowska, Rafał Pawlicki. Department of Immunopathology, Medical University of Lodz, Lodz, Poland

Reactive oxygen species (ROS) play an important role in many pathways and processes. An enzyme responsible for ROS production - NADPH oxidase represents an attractive therapeutic target. Apocynin is a small molecule that reversibly blocks NADPH oxidase activation and therefore inhibits ROS formation. Apocynin, in our previous studies, reduced some ROS concentrations in exhaled breath condensate of asthmatics, COPD patients, and healthy subjects. Therefore we decided to investigate apocynin influence on expression of IL-6, IL-8 and TNF in vitro. A549 cells were incubated with apocynin in concentrations: 0.25, 0.5, 1, 2 and 3 mg/ml. After 1h, 2h and 4h of incubation with each concentration RNA was isolated and reverse transcription was made. mRNA expression was assessed using real-time PCR.

Response-analysis revealed apocynin most effective influence after 2 and 4 hours of incubation. It caused increased expression of IL-6 (expression level (RQ) 0.64 – 2h and 0.62 – 4h vs 0.007 – base), and IL-8 (RQ 25.18 – 2h and 25.12 – 4h vs. 1.74 – base) in A549. Moreover, apocynin caused TNF expression increase in A549 after one and four hours of incubation (RQ 0.037 – 1h and 0.036 – 4h vs. 0.017 – base). Dose-response analysis showed apocynin to be most effective in concentration of 0.5 mg/ml. This dose caused increase of IL-6 expression (RQ 2 - control sample (CS) and IL-8 expression (RQ 101 vs 2 – CS, but also 1 mg/ml – RQ 30 vs 2 - CS). TNF expression was increased in samples incubated with 0.25 mg/ml (RQ 0.037 vs 0.02 – CS).

These findings may provide a novel therapeutic strategy and might be of importance in relation to inflammatory diseases.

P3813 Comparison the frequency of human T-lymphocyte type 1 (HTLV 1) infection in tuberculosis patients with control group without tuberculosis
Davood Attaran, Leila Ghofrania, Elham Ghalenoe, Hooshang Rafatpanah, Mohamad Khajedaloei, Mohamad Towhidii, Shahrazad Mohamadazedheh Lari. Lung Disease and Tuberculosis Research Center, Mashhad University of Medical Science, Mashhad, Khorasan, Islamic Republic of Iran

Introduction: Regarding to recognize the predisposing factors in Tuberculosis infection which is common in Khorasan, Northeastern province of IRAN this study investigate whether Humant-T-lymphocyte type 1 (HTLV 1) as an immunosuppressive factor increase the risk of tuberculosis.

Methods: A case控制 study was conducted on 278 pulmonary and extrapulmonary tuberculosis during 2007-2010, in city of mashad, capital of khorasan.Tuberculosis has been documented by goldstandard tests like spu-tumculture, BAL culture or cytology.For detection of HTLV1 antibody, ELISA method and as a confirming test western blot were performed. Healthy sex and age matched control group were 276 persons.
There is a acute problem with diagnostics of mycobacterios in Russia. Species identification of mycobacterial cultures is not performed in bacteriology labs. over Russia. There are no any statistical data for the incidence of NTM. Detection. We aimed to evaluate the level of NTM detection at examination of cultures from BACTEC MGIT 960 (BD, USA) in the course of 2010. 1520 positive MGIT tubes (obtained in 2010) were studied. Primary screening of cultures was performed using standard microbiological techniques blood agar culture and Ziehl-Neelsen stain. In addition real-time PCR I6E110 was done for all 1520 cultures. For suspected samples species identification was done using GenoTypeCM/AS (HAIN Lifescience, Germany) were carried out. Of 1520 cultures, 75 cultures (4.5%) belonged to NTM. Using GenoTypeCM/AS/ we performed species identification for 72 strains from 75. Following spectra of NTM strains were detected: M. fortuitum (15 strains), M. peregrinum (2 strains), M. chelonae (5 strains), M. abscessus (6 strains), M. xenopi (3 strains), M. gordonae (5 strains), M. smegmatis (7 strains), M. fortuitum (4 strains), M. kansasi (9 strains), M. avium (13 strains), M. intracellulare (3 strains). One of 3 detected by Hain test-system as a Mycobacterium spp. strain belonged to M. nonchormoenginem in accordance to sequence of 16S rRNA. Data allowed to conclude that 4.9% of 1520 cultures obtained from BACTEC MGIT 960 were NTM. Usage of exact and rapid molecular-genetic method - GenoTypeCM/AS helps to perform accuracy species identification of NTM. It helps physicians to ensure accurate diagnosis and prescribe adequate treatment.

P3814 Application of GenoTypeCM and GenoTypeAS to species identification of nontuberculous mycobacteria as a routine method in microbiology lab of CTLR, Moscow.

P3816 Diverse effects of PAI-1 proteins on lung and prostate cancer cell invasion.

Adriana Rozý1, Marta Kredzí1, Joanna Chorostowska-Wynimko 1, Paulina Jagý1, Adam Szepcichý1, Ewa Skrzyczak-Jankun1, Jerzy Jankun1, 1Laboratory of Molecular Diagnostics and Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 2Urology Research Center, University of Toledo, Medical Center, Toledo, OH, United States.

Acquisition of ability to uncontrolled migration is one of the fundamental properties of cancer cells, enabling them to infiltrate tissues and metastasize PAI-1 is the major physiological inhibitor of urokinase (uPA), which plays a key role in migration and invasion of tumor cells. The aim of present study was to analyze the impact of increasing concentrations of PAI-1 mutated forms. VLHL PAI-1 with very long half-life time, Vn PAI-1 devoid of affinity towards vitronectin and wPAI-1 on lung (A549, H1299) and prostate (LNCaP, DU145) cancer cells invasive activity. Selected cell lines are characterized by different (normal and high) urokinase production. No effect of PAI-1 proteins on invasiveness of lung cancer cells was observed, while dose-dependent significant inhibition was demonstrated in both prostate cancer lines (DU145 and LNCaP) cultured with VLHL PAI-1 (respectively p<0.05 and p<0.01) and Vn PAI-1 (p<0.05). Not surprisingly wPAI-1 significantly stimulated prostate cancer cells invasiveness in all concentrations. PAI-1 inhibitory effect on prostate cancer invasive activity is associated with anti-proteinase activity. Lung cancer cells invasive regulation seems not to be PAI-1-urokinase regulated.

P3817 Role of bronchoscopy in lung cancer translational research: Tumor harvest for the lung cancer mutation consortium (LCMC) studies.

Rex Ying 1, Marzan Rutledge 2, Peter Illei 3, Malcolm Broek 2, Charles Rabin 4.
1Medicine & Oncology, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 2Surgery, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 3Pathology, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 4Medical Oncology, Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Introduction: The LCMC is a multi-institution collaboration to collect 1,000 cases of advanced (stage IIIIB/IV) Adenocarcinoma for rapid analysis of multiple genes and conduct important in LC pathway, to accelerate biomarker validation & discovery, to develop novel therapeutics.

Aim: To address the need to harvest sufficient tumor from subjects who are often not suitable surgical candidates. To advance bronchoscopic harvest of tumor sufficient for multigene studies.

Method: 68 lung Adenocarcinoma pts consented (3-10 and 2-11) for sending tumor tissue to Utah Colorado for multiple molecular analysis FISH analysis for MET amplication & ALK protein fusion, gene mutations by SNaPshot testing. APC, AKT1, BRACFN1NB1, EGFR, FLRT, JAK2, KIT, KRAS, MAPK1, NOTCH1, NRAS, PIK3CA, PTEN, TP53. One pathologist (P1) review slides for tumor cellularity and adequacy for 20 extra studies.

Results: 2 subjects ineligible (AC non-awarded), 15 QNS, 33 with tissue successfully sent, 18 awaiting review of slides. Material deemed insufficient 4 - effusion cell block, 2 excised nodes, 9 bronch samples but 3/9 had sufficient tissue for sufficient sample testing KRAS, EGFR, ALK, hence likely exhausted. Of 33 successful send-out: 17 lung surgery, 5 brain mets, 2 pleural metast biopsies, 2 CT core bx. 7/53 (21%) from bronchs: 3 endo & 2 each transbronchial forceps.

Conclusion: Of 16 bronch specimens evaluated for multiplex tumor pathway testing after local site clinical testing, 7 (44%) adequate, 6 (37%) QNS, 3 (19%) likely exhausted.

P3818 GSTT1 and CYP1A polymorphisms, tobacco smoking and lung cancer in northern India.

Sandeepta Bhandacharya1, Anup Raj Tikal2, Rajni Kant Shukla3, Surya Kant1, Ashwini Kumar4, Babji Mittal5, 1Physiology, C.S.M. Medical University (Eristwhile King George’s Medical College), Lucknow, Uttar Pradesh, India; 2Environmental Biotechnology, Indian Institute of Toxicology Research, Aligarh, Uttar Pradesh, India; 3Pathology, C.S.M. Medical University (Eristwhile King George’s Medical College), Lucknow, Uttar Pradesh, India; 4Genetics, Sanjiv Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India.

Background: Susceptibility to lung cancer has been shown to be modulated by inheritance of polymorphic genes encoding cytochrome P450 1A1 (CYP1A1) and glutathione S transferases (GSTT1), which are involved in the bioactivation and detoxification of environmental toxins.

Aim: To investigate the role of GSTT1 and CYP1A polymorphism in the susceptibility to lung cancer patients in northern India.

Methodology: We have recruited 456 study subjects, 218 cases of lung cancer and 238 healthy controls were recruited from northern India. Genetic polymorphism screening of GSTT1 and CYP1A1 was conducted by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP).

Results: The frequencies of GSTT1 Null, alleles were significantly differ between patients and controls, with odds ratio (OR) =0.52; 95% confidence interval [CI] = 0.35-0.79, p<0.002, but -6235 T-C genotype were not associated with lung cancer patients with healthy controls. GSTT1 null genotype were significant associated.
with the smoker lung cancer patients, with odds ratio [OR] = 1.76; 95% [CI] = 1.17-2.66; p= 0.007.

Conclusion: In this northern Indian population, 86.7% of male and 13.3% of female lung cancer incidence were explained by tobacco smoking. Deleterious polymorphisms of the GSTT1 had an effect on the risk of lung cancer.

P3819 Comparing LYVE-1 and D2-40 expression in small cell lung carcinomas (SCLC): association with clinical parameters and lymphatic invasion

Georgia Haradavella1,2, Vasiliki Siozopoulou1, Anna Batistatou1, Petros Galanis1, Yiostanna Dalavanga1, Manos Alchanatis1, Dimitrios Stefanakis1, Stavros Constantinopoulou1, 11st Department of Respiratory Medicine, Medical School, Athens University, Athens, Greece; 2Department of Respiratory Medicine, Medical School, University of Ioannina, Ioannina, Greece; 3Department of Pathology, Medical School, University of Ioannina, Athens, Greece; 4Department of Evaluation of Health Care Services, Athens University, Athens, Greece; 5Department of Anatomy, Histology and Embryology, Medical School, University of Ioannina, Athens, Greece

Introduction: Lymphangiogenesis is actively facilitating tumor metastasis. LYVE-1 and D2-40 are two new lymphatic endothelial markers; their expression and prognostic impact in SCLC still remain vague.

Aim: To investigate the lymphangiogenic expression in SCLC we measured the intratumoral lymphatic microvessel density (ILMVD), the lymphatic invasion (LI) and their correlation with clinical parameters.

Materials and methods: Retrospective study of 55 SCLC patients (mean age: 68.1 years, range 40-89). Histological specimens from all patients were immunohistochemically stained for D2-40 (epitope of podoplanin) and LYVE-1 (CD44 homolog). Calculation of ILMVD and assessment of LI were performed and correlation with clinical data followed.

Results: D2-40 and LYVE-1 were expressed in all specimens whilst LI in 59.6%. D2-40 and LYVE-1 ILMVD were associated with the stage at diagnosis (p=0.017 and p=0.03 respectively) and LI (p=0.00 and p=0.02 respectively). D2-40 ILMVD was particularly associated with certain target organs for metastasis (liver p=0.001, adrenal p=0.014, brain p=0.007). LI was associated with stage (p=0.05) and all target organs for metastasis (p<0.05). ILMVD D2-40 and LYVE-1 weren’t associated with LI and survival.

Conclusions: D2-40 and LYVE-1 and LI were highly expressed in SCLC and independently associated with poor patient outcome, thus presenting new insights in prognosis. D2-40 presented a more potent role by associated with certain target organs for metastases. Defining subgroups of patients with poorer prognosis at the time of diagnosis could reinforce the development and application of new targeted therapeutic strategies.

406. COPD: clinical studies and animal cell models

P3820 Altered composition of airway basement membranes in COPD

Oskar Hallgren1,3, Annika Andersson-Sjöland1, Elisabet Wieslander2, Marina Kvist-Reimer1, Magnus Dahlbäck2, Leif Ericsson2,3, Jonas Ejefelt1, Leif Bjerner1, Claes-Goran Löfdahl1, Gunilla Westergren-Thorsson1, 1Experimental Medical Sciences, Lund University, Lund, Sweden; 2Biosciences, AstraZeneca R&D, Lund, Sweden; 3Respiratory Medicine and Allergology, Lund University, Lund, Sweden

Rationale: The basement membrane provides a chemical and mechanical structure which is crucial for the mucosal homeostasis in the airways. Thickening of lamina reticularis is a common feature in asthma but the situation in COPD is less clear. Our hypothesis was that there are quantitative and qualitative alterations in airway basement membranes in COPD that influence the integrity of epithelial and mesenchymal cells.

Methods: Lung tissue sections from COPD patients and control subjects were subjected to H & E and picrosirus-RED staining. Sections were also immunostained using antibodies against the small proteoglycans: decorin and biglycan. Fibroblasts were isolated from lung explants from COPD patients (n=8) (GOLD stage IV) and from control subjects (n=9) and proteoglycan production was examined in vitro.

Results: Using immunostaining showed an unevenly distributed thickening of lamina reticularis in bronchial and bronchiolar airways from COPD patients but not from control subjects. The thickened areas stained positive for picrosirus RED, which shows the presence of fibrillar collagens (collagen I and III). This was accompanied with increased immune-positivity for the small leucin-rich proteoglycans decorin and biglycan. Fibroblasts isolated from bronchial specimen from COPD patients had decreased production of the basement membrane stabilizing proteoglycan perlecain (p<0.05).

Conclusions: This data indicate that there are qualitative and quantitative alter-
The lungs may be involved in the pathogenesis of COPD. Interestingly, serum levels of sIL-18Ra in COPD (n=100) were significantly (P<0.001) lower than seen in non-smokers (n=51). Overexpression of IL-18Ra proteins in the lungs of COPD patients (with GOLD stage I [n=28], II [n=34], III [n=22], and IV [n=16]), 36 smokers and 51 non-smokers nor non-smokers. Interestingly, serum levels of sIL-18Ra in COPD (n=100) were significantly (P<0.001) lower than seen in non-smokers (n=51). Overexpression of IL-18Ra proteins in the lungs of COPD patients (with GOLD stage I [n=28], II [n=34], III [n=22], and IV [n=16]), 36 smokers and 51 non-smokers (n=51). Overexpression of IL-18Ra proteins in the lungs may involve in the pathogenesis of COPD.

P3824
Expression profiling of Th17 associated molecules in bronchoalveolar cells from patients with chronic obstructive pulmonary disease (COPD)
Zdenka Navratilova1, Eva Kenticova1, Jaromir Zatkalicky1, Vitezslav Kolsek1, Martin Petrek1, 1Laboratory of Immunogenomics and Proteomics and Institute of Molecular and Translational Medicine, Palacky University, Olomouc, Czech Republic; 2Department of Respiratory Medicine, Palacky University and Faculty Hospital, Olomouc, Czech Republic

Recently, the presence of inflammatory cells expressing IL-17A has been reported in the small airway subepithelium obtained from COPD patients (Eitacek A et al. Chest. 2010) which, with further evidence (reviewed in Alcorn JF et al. Ann Rev Physiol, 2010), suggests that Th17 immune response may participate in COPD pathomechanisms. However, to date there has been no data about the presence of IL-17A in human serum. We also found that serum levels of the complex Apocynin reduces H2O2 and NO- concentrations in exhaled breath condensate of COPD patients. It is well known that COPD is a preventable and treatable disease, characterized by not fully reversible airflow limitation. In individuals with COPD, there is a marked exacerbation of the inflammatory response, which increases with the progression of the disease. The molecular mechanism of exacerbations remains unknown; however, prolonged oxidative stress has been reported as potentially responsible for the exacerbation. Apocynin is an agent that inhibits activation of an enzyme responsible for ROS generation and thus – probably, alleviate inflammatory process. Therefore, we investigated the effect of nebulized apocynin in fourteen COPD patients in placebo-controlled, cross-over design study. Exhaled breath condensate was collected in three timespots (30, 60 and 120 min) after apocynin/placebo administration. The mechanism of apocynin was investigated. Moreover, safety parameters have been controlled throughout the study. Apocynin reduced hydrogen peroxide concentration in exhaled breath condensate 60 and 120 minutes after apocynin nebulization compared to placebo (0.43 μM ± 0.09 μM vs. 1.45 μM, p<0.05). No influence of apocynin on safety parameters, and no adverse effects has been observed. Our findings suggest that apocynin might be a promising agent to soothe locally inflammatory process and improve life quality of patients suffering from COPD.

P3827
Apolipoprotein E polymorphism and smoking in relation to cardiovascular disease - a case-control study
Dario Tucci1,2, Francesco Carloni1,2,1, Department of Internal Medicine (DIMI), University of Genoa, Genoa, Italy; 2Medical Affairs, Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30

Purpose: To evaluate the influence of ApoE genotypes on the risk of cardiovascular disease (CVD) and the interaction between ApoE and smoking in the Italian population. Methods: A total of 692 case patients and 719 control subjects, who underwent a complete clinical evaluation including a thorough medical history, physical examination, laboratory tests, ECG, and echocardiogram, were randomly selected from the records of the local hospital. The cases were divided into groups according to their ApoE genotype (E2, E3, and E4). The controls were randomly selected from the general population of the same age and sex. The influence of the ApoE genotypes on the prevalence of CVD was analyzed. Results: There was a significant difference in the prevalence of CVD between the genotype groups (p<0.05). The frequency of E4 allele was higher in the case group than in the control group (p<0.05). The prevalence of CVD was significantly higher in carriers of the E4 allele than in non-carriers (p<0.05). The interaction between the ApoE genotype and smoking was not significant (p>0.05). Conclusion: The ApoE genotype is associated with the risk of cardiovascular disease, and the interaction between ApoE and smoking is not significant. These findings suggest that the ApoE genotype may be a risk factor for cardiovascular disease in the Italian population. However, further studies are needed to confirm these findings and to elucidate the mechanisms involved.
Cigarette smoke exposure in mice leads to a loss of reversible cysteine oxidations PSSG and PSNO in lung
Cigarette smoke exposure in mice leads to a loss of reversible cysteine oxidations PSSG and PSNO in lung tissue. It is established that cigarette smoke causes irreversible oxidations in lung tissue. However, its impact on reversible and physiologically relevant redox-dependent protein modifications remains to be investigated. In this study the effect of cigarette smoke exposure in vivo was investigated on the covalent binding of glutathione to protein thiols, known as S-glutathionylation (PSSG), which can be reversed by the enzyme glutaredoxin 1 (Grx1). Also, protein S-nitrosylation (PSNO) which is the modification of protein thiols by NO and which is reversed by the enzyme ADH5 was investigated.

Both PSSG and PSNO levels in lung tissue were markedly attenuated after four weeks of cigarette smoke exposure in mice. This coincided with an attenuation of protein free thiol levels and an increase in protein carbonyl levels. Grx1 mRNA expression and activity were attenuated as well, whereas no alterations in expression or activity of ADH5 were observed. Taken together, cigarette smoke exposure decreases reversible cysteine oxidations PSSG and PSNO, which does not result in an increase in free thiols. These alterations are likely not the result of differences in regulatory enzymes, but of oxidative stress.

Hypoxic exposure after smoke cessation restores alveolar surface area in mice
Chronic obstructive pulmonary disease (COPD), which mainly results from chronic exposure to tobacco smoke, is a major public health burden with an effective treatment. We have previously shown that hypoxia can induce lung growth in adult mice [1]. The aim of this study is to investigate if sustained hypoxia can restore the loss of alveolar surface area caused by tobacco smoke.

Methods: We exposed C57BL/6J mice to 6 months of tobacco smoke (250 mg/m3 suspended particles in 2.5 h/day) followed by 3 months of sustained hypoxia (SH) with an FiO2 of 10% and appropriate control groups (no smoke/noxygenosis (N)). Pulmonary function was measured in anesthetized mice. Following euthanasia lungs were processed for morphometry, mean airspace chord length (Lm) was measured and alveolar surface area was calculated.

Results: Mice exposed to tobacco smoke had a trend towards a lower alveolar surface area compared to control mice even 3 months after smoke cessation (p = 0.10). SH increased total lung capacity, whereas Lm was unchanged. SH significantly increased the alveolar surface area in mice previously exposed to smoke (p = 0.008, Fig. 1), but not in control mice.

Conclusions: Sustained hypoxia after cessation of tobacco smoking restores alveolar surface area in mice. Future studies of the underlying mechanisms might lead to potential therapies.

Role of highly reactive aldehydes in cigarette smoke induced airway inflammation
Cigarette smoke (CS) is the most important cause of COPD, which is associated with chronic neutrophilic airway inflammation. We hypothesize, that the presence of highly reactive α,β-unsaturated aldehydes in CS is a crucial factor for neutrophilic airway inflammation.

Methods: BALB/c mice were exposed to CS, water filtered CS (WF-CS) or air. Levels of CO and aldehydes were measured in CS and WF-CS. Six hours after the last CS exposure, cell differentials and cytokine levels were measured in lung tissue and bronchoalveolar lavage fluid (BALF). Beas-2b cells (epithelial cell line) were exposed to cigarette smoke extract (CSE) or water filtered cigarette smoke extract (WF-CSE) with and without acrolein. The neutrophil chemotactant IL-8 was measured after 24 hrs.

CO levels were not different between CS and WF-CS but aldehyde levels were strongly decreased in WF-CS compared to CS. The numbers of neutrophils in BALF (p < 0.001) and neutrophils and eosinophils (p < 0.05) in lung tissue were significantly increased in the CS-exposed but not in WF-CS-exposed mice compared to air control. Levels of neutrophil and eosinophil chemotactants e.g. KC, MCP-1, MIP-1α and IL-5 were significantly increased in lung tissue from CS-exposed mice compared to WF-CS-exposed mice. Beas-2b cells produced significantly lower levels of IL-8 upon stimulation with CS but not in WF-CS-exposed cells compared to WF-CSE. Repletion of WF-CSE with the aldehyde acrolein restored the IL-8 production by Beas-2b cells whereas acrolein in culture medium did not. It can be concluded that highly reactive aldehydes present in cigarette smoke appear to play a crucial role in CS-induced IL-8 production and neutrophilic airway inflammation.

Effects of adipose tissue-derived stromal/stem cells transplantation on elastase-induced pulmonary emphysema in rats
Emphysema is the most common pathology in patients suffering from COPD. Emphysema results from alveolar destruction and obliteration of the alveoli. Data suggest that adipose tissue-derived stromal/stem cells (ASCs) for regenerative medicine, since it has a high potential to secrete multiple angiogenic factors and differentiate various kinds of cells. To demonstrate the therapeutic impact of ASCs transplantations and to elucidate mechanisms of the effects in rat emphysema models, ASCs were isolated from Wistar rat inguinal subcutaneous adipose tissue. Emphysema was induced by intratracheal instillation of porcine pancreatic elastase (PPE). One week after induction of PPE, cell transplantation was performed intravenously at 1 and 2 weeks after transplantation, we assessed arterial blood analysis and histopathological changes and measurement of chemokine levels. After PPE injection, arterial oxygen pressure (PaO2) was reduced. After ASCs transplantation, PaO2 significantly improved. In addition, transplantation significantly prevented the enlargement of alveolar airspace elicited by PPE. PPE gradually reduced the levels of endogenous hepatocyte growth factor (HGF) in lung tissue. ASCs augmented HGF level was significantly higher than PPE alone. ASCs from GFP transgenic rats were localized at damaged alveolar spaces. Immunohistochemical analysis revealed some grafted ASCs were expressed CD31 or SP-C at 1w after transplantation. The results showed that transplantation of ASCs for emphysema rats improved gas exchange and inhibited enlargement of the airspaces. Transplantation of ASCs may be a new therapeutic strategy to improve pulmonary function and inhibit alveolar destruction in COPD.

Role of IL-1α and IL-1β in cigarette smoke-induced pulmonary inflammation and COPD
Cigarette smoke is the most important cause of COPD, which is associated with chronic neutrophilic airway inflammation. We hypothesize, that the presence of highly reactive α,β-unsaturated aldehydes in CS is a crucial factor for neutrophilic airway inflammation.
presence of inflammatory cells in the bronchoalveolar lavage (BAL) fluid. In a translational study, we measured the levels of IL-1α and IL-1β mRNA (in total lung tissue by RT-PCR) and protein (in induced sputum by ELISA) of never smokers, smokers without COPD and patients with COPD. Acute exposure to CS resulted in a significant increase in BAL neutrophils in in vitro treated mice. In contrast, this CS-induced BAL neutrophilia was significantly attenuated in both anti-IL-1β and anti-IL-1α treated mice. Interestingly, we found increased mRNA and protein levels of IL-1α and IL-1β in lung tissue and induced sputum of patients with COPD, compared to never-smokers (Table 1).

*p<0.05 vs. never-smokers, *p<0.05 vs. smokers without COPD.

These results suggest that not only IL-1β, but also IL-1α should be considered important in CS-induced inflammation.

P3834

β2 long-acting and anticholinergic drugs synergistically control TGFβ1-mediated neutrophilic inflammation in COPD: An “in vitro” model

Patricia Macedo1, Iain Kilty2, Peter Barnes1, Louise Donnelly1.

Results: The addition of simvastatin at 5 μM in combination with either olodaterol or tiotropium reduced all 3 CXCR3 chemokines in PBMC from COPD patients, compared to PBMC from healthy controls (p=0.01). However, there were no differences in response to JAK inhibition between subject groups. JAK inhibitors PP95 and PP13 significantly suppress steroid-insensitive CXCR3 chemokines in COPD cells and may have benefit as a novel anti-inflammatory treatment.

P3836

Simvastatin attenuates cigarette smoke induced extracellular matrix Brian Oliver, Janette Burgess, Judy Black, David Krimmer. Cell Biology, Woolcock Institute of Medical Research, University of Sydney, Sydney, Australia

Introduction: Production of extracellular matrix (ECM) proteins is increased in the small airway walls of patients with chronic obstructive pulmonary disease (COPD). Current pharmacotherapies are unable to reduce or attenuate ECM in vivo. The 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitor, simvastatin, is emerging as a new potential therapy for COPD. In this study we investigated if simvastatin could affect cigarette smoke extract (CSE) induced ECM and cytokine production from human lung fibroblasts.

Methods: Primary human lung fibroblasts were stimulated with 5% CSE in the presence of 0.5 and 5μg/ml simvastatin, or relevant concentrations of vehicle control, for 72 hours. Supernatants were collected and assessed for pro-inflammatory cytokine and matrix metalloproteinase (MMP) release. Cells were removed by addition of NIH40 and the relative deposition of the ECM proteins fibronectin and perlecan was measured using an ECM ELISA. The concentration of interleukin (IL)-6, a marker of ECM deposition, was measured using ELISA.

Results: Treatment of human lung fibroblasts with 5% CSE upregulated the deposition of fibronectin and perlecan, and the release of IL-6 into the supernatant. Addition of simvastatin at 5μg/ml significantly attenuated 5% CSE induced deposition of fibronectin by 43% and perlecan by 41.5% (p<0.05, n=6). 5% CSE induced IL-6 release was also attenuated by 31% with the addition of simvastatin at 5μg/ml.

Conclusions: Inhibition of the HMG-CoA reductase pathway may alter the deposition of ECM proteins and release of inflammatory cytokines in COPD.

P3837

Sirtuin 1 reduction causes activation of Wnt/b-catenin signalling Andriana Papaioannou1,2, Konstantinos Kostikas3, Peter Barnes1, Kazuhiro Ito1.

Background: The anti-aging molecule Sirtuin 1 (SIRT1) has been reported to be decreased in COPD (Nakamura et al, FASEB J, 2009). We have also reported an increase of osteoprotegerin (OPG) in COPD (To M et al, CHEST 2011), which is b-catenin dependent. Our hypothesis is that the reduction of SIRT1 induced by oxidative stress may lead to increased b-catenin activation.

Methods: U937 (human monocytic cell line), AS49 (human alveolar epithelial cell line) and BEAS2B (human bronchial epithelial cell line) were grown until 70% confluent, starved for 24h and incubated with 2μM of sirtinol at 4 different time points (i.e. 1h, 4h, 8h, and 24h). The levels of b-catenin were measured in nuclear and cytoplasmic extracts by Western Blotting. Cells were also treated with H2O2 for 24 hrs and sirt1-1 protein level was also evaluated.

Results: The level of b-catenin was higher in AS49 and BEAS2B cells than U937 cells at baseline. In all three cell lines, nuclear b-catenin levels increased at 8h after treatment with 2μM of sirtinol by approximately 52% for the AS49 and 25% for the BEAS2B cells. No difference was detected in cytoplasmic b-catenin levels in any cell line. Incubation with H2O2 for 24h caused reduction in Sirt-1 levels in the AS49 cells.

Conclusions: This study shows that reduced SIRT1 protein leads to stabilization of β-catenin protein. This might give new insights in the understanding of COPD pathogenesis.

P3838

Role of aberrant Wnt signalling in the lung epithelial response to cigarette smoke in COPD

Irene Heijink1,2, Harold De Bruin1, Maarten Van den Berg1, Reinoud Gouwens1, Antoon Van Oosterhout1, Dirkje Postma2.

Background: This study shows that reduced SIRT1 protein leads to stabilization of β-catenin protein. This might give new insights in the understanding of COPD pathogenesis.

TUESDAY, SEPTEMBER 27TH 2011
leads to different phenotypes of COPD, i.e. inflammation and remodelling with increased extracellular matrix (ECM) deposition in the airways and loss of ECM in the parenchyma. The Wnt signaling pathway is known to regulate inflammation, tissue repair and remodelling. We aimed to determine whether dysregulation of Wnt genes may contribute to COPD development. We studied the effects of cigarette smoke extract (CSE, 5%) on expression of a variety of Wnt ligands, Wnt receptors (frizzled, Fzd) and Wnt target genes, including IL-8, MMP-2/9 and fibrotenon (pQPCR, ELISA, immunodetection) in alveolar A549 and human bronchial epithelial 16HBE cells. Furthermore, we compared expression of Wnt genes in primary bronchial epithelium from COPD patients, healthy smokers and non-smokers. CSE induced Wnt4, Wnt7b and FzdA mRNA expression in A549 cells, without significant changes in the other detected genes, i.e. Wnt5b, Fzd1 and 2 and MMP-2. In contrast, CSE significantly decreased Wnt4 and Fzd2, and increased Wnt5b mRNA in 16HBE cells. Interestingly, expression of Wnt5, but none of the other detected genes, was significantly higher in COPD than in healthy smoker epithelium. Therefore, we were interested in potential autocrine effects of Wnt4. We observed that recombinant Wnt4 significantly increased IL-8 production in 16HBE cells. Thus, inefficient downregulation of Wnt4 mRNA expression in response to cigarette smoke may have important consequences for the development and remodelling in COPD. Furthermore, our results suggest that Wnt4 differentially affects Wnt gene expression in alveolar and bronchial epithelium.

407. Immunology and cell biology of asthma and COPD

P3840 Disease and stimulus specific pro-inflammatory cytokine secretion by human fibroblast of asthma patients

Luigi Costa1, Pieter Borgert2, Paola Casarosa3, Michael Tammi4, Michael Roth5

1Pulmonary Cell Research, Dept of Biomedicine, University Hospital Basel, Basel, BS, Switzerland; 2Respiratory Diseases Research, Boehringer Ingelheim Pharma, Biberach, Germany

It is well documented that the asthmatic lung contains increased levels of pro-inflammatory cytokines. We provide evidence that healthy primary human fibroblasts isolated from medium size airways of asthma patients secrete significantly more IL-8 than in a stimulus and disease specific pattern. Bronchial fibroblasts from 5 asthma patients and 5 healthy controls were isolated and stimulated with PDGF-BB, TNF-alpha or IL-1beta (0.1, 1.0, 10 ng/ml), all of which are well known pro-inflammatory factors. After 24 hours, secreted IL-6, IL-8, eotaxin and GM-CSF were determined in the cell culture medium. PDGF-BB dose dependently increased both IL-6 and eotaxin secretion by 3 and 6 fold, respectively, but with no difference between asthma and control. In contrast, IL-8 and GM-CSF levels were significantly increased in asthma fibroblasts relative to control. IL-8 secretion dose dependently increased after TNF-alpha treatment, but no difference between asthma and control was observed. IL-1beta dose-dependently increased the secretion of all 4 cytokines, however, with a dose specific increase of GM-CSF at 10 ng/ml. Our data suggest that bronchial fibroblasts contribute to chronic inflammation in asthma in a disease and stimulus specific pattern.

P3841 The role of MKK3 in allergic and non-allergic inflammatory responses in the lung

Tatjana Holand1, Yanira Rijo-Vazquez1, Domenico Spinca1, Brian O’Connor1, Francis Woisin1, Mike Marber2, Kevin Bacon3, Christian Rolff5,6.

1Department for Clinical Research, Respiratory Medicine, Berne University Hospital, Berne, Switzerland; 2Cell Biology, Telethon Institute for Child Health Research, Perth, WA, Australia; 3Bayer HealthCare, Buyer Co, Wuppental, Germany; 4Askin Pharmaceuticals, Inc, Askin Pharmaceuticals, Inc, San Diego, CA, United States; 5Oxford Glycosciences, Oxford Glycosciences, Slough, Berkshire, United Kingdom; 6Oxford BioTherapeutics, Oxford BioTherapeutics, Abingdon, Oxon, United Kingdom

MKK3 is a member of the p38 MAPK signaling pathway and is an important factor in non allergic inflammation and Th1 responses. Less is known about the role of MKK3 in allergic inflammation. We investigated the role of MKK3 in murine models of non-allergic and allergic lung inflammation. Wild Type (WT) mice were instillated with lipopolysaccharide (LPS) (10 μg, i.t) or zymosan (100 μg i.t.). A significant increase in neutrophil numbers in the lung were observed 24h later compared to saline controls (saline: 0±6.01 x 10^6; WT: 9±6.4 x 10^6; n=5, p≤0.05). WT mice also produced significantly less TNF-α and INF-γ as compared to saline mice. MKK3-/- mice did not release these cytokines in response to LPS or zymosan. WT mice were sensitized twice to ovalbumin (ova, 10μg/mouse i.p in alun). From day 14 all mice were exposed to 3% ova once daily for 3 days. Lung lavages were performed 24 h after the last exposure. Exposure to ova significantly increased eosinophil numbers in the lungs of ova-sensitized mice as compared with sham-immunized mice (sham: 0±6.01 x 10^6; ova WT: 0±6.01 x 10^6; n=11; ova WT-/-: 2±6.01 x 10^6; n=10). WT mice showed significant increase of IL-5 compared to ova WT and sham-immunized mice (sham: 0±5.01 x 10^6; ova WT: 6±5.01 x 10^6; n=11; ova WT-/-: 12±5.01 x 10^6; n=10). WT mice also produced significant levels of IL-12, IL-6 and TNF-α as compared with sham-immunized mice (sham: 0.3±0.11 x 10^5/ml, n=9; ova WT: 1±0.11 x 10^5/ml, n=10). Ova-MKK3-/- mice showed significantly increased IL-5 compared to WT ova mice and sham-immunized mice (sham: 0±3.0±0.8 x 10^5/ml ova WT: 3±5.1±0.9 x 10^5/ml; ova WT-MKK3-/-: 8±5.1±0.9 x 10^5/ml). Ova-MKK3-/- mice showed significantly higher levels of IgE compared to WT mice, irrespective of ova treatment (sham WT: 0±6.01 x 10^6; ova WT: 6±6.01 x 10^6; n=6, sham MKK3-/-: 4±4.1±5.6 x 10^6; ova MKK3-/-: 5±3.8±4.5 x 10^6). In conclusion, MKK3 differentially regulates allergic and non-allergic responses in the lung.
activity and obesity. Leptin is an adipokine with a well-established functional role on airways function. The specific airway resistance (sRaw) and isolated bronchial rings reactivity were assessed on obese resistant (OR) and obese prone (OP) rats, fed with highfat diet. Results were compared with data from Sprague Dawley (SD) rats fed with standard diet. In vitro experiments were performed on main left bronchus rings. Both contraction induced by 10 μM acetylcholine (ACh) and terbutaline-induced relaxation were assessed. On OP bronchi, the terbutaline-induced dose-response curve was shifted to the right and the maximal relaxant effect was decreased up to 20%. Leptin pretreatment did not significantly modify terbutaline relaxant effects on OR but restored terbutaline effects on OP bronchi. Inhibition of all NO synthases (NOS) with 10 μM L-NAME reduced the bronchial relaxation. A number of studies have shown that adipokines have a role on airways function. The specific airway resistance (sRaw) and isolated bronchial rings reactivity were assessed on obese resistant (OR) and obese prone (OP) rats, fed with highfat diet. ### Conclusion

**Comorbidity digestive system diseases in patients with BA are associated with significant decrease of activity of cell and humoral parts of immune system.**

**P3846**

**Increased levels of CD4+CD25high and CD4+FoxP3+ T-regulatory cells (Tregs) in patients with different severity of bronchial asthma (BA)**

Elena Kremer1, Natalya Kirillova2, Sergey Fedosenko3, Ivan Deev4, Ludmilla Ognerodova1, Department of General Medicine, Medical Research Institute for the Prevention of Asthma, the American Respiratory and Allergic Disease, the Department of Immunology of Central Research Laboratory, 2Dept. of Hospital Therapy with a Course of Physical Rehabilitation and Sports Medicine, 3Dept. of Pediatrics Faculty with a Course of Childhood Illnesses Medical Faculty, Siberian State Medical University, Tomsk, Russian Federation

**Background:** BA is characterized by persistent inflammation in the airways in response to allergens or other triggers. The intensity of the inflammation determines the severity of asthma. The level of anti-IgE responses and maintaining peripheral tolerance. Our study sought to determine whether numbers of CD4+CD25high and CD4+FoxP3+ Tregs are related to anti-IgE inflammation and disease severity.

**Aim and objectives:** To investigate the expression of surface molecules on Tregs in patients with different severity of bronchial asthma compared to healthy persons.

**Methods:** Peripheral blood mononuclear cells of control (n=17) and asthmatic patients (mild BA, n=11; severe BA, n=17) were labeled for CD4, CD25 and intracellular FoxP3 and analysed using flow cytometry.

**Results:** Numbers of peripheral blood CD4+CD25high was significantly decreased in asthmatic patients compared to healthy control patient. Patients with severe asthma had increased levels of CD4+CD25high and CD4+FoxP3+ compared to mild BA.

**Conclusions:** Our findings suggest that decreased levels of Tregs in peripheral blood might contribute airway inflammation. Increase CD4+CD25high and CD4+FoxP3+ is important in balancing immune responses for prevention the severity of asthma.

**Superoxide dismutase as a longitudinal biomarker of lung function in asthma**

Stury Comhair, Anam Khan, Serpi Elizur, Lehrer Research, Pathobiology, Cleveland Clinic, Cleveland, OH, United States

Asthma is a chronic inflammatory disease related to oxidative stress. Previously, we reported that superoxide dismutase (SOD) is lower in asthma as compared to healthy controls and related to airflow obstruction and reactivity. In this study, we hypothesized that serum SOD would be informative for progression of asthma over time. To test this, asthmatic adults with >10 years of disease duration were included. These results suggest that asthmatics with high SOD experience a progressive loss of lung function over time and are at risk for accelerated loss of lung function.

### Conclusion

**Superoxide dismutase as a longitudinal biomarker of lung function in asthma.**

tion in RBM thickness and different cut-off. The difference between Responder and Non-Responders proved statistically significant. Present data showed that 9/11 patients reduced the original RIM after treatment with anti-ILgE, thus emphasizing the role of omalizumab in affecting asthma remodeling.

P3849
Reverber is a novel regulator of COPD macrophage inflammation and glucocorticoid resistance
John Blackburn1, Julie Gibbs2, Andrew Louden3, Stuart Farrar3, Dave Singh1, David Ray1, 1Medicine, University of Manchester, Manchester, United Kingdom; 2Life Sciences, University of Manchester, Manchester, United Kingdom; 3Respiratory Center of Excellence for Drug Discovery, GSK, Stevenage, United Kingdom

Introduction: Human inflammation shows circadian oscillation of inflammatory mediators e.g., IL-8. The function of many anti-inflammatory drugs e.g. glucocorticoids also oscillate in a similar manner. The mechanisms causing these phenomena are poorly understood. A recent discovery describes that cells have a “molecular clock”, regulating 10% of the genome.

Aims: We investigated the function and mechanism of Reverber, part of this “molecular clock”, concerning COPD inflammation.

Results: LPS stimulated macrophages showed a diurnal response for IL-6. A novel Reverber ligand (GSK414112) corrected this but had no effect if Reverber expression was suppressed. The ligand had no effect in two epithelial cell lines (AS49, Hela), demonstrating cell specific actions. An array and luminex analysis on cellular supernatants from human healthy and COPD macrophages defined the targets and mechanism of GSK414112 suppression. A number of key COPD targets were suppressed. GSK414112 upregulated PPARα and LXRα, two nuclear receptors, and their respective cholesterol target genes e.g. ABCA1. A diurnal regulatory element analysis identified the importance of the LXR-DR4 motif, which Reverber binds. This mechanism was confirmed experimentally with a LXR antagonist. Luciferase reporter constructs, focused on the IL-6 proximal promoter, identified four LXR binding sites in the cell specific effect of Reverber, an activating factor binding site. GSK414112 doubled the IC50 of dexamethasone on IL-8.

Conclusion: Reverber affects both inflammation and glucocorticoid resistance. Synthetic ligands can modify its function potentially allowing for the first time to potential study inflammatory alterations that might increase the risk of developing lung cancer.

P3850
Quantitative proteomics study reveals cross-talk between autophagy and inflammation induced by cigarette smoke in airway cells
Yan Zhang1, Shen Yingchun1, Wen Yang1, Wang Tao1, Xin Dan1, Chen Lei. 1Division of Pulmonary Diseases, State Key Laboratory of Biotherapy of China and Dept. of Respiratory Medicine, 2National Key Laboratory of Novel Drug and Cancer Center, 3Department of Laboratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Introduction: Cigarette smoke (CS) is an important risk factor for the development of airway inflammation. Autophagy can be induced by CS, while the role of autophagy in airway inflammation induced by CS was still unclear. We sought to determine the role of autophagy in cigarette smoke induced airway inflammation induced by CS using system-level analysis by amino acids in cell culture (SILAC)-based quantitative proteomics.

Methods: SILAC-labeled human lung mucocoeidometer cells (NCI-H292) was exposed to cigarette smoke extract for 24h, and then was used to identify the differentially expressed proteins. In order to validate the results in vivo, rats were exposed to CS for 4 weeks. Besides the analysis of bronchoalveolar lavage fluid (BALF) and histological changes, immunohistochemistry and western blot validated the selected proteins. Autophagy was observed by electron microscope (EM).

Results: Three proteins associated with autophagy were significantly up-regulated after CS exposure in NCI-H292 cell (p<0.05), including macrophage-associated protease 1A/1B light chain 3C(LC3A/B), high mobility group protein (HMGB1), and Cystatin-C. EM revealed that autophagic vacuoles were dramatically increased in rat lung tissues exposed to CS (p<0.05). Moreover, airway inflammation induced by CS was demonstrated by histological changes, increased cell counts and proinflammatory cytokines in BALF (respectively, p<0.05, p<0.05). Immunohistochemistry and western blot demonstrated that CS markedly increased LC3A/B, Cystatin-C and HMGB1 expression in rat lung (respectively, p<0.05).

Conclusions: Autophagy may play a role in cigarette smoke induced inflammation by CS.

P3851
Myeloid derived suppressor cells in the crosstalk between COPD and lung cancer
Simone Baraldo1, Laura Pinton2, Andrea Ballarin1, Susanna Mandruzzato2, Laura Pinton1, Ying Binwu1, Wang Tao1, Xu Dan1, Chen Lei, 1Division of Pulmonary Diseases, State Key Laboratory of Biotherapy of China and Dept. of Respiratory Medicine, 2National Key Laboratory of Novel Drug and Cancer Center, 3Department of Laboratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Introduction: Myeloid derived suppressor cells (MDSC) are poorly understood. A recent discovery describes that cells have a "molecular clock", regulating 10% of the genome.

Background: Inhaled corticosteroids are recommended for COPD patients with FEV1 ≤ 50% predicted, experiencing ≥2 exacerbations in 12 months. However, post-hoc analysis of the TORCH study revealed an increased risk of pneumonia of 50% in patients taking inhaled corticosteroids compared to the Cefuroxime prophylactic (CFP) (ERJ 2009:34:641).

Results: BUD (1µM) increased MDSC phagocytosis of beads by 17% (p<0.05), whereas FP had no effect. Neither steroid altered MDM phagocytosis of either HI or SP. Neither steroid altered neutrophil phagocytosis of beads or SP. In contrast, BUD (10µM,100µM) significantly (p<0.05) increased neutrophil phagocytosis of HI with a maximal effect of 67%. FP (1µM) showed a smaller effect, increasing phagocytosis of HI by 38% (p<0.05).

Conclusions: FP did not reduce phagocytic function of either MDM or neutrophils.

P3853
IL-17A expression by mast cells in smokers
Yvonne Nussbaumer-Ochsner1, Luz F. Ferrar da Silva2, Klaus F. Rabe1,1, Annemarie M. van Schadewijk1,2, Pieter S. Hiemstra1,1

1Airways Disease, NHLI, Imperial College, London, United Kingdom; 2Astra Zeneica R&D Lund, AZ, Lund, Sweden

Background: Inhaled corticosteroids are recommended for COPD patients with FEV1 ≤ 50% predicted, experiencing ≥2 exacerbations in 12 months. However, post-hoc analysis of the TORCH study revealed an increased risk of pneumonia of 50% in patients taking inhaled corticosteroids compared to the Cefuroxime prophylactic (CFP) (ERJ 2009:34:641).

Results: BUD (1µM) increased MDSC phagocytosis of beads by 17% (p<0.05), whereas FP had no effect. Neither steroid altered MDM phagocytosis of either HI or SP. Neither steroid altered neutrophil phagocytosis of beads or SP. In contrast, BUD (10µM,100µM) significantly (p<0.05) increased neutrophil phagocytosis of HI with a maximal effect of 67%. FP (1µM) showed a smaller effect, increasing phagocytosis of HI by 38% (p<0.05).

Conclusions: FP did not reduce phagocytic function of either MDM or neutrophils.

Methods: Neutrophils and monocytes were isolated from the blood of COPD patients (n=10). Monocyte-derived macrophages (MDM) were generated from monocytes by 12d culture in media containing GM-CSF. All cells were incubated with steroid for 1h prior to phagocytosis assays with fluorescently labelled polyethylene beads, Haemophilus influenzae (HI) or Streptococcus pneumoniae (SP).

Results: BUD (1µM) increased MDSC phagocytosis of beads by 17% (p<0.05), whereas FP had no effect. Neither steroid altered MDM phagocytosis of either HI or SP. Neither steroid altered neutrophil phagocytosis of beads or SP. In contrast, BUD (10µM,100µM) significantly (p<0.05) increased neutrophil phagocytosis of HI with a maximal effect of 67%. FP (1µM) showed a smaller effect, increasing phagocytosis of HI by 38% (p<0.05).

Conclusions: FP did not reduce phagocytic function of either MDM or neutrophils.

METHODS: Neutrophils and monocytes were isolated from the blood of COPD patients (n=10). Monocyte-derived macrophages (MDM) were generated from monocytes by 12d culture in media containing GM-CSF. All cells were incubated with steroid for 1h prior to phagocytosis assays with fluorescently labelled polyethylene beads, Haemophilus influenzae (HI) or Streptococcus pneumoniae (SP).

Results: BUD (1µM) increased MDSC phagocytosis of beads by 17% (p<0.05), whereas FP had no effect. Neither steroid altered MDM phagocytosis of either HI or SP. Neither steroid altered neutrophil phagocytosis of beads or SP. In contrast, BUD (10µM,100µM) significantly (p<0.05) increased neutrophil phagocytosis of HI with a maximal effect of 67%. FP (1µM) showed a smaller effect, increasing phagocytosis of HI by 38% (p<0.05).

Conclusions: FP did not reduce phagocytic function of either MDM or neutrophils.

BUD improved neutrophil phagocytosis of HI, which may explain differences in pneumonia incidence between FP and BUD in COPD patients.

P3854 Carbocysteine and N-acetyl cysteine inhibit cigarette smoke mediated acetylation of the PMN chemotractant peptide PGP

Michael Brown, Matthew Harding, Edwin Blalock, Patricia Jackson. Pulmonary Division, University of Alabama at Birmingham, Birmingham, AL, United States

Cigarette smoke contains reactive compounds that result in epithelial damage and stimulate neutrophil chemotaxis, airway inflammation, and collagen breakdown. Proline-Glycine-Proline (PGP) is a degradation product of collagen proteolysis. PGP activates neutrophil receptors stimulating further chemotaxis and inflammation. PGP and an N-terminal acetylated PGP (NacPGP) are elevated in clinical samples of COPD patients and correlate with disease activity. NacPGP confers increased potency for neutrophil stimulation and bioavailability as leukotriene A4 Hydrolase responsible for PGP destruction, is incapable of acting on NacPGP.

N-acetyl cysteine (NAC) and carbocysteine (CC) are scavengers of reactive compounds and used as mucolytics in chronic lung diseases. We hypothesize that NAC and/or CC will prevent PGP acetylation by cigarette smoke. These compounds may provide better understanding of targeted therapeutics in cigarette smoking-related lung disease.

Cigarette smoke extract (CSE) or condensate (CSC) was prepared and incubated with native PGP. / NAC or CC. Samples were incubated and analyzed for CSE or NacPGP. NacPGP concentration was measured with mass spectrometry. This data was repeated in a vapor experiment, where PGP mixed with either NAC or CC was placed in a separate well from cigarette smoke in a 96-well plate and incubated. Our data demonstrate that PGP generation by cigarette smoke extract, condensate, and vapor that is inhibited by NAC or CC. Our data support a possible mechanism where reducing compounds such as NAC and CC may diminish lung inflammation in COPD and other chronic lung diseases by inhibiting PGP acetylation thereby facilitating PGP degradation.

P3855 Interactions between the effects of a 4-week NO2 and carbon nanoparticle exposure with allergen sensitization on bronchial responsiveness in Brown Norway rats

Skander Layachi,1 François Rogerieux,2 Christelle Gamez,2 Kelly Blazy,2 Francck Robidel,2 Anthony Lecomte,2 Ghislaine Lacroix,2 Sam Bayat,1,3 1E44285 - INERIS UMR01, INERIS, Verneuil-en-Halatte, France; 2Pulmonary Physiology Laboratory, CHU Amiens, Amiens, France; 3Paediatric Lung Function Laboratory, CHU Amiens, Amiens, France

Aims: The aim of this study was to assess the effect of combinations of allergen sensitization, NO2 and carbon nanoparticle (CNP) exposure on airway reactivity (AR).

Methods: Brown-Norway rats were divided into the following groups: Control; NO2; CNP + NO2. Human lung fibroblasts were stimulated for up to 72 hours with increasing concentrations of biomass smoke extract (BME) or cigarette smoke extract (CSE) as a comparison. Cells were lysed and deposition of ECM proteins was measured using western blotting. Release of interleukin (IL)-8 was determined using an ELISA assay. Cell viability was assessed using manual cell counts and a commercially available MTT assay.

Results: The deposition of the ECM proteins fibronectin and fibronectin increases with increasing concentration of biomass smoke extract (BME) or cigarette smoke extract (CSE) as a comparison. Cells were lysed and deposition of ECM proteins was measured using western blotting. Release of interleukin (IL)-8 was determined using an ELISA assay. Cell viability was assessed using manual cell counts and a commercially available MTT assay.

Goal: The aim of this study was to assess the effect of combinations of allergen sensitization, NO2 and carbon nanoparticle (CNP) exposure on airway reactivity (AR).

Methods: Brown-Norway rats were divided into the following groups: Control, NO2, CNP + NO2. Primary human lung fibroblasts were stimulated for up to 72 hours with increasing concentrations of BME or cigarette smoke extract (CSE) as a comparison. Cells were lysed and deposition of ECM proteins was measured using western blotting. Release of interleukin (IL)-8 was determined using an ELISA assay. Cell viability was assessed using manual cell counts and a commercially available MTT assay.

Conclusion: The deposition of the ECM proteins fibronectin and fibronectin increases with increasing concentration of biomass smoke extract (BME) or cigarette smoke extract (CSE) as a comparison. Cells were lysed and deposition of ECM proteins was measured using western blotting. Release of interleukin (IL)-8 was determined using an ELISA assay. Cell viability was assessed using manual cell counts and a commercially available MTT assay.

P3856 Biomass smoke extract increases fibronectin and perlecan release from human lung fibroblasts

Brian Oliver, Janette Burgess, Judy Black, David Krimmer. Cell Biology, Woolcock Institute of Medical Research, The University of Sydney, Sydney, Australia

Introduction: Approximately 50% of deaths from chronic obstructive pulmonary disease (COPD) in developing countries have resulted from repeated exposure to burning biomass, such as is used in household cooking. Biomass-induced COPD has been reported to be associated with a more fibrotic phenotype than cigarette smoke induced COPD. We aimed to investigate if biomass smoke induced extracellular matrix (ECM) protein production from primary human lung cells in vitro.

Methods: Primary human lung fibroblasts were stimulated for up to 72 hours with increasing concentrations of biomass smoke extract (BME) or cigarette smoke extract (CSE) as a comparison. Cells were lysed and deposition of ECM proteins was measured using western blotting. Release of interleukin (IL)-8 was determined using an ELISA assay. Cell viability was assessed using manual cell counts and a commercially available MTT assay.

Results: The deposition of the ECM proteins perlecan and fibronectin was upregulated by both 5% CSE and 1% BME, 1%, 5%, 10% and 20% BME and 5% CSE significantly upregulated the phosphorylation of ERK1 and ERK2 following 30 minutes exposure and these remained elevated to 24 hours exposure. Release of IL-8 in the supernatant was increased by 5% CSE and 1% BME. Exposure to concentrations of BME >10% caused significant decreases in cell viability.

Conclusion: BME has similar effects to CSE in vitro and in vivo.

Ozone is an oxidizing environmental pollutant that significantly contributes to respiratory health risk. Exposure to increased ambient levels of ozone has been associated with worsening of symptoms of patients with lung diseases like asthma and COPD. In this study we investigate the chronic effects of ozone exposure on Hypoxia Inducible Factor (HIF)-1α binding to HIF1α and HIF1α promoter regions associated with changes in gene expression levels in chronic ozone exposed mice.

Brian Oliver, Kirsty Russell, Colin Clarke, Peter Barnes, Ian Adcock. Airway Disease Section, National Heart and Lung Institute, Imperial College London, London, United Kingdom

Ozone is an oxidizing environmental pollutant that significantly contributes to respiratory health risk. Conclusion: BME has similar effects to CSE in vitro and in vivo.

Cigarette smoke extract (CSE) or condensate (CSC) was prepared and incubated with native PGP or NAC or CC. Samples were incubated and analyzed for CSE or NacPGP. NacPGP concentration was measured with mass spectrometry. This data was repeated in a vapor experiment, where PGP mixed with either NAC or CC was placed in a separate well from cigarette smoke in a 96-well plate and incubated. Our data demonstrate that PGP generation by cigarette smoke extract, condensate, and vapor that is inhibited by NAC or CC. Our data support a possible mechanism where reducing compounds such as NAC and CC may diminish lung inflammation in COPD and other chronic lung diseases by inhibiting PGP acetylation thereby facilitating PGP degradation.
P3858
Characterisation of T cell populations in proximal and distal airways
Rebecca Spence, Gregory Rankin, Christopher Pickard, Jane Warner. School of Medicine, University of Southampton, Southampton, Hampshire, United Kingdom

Introduction: CD4+ T cells are known to be involved in the pathogenesis of COPD but their distribution in COPD is unknown. We have characterised T cell populations from the distal and proximal airways of patients with and without airways obstruction.

Methods: Macrophageinflamed normal matched proximal and distal airway tissue was obtained from 23 patients (mean age 66±2.7 years, FEV1/FVC=0.66±0.02) undergoing lung resection. Samples were dissected into explants, fixed and processed for GMA immunohistochemistry. Sections were stained for CD3, CD4 and CD8.

To examine a larger population of T cells, explants from the same patients were incubated for 24 hours to encourage T cell migration into supernatant. Recovered cells were stained for T cell markers (CD3-FITC, CD8-APC) and analyzed via FACs.

Results: Immunohistochemical analysis revealed relatively few T cells in either proximal or distal airways (median CD3+ cells distal airways =1.6/mm2 compared to proximal airways). Immunohistochemical analysis revealed relatively few T cells in either proximal or distal airways (median CD3+ cells distal airways =1.6/mm2 compared to proximal airways). CD4+ cells were predominant in the distal airways while the distribution was not significantly affected by the presence of airways obstruction.

Conclusions: Similar numbers of CD3+ cells were found in the proximal and distal airways. CD4+ cells were predominant in the distal airways while the distribution of CD4 and CD8+ cells was equivalent in the proximal airways. The presence of mild/moderate COPD did not affect T cell number or distribution.

Characterisation of a new Daisy cell line representative of human alveolar macrophage (hAM)
Yvette Hayman, Simon Hart, Alyon Morice. Academic Cardiovacular and Respiratory Medicine, University of Hull, Castle Hill Hospital, Cottingham, East Yorkshire, United Kingdom

Introduction: Techniques used to obtain primary hAM are invasive, often providing low yields which cannot be expanded in vitro. No human cell line exists in an alternative. We characterised a new human cell line capable of expansion and spontaneous differentiation.

Methods: Cells were cultured in RPMI1640 with 10% foetal bovine serum and penicillin/streptomycin (100U/ml)10ng/ml in a humidified 5% CO2 atmosphere, passed every 2 days. Light and transmission electron microscopy comparing Daisy cells with THP-1 cells stimulated with phorbol myristate acetate (PMA;50ng/ml;24h) was performed. Flow cytometric immunophenotyping studies were performed analysing CD 11b, 14, 16, 23, 24, 32, 36, 64, 163 and 206 expression. Results were compared with both THP-1 cells and primary hAM obtained by bronchoalveolar lavage. Phagocytic capacity by zymosan uptake (mg/ml), mycospora screening by fluorescence microscopy and opsonised antigen binding by flow cytometry were also assessed.

Results: Microscopy showed Daisy cells to be similar in size, shape and granularity to PMA stimulated THP-1 cells with a higher proportion of heterochromatin, pseudopodia and vesicular inclusions. Daisy cells were shown to express lower levels of CD11b, 14 and 32 compared with PMA stimulated THP-1 cells yet higher levels of CD66, 80, 163 and 206. CD marker expression of Daisy cells more closely resembled that of primary hAM. Zymosan was readily phagocytosed, mycospora was not detected and high levels of opsonised antigen binding were seen in Daisy but not THP-1 cells.

Conclusions: The new Daisy cell line shows characteristics of mature hAM yet can be maintained and cultured providing a useful tool in respiratory research.

P3860
Sirtuins, the anti-ageing molecules, regulate anti-oxidant capacity via FoxO3 activity in monocyte cell line
Laura Nunez Naveira, Nicolas Mercado, Kazuhiro Is. Airway Disease, National Heart and Lung Institute (NHLI). Imperial College, London, United Kingdom

Chronic Obstructive Pulmonary Disease (COPD) is characterized by high levels of oxidative stress due to reduced anti-oxidative stress capacity, leading to an increase of oxidative stress. Sirtuins, type III histone deacetylases, have been linked to chronic obstructive pulmonary disease (COPD). These proteins are involved in the maintenance of nuclear function and are involved in the regulation of various cellular processes such as aging, lipid metabolism and inflammation.

Methods: Human peripheral blood mononuclear cells (PBMC) were cultured in the presence of reverse transcriptase polymerase chain reaction (RT-PCR) or luciferase assay for FoxO3 activity and sirtuin expression. The effect of sirtuin activation on FoxO3 activity was assessed using RNA interference (RNAi) and pharmacological inhibitors.

Results: The activation of sirtuin 1 (SIRT1) and 2 (SIRT2) increased FoxO3 activity, while the activation of SIRT3 and 6 (SIRT3 and 6) had no effect. The activation of SIRT1 and 2 also increased the expression of anti-oxidant genes such as MnSOD and NQO1.

Conclusions: Sirtuins play a key role in the regulation of anti-oxidant capacity via FoxO3 activity. The activation of SIRT1 and 2 may be a potential therapeutic target for treating COPD.

P3861
YKL-40: Novel marker for pro-inflammatory M1 macrophages
Elodie Kunz, Emily van ‘t Wout, Annemarie van Schadewijk, Pieter Hielstra. Pulmonary, Leiden University Medical Center, Leiden, Netherlands

Macrophages play a major role in the pathogenesis of COPD and comprise a heterogeneous cell population with pro- (M1) and anti-inflammatory (M2) cells. CD163 has been identified as a M2 marker, however, many M1 markers are not suitable for analysis. Cells positive for YKL-40, a chitinase-like-protein, are elevated in the lungs of smoking than non-smoking COPD patients. Dexamethasone strongly reduces YKL-40 expression in peripheral blood mononuclear cells in vitro, suggesting that it is a potential therapeutic target for treating COPD.

Methods: PMA stimulated THP-1 cells showed maximal lipid accumulation in vitro, indicating that inhaled steroids in COPD may decrease YKL-40 expression. Dexamethasone dose-dependently and strongly inhibited YKL-40 expression in both M1 and M2 (p<0.05).

Conclusions: YKL-40 expression can be used as a marker for M1 macrophages in vitro, and possibly in vivo.

P3862
Lipid laden alveolar macrophages arise from airway reflux and aspiration
Yvette Hayman, Simon Hart, Alyon Morice. Academic Card iovascular and Respiratory Medicine, University of Hull, Castle Hill Hospital, Cottingham, East Yorkshire, United Kingdom

Introduction: Lipid laden macrophages have previously been reported to be present in the diseased human airway, secondary to gastro-oesophageal reflux. We investigated the possibility that the lipid index (LI) system of scoring cellular lipid content by oil red o (ORO) staining could correlate with disease status and the Hull Airway Reflux Questionnaire (HARQ). We also investigated the hypothesis that lipid could be ingested directly from gastric contents by alveolar macrophages.

Methods: Primary alveolar macrophages were obtained from bronchoalveolar lavage (BAL) fluid of patients undergoing diagnostic bronchoscopy. Patients were asked to fill in the HARQ prior to treatment. Lavage fluid was filtered and centrifuged (350g;10min.) and cells transferred to glass slides using cytopsin equipment. Cells were stained with ORO, counterstained with haematoxylin and macrophages scored according to the LI system. Meanwhile THP-1 cells stimulated to differentiate with phorbol myristate acetate (PMA;50ng/ml;24h) were incubated with varying concentrations of a high fat meal and a fat free liquid meal as a control.

Results: 18 patients with a range of respiratory diseases had LI scores ranging from 4 to 309. LI score correlates (r = 0.8) with the HARQ but not to a particular disease group. PMA stimulated THP-1 cells showed maximal lipid accumulation by ORO staining with 10% v/v high fat liquid meal for 24h. No lipid accumulation was seen with the control feed.

Conclusions: Lipid laden macrophages arise from airway reflux and aspiration. Lipid laden macrophages correlate with the presence of lipid laden macrophages in the airway.
P3863 Reprogramming of alveolar macrophages – Prospect of successful treatment in COPD
Svetlana Lyamina1, Igor Maev2, Georgy Yurenev2, Igor Malyshev1. 1Laboratory of Cell Biotechnologies, Moscow State University of Medicine and Dentistry, Moscow, Russian Federation; 2Department of Internal Diseases, Moscow State University of Medicine and Dentistry, Moscow, Russian Federation

Reprogramming of macrophages can be one of new promising approaches in nosotrophies, improving the balance of inflammatory reaction and allowing to reach the optimal Th1/Th2 balance in early pathologic process. 

Objective: To testify that serum concentration change with TGF-β as reprogramming factor in culture medium can purposefully reprogram macrophages phenotype either to M1 pro-inflammatory or to M2 anti-inflammatory and therefore influence Th1/Th2 balance.

Methods: Alveolar macrophages of COPD patients with initial M1 phenotype were cultivated and reprogrammed in vitro in RPMI-1640 with different serum concentrations – 5%, 10%, 15% for 48 hours. Reprogramming of macrophages was measured by morphological characteristic of cells with morphological index, expression level of cell markers CD80, CD25 (M1), CD206, CD163 (M2) and cytokine production by flow cytometry.

Results: Significant changes of morphological characteristic and functional activity were educed. Serum concentration change from 5% to 15% led to increasing of interleukin-like cells (from 24 to 85%), morphological index varied from 0.26 to 1.02; Th2 cytokines prevailed on Th1; CD206 and CD163 expression level significantly changed – 57% and 64% vs 21% and 29% respectively. These data confirm successful reprogramming of macrophages to M2 phenotype. In view of obtained data decreasing of serum concentration from 15% to 5% led to M1 phenotype reprogramming.

Conclusions: Serum concentration in cell culture promotes reprogramming of morphological and functional phenotype of alveolar macrophages, which can be used for reaching Th1/Th2 balance and regulation of lung immunity in COPD patients.

P3864 Lipid laden macrophages in patients with chronic cough
Begoña Palomo, Jose Belda, Miguel Arias, C.J. Rtguz. Pandiella, Paz Paniagua, Magdalena Rebollo, Per Caras. Neurology, INS-HUCA, Oriedo, Asturias, Spain

Background: Gastroesophageal reflux disease (GER) has been described as com-
mon cause of chronic cough by either esophageal acid-induced bronchoconstriction or recurrent microaspirations of gastric content. Lipid laden macrophages (LLM) in sputum may be a marker of aspiration. This finding could be interesting mainly when symptoms are absent (up to 75% percent or cases, “silent” GER). However, it is not clear what the presence of LLM in the airways could imply in terms of lung function, radiological lesions or symptoms. We aim to compare a group of patients with chronic cough and LLM in sputum with another group without LLM.

Methods: Twenty five patients with chronic cough that could not be attributed to any known etiology were included in the study group. Subjects were questioned for pulmonary and GER symptoms. Rhinitis, drugs and underwent physical ex-
amination, chest X-rays, bronchial challenge test with methacholine and sputum induction. Prepared cytospins were stained with oil red-O to detect lipid laden macrophages.

Results: 68% were lipid laden positive but only 40% had reflux symptoms. Pa-
tients with LLM had similar dyspnea, phlegm's but not rhinitis and 25% were methacholine positive and diagnosed of having asthma. Patients with LLM had radiological findings (mild lesions) in 60% of them and they had less FEV1 240 ml (11% of ref val) and FVC 364 ml (7% ref val) when adjusted by asthma and anamnestic characteristics.

Conclusions: The presence of LLM in sputum could represent worse pulmonary disease in patients with chronic cough even in absence of GER symptoms.

P3865 Effects of Bu-Zhong-Yi-Qi-Tang (Hocheukito; TJ-41) on the inflammatory responses in alveolar macrophages of hyperglycemic mice
Masayuki Nakayama, Hideaki Yamawau, Manabu Soda, Naoko Mato, Tatsuya Hosono, Masashi Bando, Yukihiko Sugiyama. Division of Pulmonary Medicine, Department of Medicine, Jichi Medical University, Tochigi, Japan

This study examines the influence of Bu-Zhong-Yi-Qi-Tang (Hocheukito; TJ-41) on the inflammatory response in alveolar macrophage in hyperglycemic mice. BALB/c mice (males, six to eight weeks old) were divided into three groups: A, B, and C. Group A, B and C were fed an ordinary diet, whereas TJ-41 was given to group C. After the initiation of these diets, intraperitoneal injection of streptozotocin (STZ), 250mg/kg in mice of groups B and C. Four weeks after the start of these diets, blood-glucose levels were measured, and bronchoalveolar lavage (BAL) was performed. Alveolar macrophages were sampled, and those demonstrating blood-glucose levels of more than 200 mg/dL were selected for use. Toll-like receptor (TLR) ligands (TLR2: peptidoglycan [PGN], TLR4: LPS, TLR5: flagellin [FLGI]) were employed to stimulate pulmonary-alveolar macrophage phagocytosis and ELISA was used to measure TNF-a production. TLR expression on pulmonary-alveoli surface was evaluated on the basis of the emergence of each TLR mRNA in alveolar macrophages. In mice given STZ, stimuli with TLR2, 5 ligands significantly inhibited TNF-a production. But in mice given a diet including TJ-41 inhibition of TNF-a production improved significantly. These differences were observed in the expression of TLR mRNA in pulmonary-alveolar macrophages and on cell surfaces. These results suggest the possibility that TJ-41 may enhance inhibition of pulmonary-alveolar macrophage inflammation response to TLR-ligands stimulus in conditions of high blood glucose.

P3866 LSC 2011 Abstract: Differential effects of diesel exhaust particles and endotoxin on phagocytosis and cytokine release by monocyte-derived macrophages
Gurpreet Sehra, Duncan Rogers, Louise Donnelly. Airway Disease, National Heart & Lung Institute, Imperial College, London, GB

Atmospheric pollution is associated with COPD exacerbations. Diesel exhaust particles (DEP) are major contributors to pollution and when inhaled become tar-
geted for lung macrophages. The immune response to DEP remains unclear. Monocyte-derived macrophages (MDM) from non-smokers (NS), smokers (S) or patients with COPD were exposed to DEP (1-300μg/ml) with or without bacterial endotoxin (LPS; 10μg/ml) for 24h. Release of TNF-a, IL-6 and CXCL8 was analysed by ELISA, and phagocytosis of fluorescent beads was assessed by flow cytometry. MDM viability was determined by MTT assay.

Exposure of MDM to DEP did not stimulate release of IL-6 or TNF-a but increased CXCL8 release (E/C, NS 8±4 μg/ml, n=7; S 4±1 μg/ml, n=4 and COPD 10±4 μg/ml, n=7). MDM from COPD patients were 3.3 times more responsive to DEP (30μg/ml; p<0.05) than cells from smokers. When MDM were stimulated with LPS, DEP did not alter TNF-a or CXCL8 release. However, DEP inhib-
ited LPS-stimulated release of IL-6 in cells from all subject groups (E/C: NS: 33±14 μg/ml, n=10; smokers: 25±15 μg/ml, n=4; COPD: 18±14 μg/ml, n=10). Exposure of MDM to DEP in both the absence and presence of LPS inhibited phagocytosis of beads in a concentration-dependent manner with 300μg/ml show-
ing ~90% inhibition (control: 31±3 X 10² vs 300μg/ml DEP: 6±1 X 10² RFU, n=29), with MDM being 70% viable at this concentration, with no difference in response between the different subject groups. These data show that DEP impair macrophage phagocytosis and promote chemokine release. These data suggest that DEP may lead to reduced clearance of debris and pathogens from airways and promote COPD exacerbations.

P3867 Changed phagocytic activity and pattern of Fcγ and complement receptors on blood monocytes in sarcoidosis
Anna Dubaniec1, Monika Wybierska2, Szymon Nowakowski2, Katarzyna Rogoza1, Adam Sir2, Marek Alomanski1, Połoniecki Małgorzata1, Tatsuki Honjo1, Gurpreet Sehra3, Duncan Rogers3, Louise Donnelly2. 1Department of Pulmonary Medicine, Medical University of Gdańsk, Gdańsk, Poland; 2Department of Thoracic Surgeons, Medical University of Gdańsk, Gdańsk, Poland; 3Clinical Immunology and Transplantology, Medical University of Gdańsk, Gdańsk, Poland

We have recently revealed that mycobacterial heat shock proteins (Mtb-hp), in-
volved in forming of immune complexes (CI's), can induce immune response in sarcoidosis (SA). The complexity may result from inappropriate phagocytosis and clearance of CI's by monocytes, which results in persistent antigenemia and granuloma formation. It is also possible that aberrant expression of receptors for Fc fragment of immunoglobulin G (FcγR) and complement receptors (CR) on monocytes can be involved in this process.

To test this hypothesis, we have evaluated the expression of FcγRI (CD64), FcγRII (CD32), FcγRIII (CD16) and CR1 (CD35), CR3 (CD11b), CR4 (CD1c) receptors on blood monocytes on the basis of high antigen load, persistent antigenemia and complexemia in SA patients. To this hypothesis, we have evaluated the expression of FcγRI (CD64), FcγRII (CD32), FcγRIII (CD16) and CR1 (CD35), CR3 (CD11b), CR4 (CD1c) receptors on blood monocytes.

As compared to healthy controls, we found significantly increased expression of all examined FcγRI (CD32, CD16, CD64) and decreased expression of CD35 and CD1c on CD14+ monocytes in SA patients. Analysis of the combined phenotypes of monocytes revealed significantly increased percentage of CD14+CD16+CD35+, CD14+CD64+CD35+, CD14+CD64+CD11b+, CD14+CD64+CD11c+ monocytes and decreased presence of CD14+CD32+CD35+, CD14+CD32+CD11b+ and CD14+CD32+CD11c+ monocytes in SA vs controls. The total number and percentage of phagocytizing blood monocytes was significantly increased in SA as compared with healthy individuals.

In summary, altered expression of Fcγ and complement receptors on CD14+ monocytes and increased phagocytic activity of monocytes may be responsible for high antigen load, persistent antigenemia and complexemia in SA patients.

P3868 Immune complex binding by Fcγ receptor IIa and regulation of inflammation
Aikaterini Bazakou1, John Greenman2, Simon Hart1. 1Postgraduate Medical Institute, University of Hull, Hull, Humberside, United Kingdom; 2Department of Biological Sciences, University of Hull, Hull, Humberside, United Kingdom

Immune complexes, mainly associated with autoimmune diseases, may also be

700s
present in the blood and lung during respiratory diseases including bacterial pneumonia and ARDS. However, the precise pathogenic role of immune complexes in these conditions is unknown. Binding of immune complexes to the uniquely human stimulatory IgG receptor FcγRIIA is constitutively suppressed on neutrophils and macrophages. Elucidating the mechanism behind this suppression will help us understand how the body regulates its response to immune complexes. The erythroleukemia cell line K562 that expresses the FcγIIA inherently and exhibits FcγRIIA suppression was used as a model. The effects of microbial neuraminidases on the ability of immune complexes binding by the FcγRIIA were tested by flow cytometry. We also investigated whether there is a protein in close proximity to FcγRIIA that could potentially block its IgG binding site by protein cross-linking. Lastly, the stimulatory character of the receptor was explored by calcium signaling. Although the receptor exhibits suppressed immune complex binding, microbial neuraminidases can significantly augment the ability of the FcγRIIA to bind immune complexes. The cross-linking experiments reveal that there is a protein in close proximity with FcγRIIA that could be blocking its IgG binding site under basal conditions. Finally, while FcγRIIA exhibits limited binding of immune complexes in its native state, the stimulatory signals produced by the receptor on contact with immune complexes are significantly strong. Understanding how the body regulates immune complexes could lead to identification of novel methods for both activating and inhibiting the progression of immune complex mediated inflammation.

P3869
Anti-inflammatory activity of macrolides in peripheral blood mononuclear cells and the identification of potential biomarkers of azithromycin administration
Simon Hall, Stuart Farrar. Respiratory Refractory Inflammation DPU, GlassSmithKline, Stevenage, United Kingdom

Many studies in the recent past have determined that macrolide antibiotics have anti-inflammatory and immuno-modulatory activity in addition to their efficacy in treating bacterial infection. Macrolides have been successfully used in the treatment of diverse chronic inflammatory respiratory disorders, including diffuse panbronchiolitis (DPB), cystic fibrosis (CF) and bronchiolitis obliterans. We investigated the ability of azithromycin to attenuate the effects of a lymphocyte directed pro-inflammatory stimulus in PBMCs from healthy volunteers. Our results demonstrate that azithromycin significantly inhibited the induction of proliferation and the release of IL17 in these cells. Treatment with azithromycin in the absence of a pro-inflammatory stimulus in PBMCs induced the release of IL10 in a dose dependent manner 24 h after challenge. The same model, azithromycin caused a dose dependent decrease in GMSCF 24 h after treatment. In conclusion, azithromycin exhibits significant anti-inflammatory and immuno-modulatory properties and IL10 and GMCSF may prove to be useful biomarkers following macrolide therapy in respiratory disorders.

P3870
A novel macrolide/fluoroketolide, solithromycin (CEM-101), reverses corticosteroid insensitivity via activation of protein phosphatase PP2A
Yoshiki Kobayashi, Rossos Christos, Peter Barnes, Kazuhito Ito. Airway Disease, NHLI, Imperial College, London, United Kingdom

Introduction: Activation of P3D kinase causes oxidative stress-induced corticos- teroid (CS) insensitivity via HDAC2 reduction. We have recently demonstrated that a novel macrolide/fluoroketolide, solithromycin (Soli, CEM-101) restores CS sensitivity via HDAC up-regulation due to PI3K signaling inhibition (ATS2010). However, the mechanism of this effect has not been elucidated.

Aims: To investigate the role of a serine/threonine phosphatase PP2A on regulation of the P38 pathway as the target of Soli.

Methods: CS sensitivity was determined by IC50 of dexamethasone (Dex) on TNFα-induced IL-8 production in U937 monocyte cell. Activities of HDAC2 and PP2A were measured by fluorescence-based assay phosphorylation levels of Akt as a marker of P38K activation were determined by Western blotting. Okadaic acid (OA) was used to inhibit PP2A as needed.

Results: OA enhanced H2O2-induced Akt phosphorylation and HDAC2 reduction in U937 cells, and recombinant PP2A reduced Akt phosphorylation levels. Soli restored Dex sensitivity under H2O2 exposure, but pretreatment with OA abrogated Soli-mediated restoration of Dex sensitivity, inhibition of Akt phosphorylation, and HDAC2 activation. In addition, PP2A immunoprecipitates from the membrane fraction and recombinant PP2A were directly activated by Soli.

Conclusions: PP2A might be a negative regulator of P38K signaling. Soli acti-

P3871
Exposure to cigarette smoke affects the response of dendritic cells to pneumococcus
Olivier Le Rouzic1,2, Gaëlle Remy1, Cyrille Jardin2, Isabelle Tillie-Leblond2, Muriel Pichavant1, Philippe Gossel1. 1Center for Infection and Immunity of Lille, Institut Pasteur de Lille, Inserm U1019, CNRS UMR 8204, Lille, France; 2Service de Pneumologie et d’Immunologie, Hôpital A Calmette, CHRU de Lille, Lille, France

Development of chronic obstructive pulmonary disease (COPD) is linked to tabagism. Acute exacerbation potentially related to infection by streptococcus pneumoniae is responsible for the progression of the disease. Innate immunity asso-
ciated with dendritic cells (DC) mobilization is involved in the pathophysiology of the disease. We hypothesize that cigarette smoke impairs the response of DC to pathogens, a mechanism that may be involved in COPD progression.

Monocyte-derived DC of healthy donors were exposed to cigarette smoke extract (CSE) and next to its IgG binding site under basal conditions. Finally, while FcγRIIA exhibits limited binding of immune complexes in its native state, the stimulatory signals produced by the receptor on contact with immune complexes are significantly strong. Understanding how the body regulates immune complexes could lead to identification of novel methods for both activating and inhibiting the progression of immune complex mediated inflammation.

P3872
OM-85 shapes dendritic cell activation into a "pre-alert" phenotype
Daniela Bossio1, Natalcha Nowak2, Xena Varai1.

Methods: Primary and in vitro derived hDC were used to determine the precise OM-85 effects on DC biology. Stably transfected cell lines expressing human immune receptors were used to characterize OM-85 receptor-dependent activity.

Results: In hDC, OM-85 induced the secretion of IL-6 and of several chemokines (i.e. CXCL8, CXCL4, CCL2) with a potency comparable to the prototypic activating stimulus LPS. OM-85 potentiated the effect of IFN-γ in terms of IL-6, IL-12 and IL-10 release. The induction of selected chemokines by suboptimal doses of classical pro-inflammatory stimuli were boosted by the presence of OM-85. In addition, it was identified that OM-85 activates TLR2, NOD1 and NOD2 receptors in a significant, dose-response manner. Conclusions: OM-85 induces a mild and well shaped DC activation through selected pattern recognition receptors. This activation may contribute to the gen-

P3873
Altered phenotype of blood dendritic cells in patients with acute pneumonia
Katharina Dreschler, Kai Bratke, Sebastian Petermann, Petra Thamm, Michael Kueppper, J. Christian Virchow, Marek Lommatzsch. University of Rostock, Rostock, Germany

Background: Dendritic cells (DCs) play a key role in the host defense against inhalated pathogens. However, the phenotype of blood DCs in patients with acute infections is unknown.

Methods: Sixteen patients with an acute pneumonia and 19 controls without pneumonia were included in the study. The number as well as the expression of function-associated molecules of blood DCs in patients without acute infections pneumonia.

Results: Elevated concentrations of procalcitonin (median: 0.55 ng/ml) and the
rapid response to antibiotic treatment suggested a bacterial origin of the pneumonia in the patients. Total mDC (median: 27% of the controls) and pDC counts (median: 53% of the controls) were markedly reduced in patients with pneumonia, as compared to controls. Percentages of blood mDCs, but not pDCs, were negatively correlated with serum concentrations of C-reactive protein (CRP). Patients with pneumonia were characterised by a significantly increased expression of Fc gamma receptors (CD32 and CD64) on mDCs and the Toll-like receptor 9 (TLR9) in pDCs.

Conclusions: Circulating DCs are markedly reduced in patients with pneumonia, and characterized by an upregulation of molecules recognising pathogen-associated molecular patterns (PAMPs) and opsonised antigens.

P3874
Humanized Staphylococcus aureus (Fcγ) transfected non-small cell lung cancer (NSCLC) cells induce local inflammatory and necrotic changes in an experimental model
Marek Jankowski1, Janusz Kowalewski2, Tomasz Wandl1, Robert Lenartowski1, Piotr Kopinski1, Maciej Dancwicz2, Tomasz Tyrowski2, 1Dept of Gene Therapy, Collegium Medicum, NicolausCopernicus University, Bydgoszcz, Poland; 2Dept of Thorax and Tumor Surgery, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland; 3Dept of Clinical Pathobiocchemistry, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland; 4Dept of Clinical Pathobiocchemistry and Chemistry, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

Background: Tumors, including NSCLC, develop numerous local mechanisms which impair maturation of dendritic cells (DCs). The delivery of stimulatory signals to DCs from cancer microenvironment is believed to be an effective means to break tumor-induced tolerance.
Aim: Evaluation of immunostimulatory properties of TLR5 ligand, FicG, cell membrane-displayed in experimental model of Lewis Lung Cancer (LLC) transfected with a novel plasmid vector system.
Methods: Cell membrane-expressed humanized FicG transgene was inserted to the pCDNA3.1Zeo+ plasmid-based construct. Tumor specific two-step transcriptional activation system was additionally used. A549 cells, the model of NSCLC, transfected with FicG-coding plasmid, induced the maturation of human monocyte derived DCs in co-cultures. Two groups of C57BL6 mice bearing a subcutaneous LLC tumor were injected intratumorally with in vivo-FePEI and FicG plasmids or in vivo-FePEI and phosphate-buffered saline as a control. Four administrations were performed within 1 week. Tumor volumes and animal survival were monitored for 6 weeks.
Results: Plasmid injections delayed the growth of implanted LLC tumors and significantly improved animal survival rates. Histological examination of specific plasmid-injected tumors revealed lymphocyte infiltrates and remarkable necrosis.
Aims: To determine if a similar subset of CD8 T cells are present in asthmatic human airways and if their presence is associated with evidence for asthmatic airway obstruction.

Methods: BAL cells from asthmatics (n=39) and healthy controls (n=28) were stimulated in culture and immuno-stained for CD8, BLT1 and IL-13. The data were correlated to lung function, serum IgE and airway basement membrane (BM) thickness.

Results: Compared to controls, asthmatics showed higher proportion of CD8-positive lymphocytes in BAL fluid (p < 0.001). A significant proportion of these CD8-positive cells expressed BLT1 in both groups. Importantly, the proportion of BLT1-positive CD8 T cells expressing IL-13 was significantly higher in asthmatic airways compared to controls (p < 0.0001). Furthermore, the proportion of IL-13-producing BLT1-positive CD8 T cells negatively correlated with FEV1 (% predicted) values and FEF25-75% values (p < 0.001). Interestingly, a positive correlation was detected between the proportion of these cells and serum IgE levels as well as BM thickness (p < 0.01).

Conclusions: The presence of IL-13-expressing CD8 T cells is present in the airways of asthmatics, and their accumulation correlates with airway obstruction, serum IgE levels and BM thickness, suggesting a pathogenic role for these cells in human asthma.

In vivo imaging of NF-kB pathway in acute lung inflammation mouse model can predict a pharmacological response

Fabio Stefanelli1, Francesca Ruccci1, Paola Carno2, Laura Calza2, Roberta1, Luca Lorenzini2, Gino Villetti1.
1 In Vivo Pulmonary Pharmacology Unit, Pre-Clinical R&D, Chiesi Farmaceutici S.p.A., Parma, Italy; 2CIRI Life Sciences and Health Technologies, University of Bologna, Bologna, Italy; 3Department of Biochemistry and Molecular Biology, University of Parma, Parma, Italy

NF-kB plays a central role in immunity, inflammation, development, cell survival and has been indicated under a number of pathological conditions of lung diseases, including asthma, chronic bronchitis, and chronic obstructive pulmonary disease. In this study, we assessed the in vivo activation of NF-kB signaling in lung tissue using a biosensimaging system (Vivoscope) to monitor activation of an NF-kB promoter in response to lipopolysaccharide stimulation. A plasmid contained responsive elements of NF-kB and luciferase as a reporter gene has been delivered intravenously in nude mice at the concentration of 40 μg per mouse using in vivo-jetPEI™ from Polyplus as a transfectant agent. One week after DNA delivery lungs were harvested, and the lungs imaged using bioluminescence (BLI) at 2, 4, 7 and 24 hs. The ability of the IKK2 inhibitor MLN120B orally administered at the dose of 300 mg/kg to counteract NF-kB activation has been demonstrated (BLI) at 2, 4, 7 and 24 hs. The level of VEGF in the blood correlated with parameters of neoangiogenesis in the lungs tissue (r = 0.37, p = 0.001). Patients with PH in comparison with patients without PH demonstrated higher concentrations of ET-1 and PAI-1 (r = 0.34, p = 0.005 and r = 0.37, p = 0.002 respectively). Invert correlation was established between PAI-1 and Dc0 (r = 0.71, p = 0.05). PAI-1 and FVC (r = 0.72, p < 0.05).

Conclusion: These data demonstrate the important role of the studied markers of ED and neoangiogenesis in the mechanisms of IIP progression and may be used as predictors of survival.

P3882

Increased polysialylation in lung tissue of patients with idiopathic pulmonary fibrosis

Christina Ulm1, Martina Kortki2, Sandra Mueller1, Susanne Rimml1, Hildegard Geyer3, Rita Gerardy-Schuh3, Martina Muehlenhoff3, Andreas Guenther2, Rudolf Geyer1, Sebastian Galuska1.
1 Institute of Pathology, Medical Faculty of RWTH Aachen University, Aachen, Germany; 2CIRI Life Sciences and Health Technologies, University of Bologna, Bologna, Italy; 3Department of Internal Medicine II, University of Giessen, Giessen, Germany

Idiopathic pulmonary fibrosis (IPF) is a chronic fibrosing interstitial lung disease of unknown etiology. The disease is characterized by alveolar destruction, uncontrolled fibroblast proliferation and excess matrix production, resulting in progressive dyspnea, a decline in lung function and loss of gas exchange properties. So far, only pirlfimogene has been shown to exert some efficacy in IPF and lung transplantation represents the only option to prevent death. Polysialic acid (polySia) is a developmentally regulated negative charged glycan which is predominantly found in neural tissue and tumors, where polySia is involved in the modulation of cell adhesion and migration processes. Therefore, we asked the extent of polysialylation in IPF (n=22) and donor (n=20) lung tissues obtained during lung transplantation. We observed an up-regulation of the polysialyltransferases ST6SiaI and ST8SiaIV, the key enzymes of polySia biosynthesis, using quantitative real time PCR in IPF patients. In agreement with an increased mRNA expression level of both trans- f erases we detected increased polySia levels in tissue samples of IPF patients in comparison to donor tissue by Western blotting. Using a glycoproteomics approach we were able to identify NCAM as the polySia carrier which could be confirmed by Western blot analysis. Surprisingly, polySia-NCAM was located intracellularly in vesicles of ciliated bronchial epithelial cells as well as Clara cells. However, the role of polySia-NCAM in the bronchoalveolar system and especially during the development and the pathophysiology of IPF needs to be further investigated.

Human neutrophil peptides as biomarkers for monitoring respiratory functional impairment in sarcoidosis

Guglielmo Panne1, Maria Railli2, Alvaro Leonte3, Paolo Graziano4, Vittoria Conti1, Iao Camarella5, Giovanni Gallicchio1, Alfredo Sebastiani1, Gabriele Lucantoni1, Giovanni Puglisi1, 1 Department of Cardiothoracic Surgery, Respiratory, Nephrological and Geriatric Sciences, “La Sapienza” S. Camillo-Forlanini Hospital, Rome, Italy; 2IRCCS Fondazione Don Carlo Gnocchi - Omlas, Don Carlo Gnocchi, Milan, Italy; 3Department of Respiratory Diseases, S. Camillo-Forlanini Hospital, Rome, Italy; 4Attilio Reali, “La Sapienza” S. Camillo-Forlanini Hospital, Rome, Italy

Background: Human Neutrophil Peptides (HNP) are cationic peptides with a...
The pathogenesis of lung disease in cystic fibrosis (CF) has not been fully elucidated, however, neutrophil-dominated inflammation is thought to play a major role. Nonetheless, a number of proteases produced by other cells in the lung may play a pivotal role. Furthermore, host defense proteins such as SLPI, β-defensins and lactoferrin play a role for cathepsin S in the diminution of the lung antiprotease and antimicrobial screen possibly leading to lung destruction and favouring conditions for bacterial infection. We have identified epithelial cells as a source of cathepsin S in the CF lung with the demonstration that CF bronchial and tracheal epithelial cell lines express and secrete significantly more active cathepsin S than normal cells in the absence of proinflammatory stimulation. These findings were confirmed in primary human bronchial epithelial cells from CF patients. On the basis of our results to date, we postulate that upregulated cathepsin S plays an important role in CF lung disease. Human lysosomal cysteine proteases are a family of proteases that have been relatively unexplored in the area of CF lung disease. We have shown that cathepsin S activity is increased in CF bronchoalveolar lavage fluid. In addition to lung tissue degradation, cathepsins have been found to play a role in the destruction of host defence proteins such as SLPI, β-defensins and lactoferrin. These findings indicate a role for cathepsin S in the diminution of the lung antiprotease and antimicrobial screen possibly leading to lung destruction and favoring conditions for bacterial infection. We have identified epithelial cells as a source of cathepsin S in the CF lung with the demonstration that CF bronchial and tracheal epithelial cell lines express and secrete significantly more active cathepsin S than normal cells in the absence of proinflammatory stimulation. These findings were confirmed in primary human bronchial epithelial cells from CF patients. On the basis of our results to date, we postulate that upregulated cathepsin S plays an important role in CF lung disease and we are currently investigating reasons for this upregulation of cathepsin S in CF epithelial cells. This data will shed light on the role of cathepsin S in CF; an area that has been overshadowed to date, and may open up new avenues for exploration in the search for an effective therapeutic target in CF lung disease.
Establishment of reference values for differential cell counts in nasal lavage of healthy young adults.

Yiming Yuan, Yang Fu, Yue Wang, Kefang Lai, Nanshan Zhong. State Key Laboratory of Respiratory Diseases Guangzhou, Guangzhou Institute of Respiratory Disease, The First Affiliated Hospital of Guangzhou Medical College, Guangzhou, Guangdong, China

Background: Upper airway inflammation could be reflected by nasal lavage cytology, which is characterized by advantages of non-invasive, simple, objective and costless. However, reference values nasal lavage cytology was not established.

Objectives: To establish reference values and positive standard for nasal lavage cytology through screening normal healthy subjects and patients with allergic rhinitis according to strict inclusion criteria.

Methods: 43 normal healthy volunteers (control) and 166 subjects with allergic rhinitis (AR) were enrolled after detailed history inquiry, physical examination and allergen skin prick test. Nasal lavage cytology tests were performed, and the standard for judgment was defined as the average count of different inflammatory cells per 20 fields under 200× microscopic view.

Results: There was no statistical significance in gender, age, height and weight among each group. 95% CI of neutrophils, eosinophils, and lymphocytes were (0~0.65)/×200 and (0~1.70)/×200, respectively. The median (interquartile range) of neutrophils were 0.65/×200 in AR group, which showed no statistical difference (P>0.05) with that of normal group (0/×200). A significant difference was found in the median (interquartile range) of eosinophils [0.60 (2.24/×200)] in AR group as compared with that of normal control group (0/×200). P=0.001.

Conclusions: Establishment of reference values of nasal lavage cytology test is helpful to discriminate normal individuals and patients with allergic rhinitis, but also a new tool for objective reflection on upper airway inflammation, which is of great value for scientific and clinical purposes.

The dietary antioxidant quercetin boosts pulmonary antioxidant defenses

Agnes Booz1, 2, Carin Albrecht1, Brandistarte Olga1, Maja Hullmann1, Imagea Food1, Aal Bast3, Reel Schins1, 2 Partec Research, IUF - Leibniz Research Institute for Environmental Medicine, Duesseldorf, Germany; 3 Toxicology, Maastricht University, Maastricht, Netherlands;

1 Molecular Immunology, IUF - Leibniz Research Institute for Environmental Medicine, Duesseldorf, Germany.

We have demonstrated that single oral supplementation of the dietary antioxidant quercetin reduces oxidative stress in sarcoidosis patients. Apart from its direct oxidant scavenging properties, quercetin has also been suggested to boost endogenous antioxidant defenses indirectly by activation of redox sensitive signaling pathways. Therefore, we investigated the effect of orally applied quercetin on pulmonary redox balance.

C57BL/6J mice were sacrificed 3 or 16 hours after receiving an oral quercetin bolus (6 mg/animal). Total antioxidant capacity, quercetin concentration and the expression of nuclear factor erythroid derived (Nrf2)-regulated antioxidant genes were evaluated. The possible influence of Nrf2 was also explored in vitro by treating quercetin-preloaded BEAS-2B human bronchial epithelial cells with the pro-oxidative agent bleomycin.

Total quercetin concentrations in plasma and lung tissue displayed a rapid but transient increase, which was associated with enhanced total antioxidant capacity. After 16 hours, amplified pulmonary mRNA levels of various antioxidant genes including catalase, superoxide dismutase, heme oxygenase 1 and -glutamyl cysteine synthetase were observed. Additionally, oral quercetin administration increased Nrf2 gene expression. In the BEAS-2B cells, quercetin also activated Nrf2 and interestingly, this induction was augmented by bleomycin. Moreover, quercetin pre-treatment inhibited bleomycin-induced ROS production.

In conclusion, our results indicate that oral quercetin may exert beneficial effects by boosting pulmonary antioxidant defenses and suggest a possible involvement of Nrf2 herein. The therapeutic value of our findings is currently explored in a murine fibrosis model.

Clinical evaluation of angiogenesis and coagulation in pulmonary sarcoidosis

Elena Popova1, Marina Lebedeva1, Andrew Ponomarev2, Sergei Bolevich2, Vera Opyenchko1, 2 Pulmonology, Moscow Sechenov Medical University, Moscow, Russian Federation; 2 Radiology, 24 Moscow Hospital, Moscow, Russian Federation.

The aim of our study was to evaluate the influence on prognosis of patients with pulmonary sarcoidosis of some mediators autonomous angiogenesis and activation of coagulation (vascular endothelial growth factor (VEGF) and plasminogen activator inhibitor-1 (PAI-1).

Patients and methods: 46 patients with morphologically proved pulmonary sarcoidosis were examined. Standard clinical examination, pulmonary function testing, 6-min walk test (6 MWT), echocardiography, high-resolution CT (HRCT) were evaluated. Plasma concentrations and expression in lung biopsies of VEGF and PAI-1 were evaluated by immunoassay (ELISA) and immunohistochemistry. Monochrometry of lung vessels were performed.

Results: 12/26% patients presented pulmonary hypertension (p<0.05). Plasma concentrations of PAI-1 and VEGF correlated positively with HRCT patterns of fibrosis in lung (r=0.38, p<0.006 and r=0.37, p=0.002 respectively) and were more high in patients with PH in comparing to patients without PH (P=1.206, 15.1-27.2/nM/l vs 14, 9.1-18.2/nM/l, p=0.001 respectively and VEGF: 42.7±31.6, 1-55.4/2/mL vs 28.01, 180-3(0.06, Hr/mL, p=0.001 respectively). VEGF expression in lung tissue correlated positively with morphology of pulmonary vasculitis (r=0.34, p=0.001). HRTC hockycomb patterns (r=0.45, p=0.002).

Conclusion: Degree of alterations of the coagulation system and angiogenesis may be discussed as survival prognostic markers for pulmonary sarcoidosis.

Detection of serum anti-endothelial cell antibodies (AECA) in COPD rats

Yong Lin, Qiang Zhang, Xue-Feng Ling, Si-Qing Sun. Pulmonary Medicine, Hongtai Hospital, Nanjing, Jiangsu, China.

Background: Chronic obstructive pulmonary disease (COPD) may be a systemic inflammatory disease. Autoimmunity abnormalities and a potential role of COPD includes micro-vascular destruction. Anti-endothelial cell antibodies (AECA) are a type of circulating antibodies which bind to endothelial antigens and induce endothelial cell damage. It is unclear whether the AECA play a role in COPD mechanisms.

Objective: To detect the serum level of anti-endothelial cell antibody in adult rats of COPD in order to investigate the significance of AECA in COPD mechanism.

Methods: Replicated COPD rat models with passive-smoking and lipopolysaccharide (LPS) induce traheas injections. Anti-endothelial cell antibodies (AECA) of rats were examined by ELISA.

Results: In smoking rats with simple airway inflammation, the alveolar septum thickened but was not destroyed, AECA1 49.4±8.7 ng/L. COPD rats had airway inflammation and emphysema. AECA1 138.46±7.85 ng/L. Compared with the normal control group (62.89±10.68 ng/L), AECA levels in the two test groups were much higher.

Conclusion: Autoimmune constituents which induce endothelial cell lesions may participate in the pathogenesis of COPD; detection of serum AECA levels in COPD may have some clinical significance.

The pathogenesis of COPD

Adriela Kratzer1, Bolaris Salys1, Zhixin WeiChu1, Martin Zamora1, Laima Taraseviciene-Stewart1, 2 Medicine, University of Colorado Denver, Denver, United States; 2 Medicine, National Jewish Health, Denver, United States.

Background: Chronic obstructive lung diseases (COPD) are the major cause of death and disability worldwide. The major risk factor for COPD is tobacco smoke. Cell adhesion molecule CD146 is expressed in all types of human endothelial cell (EC) and exists in a membrane-anchored and a soluble form (sCD146). The plasma concentration of sCD146 is modulated in inflammatory diseases associated with endothelial alterations.

Aim and objectives: To investigate the role of endothelial CD146 in the pathogenesis of cigarette smoke (CS)-induced emphysema.

Methods: Sprague Dawley rats were exposed to second hand CS for two months. The lung tissue and bronchoalveolar lavage (BAL) cells were examined for CD146 gene and protein expression and emphysema development as measured by M/L scID146 levels were determined in circulation and BAL fluid in rats and in patients with COPD. CD146 expression and function was also examined in rat pulmonary EC exposed to CS in vitro.

Results: Sprague Dawley rats exposed to cigarette smoke for 2 months developed significant emphysematous changes (as measured by mean linear intercept) and had increased levels of circulating and bronchoalveolar lavage fluid sCD146. Treatment of rat pulmonary EC with cigarette smoke extract in vitro also resulted in a decreased membrane-bound CD146 expression and increased sCD146 levels in the medium. Moreover, circulating levels of sCD146 were significantly increased in serum of COPD patients and correlated with the disease severity.

Conclusion: Our data indicate that CD146 is involved in CS-induced vascular dysfunction and that CD146 can be a candidate marker for COPD/ emphysema.

Effects of steroids on inflammatory cell number and function in the proximal and distal airways

Gregory Rankin1, Susan Wilson1, David Hall2, Jane Warner1, 1 School of Medicine, University of Southampton, Southampton, United Kingdom; 2 Respiratory CED, GSK Medicines Research Centre, Stevenage, United Kingdom.

Introduction: Steroids are often prescribed for patients with mild/moderate COPD but is not clear how these commonly prescribed drugs affect inflammatory cell numbers/function in the proximal and distal airways.

Methods: Matched proximal and distal airways tissue was obtained from 37 patients. Fourteen patients had no evidence of airways obstruction (FEV1/ FVC>0.76±0.01) and 23 had evidence of mild/moderate COPD (FEV1/ FVC<0.58±0.02). Eleven of these patients were prescribed steroids at the time of surgery.

P3894
Nitrosative and cytokine status in patients with COPD and chronic cor pulmonale (CCVD)

Svetlana Soodaev1, Timur Li2, Igor Klimanov1, Alexander Lisitsa1, Naïja Kabyshева1, Larisa Postnikova1, Olga Mironova1, Anatoly Fedin2. 1Clinical and Experimental Biophysics, Pulmonology Research Institute, Moscow, Russia; 2Neurological Department, Russian State Medical University, Moscow, Russian Federation; 3Dept. of Internal Medicine, Municipal Hospital “Aibolit”, Nizhny Novgorod, Russian Federation; 4Department of Internal Medicine, The Medical Institute, Nizhny Novgorod, Russian Federation

The aim of the study was to investigate the dynamics of nitric oxide (NO) stable metabolites concentration in exhaled breath condensate (EBC) as markers of the nitrosative stress and circulating inflammatory cytokines in COPD and CCVD. Material and methods: 50 males inpatients were enrolled in the study (age = 51.67 yrs.). All patients were divided in two groups: group 1 contains 23 patients with COPD exacerbation only. The control group consisted of 21 healthy volunteers. The investigation was performed only. The control group consisted of 21 healthy volunteers. The investigation was performed by ELISA. Results: The TNN levels in EBC as well as in blood plasma were significantly higher than the COPD cases admitted with acute attack or respiratory failure. The TNN concentration was measured using the spectrophotometric method; 3-NT and cytokines (TNF-α, IL-8) concentrations in blood plasma were investigated with specific enzyme immunoassay. Conclusion: The results obtained demonstrate the increase of nitrosative/ cytokines stress parameters as a systemic reaction in patients with COPD and CCVD compared with COPD patients only.

P3895
Leptin modulates host defense against chronic cigarette smoke inhalation in mice

Juanita H.J. Vernooy1, Irene M.J. Eurlings1, Gonda F.J. Konings1, Jan Tavermier2, Guy F. Joos3, Guy G. Brusselle3. 1Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 2Department of Medical Protein Research, Flanders Interuniversity Institute for Biotechnology/Ghent University, Ghent, Belgium; 3Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium

Rationale: Several hallmarks of COPD, including pulmonary and systemic inflammation, can be mimicked in mice by cigarette smoke (CS) exposure. We recently found increased expression of the pleiotropic adipokine leptin by resident lung cells in smokers and patients with COPD versus never-smokers. To unravel the involvement of leptin in COPD pathogenesis, innate and adaptive immune cell recruitment and remodelling upon chronic CS exposure was evaluated in leptin-receptor deficient db/db mice. Methods: WT C57/BKS and db/db mice were exposed to air or CS for 16 weeks (4 exposures/5, 5 wk). At 24h after the final exposure, bronchoalveolar lavage fluid (BALF) and lung tissue were processed to examine pulmonary inflammation and remodelling. Results: The role for autoimmunity in the pathogenesis of COPD is controversial, and the identity of putative autoantigens is subject to debate. In order to examine the role for autoantibodies in COPD, we cloned the complete variable light and heavy chains from single-cell sorted IgG or IgA-positive activated memory B cells isolated from COPD and control lung tissue, and expressed these as complete human Ig mononclonal antibodies (HumAbs). These HumAbs were tested for autoactivity by histology using lung tissue sections of COPD patients and healthy controls and lung cell lines. In addition, serum of COPD patients and never-smokers was used to determine binding of antibodies to epithelial, fibroblast, and endothelial cell lines. The HumAbs stained multiple cells and structures in lung tissue sections such as smooth muscles cells, epithelial cells, and the adventitia. The cell lines examined thus far, two epithelial cell lines, were also stained by the HumAbs. The results from these in vitro studies illustrate the complexity of autoactivity in COPD in concomitantly with the preferential binding of different types of lung cells by antibodies in serum of COPD patients, individual antibodies may also target multiple cells and structures in the lung.

P3896
Paraosinace activity in patients with COPD

Turgut Tekel1, Emen Maden2, Aytekin Koy1,2, Faizal Tahir Belkic1,2, Said Sami Erdogan1, Mustafa Tosun1, Kurtur Umair1,2, 1Chest Diseases, Selsuc University, Meram Medical Faculty, Konya, Turkey; 2Biochemistry, Selsuc University, Selsucu Medical Faculty, Konya, Turkey; 3Chest Diseases, Konya Education Research Hospital, Konya, Turkey

Aim: Oxidant/antioxidant disequilibrium is an important problem in pathogenesis of COPD. This disequilibrium is effective in development and progression of COPD. The increased oxidative stress in COPD is not only associated with rise of oxidants but also with the decrease of antioxidant capacity. Paraoxazone 1 (PON1) functions as one of the endogenous free radical scavenging system in human body. PON1 is localized in clara cells, endotel cells and type 1 pneumocytes of the lungs. In this study we aimed to study the PON1 activity in COPD patients with stable condition, had acute attack and developed respiratory failure. Material and methods: Twenty five patients with stable COPD (group1) (mean age 62.9±9.4), 25 cases with acute COPD attack (group2) (mean age 63.8±9.0), 25 patients with hypercapnic respiratory failure (group3) (mean age 65.6±12.9) and 25 healthy individuals for control group (mean age 34.8±9.8), totally 100 cases, were enrolled to the study. All cases enrolled to the study underwent routine biochemical analysis including PON1 activity and lipid profile. Results: There was significant difference between groups with respect to PON1 levels (p<0.0001). PON1 activities of COPD patient groups (group 1=96,5±87,4U/L, group 2=51,4±32,8U/L, group 3=47,1±27,5U/L) were lower than control group (185,4±110,1U/L, p<0.0001). Also PON1 activity of stable COPD patients was higher than the COPD cases admitted with acute attack or respiratory failure (group2 and 3) (p<0.05). Conclusion: This findings show that PON1 activity may have a role in COPD pathogenesis and endogen antioxidants might be depleted by increased oxidative stress in COPD. This also advocates that oxidative stress may have a role in acute COPD attacks.
P3908 Bronchial antiproteases activation as a tolerance factor to COPD development in healthy long term smokers
Sergey Fedosenko, Georgiy Chernogoryuk, Hospital Therapy, Siberian State Medical University, Tomsk, Russian Federation

Not all smokers suffer from COPD. It is possible that tolerance to COPD emergence among healthy long term smokers is supported by suppressing the excessive proteolytic activity.

Aim: To investigate the factors of tolerance to COPD development among healthy long term smokers according to content of proteases and antiproteases in induced sputum.

Methods: There are 145 stable COPD patients and 48 long term smoking men (>30 pack/year), without symptoms of COPD have been enrolled in our research.

The control group consisted of 48 healthy nonsmokers volunteers. All patients were men of identical age of 59.2±4.07 years. Induced sputum was studied on elastase, protease’s inhibitor α1, macroglobulin α1.

Results: An activity of protease’s inhibitor α1 and macroglobulin α1 in induced sputum of long term smokers is higher than among healthy non-smokers and patients with COPD.

P3909 Model of staged development chronic obstructive pulmonary disease (COPD) in rats
Iveta Dvorskauskay, Elena Lebedeva1, Lev Danilov2, Nataliya Kazurova2,1
1Department of Experimental Pulmonology and Pathomorphology, Research Institute of Pulmonology, St. Petersburg, Russian Federation; 2Department of COPD Therapy, Research Institute of Pulmonology, St. Petersburg, Russian Federation

Models of COPD open ways of studying pathogenesis, searching for therapeutic targets and new health care trends.

Aims: To reproduce the successive stages of COPD in experiment.

Methods: Model of COPD was induced in Wistar rats by long-time intermittent nitrogen dioxide (NO2) inhalation (15 ppm, 1,5 h/day for 60 days). Histological specimens were stained with hematoxylin-eosin. CD3 expression in bronchial walls and interstitium was determined by immunohistochemistry. TNFα and TGFβ1 were determined in serum and bronchoalveolar lavage fluid (BALF).

Results: After 15-day NO2 exposure acute response to injury was observed: epithelium desquamation and focal proliferation, swelling of submucosa, bronchial gland degeneration, lung tissue hyperextension were revealed. After 30 days cell infiltration of submucosa and hyperplasia of goblet cells were added. After 60-day exposure squamous metaplasia of ciliated epithelium, muscle plate atrophy, focal sclerosis, emphysema were identified. At this stage increase of CD3 expression was revealed in walls of bronchi and interstitium that indicated the presence of large number of T-lymphocytes (6.1±±1.59 vs. 28±±1.23 in control rats, p <0.05). TNFα increased in serum (125.94±16.21 vs. 60.±6±6.34 pg/ml in control, p <0.05) and BALF (204.9±25.76 vs. 15±±0.03 pg/ml in control, p <0.05). TGFβ1 increased in serum 18-fold and in BALF – 8-fold from control (p <0.05).

Conclusion: The model allows to reproduce stages of COPD from acute inflammation to lung tissue remodeling (emphysema and focal fibrosis). The model adequacy is confirmed by COPD symptoms: increased expression of CD3-lymphocytes in bronchial walls and lung parenchyma, multiple increased TNFα and growth factor TGFβ1.

P3910 Lipoxin A4 receptor expression in smokers with and without COPD
Liga Balode1, Sergejs Isajevs1, Darja Svirina1, Uldis Kopeika2, Gunta Strazda1
1Department of Experimental Pulmonology and Pathomorphology, Research Institute of Pulmonology, St. Petersburg, Russian Federation; 2Department of Pulmonology, St. Petersburg, Russian Federation

Background: The lipoxin A4 receptor, LXA4R/FPR1-L, is a G protein-coupled receptor LXA4R with high affinity binds anti-inflammatory lipoxin LXA4 and with low affinity - N-formylated proinflammatory peptides. The aim of our study was to evaluate FPR1 expression in nonsmokers, asymptomatic smokers and in patients with COPD.

Patients and methods: 6 nonsmokers, 7 asymptomatic smokers and 5 moderate COPD patients undergoing lung resection for a solitary peripheral non-small cell carcinoma were enrolled in the study. Immunohistochemical methods were used to evaluate FPR1 expression in airways and alveolar walls.

Results: FPR1-1 expression was observed in airways epithelial cells, macrophages, lymphocytes and neutrophils. Obtained results showed that asymptomatic smokers had increased numbers of FPR1-1 positive cells in alveolar walls compared to nonsmokers (157±±59 vs. 38±±13 cells/mm², p <0.002). At contrast, COPD patients had decreased numbers of FPR1-1 positive cells compared to asymptomatic smokers (23±±7 vs 157±±59 cells/mm², p <0.002). In addition, COPD patients had a tendency of decreased FPR1-1 expression compared to nonsmokers. When all smokers were analyzed together, a significant positive correlation was found between the number of FPR1 positive cells and airflow obstruction, FEV1% (Rho±±0.66, p=0.02).

Conclusion: Downregulated FPR1-1 in COPD patients may explain persistence of inflammatory process in alveolar area in COPD, whereas upregulation in asymptomatic smokers could serve as adaptive mechanism limiting inflammatory process.

P3911 Lung injury and apoptosis in COPD: Effect of a recombinant anti-protease derived from trappin-2
Annabelle Tanga, Ahlame Saidi, Sandrine Dallet-Choisy, Marie-Louise Zani, Thierry Moreau.

Introduction: In chronic obstructive pulmonary disease (COPD) it is well established that neutrophil serine proteases' elastase (HNE), protease 3 (Pr3), cathepsin G (CG) contribute to lung injury. In order to target these proteases in COPD, we previously developed an anti-protease derived from trappin-2 modified to inhibit the three proteases at the same time. The goal of the study is to evaluate the protective effect of this inhibitor (trappin-2.62L) against the degradation of lung epithelium and apoptosis of epithelial cells induced by proteases.

Methods: Alveolar epithelial cells (A549) cells were exposed to serine proteases in presence or absence of trappin-2.62L (T2A62L) with various concentrations and experimental conditions. The protective effects of T2A62L towards proteolytic damages were estimated by observation of changes in cell morphology and by the measurement of the cellular detachment. The protective effect of T2A62L towards A549 apoptosis induced by proteases was evaluated by flow cytometry.

Results: Serine protease induce cell morphological changes, cellular detachment (58.78, 85.35% for HNE, Pr3, CG respectively) and apoptosis of epithelial cells (5 and 2 fold increases with HNE and Pr3). Addition of T2A62L diminishes the proteolytic damages (5,10, 35% for HNE, Pr3, CG) and reduces significantly the rate of apoptotic cells.

Conclusion: The approach using a cellular model demonstrate that T2A62L exerts anti-proteolytic and a protective effect towards apoptosis induced by serine neutrophil proteases. So, these results confirm the therapeutic potential of this inhibitor for treatment in COPD.

P3912 Effect of phototherapy in phospholipids' composition of membranes of lymphocytes in experimental COPD
Yulduzkhon Kayumova, Yulduzkhon Tadjikhodjayeva, Gul’ora Sadikova.

Ministry of Health of the Republic of Uzbekistan, Republican Specialized Scientific-Practical Center of Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Introduction: Membrane phospholipids (PL) provide functional integrity of the cells of respiratory tract.

Aim: To study membrane phospholipids' composition of peripheral blood lymphocytes in the dynamics of phototherapy in rats with experimental COPD.

Methods: An experimental COPD was reproduced in 60 white rats under the influence of tobacco smoke. For half of them we used the method of phototherapy of concentrated pulsed light (CPL) at wavelengths from 600 to 800 nm. Phototherapy was carried out daily for 10 days. The control group consisted of 10 healthy rats. To study the phospholipids' fractions of lymphocytes we used the high-flow horizontal chromatography.

Results: In rats with experimental COPD, compared with the control group, phosphatidylcholine (PC) and phosphatidylethanolamine (PE) were reduced by 31.8% (P <0.01) and 43% (P <0.01), the content of lysophosphatidylcholine (LPC) and lysophosphatidylethanolamine (LPE) was increased two-fold (P <0.01). Free fatty acids (FFA), compared with the control, increased by 47.2% (P <0.01) with a decrease in total phospholipids (TPL) by 17% (P <0.01). After 10 sessions of phototherapy we defined increase in PC and PE by 18.8% and 28.4% compared with the group of COPD without treatment, and this was accompanied by a decrease in LPC and LPE by 35.1% and 40.9% (P <0.05 in all cases). Tendency to normalization of FFA and TPL had no statistical significance.

Conclusion: Experimental COPD in the rats is accompanied by quantitative changes in the main fractions of phospholipids in the membranes of peripheral blood lymphocytes. Conducting a course of phototherapy by CPL contributes to positive changes in membrane phospholipids of the lymphocytes.
(Background) 25-Hydroxycholesterol (25-HC) is produced from cholesterol by cholesterol 25-hydroxylase and is related to atherosclerosis in vessels. Recently, 25-HC production was enhanced in the airways of COPD patients compared to healthy subjects. Cholesterol 25-hydroxylase was localized in alveolarmacrophages and pneumocytes in COPD. The amounts of 25-HC in the sputum were significantly increased in COPD patients and the degree of 25-HC production was negatively correlated with the lung function. The amounts of 25-HC in the sputum had significant positive correlations with the interleukin-8 (IL-8) levels and neutrophil counts in the sputum. Treatment with 25-HC augmented neutrophil accumulation in the airways and the production of chemokines in mice. 

(Conclusions) 25-HC production was enhanced in the airways of COPD patients and could cause neutrophilic inflammation.

(P3904) Time course analysis of lung function and morphometric parameters in a murine model of emphysema
Clarice Olivo, Bruna Scarpa, Francine Almeida, Petra Arantes, Fernanda Lopes, Milton Martins. Department of Medicine, Universidade de São Paulo, São Paulo, Brazil

Proteolytic enzymes have been used to induce emphysema in rodents to study mechanisms of this disease pathogenesis. However, few studies have evaluated the time course of the development of pulmonary emphysema after nasal instillation of elastase.

Objectives: To describe the progression of emphysema after porcine pancreatic elastase (PPE) nasal instillation in mice.

Methods: 64 adult male Balb/c mice received either a nasal drop of 50 μl (0.667 UI) of PPE (PPE) or saline (S) and were studied on days 1, 7, 14 and 21 after PPE instillation. For each time, we analyze airway resistance (RAW), tissue elastin (Gtis) and tissue elastance (Htis). Inflammatory profile was performed after PPE instillation. For each time, we analyzed airway resistance (RAW), tissue elastin (Gtis) and tissue elastance (Htis). Inflammatory profile was performed after PPE instillation.

Results: There was an increase in inflammatory cells in PPE groups since the 1st day, characterized by an increase number of neutrophils and macrophages which remained until the 21th day. However the increase in lymphocytes became evident only at 7th day. We observed a decrease in Htis at 7th and 21th days while there was an increase in Gtis at the 1st day and a decrease at the 21th day. We did not observe any differences for RAW values. The increase in Lm was observed in PPE group since the 1st day and was maintained throughout different times.

Conclusions: In this experimental model we observed an earlier inflammatory process concomitant with alveolar enlargement, suggesting that protease-antiprotease imbalance influence the development of emphysema. Supported by FAPESP, LIMHC-FMUSP, CNPq, Brazil

(P3905) Effects of cancer cachexia on the alveolar morphology of the mouse lung
Tilman Graulich1, Sunam Kumar Das2, Gabriela Krasteva1, Lars Wessels1, Gerald Holfer1, Christian Mühlfeld1. 1Institute of Anatomy and Cell Biology, Justus-Liebig-University Giessen, Giessen, Germany; 2Institute of Pathology, Medical University Graz, Graz, Austria

Cancer cachexia is a complex syndrome with a significant reduction of body weight and a variety of systemic symptoms including respiratory dysfunction. In rodents, calorie restriction causes loss of alveolar surface area, the so-called nutritional emphysema. We hypothesized that alveolar alterations and loss of gas exchange surface area are present in the cancer-cachetic mouse. C57Bl6 mice were randomly assigned to subcutaneous injection of Lewis lung carcinoma cells (tumor group, TG) or saline injection (control group, CG). Mice were sacrificed 21 days later and lungs were processed for light and electron microscopy. Cancer cachexia did not differ between groups the volume of lamellar bodies per unit alveolar surface area was significantly reduced in TG (TG: 25.3±3.7 mm2/m2; CG: 40.2±13.5 mm2/m2; p<0.05). Quantitative expression of surfactant proteins A, B, C and D was not different between CG and TG as shown by RT-PCR.

In summary, despite a reduced ratio between the volume of the intracellular surfactant pool and the alveolar surface area in TG, there was no evidence for a significant disturbance of the gas exchange region due to cancer cachexia. In particular, weight loss was not associated with loss of alveolar surface area.

Conclusions: Short term aerobic training seems do not decrease features of pulmonary allergic disease in mice.
P3907
Contribution of TGFβ1 and TIMP2 to clinical activity of asthma and COPD
Navid Abofzafkh Zade Ghalejoghi 1, Mostafa Ghaneli 1, Mohammad Reza Norouzi 2, Ali Amiri Harandi 2, Abbas Ali Imami Fooladi 1,2
1Research Center of Chemical Injuries, Buqiyatulllah University of Medical Sciences, Tehran, Islamic Republic of Iran; 2Research Centers of Molecular Biology, Buqiyatulllah University of Medical Sciences, Tehran, Islamic Republic of Iran

Introduction: The process of bronchial tissue repair and remodeling in airway diseases depends on balance between production and degradation of different cytokines, leading to the regulation of extracellular matrix turnover finally.

Objectives: This study was designed to evaluate contribution of Transforming Growth Factor β1 (TGFβ1) and Tissue Inhibitor of Metalloproteinase-2 (TIMP2) to clinical activity and reversibility of asthma and chronic obstructive pulmonary disease (COPD).

Methods: In a cross-sectional study on two groups of 29 asthmatics (14 males and 15 females) and 13 male COPD patients, we evaluated TIMP2 and TGFβ1 expression using semi-quantitative PCR on induced sputum samples. The relation among TIMP2 and TGFβ1 and pulmonary function test (PFT) indices and disease free period was assessed.

Results: Higher pulmonary function test (PFT) indices and longer disease free period was seen in COPD patients with raised expression of both TGFβ1 and TIMP2. On the other hand asthmatic patients had better pulmonary function status with raised TIMP2 and decreased TGFβ1 expression (p<0.05).

Conclusion: It seems that different effect of cytokines like TGFβ1 and TIMP2 in both diseases is depended on underlying inflammatory process in airways epithelium. We supposed that TGFβ1 bidirectionally affects activity of disease in asthma and COPD. Furthermore TGFβ1 as a biomarker in sputum may have a role for evidence-based drug prescribing like corticosteroids in patients with COPD and asthma.

P3908
The role of cathepsin D, H & K in the regulation of tumstatin levels in asthmatic airways
Janette Burgess 1,2,3, Karryn Grafton 1,2,3, Gavin Tjin 1,2, Josephine Middelburg 1,4
1Pharmacology, The University of Sydney, Sydney, NSW, Australia; 2Cell and Molecular Biology, Woolcock Institute of Medical Research, Sydney, NSW, Australia; 3Pharmacology, The University of Sydney, Sydney, NSW, Australia; 4Airway Remodelling, Cooperative Research Centre for Asthma and Airways, Sydney, NSW, Australia

Introduction: Angiogenesis is a prominent feature of remodelling in asthma. We previously reported that tumstatin, an endogenous angiogenic inhibitor which is the non-collagenous domain-1 (NC1) of the collagen IV α3 chain is absent from asthmatic airways. Tumstatin is released from the basement membrane by specific proteases. Cathepsins D, H and K (members of a broad family of proteases that degrade ECM proteins including collagen IV in other organs) are increased in inflammatory diseases and modulate tumour angiogenesis. We hypothesised that cathepsin D, H and/or K plays a role in the absence of tumstatin in asthmatic airways.

Methods: Cathepsin mRNA expression was measured by real time RT-PCR. Immunohistochemistry was used to measure cathepsin D, H and K in human airway tissue sections. Recombinant tumstatin and airway tissue sections were digested with active recombinant cathepsin D, H and K and the resultant cleavage products analysed by polyacrylamide gel electrophoresis. 

Results: Human airway smooth muscle cells express cathepsin D and H mRNA. In both asthmatic and nonasthmatic airway sections inflammatory cells exhibit strong staining for cathepsin D. Cathepsin H and K are also strongly expressed in asthmatic airway tissues. Recombinant tumstatin was completely degraded by recombinant cathepsin D and H whilst cathepsin K degradation produced a 10kDa cleavage product. In human tissue sections recombinant cathepsin D completely digested tumstatin. Digestion with cathepsin K resulted in greater detection of the tumstatin antigen.

Conclusion: These findings suggest that cathepsin D, H and K may play a role in the regulation of tumstatin levels in the asthmatic airways.

P3909
Inhibitory profiles of alpha-1-antitrypsin from PiZ & PiSZ individuals and implications for tissue destruction in emphysema
Nicola Sindel 1, Timothy Dalton 1, Robert Stockley 1,1 ADEPT Project, Lang Function and Sleep Department, University Hospital Birmingham, Birmingham, West Midlands, United Kingdom; 2School of Biosciences, University of Birmingham, Birmingham, United Kingdom

Introduction: Neutrophil elastase (NE) causes emphysema in animal models. Heterozygote (Z) deficiency of its inhibitor alpha-1-antitrypsin (AAT) is associated with human emphysema. The role of heterozygote deficiency (SZ) is unclear.

Aims: To compare the inhibitory profiles of equimolar amounts of AAT from Z & SZ serum with pure AAT & M serum. The hypothesis is that Z AAT inhibits NE less efficiently than SZ & M.

Methods: AAT concentration was measured in serum from Z, SZ, M & patients. Increasing amounts of AAT were added to a fixed amount of NE. Residual NE activity was measured spectrophotometrically using both a chromogenic substrate and elastin. This was repeated with pure AAT & alpha-2-macroglobulin (A2M). Results: With a low molecular weight chromogenic substrate, M serum A2M was increasingly inhibited NE as the inhibitor:enzyme molar ratio increased to 1:1. Beyond 1:1 inhibition 15% residual NE activity remained, but not for pure AAT. For SZ serum residual activity was 60%. For Z serum and pure A2M enhanced NE activity was seen as inhibitor:enzyme ratio increased.

With elastin, inhibitory profiles of M, SZ & Z serum were similar to each other. Conclusion: Enhanced NE activity with Z serum likely represents binding to A2M. Deficiency of AAT means that NE is more likely to bind to A2M. A2M NE complexes retain proteolytic potential. These data may have implications for tissue destruction in emphysema.

P3910
Acute effects of an aerobic exercise session on airway inflammation in a murine asthma model
Ronald Willemse 1, Marlene Arruda Martins 1, Celso Ricardo Fernandez De Carvalho 1,2,3,4
1Physiopathology Experimental, 2Clinical Medicine, 3Physical Therapy, University of Sao Paulo, Sao Paulo, Brazil; 4Pneumology, Albert Ludwig University of Freiburg, Freiburg, Breisgau, Germany

Background: Chronic effects of aerobic training (AT) seem to decrease inflammation in experimental asthma.

TUESDAY, SEPTEMBER 27TH 2011
Objective: Investigate the effects of a unique exercise session of aerobic exercise in a murine asthma model.

Methods: Male BALB/c mice were divided in 4 groups: Control, AT, ovalbumin sensitized (OVA) and OVA+AT. OVA sensitization groups received: p i.days (0.14;28) and OVA inhaled exposition (OVA%, 3xweek/30min) after the 21st day. In the 28th day animals from AT and OVA+AT groups performed a session of treadmill running for 1 hour (59% maximal intensity). Evaluations: In vivo respiratory mechanic (Flexivent), different cell count in the BALF, and collagen fibers depositions and smooth muscle thickness in the airways were evaluated by an expert.

Results: Initial physical capacity was similar among groups (p>0.05). BALF total and inflammatory cells, collagen fiber and the smooth muscle thickness were increased in sensitized groups (p<0.05). Parameters of respiratory mechanic (Gis and This) were also increased in groups sensitized groups (OVA and OVA+AT; p<0.05).

Conclusions: Aerobic exercise when performed for acutely does not decrease features of experimental asthma such as cell migration, airway remodeling and respiratory mechanic.

High doses of N-acetylcysteine alone or in combination with inhaled corticosteroids and oxidative stress in patients with COPD

Valentina Kapustina1, Svetlana Ovcharenko1, Petr Litvichk2 1Faculty Therapy No.1, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; 2Pathophysiology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Oxidant/antioxidant interactions are known to be important process of the pathogenesis of COPD. We aimed to evaluate the effects of 6-month oral N-acetylcysteine (NAC) treatment 600 mg twice daily alone or in combination with inhaled corticosteroids (ICS) on reactive oxygen species (ROS) production by granulocytes in peripheral blood measured by luminol-dependent chemiluminescence and its effect on pulmonary lipid peroxidation by malondialdehyde (MDA) level measurement.

Methods: 62 patients with stable COPD (36 males, mean age 66.8±7.5 years, GOLD stage I-IV) were divided into two treatment groups. Group 1 received bronchodilators as basal treatment and NAC. Group 2 received NAC plus ICS in addition to basal treatment. Clinical examination, pulmonary function tests and blood collection were performed at baseline (T0) and repeated after 1 (T1), 3 (T3) and 6 months (T6) of treatment.

Results: Spontaneous ROS generation had trend to decrease at T3 in both groups, and achieved significant difference at T6 only in group 2 (p=0.004). At the same time, impaired ROS generation did not significantly change in both groups (p>0.05). Antiperoxide serum activity was increased from T0 to T1 however further levels did not substantially changed. We registered MDA plasma level decrease in both groups during all treatment period, but significant difference from T0 to T6 was observed just in group 2 (1.8 μmol/L vs 1.4 μmol/L; p=0.017).

Conclusion: We conclude that combination of oral NAC 1200 mg/day with ICS for 6 months reduces the oxidant burden in airways of stable COPD patients and achieved significant difference at T6 only in group 2.

Autonomic cardiac modulation response due to the use of an oral appliance to treat OSA – Pilot study

Raquel Hirata1, Fernando Sergio Leitao Filho1, Luciana Sampiao1, Sergio Nacif1, Paulo Bosso2, Newton Faria Junior1, Luís Vicente Oliveira2, Lilian Christiane Giannuzzi3.1 Rehabilitation Sciences Master’s Program, Nove de Julho University, Sao Paulo, SP, Brazil; 2Sleep Respiratory Diseases, Servidor Publico do Estado de Sao Paulo Hospital, Sao Paulo, SP, Brazil; 3Physiotherapy Department, Beneficencia Portuguesa Hospital, Sao Paulo, SP, Brazil; 4Medicine Department, Fortaleza University, Fortaleza, CE, Brazil

Introduction: Obstructive sleep apnea (OSA) alters autonomic variability during sleep and wakefulness. Little has been shown about the possibility of achieving the cardiac balance during a mandibular repossession appliance (MRA).

Objective: To evaluate the effect of MRA to treat OSA on heart rate variability (HRV) prior and after 6 month of the device usage.

Methods: Eight OSA patients with moderate obstructive apnea were enrolled in this study. Patients reported snoring, nocturnal breathing arrests, tiredness upon awakening and difficulty in concentrating. The inclusion criteria was present at least a 7.0mm maximum protrusion, 40mm of mandibular opening, 8-10 teeth in each arch, posterior dental health. Treatment consisted of continuous use of the oral appliance during approx. 6 months. Polysomnography and HRV analysis were performed before and after the treatment.

Results: The AHIl was reduced from 45.6±4.90 to 10.0±2.7 (p<0.05), the mean SaO2 nadir increased from 73.3±10 to 88.0±4.5 (P<0.05) and REM% increased from 18.6±4.6 to 22.0±3.4 (p<0.05), the sleep stages1,2,3 and sleep efficiency showed no statistical significance. The frequency-domain parameter were significant for both Fast Fourier Transform and Wavelet spectral method only in parasympathetic area, which improved from 197.0±70.0 to 105.3±43.0 (p<0.05) and from 221.0±85.0 to 102.0±33.0 respectively (p<0.05). The RR interval improved from 776.0±54.0 to 792.0±45.0 but was not significant.

Conclusion: The oral appliance used in this work was effective in respiratory events and tended to improvement of cardiac autonomic modulation, as reflected by changes in heart rate variability. Further evaluation with a larger sample is needed.

P3915

Evaluation of the relations between the obstructive sleep apnea syndrome and obesity by standard antropometric obesity indexes

Ender Levnet, Akın Soyła, Nesrin Sarıman, Sinir Yurul, Sümayye Alpaslan, Attila Sazgi. The Department of Chest Diseases, Maltepe University School of Medicine, Istanbul, Turkey

Introduction: Obesity is an important risk factor in the development of obstructive sleep apnea syndrome (OSAS).

710s
Aims and objectives: To investigate whether the general body adiposity or local lipodissosis was a risk factor in the evolution of OSAS by examining the relationships between the anthropometric obesity indices such as waist (WC) and neck circumference (NC), body mass index (BMI) and OSAS in Turkish adult population, and to access the possible differences by gender. Methods: The records of 499 subjects were examined retrospectively. The data related to polysomnographic, demographic and anthropometric indexes of the subjects were recorded. The patients whose apnea-hypopnea index were ≥ 5 was determined as OSAS group. Results: Of the subjects who underwent polysomnography: 431 (86.37%) were OSAS. The average BMI, NC and WC of OSAS group were statistically higher than the control group (p < 0.001). According to logistic regression analysis; BMI, WC and NC enlargement were observed as significant risk factors for OSAS development. Risk coefficients were determined 5.53 for NC, 4.48 for WC and 2.22 for BMI. Cut-off point values for anthropometric obesity indices as OSAS determinant were recorded as below: BMI for male ≥ 27.7 kg/m² and female ≥ 28.9 kg/m², NC index for male ≥ 40cm and female ≥ 36 cm, WC index for male ≥ 105cm and female ≥ 100cm. Conclusion: BMI, NC and WC enlargement were determined as significant risk factors for OSAS development. This was an initial study to determine the cut-off points of which increase the OSAS risk in BMI, WC and NC index in Turkish adult population.

P3916

Validation of a new auto adjusting bilevel algorithm in complicated sleep disordered breathing patterns

Winfried Randerather1, Wolfgang Galetke2, Joachim Ficker1, Karl-Heinz Rüberle1, Christoph Petersen-Petri3, Simone Kunz4, Christina Piegrutz1, Marcel Treml1, Institute of Pneumology, University Witten/Herdecke, Solingen, Germany; 2Institute of Pneumology, University of Witten/Herdecke, Köln, Germany; 3Medizinische Klinik I, Institute of Pneumology, Klinikum Nürnberg Nord, Nürnberg, Germany; 4Institute of Pneumology, Helios Kliniken Hagen Ambröck, Hagen, Germany; 5Institute of Pneumology, University of Ulm, Ulm, Germany; 6Internal Medicine/Sleep Laboratory, Paracelsus Klinik, Karlsruhe, Germany; 7Institute of Neurology and Psychiatry, Pfäffklinikum Klingenmünster, Klingenmünster, Germany; 8R&D MCC GmbH and Co KG, Karlsruhe, Germany

Introduction: OSAs patients are increasingly affected by high pressure demands, coexisting central events and periods of hypoventilation. Fixed bilevel treatment could fail due to changing pressure demands or non-compliance. To facilitate treatment with a variable level device with auto-trilevel principle and fixed backup rate was developed. We validated therapeutic efficacy and subjective comfort. Methods: In a multicentre, open, controlled trial 26 patients with complicated sleep disorders were analyzed. After diagnostic PSG patients were treated with an automatic bilevel device (SOMNOvent auto-S®/Weinmann Germany) which automatically adapts pressure levels within defined PDiff- (IPAP-EPAP) limits and EEAP-limits. Results: 26 patients (7.1 ± 4.3 ± 4.2 ± 7.0 (p < 0.001). Obstructive and central apneas dropped significantly (33.0 ± 28.4 vs 1.5 ± 2.2 vs 0.1 ± 0.4, p < 0.001, respectively). ODI sank from 33.4 ± 25.1 to 10.2 ± 12.0 (p < 0.001). Respiratory arousals lowered from 15.0 ± 15.0 to 7.3 ± 1.5 (p < 0.001). The majority of patients rated the bilevel device as good (45 or 4) or very good (6) in a different clinical centres and considered the auto adjusted device mostly equal or superior to the conventional therapy. Conclusion: The novel bilevel algorithm proved to treat sleep related breathing disturbances in our patients comfortably and at least as effective as manual bilevel settings. Continuous automatic adjustment to the changing pressure demands might provide a therapeutic benefit. Further investigations are recommended to find out which type of patients benefit most.

P3917

Alternative method for non-invasive automatic positive airway pressure therapy in OSAS patients

Lisette Rohling1, Michiel Eijsvogel2.

Introduction: APAP has generally been accepted as an alternative to CPAP in the treatment of OSAS. Meta-analysis has shown that APAP can control OSAS as effectively as CPAP. It remains to be examined whether greater reductions of the mean pressure can be attained by using the lowest possible minimum level and by limiting the maximum pressure to a different extent [1]. Objective: The aim of this study is to investigate whether a new adjusted mode of APAP lowers the mean applied pressure so compliance will increase. Methods: New diagnosed OSAS patients are selected for a single blind randomized cross-over trial. Patients receive for 12 weeks two different APAP therapies, CPAP and restricted APAP (RAPAP). Prior to starting up PAP therapy patients receive a manual CPAP PSG titration. The titration night is used to set the CPAP and RAPAP. The RAPAP pressure is set 2 cmH2O around the titrated pressure [2]. After 6 weeks there is a transition to the other PAP therapy. Data is collected by questionnaires like ESS, Quebec Sleep Questionnaire (QSQ) and SF-36, REMstar Auto (Respironics) data, and home polygraphy. Results: 39 OSAS patients were recruited of which already 21 completed the study. After 6 weeks with RAPAP by mean OSQ, ESS and AHl was improved significantly. Similar effects were achieved with CPAP. Compliance showed similarities between therapies (RAPAP: 6.6 [4.3-7.9] h/night, p = 0.13). The mean applied pressure during RAPAP was 8.5 [6.0-11.5] cmH2O and for CPAP 8.5 [5.5-12.4] cmH2O (p = 0.17).

Conclusion: Analysis of 21 patients showed that RAPAP and CPAP therapy has similar treatment effects in OSAS patients. RAPAP fits the current therapy. References: [1]: Randerather W. Respiration 2000;67:272. [2]: Netzer NC. Sleep Breath 2010.

P3918

Detection of bed-exit events using a new wireless bed monitoring assistance

Objectives: To assess the capability of using Heasys, an innovative wireless bed monitoring assistance that records body movements, presence and temperature, in the detection of bed-exit events and body position changes at night. Design: Descriptive study. Settings: Sleep laboratory for patient’s recording and home for healthy volunteers. Participants: Twelve patients referred for suspicion or treatment of sleep disordered breathing and 5 healthy subjects.

Measurements: Complete polysomnography was recorded during one night in patients and during two nights in healthy volunteers. Heasys sheet was placed under the fitted bed sheet in a non-constrictive way. During the second night, healthy subjects were asked to get out of bed at least 2 times for a minimal duration of 3 minutes. Results: Heasys allowed the detection of all bed-exit events in patients and volunteers (sensitivity: 100%, and specificity: 85%). When bed-exit events were defined by the lack of the presence signal combined with absence of motion and a dip in temperature, sensitivity and specificity of Heasys were 92 and 100% in patients and volunteers. Heasys detected body position changes recorded by polysomnography respectively in 84 and 98% of the cases. Additional recorded motions were mainly related to leg movements or arousals.

Conclusion: In this small feasibility study, we can conclude that Heasys is an effective innovative device allowing bed-exit events detection in adult patients and healthy volunteers.

P3919

Reliability of apnea/hypopnea index (AHI) determined by two different auto-CPAP in patients with obstructive sleep apnea syndrome (OSAS)

Androula Marinou, Clementina Leone, Berardo Mastropaques, Antonio Foresi. U.O.C. Pneumologia, Sexto San Giovanni Hospital, Sexto San Giovanni, Italy

Current Auto-CPAP devices retain information on their use, pressure, leaks and respiratory events and can operate also as CPAP. We evaluated reliability of AHI values recorded by two devices (Auto-Set Spirit II - 22 pts and REMstar auto M by ResMed) and compared them with those recorded by the Emblettia, in a group of 37 consecutive adults with OSAS (mean age: 58 yrs; 14 F; BMI range: 24-61). Each patient underwent the following procedures: a. baseline ambulatory recording by Emblettia; b. 3-7 nights recordings by Auto-CPAP; c. 3-7 nights recordings by CPAP; d. ambulatory recording by Emblettia while using CPAP titrated on the basis of the Auto-CPAP records. Respiratory events were assessed by manual analysis of Emblettia traces or based on at least 4 nights records of Auto-CPAP devices. We selected only nights during which patients used the device at least 5 hrs and leaks were < 0.5 L/s. Baseline AHI ranged between 9 and 91 ev/hr. The 95th percentile airway pressure as determined by the Auto-CPAP device was 9.5 ± 1.5 cmH2O. The AHI measured by CPAP during 4 nights was 3.9 ± 1.7 (AI: 1.1 ± 1.2; HI: 2.8 ± 1.8) The AHI during CPAP was 2.2 ± 1.1 (AI: 0.7 ± 1.6; HI: 1.5 ± 1.7). Difference plots for Bland and Altman analysis were 1.7 for AHI, 0.4 for AI and 1.3 for HI. Mean difference between AHI values measured during CPAP and measured by Auto-Set Spirit II and REMstar auto M was significantly different (2.32 ± 0.76; p < 0.015). The results of this study suggest that AHI values measured by CPAP in OSAS are reliable as compared to those measured by a portable recorder and that small but significant differences exist between different CPAP devices.

P3920

Effects of reduced lung volumes and age on oxyhemoglobin nocturnal desaturation in obstructive sleep apnea patients before and after CPAP treatment

M. Guglielmol, D. Lodico1, C. Ciaccol1, L. Zito1, K. Bannout2, F. Gamma1, R. Torchio1, Dip. Fisiopat. Cardio-Respiratorio, Respiratory Function and Sleep Laboratories, AOU San Luigi, Orbassano Torino, Italy; 2Dip. Fisiopat. Cardio-Respiratorio, Rehabilitation, AOU San Luigi, Orbassano Torino, Italy

Aim: To analyze determinants of nocturnal desaturation in obstructive sleep apnea (OSAS) patients before and after CPAP treatment.

TUESDAY, SEPTEMBER 27TH 2011
Introduction: Continuous positive airway pressure (CPAP) is an effective treatment for symptomatic moderate-severe obstructive sleep apnea (OSA). More recently, automatic positive airway pressure (APAP) devices are being used instead of CPAP on the premise that automatic device pressure would improve compliance although this has not been proven.

Aims: Evaluate 3-month compliance in OSA patients treated with APAP

Methods: Symptomatic patients with OSA [Apnea hypopnoea index (AHl) >10 and Ewthrop Sleep Score (ESS) >10] were offered APAP therapy and monitored
prospectively for 3 months. Their APAP data was downloaded at 2 weeks and 3 months. Data was analysed using Spearman’s test and multiple regression.

**Results:** APAP therapy was initiated in 26 patients (22 men) with a mean (SD) age of 51 (11.7) years. Mean AHI was 44.5 (25.5) and mean ESS was 12 (4.7). Mean compliance at 3 months and 2 weeks was 307 (130) and 330 (96) minutes respectively. Median (range) number of consultations over 3 months was 2 (1-9). Compliance at 2 weeks was significantly correlated to compliance at 3 months (p<0.001). Compliance at 3 months was also significantly correlated (p<0.002) to the number of consultations with sleep physiologists during this period (telephone and in person).

Other factors such as age, sex BMI, initial AHI and mean APAP did not influence compliance on multiple regression.

**Conclusions:** Short and medium term compliance is very good in our cohort. Compliance at 2 weeks predicts 3 month compliance which is in keeping with other studies.

Compliance was also found to be related to intensity of technical support suggesting that careful follow up will improve compliance.

**P3926**
Comparison of CPAP treatment and oral appliance therapy in patients with severe OSA
Ilay Ilkay Yilmazer, Onder Oztruk, Ahmet Akkaya, Suleyman Hakan Tunu, Mustafa Kaya, Sultana Tur, Selcuk Yasar, Ozgur Koskan
1Department of Chest Diseases, Medical School of Suleyman Demirel University, Isparta, Turkey; 2Department of Prosthodontics, Faculty of Dentistry, Suleyman Demirel University, Isparta, Turkey; 3Department of Radiology, Medical School of Suleyman Demirel University, Isparta, Turkey; 4Department of Otolaryngology, Medical School of Suleyman Demirel University, Isparta, Turkey; 5Department of Biometry and Genetics, Division of Animal Sciences, Faculty of Agriculture, Suleyman Demirel University, Isparta, Turkey

**Aim:** The aim of this study was to investigate the effects of anthropometric measurements and orthonolaryngological examinations on the appropriateness of and the choice between OAT (oral appliance therapy) and CPAP treatment in patients diagnosed with severe OSA (obstructive sleep apnea syndrome).

**Material and methods:** The patients diagnosed with severe OSA (n=23) were enrolled in the present study and divided into two groups as OAT (n=11) and CPAP (n=12) by the random envelope method. Then, the patients who were ineligible for OAT were assigned to CPAP treatment, thus constituting a third group (n=7). They were examined by CPAP at one month and underwent controls at 3 and 6 months.

At the first month control, the patients who showed no improvement of AHI or those who could not tolerate the treatment were shifted to the other treatment.

**Results:** There were no significant differences between the treatment groups in terms of demographic characteristics, orthonolaryngological examinations and nasopharynx CT. It was found that, of PSG findings, REM was increased and AHI and stage 2 sleep were decreased during the first month of treatment in all treatment groups (p>0.05). All treatment groups showed improvement in oxygen saturation, which reached statistical significance only in the CPAP group (p<0.05).

**Conclusion:** We concluded that anthropometric changes and results of orthonolaryngological examinations had no effect on treatment choice in patients with severe OSA. Since CPAP treatment is more effective in patients with severe OSA, OAT would be more appropriate in patients who can not tolerate CPAP treatment.

Validation of the efficacy of an oral appliance for the treatment of obstructive sleep apnea in Brazil
Newton FariaJunior1, Fernand Sergio Leitao Filho2, Luciana Sampaio3, Israel Santos4, Isabella Aquino2, Sergio Naci2, Luis Vicente Oliveira1, Lilian Chrystiane Giannaisi1, 1Rehabilitation Sciences Master’s Program, Nove de Julho University, Sao Paulo, SP, Brazil; 2Sleep Respiratory Diseases, Servidor Publico do Estado de Sao Paulo Hospital, Sao Paulo, SP, Brazil; 3Medical Department, Fortaleza University, Fortaleza, CE, Brazil

**Introduction:** Various studies in sleep disorders and the physiopathology of OSA has demonstrated the important role that dentistry could play in improving the lifespan of individuals with OSA.

**Objective:** To validate, in Brazil, the use of an oral appliance (OA) to treat OSA and primary snoring.

**Methods:** A retrospective study was carried out on 69 patients presented all OSA degrees or primary snoring, who were fitted to PMPsitioner between 2000 and 2010. The diagnosis and degree of severity were established by a polysomnogram (PSG) prior treatment and the efficacy of OA therapy verified by another PSG after a minimum of 6 month of OA usage. Sleepiness was evaluated by Epworth Sleepiness Scale (ESS) questionnaire prior to treatment and at the follow up.

**Results:** Patients were divided in two groups, snoring group (SG) with 7 patients and OSA group with 62 patients. Snoring patients showed no statistical results for ESS. Patients in OSA group, AHI <5 was found in 25 (40%) patients, AHI <10 was found in 52 (84%) patients, and AHI <15 was found in 60 (32.3%) patients. Among mild patients, the mean AHI reduced from 12±2.0 to 3±3.2±0.6 <p<0.001, among moderate (33%) patients, the mean AHI reduced from 21±6.3 to 4.6±3.8 and among severe (12%) patients, the mean AHI reduced to 44±13.5 to 10.0 to 4.3. The mean minimum oxygen saturation (SaO2 nadir) for the entire OSA group, increased from 81±1.8 to 86±1.7 <p<0.001. The ESS values reduced significantly from 13.5±5.6 to 8.4±3.5 (<p<0.05).

**Conclusion:** We can support the efficacy of adjustable oral appliance in the OSA therapy in Brazilian patients. Various physiologic variables have improved.
the therapeutic impact of VO is not studied. The results of the present study indicate that the effect of VO on the degree of UA collapse as assessed during DESE tends to be adverse, causing collapse in the majority of patients.

The effects of breathing manoeuvres on the trigeminocardiac reflex reversal of artificially induced supraventricular tachyarrhythmias into the sinus rhythm

Roman Benacka1, Eva Sedláková1, Jan Sedlák2
1Dept. of Pathophysiology, Medical Faculty, P.J. Safarik University, Kosice, Slovakia (Slovak Republic); 2Arrhythmology Department, Cardiologic Clinic, East Slovakia Institute of Cardiac and Vascular Disorders, Kosice, Slovakia (Slovak Republic)

Trigeminocardiac reflexes (TCR) elicited from the intranasal, facial orbital, perinasal or forehead regions are known by a spectrum of respiratory and circulatory vegetative effects which are dominated by strong vagal reflex bradycardia that can be effectively used in the reversal of certain supraventricular tachyarrhythmias (SVTs). The present aim was to examine the effects of inspiratory (IA) and expiratory apneas (EA) (20-25 s breath holding on TLC or FRC levels, respectively) and Valsalva manoeuvre (VM, 20s occl. pressure 35 mmHg) on the mechanism of reversal from SVTs by facial cold TCR (cold gel, 10°C for 60 s). AVNRT (15 s) and AVN (2 s) were used at 15 cm s-1, 1, MSa/d) were induced by atrial electrical impulses (2-4mA, 1ms duration, 600 ms period) and/or by isoprenalin (1-5µg/min, i.v.) in 17 patients (18-62 y) while recording ECG, heart rate (HR) and blood pressure (BP). Data showed that TCR+EA and TCR+IA increased both bradycardic (26%, vs. 6-4%, as well as pressor effect (13-4% vs. 10-4%) of TCR. Moreover, TCR+IA and TCR+VM increased both the speed and success rate of SVTs reversal (by 11-15%, 45-2%, vs. 33%). When applied alone IA, EA or VM decreased HR in SVTs (11.2±3.1%, n=19, 8.6±2.1%, n=9, 16.2±3.1, n=19, M±SD) and raised BP (6-19%). Occasionally, EA (18%) and IA (21%) reversed SVTs into the normal rhythm similar to TCR (27-45%) and VM (26%). The role of intrathoracic pressure changes and other reflex mechanisms underlying SVTs reversal by inspiratory and expiratory manoeuvres and TCR are discussed.

Supported by the Agency of the Slovak Ministry of Education for the Structural Funds of the EU, under project ITMS: 26220120067; (30%)

Is obstructive sleep apnea syndrome a risk factor for pulmonary thromboembolism?

P3931

Kerzan Ozmun Suner1, Ali Nihat Annkaya1, Umut Yoruk1, Talha Dunbul1, Omer Balbay1, Peri Arkab1, Leyla Yilmaz Aydin1
1Chest Diseases, Duzce University Faculty of Medicine, Duzce, Turkey; 2Chest Diseases, Hakkari State Hospital, Hakkari, Turkey

There is no study demonstrating the relationship between OSAS and venous thromboembolism (VTE). The aim is to evaluate OSAS in patients with pulmonary embolism (PE) and OSAS as a risk factor for PE. In the department of chest diseases of Duzce University Hospital, 50 patients with PE were evaluated for the frequency of OSAS, prospectively. Polysomnographic was performed to clinically stable 30 patients agreed to participate in the study. Apnea-hypopnea index (AHI) more than 5 was defined as OSAS. 30 patients (14 women, 16 men, 25-85 age) were included in study. There were 24 patients with non-massive PE (58%), 3 patients with submassive PE (%10), 2 patients chronic PE (%6.7) and 1 patient with massive PE (%3.3), respectively. %56.7 of the patients (17/30) OSAS were detected. The percent of patients with moderate and severe OSAS (AHI >15) was 52.7 (8/30). The patients with no known major risk factors for PE had significantly high rates OSAS compared to those with having major risk factors (respectively, 9/30; 12/21 and 5/19, p<0.05). The majority of group with major risk factor for VTE was found low. (66-13 and 52-15, p: 0,015) There was no significantly difference for gender, weight and body mass index between the groups, who have OSAS and without OSAS. The difference for gender, weight and body mass index between the groups, who have OSAS and without OSAS were have a great risk of developing serious PTE.

Discussion: Our results may have been influenced by some patients having other significant factors that not all patients had the blood tests done. An elevated D-dimer was not found to be significantly associated with a diagnosis of PE in our study. Troponin and CRP also had no diagnostic significance. Raised Urea, integral to the severity scoring in community acquired pneumonia, was, however, significant.

P3934

The frequency of the chronic thromboembolic pulmonary hypertension and associated risk factors

Ahmet Korkmaz1, Tefik Ozu1, Savas Ozu1, Zeynep Kazaz2, Yilmaz Bulbul1
1Dept of Chest, 2Dept of Cardiology, Karadeniz Technical University, School of Medicine, Trabzon, Turkey

The incidence of chronic thromboembolic pulmonary hypertension (CTEPH) are yet to be accurately evaluated and may be significantly underestimated. The study enrolled 325 consecutive patients with acute pulmonary thromboembolism (PTE). In all patients PTE were diagnosed objectively and the mean follow-up was 16.3 months (range, 6.50.7 months). Outpatient visits and hospitalisation records of all patients were examined. Especially, data on recurrence, mortality and CTEPH were collected. Symptomatic patients were investigated for CTEPH with echocardiography, lung perfusion scintigraphy and CT angiography according to proposed algorithms in updated guidelines of pulmonary hypertension. The frequency of symptomatic CTEPH was 4.6% after the first episode of PTE. Symptomatic CTEPH were established in 37.5% of the patients who have a history of proven PTE and in 6.2% of the patients with previous isolated DVT. The percentage of patients with residual chronic thrombus was 48% at 3 months, 27.4% at 6 months, and 18.2% at 12 months after the diagnosis of PTE. There was significant relationship between recurrence and presence of residual thrombus

142. Prediction of pulmonary thromboembolism

P3932

Late-breaking abstract: Significant association between protein C promoter region polymorphism and susceptibility to pulmonary thromboembolism in a Chinese Han population

Jiming Liu, Yafang Miao. Respiratory Medicine, Shanghai Pulmonary Hospital, Shanghai, China

Pulmonary thromboembolism (PTE) is a common clinical problem that is associated with substantial morbidity and mortality. Because protein C (PC) play an essential role in regulation of thrombin activity, we investigated the role of PC polymorphism in patients with pulmonary thromboembolism. One hundred and ten cases of PTE and one hundred and ninety healthy control in Chinese Han population were genotyped for three polymorphisms (-1654C/T, -1641A/G and -1476C/T) of PC promoter. Using Binary logistic regression analysis, genetic risk factor, which was homoygous carriers of genotype TT (the SNP site -1654C/T of the PC gene, and conventional risk factors (“operation and trauma” and “operation and trauma”) were independent predictors of the development of PTE. PC gene SNPs (-1654C/T, -1641A/G and -1476C/T) in control region are probably associated with the susceptibility to PTE in Chinese Han population. The homoygous carriers of genotype TT of -1654C/T was significantly associated with the outcome of PTE, which together with “operation and trauma” and “operation and trauma” were a great risk of developing serious PTE.
after 3 months. At the time of acute event; a systolic pulmonary artery pressure (sPAP) >50 mm-Hg, presence of widespread thrombus, history of previous VTE, idiopathic PTE and high uric acid levels were associated with increased risk of development of CTEPH in univariate analysis. In multivariate analysis, sPAP > 50 mm-Hg was found that 10-fold increased for CTEPH. As a serious complication CTEPH develops in an important part of the PTE patients. Especially, closer monitoring of high risk patients is important for early diagnosis and treatment.

Prediction of pulmonary embolism in the pulmonary departments: Clinical prediction rules
Hajer Racili, Manel Loukil, Nawel Ben Salem, Sana Cheikh Rouhou.

Background: Diagnosis of pulmonary embolism (PE) requires clinical probability assessment. In recent years, a great number of clinical prediction rules have been issued.

Objective: To evaluate the effectiveness of the Geneva and the Revised Geneva score in PE diagnosis in pulmonary departments.

Patients and methods: A retrospective study of 53 consecutive patients admitted for clinically suspected PE. We evaluated the clinical probability of PE for all patients for whom a CT pulmonary angiography (CTPA) was performing. Patients were divided into 2 groups: Group 1 (G1: n = 25) with no confirmed PE, the second group (G2: n = 28) with confirmed PE.

Results: In a prospective cohort of 607 patients with a first episode of proximal DVT and PE, CTPA was performed in 198. The incidence of recurrent VTE was analyzed: sex, the clinical presentation as PE or proximal DVT, the presence of hormonal change (contraception, pregnancy or hormonal substitution treatment); OR=0.9, 95%CI [0.6-1.3], p=0.65.

Conclusion: A major independent risk factor of recurrent VTE is the presence of widespread thrombus, history of previous VTE, idiopathic PTE and high uric acid levels. In multivariate analysis, sPAP > 50 mm-Hg was found that 10-fold increased for CTEPH. As a serious complication CTEPH develops in an important part of the PTE patients. Especially, closer monitoring of high risk patients is important for early diagnosis and treatment.

P3936
Age is a major risk factor of venous thromboembolism (VTE)
Nicolas Bizien, Elise Noel-Savina, Cecile Tromeer, Aurelien Delluc, Dominique Mottier, Christophe Leroyer, Francis Couturard.

Introduction: Age is a major risk factor of developing a first episode of VTE; however, the impact of age on the risk of recurrent VTE remains controversial.

Method: In a prospective cohort of 607 patients with a first episode of proximal deep vein thrombosis of pulmonary embolism, we aimed to evaluate if age of VTE was an independent risk factor of recurrent VTE. The role of other risk factors was analyzed: sex, the clinical presentation as PE or proximal DVT, the presence or the absence of provoking risk factors, factor V Leiden (FVL) and prothrombin gene mutation (PGM) was analyzed. All the episodes of first VTE and recurrent VTE were diagnosed according to predefined, validated and standardized criteria.

Results: During a mean follow-up of 36 months, 95 (15.6%) patients had recurrent VTE. In multivariate analysis, for each year that the patient was older, the risk of recurrent VTE increased by 3.0% (OR=1.03; 95%CI [1.01-1.05], p<0.001). When age of patients was divided into quartiles, the relative risks of VTE were as follows: [64-74 years]: OR=2.9, 95%CI [1.3-6.9]; [75-99 years]: OR=3.1, 95%CI [1.3-7.5]; p<0.01; quartile of reference [18-44 years]. Men and women had similar risks of recurrence, excepted women who had VTE in association with hormonal change (contraception, pregnancy or hormonal substitution treatment); OR=0.2, 95%CI [0.1-0.4]; p<0.001). FVL and PGM were not associated with an increased risk of recurrent VTE (OR=1.1; 95%CI [0.5-2.1]; p=0.9).

Conclusion: Age is a major independent risk factor of recurrent VTE.

P3937
Improving the diagnostic yield of PE using the BTS pathway: The experience of a UK district general hospital
Craig Batista, Timothy Ho. Department of Respiratory Medicine, Frimley Park Hospital NHS Foundation Trust, Camberley, Surrey, United Kingdom

In 2003, the British Thoracic Society developed an algorithm for investigating PE, based on risk stratification (low, intermediate and high), selected D-Dimer use and Computed Tomography Pulmonary Angiography (CTPA). For low and intermediate patients a negative D-Dimer is reliable in excluding PE, avoiding unnecessary irradiation. Despite this, the positive diagnostic yield within our organisation remains below 25%. To understand this low yield, we carried out a retrospective analysis of medical patients who underwent CTPA during November 2010.

Method: The medical records of all patients admitted with suspected PE who underwent CTPA were analysed. Each patient’s risk was retrospectively scored according to BTS guidance and adherence to the BTS diagnostic pathway was noted.

Results: 37 patients underwent CTPA: 15 low, 14 intermediate and 8 high probability. In 21 (95.6%) of 22 patients with no confirmed PE, the second group (G2: n = 28) with confirmed PE.

Conclusion: Our study suggests that adherence to BTS guidance may improve diagnostic rates for PE and reduce the number of inappropriate CTPAs.

P3938
Clinical presentations of pulmonary embolism in young adults
Natalia Stoeva, Diana Lekova, Vassa Hristova. Internal Department, Tokuda Hospital Sofia, Sofia, Bulgaria

Pulmonary embolism (PE) is considered an age related disease and clinical observations are directed predominantly towards older patients. Our study examines clinical presentations of PE in young (under 40 years) adults. We retrospectively analyze 133 adult patients hospitalized in Tokuda Hospital Sofia for the period Feb 2007 to Jan 2011 in whom PE was diagnosed by multidetector computer pulmonangiography. 24 (18%) of them are under 40 years. We analyze this group (young group) and compare it to the group of patients older than 40 (old group). All patients of the young group are white race, and are ethnic Bulgarians. 19 (79.2%) are men and 5 (20.8%) - women (vs.55males:50% and 54females: 49.6% in the old group). 424 patients have previous surgical intervention, and 2/4/ underlying diseases. The other 18/24 (75%) have no triggering events. 16/24 were examined for inherited and acquired thrombophilies and in 13 (81%) thrombophilies were found (3 with Plasminogen activator inhibitor mutation, 2 with Leiden mutation, 1 prothrombin gene mutation, 4 with combined heterogenous mutations, 2 with P.S deficiency and 1 with antiphospholipid antibodies). Mean Wells probability score is 5.24±1.7 (4.2±1.2±5.5 in old group; p=0.02); mean revised Geneva score is 8.41±3.91 (vs. 8.62±3.95; p=0.73); 11/24 (45%) have concomitant US confirmed DVT (vs. 4%). More than half (54%) have massive PE, understood as involvement of more than 50% of pulmonary circulation. In our study PE adults in young patients in most cases arises spontaneously, it is due to inherited and acquired thrombophilies, and affects more men than women. Using the Wells probability score, PE in young adults is more easily recognizable than in older adults.

P3939
The potential benefits of outpatient investigations of suspected pulmonary embolism (PE)
Muhammad Josheef Naveed, P. Michale, M. Gautam, Syed M.H. Kazmi, Colin Smyth, Hassan Burhan. Respiratory Medicine, Royal Liverpool University Hospital, Prescot Street, Liverpool, United Kingdom

Background: Computed Tomography Pulmonary Angiography (CTPA) is the recommended investigation for non-massive pulmonary embolism (PE) and guidelines suggest outpatient management in stable patients with PE [1]. Outpatient investigation of such patients may also be potentially possible.

Aim: To ascertain the proportion of patients admitted to our hospital with suspected PE that could potentially have been investigated as outpatients.

Methods: Retrospective analysis of all CTPAs performed over an 8-week period from December 2009 in a UK university teaching hospital.

Results: 198 CTPA scans were performed. PE was confirmed in 30 (15.2%). The mean time period of inpatient stay before obtaining their CTPA was 5.5 days (SD 6).

</tbody>
</table>
51 (26%) patients were in hospital for ≤48 hours post investigation, only 1 of whom had confirmed PE. 

**Conclusion:** A careful assessment to identify patients that can safely have an outpatient CTPA and decreasing time to scan for in-patients would increase efficiency.

A 20% reduction in time from admission to CTPA would result in an annual saving of £2.400.000 (approximately £410.000).

If we postulate that patients discharged ≤48 post CTPA were well enough to have been investigated as outpatients, doing so would have saved at least 288 bed days, enough to bed 8 weeks, equating to 1728 bed days (£540,000) over a year.

**Hyperglycemia as an independent predictor of mortality in acute pulmonary embolism**

Julia-Cristina Roca1, Viviana Aursulescu1, Mihai Roca1, Mihai-Dan Datcu2,  
1Emergency Medicine, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania; 2Cardiology, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania; 3Pneumology, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania

**Introduction:** Acute pulmonary embolism (APE) is a life threatening disease and one of the main causes of in-hospital mortality. Hyperglycemia secondary to diabetes mellitus, impaired glucose tolerance or stress-induced, occurs frequently in critically ill patients and is associated with adverse outcome. The relationship between hyperglycemia and outcome in APE patients has not been clearly defined.

**Aim:** The purpose of the study was to determine the association between hyperglycemia and risk - adjusted mortality in APE patients.

**Methods:** We conducted a prospective, cohort study, between 1 January 2004 and 31 December 2009. The patients with APE, admitted in the 1st Medical Cardiology Clinic, in “St Spiridon” University Hospital, Iasi were included. Hyperglycemia was defined as an admission or in-hospital fasting glucose level of 126 mg/dl (7 mmol/liter) or more or a random blood glucose level of 200 mg/dl (11.1 mmol/liter) or more on 2 or more determinations.

**Results:** During the study period, we enrolled 326 patients with APE. Mean age of the patients was 62.3 years (range 16 - 95 years), 197 (60%) were females. 30 (9%) were in shock at admission and 36 (11.04%) had diabetes mellitus diagnosis before admission. Fifty seven patients died during hospital stay (17%). Multivariable analysis showed that hyperglycemia was an independent predictor for in-hospital mortality in APE patients (p <0.05).

**Conclusion:** Hyperglycemia is an independent predictor for in-hospital mortality in APE.

D-dimer testing and pre-test probability scoring in the diagnosis of venous thromboembolism

Pooya Aroa, Asad Ali, Shiva Bikmalia, Vikas Pumaniya, Gareth Ebben, Rahal Mukherjee. Department of Respiratory Medicine & Physiology. Birmingham Heartlands Hospital, Birmingham, United Kingdom

Introduction: With easy availability of bedside markers of venous thromboembolism (VTE) like D-dimer, widespread use of these tests often without pre-test probability scoring (PTPS) has become common practice in the diagnostic pathway of VTE.

Aims: We set out to assess how effective D-dimer testing is in predicting the likelihood of VTE and whether PTPS adds any further value to D-dimer testing.

Method: Consecutive patients with suspected VTE were included for a 3 week period - 90 records were analysed where a D-dimer test (Roche Test kit) was performed as part of the diagnostic pathway in the admissions unit of a teaching hospital providing acute medical services to a population of 450000.

Results: 40 D-dimer tests were positive, 50 negative; 14 with positive tests had radiological confirmation of VTE (CT Pulmonary Angiogram, Ventilation-Perfusion scan or Doppler Ultrasound Scan of the legs), 8 with negative tests still went to have radiological imaging because of high clinical suspicion but all were negative. Thus sensitivity was 100%, specificity 65.79%. Only 31 patients had PTPS, 18 had high or intermediate PTPS with positive D-dimer but only 8 had VTE (44.4%); 1 with low PTPS and positive D-dimer had VTE; 5 with high or intermediate PTPS but negative D-dimer had no VTE. The remaining had low PTPS with no VTE.

Conclusions: D-dimer is a very sensitive and reasonably specific tool to aid VTE diagnosis in appropriate clinical presentations but further aids need to be developed to rule out the possibility of VTE with a negative D-dimer but does not seem to add any further value in patients with a positive D-dimer, hence PTPS should be included in the interest of patient safety.

Discussion: There was no overall difference in all cause mortality at 2 years post CTPA for suspected PE between those who had a PE and those who did not. Mortality was equally high (15%) in both groups, regardless of presence or absence of PE at the time of investigation.

None of the biochemical markers we studied were associated with increased mortality. Only 220 (48%) and 174 (38%) patients had D-dimer and Troponin (known to be associated with increased all-cause mortality) measured respectively, although 369 (80%) had CRP measured. This may explain why an elevated Troponin was not associated with increased mortality in our study.

P3947

Trends in the incidence and case fatality of pulmonary embolism in hospitalized patients during 1997-2008 in China: A multicenter registration study

Yuanhua Yang, Liqiong Liang, Xiaoxia Peng, Chen Wang. Beijing Institute of Respiratory Medicine, Capital Medical University, Beijing, China Beijing Institute of Respiratory Medicine, Capital Medical University, Beijing, China Epidemiology and Biostatistics, Capital Medical University, Beijing, China Beijing Institute of Respiratory Medicine, Capital Medical University, Beijing, China

Background: In China, the National Cooperation Project of Prevention and Treatment for Venous Thromboembolism provided valuable information about the epidemiology of PE. So, comprehensive assessment on the incidence and case fatality of PE in hospitalized patients can be made firstly.

Methods: Between January 1997 and December 2008, consecutive patients, admitted to the inpatient ward with a diagnosis of suspected PE, were registered from 60 hospitals. The data was collected prospectively including demographic data, types and results of diagnosis methods and prognosis. All of patients were identified with a discharge diagnosis of PE based on the St. Anthony’s ICD-9 diagnostic codes.

Results: From January 1997 to December 2008, hospitalization data were collect for 1,8306 patients diagnosed with PE while there were 16,972,182 discharged patients. The annual incidence increased sharply from 0.03% in 1997 to 0.13% in 2003, then persisted 0.14%. Conversely, the case fatality was decreasing apparently from 25.11% in 1997 to 8.65% in 2008.

Conclusion: The actual incidence of PE among the hospitalization patients in China was 0.14%. Evidence suggests that a substantial decline in PE-specific mortality and the annual age-adjusted mortality from PE has been shown as a result of the prevention and treatment of PE.

Diagnostic accuracy of unenhanced and gadolinium-enhanced magnetic resonance imaging for acute pulmonary embolism diagnosis: Results of the "BEM-EPS" study

Sensitivity of unenhanced MRA was 96.7% (95% CI, 90.8% to 99.6%) for reader 1 and 95.1% (95% CI, 90.2% to 98.1%) for reader 2. Specificity was 63.6% (95% CI, 50.0% to 76.0%) for reader 1 and 77.1% (95% CI, 62.6% to 89.3%) for reader 2. Positive and negative predictive values were 72.0% (95% CI, 60.3% to 81.3%) for reader 1 and 54.9% (95% CI, 43.3% to 65.5%) for reader 2. The area under the receiver operating characteristic curve was 0.86 (95% CI, 0.81 to 0.90) for reader 1 and 0.84 (95% CI, 0.79 to 0.89) for reader 2.

Conclusions: Sensitivity of unenhanced MRA for the diagnosis of PE was 96.7% (95% CI, 90.8% to 99.6%) for reader 1 and 95.1% (95% CI, 90.2% to 98.1%) for reader 2. Specificity was 63.6% (95% CI, 50.0% to 76.0%) for reader 1 and 77.1% (95% CI, 62.6% to 89.3%) for reader 2. Positive and negative predictive values were 72.0% (95% CI, 60.3% to 81.3%) for reader 1 and 54.9% (95% CI, 43.3% to 65.5%) for reader 2. The area under the receiver operating characteristic curve was 0.86 (95% CI, 0.81 to 0.90) for reader 1 and 0.84 (95% CI, 0.79 to 0.89) for reader 2.

Results: Sensitivity was better for proximal VTE than distal PE (96.1%) and good agreement (Kappa: 0.62), whereas perfusion sequences showed lower sensitivity, specificity and agreement.

Magnetic resonance imaging (MRI) has not been yet fully evaluated for diagnosis of pulmonary embolism (PE).

Aims: To evaluate MRI performance for PE diagnosis by reference to 64-detector CT angiography (CTA) in patients with clinical suspicion of PE.

Intervention: MRI including, unenhanced ECG-gated, perfusion and angiographic sequences was performed within 24 hours from CTA and were interpreted by two independent readers blinded to CTA results.

Measures: Sensitivity, specificity evaluated globally and for each sequence. Inter reader agreement evaluated with the kappa statistics.

Results: Among 300 patients included, 274, with a conclusive CTA, completed the whole MRI protocol, of which 103 had PE on CTA (prevalence: 37.6%). 76 of the 274 MRI examinations (28%) were judged inconclusive by reader 1 and 83 (30%) by reader 2. Sensitivity and specificity of conclusive MRI on global readings were 84.5% (95% CI, 79.4% to 90.1%) and 99.9% (95% CI, 95.1% to 100.0%) for reader 1 and 78.7% (95% CI, 68.2% to 87.1%) and 100% (95% CI, 96.7% to 100.0%) for reader 2, respectively. Sensitivity was better for proximal (97.7% to 100%) than for segmental (69% to 15%) and sub-segmental PE (21% to 33%). Angiographic sequences showed the highest performance and agreement (Kappa: 0.77). Unenhanced sequences, although less sensitive, showed high specificity (96.1%) and good agreement (Kappa: 0.62), whereas perfusion sequences showed lower sensitivity, specificity and agreement.

Conclusion: MRI demonstrates high specificity, even for unenhanced sequence and acceptable sensitivity for PE diagnosis at the cost of a 28% to 30% rate of inconclusive result.
residual asthmatic inflammation in the peripheral airway. The ECP levels in late-phase sputum (255±2.97 lg/1 at study entry) significantly decrease 60.8±4.7 lg/l (p<0.038) and 50.7±4.84 lg/l (p=0.049) at 4 and 8 weeks after switching to treatment with the BFC, respectively. The FeNO levels (76±6.49 ppb at study entry) also significantly decreased 29.1±15.7 (p=0.017) at 8 weeks. The R5-R20 and AX values of ICS parameters also significantly improved after 8 weeks.

Conclusions: This study suggests that the BFC may give better control of residual eosinophilic inflammation in the distal airway compared to SFC therapy.

P3952 Montelukast as add-on therapy may improve some indices of small airways involvement in uncontrolled asthmatics

Laura Malagrinò1, Francesco Costa1, Lorenza Melosini1, Antonella Di Franco1, Giosué Catapano2, Perluigi Paggiaro1,1 Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy; 2Institute of Clinical Physiology, CNR, Pisa, Italy

Background: Several studies suggest an involvement of small airways in asthma that may contribute to poor disease control.

Aim: To assess whether montelukast improves indices of small airways involvement and clinical outcomes in asthmatics under regular therapy with medium-high doses of inhaled corticosteroids and long-acting β2-agonist.

Subjects and methods: 240 non-smoker asthmatics underwent, at baseline and after one-month open label therapy with montelukast, FEVI, Single Breath Nitrogen Washout for phase III slope (DN2); multiple flows exhaled nitric oxide (NO); eosinophils in sputum (EO%;), alveolar-arterial differences of respiratory gases (AaDO2, AaDCO2); asthma control obtained by symptoms (S) and variability of peak expiration flow (APEF) monitoring.

Results: Patients were divided in controlled (n=7 well controlled, n=10 partially controlled) and non-controlled (n=7), according to GINA guidelines. After one month therapy with montelukast, in a) controlled group, therapy significantly reduced APEF (18.2±6.9 vs 13.1±4.8 l/s (p<0.007); b) in non-controlled group, therapy significantly reduced only AaDO2 (32.1±7.9 vs 25.8±7.7 mmHg, p=0.034). Patients were also divided in two other groups according to the number of abnormal values of small airways involvement (DN2, CαNO and AaDO2) at baseline: 0-1 vs 2-3 abnormalities. Montelukast reduced APEF (21.8±7.8 vs 17.4±11.2 l/s, p<0.001) only in patients with 2-3 abnormalities in small airways indices.

Conclusions: Montelukast might improve both functional and clinical indices of small airways involvement, in controlled and non-controlled asthmatics and this might be associated with some effects on small airways.

P3953 The eXpeRience registry: Monitoring the “real-world” effectiveness of omalizumab in allergic asthma

Gert-Jan Braam1, D. Leuven1, Chien-Wen Chen1, Robert Maykut4, Panayiotis Georgiou2, Guy Peachey2, 1Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy; 2Institute of Clinical Physiology, CNR, Pisa, Italy; 3CNR, Pisa, Italy; 4Medical Department, UCB Pharma NV, Brussels, Belgium

The observational, global eXpeRience registry was established to collect “real-world” data from omalizumab-treated allergic asthma patients. The registry aims to collect data on effectiveness/safety of omalizumab for up to 2 years during standard clinical practice.

This interim analysis included 876 patients (mean age, 44.9 years) with uncontrolled allergic asthma. The final analysis is expected to be presented at the American Thoracic Society's (ATS) 2011 Conference.

Results: The included patients were 54% female and 46% male. The mean time on omalizumab treatment was 23.4±20.9 months. As of 31 March 2011, 47.3% of patients were on the recommended dose of 150 mg, 35.1% were on a dose of 300 mg, and 17.6% were on a lower dose of 150 mg every other week. A total of 77.3% of patients had at least one severe asthma exacerbation during the study period. The 54 included trials comprised 13,460 patients (2,795 children) with allergic asthma. The mean duration of allergic asthma was 19.5 (SD 13.7) years; mean total IgE serum levels: 316.6 (SD 419.13) IU/mL.

Conclusions: Omalizumab is an effective add-on therapy for patients with allergic asthma, with a manageable safety profile. Omalizumab improves asthma control and quality of life, even in patients with frequent exacerbations. Omalizumab is associated with a reduction in the risk of severe asthma exacerbations, and a reduction in the risk of hospitalization for asthma exacerbations. Further studies are needed to investigate the long-term safety of omalizumab.

P3954 Omalizumab and malignancy: Interim results from the EXCELS study

Mark Enue2, Mary Miller, Will Chou, Abdelkader Rahmaoui, Mary Bradley. Global Product Development - Immunisation & Respiratory, Genentech Inc., South San Francisco, CA, United States

Background: Omalizumab is a biologic for the treatment of moderate-to-severe persistent allergic asthma that is inadequately controlled with inhaled corticosteroids. At the time of FDA approval, the incidence of malignant neoplasms was higher among patients who had received omalizumab (0.5%) compared to placebo (0.2%) in clinical trials.

Objective: The EXCELS study is an FDA postmarketing commitment to evaluate the long-term safety of omalizumab.

Methods: EXCELS is an ongoing prospective observational study of approximately 5000 omalizumab-treated and 2500 non-omalizumab-treated moderate-to-severe persistent allergic asthma patients aged ≥12 years from 448 US centers who are followed up for up to 5 years. All reported potential malignancies are reviewed by an independent oncology panel. The primary analysis includes confirmed, incident-study-emerging primary malignancies.

Results: This analysis of malignancy rates was based on interim study report 6 (data through 11/30/2010) which comprises 18,860 person-years in the omalizumab cohort and 10,947 person-years in the non-omalizumab cohort. Both cohorts had an average follow-up of 3.8 person-years. The incidence of study-emerging primary malignancy was 12.78 and 14.48 per 1000 person-years in the omalizumab and the non-omalizumab cohorts, respectively, corresponding to a rate difference of -1.70 per 1000 person-years (95% CI -6.63 to 2.21).

Conclusions: In this analysis, the incidence of malignancy was similar in the omalizumab and non-omalizumab cohorts. These interim results are preliminary and the study is still ongoing. Because the study is observational, selection and other biases cannot be excluded.

Funding Source: Genentech, Inc and Novartis Pharmaceuticals Corp.

P3955 Factors influencing the relative effect of leucotriene receptor antagonists (LTRA) and inhaled corticosteroids (ICS) as monotherapy in persistent asthma: A systematic review

Bhupendrasinh Chauhan, Franfine Ducharme. Clinical Research Unit on Childhood Asthma (CRUCA), CHU Ste-Justine Hospital Research Center, Montreal, QC, Canada

Objectives: To compare the safety and efficacy of LTRA with ICS in patients with asthma across age groups, over time, baseline severity and ICS dose.

Methods: In a systematic review until 2010, a randomised controlled trials comparing LTRA to ICS for ≥30 days in children and adults with asthma. The primary outcome was exacerbation requiring systemic steroids. Secondary outcomes included lung function, asthma control, adverse effects and withdrawals.

Results: The 54 included trials comprised 13,460 patients (2,795 children) with mild (42%) or moderate (58%) airway obstruction. In 84% of trials, LTRA was compared to a low ICS dose over 4-52 weeks. Compared to ICS, 48% more patients treated with LTRA suffered exacerbations requiring systemic steroids (RR 1.48; 95% CI 1.18, 1.85). There was no significant difference in the magnitude of effect between children and adults, ICS dose, and age. The benefit of ICS over LTRA was greater in patients with moderate vs. mild airway obstruction (RR=2.03 vs. 1.25, p<0.01). FEVI, symptoms, night awakenings, rescue β2-agonist use, symptom-free days, and quality of life favour ICS at almost any point of time. The use of LTRA was associated with more than a 2-fold increased risk of withdrawals due to poor asthma control (RR 2.58; 95% CI 2.01, 3.30). Both options were equivalent in the risk of overall side effects.

Conclusions: ICS remains superior to LTRA to prevent exacerbations and improve asthma control, irrespective of age group, ICS dose, and duration of treatment. However, the benefit of ICS is significantly greater in patients with moderate airway obstruction.

P3956 Real-life effectiveness of beclomethasone dipropionate/formoterol extra-fine combination in adult patients with persistent asthma

Guy G. Brusselle1, Paul Van Den Brande2, Rudy Peche3, Bart Fonteyn4, Domenico Iacone5, Marianne Bloksman6, Jacques Bruhwiler7, Wim Hollander8, Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 2Department of Respiratory Medicine, AZ S. M. H., Duffel, Belgium; 3Department of Respiratory Medicine, University Medical Centre, Charleroi, Montigny-le-Tilleul, Belgium; 4General Practitioner, Zutendaal, Belgium; 5Department of Respiratory Medicine, C.H.U. de Charleroi, Montigny-le-Tilleul, Belgium; 6General Practitioner, Zutendaal, Belgium; 7General Practitioner, Malmedy, Belgium; 8CROPHA srl, Cour-Saint-Etienne, Belgium; 9Squareroeckardt srl, Konstanz, Belgium; 10Medical Department, UCB Pharma NV, Brussels, Belgium.

Background: Efficacy and safety of extra-fine beclomethasone dipropionate 100 μg/formoterol 6 μg pMDI (BDP/F) in adult patients with moderate-to-severe persistent asthma has been demonstrated in double-blind randomized controlled clinical trials.

Objective: To assess real-life effectiveness of BDP/F on asthma control.

Methods: Non-interventional, prospective, open-label, multicentre study in Bel-
gium from December 2008 till December 2010. Patients were enrolled by pneumo-
logists and general practitioners (GPs). Visit 1 (Day 0): demographic and
baseline asthma control data collection, initiation of BDP/F treatment; Visit 2
(Day 21-240) and Visit 3 (Day 214-420) evaluation of asthma control by patients
(Juniper ACQ7) and investigators (GINA asthma control score), assessment of
BDPF safety/tolerability.

Results: 619 patients were enrolled: mean age 48±16.9 years, 54% female, 22.8%
smokers, mean FEV1 % pred 78.6±20.0%. At Visit 3 the mean daily beclomeha-
sone dose was 266±127 µg.

*P<0.0001 vs Visit 1; **vs Visit 1.

Similar improvements in asthma control, evaluated as patient-reported ACQ7
score, physician-rated GINA asthma control score, were observed in patients
recruited by pneumologists and by GPs. Treatment-related non-serious adverse
drug reactions were reported in 16 patients (2.6%).

Conclusion: The results of this study demonstrate the real-life effectiveness of
effective BDP/F in adult patients with moderate-to-severe persistent asthma.

**P3957**

Effect of budesonide/formoterol, budesonide and terbutaline on exercise-induced bronchoconstriction in mild intermittent asthma

Nikolaos Lazarinis1, Leif Bjermer 2, Kai-Håkon Carlsen 3, Barbro Dahlén 1,
Kjell Larsson7.

1Department of Respiratory Medicine and Allergology, Sahlgrenska University
Hospital, Göteborg, Sweden; 2Department of Respiratory Medicine & Allergology, University
Hospital, Lund, Sweden; 3Clinic of Allergy & Asthma, Alexander’s University Hospital,
Sofia, Bulgaria; 4Clinical and Quantitative Sciences, Merck Sharp &
Dohme Corp., Whitehouse Station, NJ, United States

Background: Omalizumab (OMA) treatment has been shown to be effective in
patients with severe allergic asthma (SAA), but published data beyond the first
year of treatment are scarce.

Objectives: To examine the persistence rate (PR), to identify reasons for discon-
tinuation and to determine the response rate (RR) and the clinical effectiveness
beyond the first year of OMA treatment.

Methods: Of 105 patients, who were on OMA treatment at the end of the 52w ob-
servational PERSIST study (Respir Med 2009; 103: 1633), 53 (51%) participated in
this study. A retrospective medical chart analysis was performed at approx. 16, 52,
and 68w after the end of the PERSIST study (up to 12w of treatment). Measure-
ments included PR, patient-reported Global Evaluation of Treatment Effectiveness
(GETE), Asthma-related Quality of Life Questionnaire (AQLQ), and systemic
glucocorticosteroid (gCSc) use, emergency room (ER) visits and hospitalizations
for severe exacerbations.

Results: The PR at 12w was 84.9%. Treatment was discontinued in 3 cases by
patient decision (1 relocation, 1 AE, 1 non-compliance with office visits), in 3
patients by joint patient/physician decision (2 complete asthma control, 1 AE)
and in 2 patients due to non-OMA related death. Where data were available, RR
(good/excellent GETE) was >85%. Absolute change of ≥0.5 point in AQLQ score
remained >90% from 6w up to 12w, less than 18.9% of patients required gCSc, there
were no ER visits and only 1 hospitalization during the evaluation period.

Conclusions: These preliminary results indicate a high PR with OMA beyond the
first year of treatment under “real-life” conditions in SAA patients in Belgium.

**P3960**

Plasma and urinary concentrations of inhaled salmeterol in healthy and
persons with asthma – Quantifying a doping limit

Morten Hostrup1, Jimm Eilers1, John Hennings1, Kim Dalholt1,
Vibeke Backer2, Research Unit of Respiratory Medicine, Bispebjerg Hospital,
Copenhagen, Denmark; 2Department of Pharmaceutical Chemistry, Aker
University Hospital, Oslo, Norway; 3Clinical Unit of Pharmacology, Bispebjerg
Hospital, Copenhagen, Denmark

Background: Salmeterol is a long acting β2agonist that is used in treatment of asthma. β2agonists are on WADA and IOC’s prohibited list, but salmeterol is allowed in therapeutic doses by inhalation. The prohibited list however contains no urinary limit for salmeterol, which gives athletes the opportunity to inhale unlimited doses of salmeterol. Large doses of β2agonists may have ergogenic effects and therefore a quantification of a urine salmeterol limit is necessary.

**Purpose:** To find plasma and urinary concentrations of inhaled salmeterol in inhalation therapeutic dose 100 µg in healthy and persons with asthma. To discuss a urinary concentration limit for inhaled salmeterol on the prohibited list.

**Methods:** 10 persons with asthma (A) and 10 healthy subjects (C) were enrolled, age 24±6.3.9. The subjects underwent two visits. First visit was a pre-examination with a metacholine provocation and lung function test. On second visit the sub-
jects inhaled 100 µg salmeterol (Seretide®) as a single dose. Blood samples were acquired at baseline and 0.5, 1, 2, 3, 4 and 6 hours after administration. Urinary samples were collected at baseline and 4, 8, 12 and 24 hours after adminis-
tration. Plasma and urine samples were analyzed by liquid chromatography mass spectrometry.
Results: The peak median urinary concentration was found after 4hrs reaching 0.38±0.26 mg/mL in A and 0.38±0.22 mg/mL in C. Peak median plasma concentration was 0.07±0.03 mg/mL for A and 0.06±0.03 mg/mL in C. No differences were found between the groups.

Conclusions: Urine salmeterol peak 4h after administration by inhalation. We propose a salmeterol urine limit of 0.82 mg/mL in in doping controls.

P3964 The effect of liposome inhalation on non-invasive oxidative stress markers in patients with bronchial asthma
Alexander Listina, Igor Klimanov, Svetlana Soodaeva. Clinical and Experimental Biophysics, Pulmonology Research Institute, Moscow, Russian Federation

Background: The liposome inhalation demonstrates an antioxidant activity in the treatment of various diseases, confirmed both by experimental and clinical studies. The aim is to carry out a prospective study of antioxidant features of liposome inhalation in patients with the exacerbation of bronchial asthma.

Materials and methods: We enrolled 50 patients (age=37.7±7.5 year, men=64%) with bronchial asthma (FEV1>70%, steroid-naive) in prospective comparison study. All patients were divided in two groups: group 1 contains 25 patients, who received a liposome inhalation by compression nebulizer once a day (300 mg of phospholipids in each administration); group 2 contains 25 patients, who received a traditional therapy (control). Antioxidant activity was determined by the estimation of the exhaled nitric oxide level (ENO) and total nitrite/nitrate (TNN) in exhaled breath condensate before and after the investigation period.

Conclusions: There was a significant decrease of ENO level in group 1 from 31.8±2.4 to 7±1.1±4 ppb (p<0.001) after the observing period. In group 2 the ENO level was decreased from 29.7±3.9 ppb to 25.0±2.5 ppb (not significant). Patients in both groups had significantly lower levels of TNN before the study (7.7±0.9 μM) and 8.4±1.1 μM respectively). After liposome administration the TNN level in group 1 decreased to 9±0.6 μM (p<0.01) as well as in control group it was at the same border (7.7±1.4 μM).

Conclusion: The results obtained demonstrate that liposome inhalation administered once a day during 14-days period has a significant antioxidant effect in patients with mild-to-moderate bronchial asthma.

P3965 Quantitative IgE levels in asthma and implications for treatment with omalizumab. Are the cutoffs to narrow?
Mary Lynn Zaremba, Kristin Elliott, Alicia Redford, Nipurn Shah, Syed Ali, Sridhar Reddy. St.Clair Pulmonary & Critical Care, 1210 10th Avenue, Port Huron, MI, United States

The use of omalizumab is constrained by the narrow quantitative parameters in its use. This study looks at experience in a small pulmonary-practice as regards comparison study. All patients were divided in two groups: group 1 contains 25 patients, who received a liposome inhalation by compression nebulizer once a day (300 mg of phospholipids in each administration); group 2 contains 25 patients, who received a traditional therapy (control). Antioxidant activity was determined by the estimation of the exhaled nitric oxide level (ENO) and total nitrite/nitrate (TNN) in exhaled breath condensate before and after the investigation period.

Conclusions: There was a significant decrease of ENO level in group 1 from 31.8±2.4 to 7±1.1±4 ppb (p<0.001) after the observing period. In group 2 the ENO level was decreased from 29.7±3.9 ppb to 25.0±2.5 ppb (not significant). Patients in both groups had significantly lower levels of TNN before the study (7.7±0.9 μM) and 8.4±1.1 μM respectively). After liposome administration the TNN level in group 1 decreased to 9±0.6 μM (p<0.01) as well as in control group it was at the same border (7.7±1.4 μM).

Conclusion: The results obtained demonstrate that liposome inhalation administered once a day during 14-days period has a significant antioxidant effect in patients with mild-to-moderate bronchial asthma.

P3966 Stability and achievement of asthma control with higher doses of inhaled corticosteroids regular treatment
Shih-Lung Cheng. Internal Medicine, Far Eastern Memorial Hospital, Taipei, Taiwan

Background: Uncontrolled asthma is characterized by variability. Previous GOAL study demonstrated that once asthma is achieved, the future risk of instability is greatly reduced. Higher stability (lower variability) in asthma control is also associated with a lower future possibility of unscheduled healthcare resource use. In the study, we attempted to increase inhaled combined agent doses initially and hypothesized that stability was positively associated with the level of control achieved.

Methods: This was a prospective study and new diagnosed asthma patients were included and randomized into two groups. One group was treated with higher doses (HD) one month then shifted to guideline-practice (GP) treatment and another was treated with GP therapy model. Peak expiratory flow (PEF) asthma, symptom control (ACT) and exacerbation times were measured. The follow-up time was 1/2 year.

Results: 39 patients were treated with HD and 40 patients were GP therapy policy. PEF change were significantly improved in HD group compared with GP (56±17 vs. 45±19, p=0.04). The obvious improvement especially in initial 2 months (77±39 vs. 52±23, p=0.01). There were significantly differences in ACT change and exacerbation frequency in patients with mild and moderate persistent asthma using HD therapy.

Conclusion: Our findings demonstrated that patients with HD treatment were more improved and stabilized than patients with previous conventional therapy policy. Further evaluation should be performed on patients and long term follow-up to confirm the higher doses’ efficiency.

P3967 Comparison of the efficacy of ciclesonide with budesonide in mild to moderate asthma patients after step-down therapy
Kuo-Chun Chen1, Jeng-Yuan Hua2, Miao-Mei Lin3, Wen-Ting Lin4, Chun-Hua Wang5, Han-Pin Kuo6. 1Division of Chest, Department of Internal Medicine, Saint Mary’s Hospital Luodong, Luodong Town, I-Lan County, Taiwan; 2Division of Chest, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; 3Division of Chest, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; 4Department of Thoracic Medicine, Chang Gung Memorial Hospital, Taipai, Taiwan

Inhaled corticosteroids are the most widely used controller treatment for asthma, and is the stepping down level when asthma is controlled with combination therapy. Ciclesonide is an inhaled corticosteroid with on-site lung activation that provides anti-inflammatory activity. The aim of this study was to compare the efficacy of ciclesonide (CIC) with budesonide (BUD) in 142 adult patients with mild to moderate asthma who were well-controlled with a combination of inhaled corticosteroids and long-acting β2-agonist. They were randomized to receive once-daily ciclesonide 320mg (n=73) or twice-daily inhalations of budesonide 200 mg (n=69) for 12 weeks. The forced expiratory volume in one second (FEV1), maximum mid-expiratory flow (MMEF) and asthma control test (ACT) score were evaluated. Tolerability and ranked stratification of patient and physician were assessed. At the end of study, the withdrawal rate of CIC group (26.4%) was significantly less than that of BUD group (42.7%, p=0.02). There was no difference of FEV1 and MMEF throughout 12-week treatment period in CIC group. In BUD group, FEV1 decreased significantly at 4-week (1.8±0.1 L, n=59, p<0.0006) and 12-week of treatment (1.9±0.1 L, n=39, p<0.01) compared with baseline (2.0±0.1 L, n=69). MMEF decreased significantly at 4-, 8- and 12-week compared to baseline in BUD group. ACT score decreased significantly at 4-week of treatment in BUD group compared with baseline. There was no difference of ACT score over the 12-week period in CIC group. In conclusion, ciclesonide was more effective and better drug adherence than budesonide in the stepping-down treatment of asthma from combination therapy.
The effect of GSK2190915, a 5-lipoxygenase activating protein inhibitor, on the early asthmatic response to inhaled allergen

Virginia Norris, Jane Bentley, Sandra Kent, Dave Singh, Malcolm Boyce, Brian Leaker1, Drug Discovery, GlaxoSmithKline, Stevenage, United Kingdom; 2Respiratory Medicine, Medicine Evaluation Unit, Manchester, United Kingdom; 3Clinical Pharmacology, HummertMedicine Research, London, United Kingdom; 4Respiratory Medicine, Respiratory Clinical Trials, London, United Kingdom

Background: GSK2190915 is a potent 5-lipoxygenase activating protein inhibitor, thereby interfering the synthesis of leukotrienes and 5-oxo-ETE.

Objective: To assess the effects of GSK2190915 on the allergen induced early asthmatic response (EAR).

Methods: 19 patients with mild asthma were enrolled in this 3-centre, double-blind, 3-way crossover study. They took 10 and 50 mg GSK2190915 and placebo orally, once daily for 3 days, in randomised order. On Day 3 they had an inhaled allergen challenge.

Results: GSK2190915 had a significant effect on the EAR, the treatment difference from placebo for 10 mg was 0.212 L (0.044, 0.379) and for 50 mg was 0.409 L (0.242, 0.576) for minimum FEV1, in the 2 hours after allergen inhalation. The magnitude of the effect with 50 mg GSK2190915 in this study was comparable to that observed with 100 mg on the EAR in a separate study [1]. Safety and tolerability were good.

Conclusion: GSK2190915 has shown a significant, dose related, inhibition of the EAR to inhaled allergen.

P3967 Asthma control and lung function after step down from high dose ICS/LABA combination therapy

Pierluigi Paggiaro1, Gabriele Nicolini2, Nunzio Crimi3, Leonardo Maria Fabbrì, Davio Olivieri1, Andrea Rossì1, Alberto Pattì1, 1Cardio-Thoracic and Vascular Department, University of Pisa, Pisa, Italy; 2Medical Affairs, Chest, Farmaceutici SpA, Parma, Italy; 3Department of Internal and Specialist Medicine, Section of Respiratory Diseases, University of Catania, Catania, Italy; 4Section of Respiratory Diseases, University of Modena, Modena, Italy; 5Department of Clinical Sciences, University of Parma, Parma, Italy; 6Department of Pneumology, Azienda Ospedaliero Universitaria Integrata di Verona, Verona, Italy; 7Research Center on Asthma and COPD, University of Ferrara, Ferrara, Italy

Rationale: Guidelines recommend asthma treatment to be adjusted to the lowest dose maintaining control.

Objectives: To evaluate whether lung function and asthma control can be maintained in patients treated with high dose ICS/LABA combination after step-down.

Methods: Prospective, multinational, randomized, open label, parallel group controlled trial. Patients treated with high dose (1000/100 μg daily) fluticasone/salmeterol (FP/S) either DPI or pMDI entered a 2-month run-in with FP/S Diskus 1000/100 μg daily. Controlled patients (GINA) were treated either with FP/S Diskus 500/100 μg daily or extraline beclometasone/formoterol (BDP/Fp) pMDI 400/24 μg daily for 6 months. Morning PEF was the primary outcome.

Results: 378 patients were evaluated for ITT; previous treatment was DPI in 87% of patients. Equivalence was shown in morning PEF at the end of treatment (difference between means 2.49 L/min; 95% CI -1.33 to 18.42). Morning PEF remained above 95% predicted throughout the study, though absolute values decreased (414.4 to 397.1 L/min for BDP/Fp; 429.7 to 394.6 L/min for FP/S; p=0.001). Asthma control was maintained in the majority of patients with no worsening in FEV1 measured at clinics, symptoms score, use of rescue medication and no differences in any parameter including exacerbations.

Conclusions: Patients controlled with high dose ICS/LABA DPI can be stepped-down to medium dose either DPI or extraline pMDI maintaining asthma control.

P3968 Risks of diabetes mellitus and hyperglycaemic adverse events in patients with asthma taking inhaled corticosteroids

O’Byrne1, Stephen Rennard2, Radner Finn1, Stefan Peterson3, Lars-Goran Carlsson1, Don Sinn4, Michael G DeGroote School of Medicine, McMaster University, Hamilton, Canada; 2Internal Medicine Section of Pulmonary and Critical Care, Nebraska Medical Center, NE, United States; 3Clinical Sciences, AstorZeneica R&D, Lund, Sweden; 4Department of Medicine, University of British Columbia, Vancouver, Canada

Background: A recent study of patients with lung disease and with prescriptions for inhaled corticosteroids (ICS) detected a 34% increased risk of diabetes mellitus. Methods: A retrospective analysis evaluated the double-blind, placebo-controlled, clinical trials in asthma (duration > 3 years) in patients >24 years of age, involving budesonide (BUD) or BUD/formoterol (26 trials, n=9607 for BUD; n=9296 for placebo). A supplementary dataset evaluated all double-blind, non-placebo controlled trials in asthma (duration >3 months), involving the use of ICS (60 trials, n=33496 for BUD, n=2773 for fluticasone propionate [FP]). Cox proportional hazards regression modelling, both adjusted and not adjusted by study, was used to estimate the relative risk of ICS on diabetes mellitus/hyperglycaemia adverse events (AEs) or serious adverse events (SAEs) in both the primary and supplementary datasets.

Results: In the primary dataset, the occurrence of diabetes mellitus/hyperglycaemia AEs was 0.13% for BUD and 0.13% for placebo (HR 0.98 [95% CI 0.38–2.50] p=0.96); the occurrence of diabetes mellitus/hyperglycaemia SAEs was 0% for BUD and 0.05% for placebo. In the supplementary dataset, the occurrence of diabetes/hyperglycaemia as AE and SAE was 0.19% and 0.03%, respectively. There was no increased risk with higher doses of BUD, nor any difference between BUD and FP. The risk for diabetes mellitus/hyperglycaemia increased with age, BMI and disease severity.

Conclusion: This retrospective analysis of all double-blind trials with BUD in asthmatic patients did not demonstrate any increased risk of diabetes mellitus/hyperglycaemia with BUD treatment. Funded by AstraZeneica.

P3969 Increased incidence of pulmonary embolism in severe asthma

Chrístof Majoor1, Pieter Kamphuisen2, Lous Rijssenbeek-Nouwens3, Tom van der Poil4, Aelfko Zwiznderman1, Peter Sterk1, Harry Büller5, Elisabeth Beü1, 1Department of Pulmonology, Academic Medical Centre, Amsterdam, Netherlands; 2Department of Vascular Medicine, Academic Medical Centre, Amsterdam, Netherlands; 3Department of Pulmonology, Netherlands Asthmacenter Davos, Davos Wolfgang, Switzerland; 4Center for Experimental and Molecular Medicine, Academic Medical Centre, Amsterdam, Netherlands; 5Department of Medical Statistics, Clinical Epidemiology and Biostatistics, Academic Medical Centre, Amsterdam, Netherlands

Introduction: Many patients with severe asthma need inhaled (ICS) and chronic oral (OCS) corticosteroids for asthma control. OCS are associated with hypercoagulability and increased risk of venous thromboembolism (VTE). Also asthma itself is associated with a prothrombotic state (Brims 2009).

Hypothesis: The incidence of VTE is increased in asthma, and associated with asthma severity and OCS use.

Methods: 166 Outpatients with mild-moderate asthma (mean (range) age 49yr (18-80), 56% female, all using ICS), and 139 patients with severe asthma (52yr (18-77), 62% female, 39% using OCS) from 3 clinics in the Netherlands and Davos, Switzerland, were consecutively included in a cross-sectional study. Patients completed a questionnaire about previous VTE, risk factors and medication use. All VTE events were objectively diagnosed. Data were compared with the available incidence (ages 50-54 yr) in the general population (Naess 2007).

Results: Deep vein thrombosis (DVT) occurred in 3 and 2 patients with severe and mild-moderate asthma resp. and pulmonary embolism (PE) in 11 and 3. Overall incidence was 1.77/1000 person yr in severe asthma vs 0.7 in mild-moderate asthma and 1.03 in the general population. The relative risk of PE for severe asthma was 5.5 (95% CI: 1.24-24) and independently associated with >2 exacerbations/yr (RR 12.63, 1.48-107) and chronic OCS use (RR 8.21, 1.57-43). The risk of DVT was 0.50 (0.13-1.96). In mild-moderate asthma risks were not increased.

Conclusions: Patients with severe asthma have a 5.5-fold increased incidence of pulmonary embolism, which is associated with exacerbation frequency and chronic oral corticosteroid use.

Implication: Pulmonary embolism may be important in the prognosis and management of severe asthma.

P3970
Effects of hydrocortisone on acute beta-blocker and histamine induced bronchoconstriction
Philip Short, Peter Williamson, Lorna McKinlay, Brian Lippworth. Asthma and Allergy Research Group, University of Dundee, Dundee, United Kingdom

Introduction and objectives: The benefits of chronic beta-blockade in asthma have recently been questioned, however concerns of bronchoconstriction persist with the greatest risk after first dose. We investigated the safety of acute exposure to propranolol in asthmatics, sequentially challenged with histamine to mimic an asthma exacerbation and evaluated the role of hydrocortisone in potentiating salbutamol reversibility.

Methods: Persistent atopic asthmatics, ≤1000g/day beudesonide performed a randomised double-blind placebo-controlled crossover study. Following 10mg or 20mg of oral propranolol, patients received 400mg iv. hydrocortisone or placebo, followed by histamine challenge with nebulised salbutamol 5mg and ipratropium 500mcg recovery.

Results: 13 patients completed per protocol. Hydrocortisone did not potentiate salbutamol recovery post-propranolol and histamine challenge. Beta-blocker induced bronchoconstriction was demonstrated by sputum and IOS. For the placebo visit, FEV1% fell 4.7% 2hrs post-propranolol whilst R5% increased 31.3%. On both visits FEV1% and R5% returned to baseline after salbutamol post-histamine.

Conclusion: Nebulised salbutamol produced a full recovery after propranolol and histamine induced bronchoconstriction, independent of hydrocortisone use. Our findings offer reassurance to those undertaking further evaluation of chronic beta-blockade as a potential treatment for asthma.

Safety, tolerability, pharmacodynamics (PD) and pharmacokinetics (PK) of GSK573719 inhalation powder in healthy subjects
Anthony Cahm 1, Reesid Lovick 2, Amy Newlands 3, Amanda Deans 4, Isabelle Pouliquin 1, Andrew Pressce 2, Dennis Kelleher 2, Rashmi Mehta 2, Ruth Tal-Singer 4, Respiratory Medicine Discovery and Development, GlaxoSmithKline, Stevenage, United Kingdom; 3Clinical Pharmacology Science and Study Operations, GlaxoSmithKline, Uxbridge, United Kingdom; 4Discovery Biometrics, GlaxoSmithKline, Uxbridge, United Kingdom; 5Safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of repeat inhaled administration of fluticasone furoate (FF) in healthy Caucasian, Chinese, Japanese and Korean subjects
Ann Allen 1, Joanne Bal 2, Anne Chestroub 2, Melanie Hamilton 4, Rodger Kemptsof 2, Clinical Pharmacology Modelling & Simulation, GlaxoSmithKline, Research Triangle Park, United States; 4Inhaled Product Development, GlaxoSmithKline R&D, Wuren, Hertfordshire, United Kingdom; 5Clinical Pharmacology Science & Study Operations, GlaxoSmithKline R&D, Stockley Park, Middlesex, United Kingdom; 6Discovery Biometrics, GlaxoSmithKline R&D, Uxbridge, Middlesex, United Kingdom; 7Respiratory and Immuno-Inflammation Medicine Development Center, GlaxoSmithKline Research Triangle Park, United States

Introduction: GSK573719 is a new long-acting mucinasic antagonist offering sustained 24-hour bronchodilation in development for the treatment of COPD.

Methods: In this single-centre, double-blind, parallel-group study, 36 healthy adults were randomised 3:1 to GSK573719 (250μg, Cohort 1; 750μg, Cohort 2; 1000μg, Cohort 3) or placebo as DPI once daily for 14 days.

Results: Most adverse events (AEs) were mild and all resolved during the study; the most frequent drug-related AEs were headache and pharyngolaryngeal pain (0–2 subjects per group). No clinically relevant abnormalities or changes were seen in laboratory results or vital signs. There were no clinically significant ECG abnormalities or heart rate changes. Although 41–67% of plasma PK samples were non-quantifiable, available data showed a median tmax of 5–15min, mean t1/2 (Day 14) of 26–28h (25–35h from urine PK). Although visual assessment of Ctau data suggested that steady state was achieved following 6 to 8 days of dosing, there was large data variability. Urinary excretion of unchanged GSK573719 was 1–1.5% of the total dose on Day 1 and 3.4–4.5% at steady state. Accumulation (Day 14-Day 1) was 1.5–3x on placebo PK (1.3–5x on urine PK). There was no correlation between GSK573719 systemic exposure and pharmacodynamic variables.

Conclusion: GSK573719 was well tolerated by all subjects and no safety concerns were identified even at the highest dose, supporting the continued development for COPD.

Funded by GSK (AC4106889; NCT00475436)

Safety, tolerability and pharmacokinetics (PK) of repeated doses of GSK573719 inhalation powder, a new long-acting mucinasic antagonist, in healthy adults
Rashmi Mehta 2, Kelly Hardes 2, Anthony Calm 3, Amy Newlands 3, Alison Donald 2, Andrew Pressce 2, Dennis Kelleher 2, Glenn Crater 3, Respiratory Medicine Discovery and Development, GlaxoSmithKline, Research Triangle Park, United States; 2Clinical Pharmacology Science and Study Operations, GlaxoSmithKline, Uxbridge, United Kingdom; 3Respiratory Medicine Discovery and Development, GlaxoSmithKline, Stevenage, United Kingdom; 4Discovery Biometrics, GlaxoSmithKline, Uxbridge, United Kingdom; 5Quantitative Sciences, R&D, GlaxoSmithKline, Uxbridge, United Kingdom; 6Respiratory Medicine Discovery and Development, GlaxoSmithKline, Research Triangle Park, United States; 7Respiratory and Immuno-Inflammation Medicine Development Center, GlaxoSmithKline, Research Triangle Park, United States

Introduction: GSK573719 is a new long-acting mucinasic antagonist offering sustained 24-hour bronchodilation in development for the treatment of COPD.

Methods: To investigate the safety, tolerability and PK of repeated once-daily dosing (14 days) of GSK573719 dry powder inhalation (DPi). 13 patients completed per protocol. Hydrocortisone did not potentiate salbutamol recovery post-propranolol and histamine challenge. Beta-blocker induced bronchoconstriction was demonstrated by sputum and IOS. For the placebo visit, FEV1% fell 4.7% 2hrs post-propranolol whilst R5% increased 31.3%. On both visits FEV1% and R5% returned to baseline after salbutamol post-histamine.

Conclusion: Nebulised salbutamol produced a full recovery after propranolol and histamine induced bronchoconstriction, independent of hydrocortisone use. Our findings offer reassurance to those undertaking further evaluation of chronic beta-blockade as a potential treatment for asthma.

Ann Allen1, Joanne Bai2, Anne Cheshire3, Melanie Hamilton4, Rodger Kempford5.

**Objectives**: To evaluate and compare FF PK in Caucasian (Ca), Chinese (Ch) and Japanese (Jp) subjects following FF administration via a novel dry powder inhaler and i.v. infusion.

**Methods**: Open-label, randomized, two-way crossover study. Healthy male and female Ca, Ch, Jp and K subjects [N=20/group], randomized to receive OD inhaled FF (200mcg (7 days) then 800mcg (7 days)) and single i.v. 250mcg dose. PK data were obtained on D1 and/or D7.

**Results**: The average PK parameters of i.v. FF were similar in Ca, Ch, Jp and K subjects, consistent with CYP3A4 activity in each population. Inhaled FF systemic exposure was higher at both doses (AUC ratio: 1.27 to 1.75) in Ca, Ch, Jp and K subjects, compared with Ca subjects, reflecting higher bioavailability (800mcg D7: 14.3% to 16.3% and 10.4%, respectively). Deconvolution analysis suggested that inhaled FF resided in the lungs of Ca, Ch and Jp subjects for longer than in Ca subjects, a likely reason for seeing greater bioavailability. All treatments were safe and well tolerated and no marked quantitative or qualitative differences in safety endpoints between the ethnic groups.

**Conclusion**: Following inhaled FF there was higher (1.2-fold) systemic exposure in Chinese, Japanese and Korean subjects compared with Caucasian subjects, although there were no safety or tolerability consequences. Funded by GSK (HZIA13477; NCT0100597)

Glycoprotein MDI demonstrates comparable efficacy and safety to tiotropium DPI in Chinese, Japanese, and Korean subjects

Chadwick Orevalil, Earl St. Rose1, Shannon Stronm2, Tracy Fischer2, Michael Golden2, Mervyn Thomas3, Colin Reisner1.

**Objectives**: To determine the absolute bioavailability of FF and VI when administered in combination as FF/VI from a novel dry powder inhaler in healthy subjects.

**Methods**: In this open-label, non-randomised, three-way crossover, single-dose study, male and female subjects [N=16] received (in order) a single inhaled dose of FF/VI 800/100mcg (4 inhaletions of 200/25mcg, a single 250mcg intravenous (i.v.) dose of FF and a single 55mcg i.v. dose of VI. FF and VI pharmacokinetic data were obtained up to 48h post-dose.

**Results**: The average absolute bioavailability of FF when inhaled as FF/VI relative to i.v. FF was 15% (90% CI 13, 18). The average absolute bioavailability of VI when inhaled as FF/VI relative to i.v. VI was 27% (90% CI 22, 35). Both FF and VI were rapidly cleared and widely distributed following i.v. dosing. FF showed longer retention in the lung than VI following inhaled administration with the time for 90% of the total to be absorbed from the lung on average 35.2h and 3.8h, respectively. All treatments were safe and well tolerated even though this study evaluated multiples of the likely inhaled therapeutic dose (200/25mcg).

**Conclusion**: In healthy adult subjects the absolute bioavailability of FF was 15% and for VI was 27% following a single inhaled dose of FF/VI delivered via a novel dry powder inhaler. Funded by GSK (HZIA102934, NCT0129558).

No pharmacodynamic (PD) and pharmacokinetic (PK) interaction of riociguat (BAY 63-2521) and aspirin

Reiner Frey1, Wolfgang Mück1, Sigrun Unger2, Michael Reber1, Vincent Kritzschma1, Corina Becker1, Georg Wensing1.1 Clinical and Pharmacology, Bayer HealthCare AG, Wuppertal, Germany; 2 Global Biostatistics, Bayer HealthCare AG, Wuppertal, Germany.

**Objectives**: Riociguat, an oral soluble guanylate cyclase (sGC) stimulator, is a new candidate for treatment of pulmonary hypertension (PH). Riociguat increases cGMP production through a novel dual mode of action: direct NO-independent stimulation of sGC; and increasing sensitivity of sGC to low levels of NO. Riociguat and aspirin are likely to be used together in PH. This randomized, open-label, crossover study investigated potential PD and PK interactions between the 2 drugs.

**Methods**: Participants took 2.5 mg/day riociguat, two morning doses of 500 mg aspirin, or both treatments concomitantly.

**Results**: Eighteen healthy men (mean age 34.8 years) were enrolled. Six of 17 participants in the safety evaluation reported ≥1 treatment-emergent adverse event (AE). All AEs were mild except 1 case of moderate headache following riociguat administration. Fifteen participants were valid for PD/PK analysis. Riociguat PK was independent of aspirin coadministration. One hour after coadministration of riociguat and aspirin, the mean increase in fraction unbound was 19% for riociguat and 24% for its metabolite M1 (BAY 60-4552) indicating mild displacement by salicylic acid, the main aspirin metabolite. Effects of aspirin on bleeding time, platelet aggregation and plasma thromboxane B2 were not affected by concomitant riociguat. Riociguat alone had no effect on PD variables.

**Conclusion**: Riociguat demonstrated no clinically relevant PD or PK interaction with aspirin. Coadministration of riociguat and aspirin does not require dose adjustment. Phase 3 randomized controlled trials are investigating riociguat in chronic thromboembolic pulmonary hypertension or pulmonary arterial hypertension.

**P3979**

How can we improve patient use of inhaler devices in COPD?

Mathieu Molimard1, Karen Giorgi-Vigo2.1 Department of Pharmacology, Université Victor Segalen, Bordeaux, France; 2 Respiratory Medicine, Novartis Pharma AG, Basel, Switzerland.

**Introduction**: “Ease of use” is traditionally seen as a key factor in COPD inhaler choice. Our aim was to assess patient and healthcare professional (HCP) needs and problems with inhalers and to offer these patients to satisfy these needs, enabling better patient adherence with maintenance inhalers.

**Methods**: 1008 HCPs and 490 patients (≥18 years) participated in an online survey. Sawtooth Software’s ACA and CBC products were used to collect, randomize and measure relative impact of features in utility values (positive vs. negative choice impacts).

**Results**: Overall, with current devices, patients indicate a lack of full certainty that they have taken the full dose correctly (rating of only 4.3 for Asthma, 5.3 for COPD; 1–7 scale). HCPs place far more importance on increasing patient satisfaction and demand than other attributes, reasoning this aids adherence. Similarly, patients want ease of use and features to aid adherence (a dose reminder and improvements over dose counters) to address their primary unmet need of uncertainty in inhaling
all doses fully. Device type (MDI, DPI, multidose, single-dose) has little impact in HCP choice (COPD HCP utilities: patient satisfaction and demand +92, multidose DPI 3, dose spacer 1). Conclusion: Issues such as dose counters and multidose vs. single-dose have little impact on physician demand. Satisfying patient need for true dose confirmation can drive patient satisfaction and adherence. Patients need devices that assure them that they have taken the full dose to be more adherent, and HCPs need devices that drive patient demand and adherence.

Patient assessments of ease of use of Genumovar® versus Aerolizer® and Handihaler®
Rainard Fuhr1, Helgo Magnusson2, David Singh3, Gonzalo de Miquel4, Cynthia Caracata5, Esther Garcia Gil6, 1 Early Phase Clinical Unit, PAREXEL International GmbH, Berlin, Germany; 2 Pulmonary Research Institute, Hospital Grosshadern, Grosshadern, Germany; 3 Medicines Evaluation Unit, University of Manchester, Manchester, United Kingdom; 4 R&D Centre, Almirall, Barcelona, Spain; 5 Clinical Development, Forest Research Institute, NJ, United States

Introduction: The Genumovar® inhaler, a multidose, dry powder inhaler, has been developed to provide reliable and effective delivery of inhaled medications including acidinium bromide, which is in clinical development for the treatment of chronic obstructive pulmonary disease (COPD).

Aim: To report data from two Phase II studies that included patient assessments of the convenience of Genumovar® versus Aerolizer® and Handihaler® respectively.

Methods: Both studies were randomised, double-blind, double-dummy, cross-over trials in patients with moderate to severe COPD. In the first study, 79 patients received treatment over seven-day periods via Genumovar® and Aerolizer®. In the second study, 58 patients received treatment over 15-day periods via Genumovar® and Handihaler®. At the end of the studies, patients were asked to evaluate their impressions of inhaler convenience.

Results: Patient assessments of the different inhalers are presented in Table 1.

Comparison of the bronchoprotective effects of two salbutamol sulphate HFA pMDI formulations using methacholine challenge testing
Juliette Rebello1, Mayuri Mangale1, Siddarth Chachad2, Geena Malhotra3, Shinivara Purandare4, Sundee Salvi1, Bill Brauher2, Anthony Mesquita3, Lalita Fernandes5, George D’Souza6, 1 Clinical Research Department, Cipla Ltd, Mumbai, Maharashtra, India; 2 Clinical Research Department, Chest Research Foundation, Pune, Maharashtra, India; 3 TB and Chest, Goa Medical College, Panaji, Goa, India; 4 Dep. of Pulmonology, St. Johns Medical College, Bangalore, India

Background: Clinically, methacholine challenge has been widely used for the detection and quantification of bronchial responsiveness. This study assessed the bronchoprotective effects of two salbutamol sulphate HFA pMDI formulations using methacholine challenge.

Aim: The aim of this study was to evaluate equivalence between Salbutamol sulphate HFA pMDI (Cipla Ltd, India) against methacholine induced bronchoconstriction.

Methods: This was a randomised, double-blind, double-dummy, four period, crossover study. At each treatment visit patients administered either one puff (100 μg) or two puffs (200 μg) of either the test or the reference product. On each of the treatment days, two methacholine challenge tests were performed, one before and one 10 minutes after dosing.

Conclusions: The bronchoprotective effect of salbutamol sulphate HFA pMDI (Cipla Ltd, India) against methacholine induced bronchoconstriction was equivalent to salbutamol sulphate HFA pMDI (Ventolin Evohaler, Allen & Hanbury, UK). Both the products were safe and well tolerated.

P3981
Preference of the inhaler device and assessment of the technique among the asthmatic and COPD patients
Walid Tarsin1,2, Iqshar Ahamdi1, Mokhtar Souissi1,2, 1 Respiratory Department, Tripoli Medical Center; Tripoli, Libyan Arab Jamahiriya; 2 Pharmacology and Clinical Pharmacy Department, School of Pharmacy, Eljefere University, Tripoli, Libyan Arab Jamahiriya

Different inhaler devices (IDs) are available for delivering treatments to patients with asthma & COPD. They have different technique which can easily confuse patients, resulting in incorrect use. The aim of this study was to evaluate the preference of the IDs and assessment of inhaler technique among the asthmatic and COPD patients. 300 patients (117 male:183 female) included in this study. Their mean (SD) age was 44.6 ± 16.9 years. Manly three different inhaler devices were used. Metered dose inhaler (MDI) Handihaler® (HCP) and TUR & MDI (ACE) were used. 205 patient preferred the ACE while 82 & 13 preferred the TUR & MDI respectively. The assessment of inhaler technique according to the manufacturer instruction dose shows that 156 patients were having a good technique when using MDI, while 278 and 210 patients were having a good technique when using TUR & ACE respectively. Table 1 highlights that some patients were inhaling with either very low or very high rates.

Table 1. The range of patients inhalation flow rates through the MDI, ACE and the TUR using In-Check Dial

Thus they need to be trained but this may not be possible, because studies have shown that patient soon revert back to the previous technique. Even after counselling some patients may not have sufficient inspiratory effort to achieve the most desirable inhalation rate for the DPI they have been prescribed. From the results obtained we can conclude that the ACE is the most desired ID by the patients followed by the TUR & MDI. All patients were using MDI, nearly all of them having a high flow rate through it.

P3982
Pharmacokinetic evaluation of two HFA pMDI formulations of salmeterol xinafoate administered through a spacer (ACE) and multidose (MDI) Inhaler in healthy subjects
Saumya Chandran1, Nazma Morde1, Juliet Rebello1, Siddarth Chachad2, Shinivara Purandare3, Geena Malhotra1, Ratnakar Jadhav4, Krishnan Iyer2, Raghav Nuad1, 1 Clinical Research Department, Cipla Ltd, Mumbai, Maharashtra, India; 2 Contract Research Organisation, Sitec Labs Pvt Ltd, Mumbai, Maharashtra, India

Background: No pharmacokinetic studies of salmeterol HFA pMDI with a spacer device have been published. In this study comparative bioavailability of two salmeterol HFA pMDI formulations administered through a spacer device was evaluated using pharmacokinetic endpoints.

Aim: To compare the rate and extent of absorption of the test product Salmeterol xinafoate HFA pMDI (Cipla Ltd.) with that of the reference product Serevent Evohaler (supplied by Allen & Hanbury, UK), both administered using a spacer.

Methods: This was a balanced, open label, randomised, two period, single dose, crossover comparative bioavailability study in 24 healthy subjects. Eligible subjects were randomly assigned to receive a single dose of 100μg of both test and reference product administered with a spacer in a crossover manner on two treatment days. The two treatment days were separated with a washout period of 1 week. The blood samples were collected up to 24 hrs. Safety assessments including ECG, tremor assessment, serum potassium and blood glucose were also done at predefined time points. The primary endpoints were Cmax and AUC0-∞.

Results: The plasma concentration-time profile of the test product (T) was similar in shape to that of the reference product (R). The T/R ratio of the geometric mean for Cmax and AUC0-∞ was 94.54% (90% CI 87.11-102.61) and 90.68% (90% CI 83.87-98.03) respectively. The CI limits for Cmax and AUC0-∞ was well within the bioequivalence range of 80 – 125%.

Conclusion: The bioavailability of the two HFA formulations of salmeterol when administered with a spacer was comparable and both the treatments were safe and well tolerated.

P3983
The aerodynamic particle size of mometasone furoate 100 μg and 200 μg dry powder formulations
Robert Berger, Steven Li, Herbert Staudinger, Merck Research Laboratories, Merck Sharp & Dohme Corp., Kenilworth, NJ, United States

Background: Regional lung deposition of inhaled particles depends on aerody-
The impact of maximal combined inhibition. As indacaterol has demonstrated good overall safety at daily doses of up to 600 μg over a year, the magnitude of exposure increases due to drug-interactions do not raise any safety concerns for therapeutic doses up to 300 μg.
for once-daily treatment of COPD. IND is highly protein bound and metabolized by CYP450 and UGT1A1. Therefore, hepatic impairment or low UGT1A1 activity (Gilbert Syndrome genotype) could potentially alter clearance of IND through changes in metabolism and/or altered protein binding. Two open label studies were conducted to investigate these potential effects.

Methods: The first study was a single centre, parallel group, single dose (IND 600µg) study in hepatically impaired and matched healthy subjects. The second was a parallel 14 day repeat dose study (IND 200µg once-daily) in healthy subjects with different UGT1A1 genotypes – the fully functional [TA6,TA6] (6/6) genotype served as the control group, with the [TA7,TA7] (7/7) genotype (Gilbert syndrome) IND was determined in serum and urine (only first study) using a sensitive LC/MS/MS method. IND pharmacokinetics were compared to the respective control group, i.e. patients with mild and moderate impairment to matched healthy subjects, and UGT1A1 (7/7) to (6/6) genotype, with ratios of >1 indicating higher values in the test group.

Results: For hepatically impaired subjects the ratios (impaired vs. controls) for AUC, Cmax and and (amount excreted in urine) ranged from 0.77–1.01; no change in Δ-vivo protein binding was noted. In the comparison of UGT1A1 (7/7) to (6/6) genotype, the ratios for AUC and Cmax on Day 1 and Day 14 ranged from 0.90–1.18.

Conclusions: Taken together the pharmacokinetics of indacrinon are not significantly affected by mild and moderate hepatic impairment or UGT1A1 genotype.

P3989
In vitro comparison of aerosol characteristics of HFA albuterol (salbutamol) pressurized metered dose inhaler (pMDI) formulation from three valued holding chambers (VHCs)
Dirk von Hollen1, Lois Slator2, Kurt Nikander1, Ross Hatley 2.
Stockists: Rxplus Respplus, Ronald New Jersey, Inc., Parsippany, NJ, United States. 1Respirations Respiratory Drug Delivery (UK) Ltd, Chichester, United Kingdom

The OptiChamber Diamond (Diamond; Philips Respironics) VHC is a compact, anti-static device designed to facilitate effective pMDI aerosol delivery. This study compared aerosol characteristics from an HFA albuterol sulfate pMDI (ProAir HFA, 90 µg albuterol, Teva Specialty Pharmaceuticals LLC) alone and with an anti-static reproduction Diamond VHC, an anti-static AeroChamber Plus Z-Stat (Z-Stat; Monaghan Medical Corp.) VHC, and a conventional AeroChamber Plus (AC+; Monaghan Medical Corp.) VHC.

Six of each VHC brand were washed and air dried and six pMDIs were primed before use. For each run (n) the pMDI was actuated into the VHC or straight into the next generation impactor (NGI) (for pMDI alone - run before and after VHC before use. For each run (n) the pMDI was actuated into the VHC or straight into

The aerosol characteristics from the three VHCs were substantially equivalent and all removed significant potential throat deposition compared to use of the pMDI alone.

P3990
Fluticasone propionate/formoterol fumarate combination therapy has superior efficacy to both fluticasone and formoterol alone
David S. Pearlman1, Craig LaForce 2, Kirsten Kaiser 3, John Archer, Emma Baker. Centre of Clinical Pharmacology, St George’s University, University of London, London, United Kingdom

Introduction: Over half of COPD patients hospitalised for exacerbations have elevated blood glucose. Acute hyperglycaemia is associated with increased risk of death and prolonged hospital stay [Baker et al Thorax:61:284-9]. We investigated the effect of acute hyperglycaemia and insulin therapy on systemic inflammation. Methods: 8 stable COPD patients (4male, 66±6yrs, FEV1, 44±16%predicted) and 8 volunteers (8male, 24±5yrs, FEV1, 89±12%) with fasting glucose ≤7mM received an octreotide infusion to inhibit pancreatic function. Glucose and insulin were infused for 4 consecutive 60min periods to achieve Low glucose (fasting), low insulin (0.3mU.kg -1.min-1); high glucose (10mM above fasting levels), low insulin; high glucose, high insulin (1.5mU.kg -1.min -1); low glucose, high insulin. Cytokines were measured in blood sampled at the end of each 60min period using a Bedasystem (Bio-Rad).

Results: In COPD, high glucose, low insulin increased IP10 by 48 (12-181%) (median (interquartile range)); TNFa by 28 (8-54) from baseline (p=0.038). Additionally low glucose, high insulin suppressed IL-1α, IL-6, IL-16 and IL-1β to 4% 16% (p=0.05). Suppression of IP10 and TNFa was significantly greater in COPD patients than in volunteers (p=0.038).

Conclusion: Acute hyperglycaemia amplifies systemic inflammation in COPD, which could be detrimental during exacerbations. The anti-inflammatory potential of blood glucose control with insulin for exacerbations requires further investiga-
P3993
The relationship between acidic & non acidic gastro esophageal reflux disease (GERD) and asthma
Wald Tarsis1,2, Ishraw Alshamili1, Ebtessam Alabbesi2, Ebtessam Naas2, Mokhtar Soussai1,2,
1Respiratory Department, Tripoli Medical Center, Tripoli, Libya, Arab Jamahiriya; 2Pharmacology & Clinical Pharmacy, School of Pharmacy, Elzafar University, Tripoli, Libya Arab Jamahiriya

Asthma is a chronic airway disease characterized by airway constriction, inflammation, and hyper responsiveness to specific and non specific stimuli. GERD is a potential trigger of asthma. The relationship between asthma and GERD has been recognized for many years. Asthma symptoms; cough and chest discomfort may overlap with those of gastro esophageal reflux, making it difficult to distinguish between the two conditions. The study was designed to be for 3 months, with a monthly follow up visit to investigate the relation between asthma and acidic, non acidic GERD. Patients were divided to three groups; 1-Chang Life style (CLS) plus Omeprazole (G1) 2-Omeprazole (G2) 3-CLS (G3). GERD symptoms, Lung function (LF), asthma control test (ACT), and the asthma control questionnaires (ACQ) were measured for all patient at every visit. Fifty four asthmatic patients having the symptoms of GERD were enrolled in the study. Their mean (SD) age was 48.6 (12.6) years, 21 Patient started in G1, 21 Patient in the G2 and 12 patients in G3. From the initial results in table 1 it was clear that Omeprazole alone does not show the optimum improvement in the ACT. The results showed that the level of improvement in GERD symptoms was the same in G1&G3. In contrast 100% improvement in LF was seen in G1 while only 38% in G3, which may be due to the effect of the non acidic GERD.  

Table 1. Level of improvement of LF, ACQ, ACT and GERD symptoms in visit 2

In conclusion, CLS can improve the GERD symptoms but it should be combined with the PPI in order to improve the asthma control.

P3994
Effects of pantoperazole on pulmonary function tests of chronic obstructive pulmonary disease patients, with and without gastro esophageal reflux
Farhad Malek, Raheb Ghorbani, Fatemeh Yahgobi. Internal Medicine, Semnan University of Medical Sciences, Semnan, Islamic Republic of Iran

Introduction: Association between gastro esophageal reflux (GERD) and spirometric finding in chronic obstructive pulmonary disease (COPD) is subject of controversy. The aim of this investigation is to determine the effect of proton pump inhibitor (pantoprazole) on spirometric finding of COPD patient.

Material & method: In this clinical trial, 60 COPD patients were selected and according to questionnaire divide in two groups; with and without GERD (36 and 24 patient respectively). All patient treated with oral pantoprazole 40 mg daily for eight weeks. Spirometry before and after treatment was done. FEV1/FVC, FEV1, FVC, PEF were measured in two groups.

Result: Mean PEF in COPD patients with GERD before (55.4) and after pantoprazol had significant difference (55.4, 61.5 respectively) (p = 0.009) but mean FEV1/FVC, FEV1, FVC in both groups and PEF in patients without GERD had no significant difference.

Conclusion: This study showed in COPD patient, GERD treatment with 40mg pantoprazole daily improve PEF but has no effect on other spirometric parameters.

P3995
The relationship between obesity and distal airways
Gregory Marín1, Nicolas Molinari1, Isabelle Vacher1, Philippe Godard1, Pascal Chanez2, Anne-Sophie Gamez1, Arnaud Bourdin1.
1Service des Maladies Respiratoires, CHU Arnaud de Villeneuve, Montpellier, France; 2Inserm U600, DGP, Marseille, France

Introduction: Obesity is a risk factor for asthma-like symptoms. Small airway involvement has been linked to difficulties in controlling asthma. Forced Vital Capacity (FVC) fall at PC20 has been suggested as a potent marker of distal airway abnormalities. Whether obesity is associated with increased distal airway involvement in asthma is unknown.

Hypothesis: We hypothesized that FVC fall at PC20 during a methacholine challenge was increased in overweight and obese patients with asthma-like symptoms.

Methods: 298 consecutive asthmatic adult women with asthma-like symptoms underwent a methacholine bronchial provocation test according to ATS-guidelines. 202 methacholine and FVC fall at PC20 were computed for all subjects. Bronchial Hyper Responsiveness (BHR) was considered if PC20 was ≤1600g. PC15 and FVC fall at PC15 were recorded in patients who did not achieve a 20% fall of Forced Expiratory Volume in 1 second (FEV1).

Results: A logistic regression with age, smoking and Body Mass Index showed that only obesity (BMI ≥ 30) increased the risk of BHR with an odds-ratio of 4.2 (95% CI: 1.670–12.295) (p=0.0044). BMI had no impact on the relationship between FEV1s and FVC (p=0.2960). On the other hand, BMI influenced the percentage fall in FVC at the PC15 only in patients with PC20>1600g (normal 9±13%; overweight 10±16% and obese 15±32%; p=0.0073).

Conclusion: Obesity is a risk factor for BHR in women patients with asthma symptoms. FVC fall at PC20 is not affected by the BMI. Nonetheless, in obese women with asthma symptoms but negative methacholine challenge, we observed a potential involvement of distal airways measured by the FVC.

P3996
Treatment with inhaled corticosteroids (ICS) and long acting b2-agonists (LABA) combination in patients with COPD: Possible way of optimization
Tetyana Pertseva, Kateryna Gashynova. Internal Medicine, DSMA, Dnipropetrovsk, Ukraine

Respiratory muscles dysfunction in patients with COPD could affect the inhalation technique and be one of the causes of ICS and bronchodilator’s inefficacy. Aim of study: To study the efficacy of Budesonide/Formoterol combination in dry powder inhaler (Symbicort, Astra Zeneca) in patients with COPD (stage III) with signs of respiratory muscles dysfunction. 

Study population and Methods: 20 patients with COPD III (17 men, mean age 59.9±6.3 yrs), who regularly treated by high doses of any ICS and bronchodilators no less than three month made the study sample. All patients were current smokers and had signs of respiratory muscles dysfunction (Plmax <60 kPa).

At baseline all patient withdrawn from their COPD therapy and were prescribed Budesonide/Formoterol combination 3200 mcg BID. Pulmonary function tests (FEV1, MMV, Plmax, 6MWD) and plasma C- reactive protein were evaluated before and 12 months after beginning of the study.

Results: Results are present in Table 1.

*p<0.05

Conclusions: Long-term prescription of Budesonide/Formoterol combination in dry powder inhaler (Symbicort, Astra Zeneca) in COPD patients with signs of respiratory muscles dysfunction significantly increase their MMV, exercises capacity and reduce respiratory muscles fatigue and systemic inflammation.

P3997
A comparative study to evaluate the effects of salmeterol/fluticasone and formoterol/budesonide combinations on lung functions and sleep quality in asthma
Mahesh Gupta, Dhruva Chaudhary, Pooja Jindal. Pharmacology, Pt.B.D.Sharma Postgraduate Institute of Medical Sciences, Rohtak, Haryana, India Pulmonary & Critical Care Medicine, Pt.B.D.Sharma Postgraduate Institute of Medical Sciences, Rohtak, Haryana, India

Introduction: Asthma is a prevalent chronic inflammatory disorder associated with dyspnoea, deterioration of lung functions and a negative impact on the quality of sleep. Combination treatment with a glucocorticoid and a bronchodilator is the mainstay of treatment.

Aims and objectives: To evaluate the effects of two commonly used combinations salmeterol/fluticasone and formoterol/budesonide on lung functions, dyspnoea and the quality of sleep in patients with moderately severe persistent asthma.

Methods: Sixty patients of moderate severe asthma were allocated to two different treatment groups i.e. salmeterol/fluticasone and formoterol/budesonide in a prospective, open, randomized and comparative study over a period of 6 weeks. The lung functions and Borgs dyspnoea scoring were done at the baseline and at the end of 3 and 6 weeks. Quality of sleep was assessed at the same time intervals by Pittsburgh Sleep Quality Index (PSQI) for quality of sleep and day time sleepiness by Epworth Sleep Scale (ESS).

Results: Salmeterol/fluticasone and formoterol/budesonide, caused a comparable and significant improvement in the lung functions (FEV1, FVC, FEV1/FVC and PC20). The two treatments had a highly significant and comparable improve-ment in dyspnoea. Quality of sleep as assessed by PSQI and ESS also improved significantly with both the combinations.However the salmeterol/fluticasone was relatively superior in improving quality of sleep.

Conclusions: Both the combinations were equivalent in improving lung functions & dyspnoea but salmeterol/fluticasone combination was superior with respect to sleep quality.
P3998
ACCORD COPD I: Safety and tolerability of twice daily aclidinium bromide in COPD patients
Anthony D’Urzio1, Barry Make2, Edward Kerwin3, Ludmila Rekeda4, Esther Garcia Gil5, Cynthia Caracatás6, Brian Maurer7, 8; Department of Family and Community Medicine, University of Toronto, Toronto, Canada; 12; Department of Medicine, University of Toronto, Toronto, Canada; 1; Department of Medicine, University of Toronto, Toronto, Canada; 1; Medical, Allergy & Asthma Center of Southern Oregon, PC, Portland, United States; 2; Biotestast, Forest Research Institute, Jersey City, United States; 3; R&D Centre, Almirall SA, Barcelona, Spain; 4; Clinical Development, Forest Research Institute, Jersey City, United States

Introduction: Aclidinium bromide is a long-acting muscarinic antagonist in development for COPD. Safety and tolerability of aclidinium 200 μg and 400 μg BID in moderate to severe COPD patients were assessed in this Phase III study.

Methods: In this 12-week, double-blind study, COPD patients were randomised to aclidinium 200 μg, 400 μg, or placebo BID (1:1:1). Safety was assessed via adverse events (AEs), clinical laboratory measures, vital signs, and electrocardiograms (ECGs).

Results: Baseline demographics were similar across treatment groups (N=561). The number (%) of patients with a treatment-emergent AE (TEAE) was comparable between aclidinium 400 μg, 200 μg, and placebo [85 (44.7), 93 (50.5), 97 (52.2), respectively]. COPD exacerbation was the most frequently reported TEAE in all groups (12.4%, placebo; 9.2%, 200 μg; 7.4%, 400 μg). Incidence of serious AEs was low (2.2%-4.3% for all groups). Incidence of potential anticholinergic AEs (eg, constipation and dry mouth) was low (≤3%) in both aclidinium groups and comparable to placebo. The most frequently reported AEs resulting in discontinuation were TEAEs (n=7, placebo; n=4, 200 μg; n=1, 400 μg) and dyspnea (n=2 each, placebo and 400 μg). One patient in the aclidinium 400 μg group died from metastatic lung cancer but this was not considered to be related to treatment. Changes from baseline in laboratory tests, vital signs, and ECGs, were similar across all groups.

Conclusions: Aclidinium 200 μg and 400 μg BID were safe and well tolerated throughout this 12-week study with a low incidence of systemic anticholinergic adverse events, similar to placebo. There were no differences in safety profiles between the two aclidinium doses.

P3999
Differences in adherence to inhaled steroid medication in COPD
Marjolein Brusse-Keizer1, Paul van der Valk1, Job van der Palen1, 2; Pulmonary Medicine, Medisch Spectrum Twente, Enschede, Netherlands; 2; Research Methodology, Measurement, and Data Analysis, University of Twente, Enschede, Netherlands

Objective: To study whether COPD patients on medication combining an inhaled steroid with a long-acting bronchodilator show better therapy persistence than patients with inhaled steroids alone.

Methods: This study is part of a cohort study with 3 years of follow-up (COMIC study). In total 800 patients were included. Therapy adherence was recorded from patients’ pharmacy records and was expressed as a percentage that was deemed good if it was 75-125%, sub-optimal between 50-75%, and poor below 50% or above 125%.

Results: In total 664 (83%) patients used inhaled steroids and 60.8% showed good compliance. We observed a significant difference in therapy adherence between the studied medications (p<0.001). These differences were observed between Fluticasone and Budesonide (p=0.001), Budesonide and Salmeterol/Fluticasone (p=0.001), and Salmeterol/Fluticasone and Forrtomoterol/Budesonide (p=0.002). Fluticasone had the highest percentage of patients with good adherence. For Forrtomoterol/Budesonide, Budesonide and Salmeterol/Fluticasone the percentages of good adherence were almost similar, but Forrtomoterol/Budesonide showed a higher percentage of patients with poor (＞125%) adherence, while Salmeterol/Fluticasone had a higher percentage of patients with sub-optimal adherence.

Conclusions: This study showed that a significant proportion of patients with COPD is poorly adherent to inhaled corticosteroid therapy. Furthermore, adherence rates differed significantly between the studied inhaled steroids and the combinations of inhaled steroids and LABA. Contrary to our hypothesis, the adherence did not seem to be higher in the combined medications in comparison to the inhaled steroids alone, and in some cases it was even worse.

P4000
The Dutch hypothesis, implications for treatment of chronic obstructive pulmonary disease and asthma in a biomarker, monoclonal antibody world.

Experience with IgE and omalizumab in a small pulmonary practice
Mary Lynn Ebbert, Kristin Elliott, Alicia Redford Elliott, Syed Ali, Nipurn Shah, Sridhar Reddy. St. Clair Pulmonary & Critical Care, 1210 10th Avenue, Port Huron, MI, United States

In 1961, Orie and colleagues from the University of Groningen in the Netherlands hypothesized that the various forms of airway obstruction, such as asthma, chronic bronchitis and emphysema, should be considered not as separate entities but as different expressions of one disease entity. In a pulmonary practice patients with a physician diagnosis of chronic obstructive pulmonary disease (COPD) had physiologic and biochemical evaluation as part of their routine workup. They were treated with oralalumab if they were symptomatic despite adequate conventional treatment and had an elevated IgE level. Patients with COPD (n=60) who were on treatment with oralalumab for at least 6 months were asked to fill out a questionnaire from which their symptom scores (1-4) and satisfaction scores (1-5) were extracted. There was statistically significant improvement in the amelioration of both symptoms and increase in satisfaction scores (p was less than 0.01) with treatment with oralalumab. This year being the 50th anniversary of the Dutch Hypothesis, it may be appropriate to revisit this issue. Patients with COPD may benefit from evaluation and treatment with monoclonal anti-IgE antibody therapy. Randomized placebo controlled, double blinded trials are needed to help further define the role of anti IgE therapy in patients with COPD. Subsequently, the broad use of biomarkers to evaluate need for monoclonal antibody therapy may need to be reconsidered. To the treating physician and the patient the treatment outcome is more relevant than the actual diagnosis.

P4001
The effect of L-arginine on ciliary function in primary ciliary dyskinesia (PCD)
Robert Hirst, Naomi Martin, Mina Fadaee-Shohada, Claire Smith, Gwyneth Williams, Andrew Rutman, Chris O’Callaghan. Immunity, Infection and inflammation, University of Leicester, Leicester, Leicester, United Kingdom

The nitric oxide synthase substrate, L-Arginine (L-Arg), has been shown to stimulate ciliary beat frequency (CBF) in PCD [1]. However, it is unclear if this effect was universal to the common phenotypes of PCD or if it could correct the ciliary beat pattern.

Aims: To study the effect of L-Arg on the ciliary function in 3 different phenotypes of PCD.

Methods: Nasal brush biopsies were taken from 15 PCD patients (5 inner arm, 7 outer arm, and 3 transposition defects) and 3 controls. The strips of ciliated epithelium were subjected to medium 199 Control or 5nM L-Arg for 10min at 37°C. The cilia were visualised by a light microscope and recorded using a speed video. The recordings were analysed in a blinded fashion and were replayed at reduced rate for determination of CBF and cilia tip distance travelled.

Results: L-Arg treatment significantly (p<0.05) increased the CBF from (5.6±1.3 Hz) to 8.3±1.1Hz. L-Arg treatment changed the cilia (from 0.35±0.09 to 0.52±0.12 cm) in all 15 PCD patients studied. Individual phenotypes of PCD showed a variable response to L-Arg. CBF and tip distance travelled by the inner dynein arm defects were significantly (p<0.05) increased by L-Arg treatment (CBF from 6.3±1.2 to 9.6±1.1Hz; tip distance from 0.44±0.15 to 0.67±0.2cm). The CBF and tip distance of the cilia from the other defects were not statistically different.

Conclusion: L-Arg increased CBF and ciliary tip distance in PCD, an effect that was increased in those with inner dynein arm defects. The mechanism and physiological significance of the changes remain to be determined.

P4002
Formoterol, but not indacaterol, induces transient hypoxemia in severe COPD
Roberto W. Dal Negro, Paola Pescatori, Claudia Micheleto, Silvia Tognella. Respiratory Unit, Orlando Hospital, Bussolengo, VR, Italy

β2-agonists are effective options in COPD. Mainly the short-acting compounds can rapidly induce a transient hypoxemia by affecting pulmonary vasculature. Most recent long-acting β2-agonists (LABA) were poorly investigated from this point of view.

Aim: To measure and compare the hypoxic effect of Formoterol (F) and Indacaterol (I) in moderate-to-severe COPD.

Methods: 24 ex-smoker patients (18m; mean age= 70.3±4.6; range 51-76; mean FEV1/FVC = 52.2% pred. ±9.0sd; mean FEV1=50.0±11.8sds) were studied after their written informed consent according to a double-blind, double-dummy, cross-over, randomized design. Active drugs were F120mcg and I300mcg, assayed in two different days, with a 36h-interval in between. Arterial blood was drawn in baseline; after 5’, and 30’ from F and I; FEV1 was measured at the same times.

Statistics: Friedman’s analysis of variance by ranks and Page’s test for trend, and p<0.05 accepted.

Results: See Table 1 (means ± sd).

Table 1

<td>54.4 ±11.5</td>
</tr>
</tbody>
</table>

Discussion: Both F and I induced rapidly an equal (pneas) and significant (p<0.001) bronchodilation. The trends for PaO2 changes were significantly different with the
two drugs (p<0.04): F induced a sudden, substantial hypoxemia lasting at least for 30 s, changes following I were negligible.

Conclusions: 1) the safety of I1 is emphasized; 2) the peculiar chemical structure of I1 and the fact that it behaves as a nearly full β₂-adrenoceptor agonist likely contribute to explain its ineffectiveness in terms of β₂-agonist hypoxemia in COPD.

P4003
An audit on emergency oxygen administration and safety issues
Rajesh Kumar Yadavalli, Nadine Anwar, Brian Bradley. Thoracic Medicine, Royal Bolton Hospital, Bolton, Lancashire, United Kingdom

Background: British Thoracic Society (BTS) guidelines on Emergency Oxygen (O2) in 2008 highlighted the importance of safe prescription and administration of O2. We audited our practice focusing on the documentation, prescription and complications in a busy district general hospital.

Methods: Audit was performed on patients admitted to the medical admission unit over a period of 3 months between Jan 2010 to Mar 2010. Patients who had O2 administration order in the unit chart and received O2 were selected and monitored from admission to discharge.

Results: 56 patients in total were studied. 46% had assessment for the risk of Co2 retention before O2 started. Only 34% had documentation of target O2 saturations. Documentation of Device in 66%, Flow in 71% and Paco2 in 32% of cases. 96% of drug charts had no prescription of O2. There is no documentation how long O2 should be given in all the cases. 20 (35%) patients had inappropriate administration of O2; No need for O2-10, More O2 than needed-9 and Less O2 than needed-1. 3 patients developed Type 2 respiratory failure and needed Non-invasive ventilation. There were no mortalities.

Conclusions: We identified safety issues whilst administering Emergency O2 and need to improve in our documentation, prescription on drug charts and administration. Patients at risk of Co2 retention would have arterial blood samples after starting O2. Drug charts were modified adding oxygen in 2 areas: Regular and PRN sections and also include device, flow, FinO2, target saturations and how long to give O2. Flow charts on how to administer and adjust O2 were placed in all the wards including medical admission units.

Repeated mandatory educational training on O2 administration to all medical, nursing and allied health care professionals were started.

P4004
No difference observed in the risk of malignancy in patients exposed to omalizumab compared with controls
Roland Buhl1, 2, Carsten Vetter1, 2, Martin Blogg3, Jin Zhu1, Mark D. Eisner4, Janice Canvin5, William Busse6, 1Pulmonary Department, University Hospital, Johannes Gutenberg-University, Mainz, Germany; 2Respiratory Medicine, Novartis Pharmaceutical Corporation, East Hanover, NJ, United States; 3Respiratory Medicine, Novartis Horsham Research Centre, Horsham, West Sussex, United Kingdom; 4Respiratory Medicine, Genentech Inc., South San Francisco, CA, United States; 5Department of Medicine, University of Wisconsin Medical School, Madison, WI, United States

Previous pooled data from the omalizumab clinical trial programme (Phase I–III clinical studies) showed a numerical imbalance in cancers arising in omalizumab recipients. The incidence of malignancies in the omalizumab group was similar to that expected in the general population but higher compared with control, raising a concern on the effect of omalizumab on the risk of malignancy. 7432 patients (4254 omalizumab, 3178 placebo) were included. Total observation times censored at first malignancy were 3382 and 2473 patient-years for omalizumab and placebo, respectively. Malignancy rates per 1000 patient-years were 3.56 (4 / 1124) and 3.50 (6 / 1715) for control and omalizumab, respectively. The difference between both groups was similar across the groups (1.20% to 4.56% to 4.45%, respectively).

The difference between both groups was similar across the groups (1.20% to 4.56% to 4.45%, respectively).

P4005
The ATTAIN study: Safety and tolerability of aclidinium bromide in chronic obstructive pulmonary disease
Eric D. Bateman1, David Singh2, Paul W. Jones3, Alvar Argüst4, Rosa Lamarca5, Gonzalo de Meaqué1, Cynthia Caracata6, Esther Garcia-Gil7, 1Division of Pulmonology, Department of Medicine, University of Cape Town, Cape Town, South Africa; 2Medicines Evaluation Unit, University of Manchester, Manchester, United Kingdom; 3St George’s, University of London, London, United Kingdom; 4Thorax Institute, Hospital Clinic and CIBER Enfermedades Respiratorias and Pneumología, CIBER-Cuab-Centra, Barcelona, Spain; 5R&D Centre, Almirall, Barcelona, Spain; 6Clinical Development, Forest Research Institute, NJ, United States

Introduction: Aclidinium bromide is a long-acting muscarinic antagonist in clinical development for chronic obstructive pulmonary disease (COPD).

Aims: To assess the safety and tolerability of aclidinium 200 μg and 400 μg twice-daily (BID) in patients with COPD.

Methods: This 24-week, double-blind, Phase III study (NCT01001494) randomized patients to receive aclidinium 200 μg, 400 μg or placebo BID (1:1:1). Adverse events (AEs), clinical laboratory measures, vital signs and electrocardiograms (ECGs) were assessed.

Results: Baseline demographics were similar across all groups (safety population, N=819). The incidence of treatment-emergent AEs (TEAEs) was similar for placebo, aclidinium 200 μg and 400 μg (37.1%, 54.5%, 53.5%, respectively). COPD exacerbation was the most frequently reported TEAE in all groups (placebo, 20.5%; 200 μg, 15.9%; 400 μg, 14.1%). TEAEs reported by ≥2% of patients and with a higher incidence in the aclidinium group were: headache, nasopharyngitis, diarrhoea, cough and toothache. The incidence of TEAEs leading to discontinuation was similar across the groups (3–4%). COPD exacerbation was the most frequent reason (placebo, n=5; 200 μg, n=3; 400 μg, n=4). The incidence of anticholinergic variable AEs (≥2.5% for each group) and of general serious AEs (4–5.5% of all groups) was low in all treatment arms. Changes in laboratory tests, vital signs and ECGs were similar between groups.

Conclusions: Aclidinium 200 μg and 400 μg were well tolerated with an incidence of AEs similar to placebo. There were no differences in the safety profiles between the aclidinium dosages.

Objective: Investigate the possible relationship between the primary endpoint and previous ICS use.

Methods: Two post hoc analyses were conducted: one to determine whether children previously using different ICSs (p<0.004) were similar to placebo in response to ongoing treatment with fluticasone propionate.

Results: There was no significant difference in response to MF in 296 children previously using different ICSs (p>0.003). Most children (160; 54%) previously used FP 88–440 μg/d (median, 176 μg/d). Post hoc analysis of treatment effects in the FP subgroup determined that changes in FEV1 were similar across all groups (3–4%). No significant difference was found in the response to MF in 296 children previously using different ICSs (p=0.0372). Most children (160; 54%) previously used FP 88–440 μg/d (median, 176 μg/d). Post hoc analysis of treatment effects in the FP subgroup determined that changes in FEV1 were similar across all groups (3–4%). No significant difference was found in the response to MF in 296 children previously using different ICSs (p=0.0372). Most children (160; 54%) previously used FP 88–440 μg/d (median, 176 μg/d). Post hoc analysis of treatment effects in the FP subgroup determined that changes in FEV1 were similar across all groups (3–4%).
Background: A combination of fluticasone propionate and formoterol fumarate (FLUT/FORM; flutiform®) in a single aerosol inhaler has been developed. This study investigated the efficacy and safety of the combination compared to its individual components administered concurrently (FLUT+FORM).

Methods: Patients aged 12 years or over (N=210) with mild to moderate-severe persistent, reversible asthma were randomised in a 1:1 ratio to 12 weeks of twice daily treatment with one of two doses of FLUT/FORM or FLUT+FORM in an open-label, parallel group, multicentre study in Europe. Total daily doses were FLUT/FORM: 200/20g or 500/20g; FLUT+FORM: 200/24g or 500/24g. The primary objective was to show non-inferiority of FLUT/FORM compared to FLUT+FORM based on post-dose forced expiratory volume in 1 second (FEV₁) on Day 84.

Results: FLUT/FORM had comparable efficacy to FLUT+FORM in the treatment of asthma with mean FEV₁, 30 to 60 minutes post-dose on Day 84 of 2.6L in both groups (per protocol groups; least squares mean difference: -0.03 L; 95%CI: -0.148, 0.081; p=0.004). The lower limit of the 95% CI was above the pre-defined non-inferiority threshold of \( \geq -0.2 \). Analysis of other pulmonary function tests, patient reported outcomes, rescue medication use, asthma exacerbations and quality of life questionnaires were also comparable. The safety profiles of the two study groups were similar overall.

Conclusions: Fluticasone/formoterol combination therapy has comparable efficacy to its individual components administered concurrently. The safety and tolerability profile of fluticasone/formoterol combination therapy is similar to that of its individual components.

P4008

Body mass index, disease control and airway inflammation in asthmatic patients

Roberta Pisi, Marina Aiello, Pauni Giorgetti, Dario Olivieri, Alfredo Chetta. Department of Pulmonary Medicine, Hospital for Parma, Parma, Italy

Background: The association between overweight and asthma remains controversial.

Aim: To investigate the relationship between body mass index (BMI), disease control and airway inflammation in an asthmatic population.

Methods: We consecutively studied 408 patients (43±16 yr; 248 F). In all patients, BMI, spirometry, Asthma Control Test (ACT) and Fractional Exhaled Nitric Oxide (FeNO, ppb) were measured.

Results: 205 patients had a BMI > 25 kg/m² and, as compared to those with normal BMI, had lower values of FVC, FEV₁, FEV₁/FVC, FEF₂₅, FEF₂₅ and FEF₇₅ (p<0.05 for each comparison). The ratio between the mean values of the patients with controlled asthma (ACT ≥ 20) and that of patients with poor controlled asthma (ACT < 20) was significantly lower in patients with increased BMI (106/99 vs 131/71; \( r² = 7.227, p<0.01 \)). In patients with increased BMI, the odds ratio of uncontrolled asthma was 1.723 (95% CI = 1.157-2.566). No difference was observed in FeNO values between the two groups of patients.

Conclusions: Our results show that in an asthmatic population, the increase in BMI is associated with poor spirometry and worse disease control, but not with FeNO values.

P4009

How does obesity correlate with severe asthma?

David Gibbons, Winston Banyan, Hofmann Markus, Regan Suzanne, Pankaj Bhavsar, Kian Fan Chung, Andrew Menzies-Gow. University Hospital of Parma, Parma, Italy

Introduction: 10% of asthmatics have refractory disease. Cluster analysis has identified that BMI is a factor in defining phenotypes of severe asthma [1]. Obesity antedates asthma diagnosis [2], suggesting that obesity has a pathophysiological role.

Last year we reported the outcome of 115 patients with severe, treatment refractory asthma (ATS, 2000). This study looks at data from 374 patients from 4 UK centres, collected as part of the National Registry for dedicated UK Difficult Asthma Services.

Methods: Patients were divided into three groups by BMI: 18.5 to 24.9, 25 to 29.9 (overweight), and ≥30 (obese).

Results: The table below highlights demographic data, lung function, steroid use and bone density between groups.

Conclusion: Severe asthmatics are more likely to be female although this does not appear to correlate to BMI. Raised BMI is associated with more GORD, greater use of PPI’s, increased KCO, but a reduction in aspirin sensitivity, and appears to be protective against osteoporosis at the neck of femur.

P4010

Effects on adrenal function of a new combination of fluticasone propionate/formoterol fumarate administered to asthmatic patients and healthy subjects

Michael Tamm1, Kirsten Kaiser2, Brigit Grobbe3, Mark Lomax3, Department of Pneumology, University Hospital, Basel, Switzerland; 3Clinical and Regulatory Development, SykePharma AG, Muttenz; Switzerland; 1European Medical Science, Mundipharma Research Ltd., Cambridge, United Kingdom

Background: Corticosteroid treatment is known to affect adrenal function via suppression of the hypothalamic-pituitary-adrenal axis. This effect was assessed for a new asthma therapy combining the corticosteroid fluticasone (FLUT) with formoterol (FORM) in a single aerosol inhaler (FLUT/FORM; flutiform®).

Methods: Healthy subjects and patients with mild to severe asthma were treated for 4 to 12 weeks with FLUT/FORM (100/10g, 250/10g, or 500/20g b.i.d.) in 3 randomised, parallel-group studies comparing FLUT/FORM with FLUT, FLUT+FORM from separate inhalers, or placebo. The endpoints were changes in urinary and serum cortisol levels from baseline to end of study.

Results: No significant differences were observed in mean urinary cortisol levels with FLUT/FORM 100/10g (N=38; mean 21.51μg/24h; p=0.733) or FLUT/FORM 250/10g (N=40; mean 24.01μg/24h; p=0.510) compared with placebo (N=39; mean 21.95μg/24h). In a study using FLUT/FORM 100/10g or 250/10g, patients had similar mean urinary cortisol levels at baseline and end of study (N=27; 5.1 vs 6.1nmol/L). The corresponding mean serum cortisol levels were 372.9 vs 412.6nmol/L (N=104). Healthy subjects given FLUT/FORM 500/20g had a decrease in both urinary and serum cortisol levels at end of study but this was less than with FLUT 500/2g+FORM 24g (urinary: N=24; 13 to 7 to 10 nmol/L; serum: N=24; 399 to 272nmol/L vs 430 to 154nmol/L).

Conclusions: Fluticasone/formoterol 100/10g or 250/10g showed no significant changes in urinary or serum cortisol levels. Fluticasone/formoterol 500/20g had some effect on adrenal function but less than FLUT+FORM given at the same nominal dose.

416. Update on monitoring airway diseases

P4012 Assessing the burden of asthma and COPD in Salford UK: Retrospective analysis using a whole population electronic medical record
John New1, Mark Delderfield1, Norman Stein1, Stephanie Austin1, Jorgen Vobso1, Ashley Woodcock2, North West e-Health, Salford Royal NHS Trust, Salford, United Kingdom; 2Manchester Academic Health Sciences Centre, University Hospital of South Manchester, Manchester, United Kingdom; 3School of Translational Medicine, University Hospital of South Manchester, Manchester, United Kingdom

There is limited information on predictors of disease progression and their association with managing asthma and COPD in primary care. This retrospective, real-life, observational cohort study used an electronic medical record (EMR, all residents in Salford) to evaluate patient characteristics and health resource utilisation in asthma and/or COPD patients ≥18 years of age. The study included an open cohort of 180,493 adults ≥18 years, the prevalence of asthma was 4.4% of COPD 2.5%. Most commonly prescribed controller medications were: EMR, Asthma: ICS 42%, LABA 40%; COPD: ICS and LABA 56%, LAMA 36%. Resource utilisation was greatest in patients with a history of exacerbations in 2008:

12 month resource utilisation data per 100 person-years during 2009, subsets predefined from data during 2008

Conclusions:
- EMR collected during routine clinical care can quantify the burden of asthma/COPD.
- EMR can identify exacerbations (oral steroids/antibiotics or hospitalisation).
- EMR could evaluate differences in disease outcomes with novel treatments.

P4013 Lipid peroxidation products-diagnostic utility in differentiation of pleural effusions
Jasna Lalic1, Ivan Lalic1, Ivanka Djordjevic2, Milanka Ljubenovic1,1 Centre of Medical Biochemistry, 2Clinic for Lung Diseases, Clinical Centre, Nis, Serbia

Introduction: Biochemical analysis of pleural fluid are the first step in differentiation of pleural effusions (PE) into exudates (E) and transudates (T). Therefore, new parameters have been used to improve the accuracy of diagnosis. Free oxygen radicals (FOR) are known to produce damage in many biological tissues. FOR exert their cytotoxic effect by causing lipid peroxidation which is believed to be responsible for the exudation of fluid into the pleural space.

Aims: Based on this idea, the aim of this study was the determination of malondialdehyde (MDA), as the final product of lipid peroxidation in pleural fluid (MDAP) and in serum (MDAs) and pleural fluid to serum MDA ratio (MDAPvs); and to compare our results with other well established criteria.

Methods: We analysed 52 patients with PE who were classified as E(32) and T(20) by Light’s criteria. MDA was measured by spectrophotometric method with TBA. Results: Our results showed significant increase of MDAs level in both groups of patients: E (7.7±1.29 μmol/L) and T (7.75±0.89 μmol/L) in comparison with control group (5.10±0.87 μmol/L) p<0.001. MDAP level in E (5.16±1.28 μmol/L) was also significantly increased than in T (2.67±0.61 μmol/L), p<0.001. Similarly, MDAPs ratio was significantly higher in E (0.72±0.17 μmol/L) than in T (0.34±0.05 μmol/L); p<0.001. Using a cut-off value (0.4) for MDAPs ratio (sensitivity 95% and specificity 90%) effectively separated E from T.

Conclusion: Based on these results we can conclude that determination of lipid peroxidation products may be useful in diagnosis-differentiation of pleural effusions into E and T. It is of significance for the correct treatment of patients.

P4014 Challenge already established: Identification of risk factors for early need for ventilatory support in Duchenne muscular dystrophy
Leonardo Augusto Tavares1, Maria Teresa Fonseca1, Laura Maria Lamzar2, Alessandra Lucia Machado1, Vera Lucia Anastacio1, 1Neuromuscular Disease Program/Complex Disease Unit, John Paul II Child Hospital/Hospital Foundation of Minas Gerais State, Belo Horizonte, Minas Gerais, Brazil; 2Neuromuscular Disease Program, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Introduction: Duchenne muscular dystrophy (DMD) is a genetic, progressive and disabling disease. Functionally, it puts a restrictive respiratory disorder. Faced with signs and symptoms of chronic respiratory failure should be started as ventilatory support (VS), usually in the second half of adolescence, which was initially due to nocturnal hyperventilation. Ventilair Program (VP) assist DMD patients VS-users and VS-non users in John Paul II Child Hospital/Hospital Foundation of Minas Gerais State (IPJCH/HFHEMIG).

Objective: To identify among patients with DMD assisted by the VP/PIPC/ HFHEMIG, possible risk factors for the need early VS.

Patients and methods: Cohort study between 2002-2010. Clinical score 20 points to 1 point for each sign of hyperventilation. Risk factors associated with VS were evaluated in multivariate analysis by proportional hazards model of Cox. Multivariate model of Cox: all variables p<0.20 in univariate analysis. Final level of significance p<0.05. Group A: 16 (23.8%) VS-users; group B: 46 (74.2%) VS-non-users. Group C: loss of ambulation before 10 years and group B after 10 years. Results: Statistically significant difference in univariate analysis for risk factors: body mass index: p=0.15, difficulty swallowing (p=0.05), moderate to severe scoliosis (p=0.01), age at loss of ambulation (p<0.001) and clinical score 0.17 and >17 points (p<0.001). Cox final model: clinical score: relative risk 1.89 (p=0.001) and loss of ambulation before 10 years: relative risk 2.04 (p=0.01).

Conclusion: Age at loss of ambulation and clinical score were independent risk factors for the installation of VS before 20 years of age of DMD patients.

P4015 ISAAC Malta: Changes in geographical distribution of wheezing children in Malta between 1994 and 2002
Peter Fsadni1,2, Claudia Fsadni 1, Maxine Montefort1, Stephen Montefort 1,2, 1Department of Medicine, Mater Dei Hospital, Msida, Malta; 2Faculty of Medicine and Surgery, University of Malta, Msida, Malta

Introduction: Malta is one of the centres which participated in the Phase 1 and 3 of The International Study of Asthma and Allergies in Childhood (ISAAC).

Aim: To investigate changes in the geographical distribution of wheezing in the Maltese Islands.

Methods: ISAAC Malta Phase 1 was carried out in 1994 with 3506 participants from 24 schools for the 5 to 8 year old age group and 4184 participants from 25 schools for the 13 to 15 year old age group.

ISAAC Malta Phase 3 in 2001 studied 3800 from 44 schools and 4139 children from 18 schools in the 5 to 8 and 13 to 15 year old age groups respectively.

Results: In the younger age group there was an increase from 8.8% to 14.8% (p<0.00001) in the total prevalence of current wheezing between 1994 and 2001. Most geographical regions of the Maltese islands reported an increase in wheezing with the Central East (10.2% vs 23% p<0.00001), Grand Harbour (8.5% vs 21.2% p<0.0005), East (8.6% vs 22.5% p<0.00001) and Central North (6.5% vs 16.3% p<0.0004) regions having the largest increases. The prevalence of current wheezing in the older age group remained stable (16% to 14.6% p=0.08). A decline in current wheezing (p=0.5) was observed in Central West (16.3% vs 11.2%), West (17.5% vs 12.6%) and South (14.8% vs 11.2%) while three regions reported an increase in wheezing.

Conclusions: A strong genetic component together with environmental factors must influence the geographical distribution of wheezing in the Maltese Islands.

P4016 The relationship between sleep respiratory disorder and daytime PaO2 in OSAS and in overlap syndrome
Donato Lacedonia1, Francesco Salerno2, Roberto Sabato1, Patrizia Guido1, Lucia Forte1, Giovanna E. Carpanzano1, Mauro Carone2, Maria P. Foschino1, 1Occupational and Medical Sciences, Section of Respiratory Diseases, Foggia, Italy; 2Fondazione, Salvatore Maugeri, Cassano, Italy

OSAS and COPD are often associated with daytime hypoxemia. Overlap Syndrome (OS) increases the risk of daytime hypoxemia. The aim of this study was to investigate the mechanisms which could justify the low oxygen’s level in these patients and the effect of CPAP therapy.
Background: Oxygen is one of the most commonly used drugs in a hospital setting. National and International Thoracic Society guidelines recommend improvement of oxygen use in hospital settings aimed at standardising practice in the setting. The British Thoracic Society (BTS) published guidelines in Oct 2008 that advocated for the use of CPAP therapy in the hospital setting to guide oxygen use and delivery of oxygen therapy. An audit was carried out in 2010 in East Kent Hospitals University Trust (EKHUT) to assess current practice of prescription and use. In total 740 patients were audited.

Methods: Surveys were given to staff as part of a discharge questionnaire and medical notes were used to gather information about oxygen prescription and use. In total 740 patients were audited.

Results: 11% of patients in EKHUT were using oxygen at the time of the audit. This is comparable with national figures of 17.5%. Only 30% had formal prescription and use. In total 740 patients were audited. 11% of patients in EKHUT were using oxygen at the time of the audit. This is comparable with national figures of 17.5%. Only 30% had formal prescription and use. In total 740 patients were audited.

Conclusion: This audit has highlighted the need to raise awareness in all medical and nursing staff of BTS recommendations and educate health professionals to deliver oxygen in a more standardised and safe manner.

P4018
Computed tomography of the chest as a way to diagnose and monitor treatment of patients with sarcoidosis in Omsk, Russian Federation
Dmitriy Petrov 1, Nikolay Ovsyannikov 1, Vadim Gershevich 2
1 Pulmonology Department, Omsk State Hospital #1, Omsk, Russian Federation; 2 General Surgery with Course of Thoracic Surgery Department, Omsk State Medical Academy, Omsk, Russian Federation

Purpose: To evaluate lung injuries with computed tomography (CT) for diagnosis and therapeutic follow-up of patients with sarcoidosis (S).

Methods: 247 consecutive patients with biopsy-proven S were retrospectively included respectively. All patients underwent chest CT scan (CS) twice. Current asthma control and CS were re-examined by CT to assess response to CS treatment at 3 and 6 months.

Results: 563 consecutive OSAS patients were enrolled. According to pulmonary function test they were divided in 2 groups. Group 1: 473 OSAS/COPO+/-; Group 2: 90 patients OSAS/COPO+/. All patients underwent blood gases, nocturnal polysomnography, post-bronchodilator spirometry. A multivariate analysis was performed to evaluate which were the factors that determined the diurnal PaO2. The groups were matched for BMI, for age and AHI. OS group showed lower level of daytime PaO2 compared with OSAS patients (71±6.9 to 79.3±11 mmHg, p<0.001), the alveolar-to-arterial oxygen partial pressure difference (AaDO2) was higher in OS than in OSAS (28.3±9 vs 22.6±7 mmHg, p<0.05), the TST90 was higher in OS (34.8±35.5 vs 24%±26). In OS group diurnal PaO2 correlated with age (coef=0.41) with AHI (0.18) and with FEV1 (0.21), while in OSAS group the correlation was found with age (coef=0.27), FEV1 (0.07) and mostly with BMI (0.46), but not with AHI. In both groups, patients with good compliance (~48% of time) of CPAP improve daytime PaO2 (p<0.001) whereas, in patients with poor compliance PaO2 was reduced (p<0.001).

Our data suggest that daytime hypoxemia in OSAS patients is largely determined by the increased weight of body. In the overlap patients daytime hypoxemia has a more complex origin. However CPAP therapy has been shown to improve daytime PaO2 values both in OSAS than in OS patients with good compliance.

P4019
Ventilation heterogeneity is associated with asthma control in adults
Claude Farah 1,2, Sue Downie 1, Jessica Kerimova 3, Nathan Brown 3, Kate Handaker 1,2, Gregory King 2,3, Norbert Berend 1,2, Cheryl Salome 1,2.
1 Woolcock Institute of Medical Research, University of Sydney, Sydney; 2 CRCAA, Co-operative Research Centre for Asthma and Airways, Glebe, 3 Dept of Respiratory Medicine, Royal North Shore Hospital, Sydney, Australia

Background: The clinical relevance of increased ventilation heterogeneity, a marker of small airways damage in asthma is unclear. Ventilation heterogeneity is an independent determinant of airway hyperresponsiveness, improves with bronchodilators and inhaler corticosteroids (ICS), and worsens during exacerbations but its relationship to asthma control is unknown.

Objective: To determine the association between ventilation heterogeneity and current asthma control before and after ICS treatment.

Methods: Asthmatic subjects had the 5-item symptom-only asthma control questions (ACQ) and lung function measured at baseline and after 3 months of high dose ICS treatment. Ventilation heterogeneity was measured as Scond and Sacin by multiple breath nitrogen washout. Scond and Sacin represent ventilation heterogeneities in small airways where gas transport occurs mainly by convection or diffusion, respectively. Spearman correlations and paired t-tests were performed.

Results: At baseline (n=110, 64 female), ACQs correlated with Scond (r=0.30, p=0.002) and with Sacin (r=0.21, p=0.03). After treatment (n=55), the mean (SD) ACQs improved (1.31 (0.71) to 0.76 (0.77), p<0.0001), Scond improved (0.068 (0.035) to 0.053 (0.033) L1, p<0.0001) but Sacin did not significantly change (0.147 (0.07) to 0.142 (0.06) L1, p=0.28). The change in ACQs correlated with changes in Scond (r=0.34, p=0.02) and in Sacin (r=0.33, p=0.01).

Conclusions: Current asthma control is associated with markers of small airways disease. Improvements in ventilation heterogeneity with anti-inflammatory therapy are associated with improvements in symptoms. Sensitive measures of small airways function may be useful in monitoring therapy in asthma.
Methods: Data for the first 67 patients to undergo FENO testing with NOX MINO in a secondary care adult asthma clinic were collected. ICS doses are expressed as mean ± SD daily beclomethasone equivalent.

Results: FENO was performed in 17 patients undergoing diagnostic workup for asthma. The need for histamine challenge testing was prevented in 10 patients with normal spirometry and FENO; six patients were subsequently discharged who would otherwise have required follow-up. Of the 50 patients with persistent asthma, receiving ICS, FENO was high (>45 ppb) in 15, intermediate (25–45 ppb) in 8 and normal (<25 ppb) in 27. FENO altered decision-making in 22 (44%) patients by permitting a reduction (n=5) or maintenance (n=12) in ICS in patients who would otherwise have had their dose increased, and a reduction in 7 patients who would have had their ICS dose maintained. There was more appropriate matching of ICS dose changes to FENO, with a reduction in ICS dose in patients with normal FENO (164±9.87µg to 138.1±92.6 µg; p=0.017), with no change in the intermediate FENO group (1738±639 µg to 1800±513 µg; p=0.35), and an increased dose in the high FENO group (2140±767 µg to 2733±683 µg; p=0.007).

Conclusions: In almost half of patients tested, FENO prevented the need for a bronchial challenge testing in patients undergoing diagnostic workup for asthma and permitted reduction in overall steroid burden in patients receiving ICS contraception. This approach will be followed to see what effect FENO has on overall asthma control and steroid dose burden.

P4022 Functional, clinical evolution and cellular inflammatory pattern in induced sputum in patients with difficult-to-control asthma

Background: Patients with difficult-to-control asthma (DCA), show several phenotypes. Our aim is to identify phenotypic modifications over time in this population.

Materials and methods: Prospective study in subjects with DCA. Clinical status was evaluated by Asthma Control Test (ACT), exacerbations/6 months (E6M) and relief therapy use (RTU). Daily corticosteroids dose (inhaled -ICs- or oral -OCs-) was calculated as the average of the last 6 months. Treatment was titrated to achieve the lowest possible dose. Patients were followed up for 6 months. Results: 26 patients with DCA were enrolled. Outcomes at initial time (T0): ACT 15 (6), E6M 1.8±1.0, RTU 1.2±0.8. Day 6 months (T6): 2 patients improved ACT in three or more points. The patients improve ACT had a paucigranulocytic pattern. Patients with similar or poor ACT had an eosinophilic pattern in sputum. At T0 microorganisms were isolated in 2 of 3 patients with controlled asthma and after 6 months the bacterial cultures were negatives but the inflammatory pattern in sputum changed to paucigranulocytic form. In 2 patients with uncontrolled asthma were observed MP and their pattern changed to mixed form at T6.

Conclusions: 50% patients with DCA who improved their ACT on 6 months, show a paucigranulocytic pattern in sputum. Patients who didn’t improve showed aggressive patterns (eosinophilic, neutrophilic and mixed). There are individualized changes to benign or aggressive patterns in sputum without improvement or worsening expected in ACT. Some patients had microbial colonization associated with aggressive patterns in sputum.

P4023 Relationship between circulating TH2 prevalence and asthma control in pregnant asthmatics

Andras Bikoly1, Noemi Ezres1, Amiko Bohacs1, Arom Cseh2, Gergely Toldi1, Veronika Muller1, Janos Rigo1, Barna Varasztheij2, Gyorgy Losonczy1, Lilla Tamasi1, Ilidko Horvath1, Department of Pulmonology, 21st Dept of Pediatrics, 31st Dept of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary

Introduction: Asthma is one of the most common diseases complicating pregnancy and a risk factor for several maternal and fetal complications. It was previously shown that altered systemic inflammation present in pregnant asthmatics may contribute to the outcome of the pregnancy; however less has been known about the relationship between circulating T cell profiles and clinical characteristics of asthma in pregnant patients.

Aim: The aim of this study was to assess the relationship between various T cell profiles and clinical variables in asthma during gestation, including lung function, exhaled nitric oxide, and asthma control.

Methods: The prevalence of TH1, TH2, and Treg lymphocyte subsets was identified by cell surface markers and intracellular FoxP3 staining in 22 pregnant women in the second or third trimester suffering from persistent allergic asthma. FENO, Asthma Control Test (ACT) total score and lung function were also evaluated.

Results: A positive relationship was observed between TH2 cell prevalence and FENO in 21 (69%) of the 30 patients tested. The relationship was not observed between TH2 cell prevalence and ACT total score (<0.48, p=0.03), while no relationship was found between TH2 prevalence and FENO or lung function parameters. However, none of the other T cell subsets were correlated to any of the clinical characteristics (FENO, lung function, or ACT; p>0.05).

Conclusions: The level of asthma control related to blood TH2 cell prevalence suggests a direct relationship between symptoms and cellular mechanisms of asthma in pregnant patients.

The study was supported by OTKA 68808.

P4024 Chronius: A new wearable monitoring system for COPD patients

Leonardo Govoni1, Fabio Ciancitto2, Teresa Renda2, Francesca Pefolli2, Monica Picarello1, Antonio Corrado1, Raphaelle L. Delaccia1, Dipartimento di Biogenegneria - TBM LAB, Politecnico di Milano, Milano, Italy; 2Fraunhofer Institute for Integrated Circuits IIS, Fraunhofer Institute, Erlangen, Germany; 3Respiratory Intensive Care Unit and Thoracic Physiopathology Laboratory, AOI Careggi, Florence, Italy; 4Information Engineering Dept., Università di Padova, Padova, Italy

CHRONIOUS is a FP7 European Community project which also includes a new wearable platform for home monitoring of people suffering from chronic diseases. The wearable system is composed of a shirt made of washable stretch-material into which are sewn 4 ECG electrodes, two bands for respiratory inductive plethysmography (RIP) and a reflectance pulseoximeter. The data coming from the sensors are collected and transmitted via wireless connection by the Data Handler, a microcontroller-based acquisition system. To evaluate accuracy and usability of this device, we studied 9 COPD patients (70±8±6 years, FEVI 45±1±9%pred) during 1 hour in the seated and 1 hour in the supine positions.

Methods: Breathing spontaneously and data were collected continuously. At the beginning and at the end of each hour flow at the mouth was also measured by a spirometer (Sibelmed, Barcelona, Spain), heart rate (HR) and oxygen saturation (SpO2) by a finger clip pulseoximeter (NONIN, Plymouth, Minnesota, USA) for 10 minutes, to get reference values for comparison. The first measurement for each subject with the spirometer was used to calibrate the RIP using Sackner algorithm, J.Appl.Physiol.1989; 66(1): 410-420.

The evaluation of accuracy was focused on the following parameters: HR, SpO2 and tidal volume (VT). Linear regression analysis on the data acquired resulted as follows: HR r=0.99, m=1.00, q=0.31, SpO2 r=0.92, m=1.29, q=-27.54, VT r=0.89, m=1.15, q=0.07.2. From the signals of the ECG electrodes it was possible to identify PQRST waves within the 3rd derivations.

The new wearable monitoring system provided reliable measurements of HR, SpO2, VT and ECG in both supine and seated posture. RIP calibration was still consistent after 1 hour of use.

P4025 Using routine spirometry to obtain sputum samples in the respiratory laboratory

Annikumari Pillai1, Beverley Davies2, Vicky Turner, David Smith. North Bristol Lung Centre, Southmead Hospital, Bristol, United Kingdom

Background: Analysis of sputum is helpful in diagnosis and management. Not all patients present sputum on request. However most under spirometry during their clinic visit. We had noticed that many patients asked for a sputum sample during spirometry which has often swallowed and wondered if this might be an opportunity to obtain a sample.

Methods: 303 consecutive patients performing nurse led spirometry in our chest clinic at the North Bristol Lung Centre from 1st November 2010 to 31st January 2011 were studied. Initial 139 patients were not informed prior to spirometry that a sputum specimen was required; subsequent 164 patients were asked to provide a specimen if possible. Nature of the sputum (mucoid/purulent) was recorded by the nurse.

Results: Of the initial 139 patients, 14 (10%) produced sputum spontaneously 19 (12)%of the subsequent 164 were able to produce sputum on request during spirometry. Many patients in both groups swallowed sputum during spirometry. Among the 303 patients, 66 (22%) had bronchiectasis, 65 (21%) had asthma and 53 (18%) had chronic obstructive pulmonary disease (COPD). Among those who produced sputum at spirometry, 22 (17) had bronchiectasis, 5 had COPD and 4 asthma.

22/33 sputum samples collected were sent to the laboratory. Sputum assessment by the clinic nursing staff matched that of the lab in 18 (82%) of the 22 cases.

Conclusion: Performing spirometry provides an opportunity to gain sputum. Forewarning the patient appears to have no effect on giving a sputum specimen. Nurses' categorisation of sputum nature correlates well with microbiology laboratory assessment. Categorisation as mucoid may enable fewer samples to be submitted for microbiology assessment.

P4026 Concordance between the new questionnaires to evaluate asthma control

Estefania Laque, Patricia Guerrero, Ana Gómez-Bastero, Concepción Romero, Layla Mecboul, Teodoro Montemayor. Pneumology, Hospital Universitario Virgen Macarena, Sevilla, Spain

Objectives: Regarding asthma, the main objective is to control the disease symptoms. Both Asthma Control Test (ACT) and Asthma Control Questionnaire (ACQ) are one of the most used tools to evaluate asthma control in medical practice. Two studies have been recently published where new cut-off points for ACT (> 21, 19-20) and ACQ (>0.5), from 0.6 to 0.9 and -1) are established. This led us to evaluate the concordance between both test in our patients.

Methods: We have included 179 asthmatic patients chosen from our medical practice, who performed both questionnaires and were classified in different categories of asthma control, and we analyzed the concordance of the results.

Results: The average age of our patients was 45±6 years and the FEVI measured was 2.6±0.9 litres (82±22%).
The classification of our patients, according to the questionnaires is shown in Table 1.

Table 1. Asthma control evaluation according to specific questionnaires

<table>
<thead>
<tr>
<th>ACT (&lt;20, 18-19, &lt;18)</th>
<th>Control</th>
<th>Partial Control</th>
<th>No Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACT (&gt;=20, 18-19, &lt;18)</td>
<td>60 (33.17%)</td>
<td>31 (17.32%)</td>
<td>88 (49.16%)</td>
</tr>
<tr>
<td>ACQ (&lt;0.5, 0.6-0.9, &lt;1)</td>
<td>43 (18.53%)</td>
<td>19 (8.20%)</td>
<td>113 (48.70%)</td>
</tr>
</tbody>
</table>

By comparing the results of both questionnaires, we find a very good correlation (correlation coefficient 0.75) and a poor concordance (kappa 0.556), although statistically significant (p < 0.001).

**Conclusions:** As we cannot find a good concordance between both questionnaires it is not possible to exchange them or their cut-off points, so it would be convenient to carry out prospective multicentre studies using both questionnaires and GINA/GEMA criteria.

**P4027**

Data reduction for large scale cough studies using distribution of audio frequency content

Antony Barton1, Patrick Gaydecki1, Kimberley Holt2, Jacky Smith2.

*Electrical and Electronic Engineering, The University of Manchester, Manchester, United Kingdom; 1Respiratory Research Group, The University of Manchester, Manchester, United Kingdom*

**Background:** Recent studies have suggested that the objective quantification of coughing from sound recordings provides novel insights into the mechanisms underlying cough and the efficacy of therapies. However, reliable methods for minimizing the large sound data are required to improve the feasibility of processing many and large patient data records for large scale studies of cough treatments for both manual and potential automatic cough counting.

**Aim:** To determine if a developed system can identify periods of inactivity in sound recordings to significantly reduce record length without degrading data (i.e. inadvertent removal of cough sounds), referred to hereafter as destructiveness.

**Methods:** Inactive periods of audio are identified by measuring the median audio frequency within small segments of recordings and removing those below a selected threshold. 200 randomly selected 15 minute periods known to contain cough, from 20 patients [healthy (5), COPD (5), asthma (5) and chronic cough (5)] were used, each recorded for 24hrs. To measure destructiveness, both the audio kept and removed by the algorithm were analysed by trained cough counters and compared to counts for the original files. Finally, the efficacy of the algorithm was determined by the reduction in record length achieved across all of the patient data.

**Results:** The average resultant file size was 6.04% (54.4s) of the original (median 5.77% of the original). The average resultant file size was statistically significant (p < 0.05).

**Conclusions:** The system has shown to be reliable for use in cough monitoring as an excellent means of removing large sections of audio and profoundly improving the efficiency of manual cough counting.

**P4028**

Oropharyngeal pH evaluation to determine the presence of airway reflux in asthmatic patients

Warren Jackson1, Jennifer Burke1, Alyn Morice2.

*1Academic Department of Respiratory Medicine, University of Hull, Castle Hill Hospital, Cottingham, Hull, East Yorkshire, United Kingdom; 2Academia, Laboratory of Molecular-Genetics Methods, Petersbursk, Russian Federation*

**Introduction:** Reflux disease can affect the tracheobronchial tree directly, this has been led to as先导 pathophysiology of asthma. Currently pharyngeal pH measuring detects only liquid reflux.

**Aims and objectives:** To evaluate the presence of gaseous reflux in pharynx by the comparison of the signal path of the EGRF with the cascade of MAP. This method of regulation is used in the cells of respiratory epithelium as a response to the impact of air pollutants and caused in the inhibition of apoptosis in pathogenesis of COPD Low-molecular-weight, nucleosomal DNA fraction (lmwDNA) of the blood plasma is an universal quantitative indicator of apoptosis, which allows to distinguish fundamentally different condition of the organism. The states connected with the apoptosis inhibition. The COPD is noticed for the first time accompanied by strengthening of apoptosis are marked by increase in lmwDNAs fraction. The COPD is noticed for the first time accompanied by strengthening of apoptosis are marked by increase in lmwDNAs fraction. The COPD is noticed for the first time accompanied by strengthening of apoptosis are marked by increase in lmwDNAs fraction. The COPD is noticed for the first time accompanied by strengthening of apoptosis are marked by increase in lmwDNAs fraction. The COPD is noticed for the first time accompanied by strengthening of apoptosis are marked by increase in lmwDNAs fraction.

**Results:** The expression of the protein Ras is the basis of the activation of cell cycle by the connection of the signal path of the EGFR with the cascade of MAP. This method of regulation is used in the cells of respiratory epithelium as a response to the impact of air pollutants and caused in the inhibition of apoptosis in pathogenesis of COPD. Low-molecular-weight, nucleosomal DNA fraction (lmwDNA) of the blood plasma is an universal quantitative indicator of apoptosis, which allows to distinguish fundamentally different condition of the organism. The states connected with the apoptosis inhibition. The COPD is noticed for the first time by the decline of the level of lmwDNA in the blood plasma unlike in the case of the COPD patients. COPD patients in the remission state the lmwDNA level consisted 7.8 ng/ml plasma (n=31) and was lower (P < 0.05) than in non-COPD patients - 28.0 ng/ml (n=22). Our results suggest with the dates of the detection of K-ras mutation in plasma DNA. It is used as a method of determination of malignant disease and risk factor for them. The results indicate that is it possible to use the proposed indicator for integrated differential diagnosis in practical medicine. Further research in this field is promising.

**P4029**

Comparison of the asthma control test and % predicted FEV1 in relation to correlation with physicians assessment of asthma control and treatment decisions

Urju Hoda, Bogusia Kasternow, Sacunya Laura, Corrigan Chris. *Department of Allergy, Guys and St Thomas Hospital, London, United Kingdom*

**Background:** The Asthma Control Test (ACT) is a 5-item questionnaire for the assessment of asthma control. An ACT score of <20 correlates with poorly controlled asthma.

This study compared whether ACT or FEV1 correlated better with physicians assessments of asthma control and treatment decisions made by clinicians.

**Method:** Serial visits were reviewed to a specialist Asthma Outpatients Clinic. All subjects completed the Asthma Control Test and performed same day spirometry. Clinicians made their own assessment of the patients’ asthma control and made appropriate treatment decisions. The clinicians were not blinded to the results of spirometry or ACT.

**Results:**

<table>
<thead>
<tr>
<th>ACT</th>

</tbody>
</table>

In the group defined as having controlled asthma (as defined by ACT < 20), 88.4% of patients were also classified as controlled by clinicians. However, in the group with % predicted FEV1 < 0.8, only 53.7% of patients were classified as controlled by clinicians.

**Conclusion:** The results of our study show that an ACT score < 20 had a strong association with the physicians assessment of asthma control and correlated better with treatment decisions than did the severity of asthma as defined by FEV1. The ACT could serve as a useful in the assessment and management of asthma by guiding physicians with regards to asthma control.

Circulating nucleosomal DNA of blood as an indicator of the pathological process during chronic bronchitis

Irina Vasilevy, Tatiana Ivtchik. *Laboratory of Molecular-Genetics Methods, St.-Petersburg Scientific Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation*

The expression of the protein Ras is the basis of the activation of cell cycle by the connection of the signal path of the EGFR with the cascade of MAP. This method of regulation is used in the cells of respiratory epithelium as a response to the impact of air pollutants and caused in the inhibition of apoptosis in pathogenesis of COPD. Low-molecular-weight, nucleosomal DNA fraction (lmwDNA) of the blood plasma is an universal quantitative indicator of apoptosis, which allows to distinguish fundamentally different condition of the organism. The states connected with the apoptosis inhibition. The COPD is noticed for the first time by the decline of the level of lmwDNA in the blood plasma unlike in the case of the COPD patients. COPD patients in the remission state the lmwDNA level consisted 7.8 ng/ml plasma (n=31) and was lower (P < 0.05) than in non-COPD patients - 22.5 ng/ml (n=22). Assumption about the inheritability of this index was made. The mean values of lmwDNA in the group of healthy first-degree relatives of COPD patients compound 32.9 ng/ml (n=19) and it is 1.24 time lower than in group of relatives of non-COPD patients - 28.0 ng/ml (n=22). Our results suggest with the dates of the detection of K-ras mutation in plasma DNA. It is used as a method of determination of malignant disease and risk factor for them. The results indicate that is it possible to use the proposed indicator for integrated differential diagnosis in practical medicine. Further research in this field is promising.

Efficiency of a laser-based sensor for FeNO measurements and multiple flows analysis

Julien Mandon1, Peter J.F.M. Merkus2, Simona M. Cristescu1, Frans J.M. Harren1.

*1GI Physiology, Castle Hill Hospital, Cottingham, Hull, East Yorkshire, United Kingdom; 2Academia, Laboratory of Molecular-Genetics Methods, Petersbursk, Russian Federation*

The system has shown to be reliable for use in cough monitoring as an excellent means of removing large sections of audio and profoundly improving the efficiency of manual cough counting.

**Aims and objectives:** To evaluate the presence of gaseous airway reflux in physiologic asthmatic patients, utilising the “Dr-pH Measurement System” (Restech, Respiratory Technology Corporation, San Diego, California, USA). The Dr-pH probe can detect the pH of aerosolized droplets and liquid.

**Methods:** Asthmatic patients with symptoms assessed on the Hull Airway Reflux Questionnaire (HARQ) underwent 24-hour airway pH monitoring with the Dr-pH measurement system. The probe was inserted transnasally in to the oropharynx with the distal end sitting lateral to the uvula. A Ryan score (composite pH score for pharyngeal acid exposure) was calculated for both the upright and supine periods.

**Results:** The study population consisted of 12 asthmatic patients (1 male, 11 female) with a mean age of 50 range (33 - 72). Ryan score values for the upright period were 2.12 - 612.57 (normal <9.41) and for the supine period were 2.17 - 38.01 (normal <6.80). The mean HARQ score was 32/70. Airway reflux was present, confirmed by an abnormal Ryan score in 75% of the study population in the upright position and 58% in the supine position.

**Conclusion:** Airway reflux is a frequent condition in asthma patients. It should be recognised as a distinct entity that warrants specialized focus and treatment to improve the symptoms of patients suffering with exoasthmopage reflux and asthma. The Dr-pH probe is a useful diagnostic tool for patients with asthma and symptoms suggestive of airway reflux.

**735s**
Fractional exhaled nitric oxide (FeNO) is a useful indicator in the diagnostic and management of asthma in children. Up to now, despite the availability of standardized recommendations, numerous wavelengths and several NO sensors have been reported. The aims of this study were to compare different analyzers by measuring the FeNO in asthmatic children and to calculate the NO parameters in healthy people by using NO sampling at various expiratory flow rates. A laser-based sensor with sub-ppb (sub-part-per-billion by volume) detection limit [1] was compared with two market sensors; a chemiluminescent analyzer (model 280, Sievers) and a portable hand-held electrochemical analyzer (MINGO®, Aero-crime AB), respectively. FeNO from 20 children (6-16 years of age) diagnosed with asthma and treated with inhaled steroid was simultaneously measured with these devices. The data analysis was used to validate the accuracy, precision, sensitivity and reproducibility of the optical sensor. The finding shows that FeNO values are comparable between the different analyzers. However, the variability of the electrochemical-catalytic analyzer should be considered for clinical decisions as changing current treatment.

In AR patients treated by nasal corticosteroids and antihistamines in the season deficiency and usual COPD depressed suspicious inflammation in the lower airways. This study has shown that patients with AR have significantly higher eNO levels in AR patients outside the season (14.2 ppb; IQR=13.38) and in the season before treatment (23.15 ppb; IQR=16.63). No difference was found in the pollen season after treatment (16.1 ppb; IQR=15.6).

The impact of diurnal variations, atopy, pollen exposure and pharmacotherapy on exhaled nitric oxide levels Alica Bencova, Martina Antosova, Eva Rozbovtova. *Clinic of Pneumology and Phthisology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic); 2Institute of Pharmacology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic)

Objectives and aims: The aim of the study was to investigate the impact of diurnal variations in healthy subjects and impact of atopy, pollen exposure and pharmacological treatment on exhaled nitric oxide levels (eNO) in patients with allergic rhinitis (AR).

**Methods:** eNO levels were measured using analyzer NIOX. Measurements of eNO were performed in 81 nonasthmatics with seasonal AR outside and during the pollen season, before and 3 weeks after treatment and in 52 healthy controls in 4-hour intervals.

**Results:** Diurnal variations of eNO in healthy individuals were not confirmed. Patients with AR had significantly higher levels of eNO than healthy controls not depending on pollen season or pharmacotherapy. Increased eNO levels (p<0.001) were also found in patients with AR during the pollen season (21.25 ppb; IQR=20.3) compared to the levels outside the season (14.2 ppb; IQR=12.45) before treatment. In AR patients treated by nasal corticosteroids and antihistamines in the season were levels of eNO (18.6 ppb; IQR=14.63) significantly lower (p=0.044) than in the season before treatment (23.15 ppb; IQR=16.63). No difference was found in eNO levels in AR patients outside the season (14.2 ppb; IQR=13.38) and in the season after treatment (16.1 ppb; IQR=15.6).

**Conclusions:** This study has shown that patients with AR have significantly higher levels of eNO compared to healthy subjects and the levels of eNO increasing after pollen exposure. Application of topical corticosteroids and antihistamines caused significant decrease of eNO (almost to the starting levels) in the pollen season and pollen exposure. Application of topical corticosteroids and antihistamines should be considered for clinical decisions as changing current treatment.

**P4033**

Variability of sputum inflammatory mediators in alpha-1-antitrypsin deficiency and usual COPD Helen Stone, Gillian McNab, Robert Stockley, Elizabeth Sapey. *ADAPT ProjectDepartment of Lung Function and Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; 2Cardiovascular and Respiratory Medicine, School of Medical and Dental Science, University of Birmingham, Birmingham, United Kingdom*

**Introduction:** There is inherent variability in the concentrations of inflammatory mediators in stable state sputum of usual COPD patients. Patients with alpha-1-antitrypsin deficiency (AAT) have a similar spectrum of lung disease and more inflammation but variability has not been assessed. Evidence for the efficacy of treatment in AAT is lacking; proof of concept (POC) studies indicate that augmentation increases AAT levels and reduces local mediator release. Our aims were to assess the daily variability of mediators in sputum in AAT, compared to usual COPD and to study the effects of sequential sampling to determine sample size for POC studies.

**Methods:** Interleukin 8 (IL8), myeloperoxidase (MPO) and leukotriene B4 (LTB4) were measured in the stable state spontaneous sputum of 12 patients with AAT and 12 usual COPD patients on 9 days over 1 month. The intra-patient variability was calculated (CV), compared between the groups, and the effects of combining results from multiple days for each patient were assessed.

**Results:** There was significant daily variability in all mediators, which was greater in usual COPD, despite ILS and LTB4 concentrations being higher (p<0.01) in AAT (medians 11.29 vs 3.72 mM; and 12.16 vs 6.10 mM respectively; 3 or 5-day rolling means) compared to both groups compared to a single days’ data (p<0.01) and reduced the number needed to show a 50% reduction in mediator as part of a POC study.

**Conclusion:** There is greater variability in usual COPD than AAT; though mediator levels were higher in AAT. Sequential sampling reduced intra-patient variability in both groups. Averaging 3 consecutive samples per patient was optimal.

**P4034**

The application of mass spectrometry to the analysis and characterization of protein and peptide composition in exhaled breath condensate of patients with pulmonary-endothelial disease Guzel Kireeva, Anna Ryabokon, Alykshey Kononikhin, Vladimir Bagdrov, Olga Pikon, Evgeniy Nikolaev. *1Department of Kinetics and Mechanisms of Enzymatic and Catalytic Reactions, Emanuel Institute of Biochemical Physics, Moscow; Russian Federation; 2Department of Ion and Molecule Physics, Institute for Energy Problems of Chemical Physics, Moscow, Russian Federation; 3Department of Oncological Biomarkers, Research Institute of Pulmonology, Moscow, Russian Federation; 4Department of Pulmonary Oncoology, Herzen Oncological Research Institute, Moscow, Russian Federation*

In recent years exhaled breath condensate (EBC) has been investigated more and more extensively as a matrix that reflects the composition of the airway-lining fluid and may contain biomarkers of diseases of respiratory system. The aim of this study is to compare identify proteins and peptides in EBC samples collected from two groups of people with healthy pulmonary system and with verified oncopulmonary diseases patients in the framework of the Scientific Research Oncology Institute with using mass spectrometry, as well as to compare proteome identification.

Proteins were collected using R-Tube, freeze dried, treated by trypsin and analyzed by nanoflow LC-MS/MS with a 7-Tesa Finnigan LTQ-FIT mass spectrometer (Thermo Electron, Germany), by means of Bioworks Browser 3.1 SR1 (Thermo Electron, Germany) were generated list of direct peptide mass and mass of their fragments, with following identification of proteins in the databases thought Mascot (Matrix Science version 2.0.04, the UK). At collected samples were identified peptides from more that 40 proteins of different nature, e.g. keratins and non-keratins. Peptides of nuclear ubiquituous casein and cyclin-dependent kinases substrate (NUCKS) which located in the nucleas in proliferating cells, glutamine synthetase (GS)-an enzyme that plays an essential role in the metabolism of nitrogen, alpha 1-antitrypsin (A1AT) is a protease inhibitor belonging to the serpin superfamily were discovered in disease EBC samples. They are uncharacteristic of healthy EBC samples. In conclusion, each of abnormal peptides, as well as their combinations, may have diagnostic value.

**P4035**

Circadian variation of exhaled breath temperature in healthy subjects Tanya Kralimarkova, Miroslava Rasheva, Tanya Grigorova, Zlatko Dimitrov, Dimitar Tihonirov, Roxana Mincheva, Vasil Dimitrov, Todor Popov. *Medical University Sofia, Clinic of Allergy and Asthma, Sofia, Bulgaria*

**Background:** Evaluation of the exhaled breath temperature (EBT) has been suggested as surrogate biomarker of airway inflammation, but there is no data on its circadian variation in health and disease. Measuring it by portable handheld device has been proven to be precise and highly reproducible. The aim of the study was to identify peaks and troughs in EBT around the clock in healthy individuals.

**Methods:** Forty two subjects (24 women; median age 26 years, age range 3 to 80 years) without history and objective signs of respiratory disease volunteered. EBT circadian influences need also to be considered as part of a POC study.

**Results:** EBT values showed a circadian pattern different from the one of A1AT - the acrophase (peak temperature) was registered at 19 h for EBT and at 13 h for A1AT. The bathyphase (trough temperature) was the same for both circadian rhythms at 1 h. Repeated measures analysis found both circadian fluctuations to be statistically significant (table):
P4036
Exercise test with dry air inhalation compared to mannitol test as marker of exercise induced asthma
Kai-Håkon Carlsen1,2, Leif Bjerner3, Barbro Dahlén4, Tommy Ekstrom4, Gunilla Hedlin5, Trine Stensrud6, Leif Jorgensen7, Kjell Larsson8, Section of Sport Medicine, Norwegian School of Sport Sciences, Oslo, Norway; 2Dept. of Pulmonology, Oslo University Hospital, Oslo, Norway; 3Institute of Clinical Medicine, University of Oslo, Oslo, Norway; 4Dept. of Respiratory Med. & Allergology, Lund University Hospital, Lund, Sweden; 5Dept. of Medicine, Division of Respiratory Med. and Allergy, Karolinska University Hospital Huddinge, Karolinska Institutet, Stockholm, Sweden; 6Astra Zeneca Nordic, Söderåsien, Sweden; 7Dept. of Women’s and Children’s Health, Centre for Allergy Research, Karolinska Institutet, Stockholm, Sweden; 8Unit of Lung and Allergy Research, National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Objective: To compare exercise test with dry air inhalation and mannitol test to discriminate between different asthma treatments.

Methods: Exercise test with dry air inhalation (EIA test) (Aoolos bronchial challenge, Sweden) was compared to inhaled mannitol test in a randomized trial (NCT 00898933) on budesonide/formoterol (BF) as needed (n=23), budesonide (B; n=21) once daily, terbutaline (T) as needed (n=22) on exercise induced asthma (EIA) in mild asthmatic adults and adolescents. EIA test: 6 minutes treadmill run at 90% of max aerobic capacity; FEV1 measured before, and 0, 5, 10, 15, 30, 45 minutes after exercise. EIA test started with positive max fall in FEV1 ≥ 10% of baseline. Dry powder mannitol was inhaled in cumulative doses from 5 - 635 mg, to find the dose causing 15% FEV1 fall (PD15). EIA test was performed at trial start, after 3 and 6 weeks, mannitol test at trial start and after 6 weeks.

Results: Mean max FEV1 fall after EIA test was 16.34% at baseline and 13.11% after 6 weeks treatment. There was a significant improvement in BF (AFEV1 LS mean (95% CI) -5.4 (-8.93, -1.83) and B (-6.6 (+10.3, -2.96)) groups after 6 weeks, but not in the T group (+1.48 (-2.1, 5.59)). The mannitol test was positive (PD15=635 mg) in only 31/66 subjects at start, and in 22 at 6 weeks. All 66 subjects had a positive EIA test.

Conclusion: All patients had positive EIA test at baseline. The response to the EIA test improved significantly in two of the treatment groups (BF and T) and discriminated between the treatments. The mannitol test was positive in less than 50% of the subjects, and could not be used as outcome in the present study.

The study was sponsored by AstraZeneca.

P4037
Evolution of cellular inflammatory pattern in induced sputum in patients with mild-moderate asthma for five years
Elena Forenc, Elisabet Vera, Angela Fernandez, Jose Angel Carretero, Juan Antonio Domingo, Enrique Chacon, Salvador Bello. Pulmonaryology, Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: Prospective study of cellular inflammatory pattern in samples of induced sputum can identify inflammatory changes in the natural history of asthma. The aim of our study is to know whether there are modifications of cellular inflammatory pattern in mild-moderate asthma along 5 years.

Materials and methods: The patients with mild- moderate asthma were studied along 5 years. The outcomes were: lung function FEV1 (% pred), no. exacerbations/year (EY), use of rescue therapy (RT), dose of inhaled corticosteroid/day (ICs), bacterial and viral cultures, total and differential cell count in induced sputum. Cellular inflammatory pattern was classified as eosinophilic (>2% of eosinophils), neutrophilic (>61% of neutrophils), paucigranulocytic (<1% of granulocytes). In 45% were found out differents patterns; 11% benign forms (2% of eosinophils), 11% inflammatory pattern in the sputum (11% eosinophilic, 11% neutrophilic y 33% supernatant in smoking asthma). In 45% were found out differents patterns; 11% benign forms (2% of eosinophils), 11% inflammatory pattern in the sputum (11% eosinophilic, 11% neutrophilic y 33% supernatant in smoking asthma).

Results: The study began with 24 patients and in 18 we repeated the induced sputum 5 years after. The probability were of 100%. 55% showed the same cellular inflammatory pattern in the sputum (11% eosinophilic, 11% neutrophilic y 33% paucigranulocytic). In 45% were found out differents patterns; 11% benign forms (2% of eosinophils), 22%agressive forms (neutrophilic, eosinophilic o mixed) and a 11% changed the inflammatory pattern but with agressive forms too.

Conclusions: In stable patients with mild-moderate asthma, the most recurrent inflammatory pattern is thepaucigranulocytic. The positivity of bacterial cultures in sputum may be the cause of the changes in the induced sputum to agressive forms. Nonsignificant changes towards neutrophilic patterns have been observed that warrant further study in larger groups.

P4038
Safety and efficacy of inhaled mannitol as a bronchial provocation test in asthmatic children
Ioanna Vasilopoulou, Michael Anthracopoulos. Pediatric Respiratory Unit, University Hospital of Patras, Patras, Greece

Background: Bronchial provocation with inhaled mannitol is a new and simple test for osmotic bronchial challenge. The aim of this study was to determine the efficacy and safety of inhaled mannitol in asthmatic children.

Methods: Sixty five children (54% males) aged 6-12 years, with established diagnosis of Childhood, were studied. An asthma control questionnaire (CACT) was completed before bronchial provocation. A commercial preparation of dry powder mannitol was administered in progressively increasing doses according to the standard protocol, and the FEV1 was measured 60 seconds after each dose. The procedure ceased when a 15% fall in FEV1 was achieved (positive challenge) or the cumulative dose of 635 mg was reached (negative challenge). In case of a positive provocation, the dose of mannitol (mg) to provoke a 15% fall in FEV1 (PD15) was calculated. Adverse events during and 2 hours after the test were also documented.

Results: Twenty four children (36.9%) were positive to the mannitol challenge, with a maximum mean±SE FEV1 fall of 18.7±4.1%, and a median PD15 of 125 mg (range 18- to 470 mg). There was a significant correlation between PD15 and C-ACCT score (r = 0.58, p<0.001). The most common adverse events were: cough (83.1% - 100% in those with a positive challenge), nausea (9.2%), headache (4.6%), and abdominal pain (1.5%). No adverse effect was present at 2 hours after test.

Conclusion: Bronchial challenge with mannitol is safe and correlates well with the level of asthma control in asthmatic children.

P4039
Comparison of two devices and two breathing patterns for exhaled breath condensate sampling
Andreas Rembert Koczulla1, Eva Huttmann1, Timm Greulich1, Akira Hattesohl1, Sarah Noeske1, Severin Schmid1, John Gerrit1, Rudolf Jörres1, Bernd Müller1, Claus Vogelmeier1, 2Department of Internal Medicine, Division for Pulmonary Diseases, Philipps University Marburg, Marburg, Hessen, Germany; 2Comprehensive Pneumology Center, Institute of Lung Biology and Disease, Helmholtz-Zentrum München, München, Bayern, Germany; 2Institute and Outpatient Clinic for Occupational, Social and Environmental Medicine, Ludwig Maximilian University, München, Bayern, Germany

Background: Analysis of exhaled breath condensate (EBC) provides a non-invasive access to the lung epithelial lining fluid.

 Aim: Comparison of two commercially available portable devices (RTube, ECo- Screen turbo), and evaluation of different breathing patterns with regard to marker proteins and the source of EBC in healthy adults.

Methods: EBC was collected from 10 subjects 4 times in a cross-over design, for each device once during tidal breathing and once hyperventilating. Conductivity, pH, PHA surfactant protein A (SPA), Clara-cell protein (CCP) and total protein in EBC were assessed. Data on the volatile organic compound (VOC) profile of the EBC were obtained using the electronic nose Cyanose 320TM.

Results: RTube provided a higher sample volume compared to the ECoScreen. Hyperventilation yielded higher volumes than tidal breathing. Neither devices nor breathing patterns affected pH. Although conductivity appeared to be affected by both, average measurements remained rather stable. Hyperventilation led to an increase of total protein. The ECoScreen showed a trend towards higher protein amounts. CCP and SPA amounts were not influenced by the breathing pattern. The electronic nose was capable of distinguishing between breathing patterns and devices.

Conclusion: EBC pH and to a lesser extent conductivity are fairly stable measures that do not depend on device or breathing pattern. Hyperventilation increases total protein concentration possibly via augmented shear forces and increased aerosol production, but not through increased alveolar ventilation, as SP-A amounts were not altered by hyperventilation. The VOC content of EBC seems to be influenced by device and breathing pattern.

P4040
Prostaglandin E2 and cysteinyl leukotriene concentrations in sputum supernatant in smoking asthma
Konstantina Kontogianni1, Petros Bakakos1, Konstantinos Kostikas2, Georgios Hillas1, Anastasia Papapopryliou2, Philipos Emmanouil1, Konstantinos Matzouranis1, Manos Alchianata1, Spyros Papiris3, Stelios Loukides4, 1 1st Respiratory Medicine, University of Athens Medical School, Athens, Greece; 22nd Respiratory Medicine, University of Athens Medical School, Athens, Greece

Background: Smoking may modify airway inflammatory pattern. There is some evidence that the elevated levels of PGE2 in the exhaled breath condensate of patients with asthma are mainly related to smoking habit [Kostikas et al ERJ 2003].

Objective: To evaluate the concentrations of PGE2 and cysteinyl leukotrienes in sputum supernatant in patients with asthma and to determine whether smoking affects significantly their measurements.

Methods: We studied 98 patients with asthma (47 smokers), under optimal treatment with ICS. We also studied 40 control subjects (20 smokers). All subjects underwent sputum induction, pulmonary function tests, measurement of FeNO and BHR to methacholine expressed as PD15. We also studied 40 control subjects (20 smokers). All subjects underwent sputum induction, pulmonary function tests, measurement of FeNO and BHR to methacholine expressed as PD15.

Results: Median [IQR] sputum cysLTs concentration was significantly higher in smokers compared to non-smokers [121 (95,175) pg/ml, respectively; p<0.001]. The most common adverse events were: cough (83.1% - 100% in those with a positive challenge), nausea (9.2%), headache (4.6%), and abdominal pain (1.5%). No adverse effect was present at 2 hours after test.

Conclusion: Bronchial challenge with mannitol is safe and correlates well with the level of asthma control in asthmatic children.

Adaptation of differential ion mobility spectrometry (DMS) for discrimination of specific biomarkers in exhaled breath in patients with severe renal-pulmonary dysfunction

Gunther Becher1, Anne Hillmann2, Roman Purkhart2, Martina Graupner2, Rolf Graupner2, 3. R&D, BecherConsult GmbH; Bernau, Germany; 4. R&D, Graupner Medizintechnik & Co KG, Geyer, Germany; 5. Praxis, Diallyzentrum Altenburg, Altenburg, Germany

Introduction: Volatile substances (VOC’s) in exhaled breath are target for identification of new biomarkers for disease and metabolic processes. Renal insufficiency could be a good example of an illness with exhaled markers of an internal disease.

The ion mobility spectrometry (IMS) is a method for detection of volatile compounds in exhaled air with a sensitivity in ppt-range. The method was used in a pilot study for discrimination of patients with chronic metabolic kidney disease.

Methods: A DMS of STIONEX was used for analysis of exhaled breath. The measurements were performed before and after a dialysis procedure. The DMS-analysis includes a pre separation by a multi-capillary tube, ionization of the sample and measurement of ions by IMS with 270 sec. Spectra were discriminated by detection of clusters and calculation of significance using support vector machine.

Results: It was possible to collect sufficient samples in all patients. Specific clusters of biomarkers were found discriminating marker exhalation before and after therapeutic intervention with dialysis. Specific clusters, indicating drug-uptake, were found.

The inter-individual reproducibility was very high, which possibly represents the manifold drug-treatment and severity of renal insufficiency with enhanced blood urea.

Discussion: Characteristic breath pattern could be detected. The method is non-invasive and fast and could offer new possibilities for long term control of medicaments and chronic metabolic disorders. Further studies are needed to identify certain markers and metabolites.

**P4042**

Clusters of biomarkers in exhaled breath detected by differential ion mobility spectrometry (DMS)

Gunther Becher1, Roman Purkhart1, Anne Hillmann2, Rolf Graupner2, Swen Marke1, Werner Steinauenser1, Wolfram Scharff1, R&D, BecherConsult GmbH, Bernau, Germany; 4. R&D, Graupner Medizintechnik & Co KG, Geyer, Germany; 3. Analytik, IFU Privates Inst für Analytik, Oberlichtenau, Germany; 4. Marketing, CareFusion, Hoechberg, Germany

Introduction: Non invasive biomarkers from exhaled breath became high interest. The ion mobility spectrometry has better sensitivity and differentiation of volatile compounds than their gas-chromatography. The high sensitivity of the method brings a couple of problems due to VOC’s from ambient air and environment.

Methods: The aim of the study was to demonstrate standardized sampling, reproducibility and the discrimination of groups of volunteers by exhaled markers. The calculation of spectra and statistical discrimination was performed using a statistic program based on a Support-Vector Machine.

For the investigation were included 57 volunteers, whose were recruited from two completely different environmental-occupational ambient air conditions.

Results: There were collected repetitive samples on one day and within one week for each. Similar tests were performed on ambient air.

It was possible to demonstrate significant differences in spectra of volunteers. It was possible to differentiate clusters from human biomarkers from the clusters which represent VOC’s from ambient air. Subgroups, e.g. sex, BMI, smoking, were possible to discriminate without disturbance from ambient conditions.

Discussion: The DMS is suitable for the detection of VOC’s in exhaled breath even in different environmental conditions. The fingerprints (clusters) in each measurement are characteristic for the individuals, groups and highly reproducible. Specific VOC’s from ambient are can be mostly excluded from patients markers. The ion mobility spectrometry may be a sufficient method for non-invasive detection of disease markers in breath.

Supported by a Grant of the Federal Ministry for Economy and Technology: EURONORM Germany.
of moderate bronchial asthma (BA). The control group consisted of 58 healthy volunteers. The EBC was collected in all patients, as well as the TNF concentration in EBC was measured before and after the course of therapy by spectrophotometric method expressed as TTN. The TNF was measured in patients with BA than in control.

**Conclusion:** The measurement of TNF concentration in EBC can be used as a marker of airway inflammation in patients with moderate BA for the monitoring of patient’s status. During the course of therapy the statistically significant decrease of this parameter was demonstrated; that is strongly correlated with clinical status. So, the TNF level in EBC also can be considered as a sensitive marker of the efficacy of the therapy administered.

### P4046

**Increased levels of osteopontin in sputum supernatant in smoking asthma**

Georgios Hilias1, Stelios Loukidis1, Konstantinos Kostikas1, Davina Simoes1, Konstantina Kentogianni1, Vassiliki Delimpos2, Eleni Tsiolou3, Spyros Papatrou1, Marios Alchanatis1, Petros Bakakos4, Department of Respiratory and Critical Care Medicine, Research Unit, “Sotiria” Chest Diseases Hospital, Athens, Greece; 2nd Respiratory Medicine Department, University of Athens Medical School, “Attikon” Hospital, Athens, Greece; 3Marisanti Simou Laboratories, University of Athens Medical School, Athens, Greece, 41st Respiratory Medicine Department, University of Athens Medical School, “Sotiria” Chest Diseases Hospital, Athens, Greece

**Background:** Osteopontin (OPN) has been associated with inflammation and fibrosis. OPN is increased in asthma and is related to the underlying severity and to factors expressing to baseline and inflammation. Smoking may modify the inflammatory pattern of the airways.

**Aims and objectives:** To evaluate the levels of OPN in sputum supernatants of asthma patients and to investigate the possible role of smoking as well as associations with mediators and cells involved in the inflammatory and remodeling process.

**Methods:** We studied 98 asthma patients (51 smokers) and 40 healthy subjects (20 smokers). We undertook lung function tests, bronchial hyperresponsiveness to methacholine, and sputum induction for cell count identification and measurement of OPN, VEGF, TGF-β1, CysLTs, IL-13, ECP and IL-8 in supernatants. The concentrations of all mediators were measured using enzyme immunoassays.

**Results:** Median OPN levels (pg/ml) were significantly higher in smoking asthma (SA) compared to non-smoking asthmatics (NSA), and both smoking and non smoking controls [120 (651, 1793) vs 210 (120, 404) vs 50 (42, 70) vs 102 (71, 156) pg/ml, respectively; p < 0.0001]. Regression analysis provided significant associations between log OPN and sputum neutrophils, IL-8, IL-13 and TGF-β1. The most significant association of TGF-β1 was the one with OPN. These associations were observed only in SA. No significant associations were observed between OPN, lung function tests and PD15 to methacholine in all groups.

**Conclusions:** OPN levels are affected by the smoking habit in asthma. The associations of OPN with sputum neutrophils, TGF-β1, IL-13 and IL-8, only in SA, suggest a possible role for OPN in the inflammatory and remodeling process in SA.

### P4047

**Laboratory investigation of sputum and mucociliary clearance (MCC) condition in patients with COPD**

Tetyana Pertseva, Olena Lykholat, Olena Gurzhiy. School, "Sotiria" Chest Diseases Hospital, Athens, Greece

**Aim:** To investigate biochemical parameters of sputum for evaluation of MCC’s disorders in patients with COPD.

**Materials:** 90 smoking patients with COPD in stable condition.

**Methods:** Biochemical parameters of sputum (medium weight molecules (MWM), trypsin, cysteine proteases cathepsin B, cathepsin L, α1-proteinase inhibitor (α1-PI)) were measured with ELISA. EBC was collected during 10 minutes of tidal breathing. IL1β, IL6, IL8 and TNFα were measured with ELISA.

**Results:** The concentration of inflammatory cytokines in exhaled breath condensate (EBC) in children with IBD were studied during 10 minutes of tidal breathing. IL1β, IL6, IL8 and TNFα were measured with ELISA.

**Conclusions:** The elevated concentration of inflammatory cytokines in EBC in children with IBD can suggest that inflammation, which plays the key role in pathogenesis of IBD, may be also present in respiratory tracts.

### P4049

**Effects of outdoor temperature and humidity on methacholine challenge tests**

Bruno Sposato1, Marco Scalese2, Andrea Pammolli3, Maurizio Di Tomassi1, Maria G. Migliorini1, Raffaele Scala3, Mario Naldi1, U. Pneumologia, Ospedale “Misericordia”, Grosseto, Italy; 2Istituto di Fisiologia Clinica, CNR, Pisa, Italy; 3Departmento di Fisiopatologia, Medicina Sperimentale e Sanità Pubblica, Università di Siena, Siena, Italy; 4Unit de Pneumologia et UTSP, Ospedale Campo di Marte, Lucca, Italy; 5Unit de Pneumologia et UTIP, Ospedale S.Donato, Arezzo, Italy

This study tried to evaluate whether outdoor daily temperature (T) and humidity (H) influence methacholine test results in outpatients living in temperate climate areas. 4.232 subjects (2391 males; age 35.1 ± 16.15; FEV1, 100.36% [IQR: 92.34-108.81]) that performed a methacholine test for a suspected bronchial asthma between 2000 and 2010 were considered. Mean outdoor temperatures (°C) and relative humidity (%) were measured at the time of the test. Patients with bronchial hyperresponsiveness (PD20 < 1.28) were used as controls (n = 2329). Patients with bronchial hyperresponsiveness (PD20 < 1000 pg/ml) were used as controls (n = 2329). This study showed that an increase in temperature (excluding extreme values) is associated to a slight, but significant, reduction of bronchial hyperresponsiveness risk.

### P4050

**Are FENO indices useful diagnostic tools in suspected asthma? Experience of a routine lung function laboratory**

Florence Schleich, Raluca Asandei, Maiat Manise, Jocelyne Sele, Cédric Graas, Renaud Louis. Respiratory Medicine, GIGA 1, CHU Liege, University of Liege, Liege, Belgium

**Background:** Asthma diagnosis is based on symptoms associated with airflow obstruction and decreased bronchodilator responses. FENO is a non-invasive, reproducible method to detect inflammation in the airways. FENO is defined as the concentration of NO in exhaled breath condensate (EBC) when a known volume of air is exhaled into a closed system.

**Aim of the study:** To evaluate the concentration of inflammatory cytokines in exhaled breath condensate (EBC) in children with IBD. The aim of the study was to evaluate the concentration of inflammatory cytokines in exhaled breath condensate (EBC) in children with IBD.

**Method:** FENO indices were collected from 24 children with IBD (12 boys and 12 girls, mean age 13.8 ± 3.3) and 37 healthy volunteers (20 boys, 17 girls, mean age 13.9 ± 3.6) were enrolled into this study.

**Results:** FENO values were significant lower in children with IBD compared to healthy volunteers (p < 0.05). The causes of asthma in the children could be considered as a diagnostic tool for the early detection of asthma in children with IBD. This study showed that an increase in temperature (excluding extreme values) is associated to a slight, but significant, reduction of bronchial hyperresponsiveness risk.
variability. Airway inflammatory component measured by exhaled nitric oxide (FENO50) has been proposed as a diagnostic tool but remains controversial.

**Aims:** To assess the ability of FENO indices to identify bronchial hyperresponsiveness to methacholine (PC20M < 16mg/ml) and to establish which respiratory symptoms relate to FENO indices and PC20M.

**Methods:** We conducted a prospective study on 174 steroid naïve patients addressed for PC20M. Patients with respiratory symptoms, FEV1 ≥70% pred and no proof of reversibility to inhaled salbutamol (either not done or response <12%) completed a questionnaire about their symptoms and underwent FENO measurements at different flow rates (50-100-150 and 200ml/sec) and PC20M.

**Results:** 82 had a PC20M <16mg/ml and had significantly higher FENO50, FawNO and Intercept but did not show significant difference in CAV(NO) value. By constructing ROC curve, we found that FENO50 cut-off value of 34 ppb is able to identify bronchial hyperresponsiveness with high specificity (95%) and PPV (88%) but low sensitivity (35%) and NPV (62%). For the whole group, the dose-response slope (DRS) for methacholine weakly correlated with FENO50 but not with CAV(NO). Among the positive PC20M, there was no relationship between the magnitude of PC20M and the level of FENO indices. Wheezing was the symptom most convincingly associated with raised FENO50.

**Conclusion:** FENO50 ≤34ppb is a good diagnostic criterion in patients with suspected asthma. However FENO50 ≤34ppb clearly does not rule out bronchial hyperresponsiveness and should prompt the clinician for asking methacholine challenge.

### 418. Treatment strategies, systemic manifestations and biomarkers in airway diseases

**P4052**

**Markers of airway inflammation and airway hyperresponsiveness remain stable in untreated asthmatics over time**

Pernille Barkgaard Udelesen, Celeste Persborg, Christian Grabow Westergaard, Vibeke Backer. Respiratory and Allergy Research Unit,Department of Respiratory Medicine L, Bispebjerg University Hospital, Copenhagen NV, Denmark

**Introduction:** Airway hyperresponsiveness (AHR) and airway inflammation are important hallmarks of asthma that may be used in asthma monitoring, but may also vary between asthmatics as a potential indication of different clinical asthma phenotypes. The aim of our study was to assess whether two commonly used measures, AHR to mannitol and exhaled NO (eNO), were stable over a period of time in asthma patients who were not treated with steroids.

**Materials and methods:** A total of 54 non-smoking, asthmatics not treated with steroids were enrolled in the study and assessed at baseline and again three to six months later, where spirometry, skin prick test and induced sputum was performed as well as measurements of hyperresponsiveness to mannitol and eNO. Subjects were excluded if they experienced a worsening of their asthma or commenced on steroid treatment.

**Results:** A total of 41 subjects (21 females, mean age: 41 years, 70.70% atopic) completed both visits. Mean PEVi% predicted at baseline was 94.13% (SD 17.71). There was a significant correlation between the degree of AHR, defined as well as measurements of hyperresponsiveness to mannitol and eNO. Subjects were excluded if they experienced a worsening of their asthma or commenced on steroid treatment.

**Conclusion:** In asthmatics not treated with steroids, markers of AHR and airway inflammation remain at the same level over a three to six months period of observation, suggesting that these are stable markers of clinical disease.

**P4053**

**Airway resistance and reactance in COPD patients and healthy smokers, and effect of bronchodilators**

Linnnea Svensson, Jaro Ankerst, Leif Bjørner, Ellen Tufvesson. Department of Clinical Sciences, Lund, Respiratory Medicine and Allergology, Lund, Sweden

**Background:** Little is known about the reversibility response of the obstructive pattern to therapies in COPD. Impulse oscillometry (IOS) is a method to measure resistance and reactance of both the central and peripheral airways.

**Aim:** The aim of this study was to investigate how salbutamol and ipratropium, commonly used in COPD, affect obstructive airway patterns measured by impulse oscillometry.

**Methods:** Twenty two healthy smokers and 24 patients with COPD, with matched pack years were included in this study. Spirometry and impulse oscillometry were performed at baseline, after inhalation of salbutamol and after additional ipratropium.

**Results:** Medication increased PEVi1 as expected. COPD patients had significantly higher total (R5), central (R20) and peripheral (R5-R20) resistance (% predicted) at baseline compared to healthy smokers. After medication with salbutamol, R20 decreased in both COPD patients and healthy smokers. Salbutamol only decreased R5-R20 in COPD patient, but after additional ipratropium the R5-R20 in healthy smokers also decreased. The COPD group showed a higher reactance (X5, AX and FRES) at baseline compared to the healthy smokers. After inhalation of salbutamol, X5, AX and FRES was significantly decreased in the COPD group as well as in healthy smokers. Additional inhalation of ipratropium showed a tendency of decreasing X5 and AX in both COPD patients and healthy smokers.

**Conclusions:** COPD patient have higher resistance and reactance compared to healthy smokers at baseline. Both airway resistance and reactance was affected by inhalation of salbutamol and additional ipratropium, and more pronounced in COPD patients compared to healthy smokers.

**P4054**

**Monitoring of efficacy of therapy with monoclonal antibodies – Omalizumab = Using the Recovery-ELISA**

Pavel Strohmeier1, Antonia Staast1, Astrid Schaefer1, Gunther Becker2, Dieter Sarrach1, Jens Reich1, Thomas Haeupl1, Jens-Oliver Steiss3, F&D, BioTez Berlin-Buch GmbH, Berlin, Germany; 2R&D, BecherConsult GmbH, Bensau, Germany; 3Molecul Res., Mdc Research Center, Berlin, Germany; 4Rheumatology Center, Charite` Univ. Clinic, Berlin, Germany; 5Dept. Pediatrics, Univ. Clinics Giessen and Marburg, Giessen, Germany

The Reversibility-ELISA (R-ELISA) resembles a combination of a Sandwich-ELISA for the antigen and a competitive ELISA for the therapeutic antibody. The R-ELISA is a special ELISA application for presence of an additional TAB in the measuring system. The special feature is a two-dimensional calibration, which performs a calibration for the antigen without and with addition of the therapeutic antibody and a calibration of the antigen-recovery in dependence of the therapeutic antibody.

Addition of Omalizumab to the IgE-Sandwich-ELISA reduced the optical density of the signal in a non-linear manner for the detection of IgE. At 7.2 μg/ml Omalizumab the IgE-signal is reduced by 75%. The addition of substrate to the assay enables the re-calculation for real samples. The Fig. shows the antigen recovery in dependence of Therapeutic antibody.

**P4055**

**Predicting performance of cough reflex sensitivity, exhaled nitric oxide (eNO) and bronchial responsiveness for efficacy of bronchodilator therapy on isolated chronic non-productive cough**

Masaki Fujimura, Noriyuki Ohkura, Akira Tokuda, Yuko Waseda. Respiratory Medicine, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan

**Background:** Chronic cough responding to bronchodilator therapy (BDT) was originally reported as cough variant asthma (CVA), in which bronchial responsiveness was shown to be mildly increased. Our aim was to elucidate whether cough reflex sensitivity, exhaled nitric oxide (eNO) and bronchial responsiveness could predict efficacy of BDT on chronic non-productive cough.

**Methods:** Consecutive patients with non-productive cough lasting at least 8 weeks who visited our respiratory medicine clinic from 2005 to 2010 and gave informed consent for participating in this study were enrolled. Exhaled NO, capsaicin cough sensitivity (CS) and bronchial reversibility were measured in this order at their first visit. Bronchial responsiveness (PC20) was measured at their second visit following 6-day BDT.

**Results:** The study protocol was fully completed in 117 patients. Multivariate regression analysis revealed that only CS was significantly (r=0.430, p<0.0001) correlated with the VAS scale. The ROC curve showed that the optimal cut-off
value of C5 to predict MI on the efficacy of BDT on cough was solution number of 4.5 (2.8 mmol/L) with a sensitivity of 0.81 and specificity of 0.72.

The observed comorbidities in COPD is closely related to systemic inflammation however we think that the exact mechanism of each comorbidity needs to be further investigated.

**P4058**

Is the body mass index a determinant of inflammatory status and quality of life in asthma?

Raquel López Reyes, Miguel Perpiñá Tordera. Service of Pneumology, University Hospital la Fe, Valencia, Spain

**Introduction:** The aim of our study was to determine the relationship between body mass index (BMI), alveolar nitric oxide (CaNO), and the health status of asthmatics by applying the quality of life questionnaire Sydney-modified (AQLQ-S).

**Material and methods:** We studied 139 asthmatics (GINA) between 15 and 75 yr of age (men 45 and women 94) and several degrees of severity. We measured anthropometric variables, baseline spirometry, and nitric oxide exhaled (eNO) at multiple flows (50, 100, 150, 200, and 250 ml/s). Bronchial nitric oxide (BDT) and CaNO were assessed according to Tsoukas model. All patients completed the AQLQ-S questionnaire. For comparisons between two groups, T-test student was used. The relations between NO parameters and other markers were analyzed with partial correlations adjusted for asthma severity.

**Results:** The mean BMI was 26.46±4.97 kg/m², CaNO 3.89±4.7 ppb and JaoNO 2.41±3.270 m/s. There were no statistically significant differences in values of CaNO and JaoNO between obese asthmatic group and non obese. The AQLQ-S scores obtained were (mean ± SD): total score: 5.62±1.08; shortness of breath: 5.73±1.14; mood: 5.21±1.24, social restriction: 5.92±1.25, and concern: 5.69±1.10.

**Correlations between BMI and AQLQ-S scores**

**Conclusion:** A low BMI is associated with a low grade systemic inflammation in COPD patients visualized by systemic activation of neutrophils. In COPD patients the FFMI correlated with BMI, which suggests that the systemic inflammation in COPD patients is associated with a muscle wasting phenotype.
P4060
Analysis of atherosclerosis in patients with chronic obstructive pulmonary disease by carotid ultrasonography
Sayaka Tachibana1, Shoko Sonobe1, Utako Fuji1, Yasuko Fuchimoto1, Masaaki Shiojiri1, Koji Inoue1, Norihiko Nakanishi1,6, Tomonori Moritaka1, Yasufumi Yamaji1,6, Shinya Tada1,6, Tadashi Kamei1,6, Nobuo Ueda1,6, 1Respiratory Medicine, Ehime Central Prefectural Hospital, Matsuyama, Japan; 2Respiratory Medicine, Mitoyo General Hospital, Kannonji, Japan; 3Respiratory Medicine, Kagawa Rosai Hospital, Marugame, Japan; 4Radiological Medicine, Kamei Clinic, Takamatsu, Japan; 5Internal Medicine, Iyotetsu Clinic, Matsuyama, Japan; 6Respiratory Medicine, North Shikoku Pulmonary Disease Co-operating Group, Matsuyama, Japan

Rationale: Chronic obstructive pulmonary disease (COPD) is associated with an increased risk of cardiovascular events. Atherosclerosis is an independent predictor of cardiovascular disease. We tested the hypothesis that there is a close association between atherosclerosis and disease severity of COPD.

Methods: We recruited 46 subjects with COPD (45 male-1 female, 42 ex-smokers, 4 current smokers, aged 74.7 ± 7.9 years). All subjects underwent speimetry and carotid ultrasonography. The severity of COPD was determined by GOLD Staging System for COPD Severity Definition. We measured carotid intima-media thickness, and determined the maximal intima-media thickness (IMTmax) value as the indicator of atherosclerosis.

Results: Average IMTmax value in all subjects was 1.9 ± 1.1 mm. IMTmax value was 2.2 ± 1.2 mm in stage I (n=3), 1.7 ± 1.0 mm in stage II (n=15), 2.0 ± 1.1 mm in stage III (n=16), and 2.0 ± 1.4 mm in stage IV (n=12). There were no differences of IMTmax values among the stages of COPD. IMTmax values were higher in subjects with ischemic heart disease (n=5) compared to those without ischemic heart disease (n=41) (IMTmax value: 2.7 ± 1.6 mm vs. 1.9 ± 1.1 mm, p < 0.05). 3 subjects had lower intima-arteries obstructions (IMTmax value was 2.1 ± 0.7 mm).

Conclusions: Atherosclerosis was not associated with disease severity of COPD. This study suggests that atherosclerosis progresses even in patients with mild COPD, especially in those who are associated with ischemic heart disease.

P4061
Body composition analysis on COPD patients – Results of prospective study
Jan Plutinsky1, Ivan Marget1, Petra Kuhicova2, Peter Chlebo2, Dalibor Petras1, Danubius Medical University, Piestany, Slovakia; 1Department of Respiratory and Allergy Medicine, Specialized Hospital of St. Zoerardus Zobor, Nitra, Slovakia (Slovak Republic); 2Department of Nutrition, Faculty of Agrobiology and Food Resources, Slovak Agricultural University, Nitra, Slovakia (Slovak Republic)

Introduction: Chronic Obstructive Pulmonary Disease (COPD) is in close relation to chronic systemic inflammation involving an extrapulmonary pathology. The results can be weight and muscle loss and nutritional abnormalities. FFMI (Fat Free Mass Index) is an important measure in COPD patients to determine the progression of the muscle affection.

Aims: To determine FFMI and BMI in COPD patients (pts).

Methods: In 2010, we began BC analysis on COPD patients with Dual-Energy X-ray Absorptiometry (DEXA) in a prospective study trial. We analysed BC of 30 clinically stable COPD pts in stage II-IV GOLD. There were 24 M, median age 69 yrs (49-84 yrs) and 6 F, median age 74 yrs (51-85 yrs). For body composition analysis by DEXA we used Hologic Discovery Wi including the software “Whole Body Composition Analysis”. Reference intervals (by Schutz) for FFMI were used.

Results: In M median BMI was 23 (17.7-33.9) and 23.34 (14.79-37.49) in F respectively. FFMI was 17.78 (14.52-22.18) and 15.47 (12.41-20.36) respectively. 13/30 pts had FFMI under the 10th percentile for their gender and age category, 16/30 pts had FFMI under the 25th percentile. The highest prevalence of low FFMI was seen in GOLD stage IV.

Conclusions: In our group, most of pts had FFMI <25th percentile. Those pts with FFMI<10th percentile have a higher risk for future physical disability. In our opinion, pts with FFMI <25th percentile need help to change their dietary habits, physical rehabilitation and nutrition support to prevent the progression of disease. Determination of FFMI would help to create procudulas formulas for COPD pts with muscle weakness and/or terminal cachexia.

P4062
Identification of microorganisms based on gas chromatography-mass spectrometry analysis of volatile organic compounds in headspace gases
J.J.B.N. van Berkel1, E.E. Stobberingh2, M.L.L. Boumans4, Moonen Moonen3, 1Respiratory Medicine, University Medical Centre, Maastricht, Netherlands; 2Department of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 3Centre for Integrated Rehabilitation Organ Failure (CIRO), Ciro, Horn, Netherlands; 4Current smoker, aged (74.7±7.9) years. All subjects underwent spiemetry and carotid ultrasonography. The severity of COPD was determined by GOLD Staging System for COPD Severity Definition. We measured carotid intima-media thickness, and determined the maximal intima-media thickness (IMTmax) value as the indicator of atherosclerosis.

Results: Average IMTmax value in all subjects was 1.9 ± 1.1 mm. IMTmax value was 2.2 ± 1.2 mm in stage I (n=3), 1.7 ± 1.0 mm in stage II (n=15), 2.0 ± 1.1 mm in stage III (n=16), and 2.0 ± 1.4 mm in stage IV (n=12). There were no differences of IMTmax values among the stages of COPD. IMTmax values were higher in subjects with ischemic heart disease (n=5) compared to those without ischemic heart disease (n=41) (IMTmax value: 2.7 ± 1.6 mm vs. 1.9 ± 1.1 mm, p < 0.05). 3 subjects had lower intima-arteries obstructions (IMTmax value was 2.1 ± 0.7 mm).

Conclusions: Atherosclerosis was not associated with disease severity of COPD. This study suggests that atherosclerosis progresses even in patients with mild COPD, especially in those who are associated with ischemic heart disease.

P4063
Pathological changes in the skeletal muscles in COPD patients
Mohamed Elnady, Maysa Sharaf El-Din, Yosef Amin, Ali El-Hindawy. Chest, Cairo University Hospitals, Cairo, Egypt

Background: Peripheral muscle weakness is a major problem in COPD, compromising the ability to exercise intolerance and decreased health status. The loss of muscle mass has been described in those patients, but little data are reported regarding the morphology of limb muscles.

Objectives: To study the pathological changes that occurs in the peripheral skeletal muscles in COPD Patients.

Methods: 50 COPD patients were chosen from the outpatient clinic of chest dis- eases, Cairo University Hospitals. Muscle biopsies were taken from the left Vastus lateralis under local anesthesia by Abram’s needle and subjected to histopatho- logical examination after staining with Hematoxylin and Eosin. The biopsies were compared to specimens taken from 10 healthy control subjects of the same sex and age group.

Results: Strong correlation was found between the severity of COPD and the degree of muscle atrophy graded from zero (normal) to 4 (marked atrophy) according to number of foci of atrophy. The one patient in stage I & 69% of patients in stage II COPD were found to have normal biopsy. Stage III, showed both mild atrophy in (45.5%) & moderate atrophy in (41%) of patients. Stage IV showed moderate atrophy in (64.3%). Marked degree of atrophy were belonged to stage III-IV & IV. 7.2% of patients. A statistically significant positive correlation was found between degree of muscle atrophy and (age, smoking index & number of exacerbations/year).

Conclusion: COPD patients showed variable degrees of peripheral skeletal muscle atrophy correlated to disease severity. Progression of COPD is associated with progression of the muscle affection.

P4064
Plasma VEGF correlates with right ventricular function in pulmonary hypertension
Judit Pako, Andras Bikos, Kristof Karlocski, Gyorgyi Coszoa, Dorottya Kovacs, Gyorgy Losenycz, Idiko Horvath. Pulmonology, Semmelweis University, Budapest, Hungary

Introduction: Pulmonary hypertension (PH) is a severe, progressive condition of the small pulmonary vessels that leads to increased pulmonary vascular resistance, right ventricular failure and death. Previous studies suggest the role of VEGF (vascular endothelial growth factor) in the pathomechanism of PH by several path- ways. Still, the relationship between airway VEGF and right ventricular function has not been investigated yet.

Aims: We aimed to evaluate the exhaled breath condensate (EBC), as an airway sampling technique for VEGF detection in subjects with PH and to compare EBC and plasma VEGF with the best noninvasive clinical sign of advanced disease, by measuring right ventricular longitudinal function, tricuspid annular plane systolic excursion (TAPSE).

Methods: 10 PH patients (6 IPAH, 2 CTEPH, 1 scleroderma, 1 congenital heart disease, 58.17 years, mean pulmonary pressure 58.21 mmHg), and 9 healthy controls (50±13 year) participated in the study. Plasma and EBC (Ruthe, Charlotteswile, US) were collected for VEGF measurements (Quantikine ELISA kit, R&D) and echocardiography was performed to assess TAPSE.

Results: In EBC the VEGF concentration was under the limit of detection in both groups. The level of plasma VEGF was significantly higher in the patient group than in controls (130.49 pg/ml; 30.40 pg/ml; p=0.004). We found significant correlation between TAPSE and plasma VEGF level in PH patients (p=0.02, r=0.69).

Conclusion: We suggest, that decrease of VEGF with advanced PAH disease can be a result of deterioration of right ventricular contractility accompanied with...
Comorbidities in the course of chronic obstructive pulmonary disease
Ines Zayan, Fatima Cherimi Ben Abdallah, Amel Chouarou, Sofia Takta, Ridha Mahouachi, Ali Ben Kched. Pneumology N, Adberlahan Mama Hospital, Ariana, Tunisia

Introduction: Chronic obstructive pulmonary disease (COPD) is characterized by chronic airflow limitation and frequent co-morbid conditions.

Purpose: To evaluate the prevalence of comorbidities in patients with COPD and assess correlations between Body Mass Index (BMI) and exacerbations.

Methods: Retrospective study including 120 patients with COPD. Symptoms, spirometry, peripheral oxygen saturation, BMI and comorbidities were obtained from patient records.

Results: The mean age was 63.3±23 years. All patients were smoking for more than 10 years. 65.8% of patients had comorbidities and the most frequent ones were: systemic hypertension (52.5%), diabetes (32.5%), heart failure (20.8%), renal failure (8.3%), anemia (8.3%), lung cancer (7.5%) and sleep apnea syndrome (SAS) (3.3%). Mean rate of exacerbations was 1.6±0.4. Patients with comorbidities had more exacerbations (2.4±0.4) than those without comorbidities (0.8±0.3).

Conclusions: Comorbidities are very common in COPD. They are associated with more severe exacerbations. Results indicate a relation between BMI and rate of exacerbations.

Usefulness of a panel of sputum markers in the evaluation of lung inflammation and functional impairment in symptomatic smokers and COPD patients
Guglielmo Guglielmi1, Stefano Calzetta2, Riccardo Tagliabue3, Monica Capogrossi1, Maria Chiara Calzetta4, Annarita Vestri4, Giovanni Puglisi5, Fulvio Benassi6, Ilio Cammarella7, Antonio Santini8, Matteo Magi9, Claudio Terzano2.

Background: COPD is a major cause of morbidity and mortality worldwide. COPD patients have a greater number of exacerbations requiring hospitalization or emergency room visits with increased healthcare costs. Comorbidities are common in COPD patients and may alter the natural course of the disease. Sputum analysis may provide useful information about the airway inflammation of COPD patients. The aim of the study was to evaluate the usefulness of a panel of markers identified in the literature that may be useful in the assessment of airway inflammation in COPD patients.

Methods: We enrolled 60 patients with COPD (30 with COPD and 30 without COPD). All patients underwent a physical examination and spirometry. Blood and sputum samples were collected and analyzed for a panel of markers including neopterin, IL-8, MMP-9, HNP, HNE, and IL-18.

Results: A significant correlation was found between the sputum markers and the clinical characteristics of the patients. The markers were found to be different between the two groups of patients with and without COPD. The markers that showed the greatest differences were neopterin, IL-8, and MMP-9. The markers that showed the least differences were HNP and HNE.

Conclusions: The panel of markers identified in this study may be useful in the assessment of airway inflammation in COPD patients. Further studies are needed to validate the potential utility of these markers in the management of COPD patients.

Airway and inflammatory profile of ORL rats: An asthma phenotype?
Elena Rodriguez1, Julia S. Barthold2, Milena Arnari3, Katie Michelena4, Yan Zhu5, Jordan Wang1, Marla R. Wolsfon1, Thomas Shaifer1,2,3,4, Nemours Research Lung Center/Immunological Research, Nemours, Wilmington, DE, United States; 5University of Maryland School of Medicine, Baltimore, Maryland, United States; 6Pharmacology, Pediatrics and Medicine. CHF, Temple Univ Sch Med, Philadelphia, PA, United States

Introduction: The ORL rat is a Long Evans strain with inherited cryptorchidism. We have observed respiratory distress and wheezing in a subset of this strain but no respiratory phenotype is available.

Objective: We hypothesized that ORL rats would exhibit airway responsiveness (AR) associated with inflammation. To address this question, we investigated...
whether respiratory mechanics and biomarkers of inflammation in these rats would be different at baseline (BL) or during methacholine (MCh) challenge induced congestion.

Material and methods: Long Evans WT (n=9) and OXL (n=14) rats were anesthetized, tracheostomized, placed in a plethysmograph (Buxco, Rodent RC Site), mechanically ventilated and challenged with 0.3 to 12.5 mg/ml of aerosolized MCh. We calculated resistance (R) and compliance (C), and lung tissue homogenates were assayed for IL-4, IL-6, and TNF-α using ELISA. Quantitative histomorphometry is ongoing. We performed 2-way ANOVA of physiological outcomes and inflammatory markers.

Results: Respiratory challenges with MCh increased R and decreased C as a function of dose and group (WT vs. OXL). OXL rats had increased (p < 0.0001) sensitivity to MCh for R. IL-6 and IL-4 expression was decreased by 23% (p < 0.0001) and 77% (p < 0.0001), respectively in OXL rats with no differences in TNF-α as compared to WT rats.

Conclusions: OXL rats compared with WT rats were significantly more responsive to MCh challenges, indicated large and small airway reactivity and exhibited decreased expression of IL-6 and IL-4 in lung tissue. The observed respiratory reactivity in this strain of OXL rats may provide a genetic animal model for the study of asthma and associated genetic/hormonal/environmental factors.

449. Diagnosis and treatment of inflammatory respiratory diseases

P4070 Impact of pulmonary tuberculosis infection on chronic obstructive pulmonary disease
Hrdaya Bibbu Ghanire, Jiang Guo Li. Respiratory, Sun Yat-Sen Memorial Hospital, Guangzhou, Guangdong, China

Background: Tuberculosis (TB) and chronic obstructive pulmonary disease (COPD) are common diseases in developing world, sharing some risk factors like smoking and low socioeconomic status.

Aim: To find out whether TB is a risk factor of COPD and to investigate any changes in COPD patients having TB infection compared to non TB cases.

Method: Retrospective study of 328 pulmonary function test (PFT) diagnosed COPD cases was done. Data of 81 patients with clinical and radiological signs of COPD, multiple bullae on radiography without lung function measurements were also taken. Control cases are 414 patients who had done chest radiography from different departments besides respiratory unit.

Result: 328 PFT diagnosed COPD patients, 141 had radiological feature of TB but only 32 of 414 control cases had those features. Odds ratio (OR) was 9.001 compared to placebo) in 10 out of the 15 patients (66.7%) (p < 0.001 compared to both control groups). All asthmatic responses were initiated with a mean 8-hour latency, were recorded at more than three consecutive time points and were sustained until the end of the 12-hour time period.

Conclusions: Specific nasal challenge could be a reliable and specific tool for the diagnosis of Alternaria-induced asthma, alternatively to bronchial challenge, in case confirmation of mould implication is necessary.

Results: Specific nasal challenge in the diagnosis of alternaria-induced asthma
Dimitrios Latisios, Despoina Papakosta, Konstantinos Peropodi, Theodoros Kontsikas, Chloé Ayratou, Katerina Manika, Dimitrios Gionelekas, Konstantinos Zarogoulidis. Pulmonary Department, Aristotle University of Thessaloniki, G. Papamakousa Hospital, Thessaloniki, Greece

Background: Allergic sensitization to Alternaria has been identified as a risk factor for the development and persistence of asthma and is associated with severe and life-threatening episodes. The interaction between upper and lower airways has not been investigated for Alternaria.

Aims and objectives: To investigate whether specific nasal challenge with Alternaria allergen can be used as a diagnostic tool for Alternaria-induced asthma.

Patients and methods: The study included 15 adults patients with mild asthma sensitive to Alternaria and two control groups: 1) 8 patients with mild, allergic asthma non-attributed to Alternaria and 2) healthy controls. Diagnosis of asthma was already established by positive both reversibility and methacholine test. Two nasal provocation tests were performed, one with normal saline (placebo) and another with Alternaria antigen (specific nasal challenge, SNC) performed at two different days, FEV1 was measured during a 12-hour period, at 18 time points and another with Alternaria antigen (specific nasal challenge, SNC) performed at two different days, FEV1 was measured during a 12-hour period, at 18 time points.

Results: A significant FEV1 decline > 20% from baseline (26.9±2.3%) was recorded after SNC (p<0.001 compared to placebo) in 10 out of the 15 patients (66.7%) (p<0.001 compared to both control groups). All asthmatic responses were initiated with a mean 8-hour latency, were recorded at more than three consecutive time points and were sustained until the end of the 12-hour time period.

Conclusions: Specific nasal challenge could be a reliable and specific tool for the diagnosis of Alternaria-induced asthma, alternatively to bronchial challenge, in case confirmation of mould implication is necessary.
P4074
Mild asthmatic patients consistently respond to natural, low dose, allergen challenge in EEC
Deepen Patel1, Navyen Patel1, Joanne Lee2, Peter Cournou3, Rod Hafner1, Anne Marie Salapatek2
1Medical Affairs, Cetene Research, Mississauga, Canada; 2Research & Development, Cetene Research, Mississauga, Canada; 3Research & Development, Circausis Ltd., Oxford, United Kingdom

Introduction: The cat allergen, Felis domesticus (Fel d1), is a common trigger of allergic rhinoconjunctivitis and asthma exacerbation. Aerosolized Fel d1 in an Environmental Exposure Chamber (EEC) reproducibly evokes nasal and ocular symptoms in cat allergic patients. Mild asthmatics’ respiratory responses inside the EEC were assessed.

Methods: Patients with history of rhinoconjunctivitis and positive SPT to Fel d1 were exposed to low, well-controlled levels of aerosolized Fel d1 in an EEC for 3hrs, over 4 consecutive days (V2a, V2b, V2c, V2d). Total nasal, ocular, and asthma (cough, wheezing, & breathlessness of shortness by breath) symptoms were collected [scale=0-3] pre-EEC and then every 30min. FEV1 was measured at screening, pre- and post-EEC. Of the patients who met eligibility criteria, 12 patients were mild asthmatics, 11 patients were non-atopic asthma. Asthma scores and FEV1 from these patients were evaluated. FEV1 measures were analyzed using paired t-test.

Results: A consistent decrease in FEV1 and an exacerbation of asthma symptoms was observed in mild asthmatic patients over 4 consecutive days. At V2a, there was a decrease of 10.9 to 87.14±6.4±5.2% (p<0.05) in % predicted FEV1 with decreases of 10.2 to 87.14±5.25% (p<0.07) [V2b], 11.9 to 84.9±5.50% (p<0.05) [V2c], and 12.2 to 85.3±5.50% (p<0.05) [V2d]. Asthma scores showed consistent increase over 4 consecutive visits with mean maximum asthma scores between 3.4 to 3.7 units.

Conclusion: Low-dose aerosolized cat allergen EEC model provides a safe, controlled and natural environment to exacerbate a clinical response in asthmatic patients indicating that the EEC model may be used for testing putative therapeutics for cat allergy induced asthma.

P4075
Tuberculin skin test sensitivity in asthma patients
Soner Demirbas, Faruk Ozer. Chest Diseases, Sogukpinar University, Meram Medical Faculty, Konya, Turkey

Aim: The aim of this study was to evaluate the tuberculin reaction which develops with Tb type 1 immune reaction in asthma in which Th2 type immune reaction is dominant.

Material and method: This study included 36 cases with allergic asthma, 64 cases with perennial allergenic asthma and 51 cases without asthma. Tuberculin skin test was applied with Montoux method to all cases and induration diameter developed after 72 hours was recorded as millimeter.

Results: Tuberculin positivity was significantly different between cases with asthma and cases without asthma (p<0.05). The tuberculin induration diameter was calculated as 10.9±6.04 mm in cases with asthma and 15.3±5.95 mm in cases without asthma. The difference between them was significant (p<0.05). There was no significant relationship between tuberculin induration diameter and BCG scar (p<0.05).

Conclusion: While the tuberculin skin test results are evaluated presence of allergic diseases should be taken into consideration.

P4076
Multiplexed IgE determination in relation to asthma, exhaled NO and bronchial reactivity: Results from a population based survey
Antonios Patelis1, Maria Gumbrjonsdottir2, Andrei Malinovschi1,2, Per Mattsson3, Annica Önell 3, Marieann Högman1,4, Kjell Alving5
1Department of Respiratory Medicine & Allergology, Uppsala University, Uppsala, Sweden; 2Department of Clinical Physiology, Uppsala University, Uppsala, Sweden; 3Department of Medical Physiology, Uppsala University, Uppsala, Sweden; 4Centre for Research and Development, Uppsala University/City Council of Gävleborg, Gävleborg, Sweden; 5Department of Children and Women’s Health, Uppsala University, Uppsala, Sweden

Background: IgE sensitization is an important risk factor for the development and management of asthma. The aim of this study was to investigate the IgE antibody profile for a broad spectrum of allergen molecules in asthmatic patients.

Methods: Participants from the European Community Respiratory Health Survey II (n=667) were tested with ImmunoCAP IS AC against 103 allergen molecules. Bronchial reactivity was measured with methacholine test and bronchial inflammation with FENO0.05.

Results: A total of 50.7% of the controls and 80.2% of the asthmatics were sensitized against at least one food, pollen, furry animals, mould or latex allergen (p<0.0001). Asthma and increased FENO0.05 were independently related to IgE against pollen and perennial inhalated allergens, while bronchial responsiveness was only independently associated with perennial allergens. Sensitization against perennial allergens was associated with asthma (OR 3.6 CI 95% 1.2-10.6) and bronchial responsiveness. Sensitization to food allergens was related to asthma and increased FENO0.05 only if IgE against pollen and/or perennial allergens were present. Simultaneous sensitization to perennial, pollen and food allergens involves the highest risk for asthma (OR 14.7 CI 95% 7.1-30.5), bronchial inflammation and responsiveness.

Conclusion: FENO0.05 values, bronchial responsiveness and risk for asthma increase with multiple sensitization to different allergen groups. IgE against food allergens increases the risk for asthma and increased FENO0.05 in subjects with simultaneous sensitization to pollen and/or perennial allergens.

P4077
Experience of applying flow cytometry to analyze immune cells in saliva from COPD patients
Ekaterina Alyakhova1, Svetlana Teplova1 1Central Medical Sanitary, Department No. 71, Polyclinic No. 3, Ozersk, Chelyabinsk Region, Russian Federation; 2Research & Development, Cetero Research, Mississauga, Canada; 3Research & Development, Chelyubinsk State Medical Academy, Chelyabinsk, Chelyabinsk Region, Russian Federation

The objective was to analyze the composition of immune cells in saliva from smoking patients with early forms of COPD employed at the radiochemical facility. A group of patients with early forms of COPD (144 individuals) employed at the radiochemical facility are under the constant follow-up for the recent ten years, in addition to 264 individuals without signs of COPD, but smokers, matched to the main group by age, gender, working conditions, smoking index and history. The study included 23 individuals from the main group and 10 individuals from the group of comparison. Leukocytes were measured in saliva, mean 2.4±10/ml.

Cell viability was determined using 7-AAD. A subpopulation of immunocytes was counted in viable cells expressing a marker, CD45. There were no significant differences in total leukocytes and cells expressing markers of granulocytes (CD13+) in saliva between COPD patients and the group of comparison, the CD13+ cells amounted to 0.36% in the main group and 0% in the group of comparison. There was a significant increase in CD3+CD4+ cells (25.85 vs 1.4% in the control group, p<0.049), and CD3+CD4+ (3.3 vs 0.6%, p=0.049) in COPD patients, which proved an increase in total T-lymphocytes and T-helpers without any increase in cytotoxic cells in mucosal/salivary region, which is constantly exposed to tobacco smoke in smoking patients with COPD. The obtained findings allow assuming involvement of CD3+CD4+ lymphocytes in pathogenesis of inflammatory alterations in COPD.
P4079
Health related quality of life and sense of coherence in adolescents with asthma

Kerstin Sundell Bergström, Sten-Erik Bergström, Gunilla Hedlin, All Tunsater
Dept. of Respiratory and Allergic Diseases, Karolinska University Hospital, Huddinge, Stockholm, Sweden Dept. of Allergology and Pulmonology, Astrid Lindgren Children’s Hospital, Stockholm, Sweden Dept. of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden Dept. of Respiratory Medicine and Allergology, University Hospital, Lund, Sweden

Aim: To prospectively study adolescents with asthma in transition from child to adult with respect to Health Related quality of life “HRQOL” and Sense of Coherence “SOC”.

Methods: Teenagers with asthma (n=156) were screened employing spirometry, bronchial challenge, skin prick test and exercise test at the time of referral and after five years. They completed the “Living with Asthma Questionnaire” and the Sense of Coherence “SOC” instrument. Discontinuous to moderate asthma were assigned randomly to an adult asthma clinic or to primary care.

Results: At both time-points the HRQOL of the men was better than that of the women (p<0.001). HRQOL improved for both men and women after five years. Lung function, atopy, bronchial hyper-responsiveness did not exert any impact on HRQOL or SOC. However poor adherence to the recommended asthma treatment was associated with lower HRQOL (OR= 0.29; 95% CI= 0.11-0.73; P<0.01). Young women who exercised regularly exhibited better HRQOL than those who did not (p<0.001). Only women with severe asthma demonstrated a poorer HRQOL. Over the five year period the men showed a significant stronger SOC compared to the women (p<0.05). Lung function and SOC remain stable regardless of the randomization to an asthma clinic or to primary care.

Conclusion: The HRQOL of adolescents with asthma improves with age. Young men with asthma have stronger SOC compared to young women. Adolescents with mild-to-moderate asthma receive appropriate care in the primary care system. The negative impact of poor adherence to asthma treatment on HRQOL emphasizes the importance of healthcare programs including patient education and support for adolescents with asthma and with special attention to young women.

P4080
Quantitative assessment of cysteinyl leukotrienes in human sputum during the allergen-induced asthmatic response and the effect of GSK2190915, a 5-lipoxygenase activating protein (FLAP) inhibitor

Ginger L. Milne 1,Warda Amin1, Stephanie C. Sanchez 1, Andrew F. Preece 2.
1Clinical Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, United States; 2Clinical Science and Study Operations, GlaxoSmithKline, Ulverstone, Midlands, United Kingdom

Accurate measurement of the cysteinyl leukotrienes (cLTs) LTC4, LTD4, and LTE4 in human sputum may be useful for assessing airway inflammation. GSK2190915 is a potent FLAP inhibitor that inhibits the synthesis of cLTs. The objective of this study was to assess the effect of GSK2190915 on the production of cLTs in human sputum using ultra pressure liquid chromatography-mass spectrometry. In this double-blind, placebo-controlled, crossover study subjects took 100mg GSK2190905 and placebo orally once daily for 5 days, in randomized order. On Day 3 they had an induced allergen challenge and on Days 4 and 5 they had induced sputum collection. Sputum was frozen at ~80°C until measurement. For analysis, 200-500μL of sputum supernatant was diluted into 1mL of water spiked with [14C]LTE4 internal standard and was extracted using an Empore C-18 solid phase extraction disk prior to analysis. The limit of detection for each analyte was 1pg/mL. LTD4 and LTE4 were detected in the five year period the men showed a significant stronger SOC compared to the women (p<0.05). Lung function and SOC remain stable regardless of the randomization to an asthma clinic or to primary care. The negative impact of poor adherence to asthma treatment on HRQOL emphasizes the importance of healthcare programs including patient education and support for adolescents with asthma and with special attention to young women.

Churg Strauss syndrome associated with montelukast treatment – Study case

Kiyoshi Sekiya, Masami Taniguchi, Hideomi Tamagaki, Kazuo Akiyama.
Clinical Research Center for Allergy and Rheumatology, National Hospital Organization, Sagamihara National Hospital, Kanagawa, Japan

Aim: To report a case of Churg Strauss Syndrome associated with montelukast treatment.

Methods: We reviewed medical records of inpatients with Churg Strauss Syndrome (CSS) treated at our hospital. The patient was a 62-year-old female with a 20-year history of moderate asthma treated with Fluticasone/Salmeterol (50/500) for 5 year and Montelukast (10mg) for 5 month (had not been on steroid treatment other than inhaled with no decreasing of steroid dose). The patient was admitted in our hospital in December with malaise, fever, headache, wheezing, musculoskeletal and thoracic pain, rhinitis and gastrointestinal. A chest radiograph showed only few reticulonodular infiltrates. Chest CT revealed infiltrates in right superior lobe. The blood eosinophilia was 52% of her total WBC count. Bronchoalveolar lavage showed 14.6% eosinophils; medullar biopsy revealed central eosinophilia. The gastric intestinal biopsy show eosinophil infiltration. Serum IgE level was elevated. The patient has more than four of the six diagnostic criteria (developed by ACR in 1990) for Churg Strauss syndrome. We believed that Montelukast use was associated with CSS. Discontinuation of Montelukast and association of oral Prednisone (1mg/kg) generated rapid improvement of the symptoms and favorable outcome. Respiratory physicians need to evaluate the risk of CSS when treating patients with LTRA. But Montelukast has been associated with CSS in a very small number. The efficacy, lack of major side effects and easy administration make Montelukast a good alternative in asthma management.

P4082
Age-specific background in inpatients with severe asthma exacerbation

Kiyoshi Sekiya, Masami Taniguchi, Hidenori Tanimoto, Kazuo Akiyama.
Clinical Research Center for Allergy and Rheumatology, National Hospital Organization, Sagamihara National Hospital, Kanagawa, Japan

Background: Characteristics resulting in inpatients with severe asthma exacerbation remain unclear. It is considered that characteristics and risk factors in inpatients with severe asthma vary depending on age. However, they are rarely investigated.

Objective: We investigated the differences in characteristics and risk factors in different age groups. We clarified the countermeasures for each age group, and aimed to reduce the number of inpatients with severe asthma exacerbation.

Methods: All asthma inpatients who were hospitalized with SpO2 <90% (on room air), the breathless at rest, the increased respiratory rate and pulse rate >120/min between 2007-2009 were investigated. We compared their characteristics among the young age group, middle age group, and advanced age group.

Results: The total number of severe asthma exacerbations was 75. In the young age group, 55.6% has mild asthma before hospitalization. The group had poor treatment adherence, a high rate of smoking, and a high percentage of severe asthma exacerbations. The percentage of continuous ICS users in the group was 22.2%. In the middle age group, 54.8% has severe asthma before hospitalization. The group had high rates of aspirin-intolerant asthma and chronic sinusitis. The percentage of continuous ICS users in the group was 61.3%. In the advanced age group, high rates of hypertension/heart disease and diabetes mellitus were observed. The group had good treatment adherence. The percentage of continuous ICS users in the group was 82.4%.

Conclusions: The characteristics and the risk factors in inpatients with severe asthma vary depending on age. We need to establish countermeasures for asthma exacerbation according to the characteristics and risk factor depending on age.

Is it useful CD4+/CD103+/CD4+ ratio for the diagnosis of lung sarcoidosis?

Laimute Jurgauskaite 1, Edvardas Danila 1, Radvile Malikaite 1, 1Heart Surgery Center, Vilnius University, Vilnius, Lithuania; 2Pulmonology and Allergology Center, Vilnius University, Vilnius, Lithuania.

The diagnosis of lung sarcoidosis relies in part on the observation of alveolar CD4+ cells and the demonstration of an increased CD4+/CD8+ ratio. This ratio has been proposed as a diagnostic tool for pulmonary sarcoidosis. But this anomaly is also found in other lung diseases too. The search for other pathognomonic criteria allowing the discrimination of sarcoidosis patients (pts.) from patients with CD4+ alveolar lymphocytosis has been disappointing.

We investigated CD103 molecules on the T lymphocytes subpopulations. The expression of these molecules was examined on BAL lymphocytes from sarcoid patients with different radiological stages (Ist. – 23 pts; II – 16 pts; III – 9 pts.). For all patients, the expression of CD3, CD4, CD8 and CD103 was assessed by flow cytometry.

We found that CD4+/CD8+ ratio in stage 1 was 6,5±4,1; II st. – 4,5±2,3; III st. – 4,1±3,3; Lefgren’s syndrome – 8,6±4,9 and other lung disemination – 1,9±1,7. CD4+/CD103+CD8+ ratio in I st. – 0,2±0,1; II st. – 0,2±0,1; III st. – 0,1±0,1; 0,4±0,2 respectively. CD4+CD103+CD8+ ratio differ significantly (p<0.05) in all stages of sarcoidosis compared with other lung disemination while CD4+/CD8+ ratio did not.

Our findings demonstrate that the combined use of CD4+/CD8+ and CD4+CD103+CD8+ ratios provides a highly sensitive indicator of lung sarcoidosis in patients with other CD4+ BAL lymphocytosis.

**Premenstrual asthma and leukotriene variations in the menstrual cycle**

José Manuel Bravo1, Antonio Pereira1, José Luís Sánchez2, José Alvaro Miguel3, Rosa Vázquez3, Ignacio Vázquez4, José María Igancio1, 1Pneumology Section, Hospital Juan Ramón Jiménez, Huelva, Spain; 2Department of Nursing, Huelva University, Huelva, Spain; 3Pneumology Section, Hospital Infantia Elena, Huelva, Spain; 4Laboratory Service, Hospital Juan Ramón Jiménez, Huelva, Spain; 5Pneumology Section, Hospital de la Serranía de Ronda, Ronda, Málaga, Spain

Several authors report an increase in leukotriene C4 in the premenstrual phase in women with severe premenstrual asthma, indicating that anti-leukotrienes could be used in treatment.

**Objective:** To analyse the role of leukotrienes in premenstrual asthma.

**Methods:** A questionnaire on respiratory symptoms and peak flow during menstrual cycle was given to women of fertile age to define them as asthmatics who suffered from premenstrual asthma or not. The total degree of asthma severity (GINA 2005). PMA was defined as a clinical or functional deterioration (≥20%) in the premenstrual phase compared with the preovulatory phase. Blood samples to measure leukotriene levels were taken during the preovulatory and premenstrual phases.

**Results:** Blood samples were taken in 62 asthmatic women, 34 of whom (53.4%) presented PMA criteria with a premenstrual deterioration of between 20% and 40%. There was no difference in leukotriene C4 levels between the preovulatory and premenstrual phases in the women who suffered from PMA (1.30 ng/mL vs. 1.31 ng/mL; p=0.32) and those who did not (1.40 ng/mL vs. 1.29 ng/mL; p=0.62).

Neither were there any differences in leukotriene levels between women with or without PMA. The results were similar for each category of asthma severity.

**Conclusions:** Our data show that leukotriene C4 does not appear to be involved in the pathogenesis of premenstrual asthma, or support the use of anti-leukotrienes in the premenstrual asthma, at least with a moderate premenstrual deterioration. No differences appeared in any of the categories of asthma severity.

**Chronic exposure to allergen and cigarette smoke induces predominantly features of COPD**

Tania Maes, Katrien B. Moerloose, Chris L. Van Hove, Kurt G. Tournoy, Guy F. Joos. Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium

**Rationale:** Tobacco smoking by asthmatics correlates with disease severity and smoking is a risk factor for COPD. We previously demonstrated in a short-term mouse model that combining allergen with cigarette smoke exposure aggravated allergic airway inflammation. Here we investigated the effects of (very) long-term combined exposure to allergen and cigarette smoke.

**Methods:** 6-8-week-old male BALB/c mice were exposed to ovalbumin (OVA) or saline (PBS) twice a week, combined with air or mainstream cigarette smoke (5 times/week) for 6 months. Bronchoalveolar lavage fluid (BAL) and lung samples were processed for immunological and histological examination.

**Results:** Six months exposure to OVA/Air, PBS/smoke or OVA/smoke induced a pulmonary inflammation with increased macrophages, dendritic cells, lymphocytes and MIP-3α in BAL compared to PBS/Air exposure. OVA and/or smoke exposure induced an airway wall remodeling (goblet cells, collagen deposition) and lymphoid neogenesis. Mice exposed to OVA/Air had airway eosinophilia, which was absent or strongly reduced in the PBS/smoke and OVA/smoke groups. OVA-IgE was elevated in both OVA/Air and OVA/smoke mice, although more pronounced in the former.

In contrast, PBS/smoke and OVA/smoke exposure, but not OVA exposure induced a marked neutrophilic inflammation (134±91×10³ and 208±36×10³ versus 7.2±10³ cells in BAL, respectively; p<0.05). This neutrophilia was paralleled by increased levels of KC. Both smoke-exposed groups also had erythrocytes.

**Conclusion:** Chronic exposure to aerosol allergens in the presence of cigarette smoke results in a pathology with predominantly features of COPD, albeit limited characteristics of airway hyperresponsiveness.

**Funding:** Belgian IAP - P6/35.
Severe asthma: Clinical features and management in Tunisia
Manel Lousli1, Samia Chichi Kohou1, Nawel Ben Salem2, Hajer Racis1, Nawel Chamsi1, Mourad Zarrouk2, Abdellaoui Chabou2.
1Pneumology Department, Abderrahmen Mami Hospital, MSP, Ariana, Tunisia; 2Research Unit: Insauffisance Respiratoire Chronique, El Manar University, Tunis Medical School MEIRS, Tunis, Tunisia

Chronic severe asthma (CSA) is a complex and heterogeneous condition with distinct subphenotypes leading to impaired quality of life and excessive healthcare need. Aim of the study was to describe the different subphenotypes of CSA and to assess its management in Tunisia.

Methods: The clinical data of 54 patients (1998-2011) with CSA were analysed. Three groups were identified according to the CSA WHO definition. G1: untreated CSA due to unavailability of therapy, G2: difficult-to-treat CSA due to compliance issues and inappropriate use of medicines, and G3: treatment-resistant CSA. The latter includes 2 subgroups: uncontrolled asthma despite the highest level of recommended treatment (G3a) and asthma which is controlled only with the highest level of recommended treatment (G3b).

Results: Patients are distributed as follows: G1: 27 patients (50%), G2: 8 patients (15%), G3: 19 patients (25%) including 9 cases of G3a (17%) and 10 cases of G3b (18%). Treatment included high doses of inhaled corticosteroids in all groups, long actingβ2-agonists were available for G2 and G3 but not for G1 due to absence of social coverage. Oral corticosteroids were prescribed in 18 patients (33%), among whom 50% belong to G1. Admissions in intensive care unit for severe exacerbation were recorded in 18 cases (29%) and near-fatal asthma was diagnosed in 11 cases (21%). CSA autoantibodies were allergy: 37 cases, allergic bronchopulmonary aspergillosis: 3 cases, gastroesophageal reflux: 4 cases and sensitivity to aspirin: 1 case.

Conclusion: Management of CSA in Tunisia hospitals still suffers from unavailability of appropriate therapy for an important proportion of patients, which makes recourse to oral corticosteroids more frequent than in the reported literature.

420. Experimental modulation of airway inflammation

P4091 Inhibition of collagen receptors: α1β1 and α2β1 integrins, has no impact on lymphocytes, but decreases eosinophil transmigration through human extracellular matrix and collagen I coated inserts
Stanislawa Bazan-Socha, Joanna Zak, Cezary Marcinkiewicz, Jacek Musial. 1Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland 2Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland 3Department of Biology, College of Science and Technology, Philadelphia, United States 4Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland

Introduction: T helper lymphocytes are likely to play a pivotal role in directing disease development and progression in asthma. We recently described presence of α1 and α2 integrins on blood eosinophils and α2 on blood CD4 and CD8 T lymphocytes in chronic asthma. We hypothesize that collagen receptors: α1β1 and α2β1 integrins may play an important role in cell transmigration to the sites of asthmatic inflammation.

Methods: We studied effects of functional active, mouse anti-human monoclonal antibodies against I-domain of α1 and α2 integrin subunit (Chemicon, USA) on eosinophil and lymphocyte transmigration through human extracellular matrix and collagen I coated cell culture inserts (Beckton Dickinson Falcon Cell Culture Dishes). Three inflammatory events – 3 μm pores sized by macroscopic care was taken to minimize the fabrication error, and excesses from the fabrication need. Aim of the study was to describe the different subphenotypes of CSA and to assess its management in Tunisia.

Methods: The clinical data of 54 patients (1998-2011) with CSA were analysed. Three groups were identified according to the CSA WHO definition. G1: untreated CSA due to unavailability of therapy, G2: difficult-to-treat CSA due to compliance issues and inappropriate use of medicines, and G3: treatment-resistant CSA. Critical immunoregulatory role for activin-A in human allergic asthma

Konstantinos Samitas, Giannis Paraskevopoulos, Catherine Hawrylowicz, Konstantinos Samitas, Giannis Paraskevopoulos, Catherine Hawrylowicz.

We have investigated the role of activin-A, a member of the transforming growth factor beta (TGF-β) family, in human allergic asthma. Activin-A is a potent immunoregulatory cytokine that has been shown to downregulate Th2 responses in allergy and autoimmune disease. However, the role of activin-A in human allergic asthma remains unclear.

Our findings indicate that activin-A significantly downregulates Th2 responses and enhances Th1 responses in human allergic asthma. Moreover, activin-A enhances the expression of Th1-related cytokines and downregulates the expression of Th2-related cytokines. These findings suggest a potential role for activin-A in the regulation of Th1/Th2 balance in human allergic asthma.

Cytokine levels were determined by enzyme-linked immunosorbent assay (ELISA) and flow cytometry. Immunohistochemistry was performed to examine the expression of activin-A in human allergic asthma tissues.

These findings have important implications for the understanding of the role of activin-A in human allergic asthma and may suggest new therapeutic targets for the treatment of allergic diseases.

Fluticasone propionate decreases MUC5AC expression in rhinovirus-infected NCI-H292 cells

Alexander Pukhalsky, Galina Shmarina, Tamara Vylegzhanina.

We have investigated the role of fluticasone propionate, a common corticosteroid used to treat allergic rhinitis, in the downregulation of the MUC5AC gene, which is responsible for the production of mucus in the airways.

Our results show that fluticasone propionate significantly decreases the expression of MUC5AC in rhinovirus-infected NCI-H292 cells. This effect is dose-dependent and lasts for up to 48 hours.

Cytokine levels were determined by quantitative real-time RT-PCR and immunoblotting. MUC5AC protein was measured by immunoblotting and immunohistochemistry.

These findings have important implications for the treatment of allergic rhinitis and other chronic respiratory conditions, as they suggest that fluticasone propionate may be a potential therapeutic agent for the downregulation of MUC5AC expression.

Activin-A significantly suppresses allergen-driven suppression of allergic responses and enhances Th1 responses in human allergic asthma

Sofia Touka, Ioanna Christopoulou, Maria S. Panoutsou, Konstantinos Samitas, Giannis Paraskevopoulos, Catherine Hawrylowicz.

We have investigated the role of activin-A, a member of the transforming growth factor beta (TGF-β) family, in human allergic asthma.

Our findings indicate that activin-A significantly downregulates Th2 responses and enhances Th1 responses in human allergic asthma. Moreover, activin-A enhances the expression of Th1-related cytokines and downregulates the expression of Th2-related cytokines. These findings suggest a potential role for activin-A in the regulation of Th1/Th2 balance in human allergic asthma.

Cytokine levels were determined by enzyme-linked immunosorbent assay (ELISA) and flow cytometry. Immunohistochemistry was performed to examine the expression of activin-A in human allergic asthma tissues.

These findings have important implications for the understanding of the role of activin-A in human allergic asthma and may suggest new therapeutic targets for the treatment of allergic diseases.
diet are probably linked with polyphenols that most likely reduce the occurrence of asthma complications. Our experimental work was aimed at influence of polyphenols on airway hyperactivity and allergic inflammation in experimental conditions of allergic asthma (21 days OVA sensitization) after their short- or long-term (21 days) administration. We compared the activities of polyphenolic compounds mixtures from red wine (Provinol) and red fruits (Flavin7) and polyphenolic substances - resveratrol and quercetin. The changes in reactivity of respiratory system after polyphenols administration were measured: by in vitro method; by in vivo method (used whole body plethysmograph). The degree of inflammation was evaluated by eosinophil calculation and by estimation of inflammatory cytokines IL-4, IL-5 in bronchoalveolar lavage fluid (BALF).

The results of our experiments showed that: Polyphenolic compounds Provinol and Flavin7 possess an efficient antiasthmatic activities. They cause bronchodilation and also suppress asthmatic inflammation in the airways. Quercetin and resveratrol are able to induce only acute bronchodilation without antiinflammatory effects. Our results demonstrate positive antiasthmatic effect of mixture of polyphenols. This outcome confirm the hypothesis, that may become an additional therapy in prevention of airway hyperresponsiveness in asthma subjects.

P4100 Cigarette smoke extract suppresses the maturation and function of bone marrow derived dendritic cells Maasoumeh Givi, Frank Redegeld, Gert Folkerts, Esmaili Mortaz. Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands. Chronic obstrutive pulmonary disease (COPD) is characterized by chronic airway inflammation. Cigarette smoke has been considered as a major factor in the pathogenesis of COPD. The potential role of DCs in the respiratory tract of smokers' and COPD patients is poorly understood. In aim of this study is to investigate the effects of cigarette smoke extract (CSE) on the maturation and function of mouse bone marrow. Bone marrow derived DCs were developed by culturing isolated cells by femurs of BALB/c mice in presence of GM-CSF (20 ng/ml) for 10 days. CSE was added to cells cultures for 10 days.

The surface expression of maturation and co-stimulatory markers were CD11c, MHC II, CD80, CD86, CD40 and CD83, respectively, as measured by FACS analysis. The functional capacity of DCs was measured by uptake of Dextran-FITC as measured by FACS analysis. The production of TNF-α, IL-6 and IL-12 was measured by ELISA. After 10 days of incubation with CSE, the DCs maturation was assessed by (MICHC/D83 compared to control, P<0.05) and co-stimulatory receptors (MICHC/CD86, MICH/CD200 compared to control, P<0.05). The cytokine production did not differ between the experimental groups. However, resveratrol with CSE resulted in significantly less cytokine production of DCs that had been exposed to CSE for 10 days compared to the non exposed cells. In addition, the uptake of FITC-Dextran was significantly decreased in DCs that had been exposed for 10 days to CSE. It cannot be excluded that the excretions in COPD patients might be due to a decreased maturation, development and function of DCs induced by cigarette smoke.

P4101 LNC 2011 Abstract: The effect of endothelin-1 on human basophil function in vitro

Katharina Cima, Silvia Blunder, Susanna Desole, Julia Günther, Judith Loffler-Ragg, Christian M. Kahler. Pneumology, Internal Medicine, Medical University of Innsbruck, Innsbruck, AT Internal Medicine, Laboratory of Rheumatology, Innsbruck, AT

Endothelin-1 (ET-1) has profinflammatory properties and contributes to allergic late-phase responses. As basophils play a key role in allergic rhinitis or asthma, we investigated the effect of ET-1 on basophils.

Cells were isolated from venous blood of healthy donors via magnetic cell sorting. To show ETA or ETB receptor expression RT-PCR was performed. The chemotactic effect of ET-1 [10⁻⁸ M] was analysed in modified Boyden chambers (positive control MCP-1 [10⁻⁸ M]). To explore ET-1 signalling, cells were preincubated with ET-1, showing ET-1 [10⁻⁸ M] to be most effective.

The results of our experiments showed that: Polyphenolic compounds Provinol and Flavin7 possess an efficient antiasthmatic activities. They cause bronchodilation and also suppress asthmatic inflammation in the airways. Quercetin and resveratrol are able to induce only acute bronchodilation without antiinflammatory effects. Our results demonstrate positive antiasthmatic effect of mixture of polyphenols. This outcome confirm the hypothesis, that may become an additional therapy in prevention of airway hyperresponsiveness in asthma subjects.

P4102 Resveratrol impairs the release of steroid-resistant cytokines from bacterial endotoxin-exposed alveolar macrophages (AM) in COPD

Jurgen Knobloch, David Jungck, Katja Urban, Andrea Koch. Medical Clinic III for Pneumology, Allergology and Sleep Medicine, University Hospital Bochum-Bergmannsheil, Bochum, Germany

Airway inflammation in COPD might be insensitive to corticosteroids. However, corticosteroids are recommended in COPD (GOLD stages III, IV) with frequent exacerbations. Resveratrol has anti-inflammatory properties and could be an alternative in COPD therapy. We investigated the effect of dexamethasone (Dex) versus resveratrol on the release of COX-related inflammatory mediators (IL-6, IL-8, GM-CSF, MCP1) and MMP9 from AM exposed to bacterial endotoxin (lipopolysaccharide, LPS). We compared never-smokers (NS), current smokers without airway obstruction (S) and current smokers with COPD (each n=12). Cytokines and MMP9 were measured in cell culture supernatants by ELISA.

The release of IL-8 and MMP9 from LPS-exposed AM was increased in COPD (each p<0.001), the release of GM-CSF and IL-6 was decreased in COPD (each p<0.05) and the release of MCP1 was without differences between the cohorts. Dex impaired the release of all cytokines and MMP9 from LPS-exposed AM of all cohorts, but for IL-8 and GM-CSF this effect was reduced in COPD (p<0.05). In AM of COPD there was an almost complete reduction of IL-6 release but only a partial reduction of IL-8, GM-CSF, MCP1 and MMP9 demonstrating a partial corticosteroid-insensitivity. In contrast, resveratrol almost completely reduced the release of all cytokines and MMP9 without significant differences between the cohorts. Our data provide evidence for a corticosteroid-resistance of AM-dependent inflammatory responses induced by gram-negative bacteria in COPD and thus question the utility of corticosteroids in COPD therapy. Instead, resveratrol may prove an alternative.

P4103 Endothelin receptor B (ETBR) dependent GM-CSF mRNA stabilization explains the higher efficacy of bosentan vs. ambisentan in the reduction of GM-CSF release from human airway smooth muscle cells (HASMCs)

David Jungck1, Jurgen Knobloch1, Katja Urban1, Eirich Stoelb2, Justus Strauch3, Juehrn Beh4, Andreas Koch1, 1Medical Clinic III for Pneumology, Allergology, Sleep Medicine, University Hospital Bochum-Bergmannsheil, Bochum, Germany; 2Department of Thoracic Surgery, Lungenklinik Merheim, Klinikum der Stadt Koln, Cologne, Germany; 3Clinic for Heart & Thoracic Surgery, University Hospital Bochum-Bergmannsheil, Bochum, Germany

Introduction: TNFs and GM-CSF are pivotal in chronic inflammatory airway diseases and lung fibrosis. TNFa-systems and ETBR-dependent Endothelin-1 (ET-1) release is required for full TNFα induced GM-CSF transcription in HASMCs suggesting anti-inflammatory potential of endothelin receptor antagonists (ERA). The MAP-Kinase ERK protects GM-CSF mRNA from degradation. Ambisentan (ETAR blocker) and bosentan (dual blocker) are available for PAH therapy.

Aim: We compared the anti-inflammatory potential of bosentan vs. ambisentan. Methods: HASMC culture, qRT-PCR, ELISA

Results: TNFs and ET-1 induce transcription and release of ET-1 and GM-CSF (each p<0.05). Bosentan reduces GM-CSF release more efficiently than ambisentan (p<0.01; EC50: 4.5 vs. 11 x 10⁻⁸M; EMAX: 63.7 vs. 54.8% reduction; n=9) but both block GM-CSF transcription similarly. Specific ETBR inhibition (BQ 789) also reduces GM-CSF mRNA. Combined blocking of ET,R (ambisentan) and ERK activity (PD 098059) leads to a greater reduction of GM-CSF release than single inhibition (each p<0.05). In the presence of actinomycin D which blocks gene transcription bosentan leads to a significantly greater reduction of GM-CSF mRNA than ambisentan (p<0.01).

Conclusion: Following TNFα-induced ET-1 release, ET-R induces GM-CSF transcription and ET-R signals via ERK to protect GM-CSF mRNA from degradation. This can explain why bosentan reduces TNFα induced GM-CSF release more effectively than ambisentan. Thus, bosentan may be superior in the therapy of early stages of chronic airway diseases by preventing the establishment of inflammation.

P4104 Effect of thrombin inhibition in a murine model of bronchial asthma

Takehiro Takagi1, Masahiro Onishi 1, Masahiro Naito 1, Atsushi Fujiwara1, Tetsu Kobayashi1, Hiroyasu Kobayashi1, Corina D’Alessandro-Gabazza1, Esteban Gabazza2, Osamu Yamasaki1. 1Department of Respiratory Medicine, Mie University Graduate School of Medicine, Tsu, Mie, Japan; 2Department of Immunology, Mie University Graduate School of Medicine, Tsu, Mie, Japan

Background: Thrombin is the effector enzyme of the coagulation system with important biological functions not only in thrombosis and hemostasis but also in inflammation. The precise role of thrombin in allergy remains unknown but recently there are some reports showing that thrombin plays an important role in the pathogenesis of asthma. In addition, previously we reported that thrombin inhibitor did not improve allergic response in murine asthma model.

Objectives: To evaluate the effect of inhibited thrombin on airway inflammation and hypersensitiveness in a murine asthma model.

750s
Methods: Bronchial asthma was induced by sensitization and challenge with ovalbumin (OVA). Littermates treated with saline were used as controls. The effect of inhaled different dose of thymus was assessed by administering prior to OVA exposure. Airway inflammation was evaluated by measuring the number of inflammatory cells and the level of cytokine in bronchoalveolar lavage fluid (BAL). Airway hyperresponsiveness was measured using a plethysmograph.

Results: The levels of IgE, IL-5, and the number of eosinophils in BAL were decreased in low dose of thymus treated mice compared to saline treated mice. The degree of airway hyperresponsiveness was significantly decreased in low dose of thymus treated mice compared to saline treated mice.

Conclusion: These results suggest thymus exerts a differential effect in bronchial asthma depending on its concentration.

P4105 Efficacy of inhaled anti-IL-13 mAb in a mouse model of asthma

Jonathan Hacha1, Maud Guider2, Kate Tomassini1, Gertrudine Paulissen1, Natacha Rocks1, Agnès Noël1, Roger Palffray1, Didier Cataldo2. Laboratory of Tumor & Developmental Biology (GIGA-Research), University of Liege, Liege, Belgium; 3Immunology Research, UCB, Slough, United Kingdom

Interleukin-13 (IL-13) is a prototypic Th2 cytokine and a potential cornerstone of asthma pathology. IL-13 is involved in IgE synthesis, bronchial hyperresponsiveness, mucus hypersecretion, subepithelial fibrosis and eosinophil infiltration. We assessed the potential efficacy of an inhaled high affinity monoclonal antibody (mAb) Fab’ fragment neutralizing IL-13 against allergen-induced inflammation and hyperresponsiveness. BALB/c mice were subjected to ovalbumin (OVA) exposure for 1, 5, and 10 weeks referred to as short term (ST), intermediate term (IT) and long term (LT) protocols respectively. The antibody was administered as an aerosol雾200 g/kg by intubation in a tower air-flow system. In a one-week OVA-exposure model (ST), we assessed the effectiveness of different doses of anti-IL-13 (0.5 to 5 mg/ml). We report a dose-dependent increase of the anti-inflammatory effect reaching a maximum at a 5 mg/ml Airway responsiveness to methacholine was measured by using the flexVent system.

In the different protocols used in this study, administration of the anti-IL-13 Fab’ by inhalation significantly decreased bronchial responsiveness to methacholine, BALF eosinophils, subepithelial cell infiltration in lungs and airway walls, bronchial peribronchial collagen deposition and smooth muscle hyperplasia. After 1 and 5 weeks of allergen exposure (ST and IT), levels of pro-inflammatory mediators IL-13, KC and IL-6 were significantly lower in lungs from mice treated with the IL-13 neutralizing antibody. In conclusion, our data generated in a rodent model suggest that inhaled anti-IL-13 Fab’ could represent a novel and effective therapy for the treatment of asthma.

P4106 Effects of corticosteroid and montelukast treatment on distal lung parenchyma and airway walls in inflammation in guinea pigs with chronic allergic inflammation

Nathalia B. Gobbato1, Flávia C.R. Souza1, Carla Máximo Prado2, Milton Arruda Martins1, Iolanda Calvo Tiberio1, Edna A. Leick1. 1Medicine, School of Medicine of University of São Paulo, São Paulo, Brazil; 2Biological Sciences, Universidade Federal de São Paulo, São Paulo, Brazil

Rationale: The effects of montelukast or dexamethasone in asthma pathophysiolo- gy are barely understood. Aim: Airway inflammation was evaluated in distal lung parenchyma and airway walls in guinea pigs (GP) with chronic allergic inflammation. GP were inhaled with ovalbumin (OVA) group-2x/week/4weeks). After 4th inhalation, GP were matured with lipopolysaccharide in the presence or absence of supernatants of bioactivity was done with human monocyte derived dendritic cells (DCs) that were matured with lipopolysaccharide in the presence or absence of supernatants or fractions. The expression of the costimulatory molecules CD80, CD86, CD80 and CD107a was then assessed by flow cytometry.

Results: 15 supernatants from 50 strains significantly reduced both CCL17 secretion of KM-H2 and LPS-induced upregulation of DC markers. The immune modulatory activity in the screening assays applied. Furthermore, the HIV-1 co-receptor was preliminary indication of the chemical nature of one soluble probiotic compound with in vitro immune modulatory effects.

P4108 The effect of M. tuberculosis chaperonin 60.1 on leukocyte migration

Yania Riffo-Vasquez1, Clive Page2, Clémence Sohra1. 1School of Medicine, King’s College London, London, United Kingdom; 2Immunology Research, UCB, Slough, United Kingdom

We have shown that M. tuberculosis Cpn60.1 inhibits allergic lung inflammation and bronchial hyperresponsiveness in mice (Riffo-Vasquez Y et al. Clin Exp All. 2008). Here we have evaluated the effect of Cpn60.1 of probiotic supernatants on lung eosinophils and leukocytes in vivo. BALB/c mice were immunized twice with ovalbumin (ova, 10μg/mouse i.p. in alum). From day 14 all mice were exposed to ova (3%) once daily for 3 days and Cpn 60.1 was given i.n.15 min earlier. Lung lavages were performed 24 h after the last exposure. To examine the recruitment of cells in the microvasculature of the cremaster muscle, Cpn60.1 at 1μg/mouse was given s.c. into the scrotal sac of ova-sensitized mice followed by 10ng of otxin 10 minutes later. Four hours later the animals were prepared for intravital microscopy. Cpn60.1 at 0.001-1 μg/mouse inhibited the migration of eosinophils into the airways (4a 4.3±3 vs vs 0α0.01: 1.1±1.2; 3.3±3.4: 1.3±1.4 and 9.4±2.2 x 107/ml; n=10 for 0.001-1 μg of Cpn60.1 respectively, p< 0.05). Four hours after eotaxin injection, saline treated mice showed a significant accumulation of cells in the extra vascular tissue (saline: 4.0±2 vs Cpn60.1: 2.3±1 cells/50 μm², n=6) and higher number of cells rolling along the vessel wall in 30 sec (saline: 12±1.12 vs Cpn60.1: 2.8±1.02) compared to Cpn60.1 treated mice. In contrast, the adherence of cells to the endothelial layer was higher in Cpn60.1 compared to saline treated mice (saline adhesion: 15.4±1.7 vs Cpn60.1: 22.4±4.8 cells/50μm², n=6) Cpn60.1 inhibits leukocyte migration to the lung in response to ova and prevented leukocyte rolling along and transmigration across the vessel wall in vivo.

P4109 Expression of hyperoxidized peroxiredoxin is enhanced in peripheral blood mononuclear cells of bronchial asthma patients

Yun-Jeong Bae1, Tae-Bum Kim2, Jae Hyung Roh3, Hee-Bom Moon4, You Sook Cho5, Keun Ai Moon6. 1Health Promotion Center, Asan Medical Center, Asan Medical Center, Seoul, 2Department of Allergy and Clinical Immunology, Asan Medical Center, Seoul, 3Internal Medicine, Yeong-Yang Gun Health Centers, Kyung Sang Bukdo, Asan Institute for Life Science, Asan Institute for Life Science, Seoul, Korea

Background and objectives: Increased oxidative stress is related to the pathogen- esis of asthma. Peroxiredoxin (Prx), ubiquitously antioxidant enzymes, also termed thioredoxin peroxidases. However, its role in the allergic inflammation remains unidentified. The present study investigates the expression and possible role of Prx and hyperoxidized Prx (Prx-SO3) in bronchial asthma patients.

Methods: At first, the expression of Prx and Prx-SO3 in peripheral blood mononuclear cells (PBMCs) of asthma patients were semi-quantitatively measured by using Western blot methods from asthma patients and control subjects. And then, to evaluate if higher sensitivity to oxidative stress exposure exists in PBMCs from asthmatics, intracellular ROS levels with hydrogen peroxide treatment were also determined by flow cytometry.
Results: The levels of Prx-SO3/Prx in PBMCs of asthma patients were signifi-
cantly higher compared to those in normal subjects and were also related with asthma severity. Furthermore, the intracellular ROS after hydrogen peroxide treat-
ment were remarkably enhanced and prolonged in multivariate risk factors, while transiently increased intracellular ROS levels were observed in control subjects.

Conclusions: The hyperoxidation of Prx may be related with increases suscepti-
bility to oxidative stress and possibly play a role in the pathogenesis of severe asthma.

LSC 2011 Abstract: P2Y2 receptor regulates VCAM-1 membrane and soluble forms and eosinophil accumulation during lung inflammation

ATP has been defined as a key mediator of asthma. In this study, we evaluated lung inflammation in mice deficient for the P2Y2 purinergic receptor. We observed that eosinophil accumulation, a distinctive feature of lung allergic inflammation, was defective in OVA-treated-deficient mice compared with OVA-treated wild type animals. Interestingly, the upregulation of VCAM-1 was lower on lung endothelial cells of OVA-treated P2Y2-/- mice compared with OVA-treated wild type animals. Adhesion assays demonstrated that the action of ATP on leuko-

cyte adherence through the regulation of endothelial VCAM-1 was abolished in P2Y2-deficient lung endothelial cells. Additionally, the level of soluble VCAM-1, reported as an inducer of eosinophil chemotaxis, was strongly reduced in the bronchoalveolar lavage fluid (BALF) of P2Y2-deficient mice. In contrast, we observed comparable infiltration of macrophages and neutrophils in the BALF of LPS-aerosolized P2Y2+/- and P2Y2-/- mice. This difference could be related to the much lower level of ATP in the BALF of LPS-treated mice compared with OVA-treated mice. Our data define P2Y2 as a regulator of membrane and soluble forms of VCAM-1 and eosinophil accumulation during lung inflammation.

421. Respiratory epidemiology: quality of life, therapy and socioeconomic

Late-breaking abstract: Postmenopausal hormone replacement therapy is associated with increased asthma hospitalization

Klaus Bonnelykke1, Ole Raaschou-Nielsen2, Hans Bisgaard1, Ole Skovsted3, Fourness Glendenning4.

Introduction: A previous study of the Danish National Health Service Database showed that Ever using HRT was positively associated with asthma hospitalization (hazard ratio (HR)=1.49; 95% confidence interval (CI):1.35-1.63). Aims: To investigate, for the first time, the association between HRT use and risk of severe asthma exacerbations requiring hospitalization in a prospective study. Methods: We observed 446 (1.9%) incident asthma hospitalizations in 23 138 women over 9.9 years mean follow-up. 11 575 (50.0%) women ever used HRT. Ever using HRT was positively associated with asthma hospitalization (hazard ratio (HR)=1.49; 95% confidence interval (CI):1.35-1.63). The risk was highest with the longest duration of HRT use (≥ 10 years: 1.51 [1.15-1.98], 3-10 years: 1.34 [1.05-1.72], < 3 years: 1.29 [1.01-1.67], reference never users). Effect modification was detected in women without anxiety (OR=1.00; 95% CI:0.87-1.17) and those who had an asthma hospitalization in combination with anxiety in relation to the reporting of dyspnoea was not well studied.

Objectives: To study the association between reduced lung function and dyspnoea, and how anxiety affects this association.

Methods: We analysed data on 5267 women and 5066 men who participated in the Lung substudy of the Nord-Tröndelag Health Study in 1995-97. In a cross-

sectional design we used logistic regression to calculate multivariably adjusted odds ratios (ORs) for dyspnoea associated with levels of FEV1% predicted and anxiety (measured by the Hospital Anxiety and Depression scale).

Results: Among women with FEV1 ≥70% predicted, those who had anxiety had an OR (95% confidence interval) for reporting dyspnoea when walking of 2.00 (0.68-5.90) compared to those without anxiety. Using the same reference group (FEV1 ≥70% predicted and no anxiety), women with FEV1 60-69% predicted had an OR of 1.24 (0.80-1.94) without anxiety and 2.77 (1.32-5.80) with anxiety. The corresponding ORs among men without and with anxiety were 1.00 (reference) and 1.23 (0.78-1.98), 1.15 (0.68-2.01) and 2.07 (1.08-4.02), respectively. The ORs for reporting dyspnoea at rest and waking up by dyspnoea showed similar patterns in both women and men.

Conclusions: Reduced lung function in combination with anxiety had a stronger association with dyspnoea than reduced lung function alone.

Functional health status and satisfaction with health in a population reporting a participation or activity limitation: Focus on COPD

Donna Goodridge1, Joshua A. Lawson2, Darcy Marciniuk1, Donna C. Rennie2, Kornelius Madani3, 4Centre of Nursing Research, 5Canadian Centre for Health and Safety in Agriculture, College of Medicine, 6College of Medicine, University of Saskatchewan, Saskatoon, SK, Canada

Background: Symptoms associated with COPD can result in participation and activity limitations as well as reduced quality of life.

Objectives: To examine the impact of COPD on functional health status (FHS) and satisfaction with health (SWH) in persons with a participation or activity limitation among a national sample of Canadians.

Methods: This survey used data from the 2006 Participation and Activity Limitation Survey (PAL3), a complex population survey of Canadians reporting a disability on the census. COPD was defined present if there was a diagnosis of COPD, emphysema, or bronchitis as the cause of disability. FHS was assessed using the Health Utility Index (HUI-3) and categorized as high, moderate, or severe. SWH was categorized as high, moderate, or low. Analyses were weighted to the population and bootstrapping used to estimate variances.

Results: The sample represents 5,185,980 adults with participation or activity limitation. Subjects without missing data (55%) for the variables of interest were included. COPD was reported as the reason for disability in 1.4% of the popu-

lation. Among those reporting COPD, 44% reported moderate and 49% reported low SWH. FHS was moderately impaired for 31% and severely impaired for 46%. After adjustment, COPD was significantly associated with a lower SWH (p<0.05), but not with FHS (p=0.12).

Conclusions: While FHS was similar to the overall population with a disability, persons with COPD had a much lower level of SWH, suggesting the need to focus on quality of life enhancement strategies.

Lung function decline predicts disability in valued life activities, which in turn predicts impaired quality of life in COPD

Paul D. Blanc1, Jonathan Singer1, Theodore A. Ormachea1, Gabriella Sanchez1, Carlos Irizarren2, Miriam Cisternas1, Patricia P. Katz1, 1Medicine, University of California San Francisco, San Francisco, CA, United States; 2Kaiser Division of Research, Kaiser Permanente, Oakland, CA, United States; 3MGC Data Services, MGC Data Services, Carlsbad, CA, United States

Background: Interrelationships among lung function, disability, and health-related quality of life (HRQL) in COPD need clearer delineation.

Methods: We carried out baseline/follow-up interviews, spirometry, and 6 minute walk tests (6MWT) for 466 participants in a COPD cohort (42% male; age 59±6; median follow-up 2.1 years). Valued Life Activities (VLA) disability was scored with a validated instrument; VLA increased disability (VLA-ID)=0.5 standard deviation increase in score baseline-follow-up (14.6% disability). We assessed respiratory-specific HRQL with the Airways Questionnaire 20-Revised. Logistic regression (including age, sex, height) estimated risk by change in absolute values of FEV1 and 6MWT for VLA-ID: linear regression (including the same covariates, VLA-ID, and baseline HRQL) predicted follow-up HRQL.

Results: Mean decline in FEV1=91 ml; mean decline in 6MWT=37 m. VLA-ID predicted worsened HRQL (p<0.001). Although FEV1, decline predicted VLA-ID (p<0.001), neither change in FEV1 or 6MWT was associated with change in HRQL. Including FEV1 and 6MWT in multivariate models, VLA-ID retained its relationship with HRQL (1.3 point change; effect size=0.29; p<0.001).

421. Respiratory epidemiology: quality of life, therapy and socioeconomic

Lung function and anxiety in association with dyspnoea – The HUNT study

Linda Lievenseth1, Torunn Lund Nilsen1, Xiao-Mei Mai2, Roar Johnsen1, Arnulf Langhammer3, 1Department of Public Health and General Practice, Norway; 2University of Science and Technology (NTNU), Trondheim, Norway; 3HUNT Research Centre, Norwegian University of Science and Technology (NTNU), Trondheim, Norway; 4HUNT Research Centre, Norwegian University of Science and Technology (NTNU), Levanger, Norway

Background: Anxiety is common among people with obstructive lung diseases. However, reduced lung function in combination with anxiety in relation to the reporting of dyspnoea is not well studied.

Objectives: To study the association between reduced lung function and dyspnoea, and how anxiety affects this association.

Methods: We analysed data on 5267 women and 5066 men who participated in the Lung substudy of the Nord-Trøndelag Health Study in 1995-97. In a cross-

sectional design we used logistic regression to calculate multivariably adjusted odds ratios (ORs) for dyspnoea associated with levels of FEV1% predicted and anxiety (measured by the Hospital Anxiety and Depression scale).

Results: Among women with FEV1 ≥70% predicted, those who had anxiety had an OR (95% confidence interval) for reporting dyspnoea when walking of 2.00 (0.68-5.90) compared to those without anxiety. Using the same reference group (FEV1 ≥70% predicted and no anxiety), women with FEV1 60-69% predicted had an OR of 1.24 (0.80-1.94) without anxiety and 2.77 (1.32-5.80) with anxiety. The corresponding ORs among men without and with anxiety were 1.00 (reference) and 1.23 (0.78-1.98), 1.15 (0.68-2.01) and 2.07 (1.08-4.02), respectively. The ORs for reporting dyspnoea at rest and waking up by dyspnoea showed similar patterns in both women and men.

Conclusions: Reduced lung function in combination with anxiety had a stronger association with dyspnoea than reduced lung function alone.
ECME: Epidemiologic study of the characteristics of women with COPD in Spain
Sagario Mayoralas1, Salvador Díaz Lobato2, Esther Anton3, Xavier Ribera4, Irene Unzueta5
1Pneumology Service, Hospital Moncloa, Madrid, Spain; 2Pneumology Service, Hospital Ramón y Cajal, Madrid, Spain; 3Medical Department, Pfizer, Madrid, Spain; 4Medical Department, Boehringer Ingelheim, Barcelona, Spain

Background: Chronic obstructive pulmonary disease (COPD) clinical trial popula-
tions are predominantly male (~75%), thus the female population is not
so well characterized.

Aims and objectives: Determine a clinical and sociodemographic profile of women
with COPD in Spain.

Methods: Multicenter, cross-sectional, observational epidemiologic study. 379
pulmonologists from health centers in Spain recruited female patients aged
≥40 yrs, smoking history ≥10 pk-ys, current COPD diagnosis and receiving
treatment/follow-up during pulmonologist visits. Clinical and sociodemographic
data were collected during study visit. Descriptive statistics were performed.

Results: 1732 women evaluated, of which: 80.8% pulmonologist diagnosis; 46.6%
primary, 30.8% secondary education; 60.1% current, 39.9% ex-smokers; 25.5% and
43.1% with history of depression or anxiety, respectively; 78.3% 65.3%, 63.1% receiving
long-acting anticholinergic, long-acting β2-agonist/corticoid, short-acting
β2-agonists. Mean age: 61.6±10.0 yrs; body mass index, 26.7±5.1
kg/m²; time, since and age at, diagnosis, 7.5±6.4 yrs and 54.1±9.8 yrs; pre-
and post-bronchodilator FEV1/FVC, 57.5±12.3% and 57.8±12.2%; O2 satur-
ation, 93.8±3.3%; PF, 35.7±19.9; SF-12 PCS and MCS scores, 37.6±10.5 and
45.7±12.0; LCADL, total, personal care, and household, physical, leisure activities,
27.2±10.9, 6.5±2.9, 11.8±5.9, 4.5±1.6, 4.4±1.8. Median no. exacerbations in
prior year, 1.0 (P25/P75: 0.0/2.0)

Conclusions: Most women in this cross-sectional study were at an age that they
could be actively working. The average FEV1; and exacerbation history suggest
an impact of the disease on these patients’ daily lives.

Supported by Boehringer Ingelheim/Pfizer.

The restrictive spirometric pattern is associated with impaired health-related
quality of life.

Stefano Guerra1, Anne-Elie Carson1, Jan-Paul Zock1, Benedicte Leynaert2,
Chirster Jansson3, Deborah Jarvis4, Josef M. Anto1

1Centre for Research in Environmental Epidemiology, CREAL, Barcelona, Spain; 2INSERM, U700, Faculté Paris Diderot, Paris VII, Paris, France; 3Department of Medical Sciences: Respiratory Medicine & Allergology, Uppsala University, Uppsala, Sweden;
4National Heart and Lung Institute, Imperial College, London, United Kingdom

Previous population-based studies have shown that a restrictive spirometric pattern
is present in a significant proportion of the adult population and is associated
with an increased risk in morbidity and mortality. However, whether and to
what extent this pattern is associated with impaired quality of life remains to
be determined. In this study, we used data from 6005 participants from eleven
European countries and the US who completed lung function tests and the Short
Form-36 (SF-36) questionnaire during the second ECRHS survey. We defined
the restrictive spirometric pattern as FVC < 80% predicted plus FEV1/FVC <
70% and the obstructive spirometric pattern as FEV1/FVC < 70%. Physical and
mental-component summaries (PCS and MCS) for health-related quality of life
were computed and scores transformed so that the mean was 50 and the SD 10.
Mean age of participants was 43 years (range 28 - 56 years) and 51% of them were
females. Overall, 5254 subjects (87.5%) had a normal, 415.6% a restrictive
and 336.5% an obstructive spirometric pattern. The mean PCS was 56.4, 46.9
and 47.6 for subjects with normal, restrictive and obstructive spirometric patterns,
respectively (p < 0.001). The corresponding MCS mean scores were 50.0, 50.1
and 45.7 (NS). After adjustment for sex, age, body mass index and smoking, the
restrictive spirometric pattern was associated with a -2.7 PCS deficit (p < 0.001)
and the obstructive pattern with a -2.2 deficit (p < 0.001), as compared with the
normal spirometric pattern. In conclusion, the restrictive spirometric pattern is
associated with significantly impaired health-related quality of life.

P4118

Dyspnoea in COPD patients reported in a primary care database
Hana Mullerova1, Chan Lu1, Maggie Tabberer2

1Worldwide Epidemiology, Quantitative Sciences, GlaxoSmithKline R&D, Uxbridge, United Kingdom; 2Global Health Outcomes, GlaxoSmithKline R&D, Uxbridge, United Kingdom

Background: Dyspnoea is a primary clinical feature of COPD [1,2]. Information
on dyspnoea recording in electronic medical record databases has not yet been
reported.

Methods: A cohort was identified in the UK General Practice Research Database
(GPRD) (01/01/2003 – 30/6/2010) with both a COPD medical diagnosis code
and spirometry (FEV1/FVC <70%) and 12months history before and after cohort
eXMIS/Read codes were used to identify and define records of dyspnoea as probable or possible (less likely associated with COPD) from cohort entry until
 censoring.

Results: A cohort of 9502 patients was identified: mean age 67 y. (SD 11),
55% males, GOLD stage I: 12%, II: 50%, III: 29%, and IV: 7%. At least one
“probable” dyspnoea code was found in 76% of COPD patients; “possible” codes
were identified in 2% of patients. Codes most frequently associated with dyspnoea
were “shortness of breath” (16% of patients) and MRC Dyspnoea Scale; 45%
patients recorded as grade 2, 34% grade 3 and 5.5% grade 4 (frequencies
based on the total cohort). Dyspnoea was more often reported by older patients
and those with more advanced disease (69% patients in GOLD stage I with “probable”
dyspnoea vs. 81% in GOLD stages II or IV).

Conclusions: Dyspnoea was reported in > 75% of COPD patients identified in
the GPRD. The high frequency of dyspnoea across all GOLD stages highlights this
symptom as a significant burden and possible unmet need in COPD treatment. MRC
Dyspnoea grade is the predominant code used, linked to the Quality Outcomes
Framework, an NHS system supporting management of selected diseases.

Symptoms experienced by COPD patients during exacerbations and their
association with healthcare utilization – EXACO study
Isabelle Tille Leblond, Frédéric Masure, Bruno Housset, Nicolas Roche, Thierry Perzy, Isabelle Boucot, François Denis, Ada Mytilu, Juliette Ostinelli, Isabelle Pitris-Merli, Céline Prival, Philippe Schick, Pulmonology: CHRU Calmette, Lille, France Pneumology, Groupe Médical Saint Rémi, Reims, France Pneumology, CHU Créteil, France Pneumology, Hôtel-Dieu, Paris, France Pneumology, CHRU Calmette, Lille, France Pneumology, Paris, France Pneumology, GlaxoSmithKline, Marly Le Roi, France Medical Department, Boehringer Ingelheim, Paris, France Medical Department, Nycomed, Paris, France Medical Department, AsthmaZeneca, Rueil Malmaison, France Medical Department, Pfre, Paris, France Pneumology, GlaxoSmithKline, Marly Le Roi, France Scientific, Kappa Santé, Paris, France

Background: Definitions of COPD exacerbations are symptom-based while sever-
is assessment often relies on the level of healthcare utilization.

Tuesday, September 27th 2011
Objectives: To assess symptoms associated with COPD exacerbations and their association with patients’ decision to seek healthcare.

Methods: Patients with GOLD stage ≥ II COPD participating in an observational study were assessed for symptoms and healthcare use associated with exacerbations by telephone interviews.

Results: 835 patients reported 527 exacerbations. The most common symptom was increased breathlessness, 82.2% of led to a medical consultation, visit to a hospital. Fever was the symptom most strongly associated with the decision to seek healthcare.

Medication and preventive measures for COPD in the BOLD study

Laurent Laforest1, Jennifer Martin 1, Edile Licaj 1, Gilles Devouassoux2, Gérard Chatte3, Mélanie Broquet3, Eric Van Gans3, Unité de Pharmacopédiologie, Université Claude-Bernard Lyon1, CHU Lyon-Université Claude-Bernard Lyon1, Lyon, France; 2Respiratory Medicine, Lyon Sud University Hospital, Pierre Bénite, France; 3Respiratory Physician, Respiratory Physician, Caluire, France

Background: High use of short-acting beta agonists (SABAs) may reflect potential risks in asthma management. A better understanding of the characteristics of high users of SABAs is critical to improve quality of care.

Objectives: To describe asthma patients with high levels of use of SABA, including clinical characteristics and medical resource utilisation.

Methods: A random sample of patients aged 16-40, with regular use of dispensed respiratory drugs (R03, ATC classification) in 2005 was selected from the French claims database (EGB). Asthma-related hospital admissions were retrieved. Patterns of use of SABAs in 2007 were described. The correlates (baseline characteristics and asthma-related variables) of using ≥ 12 SABA units in 2007 were identified.

Results: Among 2093 patients (median age = 33 year-old, 54% females), 65% were using SABAs in 2007 and 8% used ≥ 12 units during this period. These patients were more likely to have a long-term disease status (p<0.001), free-access-to-care status (p<0.01), to use higher levels of systemic corticosteroids (p<0.001), and antibiotics (p<0.001) than other patients. Higher numbers of medical visits (p<0.001) and asthma-related hospital admissions (p<0.01) were also observed in this group. Conversely, no noticeable difference appeared with age, nor with gender.

Conclusions: Many patients are still using high levels of SABAs and are possibly at risk of exacerbations. The reasons of this high use of rescue medication require a better understanding.

P4123

Ratio "inhaled corticosteroids to total anti-asthma drugs", and asthma-related hospital admissions

Laurent Laforest1, Jennifer Martin 1, Edile Licaj 1, Gilles Devouassoux2, Gérard Chatte3, Eric Van Gans3, Unité de Pharmacopédiologie, Université Claude-Bernard Lyon1, CHU Lyon-Université Claude-Bernard Lyon1, Lyon, France; 2Respiratory Medicine, Lyon Sud University Hospital, Pierre Bénite, France; 3Respiratory Physician, Respiratory Physician, Caluire, France

Background: The inadequate use of inhaled corticosteroids (ICS) remains an issue in asthma. The ratio of ICS units to total anti-asthma medications dispensed (ICS/R03 ratio) may be useful to assess the risk of severe exacerbations, leading to asthma-related hospitalisations (ARHs). We tested this hypothesis using claims data.

Objectives: To verify in claims databases whether patients with a higher ICS/R03 ratio experience fewer ARHs.

Methods: A random sample of patients aged 16-40, with regular use of respiratory drugs in 2005 was selected from the French national claims database (EGB). Three groups were defined according to the value of ICS/R03 ratio in 2007: 0% (“non users”), ≥50% (“non users”) and ≥50% (“non users”). ARHs in 2007 and 2008 were compared between the 3 groups.

Results: Among 1812 patients (mean age=32 year-old, 54.2% females), non users, inadequate users and adequate users, were 17%, 37% and 46%, respectively. ARH rate was 0.9% (in 2007 0.7% in 2008). Patients with ARH in 2007 were more numerous (p<0.0001) among inadequate users (2.1%), compared with adequate users (0.24%) and non users (0.32%). Differences were also observed in mean ARH-induced costs: 2.16 €, 48.30 € and 3.70 € for non users, inadequate, and adequate users (p<0.0005). Conclusions were similar for ARHs in 2008. Over 80% of adequate users in 2007 remained in this group in 2008.

Conclusions: Patients with ICS/R03 ratio ≥50% experience fewer ARHs than inadequate users, suggesting improved asthma control. ICS/R03 ratio may help identify asthma patients at risk of ARHs in administrative databases.

P4124
The pattern of use of asthma medication in adolescents and young adults: A nationwide study on 2.2 million people
Lars Lund-Anderesen1, Emil Frobel1, Gunnar Gulaison2, Fredrik Folk2, Casper Lund-Anderesen1, Christian Torp-Pedersen2, Backer Vibkve1
1 Respiratory and Allergy Research Unit, Department of Respiratory Medicine, Rigshospitalet, Copenhagen NV, Denmark; 2Department of Cardiology, Gentofte University Hospital, Copenhagen, Denmark

Pharmacological treatment of asthma is highly effective in controlling symptoms and improving quality of life. Within the last 15 years new drugs such as combina-
tions of ICS and long-acting beta-2-agonists (LABA) and leukotriene modifiers for treating asthma has been introduced on the Danish market. Studies have shown that these drugs have changed the pattern of prescription, but most studies on prescription pattern of asthma medication have studied selected populations or population samples.

The study aimed to identify patterns of use of asthma medication in adolescents and young adults in an unselected population.

The study population comprised all Danish individuals aged 10-40 years at January 1, 2000 (N=13,264 individuals). The population was followed until the end of 2006. From the national Danish prescription registry we collected data on all asthma medication (ATC code R03) claimed by the study population.

At every year in the study period, beta-2-agonists were the most commonly claimed drug both in number of users and number of prescriptions. The first years of the study, there was an increasing use of LABA, but after the introduction of combined ICS and LABA, the use of LABA decreased whereas there was a steady increase in use of ICS and LABA in fixed combinations. When leukotriene modifiers were introduced in 1998, usage increased rapidly the first two years and then plateaued with only a small yearly increase. The use of theophyllines more than halved during the study.

This study on the use of asthma medication in an unselected population shows a shift in the use of asthma medication, but short-acting beta-2-agonists remained the most frequently used drug.

P4125
Inhaler use among asthmatics – A cross sectional study in Alappuzha and Kottayam districts of Kerala, India
P Sulaiman Shajahan
Pulmonary Medicine, Medical College, Kottayam, Kerala, India

Introduction: Asthma is an important health problem worldwide. Medications in the inhaled forms are the best therapeutic options currently available for asthma [1]. Despite the availability of a large number of inhalers, the preferred modality of treatment seems to be low [2].

Aims: 1. To find out the proportion of asthmatics using inhalers as the preferred modality of treatment.
2. To bring out the various reasons for not using inhalers among the above study group.

Materials and methods: Study subjects were asthmatics in the age group of 15 to 45 years who attended the medical camps conducted in Alappuzha and Kottayam districts of Kerala, India during the period 2006 - 2009 (n=912). A semi-structured interview schedule on the use of inhalers were administered to collect the data.

Results: 52% of the study subjects accept inhalers as the preferred choice of treatment. 36% of these respondents do not like the inhaler as they believe the inhaler is costly and feels that inhalers are difficult to carry.

Recommendations: More health awareness programmes are needed to alleviate fears and misconceptions about inhaled medications. Patients should be properly trained on correct usage of inhalers.

Comparing the cost-effectiveness of a wide range of COPD interventions using a stochastic population model for COPD
Martine Hoogendoorn1, Maureen Rutten-van Mölken 1, Rudolf Hoogenveen2, Maiwenn Al1, Talitha Feenstra3,4, 1Institute for Medical Technology Assessment
1Institute for Medical Technology Assessment
2Department of Prevention and Health Services Research, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands; 3Department of Prevention and Health Services Research, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands; 4Department of Epidemiology, University Medical Centre Groningen, Groningen, Netherlands

Objective: To develop a stochastic population model of disease progression in COPD that includes the impact of COPD exacerbations on health-related quality of life, costs, disease progression and mortality and allows assessment of a wide range of different interventions.

Methods: The model is a multistate Markov model with time varying transition rates depending on age, sex, smoking status, COPD disease severity, and/or exacerbation type. The model simulates COPD incidence, prevalence, (severe) exacerbations, disease progression (annual decline in FEV1% predicted) and mortality. Main outcome variables are quality-adjusted life years (QALYs) and COPD-related healthcare costs. The exacerbation-related input parameters were based on quantitative meta-analysis. All important model parameters are entered into the model as probability distributions. To illustrate potential use of the model, 10-year costs and effects were projected for three different COPD interventions, one pharmacological (ICS+LABA), one on smoking cessation and one on pulmonary rehabilitation.

Results: Compared to minimal intervention, the 10-year cost/QALY ratio of 3-year implementation was €8,300 for ICS+LABA, €10,800 for the smoking cessation therapy and €17,200 for pulmonary rehabilitation. If the maximum willingness to pay would be €20,000/QALY, the probability that the cost/QALY was lower than that varied from 38% for pulmonary rehabilitation to 100% for ICS+LABA.

Conclusions: The COPD model provides policy makers with comparable information on long-term costs and effects of interventions ranging from primary prevention to care for very severe COPD and includes uncertainty around the outcomes.

Fragmented care in asthma: Data from the French national claims database
Laurent Laforet1, Jennifer Martin2, Jidie Lica1, Gilles Devaouaux1, Gerard Chatte1, Melanie Broquet1, Eric Van Gansen1
1Unité de Pharmacopédiologie, 11 rue Guillaume Paradis, Lyon University Hospital, Claude-Bernard Lyon1 University, Lyon, France; 2Respiratory Medicine, Lyon-Sud University Hospital, Lyon, France; 3Respiratory Physician, Respiratory Physician, Caluire, France

Background: Asthma management is a major public health issue. Little is known about the frequency of fragmented care in asthma patients. It is also unclear whether those patients induce higher levels of medical resource utilisation (MRU).

Objectives: To determine the proportion of asthma patients being prescribed asthma therapy by ≤2 different general practitioners (GPs), and the medical resource utilisation (MRU) induced by these patients.

Methods: A random sample of patients aged 16-40, with at least 3 reimbursements of respiratory drugs (R03, ATC-Classification) was identified in the French national claims database (EGIB). Among those, those with at least 2 visits with prescriptions for respiratory drugs in 2007 were selected. Fragmented medical care in 2007 was defined as receiving prescription for respiratory drugs from ≥2 different GPs.

Results: Patients’ MRU was studied according to the number of distinct GPs prescribing respiratory drugs in 2007.

Results: Among 1,809 patients (mean age = 32 year-old, 59% females), nearly 55% of patients received their respiratory therapy from ≥2 different GPs (2: 36%, 3: 13% ≥3: 6%). A salient increase in the dispensing of short-acting beta agonists in 2007 was observed with the level of fragmented care in 2007 (p≤0.001). Likewise, fragmented care was associated with free-access-to-care status (p≤0.01), more asthma-related admissions (p<0.01) and medical visits in 2007 (p<0.001).

Conclusions: Our data suggest that fragmented asthma care is not exceptional and may result in higher unscheduled MRU. The reasons of fragmented care require a better understanding to optimise the quality of care in asthma.

P4128
Productivity loss in ever-smoking COPD subjects from a general population
Rune Nielsen1, Anne Johansen2, Per Sigmund Bakker3
1Unité de Pharmacopédiologie, 11 rue Guillaume Paradis, Lyon University Hospital, Claude-Bernard Lyon1 University, Lyon, France; 2Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; 3Institute of Medicine, University of Bergen, Bergen, Norway

Background: We aimed to estimate productivity losses of chronic obstructive pulmonary disease (COPD) in hospital- and population-based subjects with spirometric post-bronchodilator COPD, relative to a control group.

Methods: 53 COPD-cases and 107 randomly recruited individuals without COPD were included from a general population. 102 COPD patients were recruited from a hospital register. All participants were ever-smokers, 40-66 yrs of age. In 4 standardized telephone interviews we surveyed the utilization of sick leave and disability pension during one calendar year. Productivity loss was defined as number of days in sick leave or disability pension. The outcomes in a two-part regression approach were any productivity loss (multiple logistic regression) and number of days of lost productivity (multiple linear regression). The latter model included subjects without any productivity loss.

Results: The logistic regression model showed little effect of COPD when we compared the population-based COPD cases to the controls. In the linear regression model we found the increased productivity loss was significantly higher in population-based subjects with stage II, stage III and stage IV COPD (95% CI) 73 (22 - 124), 178 (49 - 308) and 249 (33 - 465) days, compared to the controls. In addition, being a woman, a 1-yr increase in age and low education was associated with an increase of 59 (15 - 103), 6 (12 - 10) and 131 (65 - 197) days of productivity loss. Similar results were found for hospital recruited COPD patients.

Conclusions: The access to sick leave and disability pension was similar in subjects with and without COPD. The exclusion of these variables may result in considerably higher in subjects with COPD and was also associated with disease severity.

Background: The profile of allergic sensitization and its association with allergic diseases varies between different areas of the world.

Objective: To study allergic sensitization and the association with asthma and allergic rhinitis in the northern part of Vietnam.

Methods: A sample of 1500 subjects, aged 21–70 years were randomly selected from all 5782 responders of a questionnaire survey performed in 2007-2008. The subjects underwent a structured interview, a skin prick test with 10 common local allergens (rural and urban). Diagnostic tests require time consuming arrangements with specialized centers, usually located at a distance from family physicians’ surgeries.

Prevalence of asthma and allergies in childhood in Guadeloupe

Eric Elie1,2,3,4,5,6,7, Chantal Raherison3,4,5,6,7, Jacques Götin1,2, David Laurice1,2, Monique Gourtanton1,2, Gerald Marcin1,2, Marie-Alice Moumouchy1, Christine Rambojan8, Vanessa Cornely1, Rabeherison Chantal1,2,3,4,5,6,7, Association Karu-Asthme, Association Karu-Asthme, Pointe-a-Pitre, Guadeloupe; 5ORSAG, ORSAG, Basse-Terre, Guadeloupe; 6Service des Maladies Respiratoires, CHU Bordeaux, Pessac, France; 7Centre de Venerologie et des Maladies Respiratoires, Université Catholique de Chile, Santiago, Chile; 8Respiratory Medicine, Instituto Nacional Enfermedades Respiratorias, Mexico City, Mexico.

Aim: To carry out a screening study for chronic obstructive pulmonary disease (COPD) among the population in Pleven.

Material: We studied 2047 people, 764 (37.3%) men and 1283 (62.7%) women, aged ≥ 40 years. Exposure to different risk factors was found in 1837 (90%) of them. All studied patients filled in a specially designed questionnaire and did spirometry (with bronchodilatation for the ones with forced expiratory value – FEV1, less than 80% predicted value).

Results: We found COPD (both symptoms and spirometry data) in 14.9% of the studied population. The analysis of the data showed: sex - 21.7% of males and 10.8% of females (p=0.0001); age - 11.9% - 40-55 years and 19.3% above 55 years (p=0.0001); place of living - 13.9% urban and 18.8% country (p=0.01). The presence of risk factors was as follows: smoking (both current and former) - 23.2% (OR=12.2); occupation - 7.3% (OR=3.5); coal heating - 3.6% (OR=1.9); frequent respiratory infections - 15.5% (OR=8.28); family history - 13.2% (OR=6.94); air pollution - 2.3% (OR= 1.1); with multiple risk factors - 28.1% (OR= 14.8). Chronic respiratory symptoms were present in 84.9% of the COPD patients and in 43.6% of the people without airway obstruction (p=0.36, p=0.0001).

Conclusion: The study found COPD in 14.9% of the studied population. There was prevalence in males, age above 55 years and in people living in the country. Among the risk factors most important were smoking, frequent respiratory infections and genetic predisposition.

Prevalence of chronic bronchitis in the Middle-East and North Africa: Interim results of the BREATHE study

Background: Few data are available on the epidemiology of COPD outside developed countries.

Prevalence of asthma in Latin American middle-aged and older adults and its overlap with diagnosis of COPD

Ana Maria Menéndez1,2, Pedro Hallal1,3, María Montes de Oca1, AdrianaMuino1,3, Maria Victoria Lopez Varela1, Carlos Talamo2, Jose R. B. Jardim2, Gonzalo Vidalvia1,2, Rogelio Peta-Padilla2,4, Clinical Medicine, Federal University of Pelotas, Pelotas, RS, Brazil; 2Casa de Neumología del Centro de Venezuela, Caracas, Venezuela; 3Hospital Mucal, Universidad de la República, Montevideo, Uruguay; 4Clinical Medicine, Federal University of São Paulo, São Paulo, SP, Brazil; 5Departamento de Salud Publica, Pontificia Universidad Catolica de Chile, Santiago, Chile; 6Respiratory Medicine, Instituto Nacional Enfermedades Respiratorias, Mexico City, Mexico.

Objective: To evaluate the prevalence of asthma using self-reported and spirometric criteria and to analyze the overlap in asthma and COPD diagnoses.

Methods: Multicenter study (PLATINO) in five Latin America cities: Sao Paulo, Mexico City, Montevideo, Santiago, and Caracas. Individuals aged 40 + years performed pre and post-BD spirometry and answered to ISAAC. Significant reversibility was defined as a difference between post and pre-BD FEV1 or FVC; those with a 200 ml and 12% or more differences were classified as having significant reversibility.

Results: Questionnaires and pre and post-BD spirometry were available for 5,183 individuals. Out of 1,242 individuals reporting wheezing in the last 12 months, only 184 (14.8%) also had significant reversibility by spirometry. Out of 352 subjects with significant reversibility, 34.6% also reported wheezing in the last year. As a consequence, asthma by both wheezing and reversibility affected exactly 3.6% of the sample. By analyzing COPD, based on the fixed ratio criterion, and asthma by the most specific criterion (wheezing + reversibility), out of 728 individuals with COPD, only 96 (13.2%) also presented asthma. Out of the 184 individuals with asthma, 52% also had COPD. Taking these two variables together, 96 individuals, representing 1.9% of the sample, had both asthma and COPD.

Conclusion: Wheezing in the last 12 months alone does not correlate strongly with reversibility in spirometry. COPD and asthma diagnoses are mostly independent; its overlap affected only 1.9% of the sample. However, out of all asthmatic subjects, over half also presented COPD.
Objectives: The objective of this epidemiological study was to assess the prevalence and burden of COPD, chronic bronchitis and smoking in eleven countries (Algeria, Morocco, Tunisia, Egypt, Jordan, Lebanon, Saudi Arabia, Syria, UAE, Pakistan and Turkey).

Methods: A general population sample of 10 000 subjects ≥ 40yrs in each country was generated from random phone numbers. A structured interview was proposed to all subjects by telephone. Screening questions, including history of cough and spurt production, was used to identify subjects with chronic bronchitis. Individuals who smoked ≥ 10 pack-yrs and who had either chronic bronchitis or a previous diagnosis of COPD were considered to have COPD. In a subset of the study sample, assignment of COPD was confirmed by spirometry. This interim analysis assesses the prevalence of chronic bronchitis.

Results: Of 118 039 subjects contacted, 44 892 were interviewed. 978 subjects reported having symptoms of chronic bronchitis. This corresponds to a prevalence of chronic bronchitis of 2.2% (95% CI: 2.0-2.3%), ranging from 0.6% (95% CI: 0.4-1.0%) in UAE to 2.9% (95% CI: 2.1-3.7%) in Algeria. The prevalence of chronic bronchitis was higher in women (2.4%, 95% CI: 2.2-2.6%) than in men (1.8%-95% CI: 1.6-2.0%). Prevalence increased with age: 1.6% in subjects aged 40-49 yrs, 2.2% in those aged 50 to 59 yrs and 3.0% in those aged ≥ 60 yrs.

Conclusion: The prevalence of chronic bronchitis in the Middle East and North Africa seems to be lower compared to other regions of the world.

P4139

Chronic obstructive pulmonary disease in smokers with asthma

Flamen Pavlov1, Yavor Ivanov1, Pavlina Gligoska2, Tsanpa Popova3, Elena Balabanova4, Vesela Noutzov1, Pulmonary Clinic, Medical University, Plevn, Bulgaria; 2Clinical of Internal Diseases, Medical University, Plevn, Bulgaria

Aim: To find out what the prevalence of COPD amongst smokers with asthma is.

Material: The study included 154 asthmatic patients - 46 (29.9%) men and 108 (70.1%) women, aged between 40 and 69 years, all of them current or ex-smokers. The patients did spirometry and filled in a specially designed respiratory questionnaire.

Results: Spirometric criteria for COPD were found in 29.9% of all patients, in 25.6% of females and 33.3% of male patients (p=0.02). The prevalence of COPD was 23.2% amongst patients aged between 40 and 50 and 32.2% in patients above 50 (p=0.01). COPD was found in 6.1% of patients with less than 20 pack-years and in 56.2% in patients with ≥ 20 pack-years (p=0.001). More current smokers had COPD than ex-smokers - 38.2% vs. 20.5% respectively (p=0.002). The risk for COPD in smokers with asthma was OR = 15.7 (95% CI 3.8 - 64.5).

Conclusions: One third of the current/former asthmatic patients above the age of 40 in coastal Bulgaria had COPD. There was no significant difference in the prevalence of COPD between men and women patients.

P4140

COPD heterogeneity: An epidemiological perspective from the PLATINO study

M. Victorina Lopez Varela1, Maria Monte de Oca2, Adriana Muñoz3, Carlos Talamo4, Dolores Moreno2, Ana Menezes4, Rogelio Perez Padilla5, Jose Judas6, Gonzalez Valdeza7, Julio Purtz8, Ron Halbert9, Pulmonology, University of La Republica, Montevideo, Uruguay; 2Pulmonology, Carlos Talamo2, Dolores Moreno 2, Ana Menezes 3, Rogelio Perez Padilla 4, The BREATHE Study Group, The European Respiratory Society, Brussels, Belgium; 3Pulmonology, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile; 4Pulmonology, Federal University of Pelotas, Pelotas, Brazil; 5Pulmonology, Instituto of Respiratory Diseases, Mexico, Mexico; 6Pulmonology, Federal University of Campina Grande, Campina Grande, Brazil; 7Pulmonology, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile; 8Pulmonology, UCLA School of Public Health, Los Angeles, United States

PLATINO offers an opportunity to characterise COPD heterogeneity in a population-based multicenter study. 759 COPD and 4,554 non-COPD individuals were included. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes. Dyspnea, health status (HS) and physical limitations similar in non-obstructed and stage-1. COPD was characterised for potential phenotypes.

Conclusion: COPD prevalence varies across countries and different groups of COPD patients are reported in these three local epidemiological studies on COPD prevalence among Turkish population. COPD diagnosed by spirometry in two of them.

Aim: To determine COPD prevalence using spirometry and symptom based criteria in Yigilca, a town in rural area of Duzce.

Methods: The Melen Study was a cross-sectional study conducted in May and June, 2010. Study population was inhabitants of 21000 people in Yigilca. Health service of the region was supplied by six family physicians. 400 subjects from each family physician were randomly selected from electronic data base. Interviews were made by researchers face to face. The questionnaire consist of demographic and socioeconomic variables, the history items of dyspnea, cough, sputum and smoking habits.

Spirometry was performed with Vitalograph ALPHA. COPD defined as a history of dyspnea, cough or sputum production, and post-bronchodilator FEV1/FVC ≥ 70%.

Results: A total of 2298 subjects (1471 females, 827 male with a mean age of 50) were interviewed. Spirometry was performed in 1468 of 2298 participants.

COPD prevalence for adults and adults aged ≥40 years old were 4.9% and 6.7% respectively. Post-bronchodilator FEV1/FVC ≥ 70% were detected in 7.4% of 1468 participants. Sixty five percent of the study population (1495 subjects) had never smoked. Crude smoking rate of the population was 17%.

Conclusion: Although results are consistent with the literature, our study revealed a lower prevalence than other two epidemiological studies in Turkey those used spirometry in diagnose. Low levels of smoking prevalence and rural area might be effective in low prevalence.

P4142

Prevalence, relation to smoking and other factors of COPD: Evidence from population survey

Marine Gumbaryan1, Anna Kalinina1, Svetlana Shalnaya2, Alexander Derv1, Alexander Popugayev3, Elmira Volkova4, Kundal Ivanov1, 1Primary Prevention in Health Care System, National Research Centre for Preventive Medicine, Moscow, Russian Federation; 2Epidemiology and Sociology, National Research Centre for Preventive Medicine, Moscow, Russian Federation; 3Head of Public Health and Health Care, Vologda Oblast Administration, Vologda, Russia; 4Deputy Director for Scientific Work, Department for Therapy and Preventive Medicine, Ural State Medical Academy for Further Education, Chelabinsk, Russian Federation; 5Chief Specialist, Ministry of Health of Saha Republic, Yakutsk, Russian Federation

Although COPD is a leading cause of worldwide disability and mortality it remains greatly underestimated in primary health care in Russia.

The aim of this study is to provide estimates of the prevalence of COPD in Russia in relation to patterns of cigarette smoking and environmental conditions.

Methodology: Subjects aged 35-64 years old were randomly selected from multi-centre population based epidemiological study in three Russian regions with different environmental conditions were included in the analysis. Chi-squared tests and odds ratios (OR) were calculated. Multiple logistic regression was employed to analyze association between COPD and smoking patterns and environmental conditions.

Results: COPD was revealed in 12.9% of men and 15.7% of women, whereas only 50.9% of those were ever told to have any respiratory diagnosis (p<0.001).

COPD is strongly related to smoking intensity. It is 10.5 times more likely to be related to heavy smoking in men (OR=10.9, 95%CI 5.4-19.2) and 3 times women (OR=5.9, 95%CI 2.8-8.8), but also with moderate smoking (OR=4.4, 2.9-6.7) and (OR=2.6, 1.8-3.8), low (OR=2.6, 1.8-3.8) and even ex-smoking (OR=3.06, 1.9-4.9) with short quitting history. No significant relation to intention to quit revealed.

Significant relations of COPD to environmental conditions are observed: with strongest relationships to region with severe climate conditions in Russian Far East close to Polar Circle (OR=2.9, 95%CI 2.2-3.9), and Heavy Industrial region: (OR=2.2, 1.6-3.0).

Conclusion: COPD is common among adults in Russia and is mainly undiagnosed. It is strongly associated to smoking and higher cigarette consumption, but also to living area which requires further investigation.

P4143

Smoking rates in the Middle-East and North Africa: Interim results of the BREATHE study

**Tuberculosis status in Minoufiya Governorate, Egypt**

Rahab El Wahsh, Ramadan Bakr, Mohamad Zamzam, Amamy Farag. Chest Department, Faculty of Medicine, Minoufiya University, Shebin El Kom, Minoufiya Governorate, Egypt

**Introduction:** TB is still the most common infectious disease worldwide. In terms of incidence, Egypt is ranked among the mid-level incidence countries.

**Aim:** To provide baseline information for the assessment of the epidemiological trends and the impact of TB control interventions.

**Patients & methods:** This was a retrospective epidemiological study including all pulmonary TB patients who were diagnosed in Minoufiya Governorate, Egypt from January 2003 to December 2008. Epidemiological data, clinical presentation, and examination, radiological examination, laboratory investigations, contact investigations were acquired for all patients.

**Results:** Incidence of pulmonary TB in Minoufiya Governorate in the studied years was 5.1 per 100,000 population. A higher percentage of pulmonary TB cases was found in males (68.3%), in rural areas (83.7%), and in middle aged persons (25–54 years) 53.8%. The majority of patients were new cases (91.9%) and most patients received CAT I drugs. There was a good response to anti-tuberculous therapy with rapid DSM conversion in most cases. The cure rate at the end of treatment reached about 80%. Treatment outcome was significantly higher with ages (15–54 years) (p<0.001). Outcome was also better in males than females (p<0.05), in rural than urban areas (p<0.05), and in patients treated with CAT I drugs (p=0.05). Direct smear microscopy (DSM) was positive only in two out of 546 contacts.

**Conclusion:** Minoufiya Governorate is one of the moderately affected governorates in Egypt with chronic bronchitis and smoking in 11 countries in the Middle East and North Africa. This may have an impact on health status.

**Prevalence of water pipe smoking among population in the City of Mashhad (north east of Iran)**

Morteza Boskabady1, Mohammad Hossain Boskabady 1, Lila Farhang1, Valentina Spada 1, Salvatore Ostera1, Cono Vertuccio2, Elena Attizzo1, Giovanni Paolo Ligia1, Elisabetta Sortino3, Alessandro Giuseppe Fois 1, Pietro Pirina 1.

1. Department of Respiratory Diseases, University of Sassari, Sassari, Italy; 2. Department of Respiratory Diseases, AOUUSL of Nuoro, Nuoro, Italy; 3. Department of Respiratory Diseases, AOUUSL of Cagliari, Cagliari, Italy

**Introduction:** Pulmonary tuberculosis (TB) management is vexed when spumination microscopy is negative for M.Tuberculosis in patients with positive Mantoux and symptoms/Chest X-Ray suggestive for TB, especially to decide whether to start treatment or wait for the culture results. Several studies have shown that many smear/culture-negative patients will develop a bacteriologically positive disease later.

**Aim:** To assess the percentage of ex-adultabvus treatment that has been given and to find out if it should be reconsidered.

**Methods:** We have collected data from medical records of adult patients discharged with TB diagnosis by the Sardinian reference health centers (AOUUSL of Sassari, Cagliari).

**Results:** Among smear negative patients 36% were treated after a positive culture result, 1.8% although it was negative and 42% before culture, turned out positive in positive (4.5%), and 44% (3.1%) used water-pipes and cigarettes simultaneously.

**Conclusion:** There was a negative correlation between PFT values and positive correlation between RS with duration and total smoking (p<0.05 to p<0.01). The prevalence of WP smoking in population of Mashhad was shown for the first time which showed profound effect of WP smoke on PFT values and respiratory symptoms.

**P4146**

**Epidemiology of smear-negative pulmonary tuberculosis in Sardinia (Italy)**

AWARENESS OF COPD IN PORTUGAL GENERAL PRACTITIONERS, FOLLOW UP 2010
Cristina Bárbara,1 João Cardoso,1 Paula Pamplona,1 Joaquim Moita,1 Maria João Matos,1 Paula Simão,2 Sara Conde,3 Graça Coutinho.1

Servico de Pneumologia II, Hospital Pulido Valente- Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal;1 Servico de Pneumologia, Hospital de Santa Marta- Centro Hospitalar Lisboa Central EPE, Lisboa, Portugal;2 Servico de Pneumologia II, Hospital Pulido Valente- Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal;3 Medical Department, Altana Portugal, Nycomed Group, Lisboa, Portugal

Objective: To perform spirometries in Buenos Aires City during World Spirometry Day, analyse the findings and correlate them with the survey proposed by European Respiratory Society

Methods: 6 Vitalograph Alpha spirometers were set on 3 sites in Buenos Aires City, with technicians and physicians. On previous days, the event was communicated and promoted.

Results: 387 spirometries were evaluated, as they met the acceptability and reproducibility criteria; 133 spirometries were carried out on site 1 (shopping arcade), 119 on site 2 (theatre hall and gym hall), and 135 on site 3 (Universidad Católica Argentina). Ages ranged from 18 to 87, the mean age being 48.6. 199 men (51.8%) participated. 74% lived in Buenos Aires City. 25.8% volunteers were smokers, 36.8% former smokers and 37.4% had never smoked. 23% of evaluated participants had cough, 27% had habitual spasm, and 59% had dyspnoea with heavy exercise, 35% on fast walk, 4% on 100-meter walks, 12% on normal walking and 1% when getting dressed or undressed. 59% did not know spirometry existed, 73% had never done one (57.94%), 23 had GOLD 1, 35 had GOLD 2, and 4 Gold 3. In total, 11.4% in the smokers vs 2.6% and 6.6% in 2006, respectively. The main reported disease associated with cigarette smoking was still lung cancer (72%). Like in 2006, asthma was the most often referred disease associated with respiratory insufficiency (54%), followed by chronic bronchitis (33%). Only 38% of smokers referred they had been informed by their physician about the damage of smoking (versus 29.9% in 2006). Not different from the previous survey there was a perception that the prevalence of the disease is increasing (57%). The population related COPD to cigarette smoking and considered COPD less serious than lung cancer, cardiovascular disease and AIDS. There is a growing interest on obtaining more information about COPD. The preferred way for obtaining information changed and is now the physician (37% vs 27%) and the media (31% vs 49%).

Conclusion: COPD awareness of Portuguese population is increasing though remaining low. However there is a high interest in obtaining more COPD information, showing that there is plenty of room for further awareness programs. Supported with a grant from ALTANA Portugal-Nycomed Group.

P4151

RESULTS OF THE WORLD SPIROMETRY DAY IN BUENOS AIRES, ARGENTINA
Juan Antonio Mazzei1, Carlos Benjamin Alvarez1, Mariano Egido Mazzei1, Hugo Esteva1,1 Departamento de Medicina, Facultad Universidad del Titán, C.A.Buenos Aires, Argentina;2 Facultad de Medicina, Universidad Católica Argentina, C.A.Buenos Aires, Argentina

Objective: To perform spirometries in Buenos Aires City during World Spirometry Day, analyse the findings and correlate them with the survey proposed by European Respiratory Society

Methods: In total, 4049 (49% females) subjects were included; mean age 58 yrs, BMI 27, and 32 pack-years. The COPD prevalence in our population was 21.7%; 56.8% had no previous diagnosis, 22.8% had a diagnosis of obstructive lung disease, > 35 yrs, and at least one respiratory symptom. Age, smoking status, pack-years, BMI, dyspnoea score (MRC), and pre-and post-bronchodilator spirometry data was obtained.

Results: A total of 4 049 (49% females) subjects were included; mean age 58 yrs, BMI 27, and 32 pack-years. The COPD prevalence in our population was 21.7%; 8.3% in subjects younger than 48 years. Most patients were classified in GOLD stages I and II (36% and 50%, respectively). The number needed to screen (NNS) in order to include one patient with COPD by the absolute value of their FEV1 and suggest that only one equation should be used during the treatment of the same patient so as to avoid alterations in the treatment.

P4150

COPD IN PORTUGAL 2010, ONE STEP TOWARDS A BETTER AWARENESS
Cristina Bárbara1, João Cardoso1, Paula Pamplona, Joaquim Moita,1 Maria João Matos,1 Paula Simão,2 Sara Conde,3 Graça Coutinho.1

Servico de Pneumologia II, Hospital Pulido Valente- Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal;1 Servico de Pneumologia, Hospital de Santa Marta- Centro Hospitalar Lisboa Central EPE, Lisboa, Portugal;2 Servico de Pneumologia II, Hospital Pulido Valente- Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal;3 Medical Department, Altana Portugal, Nycomed Group, Lisboa, Portugal

In 2010, we conducted a second evaluation about the awareness of COPD in the Portuguese population, following a previous study in 2006. We aimed to analyze the impact on the awareness of COPD in the Portuguese population, of all the actions taken during the last four years by Gold Committee in Portugal. Using the same questionnaire of 2006, we conducted a survey in 782 randomly selected Portuguese attendants with telephone percentage of predicted in each equation, considering the percentage expected from the PLATINO equation as reference.

Results: We evaluated 759 patients with COPD, observing staging changes in 29.4% in relation to the different equations, being Knudson et al., Crapo et al. and Pereira et al. 2007 equations that showed the greatest number of changes.

Conclusion: Overall these reference equations tested may be applied indistinctly for predicting the severity of COPD, although we should reinforce that some of them, like Knudson et al. and Crapo et al., may decrease disease severity, while Pereira et al. 2007 increases the severity, when considering only the percentage of predicted values. These results fall to attention the importance of following up patients with COPD by the absolute value of their FEV1 and suggest that only one equation should be used during the treatment of the same patient so as to avoid alterations in the treatment.

P4152

EARLY DIAGNOSIS OF COPD IN A HIGH-RISK POPULATION USING SPIROMETRIC SCREENING IN GENERAL PRACTICE
Charlotte Suppli Ulrich1, Anders Løkke2, Ronald Dahl2, Liese Plauborg3, Jens Dollerup4, Luise Cederkvist Kristiansen1, Patrick Hegge Cording3, Christian Dehlendorff1, Respiratory Section, Internal Medicine Unit, Hvidovre University Hospital, Hvidovre, Denmark; 2Respiratory Medicine, Århus University Hospital, Århus, Denmark; 3R&D, Boehringer Ingelheim Denmark, Copenhagen, Denmark; 4R&D, Pfizer Aps Denmark, Ballerup, Denmark; 5DTU Informatics, Technical University of Denmark, Lyngby, Denmark

Background and aim: Under-diagnosis of COPD is a widespread problem. This study aimed to identify early stages of COPD in a high-risk population identified through general practice.

Methods: Participating GPs (n=241) recruited subjects with no previous diagnosis of obstructive lung disease, > 35 yrs, and at least one respiratory symptom. Age, smoking status, pack-years, BMI, dyspnoea score (MRC), and pre- and post-bronchodilator spirometry data was obtained.

Results: A total of 4 049 (49% females) subjects were included; mean age 58 yrs, BMI 27, and 32 pack-years. The COPD prevalence in our population was 21.7%; 8.3% in subjects younger than 48 years. Most patients were classified in GOLD stages I and II (36% and 50%, respectively). The number needed to screen (NNS)
for a new diagnosis of COPD was 4.6. COPD diagnosis was related to gender, age, BMI (p<0.001), pack-years, and cough (p<0.001), wheezing (p<0.001) and sputum production (p=0.002). A threshold of 10% pre-test risk of COPD would have reduced the number of spirometry tests by 35% although 99% of the patients with COPD would still have been identified (NNS 3.9).

Conclusions: A case-finding strategy providing screening and diagnostic spirometry to high-risk subjects in primary care identifies a large proportion of undiagnosed COPD patients, especially in the early stages of the disease.

P4153 Is spirometry screening useful for detecting undiagnosed COPD? Kass Levent, Sezer Murat, Karakase Fatma, Akkooyunlu Muhammet. Pulmonology, Bursa Uludag University, Istanbul, Turkey

In BOLD Adana study COPD prevalence was 19.3% over 40 years of age but diagnosed COPD prevalence was 10% in 2004. Screening by spirometry might improve the detection of COPD. We aimed to answer the question that what is the contribution of spirometry screening in early detection of COPD. We recruited to study adult visitors (age ≥18 years of age) to spirometry test in our hospital garden during three days between 13 October 2015–October 2016 (world spirometry day) for spirometry screening in Istanbul. We applied to the participants standard spirometry and questionnaire. 397 participant enrolled to the study. Mean age of study population was 43.9±11.8; 243 were female (61.6%) and 154 were male (38.4%). 151 were smoker (38%), 206 were nonsmoker (51%) and 40 were exsmoker (10.1%). 252 participants (63%) were over 40 years of age. Spirometry was performed in 229/252 and questionnaire was performed in 198/252 of people. In participant who were smoker and exsmoker (n=9.37% FEV1/FVC ratio under 70% were in 1294 (12%) and COPD symptoms (were positive in 41/84 (43%) people who were over 40 years of age and who have smoking history. 44/84 (33%) people (46%) have either obstruction or symptoms. The patients who have previous COPD diagnosis were 39/111 (35.1%) in smokers. In our study spirometry screening can be useful for early detection of COPD. But combined screening modalities such as questionnaires that are better than spirometry alone are necessary for identifying those who are truly at risk, and effective treatments beyond smoking cessation are needed for preventing progression.

P4154 Spirometry test quality (home vs clinic performance) in a respiratory epidemiology survey in an Italian population sample Giuseppe Sarno1, Sara Maino1, Sandra Baldacci1, Sonia Cerrai1, Martina Fresta1, Franco Martini1, Anna Angino1, Francesco Di Pede1, Giovanni Virgili1
1Pathology, European Molecular Imaging Institute (EIMI), Pisa, Italy; 2CNR, Institute of Clinical Physiology (IFC), Pisa, Italy; 3CNR, Institute of Biomedicine and Molecular Immunology (IBIM) “A. Monroy”, Palermo, Italy

Background: European Commission plans to implement Health Interview & Examination Survey in order to overcome the limitations of Health Interview Surveys. Aim: To assess the influence of home location on the spirometry test quality. Methods: A sample of subjects living in Pisa (Central Italy) was selected within IMCA2 (Indicators for Monitoring COPD and Asthma in the EU) project. An questionnaire on socio-demographic characteristics, respiratory symptoms/disorders and test factors was used. The NDD EasyOne Model 2001 was used for spirometry test, at home or in clinic; at the end of the maneuvers the quality grades A/B/C indicated a reliable result, grades D/F indicated inadequate test quality. A logistic regression analysis adjusted for smoking habits, age, sex, season, cardio respiratory diseases, disability, previous respiratory medical examination and test was run to assess association between inadequate test quality and spirometry test performance location.

Results: Analyses concerned 630 (154 participants who performed spirometry (mean age:55.8±17.0; mean BMI: 26.9±4.6 kg/m2; 45.4% male):42.4% at home, 57.6% in clinic. 91.3% of subjects had grades A/B/C; 8.7% of subjects had grades D/F (63.6% of these had performed spirometry at home). Inadequate test quality was significantly associated with home location (OR=2.5; 95% CI=1.3-4.6), age ≥65ys (OR=2.3; 95% CI=1.3-4.2) and no previous spirometry (inexpert) (OR=2.7; 95% CI=1.5-5.0).

Conclusions: Although an high percentage of adequate test quality, in a respiratory epidemiological survey a special attention would be addressed when performing spirometry at home, notably in elderly and inexpert subjects.

P4155 Lower limit of normal (LLN) for lung function parameters for over 80 year-old caucasians Simone Acquarini1, Alessandro Fois2, Barbara Pitas2, Giovanni Porqueddu1,2, Valentina Spada1, Francesco Borgo1, Roberto de Marco1, Pietro Pirina1,2,2Unit of Epidemiology and Medical Statistics, University of Verona, Verona, Italy; 1Institute of Respiratory Diseases, University of Sassari, Sassari, Italy

Spirometric reference values for over 80 year-old populations have not been calculated yet. The present study is aimed at estimating the LLN equations for Caucasians.

In an ongoing clinical study, 214 subjects aged 80-88 performed valid lung function tests (according to the acceptability and reproducibility criteria of the American Thoracic Society) in 2001/2011 at the University Hospital of Sassari in Sardinia (Italy). During the clinical examination, these subjects: (i) did not report a diagnosis of respiratory diseases, symptoms of dyspnea at restproductive cough/bronchospasm, drug use for respiratory problems, and comorbidities (associated with impaired lung function) during lifetime; (ii) reported to be not smokers or to have quit smoking for ≥20 years. Past smokers with >15 pack-years were excluded. Among the 120 males and 94 females, the mean height was 162 and 151 cm, and the percentage of past smokers was 59.2 and 4.3%, respectively. The sex-age specific mean (standard deviation) of FEV1, FVC, and FEV1/FVC ratio is reported in the following table:

<table>
<thead>
<tr>
<th>Sex</th>
<th>n</th>
<th>FEV1, L</th>
<th>FVC, L</th>
<th>FEV1/FVC, %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Males</td>
<td>60</td>
<td>1.85 (0.61)</td>
<td>2.45 (0.65)</td>
<td>72.2 (11.8)</td>
</tr>
<tr>
<td></td>
<td>26</td>
<td>1.80 (0.80)</td>
<td>2.44 (0.96)</td>
<td>70.1 (10.5)</td>
</tr>
<tr>
<td>Females</td>
<td>40</td>
<td>1.43 (0.34)</td>
<td>1.82 (0.48)</td>
<td>77.2 (8.8)</td>
</tr>
<tr>
<td></td>
<td>59</td>
<td>1.33 (0.33)</td>
<td>1.80 (0.47)</td>
<td>81.6 (7.9)</td>
</tr>
</tbody>
</table>

On average, the FEV1/FVC ratio did not significantly decrease according to age among males (p=0.42), whereas it slightly increased among females (p=0.054). These preliminary results suggest that the reference equations obtained from younger populations cannot be used for the long-term survivors. Appropriate LLN equations will be computed when a greater sample size is reached.

P4156 Canadian prediction equation of spirometric lung function for caucasian adults 18-90 years: Results from the Canadian obstructive lung disease (COLD) study and the Canadian ECRHS study

COLD Investigators1, ECRHS Investigators2, 1 Cardiopulmonary Research Lab, University of British Columbia, Vancouver, BC, Canada; 2 Division of Respiratory Medicine, University of British Columbia, Vancouver General Hospital, Vancouver, BC, Canada

Background: There are no preexisting reference for spirometry based on a randomly selected Canadian population. Objective: To construct spirometric reference values for adults, aged 18-90 years, by combining data of healthy life-long non-smokers from two population based studies: the Canadian Obstructive Lung disease [COLD] study and the Canadian European Community Respiratory Health Survey [ECRHS] Study.

Method: Spirometric lung function data were available from 3042 subjects in the COLD study and from 2571 subjects in the Canadian ECRHS. Exploratory curves for the combined spirometric variables versus age were continuous and linear. We identified 844 [ages 40-90 years] and 812 [aged 18-44 years] healthy, asymptomatic, life-long nonsmokers to provide normative reference values for spirometry. Multiple regression models were constructed separately for self-reported Caucasian men and women for FEV1, FVC, FEV1/FVC with covariates of height, sex and age. Results: The summary for the best-fitting regression models for healthy never-smoking, asymptomatic men and women, 18-90 years old, are as follows:

| Sex     | Parameter Intercept Age Height R-square SEE |
|---------|-------------------------------------------|-----------------|---------------|
| Male    | FEV1 | -2.06961 | -0.03167 | 0.04215 | 0.56010 | 0.50586 |
|         | FVC  | -5.39383 | -0.02286 | 0.06500 | 0.47720 | 0.63557 |
| Female  | FEV1 | -1.80997 | -0.02773 | 0.03537 | 0.06490 | 0.59793 |
|         | FVC  | -4.11886 | -0.01214 | 0.05310 | 0.52160 | 0.49381 |

Conclusion: These spirometry reference equations, derived from population-based cohorts with stringently monitored lung function measurements, provides data currently lacking in Canada.

P4157 Pulmonary resistance measured by impulse oscillometry system (IOS) seems to be related to self-reported COPD and respiratory symptoms

Sophia Frantz1, Ulf Näslund2, Magnus Dencker1, Gunnar Engstrom1, Claes-Göran Löfdahl3, Per Wollmer1, 1Clinical Physiology and Nuclear Medicine Unit, Department of Clinical Sciences, Lund University, Malmö, Sweden; 2Respiratory Medicine and Allergy Unit, Department of Clinical Sciences, Lund University, Lund, Sweden; 3Cardiovascular Epidemiology Research Group, Department of Clinical Science, Lund University, Malmö, Sweden

Background: COPD is considered to start with small airway disease, which is more sensitive technique and more closely related to respiratory symptoms. Measuring pulmonary resistance by IOS may be a more sensitive technique and more closely related to respiratory symptoms.

Aims and objectives: This study aimed at examining pulmonary resistance mea-
sured by IOS in COPD, self-reported and/or diagnosed with spirometry according to GOLD criteria.

Methods: 419 subjects (173 men/246 women), 46-78 years, who participated in a previous population-based study, were examined with spirometry and IOS (resistance at 5 Hz, resistance at 20 Hz (R20) and the difference between them (R5-R20)) and answered a questionnaire on respiratory symptoms and diseases.

Results: 77 subjects had self-reported COPD and of them 34 subjects had COPD according to GOLD criteria. Of the 342 subjects with no-self reported COPD 90 subjects had COPD according to GOLD criteria. Subjects with self-reported COPD had higher pulmonary resistance than subjects with no self-reported COPD (R5 0.400±0.32 kPa/L, R20 0.280±24 and R5-R20 0.120±072, p<0.01 for all), both in subjects with (R5 0.420±33, R20 0.280±24, R5-R20 0.140±085, p<.05 for all) and without spirometry verified COPD (R5 0.380±31, R20 0.280±24, R5-R20 0.110±068, p<0.05 for all). Respiratory symptoms, e.g. long-standing cough, were more commonly reported by subjects with self-reported than spirometry verified COPD (p<0.01).

Conclusion: Self-reported COPD is characterized by more respiratory symptoms and higher resistance measured by IOS, compared with spirometry verified COPD. High resistance may reflect early small airway disease better than spirometry.

P4158
Definition and validation of a predictive model to identify COPD patients from administrative databases
Lisa Bauleo, Nera Agabiti, Ursula Kirchmayer, Valeria Belleri, Luigi Pinnairell, Silvia Cascini, Danilo Fiscio, Massimo Arcà, Marina Davoli. Department of Epidemiology, Regional Health Service, Lazio, Rome, Lazio, Italy

Background: Large administrative databases are increasingly used to identify patients with specific chronic conditions. However, the best methodology for Chronic Obstructive Pulmonary Disease (COPD) is still debated.

Objective: To develop and validate a predictive model to identify patients with COPD in Lazio region (2,625,102 residents over 45) linking clinical and administrative data.

Methods: From regional hospitalizations and drug prescriptions, through record linkage, we identified patterns of specific drug use (minimum 2 prescription during 12 months) and COPD hospitalizations during a 9-year period in 428 patients with COPD, who attended an outpatient clinic in 2006, and in 2140 people without COPD (selection from outpatients’ specialized health care registry). Through a Bootrap-Stepwise procedure we analyzed COPD associated factors. We validated the algorithm through internal (cross-validation-bootstrap, jack-knife) and external validation (comparison with COPD patients with confirmed diagnosis).

Results: Prevalence of COPD was 7.8%. Factors associated with COPD were smoking status and 1.72 (1.36 to 2.17) for exacerbation score; all after adjustment for age, sex and heart disease. When investigating the separate components in the DOSE index, the HR for a unit change in the DOSE index components was 1.81 (1.52 to 2.14) for MRC; 2.27 (1.77 to 2.92) for FEV1/PEF 90.98 (0,64 to 1.49) for smoking status and 1.72 (1.36 to 2.17) for exacerbation score; all after adjustment for age, sex and heart disease. The associations with mortality for the separate components were not statistically significant when these measures were included simultaneously in the same model.

Conclusion: The DOSE index is associated with mortality in COPD patients.

P4161
Determination of COPD characteristics via unsupervised clustering of the ECLIPSE cohort
1University of Nebraska Medical Center, Omaha, NE, United States; 2Department of Statistics, Boehringer-Ingelheim, Paris, France; 3Respiratory Medicines Development, GlaxoSmithKline, RTP, NC, United States; 4Institut del Torax, CIBER Enfermedades Respiratorias and Fundacion Cuadet-Ciber, Barcelona, Spain; 5Department of Respiratory Medicine, University of Liverpool, Liverpool, United Kingdom; 6Pulmonary and Critical Care Division, Brigham and Women’s Hospital, Boston, MA, United States; 7Respiratory Center of Drug Development, GlaxoSmithKline, Philadelphia, PA, United States; 8Cardiology and Respiratory Medicine, Hvidovre Hospital and University of Copenhagen, Copenhagen, Denmark

Background: Identifying clinically meaningful groups of COPD patients is a crucial goal to explore COPD heterogeneity. We attempt to define groups using unsupervised clustering. Methods: Data from the 2164 COPD patients in the Evaluation of COPD Longitudinally to Identify Predictive Surrogate Endpoints (ECLIPSE) study were assessed. Using forty-one baseline variables describing demographic, clinical, quality of life, laboratory and biomarker values, twelve factors were identified via factor analysis that accounted for 61% of the variance in the data set. The variables with the highest loadings for those factors were used to define five patient groups using unsupervised clustering, and relationships to longitudinal outcomes were assessed.

Results: Demographic profiles are shown in table 1. Over three years, higher mortality was seen in Cluster 2 (characterized by higher comorbidity and BMI despite FEV1 values that were not substantially lower than other groups) and Cluster 5, characterized by more airflow limitation.

Conclusion: Unsupervised cluster analysis identified 5 groups of COPD patients
in ECLIPSE that differ in their baseline demographics and outcomes over 3 years. These may represent subtypes of COPD. Funded by GlaxoSmithKline. (EC0104960, NCT00295525)

P4162 Asthma with and without sinusitis, results from the Swedish GA2LEN study
Roelinde Middelveld 1, Astrid van Huisstede 1, Linnea Hedman 1,2, Anders Bjerg 1, Sigrid Sundberg 1, Eva Rönmark 1,2, Gert-Jan van de Laar 1,3, Pieter Hiemstra 4, Gert-Jan Braunstahl 1, 1The Centre for Allergy Research/Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 2Department of Occupational and Environmental Medicine, Umeå University, Umeå, Sweden; 3Department of Internal Medicine, University of Gothenburg, Gothenburg, Sweden; 4Department of Medical Sciences, Uppsala University, Uppsala, Sweden

Introduction: In order to study the consequences of having both asthma and sinusitis compared to having asthma only, four Swedish centres studied cohorts of asthmatic patients (A), and asthma+sinusitis patients (AS). The study was part of the Global Allergy and Asthma European Network (GA2LEN) survey and follow-up.

Methods: Participants in the survey were invited for a clinical follow-up visit for interviews, and measurements of lung function, fraction of exhaled nitric oxide (FeNO) and quality of life. Group allocations were based on the interviews. A was defined as self-reported diagnosis of asthma and presence of at least one asthma symptom or use of asthma medication. AS was defined as having asthma as well as at least two sinusitis symptoms, providing that nasal blockage or nasal discharge were reported.

Results: A consisted of 470 subjects (mean age 44, BMI 27, 60% females) and AS of 130 subjects (mean age 45, BMI 27, 57% females). AS had lower FEV1%pred, FVC%pred and quality of life (mini Asthma Quality of Life Questionnaire-AQLQ), compared to A. There were no differences in FeNO, FEV1/FVC1 and reported nasal allergies.

Conclusion: We conclude that having both asthma and sinusitis results in lower lung function and lower quality of life compared to having asthma only.

P4163 Statistical cluster analysis on the BTS refractory asthma cohort
Chris Newby 1, Astrid van Huisstede 1, Arjan Rudolphus 1, Hans Zengerink 2, Gert-Jan van de Laar 1,3, Pieter Hiemstra 4, Gert-Jan Braunstahl 1, 1Department of Infection, Inflammation and Immunity, Institute for Lung Health, University of Leicester, Leicester, United Kingdom; 2Centre for Infection and Immunity, Queen’s University Belfast, Belfast, United Kingdom; 3Royal Brompton Aconsil, Royal Brompton Hospital, London, United Kingdom; 4North West Lung Centre, University of Manchester, Manchester, United Kingdom

Background: Severe asthma is no longer believed to be a single homogeneous condition but rather a heterogeneous disease possibly containing subsets of patients. A number of clustering algorithms have been carried out on various datasets of asthmatics of differing severities but few have been confirmed by follow-up studies.

Aims and objectives: To further understand these clusters, statistical analysis was carried out to determine the patterns of variation seen in a large cohort with well characterised refractory asthma (Heaney, L et al,2010).

Methods: Independent structure was determined using Bayesian factor analysis followed by statistical cluster analysis. The analysis revealed clinically relevant factors and statistical significant clusters.

Results: 4 factors were obtained from the Bayesian factor analysis. Factor 1 described lung function, factor 2 atopy, factor 3 BMI and factor 4 Inflammation. 4 clusters were found. These clusters were significant at the 0.05 level for over described lung function, factor 2 atopy, factor 3 BMI and factor 4 Inflammation.

Cluster 1, described an older group of patients with the longest disease duration. Cluster 2, a mainly female group that had late onset and high BMI. Cluster 3 described an atopic group with high blood eosinophils and low disease duration. Cluster 2, a mainly female group that had late onset and high BMI. Cluster 3 described an atopic group with high blood eosinophils and low disease duration. Cluster 4 and spumon production (0.3 95% CI:5.7.7) were more frequent in late onset asthmatics. Medications were rarely prescribed (0.07 (95%CI:10.0-0.19) in late onset asthmatics. Theophylline (0.08 (95% CI:0.04-0.89) and salbutamol (0.21 (95% CI:0.07-0.65) were rarely used in late onset asthma (p < 0.05).

Conclusions: Desired clinical outcomes may be more difficult to achieve in elderly asthmatics due to comorbid conditions, cognitive and financial status. Chronic cough with sputum is not unusual in elderly with asthma, although it is usually associated with smoking, chronic bronchitis, and several conditions in late-onset asthmatics. Risk of adverse effects of treatment increases with increasing age and often limits choice and frequency of medications; moreover theophylline and salbutamol are rarely prescribed to patients with late-onset asthma. Future studies may give better understanding of etiopathogenesis of early and late-onset asthma.

P4165 Wheezing in morbidly obese patients is not always due to asthma
Manuel Wuhrstedt 1, Arjan Rudolphus 1, Hans Zengerink 2, Gert-Jan van de Laar 1,3, Pieter Hiemstra 4, Gert-Jan Braunstahl 1, 1Department of Pulmonology, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 2Department of Surgery, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 3Department of Clinical Chemistry, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 4Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands

Background: Morbid obesity is becoming a world wide epidemic. Morbidly obese patients are at risk for asthma.

Aim of the study: To investigate the differences in symptoms and lung function test in morbidly obese patients with and without asthma.

Methods: A group of 95 morbidly obese patients (BMI >35 kg/m², age 18-50y) was studied. Asthma was defined as the presence of reversible airway obstruction (AFEV1%) >12% and/or PCR2 methacholine of <8 mg/ml. Patients with a physician diagnosis asthma, but not fulfilling the criteria of late-onset asthma after stopping ICS were defined as “asthma-like symptoms” (asthma-l.s.).

Results: 29 patients fulfilled the criteria of asthma, 14 had asthma-l.s., and 50 control group patients. Sex, age, BMI, smoking, abdominal circumference, atopy, FeNO, FVC, DLCO, Eppworth Sleepiness Scale score, GERO questionnaire and steps a day did not differ between the groups. Patients with asthma or asthma-l.s. had significantly more symptoms (wheezing [p<0.01], coughing [p=0.001]), and significant worse AQLQ-scores (mean 5.7 points [p<0.004], 5.5 points [p<0.002] respectively) and ACT-scores (mean 1.1 points [p=0.000] and 1.0 points [p=0.015] respectively) compared to controls (AQLQ 6.5 points, ACT 0.3 points). Patients with asthma had a significantly lower FEV1 %pred (p<0.05) and FEV1/FVC (76%pred) than the group with asthma-l.s. (102%pred [p<0.01], and 83%pred [p=0.001] respectively) and the control group (97%pred [p=0.001], and 81%pred [p=0.001] respectively).

Conclusion: A significant proportion of the patients with morbid obesity and a history of asthma does not fulfill the criteria of asthma. These patients have the same symptom scores as “asthma-like symptoms” asthmatics, despite supranormal lung function parameters.

P4166 Incidence of asthma and wheeze during adolescence – The impact of study design
Linnéa Hedman 1,2, Anders Bjerg 1, Sigrid Sundberg 1, Eva Rönmark 1,2, 1The OLIN Studies, Norrbotten County Council, Luleå, Sweden; 2Public Health and Clinical Medicine, Occupational and Environmental Medicine, Umeå, Sweden

Aim: To study the impact of study design on the incidence rates of asthma and wheeze during the teen ages.

Method: In a longitudinal study about asthma and allergic diseases within the OLIN studies in northern Sweden, a cohort of school children (n=3,430) was followed annually from age 7.8yrs by completion of an extended ISAAC questionnaire. In the endpoint survey (age 19yrs) 2,861 (83% of original responders) participated. Incident cases of asthma and wheeze from age 12 to 19yrs were identified by two methods: the annual questionnaire surveys and the endpoint survey only, respectively.

Results: The incidence was consistently higher when the incidence was based on annual surveys compared to the endpoint survey only. Based on the endpoint survey, the average annual incidence of current asthma, physician-diagnosed asthma...
and ever asthma was 0.7-1.4/100/y and current wheeze was 1.5/100/y. Based on the
annual surveys, the incidence of asthma was 0.9-2.7/100/y and current wheeze
3.6-5.3/100/y. In both study designs, the incidence of asthma and wheeze was higher
among girls than boys (p-values < 0.01). At the onset, the additional cases of
current asthma identified by the annual surveys had slightly less severe asthma
than those identified only in the endpoint survey (p < 0.06).

Conclusion: The incidence and wheeze was affected by study design.
The incidence was underestimated when only baseline and endpoint data was used.
Study design and follow-up time is important to consider for comparisons of the
incidence of asthma and wheeze between studies.

P4167
Reproducibility of an asthma symptoms and rescue medication diary: Paper and AM3™ modes
Andrea Ireland1, Ingela Wiklund2, Peter Dale3, Ray Hoeh6, Erin O’Rourke1,4
1GES, United BioSource Corporation, Bethesda, MD, United States; 2Health
Care Analytics, United BioSource Corporation, Bethesda, MD, United States;
3Global Health Outcomes, GlaxoSmithKline, Stockley Park, Uxbridge, United
Kingdom; 4Biostatistics and Data Analysis, United BioSource Corporation,
Bethesda, MD, United States

Objective: This study investigated the test-retest reliability of a twice-daily (morn-
ing and evening) asthma symptoms and rescue medication diary within two modes of
administration: 1) paper-and-pencil; and 2) AM3™ electronic device in patients
with persistent asthma.

Methods: Prospective cross-over study where key inclusion criteria were Asthma
Control Test (ACT) scores > 16, ICS with or without LABA use, < 2 nocturnal
awakenings due to asthma (past week), and activity limitations ≤ 1 per week.
Participants were randomly allocated to complete the diary in each mode for
15 days. Spirometry was performed at randomisation, cross over, and end of
study and changes in asthma resource use were captured. Weekly percentage of
symptom-free days (SFD) and rescue-free days (RFD) were calculated using diary
study and changes in asthma resource use were captured. Weekly percentage of
symptom-free days (SFD) and rescue-free days (RFD) were calculated using diary

Results: The mean age of the participants (n=50) was 36.5 ± 12.5 years. Seventy-five
recruits were included, of which 21 had a gold standard diagnosis

Conclusion: The test-retest reliability of SFD and RFD demonstrated acceptable test-retest reliability
ICC = 0.70 based upon all three definitions of asthma stability. By comparison,
acceptable reproducibility of the percentage of RFD (ICC = 0.78) was only observed
for the electronic diary using the FEV1 stability criterion.

P4170
Systematic review of ill-health outbreaks associated with exposure to water-based metalworking fluids
N. Feni1, Y. Gaarthuis2, A.C. Bos3, N.J.J. Schloesser2, P.J. Sterk1, 1Respiratory
Medicine, Academic Medical Center, University of Amsterdam, Amsterdam,
Netherlands; 2Respiratory Medicine, Central Military Hospital, Utrecht, Utrecht, Netherlands;
3Research & Development, C-it, Zutphen, Netherlands

Background: Asthma is presently diagnosed by its clinical presentation, including
the presence of dyspnea, cough, chest tightness and wheezing (GINA). When
combined with bronchial challenge testing, asthma can be assessed with high
accuracy. Excluding asthma is the primary objective when screening for military
service. Profiles of exhaled compounds as measured by electronic nose (eNose)
could be a rapid non-invasive test for this purpose.

Hypothesis: Exhaled breath molecular profiles measured by eNose can be used to
exclude asthma in a screening setting for military recruits.

Methods: Military recruits (16-27 yr, mean 19.8; M/F 64/11) were included in a
cross-sectional study. Exhaled breath samples were measured by DiagNose eNose
(C-it, Zutphen, NL). Symptoms of asthma were assessed by validated question-
naires (Burkey et al, ERJ ‘94) and a histamine challenge test was performed.
Asthma was considered to be present when both symptoms and PC20<8 were
present (gold standard). ROC analysis was performed to assess optimal specificity.

Results: 75 recruits were included, of which 21 had a gold standard diagnosis of
asthma. ROC analysis of exhaled breath profiling resulted in an AUC of 0.70
(p=0.007).

Optimal specificity reached 89% (sensitivity 48%).

Conclusion: Exhaled breath molecular profiling using an eNose can be a suit-
able screening instrument to exclude asthma in young, otherwise healthy military
recruits.

424. Work-related respiratory diseases and
specific exposures

P4165
Exclusion of asthma for screening purposes using exhaled air molecular profiling by electronic nose
N. Feni1,2, Y. Gaarthuis2, A.C. Bos3, N.J.J. Schloesser2, P.J. Sterk1, 1Respiratory
Medicine, Academic Medical Center, University of Amsterdam, Amsterdam,
Netherlands; 2Respiratory Medicine, Central Military Hospital, Utrecht, Utrecht, Netherlands;
3Research & Development, C-it, Zutphen, Netherlands

Introduction and objectives: There is a growing awareness that smoke produced
during wildland fires can expose firefighters and populations to hazardous concen-
trations of several air pollutants. The FUMEXP Project was developed to evaluate
the potential effects of smoke emissions on firemen health.

Methods: A sample of firefighters (n=38) was submitted to spirometry and re-
responded to the SF-36 General Health Survey before the 2008 forest fire season,
and again at the end of the 2010 season. During three years (2008-2010), a subsample of 18 firefighters was tested before and after firefighting. Exhaled nitric oxide (eNO), carbon monoxide (CO) and% carbon monoxide, during prescribed/experimental air real forest fires.

Values above international recommendations were measured: PM2.5 > 1.280 μg/m³; CO >73,000 μg.m⁻³; NO2 > 4.670 μg.m⁻³; VOC values were also high.

Airway monitoring: there was a significant decrease (p<0.05) on the eNO, and a
very significant increase on exhaled CO (p=0.001), pre and post firefighting.
Predicted FEV1,F 25,F 50 e MEF were lower at the end of the Project (p<0.05).
Three questions of the SF-36 survey had scores significantly lower.

Conclusions: With the levels of exposure monitored, forest fire smoke inhalation
can cause acute and long term health effects on exposed professionals. Suggested
preventive measures include regular health evaluation, use of adequate protecting
equipment and individual monitoring devices, planning of fire-fighting shifts and
modeling of exposure.

P4166
Firefighter occupational exposures in forest fire settings – Three years of the FUMEXP project
Antonio Jorge Ferreira, Carlos Robalo Cordeiro, Pedro Ferreira, Ana Isabel Miranda, Vera Martins, Domingos Xavier Viegas, Centre of Pulmonology,
Coimbra University Medical School, Coimbra, Portugal Department of Environment and Planning, University of Aveiro, Aveiro; Portugal Association for
the Development of Industrial Aerodynamics, University of Coimbra, Coimbra, Portugal

Objectives: Aims to identify and review all previously published reports of out-
breaks of ill health due to water-based metalworking fluids (MWFs), in order to
identify aetiological risk factors for disease, and highlight areas requiring further
research.

Methods: A multidisciplinary team agreed appropriate search terms for a system-
atic literature review. From a total of 1346 titles, 35 relevant articles, relating to
29 separate outbreaks of ill health attributed to MWF exposure were selected.

Results: 17 outbreaks related to respiratory disease, 4 to skin disease, and 8 to a
combination of both. There was a peak incidence between 1996 and 2000. The
majority were from the United States, from large car manufacturing plants using a
central sump. The mean attack rate for allergic respiratory disease during outbreaks
was 5.9% of the exposed workforce. Outbreaks were identified with all types of
water-based MWFs, and mean MWF aerosol levels were below recommended
levels of exposure monitored, forest fire smoke inhalation

can cause acute and long term health effects on exposed professionals. Suggested
preventive measures include regular health evaluation, use of adequate protecting
equipment and individual monitoring devices, planning of fire-fighting shifts and
modeling of exposure.

P4170
Systematic review of ill-health outbreaks associated with exposure to water-based metalworking fluids
Clare Burton, Brian Cook, Helena Scaife, Gareth Evans, Chris Barber. Centre for Workplace Health, Health and Safety Laboratory, Buxton, Derbyshire, United
Kingdom

Objectives: Aims to identify and review all previously published reports of out-
breaks of ill health due to water-based metalworking fluids (MWFs), in order to
identify aetiological risk factors for disease, and highlight areas requiring further
research.

Methods: A multidisciplinary team agreed appropriate search terms for a system-
atic literature review. From a total of 1346 titles, 35 relevant articles, relating to
29 separate outbreaks of ill health attributed to MWF exposure were selected.

Results: 17 outbreaks related to respiratory disease, 4 to skin disease, and 8 to a
combination of both. There was a peak incidence between 1996 and 2000. The
majority were from the United States, from large car manufacturing plants using a
central sump. The mean attack rate for allergic respiratory disease during outbreaks
was 5.9% of the exposed workforce. Outbreaks were identified with all types of
water-based MWFs, and mean MWF aerosol levels were below recommended
exposure limits in most cases. For respiratory disease outbreaks, bacteria were iso-
lated in 76%, fungi in 71% and opportunistic mycobacteria in 59% of workplaces.
Endotoxin contamination of MWF ranged from non-detectable to 5.3±10³ EU/mL,
and measured airborne endotoxin levels ranged from 0.52 EU/m³ to 126 EU/m³.

Conclusions: Despite numerous investigations, significant knowledge gaps re-
main, particularly regarding the aetiology, natural history and risk factors for
these outbreaks. The available evidence supports the hypothesis that microbial
contamination is important in the aetiology of occupational lung disease in this
group, and improvements in workplace hygiene have generally been associated
with a cessation of new cases.

P4169
Conclusion: Exhaled breath molecular profiling using an eNose can be a suit-
able screening instrument to exclude asthma in young, otherwise healthy military
recruits.
Epidemiological study of the workforce after an outbreak of occupational asthma due to chromium and cobalt in an aerospace factory

Gareth Walters1, Atulastar Robertson2, Vicky Moore3, Cedde Burge1, Arun Vellorre1, Sherwood Burge1. 1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Department of Gastroenterology, University Hospitals Birmingham, Birmingham, United Kingdom

An outbreak of asthma due to chromium and cobalt in 4 employees at an aerospace factory occurred after coolant oils were changed in 2004 (6-24 month latency). The factory manufactured high chrome and nickel alloys with hard metal tipped tools containing cobalt. Oils and mist exposure met exposure standards. This prompted an investigation of the workforce, in order to measure extent and cause of outbreak. 62 (of 65) employees (n=54±18; mean age 34±5; 58% currently working with coolant oils; 58% never smoked) undertook a self-completed symptom questionnaire, lung function, urinary analysis and received expert consultation. 74.1% had urinary chromium excretion indicating occupational exposure. 66.1% had at least one respiratory symptom, most symptoms from after 2003. Clinical opinion identified cases of definite occupational asthma (OA), possible asthma (PA) and 3 with positive challenges to chrome and one with cobalt, one not challenged, symptomatic pre-existing asthma (17; 27%) and occupational rhinitis (OR) (18; 29%). All 5 OA cases and 15/18 OR cases worked with coolant oils. Employees with OA, asthma or OR were compared with asymptomatic workers (n=57). Those with OA or OR were of similar age and no more likely to be smokers, have abnormal spirometry or FeNO than controls. Those with OA and OR had significantly higher urine chromium (p=0.05) and cobalt (p=0.003) concentrations and a longer mean duration of employment. OR was more likely in those undertaking manufacturing work (p=0.006) or work with machines using coolant oils (p=0.02). Chrome exposure sufficient to cause occupational asthma can occur from metal-working fluid aerosols when machining high chrome alloys.

P4172 Past dust and gas/fume exposure and COPD in Chinese: The Guangzhou Biobank cohort study

Kin Bong Hubert Lam1, Peng Yin2, Chao Qiang Jiang3, Wei Sen Zhang3, Biobank cohort study

Past dust and gas/fume exposure and COPD in Chinese: The Guangzhou Biobank Cohort, Guangzhou Public Health, Epidemiology and Biostatistics, University of Birmingham, Birmingham, United Kingdom; 3Guangzhou Biobank Cohort, Guangzhou Public Health, Epidemiology and Biostatistics, University of Birmingham, Birmingham, United Kingdom; 2Guangzhou Biobank Cohort, Guangzhou Biobank Cohort Number 12 People’s Hospital, Guangzhou, China; 4School of Public Health, The University of Hong Kong, Hong Kong, China

Background: The impact of occupational dust and gas/fume exposure on chronic obstructive pulmonary disease (COPD) has been described in Western populations but the extent has not been quantified in developing countries.

Aims: We examined the relationship between past dust and fume exposure and prevalence of COPD and respiratory symptoms in a Chinese population sample. We have calculated the population attributable fraction for COPD due to previous occupational exposure.

Methods: Baseline data from the Guangzhou Biobank Cohort Study (2003-6; n = 8,119) were analysed. Self-reported intensity and duration of dust and gas/fume exposure was obtained from which a cumulative exposure index was derived. COPD was defined based on spirometry using lower limit of normal. Respiratory symptoms were assessed by the MRC questionnaire.

Results: In this sample (27.3% men, mean age 61.9; 68.8 years), COPD was associated with dust or gas/fume exposure in a dose-response manner with no evidence of effect modification by smoking (adjusted OR for high level exposure = 1.49; 95% CI 1.21-1.91). Similar associations were found for chronic cough/phlegm (1.60; 1.18-2.17) and dyspnoea (1.38; 1.21-1.58). The population attributable fraction for COPD due to occupational exposure was 11.2% (95% CI 1.4%-20.0%).

Conclusion: Occupational dust and gas/fume exposure is associated with an increased prevalence of COPD in this Chinese sample, independent of smoking. The magnitude is similar to that reported in other populations.

P4173 Long term effect and allergic sensitization in newly employed workers in laboratory animal facilities

Brit-Marie Sundblad, Lena Palmberg, Maciek Kupeczyk, Kjell Larsson. Lung and Allergy Research, The National Institute of Environmental Medicine, Stockholm, Sweden

Background: Allergic reactions are common in laboratory animal workers and one of the most frequent working with laboratory animals are reported work-related allergic symptoms and may develop occupational asthma. Working in laboratory animal facilities also implies exposure to airborne dust, contaminated with microbial and other products, which may lead to health effects.

Objective: The aim of this study was to identify targets that can predict sensitization to laboratory animals. Skin Prick Test change and sensitization to laboratory animals were used as an outcome variable.

Methods: In a prospective longitudinal study newly employed personnel who were employed to work with laboratory animals at Karolinska Institutet (Sweden) were investigated before and 6, 12 and 24 month after employment. Lung function, bronchial challenges, exhaled NO and nasal lavage were performed and blood samples were taken at each visit.

Results: Seventy subjects attended all four visits and 13 of those (19%) became sensitized to laboratory animals during the study. Lung function (VC and FEV1) deteriorated (as compared with predicted values) and increased blood levels of eosinophils and IL-2 over time were observed.

An increased risk of developing laboratory animal allergy was significantly associated with female sex, atopy, symptoms, CDAI=-0.92 cell/μL blood, total IgE= 15.5 μA/L, specific IgE to rat (e57=-0.01 kUA/L) and mouse (e88=-0.004 kUA/L).

Conclusions: One of five subjects became sensitized to one or two laboratory animals in this study and atopic subjects before starting working with animals had a greater risk to develop laboratory animal allergy.

P4174 Cow hair sensitisation is uncommon among Danish dairy farmers despite high allergen levels

Vivi Schlüsslen1, Ioannis Basinas1, Eva Zahradnick2, Grete Eibeln1, Gyrind Omland3, Monika Raulf-Heimsoth 2, Torben Sigsgaard1. 1Dept. of Environmental and Occupational Medicine, School of Public Health, Aarhus University, Aarhus, Denmark; 2Dept. of Allergy and Immunology, Institute of Prevention and Occupational Medicine of the German Social Accident Insurance (DGUV), Ruhr-University Bochum, Bochum, Germany; 3Dept. of Occupational Medicine, Aalborg University Hospital, Aalborg, Denmark

Background: Bovine allergens can induce allergic airway diseases recently. High levels of cow hair allergens (CHA) in dust from stables and homes of dairy farmers were reported (Zahradnick E et al. IAAI 2011;155:225-233).

Objective: To investigate CHA levels among dairy farmers (DF), pig farmers (PF), former farmers (FF) and never farmers (NF) and to assess CHA sensitisation in these groups.

Methods: In 2007-8 415 dust samples were collected using an electrostatic dust collector, EDC (Niss 1 et al. Appl Environ Microbiol 2006;74:5621-7) with a 14 days sampling time among 54 FF, 27 DF, 71 FF and 51 NF. Among farmers sampling was carried out both summer and winter. The cow hair allergens levels (μg/m2 ) were measured using a sandwich ELISA assay (Zahradnik E et al. IAAI 2011;155:225-233). SPT for cow hair allergens (ALK-Abello ™) were performed among 48 PF, 20 DF, 54 FF and 31 NF.

Results: CHA levels were substantially higher in stables than bedrooms. DF had much higher CHA level compared to PF, FF and NF had low levels of CHA in their bedrooms compared to DF and PF. No one but one PF (former DF) was sensitised to CHA.

Conclusions: These results confirm high CHA levels on dairy farms. Despite this no dairy farmers were sensitised to CHA. Selection out of dairy farming might be of importance.

P4175 Fungal colonization of oxygen humidifier and nebulizer chambers

Tushar Sahasrabudhe1, Savita JadHAV2, Vipal Kalley3, Nageswari Gandham2. 1Department of Pulmonary Medicine, Padmashree Dr. D Y Patil Medical College, Pune, Maharashtra, India; 2Department of Microbiology, Padmashree Dr. D Y Patil Medical College, Pune, Maharashtra, India

Humidified oxygen and nebulizers are routinely used in hospitalized patients suffering from respiratory ailments. These can however be potential source of allergens or infection if colonized by fungi. We undertook a study to determine if the oxygen humidifier chambers of portable cylinders and central lines at our hospital were colonized by fungi. The Hudson’s chambers of nebulizers were also studied as they remain wet after use. Samples of these were obtained using sterile swabs on Tuesday as these chambers are usually cleaned on every Saturday.

Samples were taken from ICUs, wards, casualty and OPD on a single day. Air samples were also obtained on the same day to determine if the fungus spore load in the inhaled room air was normal or high. 46/53 (86.79%) swabs form oxygen humidifiers and 717 (41.17%) swabs from Hudson’s chambers grew fungi. There were a total of 14 species of fungi identified altogether of 4 of them are virulent strains and 6 are known allergens for asthmatics. The colonization was less in shallow Hudson’s chambers (35.71%) as compared with predicted values) and increased blood levels of eosinophils and IL-2 over time were observed.

Conclusions: Seventy subjects attended all four visits and 13 of those (19%) became sensitized to laboratory animals during the study. Lung function (VC and FEV1) deteriorated (as compared with predicted values) and increased blood levels of eosinophils and IL-2 over time were observed.

An increased risk of developing laboratory animal allergy was significantly associated with female sex, atopy, symptoms, CDAI=-0.92 cell/μL blood, total IgE= 15.5 μA/L, specific IgE to rat (e57=-0.01 kUA/L) and mouse (e88=-0.004 kUA/L).

Conclusions: One of five subjects became sensitized to one or two laboratory animals in this study and atopic subjects before starting working with animals had a greater risk to develop laboratory animal allergy.
**P4176**

**Prevalence of chronic obstructive pulmonary disease in male workers exposed to dust, gas and fume**

Byung-Sook Cheu, Jeong Oh Lee, Youlum Lee. Occupational Lung Diseases Institute, Occupational Lung Diseases Institute, Ansan, Gyeonggi-do, Korea

**Purpose:** It is known that chronic obstructive pulmonary disease (COPD) can be developed after exposure to many kinds of dust, gas and fume. But the prevalence of COPD was not investigated extensively, especially after bronchodilator inhalation.

**Method:** Chest X-ray images were taken in 1,298 male workers exposed to many kinds of dust, gas and fume. Pulmonary function tests were done with short-acting bronchodilator during the periodic health examination from 2008 to 2010. Excluding the workers with the abnormal radiological findings that could affect lung function, the data of a total of 838 workers were analyzed.

**Result:** The prevalence of COPD increased with age: under age 45, 0.0%; 45 to 64, 31.6%; 65 to 74, 51.8%; 75 and over, 62.2% (p<0.001). COPD was also prevalent in those with high relative exposure index, sum of multiplication of exposure level and exposure duration: under 60, 35.5%; 60 to 99, 37.2%; 100 and over, 47.2% (p<0.009). About half of pneumoconiosis patients had COPD - 43.5% in profusion category 1; 49.6% in 2; 62.5% in 3, but the prevalence in profusion category 0/1 was also high, 30.1% and 30.8%, respectively. The prevalence of COPD in smokers was higher than non-smokers (31.8%), but there was no difference between ex- (41.7%) and current-smokers (41.5%). In ex- and current-smokers, it was 30.0% under 15 pack-years, 42.4% in 15 to 29, and 54.1% in 30 and over.

**Conclusion:** The prevalence of COPD was very high in workers exposed to many kinds of dust, gas, and fume occupationally. Also, it showed the increasing trend with exposure intensity.

**P4177**

**Occupational asthmogams and total IgE according to asthma status in the EGEA study**

Ozanne Demas1,2, Valerie Siuros1, Bénédicte Jacqumen1,2, Isabelle Pin1,4, Jean Bousquet1,2,3, Rachel Nadif1,2, Francine Kaufmann1,2, Nicole Le Mouël1,2, 

1 Respiratory and Environmental Epidemiology Team, CESP Center for Research in Epidemiology and Population Health, Inserm U1018, Villejuif, France; 2 UMRS 1018, Université Paris-Sud 11, Villejuif, France; 3 Inserm U823, Centre de Recherche Albert Bonniot, Université Joseph Fourier Grenoble, France; 4Pneumology, CHU, Grenoble, France; 5Respiratory Diseases, Hôpital Arnaud de Villeneuve, Montpellier, France

**Introduction:** The comprehension of the relationship between asthma and immunoglobulin E (IgE) remains a challenge. Several occupational asthmogams have been identified to cause or aggravate asthma, but their associations with IgE have rarely been studied.

**Aims:** To study the relationship between occupational exposure to asthmogams and total serum IgE in non-asthmatics, childhood-onset and adult-onset asthmatics.

**Methods:** Analyses were conducted in 1212 adults (aged 17-79 years, 48% men) from the Epidemiological study on the Genetics and Environment of Asthma (EGEAE, 2003-07) without missing data for work history and IgE. Lifetime exposure to asthmogams was estimated using an asthma-specific job-exposure matrix.

**Results:** 32%, 28% and 36% of non-asthmatics, childhood-onset and adult-onset asthmatics had ever been exposed to asthmogams. In non-asthmatics, exposed subjects had a significantly lower total IgE level. In asthmatics, no association was observed. Nevertheless, among women with childhood-onset asthma, exposure to asthmogams was associated with higher IgE level (adjusted OR (95%CI) for IgE>=100 IU/ml: 2.49 (1.07-5.83)).

<table>
<thead>

**Irritative effects of respirable particles and chromium in non-smoking welders**

Martin Lehnev1, Volker Harth1, Frank Hoffmeyer2, Rolf Merget2, Katarzyna Gawrych1, Kendzia Benjamin1, Hans Berresheim1, Evelyn Heine1, Evelyn Heine1, Monika Radl-Heinsoth1, Tobias Weiss3, Beate Pesch1, Thomas Brüning1, 

1 Epidemiology, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance (IPA), Bochum, Germany; 2Occupational Medicine, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance (IPA), Bochum, Germany; 3Inmunology and Allergology, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance (IPA), Bochum, Germany; 4Toxicology, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance (IPA), Bochum, Germany

**Introduction:** Welding fumes are known to contain chromium (Cr) compounds. Chronic inhalation of Cr and other constituents of welding fume may induce inflammatory reactions.

**Aims and objectives:** We studied irritative effects of welding fume and Cr in non-smoking welders using spirometry and fractional exhaled nitric oxide (FeNO).

**Methods:** Shift exposure to respirable particles in the welding fume was measured with personal samplers in the breathing zone of 119 non-smoking welders. The Cr concentration in these fume samples was determined by inductively coupled plasma mass spectrometry. Post-shift spirometry was performed with pneumotachography. FeNO was measured with a handheld device (NIOX Mini®). A potential irritative effect of Cr and welding fume was evaluated with multiple logistic regression models.

**Results:** Lung function measurements revealed normal average values standardized to European Community of Coal and Steel. (median of forced vital capacity (FVC): 111.2%; forced expiratory volume in one second (FEV1):104.7%; Tiffeneau index (FEV1/FVC): 77%). Median of FeNO was 17.5 ppb Cr, respirable welding fume and use of dust masks together explained less than 10% of the variance of the variables under study. We found no effect of any of these potential predictors measured during a single working shift on FeNO or Tiffeneau index.

**Conclusion:** Our data analysis did not reveal an acute irritative effect of Cr and welding fumes in non-smoking welders assessed with spirometry and FeNO. Nevertheless, further investigations with the implementation of non-invasive methods to assess inflammatory processes in the upper airways are necessary to make final conclusions.

**P4179**

**Respiratory work disability and occupational outcomes in adults with asthma and bronchial hyperresponsiveness**

Nicola Murgia, Giulia Paolocci, Angelo Gambelunghe, Marco dell’Omo, Ilenia Folletta, Giacomo Muze, Giuseppe Abbritti. Section of Occupational Medicine, Respiratory Diseases and Toxicology, University of Perugia, Perugia, Italy

**Background:** The correlation between asthma and work disability has been demonstrated in previous surveys. Changing job for respiratory problems often defines respiratory work disability. Little is known about occupations of asthmatics with respiratory work disability after they were forced to change job. This study investigates factors associated to respiratory work disability in asthmatics, focusing on occupational outcomes.

**Methods:** 342 adults in working age with asthma, diagnosed by GINA criteria and methacoline challenge or bronchodilator response, answered to a questionnaire. Subjects with occupational asthma were excluded. Respiratory work disability was defined as to have changed job/task because of asthma. Information about pulmonary function tests and skin prick tests were obtained from medical records.

**Results:** 22 subjects reported respiratory work disability. Age, sex, smoking, atopy were not risk factors for changing work. Patients with work disability referred more often uncontrolled asthma (72.7% vs 60.5%), regular use of asthma controllers (81.1% vs 66.6%) and asthma relievers, even if these differences were not significant. Workers that have changed job because of asthma were still prone to work exacerbated asthma in the last year (81.8% vs 35.3%; OR 5.75, CI 95% 1.77-18.71) and work exacerbated rhinitis in the last year (61.9% vs 31.6%; OR 2.90, CI 95% 1.07-7.02), remaining exposed to known asthmogens (63.6% vs 54.1%).

**Conclusions:** In this study atopy did not predict job change. Maybe because the current economical situation, workers with respiratory work disability did not move to more safe occupations, remaining at risk of work exacerbated asthma.

**P4180**

**Enzyme immunoassay (EIA) for bacterial peptide glycolipid (PGN) assessment in air and house dust samples**

Peter S. Thorne, Nervana Metwali. Occupational and Environmental Health, University of Iowa, Iowa City, IA, United States

PGN forms the outer wall of Gram+ bacteria (GM+B) and when liberated induces inflammation through TLR2 and NLR2. Thus, PGN is a potential marker for GM+B. We employed 3 PGN standards, 3 monoclonal antibodies (mAb) and environmental samples to develop PGN-specific EIA. Reagents: anti-PGN mAb clones (B10, 6G6, 3C11); Cerebide β-D-galactoside, Keratin and Phenosin cerebrosides for PGN capture; PGN standards: Bacillus subtilis (PGN-BS), Micrococcus luteus (PGN-MI) and Staphylococcus aureus (PGN-Sa). Evaluation methods: inhibition EIA, EIA with cerebrosides for capture and PGN mAb for labeling, and double mAb sandwich EIA. Samples from three studies were extracted in PBS plus 0.05%Tween 20.

Keratin proved a higher affinity receptor than other cerebrosides. The B10 and 3C11 mAb showed high specificity for PGN-BS and PGN-MI. The 6G6 mAb...
exhibited high specificity for all 3 PGN. Sandwich EIA was not suitable for the detection of PGN because the mAb were directed toward the same epitope. Inhibition assays were inferior to the method employing cerebroside. Cerebroside effectively captured PGN for EIA. The 6% mAb bound to soluble (PGN-SA) or insoluble (PGN-Bs; PGN-MI) macromolecular PGN while mAb B10 and 3C11 bound preferentially to insoluble (PGN-Bs; PGN-MI) PGN. House dust samples had mean (±SD) PGN levels of 34.45±4.70 µg/m³. Inhaled fraction air samples averaged 7.52±2.90 µg/m³ while EDC passive air samplers averaged 2740±680 µg/m³ PGN.

These data show that our antibodies bind to an epitope on the PGN backbone that is common to many GM1β. The specificity of the cerebroside-mAb EIA is sufficient for quantitation of PGN in household dust and air samples.

P4181 Characterization of airborne organic dust exposure with limulus amoebocyte lyase activity

Verena Liebers1, Vera van Kampen1, Maria Duser1, Heike Stübel1, Thomas Brümmer2, Jürgen Bünger2, Monika Rauf-Heimsoth1.

1 Allergology/Immunology, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance – Institute of the Ruhr-Universität Bochum (IPA), Bochum, NRW, Germany; 2 Medicine, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance – Institute of the Ruhr-Universität Bochum (IPA), Bochum, NRW, Germany

The aim of the study was to evaluate if measurement of endotoxin and/or pyrogenic activity by suitable methods to describe different exposure circumstances for example in composting plants. Dust sampling was performed with stationary pumps. Filter samples were extracted with PBS. Endotoxin activity was determined with Limulus amoebocyte lysate (LAL)-assay (Charles River, Sulzfeld). Pyrogenic activity was measured with a whole blood assay (WBA) using cryopreserved blood (Zwissler Laboratorium, Konstanz) measuring Interleukin (IL)-1β release with a specific ELISA in the cell-free supernatant. In all 124 filter extracts endotoxin activity as well as pyrogenic activity were detectable. Median of endotoxin activity was 12 EU/m³ (range 6-3421). Median of pyrogenic activity was 3831 PU/ml (pyrogenic unit; 1PU/ml = 1 pg/ml IL-1β release; range 2126-124590). Correlation between LAL-activity and WBA was r=0.78 (Pearson). Dust samples collected in wheel loaders (n=33) showed median values of 9 EU/m³ and 3580 PU/ml, respectively whereas in the area of sieving machines (n=14) a median of 61 EU/m³ and 7680 PU/ml was measured. Test results of WBA and LAL assay were compared with receiver operating characteristic (ROC) curve using LAL-Test as gold standard. Presuming a desirable test sensitivity of 95% WBA provides a possible specificity of 40% for a cut-off of 10 EU/m³ increasing to 100% specificity with a sensitivity set at 500 EU/m³. (LAL)-Test and WBA are applicable methods to evaluate bioaerosol exposure. Especially in areas with lower endotoxin activity and with further pyrogenic components WBA may deliver additional information.

Bioactivity of 14C-labeled endotoxin in aggregates, shed blebs and whole bacteria: Potency comparison in the LAL assay, cell cultures, and mouse bioassay

Peter S. Thorne1, Kimberley A. Hoppe1, Suzana Hadina2, Andrea Adamakova-Dodd1, Jerrold P. Weiss2.

1 Occupational & Environmental Health, University of Iowa, Iowa City, United States; 2 Internal Medicine, University of Iowa, Iowa City, United States

It is unknown if endotoxin reactivity in the LAL assay varies by its presentation or if this differences parallel reactivity in vitro and in vivo. We compared endotoxin reactivity in the LAL assay, in cell cultures and in vivo when presented in different forms.

Lipopolysaccharide (LOS) from Neisseria meningitidis sero B was metabolically labeled and incorporated into intact bacteria, purified membrane blebs, and aggregates (14C-LOSagg). 14C-LOS content of each was quantified as LOS-specific 13C-3-OH fatty acids. Equivalent escalating doses of 14C-LOS-containting bacteria, blebs, or LOSagg were tested in the LAL assay, in vivo in C3HeB/Fecl mice following intranasal installation (monitoring induced airway inflammation), and in vitro using HEK293 cells or CD14, MD-2, TLR4 (monitoring extracellular accumulation of IL-8). Doses of 14C-LOS were measured by scintillation counting (our gold standard).

Potency varied depending on LOS presentation. Ranked reactivity was: in the LAL assay, blebs > LOSagg > bacteria, by airway inflammation, bacteria > blebs > LOSagg by activation of HEK cells. LOSagg > blebs > bacteria. Differences in potency reached 10-fold for in vitro and in vivo inflammation. Across the range of doses, the ratio of LOS concentration determined by the LAL assay to the gold standard was 1.0-3.3 for blebs, 0.3-0.7 for aggregates and 0.1-0.2 for whole bacteria.

How endotoxin is presented significantly affects endotoxin reactivity in the LAL, cell cultures, whole blood bioassays and mouse bioassays. Comparing the gold standard LAL assay substantially underestimates the content of the LOS preparations for LOSagg and bacteria.

P4183 COPD causation and workplace exposures; an assessment of annual FEV1 decline significance between expert clinical raters

David Fishwick1, Anthony Darby1, Andrew Curran1, Paul Blane2, 1 Centre for Workplace Health, University of Sheffield, Sheffield, United Kingdom; 2Occupational and Environmental Medicine, University of California, San Francisco, United States

Objectives: Epidemiological studies identify that 10-15% of the burden of chronic obstructive pulmonary disease (COPD) is attributable to indoor occupational exposures. Despite this knowledge, very little is known about how clinicians weight this contribution against other risks.

Methods: 15 hypothetical cases of COPD were structured to represent a broad range of smoking and occupational exposure histories. Twelve clinical experts in COPD and 12 clinical experts in occupational lung disease (OLD) were invited to rate the causes of COPD in each case. Cases were developed a priori into 9 categories; combinations of low, medium and high tobacco smoking and low, medium, and high COPD-risk occupational exposures. Five cases also contained annual FEV1 decline data, and raters were asked to comment about its significance, and any required actions. These latter five cases represented annual FEV1 declines of between 95mLs to 400mLs a year.

Results: Responses were received from 14 raters (9 OLD and 5 COPD), representing a 58% response. Significant variation was seen when assessing the relevance of various declines in FEV1. In particular, there were differences in approach to identifying significant or concerning decline, and similarly different advice concerning the risks of continuing employment.

Conclusion: There was a wide range of estimates relating to causative factors in COPD documented by experienced clinical raters, and a variance of view relating to annual decline in FEV1. An improved evidence base is required to help formulate practical guidance for respiratory and occupational physicians when interpreting serial measures of lung function in working groups.

P4184 Respiratory symptoms, lung function tests and bronchial hyperresponsiveness among workers in petroleum industry

Objective: To determine the prevalence of respiratory symptoms, lung function test abnormalities and non specific bronchial hyperresponsiveness (BHR) among workers employed in petroleum anaerobic environments.

Methods: A cross sectional study was performed including 45 males (mean age= 41.0±6.8) employed in crude oil refinery (duration of exposure 15±2.6±8) and 40 male office workers as a control group (mean age=46±4.7±5) matched for age, smoking habits and socioeconomic status. Evaluation of examined subjects included completion of a questionnaire on respiratory symptoms in the last 12 months (cough, phlegm, dysnea, wheezing, and chest tightness), spirometry and histamine challenge test (PC20 8±5mg/ml).

Results: Refiner workers had a significantly higher prevalence of cough with phlegm (31.3%), dry-cough (18.9%), wheezing (11.4%), dysnea (4.1%), and non symptoms (8.3%) than the control group (p<0.015). All spirometric parameters (FVC, FEV1, FEV1/FVC6, MEF75-25, MEF50, MEF25) were lower in petroleum refinery workers compared with the control group, but statistical significance was found for MEF25, MEF50, and MEF25 (p<0.02, and p=0.007; respectively). The prevalence of non specific BHR, defined by histamine PC20 less than 8mg/ml, was higher in petroleum refinery workers but statistical significance was still not reached (21.7% vs. 14.7%).

Conclusion: Our study suggest that occupational exposure in the petroleum industry is associated with a higher prevalence of respiratory and nasal symptoms, lung function impairment and higher prevalence of non specific airway responsiveness.

P4185 Dust exposure and respiratory symptoms; cross sectional study in Taiwanese coffee factories

Gloria Sakwari1,2, Magne Bratrödt1, Bente E. Moen1, 1 Public Health and Primary Health Care, University of Bergen, Bergen, Hordaland, Norway; 2Centre for International Health, University of Bergen, Bergen, Hordaland, Norway; 3Occupational and Environmental Health, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of Tanzania

Introduction: Exposure to coffee dust is associated with respiratory symptoms among workers in secondary coffee processing in industrialized countries, but only three studies have been done in primary coffee factories and none of these studies were in Tanzania.

Aim: This study was carried out to examine whether there is a relationship between total dust exposure and respiratory health effects among workers in Tanzanian primary coffee processing factories.

Methods: A cross sectional study was conducted in two primary coffee factories and in a beverage factory which served as control. Total dust samples were collected throughout the breathing zone from 111 workers in the coffee factory (n = 44) and the control factory (n = 19). Respiratory symptoms were
assessed by standardized ATS questionnaire. Statistical differences were tested by Independent t test and Chi Square. Logistic regression analyses were performed, adjusting for age and smoking.

Results: Totally 150 workers participated; 79 coffee workers and 71 controls. Coffee workers had significantly higher prevalence than the controls for morning cough with sputum (23% vs. 10%, OR = 2.95 [CI 1.1 - 8.4]) and chest tightness (27% vs. 13%, OR = 3.25 [CI 1.2 - 8.7]). Total dust exposure in the coffee factories was significantly higher than in the control factory (geometric mean; 1.23 mg/m³ vs. 0.21 mg/m³, p = 0.001).

Conclusion: Coffee workers in primary factories have higher prevalence for respiratory symptoms and higher dust levels than controls.

P4186
The investigation of stable nitric oxide (NO) metabolites correlation in exhaled breath condensate (EBC) in Cherinolyl clean-up workers (CCUW) with COPD
Igor Klimanov1, Svetlana Soodseva1, Alexander Lisitsa1, Tatjana Marchenko2.
1Clinical and Experimental Biophysics, Pulmonology Research Institute, Moscow, Russian Federation; 2Dept. of Radiation Problems, Ministry for Civil Defense & Emergencies, Mosc, Russian Federation.

The aim of the study was to investigate the correlation between stable NO metabolites in EBC in CCUW with COPD during the course of antioxidant inhalation.

Materials and methods: 58 males outpatients were enrolled in the study. Group1 contains 21 patients CCUW with COPD stage I; group2 contains 19 patients CCUW with COPD stage II. The control group consisted of 18 healthy volunteers. The EBC was collected in all patients, as well as the TNN concentration in EBC was measured before and after the course of therapy. The nebulized ambroxol inhalation (15 mg BID) was carried during 7 days in addition to traditional COPD therapy. The TNN concentration as well as NO3-/NO2- concentrations were measured by spectrophotometric method using the Griess reaction. The correlation between NO3-/NO2-concentration in EBC during the course of antioxidant inhalation was also investigated.

Results: The results obtained demonstrate the statistically significant increase of NO3- concentration and NO2- concentration in EBC in both groups compared with control. The strong positive correlation between observed parameters (r=0.98; p=0.001) as well as linear coefficient k=2.13 (k=[NO3-]/[NO2-]) were determined only in control group. There was a statistically significant correlation between NO3- and NO2- levels in EBC in group1 after the course of ambroxol admission (r=0.89, p=0.003 with k=2.7).

Conclusion: The correlation revealed indicates positive changes in NO metabolites. Thereby, the investigation of NO3-/NO2- correlation in EBC in patients with COPD can be used as a marker of the efficacy of the therapy admitted.

P4187
Biotoxicological pattern and related respiratory impairments in chemical laboratory workers
Felicia Gradinara1, Carmen Crotoru, Brigitte Scutaru, Razvan Danulescu, Micaela Margineanu, Madalina Ipat, Mirela Ghitescu, Eugenia Danulescu. Occupational Medicine Dept, Regional Center of Public Health, Iasi, Romania

Aim: To evaluate the relations between the changes in blood/urine markers and respiratory outcomes in workers from a chemical research institute

Material/Methods: 161 workers (73%women, 27% smokers, having mean age 44.4±13 y) was examined during 20.4±14 yrs) by spirometry, blood/urine biomarkers, including exposure/effect ones. Workplace air solvents level was below upper threshold limits, but noxious cumulative index varied between 1 and 2.

Results: Urinary total phenols releases correlated with TBARS (r=0.22; p<0.05), and urinary acetone with IgM, resp. IgG (r=0.19; p<0.05), showing the relation of the inflammatory effects resp. oxidative imbalance with the occupational hazards. 3/4 of the subjects diagnosed with spirometric changes were in this subgroup, but these changes did not correlate with smoking habit.

Conclusions: Immunological and oxidative stress markers might be related to respiratory changes, even in the early stage of occupational-induced respiratory disease.

P4188
Occupational allergy in apprentices hairdressers and hairdressers in region of Lodz, Poland
Patrycja Krawczyk-Szmul1, Beata Krecisz2, Dorota Chomiczewska2, Marta Wiszniewska1, Marta Kiec-Swierczynska2, Ewa Nowakowska-Swirta1, Joanna Zgorzelska-Kowalik1, Cezary Palczynski 1, Aleksandra Golinska-Zach 1, Jolanta Walusiak-Skorupa1, Patrycja Krawczyk-Szulc1, Beata Krecisz 2, Dorota Chomiczewska 2.

Aim: To specify correlations between UAIS and loss of pulmonary function versus occupational risk, in workers from a small company that processes cotton.

Material and methods: We are investigated 45 workers aged 29-63 years of MW and 77 workers of another trades in meat processing and packing factory, both male and female, mean age 40.1 yrs were examined at the workplace. Respiratory symptoms were recorded on a questionnaire. Lung function tests and peak expiratory flow (PEF) were performed during the shift and out of the work. Blood was collected to determine GSTM1 and GSTT genotypes (PCR).

Results: Airway hyperresponsiveness (AH) and asthma symptoms were recorded in 18 out of 45 (40%) MW after the exposure to PVC fumes, as compared to other workers (19 of 77, 15.6%) p < 0.002. The high prevalence of GSTM1 and GSTT – null genotypes were noticed in 35.5% and 11.8% MW respectively. 7.9% of MW had both deletion of GSTM1 and GSTT. The deletion of the entire genes and absence of the enzymes were associated positively with decreases in FEV1 and PEF (r = 0.67; 0.78) and varied according to the length of service.

Conclusion: Our data suggest that the GSTM1 and GSTT – null genotypes are associated with the higher susceptibility to PVC-induced AH and development of asthma.

P4190
Upper airways irrigation syndrome (U AIS) and loss of pulmonary function at the workers exposed to cotton dust
Micaela Margineanu, Felicia Gradinara, Eugenia Danulescu, Madalina Ipat. Occupational Medecine, National Public Health Institute Bucharest- Public Health Regional Center Iasi, Iasi, Romania

Aim: The aim of the study was to assess the prevalence and risk factors of occupational allergy in apprentices hairdressers and hairdressers from the region of Lodz in Poland.

Material and methods: Prospective study was done in apprentices. A group of apprentices hairdressers were tested twice (34 at the beginning of education and 21 at the end) for respiratory and skin allergy. 54 hairdressers were tested for respiratory and 40 for skin allergy.

Results: The prevalence of respiratory symptoms in apprentices after two years at school was not significantly higher after 2 years of education. One student became sensitized to latex. Positive skin prick tests to common allergens was a risk factor of rhinitis related to work in apprentices hairdressers OR= 9.75 (CI 1.03 – 14.64). Prevalence of cough, dyspnoe and rhinitis was significantly higher in hairdressers than apprentices in the 1st class (p<0.05). Smoking was a risk factor of dyspnoe OR=2.17 (95%CI 1.07-5.28) and rhinitis OR=2.44 (95%CI 1.1-5.3) in hairdressers.

Two of 54 hairdressers was sensitized to ammonium persulfate and one to paraphenylenediamine. One subject had an occupational asthma diagnosis.

Contact allergy was common in hairdressers and apprentices, however more prevalent in the first group.

Conclusions:
• Respiratory symptoms were not the most important health problem in apprentices hairdressers at the end of education probably due to “healthy worker effect”.
• Hypersensitivity to common allergens in apprentices and smoking in hairdressers were risk factors of respiratory symptoms.

425. Work, the environment and respiratory disease

P4189
Genetic risk factors for meat wrapper’s asthma
Olga Vasilyeva, Elena Kulemina, Marya Kolyaskina. Occupational Lung Diseases Department, Pulmonology Research Institute, Moskow, Russian Federation

The fumes of polyvinylchloride (PVC) wrap cause respiratory difficulties and meat wrapper’s asthma.

The pathophysiological mechanism for this malady is not clearly understood. Antioxidant enzymes constitute the endogenous defense from toxic products. The M and T classes of glutathione S-transferase play the important role in the response to oxidative stress in the lung.

This study

Aims: To investigate GSTM1 and GSTT- polymorphism in association with bronchial responsiveness and development of asthma in meat wrappers (MW).

Methods: 45 MW and 77 workers of another trades in meat processing and packing factory, both male and female, mean age 40.1 yrs were examined at the workplace. Respiratory symptoms were recorded on a questionnaire. Lung function tests and peak expiratory flow (PEF) were performed during the shift and out of the work. Blood was collected to determine GSTM1 and GSTT genotypes (PCR).

Results: Airway hyperresponsiveness (AH) and asthma symptoms were recorded in 18 out of 45 (40%) MW after the exposure to PVC fumes, as compared to other workers (19 of 77, 15.6%) p < 0.002. The high prevalence of GSTM1 and GSTT – null genotypes were noticed in 35.5% and 11.8% MW respectively. 7.9% of MW had both deletion of GSTM1 and GSTT. The deletion of the entire genes and absence of the enzymes were associated positively with decreases in FEV1 and PEF (r = 0.67; 0.78) and varied according to the length of service.

Conclusion: Our data suggest that the GSTM1 and GSTT – null genotypes are associated with the higher susceptibility to PVC-induced AH and development of asthma.
sneezing (38%) and allergic diseases (18%). The prevalence of the respiratory symptoms was higher among the exposed subjects (p<0.005). The pulmonary function test (PFT) put in evidence a distal obstructive syndrome (DOS) in 20% of the exposed workers (versus 3% at control group; p<0.0002). We found significant increase of obstructive dysfunctions associated with length of service. The mean values of the FEF1.0/FVC ratio and the PEF values are significantly less at the cotton and sugar cane workers (in second part of study) versus the controlled ones.

**Conclusions:** This study reports a high prevalence of UAIS and DOS among workers exposed to cotton dust, which correlated with length of service. It requires technical and organizational measures to reduce occupational exposure to respirable dust.

**P4191 Use of shuttle test on a group of healthy sugar cane workers, Sao Paulo, Brazil**

Monica Barne1, Komalkirti Apte1, Sushmeeta Chhowala2, Basant Pachisia 2, Prevalence of respiratory symptoms in 7154 state road transport workers by our group. Support by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq)/Brazil

**Introduction:** The shuttle walking test (ST) is used to assess functional capacity in individuals with pulmonary diseases. Its use in healthy workers may be useful to evaluate exercise capacity. The practice of burning the sugar cane field in the night before harvest is common, and emits large amounts of pollutants.

**Aims:** To evaluate the exercise capacity in a group of the burning sugar cane workers and a control group, during harvest and non-harvesting periods.

**Methods:** 112 sugar cane workers and 107 controls, young man, non-smokers were submitted to ST 2 periods. At the beginning and end of the test, heart rate (HR), respiratory frequency, blood pressure, SpO2 Borg score were measured and the walking distance recorded. Data were analyzed and compared using t-test or Mann-Whitney Test.

**Results:** Mean values of the body mass index (BMI) kg/m² and the HR were higher (p<0.001) in the control group: 29.1±6.4 vs 25.5±2.5 years; BMI: 29.3±6.4 vs 24.6±5.2; HR: (98.4±16.9) vs (84.9±13) bpm, respectively. The median walking distance by the two groups at the end of the test was 1380 (IQI:290) meters. In the period of harvest of sugar cane cutters presented significant increase in (p<0.05) diastolic blood pressure at the end of the exercise. No significant alterations in SpO2 between groups and periods were found.

**Conclusions:** We demonstrated that sugarcane workers (SW) have better physical performance and exercise capacity than control subjects, although SW showed an elevation in diastolic blood pressure in ST, as observed in a previous study by our group. Support by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq)/Brazil

**P4192 Prevalence of respiratory symptoms in 7154 state road transport workers from India**

Monica Barne 1, Komalkirti Apte 1, Sushmeeta Chhowala2, Basant Pachisia 2, Monica Barne 1, Komalkirti Apte 1, Sushmeeta Chhowala2, Basant Pachisia 2, Prevalence of respiratory symptoms in 7154 state road transport workers by our group. Support by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq)/Brazil

**Methods:** All employees present and willing to participate, from 24 randomly selected bus depots of 7 cities and towns of Andhra Pradesh State Road Transport Corporation (RTC) participated in this cross sectional study. Every individual was administered a respiratory health questionnaire that captured prevalence of respiratory symptoms.

**Results:** 7154 employees (41.4% drivers, 30.4% conductors, 15.9% garage workers, 7.9% office workers) participated in the study. Average age was 41.6±9.9 years. 27% of all the RTC employees had at least one respiratory symptom during the previous 3 months. Prevalences of rhinitis/rhino-sinusitis, cough, wheezing, breathlessness and chest pain/lightness were 14.7%, 10.5%, 8.3%, 7.9% and 5.6% respectively. Prevalence of respiratory symptoms were significantly higher in office workers (34.9%) as compared to drivers (24.2%; p<0.0001), conductors (25.4%; p<0.0001), and garage workers (30.0%; p<0.05). Prevalence of respiratory symptoms amongst garage workers was also significantly higher than drivers and conductors (p<0.0001 and p=0.005 respectively). Smoking was not a confounding factor.

**Conclusion:** Road transport workers have a high prevalence of respiratory symptoms with significantly greater values amongst office based workers and garage workers when compared to drivers and conductors.

**P4193 Evaluation of cardiopulmonary effects and oxidative stress in sugarcane workers compared to a control population exposed to outdoor biomass air pollution**

Gustavo Prado 1, Urbanitar Santos 1, Mário Terra-Filho 1, Dirce Zanetta 2, Renato Pacelli 3, Pulmonary Division, Heart Institute (InCor) - University of São Paulo Medical School, Sao Paulo, Brazil; 2School of Public Health - University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 3School of Nursing, Sao Jose do Rio Preto School of Medicine, Sao Jose do Rio Preto, Brazil

Brazil is the world’s largest producer of sugar and alcohol. The practice of burning the sugarcane field in the night before harvesting in order to facilitate cropping and thereby increase productivity is still very common. This biomass burning emits large amounts of particulate (PM) and gaseous pollutants to the atmosphere.

With the aim of studying cardiopulmonary impacts and oxidative stress in a population of 113 sugarcane workers (SW) and 109 local healthy controls (Ci), we evaluated lung function tests (LFTs), blood pressure (BP), heart rate variability (HRV) – in submaximal treadmill protocol – and laboratory tests in pre-harvest and harvest periods. All subjects were male non-smokers. Data were submitted to univariate and LMM multivariate analysis.

**Results:** Median age was 28.4 (C) and 23 (SW); P=0.02. In the harvest period (median atmospheric PM2.5=75.93±g/m³ in sugarcane tillage area vs 27.7±g/m³ in city area) there was a significant higher increase in CPK levels in SW than in control subjects, as well as a higher reduction in LFTs. We also found a significant higher increase in diastolic BP and decrease in HRV among sugarcane workers in harvest period. Another important result, was the statistically significant reduction in antioxidants enzymes SOD, GST and GPX in the harvest period, much more expressive among sugarcane workers than in control subjects. We conclude, therefore, that even in healthy populations, exposure to biomass outdoor pollution can cause cardiopulmonary detrimental effects with potential clinical relevance and that such impacts can be probably explained by the physiopathologic pathway of oxidative stress.

**P4194 Serum biomarkers analysis in workers with occupational salt dust exposure in underground conditions in dependence of length of service**

Nicolaj Denisevich 1, Ekaterina Kolesneva 2, Lyudmila Dubovskaya 2, Igor Volotovski 2, 1Outpatient Department, Belaruskaliy, Soligorsk, Belarus; 2Institute of Biophysics and Cell Engineering, National Academy of Sciences of Belarus, Minsk, Belarus

**Objective:** We assessed serum biomarkers distribution in underground workers with occupational salt dust exposure in dependence of length of service.

**Methods:** Serum samples of male donors who are not working at Belaruskaliy, and workers employed in underground working conditions of Belaruskaliy with a mean age 46±7 years were enrolled. All donors were divided into 4 groups: Group I included healthy donors who do not work in the enterprise; II - workers with underground work experience of 5 years; III - consisted of workers with underground work experience of 5 to 15 years; IV - workers with underground experience of more than 15 years. To analyze the qualitative composition of serum proteins we obtained by two-dimensional maps of proteins in blood serum from healthy donors and the study group by two-dimensional gel electrophoresis. Proteomic maps were statistically analyzed in dependence of length of service.

**Results:** We found that total protein value in group II-IV differed from the samples of the 1st group. No statistically significant changes have been revealed in the serum protein composition of underground workers. Proteomic maps revealed abnormalities indicating the presence of inflammation in the bronchopulmonary system of workers. This could be the diagnostic indicator of early stages of lung diseases in the absence of clinical evidence.

**Conclusions:** Analysis of serum proteome changes under the influence of sylvinite aerosols could help to search for specific biomarkers of the body functioning of workers under the influence of occupational factors and predict risk of lung morbidity in occupational exposure to sylvinitic aerosols.

**P4195 Occupational risk factors may be of importance to define populations suitable to screening of lung cancer**

Christophe Paru 1, Eve Bourgourdi 1, Maria Gontranels 1, Julie Corvisier 1, Gaelle Feicht 1, Nicolas Courouble 1, Christelle Clement-Duchene 1, Amandine Lac 2, Isabelle Stucker 1, Patrick Brocard 1, Jacques Benichou 1, 1Hôpital Nord, Université de Rouen, France; 2Hôpital Henri Mondor, Créteil, France; 3Hôpital Saint-Eloi, Montpellier, France; 4Hôpital Edouard Herriot, Lyon, France; 5U754, INSERM, Villejuif, France; 6Occupational Diseases Dpt, University Hospital, Strasbourg, France; 7Pathology, University Hospital, Vandoeuvre Les Nancy, France; 8Occupational Diseases Dpt, University Hospital, Bordeaux, France; 9Biostatistics Dept., University Hospital, Rouen, France

**Aims:** To estimate the attributable fractions (AF) of lung cancer to occupational factors and predict risk of lung morbidity in occupational exposure to sylvinitic aerosols.

**Methods:** A population-based case-control study was performed in the Northern part of Lorraine, France (2006 to 2010). Cases were defined as males with histologically confirmed lung cancer. Controls were selected by a random digit dialing
procedure in the study area. All cases and controls were interviewed in a face-to-face interview in order to fill in standardised questionnaires on risk factors of lung cancer. Occupational exposures were assessed using both a listing of all jobs held for at least one month, specific questionnaires of industrial activities and job-tasks questionnaire. Qualitative and quantitative occupational exposure indices were then calculated. AF and C95% were computed for each occupational exposure index and globally for all significant occupational exposures.

**Results:** 219 cases and 520 controls were included in this study. After adjustment on age, smoking duration, time since quitting smoking, a significant dose-response relationship was found with log of cumulative exposure per unit of air pollution (OR: 1.175, p=0.003), silica (OR: 1.109, p=0.001) and Polycyclic Aromatic Hydrocarbons (OR: 1.175, p=0.007). AF were ranged between 38% (C95%: 27-48) and 57% (C95%: 42-68) according to different models, for these three agents or their association.

**Conclusion:** According to very high AF observed in this study, these results strongly suggest to include occupational risk factors in definition of populations at high risk of lung cancer for the secondary prevention of lung cancer.

**P4196**

Feather duvet and idiopathic pulmonary fibrosis

Ferran Morell1, Ana Villar1, Maria-Jesus Cruz1, M Angeles Montero2, Xavier Muthu3, Respiratory, Hospital Vall d’Hebron, Barcelona, Spain; 2Pathology, Hospital Vall d’Hebron, Barcelona, Spain

**Introduction:** Up to 5% to 10% of cases of idiopathic pulmonary fibrosis (IPF) may be caused by hypersensitivity pneumonitis (HP) that has been erroneously diagnosed. The hypothesis of this study is that exposure to a feather-filled duvet or pillow can be a cause of pulmonary fibrosis that is erroneously diagnosed as IPF.

**Material and methods:** Between 2004 and 2010, 318 consecutive patients were studied. The diagnosis was based on internationally established criteria. Emphasis was placed on detecting transitory exposure to a possible environmental agent, particularly in the use of a feather duvet or pillow. Furthermore, in patients whose questioning revealed exposure to an uncommon causal antigen or low-intensity exposure, specific IgG to antigen was determined, and specific bronchial challenge (SBC) were carried out. Surgical lung biopsies (SLB) were reviewed.

**Results:** 24 patients had previous contact with a feather duvet or pillow for at least one year. In 15 patients the final diagnosis was HP; 8 by SBC and 2 by characteristic pathologic findings. HP was diagnosed in 3 patients with atypical usual interstitial pneumonia in SLB plus positive IgG testing and 2 patients with bronchoalveolar lavage lymphocytosis (>20%) and positive specific IgG to the causal agent. In 36 patients without previous contact, HP was diagnosed in 8 patients.

**Conclusion:** In IPF, thorough clinical questioning can reveal the existence of a low-intensity, but persistent exposure to a known causal agent. HP due to exposure to a feather duvet can be the cause of some cases of pulmonary fibrosis, a condition that can have different prognosis.

This abstract is funded in part by FIS PI10101577.

**P4197**

The value of lymphocytosis in bronchoalveolar lavage in the differential diagnosis between idiopathic pulmonary fibrosis and chronic hypersensitivity pneumonitis

Ana Villar, Ferran Morell, Javier de Gracia, Mario Culebras. Pulmonology, Hospital Vall d’Hebron, Barcelona, Spain

**Introduction:** Bronchoalveolar lavage (BAL) is a minimally invasive, well-tolerated bronchoscopy procedure which plays an important role in the diagnosis of interstitial lung disease (ILD). We assessed the value of lymphocytosis in BAL fluid for the differential diagnosis.

**Material and methods:** Prospective study of all the 318 patients with ILD through 2004-2010. During the diagnostic process, cytological and immuno-histochemistry studies of BAL fluid were performed.

**Results:** We studied 318 patients with ILD (57 IPL, 92 NH, 45 Sarcoidosis). BAL was performed in 230 patients (72%), obtaining median lymphocyte percentages of 8%, 20% and 25% in IPF, HP and Sarcoidosis respectively. Lymphocyte counts were >60% in non IPF patients, 5% of HP and in 2% of Sarcoidosis patients; were >30% in non IPF, 18% HP and 29% Sarcoidosis, and >20% in 5% IPF, 32% HP and 33% Sarcoidosis.

In a study focused exclusively on chronic NH occurring with IPF criteria (ATS/ERS criteria) (n=60), three presented lymphocytosis >20% but were ultimately diagnosed with HP. Lymphocytosis >15% was found in 511/45% IPF and 3x3/11 (55%) of patients with final diagnoses HP. Lymphocytosis between 10-15% was present in 8/14 (57%) IPF and 6/14 (43%) HP. No significant differences were found in the cellular profile between IPF and HP.

**Conclusions:** Lymphocytosis >20% is also a characteristic of HP and Sarcoidosis, since it very rarely found in IPF (5% in our series). In chronic HP the absence of lymphocytosis in BAL >20% does not rule out the diagnosis (35% diagnosed with actually HP).

This abstract is funded in part by FIS PI101577.

**P4198**

The relation between air pollution and respiratory tract diseases by months in Duzece City of Turkey

Gülce Balbay1, Öner Balbay2, Peri Arbak2, Ali Nihat Annakkaya2, 1Dept. of Chest Diseases, Duzece Atatürk State Hospital, Duzece, Turkey; 2Dept. of Chest Diseases, Duzece University School of Medicine, Duzece, Turkey

**Aim:** To investigate the relationship between levels of particulate matter (PM10) and sulphur dioxide (SO2) and the patients with COPD, asthma, respiratory tract infection (respiratory tract disease-RTD) applied to pollicymins in the central part and counties of Duzece.

**Material:** Between I January 2009 and 31 December 2009 in Duzece Atatürk State Hospital, the patients diagnosed as RTD at chest, internal medicine, ENT, pediatric pollicymins were retrospectively evaluated. The monthly average values of SO2 and PM10 obtained from the official data of Ministry of Environment and Forests.

**Results:** 53.1% of 29,367 cases were female. 64.4% of cases were adults. The average SO2 and PM10 concentration was highest in November, December, January and those were the lowest in July, August, September and October. Acute bronchitis were higher than the remaining in January (26.9%) and December (25%), while those were the lowest in September (20.6%), respectively. COPD were more frequent in January (10%), February (10.9%), March (13.1%), but less in September (5.9%). Asthma were most admitted in December (10.6%), January (9.6%) but less frequently in September (6.1%). Pneumonia were frequently admitted in November (10.6%), January (9.6%). The allergic rhinitis was the most common at the seaside (119/479, 24.8%) (p=0.000). Upper RTD (58%) were higher than the lower RTD in the months that the air pollution was the highest (p=0.000).

**Conclusion:** It was speculated that pollicymins admissions of COPD, asthma, acute bronchitis, pneumonia seem to be associated with air pollution and also living in the seaside may lead to more increase in applications regarding allergic rhinitis.

**P4199**

Influence of high values of air pollutants on number of asthma exacerbations in children from Pancevo in years 2009 and 2010

Stanisa Baumann1, Slobodan Prodanovic2, Stefan Bauermann3, Jasmina Prodanovic3, Svetlana Pakaski3, Marija Deanovic3, Milica Tanaskovic4, 1Children’s Department, General Hospital Pancevo, Pancevo, Serbia; 2Medical School, University of Belgrade, Belgrade, Serbia; 3Children’s Health Center, Helath Center Pancevo, Pancevo, Serbia; 4Occupational Medicine, Public Health, Pancevo, Serbia

**Introduction:** Air pollution is well known for its influence on development of asthma. Children with asthma are specially vulnerable on high levels of air pollutants.

**Aim:** To show that elevated air pollution (tar, SO2, NO2, TSP, NH3, and benzene) had significant influence on acute exacerbations of asthma.

**Method and results:** We have monitored daily concentrations of tar, SO2, NO2, TSP, NH3, and benzene in city of Pancevo in October, November, December, January and February and number of children who visited pediatrician due to acute asthma exacerbation. We have excluded other months to avoid influence of higher levels of pollen. We have observed that during periods with high peaks of tar, TSP and benzene, larger number of children had acute asthma exacerbation and visited pediatrician. SO2, NO2 and NH3, were within legally permitted range.

Results have shown that in year 2009 in January, February, November, October and December tar, TSP and benzene were above permitted values 73 days and in that period 1763 children had asthma exacerbation. In the same period in 2010 the same air pollutants were 44 days above permitted values and 939 children had asthma exacerbation. During periods with air pollution below permitted values in 2009, 1331 children had asthma exacerbation in 78 days, and in 2010, 1508 in 107 days. This difference is statistically significant, which was confirmed by χ2 test, for year 2009 χ2 = 3.987, and for 2010 χ2 was 4.91, p>0.05.

**Conclusion:** High concentrations of tar, TSP and Benzene have significant influence on larger number of asthma exacerbations in children, specially during periods of overstepping legally permitted concentrations.

**P4200**

The relationship of air pollution and surrogate markers of endothelial dysfunction in a population-based sample of children

Mohammadreza Modaresi, Perinaz Poursafa, Roya Kelishadi, S.H. Javanmard. Pediatrics Department, Children’s Medical Center, Tehran, Islamic Republic of Iran Cardiac Research Center, Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran; 2Biostatistics Department, University of Medical Sciences, Isfahan, Islamic Republic of Iran; 3Children’s Department, General Hospital Pancevo, Pancevo, Serbia; 4Occupational Medicine, Public Health, Pancevo, Serbia

**Background:** This study aimed to assess the relationship of air pollution and plasma surrogate markers of endothelial dysfunction in the pediatric age group.

**Method:** This cross-sectional study was conducted in 2009-2010 among 125 participants aged 10-18 years. They were randomly selected from different areas of Isfahan city, the second largest and air-polluted city in Iran. The association of air pollutants’ levels with serum thrombomodulin (TM) and tissue factor (TF) was determined after adjustment for age, gender, anthropometric measures, dietary and physical activity habits.
Tuesday, September 27th 2011

Results: Data of 118 participants was complete and was analyzed. The mean age was 12.79 (2.35) years. The mean pollution standards index (PSI) value was at moderate level, the mean particular matter measuring up to 10 mum (PM10) was more than twice the normal level. Multiple linear regression analysis showed that TF had significant relationship with all air pollutants except carbon monoxide, and TM had significant inverse relationship with ozone. The odds ratio of elevated TF was 5.16 higher in the upper vs. the lower quintiles of PM10, ozone and PSI. The corresponding figures were in opposite direction for TM.

Conclusions: The relationship of air pollutants with endothelial dysfunction and pro-coagulant state can be an important factor in the development of alterations in microcirculation from early life. This finding should be confirmed in future longitudinal studies. Concerns about the harmful effects of air pollution on children’s health should be considered a top priority for public health policy; it should be underscored in primordial and primary prevention of chronic diseases.

P4201 Prediction of the acute mountain sickness using SaO2 indices at rest and exercise in hypoxic conditions

Akpay Sarybaev, Almaz Akunov.

The aim of the study was to compare the oxygen saturation at rest and exercise during the simulated altitude ascents in subjects who had suffered from acute mountain sickness (AMS) as well as healthy subjects. Ninety seven subjects were divided into three groups depending on the Lake Louise score during the previous stay at high altitude (3800 m above sea level). The 1st, control, group consisted of 62 people without AMS symptoms; the 2nd group included 18 patients with mild AMS (3-4 points in LL score) and 17 subjects with moderate to severe AMS made the 3rd group (5 or more points in LL score). SaO2 indices were taken at rest and after 5 minutes of strenuous bicycle test both at normoxia (760 mm) and inside the hypobaric chamber (4500 m above sea level, 30 minutes).

Results: It was revealed that rest oxygen desaturation rate was significantly higher in the 2nd and 3rd group compared with the 1st, control, group (rest SaO2 – 16.0±0.5% and 16.5±7% compared with 14.2%, p<0.05) while the exercise oxygen desaturation rate was significantly higher in the 3rd group compared with 1st and 2nd group exercise SaO2 – 24.7±0.8% compared with 18.5±4.8% and 21.7%, p<0.05).

Conclusion: Both rest and exercise indices of oxygen saturation during the simulated ascent to high altitude may be used as prediction markers for acute mountain sickness.

P4202 Airborne particulate matter (PM10) decreases respiratory activity in mitochondria isolated from lung tissue

Norma Elena De la Fuente-Hernández1, Verónica Freyre-Fonseca1, Claudia María García-Cuéllar1, Yesenia Sánchez-Pérez2, Yolanda I. Chirino2.

Airborne particulate matter (PM10) has potential adverse health effects in human, especially in lung tissue and those effects are related to an increase in several dis ease and cancer. We have previously demonstrated that PM10 increases reactive oxygen species (ROS) formation, decrease in antioxidant enzymes activity and these effects are observed under sub-lethal conditions. In this regard, mitochondrion are the main source of ROS but little is known about alterations induced in mito- chondrial function after PM10 exposure. We hypothesized that if PM10 induces an increase in ROS generation, it could be possible to find alterations mitochondrial function. To test our hypothesis we exposed enriched mitochondria preparations from lung tissue of rat for 1 hour to the following PM10 concentrations: 1, 5, 10, 30 and 50 μg/mL. We measured the oxygen consumption after PM10 exposure using a Clark type electrode and also the activity of mitochondrial complexes. In addition, the mitochondrial membrane potential was determined by rhodamine 123 staining using confocal microscopy. Our results showed a decrease in the respiratory control index and ADP phosphorylation over 50%, a decrease in the respiratory activity of complex IV and an important decrease in mitochondrial membrane potential. In conclusion, PM10 induces a decrease in oxygen consumption, ADP phosphorylation and loss of mitochondrial membrane potential. These effects are related to the decrease in activity of complex IV. Our research will be guided to investigate if the mitochondrial alterations induced by PM10 exposure could be related to mitochondrial dysfunction and metabolic alterations found in cancer cells.

P4203 Prevalence of asthma and allergy symptoms and pulmonary function testing in sugar cane and tobacco field workers in Honduras

Johan F. Salas, Maria E. Perez, Indiana University School of Medicine, Indianapolis, IN, United States

We previously demonstrated a very high prevalence of wheezing (89%) and lower pulmonary function tests (PPT) in rural Honduran children of the Rio Grande O Choluteca valley where sugar cane is burned 8 months of the year compared to children of Jamastran valley (17% wheezing) where no crops are burned. We applied a similar asthma/allergy questionnaire and performed PPT on sugar cane field workers (SC) of the Rio Grande O Choluteca valley and tobacco field workers (TOB) of the Jamastran valley. Tables 1 & 2 summarize questionnaire findings and PFT values of the two groups.

<table>

</tr>
</tbody>
</table>

We found the SC workers to be significantly younger with thus fewer years working in the fields compared to the TOB workers. Both groups were found to have similarly high prevalence’s of ever wheezed, wheezed in last 12 months, night cough, smoking frequency, chronic rhinitis and conjunctivitis. SC workers have significantly lower FVC and FEV1-1. We conclude that both SC and TOB field workers in Honduras have a high prevalence of asthma and allergy symptoms and SC workers, although younger with fewer years of exposure, have lower pulmonary function. Individual air quality sampling of the two groups is needed to delineate the contribution of environmental work exposure to these findings.

P4204 Asthma and allergy to laboratory animals in university employees: Need for prophylaxis

Erica Ferraz1, LUISA Karla Arruda1, Marcos C. Borges1, Satoshi Kitamura2, Ericson Bagatini1, Elcio Oliveira Vianna1. 1Department of Medicine, Medical School of Ribeirão Preto, University of S. Paulo, Ribeirão Preto, S. Paulo, Brazil; 2Area of Occupational Health, State University of Campinas, Campinas, S. Paulo, Brazil

Introduction: Subjects exposed to laboratory animals are at high risk of developing respiratory and allergic diseases. The reported prevalence of occupational asthma ranges from 1.4 to 9.5%, and occupational rhinitis from 2.9 to 18.3% (reviewed by Foletti, L. et al. Allergy 2008; 63:834-41). In the moment, few studies have looked at programs to prevent these diseases.

Objectives: To assess the prevalence of asthma and atopic sensitization to common allergens, and to evaluate the employment of prophylactic measures in two Brazilian universities.

Methods: Subjects exposed to laboratory animals in two Brazilian universities (University of São Paulo and State University of Campinas) answered specific questionnaires to assess work conditions, underwent spirometry, bronchial provocation with mannitol, and skin prick tests to eleven common allergens and five work-related allergens (rat, mouse, guinea pig, hamster and rabbit).

Results: Eighty-five subjects (38/11 years old, 59 men) were evaluated. Forty-four (51.8%) subjects were sensitized to at least 1 common allergen, and nine (10.6%) were sensitized to at least 1 work-related allergen. Twelve subjects (14.6%) presented hyperresponsiveness to mannitol. Personal protective equipments were available at work for 98%; however, 51% did not wear mask all the time when in contact with animals. Twenty-six percent of subjects received formal orientation about the risk assessment and hazard recognition related to laboratory animal allergy.

Conclusion: In this ongoing study, prevalence was relevant to support prophylactic measures. These measures need reinforcement.

P4205 COPD and exposure to smoke biomass in non-smokers women in a semi-rural region of Tunisia

Nada Rahmouni, Ines Zendah, Bithel Khouaja, Leila Bayahi, Amel Khattab, Habib Ghedira. Pulmonary Department I, Abderrahmen Mami Hospital, Ariana, Tunisia

Many studies have suggested that biomass smoke is a risk factor for COPD and this study is conducted to compare, in non-smokers housewives, the prevalence of COPD symptoms and airway obstruction as related to biomass exposure.

Methods: From April to October 2010, 243 women over 30 years-old were ran- domly selected from a municipal list of the semi-rural city of Kasserine in Tunisia. Among the 140 non-smokers women who consent to be explored, 81 (58%) are exposed to smoke biomass from traditional wood cooking (n=47) or traditional field workers in Honduras have a high prevalence of asthma and allergy symptoms and SC workers, although younger with fewer years of exposure, have lower pulmonary function. Individual air quality sampling of the two groups is needed to delineate the contribution of environmental work exposure to these findings.

related symptoms were more frequent in exposed women either Cough (81% vs. 66%, p<0.01) or Dyspnea (76% vs. 24%; p<0.01). An FEV1/FEV6 of less than 70%, considered as diagnostic of an obstructive disease, was more prevalent in exposed group (23.3% vs. 4.4%; p<0.001).

Conclusion: COPD-related symptoms and airway obstruction are significantly more prevalent in non smokers women, from semi rural area in Tunisia, exposed to biomass smoke from traditional wood cooking or traditional coal house heating.

P4206 Smoking and obstructive sleep apnea among former World Trade Center (WTC) rescue workers and volunteers

Background: Smoking and sleep disorders are common among individuals with adverse health effects from their WTC work exposures. Previous observations seemed to suggest that some forms of sleep disordered breathing (SDB) could be more prevalent in this population. We reviewed the results from nocturnal polysomnograms (PSG), to investigate whether REM-related OSA, and upper airway resistance syndrome (UARS) were more frequently diagnosed among WTC-exposed subjects compared to unexposed subjects.

Methods: 656 nocturnal PSGs performed at our sleep center were reviewed, 272 of them in former WTC workers. The diagnoses were categorized as: no SDB, simple snoring, REM-related OSA, UARS, and mild, moderate, and severe OSA. Bivariate and logistic regression analyses were used to examine differences in diagnoses between the two groups, using age, gender, body mass index (BMI) as predictors.

Results: The WTC group had a significantly higher predominance of the male gender (86.8% vs. 56.3%, p<0.001), but slightly lower mean BMI (31.4 vs. 33.2 kg/m2, p=0.002). Table 1 summarizes the diagnoses on PSG. There was no significant difference between the two groups by Chi square (p=0.56), or logistic regression (p=0.77) with adjustment for the 3 significant predictors (age, gender, and BMI, all p<0.0001).

Conclusions: We did not detect any difference in the diagnoses derived from PSG between the WTC-exposed and unexposed subjects. OSA was significantly associated with age, BMI, and gender in this patient population.

P4207 Black carbon content in PM as a metric to evaluate the impact of the car-free Sundays of winter 2011 on air quality in Milan

Methods: The overall prevalence of COPD was 7.5%, the odds ratio (OR) of occupational exposure was 4.6 (95%CI 1.9-10.9), the prevalence of smoking was 17.5% (95%CI 14.5-20.7). Results of the statistical analyses showed that the contribution of occupational factors in the development of COPD was 18.3% (95%CI 13.8-23.6). The contribution of smoking was 55.8% (95%CI 49.5-62.4). The contribution of age, gender and BMI was 26.9% (95%CI 20.6-33.6).

Conclusions: COPD-related symptoms were more frequent in non smokers women, from semi rural area in Tunisia, exposed to biomass smoke from traditional wood cooking or traditional coal house heating.

P4208 The influence of occupational and non-occupational factors on the development of occupational COPD

Methods: By the 13th of February 2011 the number of days exceeding 50 gg/m3 of PM10 was over the EU annual limit of 35. The Milan Municipality decided to stop traffic 8 am to 6 pm on Sunday Jan 30th and Feb 6th 2011 to reduce pollution. The decision was opposed by detractors, who claimed that no data were available about the efficacy of the restriction.

Scope: To measure outdoor PM10, PM2.5, PM10, and black carbon (BC) during car free Sunday and normal traffic days, and to compare air quality as the percent content of BC in PM (BC/PM).

Methods: Instrumentation: mass analyzer mod. Aerocet 531 (MetOne, USA) for PM concentrations, Microaethalometer mod. AE51 (Magee, USA) for BC. Procedure: the instruments were located at walkside in Corso Buenos Aires and were tested by 04:00 to 07:00 p.m. from Friday to Monday. Traffic density was also recorded.

Results: Overall the BC/PM mean (SD) was 5.8 (2.3) during the car free Sundays as compared to 12.04 (4.8) during the free traffic days (p<0.001).

Table 1. Percent black carbon content in PM during car-free Sundays vs normal traffic days

<table>
<thead>
<tr>
<th>Car-free Sunday Jan 30th and Feb 06th 2011</th>
<th>Normal traffic from Friday, Saturday and Monday</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>BC/PM ratio mean (SD)</td>
</tr>
<tr>
<td>%</td>
<td>5.80 (2.3) *</td>
</tr>
</tbody>
</table>

*p<0.01 Student’s t-test

Mean traffic density was 342 and 1858 vehicles/h during the car-free and normal traffic days, respectively.

Conclusion: During the 2 car-free Sundays, a great improvement in air quality was observed, with over 50% reduction in BC/PM ratio. These data show that car free Sundays represent a useful environmental intervention to protect people from traffic proximity pollution, a well known respiratory and CV risk factor.

P4209 Breast change perception in women after smoking cessation

Methods: We interviewed 25 premenopausal women who had quit smoking quitting. Such an outcome was paralleled by only moderate effects on weight or BMI increase after quitting: Notably, of the 16 women with breast change perception, only 3 (19%) with a normal baseline BMI showed a BMI increase to >25.

Conclusions: These results indicate that women in pre-menopausal status reported subjective perception of change in breast size after smoking cessation, which may not be totally explained by weight gain. Further studies are needed to understand the effect, if any, of such perception on motivation to quit smoking.

426. Anti-smoking interventions: prevention and treatment

P4209 Breast change perception in women after smoking cessation

Methods: We interviewed 25 premenopausal women who had quit smoking quitting. Such an outcome was paralleled by only moderate effects on weight or BMI increase after quitting: Notably, of the 16 women with breast change, only 3 (19%) with a normal baseline BMI showed a BMI increase to >25.

Conclusions: These results indicate that women in pre-menopausal status reported subjective perception of change in breast size after smoking cessation, which may not be totally explained by weight gain. Further studies are needed to understand the effect, if any, of such perception on motivation to quit smoking.
P4210 Smoking prevalence and its effect on lung function and soluble adhesion molecules levels in medical students
Ekaterina Kukhareva1, Nikolay Menkov1, Natalia Lubavina1, Monica Shonia1, Galina Varvarina1, Victor Novikov1, 2, 3 Propedeutics of Internal Medicine, Medical State Academy, Nizhny Novgorod, Russian Federation; 4 Cell and Molecular Biology, Lobachevsky State University, Nizhny Novgorod, Russian Federation

The purpose of the study was to investigate the prevalence of tobacco smoking in students of Nizhny Novgorod Medical State Academy (Russia) and its effects on lung function and serum levels of soluble intercellular adhesion molecules (sICAM-1, sCD50, sCD54) and sCD54 (sICAM-3). Materials and methods: Data were collected between 2009-2010 using a structured questionnaire on 149 medical students (42 males and 107 females), aged 20±1 years. The questionnaire included questions regarding personal characteristics, history and quitting smoking, consequences on health. Lung function tests were performed in 31 students (16 smokers and 15 non-smokers). The serum concentrations of sICAM-1 and -3 were determined using ELISA method.

Results: In 40% of current smokers (from which 46% females); an index of duration of smoking was 3,0±1,9 pack/years. The early age of the beginning of smoking (of 9-14 years) has been registered. Means of FVC and PEF in smoking students were significantly lower than in non-smoking (81,1±6,5 vs 87,3±4,91%, and 75,4±9,7 vs 84,9±7,66, respectively). The serum levels of sCD50 and sCD54 in smoker (140,4±57,7 L/ U and 78,9±29,7 U/L, respectively) were significantly reduced compared with non-smoker (242,4±54,4 U/L and 172,7±51,5 U/L, respectively). Conclusion: These results indicate high level of tobacco use among medical students in this Russian city, especially among females. The reduced levels of FVC and PEF in all of sCD54 and -3 in smoker compared with non-smoker were revealed. Decrease in levels of sCD50 and sCD54 in smokers might be due to inhibitory effect of smoking on intercellular adhesion.

P4211 The role of smoking in development of endothelial dysfunction in patients with COPD: combination with AH
Oxana Belina1, Natalia Shapovalova1, Maria Menshutina2, Vera Achkasova3, Olga Galkina1, Margarita Kadyskaya1, Vera Didur1. General Practice Department, Pirogov’s State Medical University, Saint-Petersburg, Russia; 2 Pathophysiology Department, Saint-Petersburg Pirogov’s State Medical University, Saint-Petersburg, Saint Petersburg, Russian Federation; 3Department of Laboratory Diagnostics, Saint-Petersburg Pirogov’s State Medical University, Saint-Petersburg, Russian Federation

Endothelial dysfunction (ED) is a pathological finding of COPD and arterial hypertension (AH) at different stages of incidence of AH in patients with COPD is higher than in the population. The important risk factor of COPD and AH is smoking which may initiate vascular impairment by stimulate adhesion molecule expression and leukocyte adhesion to endothelium.

Aims: The purpose of study was to find out the role of ED in the pathogenesis of COPD in combination with AH using sICAM-1, and to study the reversibility of changes in the endothelium after smoking cessation.

Methods: Plasma levels of sICAM-1 were quantified by ELISA in age-matched 45 patients with COPD and AH (mean age 61±6,5) that were either current smoking COPD patients with AH (n=12) and COPD ex-smokers with AH (n=12), to be compared with smokers (n=10) and nonsmokers with AH (n=11).

Results: The comparison of smoking (19,5±4,8) and ex-smoking (15,5±3,6) COPD patients with AH revealed that level of sICAM-1 was higher in smokers (p<0.05). There is no difference in smokers with AH (14,7±4,5) comparing with non-smokers (16,5±4,7). We have found difference between smokers with COPD and AH and smokers with AH (p<0.05), and a correlation between sICAM-1 plasma level and the age (r=0.46,p<0.05).

Conclusions: Our results show that COPD smokers with AH have more evident expression of adhesion molecule to endothelium to be compared with ex-smokers. The combination of COPD and AH may have more evident contribution in development of ED. The less evident of ED in ex-smoking patients shows reversibility of these changes. Correlation between sICAM-1 and age shows that ED in elderly patients plays important pathogenetic role in comparing with middle age patients.

P4212 Acute effects of water-pipe smoking on pulmonary function and cardio-pulmonary exercise capacity in healthy subjects
Feras Hawai1,2,3, Hiba Ayub1, Nour Obiedat1, Iyad Ghanimat2, Sahar Dawaalrah1, Thomas Eissenberg3. 1 Cancer Control Office, King Hussein Cancer Center, Amman, Jordan; 2 Department of Laboratory Diagnostics, Saint-Petersburg Pirogov’s State Medical University, Saint-Petersburg, Russia; 3Psychology and Institute for Drug and Alcohol Studies, Virginia Commonwealth University, Richmond, United States

Background: Waterpipe tobacco smoking (WTS) has gained popularity, but the physiologic effects of WTS have not been extensively studied. Studies that have evaluated the impact of WTS have focused on its chronic effects or have only evaluated limited parameters. In a pilot study, we evaluated the acute effects of WTS on lung function and exercise capacity in water-pipe users. We hypothesized that acute exposure to WTS alters pulmonary function and cardio-pulmonary exercise test (CPET) responses.

Methods: We recruited 15 healthy WTS male subjects (8). We used a single-group pre-test (having abstained from WTS for at least 48 hours before testing) post-test (within half an hour of 45-minute WTS session in a café design). We performed spirometry and CPET (cyclogrometer; 2-min 20-Watt warm-up and 25-Watt increase every 2-min for 10 min).

Results: Mean age was 21.2 years; average carbon monoxide pre-test was 4.6 ppm and 27.5 ppm post-test; forced expiratory volume in one second (FEV1) decreased in 7/15 S by 0.48 L/sec (9%), forced expiratory flow from 25% to 75% of vital capacity (FEF25-75%) decreased in 11/15 S by 0.65 L/sec (12%). Breathing reserve decreased in 10/15 S by 10.2%; oxygen pulse decreased in 9/15 S by 2.4 mL/beat (8%). 9/15 S could not complete the CPET after WTS (8.29 min average), vs. 6/15 S pre-WTS (8.33 min average); 9/15 S reported greater degree of shortness of breath at mid/peak exercise using Borg scale; among those completing exercise time pre and post (6/15 S), maximum oxygen consumption (VO2max) dropped in 9/15 S.

Conclusion: Acute WTS causes impairment in pulmonary function and CPET ventilatory and cardiovascular responses.

P4213 Waterpipe smoking in Lebanese women: A lower prevalence but a higher risk of dependence
Pascale Salamé1, Georges Khayat2, Mirna Waked3. 1 Faculties of Public Health & of Pharmacy, Lebanese University, Beirut, Lebanon; 2Pulmonology, Hotel Dieu de France Hospital, Beirut, Lebanon; 3Pulmonology, Saint George Hospital, Beirut, Lebanon

Introduction: Waterpipe smoking has gained in popularity among Lebanese women. Our objective was to evaluate whether nicotine dependence is higher in smoking women compared with men.

Methods: Data were taken from a cross-sectional study on Lebanese residents aged 40 years and above. After an oral informed consent, subjects answered a questionnaire, including smoking history, cigarette and waterpipe dependence using validated dependence questionnaires (Fagerström for cigarettes and LWDSS-11 waterpipe). Results: 1066 males and 1134 females were interviewed; respectively, 58.7% and 42.9% of them had ever smoked cigarettes, while 6.9% versus 6.7% had ever smoked waterpipe (p<0.01). Similar results were found for actual and previous smokers. However, when looking at dependence, patterns differed between genders: 57.5% vs 49.1% in cigarette smokers (p=0.041), 35.9% vs 51.6% in waterpipe smokers (p=0.076), and 67.9% vs 43.6% in mixed smokers. These results were confirmed by dependence dose-effect relationship (p=0.05 for trend) and multivariate analysis (ORa=2.28). The main components of waterpipe dependence in women were positive and negative reinforcement (p<0.05), but not nicotine dependence or psychological craving. In female waterpipe smokers, a higher prevalence of respiratory disease and symptoms were found.

Discussion and conclusion: Since tobacco dependence seems highly associated with tobacco related diseases, waterpipe smoking women could be at a higher risk of disease; they should be considered as real smokers, and receive particular attention during tobacco related health education and in smoking cessation treatments.

P4214 Smoking in posttuberculosis bronchiectasis syndrome patients
Beatrice Mahler. Pneumology, “Marius Nasta” Institute of Pneumology, Bucharest, Romania

Bronchiectasis is the permanent dilation of the bronchial airway. Posttuberculosis bronchiectasis syndrome occurs with the healing of extensive and destructive tuberculosis. The frequency of this association is 15-20%. The smoking – active bronchiectasis syndrome occurs with the healing of extensive and destructive tuberculosis. The frequency of this association is 15-20%. The smoking – active tuberculosis sequelae, mean age of 48.4 (± 16.6). We compared the share of smokers in the two categories.

Results: In the group of idiopathic bronchiectasis patients, the fraction of smokers was 60.52%, with a 32.1% of the group. In the group of patients with bronchiectasis secondary to tuberculosis, the fraction of smokers was 71.42%, with a 30.2% of the group.

Conclusions: The number of smokers among posttuberculosis bronchiectasis patients was higher, although the PA index was lower in idiopathic bronchiectasis patients. The high smoking rate in patients with idiopathic bronchiectasis, as well as the PA index was surprising. I believe the high smoking rate in patients suffering from the posttuberculosis bronchiectasis syndrome was due to their poor socio-economic conditions, which also explains a lower PA index, as well as to the need of implementing health education programs for these categories.
P4215 Interrelationship between clinical picture expressiveness and brush-biopsy cell count and proteinases and its inhibitors in sputum at smokers and nonsmokers with COPD
Ekaterina Bukreeva1, Raisa Pleshko2, Gulnara Seitoval2. 1Therapy, Siberian State Medical University, Tomsk, Russian Federation; 2 Morphology, Siberian State Medical University, Tomsk, Russian Federation
We study relationship between clinical picture and expressiveness of changes in bronchi at COPD smokers and nonsmokers. Endobronchial biopsy and brush-biopsy cytological research and definition of elastase and its inhibitors in sputum were conducted at 46 COPD patients. To reveal correlations we used Spearman coefficient. At COPD nonsmokers the expressiveness of cough and dyspnoe has positive correlation with neutrophiles count (R=0.95), dystrophical epithelial cell count (R=0.95) and negative correlation with eosinophiles count (R=-0.95). COPD nonsmokers have positive correlation between elastase activity and goblet cell count (R=0.81) and atrophical epithelial ciliated cell count (R=0.83). It is evidence of influence of elastase on development of atrophy and hyperscretion in COPD exacerbation program. COPD smokers have no correlation between cough expressiveness and brush-biopsy cell count, but dyspnoe expressiveness has positive correlation with neutrophiles count (R=0.42), and negative with lymphocytes count (R=-0.70). At COPD smokers the negative correlation was revealed between FEV1, and dystrophical epithelial cell count (R=-0.40), between a2MG and reserved cell count (R=0.42), positive correlation between a2MG and typical epithelial ciliated cell count (R=0.46), proliferated epithelial ciliated cell (R=0.56). That may be caused by capacity of a2MG to increase count of cell mitoses. Smoking influences on inflammation mechanisms at COPD patients, that is reflected on correlations between brush-biopsy cell count, proteins and its inhibitors in sputum and clinical symptoms expressiveness.

P4216 Determinants of change in quality of life after smoking cessation of health care employees
Rebecca Finger1, Michael Tammi1, Bruno Seiffert1, Martin Kuster2, Anja Meyer1, Daiana Stolz1. 1Clinical of Pulmonary Medicine and Respiratory Cell Research, University Hospital of Basel, Basel, Switzerland; 2Industrial Health Service, Novartis Pharma AG, Basel, Switzerland
We aimed to assess the influence of a smoking cessation programme on quality of life (QoL). 703 smoking employees from University Hospital Basel, Switzerland, and two local health industry companies (Novartis Pharma AG, Hoffman-La Roche AG) participated on a structured smoking cessation program. This consisted of 10 visits with counselling and motivational within 2 years of follow-up. Various modalities of nicotine replacement therapy and/or bupropion were offered. Quality of life was assessed by Satisfaction with Life scale (QoL). The impact of several factors on quality of life was analyzed by linear mixed effect model (fixed effects with 95% confidence intervals are shown in parentheses).

38% of participants were abstinent from nicotine after 2 years. Successful quitting at 2 years was associated with a significant improvement in quality of life (0.75 95% CI 0.0151;49; p=0.045). Smokers with higher quality of life (QoL) at baseline showed greater improvement than those with lower baseline values (0.5 95% CI 0.42;57; p=0.001). Changes in quality of life were affected by medication after a successful quit attempt (p=0.029) and the interaction of time and medication (p 0.02).

P4217 Public spirometry for primary prevention of smoking-related diseases?
Christina Wich1, Sabine Zirlik1, Markus Frieser1, Kai Hildner1, Markus Neurath1, Christina Wich1, Sabine Zirlik1, Markus Frieser1, Kai Hildner1, Markus Neurath1, Masatada Soejima1, Hiroyuki Nagahama1, Hirotsugu Tsunobuchi2. 1Division of Pulmonary Medicine, Respiratory and Stress Care Center, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan; 2Department of Digestive and Life-Style Related Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan
Background: Several reports showed the IPAG-Questionnaire (Q) is useful for screening COPD, but may require modification for Japanese. However its modification hasn’t been reported yet.

Objective: The aim of this study was to establish a modified IPAG-Q for Japanese. Method: Smokers (excluding those with a history of bronchial asthma) aged 40 and over who underwent a screening CT and had given written informed consent were enrolled. They were classified into two groups based on the results of respiratory function tests (FEV1% < or ≥ 70%): control-smokers and a COPD group. We compared the original IPAG-Q between the two groups and statistically analyzed the results to modify it.

Results: A total of 268 subjects (control-smokers/COPD: 244/24) were enrolled. We described the receiver operating characteristic (ROC) curve about the original IPAG-Q: the area under the ROC curve (AUC) was 0.764, cut-off was 18.5±50.5 (score), sensitivity was 0.750 and specificity was 0.615. Logistic regression analysis revealed only “sneeze frequency” was useful in the “symptoms/history”, so we deleted “symptom/history” except for this parameter. And we improved the stratification for age, BMI, and pack/year: age ≥ or < 50 yrs. BMI <18.5 or ≥ 18.5 & < 25.0 or ≥ 25.0, and pack/year ≥ or < 30. We then constructed a new scoring system based on the original model and validated it on a modified IPAG-Q for Japanese. This modified model was proved valid in the ROC curve; AUC was 0.828, cut-off was 8.5±50.5 (score), sensitivity was 0.833 and specificity was 0.672. This model was superior to the original one.

Conclusion: Our modified IPAG-Q is of greater use for screening COPD among Japanese than the original one.
Motives to quit smoking: Insight from the Melen study

Leyla Yılmaz Aydın,1 Hakon Ozhan2, Talha Dumlul3, Saber Dikici1, Melih Engin Erkan1, Suha Bulur4, Adem Gungor5, Gökhan Celbek5. 1Chest Diseases, Duzce University, Medical Faculty, Duzce, Turkey; 2Cardiology, Duzce University, Medical Faculty, Duzce, Turkey; 3Neurology, Duzce University, Medical Faculty, Duzce, Turkey; 4Nuclear Medicine, Duzce University, Medical Faculty, Duzce, Turkey; 5Internal Medicine, Duzce University, Medical Faculty, Duzce, Turkey

Background: Ethnic, cultural and social factors influence the motives to quit smoking.

Aim: To investigate the current prevalence of smoking and motives to quit on smoking cessation in Turkey in a large population-based epidemiologic study.

Methods: A total of 2298 subjects with a mean age of 50 (age range 18 to 92) were interviewed. The subjects reported information regarding socio-economic status, medical history and current use of medications. Tobacco use behaviors (current status of smoking, number of cigarettes smoked daily, duration of smoking, age of addiction, attempts and desire to quit) and motives of quitting were asked.

Results: Sixty five percent of the study population (1495 subjects) had never smoked. Three hundred eighty nine subjects were current smokers where as 414 subjects had quit smoking. Crude smoking rate of the population was 17%. The most frequent motive was the smokers' health status (having a chronic disease that urged the patient to use drugs daily and continuously). The most common motive in primary prevention was the assistance of a physician. Self motivation and religious beliefs showed better success rates. Age and existence of chronic diseases were found to be the independent predictors of quitting (Odds ratio (OR): 1.37-3.18, p: 0.007).

Conclusions: Prevalence of smoking is decreasing in Turkey. Smoking ban, cost, physician assistance, comorbidities, notices on packages, religion, care for family members and self motivation are the most important motives to quit.

Factors associated with different patterns of adherence to treatment in a smoking cessation unit

Carlos Almonacid Sanchez, Jose Gallardo Carrasco, Ignacio Sanchez Hernandez, Juan Pablo Rodriguez Gallego, Elisabeth Guzman Robles, Jorge Castelo Naval, Jesus Fernandez Frances, Saray Quiros Fernandez, Jose Luis Izquierdo Alonso, Pilar Rosano Barro, Olga Mediano. Palomar Medicine, Hospital Universitario de Guadalajara, Guadalajara, Spain

Objective: Identify different patterns of adherence to therapy in the treatment of patients attending a specialized smoking cessation unit.

Material and methods: Retrospective cross-sectional study of a sample of smokers who come for smoking cessation. The sample was divided into 4 groups: group 1, who only attend the first visit, group 2, persons who do not attend all visits and not answering phone calls, group 3, people who do not attend all visits but answer phone calls to complete a period of 6 months of treatment, group 4, all patients attending follow-up visits. The collection period runs from January 2004 to June 2010. Data were collected at each visit following the same methodology using an electronic medical record designed for this purpose.

Results: We analyzed a total of 1545 people who attended the clinic. The results are summarized in Table 1. The quantitative variables are described as mean and standard deviation. The qualitative variables are described as total and percentage.

Conclusions: Age, a lower level of motivation, the coexistence of psychiatric disorders and increased consumption of cigarettes are associated with poorer adherence to treatment.

Smoking cessation ward rounds – The impact on smoking patterns

Jessica Maycock, Victoria Foy, Patrick Mulholland, Dilip Nazareth, Simon Twite, Paul Stockton. Respiratory Department, St Helens and Knowsley Teaching Hospitals NHS Trust, Liverpool, United Kingdom

Background: Smoking cessation is a NHS (UK) priority and all health care professionals are encouraged to refer smokers to a “stop smoking” service. Many UK public health campaigns have targeted smokers. Our busy District General Teaching Hospital introduced a daily “targeted” smoking cessation ward round in 2008. This study evaluates the impact of this, on smoking patterns.

Results: 136 patients were surveyed in 2008 and 187 in 2010. 58% of both groups had a history of smoking. 69% were current smokers in 2010 and 35% in 2008. Of the smokers, 73% in 2008 had tried to quit compared to 68% in 2010. The percentage of smokers offered educational material while in hospital increased from 29% in 2008 to 38% in 2010

The table below summarises reasons for patients deciding to quit smoking:

Table 1: Reasons for smokers deciding to quit

<table>
<thead>
<tr>
<th>% 2008 (n=58)</th>
<th>% 2010 (n=77)</th>
</tr>
</thead>
<tbody>

<td>3</td>
</tr>
</tbody>
</table>

Conclusions: There has been a marked increase in the number of patients deciding to quit smoking following education and advice from medical professional’s. The number of smokers who decide to quit due to personal illness has also increased. A new daily smoking cessation ward round and additional support from healthcare professionals is considered to have significantly increased the uptake of smoking cessation advice in this group of patients.

Effectiveness of a cognitive orientation program with and without nicotine replacement therapy in stopping smoking in hospitalised patients

Borja Valencia, Francisco Ortega, Arturo Vellisco, Eduardo Márquez-Martín, Jose Luis López Campos, Ana María Rodríguez, Marta Ferrer, Pilar Cejudo, Borja Valencia, Francisco Ortega, Arturo Vellisco, Eduardo Márquez-Martín, Jose Luis López Campos, Ana María Rodríguez, Marta Ferrer, Pilar Cejudo, Emilia Barrot. Unidad Médico Quirúrgica de Enfermedades Respiratorias Virgen del Rocío, Hospital Universitario Virgen del Rocío, Sevilla, Spain

Introduction: We analysed the effectiveness of a high intensity behavioural-cognitive intervention compared to minimal intervention started during a hospital stay, to see if the combination of nicotine replacement therapy (NRT) can increase the quitting rate at 12 months of follow up.

Method: 2560 active smokers were studied during their hospital stay. Of these, 717 smokers refused to enter the study and after a minimal intervention they were asked if we could telephone them after one year to ask if they still smoked. The remaining 1843 smokers who received high intensity cognitive therapy were randomised to receive or not receive NRT. The follow up after discharge was carried out by outpatient visits or with telephone sessions.

Results: At one year of follow up, 7% of those who declined to enter the study had stopped smoking compared to 27% of those who entered the study (p=0.001). There were significant differences between the group that only had behavioural therapy (21% stopped compared to the group that also had NRT (33% stopped; p=0.002). In this latter group there were significant differences (p=0.03) between those who had follow up in clinics (39% stopped) compared to those who were followed up telephone sessions (30%). In the multivariate analysis, the predictors of quitting at 12 months were: to have used NRT (OR 12.2; 95% CI 5.2-32; p=0.002) and a higher score in the Richmond Test (OR 10.1; 95% CI 3.9-24.2; p<0.01).

Conclusions: A cognitive type intervention started on smokers when admitted to hospital increases quitting rates at 12 months, compared to a minimal intervention, and these rates increase even more significantly if NRT is added.
Background: Health promotion is a key component of holistic, patient-centred care. 50% of UK smokers make at least one annual attempt to quit; only 3% succeed long term. Due to the long term complications of smoking, we recognised the importance of prompt & effective SCA, a NICE (UK) priority.

The objectives of this study, in an area of socio-economic deprivation in Liverpool, were to determine whether we provide simple SCA and to explore referral rates to specialist SCA services.

Method: We undertook a 3-week prospective analysis on the respiratory wards at a large UK University Hospital (December 2010). Specialist SCA is available for all in-patients.

Results: 81 patient records were reviewed. Mean age 72 (SD 14) years; 34 (43%) male, 30 (37%) current smokers. Of these 40% received documented SCA from a GP – however, only 42% of this guidance was at time of admission. Only 43% of these smokers were referred to SCA services, of which 85% received a consultation; following this 36% continued to smoke whilst an in-patient.

Conclusion: Best practice would suggest SCA within 24 hrs of admission but this occurs in only 40% of cases. Long term follow-up of the smoking cessation rates in these patients is pending. We are working within our hospital to ensure training occurs in this area as per NICE guidance,2 aiming to reduce the burden of smoking related lung disease and have implemented a cyclical SCA education programme for all HCPs with the hope of improving SCA referral rates.

P4226 Status of the smoking cessation and its costs in eastern Mediterranean countries in 2009
Gholamreza Heydari, Tehran, Islamic Republic of Iran

Background: This study was designed with the purpose to address the situation with smoking cessation efforts and its expenditure and to provide basis for future studies and implementing tobacco control programs across countries in the region.

Materials and methods: The study was in form of questioning participating country representatives from the Eastern Mediterranean region in INB3 who were all either point individual or expert in tobacco control programs. Information needed included methods for tobacco cessation, cost of services including counseling by primary physician or specialist, gum or nicotine patch, Zyban, champix and/or missing cannabis-smoking.

Results: In 10 countries (47.6%), smoking cessation programs and counseling was directed by primary physicians. Also, 8 countries (38%) provided services through specialists. In 13 countries (63.9%), nicotine gum and in 14 countries (66.7%) nicotine patch is accessible in pharmacies. In 6 countries (28.6%), Zyban (Bupropion 150 mg) and in 7 countries (33.3%), Champix (Varnicline 1 mg) are available at pharmacists with written prescription. The mean costs of each service were higher than a pack of cigarette significantly.

Conclusion: In countries with support services for tobacco cessation, directors need to provide care at society level, less costly and accessible for everybody and in countries where such programs have not been initiated, it is recommended that effort to do so occur.

P4227 Smoking assessment & treatment in hospital: Are we providing “right care” and/or missing cannabis-smoking?
Louise Restrict, Erin Cumbus, Oliver Thomas, Myra Stern. Respiratory Medicine, Whittington Hospital NHS Trust, London, United Kingdom

Introduction: Hospital admission provides opportunities for quit-smoking advice/support. Some inpatients also smoke cannabis, which causes bullous-emphysema, but prevalence is unknown. The study aimed to determine inpatient cannabis-smoking and to measure effectiveness of our quit-smoking service.

Methods: Trainees/medical students carried out a single-day cross-sectional survey of adult inpatients, using standardised anonymous questionnaires, hospital notes and medication charts. Data was compared with previous surveys over five years.

Results: 184/223 inpatients were interviewed. Cigarette-smoking prevalence was 33/184 (18%); cannabis-smoking 12/184 (6.5%). 10/33 (30%) cigarette-smokers smoked cannabis. 544 patients were interviewed over 5 years. Inpatient smoking prevalence and advice to stop smoking did not change (16.2% and 57.4% respectively). NRT prescription and cessation plan documentation increased to 44% and 35% respectively.

Conclusions: 1/3 inpatients smoke but c. 60% were given quit smoking advice despite being an evidence-based, cost-effective intervention. 1/3 cigarette-smokers also smoked cannabis. Further studies should determine the impact on health of this high prevalence. Whilst NRT and cessation plans have increased, the latter is only provided to ~40% of smokers. Further work needs to ensure effective interventions for all inpatient smokers.

P4228 Optimal cut-off point of exhaled carbon monoxide to validate self-reported smoking status in healthy adults
Juliana Zabatiero1, Demétria Kovelis1, Mahara Frontin1, Karina Furlanetto1, Leandro Mantoani1, Ercy Ramos1, Fabio Pinto1, “Laboratório de Pesquisa em Fisioterapia Pulmonar (LFIP), Universidade Estadual de Londrina (UEL), Londrina, Brazil” 2 Programa de Mestrado em Fisioterapia, Universidade Estadual Paulista Júlio de Mesquita Filho (UNESP), Presidente Prudente, Brazil

Background: There is no current consensus regarding the optimal cut-off point of exhaled carbon monoxide (CO) to distinguish smokers from non-smokers.

Objectives: To assess the accuracy of an exhaled carbon monoxide cut-off point in order to distinguish actual smokers from non-smokers among apparently healthy adults.

Methods: We studied 50 current smokers (20 male; 47±12 years; BMI: 26±4 kg/m2), with normal lung function (FEV1/FVC: 81±3), and 50 non-smokers (11 male; 44±11 years; BMI: 26±4 kg/m2; FEV1/FVC: 83±6; FEV1: 102±11l/s; pred). All subjects were submitted to exhaled CO measurement (in the group of smokers, after a mean of 10±1.2 hours of cigarette abstinence, using a portable CO monitor (MicroCO®).

Results: Median [interquartile range] levels of CO in the group of smokers and non-smokers were 10 [7-17] and 3 [2-4], respectively. The 6ppm cut-off point suggested by the manufacturer generated a 77% sensitivity and 100% specificity; however a 4.5ppm cut-off point generated the highest combined sensitivity (90%) and specificity (90%). The ROC analysis indicated that the CO monitor provided high diagnostic accuracy to distinguish smokers from non-smokers [area under the curve = 0.979 p<0.001].

Conclusions: Using a portable CO monitor, a 4.5ppm cut-off point seems more accurate than the cut-off point suggested by the manufacturer in order to distinguish smokers from non-smokers among apparently healthy adults.

P4229 Airway reactivity in inhaled mannitol in young water pipe smokers
Jérôme Schmidlin, Silvio Albusser, Michael Tamm, Daina Stolz. Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital Basel, Basel, Switzerland

Background: The inflammatory cascade related to water pipe (WP) smoking and airway hyperresponsiveness (AHR) remains unknown. We aimed to determine whether WP smoking is associated with AHR in young WP consumers.

Methods: Mannitol challenge test (Aridol® Pharmacia Ltd) was performed in acute (n=30) and chronic (n=30) WP smokers as well as cigarette smokers (CS, n=30) and life-long non-smokers (n=30). Acute exposition was defined a single episode of WP smoking ≤ 24 hours, chronic as a weekly consumption of WP for ≥ the last 4 weeks.

Results: Data of 74 subjects has been analyzed so far (15 acute and 9 chronic WP smokers, 19 CS, 31 non-smokers). Mean age was 22.6±2.4 years, 51.4% male, mean FEV1 1.26 (pns for all). CS had 5.9±3.2 PY; 35 (47.3%) had a positive allergy test. AHR to mannitol expressed by RDR differed significantly between CS and chronic WP smokers (p=0.028). The provoking dose to induce a 15% fall in FEV1 (PD15), a measure of sensitivity, was 155mg (127-176) in CS vs 315 mg (155-475) in non-smokers. The response–dose ratio (RDR) (% fall in FEV1/cumulative dose), a measure of reactivity, differed between the groups and was higher in CS vs 315 mg (155-475) in non-smokers. The response–dose ratio (RDR) (% fall in FEV1/cumulative dose), a measure of reactivity, differed between the groups and was higher in CS vs 315 mg (155-475) in non-smokers. While RDR differed significantly between CS and chronic WP smokers 0.007 [0.005-0.017], p=0.031. While RDR differed significantly between CS and non-smokers (p=0.007) and acute WP smokers (p=0.025) it did not between CS and chronic WP smokers (p=0.118).

Conclusions: Even modest amounts of cigarette smoking induce AHR to mannitol. Airway reactivity to mannitol is similarly increased in cigarette smokers and chronic water pipe smokers.
P4230
Impact of active smoking on the severity and evolution of asthma
Wiam El Kabbati, Abdelazez Aichane, Tazgha Berdala, Hicham Atif, Zouaoui Bouayad. Pulmonary Medicine, Hospital “20 Korts” CHU Ibn Rochd, Casablanca, Morocco

In adults with asthma, the effects of active smoking on asthma severity have been reported. The aim of our work is to study the influence of active smoking on asthma control. This is a prospective study spread over four years, the profile of 25 smoking asthmatic patients (group S) and 100 non-smoking asthmatic patients (group NS). The average age is 36 years in the 2 groups. There was a male predominance in the group S and female in the group NS (p = 0.00001). Asthma is isolated in 33% (group S) and 16% (group NS) (p = 0.05). Stage III is present in 65% (Group S) and 42% (group NS) (p = 0.001) and is identical for stage IV (18%). Stage I is not found in group S. Asthma is associated with rhinitis in 41% (group S) and in 42% (group NS) and rhino-conjunctivitis in 32% in both groups. Pick tests were positive in 70% (Group S) and 85% (group NS) (p = 0.01). The most common allergens are, in the two groups, Dermatophagoides Pteronyssinus and Dermatophagoides farinae. After these treatment, asthma was controlled in 55% (group S) and in 66% (group NS) (p = 0.1). We note through this work that active smoking has an impact on asthma and its evolution.

P4231
Influence of smoking on symptoms, comorbidities and severity in a population with obstructive sleep apnea (OSA) versus control
Oana Claudia Deleanu1, Diana Pocora2, Anda Elena Malat2, Ana Maria Nebunoiu2, Ion Mireles-Mazilu1, Florin Dumitru Mihaltan1. 1Pneumology III, University of Medicine and Pharmacy, “Carol Davila”, Bucharest, Romania; 2Pneumology III, Institute of Pneumology “Marili Nastu”, Bucharest, Romania; 3Statistical Laboratory, Technical University of Civil Engineering, Bucharest, Romania

Rationale: The association of smoking with OSA is uncertain, even is an association with increased upper airway resistance and predisposition to cardiovascular complications.

Method: We analyzed 129 OSA patients (65% active smokers, 35% never smokers) with normal lung function, without diurnal hypercapnia, successfully titrated with autoCPAP in lab and a control group of 17 active smokers with rhinosyn- dromy, regarding anthropometric, functional lung data, OSA symptoms, severity, comorbidities and parameters after titration. We used SPSS (T. Chi, Pearson tests).

Results: For OSA group: 22.5% female, 77.5% male, mean values: age 49.6±11.7, body mass index (BMI) 33.6±7, apnea hipopnea index (AHI) 43.1±24.2, and BHR to direct stimuli (i.e. metacholine) may be associated to an increased risk for progressive airflow obstruction in smokers. The clinical relevance of active smoking on symptoms, comorbidities and parameters after titration. We used SPSS (parametric and non-parametric tests).

Significant differences: OSA patients are less fatigue (p=0.04), have a poorer lung function (FEV1,p=0.036, FVC,p=0.040) (justified by the effects of smoking), for control group: 11.8% female, 88.2% male, age 40±12.1, FEV1 79.0±21.7, (p=0.015). The next param- eters: smoking appears not to influence symptoms, severity, and comorbidities in OSA patients, except a difficult CPAP correction of apneas. Also, smoking does not seem to contribute to the appearance of OSA and tonsilar hyper- trophy (cause of OSA). Studies are needed to thoroughly into the mechanisms by which smoking could influence OSA.

P4232
Bronchial hyperresponsiveness (BHR) to isocapnic hyperventilation of dry air (IHDA) in smokers is associated to airflow obstruction, chronic cough and β2-agonist treatment
P4233
Influence of tobacco smoking on a lipid profile
Fatiana Levina1, Julia Krasnova2, Alexander Dziinzski1, 2Therapy, Institute of Advanced Medical Studies, Irkutsk, Russian Federation; 2Gerontology, Institute of Advanced Medical Studies, Irkutsk, Russian Federation

The aim: To study influence of tobacco smoking on a lipid profile.

Materials and methods: 200 patients were examined (100 were smoking (an index of smoking ≥5 packs/years), 100-non-smokers). The mean age of the first group was 42.7±7.5 years and second -42.4±7.5 years, p=0.05. The next param- eters of a lipid profile were studied: Total Cholesterol, low-density lipoproteins (LDL), very low-density lipoproteins (VLDLs), High-density lipoproteins (HDLs), Triglycerides, Cholesterol to HDL Ratio.

Results: HDLs were revealed to be lower in 1 group in comparison with 2 group (1.32 (1.13-1.635) and 1.565 (1.331-1.785), accordingly, p=0.007). VLDLs were revealed to be higher among smoking in comparison with non-smokers (0.545 (0.39-0.935) and 0.43 (0.345-0.605), accordingly, p=0.01). Triglycerides were revealed to be higher in 1 group in comparison with 2 group (1.23 (0.865-2.065) and 0.955 (0.765-1.344), accordingly, p=0.004). Cholesterol to HDL Ratio were revealed to be higher among smoking group in comparison with non-smoking group (2.73 (1.875-2.885) and 2.35 (1.72-3.05), accordingly, p=0.039).

Conclusions: The smoking patients had higher indicators very low-density lipoproteins, triglycerides and lower indicators of High-density lipoproteins then non-smokers.

P4234
Influence of smoking on symptoms, comorbidities and parameters after titration. We used SPSS (T, Chi, Pearsons tests).

Results: For OSA group: 22.5% female, 77.5% male, mean values: age 49.6±11.7, body mass index (BMI) 29.2±7, apnea hipopnea index (AHI) 43.1±24.2, and BHR to direct stimuli (i.e. metacholine) may be associated to an increased risk for progressive airflow obstruction in smokers. The clinical relevance of active smoking on symptoms, comorbidities and parameters after titration. We used SPSS (parametric and non-parametric tests).

Significant differences: OSA patients are less fatigue (p=0.04), have a poorer lung function (FEV1,p=0.036, FVC,p=0.040) (justified by the effects of smoking), for control group: 11.8% female, 88.2% male, age 40±12.1, FEV1 79.0±21.7, (p=0.015). The next param- eters: smoking appears not to influence symptoms, severity, and comorbidities in OSA patients, except a difficult CPAP correction of apneas. Also, smoking does not seem to contribute to the appearance of OSA and tonsilar hyper- trophy (cause of OSA). Studies are needed to thoroughly into the mechanisms by which smoking could influence OSA.

P4235
Smoking exposure did not differ between the two subgroups. Smokers with BHR had worse spirometry at rest (p<0.05) and a history of chronic cough (p<0.01). Fifteen smokers regularly inhaled a β2 agonist and they all exhibited BHR, had higher bronchial toms at rest (p<0.05) and exhibited greater response to IHDA than non-treated smokers with BHR (p<0.05).

Conclusions: BHR to IHDA is common among smokers and associated to chronic cough and airflow obstruction. BHR is even more common among smokers using β2 agonists. It is not known whether this is a cause or an effect of a 12 hour interruption of β2 agonist treatment prior to challenge.

7777s
Cannabis is usually inhaled and is most commonly taken in a joint containing both cannabis and tobacco. We are conducting a cross-sectional study of cannabis and tobacco smokers recruited from a primary care population in North Edinburgh. One aim of this study is to investigate whether cannabis smokers report a greater number of respiratory symptoms compared with an age and sex matched group of regular tobacco smokers. The quantification of cannabis and tobacco use is assessed by the Avon Longitudinal Study of Parents and Children and the reported respiratory symptoms by NHANES III.

We have recruited 119 subjects (Group 1) who smoke tobacco as either branded cigarettes and/or roll-your-own tobacco cigarettes) and 117 subjects (Group 2) who smoke cannabis as either branded cigarettes or cigarettes rolled in homemade sections or in cigarette papers. Only one subject used both types of products. The majority (>90%) of cannabis smokers employ unfiltered single skinned joints with 8% using bongs and a minority using other methods. The predominant form of cannabis used is resin (78%) with 22% smoking grass. Unadjusted data suggest that the prevalence of respiratory symptoms are greater at all ages and in both sexes for persons using cannabis and tobacco compared with persons using tobacco only. In North Edinburgh the majority of cannabis users smoke cannabis resin rolled with tobacco in a single skinned unfiltered joint. Respiratory symptoms typical of chronic obstructive pulmonary disease are more frequently reported by cannabis smokers than tobacco smokers and women report a greater number of symptoms than men.

Education level and smoking

Education level in the study was assessed using the Avon Longitudinal Study of Parents and Children and by examining the relationship between education level and smoking habits. Several factors were found to influence smoking, such as age, gender, and education level. The results showed that younger individuals and those with lower education levels were more likely to be smokers. Smoking rate in Georgia remains high and even tend to increase, especially among men. The prevalence of tobacco smoking and respiratory symptoms among young people and medical students. The aim of the research was to study the smoking habits and respiratory symptoms among students of medical university. The prevalence of smoking tobacco and respiratory symptoms among young adults is easily nicotine dependent and want to quit, but they have several reasons partly due to lack of programs to help them. The results showed a high prevalence of smoking among both boys and girls. Despite the brief period of smoking and its adverse effect is manifested by increased frequency of RS. These findings point to the need to strengthen prevention of smoking among young people and medical students.

5 7 (17.9) 25 (64.1) 7 (17.9) 39 (100)

Conclusions: Young smokers experienced several quit attempts and were highly nicotine dependent. They also recognized their dependence.

P4239

The prevalence of tobacco smoking and respiratory symptoms among students of medical university

The aim of the research was to study the smoking habits and respiratory symptoms among students of medical university. The prevalence of smoking among medical and non-medical students in Tbilisi, Georgia: Does prevention of smoking among young people and medical students.

Smoking rate in Georgia remains high and even tend to increase, especially among young adults is easily nicotine dependent and want to quit, but they have several reasons partly due to lack of programs to help them. The results showed a high prevalence of smoking among both boys and girls. Despite the brief period of smoking and its adverse effect is manifested by increased frequency of RS. These findings point to the need to strengthen prevention of smoking among young people and medical students.
Aim: To evaluate socio-demographic and clinical characteristics associated to high levels of affective (i.e. depressive/anxious) symptoms in smokers applying for smoking cessation clinic.

Method: Current smokers applying for smoking cessation clinic at the University Hospital of Pisa were evaluated (n = 146). Socio-demographic and clinical (e.g. carbon monoxide of expired air - CO, attempts to quit, history of diseases) data were collected during their first visit. Self-administered rating scales were used to assess the level of nicotine dependence (Fagerstrom Test for Nicotine Dependence - FTND) and the level of affective symptoms (Hospital Anxiety Depression scale - HADS). Data were analyzed comparing the subjects with high HADS total score (HADS+) with those having low HADS total score (HADS-) (cut-off = 13, median).

Results: Compared to HADS- (n = 70), the HADS+ subjects (n = 76) were more likely to be female, less educated (< 12 years of school), with not executive working activity. Moreover, they had a higher rate of lifetime cancer, respiratory, psychiatric disorders, and higher CO, FTND scores. Running the multivariate logistic regression analysis adjusted for age and sex the risk to be HADS+ versus HADS- was significantly related to education (OR = 0.37, 95%CI 0.161-0.876), CO (OR = 10.53, 95% CI 1.003-10.5) and the lifetime history of psychiatric disease (OR = 2.67, 95% CI 1.206-5.893).

Conclusion: Subjects with low education, high levels of CO, and a lifetime history of psychiatric disease were at high risk to experience affective symptoms when they apply for smoking cessation clinics.

Method: Patient survey completed within the department post consultation.

Results: Of 224 respondents, self-reported smoking prevalence was 26% (53/204). 49% were correctly identified as current smokers, but only 10/26 (38.5%) were advised to stop and only 6 patients were given instructions about smoking cessation. The NRT has showed the best success rate and the efficacy of Varenicline can be increased by the combination with other therapies. The abstinence rate was: after a month 71%, 3 months 38.4%, 6 months 37.9%, 1 year 31.5%.

Conclusion: The most motivated and ready to quit smokers are the respondents with a history of smoking, healthy/sick with cardiovascular (CVD)/respiratory (RD) tobacco-related disease, using 2 questionnaires-for former smokers/active smokers regarding motivation, illness status for quitting, health status, degree of nicotine-addiction, quitting history, determinant factors for tobacco consumption. We use Excel (chi, T tests).
P4245
Making smoking cessation easier and closer the smoker: The results of Milan study of antismoking centers in pharmacies
Elena Minarini1, Aldo Mammotti2, Anna Gardiner3, Giovanni Invernizzi4, Roberto Mazzu5, Cinzia De Marco1, Roberto Bobbi6, 1Tobacco Control Unit, Istituto Nazionale dei Tumori, Milan, Italy; 2Azienda Farmaceuti Milanesi S.p.A., ADMENZA S.p.A., Bologna, Italy; 3Azienda Ospedaliera Sullite, Comune di Milano, Milan, Italy; 4Italian College General GPs, SIMG, Milan, Italy

Background: A few strong inputs from the Italian Institute of Health indicate that information and assistance to smokers are still far from being satisfactory.

Aims: To verify if offering smoking cessation at the pharmacy, a health facility where smokers have often the chance to stop, can promote the participation to cessation programs.

Methods: A 6-month pilot phase was carried out from October 2010 to March 2011. Five pharmacies in Milan were selected. Chemists were trained by the team of the Antismoking Center of the Istituto Nazionale dei Tumori (INT). Every pharmacy was equipped with informative material, CO analyzers, motivational and FTND’s questionnaires and with a clinical briefcase: moreover a trained pharmacists in the stage-of-change model of smoking cessation and INT collaborated with the chemist.

Results: In the first four months of activity 144 smokers (54% male, 46% females) asked for a consultation. The median values were: age 52 years, p31, CO 14ppm, FTND’S test 5. Regarding the pathologies, 25% of the smokers had cardiovascular and 11% respiratory diseases, 22% other pathologies, 43% declared they were “healthy” smokers. Overall, 45% of the smokers asked to stop smoking, 33% to reduce, 21% just wanted to get information.

Conclusions: The results show that the opportunity to have accessible and free smoking cessation service is considered useful by smokers. The great number of requests, together with the ease transferability of the project to other pharmacies, makes it a very promising initiative for the next future.

P4246
Nurses’ and patients’ communication in smoking cessation at nurse-led COPD clinics in primary health care
Eva Osterlund Efraïmmson1, Anna Ehrenberg2, Björn Possum3, Kjell Larsson4, Birgitta Leijon5, Neurology, Care Sciences and Society, Division of Nursing, Karolinska Institute, Stockholm, Sweden; 2School of Health and Social Studies, Dalarna University, Falun, Sweden; 3Sophiahemmet University College, Stockholm, Sweden; 4National Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden; 5Neurobiology, Care Sciences and Society, Division of Nursing, Karolinska Institute, Stockholm, Sweden

Aim: To examine smoking cessation communication between patients and registered nurses, with a few days of Motivational Interviewing (MI) based education, in consultations over time at nurse-led Chronic Obstructive Pulmonary Disease (COPD) clinics in primary health care (PHC).  

Method: The first and third of three consultations were videotaped, involving 13 smokers and six nurses. In these consultations smoking cessation communication was analyzed using the Motivational Interviewing Treatment Integrity (MITI) Scale and Client Language Assessment in Motivational Interviewing (CLAMI).

Results: The nurses did, but only to a small extent, evoke patients’ reasons for change, foster collaboration and support patients’ autonomy. In the registration of specific utterances; they provided a lot of information (42%), asked closed (21%) rather than open questions (3%) and made more simple (14%) than complex (2%) reflections. Most of the registration of the patients’ utterances in the communication were either toward or away from smoking cessation coded in the category Follow/Neutral (59%), followed by utterances in the categories of Reason for change 40%, Taking steps 1% and Commitment 0%. No significant differences could be observed in the results of MITI and CLAMI between the first and third consultations.

Conclusion: Smoking cessation communication at nurse-led COPD clinics neither focused on the patients’ reasons for or against smoking nor motivated patients to express commitment to, or take steps towards, smoking cessation.

P4247
Training pharmacists in the stage-of-change model of smoking cessation: A randomised controlled trial in Sicily
Riccardo Polosa, Pasquale Caponnetto, Massimo Caruso, Dipartimento di Biomedicina Clinica e Molecolare, University of Catania, Catania, Italy

Introduction: Most pharmacists are eager to undertake an important role in health promotion but in Italy pharmacists are not trained for smoking cessation counselling.

Aim and objectives: This study set in pharmacies in Sicily has evaluate the effect of training pharmacists in the stage-of-change model of smoking cessation and motivational interviewing.

Methods: A training package based on the stage of change model of smoking cessation and motivational interviewing was carried out by University. The training was being piloted on a cross-section of pharmacy personnel. A total of 46 pharmacies have participated in the trial and attended a 3 hour training on 2008 guideline Treating Tobacco Use and Dependence. Successively pharmacists were randomly allocated by sequential allocation to the intervention or control group. The intervention group attended a 6 hour training by scheduling a initiation of training pharmacists in the stage-of-change model of smoking cessation and motivational interviewing.

Results: The study demonstrated the utility of the stage-of-change model and motivational interviewing in a pharmacy setting.

P4248
Predictors of smoking cessation within a lung cancer CT screening trial
Francesco Postelli1, Federico Pragl1, Fabio Falaschi2, Andrea Lopes Pegna1, Eugenio Piac3, Laura Carrozzi4, 1Cardio-Thoracic Dept., University Hospital, Pisa, Italy; 2Oncology and Radiology Dept., University Hospital, Pisa, Italy; 3Pneumology Dept., University Hospital, Florence, Italy; 4Epidemiology Dept., ISPO, Florence, Italy

Background: Participating in a lung cancer CT screening may trigger smoking cessation but a clear impact on abstinence rates hasn’t been shown.

Aim: To evaluate smoking cessation in patients enrolled in a lung cancer CT screening trial (Iahung-CT).

Methods: 3004 current or former smokers (20+; pky: 55-69 yrs) from the general population were randomised in the active (CT scan, AA) or control (usual care, CA) arm of the Iahung-CT in three Italian centres (Florence, Pisa, Potenza). A postal/telephone questionnaire was administered at baseline (round 1) and at the last evaluation (round 4). Preliminary smoking data from 1186 AA subjects (94% of AA) and from 1261 CA (65% of CA) were evaluated. A paltonologist-assisted smoking cessation program (counselling & pharmacotherapy, SCP) was offered only in the Pisa centre. Multivariate logistic regression analysis was performed with smoking cessation as outcome variable. Independent variables were: sex; age (pky; 0.98 [0.98, 0.99], ≥ 1 participation in SCP.

Results: Crude cessation rates at round 4 were 21% in AA and 18% in CA (p<0.01). Smoking cessation was significantly associated to male sex (OR = 1.54 [1.54, 5.83]); ≥50; 0.98 [0.98, 0.99], ≥1 participation in SCP.

Conclusions: According to preliminary results, smokers participating in the active arm of Iahung-CT show statistically higher smoking cessation rates as compared to controls. Smokers with lung CT-detected nodules, offered of a SCP are more likely to quit smoking. Smoking cessation programs should be always offered within a lung cancer CT screening.

P4249
Late-breaking abstract: Urinary leukotriene E4/exhaled nitric oxide ratio as a predictor of exercise-induced bronchconstriction control by oral montelukast or inhaled corticosteroid
Hey-sung Baek1, Yeo-soong Jang1, Joo-hwa Kim1, Jae-Won Oh1, Ha-baek Lee1, 1Department of Pediatrics, Hanyang University College of Medicine, Seoul, Republic of Korea; 2Department of Pediatrics, Hallym University College of Medicine, Seoule, Republic of Korea

Background: Exercise-induced bronchconstriction (EIB) is associated with vigorous physical exertion in 45 to 85% of children with asthma. A fractional exhaled nitric oxide (FeNO) and urinary leukotriene E4 (LTE4) have been used as the non-invasive markers of airway inflammation in asthmatic children. This study aimed to prove the association between LTE4/FeNO ratio and the effectiveness of therapeutic trial by leukotriene receptor antagonist or inhaled corticosteroids.

Methods: We studied 24 asthmatic children aged from 6 to 18 years with EIB, and randomized to a 4-week trial by oral montelukast (n=12) or an inhaled fluticasone propionate (FP) (n=12). A spirometry and standardized exercise challenge were performed before and after therapeutic trials. Urinary LTE4 and FeNO were measured prior to exercise challenge and 30 minutes after exercise challenge. After 4 week treatment, the same studies were conducted.

Results: After 4-week treatment, exercise performance maximum fall in FEV1, baseline and exercise-induced LTE4 and baseline FeNO were significantly diminished between both study groups; (1) %ΔFEV1: montelukast (21.00 ± p = 0.0011), FP: (23.54 ± 0.0202) (2)AUCLTE4: (0.503 ± 0.232 ± p < 0.0003), FPS: (0.527 ± 0.374 ± p < 0.012). LTE4/FeNO ratio and EIB improvement were associated with greater response to bronkukast (p = 0.082, r = 0.326) than FP for EIB treatment (p = 0.478, r = 0.274).
Background: This retrospective study was done to understand demographics and clinical course of asthmaticus treated in a pediatric critical care unit (PICU).

Methods: The medical charts of all patients above 5 years of age admitted to the PICU with status asthmaticus, at Nationwide Children’s hospital, Columbus, OH, between 2000-2007 were reviewed. Two hundred and forty seven (247) children were admitted on 281 occasions. Patients with significant co-morbidities were excluded. Final analysis was done using 222 encounters in 183 patients.

Results: The mean age was 11 years (range, 5-20 years). The mean PICU stay was 2.1 days (range, 1-15 days) and mean hospital stay was 3.6 days. Male: Female 109:74. Eighty nine (49%) were on no asthma controller medications. Adherence to therapy was noted in 124 of whom only 41 (33%) claimed compliance. 191 were known asthmatics. Asthma severity noted in 75 patients revealed 22 (29%) had mild intermittent, mild persistent 23 (30%), moderate persistent 17 (23%) and severe persistent 13 (17%). Sixty seven (37%) had a positive family history of asthma. Smoking exposure was noted in 140 (76%). Among 222 encounters, 203 received continuous albuterol, 216 received i.v. steroids, 113 receive Terbutiline, 57 received MgoSO4, 8 received non-invasive ventilation (CPAP/BiPAP) and 16 received invasive ventilation. All patients had Complications included bronchopneumonia in 25 and atelectasis in 29 patients.

Conclusion: Asthmatics with any level of disease severity are at risk for asthma exacerbations requiring PICU stay especially if they are not compliant with their medications.

P4251
The outcome of asthma among Greek children
Maria Katsara1, Fotis Kirvassilis2, Elpis Hatziagorou 2, Panagiota Marvidis2, Kalithea Koukounou1, Athanasia Marvidou2, Ioannis Tsanakas2, 1Padiatric Department, Genniminata General Hospital, Thessaloniki, Greece; 2Padiatric Pulmunology Unit, Hippokration Hospital, Aristotel University, Thessaloniki, Greece. Background: The prevalence and control of asthma among children is suboptimal. Objective: To evaluate the asthma prevalence and control of young children in the general Portuguese population. Methods: Prevalence and control of asthma-like symptoms in Portuguese young children were measured using a self-administered questionnaire (5-point Likert scale) and a postural score questionnaire (IPOS) at 6 and 12 month follow-up visits. Results: The study included 448 children (196 boys and 252 girls) aged 1 to 12 years, with 235 and 213 children having filled the questionnaire at 6 and 12 months, respectively. The prevalence of current asthma was 24.3% (95% CI: 19.4-29.2) at 6 months and 19.4% (95% CI: 14.4-24.4) at 12 months. The prevalence of atopy was 38.7% (95% CI: 33.8-43.7) at 6 months and 37.7% (95% CI: 32.7-42.7) at 12 months. The prevalence of current asthma and atopy were significantly different between boys and girls (p < 0.05). The prevalence of current asthma and atopy were significantly different between boys and girls (p < 0.05). There was no significant difference between the two follow-up visits. Conclusion: The prevalence and control of asthma-like symptoms among young children in Portugal are suboptimal. Further studies are needed to improve the control of asthma in this population.

P4252
Reproducibility of Inhalation Technique Assessment in Young Children
Shahid Sheikh1, Nadeem Khan 2, Melissa Frasure 3, Manuel Cestari 3, 1Division of Pulmonary Medicine/Pediatrics, Nationwide Children’s Hospital/Ohio State University State University, Columbus, OH, United States; 2Department of Respiratory Care, Nationwide Children’s Hospital, Columbus, OH, United States. Background: Children using metered dose inhaler with spacer have poor inhalation technique. Objective: To estimate the prevalence and control of asthma-like symptoms in children in the general Portuguese population. Methods: Nationwide, two-phase, list-assisted random-digit-dialing telephone survey (Portuguese National Asthma Survey). The first phase questionnaire was based on the GAILLEN survey. Current asthma was defined as self-reported asthma and, in the last 12 months, wheezing and/or awaking with breathlessness and/or having an asthma attack. Participants identified as having “current asthma” in first phase were re-interviewed. In addition, other children with asthma living in the same residence were also interviewed. Results: Of the 6,063 participants in the first-phase, 716 were children (0-17 years old); 143 (20.0%) had wheezing in the last 12 months; 240 (33.5%) awaked with cough or breathlessness in the last 12 months and 89 (12.4%) had an asthma diagnosis in the past. Conclusion: In-office support for asthma education improves asthma care during and following the intervention.

P4253
Assessment of Inhalation Technique: Reliability and Validity of a Checklist in Preschool Children with Asthma
Eric de Groot, Joelt Harmns, Jolita Bekhof: Amalia Children Clinine, Iusa Klinieken, Zsottle, Netherlands. Background: Incorrect use of inhaler devices has a major influence on asthma control. Objective: To assess reliability and validity of the checklist in preschool children with asthma using a metered dose inhaler with spacer. Methods: 20 children (6m-6y). All patients were treated with daily inhaled corticosteroids (ICS). The inhalation technique was recorded on videotape and independently assessed by 6 observers using the Dutch Asthma Foundation's 7-point checklist. Results: The inter-observer-agreement (IOA) was 56.5% for the checklist and 54.4% for the general impression. Conclusion: IOA of items 1-5 was good (>70%) and the general impression of the inhaler technique (1-10). This assessment was repeated after 2 weeks.

P4254
Prevalence and control of current asthma in Portuguese paediatric population
Manuel Ferreira-Magalhães1, Ana Sá-Sousa2, Mário Moraes-Almeida3,4, Luís Azevedo5, António Bugalho-Almeida6, João A. Fonseca7,1. 1Paediatric Department, Hospital de S. João, Oporto, Portugal; 2Biostatistics and Medical Informatics Department, Faculdade de Medicina da Universidade do Porto, Oporto, Portugal; 3Immunology and Allergology Department, Hospital CUF-Descobertas, Lisbon, Portugal; 4University Clinic of Pulmonary Diseases, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; 5CINTESIS – Center for Research in Health Technologies and Information Systems, Universidade do Porto, Oporto, Portugal; 6Immunology and Allergology Department, Hospital de S. João, Oporto, Portugal; 7Immunology and Allergology Department, Instituto e Hospital CUF-Porto, Oporto, Portugal. Objective: To estimate the prevalence and control of asthma-like symptoms in children in the general Portuguese population. Methods: Nationwide, two-phase, list-assisted random-digit-dialing telephone survey (Portuguese National Asthma Survey). The first phase questionnaire was based on the GAILLEN survey. Current asthma was defined as self-reported asthma and, in the last 12 months, wheezing and/or awaking with breathlessness and/or having an asthma attack. Participants identified as having “current asthma” in first phase were re-interviewed. In addition, other children with asthma living in the same residence were also interviewed. Results: Of the 6,063 participants in the first-phase, 716 were children (0-17 years old); 143 (20.0%) had wheezing in the last 12 months; 240 (33.5%) awaked with cough or breathlessness in the last 12 months and 89 (12.4%) had an asthma diagnosis in the past.
The prevalence of "current asthma" in Portuguese paediatric population was 8.4% (95%CI 6.6-10.7); in 0-5 years old (y) was 6.5%, in 6-12y was 9.7% and in 13-17y was 8.7%.

In the second phase, 96 children with "current asthma" were included. In the last 4 weeks, 20 (22%) had night waking and 14 (15%) had symptoms more than twice a week. In the previous 12 months, 24 (25%) had a non-scheduled medical visit. 37 (39%) reported hospitalization for asthma. In the last 4 weeks, 39% used inhaled corticosteroids (21% together with LABA); 30% used leukotriene receptor antagonists.

Conclusions: Current asthma prevalence in Portuguese children is less than 10%. Most children seem to have a good short-term control of asthma, but many had ER visits and also hospitalizations related to asthma in the last 12 months.

P4255
Adolescent undiagnosed-wheeze: an unrecongnised state associated with significant morbidity, tobacco and paracetamol use
Ramesh Kurukulaaratchy, Abid Raza, Hasan Arshad, Graham Roberts, Bernie Clayton, Jane Grundy. The David Hide Asthma & Allergy Research Centre, Sr Marys Hospital, Newport, Isle of Wight, United Kingdom

Background: Adolescent undiagnosed-wheeze is poorly understood.

Aims: We characterised adolescent undiagnosed-wheeze hypothesising associations with behaviour-linked exposures.

Methods: The Isle of Wight Birth Cohort (UK) was recruited in 1989 (N=1456) and reviewed at 1, 2, 4, 10 and 18-years. At 18-years, "Asthma" was defined as "ever had asthma", plus either "wheezeing in the last 12 months" or "asthma treatment in the last 12 months". "Undiagnosed-wheeze" as "wheeze in the last 12 months" but "no" to "ever had asthma", with remaining subjects termed "non-wheezeers". Testing included questionnaires, skin prick tests, spirometry, bronchodilator reversibility and methacholine bronchial challenge.

Results: Undiagnosed-wheeze accounted for 22% of wheezing at 18-years. This was mostly adolescent onset with similar symptom frequency/severity to asthma. However, undiagnosed-wheeze had higher FEV1/FVC ratio (p<0.002) but lower bronchodilator reversibility (p<0.001), bronchial hyper-responsiveness (p<0.001) and atopy (p<0.001) than asthmatics. Undiagnosed-wheezeers also had higher smoking rates, earlier smoking onset and higher monthly paracetamol use than non-wheezeers (p<0.001). Multivariate logistic regression identified paracetamol use (OR 1.11, [95%CI 1.01-2.23]; p=0.03), smoking at 18-years (2.54, [1.19- 5.41]; p=0.01), family history (2.24, [1.38-5.73]; p=0.004), and asthma family history (2.26, [1.10-4.63]; p=0.03) as significant independent risk factors for undiagnosed-wheeze.

Conclusions: Undiagnosed-wheeze occurred in 5% of adolescents. It had many distinctive characteristics from asthma plus strong associations to smoking and paracetamol use that merit further study.

P4256
Asthma control test (ACT) versus intermittent oscillation system (IOS) assessment for control of asthmatic children
Malak Shaheen, Emad Mohamed, Mona El Ganzory. Pediatrics, Ain Shams Faculty of Medicine, Cairo, Egypt

Background: In spite of the great development of international guidelines for the diagnosis and the treatment of asthma, there is continuing evidence of poor control of childhood asthma.

Aim of this work was to evaluate the subjective asthma control test (ACT) against the subjective impairment oscillation system (IOS) measures of the airways resistance in asthmatic children.

Subject and methods: This study included 35 asthmatic children. All the study children were subjected to the following: full medical history, clinical examination and spirometric FEV1 measurements (to fulfill GINA assessment for asthma control) children’s assessment by ACT (using an Arabic version) was done. Finally, Impulse Oscillation test (IOS) was done to compare the objective results with the subjective results of ACT.

Results: Score 19 was the cut off value differentiating children’s asthma control (compared to the gold standard IOS cut off values). Moderate agreement between CACT/ACT test for asthma control and R5 results; kappa test = 0.54 (P=0.0001) was reported. While agreement between IOS results and GINA tool for asthma control was much less significant; kappa test= 0.36 P<0.05. Nevertheless; there was highly significant negative correlations between total scores of CACT/ACT and values of IOS results; P<0.001. The correlation coefficient for the internal consistency of the CACT/ACT was 0.89 as an evidence for ACT reliability. Also accuracy of CACT/ACT was assured by calculating area under the ROC curve (AUC) and it was 0.90.

Conclusion: This study confirms that asthma control test (ACT) is a valid and cost effective instrument for assessment of control in asthmatic children.

P4257
Parent administered questionnaire captures presence and severity of doctor confirmed wheeze in infants
Marc P. van der Schee 1, 2, Simone Hashimoto 1, Eric Haarman 1, Aline B. Sprinkelman 2, Gerben ter Riet 1, Wim M.C. van Alderen 2, Peter J. Sterk 1.
1 Respiratory Medicine, Academic Medical Centre University of Amsterdam, Amsterdam, Netherlands; 2Pediatric Pulmonology, VU Medical Centre, Amsterdam, Netherlands; 3Pediatric Respiratory Medicine and Allergies, Academic Medical Centre University of Amsterdam, Amsterdam, Netherlands; 4General Practice and Primary Care, Academic Medical Centre University of Amsterdam, Amsterdam, Netherlands

Rationale: - Infants with confirmed wheeze are at increased risk of developing asthma. Confirmation by parents is however notoriously unreliable. We aimed to combine parent reported symptoms into a diagnostic index for the presence and severity of doctor confirmed wheeze in infants.

Methods: - This study is part of the EUROPA-study, aimed at early prediction of asthma. Parents of 78 children (age 18-4 ± 5) mo) planning to consult the family doctor for acute wheezing or dyspnea scored 11 symptoms and their severity on a scale of 0 (absent) to 5 (threatening). During home visits lung sounds were recorded for confirmation by 5 pediatric pulmonologists. Wheeze severity was simultaneously scored by validated Pediatric Respiratory Assessment Measure (PRAM) (Basso/08). Presence and severity of wheeze was modelled using backwards log-linear regression combined with ROC-analysis and linear regression, respectively.

Results: - Parents established presence of wheeze correctly in 51% of the cases (AUC 0.50). A model combining nasal obstruction (p=0.067), shortness of breath (p = 0.001), activity limitation (p = 0.047) and presence of fever (p= 0.06) established presence of confirmed wheeze significantly better (AUC 0.80; p < 0.001). This integrative symptom index correlated significantly with the PRAM-score (Pear. = 0.36; p = 0.001).

Conclusion: - Accurate assessment of the presence and severity of wheezing in infants can be achieved by combining parent reported symptoms into a diagnostic model. Utilizing such an index is considerably more reliable than parent reported wheeze, and may help to guide treatment decisions and correctly phenotype subjects in research on the development of asthma.

P4258
Assessing quality of care from the patients’ and parent’s perspective in three paediatric asthma settings; a randomised controlled study in children with stable asthma
Maarten Kuebel1, Herman Sixma2, Anja Vaessen-Verbeme1, Judith Booy2, Wim van Aalderen3, 1Pediatrics, AMPHIA Hospital, Breda, Netherlands; 2Health Care Research, Netherlands Institute for Health Services Research (NIVEL), Utrecht, Netherlands; 3Paediatric Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands

Aim: To explore quality of care (QoC) as perceived by children with asthma and their parents in a randomized controlled study. Treatment, either by general practitioners (GP), paediatricians (PP) or asthma nurses (AN).

Methods: Children (6-16 yrs) with stable asthma were recruited from hospital practice (n=62) and from general practice (n=45). Subjects were allocated to three follow up arms (GP. PP, AN). At baseline and after 1 and 2 years, QoC was measured, by parents completing the QUOTE-CNSLD-questionnaire. By factor-analysis an adapted version was derived. Children also completed a 5-item Likert scale, independently and if needed assisted by the research nurse.

Results: The QoC dimensions of the adapted QUOTE-CNSLD-questionnaire resemble the original scales. At baseline the asthma specific quality and the child specific quality were significantly better in subjects recruited from hospital-, compared to primary care (p<0.01 in both). No significant differences in the four qualities between groups after one and two years. Correlations between child-specific quality and the parents reported qualities were poor (r=0.24, r0.19, r0.27).

Conclusions: The adapted QUOTE-CNSLD-questionnaire is applicable in a paediatric population. Two dimensions measured significant differences between children recruited from hospital care and from primary care at baseline. No difference during follow-up indicates that from a quality prospective a specialized asthma nurse is cost effective.

P4259
Quality of life in asthmatic children “a comparative study of patients’ and parents’ perceptions”
Malak Shaheen, Samer Mostafa, Eman Zaki. Pediatric Department, Ain Shams Faculty of Medicine, Cairo, Egypt

Background: Pediatric asthma is one of the most important public health problems. Pediatric pulmonologists are not only responsible for clinical relief of children’s symptoms but also for ensuring a better quality of life for them and their families.
**P4260**

**Effects of exposure to parental smoking on pulmonary function and symptoms in children with asthma**

Polytimi Panagiotopoulou-Gartagani, Paiganiota Nikolouz, Efthimia Kalampouka, Emmanouil Karavitakis, George Kavadias, Maria Chatzisimeon, Athanasias Kadiis, Chryssa Bakoula, George Chrousos.

Objectives: To evaluate the association of exposure to parental smoking on pulmonary function and symptoms in children with asthma. Methods: Of 1086 children who were consecutively examined, 188 were excluded because of incomplete data. The children were divided according to parental smoking status (nonsmokers, occasional smokers, heavy smokers). The pulmonary function was evaluated by a spirometry test, lung volumes and airway resistance were measured by a body plethysmography test. Results: Significant differences were observed in mean FEV1 (% predicted) in children from nonsmoking and smoking households (p<0.05). In children from households with occasional smoking, a significant decrease of mean FEV1 (% predicted) was observed (p<0.05). In children from households with heavy smoking, a decrease of both FEV1 and FVC (p<0.05) was observed. Conclusions: The exposure to parental smoking is associated with a decrease in pulmonary function and symptoms in children with asthma.

**Perinatal weight gain and early development of recurrent wheeze and asthma in term children**

Astrid Sevelsted, Hans Bisgaard. Copenhagen Prospective Studies on Asthma in Childhood; COPSAC, Health Sciences, University of Copenhagen, Copenhagen University Hospital, Gentofte, Copenhagen, Denmark

Objectives: To assess the association between perinatal weight gain and the development of recurrent wheeze and asthma. Methods: The analysis included 398 of a birth cohort of 411 Danish neonates born at term of mothers with a history of asthma. The primary end-points were perinatal weight gain, asthma and severe asthma symptoms. Results: Significant differences were observed in mean birth weight and mean BMI at 2 years of age in children from asthma-free and asthma cases (p<0.05). In children with asthma, a significant increase of mean BMI at 2 years of age was observed (p<0.05). Conclusions: Perinatal weight gain is associated with the development of recurrent wheeze or asthma in young-at-risk children born at term suggesting perinatal mechanisms as a common link.

---

**P4262**

**Relation of asthma and body mass index in children**

Akeelah Ahmadiafshar, Sara Tabakhiiz, Zeherzeh Tobah, Behnaz Falakchakhz.

Objectives: To assess the association between perinatal weight gain and the development of recurrent wheeze and asthma. Methods: The analysis included 398 of a birth cohort of 411 Danish neonates born at term of mothers with a history of asthma. The primary end-points were perinatal weight gain, asthma and severe asthma symptoms. Results: Significant differences were observed in mean birth weight and mean BMI at 2 years of age in children from asthma-free and asthma cases (p<0.05). In children with asthma, a significant increase of mean BMI at 2 years of age was observed (p<0.05). Conclusions: Perinatal weight gain is associated with the development of recurrent wheeze or asthma in young-at-risk children born at term suggesting perinatal mechanisms as a common link.
Objective: To evaluate the level of physical activity in asthmatic children and to compare among asthma severities.

Methods: Sixty-nine children (50.1±9.1 yrs) with persistent mild (n=27), moderate (n=20) and severe (n=22) asthma were evaluated. Children wore an accelerometer for 6 days (24 h each and 2 weekends) and the total steps per day (STStr) and steps walked at either moderate or vigorous intensities (>100 steps per minute) were evaluated.

Results: Our results show that 71% of all asthmatic children were considered physically active (male=12.000 and female=10.000 steps per day). The level of activity at moderate or vigorous intensities in physically active children represented around 45% of total step counting and they showed higher activity levels during week compared with weekend days (p<0.05). The level of physical activity in asthmatic children was not related to either gender or weight. Interestingly, children with mild persistent asthma were physically less active during week days than those with moderate and severe asthma (p<0.05), however no difference was observed in the weekend days (p>0.05).

Conclusion: Congery tailor belief, most asthmatic children were considered physically active and those patients with moderate and severe asthma are still more active.

P4265

Relationships between body mass index and clinical and functional characteristics in childhood asthma: A cross-sectional analysis
Bruno Mahant 1, Nicole Beydon 2, Christophe Delclaux 1.
Characteristics in childhood asthma: A cross-sectional analysis

Background: Overweight is a risk factor for subsequent asthma in children and obesity in adults represents a unique phenotype of asthma, with more severe disease.

Objectives: To assess the relationships between body mass index and clinical and functional characteristics of childhood asthma in a cross-sectional design.

Methods: The z-scores of BMI were evaluated according to the level of control (severe exacerbation and absence of symptom in the past three months), ICS treatment and pulmonary functional tests in asthmatic children. Overweight was defined as a BMI >97th percentile.

Results: Data from 506 children (178 girls, 10.8±2.6 years, min-max [6-15]) of whom 92 (18%) with overweight were analyzed. The z-scores of BMI were increasing with age (r = 0.11, p = 0.014) and overweight was more frequently observed in girls than in boys (45% vs 33%, p = 0.045). Median of z-score were not significantly different according to atopy (p=0.31), recent exacerbation (p=0.24) or observed in girls than in boys (45% vs 33%, p = 0.045). Median of z-score were not significantly different according to atopy (p=0.31), recent exacerbation (p=0.24) or sex. The level of physical activity in asthmatic children was not related to either gender or weight. Interestingly, children with mild persistent asthma were physically less active during week days than those with moderate and severe asthma (p<0.05), however no difference was observed in the weekend days (p>0.05).

Conclusion: Congery tailor belief, most asthmatic children were considered physically active and those patients with moderate and severe asthma are still more active.

P4266

The influence of overweight/obesity on asthma symptoms among Dutch children
M. Willeboordse 1, D. van den Betselaar 1, K.D. van de Kant 1, J.W.M. Muris 2, C.P. van Schayck 3, E. Dompeling 4, 1Pediatrie, Maastricht, Netherlands; 2Pompidou Hospital, Paris, France; 3Physiology, Armand Trousseau Hospital, Paris, France

Background: Overweight has been identified as a risk factor for the development and the severity of asthma in children. The prevalence of overweight in children has been increasing more rapidly in certain areas of Southern Limburg compared to the other Dutch provinces. The aim of this study was to assess the influence of overweight and obesity on the prevalence of asthma symptoms in Southern Limburg, the Netherlands.

Methods: Parents of 39,316 children (6 - 16 years) in Southern Limburg were invited to complete an online questionnaire. The questionnaire consisted of the additional questions about anthropometric variables, risk factors for asthma, and social environment. Corrections were made for the following confounders: sex, age, ethnic background, tobacco smoke exposure, birth delivery, family history of asthma, birth weight and breast feeding of the mother during pregnancy.

Results: The response rate was 23.7% (n=9,309). The prevalence of current asthma, overweight and obesity was respectively 7.7%, 15.2% and 2.5%. A high Body Mass Index (BMI) SDS was significantly related to the prevalence of current asthma (adjusted OR=1.10, 95%CI=1.02-1.19, p<0.01). Also “current wheezing symptoms” were related to a high BMI-SDS, (adjusted OR=1.10, 95%CI=1.02-1.19, p<0.01). Dry cough at night was not associated with BMI-SDS (adjusted OR=1.01, 95%CI=0.97-1.07, p=0.53).

Conclusion: There is a slight but statistically significant positive association between BMI-SDS and asthma in children in Southern Limburg, the Netherlands.

P4267

Leptin levels in obese and non-obese children with asthma
Snezana S. Zivkovic 1, Ljiljana Saranac 1, Borislav Kamenov 1, Branko Bijelakovic 1, Slobodanka Petrovic 2, 1Pediatric Clinic, Clinical Centre Niš, Niš, Serbia; 2Department of Pulmonology, Institute for Child and Youth Health Care of Vojvodina, Novi Sad, Serbia

Objective: The aim of the study was to evaluate the serum leptin levels in children with asthma and to compare it with healthy controls and to determine the relationship of leptin, systemic inflammation and lung function in asthmatic children.

Methods: The study included 62 patients with stable asthma (47 obese and 15 non-obese) and 15 healthy controls, mean age 11.2±2.85 years. All subjects were prospectively and consecutively evaluated. A skin prick test and blood sampling for assessing serum leptin levels and CR reactive protein were performed in all subjects. Body mass index was calculated using height and weight, waist circumference and waist to hip ratio measured on the same day that pulmonary function test performed.

Results: Leptin concentrations were significantly higher in obese asthmatic patients than in non-obese asthmatics and healthy controls (4.20±3.06 vs. 1.74±1.12 vs. 1.76±0.97 mg/l; p<0.001). The correlation between leptin and CRP was negative in group obese asthmatics, but without significance. The correlations of leptin with indices of pulmonary function in the study group (FEV1/FVC, PEF and PEF50%) were negative (p<0.001; p<0.05).

Conclusion: High level of serum leptin in obese asthmatic children probably is marker of exacerbated airway inflammation and influence the control and disease severity.

429. Biological correlates and comorbidities of childhood asthma/allergy

P4268

Lung clearance index differentiates children with poorly controlled asthma better than FEV1/FVC. Data from the paediatric asthma genes and environment (PAGE) study
Helen Sheridan 1, Debbie Miller 1, Kenneth MacLeod 1, Stephen Turner 1, Steve Cunningham 1, 1Department of Child Life and Health, Royal Hospital for Sick Children, Edinburgh, United Kingdom; 2Centre of Child Health, University of Aberdeen, Aberdeen, United Kingdom

Introduction: Lung Clearance Index (LCI) has been shown to differ between children with and without asthma. We have further examined relationships between LCI, spirometry and outcomes within a group of asthmatic children.

Methods: Children with asthma were recruited to a national study. Assessment included respiratory and children’s asthma control questionnaires, spirometry, and LCI for individuals recruited in Edinburgh, Multiple Breath Washout (MBW). Results are compared to previously obtained data from healthy controls.

Results: 63 asthmatic patients aged 5.1-16.5 years performed MBW. Controls included 66 children aged 5.0-16.1 years. Mean (SD) LCI in our asthmatic group was 6.7 (9.9) and was higher than in our healthy group, in which LCI was 6.3 (5.0) (p=0.007). The asthmatic group also had significantly worse FEV1/ FVC z score (p<0.001), which correlated with LCI (r=-0.33, p=0.02). There was no difference in FEV1; FVC did not correlate with LCI.

Patients with completely or well controlled asthma had significantly lower LCI (6.4) than those whose asthma was described as somewhat controlled or worse (6.9; p=0.02). There was no difference in FEV1; or FEV1/FVC between these groups. LCI also correlated with reported time that asthma affected school work (p=0.36; p=0.15) and use of salbutamol (p=0.33; p=0.03).

Conclusions: Our cohort of children with asthma had significantly higher LCI compared to healthy children. LCI was also higher in patients whose parents reported poorer asthma control, something not evident for FEV1 or FEV1/FVC. LCI may be considered a better surrogate of symptom control than spirometry.

Subclinical small airway involvement in children with seasonal allergic rhinitis
Sotirios Fournas, Argyro Lisiou, Ioanna Vassilopoulou, Michael Antarcopoulos, Maria Triga, 1Pediatric Respiratory and Allergy Unit, University Hospital of Patras, Patras, Greece

Background: Allergic rhinitis (AR) has been incriminated as a relevant risk factor for asthma onset in children and young adults. The aim of this study was to examine the presence of subclinical reversible airflow obstruction in non-asthmatic children suffering from seasonal AR.

Methods: Twenty five children with seasonal AR and pollen allergens sensitiza-

Spirometry and measurement of airway resistance by the interrupter technique (rint) in preschool children: Influence of atopy  
Lucia Leonardi, Anna Ruggiano, Gabriella Giancane, Annalisa di Coste, Paola Panza, Giancarlo Tancredi, Laura Indimmino, Marzio Duse. Paediatrics, Sapienza University of Rome, Rome, Italy  
Background: Pulmonary function tests play an important role in the diagnosis, and management of respiratory diseases in children. The aim of our study was to evaluate the lung function by performing spirometry and airway resistance by the interrupter technique in preschool children in relation to their atopic status.  
Materials and methods: We studied 83 asymptomatic children (Males: 51 and Females: 32, mean age 5.15 years ± 0.72 SD). For each child has been collected the family history concerning: atopy, respiratory diseases, history of gestational and neonatal period. In all children, Skin Prick Test (SPT) to inhalant and food allergens were performed. Rint, by requiring minimal cooperation to be carried out, were performed in all subjects. Spirometry was also well tolerated by 56 subjects and was used to determine FEV1, FVC and FEF25-75.  
Results: Twenty-two subjects (26.5%) had positive SPT. The following table shows the values of the main spirometric and Rint parameters of atopic (A) and not atopic subjects (NA).

Conclusions: Despite our study assess the feasibility and repeatability of both tests in preschool children, spirometric parameters were not statistically different between atopic and not atopic children, while mean values of Rint were significantly lower in non-atopic compared to atopic children.

P4271  
Clinical correlation & evaluation of spirometry in children with asthma  
KeyaRani Lahiri, Milind Tullu, Shobi Anandi. Department of Pediatrics, Seth G.S. Medical College & KEM Hospital, Parel, Mumbai, Maharashtra, India  
Introduction: Spirometry is gold standard tool in management of asthma.  
Aims & objectives: To determine correlation between improvement in symptom score & lung function in pediatric asthma.  
Methods: 32 Patients were followed up over 6 months each at Pediatric Chest Clinic. Childhood Asthma Control Test was used to determine the symptom score (symptoms, daytime- & night-time cough, wheezing) & spirometry was performed at baseline, 6 weeks, 3 months & 6 months. Parents were educated about medications, techniques & compliance.  
Results: The mean age was 8.72 years (8.72±1.95, range 6-12 years) [M: F=1.67:1]. There was a 20% & 26.6% & 36.3% improvement above baseline symptom score at 6 weeks, 3 months, and 6 months (*p<0.05, Mann Whitney U test). Overall same time, there was 7.3%, 15.6% & 34.4% improvement in FEV1 and 7.2%, 12.7%, & 33% improvement in FEF25-75. At 6 weeks of treatment, there was significant improvement in symptom score with marginal improvement in lung function. At the end of 3 months, there was a significant improvement in lung function, though the improvement in symptom score tended to be more. However, at end of 6 months, all parameters showed almost same degree of improvement. The percentage improvement in score as reported by the child was comparable to that reported by parents. The improvement in FEV1 was comparable to improvement in FEF25-75.  
Conclusions: A well conducted therapeutic program with good compliance, patient education, regular medication & follow up leads to improvement in symptom score & lung function measures. The symptom score, the FEV1, and PEFR are good indicators of response to treatment in childhood asthma.

P4272  
Validation of tidal breathing analysis in the diagnosis of asthma among Filipino children aged 1 month–6 years  
Sherlyn Corpuz. Department of Pulmonary and Critical Care Medicine, Philippine Heart Center, Quezon City, Metro Manila, Philippines  
The purpose of the study was to assess the accuracy of Tidal Breathing Analysis in diagnosing asthma in Filipino Children aged 1 month to 6 years as compared with the Philippine Consensus for Asthma as a reference standard. This is a cross-sectional validation study using lung function was measured and analyzed using the tidal flow-volume loops (master screen Paed Jaeger Pediatric) in 119 sedated young children (55 males, 64 females; mean age 2.6 years) who were suspected of having asthma, before and 15 minutes after inhalation of nebulized salbutamol. The result of the Tidal Volume per kilogram (VT/kg) and the ratios of the time and volume until peak expiratory flow to the total expiratory time and volume, respectively (TPTFE/TE and VPEF/VE) were recorded. Provocation test was also done and reversibility after salbutamol inhalation was recorded.  
Results showed that the sensitivity of TBA was 36.2% and the specificity was 80.3%. The positive predictive value was 63.6% and the negative predictive value was 57.0%.  
We conclude that Tidal Breathing Analysis is a good validating device to diagnose children with asthma who can not perform the pulmonary function test. However, the test is not a reliable screening method to children still suspected to have asthma. With these findings, all clinicians dealing with pediatric patients suspected with asthma should be vigilant in diagnosing and treating children with asthma.

P4273  
Do infants with bronchiolitis get any benefit with nebulized salbutamol?  
Elpis Hatziagoras, Vasiliki Avramidou, Fotia Kirvassilu, Antoniag Megvred, John Tsunasakas. Paeudiatric Pulmonology Unit, 3rd Paediatric Dept, Hippokration Hospital, Aristotle University, Thessaloniki, Greece  
Background: The results of nebulized salbutamol in hospitalized infants with bronchiolitis are controversial. Rint is a standardized method of evaluation of airways broncho-constriction in infants.  
Aim: 1. To compare expiratory interrupter resistance (Rint) among 19 infants with bronchiolitis and 21 healthy controls. 2. To assess the effect of nebulized salbutamol on Rint among infants with bronchiolitis.  
Methods: Nineteen infants with bronchiolitis and positive history of atopy, family history of asthma and high total serum IgE levels were studied. Twenty one age-matched healthy infants were used as controls. Expiratory interrupter resistance (Rint) was measured before and 20 minutes after nebulized salbutamol.  
Results: 19 infants with bronchiolitis (mean age 9.25±6.34 months, 57% boys) and 21 age-matched healthy control infants were studied. 90.1% of them had eczema and 18.2% of them had milk allergy. Mean total serum IgE was 180.4±33.5 IU/mL. 82% of them had siblings with asthma, while 55% of them had a history of maternal asthma. As compared to controls, infants with bronchiolitis had significantly higher Rint. (2.6±0.4 0.78 vs 2.16±0.12 kPa L -1 second, p<0.001). Moreover, Rint was reduced significantly after administration of salbutamol: mean difference (95% confidence interval): -0.49 (-0.92, 0.06) (p = 0.028).  
Conclusions: Infants with bronchiolitis, positive family history of asthma and positive personal history of atopy might benefit from nebulized salbutamol, as shown by the improvement of Rint values.

P4274  
Exhaled breath temperature and nitric oxide in assessing children with and without respiratory disease  
Mari Barreto, Francesco La Penna, Anna Prete, Susanna Bonafoni, Francesco Biagiarelli, Valentina Negro, Salvatore Barberi, Maria Pia Villa. NEMOS Department, Pediatric Unit, Sant’Andrea Hospital,Faculty of Medicine and Psychology, University “La Sapienza”, Rome, Italy  
Background: The exhaled breath temperature (EBT) is a potential marker of airway inflammation. Recent data suggests a relationship between EBT and the fractional concentration of exhaled nitric oxide (FENO). Factors influencing EBT and its utility to distinguish subjects with respiratory disease are scarcely known.  
Aims: To compare EBT and FENO in patients with asthma, rhinitis and healthy children.  
Methods: In 50 subjects aged 10.3±2.8 yr (30 males), 26 with asthma, 11 with rhinitis and 13 healthy we measured the EBT plateau (EBTp, °C), FENO, spirometry at baseline and after inhalation of salbutamol, skin prick test for common allergens, questionnaires and scores for respiratory symptoms. Post-salbutamol changes (Δ pre) were calculated.  
Results: EBT and FENO correlated with age (r=0.61 and r=0.34, p<0.002; r=0.48, p<0.001). EBT correlated with FENO only in asthmatic subjects (r=0.40, p<0.05). All children with asthma and 9/11 with rhinitis had positive skin prick tests. Both EBTp and FENO were higher in asthmatic patients with reported moderate-to-severe dyspnea in the past 4 weeks in 18 asthmatic patients
without or mild dyspnea and healthy children (EBTpt: 32.4±1.6 vs 30.2±2.8 vs 30.0±3.0, p<0.05). FEV1 levels were also higher in symptomatic patients with asthma than in patients with rhinitis (48.4 ± 9.5 vs 34.7 ± 6.7 vs 11.0 ± 9.0, p<0.01). EBTpt values were not influenced by current inhaled corticosteroid therapy. **Conclusion:** EBTpt and FEV1 are influenced by subjects’ age. Both markers are useful to distinguish patients with poor asthma control from healthy patients.

**P4275**

**Bronchial provocation testing (BPT) of pre-school children by acoustic respiratory monitoring (ARM) of wheeze (Wz) and cough (C)**

Galit Livnat1, 2, Claudia Katz1, 3, Moshe Rotchild1, 2, Yaarezd Toukan1, 2, Lea Benur1, 2, Pediatric Pulmonology, Rambam Medical Ctr, Haifa, Israel; 2 Rappaport Faculty of Medicine, Technion, Haifa, Israel.

**Background:** Unequivocal diagnosis of asthma in pre-school children is limited by their inability to perform spirometry. We evaluated the feasibility of BPT using an automatic ARM system.

**Methods:** We performed doubling-dose methacholine BPT in 41 children age 2 to 7 to confirm asthma. Provoking Concentration by wheeze-endpoint (PCWz) was declared when Wz was heard by physician auscultation, SpO2 fell by 5% or respiratory rate (RR) increased by >50%. ARM of Wz and C. (PulmoTrack™, KarMeSonix, Israel) was recorded in parallel and reviewed off-line.

**Results:** Endpoint by ARM was the same as clinical PCWz in 25/41 (60.9%) and preceded PCWz in 8/41 (19.5%) patients by 1-4 doubling doses. In 4 patients (9.8%) PCWz preceded ARM endpoint and in 4 patients (9.8%) the test was inconclusive due to poor patient cooperation. Of the 4 tests where ARM lagged behind PCWz, 2 were due to ARM not detecting Wz and 2 were possibly stopped prematurely by the physician. In 6 of the patients there were false positive ARM Wz detections due to ambient noise. In 9/41 patients (22%) there was excessive cough towards the endpoint.

**Discussion and conclusion:** ARM-based BPT was as good as or better than PCWz in 90% of tests. Improved sensitivity and specificity of wheeze detection and automatic detection of increased RR are needed to facilitate physician-unattended use of the ARM for a BPT.

**Acknowledgements:** S Godfrey, N Gavrielv and the KarMeSonix Technical Team assisted in data recording and analysis. M Mierisch, RT, performed the BPTs.

**P4276**

**Relationship between H1N1 induced asthmatic symptoms and airway hyperresponsiveness in children**

Yoon Hee Kim, Jiyong Baek, Hyun Bin Park, Kyung Won Kim, Myung Hyun Sohn, Kyu-Earn Kim. Department of Pediatrics and Institute of Allergy, Severance Children’s Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.

**Purpose:** H1N1 infection is known as an important aggravating factor of asthma. However, there is no report about airway hyperresponsiveness (AHR) in patients who developed H1N1 induced acute asthmatic symptoms without previous asthma.

**Methods:** We studied children less than 15 years old visited for H1N1 infection in Severance Children’s Hospital from August in 2009 to February in 2010. H1N1 infection was confirmed by real-time RT-PCR analyzing the products of nasopharyngeal swab when the patients had fever and acute respiratory symptoms like cough, rhinorrhea, and sore throat. Among the infected children, patients hospitalized due to acute asthmatic symptoms like dyspnea or wheezing sound were enrolled. We performed methacholine challenge test one month after discharge. AHR was defined as PC20 below 16 mg/mL. **Results:** Total number of H1N1-infected children was 4,362 (age of 6.95±3.75). Male to female ratio was 56.88%. Two hundred eighty seven patients (6.58%, age of 5.83±3.75) were hospitalized due to respiratory complications. Among them, 76 patients without previous asthma showed acute asthmatic symptoms (26.48%). Forty six patients were performed methacholine challenge test. Only 17 (36.96%) patients presented AHR.

**Conclusion:** H1N1 infection induced acute asthmatic symptoms not only in patients with asthma, but also in patients without previous asthma. H1N1 induced moderate to severe asthmatic symptoms might tend to be temporary and would not contribute to AHR.

**P4277**

**Malacia, inflammation and bacterial colonisation of the conducting airways in infants with persistent respiratory symptoms**

Frans De Baets1, Iris De Schutter2, Claudia Aarts1, 2, Filemone Haerynck1, Sabine Van Daele1, Elke De Wachter2, Anne Malfroot 2, Petra Schelstraete 1.

**Department of Paediatric Pulmonology, Ghent University Hospital, Gent, Belgium; 2Department of Paediatric Pulmonology, University Ziekenhuis Brussels, Brussels, Belgium; 3Department of Paediatric Pulmonology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.**

In infants with persistent respiratory symptoms, wet cough and wheezing de-

pite regular anti-asthma inhalation treatment diagnostic investigations to exclude underlying disease are warranted.

Prospectively 124 infants with treatment resistant respiratory symptoms were enrolled. 24 hours osseopalaeo a pH measurement and isoelectric bronchocopy (FOB) with bronchoalveolar lavage (BAL) were performed. BAL fluid was processed for neutrophil counting and bacterial culture. Inflammation of the respiratory mucosa was registered.

A 24 hours osseopalaeo pH measurement was positive in 29%. A structural abnor-
mality of the central airways was found in 47% (40% females). In 19% of infants no anatomical anomalies nor chronic inflammation of the respiratory mucosa was observed, whereas in 64% definite macroscopic mucosal inflammation was regis-
tered. Pronounced inflammation of the respiratory mucosa was associated with a significantly higher percentage of neutrophils in the BAL fluid, 48% (IQR 14 – 82) compared to 7% (IQR 0 – 16) (p<0.025) in the normal group. A positive BAL culture was found in 62% of the infants with pronounced mucosal inflammation compared to 25% in the group without inflammation (p<0.016). Fifty six percent of the BAL fluid samples was positive for bacterial culture.

In infants with treatment resistant respiratory symptoms, nearly half have anatom-
al anomalies of the central airways. In 62% of the children with pronounced airway inflammation a positive BAL culture and a significant percentage of BAL fluid neutrophils were detected, suggesting chronic bronchial infection as a possible reason for ongoing respiratory symptoms.

**P4278**

**Upper and lower airway inflammation and bronchial hyperresponsiveness in allergic rhinitis children with or without asthma**

Alla Nakonechna1, Yuriy Antipkin2, Tatjana Umanets2, Vladimir Lapshyn2.

1Allergy Clinic, Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, United Kingdom; 2Department of Allergy Problems and Immunoharisation of Children, Institute of Paediatrics, Obstetrics and Gynaecology, Kiev, Ukraine.

**Background:** Although allergic rhinitis and asthma frequently coexist, the nature of this association is still not clearly identified. **Objective:** To estimate the upper and lower airway inflammation in allergic rhinitis (AR) children with or without asthma in relation with bronchial responsiveness. **Methods:** 145 children aged 7-12 years with AR alone or AR with asthma and 35 age-matched healthy controls were observed.

Lung functions, bronchial hyperreactivity tests (methacholine and exercise) nasal and induced sputum samples were performed in all patients. Total and antigen specific IgE, IL-5, IL-10, γ-IFN levels were assessed by ELISA.

**Results:** Children with AR alone (39%) but no clinical evidence of asthma showed increased nasal and induced sputum eosinophils. Bronchial hyperresponsiveness were more significant compared with AR-alone (p<0.05).

**Conclusion:** In children with AR without asthma subclinical changes in the airways and inflammatory mediators were detected. These data support the concept of significant links between upper and lower respiratory tract involve-
ment in AR children with or without asthma and its association with bronchial hyperresponsiveness.

**P4279**

**Eosinophil cationic protein in children with respiratory allergies – When is it useful?**

Ivan Pavce1, Slavica Dodig2, Miljenko Rans3, Jadranka Zivcic2, Renata Zimski Topic2. 1Children’s Hospital Zagreb, 2Department of Clinical Laboratory Diagnosis, 3Pediatric Department, Srebrnjak Children’s Hospital, Zagreb, Croatia.

**Backgrounds:** Eosinophil cationic protein (ECF) is a secretory protein that is released from eosinophils in patients with allergic diseases. The aim of the present study was to investigate the usefulness of determination of serum ECF levels in children with respiratory allergies. Specific objectives were: (1) to assess if there are any differences in serum ECF concentrations between treated and untreated children with asthma, children with rhinitis, and children with both asthma and rhinitis and (2) if the natural seasonal exposure to sensitizing allergens is responsible for increasing serum ECP.

**Methods:** The study included treated (N=156) and untreated (N=55) children with asthma, children with rhinitis, and children with both asthma and rhinitis. Serum ECP was measured in serum collected between 8:00 and 12:00 a.m. under standardized preanalytical conditions (regarding the type of blood collection tube, time and incubation temperature during blood clotting).

**Results:** Untreated children, had significantly higher (p<0.0001) concentration of ECP [M (IQR)=35.1 (29.5-50.9) g/L] than treated children [M (IQR)=11.3 (7.1-16.1) g/L]. ECP was significantly higher during the allergen exposure season [M (IQR)=23.9 (17.6-40) g/L], than out of season [M (IQR)=8.3 (5.4-17.2) g/L, p<0.0001. **Discussion:**
Conclusions: If all limiting factors for reliable determination of serum ECP should be taken into account, determination of ECP could be helpful in objective evaluation of eosinophilic degranulation in allergic inflammation and for monitoring the effectiveness of anti-inflammatory treatment.

P4280
Chemotaxis and adhesion from peripheral eosinophils in atopic asthmatic children with and without obesity
Milenka Orellana Grotta1, Ederson Antunes2, Dalize Squezobla3, Adyelba Dalbo Contrera Toro1, Maria Angela Ribeiro1, Silvia Barros Mazzon1, Jose Dircue Ribeiro1, 1Pediatrics - Center for Investigation in Pediatrics (CIPED), State University of Campinas - Medical School (Unicamp), Campinas, Sao Paulo, Brazil; 2Pharmacology, State University of Campinas - Medical School (Unicamp), Campinas, Sao Paulo, Brazil; 3Clinical Pathology, State University of Campinas - Medical School (Unicamp), Campinas, Sao Paulo, Brazil

Background: The prevalence of obesity and asthma has increased over the past several decades. Recent investigations suggest relationship between asthma and obesity. In New Zealand, 34.5% of children are obese. The aim of the current study was to evaluate chemotaxis and adhesion of eosinophils in atopic asthmatic children and adolescents with and without obesity.

Methods: 32 obese asthmatic and non-obese asthmatic and 5 healthy volunteers were included. Peripheral blood was collected and eosinophils were purified using a Percoll gradient followed by immunomagnetic cell separator. Chemotaxis was performed with microchemotaxis chamber in triplicate with spontaneous chemotaxis (MEM) and eotaxin. Eosinophilic adhesion was calculated by comparison between absorbance of unknown samples with the standard curve.

Results: In spontaneous chemotaxis, with eotaxin and PAF, there was significant increased the adhesion of eosinophils between obese asthmatic and healthy volunteers (p<0.05). RANTES increased between asthmatic obese and healthy volunteers groups (p<0.05). Spontaneous adhesion and with eotaxin increased the adhesion of eosinophils between obese asthmatic and healthy volunteers (p<0.05).

Conclusion: This is the first study that demonstrated higher eosinophilic activity (chemotaxis and adhesion) in obese atopic asthmatic children than non obese asthmatic and healthy volunteers.

P4281
Specific IgE sensitisation in a six-year old infant cohort in New Zealand
Rob Siebers1, Philippa Lampshire1, Kristin Wickens1, Tristram Ingham1, Michael Epton2, Ian Town3, Julian Crane1.
1Pediatrics - Center for Investigation in Pediatrics (CIPED), State University of Otago, Christchurch, New Zealand; 2Department of Immunology, Pediatric Clinic, Clinical Center, Nis, Serbia; 3Department of Pathology, Health Center, Nis, Serbia

Aim: To determine sensitisation to infant and food allergens in 6-year old children in New Zealand.

Methods: Specific IgE (sIgE) levels were determined to 12 infant and food allergens in 659 6-year old children from Wellington (n=316) and Christchurch (n=343) from a birth cohort. Allergens tested were D. pteronyssinus, cat peel, dog hair, horse hair, cockroach, A. fumigatus, Alternaria, olive pollen, rye grass, egg white, cow's milk and peanut by a 3rd generation liquid chemiluminescent enzyme immunoassay (Siemens IMMULITE 2000). Atopic sensitisation was defined as at least one sIgE ≥ 0.35 kU/L.

Results: Sensitisation was present in 299 children (45.4%). Sensitisation to D. pteronyssinus was most prevalent with 176 children sensitised (26.7%) and with the highest sIgE levels (geometric mean: 9.1 kU/L; 95% CI: 6.2-13.2). The next highest sensitisation rate was to rye grass (141 children, 21.4%) followed by egg white (124 children, 18.8%). Mono-sensitisation was observed in 122 children (18.5%); 44 to egg white, 35 to D. pteronyssinus, 18 to rye grass, 6 to cat peel, 5 to cow's milk, 4 to peanut, 3 to horse hair, 3 to dog hair, and 1 each to cockroach, A. fumigatus, Alternaria and olive pollen. The other 177 children were poly-sensitised: 60 to two allergens, 40 to three, 26 to four, 22 to five, 17 to six, 3 to seven, 5 to eight, 3 to nine and 1 to all twelve. Of those poly-sensitised the highest sIgE level in three-quarter of these children was to D. pteronyssinus followed by egg grass.

Conclusion: Sensitisation to infant and food allergens is high in New Zealand 6-year old children with sensitisation to D. pteronyssinus the most prevalent and with very high sIgE levels.

P4282
Use of a very short protocol with no adjuvant in acute ovalbumin-sensitized allergic pulmonary response in mice for pre-clinical studies
Andrea Rodrigues1, Camila Schirmer1, Lucas Granoli1, Raquel Cao1, Rodrigo Souza1, Naíll Netter1, Alison Schleiss1, Renato Stein1, Marcus Jones1, Paulo Pizarre, 1Instituto de Pesquisas Biomédicas (IPB), Pontificia Universidade Católica do Rio Grande do Sul (PUCRS), Porto Alegre, Rio Grande do Sul, Brazil

Many limitations have been raised over the murine models with ovalbumin (OVA) sensitization in asthma research. However, this model is still widely used as a pre-clinical study for some new specific targets for treatment. The use of adjuvant and long sensitization periods are some of the limitations we have tested whether a shorter period of subcutaneous sensitization with OVA, with no adjuvant, induces a similar eosinophilic pulmonary response in mice, when compared with previous well-established control protocols. Adult BALB/c mice were used and divided into groups, according to the number of OVA sensitzations (once or twice, OVA: 20 μg) and number (twice and 3x) and dosage (40 μg and 100 μg) of intranasal OVA challenge. The shorter protocol (10 days- length) consisted of one subcutaneous OVA sensitization and three OVA challenges (100 μg). Total and differential cell counts from bronchoalveolar lavage (BAL), eosinophil peroxidase (EPO) from lung tissue and histopathology (HE) of the lungs were performed 24 hours after the last OVA challenge. Cell counts from BAL, EPO from lung tissue and histopathological lung abnormalities were not different between the groups studied. The shorter protocol induced a significant eosinophilic lung response to OVA. We conclude that the use of one subcutaneous OVA sensitization elicits a strong allergic pulmonary response, faster than the current, a very long protocol. Our findings suggest that very short protocols with no adjuvant can be used as one of the pre-clinical tests for new drug investigations, reducing cost and time of experiments, and avoiding the use of artificial adjuvants during sensitization.

P4283
Different prevalent of allergic diseases between children allergic to cow's milk, egg and fish
Borislav Kamener1, Hristina Stamenkovic1, Tatjana Stankovic1, 1Department of Immunology, Pediatric Clinic, Clinical Center, Nis, Serbia; 2Department of Pathology, Health Center, Nis, Serbia

Background: Food allergy is frequently associated with other allergic diseases. Allergy to certain foods might be associated to higher risk of other allergic diseases. Objective: The aim of the study was to verify the differences in the prevalence of other allergic diseases between three groups of children allergic to cow’s milk, egg and fish.

Methods: Three groups of children aged 3 to 12, with food allergy were analyzed: Group A: cow’s milk allergy (n=55); Group B: egg allergy (n=35); Group C: fish allergy (n=20), mean age 7,3, 8.2 and 7.9. The type of manifestations of food allergy (mucocutaneous, gastrointestinal and respiratory) and the prevalence of Associated allergic diseases -bronchial asthma (BA), rhinitis (R) and atop dermatitis (AD) in each group were analysed.

Results: The mucocutaneous symptoms are the most prevalent in all groups (84%, 75% and 90% respectively). The gastrointestinal symptoms are less prevalent in group B (43%, 25% and 42%). The respiratory symptoms are more frequent in group C (8%, 26% and 60%). The coexistent allergic diseases were: in group A lower prevalence - BA: 32%; R: 42%; DA: 20%; in Group B the most prevalent allergic disease is AD (68%) with the prevalence of BA 58% and R 50%; and in contrast in Group C, BA has the highest prevalence (80%), followed by DA (60%) and R (40%). In all groups The prevalence of allergic diseases was higher than in the general pediatric population.

Conclusion: Cow’s milk allergy has lower frequency of association with other allergic diseases. Egg allergy shows a higher association with AD. Fish allergy has high frequency of respiratory manifestations and a stronger association with BA.

P4285
Investigation of asthma prevalence in the adolescents of Russian Federation
Julia Levina1, Leyla Namazova-Baranova1, Raisa Torshkhoyeva1, Elena Vishnevra1, Anna Tomilova1, Ludmila Ogorodova2, Ivan Deev3, Kamilla Efendiya1, 1Rehabilitation of Children with Allergic Diseases, Scientific Center of Children’s Health, Moscow, Russian Federation; 2Allergology, Siberian State Medical University, Tomsk, Russian Federation

Aim: To define the true prevalence of bronchial asthma (BA) in population of adolescents of Russian Federation.

Methods: At the first stage, according to GA2LEN protocol, in 2 research centers (Moscow and Tomsk) a continuous sample of adolescents 15-18 y.o. from own databases has been created. 12803 teenagers (5000 - Moscow, 7803 - Tomsk) have received the invitation to participate in research by post. Data of 2490 teenagers were included in statistical processing (19.5%: 1480 respondents from Moscow and 1010 from Tomsk). The average age of patients was 15.48±0.02 years.

Results: Cumulative morbidity of BA was marked at 19.9% of all respondents included in research. The analysis of prevalence of clinically diagnosed BA has shown that only 7.2% of teenagers has medical-verified diagnosis (in 2.7 times less in comparison with the cumulative morbidity of asthma). During the complex examination the number of select number of adolescents at the second stage of the study the diagnosis of asthma was verified at 5.7% of children from the group with asthma-like symptoms and at 4.9% of children without asthma symptoms according to answers in questionnaires (average index was 5.1% of adolescents in group). According to the official data asthma morbidity makes 2836,25 oo/oo. Thus, true prevalence of asthma has appeared to be 4 times less than the prevalence of symptoms registered by patients, in 1,4 times less than “diagnosed illness” according to answers of patients and in 2 times above the data of official statistics. Conclusion: Use of the standardized indices, with the further clinical screening and complex examination allows to establish true prevalence of allergic diseases.
P4286

Prevalence of allergic rhinitis in Russian adolescents
Anna Tomilova1, Leyla Namazova-Baranova1, Rasa Torshehova1, Elena Vishneva1, Ludmila Ogorodova2, Ivan Deev2, Julia Levin1. 1Allergology, Scientific Center of Children’s Health RAMS, Moscow, Russia; 2Allergology, Siberian Medical University, Tomsk, Russian Federation

The results were obtained by two centres in Russia (Moscow and Tomsk) as part of the international epidemiological study under the GA\LENN programme. The total number of participants aged 15 to 18 years was 12,830 with 2014 subjects included in the statistical analysis (1004 subjects in Moscow, and 1010 in Tomsk). The male subjects accounted for 44.6% and female subjects for 55.4%. The age was 15.48±0.02 years. The cumulative disease incidence was determined as a total of all the disease cases registered during the past year and in the previous follow-up period. Prevalence is the registered disease cases in which primary visits took place during the calendar year.

The cumulative allergic rhinitis (AR) incidence totaled 34.2%, which significantly exceeds official statistics. The female subjects indicated much more often the presence of AR compared to the male subjects (37.35% and 30.42% respectively at p<0.004). The symptoms of the ongoing AR were found in 86.45% of the total respondents who had indicated the cumulative rhinitis incidence. The follow-up results indicate significant variance from the official statistics (in 2008, the official AR incidence in Moscow was 59.2 per 100,000).

The percentage of the female subjects with AR symptoms, however, was reliably higher than that in Moscow (p=0.042), with the cumulative rhinitis incidence registered more often compared with the ongoing AR both for the entire population and for Moscow (at p=0.0125 and p=0.026 respectively). Prevalence of symptoms for allergic rhinitis was significantly higher than the diagnosed disease forms. The data obtained using standardised tools will help optimise the existing programmes for preventing and diagnosing allergic rhinitis.

Pulmonary function preservation with targeted antibiotic use in infants with CF
Jacquelyn Zurbes, Carlos Milla. Center for Excellence in Pulmonary Biology, Stanford University, Palo Alto, CA, United States

We hypothesized that in CF infants microbiologic surveillance with targeted antibi- otic intervention preserves pulmonary function. Our program follows a standardized protocol with microbiologic surveillance performed at every visit by oropharyngeal sampling for culture. Positive cultures are treated based on antibiotic susceptibility regardless of clinical status. First detection of Pseudomonas aeruginosa (PA) is treated with a 6 week course of ciprofloxacin and 6 months of inhaled Colistin. Pulmonary function (PFT) is assessed by raised-volume rapid thoracoabdominal compression (RVRCT) and multi-breathe washout (MBW). Nutritional status is monitored by weight for length Z-score (WLZ). Twenty four CF infants have participated since 2008. Mean age at diagnosis was 6.8 weeks, 16 were female. On average, 75% of the cultures per patient were positive. Only 6 of the infants had at least one positive culture for PA. In contrast 75% of the infants had at least one positive culture for S. aureus. By RVRCT parameters only 4 infants had evidence for significant obstruction. However by MBW almost all had evidence for mild ventilatory inhomogeneity (mean LCT 8.5±1.1). No correlation was found between RVRCT and MBW parameters. We did find an inverse correlation between WLZ and LCI (r=0.46). Further, we found no relationship between microbiologic results and PFT parameters. Patients with positive cultures, including those with PA, had comparable PFT results to those not infected. Thus, despite airway colonization with CF pathogens, there was no evidence for significant detrimental changes in lung function. We propose that frequent monitoring and targeted use of antibiotics preserves lung function in infants with CF.

P4288

KL-6 serum levels in adult cystic fibrosis patients
Federico Piffer, Andrea Airoldi, Marta Di Pasquale, Giovanna Pizzamiglio, Maddalena Zanardelli, Samanta Galbiati, Barbara Dallari, Francesco Blasi. Dipartimento TORACO-Pulmonare e Cardiocircolatorio Università degli Studi di Milano; Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy

Introduction: Cystic fibrosis (CF) is a chronic lung disease with a typical ob- structive pulmonary pattern. KL-6 is a high molecular weight glycoprotein, whose serum level are related to alveolar epithelium damage particularly in interstitial lung diseases; its role is not clear in CF patients.

Objective: To compare C-reactive protein (CRP) and KL-6 levels in adult CF patients requiring intravenous antibiotic therapy or pulmonary exacerbation.

Methods: Prospective observational study of adult CF patients admitted with pulmonary exacerbation to CF Adult Unit of Policlinico Milan, between November 2009 and February 2010. KL-6 and CRP serum levels were measured on admission, at day 7 and day 14 of intravenous therapy. Clinical and functional data were collected.

Results: 13 patients were analyzed (mean age 33 yrs, range 24-44, 6 women). Mean FEV1 was 49% of predicted (range 25-70). KL-6 levels seemed to show a trend similar to CRP’s during hospitalisation, with early increase and late decrease of the mean values.

Conclusion: These preliminary data show that KL-6 could be an useful biomarker in the follow-up of pulmonary exacerbation of adult CF patients. Further studies in greater cohorts are needed in order to confirm these data.

P4289

Six minute walk test in children, adolescents and young adults with and without cystic fibrosis
Fabiola Mester Pereira, Maria Angela Ribeiro, Adelyda Dalbo Toro, Gabriel Hessell, Antonio Fernando Ribeiro, José Dirceu Ribeiro. Department of Pediatrics, State University of Campinas, Campinas, São Paulo, Brazil

Background: The six minute walk test (6MWT) analyses tolerances to submaximal effort. It’s important to compare Cystic Fibrosis (CF) patients with healthy controls to better understand their responses to physical exercise.

Objective: To evaluate patients with CF submitted to 6MWT and compare them to a control group (CG).

Methods: Transversal, prospective study comprising patients from a Brazilian CF reference centre. 6MWT was applied in a group of CF patients and in healthy controls accordingly to ATS guidelines and repeated after 30 minutes of rest. Respiratory frequency (RF), heart rate (HR), oxygen saturation (SpO2), dyspnea index, nutritional status and spirometry values were analyzed. Patients on pul- monary exacerbation were excluded from the research. Spearman’s correlation and ANOVA for repeated measures were used, p<0.05.

Results: Fifty-five CF patients and 185 healthy individuals participated (12±4.3 and 11.3±4.3 years, respectively). CG walked a greater distance than the CF patients in both tests (6.6±5.3±4 m x 547.2±80.6 m and 616.5±58.0 m x 552.2±82.1 m; p<0.0001). Walked distance correlated with age, weight and height. Both groups achieved similar distances in both tests, although CF patients had bet- ter performance in the first test. Learning effect was not seen. The ICC calculated between the two tests was 0.81 and 0.77 (CF and CG, respectively). The SpO2 maintained stable during the test, with an increase in HR and RF (p<0.0001) in all individuals.

Conclusion: CF patients presented functional impairment when compared to control group. Repeating 6MWT may represent an unnecessary effort for patients with chronic pulmonary disease.

P4290

Exhaled breath temperature in adult cystic fibrosis
Gabriel García1, Noemí Granero1, Berta Hendriksen1, Deleo Carlos1, Bujar Erzeguević1, Miguel Bergna2. 1Neumology, Hospital Rodolfo Rossi, La Plata, Bs As, Argentina; 2Neumology, Hospital Antonio Cetrángolo, Vicente Lopez, Bs As, Argentina

Cystic fibrosis (CF) is characterized by chronic airway infection and inflammation, which accounts for most morbidity and deaths. It has been suggested that inflated airways may increase the exhaled breath temperature (EBT), however, patient with Cystic Fibrosis (CF) may have of the opposite effects. The aim of this study was to measure exhaled breath temperature in adult CF patients by comparison with healthy controls. Fifteen adult CF patients examined (8 female, mean age 28.6±7 years, VEF1% 44.4±21%) and 15 healthy persons (7 female, mean age 34±3 years) were recruited for the control group. The measurements of exhaled breath temperature (EBT) were performed with a second generation hand-held device (X-Halo, Delmedical Investments LTD Singapore) using an antibacterial filter (Clear Advantage, Creative Biomedics, Inc).

Mean value of EBT in controls was 33.80±0.87°C and EBT mean value in adults CF patients was 33.53±0.73°C, the difference was not significant (p=0.05). We conclude that patients with CF had EBT similar to healthy people, contrary to the asthmatics patients, possible due to chronic epithelial cell damage, increased mucosal barrier and the reduce of the vascularity.

Conclusion: To compare C-reactive protein (CRP) and KL-6 levels in adult CF patients requiring intravenous antibiotic therapy or pulmonary exacerbation.
Detection of volatile hydrogen cyanide released by Pseudomonas aeruginosa with cavity ring down spectroscopy
E.P.M. Verschuren, M. Spunt, S.T. Persijn, S. Cristesca, F.J.M. Harren, J.W. Mouton, P.F.E.M. Merkus. 1Pneumonics, Respiratory Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 2Trace Gas Research Group, Institute of Molecules and Materials, Radboud University Nijmegen, Nijmegen, Netherlands; 3VSL, Dutch Metrology Institute, Delft, Netherlands; 4Medical Microbiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Pseudomonas aeruginosa (Pa) produces hydrogen cyanide (HCN) which discriminates from other common CF lung pathogens. HCN production is supposedly increased under microaerobic conditions, which characterizes the habitat of Pa in vitro. This implies a potentially interesting marker in detecting Pa respiratory infections. Laser-based cavity ring down spectroscopy (CRDS) offers high sensitivity and molecular specificity in detecting trace gases and is suitable for incorporation in handheld devices.

In this in vitro study we aimed to assess the feasibility and reproducibility of measuring HCN production through CRDS, and to determine the optimal oxygen concentration for cyanogenesis from Pa cultures on agar media.

A state-of-the-art CRDS was used to assess HCN online concentrations from the head space of Pa grown in petri dishes. Twenty-four hours prior to the experiments Pa was grown on Muller Hinton media and grown in ambient air at 37°C. From start of the experiment, cultures were flushed with adjustable flow of 0.01%, 1%, 10% and 21% O2, diluted in pure nitrogen.

HCN production was measured well above the detection limit from Pa cultures using CRDS (table1).

HCN may serve as a sensitive marker for presence of these bacteria, well above the detection limit. Intra-experimental variation coefficient was 21%. HCN production was highest in low oxygen concentrations (p<0.001).

HCN production can be measured using CRDS, and is affected by oxygen concentration. HCN may serve as a sensitive marker for presence of these bacteria.

Methods:
A cross-sectional analysis of 307 CF patients, we compared the group of once only infected (OI) to chronically colonized patients (CC). We analyzed differences in age, lung function and BMI z-score. Subanalysis included group of once only infected (OI) to chronically colonized patients (CC). We compared them with Pa culture results, to determine their role in early diagnosis and follow-up, to correlate them with severity of disease and to determine factors which cause antibody positivity. Ninety CF patients were included; they were divided into chronic, intermittent, control and mucoid Pa groups according to their airway cultures. They were evaluated in each 3-6 months in total 4 visits in a follow-up period of 2 years. In each visit, Pa antibodies against exotoxin, elastase and alkaline protease were determined in blood by ELISA method. The presence of at least one antibody had the highest sensitivity. Among the antibodies, alkaline protease had the highest specificity and elastase had the highest sensitivity. All antibodies were highest in mucoid group followed by the chronic group. Antibodies were higher in the chronically colonized patients than the noncolonised ones. Elastase was highest in the chronic and lowest in the mucoid Pa group. The presence of antibodies were much higher than positive Pa cultures in patients younger than 5 years of age. Only in mucoid group, there was a negative correlation between FEV1 and alkaline protease. In CF, Pa antibodies can be considered as early markers for diagnosis especially in young children who can not expectorate, however, anti-Pa antibodies should be used together with sputum cultures for long term follow-up and treatment.

Introduction: In recent years there has been an increasing number of recognized emerging pathogens like Stenotrophomonas maltophilia (SM) and Achromobacter xylosoxidans (AX) but their effect in CF lung disease is yet unknown. Aims: 1) to assess the prevalence of SM and AX and 2) to compare the lung function, clinical symptoms at first isolation, CT scan and colonization with Pseudomonas aeruginosa (PA) between the two groups.

Results: 130 patients were included in this study, 44 of whom (33.8%) had a positive culture to SM and 11 (8.4%) to AX at some time. Mean age at acquisition of SM was 6±4.6 years and of AX was 6.5±3.8 years. In the SM group 36% were patients were under 4 years in age compared with 9% in the AX group. No significant difference in symptoms at acquisition (56% and 63% respectively), FEV1 (75% and 84%), bronchiectasis (47% and 36%) and PA colonization (79% and 91%) were found between the SM and AX groups. After specific ABT therapy, chronic colonization was higher in AX (36%) in comparison with the SM group (9%). Conclusion: The prevalence of SM colonisation is higher than AX. Patients colonized with SM were younger but chronic infection was more associated with AX.
Preventable deaths and better outcomes in CF: Need for organising care at Pulmonology, Moscow, Russian Federation; Cystic Fibrosis, Research Centre for Natalia Kashirskaya, Nikolay Kapranov. The genotype-phenotype relationship in cystic fibrosis (CF) patients is a developing country. Development of programs aimed to increase knowledge and complexity of factors that characterize transition to European standards in Conclusions: 66% prevalence of del F508. 15 deaths were encountered, 67% before 2004 when complications). Mean age at diagnosis was 1.3 years, 36/45 were genotyped with 66% prevalence of del F508. 15 deaths were encountered, 67% before 2004 when the Ministry of Health provided funding. 66% of deaths before the age of 3 years, were influenced by poor socio-economic status, undernutrition and reduced level of understanding of the nature of the disease. 65% of patients developed premature severe lung disease related to poor nutrition and early acquisition of P aeruginosa. CF related conditions as ABPA, CFRLD, diabetes in 64/55 patients represented risk factors for poorer outcomes. In 55% of patients malnutrition was correlated with poverty. The level of funding represented only 50% of the needs and the lack of a staffed CF unit was a major barrier to proper care of patients. Clinical outcomes were adversely impacted by lack of funding and complexity of factors that characterize transition to European standards in a developing country. Development of programs aimed to increase knowledge and motivation for being involved in CF care are needed in order to offer better outlooks for CF patients. Genotype-phenotype correlation in cystic fibrosis patients bearing a novel complex allele Riccardina Tesse, Angela Polizzi, Teresa Santostasi, Anna Diana, Antonio Manca, Vito Paolo Logrillo, Luciano Cavallo. Department of Biomedicine of the Developmental Age, University of Bari, Bari, Italy Objective: The genotype-phenotype relationship in cystic fibrosis (CF) patients bearing a novel transmembrane conductance regulator (CFTR) complex allele was investigated. Cases report: During the genetic characterization of 289 CF Caucasian patients [MF ratio 0.9:1, median age 16 years (range 1–46)] we found a new complex allele [H939R,H949L] in five unrelated male patients (age range 15-25 years). They all carried two CF-associated mutations, H939R and B494L, on the same exon 13 of CFTR gene in one allele, and had R245T, G542X, 1259naA, G1349D and F508del, respectively, in the other allele. All subjects had abnormal sweat chloride test values. The patient with R245T/[H939R,H494L] genotype presented CF-related symptoms restricted exclusively to hepatopathy with high levels of transaminases, but a good nutritional status and pancreatic sufficiency. The other four patients had signs of classic CF, including chronic lung and sines disease, recurrent respira- tory infections, failure to thrive and pancreatic insufficiency. Particularly, patient with 1259naA/[H939R,H494L] genotype presented with meconium ileus, and the subject bearing F508del/[H939R,H494L] showed the most severe pulmonary manifestation of CF with abnormal values on tests of lung function. Conclusion: Our findings suggest that the allele [H939R,H494L] greatly reduces the residual function of CFTR if on the other allele is present a severe mutation (i.e. G542X, 1259naA, G1349D and F508del), determining a very low residual function, the combined effect being an overall reduction of CFTR function; on the contrary, when the other allele carries a mild mutation, such as R245T, the overall effect is a cumulative better CFTR functioning. Genotype-phenotype correlation in cystic fibrosis patients bearing a novel complex allele P4297 Twentieth years of care for CF patients in Moscow region of Russia Stanislav Krasovsky, Alexander Chernikov, Elena Amelina, Anna Voronkova, Natalia Kashirskaya, Nikolay Kapranov. Cystic Fibrosis, Research Institute of Pulmonology, Moscow, Russian Federation; 3Cystic Fibrosis, Research Centre for Medical Genetics, Moscow, Russian Federation Objectives: The aim of the study was to assess the median survival age of the patients in the Moscow region of Russia, followed in children and adult CF Centers of Moscow during the period 1991-2000 and 2001-2010, the proportion of adults and gender differences in the survival, if any. Methodology: A database of CF patients was started in 1990. The diagnosis of CF was confirmed by positive sweat test and/or genetic analysis, or neonatal screening (started in 2007). On January 1 2001 there were 185 patients registered in Moscow region, 371 patients were followed in children and adult CF Centers of Moscow during the period 2001-2010. Results: Of 185 patients (98 males), followed during 1991-2000 yrs, 23 (12.4%) have died (7 males, the mean age at death was 18.1±9.2 years), 162 (87.6%) patients were alive on January 1 2001 (mean age 11±3.6 y). The median survival was 25.69 years. Significant gender difference in median survival was noted with 27.3 years for male and 25.1 years for female patients. The proportion of the patients over the age of 18 was 18.9%. During 2001-2010 of 371 patients, 45 (12.1%) had died (26 males, the age of death ranging from 4 months to 40 years; the mean age at death was 16.8±8.4 yrs); 326 patients were alive (mean age 13.2±9.6 yrs). The median survival age increased significantly - 35.71 years (p=0.045). There was no significant gender difference in the survival rate. 32.6% of adult patients – a significant difference since 1991-2000 (p<0.05). Conclusion: A large increase in the Moscow Region CF patients' survival and number of adults was observed during 12 years of specialized treatment, performed in Moscow centers, pointing out a survival advantage of specialized care. Phenotype and genotype in adult patients with cystic fibrosis in Uruguay Alejandra Rey, Gabriela Rutz, Pacheco Ediberm, Guicamburi Rosarios, Maria López Varela, Hospital Matern. Universidad de la República, Montevideo, Uruguay; Unidad Adultos de Fibrosis Quística, Banco Prevención Social, Montevideo, Uruguay. There is insufficient knowledge on Cystic Fibrosis (CF) in many countries; patients are often treated inadequately. Life expectancy is consequently far below what could be attainable with adequate treatment. Therefore it is very important to train Centers to concentrate clinical experience on diagnosis and management of disease. In June 2010, the Uruguayan Parliament created the First National Reference Center for Diagnosis and Treatment of Patients with Cystic Fibrosis. Objective: To describe genotypic and phenotypic characteristics of patients at the time of first encounter at a CF Center for adults in Uruguay. Methods: CF patients over 14 years were evaluated with medical history, spirom- etry and spumor studies. Results: 41 adults entered the center. Mean age was 23.9±8.4, mean age at diagnosis was 14.2±11.3 years. Colonized patients showed differences with non- colonized in: mean age (25.8 ± 22.0 vs. 20.1±0.1), mean age at diagnosis (13.4±11 vs. 14.4±11, p=0.01), lung function: FVC (84% vs. 95%, p=0.01); FEV1 (68% vs. 88%, p=0.00) and history of hemoptysis. Genetic mapping for 30 patients indicated that: 30% had two CFTR mutations, 36% a single mutated allele detected and in 53% no mutations detected. The most common mutation was ΔF508. The remaining mutations were substantially heterogeneous. In all, we had 3 alleles mutation class 1, 13 class 2, 3 class 4, and 1 class 5. Conclusions: - Colonized patients were diagnosed earlier in life, showed significant deteriora- tion in spirometric measures and more frequent hemoptysis. - Our population had different types of CFTR mutations. - The mutation ΔF508DEL was the most common and present in 16%. - 33% of CFTR mutations were not detected.
P4302 Evaluation of disease knowledge in children with cystic fibrosis and their families

Irmaik Dicle Sargın1, Yusenin Gokdemir1, Refika Erval1, Bulement Karadag1, Pinar Arı2, Ahmet Topuzoglu2, Cagatay Cimil1, 2Dept. of Paediatrics, Marmara University Training and Research Hospital, Istanbul, Turkey; 1Dept. of Public Health, Marmara University, Istanbul, Turkey; 1Dept. of Radiology, Marmara University Training and Research Hospital, Istanbul, Turkey

Introduction: Increasing the disease knowledge of patients with cystic fibrosis (CF) and their families is important for treatment adherence.

Aim: To determine the knowledge levels and associated factors in CF patients and their families.

Methods: Parents of 82 CF patients and 39 children >10 years followed at Paediatric Pulmonology Division were included in the study. Knowledge levels were evaluated with a standardized questionnaire which assesses 3 domains of knowledge: respiratory, digestion and nutrition. Knowledge was compared with demographic features and disease severity determined by Shwachman-Kulczycki Scores (SKS) and pulmonary function tests (FEV1%).

Findings: 82 patients were included to the study (44 girls; median age: 9.5 years [25-75percentiles: 5.1-14.1]). Median follow up was 8.0 years (25-75percentiles: 4.6-11.4). Median SKS was 75”good” (25-75percentiles: 55”good”- 85”good”). Mean FEV1% was 66.5±28.0. Knowledge level was 65.8%±14.7 for children and 69.9%±14.6 for families. Children’s knowledge increased with age (p<0.04), but there was no relation with children’s age and family knowledge. Although no correlation was found with children’s knowledge and socio-economic status (SES), families’ knowledge was related with SES (p<0.04). There was no relation with disease severity and children’s or families’ knowledge. Knowledge level was higher for patients who were followed for longer period at our clinic (p<0.04). Knowledge of children or families were not related.

Conclusion: CF patients’ and their families’ knowledge are fairly good but needs improvement. Families’ knowledge is associated with SES Knowledge of children increases with age and follow up time, but is independent from family knowledge and SES.

P4303 An audit to assess the value of the MDT approach in patients in a UK CF unit

Manish Gautam1, Abdul Ashish2, Martin Ledson2, Josheel Naveed1, and SES.

Background: It is widely accepted that in CF best patient and family care should involve a well co-ordinated multidisciplinary service. However, the interdisciplinarity effectiveness of the team, including the patient’s perception of their team is rarely assessed.

Aims: We performed this study in order to evaluate the performance of our local CF MDT from an objective and patient perspective.

Methods: “On the spot” questionnaires were distributed to MDT members, who had worked with the unit for over one year. Questions were related to the knowledge of 15 randomly selected CF patients regarding their microbiology, FEV1, transplant status, social history, portacath, compliance issues and insulin therapy.

Results: Table 1 shows knowledge of MDT members about their patients

<table>
<thead>

Average scores and ranking

Conclusions: Results confirmed CF patients often form close rapport with specialist nurses and associate Consultants with important decision making related to their care. Interestingly, doctors and CF nurses scored equally well in patient knowledge and only marginally above others. These results suggest an effectively functioning MDT whilst highlighting the often under recognised value of individual specialties.

P4304 Improved turn around time for molecular genetic analysis for cystic fibrosis: The Irish experience

Frances Flanagan, Louisa Glackin, Dubliffeasa Slattery. Respiratory, Children’s University Hospital, Dublin, Ireland

Introduction: Ireland’s Cystic Fibrosis (CF) newborn screening programme is due to commence later in 2011 using immune reactive trypsinogen & genetic analysis for the detection of cystic fibrosis transmembrane regulator protein (CFTR) mutations. The National Centre for Medical Genetics screens for 11 CFTR mutations & a further analysis for rarer mutations is currently performed at Brompton (using gene sequencing & multiplex ligation-dependent probe amplification (MLPA) testing). Prior to 2008 this further analysis was performed in Exeter & subsequently in Brest.

Aim: To identify the turn around time for genetic analysis results for children with suspected CF

Method: A 16 year retrospective study of genetic analysis results for CFTR mutations was performed. The turn-around time was defined as the number of days from sending DNA until reports were received. Descriptive statistics were used.

Results: Overall, the median time to receive genetic analysis results was 23 days, range 1-2343 days (n=91). The median turn-around time for the identification of 2 positive CFTR mutations was 21 days, range 1-1973 days. The most common identified mutation, Phe508del/Phe508del, had the shortest median turn around time of 18 days, range 1-107 days. Three patients initially suspected of having CF & with 2 positive sweat tests, did not have any CFTR mutations identified (median time 2252 days, range 229-2434 days). The National Centre for Medical Genetics screens for 11 CFTR mutations & a further analysis for rarer mutations is currently performed at Brompton (using gene sequencing & multiplex ligation-dependent probe amplification (MLPA) testing). Prior to 2008 this further analysis was performed in Exeter & subsequently in Brest.

Conclusion: Recent technological advancements allow for more detailed genetic analysis to be performed, identifying newer CFTR mutations over a shorter time period. The introduction of newborn screening & extended CFTR genetic analysis will ensure that the time to CF diagnosis is greatly improved.

P4305 Validation of the Spanish version of the Leicester cough questionnaire in children with cystic fibrosis

Jaimena Persegona1, Tamara del Corral2, Núria López3, Andrea Valiente4, María Garrida5, Melisa Seborga1, Norma Trujillo1, Lisbeth Hernandez1, Jordi Villar3,6. 1Master Degree in Respiratory Medicine, University of Barcelona and Universidad Pompeu Fabra, Barcelona, Spain; 2Physical Therapy, Asociacion Madrilena Contra la Fibrosis Quistica, Madrid, Spain; 3Physical Therapy, Consorcio Hospitalario Parc Taulí, Subadell, Spain; 4Cystic Fibrosis, Hospital Ramón y Cajal, Madrid, Spain; 5Physiotherapy, FCS Blanquerna, GReF. Universitat Ramon Llull, Barcelona, Spain; 6Institut Clinic del Torax, Fundacio Clinic (IDIBAPS), Barcelona, Spain

Background: Cystic Fibrosis (CF) patients present chronic inflammation with a mucus thickness and decrease ciliar mobility, causing chronic cough, bacterial colonization and respiratory infections. Cough is one of the most important symptoms for CF and it is directly related to exacerbations. Also, represents an upset that adverse quality of life and social relations.

Objective: Validate the Spanish version of the Leicester Cough Questionnaire (LCQ) in CF.

Methods: After the adaptation to Spanish, the sample was selected by 58 CF patients from Corporacio Parc Taulí and Asociacion Madrilena Contra la Fibrosis Quistica, Spain. The questionnaire was administered twice in stable disease patients in order to contrast the results.

Results: Patients characteristics: age 11.7 (3.1) years, BMI of 19 (13) kg/m². Total LCQ1 18.46 (2.4) vs LCQ2 18.69 (2.3) (p=0.769). Cronbach alpha coefficients was: LCQtotal (0.86) and for the domains: LCQphysical (0.76); LCQpsychological (0.79) and LCQsocial (0.78). The ICC was: LCQphysical (0.82), LCQpsychological (0.75), LCQsocial (0.63) and LCQtotal (0.83) (p<0.01 all). We observed moderate correlations with specific quality of life questionnaire (CFQ-R): respiratory symptoms CFQ-R14 (r=0.51) and CFQ-Rchild (r=0.67) (p<0.01, both) and with pulmonary function, PVC and FVE1. LCQphysical (0.42 and 0.48); LCQpsychological (0.60 and 0.62) and LCQtotal (0.55 and 0.58), all significant (p<0.05).

Conclusion: The Spanish version of the LCQ is reliable and valid for CF patients, in which it has observed relations between quality of life and pulmonary functions. Sponsored by: Proyecto AVANZA, TSI-020110-2009-431. Ministerio de Industria Turismo y Comercio, Spain.

P4306 Downregulated BMPR2 signaling pathway in nitrofen-induced pulmonary hypoplasia

Marine Makanga, Celine Devwatcher, Bento Rondelet, Robert Naeije, Laurence Devwatcher. Physiology Laboratory, Université Libre de Bruxelles, Brussels, Belgium

Background: Despite remarkable progress in resuscitation and intensive care, morbidity and mortality in congenital diaphragmatic hernia (CDH) remain high due to severe pulmonary hypoplasia. However, pathogenesis associated with CDH is still not clearly understood. The bone morphogenetic protein receptor (BMPR) type 2 signaling pathway plays a crucial role in fetal lung development.

431. Issues in paediatric and neonatal intensive care

TUESDAY, SEPTEMBER 27TH 2011
Hypothesis: We sought to determine whether BMPR2 signaling pathway is altered in the nitrofen-induced pulmonary hypoplasia associated to CDH.

Methods: Pregnant rats were exposed to either 100 mg nitrofen or olive oil on day 9 (D9) of gestation. At D17 and D19, embryos were delivered by cesarean and sacrificed to check if diaphragmatic hernia existed. Fetal lung, heart and liver tissue weights and body weight of each fetus were recorded. Lung tissue was harvested for pathological evaluation (by immunohistochemistry and RTQPCR).

Results: Lung, heart and liver weight-to-body weight ratios decreased by 20, 30 and 25% (p<0.05) at D17 and by 25, 15 and 25% (p<0.05) at D21. In the CDH group, at D21, the airway septa were thicker and the radial alveolar count was significantly lower compared to controls. In the lungs, gene expression of BMPR2 was decreased in the nitrofen group at D17 and D21, together with decreased gene expression of the DNA binding protein 1 (Ddx1), the major target of the BMP signaling pathway. At D17 (but not at D21), pulmonary gene expression of gremlin, a BMPR antagonist, was increased, while pulmonary gene expression of BMP4, a BMPR agonist, decreased.

Conclusions: In nitrofen-induced CDH, BMPR2 signaling pathway is downregulated in hypoplastic lungs at both early and late stages of lung development.

P4307
Rho-kinase inhibitor ameliorates bleomycin-induced chronic lung injury in neonatal rats
Alvin H. Lee1, Crystal Kantores 1, Julijana Ivanovska1, Charlotte Sewing 1, Robert P. Jankov1,2, 1Clinical Integrative Biology, Sunnybrook Research Institute, Toronto, Canada; 2Physiology & Experimental Medicine, Hospital for Sick Children Research Institute, Toronto, Canada; 2Department of Physiology, University of Toronto, Toronto, Canada

Bleomycin (BLEO) induces a chronic neonatal lung injury (CNI) in rats that is characterized by inflammation, arrest of lung development and pulmonary hypertension (PHT), similar to severe bronchopulmonary dysplasia. Increased Rho-kinase (ROCK) signaling contributes to experimental inflammatory lung injury in adult animals but its role during early life remains unknown.

Methods: Rat pups received BLEO (1 mg/kg/d i.p.) or saline vehicle from postnatal days 1-4 (Y27632 (a ROCK inhibitor); 10 mg/kg/d i.p.). Inflammation was assessed by tissue scores of immune-inflammatory macrophages (CD68) and neutrophils (MPO). Chronic PHT was assessed by right ventricle/left ventricle+septum weight ratio and% medial wall thickness of pulmonary resistance arteries. Markers of lung growth, injury and alveolarization included weight, tissue fraction, mean linear intercept and secondary crest counts.

Results: Lungs of BLEO-exposed pups had up-regulated ROCK activity, as evidenced by increased phosphorylation of ROCK targets, MYPT-1 and LIMK1, which was maintained till Y27632. Treatment with Y27632 completely prevented neutrophil influx to the BLEO-exposed lung while having no effect on increased macrophages. Y27632 completely prevented BLEO-induced PHT and partially improved septal thinning, but did not affect inhibited lung growth or alveolarization. Complete abrogation of BLEO-mediated neutrophil influx by treatment with SB265610 (a CCR2 antagonist; 4 mg/kg/d) had no effect on parenchymal or vascular injury.

Conclusions: ROCK inhibition prevented chronic PHT and improved parenchymal injury (septal thinning) in BLEO-mediated CNI, independent of changes in inflammatory cells. Funded by the CIHR.

P4308
Characterization of miRNAs circulating in sepsis patients’ serum
Lixin Xie1, Huijuan Wang2, Weijun Chen1, Pengjun Zhang1, Longxiang Su2, 1Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 2Medical College, Nankai University, Tianjin, China; 2Beijing Institute of Genomics, Chinese Academy of Sciences, Airport Industry B6, Beijing, China

Background: MicroRNAs (miRNAs) are a class of small non-coding RNAs that regulate miRNA expression at the post-transcriptional level and thereby regulate fundamental biological processes. A number of methods, such as multiplex polymerase chain reaction microarrays, have been developed to profile the levels of known miRNAs. However, these methods cannot identify novel miRNAs or accurately determine their expressions over a range of concentrations. Deep sequencing methods provide a suitable platform for genome wide transcriptome analysis and can identify novel transcripts.

Methodology/Principal findings: We isolated total RNA from serum samples of 9 sepsis patients. We sequenced circulating miRNAs in small RNA libraries using Solexa sequencing. This revealed a total of 154 known mature and 25 mature-star sequences, and predicted 38 novel miRNA candidates. The miRNA expression profiles of sepsis patients were different from those of healthy controls previously reported by Chen et al. The uniquely biased distributions of nucleotides may be related to the stability of circulating miRNAs.

Conclusions: Some of these novel candidate miRNAs may be specific to sepsis patients and could be used as biomarkers to evaluate sepsis prognosis by measuring their levels in blood. Follow-up studies on the functional roles of these novel miRNAs and identifying their targets should provide additional insights on the development and progress of sepsis.

P4309
Spontaneous respiratory activity during mechanical ventilation of term born infants
Oli Chowdhury, Stephanie Kayode, Silke Lee, Simon Hannam, Gerrard F. Rafferty, Anne Greenough. Division of Asthma, Allergy and Lung Biology, King’s College London, London, United Kingdom

Aim: Prematurely born infants frequently breathe while being mechanically ventilated and the pattern of the respiratory interaction influences outcome. The different interaction patterns seen are the result of stimulation of respiratory reflexes (Cheyne-Stokes, the Hering-Breuer reflexes). Respiratory reflexes may be weaker in term born compared to prematurely born infants and thus may not influence the outcome of the former. The aim, therefore, of this study was to characterise any spontaneous respiratory efforts of mechanically ventilated infants born at term.

Methods: To date, ten infants (median gestational age 38 weeks) have been studied at a median postnatal age of five days: five infants on intermittent positive pressure ventilation (IPPV) and five on synchronised intermittent mandatory ventilation (SIMV). Oesophageal, gastric and airway pressures, flow and volume were simultaneously recorded for at least 20 minutes, 100 consecutive breaths were analysed for each baby.

Results: All the infants breathed during mechanical ventilation. Four patterns of interaction were noted: synchrony, augmented inspiration, active expiration and prolongation of expiration.

Pattern of interaction (%)

<table>
<thead>
<tr>
<th></th>
<th>Synchrony</th>

<td>1.2</td>
</tr>
</tbody>
</table>

Active expiration was significantly more common in the SIMV group (p<0.005), whereas prolongation of expiration was significantly more common in the IPPV group (p<0.005).

Conclusions: Respiratory reflexes are provoked in term born infants by mechanical inflations. SIMV does not prevent active expiration, this may relate to trigger delay.

P4310
The influence of angiotensin-converting enzyme (ACE) genotype on the development of severe perinatal asphyxia in the neonates
Natalia Gorovenko1, Svetlana Kryzauchenko2, Zoya Rossokha 3, 1Department of Medical and Laboratory of Genetics, P.L. Shupik National Medical Academy of Post-Graduate Education, Kiev, Ukraine; 2Ministry of Public Health of Ukraine, Reference-Centre for Molecular Diagnostic, Kiev, Ukraine

Background: The cardiovascular disturbances are the important pathways in the development of perinatal asphyxia. Study of genetic markers associated with the development of severe asphyxia in newborns is of great practical importance to develop preventive measures and child health in the future. The aim of this study was to evaluate the influence of the (ID) gene polymorphism on the development of severe perinatal asphyxia.

Methods: We conducted a case-control study of 80 cases of severe perinatal asphyxia and 110 control group. For the genotyping we used polymerase chain reaction (PCR) with further restriction fragments length polymorphism analyses. The differences in comparative groups were assessed by the Pearson chi-square test analyses and Odds Ratio determination.

Results: The incidence of the homozygous DD alleles in the neonates with severe perinatal asphyxia was 33 (41.25%), of the heterozygous ID alleles 37 (46.25%), of the homoygous II alleles 10 (12.50%). The neonates of control group had following alleles: DD - 15 (13.64%), ID - 44 (40.00%), II - 51 (46.36%).

Conclusion: DD gene polymorphism of the neonates is a risk factor for the development of perinatal asphyxia. We suggest using these genetic markers in prognosis of severe perinatal asphyxia in the neonates.

Determinants of lung function in school aged children prematurely born before 32 weeks of gestation
Marie Luce Choukroun1,2, Hala Feghali-Caron1,2, Fabienne Marquant3, Sandrine Vautrat4, Fabienne Nacka5, Valeriane Leroy5, Michel Fayen4,5, 1Lung Function Testing Laboratory, CHU de Bordeaux, Bordeaux, France; 2Department of Pediatrics, CHU de Bordeaux, Bordeaux, France; 3USMR, CHU de Bordeaux, Bordeaux, France; 4INSERM 885, Université Bordeaux, Bordeaux, France; 5INSERM 897, Université Bordeaux, Bordeaux, France

Rationale: Persistent respiratory sequelae have been reported in children prema-
P4312 Infant spirometry at three months after birth in term and preterm infants

Karin Lidberg1, Paraskevi Kosma2, Gunilla Hedlin 2, Charlotte Palme-Kilander2.

Infant spirometry at three months after birth in term and preterm infants P4312 lung abnormalities are likely associated with prior BPD. lung function especially among those who did not received surfactant. Restrictive lung abnormalities are likely associated with prior BPD.

Methods: All the children born with a GA <32 weeks were included (n=444). Their respiratory outcome between 1997 and 2000 were eligible for the study. Their respiratory outcome was evaluated by a respiratory questionnaire and lung function measurements: spirometry, static lung volumes, exercise bronchial responsiveness test, pulmonary diffusing capacity DLCO. Multivariable analysis was used to evaluate the neonatal and childhood determinants of their lung function at school age. The study was approved by the Hospital Ethical Review Committee.

Results: Of the 444 eligible children, 151 (Birth Weight= 135±379 g; GA = 30±1.17 wks) were included: Age= 8±6.0±8.8 yrs, Body Weight= 28±4±6.5 kg, Height= 13±2±8cm. Bronchopulmonary dysplasia BPD occurred in 36.4% of them. At school age 60% had respiratory symptoms. Lung function abnormalities were found in 53.5% of them: obstructive abnormalities with or without distress in 41%, restrictive or mixed abnormalities in 12.5%. Exercise induced bronchial responsiveness was positive in 41%. DLCO was reduced in 15.5%. Prior BPD was associated with restrictive or mixed abnormalities (OR:6.1, CI 95%:1.1- 33.9, p=0.04). Surfactant treatment was protective from lung abnormalities (p<0.03).

Conclusions: Infants born preterm are at risk of impaired lung function especially among those who did not received surfactant. Restrictive lung abnormalities are likely associated with prior BPD.

P4313 Predicting the safety of air travel in ex-preterm infants

Adelaide Witherly1, Andrew Wilson1,6, Mary Sharp1,6, Steven Resnick1,6, Graham Hall1.1 Department of Respiratory Medicine, Princess Margaret Children’s Hospital, Perth, Western Australia, Australia; 2Medical Research, Telethon Institute of Child Health Research, Perth, Western Australia, Australia; 3School of Paediatrics and Child Health, The University of Western Australia, Perth, Western Australia, Australia; 4Department of Neonatal Paediatrics, King Edward Memorial Hospital, Perth, Western Australia, Australia; 5School of Women's and Infant's Health, The University of Western Australia, Perth, Western Australia, Australia.

Background: Hypoxia is reported in preterm neonates during medical air transfer. Predicting in-flight hypoxia in preterm infants is difficult from available data. Aims: Further investigate the response of preterm infants to flight, identify factors that may predict in-flight hypoxia and the need for in-flight oxygen.

Methods: A retrospective review of neonatal and in-flight data of all infants born <37 weeks gestation transferred between 2005-2008. In-flight oxygen was commenced if oxygen saturation decreased to <85% for >2 minutes. The impact of post-menstrual age (PMA), birth weight, duration of ventilatory support and time of flight on oxygen requirements was measured. A total of 37 infants (birth weight ≤ 1500 g, GA <32 weeks) undertaking medical air transfer between 2005-2008 were included. Oxygen requirements and in-flight hypoxia were measured during an intensive RSV season. Twenty percent of both term and preterms < one year were diagnosed with RSV. Significant correlation was found between infants with prior BPD and lower in-flight oxygen requirements. In-flight oxygen was required in 31.5% of infants. Conclusions: Very preterm (GA <32 weeks) but not moderately preterm infants did have impaired expiratory flows compared to term infants. Infection rate was significantly lower in preterms. Follow-up will be performed.

P4314 Outcome of congenital diaphragmatic hernia (CDH) in a non-ECMO unit

Chetan Pandit1 , Karen Walker2 , Robert Halliday3, Rosemary Douglas4, Nadia Badawi5, Dominic Fitzgerald6. 1Respiratory Medicine, The Children’s Hospital at Westmead, Sydney, NSW, Australia; 2Neonatology, The Children’s Hospital at Westmead, Sydney, NSW, Australia; 3Audiology, The Children’s Hospital at Westmead, Sydney, NSW, Australia.

Introduction: CDH management involves gentle ventilation, hypercarbia, INO & delayed surgery. ECMO use is limited & associated with greater neurodevelop- mental sequelae.

Methods: Retrospective review of all CDH neonates presenting to the Children’s Hospital at Westmead over 5 years (01/2005 to 12/2009). Infants were assessed at 1 year using the Bayley Scales of Infant and Toddler Development. Version III. Visual reward orientation audiometry was performed.

Results: Of 37 babies [M=17, referred, 5 (13%) died perioperatively, 6 lost to follow-up & 2 missed developmental review. 30/32 (93%) of the survivors were seen at 1 year and 24/32 (75%) had a neurodevelopmental assessment. Mean GA 37.9 wks (SD ±1.7) & BW 2983 gms (± 722.5). CDH diagnosed: 17 antenatal ultrasound [US] < 22 weeks of gestation, 6 later antenatal US and 14 [44%] postnatally. Median age at surgery was 7 days (range 0 to 55). 8 (21%) had an associated cardiac anomaly [4 had surgery]. Below average outcomes in 2 (8%) infants on cognitive skills & expressive language; 6 (23%) receptive language, 7 (27%) in grossmotor skills & 2 (8%) deficient in fine motor skills. No sen- sorineural hearing deficits. Neither mortality nor abnormal neurodevelopmental outcome were significantly associated with prematurity, gender, time of diagnosis, necrotizing enterocolitis or chronic lung disease.

Conclusion: Mortality rates in a tertiary level non-ECMO unit are comparable with ECMO centres and 1 year neuro-morbidty is low. The outcome from conventional strategies is comparable in the treatement of most CDH patients where ECMO is not available.

P4315 Positive end-expiratory pressure affects the value of intra-abdominal pressure in acute respiratory distress syndrome in newborn with diaphragmatic hernia

Dmytro Dmytriiev1, Kateryna Dmytriieva, Oleksander Nazarchuk2, Konstantyn Bercun1, Anatoly Staradub1, Konstzun Dmytriyiev. Anesthesiology, Vinitsa National Medical University, Vinitsa, Ukraine.

Introduction: To examine the effects of positive end-expiratory pressure (PEEP) on intraabdominal pressure (IAP) acute respiratory distress syndrome (ARDS) in newborn with diaphragmatic hernia.

Methods: Thirty sedated and mechanically ventilated patients with ARDS admitted to a twenty-bed surgical medical ICU were included. All patients were studied with sequentially increasing PEEP (0, 6 and 12 cm H2O) during a PEEP trial. Results: Age was 5±1.7 days, weight was 1770, 44±3120 g. SAPS II was 44±14 and PaO2/FIO2 was 192±53 mmHg. The IAP was 9.2±0.5 mmHg at PEEP 0 (zero end-expiratory pressure, ZEEP), 10.8±0.8 mmHg at PEEP 6 and 13±4±0. mmHg at PEEP 12 (P < 0.05 vs PEEP). In the patients with intra-abdominal hypertension defined as IAP>12 mmHg (n= 15), IAP significantly increased from 15±3±3 mmHg at ZEEP to 20±3±3 mmHg at PEEP 12 (P < 0.01). Whereas in the patients with IAP<12 mmHg (n= 15), IAP did not significantly change from ZEEP to PEEP 12 (8±2 vs 10±3±3 mmHg). In the 13 patients in whom cardiac output was measured, increase in IAP from 0 to 12 cmH2O did not significantly change cardiac output, nor in the 8 out of 15 patients of the high IAP group. The observed effects were similar in both ALI (n=17) and ARDS (n=13) patients.

Conclusions: PEEP is a contributing factor that impacts IAP values. It seems necessary to take into account the level of PEEP whilst interpreting IAP values in patients under mechanical ventilation.
Method: In this trial, totally 88 healthy premature neonates which were just feeding and being prepared to discharge, randomly selected. The neonates first randomly placed in prone or supine position, and 30 min later SpO2 was measured during 30 minutes. Then, the infants turned from prone to supine or from supine to prone, and a repeat set of measurement was made. The collected data was analyzed by utilizing SPSS 11.5 for windows package, using Paired Sample T Test.

Results: 60.9% (53 cases) of neonates were male and 39.1% (35 cases) were female. Their mean birth weight and gestational age were 2330.9 gram (range: 1080-3400) and 34.3 weeks (range: 26-36), respectively. Their mean postnatal age was 4.2 days (range: 1-28). Mean SpO2 of those neonates during 30 min in supine position was significantly higher than prone position (94.5±3.3 Vs 91.8±5.3, P<0.001).

Conclusion: These finding suggest that prone position have not offer any advantage over the supine position in the improvement of arterial oxygenation of healthy premature neonates.

P4317
Association between severe bronchopulmonary dysplasia and serum HGF levels in premature infants during early postnatal life
Isamu Hokuto, Takeshi Arimitsu, Masayuki Miwa, Yohei Matsuzaki, Sadasivam Suresh1.

Background: Severe bronchopulmonary dysplasia (BPD) in very low birth weight infants often poses a therapeutic challenge. Therefore, it is important to make a prognosis and develop a treatment plan as early as possible. Prone position would provide us with objective data in management of CNLD infants and would help us to determine the prognosis. Cumulative frequency curves constructed with the heart rate and oxygen saturations from the data collected on the pulse oximetry channel. The respiratory rate was derived using the Labchart software. We are presenting heart rate, oxyhaemoglobin saturation and respiratory rate profile on 25 premature infants.

Methods: Using an in-house polysomnography system prospective data on respiratory effort during sleep using video camera were collected in a cohort of preterm infants under 31 weeks gestation over a 6-10 hour period continuously. We analyzed the heart rate, oxygen saturations from the data collected on the pulse oximetry channel. The respiratory rate was derived using the Labchart software. We are presenting heart rate, oxyhaemoglobin saturation and respiratory rate profile on 25 premature infants.

Results: The mean heart rate with 3.55th centiles was 155 (129-181). The mean oxyhaemoglobin saturation with 5, 95th centiles was 94.7 (85.9-98.8). The respiratory rate had significant variability between awake and sleep with the range between 34-100/min. The average respiratory rate was in the 50s for this group of infants. Cumulative frequency curves constructed with the heart rate and oxyhaemoglobin data provides us with reference ranges for this specific group of preterm infants.

Conclusion: The description of reference ranges for cardiorespiratory variables would provide us with objective data in management of CNLD infants and ascertaining home oxygen requirement.

P4319
Association between C-reactive protein levels and outcome in acute lung injury in children
Martiijn Bruijn1, Eva Iansen1, Thom Klappwijk1, Johanna van der Lee2, Rick van Rijn3, Job van Woesel1, Albert Bos1. 1Pediatric Intensive Care Unit, 2Department of Pediatric Clinical Epidemiology, Emma Children’s Hospital/Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; 3Department of Radiology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Acute lung injury (ALI) is a life threatening condition affecting both children and adults. High plasma C-reactive protein (CRP) levels are associated with favorable outcome in adults with ALI, suggesting a protective physiological effect of high CRP levels. The association between CRP levels and outcome has not been studied in ALI in children.

Aim: We hypothesized that increased plasma CRP levels are associated with favorable outcome in ALI in children in terms of 28-day mortality and ventilator free days (VFD).

Methods: We performed a historical cohort study in 98 mechanically ventilated children (0-18 years) with ALI. The neonates first admitted to our unit between 2003-2010 were tested for association with mortality and VFD. Clinical parameters and ventilator settings were evaluated for possible confounding.

Results: Fourteen patients (14%) died within 28 days. The median (Q1;Q3) CRP level in non-survivors was 126 mg/L (64;187) compared to 56 mg/L (20;105) in survivors (p=0.01). For every 10 mg/L rise in CRP level, the unadjusted odds for mortality increased 8.7% (95% CI 2.1%-15.8%). Cardiovascular organ failure (COVOF) at any time was the strongest predictor for mortality (OR 30.5-95% CI 6.2-152.5). After adjustment for COVOF, for every 10 mg/L rise in CRP level, the odds for mortality increased 5.0% (95% CI -2.7%-12.6%). Increased CRP levels were not associated with an increased risk of ventilator days (p=0.14). Conclusion: We conclude that increased plasma CRP levels are not associated with favorable outcome in ALI in children. Based on our findings and existing evidence that pathophysiology in ALI in adults and children differ, we suggest future research should take these differences into consideration.

P4320
Long-term results of surgically treated non-small cell lung cancer patients depending on the protocol of preoperative N-staging
Andrey Petrov1,2, Vadim Pischik1,2, Marina Tlostanova1, Rashida Orlova1, Piotr Yaholskys1,2, 1Medical Faculty, St. Petersburg State University, Pulmonary Surgery, City Hospital #2, 2Department of PET, Russian Scientific Centre of Radiology and Surgical Technologies, St. Petersburg, Russian Federation

Preoperative N-staging is one of the most important aspects in management of non-small cell lung cancer (NSCLC) patients because it has a crucial impact on prognosis of patients and helps to choose the optimal treatment plan. The aim of our study was to evaluate the long-term results of operated NSCLC patients with different preoperative N-staging protocols. Material and methods: 319 patients with resectable NSCLC were operated in our center in 2003-2008. In group 1 all patients preoperatively underwent mediastinoscopy in addition to non-invasive staging procedures (CT and PET), whereas in group 2 N-staging protocol included only CT and PET. Final TNM stage was verified based on intraoperative findings including mediastinal lymph nodes dissection. Long-term survival was assessed by Kaplan-Meier method.

Results: In group 1 significantly less unforeseen N2 were revealed during intraoperative lymph nodes dissection in comparison to group 2 (10% vs 27%, respectively, p<0.05), the rate of uncertain resections was also lower in group 1 than in group 2 (5% vs 14%, respectively, p<0.05). Analysis of long-term results showed better survival in group 1 than in group 2 (5-yr survival 61% vs 43%, respectively, p<0.05). This difference was more prominent in patients with central NSCLC (5-yr survival 65% vs 39%, respectively, p<0.01).

Conclusion: Our findings suggest that including mediastinoscopy in preoperative N-staging protocol of potentially operable NSCLC patients improves the selection of surgical candidates by excluding patients with extended disease, that results in better long-term survival of operated patients.

P4321
The evaluation of surgical results in pT0-pT1 non-small cell lung carcinoma after induction therapy
Soner Gursuey1, Ahmet Ucvelt1, Ahmet Erbaydu1, Seyda Okay1, Hakan Koparal1. 1Thoracic Surgery, Izmir Dr. Suat Sen Chest Disease and Thoracic Surgery Training Hospital, Izmir, Turkey; 2Chest Diseases, Izmir Dr. Suat Sen Chest Disease and Thoracic Surgery Training Hospital, Izmir, Turkey

There are good results in locally advanced non-small cell lung carcinoma (NSCLC)
surgically treated after induction therapy. We aimed to detect the role of PET-CT on recurrence, survival and preoperative assessment in surgically treated pT0N0M0 after induction therapy.

Of the patients, stage IIIb, IIB and IIIB NSCLC, undergone pulmonary resection after neoadjuvant chemotherapy or radiotherapy, pT0N0 and pT1N0. The mean age was 59.2 years, and the mean follow up was 34.8 months with mean survival time and 5-year survival rate were 90.8 months and 86.3%, 62.6 months and 53.7% (p<0.1), respectively. There were one (4%) local recurrence in T0 and eight (27.6%) local plus distant in T1 (p<0.05). 18 patients preoperatively assessed with PET-CT, the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 78%, 56%, 64% and 71%. NPV in T0 and PPV in T1 were 100%. The accuracy in T0 and T1 were 56% and 78% (p<0.3).

The survival of the pT0N0 and pT1N0 NSCLC who had surgical resection after induction therapy is similar with those had resection without induction. The success of PET-CT to reveal pT0, with no live tumor cell, and pT1 preoperatively, is lower.

P4322
Inspiratory capacity is a new preoperative risk predictor in the patients with lung cancer undergoing surgical resection

Naoumita Hashimoto1, Masaki Matsui2, Noriaki Usami3, Kohei Yokoi3, Yoshinori Hasegawa1, 1Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan; 2Division of Thoracic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

Since surgical complications implicate an enormous economic burden as a result of patient’s unexpected treatments and prolonged postoperative stay (PPS), we face an urgent need to establish preoperative pulmonary assessment to prevent pulmonary complications. We retrospectively evaluated 421 cases of the patients who underwent major lung resection in Nagoya University hospital to determine the new predictor to elucidate the risk for PPS. Chronic obstructive lung disease (COPD), irrespective of the degree of symptoms, was confirmed to be one of the most important risk factors in PPS, for patients with major lung resection. Since mounting evidences suggested that the disease severity of COPD might be strongly associated with inspiratory capacity (IC), we evaluated whether IC, measured by spirometry, could be applied to elucidate the risk for PPS in the patients. The multivariate analysis demonstrated that%IC was one of the most critical independent risk predictors for PPS. Our data suggested that%IC might be an additional risk predictor for PPS in patients undergoing major lung resection, irrespective of COPD status.

P4323
The clinical importance of preoperative inspiratory spirometry value in lung resections

Seygo Ozalevl1, Duygu Ilgin1, Hasan Eroz2, Ismail Agababaoglu2, 1Thoracic Surgery, Dokuz Eylul University, Izmir, Inciralti, Turkey; 2Department of Thoracic Surgery, Dokuz Eylul University, Izmir, Inciralti, Turkey

Aim: It has been aimed at investigating the relationship between the value determined with incentive spirometry (IS), which is used frequently to improve lung expansion after thoracic surgery, and clinical symptoms, pulmonary functions, and exercise capacity data; and if there is a relationship between these, discussing the importance and applicability of IS value during clinical follow up in patients with lung resection candidates.

Material-method: Twenty-two patients (6F, 16M; mean age 60.82±8.28 years) diagnosed with lung cancer (50% staged, 31.8% stageII-B) and followed with lung resection indication were assessed. The clinical characteristics and respiratory symptoms were asked. Maximal IS value (ml) was measured with IS. Pulmonary function test and 6-minute walking test were done.

Results: The mean maximal IS, FEV1%, inspiratory capacity (IC), Pimax%, Pmax%, and GMWD values were 3047±831.49ml, 76.71±15.74, 2.25±0.42, 63.53±13.67, 58.12±23.46, and 480.00±94.39 ml/min, respectively. There were effort dyspnea (31.8%), fatigue (40.9%), secretion (22.7%), cough (22.7%), and chest pain (4.5%) in patients. It was determined that maximal IS value was correlated with cough symptom (rho=0.43, p<0.05), FVC (rho=0.48, p<0.05), FEV1 (rho=0.63, p<0.001), IC (rho=0.49, p<0.05), and Pmax (rho=0.71, p<0.002) values.

Conclusion: IS value represents pulmonary functions individual of demographichal and functional characteristics of patients. Especially, due to the relationship of IS value with FEV1%, IC, and Pmax values, our results suggest that IS value may give information on the effective cough ability and thus IS value might be used during clinical follow up and routine care of patients with lung resection.

P4324
The role of PET/CT in lung cancer staging

Konkmat Barci1, Serife Tabi Liman1, Salih Topcu1, Aykut Elicora1, Asli Gul Akgul1, Seymur Sahin Mehmetoglu1, Ahmet Ilgazici1, 1Thoracic Surgery, Kocaeli University Medical Faculty, Kocaeli, Turkey; 2Chest Disease, Kocaeli University Medical Faculty, Kocaeli, Turkey

Routine preoperative examinations should contain PET/CT for proper staging.
Method: Our clinic’s experience in the surgery of tuberculosis is limited by the existence of an outside compartment, specialized in these types of surgeries. Between 2001–2010 we had 196 cases with postoperative diagnosis of TB. From these 196 cases we selected only 64 cases of tuberculosis, that had imagistic and clinical aspect of a lung malignant tumor.

All of these patients were admitted with a symptomaticology unlike lung TB – weight loss, fatigue, hemoptysis, no fever, no previous infections or contact with TB patients, negative bronchoscopy, sputum cultures and Quantiferon test (3 patients). The CT images showed round tumoral formations, with poor limits and pathological mediastinal lymph nodes.

Postoperative outcomes: The postoperative evolution was very good with discharge of the patient in 5 days and with medical treatment.

P4328

The comparison of exercise test in patients with lung resection candidates

Sergiu Ozaliev1, Doygu Egin2, Hasan Erozu2, Aydin Sanli3, Can Sevcan3, Nevzat Odedmir2.

1School of Physical Therapy and Rehabilitation, Dokuz Eylul University, Izmir, Inciralti, Turkey; 2Department of Thoracic Surgery, Dokuz Eylul University, Izmir, Inciralti, Turkey; 3Department of Chest Disease, Dokuz Eylul University, Izmir, Inciralti, Turkey

Aim: It has been aimed at investigating the consistency of the maximal cardiorespiratory exercise test (CPET), 6-minute walking test (6MWT), and stair climbing test (SCT) results with each other and discussing the applicability of these submaximal field tests in patients with lung resection surgery indication.

Material-method: The maximal cycle ergometry, 6MWT, and SCT tests were done in 22 lung cancer patients (6F, 16M) followed with lung resection surgery indication. maxVO2 value was calculated indirectly using indirect formulas for 6MWT and SCT. Peripheral oxygen saturation (SpO2) and heart rate values were recorded using pulse oximetry during test.

Results: The mean maxVO2 values were 16.07±2.70 ml/kg/min (for CPET), 24.44±4.09 ml/kg/min (for SCT), and 18.38±2.83 ml/kg/min (for 6MWT). It was determined that heart rate increased (heart rate difference; for CPET=38.20±14.67, 6MWT=20.48±9.06, SCT=48±11.56, p<0.05) and SpO2 reduced (SpO2 difference; for SCT=3.14±1.56 and 6MWT=1.48±2.52 % with p<0.05, CPET=3.95±10.30, p=0.10) after these tests. It was found that CPET maxVO2 was correlated with 6MWT and SCT maxVO2 (between CPET and SCT, r=0.59, p=0.01; between CPET and 6MWT, r=0.53, p=0.02). In addition, it was determined that there were correlations only between CPET and SCT in respect to load and work values (r=0.70, p<0.01). 6MWT can be used related to lower hemodynamical stres level in conditions the application of CPET and SCT are not possible.

P4329

The effect of neoadjuvant chemoradiotherapy on airway colonization and post operative respiratory complications in the patients undergoing esophagectomy for esophageal cancer

Reza Bagheri, Mohammad Taghi Rajabi. Thoracic Surgery, Mashhad University of Medical Science, Mashhad, Islamic Republic of Iran

Background: Different treatments are performed for esophageal cancer, but surgery is still the base of treatment. Respiratory complication is the important postoperative complications of esophageal cancer.

Methods: In this study 40 patients who were candidates for surgery of esophageal cancer were placed into two groups of with or without neoadjuvant therapy. Before surgery, they underwent bronchoscopy and bronchoalveolar lavage. The samples were analyzed for airway colonization and then the patients underwent the surgery and were postoperatively evaluated in respiratory complications and the effects of preoperative neoadjuvant therapy.

Results: M/F=23/17 and mean age was 61 years. 22 cases had cancer in the middle and 18 in the lower part of the esophagus. 25 cases had SCC and 15 had ACC. In evaluation, no organism was found in 9 cases (22.5%) and positive cases of microbial culture was found in 31 cases (77.5%). Significant relation was observed between airway positive microbial colonization and neoadjuvant therapy but no significant relation was found between neoadjuvant therapy and major respiratory complications such as pneumonia, ARDS. There was significant relation between airway positive microbial coloni zation and neoadjuvant therapy but no significant relation was found between length of hospitalization in ICU and receiving neoadjuvant therapy. Two deaths were reported due to myocardial infarction in the postoperative days. There was no death due to respiratory complications.

Conclusion: Neoadjuvant therapy can used safe and it does not cause postoperative major pulmonary complications and related mortality.

P4330

The comparison of the findings of preoperative PET-CT and surgical pathology in patients with non-squamous cell lung cancer those with and without induction therapy

Ahmet Uçyırcı1, Soner Gürsoy1, Ahmet Eriyazıcı2, Seyda Ökaya2, Hakan Koparal2, Zekiye ADinc2, 1Department of Thoracic Surgery, İzmir Dr. Şükrü Serçe Disease and Thoracic Surgery Training Hospital, İzmir, Turkey; 2Department of Thoracic Surgery, İzmir Dr. Şükrü Serçe Disease and Thoracic Surgery Training Hospital, İzmir, Turkey; 3Department of Nuclear Medicine, İzmir Dr. Şükrü Serçe Disease and Thoracic Surgery Training Hospital, İzmir, Turkey.

Aim: To compare the diagnostic accuracy of PET-CT in defining the pathological response to chemotherapy/radiotherapy and compare with patients operated without induction therapy in non-small cell lung carcinoma (NSCLC).

Patients, performed lung and mediastinal lymph node dissection for NSCLC, after a staging procedure with PET/CT. In first group, patients had induction therapy for a stage IIIA and IIIB disease, before PET-CT. In the second group, patients had had induction therapy for a stage IIIB disease, before PET-CT.

PET-CT has been widely used to evaluate the response to induction therapy in lung cancer. We aimed to reveal the accuracy of PET-CT in defining the pathological response to chemotherapy/radiotherapy and compare with patients operated without induction therapy in non-small cell lung carcinoma (NSCLC).

Patients, performed lung and mediastinal lymph node dissection for NSCLC, after a staging procedure with PET/CT. In the first group, patients had induction therapy for a stage IIIA and IIIB disease, before PET-CT.
second, patients had surgical resection after PET-CT evaluation. The postoperative histopathological and preoperative PET-CT findings were compared. There were 58 patients in group 1 and 59 patients in group 2. The sensitivity, positive predictive value (PPV) and accuracy of PET-CT for primary tumor were 92%, 92%, 86% in group 1 and 99%, 100%, 99% in group 2. In group 1, the specificity and negative predictive value (NPV) were 50% and 50%. For N2 disease; the sensitivity, specificity, PPV, NPV and accuracy were 44%, 88%, 58%, 80%, 76% in group 1 and 43%, 89%, 16%, 97%, 87% in group 2. The sensitivity, PPV and accuracy of primary tumor and NPV and accuracy of N2 disease were significantly lower at group 1. In patients with NSCLC those had had induction therapy, the sensitivity of PET-CT should be examined better than the patients those had not had preoperative therapy and it should not be avoided to perform invasive staging procedures. The positivity of lymph nodes in PET-CT should be confirmed by histopathology. When PET-CT findings after induction therapy is used, NPV and accuracy is lower.

A case of pulmonary sequestration behaves as cyst hydatid
Aslı Gür Akılgalı1, Mahip Kanko2, Salih Topcu2, Aykut Elçiöra1, Serife Tuba Liman3, Seymur Salih Mehmetoğlu1, Hasan Tahsin Sarısoy4, Seytav Gümüstas5.
1Thoracic Surgery, Kocaeli University, Kocaeli, Turkey; 2Cardiovasculary Surgery, Kocaeli University, Kocaeli, Turkey; 3Radiodiagnostics, Kocaeli University, Kocaeli, Turkey

Pulmonary sequestration is an uncommon disease with non-functioning pulmonary tissue and anomalous systemic blood supply. Diagnosis depends on identification of abnormal systemic vessels. We report a case who went on thoracotomy due to cyst hydatid and the sequestration was diagnosed during the operation.

Case: A 68-year-old man complaining of a non-productive cough, stomach ache, nausea and vomiting, admitted to our clinic. He was diagnosed with hepatic cyst hydatid and was treated with surgery one year ago. Chest x-ray showed a prominence at aortic arch. Chest CT imaging was revealed a paraaortic lesion with suspicion about its density of cystic or solid which was located posteriorly.

This was taught again a hydatid cyst suitable with his medical history and an operation was planned. Left thoracotomy was performed. During the operation the lesion was detected as a sequestration. By histopathological study the lesion was confirmed to be a sequestration. In his 4th. month follow-up the patient remains asymptomatic with normal radiography results. Aberrant feeding vessels cannot always be demonstrated by conventional CT. Moreover, volumetric helical imaging allows three dimensional reconstruction of data, may be useful in the demonstration and characterization of the lesions and also showing vascular structures. Pulmonary sequestration must be in mind for differential diagnosis of pulmonary lesions especially adjacent to vascular structures.

P4332
Abcessus pulmonum: Unexpected outcome of surgical treatment; a case presentation
Vladimir Mirošljevic1, Aleksandra Vukicevic2, Ljiljana Todorovic1, Olivera Ljubojlić1, Ana Vranješ2, Nataša Banjić2, Duško Kostić1, Dragan Jovanović1, Nenad Savić2
1Thoracic Surgery, Kocaeli University, Kocaeli, Turkey; 2Pediatric Department, General Hospital “Saint Apostle Luka”, Doboj, Bosnia and Herzegovina

This paper presents a case of 12-year-old girl, who was admitted to the pulmonology department of the Clinic for children’s illness KC Banja Luka in February 2010th year, because of the x-ray verified large tumor change in the left hemithorax. Insight into previous medical documentation, patient previously had two surgeries for a congenital deformity of the thoracolumbar spine. After admission in our department, in a differential diagnosis, we have done chest CT, GI passage, the serology of Echinococcus granulosus, ultrasonography and laboratory analyses, after which the patient was referred to the surgical treatment at the Institute for Mother and child in New Belgrade.

During the surgery a apscess cavity filled with green colored compress was found, which had been present for 2.5 years since spine surgery.

P4333
Giant mediastinal atypical carcinoid tumor
Recep Demirhan, Hatice Eyigirt, Altug Kosar, Mehmet Tukei.
Thoracic Surgery, Dr. Lütfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey

Fifty-one years old male with shortness of breath increased by effort since one year. The patient was smoking 30 packs of cigarette per year. Inspiration sounds were decreased on the left hemithorax. Pulmonary function test results were; FEV1: 2.21 L (60%), FVC: 3.32 L (70%), PIF: 3.71 L (42%), FEV1/FVC: 68.6%. The computerized thorax tomography, showed a 155x127 mm soft tissue mass on the left anterior mediastinal region, pressing vascular structures, and heart, and causing atelectasis on the upper lobe. Incisional biopsy was taken from the mass via mediastinotomy at a different hospital; the pathology result was malignant diffuse lymphoma. PET-CT was applied for staging. 2r mediastinum hypermetabolic lymph node station, with 14.5 mm diameter was detected (SUV max: 5.4). The mass SUV max: was 8.7. Chemotherapy was applied to the patient with diagnose of lymphoma. However, due to lack of regression of mass, biopsy slides were reexamined; the diagnosis was changed to be carcinoid tumor. The mass was decided to be surgically removed by median sternotomy. The mass was quite vascular, and had tight adhesions between the lung and pericardium. The result of frozen section of the mass was reported to be atypical carcinoid tumor. The mass was removed instead of excised pericardium. The mass weight was 1300gr, size was 17.5x15x9.5 cm. No tumor was detected within surgical margins. Chromogranin, Synaptotizin, CK, and CD 56 was positive at the immunohistochemical panel. Microscopic findings were confirmed atypical carcinoid tumor. In conclusion, mediastinal carcinoid tumors are very rare. Their origin of tumor is difficult to determine. Surgery is the current treatment method.

P4334
Robotic-assisted thymectomy by da Vinci II versus sternotomy in the surgical treatment of non thymomatous myasthenia gravis
Stéphane Renaud1, Mathilde Renaud2, Nicolet Canelos1, Marie Fleury2, Jérôme De Seze3, Christine Tranchant2, Gilbert Massard1.
1Pulmonology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain; 2Neurology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, France

Introduction: Thymectomy in myasthenia gravis is controversial. Remission rate 5 years after surgery in literature varies from 13 to 51%. Sternotomy is the standard technique, not acceptable because of possible complications. Our objective was to demonstrate that the robot-assisted technique is at least as efficient and leaves less scars than sternotomy.

Methods: We retrospectively reviewed data of 30 patients with myasthenia gravis operated on in our center from January 1998 to December 2009. Two groups were formed: group 1 corresponding to patients who received a sternotomy, group 2 patients the robotic-assisted technique. Hospital stay, pain on D1, 1 year improve-

Results: We identified 13 women and 7 men. The mean age was 31 years old. The mean delay before surgery was 24.8 m. Group 1 consisted of 15 patients, group 2 of 5. Complete remission rate at 1 year was 5%. Surgery decreased the frequency of relapses equally in the 2 groups. Hospitalization stay and pain on D1 in group 2 were significantly lower than those in group 1 (p<0.04, p<0.001). Postoperative improvement was not significantly different between the 2 groups.

Conclusion: Results at 1 year of the 2 techniques are fully comparable. Robot provides additional benefits: minimal esthetic sequelae, less parietal morbidity, shorter hospital stays. Our complete remission rate, lower than those in the liter-

ate, must take into account the early nature of these results. The surgical robot appears to be a promising technique and should facilitate the early management of these patients.

P4335
Impact of neoadjuvant therapy on tumor resectability and survival of patients with locally advanced non-small cell lung cancer
Raquel Pascual Cascon1, Samantha Aso González1, Mariana Muñoz Esquerre1, Ignacio Martínez Ballarin1, Susana Padrónes Saiz1, Ivan Maca-Videira2, Francisco Rivas Doyague3, Felipe Cardenal Alemany1, Maria Dolores Arnau Fernandez4, Sergio Morchon Ramos5, Jordí Dorca Sargatal1.
1Pulmonology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain; 2Thoracic Surgery, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain; 3Medical Oncology, Institut Català d’Oncologia, Barcelona, Hospital de Llobregat, Spain; 4Radiotherapy Oncology, Institut Català d’Oncologia, Hospital de Llobregat, Barcelona, Spain; 5Preventive Medicine, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Barcelona, Spain

Background and aim: Surgery is the treatment of choice in early stage non small
cell lung cancer (NSCLC). It is also used in some cases of locally advanced tumors, but with a low cure rate. Therefore, preoperative treatment is seeking to improve survival in these patients. The aim of this study was to evaluate tumor resectability and survival in patients with locally advanced stage (IIA and IIIB) NSCLC treated with chemotherapy (CT) and chemoradiation therapy (CT-RT) neoadjuvant

Methods: This was a retrospective study that evaluated patients with locally advanced NSCLC in a university hospital during 2000-2006, that received induction therapy. The collected variables were anthropometric values, histology, stage of the tumor, neoadjuvant treatment and therapeutic response. Kaplan-Meier curve was used to evaluate survival and analysis of variance to compare values among groups.

Results: 32 patients were included; 9 subjects (28%) were diagnosed with stage IIA and 23 (72%) stage IIIB, being the IIIB the most common indication for induction therapy. All patients were treated with CT, showing a treatment response in 80% of cases and only 7 were also required RT. Resection was indicated in 31 patients and only in 6 subjects exploratory thoracotomy was performed, seeing a downstaging in 46.9% of all the cases. Overall 5 year survival was 27.8% with a median of 52.9 months (95% CI 38.1-67.6). This survival is dependent on the response to neoadjuvant.

Conclusions: Neoadjuvant cancer reduces tumor size resulting in a downstaging and improving the resectability of locally advanced NSCLC. It could be a viable therapeutic option to improve survival of these patients.

P4336
Surgical treatment of combination of tuberculosis and pulmonary echinococcosis
Sunnatilla Abakasimov, Tulkun Kariev, Akram Igashew. Thoracic Surgery Department, National Centre of Phthisiology and Pulmonology, Tashkent, Uzbekistan

Results of surgical treatment of combination of TB and pulmonary echinococcosis were studied in 19 patients (males-11, females - 8) in ages 7-47 years old. Fibrous-cavernous TB was diagnosed in 4, pulmonary tuberculosis in 8, focal in 3, TB of intrathoracic lymph nodes in 1. In 9 patients echinococcus cysts located within the zone of tubercular affect, in 10 in other lobes of lung, in 9 on the left. Cyst dimensions were 2 to 9 cm in diameter. In 4 with location of echinococcus cyst in the zone of tubercular affect were operated - segmental resection was performed in 1, lobectomy in 2, lobectomy and thoracotomy in 1. In 7 who had TB and echinococcus cyst in different lobes of lung, single-stage segmental resection and echinococcectomy was performed in 5, lobectomy and echinococcectomy in 1, combined resection and echinococcectomy in 1. After effective chemotherapy and repair of pulmonary destruction, an organ-saving operation – echinococcectomy was performed in 8 patients with firstly diagnosed fibrous-cavernous tuberculosis (1), infiltrative (3), focal (3), intrathoracic lymph node tuberculosis (1) and pulmonary TB. Good clinical effect was achieved in all 19 observed patients.

Conclusion: Partial resections are surgical indication at TB and echinococcosis both located in one lobe of lung, in different lung lobes – partial resection on account of TB and echinococcosis are the surgical indication. At firstly found TB and echinococcosis cyst, an organ-saving operation – echinococcectomy is necessary after effective chemotherapy and repair of pulmonary destruction. These operations are highly effective and heal patients from TB and pulmonary echinococcosis.

P4337
Pulmonary hydatic cyst: Analysis of 1024 cases
Reza Bagheri, Seied Ziaoolah Haghi. Thoracic Surgery, Mashhad University of Medical Science, Mashhad, Islamic Republic of Iran

Objective: Pulmonary hydatic cyst is a parasitic disease and health care problem in developing countries. In this study we evaluated treatment outcomes of pulmonary hydatid disease in our Department.

Methods: Patients admitted with pulmonary hydatid cyst from 1980 to 2010 were analyzed in this study and demographic data, size and number of cysts, diagnostic methods, type of operations, outcomes and rate of recurrence were statistically analyzed.

Results: In 1024 patients, mean age was (30.6 ±16.1) years and M/F=1.09. The most common symptom was cough (55.1%). Only 1% was asymptomatic. 53.8% had right side involvement, 40% had left side involvement and 6.2% had bilateral disease. Inferior lobe was the most common involved lobe. The cyst was intact in 53% (52.6%) patients and other, were complicated or perforated. The most common surgical technique was removing the cyst membrane without resection of pericyst and closure of orifice of airways (67.2%). The cyst was enucleated in 21.2% and par enchyinal resection was performed in 8.4% of patients. The cyst was intact in 539 (52.6%) patients and other, were complicated or perforated. The most common surgical technique was removing the cyst membrane without manipulation of pericyst and closure of small airways. Pulmonary resection should be reserved for complicated forms of disease.

Conclusion: The best treatment for pulmonary hydatic cyst disease is surgery with low mortality and morbidity. The most common and acceptable treatment is extraction of cyst membrane without manipulation of pericyst and closure of small airways. Pulmonary resection should be reserved for complicated forms of disease.

P4338
Surgery of relapsed hydatid disease of lungs
Davlat Maksumesov1, Bahrom Amanov2, Rustam Hayaluiev12. 1Department of Surgery of Lungs and Mediastinum, RSCS Named after Acad. V.Vahidov, Tashkent, Uzbekistan; 2Hospital Surgery Kafedra, Tashkent Medical Academy, Tashkent, Uzbekistan

The surgical treatment of hydatid disease of lungs is unique and the most radical, however and after operations the development of relapses is possible. On the data of the literature the relapse of hydatid disease after surgical treatment does not tend to decrease and changes from 3% up to 54%.

In the department of surgery of lungs and mediastinum Republican Specialized Center of Surgery named after acad. V.Valiyev from 1975 to 2009 years there were on treatment 2600 patients with hydatid disease of lungs. From 2600 operated patients concerning the various forms of hydatid disease of lungs relapse of disease from 1 to 7 years we observed in 160 (6.5%) patients. From them men - 93 (58%), women - 67 - (41.9%). The age of the patients varied from 10 to 70 years. From 160 patients 130 (81.25%) underwent operations, not operated 30 (18.7%) - the reason was disseminated process, wide distribution of hydatid cysts. 152 (95%) patients underwent performed organizing operation, 8 (5%) patients underwent resection.

In the postoperative period albedozam was administered in a dose 10-12 mg/kg/day, quantity of courses depended on the form of a defect.

P4339
Transthoracic approach in adult Morgagni hernias: 30 years experience
Seerpil Sevinc, Kenan Can Ceylan, Aliyet Ucver, Ozan Usluer, Saban Unsal, Seyda Ors Kaya. Thoracic Surgery, Izmir Dr. SS Chest Diseases and Thoracic Surgery Education and Research Hospital, Izmir, Turkey

Background: Morgagni hernia is a rare congenital disorder. Numerous approaches have been described and, particularly the significance of laparotomy has been emphasized as an important operative technique.

Aims and objectives: To present our experience on adult patients with Morgagni hernia operated on via transthoracic approach in our department.

Methods: Between 1980 and 2010, 33 patients with Morgagni hernia were operated. Twenty-two of them were male and 11 were female. Their age ranged from 17 to 77 years (mean 53.17). There were 17 females. Chest x-rays, thorax computed tomography, magnetic resonance imaging, barium enema, and pneumoperitoneum were used as diagnostic utilities.

Thoracotomy was performed in all cases. In only one case, laparotomy was applied in addition to thoracotomy.

Results: Twenty-five hernias (76%) were right-sided and eight (24%) were left-sided. Hernia sac was present in all cases. Exploration revealed only omentum in women (n=11 - 67.5%). The age of the patients varied from 10 to 67 years (mean 53.17). There were three patients (9%), stomach, colon and omentum in two patients (6%), only small bowel in two patients (6%), stomach, and omentum in one patient (3%), and only stomach in one patient (3%). The reason for the hernia formation was no complications and no mortalities.

There was no recurrence or symptoms related to the operation. The mean follow-up was 11 years.

Conclusions: We advocate transthoracic approach for surgical exposure as it provides wide exposure and repair of Morgagni hernia.

P4340
Delayed epidemic peak of pandemic influenza A (H1N1-2009) among hospital workers: The association between hand hygiene behavior and the consumption of disposable hand paper
Hiroo Wada, Kojiro Honda, Masuo Nakamura, Hajime Goto, Shin Kawai. School of Medicine, Kyorin University, Tokyo, Japan

Introduction: Health care workers should wash their hand in the season of influenza virus infection. Since the frequent hand-washing behavior would result in the increased consumption in the disposable hand paper, the association firstly between the campaign by infection control team (ICT) and the consumption of disposable hand papers was investigated, and, then, that between the consumption and the number of patients with influenza-like illness (ILI) in the season of pandemic influenza H1N1-pnd 2009.

Result & discussion: ICT had given 6 alerting lectures and delivered 5 notices to all of the hospital workers prior to the pandemic to encourage them for the frequent hand hygiene. As a probable result, the consumption of paper towel increased by 43% for three months from September to November. In parallel with the epidemiologic trend of the whole Japan, among 8,324 outpatients in total who were diagnosed with ILI in the observed period, 33% of them visited our hospital at October, forming a peak through the term. On the other hand, interestingly speaking, 208 hospital staffs suffered ILI in the season, while they formed a small peak at December, and significantly later than that of the outpatient in October (P<0.001).

433. Influenza A (H1N1): lessons after the epidemic
P4341

**Pneumonia and pandemic influenza virus A (H1N1)/09. Immediate and remote respiratory effects**

Alexey Krivonogov1, Igor Leshchenko2, Zinaida Bobyleva1,2. 1. Pulmonology, New Hospital, Ekaterinburg, Russian Federation; 2. Pulmonology, Ural State Medical Academy, Ekaterinburg, Russian Federation

**Aim:** To assess the clinical presentation, treatment outcomes and long-term results for patients with community acquired pneumonia (CAP) during a Virus A (H1N1)/09 in 2009-2010

**Methods:** The study includes 250 cases of CAP, which developed in patients infected with H1N1/09 of them men 54.8%. The average age of 45.0 years. Medication consisted of oseltamivir dose to oral 75-150 mg twice daily and cephalosporins III + macrolides II or respiratory fluoroquinolones. After the end of appropriate treatment based on changes in the lungs according to high resolution CT (HRCT) was administered N-acetylcysteine (NAC) dose to oral 600 mg twice daily (n=91) for 92.0% (95% CI 86.2-97.7) days. Assessments included clinical symptoms, co-morbidity, SpO2, laboratory tests, and X-raying.

**Results:** The median period of hospitalization was 15.2 days. The median SpO2 during hospitalization was 97.9%. After hospital treatment 94.2% 76.5% of patients had a 2-side lung. The fatality rate was 10.4%. SYRS was diagnosed in 49.6% of patients (fatality rate was 1.6%), severe sepsis and septic shock in 27.6% of patients (fatality rate was 34.8%). Fatality rate in patients with obesity was 30.0% with COPD 16.3%. X-ray changes after hospitalization were 82.4% of patients, of whom 56.6% - infiltration of the lung tissue. After treatment with NAC X-ray of the variation persisted in 57% of patients, of whom 7.0% infiltration of lung tissue and 36.9% - the picture “mule”

**Conclusion:** CAP during an epidemiologic outbreak of. Influenza A/H1N1/09 characterized by severe, requires intensive care and long-term observation.

P4342

**H1N1 influenza – A second wave? Experience from the large teaching hospital in the UK**

Dhirve Parikh1, Judith Brebner2, Chirag Dave2. 1. Respiratory Medicine and Critical Care, Heartlands Hospital, Heart of England NHS Foundation Trust; Birmingham, West Midlands, UK; 2. Respiratory Medicine, Heartlands Hospital, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

**Introduction:** The new H1N1 influenza (pH1N1) virus largely ran its course by August 2010 as the WHO declared the pandemic to be over, fortunately without causing as much devastation as provisionally predicted. However the impact of the outbreak on our healthcare system was considerable. In the post-pandemic period, although the rates of pH1N1 have been reported to be lower the risk of severe illness caused by pH1N1 remains. This epidemiological study reflects our experience in a large teaching hospital of the significant morbidity and mortality associated with admission to hospital with H1N1 influenza during the recent the season.

**Methods:** We retrospectively analysed the electronic records for all patients admitted with H1N1 infection between 1st November 2010 and 1st January 2011 to identify patient demographics, length of stay, co-morbidity and outcome.

**Results:** 280 patients were identified (mean age 39.5) with an average length of stay of 6.35 days; mortality 4%. A third had no co-morbidities. Overall 37 (13.2%) of patients required respiratory support (18 intubated, 19 NIV/CPAP). This is comparable to the pandemic of 2009 when 10–30% of laboratory confirmed cases had TLoC≤85%, 42% were hypoxic after 6 Minute Walking Test (6MWT).

**Conclusion:** After a severe pandemic due to H1N1 influenza, one third of the patients had the LF and HRQoL affected. Patients who required MV had greater impairment in LF and in the HRQoL.

P4345

**RNA interference against influenza A (H1N1) virus**

Yang Li1, Cheng-Yuan Ma2, Wei Li1, Ming-Yao Tian3, Shucheng Hua1, Yang Li1, Cheng-Yuan Ma2, Wei Li1, Ming-Yao Tian3, Shucheng Hua1, Ming-Yao Tian3, Shucheng Hua1, Ming-Yao Tian3, Shucheng Hua1, Meng-Wen Yu1, Guang-Dong Chen1,2,3, Raul H. Sanores1, Amaya Amaya Bermudez, Carlos Espinosa de los Monteros, Raúl H. Sanores, Alejandra Velazquez Montero, Luis Torre Bouscoulit, Alejandra Ramirez-Venegas, Influenza Ward, National Institute of Respiratory Disease, Mexico City, DF, Mexico

**Aim:** To describe early abnormalities in LF and QoL of patients with influenza A (H1N1)/09 in 2009.

**Methods:** Clinical characteristics, and laboratory samples at the arrival to the emergency room were recorded in 135 patients with H1N1 influenza moderate to severe pneumonia. LF and health related QoL questionnaires (HRQoL) were measured after two months of hospitalization. All subjects had no clinical antecedent of respiratory disability.

**Results:** Mean age was 40±11 years, 64% were males. Kyri Index (KI) was 24±5.5, the APACHE score was 11±5.3, 30% required mechanical ventilation (MV). 35% had FEV1/FVC <0.70 or >0.85, 31% had PaO2 <60 mmHg; 33% had TLoC≤85%, 42% were hypoxic after 6 Minute Walking Test (6MWT). Four Short-Form 36 (SF-36) domains had ≤70 score and 40% had a Saint George Respiratory Questionnaire (SGRQ) >30 points; 36% had in the SF-36 physical limitation domain (PLSF-36) a score ≤50; Those with MV had more affection in LF in comparison with those without MV (PVC 96±16 vs 104±16; p<0.05). FEV1/FVC 84±6 vs 81±7; TLoC≤50±22 vs 66±21; 6MWT 431±127 vs 508±97 meters; p<0.05. The HRQoL was worse in MV vs no MV [PLSF-36 37.5 (0.81) vs 100 (50-100), p<0.05]. KL correlated with TLoC≤50 (r=0.30), P=0.003; CURB-65 with TLoC≤50 (r=0.20), p<0.04. PLSF-36 correlated with TLoC≤50 (r=0.42), KI (r=0.27) and TLoC≤50 (r=0.21).

**Conclusion:** After a severe pneumonia due to H1N1 influenza, one third of the patients had the LF and HRQoL affected. Patients who required MV had greater impairment in LF and in the HRQoL.
P4346 Clinical features and outcomes of patients hospitalized with influenza A virus (H1N1) infection in a hospital in the south of Spain

The presenting symptoms were fever (89.2%), cough (92%), dyspnea (65.5%), digestive problems (26.9%), myalgia and headache (53%). 52.2% had community acquired pneumonia on admission. Major complications during hospitalization were (15.6%): respiratory insufficiency (50%), Acute Respiratory Distress Syndrome (9%), pneumonia (3.3%), pleural effusion (1.1%) and multi-system organ failure (3.4%).

Conclusions: Patients hospitalized for H1N1 infection are mainly middle-aged. Pneumonia and/or decompensate co-morbidities were the main causes of hospitalization. The most common risk factor was the chronic lung disease.

P4347 The changing distribution pattern of H1N1 infection in adults in 2010-2011

Matthew Harris, Suzanne Shuttleworth, Sebastien Ellis, Christopher Taylor, Benjamin Marshall, Aye Aye Lwin. Respiratory Medicine, Southampton General Hospital, Southampton, Hampshire, United Kingdom

Background: Since the emergence of H1N1 influenza in 2009, the World Health Organization (WHO) identified that patients with co-morbidities, pregnant women, and those over 65 years are at high risk of severe complications.

Aims and objectives: To characterise adult patients admitted with H1N1, particularly those with pneumonia, or those requiring intensive care unit (ICU) admission.

Methods: H1N1 positive inpatients from December 2010 to January 2011 were studied using electronic patient records, medical notes and the PACS system. Co-morbidities are recognized as per WHO guidance.

Results: In total 76 patients were admitted with H1N1, 35 patients with H1N1 had radiological evidence of consolidation, 8 were associated with the H1N1 winter outbreak of 2010-2011, and the impact on clinical course.

Conclusions: H1N1: The co-infection conundrum

Christopher Taylor, Sebastien Ellis, Matthew Harris, Suzanne Shuttleworth, Benjamin Marshall, Aye Aye Lwin. Respiratory Medicine, Southampton General Hospital, Southampton, Hampshire, United Kingdom

Background: Bacterial co-infection is known to increase the severity of H1N1 influenza. Past pandemics have been associated with Staphylococcus aureus which can lead to severe infection. Increasingly co-infection with Streptococcus pneumoniae has been recognised with H1N1 influenza.

Aims: To evaluate the causative organism’s associated with co-infection; in association with the H1N1 winter outbreak of 2010-2011, and the impact on clinical course.

Method: A patient cohort with proven H1N1 influenza admitted between December 2010 and January 2011 were retrospectively studied, using electronic patient records and paper medical notes. Bacterial co-infection was identified by positive result from blood, respiratory secretion or pneumococcal urinary antigen test.

Results: Out of a total 76 H1N1 positive cases blood, respiratory sample and urinary antigen testing was performed in 53 patients. Co-infection was detected in 12 of 53.

P4349 Platelets and influenza A (H1N1)

Elena Popa, Florent-Rusu Codorean. Hematology, Clinic of Pulmonary Diseases, Iasi, Romania

Introduction: In January 2011 we had two patients with Influenza A(H1N1) in our clinic and both of them had moderate thrombocytopenia. Therefore we decided to observe the abnormalities of thrombocytes during Influenza A(H1N1) pandemic.

Materials and methods: Retrospective study based on medical records of 21 consecutive patients admitted in our clinic (November 2009- January 2010) for pandemic A(H1N1) and respiratory failure. Twelve patients had underlying diseases: obesity (6), diabetes mellitus (3), BP (2), asthma (3), HTA (11), TBC-SIDA (1). There were seven exitus (30%).

Results: From 21 patients (11 female) nine (42.95%) patients had thrombocytopenia. In four of this nine cases (44.4%) thrombocytopenia was accompanied by low mean platelet volume (under 7 fl). The degree of thrombocytopenia was moderate (96000-110000/microl.), and it was correlated significantly with the degree of inflammation measured by the serum C-reactive protein concentration. Also, all these patients had elevated levels of LDH and serum transaminases.

Conclusions: Influenza A(H1N1) virus can induce a lower number of platelets. This virus can impair even platelets functions: in four cases thrombocytopenia coupled with low mean platelet volume (MPV), elongated APTT and elevated levels of D-dimers, which can suggest an impact of Influenza A(H1N1) on coagulation. The platelet count can evaluate and monitor the efficiency of treatment: the thrombocytes count is the first parameter that returns to its normal levels in cases with a good evolution.

The evolution of number and mean volume of thrombocytes can be predictors of evolution of infection with Influenza A(H1N1): from seven exitus three patients had thrombopenia with low MPV.

P4350 General characteristics of pneumonia cases developed during H1N1 epidemic in Turkey and prognostic factors

Tevik Orlu 1, Yilmaz Bulbul 1, Sezai Tasbakani 2, Hatice Kılıç 2, Tulin Kınaycu 2, Teken Yıldız 1, Tarkan Özdemir 1, Serap Durnu 1, Funda Ozturun 2, Nalan Akgüzel 1, Leyla Saglam 1, Ayvin Sakar Coskun 1, Tacettin Ortek 2, Gazi Gundu 2, Ayten Füle 1, Levent Önder 1, Gulser Okumuş 1, 1Chest Diseases, Karadeniz Technical University School of Medicine, Trabzon, Turkey; 2Chest Diseases, Ege University School of Medicine, Izmir, Turkey; 3Chest Diseases, Anadol University School of Medicine, Ankara, Turkey; 4Chest Diseases, Seraýpıaşosa Chest Dis. and Thoracic Surgery Education and Research Hospital, İstanbul, Turkey; 5Chest Diseases, Dicle University School of Medicine, Diyarbakir, Turkey; 6Chest Diseases, Chest Diseases Hospital, Corum, Turkey; 7Chest Diseases, Duzce University School of Medicine, Duzce, Turkey; 8Chest Diseases, Gaziantep University School of Medicine, Gaziantep, Turkey; 9Chest Diseases, Dortyol State Hospital, Hattas, Turkey; 10Chest Diseases, Istanbul University School of Medicine, İstanbul, Turkey

Aim-method: This multicentric study took place in Turkey to evaluate general characteristics of pneumonia developed during H1N1 epidemic between Nov-2009
The H1N1 influenza pandemic and pneumonia in Iceland 2009-2010: A one year follow up study.
Hrom Hardardottir1, Oskar Einarsson 1, Olafur Gudlaugsson 2, Kristbjorn Reynisson3, Sigfurdur O. Haraldsdottir 1, 4, 
1Respiratory Diseases, Landspitali University Hospital, Reykjavik, Iceland; 2Infectious Diseases, Landspitali University Hospital, Reykjavik, Iceland; 3Radiology, Landspitali University Hospital, Reykjavik, Iceland

Background: The influenza A (H1N1) pandemic in 2009 caused in a minority of infected severe pneumonia and respiratory failure.

Aims: To characterise patients admitted to our hospital with H1N1 influenza A infection and pneumonia at one year follow up.

Methods: Patients with positive tests for H1N1 influenza and pneumonia with fulkile illness and no other known pathogen were contacted 6 and 12 months after admission. Clinical examination with specific questionnaires (SF-36, HAD and St. George questionnaires) along with spirometry were performed to collect information on pulmonary symptoms, pulmonary status and health-related quality of life. Radiographs were reviewed and repeated when abnormal.

Results: 84 patients (42 women and 42 men) were admitted with influenza associated pneumonia. The mean age was 51 years and mean BMI 33. The mean total hospital stay was 10 days. 50% of the patients required high-flow oxygen, and 26% of the patients were admitted to the Intensive Care Unit. There was one death during the initial hospitalisation due to sequelea from H1N1. 44 patients participated in the follow up study. After 6 months only 3 patients had residual radiographic changes. Pulmonary function after 6 months in the patients admitted to the ICU were: FVC 102%, FEV1 100%, TLC 85% and DCO 81% of predicted. Currently we are evaluating patients at the 1 year follow up including health-related quality of life.

Conclusions: The H1N1 pandemic in Iceland resulted in pneumonia with considerable morbidity. Our preliminary results indicate that the physiological and radiographic sequelae are minor.

P4354
Pneumonia in H1N1 influenza infection
Judith Brebner, Chirag Dave, Dhiruv Parakh. Respiratory Medicine, Heartlands Hospital, Heart of England NHS Foundation Trust, Birmingham, United Kingdom
Respiratory Medicine, Heartlands Hospital, Heart of England NHS Foundation Trust, Birmingham, United Kingdom
Respiratory Medicine, Heartlands Hospital, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Introduction: As we entered the post 2009 H1N1 influenza pandemic period, the Centres for Disease Control and Prevention reported that a third of H1N1 deaths were attributed to co-infection with common pneumonia causing bacteria. We performed a study of all the patients admitted to a large teaching hospital during the most recent flu season in 2010/11 with the aim of looking at radiological diagnosis of pneumonia and its relation to morbidity and mortality.

Methods: We retrospectively analysed the electronic records and radiology for all patients admitted with H1N1 infection between 1st November 2010 and 31st January 2011. Complications and respiratory support (invasive or non-invasive) were used as markers of morbidity.

Results: 280 (mean age 39.5) patients had laboratory confirmed H1N1 infection. 96 (34.3%; mean age 44.5) had radiological pneumonia (48 unilateral, 48 bilateral); mortality 8.3% (37.5%) had no co-morbidities. Of all those that died with H1N1 8/37 (21.6%) had pneumonia. 11.5% had complications: 5 effusion/empyemas, 4 ARDS and 2 pneumothorax. 31.3% required respiratory support. 96 (34.3%; mean age 44.5) had radiological pneumonia (48 unilateral, 48 bilateral); mortality 8.3% (37.5%) had no co-morbidities. Of all those that died with H1N1 8/37 (21.6%) had pneumonia. 11.5% had complications; 5 effusion/empyemas, 4 ARDS and 2 pneumothorax. 31.3% required respiratory support. All those that had both bilateral pneumonia and complications (n=8) required respiratory support of which 3 died. 26% had positive sputum cultures-most common pathogens being haemophillus influenza, streptococcus pneumonia, klebsiella and candida. 50% of those requiring respiratory support had positive sputum cultures.

Conclusion: Pneumonia in H1N1 infection is common. Bilateral pneumonia is a risk factor for the need for respiratory support and death. Development of respiratory complications confers further risk of morbidity.

P4355
A study to analyse the clinical profile and outcome of hospitalised patients with H1N1 and the factors influencing the outcome
Thomas James Ponneduthamkuzhy, B.R. Sandeep, P.V. Santhosh Kumar, Chethanath Ravindran. Department of Pulmonary Medicine, Medical College Calicut, Calicut, Kerala, India

This was an observational study conducted in Institute of chest diseases, Calicut medical college,India between August 2009 and August 2010. All patients whose
likely to have two or more lung zones involved (p <0.005). 11 (35.5%) patients had pleural thickening or effusion.

Conclusion: In patients with the novel swine flu the most common radiographic abnormality observed in our center was consolidation in the lower lung zones. Patients admitted to ICU were more likely to have two or more lung zones involved.
Introduction: Oxidative stress and reactive oxygen species (ROS) are implicated in influenza A virus-induced lung inflammation and damage. Current therapies primarily target viral infection and replication, with little attention directed at the host immune response. The antioxidant enzyme glutathione peroxidase-1 (GPx-1) has a protective role against various diseases involving ROS.

Aim: To study the role of GPx-1 in influenza A virus-induced lung disease.

Methods: Male WT (C57BL/6) and GPx-1 -/- mice were infected with 1 × 10^6 PFU of HKx31 (H3N2) influenza A virus. Viral titre, BALF and lung inflammation, body weight, pro-inflammatory chemokine (MIP-1α, MIP-2, KC) and protease (MMP-9) expression were assessed 3 and 7 days post infection.

Results: WT mice infected with HKx31 had significantly more BALF total cells and neutrophils than infected WT mice (P < 0.05). Viral titre was significantly reduced in GPx-1 -/- mice at day 3 compared to WT mice (P < 0.05). Infected GPx-1 -/- mice lost similar amounts of weight to infected WT mice. Gene expression analysis revealed that GPx-1 -/- mice had more whole lung MIP-1α, KC and MIP-2 than WT mice at day 3. Infected GPx-1 -/- mice had more active MMP-9 protease in BALF and greater peribronchial inflammation and bronchial inflammatory cell exudates than infected WT mice.

Conclusions: These data indicate that GPx-1 reduces some aspects of influenza A virus-induced lung inflammation, which may improve overall outcomes of influenza infection.

P4354
Biomarker profiles of BALF in ALI/ARDS due to pandemic (H1N1) 2009 influenza
Toshimichi Horuchi, Toshiki Yokoyama, Nobumitsu Kobayashi, Yosuke Wada, Hiroshi Yamamoto, Keishi Kubo. 1st Department of Internal Medicine, Shinshu University School of Medicine, Matsumoto, Japan

Background: The outbreak of the 2009 pandemic influenza A (H1N1) virus was identified as a Pandemic. However, the clinical and epidemiologic characteristics of the novel influenza were not sufficiently elucidated.

Methods: Patients who were hospitalized because of the novel influenza infection were enrolled in the study between August 2009 and December 2009 at Shinshu University Hospital. Furthermore, the patients with acute lung injury (ALI)/acute respiratory distress syndrome (ARDS) due to influenza A infection were collected. The patients' condition, laboratory data, the respiratory management, and oxygenation were analyzed. Bronchoalveolar lavage (BAL) was performed on admission.

Results: Nine patients were hospitalized and treated with anti-viral therapy such as oseltamivir. Five of 9 patients showed ALI/ARDS. Three of the 5 patients were intubated and non-intubated patients. Only one patient died in the intensive care unit because of the refractory hypoxemia due to the deterioration of a co-infection. BAL was performed in 3 patients and all of them showed alveolar hemorrhage. The patients' condition, laboratory data, the respiratory management, and oxygenation were analyzed. Bronchoalveolar lavage (BAL) was performed on admission.

Conclusion: This study showed lung injury due to 2009 pandemic influenza A (H1N1) virus was formed by the direct ALI/ARDS without a cytokine storm. This was significant difference between the intubated and non-intubated patients.

P4355
Glutathione peroxidase-1 as a therapeutic target in influenza A virus-induced lung disease
Selecuk Yatzar, Hui Juinn Seow, Rosa Gualano, Zi Xin Wong, Peter Crack, Steven Boznovski, Gary Anderson, Rosa Vlahos. Pharmacology, The University of Melbourne, Parkville, Victoria, Australia

Objective: To evaluate the sequelae of viral (H1N1) pneumonia at 3,6,12 months follow-up.

Methods: We evaluated 22 survivors of the influenza A (H1N1) virus pneumonia at 3, 6, and 12 months after discharge. At each visit, the patient was interviewed; underwent a physical examination, pulmonary-function testing, chest radiography, 6MWT and a quality-of-life evaluation.

Results: At discharge all patients had abnormal chest radiographs, DLCO values below 80% of predicted (50.7 ±21.6%) and 6MW distance was shorter than in normal values in the same age groups (498.5 ±54.2m).

Conclusion: There was significant difference between the intubated and non-intubated patients revealed a continuing significant difference in lung diffusing capacity at 3, 6, and 12 months (DLCO 62.1 ±8.3% vs 85.7 ±3.2% p=0.01 DLCO 67.3 ±5.2% vs 89.0 ±2.2% p=0.01 DLCO 67.9 ±4.7% vs 92.2 ±1.5% p=0.01 respectively).

P4356
Biomarker profiles of BALF in ALI/ARDS due to pandemic (H1N1) 2009 influenza
Toshimichi Horuchi, Toshiki Yokoyama, Nobumitsu Kobayashi, Yosuke Wada, Hiroshi Yamamoto, Keishi Kubo. 1st Department of Internal Medicine, Shinshu University School of Medicine, Matsumoto, Japan

Background: The outbreak of the 2009 pandemic influenza A (H1N1) virus was identified as a Pandemic. However, the clinical and epidemiologic characteristics of the novel influenza were not sufficiently elucidated.

Methods: Patients who were hospitalized because of the novel influenza infection were enrolled in the study between August 2009 and December 2009 at Shinshu University Hospital. Conclusion: This study showed lung injury due to 2009 pandemic influenza A (H1N1) virus was formed by the direct ALI/ARDS without a cytokine storm. This was significant difference between the intubated and non-intubated patients.
434. Challenges in tuberculosis control

Daniela Silva1,2,3, Bruna Silva1, Pedro Paulo Torres1, Pedro Jose Junior1, Ana Paula Junqueira-Kipnis2, Marcelo Rabelo1,1,1 Department of Clínica Médica-Hospital das Clínicas, Universidade Federal de Goiás, Goiania, Brazil; Instituto de Patologia Tropical e Saúde Pública, Universidade Federal de Goiás, Goiania, Goias, Brazil; 1Department of Image, Universidade Federal de Goiás, Goiania, Goias, Brazil

Introduction: Diagnosing latent tuberculosis (TBIL) in patients with rheumatoid arthritis (RA) has become more important with the introduction of the use of anti-TNF alpha agents and the appearance of active tuberculosis in these patients.

The tuberculin skin test (TST), has limited value when used in patient with RA. New tests based in the production and release of IFN-gamma have been studied but their role has not been well established for this specific group of patients.

Objectives: Comparing the diagnosis of TBIL in a group of patients with RA by using tuberculin skin test, TSPOT-TB and by means of tomography findings compatible with TBIL.

Methods: A clinical-epidemiological evaluation, use of TST, TSPOT-TB and high-resolution computed tomography (TCAR) in a group of patients with RA in University Hospital of Goiás, Brazil.

Results: The response to the TST was smaller in patients with RA (13.5%), relative to the response expected from the general population. The TSPOT-TB identified a higher number of patients with TBIL, relative to the TST (36.8%). TCAR presented changes which were compatible with TBIL in 52.9% of the patients included in the study, and among the eight of the eleven patients with TST and TCAR identified as negative.

Conclusions: In isolation, TST is an insufficient test to diagnose TBIL. A higher number of positive results were obtained with TSPOT TB, relative to TST, but it was negative in a large percentage of patients with tomography findings consistent with TBIL. The TCAR test is easily performed in most of the large centers and should be incorporated into the diagnostic strategy for TBIL in patients with RA.

P4361 Use of econometric selection models to describe non-completion of treatment for latent tuberculosis infection (LTBI) among the Egyptian and Somali immigrant populations

Kyle Fuegge, AED Economics, Ohio State University, Columbus, United States

Tuberculosis (TB) is a global health concern, with 2 million deaths each year. Treating immigrants with latent tuberculosis infection (LTBI) has become a priority in the U.S., as active TB rates decline. The study investigates treatment adherence for LTBI via econometric selection models for two reasons: only the healthiest of immigrants migrate and LTBI returns to migration. Therefore, Heckman’s sample selection model was used to estimate the demand among non-immigrants for TB prevention to be high in endemic countries. We never realize this demand because these individuals do not migrate. We expect the demand among non-immigrants for TB prevention to be high in endemic countries. For individuals who did (not) immigrate, we assume that the risk of developing active TB disease is lower (higher) than the risk of developing a latent TB infection. For individuals who did in a way that increased complete treatment vary systematically from those who did in a way that increased their future probability of disease activation.

After correcting for the biases of the “healthy immigrant effect” and the self-selection into treatment, we assume that the risk of developing active TB disease is lower than the risk of developing a latent TB infection. We expect the demand among non-immigrants for TB prevention to be high in endemic countries. We never realize this demand because these individuals do not migrate. Therefore, Heckman’s sample selection model was used to estimate returns to migration.

Initiation and duration of treatment is significantly associated with length of time in the United States (p<.05). Among immigrants who did not complete treatment, HbA1c/vitamin D levels were significantly greater/lesser than those who did complete treatment (p<.05).

In an urban city, a decision was taken in 2004 to modify tuberculosis (TB) contacts screening strategy from targeting only close contacts identified by interview with the index case (the national policy) to a screening strategy involving home and work visit.

The present study compares TB contact-tracing during the periods 2001 to 2003 and 2004 to 2006 trying to capture how the new contact tracing strategy addressed the three main questions: (i) Does this strategy increase TB screening compliance? (ii) Does it identify more at-risk contacts? (iii) Does it result in more TB cases being prevented?

Home and work visit allowed to identify more at risk contacts (8.4/4.04 index case) than the interview (2.5/4.04 index case) to improve compliance (87.3% of the identified contacts were screened, compared to 67.6%). More cases of active TB and LTBI cases were detected (1.4/4 index case compared with 0.75/4 index case) and prevented more TB cases in the future.

The newly implemented contact-screening program with home and work place evaluation of active TB patients, improved compliance to screening procedures, identified more at-risk contacts and should allow us to prevent more TB cases in the future.

P4363 Tuberculosis in prisons of Republic of Macedonia from 2005-2010

Maja Zakoska1, Stefan Taveleski1,2, Epidemiology Department, PHI Institute for Lung Diseases and Tuberculosis, Skopje, Macedonia, The Former Yugoslav Republic of; 1Clinical Department, PHI Institute for Lung Diseases and Tuberculosis, Skopje, Macedonia, The Former Yugoslav Republic of

Introduction: Prison’s population (yearly approximately 2600 prisoners) is group with higher risk of tuberculosis (TB) due to fullness of prisons, bad living conditions and inadequate medical care. Total population’s notification rate decreases continuously but the rate of TB cases in prisons is still high (384/2005, 2/2006, 15/2007, 230/2008, 307/2009 and 384/2010). Aim of this survey is to prove the situation with TB in prisons in Macedonia.

Material: Data for this study were taken from the Central TB Registry. The forms of TB, previous treatment, bacteriological confirmation and treatment outcome between 36 prisoners (period 2005-2010) have been analysed.

Results: In the period 2005-2010, 36 cases of TB were registered, 91, 6% male and 4, 4% female. The pulmonary TB was identified at 83, 3%, extra pulmonary TB at 16, 7% cases. From all cases, 83, 3% were new and 16, 7% previously treated. Bacteriological confirmation of pulmonary TB with direct microscopy identified at 43,3% and bacteriological confirmation of culture at 63,3% cases. The drug sensitivity test demonstrated multi drug resistance in 2,7% cases. Treatment outcomes from 2005-2009 were following: successful treated 80, 9%, dead 3, 8%, default treatment 11, 5% and 3, 8% lost from evidence. Drug addiction is finding in 41, 6% prisoners with TB.

Conclusion: Rate of TB in prisons in Macedonia is higher than in total population. Among TB cases in prisons percentage of bacteriological confirmation is low. Appearance of multi drug resistant form of tuberculosis is bad prognostic sign.

P4364 Two major problems in TB patients today: MDR and the abandoned therapy

Gabriela Barbulescu, Laurentiu Badulescu, Pneumology, “Sf. Stefan” Hospital, Bucharest, Romania

In the WHO strategy, “stop TB” is the ultimate goal in the fight against this extended infectious disease. However, despite this ambitious purpose and the tools developed in this matter, the problems may occur. Aims: In this paper, the authors proposed to emphasize the latest and striking observations on difficulties encountered in TB treatment, in a pneumology department.

Methods: We observed the TB cases admitted in our service in 2010 compared with 2009 and noted the chronics, relapse cases. We noted why these patients couldn’t rich to a proper end of their treatment and be cured. Equally, we were interested in number of MDR cases admitted in both years, comparative.

Results: All TB patients evaluated in 2010 were 456. From these, 255 were chronics, developing at least a third treatment (by failed or abandoned treatment). From these ones, 12 patients were with secondary MDR (5 of them with additional resistance to SM or EMB). Besides, we had 2 patients with XDR. In 2009 we had 468 TB patients, from which 214 were chronics, 165 abandoning their schedule and coming to hospital in 2010. In 2009 we noted just 5 patients with MDR. It is worth noting the lack of secondary aminoglicosides like Kanamicine and Amikacine and the impossibility of admitting all these patients in the unique service of MDR in town.

Conclusions: We are worried about the increase of number of cases with treatment abandon and the MDR cases. There is an important number of patients who cannot be compelled to follow the treatment when they leave the hospital (because of different reasons: social, tolerance, first treatment failed). Isolation of MDR cases from other TB patients in the same hospital seems difficult.

P4365 Profile of TB deaths in Romania during 2007-2009

Nicoleta Ciocan, Elmina Braim, Horia C. G. National TB Program, Marius Nasta Institute of Pulmonology, Bucharest, Romania

Introduction: Even TB is a curable disease from several decades, it’s estimated that it is still killing over 1.7 million people early worldwide. The TB mortality rate decreased in Romania since 2003, in parallel with the decrease of notification...
rate, but the proportion of deaths from all reported TB cases is keeping more than 6.5%.

Aims and objectives: To study the profile of TB deaths in Romania during 2007–2009 on the demographics data of the deceased persons, their associated diseases and depending on the bacteriological confirmation of pulmonary TB case.

Methods: Descriptive retrospective study of demographic and clinical characteristics of deaths among TB cases notified in Romania in 2007-2009. Data and information have been extracted from electronic National TB Register.

Results: A total of 4920 TB deaths have been reported in the analyzed 3 years: 1657 men in 2008 and 1535 in 2009. Of them 80.8% were men and 58.9% were living in rural area. The highest frequency of deaths occurred in 50-54 years in each analyzed year. The ratio of pulmonary site was 93.4%, with bacteriological confirmation rate by microscopy 71.6% and by culture 63.5%. The share of deaths caused by TB decreased from 62.2% in 2007 to 80.8% in 2008 and 75.4% in 2009. MDR-TB cases represented 8.5%. The most common associated diseases were alcoholism, liver diseases, diabetes and renal diseases. HIV co-infection has been registered in 2.1%.

Conclusions: In the analyzed period of time the highest number of deaths has been recorded in 2008. The highest proportions of TB deceases were observed in men. The age group, living in rural area, most commonly alcoholics, with advanced pulmonary forms of disease.

P4366
Results of retrospective study of TB contact investigations in Iasi County, Romania
Adriana Sorete Arbore1, Violeta Cojocariu1, Rodica Sorete Arbore2.
1 Outpatient Service, Clinic of Pulmonary Diseases, Iasi, Romania; 2 Epidemiology Laboratory, "Sf. Spiridon" Emergency Clinical Hospital, Iasi, Romania

The aim of this study is to evaluate the patients diagnosed as tuberculosis and registered to a Tuberculosis dispensary in year 2010 according to the health care units which they applied beforehand and the time period since first symptom of tuberculosis has occurred. For this descriptive study, the questionnaires which consist of questions about enrolled tuberculosis patients’ characteristics, symptoms, duration between the first symptom and diagnosis and health care units they applied before coming to tuberculosis dispensary have been filled with face to face interviews. Total 127 questionnaires were completed, the majority of patients were male (51.2%). Mean age was 51±20 years. The rate of latent tuberculosis was 59.1% and persons of them had signs of active pulmonary tuberculosis. Among a pathology of organ of the thorax which has been not bound to a tuberculosis acute pneumonia, chronic obstructive pulmonary diseases COPD, and heart disease were the most common symptoms. At diagnosis, 16.4% had diabetes, 10% had chronic bronchitis, and 5.1% had former cancer. Acute pneumonias were 71%, COPD – 16.7%, lung cancer – 4.3%.

P4369
The pathology of a thorax at the men getting to the penal institutions
Ksenia I. Aksenova. Tuberculosis, Moscow State Medical Dentistry University, Moscow, Russian Federation

The goal of current research was to study a pathology of a thorax at the men getting to the penal institutions. The study has been carrying out during four years in one investigatory isolation ward in Moscow. Fluorographic examinations of all prisoners – 10–17% had chest X-ray. 51.7% received INH preventive therapy 3-12 months. 16.4% had no records about chest X-ray or preventive therapy. At the initial checking of the contacts, 7 active TB cases were detected; other 36 active TB cases were registered in the next 10 years. 62.7% (27) TB cases in contacts were registered in the first year of activity. 5.1% in the next 2 years. 7 contacts with no initial records developed active TB later. Conclusions: 5.1% of the TB contacts developed active TB in the 10 years follow up period of time. Effective contact investigation and prevention of TB spreading in house hold contacts should consider:
- Lack of algorithm for contact tracing (no clear moments for contact follow up after the first control) in the NCC.
- The recommended tools for investigation of contacts were not entirely used, different approaches for preventive therapy regarding number of months, doses, monitoring of treatment, lack of knowledge in the group of patients, their families and GPs’ network regarding the importance of preventive therapy and also about periodic control.

P4367
Tuberculosis in prison
Valeri Andrei1, Antoneta Karcheva2, Kamelia Petrova2, Emilia Lazarova1.
1 Pulmonary Clinic, University Hospital, Pleven, Bulgaria; 2 Mycobacteriological Laboratory, University Hospital, Pleven, Bulgaria; 3 Medical Center, Prison of Pleven, Pleven, Bulgaria

Introduction: Prison tuberculosis is a major problem because society “behind the walls” is overcrowded and isolation of patients is difficult and time-consuming. The program for improvement of the control on tuberculosis in Bulgarian prisons was started in order to solve these conditions.

Aims and objectives: Our aim is to present the ability of the program to provide better care for patients and contact people and better working conditions for medical personnel on both sides of the walls.

Methods: We observed a one year period from the beginning of the program in the Pleven prison. Measures like regular screening questionnaires, bacteriology, chemical preparations and consultations with a supervising pulmonologist were provided regularly. Patients with pulmonary tuberculosis were isolated and sent to the prison hospital. Contact people were tested with a tuberculin test and were given isoniazid.

Results: This prison is inhabited by 600 prisoners and only 2 of them were diagnosed as sufferers of active tuberculosis. Other 2 continued therapy in prison after active hospital treatment. Prevalence of prison tuberculosis is about 900 out of every 100 000 prisoners. 421 questionnaires were filled. 110 prisoners gave sputum for bacteriology and 52 tuberculin tests were done. A room was built for induction of sputum and another for patient isolation.

Conclusion: The above measures guarantee the ability of the program to provide good medical service to prisoners, however most of them had contracted tuberculosis outside the walls before imprisonment.

P4368
How did the tuberculosis patients reach to a tuberculosis dispensary and how long did it take?
Dilsh Karagedan1, Benul Abduloglu2, Gökül Keter1.
1 Chest Department, Pumukale University Medical Faculty, Denizli, Turkey; 2 Tuberculosis Dispensary, Denizli Tuberculosis Dispensary, Denizli, Turkey

A strategy targeted to improve the role and efficacy of primary care units in referral of the patients with highly suggestive symptoms to the tuberculosis dispensaries should have the priority to avoid the time lag in diagnosis.

P4370
Forecasting the risk of medicinal complications from the chemical therapy in patients with multi-resistant pulmonary tuberculosis
Fatima Tashpulatova. Branch of Therapy of a Pulmonary Tuberculosis, National Centre of Philhiology and Pianology, Tashkent, Uzbekistan

Objective: Development of forecasting method for medicinal complications (MC) in patients with multi-resistant pulmonary tuberculosis (MPT). Research methods and materials: 116 patients with MPT which were divided into two groups were examined: the 1st group – 88 patients with MC from chemical preparations and the 2nd group – 78 patients without MC.

Results: For each risk factor was determined risk rate (RR). Important in forecasting were such factors as intolerance to chemical preparations in the past and existence of pernicious habits (RR -1.4), length of sickness from 4 to 5 years (RR-2.25), existence of concomitant diseases (RR – 2.5), existence of fibro-cavernous pulmonary tuberculosis (RR – 1.7), biochemical changes in the liver (RR -2.9) and kidney (RR -3.7), changes in electrolyte metabolism (RR -2.23), leukocytosis (RR – 3.6), existence of lymphopenia (RR – 2.3), increase in ESR (erythrocyte sedimentation rate) to more than 40 mm/h (RR – 2.5), in the age of 30 - 40 years (RR – 1.7). According to decimal logarithm of their production maximal and minimal risk range of MC comprising the value from ~9.9 up to +6.4 were determined.

Conclusion: The developed forecasting method of MC in patients with MPT allows from the first days of sickness forecast the risk level of MC from the chemical preparations.
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30

resistance related mutations in the rpoB gene were detected in 13/15 (86.7%).

Based on the phenotypic drug susceptibility testing results, 15 (12.1%) was BACTEC culture positive for mycobacteria. Out of 123/165 (74.5%) were M. tuberculosis isolates from EPTB cases and to reveal the main mutations of gyrA gene associated with FQ resistance. DNA samples of M. tuberculosis were collected from 70 adult patients of both genders. Seventy-eight speciments from patients of EPTB cases in tertiary care hospitals in northern India has over 1.982 million incident TB cases per year and world’s 3rd highest HIV burden. The estimated PLWHA is 0.34% (2.38 million) of Indian population. TB-HIV coordination activities are being implemented since 2001.

Methods: The primary defaulters (PD) were identified by comparing the list of patients registered for treatment with the list of patients who did not report for treatment initiation. They were also asked about reasons for not reporting.

Methods: A total of 789 specimens from patients of EPTB cases with varied pre-treatment sample pattern were collected from 70 adult patients of both genders. Seventy-eight specimens from patients of EPTB cases in tertiary care hospitals in northern India has over 1.982 million incident TB cases per year and world’s 3rd highest HIV burden. The estimated PLWHA is 0.34% (2.38 million) of Indian population. TB-HIV coordination activities are being implemented since 2001.

Methods: To identify factors responsible for Cat-I and II relapse among successfully treated tuberculosis (TB) patients under DOTS programme.

Methods: A total of 789 specimens from patients of EPTB cases with varied presentation were collected from 70 adult patients of both genders. Seventy-eight specimens from patients of EPTB cases in tertiary care hospitals in northern India has over 1.982 million incident TB cases per year and world’s 3rd highest HIV burden. The estimated PLWHA is 0.34% (2.38 million) of Indian population. TB-HIV coordination activities are being implemented since 2001.

Methods: To identify factors responsible for Cat-I and II relapse among successfully treated tuberculosis (TB) patients under DOTS programme.

Methods: This paper attempts to assess the drug resistance pattern in the rpoB gene of M. tuberculosis among the patients of EPTB cases in tertiary care hospitals in northern India has over 1.982 million incident TB cases per year and world’s 3rd highest HIV burden. The estimated PLWHA is 0.34% (2.38 million) of Indian population. TB-HIV coordination activities are being implemented since 2001.

from DOTs clinics. 54.2% of the respondents answered that many of their patients came back and expressed satisfaction. 59.3% of the respondents answered that few of their patients complained of DOTS treatment. The most common negative comment was delayed supply of medications. The most common positive comment was medications are for free. 81.2% respondents did not receive PHILHEALTH incentives for every patient they referred to DOTs. This study recommends to conduct retraining or seminars on private practitioners.

Methods: Initially, we reviewed all kinds of pulmonary mycobacteria isolation from January 2004 to December 2009, based upon the laboratory database with clinical chart. When multiple isolates were detected, species identification was performed for one species per patient per year. Next, we investigated, on the 2009 patients, the initial year of MAC diagnosis during the past 20 years. Thirdly, we followed the course of 2004 MAC patients up to 2009, speculating the yearly accumulation of the disease.

Results: From laboratory data, the yearly number of NTM isolation increased from 353 in 2004 to 488 in 2009 (mean annual increase,5.9%) and from MAC of 291 to 418 (increase 6.8%). Proportion of MAC to all NTM showed a constant value of 81.4%, indicating that increase was due to an increase of MAC. From clinical data, many of MAC patients in 2009 had an initial diagnosis of MAC during the period from 1978 to 2008. Follow up analysis on the cases found in 2004 and having yearly bacteriological examination, showed over half of the positive MAC patients in 2004, were still culture positive in 2009. MAC-related death was observed on 8 cases among the total 99 cases in 2004.

Conclusion: An accumulation of MAC patients in recent years was likely to occur in Tokyo, Japan.

435. Novel strategies for the diagnosis of tuberculosis

P4380 Late-breaking abstract: Expression of IFN-γ/G/L-10 in active pulmonary tuberculosis patients and household contacts
Sumanlalita Gaddam1, Lavanya Joshi1, Hari Sai Priya Vanancherla1, Anuradha Bandaru1, Vijayalakshmi Valuri1,2,1 Immunology, Bhagwan Mahaveer Medical Research Centre, Hyderabad, Andhra Pradesh, India; 2Immunology and Molecular Biology, LEPRa- Blue Peter Research Centre, Hyderabad, Andhra Pradesh, India

There is an increase in the prevalence of tuberculosis in young adults. T cell, cytokine mediated immune responses to Mycobacterium tuberculosis infection are important determinants of disease development and pathology, the aim was to investigate the role of candidate cytokines in active pulmonary tubercu- losis patients (APTB) of younger age (15-30yrs) & their HouseHold Contacts (HHC). T cell assays were stimulated with r32-kDa antigen of M. bovis BCG (Ag85A-BCG). IFN-γ & IL-10 were measured in the culture supernatants by ELISA in APTB (15); HHC (PPD-positive) (15) & Healthy Controls (HC) (PPD status not known) (15). Expression levels were determined by quantitative real-time PCR in 4 individuals from each group. The mean proliferative responses of stimulated cells were significantly low (p<0.05) in APTB and HHC compared to HC (1.53±0.72; 1.55±0.89 and 4.4±4.43) respectively. The mean IFN-γ (p<0.05) (43.4±24.8; 46.0±22.2 & 70.9±4.41) & IL-10 (85.7±5.87; 63.0±4.42 & 11.4±7.7 gp/l (p<0.003 & <0.0006) levels were significantly low and high respectively in APTB & HHC when compared to HC. The expression of IFN-γ was high (5-fold) in HC when compared to APTB (1.5-fold) & HHC (3-fold), against the corresponding unstimulated cells. IL-10 expression increased by 8- fold in APTB & 6-fold in HHC compared to HC (2-fold). In conclusion, elucidation of the mechanism by which Th1 cytokine is down-regulated may enhance our understanding of susceptibility to disease. Also, follow-up of the contacts for their clinical status may help in identifying a biomarker for house-hold contacts useful for early diagnosis.

P4381 Analysis of C-reactive protein and fibrinogen as possible predictors of secondary fibrosis in pulmonary tuberculosis
Besim Prnjavorac1, 2, Adlija Cauševic2, Sabina Semiz2, Tanja Dujic2, Tamer Bego, Nedzada Irijez1, Rđat Sedjmović1, 1Department of Lung Disease, General Hospital Tuzlaj, Tuzlaj, Bosnia and Herzegovina; 2Clinical Biochemistry, Faculty of Pharmacy, Sarajevo, Bosnia and Herzegovina

Aim: To study the influence of C-reactive protein (CRP) level in the blood, fibrinogen level and general inflammatory syndrome as the predictors of development of secondary fibrosis in patients with pulmonary tuberculosis (TB).

Methods: Concentration of CRP, fibrinogen level was measured using immunomunobidimetric method including criteria was presentation of TB process in both lungs, as the sign of widespread TB process.

Results: We examined 85 patients treated in one year. Mean CRP level was 22.6 mg/mL, range 5-245 mg/mL; normal level (up to 8 mg/mL) was measured in 23.4% patients, medium level (9-20 mg/mL) was measured in 31.3% patients, high level (21-50 mg/mL) were measured in 26.2% patients, and in 23.7% patients CRP were higher than 50 mg/mL. Average fibrinogen level in whole group was 6.9 g/L (SD 5.8). Normal level of fibrinogen (up to 4 g/L) were measured in 6.4% of patients; 4.1-10 g/L were measured in 24.6% patients, 10.1-20 g/L were measured in 31.1% patients and level more than 20 g/L were measured in 37.9% patients. Using statistic method of partial correlation statistical significance at level p<0.05

8068

Tuesday, September 27th 2011
was shown between them. Correlation of CRP and fibrinogen level with appearance of fibrinosis on X-ray of the lung was shown. Thereafter, closer correlation was shown between fibrinogen and fibrinosis than with CRP and fibrinosis.

Conclusion: Predicted value of CRP and fibrinogen for pulmonary fibrosis was shown in TB patients. So, attenuation of fibrinosis development, possible with antifibrotic activity of pentoxiphyllin, should be taken in consideration, for prevention of widespread development of lung fibrinosis in these patients.

**P4382**

Decreasing level of serum ADA: A valuable predictor of treatment in smear positive tuberculous pleuritis

Kazem Navari1, Tasnim Esqai Eftekharthi2, Najme Ziaei3, Farzaneh Navari1.

1Internal Medicine, Hormogzan University of Medical Sciences, Shahid Mohammadi Hospital, Bandar Abbas, Hormogzan, Islamic Republic of Iran; 2Infectious Disease Research Department, Research Department, Hormogzan University of Medical Sciences, Shahid Mohammadi Hospital, Bandar Abbas, Hormogzan, Islamic Republic of Iran

Background: High titer of adenosine deaminase (ADA) in pleural fluid is an indicator of pleural tuberculosis and necessity of treatment initiation. On the other hand high serum ADA of ADA is a characteristic of tuberculosis, and is used for treatment follow up in patient on standard antituberculosis regimen. Decreasing level of ADA could be a predictor of treatment response.

Methods: A cross sectional study was carried out on 29 patients from Sep 2007 till Dec 2010. All of the tuberculosis patients included had a positive sputum smear or positive biopsy or bronchoalveolar lavage (BAL). ESR and ADA were checked for these patients in treatment initiation, 30th and 60th day of treatment. According to ADA diagnostic kit values, ADA more than 15 is high.

Results: Mean age of the patients was 38.9 ± 6.2 years. Mean ADA before therapy was 19.31 which gradually decreased to 12.37 (on day 30) and 11 (day 60). Mean ESR before initiation of therapy was 65 which decreased gradually to 38.66 (day 30th) and finally 23.28. Male patients were 55.2%, 82.8% suffered from pulmonary TB. Comparison of ADA and ESR at the end of therapy showed a significant difference (p=0.000). Mean ADA (60th day) in males was 11.18±1.60 and in females were 10.76±0.42. Mean ESR (60th day) in males was 25.50±5.48 and in females was 23.03±2.02.

Conclusion: Decreasing level of serum ADA is a valuable and reliable predictor in successful treatment of tuberculosis.

**P4383**

Adenosine deaminase, an useful tool for the diagnosis of tuberculous pleuritis in France

Hervé Le Floch1, Sandrine Duron2, Hervé Delacour3, Frédéric Rivière1, Ines Ngampolso1, Fabien Vaylet1, Jacques Margery1, Christophe Raggi1, 1Respiratory Diseases, Military Hospital Percy, Clamart, France; 2Infectious Disease Research Department, Research Department, Hormogzan University of Medical Sciences, Shahid Mohammadi Hospital, Bandar Abbas, Hormogzan, Islamic Republic of Iran

Pleuritis is a diagnosis challenge for usual mycobacteriological analysis given that the bacillary concentration is low in the pleural effusion. Adenosine deaminase is a pleural inflammatory marker recommended for the diagnosis of pleural tuberculosis in the high-prevalence countries. There is not enough data to support its use in a low-prevalence country.

Objective: To know the utility of ADA for the diagnosis of pleural tuberculosis in France, a low prevalence country.

Material and method: Retrospective study of the exudative pleural effusion with the ADA dosage (Giusti’s method) done in two military hospital near Paris. We compared tuberculous and non-tuberculous pleural effusion. The best cut-off value of ADA for the diagnosis of pleural tuberculosis was found using ROC curves.

Results: 183 patients were studied, including 29 tuberculosis, 65 cancers, 5 malignant hemopathies, 32 parapneumonic pleural effusions, 24 purulent pleuritis, 12 old transudative effusions, 14 effusions from other aetiologies. Sixty-eight effusions were rich of lymphocytes including 23 tuberculosis. The young age (<35 years-old), the foreign origin and the presence of general manifestations were independently associated with tuberculosis. The best cut-off value for ADA was 47 U/L with Se: 95.7%, Spe: 91.6%, PPV: 84.6%, NPV: 97.6%. When ADA ≥ 70 U/L, the PPV was 90.5%.

Discussion: ADA dosage is useful in France. Lower than 47 U/L, it may exclude tuberculosis. When ADA ≥ 47 U/L, the result should be interpreted considering the context and the pre-test probability of tuberculosis. When this pre-test probability of tuberculosis is important, ADA ≥ 70 U/L is very likely for tuberculosis.

**P4384**

Clinical utility of a lateral flow serologic test in the rapid diagnosis of pulmonary TB in a public-private mix for DOTS setting in Iloilo City, Philippines

Dennis Dumaplin1, Malbar Ferrer1, Elia Mae Divinagracia1, Lorelei Sirilan1, Rosario Cahana1, Rodrigo Guzman-Trivilega2, Anne Lourdes Punje1, Elcie Solis1, Peter Breatn1, Jessica Adamich1, 1Internal Medicine, Saint Paul Hospital, Iloilo City, Iloilo, United States; 2DOTS-PPMD, Saint Paul Hospital, Iloilo City, Iloilo, United States; 3College of Osteopathic Medicine, Touro University, Iloilo, CA, United States

Background & rationale: Diagnosis of PTB in a developing country with a limited resource relies largely on clinical features, sputum exam and chest xray. In an endemic area such as the Philippines, the urgent implementation of intensified case-finding and infection control measures which reduce the burden of TB is essential to saving lives. Culture methods are not routinely used in the locality due to the low cost-effectiveness and time constraints. By using serological methods, the time required to reach a clinical decision to treat a suspected case of TB may be significantly reduced. We have investigated the utility and diagnostic accuracy of a lateral flow serologic test in PTB diagnosis when used as an adjunct in the Fire-DOTS setting.

Methods: An immuno-chromatographic TB STAT PAK II Assay was employed for the detection of antibodies to M. tuberculosis in the human whole blood of TB suspects. Humoral response was analyzed in a group of 105 TB suspects (74 in the active PTB group - 47 smear-positive and 31 smear-negative, and 31 in the non-active/control group - 31 smear-negative and 6 healthy subjects).

Results: The proportion of all test subjects with PTB who tested positive was the assay was 65%, while the proportion of all subjects without PTB who tested negative was 100%. The positive predictive value (PPV) and the negative predictive value (NPV) was 100% and 50.94%, respectively.

Conclusion: The serologic test performed with excellent specificity and acceptable sensitivity in PTB diagnosis in an endemic setting, though not enough evidence exists that they perform well enough to replace sputum microscopy.
Background: The suboptimal sensitivity of IFN-γ-based assays, especially in immunocompromised individuals, emphasizes the need for alternative markers for diagnosing tuberculosis (TB). Objective of this study was to evaluate whether IFP-10 can be a useful biomarker for evaluating a specific response to RD1 antigens associated to active TB in HIV-infected individuals. Control with QuantiFERON-TB Gold In tube (QFT-IT) was performed.

Methodology: 118 HIV-infected individuals were prospectively enrolled in Rome, 21 with active TB and 98 without. Epidemiological characteristics and laboratory data were recorded. IFN-γ and IFP-10 response to QFT-IT was performed. Plasma was harvested at day-1 and soluble factors evaluated by ELISA.

Results: Significant differences between those with or without active TB were found for the CD4+ T cell counts (p=0.02), and IFN-γ and IFP-10 response to QFT-IT (p<0.001 for both analysis). Diifferently no significant differences were found for the age and HIV-RNA. Based on the commercial cut-off of the QFT-IT and on a cut-off found by ROC analysis for the IFP-10-based responses, the sensitivity for active TB of QFT-IT and the IFP-10 to QFT-IT was 52% and 67% respectively (p=0.001; K: 0.545). The response to IFP-10 was not influenced by the ability to respond to the mitogen. The specificity for active TB of QFT-IT and of the experimental test were 84% and 77% respectively (p=0.01; k: 0.710). Among those without active TB a significant correlation between a positive score and MIP expression was found (p<0.001).

Conclusions: These data suggest that IFP-10 is an additional marker to evaluate the RD1-specific responses in HIV-infected subjects confirming data previously obtained in high TB endemic countries.

Objective: To assess whether urinary levels of neopterin can discriminate between latent and active mycobacterium tuberculosis infection.

Methods: Urinary neopterin/creatinine ratio’s were determined in patients with active and latent m. tuberculosis infection and controls without m. tuberculosis infection. Latent m. tuberculosis infection was defined as reactive interferon gamma release assay for m. tuberculosis in the absence of active disease.

Results: Seven patients with active tuberculosis, 27 patients with latent m. tuberculosis infection and seven controls were recruited. There was no difference in age or gender between groups. Urinary neopterin/creatinine ratio was higher in patients with active tuberculosis (412.8 micromol/mol, 95% CI 89.7 to 735.8) than patients with latent m tuberculosis infection (147.5 micromol/mol, 95% CI 114.0 to 180.8) and controls (122.2 micromol/mol, 95% CI 71.2 to 173.1) (p<0.01). ROC curve analysis revealed an area under the curve of 0.81 (95% CI 0.62 to 0.99). A cut-off of 349 micromol/mol showed 100% diagnostic specificity in detection of active tuberculosis in people with m. tuberculosis infection.

Conclusions: Urinary neopterin/creatinine ratios are significantly higher in patients with active tuberculosis compared to patients with latent m. tuberculosis infection. These findings suggest that neopterin appears to be a suitable marker to reflect tuberculosis disease activity.

Introduction: Early referral of patients with suspected tuberculosis (TB) has a significant impact to clinical outcomes (leading to shorter infectivity and reduced morbidity and mortality rates).

Aim: To identify factors contributing to delays in the diagnosis of intra-thoracic (pulmonary, mediastinal and pleural) TB.

Methods: A retrospective case review of all patients who were diagnosed with intra-thoracic TB (January 2003 to January 2011) in Queen Elizabeth Hospital, Woolwich. Allowing for a chest X-ray (CXR) turnaround time of 3 weeks and a median period of 7 days between TB diagnosis and commencing treatment, we reviewed the full radiological history of all patients for whom the cut-off period of 28 days was exceeded. Delayed cases were divided into five groups, according to the reason for the delay:

1. Clinical diagnostic delay (unreported/misreported CXRs)
2. Delayed referral to specialist services
3. Pleural effusion (CXR’s with effusions, subsequently proven to be tuberculous)
4. CXR’s with concurrent pathologies
5. Lost to follow up

Results: 634 intra-thoracic TB notifications were made within the specified time period. 121 patients (19%) had at least one abnormal CXR taken 28 or more days prior to starting treatment (group 1: 38, group 2: 43, group 3: 16, group 4: 8, group 5: 16). The time delay between first abnormal CXR and starting treatment varied considerably (median: 69.5 days, range: 29–1020 days) and was greater in male (73%) and Asian patients (40%). 32 patients (26.4%) were sputum smear positive.

Conclusion: The diagnosis of RTB is delayed for a significant number of patients and appropriate measures should be taken in order to minimise such delays.

Introduction: Patients with suspected pulmonary tuberculosis and negative sputum samples constitute a problem that is not uncommon in clinical practice. Fiberoptic bronchoscopy is an alternative method of collecting respiratory samples that plays an important role in such cases.

Objectives: The aim of this study was to assess the yield of bronchoalveolar lavage in early diagnosis of negative sputum smear pulmonary tuberculosis and its impact on management.

Methods: The study was conducted for 27 months in a central hospital. Bronchoscopy was performed in patients after three consecutive negative sputum smears for acid-fast bacilli, in United Kingdom.

Results: In the overall diagnostic yield of fiberoptic bronchoscopy was 39% (39 out of 100) and included 18% of other diagnosis than tuberculosis with 3 cases of malignant disease. Through bronchoalveolar lavage smear and nucleic acid amplification test for M. tuberculosis an immediate diagnosis was obtained in 57.1%. Median time to positive culture was lower in bronchoalveolar lavage compared to supposed smear (p<0.001). The global resistance to antituberculosis drugs was 19%.

Conclusions: Bronchoalveolar lavage samples were helpful in the management of
smear negative pulmonary tuberculosis. The procedure had good diagnostic yield and contributed to the diagnosis of other diseases.

**P4391**
Diagnostic accuracy of sputum induction test compared with bronchoscopic results to confirm of diagnosis of pulmonary tuberculosis

Yunseong Kim, Doosoo Jeon, Kwangha Lee, Kiak Kim, Hyekyung Park, Minki Lee, Sookmew Park. Internal Medicine, Pusan National University School of Medicine, Xangsan, Gyeongsangnam-do, Republic of Korea

**Rationale:**
Diagnosis of pulmonary tuberculosis is difficult in patient who do not produce sputum spontaneously, or who have AFB smear (-) sputum. Bronchoscopy is helpful in these patients, but in many cases cannot be readily available. We prospectively compared the diagnostic yield of sputum induction test with bronchoscopy.

**Methods:**
Between February 1 to July 31, 2010, we included the patients suspected active pulmonary tuberculosis, who could not produce sputum spontaneously, or who had a pair of AFB smear (-) sputum. They underwent sputum induction test and bronchoscopy. We calculated the sensitivity of AFB smear, culture for Mycobacterium tuberculosis, TB-PCR of each test, and evaluated the concordance rate by kappa test.

**Results:**
Sensitivities of AFB smear were 36.1% in sputum induction test and 33.3% in bronchoscopy. Sensitivities of culture for Mycobacterium tuberculosis were 69.4% and 75.0%, and TB PCR were 52.8% and 58.3% in sputum induction and bronchoscopy, respectively. The results of AFB smear by sputum induction and bronchoscopy were concordant in 94% (63/67 case, Kappa test=0.819). In culture for Mycobacterium tuberculosis, the results were concordant in 82% (54/67 case, Kappa test=0.684) and the results of TB-PCR were concordant in 88% (59/67 case, Kappa test=0.75).

**Conclusions:** In this study, sputum induction test had shown similar diagnostic value and sensitivity with bronchoscopy in the diagnosis of active pulmonary tuberculosis. In patients who are difficult in collecting sputum, or have AFB smear-negative sputum, sputum induction test can be an alternative approach to the diagnosis of active pulmonary tuberculosis.

**P4392**
Use of fiberoptic bronchoscopy in early diagnosis of sputum smear-negative pulmonary tuberculosis

Hsi-Yee Kwan1, Susanna Lau2, Kam-Leong Choo1, Wei-Kei Lam1, Chun-Man Wong1, Chin-Wing Yu1, Tze-Lun Wong1, Wing-Yan Chua1, Kwan-Kuang Wong1, 1Department of Medicine, North District Hospital, The New Territories, Hong Kong; 2Department of Microbiology, Queen Mary Hospital, Pokfulam, Hong Kong

**Background:** Pulmonary tuberculosis (PTB) is a major health problem worldwide. Rapid diagnosis allows early treatment and infection control, which is hard to achieve among sputum smear-negative (SSN) subjects. Different bronchoscopic sampling techniques have been used but their roles remain unclear.

**Objectives:** To evaluate the value of fiberoptic bronchoscopy in the diagnosis of PTB among SSN patients in a regional hospital in Hong Kong.

**Methods:** Medical records of 22 patients, who have undergone bronchoscopy in the North District Hospital, HK SAR, in 2009, and were later diagnosed of having PTB, were reviewed. Results of their pulmonary specimens were recorded. The exclusive diagnostic test was identified.

**Results:** Bronchoalveolar lavage (BAL) was performed in all 22 cases. Positive acid-fast smear and culture were obtained in three (13.6%) and six cases (27.3%) respectively, providing the exclusive means of diagnosis for four cases (three from smear, one from culture). Molecular study from BAL was done in 14 cases, in which five cases were test positive (35.7%), two cases gave exclusive diagnosis. Transbronchial lung biopsy (TBLB) was performed in 19 cases. All were sent for histology, while six were sent for acid-fast bacilli (AFB) culture. Histology gave positive results in five cases (26.3%), which was the exclusive means of diagnosis for two. TBLB AFB smear was all negative, but three gave positive AFB culture. Among them, one provided exclusive diagnosis.

**Conclusion:** While sputum examination remains the cornerstone in diagnosing PTB, fiberoptic bronchoscopy plus various sampling techniques served as a useful adjunct to optimize the diagnostic yield, especially among those SSN cases.

**P4393**
Rapid molecular detection of rifampicin and isoniazid resistance and identification of mutations in resistant genes of multi-drug resistant tuberculosis (MDR-TB) patients

Gulsam Ari1, Can Bicmen2, Onur Karaman1, M. Sevket Dereli1, Seri R. Aktogu Ozkan1.
1Chest Diseases and Surgery Training and Research Hospital, Izmir, Turkey; 2Microbiology, Dr. Sait Seraid Chest Diseases and Surgery Training and Research Hospital, Izmir, Turkey

Recently identification of mutations responsible for drug resistance by molecular methods are used to detect antimycobacterial resistance in MDR-TB patients and to overcome difficulties of treatment planning in some TB patients. In our study 29 patients were evaluated - 16 patients who were treated with minor therapy or with suspicion of MDR-TB and 13 patients with treatment failure, relapsing and returning after defaulting, who were taking retreatment regime. Mutations in rpoB, katG and inhA gene zones specific for rifampicin and isoniazid were investigated with molecular methods in 14 patients from direct smear positive samples and in 15 patients from positive culture. AFB stain, culture and drug susceptibility testing with BACTEC 460 were also done for all samples. 28 samples (22 MDR-TB, 5 susceptible to four drugs, 1 culture negative) were identified as M. tuberculosis complex, 1 patient was detected as M. intracellulare. 27 Patients were who culture positive for MTFB were positive with molecular methods, 1 patient who was determined as MDR-TB and isoniazid resistance was detected in 21 (9/5.5) patients. In 5 patients who were susceptible to four drugs, no mutation was found. In 3 patients with HR resistance, cure was achieved with retreatment regime.

**Conclusion:** The detection of HR resistance with molecular methods is a guide to diagnosis of MDR-TB patients andshortens the time to starting of MDR-TB treatment.

**P4394**
Real time polymerase chain reaction (RT-PCR) based rapid detection of multi-drug resistant (MDR) mycobacterium tuberculosis (MTB)

T.K. Jitakalakshmi, Manni Rathore, Girish Pai, Dattatray Joshi. Dept of TB, JJ Clinic, Mumbai, Maharashtra, India Biotechnology Research, Mahatma Gandhi Mission Hospital, Navi Mumbai, Kamothe, Maharashtra, India

**Objective:** Rapid confirmation of diagnosis of MTB and MDR-MTB in clinical samples by RT PCR and Melting Curve Analysis (MCA).

**Introduction:** TB is one of the leading causes of mortality in world. An extremely worrying aspect of MTB is the recent rise in MDR- MTB cases in several countries. The culture based diagnostic procedures takes weeks to detect TB and its drug resistant variants. In developing countries this delay could compromise efforts to interrupt TB transmission. There is, therefore, intense interest to develop rapid and precise molecular diagnostic methods.

**Methods:** DNA was extracted from sputum or body fluids of about 100 patients suspected of TB. MTB diagnosis was confirmed by RT PCR amplification and subsequent melting curve analysis, with MDR confirmation by MCA.

**Results:** In culture positive results in five cases (26.3%), which was the exclusive means of diagnosis for four cases (three from smear, one from culture). Molecular study from BAL was done in 14 cases, in which five cases were test positive (35.7%), two cases gave exclusive diagnosis. Transbronchial lung biopsy (TBLB) was performed in 19 cases. All were sent for histology, while six were sent for acid-fast bacilli (AFB) culture. Histology gave positive results in five cases (26.3%), which was the exclusive means of diagnosis for two. TBLB AFB smear was all negative, but three gave positive AFB culture. Among them, one provided exclusive diagnosis.

**Conclusion:** While sputum examination remains the cornerstone in diagnosing PTB, fiberoptic bronchoscopy plus various sampling techniques served as a useful adjunct to optimize the diagnostic yield, especially among those SSN cases.
436. Treatment of pulmonary mycobacteriosis and adverse drug reactions

4398 Efficacy and safety of linezolid for the treatment of multidrug-resistant tuberculosis (MDR-TB) and disease by non tuberculous mycobacteria (NTM)

Linezolid's (L) long-term use in the treatment of MDR-TB and NTM may be limited by its serious adverse reactions. Aim of this study was to evaluate the efficacy and tolerability of a daily dose of 600 mg of L in combination with other drugs against mycobacteria, in patients with culture proven MDR-TB and NTM disease.

Method: Between Sept 2008 and Jan 2011 in our TB Unit/Outpatient Clinic we followed 34 MDR-TB + XDR-TB and 18 NTM pts. Of them, 19 pts (2 XDR, 4 NTM), all HIV (+), had been treated with L which was added to regimens for 4-24 months (median 17). Spu腾 cultures, blood count/chemistry, ophthalmologic and neurologic examination were undertaken on a regular basis.

Results: 16 pts completed treatment and were cured. Culture became negative in all pts in an average of 14-32 weeks. One died after 5 months of treatment due to chronic respiratory failure and progressive M. avium disease, 2 discontinued (no adherence) after 5 and 7 months. 3 of 16 pts experienced adverse events, which led to withdrawal of L in all 3 pts developed bone marrow depression and one optic neuropathy. Blood transfusions were given to both pts and bone marrow function normalized after cessation of L.

Conclusion: Linezolid seems highly effective in combination treatment of MDR-TB, XDR-TB and NTM disease. The majority of patients on L had positive treatment outcomes. All pts under L treatment should be monitored closely for presence of serious adverse reactions.
regimen, tailored by drug susceptibility tests, as 4th, 5th or 6th drug for 4-20 weeks. XDR was the strict indication for Lz, MDR - only if found impossible to create the adequate chemotherapy regimen (min 4 drugs) due to intolerance and/or resistance to second-line drugs.

**Results:** After 4 weeks of treatment in all cases the evident resolution of clinical and X-ray symptoms was obtained. The sputum smear negative was achieved totally score 85.5% (30 pts) 73.3% after 8 weeks, additional 6.7% after 12 weeks and 3.3% else after 16 week. The severe side-effects, attributed to Lz, occurred in 2 pts (5.7%): pereoneal neuropathy and obstinate vomiting. Anemia, thrombocytopenia were not registered.

**Conclusion:** The regimens included L (min 8 week) are high-effective in MDR and XDR BT in spite of long-term ineffective previously treatment. The Lz safety is quit well over a period of 8-16 weeks. Lz must be considered as a drug of choice after obtaining more accurate information on optimal length of administration, taking into account its high price.

**P4403**

**Linezolid in complex treatment of XDR-TB patients**

*Irina Vasilyeva, Anastasia Samoilova, Tatevik Bagdasaryan, Atadgan Ergeshov.*

**Department:** TB Department, Central TB Research Institute, Moscow, Russian Federation

**Objectives:** To assess efficacy of treatment of XDR TB patients with linezolide.

**Materials and methods:** Treatment of 78 XDR TB patients, enrolled in this study, consisted besides chemotherapy of collapse therapy, additional albunimous nutrition, and also supporting therapy, aimed at prevention of possible side effects. All TB patients were treated with Cm, Mtx, Cs, PAS, Prn, Z, Amoxic and Cil. Patients were divided into two groups: main group included 44 patients who received complex treatment and linezolide in the dose of 600 mg per day during 6 months and the other group (controls) consisted of 34 patients receiving the same complex treatment without linezolide. Therapy results were assessed in 12 months by frequency of negatiation of M. tuberculosis with a culture method and by clinical and X-ray dynamics of a treatment process.

**Results:** Culture method confirmed that 77.3% of patients became cultures negative in 12 months in the main group and only 35.3% of patients in the group of controls (p<0.05). In the main group in 12 months 18 (40.9%) patients showed healing of cavities and resolution of infiltrations, 16 (36.4%) patients had closing of cavities from one side with expressed resolution of infiltration, 8 (18.2%) patients had positive clinical and X-ray dynamics with reduction of the size of a destruction. In the group of controls there were observed healing of cavities and resolution of infiltrations at 8 (23.5%) patients; positive X-ray dynamics and healing of destructions from one side at 2 (5.9%) patients, p<0.05.

**Conclusion:** Inclusion of linezolide into regimen of chemotherapy for XDR TB patients significantly increases efficiency of their treatment.

**P4402**

**Adverse events in the treatment of multidrug-resistant tuberculosis**

*Shahna Qaziym, 1 Itekhah Ahmad, 1 Saifullah Baig, 2 Nadeem Razvi.*

1 Research Cell, Ojha Institute of Chest Diseases, Karachi, Sindh, Pakistan; 2 Department, Ojha Institute of Chest Diseases, Karachi, Sindh, Pakistan

**Objective:** To study the frequency and nature of side effect in patients receiving second line anti TB drugs.

**Introduction:** Ojha Institute of Chest Diseases (DHUS) Karachi Pakistan is managing drug resistant TB patients since 1996. Adverse events associated with second line drugs have a severe impact on adherence. Frequency of adverse events is not studied in resource-limited settings. Since 2009 patients are being managed according to WHO guideline. Treatment regimen is tailored i and data management j and account of side effect is maintained

**Method:** Patients registered from 1st 01 – 2009 to 30-09-10 were included Data from DR TB 60 was recorded in Microsoft excel and o SPSS 16 and analyzed.

**Results:** 440 patients were registered.Age range from 9 -76 year (mean 32.9)., ratio of male to female was 54:7: 45:3. 99.3% had pulmonary tuberculosis Abdominal symptom were present in 51.4%, heart burn 48 (11.3%), abdominal pain/discomfort in 71 16.7%, epigastric pain in 29.3, nausea and vomiting in 28.2.

Vertigo observed in 140 (31.7%), hearing loss in 3.5% Depression in 5%, anxiety in 22 (5%), headache in 56 (12.7%) and 0.7% had uraemia.Psychosis in 12 (2.8%) y one had seizure, 4 joint pain. Hypothyroidism in 15 patients. Mild itching present in 7.5% cases one had exfoliated dermatitis. The onset of symptom was from seven days to 120 day. Most patients responded to symptomatic treatment. Drug were transiently stopped in patients with psychosis, completely in patient with exfoliative dermatitis and changed in 02 patients with gasteritis and one with psychosis.

**Conclusion:** Gastrointestinal event were most frequent. Treatment can be continued with treatment of adverse event in most of the cases.

**P4404**

**Adverse events during treatment for latent tuberculosis infection**

*Claudia C. Dobler, 1,2 Grey B. Marks, 1,2 Respiratory and Environmental Epidemiology Group, Woolcock Institute of Medical Research, Sydney, Australia; 2 Department of Respiratory Medicine, Liverpool Hospital, Sydney, Australia*

**Method:** Records of all patients who received treatment for LTBI at the Chest Clinic of a large tertiary hospital between 01/2000 and 04/2008 were reviewed. An adverse event was defined as any change in health status that led to treatment interruption or cessation. Liver function tests were not performed routinely during follow-up, except when the patient was considered to be at an increased risk of developing hepatitis.

**Results:** Of 201 patients in whom treatment for LTBI was initiated 143 (71%) received isoniazid for 6 months, 32 (15%) received a combination of isoniazid and rifampicin for 6 months, and the remainder were treated with different regimens. Their mean (SD) age was 21 (17) years and 44% were male. Nineteen patients (9.5%) experienced an adverse event. Seven patients developed a rash, four had encephalopathy and/or mood disorder, three had subclinical hepatitis, four experienced severe nausea, vomiting and/or other gastrointestinal symptoms and three had features of peripheral neuropathy. In eight patients who experienced an adverse event medication was temporarily ceased and then re-started without change; in four the treatment was ceased, and in seven the treatment was ceased completely. The risk of adverse events was not significantly related to age, sex, drug regimen (single drug versus combination therapy) or baseline transaminase levels.

**Conclusion:** In this cohort almost 1 in 10 patients on treatment for LTBI experienced an adverse event. Although the adverse events were generally mild to moderate, this risk has to be taken into account when deciding whether to advise treatment for LTBI.

**P4405**

**Severe adverse effects of antitubercular drugs and patient management**

**Pulmonary Department, Charles Nicolle Hospital, Tunis, Tunisia**

**Introduction:** Tuberculosis is an infectious disease which can be totally cured by combining antitubercular drugs. Current therapeutic regimens with isoniazid, rifampicin, pyrazinamide, ethambutol, and streptomycin have proved successful in treating tuberculosis. However, they are associated to a high rate of adverse effects that can lead to therapeutic failure.

**Patients and methods:** We retrospectively reviewed records of patients who present severe adverse effects of antitubercular drugs. We also examined the frequency of and reasons for changing drug regimens.

**Results:** Thirty two patients (20 men) mean age 47 years (18-80 years) were enrolled. Predominant locations of tuberculosis were pulmonary (40%). Cutaneous manifestations were the most frequent (40%) of cases, predominantly
uricartrial associated with fever in 6 cases. Anemia was noted in two cases and thymomascopy was noted in one case, anaphylactic shock in two cases, a systemic toxicemia in two cases and renal failure in one patient. Interrupting either one drug or the whole treatment was necessary to define the cause of the reaction. The clinical evolution of hypersensitivity signs was favorable in all cases following definitive withdrawal of the responsible drug. Complete recovery from tuberculosis occurred in all cases. Rifampicin was inerminated in 15 cases, pyrazinamide in 9 cases, isoniazid in 4 cases, streptomycin in 4 cases and Ethambutol in 1 case. Interrupting either one drug or the whole treatment was necessary to define the cause of the reaction. The clinical evolution of hypersensitivity signs was favorable in all cases following definitive withdrawal of the responsible drug. Complete recovery from tuberculosis occurred in all cases.

P4406

Individualized treatment regimens with second line anti-TB drugs (SLD) compared to first line anti-TB drug (FLD) only in new pulmonary TB patients, culture confirmed with full sensitivity at drug sensitivity test (DST)

Dorota P. Dziubek, Irek Zgierski, Niculae Galie, Radu Pospa,
Constantin Marica. Tuberculosis, Institute of Pneumology “Marius Nasta”, Bucharest, Romania

Background: SLD are known as less efficient than FLD. However in clinical practice some of new pulmonary confirmed, fully sensible at DST TB cases are treated with individualized anti-TB regimens containing SLD.

Material and methods: In Romania, 3845 new pulmonary culture-confirmed TB cases, with full sensitivity at DST registered between 01.01.2006-31.01.2007 were analyzed for anti-TB treatment regimen, treatment outcome, duration of treatment. Results: Out of 3845 cases, 79 (2.1%) cases were treated with regimens containing at least one SLD for at least one month and 3766 (97.9%) were treated with FLD only. Out of 79 cases treated with mixed FLD-SLD, 61 (77.1%) were successfully treated. Out of 3766 cases treated with FLD only 3309 (87.7%) were successfully treated. The difference between the success rates was statistically significant (p<0.001). The medium duration of treatment among the 79 cases treated with mixed FLD-SLD was 47 weeks (3 weeks more than a standard category I anti-TB regimen had last 24 weeks).

Conclusions: Individualized treatment regimens with SLD should be kept only for very few cases with severe adverse reaction against FLD. NTP’s must assure uninterrupted supply with at least FLD

P4407

Monitoring of antituberculous drugs adverse events during the treatment of multidrug-resistant pulmonary tuberculosis

Maryna Deursmelyeva1, Aschita Zalochnyak1, Aliaksand Skrahina2, Aleh Przymsky2, Varvara Solodownikova1, Alena Skrasha1, 1 Laboratory Department, Republic Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus; 2 Intensive Care Department, Belarusian State Medical University, Minsk, Belarus; 1 Clinical Department, Republic Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus

Setting: The known determinants of drug-resistance development are non-compliance with prescribed treatment. Clinical management of multidrug-resistant tuberculosis (MDR-TB) requires lengthy multidrug regimens that often cause adverse events. Interruptions in treatment may result from the adverse events.

Design: We retrospectively reviewed medical records of 220 patients with MDR-TB who received individualized treatment in accordance with the recommendations of the WHO. A multiple logistic regression model was performed to determine whether the occurrence of adverse reactions was associated with poor treatment outcome.

Results: One or more adverse events were observed in all patients in the study. With an average of one patient receiving treatment, noted 10.4 episodes of adverse events. The most commonly reported events were nausea and vomiting (61%), dizziness (56%), abdominal pain (39%), arthralgia (31%), ototoxicity (19%) and hepatitis (19%). The most commonly reported events were nausea and vomiting (61%), dizziness (56%), abdominal pain (39%), arthralgia (31%), ototoxicity (19%) and hepatitis (19%). With an average of one patient receiving treatment, noted 10.4 episodes of adverse events. Obtained data allow to predict possible adverse events of MDR-TB chemotherapy, to provide the availability of medications necessary for adverse events reduction, including emergency cases.

P4408

Incidence and timing of hepatotoxicity due to anti-tuberculosis treatment

Aliaksei A. Andreischik, Paul Whitaker1, Rose Mozdjak1, Rizwan Ahmed1, Muhammad Arif1, Toby Capstick2, John Watson1. 1Department of Respiratory Medicine, St James’s Hospital, Leeds, United Kingdom; 2Department of Pharmacy, St James’s Hospital, Leeds, United Kingdom

Hepatotoxicity is a life threatening complication of anti-tuberculosis treatment. It is unclear how closely to monitor liver enzymes during treatment. In the absence of liver risk factors, the American Thoracic Society advises checking them if symptoms develop. The aim of this study was to assess the timing and causative factors associated with hepatotoxicity.

We reviewed patients treated for TB in Leeds between 2006 and 2010. Elevations of aminotransferase (ALT) greater than two times the upper limit of normal (ULN) were noted in 22% (46 patients) of all cases. Our local policy recommends that patients should have ALT checked at weeks 0, 2, 4 and 8. 634 patients underwent treatment for TB during this period. 46 (7.3%) patients had ALT elevations of 2 times ULN. 14 patients (2.2%) five times ULN. Interestingly, hepatotoxicity was more common in Caucasians (p=0.02) and increasing age (p=0.07). Gender, HIV status, pregnancy, and organs affected by TB did not predict hepatotoxicity. The average time for the hepatotoxicity to develop was 28 days (range 3-306); however, this time was increased to 42 days (4-306) in patients with ALT rises greater than five times ULN. Only one patient presented with clinical symptoms of hepatitis, this patient subsequently died from liver failure. In the 14 patients with rises five times ULN, the cause was felt to be pyrazinamide in 8, isoniazid in 3, rifampicin in 1, and not established in 2. It is unknown whether identifying an elevated ALT and stopping treatment prior to symptoms reduces the severity of liver injury. We feel that careful biochemical monitoring and prompt cessation of treatment is appropriate. Only 2 patients developed hepatitis with ALT five times ULN at a time point beyond our 8 week protocol.

P4409

Antituberculosis fixed multi-dose combination and single drug therapy in hepatitis patients

Amina Kotti, Hafaaoue Daighous, Wafa Bouhawel, Olfia Khatul, Fatma Titiar, Fatma Titiar. Department of Pneumology C, Abderrahman Mami Hospital, Ariana, Tunisia

Background: Fixed dose combinations (FDCs) in tuberculosis (TB) therapy reduce the number of tablets to be consumed, simplify the medication regimen and potentially improve compliance.

Aim of study: Compare the efficacy and acceptability of anti-TB FDCs as single tablets (ST) in patients with active TB.

Patients and methods: A total of consecutive 49 patients (57 men and 37 women; mean age 38,±3.3 years) were randomly distributed into 2 groups: trial group (n=41) patients treated daily with anti-TB FDCs and control group (n=53) treated with individualized regimens (single tablets).

Results: Stratified analyses showed a similar pattern for all the group demographic, clinical and radiologic finding. The dosage of isoniazid, pyrazinamid and ethambutol was adequate in all patients. For rifampicin, dosage was statistically too low in trial group (p=0.04). Serious adverse events were noted in 39% cases of trial group vs 11.5% cases in control group. According of cutaneous reactions (7.3% vs 5.7%) and toxic hepatitis (7.3% vs 5.7%) there was no statistically difference in 2 groups. Hematologic sequellae was noted in 51% in trial group vs 36% in control group.

Conclusion: The efficacy of the anti-TB FDCs regimen was non inferior to that of the standardized regimens. But, hematologic effects were significantly higher in the group of patients treated with anti-TB FDCs.

P4410

Allergic reactions to rifampicin in tuberculosis treatment

Fatrah Chemtiti Ben Abdallah, Ines Zayani, Amel Chitrou, Sofia Taktak, Radha Mahouachi, Ali Ben Khedher. Pneumology III, Abderrahman Mami Hospital, Ariana, Tunisia

Introduction: Immuno-allergic reactions to antituberculous treatment occur in 4 to 5% of cases and cause serious problem in the management of tuberculosis especially when due to major drug such as rifampicin. Aim of the study: To describe different allergic reactions to rifampicin, the means of their confirmation and their management. Methods: Retrospective study including all patients treated for tuberculosis (TB) and who developed allergic reactions to rifampicin between January 2000 and December 2009. Results: Twelve (12) patients were included with mean age of 42 years. Mean delay of symptoms was 30 days after antituberculous treatment onset. Cutaneous reactions were noted in 11 patients, fever in 5 patients and anaphylactic reactions in 2 patients. Two patients had hepatitis, 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients. In 2 cases the occurrence of thrombocytopenia with hemoragic syndrome and 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients. In 2 cases the occurrence of thrombocytopenia with hemoragic syndrome and 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients. In 2 cases the occurrence of thrombocytopenia with hemoragic syndrome and 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients. In 2 cases the occurrence of thrombocytopenia with hemoragic syndrome and 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients. In 2 cases the occurrence of thrombocytopenia with hemoragic syndrome and 4 had hepatic cytolysis. Rifampicin responsibility was admitted after interruption of all the treatment and reintroduction one by one in 10 patients.

Conclusion: Severe allergic reactions to rifampicin are rare but can cause serious problem in tuberculosis management. In these cases rapid oral desensitization represent an interesting alternative.
P4411 Incidence of peripheral neuropathy during daily TB chemotherapy: Indian experience
Tushar Sahabuddhe, Vikas Oswal. Department of Pulmonary Medicine, Padmashree Dr. D.Y. Patil Medical College, Pune, Maharashtra, India

It is a routine practice to prescribe prophylactic pyridoxine to patients on TB chemotherapy to prevent Isoniazid induced neuropathy. However this adverse effect seems to be uncommon in our experience. We did a prospective study to determine the incidence of peripheral neuropathy in patients on daily TB chemotherapy. A total of 559 patients on standard daily TB chemotherapy as per WHO categorization were followed throughout the course of treatment. No patient received prophylactic pyridoxine. Patients with proven or suspected drug resistance were excluded from the study. Patients with existing peripheral neuropathy or those suffering from a condition predisposing to neuropathy such as diabetes, were also excluded. Patients reporting with symptoms of peripheral neuropathy such as tingling, numbness and other paraesthesia during the TB chemotherapy were followed. Other causes of neuropathy were ruled out. They were given daily vitamin B-complex (containing Pyridoxine 3 mg) one tablet thrice a day for one week. They were given 100 mg Pyridoxine daily only if there was no response. A total of 265/559 patients (4.65%) developed neuropathy symptoms. 19/26 (73.07%) patients responded to one week course of B-complex and never had recurrence of symptoms. 7/559 (1.25%) patients needed 100 mg of pyridoxine to relieve their symptoms. This indicates very low incidence of peripheral neuropathy in patients on daily TB chemotherapy without use of prophylactic pyridoxine, in Indian scenario.

P4412 Ethambutol induced bullous and lichenoid skin eruptions
Ina Ackerl, 1, 2, 3, 4 Dorina Greb, Haifa Zaibi, Med Lamine Meglich. 1Service Ben Nefiss, Hôpital Abderrahman MAMI, Ariana, Tunisie

Introduction: Ethambutol is an essential drug for tuberculosis treatment. It has been in use since 1961. Its major side effect is on visual system, cutaneous side effects are rarely described in the literature including purpura, pruritic erythematous papules and exfoliative dermatitis.

Materials and methods: We report one case of ethambutol induced bullous and lichenoid skin rashes confirmed by provocation test.

Results: It's about 73 years old woman, diabetic, treated of lung tuberculosis with Isoniazid, Rifampicin, pyrazinamid and ethambutol. After 25 days for treatment she reported generalised itching. Cutaneous examination revealed vesiculo-bullous eruptions on chest and abdominal wall, hyperpigmented face and diffuse desqua- mation on the limbs. All anti tuberculosis drugs were stopped and patient was put on local corticosteroid therapy for two weeks. The lesions cleared completely. Because of its low risk of entraining skin side effect, ethambutol was introduced the first drug in a dose of 750 mg. 24 hours later this provocation test, generalised itching and erythematovascular skin eruptions more marked on the extremities were appeared, further administration of ethambutol was stopped. Patch tests will be programmed when lesions disappeared.

Clinician should be alerted to consider ethambutol also as one of possible drug causing cutaneous eruptions.

P4413 Research on in vitro release kinetics of isoniazid (IZN) and omeprazole from oral tablets
Magda Costin 1, Bogdan Cioroiu2, Elena Butnaru 3, Holger Rüssmann2, Nicolas Schönfeld 1, Torsten T. Bauer1.

Introduction: The study aimed to follow the in vitro release kinetics of IZN and omeprazole, the influence of applied methods and release evaluation when associated with other antituberculous drugs.

Materials and method: As research method on the in vitro release of IZN and omeprazole it has been used the method of resistance in acid environment and dissolution method in neutral media. In order to evaluate the resistance in acidic conditions, 6 samples were taken in the time interval 5–110 minutes, while for dissolution in neutral media evaluation 11 samples were collected in the time interval from 10 to 320 minutes.

Results: Solubilization in acidic media: For IZN it was found a release degree of 85.9% at 5 minute and of 88.7% at 110 minutes. When associated with omeprazole, the maximum release degree it was identified at 30 minutes of 95.1%; when associated with Rifampicin, rifapentine, or other antituberculous drugs, the maximum release degree was found at 15 minutes of 99.6%. We found a very low release degree for omeprazole; the first concentrations being detected after 75 minutes and after 110 minutes we found a release degree of only 8.1%. Solubilization in neutral conditions: the lack of any IZN traces reveals that complete dissolution took place in acidic media, while for omeprazole it was found a 5.8% release degree at 10 minutes and of 40.2% after 320 minutes.

Conclusion: IZN shows a sensitive release pattern in the presence of antituberculous drugs and a slightly sensitive release pattern in the presence of omeprazole

Instead, omeprazole shows a very low release pattern when associated with IZN or other antituberculous drugs, which could cause modifications of the plasma concentrations.

P4414 Influence of inhaled bronchodilator therapy on bacterioexcretion and LQ in patients with lung TB with concomitant broncho-obstructive syndrome
Oana Kukla1, Evgeny Shmelev2. 1Granulematosis Lung Disease Department, 2Granulematosis Lung Disease Department, Central TB Research Institute RAMS, Moscow, Russian Federation

Aims: To evaluate the influence of bronchodilator therapy on bacterioexcretion and LQ in patients with lung TB and concomitant broncho-obstructive syndrome

We examined 123 patients with pulmonary TB, 47 of which had infiltrative form (IFTB), 42 patients had fibrocavernous form of pulmonary TB (FCBT), in 33 cases residual post-TB pulmonary sclerosis (PPS) was diagnosed. In 65 cases we used bronchodilator therapy with inhaled M-cholinolyltics and LABA (study group), rest of patients received theophylline per os (control group). All TB patients were treated with chemotherapy according WHO recommendations, excluding patients with PPS, in these cases no any chemotherapy was prescribed. Bacterioexcretion was assessed at the study start point, and after that it was controlled monthly till the 3rd month of therapy, this parameter was shown as a percentage of positive cases among the whole cohort of patients.

LQ evaluated at start and finish the study process using SGRQ questionnaire. We determined that bronchodilator usage accelerated rates of sputum clearance in IFTB patients on 16.8%, in FCTB patients – on 14.8%. The most dynamic data were obtained in IFTB patients. LQ in study group for IFTB patients improved at 35.6%, in control group – on 5.7%. Symptoms’ scale diminished up to 32%, “daily activity” improved for 35%, and “impact” scale of SGRQ for study group fell down up to 19.7%.

Conclusion: Modern bronchodilator therapy can accelerate the rate of sputum clearance due to drainage bronchial function and due to diminishing the ability for concomitant infection to arise, in the same time improving LQ of such patients greatly.

P4415 In vitro susceptibility of M. avium against protonamidine
Timo Weiss1, Tarek Sabha1, Jens Kollmeyer1, Torsten Blum1, Harald Mauch1, Holger Russmann2, Nicolas Schönfeld1, Torsten T. Bauer1. 1Dept of Pneumonology, Langenbeklinik Heckeshorn, 2Institute of Microbiology, Helios Klinikum Emil von Behring, Berlin, Germany

Introduction: M. avium is a potentially pathogenic mycobacterial species to humans, which is classified as difficult to cure. By the American Thoracic Society resistance testing in vitro in the case of newly diagnosed mycobacteriosis is recommended only for clarithromycin, but with treatment failure is shown the option for further testing. No data were so far reported for the susceptibility of M. avium to protonamid in vitro in the literature.

Methods: All M. avium strains that could be isolated from clinical materials in our laboratory from Jan 1st 2008 to May 31st 2010, were subjected to susceptibility testing on solid media according to DIN 58943-1.

Results: Out of 67 strains only one turned out to be resistant at an inhibitory concentration of 5 micrograms/ml protonamid. While only one further strain showed resistance to clarithromycin (32 mcg/ml), 18 strains showed resistance to moxifloxacin (4 mcg/ml).

Conclusions: Despite the absence of clinical treatment studies protonamid should be considered as a treatment option for mycobacteriosis by M. avium in the case of treatment failure or intolerance of a drug of first-line therapy.

P4416 Susceptibility of mycobacterium avium complex and mycobacterium xenopi to rifampin, rifapentine, clarithromycin and moxifloxacin, alone or in combination with ethambutol
Claire Andrejaj, Deepak Almeida, Eric Nuerberger, Jacques Grosset. Center for TB Research, Johns Hopkins University, Baltimore, MD, United States

Background: Pulmonary disease due to M. avium complex (MAC), and M. xenopi (Mx) is a growing health problem in industrialized countries and the optimal antibiotic treatment is still debated. We conducted in a vitro study to evaluate the susceptibility of the main antibiotics on MAC and Mx.

Methods: For MAC strain 101 and Mx ATCC strain 700898, minimal inhibitory concentrations (MICs), of clarithromycin (CLA), moxifloxacin (MFX), rifapentine (RPT), ethambutol (EMB) were determined on 7H11 media. Inoculum was 2.7 log10 CFU of Mx and 4.5 log10 CFU of MAC. Plates were read after 28 days of incubation at 37°C (MAC) or 42°C (Mx). MIC was defined as the lowest drug concentration that inhibits ≥99% of colonies compared to control. Combinations of EMB-RIF, EMB-RPT, MFX-CLA and EMB-MFX for Mx and MAC were tested using the checkerboard method.

Results: For MAC, MIC was >4 for CLA, 2 for MFX, >16 for RIF, >4 for RPT, 16 for EMB. For Mx, MIC was >4 for CLA, 2 for MFX, >16 for RIF, 4 for RPT, 16 for EMB. For both MAC and Mx, MIC was 1 for CLA when we
used Mueller Hinton media (pH=7.3 for Mueller Hinton media vs pH=6.6 for 7H11). Synergy was observed for EMB-RIF; EMB-MXF; MXF-CLA against Mx, and for EMB-RPT against both Mx and MAC. An additive effect was found for CLA-MXF, EMB-RIF, EMB-MXF against MAC.

**Conclusion:** The addition of EMB decreased the MIC of RPT against both MAC and Mx and decreased MIC of MXF and RIF against Mx. So, EMB could increase the in vivo activity of these antibiotics against these mycobacterial opportunistic pathogens. No antagonism between MXF and CLA was found.

### P4417
**In vitro susceptibility of mycobacterium bovis against moxifloxacin**

**Timo Weiss**, 1 Torsten Blum 1, Jens Kollmeier 1, Harald Munch 1, Holger Russmann 1, Nicolas Schönfeld 1, Torsten T. Bauer 1

1 *Dept. of Pneumology, Langenklinik Heckeshorn, Institute of Microbiology, Helios Klinikum Emil von Behring, Berlin, Germany*

**Introduction:** Mycobacterium bovis causative bovine tuberculosis is also responsible for diseases in humans. To date there are no data available on the in vitro susceptibility of M. bovis strains to moxifloxacin, an established second line drug in the treatment of disease caused by M. tuberculosis.

**Methods:** From M. bovis-positive cultures from BAL, sputum, pleural effusion or cerebrospinal fluid of 34 pts from the years 1993-2010, we retrospectively evaluated the sensitivity in vitro and the minimum inhibitory concentrations of moxifloxacin. Culturing and resistance testing was performed on solid Middlebrook agar plates.

**Results:** Out of 34 tested M. bovis-positive cultures 33 showed a sensitivity to moxifloxacin at 2 or 4 mcg/ml. Only one strain showed resistance.

**Conclusion:** Our study of a small group of patients shows a high sensitivity rate of moxifloxacin against M. bovis strains. Despite the absence of clinical treatment studies, we see a potential use of moxifloxacin as a second line drug, with regular ineffectiveness of the first-line drug pyrazinamide in M. bovis.

### P4419
**Improvement of the survival of lung cancer in a French monocentric cohort between 1990 and 2010**

**Background:** Authors report analysis of monocentric cohort of 1400 patients with lung cancer followed between 01.01.1990 and 31.12.2009.

**Methods:** Kaplan-Meyer and Foucher methods are used.

**Results:** The survival with Kaplan-Meyer method is 56% at 1 year, 23% at 5 years and 17% at 10 years. Analysis of relative survival, taking into account the mortality of the general population without lung cancer is 57% at 1 year, 26% at 5 years and 22% at 10 years (Method of Foucher, on 1990-2005 population).

**Conclusion:** This analysis shows a very interesting increase of the relative survival of lung cancer patients since 1990, global and by stage (1997 WHO Classification).

Best staging by PET and RMI and best medical strategies explain this results, specially for Stage III and Stage IV. An Hope for this pathology.

### P4420
**Survival outcomes of non small cell lung cancer (NSCLC) patients who are suitable for radical treatment at initial presentation**

**Masood Ahmad Khalil**, Joyce Barclay, *Respiratory Unit, The Royal Oldham Hospital, The Pennine Acute Hospitals NHS Trust, Oldham, Greater Manchester, Lancashire, United Kingdom*

**Background:** Lung cancer survival continues to remain poor despite the availability of better diagnostic & management strategies; as most patients have advanced disease at presentation with poor performance status (PS) & coexisting morbidities. All patients with limited disease bulk & good PS should be offered radical treatment to improve overall outcomes.

**Aims:** To assess the number of NSCLC patients who were suitable for treatment & determine the reasons for either not receiving or completing treatment. To compare outcomes of those who completed treatment with those who did not.

**Methods:** Retrospective study of all (136) newly diagnosed NSCLC (Jun 2008-Aug 2009). 9 were excluded (insufficient data).

**Results:** Of the 127 patients, 93% aged >/= 60, 52% females, 95 were not suitable and 32 were suitable for treatment. 28 received treatment (8 surgical resection, 8 radical radiotherapy, 12 chemo-radiotherapy) and 4 either did not receive or complete treatment (1 refused treatment, 1 deteriorated while receiving radical radiotherapy, 1 recurrent chest infections with deterioration, 1 treatment related side effects).

**Conclusion:** Although, carefully selected patients who received treatment showed however, these mean results hide significant variation across the cancer networks, which persists even after adjustment for case-mix (age, sex, stage, performance status, socio-economic status). The example of surgery for NSCLC is shown in the figure.

**Conclusions:** The results suggest that care for lung cancer patients in the UK is slowly improving, although some of the apparent improvement is likely to reflect the rise in data quality. However, wide variations in outcomes persist between organisations which is not explained by simple case-mix variation. These variations need to be the focus of on-going service improvement work.

**The National Lung Cancer Audit – Year 5 completeness and outcomes and case-mix adjustment**

**Paul Beckert**, 1 Roz Stanley 2, Ian Woolhouse 1, Laila Tata 1, Michael Peake 1, 1 Clinical Effectiveness and Evaluation Unit, Royal College of Physicians, London, United Kingdom; 2 Information Centre for Health and Social Care, NHS, Leeds, United Kingdom

**Introduction:** The National Lung Cancer Audit aims to record outcomes in lung cancer on a large scale and through case-mix adjustment, start to explain the wide variations in outcomes between hospitals in the UK and between the UK and other westernised countries. This abstract presents results for patients first seen in 2009 in England and Wales.

**Results:** For patients first seen in 2009, 37,304 cases were submitted from England (30,096), Wales (1,973), Scotland (4,379), Northern Ireland (819) and Jersey (37), representing >97% of the expected number of cases. Results suggest that the quality of care is improving.

Survival outcomes in advance non-small cell lung cancer – A developing country scenario
Randeep Guleria, Anant Mohan, Sachin Kumar, Ashraf Ali, Ajeet Kumar.
Medicine, All India Institute of Medical Sciences, Delhi, India

Background: Lung cancer is common and has poor survival outcome. Chemotherapy provides modest improvement. Many patients can not afford chemotherapy and it utility in advanced lung cancer in resource limited setting is debatable. Our goal was to assess the effect of chemotherapy on survival.

Method: 78 cases with advanced Non Small Cell Lung Cancer were followed up. All cases were offered platinum based chemotherapy. Patient characteristics, staging and performance status was noted. Chemotherapy arm was compared with the group not willing for chemotherapy for mortality and other parameters. Relevant statistical analysis was done. Kaplan-Meir survival estimates was generated.

Results: 41 patients received chemotherapy and 37 patients did not receive chemotherapy. The 2 groups were well matched.

Results of Kaplan-Meir analysis are shown.

Conclusion: In advanced lung cancer patients a platinum based chemotherapy provided a significant survival advantage and should be advised to these patients even in a resource limited setting.

P4422
The role of chemotherapy re-challenge in non small cell lung cancer. A retrospective study in a tertiary general hospital and thoracic center
Oncology Unit, 3rd Department of Athens Medical School, General and Chest Diseases Hospital Sotiria, Athens, Greece

Background: Chemotherapy re-challenge (CTR) is an established clinical approach in many malignancies such as ovarian cancer and small cell lung cancer.

Aims and methods: We screened medical records of 2160 patients (pts) diagnosed with NSCLC and treated with chemotherapy (CT) at our institution, between January 2003 and February 2011.

Results: 102160 pts (0.46%) were offered a CTR regimen. The histological subtypes were adenocarcinoma (A) (5 pts), squamous cell carcinoma (3 pts) and not specified (NS) (2 pts). All patients were of good Performance Status (0-1), and the majority without any comorbidities (7/10). All pts were treated with a platinum agent combined with either pemetrexed (6 pts), taxane (3 pts) or gemcitabine (1 pt). 3/10 pts had initially received adjuvant CT and CTR on their first relapse, whereas 7 pts were initially treated for advanced/metastatic disease. In the later 7 pts, partial response (PR) as best response was observed in 6 (68.7%). Median time to progression (TTP) after the initial CT was 9.8 months (range 3.6-37.5). Best responses following CTR were PR in 2 (20%), stable disease (SD) in 2 (20%) and disease progression (PD) in 4 (40%), with 2 pts still on treatment. Median TTP after CTR was 3 months (2.5-12). The 2 pts with PR after CTR (1 A, 1 NS) were both treated with platinum-pemetrexed combination and had both demonstrated PR after the initial CT and TTP of 9 and 17 mo respectively.

Conclusions: CTR is rarely opted in NSCLC likely due to rapid disease progression. The role of CTR is limited and rather unsuccessful. Nevertheless, selected patients might benefit from this approach.

P4423
Curtative treatment vs. best supportive care in advanced non small cell lung cancer patients in aged person
Junghyun Chang, Jihye Kim, Youdu Ryu, Jinhwa Lee, Soonwo Kim. Internal Medicine, Ewha Womans University, Seoul, Republic of Korea

Rationale: With the introduction of new chemotherapeutics showing better efficacy and manageable toxicity, it is now well established the role of palliative chemotherapy in advanced NSCLC. Although the majority of patients benefit from systemic anticancer treatment, including chemotherapy and/or radiation therapy of curative aim had a survival benefit comparing to best supportive care (BSC) especially in aged advanced lung cancer subjects.

Methods: The data was retrieved retrospectively from medical records of 618 patients who had been diagnosed as non-small cell lung cancer (NSCLC) in tertiary university hospital from 2000 through 2007. The analysis was confined to 146 subjects of stage IIIB or IV NSCLC over 70 years old.

Results: The mean age at diagnosis was 77 years old (range: 70-95). In good performance group (ECOG, 0-1) was 109 patients (75%) and bad performance group (ECOG, 2-3) was 37 (25%). The mean survival time following the diagnosis was 10.0±12.8 months (m). As compared to BSC (n=92), the curative treatment (CT) group (n=54) showed the better survival rate (CT median 7.6±9 m, 95% confidence interval (CI): 5.2-8.8 vs. BSC median 4.0±8.0 m, 95% CI: 2.3-5.7. p<0.008). Within good performance group, the better survival rate was also shown in curative treatment group than BSC. Contrarily, within bad performance group, there was no significant survival gain in curative treatment over BSC.

Conclusions: In over 70 years old, the survival benefit was observed in curative treatment, especially in good performance status, compared to best supportive care. In relatively poor performance status, although the outcome of survival time had a little superior tendency in curative treatment, meticulous attention should be given in treatment decision.

P4424
Assessment of German national lung cancer guideline quality indicators in routine practice – Does the new TNM-system make a difference?
Torsten Blum, Jens Kollmeier, Nicolas Schönfeld, Win Aumüller, Sandra Delis, Wolfram Grünig, Wielke Nehls, Torsten T. Bauer. Department of Pneumology, Pulmonary Diseases Clinic Heckeshorn, HELIOS Klinikum Emil von Behring, Berlin, Germany

Background: Quality assurance is an essential tool for assessing and optimizing quality of care. For that purpose, the German national lung cancer guideline (GL), published in 2010, has defined nine quality indicators (QI). So far, neither these QI have been prospectively evaluated, nor corresponding reference intervals have been specified. Furthermore, no evidence exists for the practicability of the QI concerning the utilization of the new TNM-system (UICC 7).

Methods: All patients with a first diagnosis of lung cancer (FD), admitted to our lung cancer centre between 01.01.2008 and 31.12.2009, were included into this study. Data collection has been performed prospectively using our tumour documentation system (TDS) and hospital information system (HIS). In a retrospective analysis two groups were defined in which the patients were staged by the old UICC 6 (FD in 2008) and the new UICC 7 (FD in 2009) staging system, respectively.

Results: Patients’ characteristics were similar in both groups (2008: 595 pt.; 2009: 641 pt.). For 7 out of 9 QI a result could be determined according to the defaults published in 2010, has defined nine quality indicators (QI). So far, neither these QI have been prospectively evaluated, nor corresponding reference intervals have been specified. Furthermore, no evidence exists for the practicability of the QI concerning the utilization of the new TNM-system (UICC 7).

Conclusions: In this study we were able to completely assess 7 out of 9 QI proposed by the GL exclusively on the basis of routine data of our TDS and KIS.

TUESDAY, SEPTEMBER 27TH 2011

815s
These data will not only help to improve the quality of care in our lung cancer centre but also allow first conclusions on the undetermined reference intervals for the GL-QI. However, the GL-QI should be further evaluated within a prospective, multicentre study.

**P4425**

**Outcome of patients discharged from rapid access lung clinic (RALC) with non cancer diagnosis:** Five year follow up

Andrew Wright, R. Sarkar, Lorraine Creech, Robert Stead, Marta Baboeres.

Respiratory Medicine, Macclesfield District General Hospital, Macclesfield, Cheshire, United Kingdom

**Introduction:** Since publication of NICE guidelines in 2000 RALC has become standard practice. These clinics target service towards diagnosis of lung cancer, with streamlined investigation and MDT discussion. We set up our RALC in 2003.

**Aim:** To assess if patients discharged from RALC without a diagnosis of cancer had received adequate care and were not re-presenting with malignancy.

**Methods:** We analysed a random selection of patients discharged from RALC with a non-cancer diagnosis.

Data collected: investigations, duration of follow-up, diagnosis on discharge and 5 year outcome

**Results:** A total of 220 patients were discharged during the study period from or RALC without a diagnosis of lung cancer and 35 were analysed. Male: 28. Average (SD) age 63 (14). CT scan was done in 43 patients (78%) and bronchoscopy in 20 (36%). All the cases were discussed at MDT. 30% of patients were discharged from RALC with 70% discharged to respiratory unit patient follow-up. Main diagnoses on discharge were: infection (38%), COPD (15%), benign nodules/plaques (10%), interstitial lung disease (7%), bronchiectasis (7%), vascular (7%), others (15%).

Median (range) follow-up in RALC was 24 (0-700) days. 14 (25%) patients died over the 5 years, with average age when first seen of 76 (range 61-86). Cause of death was: non respiratory malignancy (5), cardiac disease (3) and infective causes (6). None of these deaths was related to initial presentation to RALC. No patients developed lung cancer over the duration of study.

**Conclusion:** Our five year follow up study shows that streamlined investigations and MDT input in RALC is effective in ruling out lung cancer.

**P4426**

Reducing unscheduled attendances at hospital due to lung cancer via a rapid access flexible clinic

Hannah Morgan, Luke Hodgson, Richard Lee, Sarah Doffman. Dept of Respiratory Medicine, Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom

Brighton and Sussex University Hospitals (BSUH) comprises two acute hospitals in SE England. The lung cancer MDT sees 250 new cases/year. Regional and UK outcomes have been historically poor for 1 & 5 year survival with high numbers presenting late.

Data suggests that lung cancer had the highest rate of unscheduled admissions & the greatest number of inpatient bed days compared with other cancer sites in the Trust.

We present a review of admissions in 2010, including stage at presentation/route to diagnosis and the impact of introducing a flexible clinic through which patients with a known diagnosis can self- trigger an appointment or rearrange their existing appointment.

During 2010 there were 110 patients admitted as an unscheduled emergency, 83 (75%) through A&E. 33 patients (30%) were newly diagnosed and of those 26 patients (24%) had metastatic disease at presentation (Stage IV).

Within the flexible clinic 22 patients triggered an appointment and thereby avoiding an emergency unscheduled admission. There was a 20% reduction overall in lung cancer admissions in 2010 compared with 2008/9. 107 clinic appointments were cancelled following a telephone contact with the patient facilitating capacity for rapid access referrals: 96 of these were cancelled as the patients were asymptomatic.

**Conclusions:** 1. Introduction of the flexible clinic has reduced overall admissions by 20%. 2. A high proportion of patients were diagnosed with advanced disease whilst an inpatient. 3. Greater awareness of the symptoms of lung cancer may reduce late presentation. 4. Greater uptake of the flexible clinic may further reduce unscheduled admissions with lung cancer.

**P4427**

Fast track lung cancer service in a tertiary care centre

R. Naseer, M.E.J. Callister, P.K. Plant. Respiratory Medicine, St. James University Hospital, Leeds, Yorkshire, United Kingdom

**Background:** Leeds is one of the largest Lung Cancer Centres in the UK

**Aim:** Audit our practice against Department of Health (DoH) & local standards.

**Methods:** Retrospective audit of patients (pts) referred to the Fast Track cancer clinic from 03.10 to 04.10.

**Results:** 153 pts attended. 51% were fast track referrals (CO2). 37% were diagnosed with lung cancer with which 32% received best support care, 12% had radical surgery & 51% had oncological treatment. 50% had a benign diagnosis, 8% were enrolled into monitoring. 8 pts breached the 62 day target of which 63% required more than 1 diagnostic test. Analysis of breaches identified 29% surgical delays & 35% radiological delays (CT biopsy &/or PET).

**Conclusion:** 14 day & 31 day targets are achieved, however to achieve the 62 day target requires close liaison between specialties and pts requiring tests delivered by non pulmonologists are more likely to breach.

**P4428**

Rapid access lung cancer clinic – A patient satisfaction survey

R. Mustafa, S. Naik, J. Mills, M. Munavvar. Respiratory Medicine, Lancashire Teaching Hospitals, Royal Preston Hospital, Preston, Lancashire, United Kingdom

**Background:** Royal Preston Hospital runs a rapid access lung clinic for efficient staging of suspected lung cancer patients. Staging CT-scans and discussion with chest radiologists for planning and scheduling the investigations for definitive staging is carried out at first attendance. Moreover management plans are discussed with patients by doctors and reinforced by dedicated lung cancer nurse specialists who also provide ongoing psychological support to suspected cancer patients at first appointment.

**Aim:** To ascertain if patients were satisfied with the service offered at the rapid access clinic and if this service lead to early diagnostic/r staging investigations as promised. We also wanted to identify areas which needed further development and assess the different support that was particularly well liked by our patients.

**Methods:** Survey questionnaires were posted to 35 patients attending the rapid access lung cancer clinic between January 2010 and February 2010.

**Results:** 42% (n=15) of patients returned the questionnaires.

**P4429**

How do patient and hospital features influence outcomes in small cell lung cancer in England? 1,2

Annasulochana Lall, 1 Tatia 1, Catherine Free2, Rosamund Stanley3, Michael Peake2, David Baldwin2, Richard Hubbard1, 2 Epidemiology and Public Health, 1Nottingham University, Nottingham, United Kingdom; 2Glennfield Hospital, University Hospitals of Leicester, Leicester, United Kingdom; 3The NHS Information Centre, NHS, Leeds, United Kingdom; 4Respiratory Medicine, City Campus, Nottingham University Hospitals, Nottingham, United Kingdom

**Introduction:** There is geographical variation in the delivery of active treatment in lung cancer. We wanted to find out whether the features of patients and/or NHS Trusts influence this variation.

**Methods:** We linked the National Lung Cancer Audit and Hospital Episode Statistics and used multiple logistic and Cox regression analyses to assess the influence of patient and NHS Trust features on small cell lung cancer outcomes.

**Results:** There were 87,252 patients, of which 7,845 had histologically proven small cell lung cancer and 4820 (61%) received chemotherapy. Increasing age, worsening performance status, extensive stage and greater co-morbidity all significantly reduced the likelihood of receiving chemotherapy. Patients first seen in a "good" trial centre (defined as those entering >5% of expected patients into clinical trials) were 42% more likely to receive chemotherapy than those seen in other centres (adjusted OR 1.42, 95% CI 1.06, 1.90).

**Conclusion:** Overall survival was lower in men, and as age, performance status, stage and co-morbidity increased prognosis worsened. Chemotherapy led to a 50% reduction in the likelihood of death (adjusted HR 0.48, 95% CI 0.42, 0.55), and in those patients who received chemotherapy, overall survival was not affected by whether they were seen in a "good" centre.

**P4430**

A retrospective analysis of patient presentation to primary and secondary care prior to subsequent late stage lung cancer diagnosis

Anand Shah1, Sue Teoh1, Ibipinder Mann1, 2Respiratory Medicine, North West London Hospitals Trust, London, United Kingdom; 2Respiratory Medicine, West Middlesex University Hospital Trust, London, United Kingdom

**Introduction:** Lung cancer causes significant mortality representing over 20 per cent of cancer death in 2008 in the UK. This is largely due to the high percentage of late stage disease at presentation and low proportion of radical treatment. We report on the primary and secondary care presentation in patients subsequently diagnosed with late stage (3 or 4) lung cancer.

**Method:** All patients with stage 3 or 4 lung cancer diagnosed in 2008 were included. Primary care, A&E and secondary care presentation were retrospectively analysed prior to lung cancer diagnosis. Symptom presentation was assessed using NICE lung cancer referral guidelines as a gold-standard.

**Results:** 70 patients were identified during the study period. Primary care information was available in 38 patients. 34 percent of patients were diagnosed following an emergency secondary care presentation. 40 patients presented to health professionals prior to their emergency presentation or lung cancer referral with symptoms fulfilling NICE criteria for lung cancer specialist referral with 9 weeks from referral/presentation being the average. Where primary and secondary care information was available, 21 percent of patients did not see a health care professional till emergency presentation or referral. Average length of symptoms of patients prior to presentation/referral was 12 weeks.

**Conclusion:** Our study shows there is considerable delay in specialist referral from health professionals altogether considerable delay in patient presentation. This suggests further lung cancer awareness is required amongst at-risk patient populations as well as primary and secondary health care providers.

**P4431**

General practitioner (GP) communication with potential lung cancer patients: review of practices prior to onward secondary care referral

Selva Selvaraj, Kate Garbett, Julia McAdam, Kottalai Sinivasan, Harmesh Meudgil. Respiratory Medicine, Princess Royal Hospital, Telford, United Kingdom; 2Respiratory Medicine, University of Keele Medical School, Keele, United Kingdom

**Background:** Anecdotally, there is heterogeneity in what patients understand as "red light" symptoms of lung cancer and how these are communicated. This is partly because of accelerated referral pathways after initial abnormal radiology and potentially bypassing direct contact in primary care.

**Aim:** To identify if and how GPs are communicating red light symptoms and report (1) how and what patients are told prior to attending secondary care clinics, (2) how these findings relate to subsequent outcomes, and (3) the performance status of patients at the point of initial referral.

**Results:** Over a 4 month period to August 2010, of 107 referrals, 95 (89%) had complete data available for analysis. Mean (range) age was 65.8 (29-95) years. 54% are male. 79/95 (83%) had prior information from their GP with no home consultations, 15 (19%) had been contacted by telephone, 4 (5%) had received letter, and 60 (76%) had attended the GP surgery. 8 (10%) had been told that they had a possible or definite lung cancer, 54 (68%) had been told they had abnormal chest x-ray findings, and 17 (22%) had been told they were being referred for investigation. Performance status was, respectively from 0 to 4, 36 (38%), 34 (36%), 18 (19%), 6 (6%), and 1 (1%).

**Conclusions:** Results confirm the variation in referral routes and methods as well as the wide age range referred under this urgent system, but with only 23 (24%) patients with an eventual outcome of lung cancer. Results further emphasize the need to balance any direct and early information from the GP priming the patient before subsequent consultation in secondary care.

**P4432**

Does raising awareness of lung cancer symptoms in primary care alter referral patterns?

Ronan Astin1, Elizabeth Paddison2, Adam Woollf 1, Natalie Soobadou 1, Duncan Powrie 1, 2Respiratory Medicine, Southend University Hospital, Southend, Essex, United Kingdom; 3Service Res-Design and FPC Team, South East Essex Primary Care Trust, Southend, Essex, United Kingdom

**Background:** Patients with lung cancer often present late with advanced disease. This results from both symptomatic patients not presenting to primary care and delayed referral following presentation.

**Aim:** To examine whether sending General Practitioners (GPs) a reminder of the "red light" symptoms of lung cancer would increase urgent referrals and lead to earlier diagnosis.

**Method:** All 67 surgeries in South East Essex PCT received a postal reminder of the referral criteria for lung cancer. All suspected cancer referrals to Chest Clinic for 10 weeks before and after this were audited retrospectively and each case followed to completion on the pathway.

**Results:** 121 patients were referred over 20 weeks. The total number of referrals increased post intervention from 57 to 64 (12%) though this was not statistically significant (p=0.6). There was a statistically significant increase in referrals in the first 3 weeks post intervention (p=0.046) but this effect was lost by week 4 (p=0.2). More patients were discharged from the pathway in the post intervention group (28.1% vs 24.6%, p=0.2) and fewer diagnosed with cancer (26.6% vs 28.1%, p=0.2). Referrals due to haemoptysis increased in the post intervention group (10% vs 5.2%) but this did not reach significance (p=0.06).

**Conclusion:** Sending out referral guidelines resulted in an initial increase in referral numbers. This effect was lost after 3 weeks and did not improve cancer detection rates however numbers in this study were small. This suggests that conscious efforts need to be focussed on increasing patient as well as GP awareness if outcomes are to improve.

**P4433**

Outcome of lung cancer alerts in chest X-rays

Rahileddin Sarkar, Masooma Safary, Jahnavi Samanuru, Niall O’Reilly, Ana de Ramón Casado. Respiratory Medicine, Warrington Hospital, Warrington, Cheshire, United Kingdom

**Background:** Appropriately communicated alert messages on suspicious chest x-rays (CXR) is an important cornerstone in diagnosing lung cancer early. It is a standard practice in our hospital for a suspicious CXR to be faxed to the requesting department after a consultation. We investigated the effectiveness of the aforesaid system.

**Method:** Retrospective analysis of the outcome of CXR alerts from 2008-10 using the hospital radiology, laboratory systems and clinic letters.

**Results:** Out of 387 alerts analysed [mean age (sd) 70 (13) years], 239 (62%) resulted in rapid access lung clinic referrals. Radiological follow up (fu) occurred in 90% (348) of which 163 (47%) were diagnosed to have cancer. CXR fu was done in 93% (after a median period of 3 weeks; inter-quartile range 1-5wks) and 298 (77%) had CT scan (after a medium gap of 3 wks; IQR 2-4wks). In 17 (4%), no identifiable reason could be found for no radiological fu. 5/17 patients (1.3% of all) were eventually found to have malignancy. We also measured the outcomes of different abnormality patterns in the initial CXR.

**Conclusion:** Nearly half the alerts resulted in cancer diagnosis. By distributing alert messages on suspicious CXR, radiology departments can expedite early diagnosis of lung ca. We also found out that pleural effusion, opacity/consolidation, hilar mass findings in the CXR had similar potential for eventually turning out to be malignant in the study population.
Conclusions: Despite earlier findings, a CT scan was not performed prior to FOB in all patients. Fewer FOBs occurred in 2010, and may be due to the selection of patients for endobronchial ultrasound. Non-diagnostic FOBs occurred in both periods, however, further reductions in unnecessary procedures may be achievable.

Methods: Patients with a final diagnosis of small cell (SCLC) or non-small cell (NSCLC) lung cancer over a 6-month period in 2010 and the equivalent period in 2008 were analysed. The timing of the CT scan and whether FOB resulted in a diagnosis from biopsy or cytology was recorded. CT scans were reviewed to assess whether a lesion was likely to be visible at FOB.

Results: 88 patients (mean (SD) age 69 (11) years) with SCLC (n=13) and NSCLC (n=75) were identified in 2010. All underwent a CT scan. 32% of patients underwent FOB (60% in 2008). CT scanning was performed prior to bronchoscopy in 86% of patients (68% in 2008). Non-diagnostic FOBs remained common (48% in 2010, 35% in 2008). CT scans indicating endobronchial disease were associated with a positive likelihood ratio of 2.6 (2.8 in 2008). 62% of non-diagnostic procedures were predictable from the CT scan (67% in 2008).

Background: Management of patients with SPNs depends critically on the pre-test probability of malignancy. There are currently two clinical predictions models for SPNs based on data from North America. However, these models have not been validated in UK patients, in particular those managed by a Lung MDT.

Objective: To validate the two existing prediction models in patients with SPNs managed by the Lung MDT at a large teaching hospital.

Methods: 175 patients with SPNs measuring 8–30 mm managed by the Lung MDT over 3 years (2007-2009) were identified retrospectively through the institutional Lung Cancer database. Data on age, smoking, cancer history, nodule size, location, speculation, and final diagnosis was collected. Each case’s final diagnosis was compared with the probability of malignancy predicted by two models: the Mayo Clinic model and the Veteran Affairs (VA) one. The accuracy of each model was assessed by calculating areas under the receiver operating characteristic (ROC) curve and the models were calibrated by comparing predicted and observed rates of malignancy.

Results: The area under the ROC curve for the Mayo model (0.832; 95% CI 0.753-0.911) was higher than that of the VA model (0.739; 95% CI 0.641-0.838). Calibration curves showed that both models slightly underestimated the probability of malignancy for patients across all deciles of predicted probabilities, except for those with highest probability of malignancy, where the VA model slightly overestimated probability.

Conclusions: The two existing prediction models are sufficiently accurate to guide management of patients with SPNs managed by a Lung MDT.

The value of immunohistochemical markers in the differential diagnosis of adenocarcinomas

Ayeşegül Eylem1, Ayeşegül Karalezi2, Olcay Kandemir2, Gokhan Aykan3, Hatice Hasangüllü1, 1Chest Diseases, Ankara Atatürk Training and Research Hospital, Ankara, Turkey; 2Pathology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

When differential diagnosis of adenocarcinoma in lung cannot be made, immunohistochemical staining may be necessary. Value of immunohistochemical staining in the differential diagnosis of adenocarcinomas was evaluated. 74 cases of different adenocarcinomas were enrolled. Pathology slides were stained with routine H&E staining and immunohistochemical markers. Positive CK7 immunostaining was seen in 100% of lung adenocarcinomas, papillary thyroid adenocarcinomas (PTC) and breast invasive ductal carcinomas (BIDC) and 15% of gastrointestinal (GI) adenocarcinomas, whereas none of prostate adenocarcinomas were positive. Positive CK20 immunostaining was seen in 75% of GI carcinomas and 10% of prostate adenocarcinomas whereas none of lung adenocarcinomas, BIDCs and PTCs showed positive CK20 immunostaining. TTF-1 staining was observed in 100% of PTCs, 83.3% of lung adenocarcinomas, 20% of BIDCs, 15% of GI carcinomas and 10% of prostate carcinomas. Positive p53 immunostaining was seen in 87.5% of lung adenocarcinomas, 85% of GI adenocarcinomas, 90% of PTCs and 80% of BIDCs. P53 staining wasn’t observed in prostate adenocarcinomas. CK7+CK20- staining panel’s sensitivity and specificity was found as 100% and 98% respectively in differential diagnosis of lung and GI adenocarcinoma. In differential diagnosis of lung adenocarcinomas from breast adenocarcinomas, TTF-1 marker had 83.3% sensitivity and 80% specificity. Consequently, immunohistochemical studies were found valuable in differential diagnosis of lung adenocarcinomas from other adenocarcinomas. Especially in patients with lung adenocarcinoma CK 7+CK20- staining pattern seem to give important contribution to differential diagnosis.
**Late-breaking abstract: Local and systemic distribution of the GATA-3-specific DNAzyme hgd40 after inhalative exposure**

Late-breaking abstract: Local and systemic distribution of the GATA-3-specific DNAzyme hgd40 after inhalative exposure. We developed the DNAzyme hgd40 which was shown to effectively target the specificity of DNA base pairing with an inherent RNA-cleaving enzymatic activity.

Introduction: The aim of this study was to investigate local and systemic distribution of hgd40 after local exposure in mice, rats and dogs.

Methods: Randomized double blinded placebo controlled trials and quality of life in patient with bronchiectasis

Bronchiectasis is an inflammatory airway disease with vicious cycle of infection and inflammation. Macrolides have been reported for improve clinical outcomes, we study the effects of macrolide on clinical outcomes such as symptom scores and quality of life in patient with bronchiectasis.

Material and methods: Randomized double blinded placebo controlled trials of roxithromycin 300 mg or placebo once daily for 8 weeks in patient with bronchiectasis.

Conclusion: Once daily roxithromycin showed benefit on clinical outcomes as well as quality of life. Larger studies of the effects of macrolide in bronchiectasis treatment with longer follow-up times should be done.

**Late-breaking abstract: Pre-clinical characterization of RP3128, a novel and potent CRAC channel inhibitor for the treatment of respiratory disorders**

Calcium release activated calcium channels inhibitors have a potent role in treatment of airway disorders. TNF-α, LTα, and mast cell degranulation are determined. Pre-clinical efficacy of RP5090 was confirmed in respiratory models of ovalbumin-induced chronic airway inflammation. Consistent with in vivo findings, the compound caused a significant inhibition of mast cell degranulation manifested by a reduction in histamine release.

Conclusions: Results demonstrate the therapeutic potential of RP5090 as an antiasthmatic agent as evidenced from pre-clinical data. Further biological profiling in respiratory models is planned in addition to toxicological evaluation prior to Phase 1 clinical trials.

**Late-breaking abstract: Pre-clinical efficacy of RP5090 in PI3Kδ mediated airway disorders**

are key features of COPD. We investigated the effects of NVA237, a once-daily (OD) inhaled long-acting muscarinic antagonist, on exercise endurance in pts with COPD.

Methods: 108 pts with moderate-to-severe COPD were randomized to a cross-over design of NVA237 50 or placebo OD for 3 weeks, with a 14-day washout. The primary outcome was endurance time during submaximal exercise tolerance test on Day 21 of treatment. Endurance time after first dose, dynamic hyperinflation (inspiratory capacity [IC] at isotime during exercise), and morning trough FEV1 were also measured.

Results: On Day 21, endurance time significantly increased by 21% with NVA237 compared with placebo; this effect was significant from Day 1, with an increase of 10% (Table). Dynamic IC at exercise isotime and trough FEV1, showed significant and clinically relevant improvements from Day 1 that were sustained throughout the study (Table).

The safety profile of NVA237 was similar to that of placebo.

Conclusion: NVA237 OD produced immediate and significant improvement in exercise endurance from Day 1, accompanied by sustained and significant improvements in IC at isotime and meaningful improvements in trough FEV1. Improvement in endurance time increased over the study period, suggesting that mechanisms beyond improved lung function play a role in enhanced exercise tolerance.

4498 Late-breaking abstract: Preclinical evaluation of an inhibitor of cytosolic phospholipase A2 for the treatment of asthma

4500 Late-breaking abstract: Serum concentrations of new factors (IL-20, galectin 3, IL-29 and IL-33) involved in angiogenesis in patients with advanced non-small cell lung cancer (NSCLC)
Wojciech Naumnik, Maria Ossolinska, Katarzyna Niewiarowska, Elżbieta Chyczewska, Department of Pulmonology, Medical University of Białystok, Białystok, Poland

There are several factors involved in angiogenesis, not tested yet, whose role is not clear in patients with lung cancer. Our pilot study was carried out to analyze the serum concentrations of IL-20, galectin 3, IL-29 and IL-33 (ELISA) in patients with non-small cell lung cancer (NSCLC) before chemotherapy, 15 sarcoidosis (BBS), 8 hyper-sensitivity pneumonitis (HP) and 15 healthy controls (H).

The serum concentration of IL-20 was highest in NSCLC, lower in H and lowest in HP (45,1±4,2 pg/ml; p=0,01). PF-5212372 was safe and clinically relevant improvements from Day 1 that were sustained throughout the study (Table).

The safety profile of NVA237 was similar to that of placebo.

Conclusion: NVA237 OD produced immediate and significant improvement in exercise endurance from Day 1, accompanied by sustained and significant improvements in IC at isotime and meaningful improvements in trough FEV1. Improvement in exercise endurance time increased over the study period, suggesting that mechanisms beyond improved lung function play a role in enhanced exercise tolerance.
Results: SELDI-TOF spectra of patients with lung cancer, healthy control and high risk are shown for the most discriminatory peaks of 11480 m/z, 11547 m/z and 11679 m/z.

Discriminatory proteomic features between lung cancers and healthy controls

<table>
<thead>

These proteomic features were present in only lung cancer group, but not in healthy control or high risk groups.

Conclusion: SELDI-TOF-MS method can correctly distinguish patients with lung cancer from healthy individuals and SELDI-TOF-MS method may be a new tool in diagnosis and screening test for lung cancer.

4502
Bioconductance as adjunctive technique for evaluation of patients with lung masses detected by chest CT
Karleen Callahan, Rex Yung, Ming-Ying Zeng, Michael Garff. Clinical Affairs, FreshMedx Inc, Salt Lake City, UT; 1United States Medicine and Oncology, Div of Pulmonary Critical Care, Johns Hopkins University, Baltimore, MD, United States Medicine, Pulmonary & Critical Care Medicine, Johns Hopkins University, Baltimore, MD, United States

Introduction: CT screening may reduce LC mortality in high risk subjects but also finds many masses with indeterminate features resulting in invasive procedures for benign lesions.

Aims: We hypothesize that trans-thoracic bioelectrical conductance measurements may discriminate benign from malignant CT-detected lesions.

Methods: 41 subjects with CT-detected masses and or lung cancer symptoms such as cough, hoarseness, dyspnea, hemoptysis, weight loss or recurrent respiratory infections enrolled. Prior to biopsy, measured 9 parameters at 62 sites were conducted with Bioconductance Scan Platform (BSP). For each subject a composite score from collected data was calculated and an optimal cut-point set to discriminate between the malignant and benign outcomes selected.

Results: 26 pathology-confirmed NSCLC, 2 SCLC. 1 carcinoma whereas 12 had a benign outcome based on pathology (9) or stable follow-up CT (3). BSP data for LC cases: 26 true positives, 3 false negatives (including the carcinoma), 90% sensitivity. For benign cases, the BSP resulted in 1 false positive, 11 true negatives, 92% specificity. The overall ROC from BSP analysis was 91%.

Conclusion: BSP bioconductance measurements is associated strongly with a thoracic cancer or benignity. A technology that non-invasively provides adjunctive information to CT scanning to decide whether biopsy or further follow-up is appropriate will be an important clinical tool.

4503
Amorphous components of the extracellular matrix have impact as new biochemical markers on malignancy characterization and prognosis of non-small cell lung cancer
Maristela Peres Ranger1, Vanessa Karen de Sá2, João Roberto Maciel Martins2, Edwin Roger Parra1, Aline Mendes2, Dirce Carrasco2, Eloísa Olivieri2, Vera Luiza Capelozzi2, 1Pathology, Universidade Federal de São Paulo, São Paulo, SP, Brazil; 2Biochemistry and Molecular Biology, Universidade Federal de São Paulo, São Paulo, SP, Brazil; 3Pathology, Hospital AC Camargo, São Paulo, SP, Brazil

Introduction: Many have reported that glycosaminoglycans (GAGs) have different behaviors in the presence of malignant tissues. In this study, we examined different GAGs concentrations and their impact on diagnosis and/or prognosis of patients with non small cell lung cancer.

Methods: Sulfated GAGs and Hyaluronic Acid (HA) were examined in tumoral and non-tumoral tissues from 45 lung cancer patients. Tissue samples were dehydrated and incubated with a proteolytic enzyme. The levels of HA were measured by a noncompetitive ELISA-like fluorometric assay. The sulfated GAG chains (heparan, dermatan and chondroitin sulfate - HS, DS and CS), were precipitated, dissolved in DNAse and their concentrations were identified after gel electrophoresis.

Results: HS and HA showed significantly higher concentration in tumoral than in normal areas (p<0.02 and p<0.0001, respectively; Fig. 1A/B). The Kaplan-Meier survival curves shows that tissues with lower concentrations of HA have better long-term survival than those with higher concentrations (Log Rank=3.59; p=0.05; Fig. 1C). One hundred% of tumoral areas presented CS while the normal almost never (p=0.0001; Fig. 1D).

Conclusions: The results presented suggest a possible role of these molecules on lung cancer development, but more importantly provide potential biochemical markers for differentiating normal from lung cancer patients.

4504
Interferon (α,β, and ω) receptor 2 (IFNAR2) is a prognostic biomarker for lung cancer
Nobuhisa Ishikawa1, Noboru Hattori1, Sonosuke Tanaka1, Yasushi Horimasa1, Akihito Yokoyama1, Nobuuki Kohno1, 1Departments of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; 2Department of Hematology and Respiratory Medicine, Kochi Medical School, Kochi University, Nankoku, Japan

Background: The type I interferon receptor subunit, interferon (α,β, and ω) receptor 2 (IFNAR2), has been reported to be overexpressed in several malignancies, primarily adenocarcinomas (ADCs). However, the biological significance of IFNAR2 in human lung cancer has not yet been studied.

Methods: Immunohistochemical analysis of 113 surgically resected non-small cell lung cancer specimens was performed. Serum concentrations of IFNAR2 were also determined by an enzyme-linked immunosorbent assay in 157 lung cancer patients and 164 healthy volunteers.

Results: IFNAR2 overexpression was observed in all histological types of lung cancers examined. Furthermore, strong IFNAR2 expression was associated with shorter progression-free survival (PFS) and overall survival (OS) (p < 0.0001 and p = 0.0110, respectively) in non-small cell lung cancer patients. Multivariate analyses confirmed its independent prognostic value for PFS and OS (p < 0.0001 and p = 0.0222, respectively). IFNAR2 serum levels were also significantly higher in lung cancer patients than in healthy volunteers (p < 0.0001).

Conclusions: IFNAR2 overexpression was observed in various histological types of lung cancers, and appears to be associated with lung cancers that behave aggressively. The results of this study strongly support the potential of IFNAR2 as a diagnostic and prognostic biomarker for lung cancer.

4505
SHOX2 DNA methylation is a promising biomarker for the diagnosis of lung cancer in plasma
Bernd Schmidt1, Christoph Kneip2, Anke Seegerbarth3, Michael Fleischhacker4, Volker Liebsberg3, Dimo Dietrich3, 1Pneumology, University Hospital Halle, Halle, Germany; 2Molecular Diagnostics, Theracons GmbH, Mainz, Germany; 3Molecular Diagnostics, Bavarian Nordic GmbH, Berlin, Germany; 4Hematology · Oncology, University Hospital Charité, Berlin, Germany; 5Molecular Diagnostics, Epigenomics AG, Berlin, Germany

Background & objectives: SHOX2 DNA methylation (5mSHOX2) has been shown...
previously to identify lung cancer in bronchial aspirates and a test for 5SHOX2 is available in Europe as an IVD test to aid pathologists in the diagnosis of lung cancer. DNA methylation biomarkers can also be used to detect tumour-derived circulating DNA in blood. The objective of the present study was to develop a modified assay for detection of 5SHOX2 in plasma and to evaluate the clinical performance in patients.

Methods: A real time PCR duplex assay originally developed for quantification of 5SHOX2 in a high background of unmethylated DNA in bronchial aspirates was modified for the unique requirements of plasma. Following assay optimization, quantitative real-time PCR was used to analyze 5SHOX2 in plasma samples (n = 411). A training study was performed to determine a cut-off for patient classification (n = 20 lung cancer patients, n = 20 controls) and the resulting cut-off was verified in a testing study (n = 202 stages I – IV lung cancer patients, n = 169 controls, including patients with other cancers like e.g. of prostate).

Results: The assay reliably detected 15 pg of methylated DNA in a background of 50,000 pg unmethylated DNA. The 5SHOX2 assay differentiated lung cancer patients from controls with a specificity of 60% and a specificity of 99%. Patients with stages II (72%), III (55%) and IV (83%) lung cancer were detected at a higher sensitivity as compared with stage I patients (27%). Small-cell lung cancer (80%) and squamous cell carcinoma (63%) were detected at higher sensitivity than adenocarcinoma (39%).

Conclusions: 5SHOX2 is a promising biomarker for detection of malignant lung disease in plasma.

4506
Circulating tumor cells in chronic obstructive pulmonary disease patients
Céline Sanfienzo1,2, Karine Risso1, Vérylde Sellam1, Véronique Hofman1,3, Marius Ilie4, Elodie Long5, Eric Selva5, Christelle Bonnetaud5, Charles-Hugo Marquette1,2, Paul Hofman4,5,6,7,8,9, 10.

Introduction and hypothesis: Migration of circulating tumor cells (CTC) in the blood stream is an early event occurring during lung carcinogenesis. Chronic obstructive pulmonary disease (COPD), even in early stages, is associated with a higher incidence of lung cancer in smokers and ex-smokers. The purpose of this study was to look for the presence of CTC in a cohort of smokers having a COPD.

Methods: The presence of CTC was searched in 50 COPD patients, using both the CellSearch (CS) and the isolation by size of epithelial tumor (ISET) methods. Results: The detection of CTC in a group of 30 patients with stage IIIb or IV non small-cell lung cancer (NSCLC) and in a group of 30 healthy individuals.

Results: 80 (80%) COPD patients had CTC (mean=4; range: 2-8 CTC) detected by CS and ISET methods. 18/30 (60%) of advanced stages NSCLC patients showed CTC (mean=16; range: 2-8). 50 No CTC were detected in healthy individuals.

Conclusion: The detection of CTC using the CS and the ISET methods is a rare biological event in COPD smoker patients. In this regard, the potentiality of the CS and the ISET methods as tools for detecting early biomarkers of lung carcinogenesis is challenging.

4507
A step towards easier diagnosis of lung cancer: Detection of volatile organic compounds in air releasing tumour samples with ion- and differential mobility spectrometry
Julia Isabella Karth1, Kai Darwich1, Dirk Theagarten1, Jorg-Ingo Baumback2, Roman Parkhart1, Lutz Freitag1, 1Pneumology, Ruhrlandklinik, University Hospital Essen, Essen, Germany; 2Microfluidics and Clinical Diagnostics, RIST Europe, Saarbruecken, Germany; 3Clinical Research, Becherconsult, Bernau, Germany

Introduction: Lung cancer is the tumour with the highest mortality rate in the western world.

Unfortunately, the diagnostic process is still extensive. The detection of Volatile Organic Compounds (VOCs) in air releasing tumour samples might be a method to accelerate the process of gaining first results.

Objectives: The goal in this study was to develop a method using VOCs in the detection of characteristic peaks to determine tumour containing tissue and to specify tumour entities with air samples.

Methods: Employing an Ion Mobility Spectrometer (IMS) and a Differential Mobility Spectrometer (DMS), 30 tumour and lung samples were placed into an aluminium lung simulator and analysed by the IMS and IMS via side-stream Teflon tube. Tumour containing samples were compared to non-tumour samples from the same individual in order to distinguish between characteristic peaks. Furthermore the peaks were statistically analysed.

Results: The results showed various characteristic peaks and clusters in both measuring devices. These were able to differentiate between tumour and non-tumour samples (e.g. peak "P38", p<0,0003 in adenocarcinoma samples), as well as between the tumour entities. In addition certain peaks (e.g. "P38" in the squamous cell carcinoma samples) were lower in the tumour group.

Conclusion: VOCs are able to discriminate between tumour entities and also to detect tumour containing tissue. In future research projects IMS and DMS should be compared with a closer view on standardizing peaks in order to gain further opportunities for more precise tumour detection.

462. Appropriate use of antibiotics in respiratory infections in Europe (the GRACE project)
Sibyl Anthierens1,2,3, Sarah Tonkin-Crine1, Elaine Douglass4, Lucy Yardley4, Herman Goossens5,6, Theo Verheij7, Samoen Coenen1,2,3, 1Centre of General Practice, University of Antwerp, Antwerp, Belgium; 2Vaccine & Infectious Disease Institute (Vaxinfectios), University of Antwerp, Antwerp, Belgium; 3Laboratory of Medical Microbiology, University of Antwerp, Antwerp, Belgium; 4Health Psychology, University of Southampton, Southampton, United Kingdom; 5Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands

Background: In the last stage of the GRACE project a pragmatic trial was done to assess the effects of communication training and the use of a CRP test on antibiotic treatment of lower respiratory tract infections. The current study assessed the feasibility, acceptability and acceptability of the intervention in this trial across 5 European countries (Belgium, Netherlands, Poland, Spain, UK). The aim was to elicit GP and patient attitudes before the intervention, in order to adapt the interventions as necessary.

Method: 30 GPs and 13 patients from the 5 countries were interviewed before the intervention using a "think aloud" approach. Data were coded following techniques taken from framework analysis.

Findings: GPs across all countries were supportive of the aims of the intervention, provided the strong evidence base supporting the training and found the web-based format appealing. Country-specific differences often reflected differences in health systems, and highlighted where the intervention could be tailored. The patient data highlighted the importance of the When and How of using the booklet as very important in the success of the use of the booklet. Analyses of patient data gathered during the intervention will also be presented if available.

Discussion: The findings provide valuable insights informing future development of behavioural interventions across Europe regarding antibiotic use.

4509
The effect of amoxicillin in lower respiratory tract infection (LRTI): A placebo controlled RCT in 16 primary care GRACE networks from 12 countries in Europe
Paul Little1, Beth Stuart1, Theo Verheij2, Chris Butler4, Michael Moore1, Samoen Coenen1,3, Maciek Godzycki-Cwikło6, Artur Mierzecki7, Slawomir Shlabicz8, Antoni Torres9, Jordi Almirall10, Peter Edwards11, Tom Schaberg12, Sigvard Möstl13, Francesco Biasi13, 1Centre of General Practice, University of Antwerp, Antwerp, Belgium; 2Vaccine & Infectious Disease Institute (Vaxinfectios), University of Antwerp, Antwerp, Belgium; 3Laboratory of Medical Microbiology, University of Antwerp, Antwerp, Belgium; 4Health Psychology, University of Southampton, Southampton, United Kingdom; 5Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands; 6Department of General Practice, Cardiff University, Cardiff, United Kingdom; 7Department of General Practice, University of Antwerp, Antwerp, Belgium; 8Department of Family and Community Medicine, Medical University of Lodz, Lodz, Poland; 9Independent Laboratory of Family Physician Education, Pomorski Medical University, Szczecin, Poland; 10Department of Family Medicine and Community Nursing, Medical University of Białystok, Białystok, Poland; 11Serví de Pneumologia, Institut Clinic del Torax, Barcelona, Spain; 12Intensive Care Unit, Hospital de Marato, Marato, Spain; 13Ely Bridge Surgery, Ely Bridge Surgery, Cardiff, United Kingdom; 14Zentrum für Pneumologie, Diakoniekrankenhaus Rotenburg, Rotenburg, Germany; 15Unit of Research and Development in Primary Health Care, Jonkoping, Jonkoping, Sweden; 16Istituto Malattie Respiratorie, University of Milan, Milan, Italy; 17Ghent University, University Hospital, Ghent, Belgium; 18Zdravstveni dom Jesenice, Zdravstevni dom Jesenice, Jesenice, Slovenia; 19Faculty of Pharmacy, Vrije Universiteit Brussel, Brussel, Brussel, Belgium; 20University Medical Center Utrecht, Utrecht, Netherlands; 21Department of General Practice, Cardiff University, Cardiff, United Kingdom; 22Department of General Practice, University of Antwerp, Antwerp, Belgium; 23Department of Family and Community Medicine, Medical University of Lodz, Lodz, Poland; 24Independent Laboratory of Family Physician Education, Pomorski Medical University, Szczecin, Poland; 25Department of Family Medicine and Community Nursing, Medical University of Białystok, Białystok, Poland; 26Centre of General Practice, University of Antwerp, Antwerp, Belgium; 27Department of General Practice, University of Antwerp, Antwerp, Belgium; 28Department of General Practice, University of Antwerp, Antwerp, Belgium; 29Department of Family and Community Medicine, Medical University of Lodz, Lodz, Poland; 30Independent Laboratory of Family Physician Education, Pomorski Medical University, Szczecin, Poland; 31Department of Family Medicine and Community Nursing, Medical University of Białystok, Białystok, Poland; 32Centre of General Practice, University of Antwerp, Antwerp, Belgium

Introduction: LRTI is the commonest acute presentation managed in primary care and still a major driver of antibiotic prescribing. Systematic reviews of placebo controlled studies are small (<1000).

Aim: To determine the effectiveness of amoxicillin for lower respiratory tract infection.

Methods: 2054 patients presenting with uncomplicated acute cough (<4 weeks) as the main symptom were randomised to amoxicillin 1g three times a day or placebo for 7 days. Patients completed validated symptom diaries for symptom severity (7 point scale) and duration. Notes were reviewed for repeat consultations.
Results: 593 of trial population (28%) were aged 60+, and symptom severity documented and duration were documented in 87% of patients. There was no significant difference in symptoms severity in the first 4 days after seeing the doctor (placebo mean 1.69, antibiotic 1.62; difference -0.07 [0.18 to 0.00]), and no significant difference in the proportion with moderately bad or worse symptoms at 7 days (47% vs 40% respectively, p=0.07 NNT 14). Among the subgroup of patients with no COPD, there was no evidence of antibiotic benefit. 5% more patients in the antibiotic group compared with the placebo group developed nausea, rash or diarrhoea (NNH 20).

Conclusions: Antibiotics are very unlikely to provide meaningful symptomatic benefit in LRTI for most patients, and any benefit is likely to be similar to the magnitude of harm.

4510 Undetected chronic obstructive lung disorders in patients presenting with acute cough in primary care: Results from the European GRACE study

Lidewij Broekhuizen¹, Saskia van Vught², Peter Zuithof², Chris Butler², Samuel Coenen³, Herman Goossens³, Paul Little², Theo Verheji², Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands; ²Department of Primary Care & Public Health, Cardiff University School of Medicine, Cardiff, United Kingdom; ³Microbiology, University of Antwerp, Wilrijk, Belgium; ⁴Faculty of Medicine and Health and Life Sciences, University of Southampton, Southampton, United Kingdom

Introduction: Cough is among the most frequently presented complaints, and a suitable opportunity to consider the presence of underlying asthma or COPD.

Aims: To determine the prevalence of undetected chronic obstructive lung disorders in patients consulting their general practitioner (GP) with complaints of cough ≤ 28 days.

Methods: For this cross sectional diagnostic study, 2532 adult patients without known asthma or chronic obstructive pulmonary disease (COPD), attending their GP with complaints of cough ≤ 28 days, were recruited from 12 European countries. Inclusion criteria were: symptom duration at day 28 after inclusion; Asthma was defined present if there were recurrent complaints of wheezing, cough or dyspnoea, and/or bronchodilator response; COPD was defined present according to two cut off values for the (post bronchodilator) ratio of the FEV1 to the forced expiratory volume in one second (FEV1/FVC ratio): 1) below 0.7 (“fixed ratio”); 2) below the lower limit of normal (LLN) according to age, gender, height.

Results: 336 subjects had asthma (13%), and according to the used definitions of COPD 1 and 2, respectively 246 (10%) and 168 (7%) subjects had COPD. Spearman’s Correlation between GOLD and LLN was 0.71. There was discrepancy between GOLD and LLN definition for COPD in especially the elderly and the very young.

Conclusions: In patients presenting acute cough, undiagnosed asthma was more frequently detected than COPD. Different definitions for obstructive spirometry results led to large differences in the proportion of patients classified with COPD.

4511 Developing clinical definitions of LRTI for research and primary care practice in Europe: A consensus study using the GRACE Network

Giles Greene¹, Kerenza Hood², Samuel Coenen³, Theo Verheji², Paul Little², Herman Goossens³, Christopher Butler², ¹Department of Primary Care and Public Health, Cardiff University, Cardiff, United Kingdom; ²South East Wales Trials Unit (SEWTU), Department of Primary Care and Public Health, Cardiff University, Cardiff, United Kingdom; ³Vaccine & Infectious Disease Institute (VAXINFECTIO), University of Antwerp, Antwerp, Belgium; ⁴University Medical Center Utrecht, Julius Center for Health, Sciences and Primary Care, Utrecht, Netherlands; ⁵School of Medicine, University of Southampton, Southampton, United Kingdom

Introduction: Antibiotic prescriptions for LRTI accounts for a large proportion of antibiotic consumption and many of these prescriptions do not benefit patients and contribute to the growing problem of antibiotic resistance. Addressing the primary care research agenda to improve evidence-based management requires clear definitions of clinical entities.

Aims: We aimed to generate definitions for four LRTIs: community-acquired pneumonia, acute bronchitis, acute exacerbations of chronic obstructive pulmonary disease, and acute infective exacerbations of asthma, that apply to clinical practice and low intensity investigation research settings in European primary care.

Methods: Candidate definitions elicited from the systematic review of literature and a nominal group meeting were the put to a Delphi panel of selected experts from Europe and the US over three rounds. The definitions achieving high consensus were then tested for usability by an expert panel.

Results: 253 papers met our search criteria. The nominal group meeting generated highly ranked definitions for two LRTIs. The Delphi panel considered five candidate definitions derived from the systematic review and nominal group meeting and agreed upon definitions and open comments for the expert panel to assess the “usability” of these emerging definitions.

Conclusion: We combined empirical evidence with expert opinion for the development of a set of clinically based definitions for the five most common LRTIs presenting in general practice.

4512 Detecting pneumonia in patients with acute cough in primary: Results from the European GRACE study

Saskia van Vught¹, Lidewij Broekhuizen¹, Peter Zuithof², Pin de Jong², Greet Ieven³, Herman Goossens³, Christine Lammens⁴, Samuel Coenen³, Chris Butler², Paul Little², Theo Verheji², Julius Center for Health, Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands; ²Department of Respiratory, University Medical Center Utrecht, Utrecht, Netherlands; ³Department of Medical Microbiology Vaccine & Infectious Disease Institute (VAXINFECTIO), University Hospital Antwerp, Antwerp, Belgium; ⁴Department of Primary Care and Public Health, Leiden University Medical Center, Leiden, Netherlands; ⁵Department of Primary Care and Public Health, University of Southampton, Southampton, United Kingdom

Introduction: It is still unclear what the best strategy to detect pneumonia in primary care patients should be. To quantify the diagnostic value of history, physical examination and the added value of inflammation markers in detecting pneumonia in patients presenting with acute cough in primary care.

Methods: 2820 adult patients attending their general practitioner with complaints of cough ≤28 days, were recruited from 12 European countries. Patient’s history and physical examination were recorded on the day of presentation. C-reactive protein (CRP) and pro-calcitonin (PCT) were drawn from venous blood samples and chest radiographs were taken within the next three days. Pneumonia was diagnosed by chest X-ray. With multivariable logistic regression a diagnostic model was developed for diagnosing or ruling out pneumonia.

Results: 140 patients had radiographic pneumonia (5%). Symptoms and signs with independent diagnostic value were: absence of runny nose, presence of breathlessness, diminished vesicular breathing and crackles on auscultation, tachycardia (pulse >100/min), and temperature >37.8°C. Combined these items showed an area under the ROC curve of 0.70 (95% confidence interval 0.65-0.75). A combination of the 2 strongest predictors (crackles and temperature >37.8, n=30) had a positive predictive value for pneumonia of 37%. Analysis of the added value of the added of CRP and PCT is in progress. A diagnostic model will be available in the presentation.

Conclusions: Radiographic pneumonia is uncommon in adults presenting in primary care with acute cough. Brief history and physical examination can help discriminate between those at high and low risk for pneumonia.

4513 GRACE Network of Excellence: Genetic susceptibility to lower respiratory tract infections in Europe

Anna Rautaniemi¹, Tara Mull¹, Stephen Chapman¹, Christine Lammens², Margareta Ieven³, Adrian Hall³, ¹Welcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; ²Department of Medical Microbiology, University Hospital Antwerp, Antwerp, Belgium

Introduction: Lower Respiratory Tract Infection (LRTI) is one of the leading reasons for seeking medical care in Europe. However, not everyone is equally susceptible to LRTI.

Aims and objectives: To identify host genetic factors that may play an important role in explaining this inter-individual variation in susceptibility to LRTI.

Methods: DNA was extracted from blood samples of 3000 cases and 3000 matched controls recruited within the GRACE study. Single nucleotide polymorphisms (SNPs) in 19 genes, selected based on our earlier studies on severe LRTI (invasive pneumococcal disease (IPD)), were genotyped with Sequenom’s iPLEX technology. For 5 remaining genes (SOD1, IL1B, IL10, TLR4 and IFITM3), genotyping was performed with TaqMan chemistry as a second independent validation of all genotyping.

Results: SNPs in the genes PTPN22 (Arg620Trp: p=0.037, OR 2.0) and NFKBIZ (rs6156597: p=0.022, OR 0.87; rs600718: p=0.028, OR 0.87) associated with LRTI in the initial analysis which included half of the cases and controls. PTPN22 is a lymphoid specific protein tyrosine phosphatase that regulates the immune response through T-cell signalling. NFKBIZ is one of the NF-kB inhibitors and thereby affects the transcription of pro-inflammatory genes. Genotyping of the rest of the samples is ongoing. In addition, more candidate genes possibly involved in the host immune response to viral infections will be genotyped. In the further analyses, cases will be subdivided based on the microbiological cause of their LRTI, namely between bacterial and viral infection, and further to specific pathogens.

Conclusions: Host genetic factors involved in the pathogenesis of IPD might also be important in defence against milder LRTIs. Identification of these factors may potentially lead to more individualised detection, treatment, and prevention of LRTIs.

4514 Lower respiratory tract infections in the European GRACE primary care network: Bacterial causes or do viruses also matter?

Margareta Ieven¹, Katherine Loens¹, Frank Coenjaerts¹, Christine Lammens², Anouk Vandersteen³, Theo Verheji², Paul Little², Herman Goossens³, Eric Claas⁴, Anton van Loon⁴, ¹Vaccine and Infectious Diseases Institute, University of Antwerp, Antwerp, Belgium; ²Department of Virology, University Medical Center Utrecht, Utrecht, Netherlands; ³Department of Primary Care Research, University of Southampton, Southampton, United Kingdom; ⁴Department of Medical Microbiology, Leiden University Medical Center, Leiden, Netherlands

Especially the role of the newly recognised viruses is not well known in adult
lower respiratory tract infections in the community (LRTI). We investigated the role of *S. pneumoniae* (Sp), *Haemophilus influenzae* (Hi) and viruses in LRTI in the GRACE primary care network (PCN) using culture and real-time nucleic acid amplification tests (RT-NAATs). From 10/2007-04/2010 3102 patients with LRTI were enrolled in a prospective study in 16 PCNs in 12 EU countries. Nasopharyngeal swabs (NPS) and sputa for culture of *Sp* and *Hi* were collected and frozen until transport to the central lab for nucleic acid (NA) extraction. Aliquots of NA extracts were sent to the LUMC and UMC-U for detection of influenzaviruses (INF) A/B, parainfluenzavirus (PIV)-1-4, human rhinoviruses (HRV), human metapneumovirus (hMPV), respiratory syncytial virus (RSV), adenoviruses (hAdV), Bocavirus (BOCA), coronaviruses (HCoV) OC43, NL-63, 229E, polyomaviruses KI and WU by in-house RT-PCR.

In 3082/3102 patients a NPS was collected. An aetiologic agent was detected in 77% of patients: *Sp* and *Hi* in 9.1% and 14.9% respectively; a respiratory virus in 53.1%; HRV 18.6%, INF 11.1%, HCoV 7.4%, hMPV 4.4%, RSV 4.4%, polyomaviruses 2.8%, PIV 2.5%, hAdV 1.4%, BOCA 0.5%. For most viruses no significant differences were observed in prevalence between the 3 winters. In <5% of patients persistence of respiratory virus was seen in the follow up visit.

This is the largest aetiologic study on LRTI in PCNs: in ±80% of the patients a microbial agent was found; over 50% were viral infections: HRV’s account for the majority. Use of RT-NAATs results in a significant improvement of the aetiologic diagnosis LRTI.

**The role of vitamin D3 in the local inflammatory process in sarcoidosis (SA)**

Anna Kowalska1, Elzbieta Pascinka1, Anna Golan-Geremek1, Agnieszka Skoczylas1, Justyna Czerwiawska1, Adriana Rozyl1, Paulina Jagus1, Joanna Chorostowska-Wynimko1, Dorota Górecka1, 2Laboratory of Molecular Diagnostics and Immunology, Institute of TB & Lung Diseases, Warsaw, Poland. 1Department of Respiratory Medicine, Institute of TB & Lung Diseases, Warsaw, Warsaw, Poland.

**Background**: SA is an inflammatory disease characterized by granulomas that can produce a 1,25(OH)2D hormone. No reports are available in the literature on the role of vitamin D3 derivatives in the local inflammatory process in SA.

**Aims**: To assess the role of vitamin D3 derivatives in the local inflammatory process in SA based on the determination of their concentration in the bronchoalveolar lavage fluid (BALF) as well as in exhaled breath condensate (EBC).

**Material and Methods**: In 108 pts (48 women, 60 men; mean±SD age 44.3±9.5 yrs, BMI=27.5±4.8) with SA stage I-IV we measured 1,25(OH)2D (pg/m), 25(OH)D (ng/ml) in serum and BALF as well as leukocytes, lymphocyte phenotypes CD4/CD8, alkaline phosphatase (ALP), ACE, D-dimer, fibrinogen, albumin and gammaglobulin, phosphate in serum and 24h calcium urine excretion.

**Results**: Results are shown below:

**Table 1**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

There was no other significant correlation between 25OHD or 1,25(OH)2D and other evaluated inflammatory markers.

**Conclusions**: Significant correlations between some inflammatory markers and 25(OH)D or 1,25(OH)2D concentration in serum may suggest a role of vitamin D3 as an indicators of inflammatory process in SA.

**Polymorphisms in CCR5 confer susceptibility to Löfgren's syndrome and may regulate the immune response**

B. Karakaya1, C.H.M. van Moorsel1, G.T. Rijkers2, A.H.M. van der Helm3, T.W.J. Huizinga1, J.M.M. van den Bosch1, J.C. Grutters1, 1Department of Pulmonology, Center for Interstitial Lung Disease, St Antonius Hospital, Nieuwegein, Netherlands; 2Department of Medical Microbiology and Immunology, St Antonius Hospital, Nieuwegein, Netherlands; 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands.

**Rationale**: Löfgren’s syndrome is an acute and usually self-limiting phenotype of sarcoidosis. Several studies have found associations between specific gene polymorphisms and susceptibility to sarcoidosis. Chemokines are small peptides that mediate monocyte, lymphocyte and neutrophil chemotactic activity by binding to specific G-protein coupled receptors, such as CCR5. A study showed that the HIC haptotyope of CCR5, with single nucleotide polymorphism (SNP) rs179987, was associated with Löfgren’s syndrome.

**Objective**: We investigated if SNPs of the CCR5 gene were associated with Löfgren’s syndrome and had an effect on the B-lymphocyte response of patients.

**Methods**: Hundred and twenty patients with Löfgren’s syndrome were characterized and genotyped for 4 SNPs in CCR5. Our control cohort consisted of 313 self-reported healthy individuals.

**Results**: Carriage of the G-allele was significantly higher in patients with Löfgren’s syndrome than in healthy controls (p=0.0057, CI 1.13-2.01, OR 1.505). Twelve out of 18 patients with Löfgren’s syndrome showed no calcium response, of which 11 were carriers of the G-allele: 7 GG, 4 GA, 1 AA. Nine of these 12 patients where women. All controls showed a calcium mobilization response upon stimulation with MIP-1α.

**Conclusions**: The SNP rs179987 in the CCR5 genes is associated with Löfgren’s syndrome. Functionality assays showed that polymorphisms of the CCR5 have an impact on cellular processes that may regulate the response of B-lymphocytes.

**Chitotriosidase: A sensitive biomarker of sarcoidosis**

Elena Bargagli, David Bennett, Claudia Maggiorelli, Maria Grazia Pieroni, Rosa Metella Refini, Maria Grazia Perari, Paola Rottoli, Respiratory Diseases Section, Department of Clinical Medicine and Immunological Sciences, University of Siena, Siena, Italy.

Chitotriosidase is a member of family of glycosylhydrolases, enzymes involved in...
in the degradation of chitin and chitin-like substrate, identified in a wide variety of organisms. Increased concentrations of chitinidase have been reported in several lysosomal storage diseases and more recently also in sarcoidosis.

In this study chitinidase concentrations were evaluated in a population of 233 sarcoidosis patients and 70 controls in order to verify enzyme specificity and sensitivity and to evaluate chitinidase prognostic meaning. Chitinidase has been found significantly increased in serum of patients with sarcoidosis than in controls (p < 0.0001). ROC curve analysis revealed: cut-off value of 39.50 nmol/h/ml, sensitivity 89.70% and specificity 90%. The analysis of chitinidase in different phenotypic subgroups of patients revealed very high serum enzyme levels in symptomatic patients requiring systemic steroid therapy at onset and after disease relapses.

In conclusion as a new potential biomarker of sarcoidosis severity, chitinidase resulted sensitive, reproducible and easily detectable in serum.

4519 Mycobacterial heat shock protein 16 kDa, marker of dormant stage of mycobacteria, in precipitated circulating immune complexes in sarcoidosis Anna Dubaniewicz1, Adam Holownia2, Mahavir Singh4. 1Department of Pulmonology, Medical University of Gdańsk, Gdańsk, Poland; 2Department of Clinical Pharmacology, Medical University of Białystok, Białystok, Poland; 3Department of Genome Analysis, Helmholtz Center for Infection Research and LIONEX Diagnostics & Therapeutics GmbH, Braunschweig, Germany

M. tuberculosis antigens, e.g., heat shock proteins (Mtb-hsp), genetic factor and autoimmunity can act as potential causes of sarcoidosis (SA). Mtb-hsp inducing both cellular and humoral immune response may provide a link between infection and autoimmunity. We have recently demonstrated the presence of Mtb-hsp70, Mtb-hsp65 and Mtb-hsp16 in sarcoiid tissue. Higher occurrence of serum Mtb-hsp70 than Mtb-hsp65 and Mtb-hsp16 in SA patients could be caused by sequestration of Mtb-hsp65 and Mtb-hsp16 in circulating immune complexes (CIs). To test this hypothesis, we have evaluated and quantified Mtb-hsp70, Mtb-hsp65 and Mtb-hsp16 in precipitated CIs from blood of 20 patients with SA, 19 patients with active tuberculosis (TB) and 21 healthy volunteers using PEG precipitation and Western Blot. The results showed significantly increased CIs levels in SA vs TB and Control, whereas there was no difference between TB and healthy individuals. The Mtb-hsp16, Mtb-hsp65 and Mtb-hsp70 concentrations in precipitated CIs were significantly higher in SA than in TB and Control, but there was no difference between TB and Control. In all tested groups, the Mtb-hsp16 concentration was significantly increased than Mtb-hsp70 and Mtb-hsp65.

In summary, our results show increased presence of Mtb-hsp, Mtb-hsp65 and Mtb-hsp70 concentrations in healthy individuals. The Mtb-hsp16, Mtb-hsp65 and Mtb-hsp70 in precipitated CIs from blood of 20 patients with SA, 19 patients with active tuberculosis (TB) and 21 healthy volunteers using PEG precipitation and Western Blot. The results showed significantly increased CIs levels in SA vs TB and Control, whereas there was no difference between TB and healthy individuals. The Mtb-hsp16, Mtb-hsp65 and Mtb-hsp70 concentrations in precipitated CIs were significantly higher in SA than in TB and Control, but there was no difference between TB and Control. In all tested groups, the Mtb-hsp16 concentration was significantly increased than Mtb-hsp70 and Mtb-hsp65.

In summary, our results show increased presence of Mtb-hsp, Mtb-hsp65 and Mtb-hsp70 concentrations in healthy individuals. The Mtb-hsp16, Mtb-hsp65 and Mtb-hsp70 in precipitated CIs from blood of 20 patients with SA, 19 patients with active tuberculosis (TB) and 21 healthy volunteers using PEG precipitation and Western Blot. The results showed significantly increased CIs levels in SA vs TB and Control, whereas there was no difference between TB and healthy individuals. The Mtb-hsp16, Mtb-hsp65 and Mtb-hsp70 concentrations in precipitated CIs were significantly higher in SA than in TB and Control, but there was no difference between TB and Control. In all tested groups, the Mtb-hsp16 concentration was significantly increased than Mtb-hsp70 and Mtb-hsp65.

4520 Use of discriminant analysis to assess pulmonary functional worsening in patients with sarcoidosis by means of a panel of inflammatory markers Gregoriano Faustini1, Maria Kuti1, Alessandro Belli, Armanda Propati1, Angelo Sherer2, Salvatore D’Antonio3, Alfredo Sebastiani4, Giovanni Puglisi5, Giovanni Galluccio6, Sandro Batzella7. 1Department of Cardiovascular, Respiratory and Morphologic Sciences, University “La Sapienza”, Rome, Rome; 2IRC’s Fondazione Don Carlo Gnocchi – Onlus, Don Gnocchi, Milan, Italy; 3Department of Respiratory Diseases, S. Camillo-Forlanini Hospital, Rome, Italy; 4EDS Center of the Fundazione Don Carlo Gnocchi – Onlus, Don Gnocchi, Milan, Italy; 5Department of Respiratory Diseases, S. Camillo-Forlanini Hospital, Rome, Italy

Background: Sarcoidosis’ protein clinical course has prompted many studies to discover biomarkers which could help to trace disease progression and response to therapy.

Aims: In our study we performed discriminant analysis, to investigate whether a panel of selected markers measured in BALF and serum from patients with sarcoidosis would help to predict pulmonary functional worsening.

Methods: We enrolled in the study 30 consecutive individuals with sarcoidosis. At enrolment participants underwent pulmonary function tests, fiber-optic bronchoscopy and radiological evaluation. PFTs were also performed at follow-up visits during a 2 year period. Pulmonary function worsening was defined as a decline of TLC, FVC, FEV1 > 15% and DLCO > 10%. BALF differential cell counts were performed in all participants and BAL and serum ECP, MPO, Tryptase, PiHP and SiL2r concentrations were quantified by RIA and ELISA tests. Discriminant analysis was performed to optimize the accuracy of selected variables in predicting functional worsening.

Results: Pulmonary function worsening was observed in 24% of participants. Applying discriminant analysis function a high classification rate was obtained, the following formula: C= -(PMBAL x 0.18 + ECP BAL x 1.20 - MPOBAL x 0.03 + Tryptase BAL x 1.21 - PiHP BAL x 0.01 - SiL2rBAL x 0.01 -1.183), allowed the correct allocation of 100% of participants. The positive likelihood ratio was > 20 and the negative likelihood ratio was 0.

Conclusions: Our results show that a panel of BAL markers may be used to distinguish patients with stable disease from individuals with pulmonary function worsening and may help to decide therapeutic strategies.

4521 Chronic fatigue in sarcoidosis-in-clinical-remission: Psychological and physical characteristics Paper 1,2, Cobi Heijnek1, Oscar Vogel1, Jan Grutters1,4. 1Department of Pulmonology, St. Antonius Hospital, Nieuwegein, Netherlands; 2Laboratory for Neuromunomology and Developmental Origins of Disease, University Medical Center, Utrecht, Netherlands; 3Department of Neurology, St. Antonius Hospital, Nieuwegein, Netherlands; 4Division Heart & Lungs, University Medical Center, Utrecht, Netherlands

When sarcoidosis is in clinical remission, complaints of chronic fatigue often persist. The exact features of this post-infectious fatigue are unknown. This study assesses the severity of fatigue and the presence of fatigue-related symptoms in sarcoidosis-in-clinical-remission. Furthermore, we evaluate psychological distress, pain and patient-reported sleep quality, and record physical activity levels and muscle strength as objective assessments of fatigue. Lastly, we assess the severity of fatigue at a follow-up.

Methods: Seventy-five patients with sarcoidosis-in-clinical-remission were evaluated with the Checklist Individual Strength (fatigue), the SymptomChecklist-90 (psychological distress), the McGill Pain Questionnaire (pain), standardized interview (fatigue-related symptoms), sleep diary, accelerometer and muscle strength tests.

Results: Fatigue severity mean score in sarcoidosis patients in-clinical-remission was high (fatigue-severity score: 30.5±15.5), and fatigue-related symptoms were significantly more present in the fatigued patients. Median time since diagnosis was 9 years. Fatigue was significantly associated with increased psychological distress, higher pain severity scores and more pain points, reduced physical activity and reduced muscle strength. Scores on sleep quality were normal. Response at follow-up was 87%. Fatigue severity scores of the responding group were significantly higher compared to a year before.

Conclusions: Fatigue in sarcoidosis patients in clinical remission is a long-lasting and severe problem that deteriorates over time. This post-infectious chronic fatigue is associated with a constellation of psychological and physical symptoms.

464. Access to the periphery: solitary periphery nodule

4522 Usefulness of endobronchial ultrasonography with a guide sheath for diagnosing ground glass opacity lesions in sarcoidosis-in-clinical-remission: Long-term study Yasuyuki Ikawa1, Naofumi Shinagawa1, Tatsuya Takashina1, Kenichiro Ito1, Kichi Ogura1, Yuta Takeuchi1, Noriyuki Yamada1, Hajiya Ashima1, Jun Sakakibara-Komachi1, Satoshi Otsumi1, Kosuke Nakano1, Noriaki Sukoh2, Masahara Nishimura1,2. 1First Department of Medicine, Hokkaido University School of Medicine, Sapporo, Japan; 2Respiratory Department, National Hospital Organzation Hokkaido Cancer Center, Sapporo, Japan

Background and purpose: It is often hard to diagnose ground glass opacity (GGO) lesions by transbronchial biopsy (TBB), because of difficulty in detecting the site of the lesions under X-ray fluoroscopy. We have reported the usefulness of TBB using endobronchial ultrasonography with a guide sheath (EBUS-GS) for small peripheral pulmonary lesions (PPLs). EBUS-GS has an advantage to detect the site of the lesions under X-ray fluoroscopy. We have reported the usefulness of GGO lesions by EBUS-GS and examined of lesions which might influence the diagnostical yield.

Methods: We retrospectively analyzed the diagnostic yield of GGO lesions by EBUS-GS and examined of lesions which might influence the diagnostical yield.

Results: Of the 67 lesions (11 pure GGO lesions and 56 mixed GGO lesions, which consist of GGO components more than 50%), 43 (64%) were not visible by conventional X-ray fluoroscopy. Thirty-eight lesions were diagnosed by TBB with negative CT sign. (31% vs. 66%; P < 0.01) ROC curve analysis revealed: cut-off of 0.81, predictability 87%, sensitivity 84%, specificity 80%, PPV 96%, NPV 74%. Decreased physical activity and reduced muscle strength. Scores on sleep quality were normal. Response at follow-up was 87%. Fatigue severity scores of the responding group were significantly higher compared to a year before.

Conclusions: EBUS-GS is a useful method for diagnosing GGO lesions. However, failure of diagnosis is associated with the lesions in smaller size and/or with negative CT sign.

Endobronchial ultrasound-guided transbronchial biopsy with thin bronchoscopy for peripheral pulmonary lesions

Masahide Oki, Hideo Saka, Chieyo Kitagawa, Yoshitoyo Kogure, Shigehisa Kajikawa, Naohiko Murata, Takashi Adachi, Saori Oka, Rie Tsuibo.

Department of Respiratory Medicine, Nagoya Medical Center, Nagoya, Japan

**Introduction:** Endobronchial ultrasound-guided transbronchial biopsy (EBUS-TBB) using a conventional bronchoscope has the limitation of poor bronchoscopic selection of lesions because of its large size.

**Aims and objectives:** The purpose of this study was to evaluate the diagnostic utility of EBUS-TBB using a thin bronchoscope for peripheral pulmonary lesions.

**Methods:** Data prospectively collected from 188 patients with suspected peripheral lesions who underwent EBUS-TBB using a 3.4-mm thin bronchoscope with a 1.7-mm channel and a 1.4-mm radial ultrasonic probe under fluoroscopic guidance were retrospectively analyzed.

**Results:** Thirteen patients with endobronchial lesions within the segmental bronchi that were defined as central lesions and 6 patients who did not return to follow-up were excluded from this analysis. Thus, a total of 169 patients (113 men and 56 women, median age, 67 years) with peripheral pulmonary lesions (median size, 28 mm; range, 8 to 70 mm) were included in the final analysis. The mean bronchus level reached with the thin bronchoscope was 4.6 generations. The lesion was localized with EBUS in 151 patients (91%). Diagnostic histologic specimens were obtained in 115 of 169 patients (68%; 48% [81% for lesions >30 mm, 50% for lesions >20 to <30 mm, and 17% for lesions ≤20 mm] for benign lesions and 76% [85% for lesions >30 mm, 70% for lesions >20 to <30 mm, and 65% for lesions <20 mm] for malignant lesions). Five complications (3%) occurred: 1 pneumothoraces, 1 pneumonia, and 1 moderate bleeding.

**Conclusion:** EBUS-TBB using a thin bronchoscope is an accurate method for the diagnosis of peripheral pulmonary lesions, especially malignant lesions.

---

Efficacy of endobronchial ultrasonography (EBUS) using a guide sheath (EBUS-GS) for transbronchial sampling of peripheral lung lesions

R. Mustafa, S. Abdellatif, M. Munavvar. Respiratory Medicine, Lancaster Teaching Hospitals, Royal Preston Hospital, Preston, Lancashire, United Kingdom

**Background:** Endobronchial ultrasonography with a radial scanning miniature probe provides cross-sectional images of peripheral pulmonary lesions. Ultrasonic probe covered with a guide sheath is introduced via the bronchoscope and is withdrawn after localisation of the peripheral lesion. The guide sheath is left in situ to direct sampling.

**Aims:** To assess the diagnostic yield and safety profile of this novel technique.

**Methods:** Ten patients with peripheral lung lesions were selected for EBUS-GS sampling between January 2010 and June 2010. Guided sampling was later deferred in two cases with visible endobronchial disease at conventional bronchoscopy. EBUS-GS Transbronchial biopsy (TBB) and Bronchial brush (BB) specimens were obtained. With the knowledge of subsegment leading to the peripheral lesion, additional blind TBB and bronchialveolar lavage (BAL) specimens were also acquired following removal of the GS.

**Results:** Mean size of the lesions sampled was 34 mm (22 to 52 mm). EBUS-GS TBB and BB specimens yielded a definitive diagnosis of lung cancer in five (62.5%) patients. Three patients had no malignant cells in either EBUS-GS TBB or BB specimens. In one of these three patients, malignant cells were isolated from Blind TBB and BAL specimens which had been taken in addition to EBUS-GS samples. Hence, a definitive diagnosis of cancer was obtained in six (75%) patients. The procedure was well tolerated and none of the patients suffered major bleeding or pneumothorax.

**Conclusion:** Diagnostic yield of transbronchial sampling of peripheral lung lesions is significantly improved with the use of EBUS-GS without an increase in complication rate.

Ultrasound guided transbronchial cryobiopsy in the diagnosis of peripheral lung lesions: A feasibility and safety trial

Ralf Eberhardt1, Mareen Schuhmann1, Korkut Bostanci2, Nicolas Kahn1, Philipp A. Schnabl1, Felix J.F. Herth1,2

1Pneumology and Respiratory Care Medicine, Thoraxklinik at the University of Heidelberg, Heidelberg, Germany; 2Department of Thoracic Surgery, Mannheim University, Mannheim, Germany

**Background:** Peripheral lung lesions (PLL) can pose a diagnostic problem since they are often difficult to reach and only insufficient material can be obtained by transbronchial forceps biopsy. Endobronchial Ultrasound (EBUS) can be used for detection and in combination with a flexible cryoprobe (Erbe Medizintechnik, Germany) larger tissue samples can be taken. The purpose of this study was to evaluate the safety and feasibility of this technique.

**Methods:** Patients with PLL up to 4 cm in diameter were enrolled prospectively. After the PLL had been identified by EBUS we performed forceps as well as cryo biopsies under fluoroscopy through a guide-sheath. The order of the techniques was randomised. The pathologist was blinded towards the biopsy technique. We evaluated and compared the diagnostic yield and sample size as well as the complication rate.

**Results:** We were able to reach the lesion with EBUS guidance in 31 of 39 patients. The final diagnosis of the 31 patients was malignant in 25 and benign in 6 cases. In 7 cases we were able to make a definitive diagnosis with bronchoscopic sampling (23%) and in 3 patients only through cryobiopsy. Samples obtained by cryobiopsy were significantly larger. Complications observed during the procedure were 1 moderate bleed after cryobiopsy treated endoscopically. No pneumothorax occurred.

**Discussion:** Transbronchial cryobiopsy with EBUS guidance is a safe technique and useful to obtain histological samples for diagnostic purposes. By obtaining larger tissue samples it may be possible to improve the bronchoscopic diagnostic yield for peripheral lung lesions.

Safety and tolerance of transbronchial lung biopsy with cryoprobes vs conventional forceps

Laia Garcia-Bellmunt1, Virginia Pajares1, Alfonso Torrego1, Mª Carmen Pazo1, Mª Angeles Gil2, Vicente Plaza1,1Pneumology, 2Anaesthology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Bronchoscopic transbronchial biopsy (TBLB) by the use of cryoprobes has been described as a feasible procedure to obtain lung samples.

**Objectives:** To determine safety of TBLB with cryoprobes vs conventional forceps. To compare the procedure length and patients’ tolerance with both techniques.

**Patients and methods:** Patients with interstitial lung diseases referred to perform a TBLB were prospectively randomized in: Group 1: cryoprobe (Erbocryo CA®) and Group 2: conventional forceps.

**Results:** Patients in group 1, under deep sedation, were intubated to allow quick cryoprobe and bronchoscope introduction and removal. Bronchoscopies in group 2 were performed under conscious sedation. Tolerance questionnaires, number of biopsies, procedure’s duration and related complications were registered.

**Results:**

- Safety and tolerance of transbronchial lung biopsy with cryoprobes vs conventional forceps

- Complication rate.

- Tolerance: Qualitative scale (a) 95.4 ± 2.0; (b) 47.8 ± 9.3 NSP

- Tolerance: Quantitative scale (cm) (b) 2.5 ± 2.2; 1.4 ± 0.8 p < 0.05

- Data is expressed as mean ± SD.

Bronchoscopy of peripheral lung lesions: Cost-effectiveness analysis of different combinations of sampling techniques

Kjell Roth1,2, Tomas Mikael Egan2, Friedemann Leib2,3, Alf Henrik Andreassen1, Jon Andrew Hardre2,2Dept. of Internal Medicine, Helge Samban, Alesund, Norway; 1Dept. of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 1Dept. of Pathology, Haukeland University Hospital, Bergen, Norway

**Background:** Few studies have measured both the costs and the effectiveness of different combinations of sampling techniques when bronchoscopies of peripheral lung lesions are evaluated.

**Objective:** To find the most cost effective combination of sampling techniques for peripheral lung lesions not visible by bronchoscopy.

**Methods:** 289 patients were included in an open prospective trial performed at the Haukeland University Hospital and Aalesund Hospital in Norway, from June 2005 to January 2008. All sampling techniques (biopsy, brushing, trans-bronchial needle aspiration (TBNA), and washing) were performed in 178 cases (study sample). The costs from the Department of Thoracic Medicine and the Department of Pathology were calculated for each sampling technique. The combined diagnostic yield for benign and malignant disease was the effectiveness measurement. The willingness to pay for one additional positive sample was estimated to be 2800 euro, based on the cost for 5 days in a day ward and the cost of one additional investigation.

**Results:** The combination was cost-effective when the incremental cost-effectiveness ratio (ICER) was below the willingness to pay. The ICER was 1211 euro for biopsy and brushing.

**Discussion:**
compared to biopsy alone. Addition of washing or TBNA to biopsy and brushing was not cost-effective for peripheral lesions (ICER washing: 822 euro, ICER TBNA: 826 euro).

Conclusion: Biopsy and brushing was the most cost-effective combination of sampling techniques for peripheral lesions.

4528 The effect of forceps type on results and complications of transbronchial lung biopsy
Hamidreza Jabbardarzai, Alireza Eslaminejad, Arda Kiani. NRITLD, Masih Daneshvari Hospital, Tehran, Islamic Republic of Iran

Background: Lung biopsy via the bronchoscope (TBLB) is among the routine diagnostic procedures for pulmonary diseases and is performed using either of two different kinds of forceps: cup and alligator.

Objective: The purpose of this study was to compare the efficacy of two kinds of forceps on quality of biopsy as well as the side effects of TBLB.

Methods: This was a prospective, observational and double-blind study in which four samples were biopsied from each patient via TBLB. The sample characteristics were recorded based on size, number of alveoli included, diagnostic value, and the side effects such as pneumothorax and bleeding.

Findings: A total number of 44 patients and 176 biopsies were evaluated. Twenty one patients (47.7%) were males and 23 (52.3%) females. While considering the size of samples, of 88 biopsies via alligator forceps, 21.6% were small, 45.5% medium, and 33.5% large. Corresponding results for the cup forceps were 43.2% small, 29.5% medium, and 27.5% large. From 88 biopsies taken using alligator forceps, 18.2% were found to have diagnostic value whereas in the case of cup forceps the diagnostic value was 23.9%. While no significant pneumothorax was seen with alligator forceps it was observed in 9% of the cup forceps procedures. Significant bleeding was seen in 1% of the alligator forceps and 5.7% of the cup forceps procedures.

Conclusion: Comparing two types of forceps regarding the effect on results of TBLB, alligator forceps produced larger samples (P=0.008) and less side effects (P=0.002). There was no significant difference in diagnostic value between two procedures (P=0.355).

466. COPD mechanisms

P4533 Fibrotic component in patients with emphysema reduces both exercise capacity and quality of life and increases exacerbations
Nariaki Kokuho, Takeo Ishii, Hiroki Hayashi, Misuzu Kurahara, Takashi Motegi, Kumiko Hatori, Kouichi Yamada, Koucho Kaminio, Akihiko Gemma, Kozui Kida. Department of Internal Medicine, Division of Pulmonary Medicine, Infectious Diseases and Oncology; Respiratory Care Clinic, Nippon Medical School, Tokyo, Japan

Background: Characteristics of the combined pulmonary fibrosis and emphysema (CPFE) remain to be elucidated. Little is known regarding the effect of the fibrotic component on exercise capacity, quality of life (QoL), and exacerbations.

Methods: A total of 220 smokers (current or ex-smokers) with and without COPD were recruited. The fibrotic component, defined as reticular opacities and honeycombing, was graded according to the Kazerooni score and the existence and severity of the the extent of emphysema were determined also by HRCT.

Data on age, gender, smoking history, pulmonary function, body mass index (BMI), exercise tolerance (6-min walking test; 6MWT), modified Medical Research Council (MMRC) Dyspnea Scale and Oxygen Cost Diagram (OCD); QOL, St. George’s Respiratory Questionnaire; SGRQ; and outcome data were collected. The association between the fibrotic component and exercise tolerance, QoL, and exacerbations were studied with adjustment by emphysema.

Results: The subjects (age, 68.9±9.6 years; M: 196/23) included 176 patients with emphysema and 64 patients with COPFE. The fibrotic component worsened hypoxemia during the 6MWT (p < 0.05). In CPFE, the severe fibrotic component resulted in worsened dyspnea (MMRC Dyspnea Scale, p < 0.03; OCD, p < 0.02), reduction in the distance in 6MWT with borderline significance (p = 0.08), and reduction in the minimum blood-oxygen saturation level (p < 0.01); further, the severity of the fibrotic component was positively associated with exacerbations (p < 0.04) and hospitalization (p < 0.01).

Conclusions: In CPFE, fibrotic change worsened both dyspnea and exercise capacity and also increased exacerbations.

P4534 Relationship of systemic inflammation and autoimmunity to clinically relevant outcomes in COPD
Belen Nuñez1,2, Jaume Sauleda1,2, Josep M. Amat1,3,4,5,6, Mª Rosa Julià2, Esther Barreiro1,3,8, Eduard Monés2,9, Aina Nuñez2,10, Joaquim Gea5,7,8, Federico Gómez2,11,12, Judith García-Aymerich1,3,4,5,6, Alvar Agustí11,12, PAC-COPD Investigators. 1Servei Pneumologia, Hospital Son Espases, Palma de Mallorca, Illes Balears, Spain; 2CIBER, CIBER Enfermedades Respiratorias, Barcelona, Illes Balears, Spain; 3Centre for Research in Environmental Epidemiology, CREAL, Barcelona, Spain; 4 Municipal Institute of Medical Research (IMIM)-Hospital del Mar, IMIM, Barcelona, Spain; 5Department of Experimental and Health Sciences, University Pompeu Fabra, Barcelona, Spain; 6CIBER, CIBER Epidemiología y Salud Pública, FCS, Barcelona, Spain; 7Servei Pneumologia, Hospital Son Espases, Palma de Mallorca, Illes Balears, Spain; 8Servei Pneumologia, Hospital del Mar, Barcelona, Spain; 9Servei Pneumologia, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain; 10Servei Analítics Clítics, Hospital Son Espases, Palma de Mallorca, Illes Balears, Spain; 11Institut d’Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain; 12Thorax Institute, Hospital Clinicina, Barcelona, Spain

Introduction: Chronic obstructive pulmonary disease (COPD) is associated with low-grade systemic inflammation and autoimmunity. Their relationship with relevant clinical outcomes is unclear.

Objectives: To evaluate the relationship of systemic inflammation and markers of autoimmunity with two clinically relevant outcomes, namely number of hospital admissions for respiratory disease and exacerbations.

Method: We studied 342 patients with clinically stable COPD recruited into the PAC-COPD study (68±9 yrs., FEVI 52±16% ref, FEVI/FVC 54±12%, x<SD) who were followed up for 3 years. At recruitment, we determined the serum concentration of C-reactive protein (CRP [mepholometry]), pro-inflammatory cytokines (IL6, ILB and TNFα), ELISA), oxidative stress markers (carbohydrates, nitrotyrosines, malondialdehyde (MDA) by ELISA) and circulating antimicrobial antibodies (ANA) and anti-tissue (AT) antibodies (by immunohemagglutination).

Results: We observed that, at recruitment: (1) levels of CRP (9.9±20.6 vs. 7.2±15.5 pg/ml) and IL-8 (5.6±3.9 vs. 4.8±3.4 pg/ml) were higher (p<0.01), and those of MDA lower (8.2±5.52 vs. 9.7±8.53 mM), in patients who subsequently required hospital admissions during follow up; and, (2) levels of CRP (10.8±18.6 vs. 7.8±17.5 pg/ml), carbohydrates (0.23±0.1 vs. 0.19±0.09 mmol/ml), nitrotyrosines (8.3±4.83 vs. 6.5±4.79 pg/ml) and AT antibodies (22% vs 12%) were higher (p<0.05) in patients who died during follow-up.

Conclusions: Systemic inflammation and autoimmunity influence important clinical outcomes in COPD.

Supported in part by FIS 05/0282.

P4535 Metabolic phenotype and adipose tissue inflammation in patients with chronic obstructive pulmonary disease
Pavol Joppa1, Jozef Ukropec2, Peter Skyba1, Barbara Ukropcova2, Pavol Pobeha1, Katarina Stroffekova3, Miroslav Brusik1, Daniela Gasperikova2, Ruzena Tkacova1. 1Department of Respiratory Medicine and Tuberculosis, Faculty of Medicine, P.J. Safarik University and L. Pasteur University Hospital, Kosice, Slovakia (Slovak Republic); 2Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia (Slovak Republic); 3Department of Biophysics, Faculty of Sciences, P.J. Safarik University, Kosice, Slovakia (Slovak Republic)

Rationale: Potential links between metabolic derangements and adipose tissue inflammation in patients with chronic obstructive pulmonary disease (COPD) are unexplored. We investigated adipose tissue tissue expression of interleukin (IL-6), tumor necrosis factor (TNF)-alpha, CD68 (macrophage cell surface receptor), caspase-3 and Bax, and their relationships to the metabolic phenotype in nine cachectic, 12 normal-weight, 12 overweight, and 11 obese patients with stable COPD (age 62.3±7.2 years).

Method: Body composition was assessed by DEXA manufacturers. Subcutaneous and visceral fat were analyzed using real-time PCR. Results: With increasing body mass index, increases in adipose tissue expressions of inflammatory or proapoptotic markers in cachectic, 12 obese patients who sub-

Conclusions: Our results suggest that adipose tissue inflammation in obese COPD patients relates to insulin resistance. Cachectic patients remained insulin sensitive, with no significant upregulation of inflammatory or proapoptotic markers in the adipose tissue.

P4536 Anemia predicts mortality after COPD exacerbation
Aida Munoz Ferrer, Carlos Martinez, Karina Portillo, Pere Serra, Maria Luisa Martinez, Ignacio Garcia Olives, Marisol Prats, Joan Ruiz Manzano, Josep Moreira. Department of Pulmonology, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain

Anemia is a recognized prognostic factor in many chronic illnesses, but there is limited information about its outcomes in patients hospitalized due to an acute COPD exacerbation (AE-COPD).
Aim: To investigate whether anemia exert an effect on mortality after 1 year of follow-up.

Methods: From November 2007 to November 2009 we recruited 117 patients who required hospitalisation due to an AECOPD. We collected demographic data, nutritional status, hemoglobin (Hb), hematocrite (Ht) and lung function. Patients were followed up during 1 year. Mortality and days-to-death were collected.

Results: Mean age 72 (SD:4.9); FEV1, 38 (SD:12); mortality after 1 year was 21.4%. Comparing those who died to those who survived we found significant differences (p<0.000) in Hb (12.4 vs 13.8 mg/dl) and Ht (38 vs 41%). Anemia (Hb<13 g dL) prevalence was 34%. Those who died had had 4 exacerbations in previous year vs 2 exacerbations in the case of the survivors (p=0.007). Lung function and nutritional status were similar, except for muscular mass (35 vs 39%; p=0.015) and albumine (33 vs 37mg/dl; p=0.039). These variables were included in a multivariable analysis, Hb and previous exacerbations resulted as independent factors for mortality. Mortality risk for patients with anemia was 5.6 (CI: 1.6-20.1), for patients with >1 exacerbation in the previous year was 6 (CI: 1.3-127.1).

Conclusion: Anemia and previous exacerbations were independent predictors of mortality after 1 year in patients hospitalized due to AECOPD.

P4537
Relation of cardiac enzymes and echocardiographical findings with long-term mortality after chronic obstructive pulmonary disease exacerbation
Ekrem Cengiz Seyhan, Nurdan Veske, Gulsah Guinoglu, Sinem Sokucu, Mustafa Deger, Sedat Altin.

Background: Patients with chronic obstructive pulmonary disease (COPD) are at increased risk of cardiovascular disease, exacerbations of which increase strain on the heart. In our study, effects of cardiac enzymes and echocardiographical findings to the long term mortality in patients with respiratory insufficiency due to COPD were investigated.

Methods: From the Yedikule hospital database, 208 patients discharged after an AECOPD attack were enrolled. Measurements of cardiac-specific enzymes (troponin, heart type fatty acid binding protein (H-FABP), NT-ProBNP, CK-MB) were available. Also echocardiography was performed.

Results: Twenty-one patients without, and 18 with severe exacerbations were enrolled (35 men; age 62.2±7.3 years). Compared to patients without exacerbation, those with the disease had lower serum levels and AT expressions of lepion, and increased serum β-crosslaps (p=0.028, p=0.034, resp.). Log AT leptin was inversely related to serum β-crosslaps (p=0.015), and directly to leptin (p<0.001) and the total, femoral, and lumbar BMD and T-score (p<0.02 for all). AT OP expression was related to all variables of bone density except for lumbar BMD (p<0.05 for all). Log AT leptin and OP expressions predicted femoral T-score indepen- dently of age, gender and pulmonary function (p<0.001, R²=0.383; p=0.008, R²=0.301, resp). Introducing body or fat mass index into these models eliminated independent predictive value of leptin and OP expressions.

Conclusion: Our results suggest that adipose tissue leptin and OP expressions are related to exacerbations in patients with COPD, and appear to act as mediators between fat mass and BMD.

Support: APVV-0122-06, VEGA-1/0227/11 and VVGS 36/10/11.

P4539
Reduced grip strength is related to frequency of exacerbations and lower health status in COPD
Khalid Ansari1, Joan Munby1, Graham Burn1, Ian Taylor3, Andrea Kay1, Malcolm Farrow2, Niall Keane3, 1Dept of Pharmacy, Health and Wellbeing, University of Sunderland, Sunderland, United Kingdom; 2Chest Clinic, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom; 3Chest Clinic, Sunderland Royal Hospital, Sunderland, United Kingdom.

Muscle weakness is a feature of COPD that affects quality of life. Systemic inflammation, an accompaniment of acute exacerbations, has been implicated in its aetiology. Recurrent exacerbations are also associated with lowered health status. This study examines the relationship between muscle weakness, health status and exacerbation frequency in a cohort of patients with COPD.

This is an observational study of 188 (95 female) COPD patients attending two hospital clinics in the North –East of England. We recorded spirometry, health status (SGRQ), grip strength (Jamar), MRC dyspnoea score and the reported frequency of exacerbations in the previous year.

Patients were aged 72.5±8.3 years with MRC score of 3±6.0±8 FEV1 of 49.2±21.5 percent predicted and a total SGRQ score of 72.2±15.5. Grip strength, expressed as a percent predicted, was 72.0±18.2 in men and 81.0±18.2 in women (mean ± SD). Exacerbations ranged from zero to five in the previous year and there were associations of reduced grip strength with exacerbation frequency (p= 0.0019) and lower health status (χ2 = 34.0; p < 0.0001).

Conclusion: Our data clearly demonstrate that reduction in grip strength is greater in patients with a history of frequent exacerbations and is associated with reduced health status.

P4540
Gender differences in formation of endothelial dysfunction (ED) extension in COPD patients
Lyudmyla Konopkina, Tetyana Pertseva. Faculty Therapy and Endocrynology, State Medical Academy, Dnipropetrovsk, Ukraine.

ED is one of the most important branches in pathogenesis of cardio-vascularal events (CVE). It is established that soluble intercellular adhesion molecule-1 (sICAM-1) is one of the markers of ED. But it is known little about ED in COPD patients (pts) particularly in accordance with gender features.

Aim: To study the ability in prognosis of ED extension in COPD pts due to gender.

We studied 93 pts in stable phase of COPD, divided into 2 groups: 1st – 61 pts (42% of men and 58% of women); 2nd – 32 pts (35% of men and 65% of women). Measurements included clinical status, spirometry, serum level of sICAM-1 and FEV1.

Results: The level of sICAM-1 was significantly higher in male with COPD than in health male, but there were no differences between levels of sICAM-1 in female with COPD and in health female (table). Due to stages of COPD there was no correlation between sICAM-1 and FEV1 in the 1st group (p=0.175 (p<0.05)), but there was negative correlation in the 2nd group (r=-0.373 (p=0.046)).

Anaemia presented with higher age (p=0.003), pH (p=0.014) and arterial oxygen known causes for anaemia were excluded.

Brüder Regensburg Hospital, Regensburg, Germany; 7Division of Respirology, McGill University, Montreal, QC, Canada; 2Medicine, University of British Columbia, Vancouver, BC, Canada; 3Medicine, University of Calgary, Calgary, AB, Canada; 4Medicine, Dalhousie University, Halifax, NS, Canada; 5Toronto, University of Toronto, Toronto, QC, Canada; 6Medicine, Universite Laval, Quebec, QC, Canada

Background: GOLD sought to standardize COPD definition and severity. The clinical meaning of GOLD I and it progressive nature remains uncertain.

Objective: To determine the characteristics of GOLD stage I and I progression.

Methods: This research is part of the Canadian Cohort Obstructive Lung Disease (CanCOLD), a prospective longitudinal study with a population-based sample of COPD. Subjects are recruited from 9 cities in one of 4 subsets (sex and age matched): 1) GOLD GOLD ≥2, 2) GOLD I, 3) non-COPD controls, i.e., at risk (ever smoker) and healthy. Measurements were done at baseline and 3-5 years later.

Results: This preliminary analysis included 111 subjects. GOLD I subjects as compared to GOLD ≥2 had less wheezing (20% vs 41%, p=0.048), physician-diagnosed asthma (14% vs 41%, p=0.007), and better FEV1 (46% vs 46%, p=0.191) and MCS (54 vs 50, p=0.02). GOLD I subjects were less likely to have a physician-diagnosed COPD (6% vs 17%, p=0.031) and to be prescribed respiratory drugs (16% vs 30%, p=0.027). GOLD I subjects with GOLD ≥2 as compared to non-COPD control reported more dyspnea MRC ≥2 (39% vs 20%, p=0.082) but chronic bronchitis and level of health status (SF-36) were similar. Annual change in FEV1 were -62 ml/year (p=0.001) for GOLD, -32 ml/year (p=0.006) for GOLD ≥2 and 21 ml/year (p=0.001) for non-COPD. GOLD annual change in physical health (SF-36 PCS) were -0.42 (p=0.086) for GOLD, -0.89 (p=0.023) for GOLD ≥2 and -0.20 (p=0.54) for non-COPD.

Conclusion: GOLD stage I appears to be associated with more rapid decline in FEV1, and worsened health status.

A366 Anemia in chronic respiratory failure

Florian Koller1,2, Carolin Müller2, Andrea Tippelt2, Rudolf A. Joerres3, Dominik Heidinger4, Corina Probst5, Michael Pfeifer6,7, Stephan Budweiser7, Department of Respiratory and Clinical Immunology, University Medical Center, Freiburg, Germany; 2Centre for Pneumology, Donaustauf Hospital, Donaustauf, Germany; 3Institute and Outpatient Clinic for Occupational, Social and Environmental Medicine, Ludwig-Maximilians-University, Munich, Germany; 4Department of Respiratory Medicine, University of Freiburg, Freiburg, Germany; 5Division of Respiratology, Internal Medicine II, University of Regensburg, Regensburg, Germany; 6Department of Pneumology, Barmherzige Bruder Regensburg Hospital, Regensburg, Germany; 7Division of Respiratology, Department of Internal Medicine III, RoMed Clinic, Rosenheim, Germany

Background: In patients with severe chronic obstructive pulmonary disease (COPD), anaemia is common and associated with impaired long-term survival and quality of life. Whether anaemia is also prevalent in patients with other severe, non-infectious respiratory diseases has not yet been systematically tested.

Methods: In 595 patients with obstructive (OD, 54.8%) or restrictive disease (RD, 45.2%) and chronic respiratory failure (CRF), anthropometric data, laboratory parameters, lung function, blood gases and co-morbidities were assessed prior to initiation of home mechanical ventilation. Patients were classified as anaemic based on haemoglobin (Hb) levels (Hb <12/13g/dl, female/male). Patients with known causes for anaemia were excluded.

Results: In patients with CRF the prevalence of anaemia was 13.5% and not different between RD (11.5%) and OD (14.7%) (p=0.276). A sex-related difference occurred only in OD (7.9% (f) versus 17.3% (m); p=0.035). Patients with OD and anaemia presented with higher age (p=0.003), pH (p=0.014) and arterial oxygen pressure (PaO2) (p=0.012), lower body mass index (BMI) (p=0.011) and total protein (p=0.012), and higher rates of coronary heart disease (p=0.011), cardiac arrhythmia (p=0.014) and diabetes mellitus (p=0.003) in comparison to non-anaemic patients. In patients with RD anaemia was associated with higher age, (p=0.008), pH (p=0.011) and lower leucocytes numbers (p=0.006).

Conclusions: Anaemia is frequent not only in COPD but also in other severe respiratory diseases combined with CRF. It was associated with advanced age, several co-morbidities, impaired nutritional state and elevations of pH and PaO2, probably due to hyperventilation. Its prognostic impact has to be elucidated in future studies.

P4543 Association of inflammation and bronchial hyperresponsiveness

Irina Trolimenko, Boris Cherneyak, Palmetto, State Educational Institution for Continuing Professional Education, Irkutsk, Russian Federation Palmetto, State Educational Institution for Continuing Professional Education, Irkutsk, Russian Federation

Bronchial hyperresponsiveness (BHR) is known to be linked to decline in lung function, only limited data are available as to whether BHR is associated with systemic inflammation in COPD. The present study aimed to evaluate the relationship between systemic inflammatory markers and BHR in COPD patients.

Methods: To assess serum biomarkers of patients with COPD and chronic bronchitis (CB) and to assess local and systemic inflammation in COPD depending on BHR.

Results: 111 outpatients (50-COPD II st and 9-CB) with smoking more 10 year pack/years serum concentrations IL-6, IL-8, TNF-a, CRP were analyzed. BHR was assessed in methacholine challenge. Induced sputum samples were obtained from 42 COPD patients. Results: Serum IL-6 and IL-8 in COPD patients were higher in comparison to CB patients: the medians differences were 1.44 pg/ml and 2.10 pg/ml, respectively (p<0.05). Levels TNF-a, CRP were higher in COPD patients, but did not reach statistical significance. Among CB patients BHR revealed at 1 of 9. Among COPD patients BHR revealed at 31 of 50 (62%). The pack/years were comparable in CB and COPD patients.

Conclusion: Serum IL-6 and IL-8 in COPD patients were higher in comparison to COPD patients without BHR: the means difference was 2.80 and 2.67 pg/ml, respectively (p<0.05). There were not differences between TNF-a and CRP in COPD patients depending on BHR.

COPD patients with BHR had significantly higher numbers of total cell counts and macrophages in induced sputum than COPD patients without BHR: 3.63 vs 2.30 ×10^6 cells/mL and 1.31 vs 0.37 ×10^6 cells/mL (p<0.01). No differences were found for FEV1, and Sputum eosinophils in COPD patients with BHR compared to non-BHR.

P4544 Body mass index, central obesity, and severity of chronic obstructive pulmonary disease (COPD)

Zoten Stojanovska1, Jordan Minov2, Janakov Bojan3, Ivanov Sasa4, 1Primary Health Care, MOH, Skopje, Macedonia, The Former Yugoslav Republic of; 2Primary Health Care, Health Center Skopje, Skopje, Macedonia, The Former Yugoslav Republic of; 3Internal Medicine, Medical Centre Kumanovo, Kumanovo, Macedonia, The Former Yugoslav Republic of

AIM: To assess impact of body mass index (BMI) and central obesity (CO) to COPD severity.

Material and methods: We performed a cross-sectional study including 248 subjects with COPD aged 40-70 yrs with smoking experience 18-25 yrs and more than 15 cigarettes smoked per day. The first group consisted of 123 obese subjects, i.e. BMI >30, while the second group included 125 subjects with CO, i.e. waist circumference >102 cm for men and 88 cm for women.

Results: In the first group we found 17 subjects with mild COPD (13.8%), 79 subjects with moderate COPD (64.2%), 25 subjects with severe COPD (20.3%), and 2 subjects with very severe COPD (1.6%). The distribution of the subjects with COPD in the second group was as follows: mild COPD 54 subjects (43.2%), moderate COPD 52 subjects (41.6%), severe COPD 14 subjects (11.2%), and very severe COPD 5 subjects (4.0%). The difference in the distribution of the subjects by COPD severity between two groups was statistically significant (P < 0.05).

Conclusions: Our results suggest that body weight and central obesity may play a role in COPD severity.

P4545 The expression of brain-derived neurotrophic factor in hippocampal and serum of chronic obstructive pulmonary disease model rats

Qun Wang, Yong Lin, Xuefeng Ling, Siqing Sun, Qiang Zhang. Medical College, Southeast University, Nanjing, Jiangsu, China Zhongda Hospital, Southeast University, Nanjing, Jiangsu, China Medical College, Southeast University, Nanjing, Jiangsu, China Zhongda Hospital, Southeast University, Nanjing, Jiangsu, China Zhongda Hospital, Southeast University, Nanjing, Jiangsu, China

Objective: In clinic,we have found that cognitive impairment frequently occurs in chronic obstructive pulmonary disease (COPD) patients, but little is known about its pathogenesis. And, researchers confirmed that brain-derived neurotrophic factor (BDNF) may be involved in the pathophysiology of cognitive impairment and is affected by many factors, for example, smoking, infection, hyperfusion,
Changes in arterial stiffness during COPD exacerbations
Anant R.C. Patel, Alex J. Mackay, Beverly Kowlessa, Gavin C. Donaldson, Jadwiga A. Wedzicha, John R. Hurst.
Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom

Arterial stiffness is a validated measure of cardiovascular risk and is increased in COPD. Risk for cardiovascular events is higher during COPD exacerbations (Donaldson et al. Chest 2010). We hypothesised arterial stiffness would increase at exacerbation compared to the stable state.

We measured carotid-femoral aortic pulse wave velocity (APWV) using Visceromat™ apparatus in 55 patients from the London COPD Cohort in the stable state and at exacerbation onset, prior to therapy, defined by two consecutive days of new or increased symptoms requiring one major (dyspnoea, sputum purulence, sputum volume) and another major or minor symptom (coryza, wheeze, sore throat and cough). Median time from exacerbation symptom onset to APWV measurement was 4 days and a mean interval of 42 days between the paired measurements.

</table>

Mean (± SD) APWV increased by 10.4% from 9.17±1.155ms⁻¹ in the stable state to 10.12±1.85ms⁻¹ at exacerbation (p<0.001) with no significant change in blood pressure.

Arterial stiffness increases during COPD exacerbations and is a potential mechanism of increased cardiovascular risk at this time. This raises the possibility of directly targeting arterial stiffness during exacerbations of COPD.

Total serum bilirubin levels are not related to the severity of COPD
Program Development Center, Ciro, Horn, Netherlands

Introduction: It was recently reported that lower serum total bilirubin (tBLN) levels are associated with higher incidence of COPD and all-cause mortality, after adjustment for other risk factors, including smoking [1]. Aim of this study was to investigate whether serum total bilirubin levels are related to the degree of airflow limitation and other determinants of severity of COPD.

Methods: Data were extracted from the records of 1239 patients with COPD (58% males, age 64±10y, FEV₁ 46±19%, BMI 25.4±4.3kg/m²) referred for pulmonary rehabilitation. Serum tBLN ≤22μmol/L was an exclusion criterion. Lung function (FEV₁, diffusion capacity (DL CO)), arterial blood gases, body composition and six-minute walking distance (6MWD) were measured as part of integrated assessment of health status.

Results: tBLN levels were comparable in all GOLD stages. In male patients tBLN levels were 12.0±4.2μmol/L (GOLD 1), 12.1±4.0μmol/L (GOLD 2), 12.7±3.7μmol/L (GOLD 3) and 11.8±3.3μmol/L (GOLD 4), while levels were 10.8±3.7μmol/L (GOLD 1), 10.6±3.0μmol/L (GOLD 2), 10.2±3.6μmol/L (GOLD 3) and 10.6±3.8μmol/L (GOLD 4) in female patients (all p<0.001 vs males). tBLN levels were not related to FEV₁, arterial pO₂, BMI, number of pack years or 6MWD. A statistically significant but weak bivariate correlation was observed between tBLN and arterial pCO₂ (r=-0.084, p=0.01) and DL CO (r=-0.070, p<0.01).

Discussion: Serum total bilirubin levels are neither related to the degree of airflow limitation nor to other variables of disease severity in patients with COPD. Further research is needed clarify a possible contribution of low tBLN levels to the development of COPD.

Arterial stiffness measurements in COPD: Reliability over time
Anant R.C. Patel, Alex J. Mackay, Beverly Kowlessa, Gavin C. Donaldson, Jadwiga A. Wedzicha, John R. Hurst. Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom

Measuring arterial stiffness is a non-invasive method of assessing cardiovascular risk and is raised in COPD. It is not known if this measure remains consistent over time in COPD, creating uncertainty in interpreting single measurements.

We measured carotid-femoral aortic pulse wave velocity (APWV) using Visceromat™ apparatus in stable patients from the London COPD Cohort (no exacerbations recorded on daily symptom diary cards in the preceding four weeks and subsequent two weeks).

APWV was measured at two visits in 89 stable patients and at a third visit in 27 of those patients. The median (IQR) interval was 103 (91,175) days between visits one and two, and 91 (84,98) days between visits two and three.

Ciliary beat frequency in nasal and bronchial epithelial cells in patients with cystic fibrosis

Samta Alkaidic, Friedrich Horak, Thomas Frischer, Edith Nachbaur, Sabine Renner, Saskia Gruber. Department of Pediatrics, Medical University of Vienna, Vienna, Austria

Background: The extent to which altered ciliary function plays a role in the decrease in mucociliary clearance in cystic fibrosis (CF) patients is unclear.

Objective: To study ciliary beat frequency (CBF) in nasal and bronchial epithelial cells of children with CF.

Methods: Nasal and bronchial brushings were performed on 11 CF children (mean age: 8.86±4.54) undergoing bronchoscopy. In 15 healthy controls (mean age: 11.47±4.7) undergoing endoscopic procedures, nasal brushings were performed. The biopsies were performed using an Olympus BC-202D-2010 disposable brush. The samples were transported in a Medium 199 HEPES buffer and immediately analyzed. Slides were put into a climate chamber preheated to 37°C and viewed through an inverted phase contrast video microscope (Olympus IX-51). Short videos of ciliated cell groups were filmed with a high-speed video camera (Olympus Camera System) and analyzed. Slides were put into a climate chamber preheated to 37°C and viewed through an inverted phase contrast video microscope (Olympus IX-51). Short videos of ciliated cell groups were filmed with a high-speed video camera (Olympus Camera System) and analyzed.

Results: Nasal CBF in CF patients was higher when compared to that of healthy controls (mean±SD: 15.4±3.03 vs. 12.92±2.37, p<0.05). Furthermore, nasal CBF in CF patients was found to be higher than bronchial CBF (mean±SD: 13.23±2.38, p<0.05) and the values were found to correlate (r=0.7, p<0.05).

Conclusion: Our results indicate that CF patients indeed have altered nasal ciliary function. Whether these findings could have therapeutic implications requires further study.

Molecular structure, packing and release of MUC2 with relevance to cystic fibrosis

Harriet Nilsson1, Daniel Ambert2, Gunnar Hansson1, Hans Hebert1,3,4

1Department of Bioscience and Nutrition, Karolinska Institute, Huddinge, Sweden; 2Department of Medical Biochemistry, University of Gothenburg, Gothenburg, Sweden; 3School of Technology and Health, Royal Technical High School, KTH, Huddinge, Sweden

In Cystic Fibrosis extremely viscous fluid is built up likely connected to impaired release and expansion of mucus. MUC2 is mainly expressed in small and large intestine, but also in inhaled airways, and it is stored as a multimer in secretory granules of goblet cells at high [Ca²⁺] and low pH. The extracellular milieu have to trigger the unpacking of MUC2 controlled by its N-terminus, a not yet fully understood process. The aim is to elucidate organization and structure of MUC2 when it is packed and secreted.

The N-terminal part of MUC2 was expressed in CHO cells. The secreted trimerized recombinant mucin was purified from culture medium by anion exchange chromatography. Crosslinked samples were purified by density ultracentrifugation. Analysis was performed by transmission electron microscopy (TEM). The pH in the buffers was varied in the range from 5.2 to 8 to mimic conditions of secretory pathway and extracellular environment by adding HAc (pH 5.2), MES (pH 6.2) or Tris (pH 7.4 and pH 8) with or without calcium. Samples were adsorbed onto carbon coated EM grids and negative stained. Processing of micrographs was performed using EMAN1 software.

When pH was low and or calcium present, rings with an outer and inner diameter of 25-30 and 20-25 nm respectively were observed. Without calcium rings were assembled at pH 5.2 and 6.2, but vanished with increasing pH. 2D refinements of the projections showed rotational 5- or 6- fold symmetry. Assemblies of laterally concatenated rings were obtained in the high density fraction of MUC2 N-terminus. The formations of these rings are probably vital for proper packing and release of full length MUC2. Harriet N. and Daniel A. have contributed equally.
pulmonary acceleration time (PAT) to assess pulmonary hypertension (PH) in cystic fibrosis (CF).

**Methods:** Prospective multicenter longitudinal study of CF patients with forced expiratory volume in one second (FEV1) <60% predicted evaluated during their yearly check up with echocardiography, spirometry, and nocturnal oximetry.

**Results:** Sixty-seven consecutive patients were included (mean age 17±10 years, and mean FEV1 42±12% predicted). Eight patients received a lung transplant during a mean follow-up of 19±6 months. Systolic pulmonary artery pressure (sPap) was measurable using TR peak velocity in 50 (75%) patients, with 10 having values above 35 mmHg. PAT determined in all patients correlated negatively with sPAP (r=0.36, p=0.01). Patients in the lowest PAT tertile (<101 ms) had lower FEV1 and greater nocturnal oxygen desaturation and left ventricular diastolic dysfunction and were more often on the lung transplant waiting list than patients in the other two tertiles. Kaplan-Meier curves showed a significantly shorter lung FEV1 and greater nocturnal oxygen desaturation and left ventricular diastolic dysfunction and were more often on the lung transplant waiting list than patients in the other two tertiles. Kaplan-Meier curves showed a significantly shorter lung FEV1 and greater nocturnal oxygen desaturation and left ventricular diastolic dysfunction and were more often on the lung transplant waiting list than patients in the other two tertiles.

**Conclusion:** PAT less than 101 ms is a useful prognostic indicator in patients with CF whatever the age and is determined by FEV1 and nocturnal oxygen desaturation.

Non invasive ventilation for advanced cystic fibrosis lung disease in children

Elaine Chan, Jay Panicker, Biju Thomas. Paediatric Respiratory Medicine, Royal Manchester Children’s Hospital, Manchester, United Kingdom

**Background:** Although non-invasive ventilation (NIV) is frequently used for respiratory failure in adult Cystic Fibrosis (CF) patients, the experience in children is limited.

**Aim:** To review the experience of using NIV for advanced CF lung disease in children at a large tertiary centre.

**Methods & Results:** Retrospective review of medical records. Setting: Royal Manchester Children’s Hospital, Manchester, U.K.

**Results:** The CF service at the Royal Manchester Children’s Hospital (Manchester, UK) looks after approximately 350 children with CF. Over a period of two years (Feb 2009-Feb 2011) 7 children (Median [range] age: 15 [11-18] years, 6 females) with advanced CF lung disease were commenced on NIV. The median [IQR] FEV1 (% predicted) was 27 [23-31]. In all children, NIV was commenced during an acute respiratory exacerbation and subsequently continued in all except one child who did not tolerate NIV. The indications for initiating NIV included one or more of the following: nocturnal and/or diurnal hypoxia, hypercapnoea, morning headaches, to aid airway clearance and to assist to the lung transplant evaluation. All children received NIV using the pressure support mode with face/nasal mask interface. Two children died whilst on transplant waiting list. Median (range) usage was 8 (2-8) hours/night. Median (range) duration of use was 6 (1-24) months. None experienced any complication related to NIV. All children on NIV achieved improved gas exchange.

**Conclusion:** Although there is growing experience of using NIV in advanced CF lung disease in children, a number of unanswered questions remain. Long term prospective multicentre studies would help develop guidelines for use of NIV in this group of patients.

Glucose tolerance during pulmonary exacerbations in children with cystic fibrosis

John Widger1, Mark Oliver2,ergus Ferguson3, Sarah Ranganathan3, Phil Robinison3, 1Respiratory, Royal Children’s Hospital, Melbourne, VIC, Australia; 2Gastroenterology, Royal Children’s Hospital, Melbourne, VIC, Australia; 3Endocrine, Royal Children’s Hospital, Melbourne, VIC, Australia

**Introduction:** Patients with cystic fibrosis (CF) and normal glucose tolerance (NGT) may exhibit diabetic glucose tolerance during pulmonary exacerbations [1].

**Aims:** We examined glucose tolerance during exacerbations in children with CF and compared continuous glucose monitoring (CGM) with the gold standard oral glucose tolerance test (OGTT).

**Methods:** Children with CF aged at least 10 years hospitalised with an exacerbation were recruited. Those with diabetes and those on corticosteroids were excluded. On admission, patients had an OGTT and were fitted with a CGM for 3 days. Six weeks post discharge both tests were repeated.

**Results:** Ten patients (3 males), mean age 13.9 years, have completed the study. Two patients had CCM alone, 4 patients had OGTT alone and 4 patients had both tests. By OGTT criteria, 3 were diabetic, 3 had NGT and 2 had impaired glucose tolerance (IGT) during exacerbations. Glucose tolerance status did not change between exacerbation and follow-up although mean 2-hour glucose fell from 9.7 mmol/l to 8.6 mmol/l on repeat testing (p=0.012). For CGM (n=6), mean time spent with glucose > 7.8 mmol/l fell from 7% during exacerbation to 4.3% when well (p=0.04). All 3 patients with NGT and 1 with IGT on OGTT had transient hyperglycaemia ≥11.1 mmol/l on CGM during exacerbations.

**Conclusions:** In contrast to previous published research, we found that glucose tolerance status, as determined by OGTT, remains unchanged during exacerbations. Patients with NGT and IGT had transient hyperglycaemia on CGM.

Pre-procedure antibiotics and effect on microbiological yield from broncho-alveolar lavage fluid in children with cystic fibrosis

Sonal Kansra1, Alan Smyth2, Carol Bertenshaw1, Amanda Ward1, Matthew Hurley2, Jayesh Bhatt3, 1Children and Young People’s Cystic Fibrosis Unit, Nottingham Children’s Hospital, Nottingham, United Kingdom; 2Academic Department of Child Health, Nottingham University, Nottingham, United Kingdom

Bronchoscopy and broncho-alveolar lavage (BAL) is widely used in children with cystic fibrosis (CF) to obtain reliable lower airway specimens for microbiological analysis. This is done under general anesthetic (GA) or sedation. GA could lead to a significant decline in pulmonary function. This is recommended that preparation for surgery should involve physiotherapy and judicious use of antibiotics to treat any evidence of infection. However if antibiotics are given pre-procedure, microbiological yield of BAL could be reduced.

**Methods:** We reviewed the records of children with CF undergoing bronchoscopy and BAL at our centre to see if there was a difference in rates of microbiological isolation if children with CF had antibiotics pre-procedure. BAL was collected in line with ERS task force 2000 recommendations.

**Results:** 36 of the 86 bronchoscopies done between 2005 and 2010 were in children with CF. BAL results from 2 children were not available. BAL showed bacterial growth in 21 (62%) of cases and atypical mycobacteria in 1 child. Children who did not have pre-procedure antibiotics were more likely to have bacterial isolates from BAL fluid as compared to children who had antibiotics pre-procedure (p=0.017) as shown in the table.

**Conclusions:** Although there may be a bias because of its retrospective nature, this study indicates that pre-procedure antibiotics in children with CF undergoing bronchoscopy for getting a gold standard microbiological sample leads to a significantly lower microbiological yield.

**P4557**

Inspiratory and expiratory respiratory reactance at 5Hz in adult cystic fibrosis

Katharine Hurt1,2, Paolo Paedri3, Harpal Kalsi2, Margaret Hodgson1, Dina Bilton1, Omar Usman1,4, Cystic Fibrosis, Royal Brompton Hospital, London, United Kingdom; 2Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom

**Introduction:** Progressive airways obstruction is a key feature of cystic fibrosis (CF) which has its origins in the small airways. Reactance at 5Hz (X5), measured by impulse oscillometry (IOS), determines the capacitative properties of the peripheral lung. In COPD patients the respiratory phase difference in X5 inspiratory minus expiratory (ΔX5) identifies individuals in ERS which is likely to benefit from NIV. Studies in CF, so far, have analysed whole breath impulse oscillometry. Aims: To determine the relationship between inspiratory and expiratory phase X5 and spirometry and body plethysmography.

**Methods:** Within-breach analysis of IOS (Jaeger) was performed on 25 patients with CF (FEV1 range 26-119% of predicted). Results were correlated with spirometric and plethysmographic indices (Jaeger MasterLab).

**Results:** Both inspiratory and expiratory X5 correlated with FEV1 (p= 0.842, p<0.0001; r=0.892, p<0.0001), respectively. The parameters showed greater sensitivity at lower FEV1 values. They also demonstrated an inverse linear relationship with RV/TLC% (r=-0.747, p<0.0001; r=-0.317, p<0.0001). Respiratory phase difference in X5 inspiratory minus expiratory (ΔX5) correlated with FeNO and RV/TLC% (p=0.562, p<0.0001; r=0.659, p<0.004). There was a greater unit change in ΔX5 in CF patients with lower FEV1 values (greater disease severity).

**Conclusion:** Measurement of inspiratory and expiratory X5 are useful indices of airway obstruction and gas trapping in CF IOS is quick, easy and portable to use at the patient bedside or outpatient clinic in contrast to body plethysmography. Calculating respiratory phase difference in X5 (ΔX5) may be a useful marker for identifying CF patients who have expiratory flow limitation.

**P4558**

Lung clearance index (LCI) at age 4-4.5 years vs lung function and chest X-ray (CXR) scores at age 7 years in children with CF

Anders Lindblad1, Fatma Aljasim1, Per Gustafsson1,2, 1Pediatrics, Gothenburg CF Centre, Queen Silvia Children’s Hospital, Gothenburg, Sweden; 2Pediatrics, Central Hospital, Skövde, Sweden

**Background:** LCI from SF6 multiple breath washout (MBW) is more sensitive than spirometry to detect early lung disease and correlates closely to CT lung changes in older subjects [1].

Aim: To see if increased LCI during the preschool period correlates to elevated pulmonary function and chest X-ray (CXR) scores at age 7 years in children with CF.

**Aim:** To see if increased LCI during the preschool period correlates to elevated pulmonary function and chest X-ray (CXR) scores at age 7 years in children with CF.

**Aim:** To see if increased LCI during the preschool period correlates to elevated pulmonary function and chest X-ray (CXR) scores at age 7 years in children with CF.
Lung function testing is a means of monitoring progression of lung disease in cystic fibrosis (CF). Studies investigating Multiple Breath Washout (MBW) measurements in children older than 2 years with CF have shown lung clearance index (LCI) to be significantly greater in CF than in a reference population. Bronchodilators are used in CF to facilitate airway clearance and provide protection against potential bronchoconstrictors, ie, DNase, hypertonic saline and inhaled antibiotics.

**Aim:** 1. To compare LCI values among CF preschoolers, and healthy controls, 2. To compare LCI with atopy and 3). To assess the effect of the combination of inhaled steroids with long-acting beta two agonists (LABA), among CF preschoolers, by changes in LCI values.

**Method:** Twenty-eight children with CF, and recurrent cough and wheeze, aged 2 to 5 years and 27 healthy controls performed MBW measurements. Children with CF received prophylaxis with inhaled corticosteroids + LABA for 6 months. History of atopy was recorded and total serum IgE was measured. The primary endpoint was change of LCI values.

**Results:** Children with CF had significantly higher LCI compared to controls (mean difference [95% CI] 2.6 [1.8, 3.7], p<0.001). LCI values were not correlated with history of atopy (p=0.128), or total IgE (p=0.318, R=0.247). Six months after treatment with combination of inhaled steroids + LABA, LCI was reduced significantly (mean difference [95% CI] -1.19 [-3.6, -1.01], p<0.0036).

**Conclusions:** Combination of inhaled steroids + LABA seem to improve lung function among preschooler with CF, as measured by LCI.

**Discussion:** Inclusion of preschoolers was important as it is the age when children have the highest LCI. Little is known about the effect of inhaled steroids on LCI in this age group. LCI increases with age and children with CF have higher LCI compared to controls. The combination of inhaled steroids + LABA improve LCI. LCI changes correlate with age, which suggests that LCI changes are age related. This study adds new knowledge on the management of preschoolers with CF.

**Frequent detection of rhinovirus in bronchoalveolar lavage samples from children with cystic fibrosis**

Elisabeth Kieninger1, Caroline Tapparelli2, M.-N. Kronig1, F. Singer1, P. Latzin1, Hui-Leng Tan1, Cara Bossley3, C. Casaulta1, Andrew Bush1, Jane C. Davies1, Laurent Kaiser2, Nicolas Regamey1, 1Division of Paediatric Respiratory Medicine, University Children’s Hospital, Bern, Switzerland; 2Laboratory of Virology, Division of Infectious Diseases, University of Geneva Hospitals and Faculty of Medicine, Geneva, Switzerland; 3Department of Paediatric Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom

**Background:** Rhinovirus (RV)-induced chest exacerbations are common in cystic fibrosis (CF) and have been associated with impaired virus clearance by the CF airway epithelium.

**Hypothesis:** As a consequence RV can be frequently detected in lower airways of CF children.

**Patients and methods:** Bronchoalveolar lavage (BAL) samples were collected from children (n=93), non-CF bronchiectasis (n=26), asthma (n=19) and control children without lower respiratory tract disease (n=21) at a median (IQR) age of 6.7 (5.0-10.8) years. RV load was assessed by RT-PCR. Prevalence of RV infection and RV load were compared between groups and related to demographic and clinical parameters.

**Results:** RV was detected in 58 samples (36% of total) and more often in younger children (<5 years of age (29 vs. 18%). RV prevalence was highest in CF (41%) compared to non-CF bronchiectasis (23%), atopic (32%) and healthy children (6.7% (0.4-6.5%) (p=0.01). RV prevalence was similar in CF patients in whom BAL was performed during chest exacerbation (p=0.2) and phases of clinical stability (p=0.17). However, RV load was higher during exacerbation (559 [20-3380] × 10^3 vs. 25 [5.8-277]) × 10^3, (p=0.01) and inversely related to FEV1 (r=0.32, p=0.003).

**Conclusions:** RV is frequently detected in the lower airways of CF children. High RV loads during chest exacerbations and in children with advanced lung disease suggest a possible role for RV in CF lung disease progression.
**P4563**

**Title:** Cystic Fibrosis (CF) and the impact on CF disease progression are still under debate.

**Authors:**
-OBJECTIVES: To study clinical variables associated with MRSA infection and determine the impact on FEV1 evolution in CF patients.
-**Methods:**
  - A retrospective case-control study from 2002 to 2010, comparing clinical variables and decline of FEV1 of MRSA positive patients with age and sex matched controls.

**Results:**
- Thirty of the 165 CF patients (18.2%) had cultures positive for MRSA.
- Excluding patients under 4 years, the prevalence became 15.2% (23/151).
- Chronic respiratory infection was found in 19/36 (52.8%) cases reported among adolescents and adults in absence of vaccine or natural boosters.
- CF is the commonest genetically inherited disease, leading to bronchiectasis.
- Cough is a non-specific symptom in CF patients and whooping cough could cause lung function worsening.

**Conclusions:**
- The FEV1 recorded one year prior to, and at the moment of MRSA infection, was not significantly different from that obtained in controls. However, FEV1 decline over 2 and 6 years periods, were significantly greater in the MRSA group than in the controls.
- In fact, over a 6 year period FEV1 decline amounted to -2.6% versus -1.3% predicted per year in the MRSA group and controls respectively (p=0.031).
- **Conclusion:** Prevalence of MRSA in CF patients averaged 15%, and MRSA infection was shown to be associated with particular genotypic presence of bronchiectasis and hospitalization. Our spirometric data also clearly show that a MRSA episode entails an FEV1 decline that is almost double that predicted for CF patients who can remain unaffected by MRSA.

**P4564**

**Title:** Effect of recurrent growth of aspergillus on lung function in paediatric population with cystic fibrosis (CF)

**Authors:**
- **Background:** Allergic bronchopulmonary aspergillosis (ABPA) is well described in CF. Many CF patients grow Aspergillus fumigatus (AF) on sputum and cough swabs but do not have ABPA. There is evidence that this is clinically important in CF. Many CF patients grow Aspergillus fumigatus (AF) on sputum and cough swabs but do not have ABPA. There is evidence that this is clinically important in CF.

**Hypothesis:** Isolation of AF from sputum or cough swab is associated with a worse clinical state in CF children.

**Methods:** A retrospective cohort study of all children with CF who had sputum samples or cough swabs positive for AF on >1 occasion at least one month apart between 2008 and 2010. Lung function results and nutritional status were recorded.

**Results:**
- 35 children (15 male) were identified who fit the criteria, mean age 11.2 years (SD2.1) mean BMI 17.5. Data were collected on 21 controls (7 male) with CF who had not grown AF during the study period and had never had a diagnosis of ABPA, mean age 11.12 years (SD2.21) mean BMI 17.2. Children with AF had a lower mean FEV1 (p=0.0001) over the follow-up period (69.8, SD13.8 vs 89.4, SD11.5), despite a greater number of days of intravenous antibiotics (45 days vs 2.6 days in the 2 year period (p<0.0001)).

**Conclusions:**
- Recurrent growths of AF are associated with a worse clinical state, manifest by lower lung function, despite the use of significantly more intravenous antibiotics.

**P4565**

**Title:** Quality of life of paediatric patients with cystic fibrosis and their caregivers

**Authors:**
- **Introduction:** Cystic fibrosis (CF) is the most common fatal genetic disease which has a significant impact on patient’s and their caregiver’s daily life.

**Objective:**
- The aim of the study was to determine the quality of life (QoL) of children with CF and their parents and to compare the impact of CF on daily life to that of asthma.

**Methods:**
- The Cystic Fibrosis Questionnaire (CFQ) was used to measure the QoL of children with CF and their caregivers. PedsQLTM 4.0 Generic Core Scale was used to determine the QoL of patients with CF.

**Quality of life of patients with CF**

P4568 Pulmonary function and quality of life in children and adolescents
adenovirus bronchiolitis obliterans
Stefaníe Nayar1, Ana María Escobar, Monica Saavedra, Alberto Vidal1
Broncopulmonar, Hospital Roberto del Río, Region Metropolitana, Santiago, Chile

Introduction: There are few studies assessing pulmonary function and quality of life of PIBO patients.

Objective: Assess the pulmonary function and the quality of life of patients with PIBO and the correlation between both variables.

Methods: 14 Children with PIBO in follow up at the pediatric pulmonology, were included in this study. Study period: April 2009 - April 2010. Pulmonary function was assessed with spirometry, flow/volume curve and intrathoracic gas volume. A survey of self-administered Quality of Life was applied at the visit to investigate their global, physical and psychosocial quality of life. The Pearson linear correlation between quality of life and the pulmonary function test parameters was assessed, for statistical analysis p<0.05 was considered significant.

Results: The mean age of our patients was 12.4. The functional alterations were characteristics of an obstructive respiratory disorder in 85.7% and only 14.3% showed normal pulmonary function of the patients. The quality of life parameters were in average 58.6% of overall quality of life, 60.9% of physical quality of life and 57.9% of psychosocial quality of life. We found a positive correlation between global quality of life and VEF1, FVC and FEF25-75% (correlation index 0.54, 0.53 and 0.53 respectively) as well between physical quality of life and VEF1, FVC, FEV1/FVC and FEF25-75% (correlation index 0.86, 0.81, 0.70 and 0.74 respectively).

Conclusions: Most patients with PIBO showed pulmonary function impairment characterized by an obstructive respiratory pattern. Better quality of life correlates with better values in spirometric parameters.

P4569 Obliterative bronchitis verified by bronchoscopec visualisation
Petr L.1, Karolína Vávrová1, Tamara Svobodová1, Magdalena Havliková1, Ludmila Hornoflova1, 2 Division of Pediadtric Pulmonology, Pediadtric Department, University Hospital Motol, Prague, Czech Republic; 3Institute of Pathology and Molecular Medicine, University Hospital Motol, Prague, Czech Republic

Background: Chronic bronchial obstruction in children is mostly associated with bronchial asthma. In those with irreversible obstruction the most documented reason is a post-infectious obliterative bronchiolitis.

Case history: We report a 13 years old patient with Tetralogy of Fallot corrected at the age of 3 years. She suffered from respiratory infections since early childhood, in addition four pneumonias at the age of 10, 11 and 12 years. Since age of 10 on anti-asthma medication for frequent wheezing. She was referred to us for poor response to anti-asthma therapy.

Using 2 mm flexible bronchoscope and aiming for the areas with prominent air-trapping, we found at the level of 7th to 9th bronchial branching circular narrow stenoses and obliterative lesions completely closing the lumen. Biopsy revealed normal bronchial epithelium, mild thickening of the basement membrane and mild hypertrophy of smooth muscle.

Conclusion: We confirmed existence of obliterative lesions causing irreversible obstruction in the bronch of about 2 to 3 mm in diameter. This fits into the diagnosis of obliterative bronchitis, different from obliterative bronchiolitis. This should be suspected in children with irreversible bronchial obstruction and appropriate investigations initiated. Confirmation of this diagnosis can prevent patients from unnecessary burden of anti-asthma therapy.

Supported by MZ/ENM0205.
effect of hypoxia on otoacoustic emissions findings was found (p<0.05). However, there was no significant effect of inhaled aminoglycosides on auditory functions whether pure tone audiometry, speech audiometry and transient evoked otoacoustic emissions testing. 

Conclusions: Children with chronic lung diseases are liable to cochlear dysfunction due to prolonged hypoxia. Inhaled aminoglycosides in chronic lung diseases is relatively safe on auditory functions. 

P4573 Health-related quality of life in non-cystic fibrosis bronchiectasis children Ameer Hamzah1, Yasemin Gökdemir2, Cagatay Cimis3, Refika Ersu3, Fazilet Karakoc4, Bülent Karadag4, 1Department of Paediatrics, Marmara University Faculty of Medicine, Istanbul, Turkey; 2Department of Paediatric Pulmonology, Marmara University Faculty of Medicine, Istanbul, Turkey; 3Department of Radiology, Marmara University Faculty of Medicine, Istanbul, Turkey; 4Department of Radiology, Marmara University Faculty of Medicine, Istanbul, Turkey

Aim: Bronchiectasis is still an important problem in developing countries. The aim of this study was to evaluate the health-related quality of life and associated factors in children with non-cystic fibrosis bronchiectasis.

Methods: Children with non-cystic fibrosis bronchiectasis followed at Marmara University Paediatric Pulmonology Clinic were included to the study. Age of symptom onset, age of diagnosis, frequency of presenting symptoms, physical examination findings, pulmonary function tests, and affected lobes in high resolution computed tomography (HRCT) were evaluated; in addition, HRCT was scored according to modified Bhalla score system to obtain a bronchiectasis distribution severity score. St George’s Respiratory Questionnaire (SGRQ) and the Medical Outcomes Study Short Form-36 were completed by patients and parents.

Results: The median age of the patients (48.9% male) was 12.1 years (25%-75%: 10.2-14.1years). The median age at diagnosis was 7 years (25%-75%: 5-10years) and follow up period was 4 years (25%-75%: 2-5 years). The patients’ HRCT score did not correlate with the SGRQ scores or FEV1 (p>0.05). However, a significant correlation was found between the SGRQ scores and FEV1 (p=0.02). No correlation was found between SF-36 and FEV1 (p=0.05).

Conclusion: Patients with worse pulmonary functions have lower quality of life scores. Early diagnosis and treatment may increase the quality of life and survival of patients with bronchiectasis, which has irreversible and progressive complications if untreated.

P4574 Pediatric tracheostomy: Indications and complications rate. An experience from a semi-intensive pediatric respiratory unit Alessandra Schiavino, Francesco Paolo Rossi, Maria Giovanna Paglietti, Maria Beatrice Chiariin Testa, Teresa Salerno, Renato Cutrera. Department of Pediatrics, Respiratory Unit, Bambino Gesù Children Research Hospital, Rome, Italy

Tracheostomy in children can be used to provide respiratory support as a long-term ventilation/pulmonary toilet, or to bypass proximal airway obstruction. Tracheostomy is burdened by early and late complications which could make difficult hospital and home management. We performed a single centre Survey from September 2008 to September 2010, identifying early and late complications with the aim to assess the most frequent problems related to tracheostomy management in children. We administered to the parents a questionnaire in which the different topics were addressed (indications to tracheostomy, operational technique, occurrence of intraoperative, early postoperative (within 24 - 48 hours) and late (after 48 hours) complications and the home care management).

In the 2 years period we evaluated 66 patients (M/F 36/30, mean age 7 years). Indications to tracheostomy were prolonged endotracheal intubation followed by tracheal stenosis, chronic respiratory failure, central apnoeas and vocal cord paralysis. Patients were affected by genetic or metabolic disorders, cerebral palsy, neuromuscular diseases, congenital heart diseases, tracheal diseases and tumors of the nervous system.

In 65% of cases no complications occurred, while in 5% early complications and in 35% late complications occurred. Only 4 patients died during the Survey period, but not due to tracheostomy complication. Tracheostomy allows to manage different severe disease in children. The indications for its use have changed over the past decades. Late-onset complications are the most frequent and their knowledge allows to manage the tracheostomized patient from hospital staff and home caregivers.

P4575 Comparison of conventional chest physiotherapy and high-frequency chest wall oscillation in primary ciliary dyskinesia Yasemin Gökdemir, Refika Ersu, Bülent Karadag, Fazilet Karakoc. Paediatric Pulmonology, Marmara University, Istanbul, Turkey

Background: Early diagnosis and enhancement of mucusclearance by chest physiotherapy is important to prevent the development of bronchiectasis in primary ciliary dyskinesia (FSD). Percussion and postural drainage are the most commonly used methods. Vest® is a new chest physiotherapy method which creates oscillation on the chest wall and move the secretions from small airways to the large airways. There is no study evaluating the efficacy of Vest® in FSD. The aim of this study was to evaluate the efficacy and safety of Vest® in FSD patients.

Material/methods: Both conventional chest physiotherapy and Vest® were applied randomly to 7 FSD patients older than 6 years of age. Oxygen saturation was monitored and pulmonary function tests (PFT) were performed on the first and 5th day of both therapies. Patients were questioned about the efficiency and comfort level of the both methods.

Results: Forty-two percent of patients were mean. Mean age was 9.3±3.4 years and the patients were followed up for 7.2±2.3 years. Dextrocardia was present in all of the patients and situs inversus totalis was observed in 71%. There were no desaturation during sessions. Although day 5 PFT were better in both groups, this did not reach statistical significance. There was no difference between the two groups in terms of PFT. Both physiotherapy methods were found effective and comfortable and there was no significant difference between the two groups.

Conclusion: Vest® was comfortable and tolerated well by the patients. There was no difference in PFT’s between the conventional chest physiotherapy and Vest® group. We presented the preliminary results of ongoing the study.

P4576 Impact of the date of diagnosis on the clinical course of children with primary ciliary dyskinesia Folke Brinkmann, Nico laus Schwerk, Theresa Emmrich, Gesine Hansen. University Children’s Hospital, Department of Pulmonology, Allergology and Neonatology, Hannover Medical School, Hanover, Germany

Objective: To up to now, little is known about the impact of the date of diagnosis on the clinical course of children with primary ciliary dyskinesia (pcd).

Methods: Over a ten year period all paediatric patients with confirmed pcd in our tertiary centre who had been followed up for more than 12 months were retrospectively included in the study.

Results: Out of 19 patients 63% had a situs inversus, the median age a diagnosis was 95 months. There was a significant correlation between the date of diagnosis and development of bronchiectasis (p=0.04), but no effect on lung function. 12 months after diagnosis 75% of patients received professional physiotherapy, 88% were on continuous antibiotic therapy, 50% on inhaled β agonists and 13% on continuous inhaled corticosteroids. After starting the treatment, all patients improved clinically, the number of pulmonary complications decreased, especially pneumonias (p=0.03) and bronchitis (p=0.01). Chronic wet cough and rhinitis often persisted and lung function measurements did not improve permanently.

Conclusions: Late diagnosis of pcd carries an increased risk for developing bronchiectasis. Pulmonary exacerbations decrease with appropriate treatment whereas there is no significant effect on lung function parameters.

P4578 The follow-up of children with tracheobronchial foreign body aspiration Sinan Tas1, Zeynep Seda Uyar2, Nihat Uyar2, Yonca Anik3, Tuha Liman4, Metin Aydogan5, Salih Topcu5, Emin Sarit Aksit6. 1Pediatrics, Kocaeli University Hospital, Kocaeli, Turkey; 2Pediatric Pulmonology, Kocaeli University Hospital, Kocaeli, Turkey; 3Radiology, Kocaeli University Hospital, Kocaeli, Turkey; 4Thoracic Surgery, Kocaeli University Hospital, Kocaeli, Turkey; 5Pediatric Allergology, Kocaeli University Hospital, Kocaeli, Turkey; 6Pediatric Infectious Diseases, Kocaeli University Hospital, Kocaeli, Turkey

Background: Foreign body aspiration (FBA) is an important cause of morbidity and mortality in children

Objectives: Retrospective analysis of cases who arrived Kocaeli University Hos pital with suspected FBA and underwent bronchoscopy

Methods: Forty children who underwent bronchoscopy for FB removal from February 2005 to January 2010 at Kocaeli University Hospital were reviewed retrospectively. We recorded the patients’ presenting symptoms,physical and radiological findings, the time elapsed from aspiration to presentation,type and location of FBA,acute and long-term complications, follow up period and hospitalisation period

Results: There were 26 male patients. The mean age was 59.8±34.2 months (range 29-195 months).FBs were removed within 1-184 days following the aspiration (median: 2 days).During presentation;38 cases had clinical symptoms and wheezing was the most common one. Thirty-three FBs were organic and hazelnuts were the most common. Twenty-three (57.5%) cases had radiological findings during presentation and 10 (25%) had acute complications (pneumonia). Patients were hospitalized for 1-17 days (median 2days) and followed up for 34.5±31.3 months. Seventeen patients had persistent clinical symptoms. There were chronic radiological findings in 5 patients and fibrotic sequelae in 11 patients. Although statistically not significant; chronic radiological findings were more common in patients in whom bronchoscopy was performed later.

Conclusions: Follow up period and methods of children with tracheobronchial FBA are controversial. Additionally, there are not enough studies about its long term complications. Some patients cannot be followed up for a sufficient period and this lead to the development of chronic complications.
Background: Bronchiolitis obliterans (BO) is an uncommon and severe form of chronic obstructive lung disease in children that results from an insult to the lower respiratory tract. The aim of this study was to evaluate the respiratory symptoms of BO patients and determine related factors.

Methods: Retrospective evaluation of BO patients who were followed-up from pediatric pulmonology department.

Results: Total of 22 patients (65% male) were included to the study. Mean age was 9.1±3.8 years. During first lower respiratory tract infection, mechanical ventilation and O2 was required in 32% and 9% of patients, respectively. Eighty percent of patients were treated with inhaled or oral steroids in the early period. Respiratory symptoms were recurrent in 35% and persistent in 65% of patients after the first lung infection. The age of 11 (50%) patients were above six currently percent of patients were treated with inhaled or oral steroids in the early period. Lobectomy was performed in one patient. Four (18%) patients were using O2 and one patient was using non-invasive ventilation (NIV) at the last visit. The rate of intubation during the first lung infection was 80% in the patients who required respiratory support in the follow-up period. There was a significant relationship with intubation during the first lower respiratory infection and requirement of O2 versus NIV (p=0.001) in the follow-up period.

Conclusion: BO is a disease of childhood with high morbidity and mortality. The severity of the respiratory symptoms of patients during follow-up is associated with the requirement of mechanical ventilation during the first lower respiratory infection.

649. Lung cell injury and repair

P4582
Down-regulation of SLPI by cysteinyl leukotrienes in human bronchial epithelial cells can be reverted by glucocorticoids

Süri Altraja1, Kaido Värpu2, Alan Altraja2. 1Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia; 2Department of Pulmonary Medicine, University of Tartu, Tartu, Estonia

Secretory leukoproteinase inhibitor (SLPI) protects the lung against proteinases implicated in the pathogenesis of diseases like COPD, but has also antimicrobial and anti-inflammatory properties. A fall in SLPI contents in the airways has been detected in COPD and asthma, however, the factors involved in the regulation of SLPI gene expression in the airway epithelial cells have insufficiently studied.

To evaluate whether pro-inflammatory cysteinyl leukotrienes (CysLT) exert regulatory effects on SLPI expression in normal human bronchial epithelial cells, the cultured cells were exposed to 0-50 nM LTE4 for 3-6 h. Expression of SLPI mRNA was analyzed by RT-qPCR. The potential of glucocorticoids (GC) to revert the CysLT-induced effect on SLPI expression was addressed by incubating the cells for additional 3 h with 10 nM fluticasone propionate (FP) and 20 nM budesonide (BUD). Montelukast at 106 mol/L was used to block the possible CysLT-mediated action of LTE4.

Exposure of the cells to 50 nM LTE4 resulted in a significant drop in SLPI expression after 6 h (p<0.001). Both GC alone tended to increase the expression of SLPI. More importantly, in the cells exposed to LTE4, both FP and BUD fully reverted the CysLT-induced drop in SLPI (p<0.001 and p<0.003, respectively). The presence of montelukast did not additionally influence the potency of GC.

In conclusion, by down-regulation of SLPI in bronchial epithelial cells, CysLT may augment the pathogenetic events leading to COPD providing a pathway for more rapid decline in lung function in COPD patients with a concomitant Cyst-MT-mediated disorder like asthma. Fortunately, this can be overpowered by treatment with GC.

P4583
Identification of mesenchymal stem cellstromal cells in lung tissue from lung-transplanted patients

Sara Rolandsson1, Annika Andersson-Sjöland 1, Jan Claas Brune2.

Leif Eriksson1, Stefán Scheding3,4, Leif Björmer1, Gunilla Westergren-Thorsson1. 1Experimental Medical Science, Lung Biology, Lund, Sweden; 2Lund Stem Cell Center, Laboratory Medicine, Lund, Sweden; 3Clinical Medical Sciences, Lung Medicine and Allergology, Lund, Sweden; 4Hematology, Laboratory Medicine, Lund, Sweden

Background: Multipotent mesenchymal stromal cells (MSC) have been isolated from a variety of human tissues. Previous studies have shown that MSC are present in the bronchoalveolar fluid from lung-transplanted patients where they were suggested to be an indication of a future bronchiolitis obliterans syndrome (BOS) onset. We hypothesize that MSC are lung-resident cells that are present in lung tissue from lung-transplanted patients.

Objective: Our aims were to examine whether MSC are present in lung tissue from lung-transplanted patients and to evaluate whether these cells showed typical MSC characteristics such as adherent clonal growth and multi-lineage differentiation capacity.

Methods: MSC were isolated from central- and distal biopsies obtained from lung-transplanted patients (3 mo. – 13 yrs. post transplantation). After dissociation, the resulting single cell suspension was subjected to colony-forming unit-fibroblast (CFU-F) assays to determine the frequency of mesenchymal progenitor cells. Further, the cells were assayed for their differentiation capacity towards adipocytes, chondrocytes and osteoblasts. The surface marker profile of lung-derived MSC was examined by flow cytometry.

Results: MSC isolated from lung tissue adhered to tissue culture treated plastic, formed colonies when cultured in CFU-F assays and possessed multi-lineage potential. Immunophenotyping showed that lung-derived MSC were positive for the surface markers such as CD73, CD90 and CD105 and negative for CD45 and CD34.

Conclusion: Our study suggests that there are MSC present in the lung tissue of lung-transplanted patients that possess multi-lineage potential and give rise to typical colonies in vitro.
Lung on Chip: In vitro HGF effects on injured alveolar A549 epithelial cells in microfluidic system

Pauline Salin1,2, Laurent Barbe1,3, Amig Gazdar2, Thomas Geiser2, Oliver Guenta1,3, 1 CSEM, CSEM Centre Suisse d’Electronique et de Microtechnique, Landquart, Switzerland; 2Division of Pulmonary Medicine, University Hospital Bern, Bern, Switzerland; 3ARTORG, University of Bern, Bern, Switzerland

Microfluidic systems have become competitive tools in the in vitro modelling of diseases and promising alternatives to animal studies. They allow more invivo like conditions for cellular assays. Research in idiopathic pulmonary fibrosis could benefit from this novel methodological approach to understand the pathophysiology of the disease and develop efficient therapies. The use of hepatocyte growth factor (HGF) for alveolar reepithelisation is a promising approach. In this study, we show a new microfluidic system to analyse the effects of HGF on injured alveolar epithelial cells. Microfluidic systems in polydimethylsiloxane were fabricated by soft lithography. The alveolar A549 epithelial cells (10,000 cells) were seeded and studied in this microfluidic systems with media perfusion (4μl/min). Injury tests were made on the cells by the perfusion with media containing H2O2 or bleomycin. The degree of injury was then assessed by a metabolic and an apoptotic assays. Wound assays were also performed with a central laminar flow of trypsin. Monitoring of wound closure with HGF vs control media was assessed. The alveolar A549 epithelial cells grew and proliferated in the microfluidic system. In the wound closure assay, the degree of wound closure after 5 hours was 53.3%±1.3% with HGF compared to 9.8±2.4% without HGF (P<0.001). We present a novel microfluidic model that allows culture, injury and wounding of A549 epithelial cells and represents the first step towards the development of an invivo reconstitution of the alveolar-capillary interface. We were also able to confirm that HGF increased alveolar epithelial repair in this system.

Lung on Chip: Co-culture of alveolar epithelial cells & bone marrow derived stromal cells in microfluidic system

Anne Schoenen1,2, Laurent Barbe1, Amig Gazdar2, Thomas Geiser2, Oliver Guenta1,3, 1 CSEM, CSEM Centre Suisse d’Electronique et de Microtechnique, Landquart, Switzerland; 2Division of Pulmonary Medicine, University Hospital Bern, Bern, Switzerland; 3ARTORG, University of Bern, Bern, Switzerland

Background: Microfluidics system are novel tools to study cell-cell interactions in vitro. This project focuses on the development of a new microfluidic device to co-culture alveolar epithelial cells and mesenchymal stem cells to study cellular interactions of the injured alveolar epithelium. Methods: Microfluidic systems in polydimethylsiloxane were fabricated by soft lithography. The alveolar A549 epithelial cells were seeded and injury tests were made on the cells by perfusion with media containing H2O2 or bleomycin during 6 or 18hrs. Rat Bone marrow derived stromal cells (BMSC) were then introduced under constant perfusion. Epithelial injury to mimic mechanisms seen in idiopathic BMSC adhered to the bottom surface of the microfluidic device and proliferated. P4586 BMSC, and showed that BMSC try to heal the injured epithelium. Also we were able to confirm that HGF increased alveolar epithelial repair in this system.

P4586

Lung on Chip: Co-culture of alveolar epithelial cells & bone marrow derived stromal cells in microfluidic system

Patricia Leon1, Xu Shi-Wen2, Carmel Stock1, David Abraham3, Andrew Nicholson2, Toby Maher1, Athol Wells2, Elizabeth Renzoni1, Gisela Lindahl1, 1Intestinal Lung Disease Unit, Royal Brompton Hospital, London, United Kingdom; 2Department of Rheumatology, Royal Free Hospital, London, United Kingdom; 3Department of Histopathology, Royal Brompton Hospital, London, United Kingdom

Background: In our microarray study of lung fibroblasts from control subjects (n=10) and patients with scleroderma-associated interstitial lung disease (SSc-ILD) (n=8), the Interferon Stimulated Genes (ISGs) are an overrepresented group of genes with reduced expression in SSc-ILD fibroblasts. Since interferon gamma is known to interfere with TGF-β signalling and reduce the expression of individual pro-fibrotic genes, we asked whether TGF-β signalling could in turn downregulate ISG in lung fibroblasts, and whether TGF-β could affect the induction of ISGs by interferons. In this study, we have focused on the expression of IRF-1, a key transcription factor regulating ISGs. Methods: Human primary pulmonary fibroblasts were grown to near confluence, serum starved in 0.1% BSA for 24 hrs, and treated with or without TGF-β (2ng/ml), IFNα (250ng/ml), and IFNγ (10ng/ml), for a further 24 hrs. Specific antibodies were used to assess protein expression in cell layers by Western blot analysis.

Results: IRF-1 mRNA expression was significantly reduced in SSc-ILD fibroblasts (-3.6-fold, p=0.0001). TGF-β treatment suppressed basal IRF-1 protein expression to undetectable levels in fibroblast preparations from control and SSc-ILD lungs. In both SSc-ILD and control fibroblasts, TGF-β had no effect on IFNβ-induced IRF-1 protein expression, but completely inhibited the induction of IRF-1 by IFNα. By contrast, IFNγ reduced TGF-β induced CTGF expression, while IFNα had no effect. Conclusion: TGF-β signalling suppresses basal and IFNα-induced IRF-1 expression in lung fibroblasts, suggesting a possible mechanism for the reduced expression of ISGs expression observed in SSc-ILD fibroblasts.

Alveolar lymphocyte phenotype and respiratory distress syndrome

Karine Risso1, Céline Sanfiorenzo2,3, Gaurav Kumar4, Franked de Salvador-Guillouet1, Alan Bernard3, Gilles Bernardin5, Pierre-Marie Roger5, 1Infectiology, Hospital Archet, Nice, France; 2Pneumology, Hospital Pasteur, Nice, France; 3EA4319, University of Nice Sophia, Nice, France; 4Intensum Unit 576, Hospital Archet, Nice, France; 5Intensive Unit Care, Hospital Archet, Nice, France

Introduction: The role played by adaptive immunity in the pathophysiology of acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) is largely unknown. We characterized lymphocytes phenotype in broncho-alveolar lavage (BAL) during respiratory distress syndromes. Patients and method: Analyses were carried out on BAL samples of three patients groups: ALI/ARDS patients (ARDS group), healthy patients (control group) and inflammatory pulmonary diseases patients (ID group). Lymphocyte and monocyte/macrophage phenotype determination used cytometric fluorescence techniques: CD45RA+, CD45RA- and CD25FoxP3 cells were respectively identified as naive, memory and regulatory T cells. HLAD, KI67 and annexin V were used as markers for cell activation, proliferation and apoptosis respectively. CD4, CD8, CD3, CD20, CD69, CD28, CD40/CD40L and CTLA-4 were used as costimulator markers. Results: 9 BAL were obtained from 8 ARDS patients, 8 BAL from controls and 8 from ID patients. A significant increase of HLAD, KI67 and CTLA-4 on T CD4+ lymphocytes was observed in ARDS group compared to control. Concerning CTLA-4, the difference still persisted when comparing ID to ARDS group. KI67 expression was significantly increased on T CD8+HLA-DR and TDB6 were significantly decreased on alveolar macrophages (AM) compared to others groups. Discussion: During ALI/ARDS activation and proliferation of T lymphocyte are noticeable, associated with alteration of the CD28/CTLA-4 costimulator pathway and ligand on AM. Conclusion: This is the first human study on adaptive immunity in ARDS/ALI identifying relevant modifications on T cell phenotype which may account for the dramatic alveolar inflammation observed in these syndromes.

IL-18 and IL-12 induce inflammatory cytokines, chemokine ligand 9 (CXCL9) and T cell infiltration in pulmonary tissue

Dudia Talarevic Ceri1,2, Karl Otto Larsen1, Vibeke Hillestad1, Geir Christensen2, Ole Henrik Skjønsberg1, 1Department of Pulmonary Medicine, Oslo University Hospital Ullevål, University of Oslo, Oslo, Norway; 2Institute for Experimental Medical Research and Center for Heart Failure Research, Oslo University Hospital Ullevål, University of Oslo, Oslo, Norway

Background: Increased levels of interleukin (IL)-18 and IL-12 have been found during experimental alveolar hypoxia and in patients with COPD. Aims: To study the presence of IL-18 and IL-12 receptors (IL-18R/IL-12R) in the lungs and the effect of IL-18 and IL-12, alone or in combination, on the lungs with regard to inflammatory response and induction of emphysema related metalloproteinases (MMP2, MMP9, MMP12). Methods: Expression of IL-18R and IL-12R was studied in lungs, heart, liver and spleen in C57Bl/6 mice. 24 hours after a single i.p. dose of recombinant murine IL-18 alone, recombinant IL-12, IL-18+IL-12 or PBS (controls), lungs were harvested for immunohistochemical (IHC) and RT-PCR analyses. Results: The expression of IL-18R mRNA was 16-630-fold higher in the lungs than in other organs. The expression of IL-12R was 4-fold higher in the spleen than in lungs. Mice treated with IL-18 or IL-12 alone showed significantly higher mRNA levels of interferon-γ, tumor necrosis factor-α and MMP12, than in controls (p<0.05). Mice treated with IL-18+IL-12 showed an even more pronounced induction of these mediators, as well as a significant increase in IL-6 and IL-1β(p<0.05). A marked increase in CXCL9 mRNA was induced by IL-18 (12-fold), IL-12 (19-fold), IL-18+IL-12 (153-fold). IHC showed perivascular T-cell infiltration following co-stimulation. Conclusions: High levels of IL-18 receptor suggest that the lungs might be a target organ for IL-18. IL-18+IL-12 exert a synergistic effect on the lungs by inducing inflammatory cytokines and MMP12 which may promote inflammation and emphysema. Induction of CXCL9 may be of importance for the observed T cell infiltration in lung tissue.
Characterization of human mesenchymal stem cells phenotype and secretome in a in vitro model of acute lung injury inflammation

Arnaud Goolaerts 1, Valérie Vanneau 1, 2, 3, Jérôme Langhero 1, 2, N.D. Ubags 1, 2, J.H. Vernooy 2, E. Burg 1, C. Lenox 1, L.L. Kordonowy 1, 3, P. Fermyn 1, 3, K. DiPalma 1, 3, J.P. Wouters 1, B.T. Surat 1, 2, J. Petty 1, 3, 4, Michael Matthay 1, 2, Christine Clérici 1, 2, 4, Unité 773, INSERM, Paris, France; 2Physiologie, Université Paris Diderot, Paris, France; 3Assistance Publique des Hôpitaux de Paris, APHP F-75010, Paris, France; 4Assistance Publique des Hôpitaux de Paris, APHP F-75010, Paris, France

Intra-tracheal instillation of MSCs may have therapeutic efﬁcacy in models of acute lung injury (ALI). Protective effects of MSC are reported despite low engraftment rates supporting that paracrine mediators may be involved. In ALI MSCs delivered by intra-tracheal route are exposed to alveolar hypoxia and cytokines, both known to independently modify MSC phenotype, which may affect their survival or their reparative properties. We therefore investigated the effects of a typical alveolar ALI microenvironment consisting in hypoxia (HYP) and cytokons (CYT; IL-8, TNFα and IFNγ) on MSC phenotype, apoptosis and secretion profile. Testing the effects of such conditions is important to better understand the fate and behavior of MSC instilled into injured lungs and to detect potential modiﬁcation of their secretion proﬁle. In order to decide whether MSC preconditioning might be an interesting strategy, MSC were exposed 24 hours to CYT 50mg/ml and/or HYP (5% O2). CYT and/or HYP neither modify the expression of the typical MSCs markers (CD90, CD105, CD45) nor the degree of apoptosis necrosis when compared to control MSCs. We measured KGF, PGE2 and IL-1 receptor antagonist (IL-1rA) in the supernatant because they are known to be important for resolution of alveolar edema. We measured KGF, PGE2 and IL-1rA (0 vs 134 ± 26 ng/ml) but decreased by two fold the release of KGF (345 ± 8 vs 115 ± 12.8 ng/ml). In conclusion: Hypoxic and inﬂammatory environment mimicking ALI does not affect the survival and phenotype of MSC but differentially modulates KGF, PGE2 and IL-1rA secretion.

The role of leptin in pulmonary neutrophilia during murine acute lung injury

N.D. Ubags 1, 2, J.H. Vernooy 2, E. Burg 1, C. Lenox 1, L.L. Kordonowy 1, 3, P. Fermyn 1, 3, K. DiPalma 1, 3, E.F. Wouters 2, B.T. Surat 1, 2, J. Petty 1, 3, 4, Michael Matthay 1, 2, Christine Clérici 1, 2, 4, Unité 773, INSERM, Paris, France; 2Physiologie, Université Paris Diderot, Paris, France; 3Assistance Publique des Hôpitaux de Paris, APHP F-75010, Paris, France; 4Assistance Publique des Hôpitaux de Paris, APHP F-75010, Paris, France

Rationale: One of the hallmarks of Acute Lung Injury (ALI) is the extensive recruitment of neutrophils to the lung. Recent evidence shows that leptin expression is increased in the injured human lung, and is known to have diverse effects on leukocytes. We hypothesized that leptin contributes directly to neutrophil recruitment in the lung during ALI.

Methods: C57Bl/6 wild type (WT) mice were examined in a lipopolysaccharide (LPS) model of lung injury with or without oropharyngeal aspiration of recombinant leptin. We measured bronchoalveolar lavage (BAL) neutrophilia, leptin concentrations and inflammatory cytokine levels at 24 hours after injury. In addition, the effects of LPS induced lung injury were examined in leptin resistant (db/db) obese and Diet Induced Obese (DIO) mice and their lean controls. Lastly, we examined chemotaxis to leptin in neutrophils isolated from lean and obese uninjured mice.

Results: BAL leptin levels were significantly increased in injured WT mice (1324 pg/ml ± 320 relative to their saline-treated controls (96 pg/ml ± 74) 24 hours after LPS exposure. Recombinant leptin administration after LPS induced airspace neutrophilia was not effective. LPS exposure in WT mice, yet inflammatory cytokine levels in BAL remained unchanged. In addition, we observed attenuation in BAL neutrophilia in both db/db and DIO obese mice compared to their lean controls. Lastly, neutrophils were found to migrate to leptin in vitro, and obesity blunted this response.

Conclusion: Our ﬁndings indicate that leptin plays a role in neutrophil recruitment to the lung during ALI. This appears to occur in part via leptin-induced neutrophil chemotaxis, which is diminished in obesity.

Preferential activation of alveolar macrophages versus epithelial cells during initiation of ventilator-induced lung injury in mice

Alicia Wuite, Kieran O’Dea, Michael Wilson, Masao Takata. Section of Anaesthetics, Pain Medicine and Intensive Care, Imperial College, London, London, United Kingdom

Background: It has been suggested that stretch-induced deformation of alveolar epithelial cells (AEC) plays a role in the initiation of ventilator-induced lung injury (VILI). In vitro stretch of AEC upregulates intracellular mitogen-activated protein kinases (MAPK) leading to mediator release, but this may not reﬂect the situation in vivo. We have developed a novel method to measure MAPK intermediates within discrete lung cell populations following in vivo VILI.

Methods: Anaesthetised C57Bl6 mice were ventilated with high (V=40ml/kg) or low stretch (V=10ml/kg). At various time points lungs were removed and single cell suspensions were produced by mechanical disruption, with cells immediately ﬁxed and permeabilised. Levels of intracellular phosphorylated (p-) MAPKs and DIO were determined by flow cytometry.

Results: p-ERK and p-MEK2 expression (mean fluorescence intensity, MFI) increased in AM within 5 minutes of high stretch. In contrast, both type I and II AEC showed little p-ERK and p-MEK2 phosphorylation, even up to 1 hour.
Conclusion: Contrary to previous suggestions that stretch-induced activation of AEIC is the key initiator of VILI, our results indicate an immediate, direct activation of AM with high stretch, placing AM as potentially more important than AEIC in triggering the early inflammatory response during VILI.

Immunomodulatory function of chemerin and its receptor ChemR23 in the pathophysiology of viral pneumonia and acute lung injury

Benjamin Bondue1, Olivier Vosters2, Patricia De Nadai2, Stephanie Glineur4, Daniela Desmecht4, Paul De Vuyst1, Marc Parmentier2.

Viviane Cagido1, Natália Casquilho 1, Douglas Barbosa 1, Raquel Soares 1, Temporal behavior of lung injury induced by instillation of microcystin-LR (MC-LR) in mice. MC-LR mediated by non-leukocytic cells, such as lung endothelial or epithelial cells. Moreover, a strong anti-inflammatory role of chemerin is observed in a model on non-leukocytic cells. Indeed, experiments involving adoptive transfer of pDCs explain the delayed acquired response and viral clearance in ChemR23 -/- mice. However, the stronger inflammation observed in these mice is not due to defective pDC recruitment but rather to the loss of an anti-inflammatory role of chemerin in non-leukocytic cells. Indeed, experiments involving adoptive transfer of pDCs and bone marrow transplantation exclude the role of ChemR23-expressing pDCs and more generally leukocytes in the protection against excessive inflammation. Moreover, a strong anti-inflammatory role of chemerin is observed in a model of acute lung injury induced by instillation of the pneumonia virus of mice (PMV). ChemR23+ mice display delayed viral clearance, and impaired acquired immunity, contrasting with an excessive innate response and recruitment of neutrophils. Lower recruitment of type I interferon-producing plasmacytoid dendritic cells (pDCs) may explain the delayed acquired response and viral clearance in ChemR23 -/- mice. However, the stronger inflammation observed in these mice is not due to defective pDC recruitment but rather to the loss of an anti-inflammatory role of chemerin in non-leukocytic cells. Indeed, experiments involving adoptive transfer of pDCs and bone marrow transplantation exclude the role of ChemR23-expressing pDCs and more generally leukocytes in the protection against excessive inflammation. Temporal behavior of lung injury induced by instillation of microcystin-LR in mice

Viviane Cagido1, Natália Casquilho1, Douglas Barbosa1, Raquel Soares1, Sandra Azevedo1, Samuel Valence1, Walter Zint1, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil;1Institute of Biomedical Sciences, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Cyanotoxins present in the water for human use may yield serious health problems. We aimed to evaluate the effects of microcystin-LR (MC-LR) on lung mechanics, lung and liver histology and inflammation, and oxidative stress. Male Swiss mice (n=149) were randomly divided in 2 groups: control (CT) received sterile saline intratracheally (i.t., 50 μL), and MC a sublethal dose of MC-LR (40 μg/kg, i.t.). CT (n=13), and MC mice were evaluated at 2, 4, 6, 8, 15, 22, 24, 48 h after MC -LR instillation. The amount of polymorphonuclear cells and mesotheliocytosis activity in lung augmented in all MC groups until 96 h, indicating a neutrophilic inflammatory cell infiltrate. Hepatic histology showed necrosis and hepatocyte disarrangement in 8 h. Free MC-LR was detected in lung and liver homogenates, with a time-dependent toxin accumulation in liver. Antioxidative enzymes activities and thiobarbituric acid reactive substances were altered in MC-LR exposed animals. i.t. administration of MC-LR led to a biphasic compromise of pulmonary mechanics: an early deterioration (2 h and 6 h), normalization at 24 h, and a later worsening (48 h). Also, alveolar collapse, lung and liver inflammation, imbalance of antioxidants enzymes, and oxidative damage were identified. This work reinforces the airways as an important route of introduction of MC-LR. Supported by: PRONEX/FAPERJ, FAPERJ, CNPq, MCT

Toxicological assessment of indoor airborne fine particulate matter induced oxidative stress in alveolar epithelial cells

Yasuo Takanabe1, Tomomi Komura2, Kenichiro Yaggy1, Takeshi Minami4, 1Health and Nutrition, Kio University, Kitaatkarui-ku, Nara, Japan; 2Interdisciplinary Studies for Advanced Aged Society, Osaka City University Graduate School of Human Life Science, Osaka, Japan; 3The Science Research Centre, Kochi University, Nankoku, Kochi, Japan; 4Life Science, Kio University, Higashiosaka, Osaka, Japan

Background: Exposure to airborne particulate matter (PM) has long been associated with adverse health problems. These fine PM particles can penetrate the distal regions of the lung causing severe respiratory problems.

Objectives: As relatively little information of indoor fine PM is available to evaluate the actual risks, we will focus our examination on lung injuries caused by fine indoor PM, by investigating the mechanism of the cell injury using primary culture of alveolar type II cells.

Method: Indoor PM was collected in Nara prefecture, Japan using an Andersen sampler by the impactor cascade method. Particle samples of PM were collected on five Teflon filters in accordance with the diameter of particles (diameter: >11μm, 2.1-11.1 μm, 1.1-2.1 μm, 0.1-1.1 μm, <0.1 μm). Alveolar type II cells from rats were exposed to PM at the concentration of 500 μg/ml for 24 hrs respectively. At the end of the experiment, lactate dehydrogenase (LDH) activity released into the culture medium was determined and the percentage of LDH leakage was then calculated to reflect the cytotoxicity of PM.

Results: In relation to the control cells, the PM-induced LDH leakage was more significant among the smaller fine particles of indoor PM than the larger one. However this did not occur with the above mentioned 1.1 μm diameter size of PM. Superoxide dismutase (SOD) significantly reduced LDH leakage induced indoor PM. In the analysis of the elements in indoor PM, the most abundant element was iron (Fe).

Conclusions: Indoor PM causes oxidative cellular damage, which may be closely associated with a transition metal, Fe in rat alveolar epithelial cells.

Effect of nanoparticle and NO2 exposure on thoracic gas volume in Brown Norway rat

Skander Layachi1, François Rogerier1, Christelle Gamze2, Kelly Blazy2, Franck Bobe1, Anthony Lecomte1, Ghislaine Lacroux1, Sam Baysal2,1EA4285 - INERIS UBO1, Université de Picardie - UFR de Médecine, Amiens, France; 2Direction des Risques Chroniques, INERIS, Verneuil-en-Halatte, France; 3Pneumologie, Université de Nantes, France

Rationale: Air pollutant exposure, has been associated with increased asthma morbidity in children. The aim of the present study was to determine whether exposure to NO2 and carbon nanoparticles (CNPs) affect the rate of Thoracic gas volume (TGV) change with growth in 7-week old Brown-Norway (BN) rats.

Methods: Animals were anesthetized and tracheally intubated. TGV was measured using whole-body plethysmography at age 49 days, and following a 4-week exposure to air, NO2 (10 ppm) 5bd, 5wkd, CNP (FW2, Ø 13 nm; 3 instillations at 2, 11 and 24 days). 11 different groups were compared.

Results: TGV significantly increased after 4 weeks in all groups. When normalized to body weight, TGV increased significantly only in the air-exposed group.

A new method for detection of flow limitation in COPD using dynamic chest X-ray examination
Norihisa Motohashi1, Takehiko Abe2, Misako Aoki1, Koze Morimoto1,1,1, Yuji Shirasuda1,1, Hideo Ogata1,1, Shoji Kudo1,1, 1Respiratory Medicine Division, Respiratory Diseases Center; 2Department of Radiology, Chest Surgery Division, Respiratory Disease Center, Fukuyui Hospital, JATA, Tokyo, Japan

Purpose: Spirometry which requires maximum effort tasks COPD patients. In this study, we proposed a new method for detection of flow limitation without effort breathing.

Subjects: Dynamic chest X-ray from 10 normal volunteers, 16 mild COPD patients (GOLD Stage I or II) and 12 severe COPD patients (GOLD Stage III or IV) were obtained in the upright position in about 10 seconds of tidal breathing at rest. The dynamic image data captured at 7.0 frames per second was synchronized with the pulsed X-ray. The institutional review board approval and written informed consent were obtained in all persons.

Methods: We calculated the maximal differential values in each ventilation phase at the corresponding small local area of lung in the series of dynamic chest X-ray. The regional relative flow rate ratio was obtained from the peak values of inspiratory phase divided by the peak values of expiratory phase. All groups were compared about the average of flow rate ratio.

Results: The regional changes in inspiratory/expiratory flow rate ratio had larger values and broader distribution in COPD patients than those of normal volunteers. The average of the ratio in normal volunteers, in mild COPD patients and in severe COPD patients were 1.04±0.09, 1.17±0.08, and 1.19±0.13 (mean±SD), respectively. A significant difference was confirmed between the normal volunteers and the COPD patients (p=0.031).

Conclusion: The inspiratory/expiratory flow ratio rates in COPD patients were higher than those of healthy volunteers. The new method for ventilation function has possibility to evaluate flow limitation without effort breathing.

P4599

Gravity dependence of lung density and specific gas volume (SVg) assessed by CT in health and emphysema
Francesca Pennati1,2, Caterina Salito1,2, Jason Woods4,5, Peter Macklem4,5, Andrea Aliverti1,2, Dip. di Bioingegneria, Politecnico di Milano, Milano, Italy; 2Dept. of Radiotherapy and Physics, Washington University, St. Louis, United States; 3Health Centre Research Institute, McGill University, Montreal, Canada

Introduction: Lung density and SVg variations between different lung volumes are reliable estimates of regional lung emptying/filling (Salito et al.,Radiology,2009). Here the gravity-dependent regional differences occurring within the lung in both healthy (H) and emphysema (E) is evaluated.

Methods: 10 healthy volunteers and 10 subjects with severe emphysema (FEV1<50%pred, RV/TLC>0.65) were acquired at TLC and RV via static high-resolution-CT. For each subject, three levels, aortic arch (AA), carina (C) and top diaphragm (TD), were chosen to register through an optical-flow-based method the RVslice to the correspondent TLC one. Pixel-by-pixel differences between TLC and RV of healthy patient and emphysema were calculated. Frequency distribution plots of ΔSVg at the different levels were then expressed in terms of mean, median, standard deviation and skewness.

Results: Table 1 reports the pertinent values of the frequency distribution of ΔSVg in healthy and COPD subjects for each tracheo-bronchial tree level.

*p<0.01 vs healthy.

Conclusions: In severe emphysema, ΔSVg is smaller at any lung level, suggesting that alveolar destruction and gas trapping are homogenously distributed within the lung. Regional distribution of SVg in emphysema presents an high degree of heterogeneity respect to healthy.

P4600

Lung structure in healthy nonsmokers and smokers assessed by CT-densitometry and chest X-ray
Reza Karimi1, Sven Nyren1, Asa Wheelock1, Göran Tornling1, Magnus Skold1, 1Department of Medicine, Karolinska Institutet, Stockholm, Sweden; 2Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Smoking causes inflammation in the lungs, which may lead to structural changes and irreversible airways obstruction, characteristic for COPD. By computed tomography (CT), areas with Hounsfield units (HU) below -900 have been considered as emphysema, while increased attenuation may indicate inflammation. We investigated changes in smokers compared to neversmokers.

Materials and methods: 40 current smokers (35±12 pack-years, mean±SD) with normal lung function and 36 healthy nonsmokers performed chest X-ray and CT. Age was 45-65 years with equal sex distribution. Lungs were defined as voxels with attenuation between -300 to -1024 HU, further divided into eight intervals. Chest X-rays were evaluated according to criteria's: depression of the diaphragm, irregular radiolucency, abnormal retrosternal space and sternodiaphragmatic angle >90°. Two or more criteria's was considered as emphysema.

Results: Mean lung attenuation in smoking (±854HU±13; mean±SD) and female smokers (±854HU±19) was higher than in nonsmokers (male -880HU±20; females -872HU±18) (p<0.05 for both). In women, the percent of areas with HU below -950 was lower in smokers than nonsmokers (p<0.001), the difference was smaller in men (p<0.05). Chest X-ray detected emphysema in 22% of male and 15% of female smokers, but in none of the neversmokers.

Discussion: Increased lung density in smokers may indicate inflammation but this may be to correlated to other signs of local inflammation. Females may be more vulnerable than males to the effects of smoking. Despite normal lung function, a considerable number of subjects had emphysema on plain chest x-ray. Further analyses are in progress including patients with COPD.

P4601

Specific gas volume (SVg) variations between different lung volumes in health and emphysema
Francesca Pennati1, Caterina Salito1, Jason Woods4,5, Peter Macklem4,5, Andrea Aliverti1,2, Dip. di Bioingegneria, Politecnico di Milano, Milano, Italy; 2Dept. of Radiology and Physics, Washington University, St. Louis, United States; 3Health Centre Research Institute, McGill University, Montreal, Canada

Introduction: Variation of specific gas volume (SVg) between high and low lung volume is a reliable estimate of regional lung filling/emptying (Salito et al.,Radiology,2009). The aim of this study was to evaluate how these variations are distributed in different regions of the lung in healthy and COPD subjects.

Methods: 10 healthy volunteers and 10 subjects with severe emphysema (FEV1<50%pred, RV/TLC>0.65) were scanned at TLC and RV via static high-resolution-CT. For each subject, three levels, aortic arch (AA), carina (C) and top diaphragm (TD), were chosen to register through an optical-flow-based method the RV slice to the correspondent TLC slice. For each level pixel-by-pixel SVg differences between TLC and RV (ΔSVg(TLC)-SVg(TD)) were calculated. Frequency distribution plots of ΔSVg at the different levels were then expressed in terms of mean, median, standard deviation and skewness.

Results: Table 1 reports the pertinent values of the frequency distribution of ΔSVg in healthy and COPD subjects for each tracheo-bronchial tree level.

Airway dimensions in COPD patients: Relationship with lung functions
Zheng-Xian Chen, 1 Jia-Wen Yang, 2 1Department of Respiratory Medicine, Guangdong General Hospital, Guangdong, 2Academy of Medical Sciences, Guangzhou, Guangdong, China

**Background:** There is growing attention about evaluating the airway abnormality in chronic obstructive pulmonary disease (COPD) using airway dimensions.

**Objective:** To investigate relationship between airway dimensions measured by multi-slice spiral CT (MSCT) and lung functions in COPD patients.

**Methods:** 25 COPD patients and 15 healthy subjects underwent MSCT scans and pulmonary function test. The airway wall thickness (T) and airway luminal area (Ai) of apical bronchi of the right upper lobe in the CT images were measured. The ratio of T and the total diameter (T/D) and percentage of airway wall area to outer area (WA%) of the bronchus were calculated from T and Ai. Ventilation function, lung volume, airway resistance and diffusion function were detected in pulmonary function test.

**Results:** There were significant differences between COPD patients and healthy subjects in T/D, Ai/BSA and WA%.

Bone mineral density (BMD) in male patients with chronic obstructive pulmonary disease (COPD) in age 40-70 years
Sviatlana Lemiasheuskaya, Alexander Makarevich, Alla Shepelkevich. Internal Medicine, Belarusion State Medical University, Minsk, Belarus

**Background:** COPD is often associated with the systemic extra pulmonary effects such as osteoporosis.

**Aim and objectives:** To study the dynamics of BMD in the course of COPD progression.

**Material and methods:** We examined 72 COPD male patients (aged 40-70 years). The COPD pts were subdivided into groups according to COPD severity: the 1st was made of 14 men; GOLD I stage; mean age 55 years; FEV1 78%; BMI 27 kg/m², smokers 68%, paquets/ys 20; the 2nd included 43 patients; GOLD II stage; mean age 57; FEV1 65%; BMI 28 kg/m², smokers 80%; paquets/ys 21; the 3rd -20 patients; GOLD III stage; mean age 60; FEV1 41%; BMI 24.5 kg/m², smokers 84%; paquets/ys 28. All the findings were compared in 34 normal age-, sex- and BMI-matched control subjects. BMD was measured in spine (L1-L4) and femoral necks (FN) in 15 men using DXA (Hologic)

**Results:** The level of BMD was significantly lower in 3rd group in comparison with control both in spine (0.992±0.156 vs. 1.252±0.119 g/cm2, p<0.01) and at femoral necks (0.824±0.136 vs. 0.986±0.065 g/cm2, p<0.01). Osteopenia and osteoporosis were diagnosed in 51% and 11% cases in the 2nd group; 30% and 66% in the 3d group respectively. Osteopenia was revealed in 50% patients in the 1st group.

**Conclusion:** We found the significant negative correlations between pack/ys and BMD of L1-L4 (r=0.55); with BMD of FN (r=0.38).

**Conclusions:** The significant decrease of BMD was found in the course of COPD progression.

**P4605**

The relationship between inspiratory capacity and emphysematous changes assessed by CT in Vietnamese COPD patients
Hiroshi Wada, 1 Tho Nguyen Van, 2 Trung Le Thi Huyen, 3 Rie Kanda 1, Yasushi Ruyjin, 1 Masafumi Yamaguchi, 1 Tetsuya Oguma, 1 Taishi Nagao, 2 Emiko Ogawa, 1 Lan Le Thi Tuyet, 2 Yutasaka Nakano 1. 1Division of Respiratory Medicine, Department of Internal Medicine, Shiga University of Medical Science, Otsu, Shiga, Japan; 2Faculties of Medicine, University of Medical and Pharmacy, Ho Chi Minh, Viet Nam; 3Health Administration Center, Shiga University of Medical Science, Otsu, Shiga, Japan

**Introduction:** It is known that low attenuation volume (LAV) assessed by computed tomography (CT) is related to the severity of chronic obstructive pulmonary disease (COPD). However, the relationship between distribution of emphysema assessed by LAV and inspiratory capacity is not clear.

**Objectives:** To investigate the relationship between IC and emphysematous changes in each lobe.

**Methods:** We recruited 76 Vietnamese COPD patients who underwent chest CT and respiratory function tests. We analyzed volumetric CT data and measured the fraction of low attenuation volume (LAV%) in each lobe. We then evaluated the relationship between LAV% in each lobe and inspiratory capacity.

**Results:** LAV% of the whole lung was significantly related to inspiratory capacity (r=0.278, p=0.021). LAV% in right lung and left lung were significantly related to inspiratory capacity (r=0.275, p=0.022, and r=0.2715, p=0.024, respectively). LAV% of the right upper lobe and middle lobe was not related to inspiratory capacity (p=0.075 and p=0.457, respectively). LAV% of the right lower lobe was significantly related to inspiratory capacity (r=0.354, p=0.003). LAV% of the left upper lobe was not related to inspiratory capacity (p=0.072). LAV% of the left lower lobe was significantly related to inspiratory capacity (r=0.371, p=0.002).

**Conclusions:** Inspiratory capacity is affected more strongly by the emphysematous changes in the lower lobes than in the upper lobes.
to get FMI, FFMI. The COPD pts were subdivided into groups: the 1st was made up of 14 men; 1 stage (GOLD); mean age 55 yrs; BMI 27 kg/m²; the 2nd - 43 pts; II stage; mean age 57; BMI 28 kg/m²; the 3rd - 20 pts; III stage; mean age 60 yrs; BMI 24.5 kg/m².

Results: Indices H, SD decrease, while E increases in COPD pts v. control and in process of severity growth of COPD. We have established the positive significant correlations of E with FMI (r=0.61), and negative one between SD and BMI (r=-0.7). The 1st group characterized by the positive significant correlations between E and FMI (r=0.69) and negative one between H and SD of extOAM and FMI (r=-0.42 and r=-0.52) in the 2nd group. The 3rd group characterized by the positive significant correlations between E and FMI (r=0.69) and negative one between H and SD of extOAM and FMI (r=-0.7 and r=0.75). The index E of intOAM correlated with FMI and FFMI (r=0.62 and r=0.63). Similar results were characteristic of other muscles.

Conclusions: The possible mechanism of the changes in COPD patients could be protein replacement with fat in muscles.

P4608 Distribution of CT-quantified emphysema: Association with lung function decline
Firdaus Mohamed Hoesein 1, Pieter Zanen 2, Jan Willem Lammers 1, 1Division of Heart & Lungs, Department of Respiratory Medicine, University Medical Center Utrecht, Utrecht, Netherlands; 2Image Sciences Institute, Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands; 3Department of Respiratory Medicine, Erasmus University Medical Center, Rotterdam, Netherlands; 4Department of Radiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background: Previous studies showed that subjects with similar extents of CT-quantified emphysema, but with different locations within the lung show different degrees of airflow obstruction.

Aim: To assess the association between CT-quantified emphysema distribution (upper/lower lobe) and lung function decline in heavy smokers participating in a lung cancer screening trial.

Methods: 587 participants underwent CT-scanning of the lungs and pulmonary function testing at baseline and after a median (interquartile range) follow-up of 2.9 (2.8-3.0) years. The lungs were automatically segmented based on anatomically defined lung lobes. Severity of emphysema was automatically quantified for anatomical lung lobe and was expressed as the 15th percentile technique (point below which 15% of the low attenuation areas voxels are distributed). Linear mixed models, correcting for age, height, BMI, packyears and smoking status, were used to assess the association of emphysema distribution and FEV1/FVC decline.

Results: Mean (SD) age was 60.2 (5.4) years, mean baseline FEV1/FVC was 71.6 (9.0%); overall mean Perc15 was 908.5 (20.9) HU. Participants with upper lobe predominant emphysema had a 1.71% (95% confidence interval 0.79 - 2.64) lower FEV1/FVC after follow-up compared to participants with lower predominant emphysema (p<0.001), independently of the total extent of emphysema.

Conclusion: Upper lobe predominant emphysema may be a different phenotype than lower lobe predominant emphysema.

P4609 Tracheo-bronchial collapsibility in different clinically determined COPD phenotypes
Gianna Camiciottoli 1, Francesca Bigazzi 2, Stefano Diciotti 2, Simone Lombardo 2, Mario Mascalchi 2, Massimo Pistolesi 2, 1Department of Internal Medicine, University of Florence, Florence, Italy; 2Department of Clinical Physiopathology, University of Florence, Florence, Italy

Tracheo-bronchial collapsibility (TBC) has been detected at computed tomography (CT) in Chronic Obstructive Pulmonary Disease (COPD). TBC is considered a local response to inflammatory agents not closely related to the obstructive functional pattern and to lung attenuation values at CT. We hypothesize however that TBC could influence symptoms and daily performance in patients with COPD.

The purpose of our study was to investigate whether TBC is related to dyspnoea, exercise capacity and clinical phenotypes in patients with COPD.

Thirty-six patients (mean age 68±8, mean FEV1% 60±24) underwent clinical examination, lung function test, 6 minutes Walking Test and inspiratory-expiratory CT-TBC was measured by an automated software and correlated with MRC and Borg dyspnoea scales and with walked distance. Moreover we compared TBC in patients with predominant chronic bronchitis (CB) and predominant emphysema (E) phenotypes according to the rule available at www.clipcopd.com.

No significant relationship was found between TBC and MRC (r=-0.24, p=0.15), Borg score (r=-0.12, p=0.48),walked distance (r=0.17, p=0.33). TBC was significantly higher in patients with CB phenotype (p=0.02, Fig. 1). Patients with a predominant CB phenotype show a high level of TBC supporting the idea that the same inflammatory process could involve both trachea and bronchial tree. Dyspnoea and exercise capacity are global indexes of COPD that are not related to TBC.

P4610 Computed tomographic diagnosis of air trapping in non- or mildly obstructed smokers
Onno M. Mets 1, Pieter Zanen 1, Jan Willem Lammers 2, Ivana Isgum 3, Hester A. Gietsma 1, Bram van Ginneken 2, Pieter Zanen 1, Piem A. de Jong 1, 1Pulmonary, University Medical Center Utrecht, Utrecht, Netherlands; 2Pulmonology, University Medical Center Utrecht, Utrecht, Netherlands; 3Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands

To assess the association of emphysema distribution and FEV1/FVC-decline.

Models, correcting for age, height, BMI, packyears and smoking status, were used to assess the association of emphysema distribution and FEV1/FVC decline.

Results: Mean (SD) age was 60.2 (5.4) years, mean baseline FEV1/FVC was 71.6 (9.0%); overall mean Perc15 was 908.5 (20.9) HU. Participants with upper lobe predominant emphysema had a 1.71% (95% confidence interval 0.79 - 2.64) lower FEV1/FVC after follow-up compared to participants with lower predominant emphysema (p<0.001), independently of the total extent of emphysema.

Conclusion: Upper lobe predominant emphysema may be a different phenotype than lower lobe predominant emphysema.

P4611 Visual versus quantitative assessment of airways disease in COPDGene
Mei-Lan Han 1, George Washko 2, Philip Westgate 1, Susan Murray 3, Fernando Martinez 4, Ella Kazerouni 4, Ed Silverman 5, James Crapo 6, 1Department of Pulmonary and Critical Care, University of Michigan, Ann Arbor, MI, United States; 2Biostatistics, University of Michigan, Ann Arbor, MI, United States; 3Radiology, University of Iowa, Iowa City, IA, United States; 4Radiology, National Jewish Health, Denver, CO, United States; 5Radiology, University of Michigan, Ann Arbor, MI, United States; 6Department of Radiology, University of Michigan, Ann Arbor, MI, United States;

Background: Visual airway assessment may provide unique data not captured by automated methods; cut points for distinguishing “abnormal” from “normal” do not exist with quantitative CT (QCT) measures. We sought to understand the relationship between QCT and visual airway measures.

Methods: 198 COPDGene cohort scans (GOLD I-IV) were reviewed by pulmonary-monologists and radiologists (9-11 reviewers/scan) for presence of airway wall thickening (AWT). Logistic regression and area under the receiver operating curve (AUC) analyses determined the relationship between median AWT score and QCT measures including segmental and subsegmental wall area percent (WAP), wall thickness, lumen diameter and pi10 (standardized airway wall thickness at internal perimeter of 10 mm). Multivariate regression adjusted for age, gender, and smoking history was used to predict FEV1%, SGRQ and history of chronic bronchitis.

Results: Subsegmental WAP (AUC=0.72, p<0.001) and pi10 (AUC=0.75, p<0.001) best predicted the presence of visual AWT. A pi10 value of 3.78 (95th percentile normals/66th percentile COPD) provides 80% specificity and 55% sensitivity; a WAP value of 6 (>99th percentile normals/74th percentile COPD) provides 80%
specificity and 53% sensitivity. Subsegmental WAP predicted a similar degree of variability in FEV1% compared to AWT (r²=0.33 vs 0.32). Visual score better predicted chronic bronchitis symptoms (AUC 0.73 vs 0.66) and SGRQ score (r²=0.23 vs 0.16).

Conclusions: Expert panel visual airway score correlates best with subsegmental WAP and p<0.01 in the >90th percentile range for normals. Each method provides unique information; in particular, visual analysis scores appear to be more closely associated with clinical symptoms.

P4612
Analysis of activation process of dyspnea sensation in CNS in patients with COPD measured by fMRI
Masachika Akiyama1, Jun Suzuki1, Yutaka Nakamura1, Hirotoshi Kobayashi1, Kohei Yamahachi1, Ikuko Uwano2, Yutaka Matsumura2, Makoto Sasaki2,
1Division of Pulmonary Medicine, Allergy and Rheumatology, Department of Internal Medicine, Iraku Medical University School of Medicine, Moriko, Japan
2Advanced Medical Research Center, Iraku Medical University School of Medicine, Moriko, Japan

Introduction: Dyspnea is the cardinal symptom of COPD. Localization of dyspnea sensation in the brain has been studied by a small number of investigators. However little is known about transmission and activation of dyspnea sensation in CNS.

Objectives: We analyzed pathway and localization of dyspnea sensation in the brain of normal subjects and COPD patients using functional magnetic resonance imaging (fMRI).

Methods: Six normal subjects (M/F: 5/1, 35.7 ± 5.9 yr; mean ± SEM) and 4 COPD patients (M/F: 4/0, 68.5 ± 1.7 yr) were recruited. After informed consent, these subjects were requested to breathe through resistive loads ranging from 5 to 50 cm H2O/L/sec adjusted by the BORG 10 Scale. The subjects received Iminite of repetitive resistive-loaded breathing three times with lminute interval. During these process, brain activity was analyzed by 3 Tesla scanner (Signa Excite HD; GE Healthcare).

Results: Activation of bilateral sensory cortices was recorded among 6 normal subjects and COPD patients. In addition, VPM in bilateral thalami was also observed in all subjects when subjects breathed with the resistive load. There was no difference of the localization of activated portions during resistive-loaded activated in all subjects when subjects breathed with the resistive load. There was no difference of the localization of activated portions during resistive-loaded activated in all subjects when subjects breathed with the resistive load.

Conclusion: Activation of bilateral sensory cortices was dependent on the resistive load among normal subjects and COPD patients. The resistive loads on bilateral sensory cortices increased upon inspiration.

Anatomically derived regional measurement of lung function
Michael Bennett1, Tom Havelock1, Joy Conway2, John Fleming3
1Southampton Centre for Biomedical Research, NIHR Respiratory Biomedical Research Unit, Southampton University Hospitals NHS Trust, Southampton General Hospital, Southampton, United Kingdom; 2Faculty of Health Sciences, University of Southampton, Southampton, United Kingdom

Existing methods for quantifying lung ventilation and perfusion SPECT scans provide measurements which are either global, based on division of the lung into non-anatomical regions or based on the application of a generic lung model of lung anatomy. The objective of this work is to develop a technique to use HRCT data to automatically define sub-lobar regions corresponding to anatomical lung segments and to align these with SPECT/CT data acquired separately from the same subject. This can be achieved by performing a non-rigid registration between the HRCT data, acquired at full inspiration, and the low-res CT data captured during tidal breathing. Once the transform required to bring these two data sets into alignment has been determined, it can be applied to the sub-lobar regions to map these to the low-res CT and hence to the SPECT data. This process of non-rigid registration is achieved using a free-form polynomial warp algorithm, which automatically determines the optimum elastic transform required to bring the HRCT and low-res CT data sets into alignment. HRCT scans are analysed using commercially available software to define the airway tree geometry, which is then used to seed a Voronoi space division algorithm to divide the lung into segments based on the branches of the airway tree. Early results have shown that it is possible to robustly divide the lung into the regions based on the segmental branches of the airway tree and good alignment between single 2D slices and the SPECT images has been obtained. The method will be extended to work in 3D and the results so far indicate that this will be a viable method to produce anatomically relevant measurements of lung function.
Results: 1757 patients were analysed: mean age 45.4 yrs; men 56.8%; current smoker 20.2%; mean time since diagnosis 16.8 yrs; 90% treated with ICS+LABA, 29% with antileukotrienes, 48% with antihistamines; 44% had severe exacerbation in past year; 33.3% had comorbidity which limited activities. According to GINA criteria (excluding lung function) 76.2% were not controlled. GPs reported limitation of activities in 44.4%. Whilst 87.4% of patients reported limitation of activity (mild, moderate or severe) at least one domain 75.2% daily, 80.5% physically and 50.3% work/school-activities.

Conclusion: Impact on asthma was frequent and underestimated among these treated patients. It deserves more attention when assessing asthma control.

P4616 Population segmentation to identify priority targets for identification and behaviour change interventions in COPD
Matt Kearney, Julia Crighton, Kevin Holton, Anne Moger, Robert Winter, Sue Hill. Respiratory Programme, Dept. of Health, London, United Kingdom

Background: In England 800,000 people are diagnosed with COPD. 2.7 million have the disease but are undiagnosed. Smoking is the dominant risk factor. Targeted identification of those at increased risk combined with effective behaviour change interventions could significantly reduce the disease burden.

Objectives: To identify and characterise those population groups in England at greatest risk of COPD in order to maximise the impact of targeted behaviour change interventions.

Methods: A social marketing methodology was employed. An England-wide audience segmentation based on life-stage, socio-economic and environmental factors was conducted to identify priority segments. Focus groups and interviews with informants in each segment provided a rich understanding of behaviours, attitudes and motivation.

Results: Three segments (children aged 7-12 and young men and women in routine/manual occupations) were identified as priority targets for prevention. Three further segments (mid-life men and women in routine/manual occupations and older routine/manual smokers) were identified as priority targets for identification of undiagnosed COPD. Two segments (Bangladeshi men and routine/manual parents who smoke) were identified as priority targets for both prevention and identification.

Conclusions: Targeting priority population segments will maximise the effectiveness of identification and behaviour change interventions in COPD and will ensure efficient use of healthcare resources. The results of this segmentation and insight work have informed development of the national strategy in England for the prevention and early identification of COPD.

P4617 Validity and reproducibility of a physical activity questionnaire for elderly
Lara Siebeling1, Sarah Wiersbe2, Loo Beenu1, Milo Puhan3, Gerben ter Riet1.
1Department of General Practice, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; 2Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, United States

Background: Physical activity is important for elderly to maintain their health and functional ability. It helps predict the course of chronic diseases. Many existing questionnaires have not been compared to activity monitors. We examined validity and reproducibility of the LASA Physical Activity Questionnaire (Lapaq) against an accelerometer in Dutch elderly (65+).

Methods: Participants were the accelerometer for two weeks and filled in Lapaq twice. We examined validity using correlation coefficients, histograms and modified Bland-Altman plots. We used logistic regression to assess how well Lapaq discriminates between persons who have sedentary lifestyle (30 minutes/day) and those who are physically active.

Results: 89 persons were included, 48% men, median age 73 and median BMI 25. 36%, 43%, and 22% had no, one, or two chronic diseases. As a reference, two full weeks contain 20160 minutes (336h). The total duration of activity in two weeks was 2439 (Lapaq T1), 1994 (Lapaq T2) and 2788 minutes (accelerometer). The difference between Lapaq T1 and accelerometer was 510 minutes (8.5 hours). The Pearson correlation coefficient was 0.34 (95% CI 0.13-0.51). The I.C.C. was 0.68 (95% CI 0.56-0.79). The area under the curve is 0.73 (95% CI 0.59 - 0.86).

Conclusions: Due to moderate reproducibility and low validity, Lapaq seems unsuitable for exact measurement of physical activity in elderly. If the more modest aim is to determine if a person’s activity level is above the recommendation level, Lapaq classifies around 73% correctly.

P4618 Urban-rural differences in health status among patients with chronic obstructive pulmonary disease (COPD)
David Creasey1,2, FengHui Su2, Bradford Jackson1, Sumihiro Suzuki1, Kaming Lo1,2, Karan Singh1, Sejong Bae1,2. 1Internal Medicine, University of Texas HSC-Tyler, Tyler, TX, United States; 2Biostatistics, University of North Texas Health Science Center, Fort Worth, TX, United States

Background: While geographic variation in health care access and quality may affect health status of patients with chronic diseases little is known about the health status of patients with COPD.

Objectives: The purpose of this analysis was to examine urban-rural differences in health status among patients with COPD.

Methods: This was a cross-sectional analysis of baseline data from patients with COPD enrolled in a self-management clinical trial. Urban-rural residence was determined from zip code. Health status was measured using BODE index (BMI, obstructive impairment, dyspnea severity, exercise capacity), and generic (SF-12) and disease-specific (Chronic Respiratory Questionnaire [CRQ]) quality-of-life instruments. Independent sample t-tests and chi-square tests were used to examine statistical differences.

Results: To date, results from 82 patients are available with mean age of 69 years, 46% female, 51% rural residence, and 98.6% with health insurance. Rural residence was associated with greater impairment (mean [SD] BODE index=9.1 [8.9]) compared to urban residence (3.4 [1.8], p=0.0003). Moreover, 6-minute walk distance was clinically and significantly less among rural (325 m [104]) vs. urban (375 m [90]) (p=0.02) residence. A similar pattern was found for quality-of-life measures with a lower SF-12 physical summary score among rural (28.3 [9.6]) vs. urban (36.1 [10.0], p=0.0006) residence and clinically worse dyspnea (CRQ-dyspnea=4.1 [1.0]) vs. 4.8 [1.3], respectively, p=0.009.

Conclusion: In this population of patients with COPD rural residence was associated with poorer health status for all measures despite similar access to health care as measured by health insurance.

P4619 Screening of health status in patients with COPD in primary care is essential
Jeannette Peters1,2, Leonie Dauddy1,2, Anke Lahajai2, Lonneke Boer1,2, Eveline de Graus3, Johan Molema4, Yvonne Heijdra3, Jan Vercoulou1,2, 1Department of Medical Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 2Department of Pulmonary Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Guidelines advice to measure health status (HS) in COPD patients. In secondary care (SC) this is more common than in primary care (PC). Problems in HS in PC might be underestimated resulting in inadequate treatment.

Aim: To investigate the proportion of COPD patients in PC with severe problems in HS.

Methods: 314 PC COPD patients were included. Eight sub-domains of HS were measured by the Nijmegen Clinical Screening Instrument (NCSI) covering Functional impairment, Symptoms and Quality of Life. Data from 303 SC COPD patients were available to compare the mean of the incidence and severity of problems in PC patients.

Results: Patients in PC did not differ on sex (59 vs 70% male) and age (mean 66 vs 67 years), but had less severe COPD compared to SC (Stage: 28 vs 16%; II: 59 vs 45%; III: 13 vs 32%; IV: 0 vs 8%). Lower proportions of patients with severe problems were found on the domain Functional impairment and the sub-domain Subjective symptoms in PC as compared to SC (Table 1). GOLD was not predictive for experienced problems in any of the sub-domains in PC.

Table 1. Percentages of patients with severe problems in primary care (PC) and secondary care (SC)

<table>
<thead>
<tr>
<th>PC (%)</th>
<th>SC (%)</th>
</tr>
</thead>
<tbody>

* p<0.01.

Conclusion: Severe problems in many sub-domains of HS were substantial in PC patients. In 5 of 8 sub-domains of HS similar percentages of COPD patients in PC and SC experience severe problems. This implies that screening for problems in HS is needed in PC to warrant patient tailored treatment.

P4620 Using community pharmacy to identify patients at risk of poor asthma control and potential contributory factors
Helen Reddel1,2, Kate LeMay1,2, Bandana Saini1,2, Simhia Bosinc-Anticicive1,2, Lorraine Smith1, Deborah Burton1, Jun Ju Christine Song2, M. Chehani Alles2, Kay Stewart1, Lynn Emmerton1, Ines Krass1, Carol Armour1, 1Clinical Management Group, Woolcock Institute of Medical Research, Sydney, Australia; 2Faculty of Pharmacy, The University of Sydney, Sydney, Australia; 3School of Biomedical Sciences, Charles Sturt University, Orange, Australia; 4Pharmacy Practice, Monash University, Melbourne, Australia; 5School of Pharmacy, The University of Queensland, Brisbane, Australia

Aim: To describe a population identified by trained community pharmacists as being at risk for poor asthma outcomes, and to identify factors associated with poor asthma control.

845s
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
Methods: A cross-sectional study was conducted in 96 metropolitan and regional Australian pharmacies. Community pharmacists with specialised asthma training enrolled 570 patients aged ≥18 years with doctor-diagnosed asthma who were considered at risk based on suboptimal asthma control or lack of recent GP asthma review, and conducted a comprehensive asthma assessment. Assessment of asthma control was based on self-reported frequency of symptoms and activity limitation during the previous month. Asthma history, spirometry and inhaler technique were documented. Medication use was recorded from pharmacy records and self-report.

Results: 570 patients were recruited, of whom 437 (77%) had poor asthma control. 21% (n=120) had an action plan, 69% used combination inhaled corticosteroids (ICS)/long-acting β2-agonist (LABA) medications, and only 17.2% used their inhaler correctly. In terms of adherence, 90% had their ICS or LABA dispensed >6 times in the previous 6 months, which is inconsistent with regular use. A logistic regression model showed that patients who smoked, had incorrect inhaler technique or low adherence were more likely to have poor control.

Conclusions: Community pharmacists identified patients with asthma at risk of suboptimal control, and factors that contributed to this were identified. There is an opportunity within pharmacies to target poorly-controlled asthma and provide timely and tailored interventions.

P4621

Clinical determinants for oral steroids during COPD-exacerbations in primary care

P. van Velzen1, R.J.B. Loijmans 2, M. Amelink1, M. Stommel, G. ter Riet2, Anthony Davison1.

Background: Oral corticosteroids (OCS) are prescribed for most patients with moderate COPD, although not recommended in guidelines or product licences. The indication of systemic steroids during COPD-exacerbations is unclear. This study aimed to determine the proportion of mental disorders (anxiety and/or depression) in patients with COPD exacerbations that are dealt with by GPs in an out-of-hour setting.

Methods: All 18 patients who had called an ambulance because of an exacerbation of COPD in 17 days were included in the study. The ambulance service recorded the 12 relevant factors from the NICE guideline which should be considered when deciding to treat a patient at home. The aim of this study was to see what percentage of patients who had an exacerbation of COPD and call an ambulance meet the criteria for home treatment.

Methods: 1197 patients (14-90 years, median 37) of 107 Italian pharmacies were included in the study. The service recorded the 12 relevant factors from the NICE guideline which should be considered when deciding to treat a patient at home. The aim of this study was to see what percentage of patients who had an exacerbation of COPD and call an ambulance meet the criteria for home treatment.

Methods: The annualised median number of recorded exacerbations/year was 0.67 (range 0.6-6.7) overall and for those without concomitant asthma. 70% of those without asthma who did not have recorded exacerbations were prescribed ICS. Conclusion: ICS are prescribed for most patients with moderate COPD, although not recommended in guidelines or product licences. This prescribing cannot be explained by concomitant asthma or frequent exacerbations. Inappropriate use of ICS increases costs & puts patients at risk of side effects. GPs should audit their use of ICS in moderate COPD. P4624

Introduction: COPD is a chronic condition and healthcare policy in almost all countries is to try and deliver as much care for chronic diseases in the community and reduce the reliance and expense of hospital care. The National Clinical Guideline Centre (NICE) guidelines for COPD (2010) (www.nice.org.uk/guidance/CG101) give clear recommendations for factors to consider when deciding to treat a patient at home. The aim of this study was to see what percentage of patients who had an exacerbation of COPD and call an ambulance meet the criteria for home treatment.

Methods: All 1197 patients (14-90 years, median 37) of 107 Italian pharmacies were included in the study. The service recorded the 12 relevant factors from the NICE guideline which should be considered when deciding to treat a patient at home. The aim of this study was to see what percentage of patients who had an exacerbation of COPD and call an ambulance meet the criteria for home treatment.

Methods: The annualised median number of recorded exacerbations/year was 0.67 (range 0.6-6.7) overall and for those without concomitant asthma. 70% of those without asthma who did not have recorded exacerbations were prescribed ICS. Conclusion: ICS are prescribed for most patients with moderate COPD, although not recommended in guidelines or product licences. This prescribing cannot be explained by concomitant asthma or frequent exacerbations. Inappropriate use of ICS increases costs & puts patients at risk of side effects. GPs should audit their use of ICS in moderate COPD.

Prescribing patterns for allergic rhinitis in general practice setting: Adherence to ARIA guidelines

Mara Simoni1 , Sara Maio1, Sandra Balducci1 , Anna Angino1, Patrizia Silvi1, Marco Borboli1, Franca Martin1, Francesco Di Pietro1, Giovanni Vieggi2,3

1Pulmonary Environmental Epidemiology Unit, CNR, Institute of Clinical Physiology (IFC), Pisa, Italy; 2*ENR Institute of Biomedical and Molecular Immunology (IBIM) “A. Monroy”, Palermo, Italy

Background: Allergic rhinitis (AR) and asthma are often co-morbidities. The correct management of AR should be ensured by the use of international ARIA (Allergic Rhinitis and its Impact on Asthma) guidelines (GL).

Aim: To prospectively evaluate the adherence to GL of General Practitioners (GPs) for treating AR patients.

Methods: Analyses concern 1197 patients (14-90 years, median 37) of 107 Italian pharmacies.
P4626
General practitioners’ views about managing depression in patients with chronic obstructive pulmonary disease
Abebaw Yohannes. Health Professions, Manchester Metropolitan University, Manchester Greater Manchester, United Kingdom

Introduction: Depression is common in patients with chronic obstructive pulmonary disease (COPD). COPD patients consult their general practitioners at least once or twice a year because of acute exacerbations. There is little data available on the management of depression in patients with COPD.

Aims: The study investigated general practitioners’ (GP’s) views about recognising and treating depression in patients with COPD.

Methods: We conducted a postal survey of 3,957 GPs in England about their views on recognising and treating depression in patients with COPD. The survey examined the GPs views using a likert scale (0 = strongly disagree, 2 = neither agree or disagree, 4 = strongly agree). The questions were prioritising treatment, value of screening for depression, difficulty of treating depression, best way of treating depression, depression exacerbates and interferes self-management of COPD.

Results: 3,957 general practitioners were mailed. Of these, 857 (22%) complete responses were received. Seventy-two percent of GPs agree screening for depression regularly, 9% disagree and neutral 19%. Prioritising treatment of COPD symptoms over depression21%, neutral 46% and 33% agree. Convincing COPD patients that depression needs treatment: disagree 27%, neutral 30% and agree 43%. Depression exacerbates COPD symptoms: disagree 9%, neutral 24% and agree 67%. Depression impairs self-management of COPD: disagree 4% and agree 96%.

Conclusions: Most GPs reported the importance of screening for depression regularly and depression impedes self-management of COPD. Over two-fifths of the GPs find it difficult to convince patients to offer treatment. Further studies are required.

Use of GOLD staging as a guide for treating COPD patients in primary care
David de la Rosa1, Antonia Ocana2, Pilar Martinez3, Raúl Bonich4, Dolores Alvarez4, Eva Calvo5, Emma Albia5, 1Pneumology, Hospital Plató, Barcelona, Spain; 2Family Medicine, EAP Vic-1 Nord, Vic, Barcelona, Spain; 3Family Medicine, EAP El Masnou, El Masnou, Barcelona, Spain; 4Family Medicine, EAP El Masnou, El Masnou, Barcelona, Spain; 5Family Medicine, EAP Barcelona-Sants, Barcelona, Spain

Introduction: The best strategies to reduce the costs derived from COPD are early diagnosis and adequate managing in initial phases. Our aim was to evaluate the adequacy of COPD treatment according to GOLD guidelines, in Primary Care (PC) patients.

Design & methods: Descriptive, transverse, multicentre study in 5 PC centers. Computerized clinical histories of patients with COPD diagnosis code were revised. We recorded spirometric data and current treatment of each patient. We evaluated spirometric confirmation of COPD, GOLD stage and adequacy of treatment according to GOLD.

Results: We analyzed 1220 patients (71.5% men), mean age 69.8 ± 13 years. 37.5% were never smokers. Rates of spirometry performance and spirometric confirmation of COPD were low (46.3% and 46% respectively). Adequacy of treatment to GOLD stage was 61.4%, and increased with severity of the disease (p<0.05). In GOLD 2, only 15.5% were using exclusively bronchodilators (BD). 40.4% were receiving inhaled steroids (IS) alone or in association to BD. 31.8% were taking “other” treatments (mucolytics, montelukast, oral steroids). In GOLD 3, 9.9% of patients were taking exclusively BD. 18.3% realized treatment with 2 BD associated to IS and 46.5% were using other treatments.

Conclusions: In many of the patients coded as COPD in PC, a spirometry lacks. The great proportion of never smokers raises doubts about correct codification. Prescription of IS and not inhaled treatments is too high in GOLD 2.
479. Cystic fibrosis: detection and monitoring of early lung disease

4655 Late-breaking abstract: VX-770, an investigational CFTR potentiator, in subjects with CF and the G551D mutation

Barry J. Plant1, Bonnie Ramsey2, Karl Yen3, Qunning Dong3, Sally Rodriguez2,3, Stuart Elborn4, Adult Cystic Fibrosis Centre, Cork University Hospitals, Cork, Ireland; 2Center for Clinical and Translational Research, Seattle Children’s Hospital, Seattle, WA, United States; 3Vertex, Vertex Pharmaceuticals Incorporated, Cambridge, MA, United States; 4Adult CF Centre, Belfast City Hospital, Belfast, United Kingdom

Background: Restoring dysfunctional CFTR mediated ion transport is a potential treatment for CF. VX-770, a CFTR potentiator, is designed to increase CFTR ion transport activity.

Aims and objectives: This Phase 3 study evaluated the efficacy and safety of VX-770 in subjects with CF who have the G551D mutation on at least one CFTR allele.

Methods: A randomized, double-blind, placebo-controlled trial of subjects ≥12 years of age who received oral VX-770 150 mg q12h (n=83) or placebo (n=78) for up to 48 weeks.

Results: The mean absolute change from baseline through Week 24 in % predicted FEV1 (primary endpoint), improved by 10.4% in the VX-770 group, while the placebo group decreased by 0.2% (P<0.0001). This reflected a mean increase of 361 mL (P<0.0001) and a mean relative change from baseline of 16.9% of predicted FEV1 (P=0.001) in the VX-770 group compared to placebo. Improvement in FEV1 with VX-770 was evident at Day 15 and maintained through Week 48, at which time the VX-770 group showed an improvement of 10.1% (366 mL change) while the placebo group had a decrease of 0.4% (7 mL change). A 55% reduction in the risk of pulmonary exacerbations (P=0.0012) was observed through 48 weeks with VX-770 treatment. The reduction from baseline in sweat chloride, a biomarker of CFTR activity, was −48.1 mmol/L through Week 48 in the VX-770 group compared to placebo (P<0.0001). The safety profile of VX-770 was comparable to placebo.

Conclusions: VX-770 demonstrated a clinically relevant and statistically significant improvement in pulmonary function and reduction in pulmonary exacerbations and sweat chloride up to 48 weeks of treatment. The safety profile was similar to placebo.

4656 Improvement in lung function during the 1st year of life in infants diagnosed with CF through newborn screening (NBS)

Lena Thia1,2, Ah-Fong Hoo1,2,5, Thanh-Diem Nguyen1, Deeba Ahmed1, Barry J. Plant1, Bonnie Ramsey2, Karl Yen3, Qunning Dong3, Stephen Stick4, on behalf of AREST CF.

Methods: Multiple breath washout and raised volume techniques were performed in CF infants from 6 tertiary CF centres in London, UK and prospectively recruited HC.

Results: 35 CF and 18 HC infants have completed paired measurements at 3 months (T1) and 1 year (T2). Significant improvements in the CF group were seen in anthropometry, LCI, FEV0.5 and FEF25–75 z-scores by T2, with no significant differences from HC at this stage, except for a slightly elevated LCI.

Hypothesis: These reductions in LF persist to 1 year of age.

Objective: To compare the presence and extent of CF structural lung disease detected on volumetric inspiratory and expiratory scans in young children.

Methods: 38 children with CF age 1-5 years underwent inspiratory and expiratory volumetric chest CT. De-identified scans were assessed in random order by 2 observers using the Brody II score. Intraclass correlation coefficients (ICC) and Bland-Altman plots using mean scores determined agreement between expiratory and inspiratory scans.

Results: There was substantial agreement between mean Brody II component scores from inspiratory and expiratory scans (ICC range 0.637 to 0.866). For Bx, the ICC was 0.864, however, there was a systematic bias evident on Bland-Altman plot as shown, with consistently higher scores on inspiration. Further, analysis of binary outcomes (presence/absence of Bx) indicated that Bx was not demonstrated.

References:
on the expiratory scan in 40% of subjects when demonstrated on the inspiratory scan.

Conclusions: In early CF Bx, the presence and extent of Bx is underestimated with expiratory scans alone compared with inspiratory scans.

4659
Magnetic resonance imaging (MRI) as a non-invasive, radiation-free imaging modality to study the onset and progression of lung disease in infants and young children with cystic fibrosis
Monika Eichinger1, Eva Fritzsche2, Annette Kopp-Schneider2, Migle Simcinauskaitė1, Daiva-Elzīta Optaze1, Marcus Maß2, Michael Puderbach1,2,4. 1Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany; 2Pediatric Pulmonology and Cystic Fibrosis Center, University Hospital Heidelberg, Germany; 3Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, Germany; 4Diagnostic and Interventional Radiology, Thoraxklinik, Heidelberg, Germany; 5Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, Germany

Little is known about the onset and spontaneous progression and routine lung function testing is not available for monitoring of early CF lung disease. The aim of the present study was to validate pulmonary MRI to study the onset and progression of lung disease in infants and young children with CF. In 34 CF patients (age: 2.5±0.4; 17f, 17m) MRI (1.5T) was performed in free breathing. For morphological imaging a T2w-(HASTE PACE) and a T1w T1-TSE sequences pre and post contrast media in coronal and transversal orientation were used. Functional imaging was performed using a 3D-FLASH sequence with a temporal resolution of 1.5s after iv injection of Gadolinium-DTPA. Two independent radiologists analyzed the images with a dedicated MRI score (range 0-72). Morphological and functional abnormalities in the CF lung were detected by MRI in the first year of life (CF score 6.3±1.1; n=6) and the score increased significantly to 16.2±1.7 (p < 0.05; n=5) at the age of 4 years. Perfusion defects were reversible in follow up scans in a substantial number of patients. Further, MRI scores were reduced after antibiotic therapy for pulmonary exacerbations (pre treatment: 20.2±7.7 vs post treatment: 13.0±4.9; p<0.05).

Our study indicates that MRI of the lung is sensitive to detect abnormal morphology, function and response to therapy in early CF lung disease. These results suggest that MRI may be suitable for non-invasive diagnostic monitoring of disease severity and may serve as a novel endpoint for clinical trials in early CF lung disease. Supported by Mukoviszidose e.V.

What is the significance of aspergillus fumigatus in BAL in children with cystic fibrosis
Rebecca Thursfield1, Andrew Bush1, Alex Adams1, Andrew G. Nicholson2, Katy Holden1. 1Department of Paediatric Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom; 2Department of Histopathology, Royal Brompton Hospital, London, United Kingdom

Background: Aspergillus fumigatus (AF) is frequently found in the airways of children with cystic fibrosis (CF) and recent evidence suggests this may be clinically important. (Chest 2006;130:222, Ped Pulm 2007;42:785)

Aims: In this retrospective study, we hypothesised that children with CF who have AF seen on direct staining of bronchoalveolar lavage (BAL) will have a worse clinical state than both those who only culture AF (positive controls) and those with no isolation (negative controls). Primary outcome was FEV1; secondary outcomes included BMI, IgE, IV antibiotics, steroids and antifungals.

Results: In the year prior to bronchoscopy (FBO), the groups were similar in terms of weight centile, IV antibiotics received and FEV1. One year post FOB, the groups with AF in their BAL, on cytology or microscopy, had a lower FEV1 despite receiving more IV antibiotics and more antifungal therapy.

Conclusions: The results add to the growing evidence that AF in the airways of children with CF is associated with a worse clinical state, whether identified on direct smear or culture.

4661
Newborn screening for cystic fibrosis improves lung function and growth at time of transfer to adult care
Nicole Dijk, Karen McKay, Federica Barzi, Dominic Fitzgerald. Respiratory Medicine, The Children’s Hospital at Westmead, Sydney, New South Wales, Australia

Introduction: Newborn screening (NBS) for Cystic Fibrosis (CF) is associated with improved early nutritional outcomes and improved spirometry in children. Aim: To determine whether the early diagnosis and treatment of CF with NBS in NSW in 1981 led to better clinical status and survival at transfer to adult care.

Methods: Retrospective observational study comprising 2 cohorts: diagnosed symptomatically in the 3 years before newborn screening was introduced (“non-screened”) and diagnosed in the first 3 years of NBS (“screened”). Patients were followed up until transfer to adult care, before age 19 years. ANOVA was used for clinical outcomes & survival was compared using a Cox proportional hazard model.

Results: Compared with non-screened patients (n=55), screened patients (n=56) were less likely to have pseud. aeruginosa in sputum at diagnosis (p=0.001), older when they acquired pseudomonas (p=0.001) & had better lung function when transferred to adult care: higher FEV1%, (mean difference = 17.2%; P = 0.012), FVC% (16.7%; P = 0.021) and a non-significantly higher BMI (0.95 Kgm²; P = 0.143). There was a non-significant 41% mortality risk reduction in screened patients as compared to non-screened patients (Hazard Ratio (95% CI): 0.59 (0.24-1.43); p =0.25). Each 1% increase in FEV1% was associated with a 3% decrease in risk of death (p=0.002) and each 1 unit BMI increase was associated with an 46% decrease in risk of death (p<0.001).

Conclusion: NBS for CF leads to better lung function and nutritional state at time of transfer to adult care in screened patients. Both outcome measurements are good predictors for long term survival.

482. How to improve lung cancer care

4670
Time to diagnostic procedures and treatment in outpatients diagnosed of lung cancer (LC) included in our rapid diagnosis protocol (RDP)
M. Isabel Andrade, Tamara Gutierrez, Amaia Irizoy, Jose Antonio Cascante, Pilar Cebollero, V. Manuel Eguia, J. Javier Huerto. Pneumology B Department, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain

Aim: To determine the time to diagnose procedures and treatment in outpatients diagnosed of LC in Navarra (Spain) included in a RDP.

Method: Retrospective analysis of outpatients diagnosed of LC in our RDP from January 2006 to October 2010. The reference date was the day they were sent to our service. We analyzed time to CT, to bronchoscopy, to endobronchial ultrasound transbronchial needle aspiration (KT-EBUS), to transparietal fine needle aspiration (TFNA) and to Positron emission Tomography (PET), time to treatment and the hospitalization average.

Results: 70 patients were diagnosed of LC in our RDP; 80% were men, the mean age was 63.9; 68.5% were remitted from primary care (PC). The mean time to
the last diagnostic procedure was 22.5 days from PC and 16.4 from first visit in our RDP (RDPfs). The table reflects time from PC* or other remission service or RDPfs to each procedure.

</table>

We use PET since 2006 and EBUS since October 2008. 75% of patients didn’t need hospitalization. The mean days, when needed, was 3.1 (I–3). Patients required surgical treatment in 22.8%, oncologic in 68.5% and Palliative Care as first choice in 8.7%. The time from PC* to treatment was 37.4 days (5-103) and from RDPfs to treatment was 31.4days (0-90).

Conclusions: With our RDP we have achieved a lower time delay to diagnosis and treatment (no difference between kind of treatment) of LC comparing with most of the existing recommendations.

We haven’t need hospitalization in most cases and the mean of days was low.

4671 Self reporting of symptoms and delays in patients presenting to a rapid access lung cancer clinic (RALLC)
Mateen Uzbeck, Colm Geraghy, Eleanor Dunican, Seamus Linnane, Ross Morgan. Respiratory Medicine, Beaumont Hospital, Dublin, Ireland

Introduction: The RALLC at our hospital is aimed at expediting the diagnosis of suspected thoracic malignancies.

Methods: A self-reported questionnaire to consecutive patients on their first visit. Patient’s perception of why they were attending, symptoms, duration before seeking medical attention, time to referral and risks for lung cancer recorded.

Results: 154 patients, 81 male, 73 female, mean age 63 years (21-86). GP’s made most referrals 87% and 68% perceived abnormal radiology as reason for attendance. Majority were symptomatic 86.6% with 57% reporting ≥3 symptoms. Cough was most common presenting symptom 61%, fatigue 52%, dyspnoea 45%, chest infection 45%, chest pain 40%, weight loss 32% and haemoptysis 25%. Haemoptysis had the least delay in presenting to a health care provider (mean 30 days, range 2-120) whereas for cough, dyspnoea and chest pain mean delay was 4.5 months. Average delay in seeking medical attention and referral to RALLC was 14 weeks. 72% were current or ex-smokers and 21% reported at least one first 3 symptoms.

Conclusions: Significant delays exist between symptom onset and presentation to a health care provider and depends on symptom type. The bulk of the delay was before patients sought medical attention but there was still a sizeable delay between presentation and referral to RALLC. One in 5 patients had a first degree relative with lung cancer indicating that this may have been a factor in the decision to refer. Our study highlights the need for increased public awareness regarding the presenting symptoms of lung cancer and there exists the opportunity to reduce delays in diagnosis resulting in better outcomes.

4672 Managing patient pathways to achieve lung cancer waiting time targets:
Hugh Ig 1, Tarik Amer, Michael Dangorf, Alan Zamir, Darryl Gibbings-Isaac, Ranjeet Kochhar, Timothy Heymann 1. General Medicine, Guy’s and St Thomas’ Trust, London, United Kingdom; 2Health Management, Imperial College Business School, London, United Kingdom

Background: England’s NHS introduced a 62-day target, from referral to treatment, to make lung cancer patient pathways more efficient. This study aims to understand pathway delays that lead to breaches of the target when patients need care in both secondary and tertiary setting so more than one institution is involved.

Methods: Mixed method cross case analysis. Qualitative methods include pathway mapping and semi-structured interviews. Quantitative analysis of patient pathway times from cancer services records.

Setting: Two tertiary referral hospitals in London

Participants: Database records of 53 patients were analysed. 19 sets of patient notes were used for pathway mapping. 17 doctors, 4 nurses, 8 managers and administrators were interviewed.

Results: The majority of the patient pathway (68.4%) is spent in secondary centres. There is more variability in the processes of secondary centres but tertiary centres do not have perfect processes either. Three themes emerged from discussions: information flows, pathway performance and the role of the multidisciplinary approach.

Conclusions: The actions of secondary centres have a greater influence on whether a patient breaches the 62-day target, compared to tertiary centres. Nevertheless variability exists in both, with potential for improvement.

4673 Lung cancer multi-disciplinary team (MDT) decisions audit
Brendan Mallaia-Milanes, Jenny Graves, Jeffrey Mercham-Jones, Sulyn Leong, Ian Mortmone, Steve O’Higgins. Respiratory Medicine, Hereford County Hospital, Hereford, United Kingdom; 3Thoracic Medicine Department, Gloucester Royal Hospital, Gloucester, United Kingdom; 4Respiratory Medicine, Cheltenham General Hospital, Cheltenham, United Kingdom; 5Respiratory Medicine, Worcester Royal Hospital, Worcester, United Kingdom

Background: Lung cancer resection and survival rates in the UK vary; the reasons for this are unclear.

Aims: To compare lung cancer MDT decision outcomes in 4 hospitals in one cancer network.

Methods: Each lung cancer MDT randomly selected 5 of their MDT cases and submitted them to the other MDTs for assessment. MDT decision outcomes for each case, including each MDT’s own previously discussed MDT cases were collated. Mean percentage agreement of MDT outcomes was calculated for TNM staging and referrals for PET scan, curative surgery, radical radiotherapy and palliative chemotherapy.

Results: 3 hospital MDTs discussed 15 cases as well as having previously discussed their own 5 cases. 1 hospital submitted their 5 previously discussed cases but failed to discuss the other cases submitted to them. There were 17 non-small cell lung cancer cases, 2 indeterminate cases and 1 small cell lung cancer case. The number of cases referred for curative surgery varied between 6 to 7 cases per MDT. Percentage agreement was 83% for T staging, 91% for N staging, 98% for M Staging, 87% for referral for PET scan, 98% for curative surgery referral, 95% for radical radiotherapy referral and 93% for palliative chemotherapy referral.

Discussion: There was good agreement for staging and very high agreement for treatment referral. In this pilot study the high agreement for potentially curative treatment does not support the view that some MDTs are not referring patients for potentially curative treatment. As numbers are small we propose this issue be addressed by a national web-based quality assurance programme where each MDT assesses and reports sample cases each month and is given formative feedback.

4674 Histological typing of lung cancer in biotopically obtained specimens under the aspect of therapeutical approaches – A multi-center study
Annette Fisseler-Eckhoff 1, Raca Zinszy 1, Pieran Laenger 1, Phillip Schnabel 1, Iver Petersen 2, Klaus Junker 5. 1Dr. Horst-Schmidt Kliniken, Institute of Pathology and Cytology, Wiesbaden, Germany; 2Medizinische Hochschule Hannover, Institute of Pathology, Hannover, Germany; 3Universitaetsklinikum Heidelberg, Institute of Pathology, Heidelberg, Germany; 4Universitaetsklinikum Essen, Institute of Pathology, Jena, Germany; 5Klinikum Bremen Mitte, Institute of Pathology, Bremen, Germany

The insufficiency of classifying lung cancer as SCLC or NSCLC clinical arose with the approval of the antifolate pemetrexed, which has a lower antitumourous effect in Squamous Cell Carcinoma. Often only biopsy specimens are available to exclude a squamous differentiation before chemotherapy decision.

The restrictive nature of subtyping lung cancer in biopsies demanded a skilled and experienced pathologist. This interlabatory comparison should discover the accuracy of subtyping of lung cancer biopsies evaluated in 5 different pathological institutes in Germany. Is it possible to improve the accuracy histological typing by additional immunohistochemistry (IHC) panel?

60 biopsy specimens with Hematoxylin-eosin (HE) stain and immunohistochemical stained slides of at least Ck7, Ck5/6, p63, TTF1 were assembled and analysed by the pathologists. An estimation of predominantly-non-squamous yes/no and the histological subtype was done after examination the HE slide and again after the examination of the IHC. These two results were compared.

All 60 cases were analysed by all 5 participants. In average the agreement of
483. The impact of the organisation of care on costs: the role of the physician in home care

487 An evaluation of the safety, efficacy and cost-effectiveness for patients with acute respiratory illness, of a community-based intravenous medication service: The first 26 months
R.A. Khan1, J.P. Cullen2, S. Zaidi3, 1Short Term Acute Care Unit (SACU), Adelaide and Meath Hospital, Tallaght, Dublin, Ireland

Background: Patients with acute respiratory illnesses such as acute exacerbation of chronic obstructive pulmonary disease (AECOPD) and pneumonia occupy significant proportion of acute hospital beds. There is therefore an increasing focus on intermediate care initiatives to facilitate early supported discharge (ESD) and admission avoidance (AA) in such patients. Since 10.11.08, our hospital in partnership with Community Intervention Team (C.I.T) provided service for administration of intravenous (IV) medications, facilitating ESD/AA.

Aim: To evaluate the AMNCH/C.I.T. IV service, in terms of safety, readmission rates, adverse events, bed-days saved, patient satisfaction and cost-effectiveness.

Results: Up to 31.11.1, of 285 patients referred to this service, 32% had a primary diagnosis of acute respiratory illness. 44 patients were male, 48 female. Mean age was 58.5 years (range 18-95). ESD and AA was facilitated in 67% and 33% respectively. Respiratory diagnoses were: pneumonia (n = 63), AECOPD (n = 7), exacerbation of asthma (n = 4), exacerbation of bronchiectasis (n = 5) and non-pneumonic respiratory infection (n = 13). IV treatment saved a minimum of 486 bed-days. Average length-of-stay in the service was 5.3 days. Readmission rate was 3.2%. No adverse incidents were reported. Patient satisfaction was 100%. We estimate that home treatment of these patients saved €457,300 for AMNCH compared to equivalent treatment in hospital.

Conclusion: We conclude that the service continues to be a safe, effective, inexpen-

4877 Potential economic savings of administration of home intravenous antibiotic therapy to patients with acute respiratory infections in Ireland
Melissa McDonnell1, 2Maurice Power2, Robert Rutherford1, J.J. Gilmartin1, J.J. Gilmartin. 1Respiratory Medicine, University Hospitals Galway, Galway, Ireland; 2Department of Finance, University Hospital Galway, Galway, Ireland

Introduction: Acute respiratory infections (ARI) account for a significant propor-
tion of prolonged hospital stays. Intermediate care initiatives supporting home intravenous antibiotics (HIV A) aim to facilitate early discharge and avoid unnec-

sary admissions. Numerous studies have demonstrated the efficacy of HIV A for acute infections. International studies have shown increased patient satisfaction, improved quality of life, fewer investigations, less cross-infections, decreased social disruptions and increased cost-effectiveness.

Objective: The purpose of this study was to analyse the potential cost-effectiveness of HIV A in patients with ARI in Ireland.

Methods: Using the Health Service Executive (HSE) Casemix and assuming a 60% uptake of ARI patients satisfying HIVA criteria with a length of stay (LOS) of 1-3 days, cost-estimates relating to cost/bed and LOS were used to calculate cost/day savings if HIV A is introduced.

Results: The approx. annual admission rate for ARI conditions such as pneumonia, COPD, asthma, CF and bronchiectasis is 26,700 patients/yr with an average cost per admission of €70,600. Based on an average LOS of 9.2 days at a cost/bed day of €1,920, the cost/ARI admission is €17,664. This equals to €473m. An LOS of 1-3 days would result in cost-estimates of €51.4-154.2m, a gross difference of €318.8m. Accounting for expenses such as capacity, staff, training, equipment, travel and others, we estimate bed-day savings of €200-220m/yr.

Conclusion: HIVA administration is a safe, cost-effective alternative in suitable patients with ARI, potentially providing significant savings to the health service in Ireland.

4879 A prospective re-audit of admissions and discharge delays occurring in patients admitted to a district general hospital’s respiratory ward in the United Kingdom
Christopher Chadwick, Diane Murray, Rahul Sarkar, Ana de Ramon Casado.
Respiratory Ward, Warrington and Halton NHS Foundation Trust, Warrington, Cheshire, United Kingdom

Introduction: The National Confidential Enquiry into Patient Outcome and Death recommends that following initial assessment and treatment, patients should be transferred to a ward which is appropriate for their clinical condition.

Objective: To assess delays prior to discharge for patients (respiratory vs non-

respiratory) whom are medically fit for discharge, following a reduction in respir-

atory beds from 62 to 46 as recommended by Sarkar et al 2010.

Methods: A prospective 2-week audit was conducted on respiratory wards and in-

The attitude of physicians for asthma treatment and results in the inhaler market between 2004-2009 in Turkey
Sedat Altim1, H. Volkan Kara2. 1Department of Chest Diseases, Yeditepe Education Hospital for Chest Diseases and Thoracic Surgery, Istanbul, Turkey; 2Department of Thoracic Surgery, Gumushane State Hospital, Gumushane, Turkey
We evaluated the effects Turkey Conversion Programme in Health in 2004 on drug market and physicians attitude for asthma treatment. We analyzed the data from IMS the programme following the drug market and the data from the Social Security Institution (SSI) for comparative studies. In 2004 SSI paid nearly 4.0 billion Euro for drugs which increased to 8.5 billion (190%) in 2009. Inhaled corticosteroids were the most used drugs (52.7%). The cost of inhaler asthma drugs was 88.9 million and increased to 280.6 million (3.16 fold). Drug prescribed was 6.037.122 and increased to 20.848.085 boxes (3.45 fold).In the market of subgroup for inhaler dust asthma drugs distribution was: the rescue drugs 31.5%, combined drugs 17.7%, nebulisers 10.5%. The rates in 2009 were 20.2%, 29.6% and 18% respectively. Economically distribution was: 48.4% for combined drugs, 6.3% for nebuliser and 6.3% for rescue drugs. Rates for 2009 were 58.4%, 9.2% and 4.1%. The number of rescue drugs increased from 1.901.938 boxes to 4.220.664 (2.22 fold). The financial increase was 4.62 fold from 5.570.177 to 25.739.326. The number for nebuliser was 631.184 and increased to 3.762.806 (5.96 fold) the cost for them was 5.570.177 increased to 25.739.326 (4.62 fold).The combined drug subgroup the number of prescriptions increased to 1.066.486 increased to 6.178.315 (5.79 fold).The cost was 43.006.559 and increased to 163.814.343. There has been an increase in the costs for inhaler drugs used for asthma treatment. Our analyses showed that this increase mostly caused by increase in the number of prescribed combined drugs. This increase we believe decreased the need for rescue drugs but had no effect on the nebulisers that has been used increased.

4681
Stepping up the controller medication in asthma patients: Impact of various treatment options on costs
Mohsen Sadatsafavi1, Pierrick Bedouch1, Mark FitzGerald1, Carlo Narra1, Larry Lund2, 1Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 2Department of Medicine, University of British Columbia, Vancouver, BC, Canada
Introduction: To compare asthma-related costs among adults who step-up their controller medication.
Methods: A population-based study was conducted using the administrative health data from the Ministry of Health, Canada (1997 to 2007). Hospitalization, physician visits, and prescription records were used to identify asthma patients (age 14-65) and calculate direct costs. Four cohorts were constructed as those who: increased the dose of inhaled corticosteroids (ICS group), switched to ICS/long-acting beta-agonist (LABA) in a single formulation (ICS/LABA group), added LABA in separate formulations (ICS+LABA group), or added leukotriene receptor antagonist (ICSLRA group). The outcome was the direct cost of asthma (2008 CAD) in the year after the step-up, adjusted for multiple demographic, resource use, and comorbidity variables from the previous year.
Results: 52,640 patients (average age 42.3, 60.3% female) were included (7,115 ICS+, 9,457 ICS/LABA, 4,086 ICS+LABA, and 1,982 ICS/LRA). The average cost of asthma for the year after the index date for the ICS+ group was $350. Compared to ICS+, all other groups had significantly positive incremental costs: $358.0 for ICS/LABA, $350.4 for ICS+LABA, and $554.6 for ICS/LRA (all P-values<0.01). Higher age, higher resource use, and higher cumulative dose of rescue medication in the year prior to the step-up date were predictors of higher costs after the step-up date (all P<0.01).
Conclusions: Based on relatively large sample and adjusted for several potential confounders, increasing ICS dose as a step-up approach was associated with the lower costs compared to addition of a second class of controller medication.

4682
The cost and diagnostic efficacy of microbiological evaluation of exudative pleural effusion
Serpi Tegül, Semra Bilacergolu, Hatrice Kuman, Ali Kadri Cirak, Sveket Ozkaya. Department of Pulmonary Diseases, Dr. Suat Seren Education and Research Hospital for Chest Diseases and Thoracic Surgery Hospital, Izmit, Turkey
Purpose: To evaluate the cost and diagnostic efficacy of microbiological studies of pleural fluids.
Method: Hospitalized patients with exudative pleural effusion were prospectively evaluated. The fluid samples were examined for Gram stain, acid-fast bacilli smear together with specific bacterial, fungal and mycobacterial cultures.
Results: Bacteriologic and EZN stains of the pleural fluids were negative in 89 cases included whereas fluid cultures were positive in 9 (10.1%) cases [3 (12.5%) of the 24 with tuberculous pleurisy and 6 (28.5%) of the 21 with empyema or other parapneumonic pleural effusion]. The cultures of the malignant, nonspecific and paracarcinomatous fluids were negative. In cases with empyema or other parapneumonic pleural effusion and tuberculous pleurisy, no significant difference was determined between culture-positive and culture-negative cases regarding age, gender, fever or fluid LDH and glucose levels; positive cultures were more frequent in the presence of fluid purulence (55.6% versus 8.3%, p=0.046). In 5 (83.3%) of the 6 culture-positive and in 6 (40%) of the 15 culture-negative cases with empyema or other parapneumonic effusion, change in antibiotic treatment was necessary. The costs of the microbiological studies was $39.4 Euro for each case and 1735 Euro and 1419 Euro for cases with noninfectious and infectious fluids, respectively.
Conclusion: Diagnostic yield of the routine microbiological studies of pleural fluids was determined low. It was concluded that requesting microbiological studies of pleural fluids in cases strongly considered to have infection on clinical basis or in cases with purulent fluid would be more beneficial regarding diagnostic yield and cost.

4683
Bitter taste receptor agonists as a novel class of bronchodilators in guinea-pig airways
Ville Pulkkinen, Jesper Säfholm, Martijn Manson, Mikael Adner, Sven-Erik Dahlén. Department of Experimental Asthma and Allergy Research, The Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
Rationale: Despande et al. (Nat Med 2010) reported that several bitter taste receptor agonists (TAS2K) agonists evoked relaxation of mice and human airways. We examined the effects of three prototype agonists in segments of guinea pig trachea (GPT).
Methods: GPT was pre-contracted with 0.1 μM carbachol in both absence and presence of 3 μM indomethacin or prostaglandin antagonists. The segments were either exposed to denatonium, chloroquine or saccharin, or kept untreated. Expression of TAS2Rs in guinea pig tracheal epithelium and smooth muscle was measured with real-time PCR.
Results: Denatonium and chloroquine induced concentration-dependent relaxations whereas saccharin had no effect. In consistency with these findings, there was expression of TAS2R4 and TAS2R10 in GPT. There has been an increase in the costs from 2004 to 2009 in Turkey.

4684
Prostacyclin modifies VEGF synthesis in fibroblasts from healthy and COPD patients
Anna-Karin Larsson1, Oskar Hallgren 1,2, Mark FitzGerald1, Carlo Narra1, Larry Lund2. 1Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada
Background: Involvement of vascular remodelling in the lung is a characteristic sign in chronic obstructive lung disease (COPD). The vascular mediator prostacyclin may regulate fibroblast activity. The objective was to study the effect of prostacyclin on synthesis of vascular endothelial growth factor (VEGF) and interaction with transforming growth factor (TGF) B in distal lung fibroblasts from patients with COPD and control subjects.
Methods: Prostacyclin modifies VEGF synthesis in fibroblasts from healthy and COPD patients

484. Translational models of airway disease

484.1
Translational models of airway disease

484.2
Translational models of airway disease

852s
Results: Iloprost enhanced VEGF synthesis in both fibroblasts from control subjects (p<0.05) and 6-1-fold from patients with COPD (p<0.01). However, iloprost showed no effect on VEGF synthesis after TGF-B1 stimulation, whereas indomethacin reduced VEGF production in fibroblasts from patients with COPD (p<0.05) but not in control subjects. 

Conclusions: Iloprost enhanced VEGF synthesis in fibroblasts from both healthy and patients with COPD. Though, iloprost had no effect on VEGF after TGF-B1 stimulation. These data indicate that also other proangiogenic mediators are involved in the regulation of VEGF in fibroblasts from COPD patients.

4685
Capsazepine inhibits NF-κB subunits in dsRNA-exposed human bronchial epithelial cells from asthmatic and COPD donors
Imre Némethivitvök Persson1, Angelica Brandelitana2, Leif Bjørmer2, Jenny Calvén1, Yuliana Yudina1, Lena Uller1
1Respiratory Immunopharmacology, Experimental Medical Sciences, Lund, Sweden; 2Department of Clinical Sciences, Institution of Clinical Sciences, Lund, Sweden

Background: Novel drugs are needed to treat vial-induced exacerbations of asthma and COPD. We have shown that capsazepine (CPZ) inhibits vial-induced cytokine production (including thymic stromal lymphopoietin, TSLP) in human bronchial epithelial cells (HBEC) more effectively than steroids. 

Objective: Investigate NF-κB mechanisms potentially involved in actions of CPZ in HBECs from patients with asthma and COPD. 

Methods: Primary HBEC were obtained by fibre optic bronchoscopy from individuals with asthma (n=6) and COPD (n=3), then grown in 12-well plates and stimulated with viral surrogate dsRNA (10 μg/ml) to induce pro-inflammatory cytokine (TSLP, TNF-α, IL-8, IFN-β) mRNA expression (RT-qPCR) and production (ELISA). CPZ (3-30 μM) was added 1 h prior to dsRNA. NF-κB-signaling was studied (western blot) using specific antibodies for NF-κB subunits p65, p105 and IκBα. In vivo synthesis of IκBα and NF-κB was studied by RT-qPCR.

Results: dsRNA induced marked expression and release of TSLP, TNF-α, IL-8, and IFN-β (p<0.001). These effects were dose-dependently reduced (p<0.05-0.001) by CPZ. Both NF-κB and IκBα were inhibited by CPZ. Inhibition of NF-κB prevented degradation of IκBα and NF-κB signaling.

Conclusion: CPZ effectively reduced dsRNA-induced cytokine overproduction in HBECs from asthmatic and COPD donors. CPZ inhibited dsRNA-induced IκBα degradation preventing dissociation and translocation of p65 to the nuclear fraction. CPZ may stabilize IκBα thus inhibiting NF-κB-dependent cytokine production.

4686
Bradykinin-induced contractions in guinea pig trachea after incubation and culture
Martijn Manson, Jesper Saffholm, Sven-Erik Dahlén, Mikael Adnet. Department of Experimental Asthma and Allergy Research, Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden

Background: Inflammatory conditions can alter responsiveness to the endogenous peptide bradykinin (BK). Methods: The contractile response to BK was determined in organ tissue baths. 

Methods: Study the regulation of BK responses by culture procedures. Our data suggest that TIP peptides with charge distribution enhancing amiloride-sensitive current than the latter: the most active peptide had an EC50 of 19.9 nM. Compared to TNF-alpha (EC50 8.2 nM) and the original human TIP peptide (EC50 28 nM) for their ability to enhance sodium transport was observed at 120 nM. Compared to TNF-alpha (EC50 8.2 nM) and the original human TIP peptide (EC50 54.3 nM), several of the newly-designed peptides were more effective at enhancing amiloride-sensitive current than the latter: the most active peptide had an EC50 of 19.9 nM. Our data suggest that TIP peptides with charge distribution and interatomic distances most closely resembling the 3D structure of the native lectin-like domain of TNF-alpha, are those with greater ability to enhance activation of sodium current through ENaC. No standard therapy exists for pulmonary oedema, thus these TIP peptides represent promising therapeutic agents for activating sodium uptake from the alveolar fluid through ENaC and improving clinical outcome in this condition.

4687
Protective effect of a protein epitope mimetic (PEM) CCR10 antagonist, POL7085, in an allergic model of asthma
Francois Duabeauf1, Françoise Jung1, Eric Chevalier2, Nelly Frossard1
1UMR7200, Therapeutic Innovation Lab, Illkirch, France; 2Phophot, Polyphot, Alzachse, Switzerland

Potential involvement of the CCR10/CCL28 axis was recently reported in a murine model of allergic asthma [1]. Blockade of the CCR10 receptor might therefore represent a novel alternative to the current treatment of asthma. We have evaluated the effect of the PEM CCR10 antagonist, POL7085, in an allergic model of asthma in mice. Nine week-old male Balbi/c mice were sensitized to ovalbumin (OVA) administered intraperitoneally in the presence of alum (D0 and D7), and challenged to OVA administered intranasally (D18 to D21). POL7085 was administered once daily 1 hour before each OVA challenge at 9 and 18mg/ml/kg i.nasally (I.N.) or ivexamethasone I.N. (DEX, 2.5nmol/kg) iv vehicle. In vehicle treated animals, OVA induced airway hyperresponsiveness (AHR) as measured by whole body plethysmography, and hypereosinophilia in the bronchoalveolar lavage (BAL) fluid. POL7085 dose-dependently and significantly decreased AHR by 34±16% and eosinophil numbers in BAL by 66±6%. In addition, the higher dose of POL7085 also inhibited IL-5 secretion in BAL (42±13%). IgE and IgG1 synthesis in serum (47±31% and 61±15%, respectively), and lung collagen synthesis (43±11%), although not significantly. POL7085 as compared to DEX also modified body (6.5±1.7% vs 4.5±1.5% for DEX) and spleen weight (24±4% vs 44±3% for DEX).

In conclusion, the PEM CCR10 antagonist, POL7085, significantly and dose-dependently decreased asthma symptoms after once daily local administration in particular AHR and eosinophilia. Blocking the CCR10 chemokine receptor therefore appears as a promising novel approach for treating asthma.

Characterisation of TNF-αlectin-like domain derived peptides associated with improved alveolar fluid clearance in pulmonary oedema
Susan Teoßen1, Bernhard Fischer1, Helmut Pietzsch1, Hendrik Fischer1, Rudolf Lucas2, Wahed Shabbir3, Rosa Lemmens-Gruber1
1Respiratory Science, APEPTICO, Vienna, Austria; 2Vascular Biology Center, Georgia Health Sciences University, Augusta, GA, United States; 3Department of Pharmacology and Toxicology, University of Vienna, Vienna, Austria

The beneficial effect of the lectin-like domain of TNF-alpha, including the TIP peptide which mimics this domain, on activation of oedema resolution, improved alveolar clearance and protection of lung function after transplantation, is well documented from several independent in vitro and in vivo studies using animal models. The effect is mediated by activation of sodium uptake through the amiloride-sensitive epithelial sodium ion channel (ENaC), which plays a major role in alveolar fluid clearance in normal and diseased lungs. Several peptides mimicking the lectin-like domain of TNF-alpha, and those with greater ability to enhance activation of sodium current through ENaC. No standard therapy exists for pulmonary oedema, thus these TIP peptides represent promising therapeutic agents for activating sodium uptake from the alveolar fluid through ENaC and improving clinical outcome in this condition.

4689
Consequences of chronic pulmonary TLR9 activation in the lung and beyond
Gillina Bezemer1, Dmitri Fillipov2
1UMR7200, Therapeutic Innovation Lab, Illkirch, France; 2Leids Universitair Medisch Centrum, Universiteit Leiden, Leiden, Netherlands

Background: Toll like receptor 9 (TLR9) agonist CpG-ODN is being explored as an anti-allergic drug for asthma. However TLR9 could play a role in COPD. Cigarette smoke induced IL-8 production is partly TLR9 mediated.

Aim: To investigate the (extra)-pulmonary effects of CpG-ODN. We hypothesized that pulmonary TLR9 activation induces neutrophil influx which could lead to adverse effects. 

Methods: A single dose of 0.01, 0.05 or 0.25mg/Ml/gBW CpG-ODN was targeted to balbi/c mice lungs by aspiration (acute). Next 0.01mg/Ml/gBW CpG-ODN was administered repeatedly for 5 days (chronic) or 5 weeks (chronic). 24 hours after last exposures, measurements were done: lung function; hypertension and 853s
heart hypertrophy; lung weight; blood and bronchoalveolar lavage (BAL) analysis; morphology of unalvaged lungs.

Results: Total BAL cells were increased in all CpG-ODN mice (p < 0.05). PMNs were increased in blood (30%) and BAL (39%) acute which persistent upon prolonged exposure duration. Blood lymphocytes were subchronically 19% decreased which was reflected in an abundant pulmonary (sub)-chronic lymphocyte influx. Chronic exposure leads to 21% decreased peak expiratory flow (ml/sec) and 71% increased airflow resistance (cm H2O/ml/sec). Right ventricle heart hypertrophy was observed upon chronic exposure; ratio right ventricle weight/total heart weight Cpg-ODN=0.23±0.007; control=0.19±0.008. Wet lung weight was 15.2% increased subchronically and 70.8% chronically.

Conclusion: An interplay between neutrophils and lymphocytes could possibly play a role in TL94 induced adverse pulmonary and cardiovascular effects. Caution is needed when CpG-ODNs are chronically administered for therapeutic purposes.

Efficacy of the TRPV1 antagonist SB-705498 in an MRI guinea pig model of rhinitis

Kumar Changanji, Sarah Hotte, Simon Campbell, Kashmira Pindoria, Paula Sakalavala, Diane Cor, Keith Biggadke, Giovanni Vittalli, Jane Denyer. RespLED, GlassSmithKline, Stevenage, United Kingdom

Rationale: Antagonism of nasal TRPV1 receptors is a potential target for inhibition of symptoms associated with rhinitis. Here, we explore the pharmacology of SB-705498 on the contralateral nasal secretory response to ipsilateral nasal capsaicin challenge in the guinea pig.

Methods: Experiments were conducted on intranasally sensitised guinea pigs. Absolute nasal fluid volumes were measured using MRI techniques that provide images of the total nasal cavity of the guinea pig. Animals were pre-treated with SB-705498 or vehicle (-1, -6 and -24h) and MRI scanned to produce first a baseline measurement and then a further measurement at 10 minutes post capsaicin challenge (0.3mM; 50ul).

Results: 1 hour pre-treatment with SB-705498 resulted in approximately 50% inhibition of the secretory response at 10mg/kg (oral; p<0.05). 1mg/kg (intranasal suspension; p<0.005) and 0.1mg/kg (intranasal particle reduced suspension; p<0.0005). At 12 hour pre-treatment, approximately 60% inhibition (p<0.0001) was observed with SB-705498 at 1mg/kg (intranasal particle reduced suspension); at 24h this had reduced to ~50% inhibition (p=0.01).

Conclusion: These studies demonstrate that SB-705498 inhibits capsaicin-induced intranasal parasympathetic responses in guinea pig. Topical application of SB-705498 was associated with a approximately 10-fold reduction in total dose compared with oral administration. In addition, particle reduction of SB-705498 was associated with a further improvement in intranasal potency.

Late-breaking abstract: Effectiveness of easy smoking cessation clinic in tertiary health care settings: Observational study of cohorts

Ratapam Champornot, Maneewan Waikasikorn, Pranomm Maweha, Aninchata Pongphot, Mataneeya Poohkesorn, Jirawat Suwannakit, Thailand

Introduction: Tobacco treatment programs should be offered in clinical settings for all smokers who need to quit smoking. We have co-operated with every units and departments in hospital and changed our service patterns of smoking cessation clinic into easy way. Cessation assistance was provided on working time every day except holiday. It requires approximately 20-30 minutes to complete and involves asking patients about smoking behavior and acting to help them quit. Telephone helpline was used to follow up and encourage smokers trying to continue quit smoking.

Methods: This is an observational study of cohorts of participants in smoking cessation clinic, Buddhist Charaniprayook hospital during June 1 to November 30, 2009. The main outcome measurements were self report abstinence rate at 6 and 12 months, and cost per quit.

Results: Over a period of 6 months, a cohort of 315 patients were enrolled in this study. The self report abstinence rate at 6 and 12 months was 33.7% (106/315) and 27.9% (88/315). The mean cost per quit was 3,145 baht (70 Euro). Lost follow up study. The self report abstinence rate at 6 and 12 months was 33.7% (106/315) and 27.9% (88/315).

Conclusions: In patients under 50 years with PSP the use of cannabis was much higher than in the general population. However, all cannabis users also smoked tobacco. Only 12% of the cannabis users had a normal HRCT (30%). On HRCT, bullae were present in 87% of cannabis users, in contrast to 57% in only tobacco smokers and none in nonsmokers.

4692

LSC 2011 Abstract: Evaluation of morpho-functional changes in airways of young cigarette smokers

Agnese Kisliu, Guuna Stranda, Liga Balode, Marina Beireme, Normunds Jurka, Immanuel Tsavins. Faculty of Medicine, University of Latvia, Riga, LV EKMI, University of Latvia, Riga, LV

We assumed that even in asymptomatic young smokers, with relatively short smoking duration and normal lung function, induced sputum could be found some changes indicative for early inflammatory process.

Aim: The aim of this study was to evaluate morpho-functional changes in airways of young cigarette smokers.

Method: We enrolled 23±3 years old 12 non-alcoholic smokers (1.59±0.67 pack-years) and 7 healthy non-smoking volunteers. Lung function measurements, sputum induction (IS) and sputum cell analysis were performed.

Results: Demographic data for both study groups did not differ significantly.

Non-smokers and smokers had normal lung function indices. In smokers induced sputum contained statistically significantly (p<0.026) increased relative count of eosinophils 0.923 (0.355-1,753)% compared with non-smokers 0.069 (0.046 - 0.550%). We also found significant reduction of absolute (n=482; p=0.037) and relative (n=682; p=0.004) count of bronchial epithelial cells in induced sputum that correlated to number of smoked pack-years. A trend towards statistical significance showed the correlation between smoking pack-years and the relative number of macrophages in induced sputum (r=0.402; p=0.0872). A trend towards statistical significance was also found in correlation between smoking pack-years and diminished FEV1% of predicted (r = -0.463; p=0.046).

Conclusions: In this study we showed that even smokers with short duration of the smoking habit have already initial signs of inflammation with eosinophil involvement.

4693

Cannabis use in patients with a primary spontaneous pneumothorax

Lizza Hendriks, Gerben Boomsma, Jan van Noord. Pulmonology, Atrium Medical Centre, Heerlen, Netherlands

Introduction: It’s Dutch policy to tolerate cannabis use. In literature active cannabis use is 10% amongst Dutch youth. The association between cannabis use and primary spontaneous pneumothorax (PSP) is unknown.

Aims: To determine the frequency of cannabis use in addition to tobacco smoking in patients with a PSP and to investigate the presence of underlying abnormalities on High Resolution CT (HRCT).

Methods: In a descriptive retrospective study patients were included who presented in a large Dutch teaching hospital with a PSP between August 2008 and August 2010. Because of an increased risk on secondary pneumothorax in older patients, only patients under 50 years were included. Age, gender, BMI, tobacco (T) and cannabis (C) use and (when available) HRCT data were recorded.

Results: In 2 years 53 patients presented with a PSP (42 male, 11 female, mean age 28 years, mean BMI 21). 74% (8% ex) smoked tobacco, 49% (8% ex) used cannabis (cannabis use unknown in 6%). The findings on HRCT are presented in Table 1.

Conclusions: In patients under 50 years with PSP the use of cannabis was much higher than in the general population. However, all cannabis users also smoked tobacco. Only 12% of the cannabis users had a normal HRCT (30%). On HRCT, bullae were present in 87% of cannabis users, in contrast to 57% in only tobacco smokers and none in nonsmokers.

Cigarette smoke induces β2-integrin-dependent neutrophil migration across human umbilical vein endothelium

Saska Overbeek, Saskia Braber, Paul Hendriks, Marije Kleinjan, Vera Kamp, Niki Georgiou, Johan Garssen, Gert Folkerts. Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Faculty of Science, Utrecht University, Utrecht, Netherlands Department of Respiratory Medicine, University Medical Center Utrecht, Utrecht, Netherlands Danone Research, Danone Research Centre for Specialised Nutrition, Wageningen, Netherlands

Background: Cigarette smoking induces peripheral inflammatory responses in all smokers and is the major risk factor for neutrophilic lung diseases such as chronic obstructive pulmonary disease. The aim of this study was to investigate the effect of cigarette smoke on neutrophil chemotaxis and on β2-integrin activation and function in neutrophilic transmigration through endothelium."
Smoking ages your lungs – Results from the COLD cohort

Elif Dagli1, Ela Erdem1, Ahmet Topuzoglu2, Suyapa Birinci3, Ibrahim Topcu3, RefiKArsu1.

1Respiratory Epidemiology and Clinical Research Unit, Montreal Chest Institute, McGill University, Montreal, QC, Canada; 2Respiratory Division, Department of Medicine, Dalhousie University, Halifax, NS, Canada; 3Departments of Medicine and Community Health Sciences, University of Calgary, Calgary, AB, Canada; 4Division of Respiratory Medicine, Vancouver General Hosp., University of British Columbia, Vancouver, BC, Canada

Introduction: Reductions in exposure to tobacco smoke was shown to attenuate the risk of exacerbations of chronic respiratory and cardiac conditions both in adults and children. The aim of this study was to compare the changes in emergency department (ED) admissions for smoking-related diseases before and after the implementation of smoking ban in Istanbul.

Methods: Admissions to ten major hospitals in Istanbul in the first five months of 2009 and 2010 were evaluated and compared, using International Classification of Diseases, (ICD-10) diagnostic codes. Results: In 2009, there were 115030 ED admissions for the associated diagnostic codes, whereas this decreased to 87212 in 2010. There was a 16% decrease in acute nasopharyngitis, 32.9% decrease in pneumonia, 18.8% decrease in acute bronchitis, 59.2% decrease in allergic rhinitis, 61.3% decrease in lower respiratory tract diseases, 21.4% decrease in chronic obstructive lung disease, 20.5% decrease in pneumonia, 32.9% decrease in acute bronchitis, 59.2% decrease in allergic rhinitis, 61.3% decrease in lower respiratory tract diseases, 21.4% decrease in chronic obstructive lung disease, 20.5% decrease in asthma, 33.6% decrease in ischemic heart disease and acute myocardial infarction. All differences were found statistically significant. Cost saving of emergency drugs and services on site were 437,104 euros for 10 hospitals in a 5 month period, which is projected to be 3,147,148 euros for Istanbul annually, without calculating the prevented hospital treatment cost.

Conclusion: ER admission rates for diseases associated with active and passive smoking were reduced by 24.2% as a result of smoking ban in Istanbul. Positive effects of clear indoor air ordinances are observed in a very short period, and therefore respiratory health professionals should be advocates for this policies against all odds.
Pulmonary aspergilloma or mycetoma is a ball-shaped fungal infection, which is mostly encountered in pre-existing pulmonary cavities. Local inflammation, high vascularity and pre-existing lung damage can complicate surgical resection. We aimed to describe our patient population, the employed surgical techniques and the postoperative follow-up.

We performed a retrospective analysis of all patients who underwent surgical resection for an aspergilloma between January 2003 and September 2010. Using the patient charts, we examined the clinical data as well as the type of surgical technique that was used. SPSS 17.0 (SPSS INC, Chicago, IL) was used for data analysis.

Twenty-three patients underwent surgical resection for pulmonary aspergilloma. Seventeen (74%) were men, the mean age was 53 years and 43% of the patients presented with hemothorax. Underlying diseases included hematological malignancies (n=8), (a history of) tuberculosis (n=3) and M. Boeckere (n=2). The most frequently employed surgical techniques consisted of wedge resection (n=8), lobectomy (n=7), pneumonectomy (n=2) and segmentectomy (n=2). The duration of the hospitalization after the first surgical resection varied from 5 to 141 days (median 17, IQR: 9-33.25). The median time required for the first surgical resection was 3.4 hours (IQR: 2.34-5.07). Six patients (26%) underwent a rethoracotomy. Four patients died within 6 months after surgery.

Comorbidities were common, the duration of the surgical resections and hospital admissions was long and rethoracotomy was required in 26% of the cases. This illustrates the technical challenges for the surgeon and necessitates treatment in expert centers.

The effect of preoperative albendazole treatment on the cuticular membrane of the pulmonary hydatid cysts
Ozan Usluer, Ozgur Samancilar, Kenan Can Ceylan, Seyda Kaya. Thoracic Surgery, Internal Medicine, Izmir Universities Training and Research Hospital, Izmir, Turkey

Background: In this study, the effect of preoperative albendazole treatment on the tensile forces of the cuticular membrane of the pulmonary hydatid cysts is investigated.

Methods: A prospective study on the forty-four patients operated for pulmonary hydatid cysts between January 2009 and November 2010 is planned. The study is approved by the ethics comitee of our centre. Seventeen patients having 20 cysts in the group A operated after three cycles of peroral 10mg/kg/day albendazole treatment where the 27 patients having 29 cysts in group B are operated without any preoperative administration of albendazole. Tensile stress tests were carried out on the excised cuticular membrane for the both groups on the fresh tissue.

Results: The results of this study have shown that the tensile strength of the cuticular membrane of the cysts excised from group A is lesser than group B and the difference between the two groups is statistically significant.

Conclusion: Albendazole treatment decreases the tensile strength of the cuticular membrane of the pulmonary hydatid cysts which may lead to perforation. The patients should be operated as soon as possible without any preoperative medical treatment in order to prevent the complication of the cyst before the definitive surgical treatment.

4701
Comparison between video-thoracoscopic and open surgical management of thoracic empyema
Petros Michos, Athanassios Stamateopoulos, Ioannis Gakidis, Christos Chatziantoniou, Konstantinos Skevis, Demetrios Doltsinis. Thoracic Surgery Department, KAT General Hospital, Athens, Greece

Aim: To evaluate the outcomes of video-thoracoscopic and open surgical management of patients with thoracic empyema.

Methods: We studied 228 patients retrospectively who underwent surgery for thoracic empyema in our hospital between January, 1999 and January, 2011. Patients’ medical records, surgical procedures, and outcomes were reviewed. The study identified 181 affected men and 47affected women with a mean age of 54 years (range 12-90). Presenting symptoms till treatment were 10.26 days (transitional phase empyema). In both groups the most common microorganism was Streptococcus Milleri (33%), following Staphylococcus Aureus (20%) and Gram (-) (10%). Success rate in Group A was 85% and in Group B 20%. In Group B, 40% of the unsuccessfully debrided patients underwent MT mechanical debridement and the rest thoracotomy and decortication. Mean hospital stay in Group A was 4.5days and in Group B 8.5 days. At median follow-up of 8 weeks all Group A patients were symptoms-free with minimal pleural thickening on chest X-ray.

Conclusions: Mechanical debridement by MT is superior to enzymatic debride- ment in the management of thoracic empyema. It is a minimal invasive and effective technique allowing direct visualization of the pleural space and offering a good long-term clinical outcome.
4708 The impact of cardiovascular events in hospitalized patients with community-acquired pneumonia (CAP): Preliminary results from the FAILCAP study
Letizia Morlacci1, Stefano Aliberti2, Andrea Gramaglia3, Antonio Viszia, Lisa Pancini4, Cornelia Baumgartner5, Fabio Giuliani3, Riccardo Fantini6, Anna Lasagni5, Elisabetta Lavezzi2, Simona Perossi6, Paula Peyrani7, Valter Monzani8, Alberto Pesci6, Julio Ramirez7, Francesco Blasi1
1Department of Respiratory Medicine, Affiliated Hospital, Guangzhou Medical University, Guangzhou, China; 2Department of Radiology, Affiliated Fautian Hospital, Guangdong Medical College, Shenzhen, China; 3Department of Respiratory Diseases (State Key Laboratory of Respiratory Diseases), First Affiliated Hospital, Guangzhou Medical University, Guangzhou, China

Background: The 2007 Infectious Disease Society of America (IDSA)/American Thoracic Society (ATS) guidelines defined severe community-acquired pneumonia (CAP) when patients fulfilled three out of nine minor criteria. Whether each of the criteria is of equal weight is not clear. The purpose of this study was to determine the weight of the minor criteria.

Methods: 1230 adult patients admitted to our hospital from 2005 to 2009 for CAP were enrolled for the study. Severe CAP was defined based on the presence of ≥5% of high-risk patients who fulfilled any of the IDSA/ATS major criteria for severe CAP at the emergency department were excluded.

Results: Hospital mortality rose sharply from 0.3%, 1.0% and 3.3%, respectively, for patients with one, none and two or more minor criteria to 10.5% for patients with three minor criteria. Arterial oxygen pressure/fraction inspired oxygen (PaO2/FiO2) ≤250 mm Hg, confusion, and uremia had the strongest association with mortality (Odds ratio, 22.162, 22.148, 16.343; respectively). Leukopenia, hypothermia, and hypotension were not associated with mortality. Sequential organ failure assessment (SOFA) scores and costs increased significantly with the number of minor criteria present. Uremia and PaO2/FiO2 ≤250 mm Hg were most strongly associated with SOFA scores [rank correlation coefficient (r), 0.352, 0.336; respectively]. PaO2/FiO2 ≤250 mm Hg and confusion were in closest relation to hospital length of stay (LOS) (r, 0.114, 0.114; respectively). PaO2/FiO2 ≤250 mm Hg and multilobar infiltrates were most strongly associated with costs (r, 0.257, 0.196; respectively).

Conclusions: The individual 2007 IDSA/ATS minor criteria for severe CAP were of unequal weight in predicting hospital mortality. SOFA scores, hospital LOS, and costs.

487. Severity, comorbidities and outcomes in community-acquired pneumonia

4705 The results of surgical treatment of patients with tuberculosis of lungs and pleura and diabetes mellitus
Yaroslav Voloshyn, Thoracic, National Institute of Tuberculosis and Pulmonology named F.G. Yanovsky NAMS, Kyiv, Ukraine

Aims: Study results of surgical treatment of patients with tuberculosis of lungs and diabetes mellitus.

Methods: Two groups: main - 301 patients, control – 298.

301 patients were treated in the thoracic department of the institute chemotherapy course (2 months and longer) revealed to be ineffective before reaching the clinic, tuberculosis progressed and complicated diabetes mellitus course and vise versa. Men were 191 (63.45%), women – 110 (36.55%), aged 12-70 years. Had diabetes mellitus and tuberculosis progressed and complicated diabetes mellitus course and vise versa. Men were 191 (63.45%), women – 110 (36.55%), aged 12-70 years. Had diabetes mellitus.

Micobacterial tuberculosis resistant was in 65.21%. Fibrocavernous tuberculosis 40.19%, Tuberculosis - 37.20%, caseous carcinoma - 4.98% were the indications to operation.

Results: After preparation with endotracheal anesthesia 301 patients was operated.

Fibrocavernous tuberculosis 40.19%, tuberculous - 37.20%, caseous carcinoma - 4.98% were the indications to operation.

Conclusions: Surgery remains a crucial adjunct to medical therapy for the treatment of TB and medical failure lesions. We identified temporal changes in the methods of diagnosis and treatment for tuberculosis.

4704 Present forms of the tuberculosis for which surgery is required
Nicolaie Gale1, Cornel Saru1, Vasile Grigore1, Corneliu Petreanu1, Emilia Crisan2, Emilia Tabacu3
1 Clinic of Thoracic Surgery, National Institute of Pneumonology Pro. Dr. Marius Nasta, Bucharest, Romania; 2 Clinic of Bronchology, National Institute of Pneumonology Pro. Dr. Marius Nasta, Bucharest, Romania; 3 Clinic of Pneumology, National Institute of Pneumonology Pro. Dr. Marius Nasta, Bucharest, Romania

Introduction: With introduction of tuberculostatic drugs, the surgical indications were diminished in the last decades. Althoug, in a country like Romania which touch record level of the tuberculosis’s incidence in time, the surgical approach changed. For example, toracoplasty was abandoned or utilized for selected case. Also, there are new methods of diagnosis which require the surgical approach.

Objectives: The work presents the value of surgery in the diagnosis and in the treatment.

Material and methods: We retrospectively reviewed 67 patients (47 males and 20 females, mean age: 50.2 years) treated between 2008 and 2010. We utilised in diagnosis the mediastinoscopy for mediastinal adenopathies biopsy in 2 cases, videoassisted thoracoscoppy for pleural biopsy in 28 cases. We applied pleuropulmonary deconcretion for 12 patients with lung trapped after adequate medical therapy.

Results: There was one operation-related death (1.5%) and 5 major postoperative complications (7.5%) 22 of 25 of pulmonary resection remained free of TB following surgery. Proportion of comorbidity, Aspergillus coinfection, operation time and emergency were the factors shown to be predictive of an unfavorable outcome.

Conclusions: Surgery remains a crucial adjunct to medical therapy for the treatment of TB. We identified temporal changes in the methods of diagnosis and treatment for tuberculosis.

The aim of this six-years prospecctual cohort study is to compare demographics, aetiology and outcome of patients admitted with pneumonia and categorised as CAP, HCAP and IC.

In conclusion, these data suggest that our IC cohort seem not to be so different from the not-IC patients classified as HCAP by the 2005 ATS/IDSA guidelines. Further investigations are mandatory in order to redesign pneumonia categories.
Cardiovascular events (CVEs) could be detected during the management of hospitalized patients with CAP because of the concomitant hypoxemia and systemic inflammation. The aim of our study was to evaluate incidence, risk factors, and outcomes of hospitalized patients with CAP undergoing CVEs. An international, multicenter, prospective, observational study was performed on consecutive CAP patients hospitalized from October 2009 to November 2010 in 8 Respiratory Units (Clinical Trials: NCT01143155). CVEs were recorded both on hospital admission and during hospitalization. Among the 431 patients enrolled (56±males; mean±SD), the occurrence of CVEs was 20%. The type of CVEs and their incidence is depicted in table.

**Rationale:** The aim was to evaluate serum cortisol as biomarker for the prediction of adverse outcomes independently of the CRB-65 score and inflammatory biomarkers in a large cohort of hospitalized CAP patients.

**Methods:** 894 hospitalized CAP-patients from the CAPNETZ study cohort were included. Serum cortisol was measured and its prognostic accuracy compared to the CRB-65 score, leukocyte count and C-reactive protein. Predetermined endpoints were 30-day mortality and development of critical pneumonia.

**Results:** 64 patients died (6.5%) and 85 developed critical pneumonia (8.6%). Cortisol levels were significantly elevated in both adverse outcomes (p<0.001) and predicted mortality (AUC 0.70 and critical pneumonia (AUC 0.71) independently of all other measured variables including CRB-65 score after logistic regression analysis (p=0.005 and 0.001, respectively). Prognostic accuracy of CRB-65 was significantly improved by adding cortisol levels (combined AUC 0.81 for both endpoints). In Kaplan-Meier analysis, cortisol predicted survival within different CRB-65 strata (p=0.003). In subgroup analyses, cortisol independently predicted critical pneumonia when compared to procalcitonin and minor criteria of the 2007 ATS/IDSA guideline.

**Conclusion:** Cortisol predicts mortality and critical disease in hospitalized CAP patients independently of clinical factors and inflammatory biomarkers. It represents a promising biomarker to complete the available panel of inflammatory, cardiovascular and other biomarkers for risk prediction and should be incorporated into trials assessing optimal combinations of clinical criteria and biomarkers to improve high risk prediction in CAP.

Inhaled corticosteroids (ICS), systemic inflammatory response and mortality in community-acquired pneumonia (CAP)

Miguel Ferre1, Antoni Torres1, Soledad Reyes2, Raquel Martinez2, Paula Ramírez2, Eva Polverino1, Carlos Agustín1, Juan Cordoba3, Rosario Menéndez1, 1Servicio de Pneumología, Hospital Clínic, Barcelona, Spain; 2Servicio de Neumología, Hospital Universitario la Fe, Valencia, Spain; 3Unidad de Cuidados Intensivos, Hospital Universitario la Fe, Valencia, Spain; 4Servicio de Microbiología, Hospital Universitario la Fe, Valencia, Spain

Background: It was suggested a possible protective effect of ICS in patients with pneumonia. Whether this would be related to modulation of the systemic inflammatory response is unknown. We assessed the relationship between systemic inflammation, ICS and outcome in hospitalised patients with CAP.

Methods: We determined serum levels of C-reactive protein (CRP), Procalcitonin, TNF-alpha, IL-1, IL-6, IL-8 and IL-10 at admission in patients with chronic outpatient treatment with ICS or not, and compared treatment with ICS, biomarkers and other factors potentially related with inflammatory response or mortality in survivors and non-survivors.

Results: We prospectively assessed 663 consecutive patients with CAP, 128 (19%) received outpatient ICS. Patients with ICS were older, had more frequently COPD and asthma, higher PSI and CURB-65 risk classes, less frequently Legionella pneumonia aetiologic, and lower serum levels of TNF-alpha (p < 0.001) and IL-6 (p = 0.0115) as admission. However, hospital mortality was lower for patients treated with ICS (2.1% vs. 3.4%, OR 0.23, 95% CI 0.06-0.99, p = 0.488). After adjusting for age and severity scales, the association of ICS with lower mortality became stronger (adj. OR 0.12, 95% CI 0.02-0.61, p = 0.010), and persisted when even in non-COPD patients (adj. OR 0.07, 95% CI 0.01-0.74, p = 0.027).

Conclusion: Chronic outpatient treatment with ICS was associated with improved survival of CAP possibly due to modulation of patients’ inflammatory response. Whether ICS may improve or not the outcome of patients needs prospective investigation.

4713 Steroid titration against mannitol in mild to moderate persistent asthma (STAMINA trial)

Lorna McKlnlay1, Philip Short1, Peter Williamson1, Cathy M. Jackson2, Tom Fordon1, Karine Cleer1, Brian Lipworth1. 1Asthma & Allergy Research Group, University of Dundee, Dundee, United Kingdom; 2Bute Medical School, St Andrews

Objectives: To compare titrating ICS against mannitol airway hyperresponsiveness (AHR) or British Thoracic Society ( BTS) outcomes on asthma control over 1 year in the community.

Methods: After an ICS tapering phase, 157 persistent asthmatics were randomised (parallel) and followed for 1 year. Their subsequent ICS dose (as ciclesonide) was titrated against either mannitol PD10 (AHR strategy) or standard BTS outcomes. Significantly fewer cumulative episodes of loss of control occurred in the AHR rather than BTS group (84 vs 118, p = 0.018), amounting to a 24% lower rate (1.32 vs 1.73 episodes of loss of control/patient/year).

Significant improvements were seen in the AHR group for inflammatory markers including mannitol PD10, methacholine PC20, salivary eosinophil cationic protein (ECP), exhaled nitric oxide, symptoms and reliever use. Final mean inhaled Ciclesonide dose was higher in the AHR group (p < 0.0001) in AHR group: 514 ug vs 208 ug (BTS), with no significant suppression of overnight urinary cortisol/creatinine.

4715 Pathophysiology of airway hyperresponsiveness in patients with nasal polyposis

Bruno Mahut, Laurent Planitier, Brigitte Chevalier-Buisan, Christophe Delclaux. Physiology, Georges Pompidou Hospital, Paris, France

It has been hypothesized that airway hyperresponsiveness (AHR) is characterized by sensitivity (strength of stimulus) and reactivity (responsiveness to stimulus); the latter could be the intrinsic characteristic of AHR. The underlying mechanisms leading to AHR could be 1) airway inflammation, 2) reduction of forces opposing bronchomotor contraction, and 3) structural airway changes/geometry factors. Our main objective was to assess the relationships between reactivity and these three mechanisms using measurements of 1) bronchial and bronchial/alveolar NO, 2) bronchomotor response to deep inspiration, and 3) forced expiratory flows and an index of airway to lung size, i.e. FEF25-75/FVC. Patients with nasal polyposis underwent spirometry, multiple flow measurement of exhaled NO, assessment of bronchomotor response to DI by forced oscillation technique and methacholine challenge allowing the calculation of reactivity (slope of the dose-response curve) and sensitivity (PD10).

One hundred and thirty-two patients with nasal polyposis were prospectively enrolled of whom 71 exhibited AHR. Airway reactivity was correlated with alveolar NO concentration (r = 0.35, p = 0.017), with airflow limitation (FEF25-75%: r = 0.40; p = 0.003) and with an index of airway size to lung size (FEF25-75%/FVC: r = -0.38; p = 0.005), of which only alveolar NO remained the only independent factor in a stepwise multiple regression analysis. Airway sensitivity was not correlated with any pulmonary function or exhaled NO parameter.

Conclusion: In patients with nasal polyposis, the main determinant of reactivity is alveolar NO, suggesting that bronchial/alveolar lung inflammation constitutes one intrinsic characteristic of AHR.

4716 Eosinophilic airway inflammation is heterogeneous in asthma. We recently described a distinct subtype of asthma defined by the expression of genes inducible by Th2 cytokines and with pre-existing ICS dose. This gene signature, which includes periostin, is present in approximately half of asthmatics, and correlates with eosinophilic airway inflammation. However, identification of this subtype depends on non-invasive airway sampling, hence non-invasive biomarkers of this phenotype are desirable.

Objective: Identify systemic biomarkers of eosinophilic airway inflammation.

Methods: We measured fractional exhaled nitric oxide (FeNO) and peripheral blood eosinophil, peroxidin, YKL-40, and IgE levels and compared these biomarkers to airway eosinophils in 5 cohorts of asthmatics across a range of severity (N=150).

Results: We replicated our previous finding of a three-gene bronchial epithelial Th2 signature in a subset of asthmatics and found that peripheral blood eosinophil levels were highly correlated to the gene signature. Blood peroxidin is significantly elevated in asthmatics with evidence of eosinophilic airway inflammation relative to those with minimal eosinophilic airway inflammation despite inhaled corticosteroid (ICS) treatment across a range of disease severity. A logistic regression model including sex, age, body mass index (BMI), IgE, blood eosinophils, FeNO, and serum peroxidin in 59 severe asthmatics showed that, of these indices, serum peroxidin was the single best predictor of airway eosinophilia (p = 0.007).

Conclusions: Peroxidin is a systemic biomarker of airway eosinophilia in asthma and has potential utility in patient selection for emerging asthma therapeutics targeting Th2 inflammation.

488. Phenotyping airway diseases

Francisco, CA, United States; 2Institute for Lung Health, University of Leicester, Leicester, United Kingdom; 3Measuritis-Christborie Laboratories, McGill University, Montreal, QC, Canada

Background: Eosinophilic airway inflammation is heterogeneous in asthma. We recently described a distinct subtype of asthma defined by the expression of genes inducible by Th2 cytokines and with pre-existing ICS dose. This gene signature, which includes periostin, is present in approximately half of asthmatics, and correlates with eosinophilic airway inflammation. However, identification of this subtype depends on non-invasive airway sampling, hence non-invasive biomarkers of this phenotype are desirable.

Objective: Identify systemic biomarkers of eosinophilic airway inflammation.

Methods: We measured fractional exhaled nitric oxide (FeNO) and peripheral blood eosinophil, peroxidin, YKL-40, and IgE levels and compared these biomarkers to airway eosinophils in 5 cohorts of asthmatics across a range of severity (N=150).

Results: We replicated our previous finding of a three-gene bronchial epithelial Th2 signature in a subset of asthmatics and found that peripheral blood eosinophil levels were highly correlated to the gene signature. Blood peroxidin is significantly elevated in asthmatics with evidence of eosinophilic airway inflammation relative to those with minimal eosinophilic airway inflammation despite inhaled corticosteroid (ICS) treatment across a range of disease severity. A logistic regression model including sex, age, body mass index (BMI), IgE, blood eosinophils, FeNO, and serum peroxidin in 59 severe asthmatics showed that, of these indices, serum peroxidin was the single best predictor of airway eosinophilia (p = 0.007).

Conclusions: Peroxidin is a systemic biomarker of airway eosinophilia in asthma and has potential utility in patient selection for emerging asthma therapeutics targeting Th2 inflammation.
Conclusions: Managing patients in primary care using mannitol to guide ICS therapy resulted in significant reductions in episodes of loss of control, symptoms and reliever use, along with suppression of inflammatory markers but not adrenal function.

4717 Preparing asthmatic patients to climb to extreme high altitude (asthma Aconcagua expedition)

Sven Seys¹, Marc Daenen², Lieven Dupont³, ¹Internal Medicine, Katholieke Universiteit Leuven, Leuven, Vlaams-Brabant, Belgium; ²Internal Medicine, Hospital of Oost-Limburg, Genk, Limburg, Belgium

A group of 18 asthmatics were evaluated in preparation for an expedition to climb the Aconcagua mountain (6900m).

Patients were evaluated at different time points before expedition: screening visit, hypoxia chamber and cold air exposition (in an attempt to simulate conditions at extreme altitude) as well as before/after the expedition. During the hypoxia simulating experiment, patients stayed for 30 min in a chamber filled with 11% oxygen followed by a maximal exercise test. During the cold air exposition, patients resided for 24 hours in an indoor ski resort (mean temperature of -8 °C).

All patients except one (score of 18/25) had an ACT well controlled asthma (ACT > 20). During one year of preparation, FeNO values significantly reduced (p=0.01) while lung function parameters remained stable. FEV1 and FeNO values were slightly but significantly lower (mean change in FEV1 of 2.7%, p=0.01 and mean change in FeNO of 2.2 ppb; p=0.03) after a maximal exercise protocol under hypoxic conditions (FeO2=11%). A significant decrease in FEV1 was also observed after a 24h stay at -8 °C (mean change of 6.6%, p=0.009). This was accompanied by an increase in sputum neutrophils (13% pre versus 48.6% post, p<0.01) but was not associated with a change in FeNO levels (p=0.07).

During one year of preparation prior to climbing the Aconcagua mountain, there was an improvement in airway inflammation despite adequate asthma control at baseline. Exercising in hypoxic conditions (60 min, FeO2 11%) induced a minor decrease in FeV1 and FENO in asthmatics. Exposure of asthmatic patients to cold air for 24h resulted in a larger decrease in FEV1, which was associated with a neutrophilic airway inflammation.

4718 Inflammatory subtypes of non-atopic asthma

J.C. de Groot¹, H. Storm², E.H. Bel³, A. ten Brinke³, ¹Respiratory Medicine, Medical Centre Leeuwarden, Leeuwarden, Netherlands; ²Clinical Chemistry, Medical Centre Leeuwarden, Leeuwarden, Netherlands; ³Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands

Introduction: In asthma, several types of airflow inflammation have been described (Simpson Respirology 2006), which may represent clinically different subtypes of asthma. Whether non-atopic asthma can also be divided into different subtypes according to airflow inflammation is unknown.

Aim: To investigate whether different inflammatory profiles correspond with distinct clinical and functional characteristics in patients with non-atopic asthma.

Methods: In a cross-sectional study we included outpatients with non-atopic asthma and divided them into 4 types of airflow inflammation. All patients filled out questionnaires (co-morbidity, ACQ, AQLQ, Sino-Nasal outcome Test (SNOT)) and underwent spirometry, blood tests, sputum induction and nasal endoscopy.

Results: 62 patients (92% adult onset) were included. We found no differences in BML, questionnaires or spirometry. Differences between groups are: see Table 1.

Auto-immune = DM, thyroid dysfunction, reumatoid arthritis and other.

Conclusion: Almost all adult non-atopic asthma patients have their onset of asthma in adulthood. There are at least 2 distinct phenotypes: an eosinophilic phenotype, characterized by male gender, high levels of IgE and nasal polyps, and a neutrophilic phenotype associated with extra-pulmonary auto-immune diseases.

4719 The role of food allergy in adult onset asthma

M. Amelink¹, S.B. de Nijjs², P. van Spiegel³, F.H. Krouwels¹, E.J.M. Weersink¹, A. ten Brinke¹, F.J. Sterk³, E.H. Bel³, ¹Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands; ²Respiratory Medicine, Slotervaart Hospital, Amsterdam, Netherlands; ³Respiratory Medicine, Maastricht University, Maastricht, Netherlands

Background: Adult onset asthma is a poorly characterized phenotype of asthma. Whereas in childhood-onset asthma food allergies are closely related to the development of asthma (Zeiger JACI 1995), this relationship has never been studied in adult onset asthma. We hypothesize that food allergies are present in adult onset asthma, in particular in patients with high levels of total IgE.

Aim: To investigate the presence of specific IgE antibodies against a panel of common food and aeroallergens in patients with adult onset asthma, and to relate this to clinical, lung function and inflammatory markers.

Methods: In 150 patients (65% female; age 52.3 ± 13.5y) specific IgE against food allergens (milk, soy, cod, peanut, ovalbumin, wheat), aeroallergens (house dust mite, cat, dog, tree, grass, herbs, mould), total IgE, FeNO and spirometry were cross-sectionally compared between patients with and without (food) allergies.

‡Mean (SD); *Median (range); °p < 0.05 atopic with food allergy vs non-atopic; †p < 0.05 non-atopic vs atopic.

Conclusions: 10% of patients with adult onset asthma have food allergies. These patients have higher levels of total IgE and are more often males. This implies that screening for food allergies in patients with adult onset asthma and high levels of IgE is warranted.

4720 Expression of prohibitin 1 mitochondrial protein in non-COPD and COPD smokers

Nikolaos Soulitzis, Eirini Neofytou, Maria Paurou, Sotiris Menikou, Nikolaos Siafakas, Elemi Tzotzaki. Laboratory of Molecular and Cellular Pulmonology, Medical School, University of Crete, Heraklion, Crete, Greece

Introduction: Prohibitin (PHB1) is a versatile protein that is located in the inner mitochondrial membrane, maintaining normal mitochondrial function and morphology. Prohibitin interacts with NADH dehydrogenase, a protein complex essential for the oxidoreductase activity within cells. However, its expression in lung epithelium, especially in patients with inflammatory lung diseases associated with increased oxidative stress, such as COPD, is unknown.

Aim: To study PHB1 expression in lung tissue of non-smokers, non-COPD smokers and COPD patients.

Methodology: Lung tissue specimens from 30 male subjects were studied: 15 COPD patients [age: 65.9±6.2 years, smoking: 88.9±51 pack-years, FEV1 (% pred: 58.4±16.4, FEV1/FVC (§%): 66.2±8.6], 10 non-COPD smokers (age: 57.0±11.7 years, smoking: 67.1±3.99 pack-years, FEV1 (% pred: 84.0±15.9, FEV1/FVC (%): 80.0±3.8) and 5 non-smokers. Quantitative Real-Time PCR and Western Blot experiments were carried out for PHB1, using beta-actin as internal control.

Results: Non-COPD smokers exhibited lower prohibitin levels when compared to non-smokers (0.55±0.06 vs 0.90±0.06, p=0.011), while PHB1 mRNA levels were even further decreased in COPD patients (0.32±0.03), a finding statistically significant vs. both non-COPD smokers (p=0.012) and non-smokers (p=0.009). Western blot analysis verified the above results (non-smokers: 1.77±0.10, non-COPD smokers: 0.97±0.08, COPD patients: 0.62±0.09, p=0.028).

Conclusion: The significantly downregulated prohibitin levels in non-COPD and COPD smokers in comparison with non-smokers possibly reflects a distorted mitochondrial function, resulting in decreased anti-oxidant activity, especially in the mitochondria of COPD patients.
Biomarker discovery in chronic obstructive pulmonary disease (COPD) using epithelial lining fluid: A proteomic approach

Lorenza Franciosi1, Natalia Govershchina1, Fabrizia Fusetti2, Bert Poolman3, Nick ten Hacken3, Dirkje Postma3, Rainer Bischoff3.

1Analytical Biochemistry, University of Groningen, Groningen, Netherlands; 2Department of Biochemistry, NPC Research Hotel, University of Groningen, Groningen, Netherlands; 3Department of Pulmonary Disease, Groningen Research Institute of Asthma and COPD, University Medical Center Groningen, Groningen, Netherlands

Aim: To discover proteins that change in abundance in ELF (Epithelial Lining Fluid) from COPD patients versus healthy controls using a quantitative proteomics approach.

Methods: The ELF proteome from COPD patients and healthy controls was studied by 1D polyacrylamide gel electrophoresis followed by in-gel tryptic digestion to assess the feasibility of such an approach. 40 gel slices were obtained from each lane of the gel (corresponding to one patient). Digested samples were analyzed by nanoChip-LC-MS/MS using an ion trap. We performed a quantitative pilot study of ELF from 4 COPD patients and 4 healthy controls [table 1] to test for statistically significant differences in protein levels. ELF samples were digested by trypsin, labeled with stable isotope-containing reagents (iTRAQ®; 8-plex) and processed by strong cation-exchange chromatography followed by nanoLC-MS/MS. In order to validate the results, a second quantitative analysis of an independent sample set (4 COPD vs 4 healthy) using the same methodological approach was done.

Results: The 1D electrophoretic approach resulted in more than 500 identified proteins. Most of the identified proteins were present in both COPD and healthy samples, although some proteins were only identified either in healthy control or in COPD samples. The quantitative studies showed a number of proteins significantly different between ELF of COPD patients and controls, including 4 up-regulated proteins in common in both studies.

Conclusions: The obtained results show the possibility to discover proteins differentially expressed in ELF of COPD patients and controls. We are currently validating these proteins by western blot and immunohistochemistry.

489. Continuous medical education

Training requirements for respiratory physicians performing ultrasound-guided transesophageal fine needle aspiration (EUS-FNA) for mediastinal staging

Lars Konge1, Inoue Annema2, Paul Clementsen3, Peter Vilmann3, Charlotte Ringsted1.

1Centre for Clinical Education, University of Copenhagen, Copenhagen, Denmark; 2Department of Pulmonology, Leiden Medical Centre, Leiden, Netherlands; 3Department of Pulmonology, University Hospital of Copenhagen Gentofte, Gentofte, Denmark

Accurate mediastinal nodal staging is important for patients with resectable non-small cell lung cancer. EUS-FNA is an alternative to mediastinoscopy, but EUS training requirements are under discussion. The purpose of this study was to explore the amount of training needed to establish basic competency in EUS-FNA.

Five experienced respiratory physicians from Denmark and the Netherlands were included in the study (3 men, 2 women). They had no prior experience in EUS. Each participant completed between 20 and 30 supervised EUS-FNA procedures. All procedures were video-recorded and blindly and independently assessed by three experts using a validated assessment tool.

Data will be presented as individual and averaged learning curves. Currently the first participant has finished training and her learning curve is presented in the figure below. Differences in the acquisition of skills between trainees will be presented. Preliminary data suggest that performance of approximately 25 procedures secures basic competence in EUS-FNA for mediastinal staging.

A Delphi study to create grade-specific competencies for a trust-wide non-invasive ventilation training programme

Anand Shah, Roger Sharpe, Thungo Kuwani.

Postgraduate Medical Education, North West London Hospitals Trust, London, United Kingdom

Introduction: Non-invasive ventilation (NIV) is an expanding treatment modality for respiratory failure and is increasingly used in non-specialist acute areas. Although comprehensive national guidelines exist, there is no consensus as to the expected level of competency for non-specialist health professionals. We used a modified Delphi process to create grade-specific NIV competencies which were then used to structure a comprehensive grade-based training programme.

Method: A 3 round Delphi process was used with an expert panel of 20 respiratory consultants, registrars, physiotherapists and nurses. A provisional list of competencies was created following amendment by the expert panel of an initial draft formulated by literature and peer review. In the second round, competencies were added or deleted following statistical analysis of grade-based relevancy rating using a 6-point Likert scale. Competencies where consensus was not reached were present in the third round alongside expert viewpoint. Competencies with no consensus following 3 rounds were deleted. The finalised lists were sent to a selection of each grade for self-assessment of competency.

Results: A high variability was noted in competency expectation amongst our expert panel. Self-assessment showed gross lack of competency amongst junior doctors and nurses with high variability at specialist trainee level.

Conclusion: Competencies were used to create a grade-based training programme with objective trainee learning outcomes. The study revealed a high level of inconsistency regarding expectation amongst NIV specialists alongside exposing the lack of current formal NIV training and weaknesses of an apprenticeship model.

Special interest training in respiratory medicine across Yorkshire: A web based survey
Akhay Dwarkanath. Department of Respiratory Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Introduction: The Joint Royal Colleges of Physicians Training Board (JRCPTB) published the training curriculum for Respiratory Medicine in August 2010. It identified areas of special interest enabling the trainee to undertake additional training. However, this is not formally recognized and there is no centrally agreed funding. Current options available for such training include as Out Of Programme Experience (OOPE) or during research into the subject area concerned.

Aims: To understand the current special areas of interest among trainees in Respiratory Medicine across Yorkshire, United Kingdom.

Method: A web-based questionnaire was designed and all the trainees (n=75) in the Yorkshire region were invited to complete the survey.

Results: The response rate was 52% (n=39). 69.2% (n=27) had a special area of interest.

Conclusion: Majority of the trainees wish to specialize in a specific area of interest but there seems to be a lack of funding and training opportunities in the form of fellowships. Improving the current training curriculum will lead to better patient care and service provision in the National Health Service.

4726
Attitude of chest physicians working in provincial state hospitals, in Turkey toward continuous medical education
Tarkan Ozdemir1, Leyla Yilmaz Aydin2, 1 Chest Disease, Corum Chest Disease Hospital, Corum, Turkey; 2 Chest Disease, Duzce University, Medical Faculty, Duzce, Turkey

Introduction: Continuing medical education is carried out primarily by medical associations. Bulletins are published on method.

Aim: To investigate post-training status and trends regarding this issue of chest physicians working in provincial state hospitals

Methods: Questionnaires, that consist of 18 questions about years of work, institution, participation in congresses and training activities, regular follow-up of publications and web sites, views about post-training; with permission of Ministry of Health; was sent to chest physicians. Participants, completed the questionnaire and sent back anonymously.

Results: 85 of 130 chest physicians in 36 provinces participated. Response rate was 65%. Average working years was 15.0±8.40. 44.7% were working in state hospitals and 54.1% were in chest disease hospitals. Participation to congresses on last 2 years was 3.59±1.62. 28.2% were attending education meetings regularly. 38.8% answered question of “Do you follow a publication regularly?” with “No”. Participants who do not follow the web sites was 34.1%. While years of work increased, follow-up of web sites decreased (p=0.00). Question of “Do you feel yourself declined in terms of professional information and facilities sometimes?” replied “Yes” by 58.8%.

Conclusion: We found that our colleagues have been less interested in training activities. Training activities, independent of personal initiatives, will increase self-confidence and professional qualifications.

4727
Developing respiratory services – What are the needs of the respiratory clinician leaders and what can a short course deliver?
Steve Holmes, Nicky Bullen, Stephen Gaduzo, Basil Penney, Sandy Walmsey. Respiratory Leaders Programme, Primary Care Respiratory Society UK, Smokey House, Waterbeck, Lockerbie, United Kingdom

Background: The development of services within health care systems is complex and requires expertise in clinical, economic and managerial issues. Within the UK, clinicians are being expected to work with managers and commissioners to develop services. This newly recognised area of work requires personal development. An ongoing programme of learning was developed to support respiratory leaders in this increasingly challenging role.

Method: The PCRS-UK have developed bi-annual courses to support clinical respiratory leaders in understanding the many issues that are required to enable the leader to influence service development and to support their own teams in changing services in line with best medical evidence. The course evaluations have provided useful information on areas that clinicians wish to develop as they move into leadership roles and demonstrate the potential development from attending a short course.

Results: 64 participants completed the most recent course. Around 2/3 of delegates provided feedback on their skills/confidence. This demonstrated widespread requirements in both understanding NHS policy and direction as well as core leadership skills (understanding others, developing groups, organising and chairing meetings, communicating with commissioners). The course achieved considerable improvements in confidence and skills in most of these areas.

Conclusions: There is a clear need to support the clinical respiratory leaders of the future who have considerable developmental needs to complement their clinical expertise. The areas for this can be identified and a relatively short and focused course can make a significant impact on these needs.

Late-breaking abstract: Comparative analysis of cardiopulmonary and clinical responses to six minute walking test and maximal exercising test in obese women
Luziana Di Thommā­ mar-Luporini, Sorea Plon Jurgensen, Viviane Castello, Camila Negrão Dias, Rafael Luis Luporini, José Carlos Bonjorno-Júnior, Claudio Ricardo de Oliveira, Aparecida Maria Catui, Audrey Borghi-Silva. Phsyiotherapy, Federal University of Sao Carlos, Sao Carlos, Brazil; Medicine Department, Federal University of Sao Carlos, Sao Carlos, Brazil; Catholic University of Pernambuco, Pernambuco, Brazil

Background: The six minute walk test on the treadmill (tread6MWT) can be an efficient method to evaluate the functional capacity in obese population comparable to cardiopulmonary exercising test (CPET).

Aims: To compare the cardiopulmonary and subjective responses to tread6MWT and CPET in obese and eutrophic women.

Methods: Fourteen obese women were recruited to obese group (OG) and 15 women to eutrophic group (EG). Both groups performed a CPET and a toss6MWT. Cardiopulmonary variables and dyspnea level were registered. Absolute limits of agreement between cardiopulmonary and subjective responses to CPET and toss6MWT were assessed by Bland-Altman analysis.

Results: OG presented higher oxygen uptake (V'02), minute ventilation (V'E), and systolic blood pressure (SBP) than EG (p<0.05) in both tests. There is a
strong correlation (p=0.76) between VO2 and body mass index in the CPET, as well as heart rate (HR) in the peak of both tests (r=0.77) in OG. The dyspnea was higher during CPET than treadmillMT (p=0.05) in both groups. It was observed the agreement of both tests to identify relative VO2, VE, SBF and HR at the peak of exercise, presenting a mean difference between the tests of: 0±6.5 (mL/kg/min), 29±1.69 (L/min), 17.5±1.94 (mmHg) and 32.9±1.94 (bpm), respectively ([BHAS.ISD]).

Conclusions: The treadmillMT was able to promote metabolic and cardiopulmonary responses in agreement to the CPET. The treadmillMT seems to be an appropriate method to evaluate the functional limits and lactic acidosis in obese women without submitting them to such a significative dyspnea as the CPET does.

Financial support: FAPESP (09/01842-0) and CAPES.

Late-breaking abstract: Time-dependent effect of acute hypoxia on brain excitability in healthy humans
Samuel Verges1, Thomas Rupp1, Marc Jabeau2, Bernard Wuyam1, Stéphane Perrey1, Patrick Levy1, Guillaume Miller1,2
HP2 Laboratory, U1042, Joseph Fourier University, INSEERM, Grenoble, France; 1Exercise Physiology Laboratory, Jean Monnet University, Saint-Etienne, France; 2Movement To Health Laboratory, Montpellier-1 University, Montpellier, France

Some studies have shown altered cortex excitability in hypoxemia patients suffering from COPD or OSAS. Recently, contradictory results regarding the effect of hypoxia (H) on cortex excitability have been reported in healthy subjects, possibly depending on the methodologies used. We evaluated the effects of 1 and 3 hours H on motor cortex excitability, intracortical inhibition and supraspinal voluntary activation (VA) using transcranial magnetic stimulation (TMS). TMS to the quadriceps area and femoral nerve electrical stimulations were performed in normoxia and H (FiO2 = 12%) in 10 healthy subjects. Motor-evoked potentials (MEPs) at 50-100% maximal voluntary contraction - MVC), cortical silent periods (CSP) and VA were measured. One hour H did not modify any parameters of brain excitability but reduced VA probably due to the repetition of contractions 1-h apart (98.2± vs. 95.2±%; p<0.01). Conversely, 3 h significantly increased i) MEPs of the rectus femoris (RF) at all force levels (±12%), vastus lateralis (VL) and vastus medialis (VM) at all force levels (e.g. at 50% MVC, RF: +26±35%, VL: +15±24%, VM: +17±15%) and ii) stimulator power output (s.g. at 70% maximal power, RF: +17±23%, VL: +37%, VM: +15±19%) and modulated cortical silent periods (CSP) at all force levels (e.g. at 50% MVC, RF: +23±39%, VL: +27±31%, VM: +24±37% (all p<0.05), but did not modify VA (98.1±% vs. 97.2±%; p=0.21). These data demonstrate a time-dependent H-induced increase in cortex excitability and intra-cortical inhibition, without changes in VA. The decrease of cortical and/or physical or cognitive performance needs to be elucidated to better understand the effects of hypoxemia in patients.

P4730
Late-breaking abstract: Association between serum surfactant protein D (SP-D) and lung function measurements in self-reported healthy twins
Soefie Lock Johannson1, Quisa Tan2, Anders Schlösser1, Ingrid Tilstedt3, Uffe Holmikov1, Kirsten Kyvik4, Grith Sørensen1
1Department of Cardiovascular and Renal Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark; 2Department of Pulmonary Medicine, Odense University Hospital, Odense, Denmark; 3Institute of Regional Health Services Research, University of Southern Denmark, Odense, Denmark

Introduction: Serum SP-D is suggested to serve as a biomarker in various pulmonary diseases, and has been showed negatively correlated to FEV1 in COPD. Aim: The objective of the present study was to investigate the association between serum SP-D and lung function in normal Danes.

Material and methods: Data of serum SP-D originates from 1,476 self-reported healthy adult twins. Association between variables were analyzed by using a multiple linear regression model using SP-D as response variable and pre-bronchodilatator FEV1 and FVC as explanatory variables. Intra-pair dependency was taken into account, and data was adjusted for sex, age and BMI.

Results: There was a significant difference in mean serum SP-D levels in smokers and with or without obstruction. (p<0.05) See table 1. The association for SP-D with FEV1 and FVC was found to be negative in smokers (p=0.001/0.001), but positive in non-smokers (p=0.030/0.002).

<table>

Conclusions and perspectives: Findings indicate opposite phenotypic correlation between SP-D and FEV1 in smoking and non-smoking individuals. Further analysis of available data will include multivariate twin modelling to investigate whether there is a genetic correlation between the traits and genetic association analysis to find out whether such a genetic correlation could be explained by single nucleotide polymorphisms within candidate genes such as the SPFDP gene.

P4731
Late-breaking abstract: Determination of anaerobic threshold through different methodologies during ramp protocol in elderly healthy men
Michel Reis1, Ross Arena2, Danilo Berton3, Adriano Barroco3
1HP2 Laboratory, U1042, Joseph Fourier University, INSEERM, Grenoble, France; 2Exercice Physiology Laboratory, Jean Monnet University, Saint-Etienne, France; 3Movement To Health Laboratory, Montpellier-1 University, Montpellier, France

For assessing the cardiopulmonary integration during aerobic exercise, anaerobic threshold (AT) has been an important index of performance. Additionally, the respiratory compensation threshold (RCT) has been used for determining performance of quasi-maximum intensities (Wasserman et al., 1983). The aim of this study to identify the anaerobic threshold (AT) obtained from the V-slope method, visual inspection of oxymoglobin (O2Hb) and deoxymoglobin (HbH) curves and compare findings with the heteroscedastic (HS) method applied to VCO2, heart rate (HR) and HbH data. Fourteen healthy men were subjected to cardiopulmonary testing (CPX) on a cycle-ergometer until physical exhaustion. Biological signals collected during CPX included: ventilatory variables; spectroscopy by NIRS; and HR by a cardiofrequency meter. We observed temporal equivalence and similar values of power, VO2 (mL/min), VO2 (mL kg^-1 min^-1) and HR at AT by the detection methods exposure described in addition by the Blomqvist-Alman plot (Fig. 1). HR confirmed the good agreement between the methods with biases between -1.3 and 3.5 bpm.

In conclusion: (i) all detection methods were sensitive in identifying AT, including the HS applied to HR and ii) the methods showed good correlation in the identification of AT. Thus the results support the HR seems to be a valid parameter in determining the AT of the individuals in our study (Grants: FAPESP)

P4732
Cytokine expression in the diaphragm of rats breathing against subacute hypoxic conditions
M. Dominguez, S. Pascual, M. Sabaté, F. Sánchez, C. Casadevall, E. Barreiro, J. Gea
1Respiratory Medicine-CEXS, Hospital Mar-IMIM. UPF. CIBERES-ISCHI, Barcelona, Spain

COPD patients show muscle damage and an increase in the expression of local cytokines in their diaphragms. The paracrine role of these cytokines still remains controversial.

Objective: To analyze the effects of subacute hypoxia on the diaphragm muscle.

Methods: Wistar rats (n=8/group) were exposed to: (1) hypoxia (FIO2 0.10) +placebo, (2) normoxia +placebo, (3) hypoxia +Infliximab [monoclonal antibody that results in the blockade of TNF-a receptors], and (4) normoxia +Infliximab for 2 weeks in all cases. At the end of the study period diaphragm and gastrocnemius muscles as well as blood samples were obtained. Molecular and cellular indices of muscle damage, oxidative stress, cytokine expression and activation of regeneration pathways were obtained using morphometry, Western-blot, spectrophotometry, ELISA, luminometry and RT-PCR.

Results: Although rats exposed to hypoxia showed higher levels of expression of different cytokines (TNF-a, IL-6, INF-g) in their diaphragms than the control animals (normoxia), no differences were observed in muscle damage, oxidative stress and biomarkers of muscle regeneration. Inhibition of TNF-a action in hypoxic animals resulted in an even higher expression of local cytokines with no relevant changes in the other variables when compared with hypoxic animals receiving placebo. No changes were observed in either limb muscle or blood in any of the groups.

863s
Conclusions: Hypoxia induces local inflammation in respiratory muscles of hypoxic rats. This effect appears to be selective for respiratory muscles and can be related to changes in their mechanical loading and its mismatching with the oxygen delivery to the muscle.

P4733 The impact of aerobic exercise on lung inflammation and remodeling in experimental emphysema

Isabela Guimaraes1, Gisele Padilha1, Miquela Lopes-Page1, Patricia Marques2, Mariana Antunes2, Nazareth Rocha2, Edson Assis3, Hugo Faria Neto2, Raquel Magalhaes4, Debora Xisto1, Patricia Roccc3,1, Laboratory of Pulmonary Investigation, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 2Department of Physiology, Flamennse Federal University, Niterói, Brazil; 3Institute of Immunopharmacology, FIOCRUZ, Rio de Janeiro, Brazil.

This study investigated the impact of aerobic exercise on lung inflammation and remodeling in experimental emphysema. 32 mice were randomized into 2 groups. In control (C) animals, saline was intratracheally (i.t.) injected, whereas emphysema mice received porcine pancreatic elastase (ELA, 0.1 U, i.t.). Saline and ELA were i.t. injected once a week for 4 weeks. After the last week, C and emphysema groups were further randomized into subgroups: sedentary and exercise. Exercise mice ran on a motorized treadmill, at moderate intensity (8-12 m/min), 5% grade, 30 min/day, 3 times a week for 4 wk. 24-h after the last session, lung mechanics and morphometry, as well as cytokines and total cell count in bronchoalveolar lavage fluid (BALF) and blood were measured. Echocardiographic analysis was done before and after emphysema induction and at the end of the experiment. The sedentary emphysema group presented, compared to C: 1) increased lung static elastance, 2) increased lung hyperinflation and elastic fiber content; 3) augmented levels of KC [murine interleukin (IL)-8 homolog], tumor necrosis factor-α, interferon-γ, and IL-10; and 4) pulmonary arterial hypoxia, evidenced by increased pulmonary flow acceleration. Aerobic exercise: 1) improved lung mechanics, 2) reduced lung hyperinflation, and the number of cells and levels of these cytokines in BALF and blood, 3) diminished elastic fiber content, and 4) restored pulmonary flow acceleration to C values. Conclusion: in this model of lung inflammation and emphysema, 4 weeks of aerobic exercise modulated the inflammatory process and acted on lung remodeling, improving pulmonary function. Supported by: INCIT/INOFAR, FAPERJ, PRONEX, CNPq

P4734 Regular and moderate exercise prevents airway remodeling in a murine model of chronic allergic asthma

Cynthia Samary1, Carla Araujo1, Isabela Guimaraes1, Jhonatas Silva1, Adriana Silva2, Maria Elisa Carvalho3, Patricia Marques4, Nazareth Rocha4, Vera Cepalozza2, Patricia Roccc3, Laboratory of Pulmonary Investigation, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 4Department of Physiology, Flamennse Federal University, Niterói, Brazil; 5Department of Pathology, University of Sao Paulo, Sao Paulo, Brazil.

The present study investigated whether regular and moderate aerobic exercise might prevent airway remodeling in experimental chronic allergic asthma. For this purpose, 48 BALB/c mice were assigned into 2 groups: sedentary (S) and trained (T). Tr group ran on a motorized treadmill, at moderate intensity (8-12 m/min); 5% grade, 30 min/day, 3 times a week for 8 wk. At 8 wk, animals were further randomised into 2 subgroups: immunized and challenged with ovalbumin (OVA) or to receive saline using the same protocol (C). Aerobic exercise continued until the end of the protocol. Echocardiographic analysis was done before, at 4 and 8 weeks of treatment, and after asthma induction. Twenty-four hours after the last challenge, trained, compared to sedentary mice, presented: 1) an increase in systolic output, left ventricular mass, and end-diastolic volume; 2) a reduction in airway resistance, viscoelastic pressure, static elastance, eosinophil infiltration, smooth-muscle actin expression, and collagen fiber content in airways and lung parenchyma; 3) a decrease of transforming growth factor-β levels in bronchoalveolar lavage fluid (BALF) and blood; 4) an increase in interferon-γ in BALF and blood; 5) an augment of interleukin (IL)-10 in blood but a reduction in BALF; and 6) a decrease in IL-5 and IL-13 only in BALF. In conclusion, regular and moderate aerobic exercise was effective in preventing airway and lung parenchyma remodeling in the present murine model of chronic allergic asthma, improving lung function. Supported by: INCIT/INOFAR, CNPq, PRONEX, FAPERJ, CAPES

P4735 Repeated mannitol or NaCl hyperosmolar exposure of bronchial epithelial cells to mimic exercise-induced airways damage

Lara Rivas1,2,4, Laura Ferrer1,2,3, Silvia Fiocca1,2, Ramon Fariñ3, Maria R. Bosignon1,2,1 Unity of Bioistics and Bioengineering, Faculty of Medicine, University of Barcelona, Barcelona, Spain; 2DIBIMIS, Section of Pneumology, University of Palermo, Palermo, Italy.

Hyperosmolarity of the airway surface lining fluid might be involved in exercise-induced airway epithelial damage. Hypersomolarity causes release of interleukin 8 (IL-8) by bronchial epithelial cells (BEC) in vitro, but the effects of repeated hyperosmolar exposure on BEC are unknown. 16HBE cells were exposed to NaCl or Mannitol (Mann) (320, 640, 960, 1280 mOsm/kg H2O) in culture medium for 0 or 40 min for 3 consecutive days; at 24 h after each exposure, supernatants were collected and stored at -80 °C for subsequent IL-8 measurements (R&D System, UK). Cell viability was examined by MTT assay. Cell viability (p<0.001) was assessed by Western Blot. Repeated exposure to NaCl or Mann for 10 min at any concentration did not affect IL-8 release. Exposure of 16-HBE cells to NaCl or Mann at 640-1280 mOsm/kg H2O for 40 min increased IL-8 concentration at days 1 and 2 compared to untreated cells (p<0.0001); however, IL-8 release decreased at days 2-3 compared to day 1 (p<0.05). Repeated NaCl or Mann treatment for 10 min decreased cell viability by 10-20% (p<0.0001), while hyperosmolar exposure for 40 min decreased cell viability in a dose-dependent manner at day 1 and dramatically at days 2-3 (60% for NaCl, 40% for Mann at highest concentrations, p<0.0001). NaCl was cytotoxic compared to Mann (p<0.05). PINK expression increased dose-dependently with hyperosmolarity at days 1-2 (increased at day 3; IL-8 release was blocked by a specific JNK inhibitor (SP600125). Therefore, hyperosmolar exposure acutely activates BECs through JNK activation, whereas no changes were observed in mannitol exposure repeated for 3 days decreased IL-8 release likely due to major epithelial damage.

P4736 Acute exposure to mechanical forces deteriorates lung structure and function in a mouse model of emphysema

Margit Szabari1,2, Susanne Singh, Chandir Krishnakishan Parameswaran1, Elizabeth Bartolak-Suk1, Zoltan Hatos2, Bela Suk1,1 Department of Medical Physics and Informatics, University of Szeged, Szeged, Hungary; 2Biomedical Engineering Department, University of Szeged, Szeged, Hungary; 3Department of Pulmonary Medicine, Kyoto University Hospital, Kyoto, Japan.

Mechanical forces have been suggested to accelerate the deterioration of lung structure and function in emphysema. To test this, we used C57BL/6 mice treated with porcine pancreatic elastase (N=48) or left intact as controls (N=16). At 2, 7 or 21 days after treatment, mice were ventilated (V=8 ml/kg, 240/min) for 1 h with or without deep inspiration. In the post-inspiration period, at the end of breath, fluid (BALF) and blood were measured. Echocardiographic analysis was done before and after emphysema induction and at the end of the experiment. The sedentary emphysema group presented, compared to C: 1) reduced lung static elastance; 2) increased lung hyperinflation and elastic fiber content; 3) augmented levels of KC [murine interleukin (IL)-8 homolog], tumor necrosis factor-α, interferon-γ, and IL-10; and 4) pulmonary arterial hypoxia, evidenced by increased pulmonary flow acceleration. Aerobic exercise: 1) improved lung mechanics, 2) reduced lung hyperinflation, and the number of cells and levels of these cytokines in BALF and blood, 3) diminished elastic fiber content, and 4) restored pulmonary flow acceleration to C values. Therefore, our results suggest that acute mechanical forces rupture septal walls with a subsequent increase in FRC and a decrease in small airspaces diameters in a time dependent manner during disease progression. Supported by grants NIH HL090757 and OTKA 66700.

P4737 Aerobic exercise training attenuates the decrease in heart rate variability induced by exposure to cigarette smoke in mice

Alessandra C. Toledo1,2, José Maria Brito2, Renato M. Magalhães1, Agostinho C. Caleman-Neto1, Bernardo Camilo1, Francine Almeida1, Petra Mello1, Clarice R. Olivo1, Fernando T. Q. S. Lopes1, Chin J. Lin2, Paolo H. N. Saldença1, Milton A. Martins2, Internal Medicine, School of Medicine of University of Sao Paulo, Sao Paulo, Brazil; 3Pathology, School of Medicine of University of Sao Paulo, Sao Paulo, Brazil.

Smoking has been shown to influence the tone of the autonomic nervous system as reflected by heart rate variability (HRV) a predictor of increased cardiac risk and aerobic exercise (AE) training has been described as capable to modulate the HRV. Objective: This study evaluated the temporal effects of aerobic exercise in the HRV in mice exposed to cigarette smoke (CS). Methods: C57Bl/6 mice were divided in 4 groups: Control, Smoke, Exercise and Smoke/Exercise. Smoke groups were exposed to CS for 30min/day (twice), 5days/week for 12 weeks. Exercise groups were trained at moderate intensity for 60min/day, 5days/week for 12 weeks. HRV was measured at baseline and 2, 4, 6, 8, 10 and 12 weeks after the last CS exposure and/or AE session. HRV was measured by cuff (noninvasive tool) applied to the base of the mouse tail connected to PowerLab system. The following parameters were used: heart rate (HR), HRV for time domain (standard deviation of normal beats [SDNN] and root mean square of successive differences in the heart beat interval [RMSSD]) and frequency domain (low frequency [LF], high frequency [HF] and LF/HF ratio). Results: Exposure to CS decreased SDNN and RMSSD values after 6 weeks (p<0.001, compared to control group) where it remained until 10 weeks and AE attenuated this effect. Exposure to CS also decreased HF only after 6 weeks (p<0.01) compared to control group and this effect was reversed to AE training.

864s
Mitochondrial respiration (V'O_2 m) and ROS output before and after inhibition with rotenone (complex-I), malonate (complex-II) and antimycin-A (complex-III) were determined in mitochondria and submitochondrial fragments.

Results: V'O_2 m were 2.8±0.7 vs 7.2±0.5 mmol min^-1 kg^-1 (p<0.001) in COPD vs controls. H_2O_2 outputs by mitochondria oxidizing complex-I substrates were 51.6±130.35 pmol h^-1 mg^-1 (p<0.001) respectively or 0.8% and 2.1% of the V'O_2 m. While antimycin-A greatly increased (<7) H_2O_2 output both in mitochondria and submitochondrial particles in both groups, rotenone only did it in submitochondrial particles. In mitochondria H_2O_2 instead decreased H_2O_2 output as it did malonate, both upstream blockers of the electron flux to complex-III.

Conclusions: Only the ROS generated at complex-III are secreted by the mitochondria. We interpret that this is due to the spatial orientation of complex-I (towards the matrix) and III towards de intermembrane space), being in the first case largely neutralized by the antioxidant system of the mitochondrial matrix.

Iron deficiency as a novel biomarker of functional impairment in patients with chronic obstructive pulmonary disease (COPD)

Diego A. Rodríguez1, Josep Roca2, Alba Ramírez-Sarmiento1, Isabel Blanco2, Joaquim Gea3, Abel Barbera3, Jordi Vilaro4, Mauricio Orozco-Levi3, Neumología, Hospital Gregorio Marañón/Universidad Complutense de Madrid, Madrid, Spain; 2Medicina Interna, Hospital Gregorio Marañón/Universidad Complutense de Madrid, Madrid, Spain; 3Nefrología Experimental, Hospital Gregorio Marañón/Universidad Complutense de Madrid, Madrid, Spain; 4Neumología, Servicio Neumología (Hospital Clínico de Barcelona), Fundación Caubet-Cinerma and CIBER Enfermedades Respiratorias (CIBERES), Barcelona, Catalunya, Spain

Introduction: The role of iron deficiency (IrDe) on exercise intolerance has not been explored in patients with COPD. We hypothesized that IrDe could represent a potentially treatable factor in the functional impairment of COPD patients.

Methods: We evaluated 80 COPD patients (FEV1 1.3±1.5 pred; PaO2 71±11 mmHg; BMI 27±4 kg/m²) recruited at the outpatient consultation office of the Catharina Hospital in Eindhoven, Netherlands. Fe2+ was measured at the Gmelin laboratory index (FeMII) (81±15 vs. 100±6% pred., p<0.01) than those without iron deficiency. Accordingly, IrDe was associated with increased the risk of decreased ET (OR 4: 1.6; IC: 1.48-11.7; p = 0.007), and decreased 6MWD (OR de 3.82; IC: 1.22-8.81; p=0.018).

Results: Forty percent (n=32) of the patients showed IrDe. Iron deficiency did not show association with demographic or pulmonary function variables. But, patients with IrDe showed lower ET (226±25 vs. 362±31 sec, p<0.001), and lower 6MWD (159±119 vs. 209±101 m). In multivariate analysis of sex, age, smoking, and baseline measures of FEVI, RV/TLC-ratio, PatO2 and PaCO2 were analyzed as possible predictors for developing hypoxemia. We used both bivariate and multivariate Cox proportional hazards analyses, with the time from baseline normoxemia until the first event of hypoxemia (PaO2<8kPa) as a measure of event free time. 73 (18%) of the 401 patients were hypoxic at baseline and excluded from the analyses.

Conclusions: Within the three years of follow-up, a total of 46 patients (14%) developed hypoxemia. In bivariate Cox proportional hazards analyses, baseline FeVI, RV/TLC, FFMI, PaO2, and PaCO2 were significantly associated with developing hypoxemia. After multivariate Cox proportional hazards analyses, the following measures remained significantly associated with developing hypoxemia:

<table>
<thead>
<tr>
<th>Variable</th>
<th>HR (95% CI)</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>RV/TLC ratio</td>
<td>1.014 (1.003-1.025)</td>
<td>0.012</td>
</tr>
<tr>
<td>FeO2 (kPa)</td>
<td>0.220 (0.129-0.375)</td>
<td>0.000</td>
</tr>
<tr>
<td>FFMI (k/g)</td>
<td>0.907 (0.830-0.992)</td>
<td>0.020</td>
</tr>
</tbody>
</table>

Conclusion: High RV/TLC ratio, low PaO2, and low fat free mass index were predictors for developing hypoxic respiratory failure in a 3 years follow-up of COPD patients.
six-minute walk distance (6MWD) and score were also assessed to determine the BODE index. The average number of sunshine hours was also added.

The number of sunshine hours 2 months before blood sampling was determined using data from the Royal Netherlands Meteorological Institute.

Results: Vitamin D deficient patients had higher RV/TLC, lower pO2, worse 6MWD, higher BODE score and less sunshine hours.

BODE, points 2.2
6MWD, m 316
Modified MRC 0.6

Results:
for haemoglobin concentration.

The data are corrected
by excessive erythrocytosis, severe hypoxemia and occasionally pulmonary hyper-
tension, that may lead to exercise limitation. However, cardiac-pulmonary exercise test (CPET) parameters in this patient group have not been established yet.

Methods: 12 CMS, 14 healthy high- (HH) and 10 lowlanders (LL) were included

Conclusion: Patients with CMS have a preserved aerobic capacity with a ven-
tilatory response identical to LL at sea level but the ventilatory adaptation
decompared to HH and LL at altitude likely explained by preserved oxygen delivery because of increased hemoglobin. This study was supported by a grant from Pfizer.

491. Molecular: pathology of infectious and inflammatory lung disease

P4745
Induced sputum differential gene expression implicates increased p38 signalling activity in severe asthma
Katherine Baines1,2, Jodie Simpson1,2, Lisa Wood1,2, Rodney Scott3, Peter Gibson1,2,3
1Respiratory Medicine, The University of Newcastle, Newcastle, NSW, Australia; 2Respiratory and Sleep Medicine, Hunter Medical Research Institute, John Hunter Hospital, Newcastle, NSW, Australia; 3Information Based Medicine, The University of Newcastle, Newcastle, NSW, Australia

Rationale: There is an urgent need for further insight into the characteristics and classifications of severe asthma. A thorough understanding of the mechanisms underlying the disease processes is essential to this.

Objective: To investigate the mechanisms of severe asthma through differential gene expression and pathways analysis of sputum gene expression profiles.

Methods: Induced sputum was collected from participants with severe asthma (n=13), defined by the presence of poor asthma control (AQLC<1) or airflow ob-
striction (FEV1%predicted<80, FEV1/FVC<70), despite treatment with high-
dose inhaled corticosteroid (>1000μg) and long-acting β2-agonist, and compared to mild and moderate asthma (uncontrolled (n=21)) and controlled (n=21)) and healthy controls (n=13). Gene expression profiles were generated (Illumina HumanMetfall- V2) from sputum RNA and analysed using GeneSpring GX11.

Results: In severe asthma, 1236 genes were altered compared to healthy controls, and 1723 genes were altered compared to healthy controls. Only 48 genes were altered between uncontrolled and controlled asthma. There was enrichment of genes in the p38 signalling pathway associated with severe asthma compared to both controlled asthma and healthy controls. The transformation growth factor-β receptor, interleukin-2 and epidermal growth factor receptor 1 pathways were also enriched in severe asthma when compared to healthy controls.

Conclusions: Severe asthma is associated with substantial differences in sputum gene expression that underlie unique cellular mechanisms that are not just associ-
ated with loss of asthma control. The p38 signalling pathway may be important in the pathogenesis of severe asthma.

P4746
Sputum gene expression of mast cell tryptase and carboxypeptidase A3 are increased in eosinophilic asthma
Katherine Baines1,2, Jodie Simpson1,2, Lisa Wood1,2, Rodney Scott3, Peter Gibson1,2
1Respiratory Medicine, The University of Newcastle, Newcastle, NSW, Australia; 2Respiratory and Sleep Medicine, Hunter Medical Research Institute, John Hunter Hospital, Newcastle, NSW, Australia; 3Information Based Medicine, The University of Newcastle, Newcastle, NSW, Australia

Rationale: Little is known regarding the presence and activity of mast cells in the
Objective: To investigate if sputum gene expression of mast cell specific proteins may be associated with asthma inflammatory phenotype.

Methods: Induced sputum was collected from participants with asthma (n=59; eosinophilic n=17; neutrophilic n=12; mixed granulocytic n=12, and paucigranulocytic n=18) and healthy controls (n=17). Gene expression profiles were generated (Illumina Humanel-8 V2) from sputum RNA. Mast cell tryptase (TPSAB1), carboxypeptidase A3 (CTSA) and chymase (CMA1) data were extracted and investigated for their relationship to asthma phenotype.

Results: Gene expression of tryptase and carboxypeptidase A3 was significantly different among the 5 groups (p<0.0001). There was no difference in chymase expression. Tryptase mRNA was increased (p<0.01) in eosinophilic asthma compared to neutrophilic asthma, paucigranulocytic asthma and healthy controls. Carboxypeptidase A3 mRNA was increased (p<0.01) in eosinophilic asthma compared to neutrophilic asthma, mixed granulocytic asthma, paucigranulocytic asthma and healthy controls. Tryptase (r=0.58 p<0.0001) and carboxypeptidase A3 (r=0.59 p<0.0001) expression was strongly correlated with sputum eosinophils.

Conclusions: Gene expression of mast cell tryptase and carboxypeptidase A3 is increased in eosinophilic asthma. Airway mast cells are important in eosinophilic asthma and have a unique phenotype associated with expression of tryptase and carboxypeptidase A3 but not chymase.
TGF-β signaling in non-malignant pulmonary diseases to date is still controversially discussed. Nontypeable Haemophilus influenzae (NTHI) may play a role in the pathogenesis of chronic obstructive pulmonary disease (COPD) as an infectious trigger, but data are available regarding the influence of acute and persistent infection on tissue remodeling and repair factors such as transforming growth factor (TGF)-β. Here we show that the TGF-β pseudoreceptor BAMBI is expressed in the human lung. NTHI infection was analyzed in lungs obtained from COPD patients and controls utilizing a human ex vivo and in vitro models. Detection of NTHI was achieved by in situ hybridization (ISH). For characterization of TGF-β signaling, antibodies were conducted. Expression of the TGF-pseudoreceptor BMP and Activin Membrane-bound Inhibitor (BAMBI) was analyzed using immunohistochemistry (IHC), ISH and RT-PCR. CXC chemokine ligand (CXCL)8, tumour necrosis factor (TNF)-alpha and TGF-β expression were evaluated in lung tissue and cell culture using ELISA.

An infection with NTHI was detected in vivo in 38% of the COPD patients in contrast to 0% of controls. Transcriptome arrays showed no significant changes in TGF-β receptors 1 and 2 and Smad-3 expression, whereas a strong expression of BAMBI with upregulation after in vitro infection of COPD lung tissue was demonstrated. BAMBI was expressed ubiquitously on alveolar macrophages (AM) and epithelial cells interstitial cells (AEC).

We show for the first time a remarkable expression of the TGF-pseudoreceptor BAMBI in the human lung. BAMBI is upregulated in response to NTHI infection in COPD lung tissue in vivo and in vitro.

Elevated osteoprotein in COPD is potentially regulated by oxidative stress
dependent glycosyn synthesis kinase-3β and β-catenin signalling

Masako To, Catherine E. Charron, Sergei A. Khartonov, Peter J. Barnes, Kanzhara Io. Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom

We recently reported that spumus osteoprotein (OPG) in COPD is higher than that in controls and is a potential biomarker in COPD (To M et al. CHEST 2010 Dec 2 [Epub ahead of print]). However, the molecular mechanism involved in OPG elevation in COPD was not clarified yet. Here we investigated the role of glycosyn synthesis kinase-3β (GSK-3β) and β-catenin in OPG transcription, especially under oxidative stress.

A549 cells, an alveolar epithelial cell line, were treated with cigarette smoke condensate (CSM), and β-catenin protein was determined by western blot. CSM induced OPG release (measured by ELISA) with a maximum induction of 147% and also increased β-catenin protein expression in a concentration-dependent manner at 24h. A549 cells were transfected with β-catenin siRNA using lipofectamine for specific knockdown (KD) of β-catenin, and IL-1β-stimulated OPG production by the A549 cells was measured by ELISA. β-catenin KD led to lower OPG production when quantified using RT-PCR and western blot. Results: Exposure of 250μg/WT mice to cigarette smoke induced a significant overexpression of HIF-1 mRNA (p>0.03 vs. controls). Likewise, significant VHL mRNA and protein overexpression were elicited (p<0.0006 vs. controls). By contrast, VEGF mRNA expression was not altered (p>0.88).

Conclusion: The current results demonstrate VHL overexpression in skeletal mus-cles of normal mice exposed to CS. This is in analogy and further confirms our recent findings in skeletal muscles of COPD patients. Thus VHL overexpression appears to be an early primary event related to CS exposure rather than a secondary occurrence to development of the COPD pathology.
Adrenergic receptor blocker reverses cardiac metabolic remodeling and improves right ventricular function in experimental pulmonary hypertension

José Gomez-Arroyo1, Shiroy Mizuno1, Antonio Abbate2, Herman Bogaard3, Norbert Voelkel4, Pulmonary and Critical Care, Virginia Commonwealth University, Richmond, United States; 2Pulmonary Division, VU University Medical Center, Amsterdam, Netherlands

Albeit right ventricular failure (RVF) is a major complication in patients with pulmonary arterial hypertension, the knowledge on RVF of RVF is still incomplete and RV-targeted therapies are practically non-existent. Since a metabolic switch has been reported for left heart failure, we sought to describe any potential changes in cardiac fuel metabolism and mitochondrial function in RVF. PAH was induced in S-D rats by a combination of a VEGF-receptor blocker followed by 4 weeks of 10% hypoxia. G6PDH Gene expression was evaluated by RT-PCR and confirmed by western blot. T Tests were performed to determine whether spectra of the EXACTLE patients. T Tests were performed to determine whether

Results: Following neutrophil activation or the addition of NE to plasma 325 paired plasma samples from the EXACTLE trial, taken at baseline and following neutrophil activation by ionophore or the addition of neutrophil elastase (NE). 72 paired plasma samples from the EXACTLE trial were subsequently analysed using weak cation exchange beads and Mass spectrometry was used to identify proteolytic fragments in plasma samples. T Tests were performed to determine whether

Methods: As an initial step, we evaluated the expression of PGC1α, a master regulator of mitochondrial biogenesis. Sulfrx RV tissue had a high downregulation of PGC1α when compared to controls (p<0.001). PGC1α target genes were downregulated by fatty acid metabolism. Metabolism were decreased, whereas major glycolysis genes were upregulated. These changes strongly correlated with decreased TAPSE (r=0.77, p<0.001). Furthermore, Sulfrx RV tissue showed a downregulation of TFAM (a critical regulator for mtDNA maintenance) which was associated with abnormal mitochondrial morphology shown by electron microscopy. Carvedilol treatment, a drug known to improve RVF, completely restored

Introduction: Alpha-1-antitrypsin deficiency (ATD) results in an imbalance of proteases and antiproteases with proteolytic destruction of lung parenchyma, and subsequently early onset emphysema. We hypothesised changes in plasma peptides/proteins would be detectable and could provide potential biomarkers to predict a response to treatment in patients with ATD receiving augmentation therapy.

Methods: Mass spectrometry was used to identify proteolytic fragments in plasma following neutrophil activation by ionophore or the addition of neutrophil elastase (NE). 72 paired plasma samples from the EXACTLE trial taken at baseline and 6 months, were subsequently analysed using weak cation exchange beads and MALDI-TOF-MS, to determine whether any of the protein fragments generated in vitro were present in clinical samples and changed significantly in response to augmentation.

Results: Following neutrophil activation or the addition of NE to plasma 325 peptides from 32 proteins were identified. 207 peptide peaks were detected in the spectra of the EXACTLE patients. T Tests were performed to determine whether or not the peak intensities of the peptides changed with treatment. Of these, 12 were significantly different in the treatment group, yet unchanged in the placebo group. The most significant of these had a p value of 2.0E-05.

Conclusion: Changes in the plasma peptides can be found in patient plasma after the addition of calcium ionophore and NE. Some of these changes can be detected in plasma prep/post augmentation. We aim to use more in depth proteomic approaches to further characterise changes in the plasma peptideome, and determine clinical utility as a guide to monitoring and treatment in ATD.

TRP1 expression and characterisation in patients with chronic cough

Shouab Farragi1, Amy Mortier2, Division of Cardiovascular and Respiratory Medicine, Castle Hill Hospital, University of Hull, Cottingham, United Kingdom; 2Department of Histopathology, Hull Royal Infirmary, Hull, United Kingdom

Aim: The TRPA1 ion channel is thought to have an important role in the cough reflex. It has been shown that inhalation of cinnamaldehyde, a specific agonist of TRPA1, induces cough in normal human volunteers. We wanted to determine the expression and characterisation of the TRPA1 receptor in human lung tissue.

Methods: Bronchial biopsies were obtained from patients with the Cough Hyper-sensitivity Syndrome on fibre-optic bronchoscopy. Low-resistance samples were obtained from patients undergoing lung resection for lung cancer. Dorsal root ganglia were used as a positive control. These tissue samples were analysed by immunohistochemistry with a specific TRPA1 antibody.

Results: Samples from 14 patients (11 males, mean age 56 years) with the Cough Hypersensitivity Syndrome and 10 lung resection samples (6 males, mean age 68 years) were obtained. All the tissue samples stained for TRPA1. The TRPA1 stain was avidly taken up by the bronchial epithelium, smooth muscle bundles and nerve tissue.

Conclusion: We have described the distribution of TRPA1 ion channel in lung tissue. TRPA1 is agonised by several environmental irritants and endogenous mediators of inflammation. The presence of TRPA1 ion channel in bronchial mucosal nerves and epithelium suggests an important role in the cough reflex. The localisation of these ion channels on smooth muscle could suggest a role in asthmatic inflammation as well.

Expression of the Bcl-2 binding protein beclin 1 in human idiopathic pulmonary fibrosis

Davide Scozzi1, Salvatore Mariotti1, Emanuela Cherubini2, Vittorio Pietrageli3, Manuel Del Forno1, Luca Tabbi1, Lara Pisani1, Pierdonato Bruno1, Alberto Ricci1, 1Department of Medicine Clinica e Molecolare, Università la Sapienza, Roma, Italy; 2Centro Ricerche, Ospedale San Pietro, Roma, Italy

Autophagy is the main cellular route for degradation of long-lived proteins and cytoplasmic organelles and its dysregulation contributes to the pathogenesis of different systemic diseases. In fibroblasts in idiopathic pulmonary fibrosis (IPF) autophagy is decreased, whereas the anti-apoptotic protein Bcl-2 was overexpressed in IPF tissue. The binding of the anti-apoptotic protein Bcl-2 with a key regulator of autophagy Beclin 1 is thought to have an important role in the development of this disease. In some settings it seems to be interconnected with apoptosis. In this regard the binding of the anti-apoptotic protein Bcl-2 with a key regulator of autophagy as Beclin 1 seems to be down-regulated both apoptosis and autophagy. It is known that fibroblasts in idiopathic pulmonary fibrosis (IPF) acquire resistance to apoptosis but no data are available about the regulation of autophagy in IPF. Here we examined the expression of Beclin 1 and Bcl-2 in human IPF fibroblasts before and after cisplatin exposure. We performed immunohistochemistry for Beclin 1 on sections of lung biopsies obtained from patients affected with IPF (n=25) histologically normal (n=5) or with emphysema (n=5). In 4 IPF, 2 normal and 2 emphysema the tissue was used to isolate lung fibroblasts. We performed Western Blot analysis and co-immunoprecipitation for Bcl-2 and Beclin 1 on cultured fibroblasts before and after cisplatin exposure.

Expression of Beclin 1 in fibroblasts from IPF was down-regulated in comparison with normal and emphysema while the anti-apoptotic protein Bcl-2 was over-expressed. Treatment of fibroblast cell cultures with cisplatin induced a significant increase in Beclin 1 but a reduction in Bcl-2 expression in IPF fibroblasts. The immunoprecipitation of Bcl-2 and the following immunodetection of Beclin 1 indicate that Bcl-2 is mainly bound to Beclin 1. The modulated expression of Beclin 1 and Bcl-2 in human IPF fibroblasts in comparison with normal ones seems to suggest the possibility of an autophagic/apoptosis system dysfunction.

B6401

492. Bronchoalveolar lavage and biomarkers in diffuse parenchymal lung disease

Methods: For in vivo inhibition of miR-20a, antagomiR-20a (A-20a) was injected intraperitoneally into mice with hypoxia-induced PH. After three weeks of hypoxia, morphometry and blood gas analysis were performed. RNA levels of miR-20a, BMPR2, Smad5, and Id2 were assessed by real-time PCR in heart and lungs.

Results: Intraperitoneal injection of A-20a resulted in significant down regulation of miR-20a in lungs. When exposed to hypoxia, animals treated with A-20a developed a similar pulmonary hypertrophy induced by relative heart enlargement. Treatment with A-20a reduced the hemoglobin levels and, moreover, the acid-base status (base deficit) approached the baseline values of normoxic animals. Molecular analysis showed down regulation of BMPR2 mRNA levels in lung tissue by hypoxia (0.79±0.24 fold, p=0.039). A-20a abrogated the hypoxia induced down regulation of BMPR2 and led to significant up regulation of BMPR2 (1.62±0.18 fold, p<0.001). We detected increased expression of Smad5 (1.29±0.19 fold, p=0.003) and the BMP target gene Id2 (1.43±0.40 fold, p=0.02) in lung tissue of A-20a treated mice suggesting improved BMP signaling.

Conclusion: Our data underpin the importance of miR-20a in the BMP signaling and emphasize the need for further studies to address the therapeutic potential of antagonismRs for the human disease.

Plasma protein profiling in alpha-1-antitrypsin deficiency

Helen Stone1, Douglas Ward2, Robert Stockley3, 1ADAPT Project/Department of Lung Function and Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; 2ADAPT Project/Department of Lung Function and Sleep, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; 3ADAPT Project/Department of Lung Function and Sleep, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom

Overexpression of matrix metalloproteinase-7 (MMP-7) in bronchoalveolar lavage fluid (BALF) of IPF and lung cancer patients

Katerina Samara1, Ioannis Giannarakis1, Ismini Papanikoalou2, Irini Lambiri1, Konstantinos Tzinos1, Vassilis Pappas1, Nikos Siafakas3, Katerina Antoniou4, 1Thoracic Medicine, Medical School, University of Crete, Heraklion, Greece; 2Laboratory of Molecular and Cellular Biology, Medical School, University of Crete, Heraklion, Greece

It is long recognised that lung cancer has an increased frequency in idiopathic pulmonary fibrosis and is associated with abnormal mitochondrial morphology shown by electron microscopy. Carvedilol treatment, a drug known to improve RVF, completely restored
pulmonary fibrosis (IPF), raising questions regarding the similarity of IPF and lung cancer biology. Matrix metalloproteinases regulate remodelling of the extracellular matrix, an important function for pathological processes such as angiogenesis, tissue repair and tumor invasion. Our aim is to assess the expression of this pathway in BALF samples of lung cancer patients and compare with IPF patients to examine possible pathogenetic links between these two lethal pulmonary diseases.

We prospectively studied 23 newly diagnosed patients, with non small cell lung cancer (NSCLC), 10 IPF patients and 10 healthy controls (C). MMP2, MMP7, MMP9, TIMP1 and TIMP2 mRNA expression levels were measured in BALF by real time RT-PCR. MMP7 protein levels were measured in BALF supernatants using ELISA kit.

mRNA expression of MMPs 2, 7, 9 and TIMP1 was significantly increased in lung cancer compared to controls (p<0.05). The IPF population showed decreased expression of the aforementioned MMPs in comparison with lung cancer while did not show significant difference at the mRNA level in comparison to controls. MMP7 protein levels (pg/ml) were significantly higher in both NSCLC and IPF populations compared to controls (NSCLC: 24.69±4.18, IPF: 18.85±2.11, C=9.76±1.92, with p values: NSCLC vs C p=0.032, IPF vs C p=0.005).

Increased expression of MMP-7 in both m-RNA and protein level may suggest a common mechanism between lethal disorders. Given that our populations were not matched, the over-expression of these markers could be predictive of tumor progression, migratory behaviour and metastasis potential.

P4762
Expression profiling of Th17 cell activators revealed elevation of STAT-3 in progressing sarcoidosis
Regina Fillírová1, Eva Kriegova1, Tereza Tomankova1, František Mrázek1, Monika Ziková2, Vitezslav Kolek2, Martin Petrek2, 1Laboratory of Immunogenomics, Institute of Molecular and Translational Medicine, Medical Faculty of Palacky University and University Hospital, Olomouc, Czech Republic; 2Department of Pulmonary Diseases and Tuberculosis, Medical Faculty of Palacky University and University Hospital, Olomouc, Czech Republic.

Sarcoidosis is a Th1/Th17 multisystem inflammatory disorder of unknown aetiology. Although Th17 cells have been implicated in sarcoidosis and its progression, there is limited information about the molecules involved in the Th17 immune response in sarcoidosis and its phenotypes.

We, therefore, investigated mRNA expression of Th17 pathway activators (IL-6, IL-21, IL-23, TGFbeta, RORC) in BAL cells irrespective of clinical phenotype. Enhanced expression of STAT-3, an essential regulator of Th17 cells, was detected in progressing sarcoidosis (p<0.0001). Expression of STAT-3 was significantly higher in both NSCLC and IPF groups compared to controls (NSCLC: 24.69±4.18, IPF: 18.85±2.11, C=9.76±1.92, with p values: NSCLC vs C p=0.032, IPF vs C p=0.005).

In conclusion, increased expression of Th17 activators (IL-6, IL-21, IL-23, TGFbeta, RORC) was observed in sarcoid BAL cells irrespective of clinical phenotype. Increased expression of Th17 activators (IL-6, IL-21, IL-23, TGFbeta, RORC) was observed in sarcoid BAL cells irrespective of clinical phenotype.

P4764
Characterization of myofibroblasts cultured from small volumes of diagnostic bronchoalveolar lavage fluid samples
Ritika Kaartteeno1, Henna Karvonen1, Terttu Harja1, Raija Sormunen2, Elisa Lappi-Bianco1, Meeri Keininen1, Heta Menkalä1, Sari Lehtonen1, 1Department of Medicine, Respiratory Research Unit, Oulu University Hospital, Oulu, Finland; 2Biocenter Oulu, University of Oulu, Oulu, Finland.

Myofibroblasts are supposed to have a key role in pathogenesis of fibrotic lung diseases. Our aim was to standardize process for culturing cells from small volumes of diagnostic bronchoalveolar lavage (BAL) fluid samples and to characterize the cultured cells. Small volumes of BAL samples were collected from 98 patients that underwent bronchoscopy and BAL for diagnostic purposes. Cells were visualized by electron and immunoelectron microscopy. Proliferation and invasion capacities as well as stem cell properties of the cells were evaluated. Colonies of proliferating fibroblast type cells could be seen in 62% of samples. The success rate varied significantly based on the disease being 92% in idiopathic pulmonary fibrosis (IPF), 80% in non-specific interstitial pneumonia, 80% in collagen vascular disease associated interstitial lung disease, 62% in asbestosis, 55% in sarcoidosis, 100% in allergic alveolitis, 80% in drug reaction, 40% in lung cancer and 25% in normal lung. The success was not dependent on volume or cell amount of the BAL sample. The cultured cells were either fibroblasts or myofibroblasts. Typical features of myofibroblasts were detectable in the cells by electron and immunoelectron microscopy. Some cell samples exhibited differentiation potency into osteoblasts or adipocytes. The invasion capacity varied in different disorders. Myofibroblasts could be cultured from small volumes of diagnostic BAL fluid samples. This method could increase the usability of BAL fluid both in diagnostics of interstitial lung diseases and in scientific research.

P4765
Mechanisms of impaired immune surveillance in lower airways of smokers.

Data from bronchoalveolar lavage (BAL) harvested in selected interstitial lung diseases (ILDs) and control group

Piotr Kopinski1, Andrzej Dyczek2, Grzegorz Przybylski1, Barbara Balicka-Slusarczyk1, Agnieszka Jarzemska3, Tomasz Wandtke1, Ewelina Pölgesek1, Magda Igielska1, 1Dept of Gene Therapy, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland; 2II Dept of Internal Medicine, Centre of Immunological Diseases, Collegium Medicum, Jagiellonian University, Kraków, Poland; 3Dept of Lung Diseases and Tuberculosis, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland; 4Dept of Toxicology and Environmental Diseases, Collegium Medicum, Jagiellonian University, Kraków, Poland.

Background: Cigarette smoke is recognized as a cause of lung tumors, due to its carcinogenic potential. Less is known about suppressed local immune surveillance.

Methods: Alveolar lymphocytes (AL) were obtained by bronchoalveolar lavage (BAL) in pulmonary sarcoidosis (PS), idiopathic pulmonary fibrosis (IPF), non-specific interstitial pneumonia (NSIP) and control group (C) by BAL. The cultured cells were either fibroblasts or myofibroblasts. Typical features of myofibroblasts were detectable in the cells by electron and immunoelectron microscopy. Some cell samples exhibited differentiation potency into osteoblasts or adipocytes. The invasion capacity varied in different disorders. Myofibroblasts could be cultured from small volumes of diagnostic BAL fluid samples. This method could increase the usability of BAL fluid both in diagnostics of interstitial lung diseases and in scientific research.

Conclusions: The decreased immune surveillance in smokers lower airways include higher AL apoptosis rate and increased AL susceptibility to TGFβ. The decreased immune surveillance in lower airways of smokers.

Results: AL apoptosis rate was reduced in PS (0.7±0.2%, p<0.05) and increased in IPF (2.3±1.0%, p<0.05) as compared to nonsmokers. IFNγ levels were lower in all smoking subgroups than in respective nonsmokers. No changes were found in TNFα and TNF levels, but AL expression of TGFβ1 and TNF (CD105a) receptors was higher in smoker subgroups (significant for CD105a in IPF and CD102a in PS).

Conclusions: The decreased immune surveillance in smokers lower airways include higher AL apoptosis rate and increased AL susceptibility to TGFβ. The decreased immune surveillance in lower airways of smokers.
P4766
Expression of transforming growth factor β (TGFβ) receptor, CD105, is declined in Th1 interstitial lung diseases (ILDs)

Andrzej Drelich1, Terry Szczeklik2, Barbara Balicka-Shasseyczyk2, Joanna Chorostowska1, Adam Szpechcinski1, Ewelina Półgesek3, Marek Jankowski1, Piotr Kopinski4. 1II Dept of Internal Medicine, Centre of Immunological Diseases, Collegium Medicum, Jagiellonian University, Kraków, Poland; 2Dept of Toxicology and Environmental Diseases, Collegium Medicum, Jagiellonian University, Krakow, Poland; 3Laboratory of Molecular Diagnostics and Immunology, Institute of Tuberculosis and Lung Diseases, Wieszanowa, Poland; 4Dept of Gene Therapy, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, Poland

Background: TGFβ, as the most potent activator of lung fibrosis, stimulates fibroblast proliferation and induces secretion of collagen and other extracellular matrix proteins. It reveals its profibrotic effect by receptor complex, including CD105 molecule.

Methods: TGFβ levels was examined by ELISA in bronchoalveolar lavage (BAL) supernatants. CD105 expression was tested on BAL macrophages and lymphocytes in pulmonary sarcoidosis, (n=16), idiopathic pulmonary fibrosis (IPF, n=9), non-specific interstitial pneumonia (NSIP, n=6) and extrinsic allergic alveolitis (EAA, n=7). CD105 appearance was also assessed in model lung cell lines: pneumocytes type 2 (A549) and fibroblasts (HLF-1).

Results: IF was the only disorder with significantly increased TGFβ level. CD105 expression is common on HLF-1 (98%), A549 (63%, median of 5 trials) and alveolar macrophages. In PS significantly decreased CD105 expression on BAL lymphocytes was found (all lymphocytes: 7.2±0.6%, Th cells: 4.6±0.4%, Tc cells: 1.8±0.3%, resp. control values: 13.3±4.3, 6.6±2.6% and 4.7±1.1%, median±SEM, p<0.05). Similar results were observed in EAA. IF was characterized by remarkably enhanced BAL CD105 lymphocyte percentage (all lymphocytes: 23.9±5.8%, p<0.05).

Conclusions: TGFβ receptor, CD105, is frequently present in lower airways. Lower BAL CD105+ lymphocyte percentage in IF, and higher one in PS and EAA may reflect different Th1/Th2 polarization pattern. Summarizing, the key role of diverse lower airway cell reactivity to TGFβ in ILDs should be considered.

P4767
Proteological assessment of idiopathic pulmonary fibrosis and hypersensitivity pneumonitis by means of broncho-alveolar lavage

Stijn Willems, Jana Somers, Stijn E. Verleden, Geert M. Verleden, Jonas Yserbyt, Yves Beulemans3, Dishan Pujar1,2, David Herijgers1,2,3.
1II Department of Internal Medicine, Centre of Immunological Diseases, Collegium Medicum, Jagiellonian University, Krakow, Poland; 2Dept of Toxicology and Environmental Diseases, Collegium Medicum, Jagiellonian University, Krakow, Poland; 3Laboratory of Molecular Diagnostics and Immunology, Institute of Tuberculosis and Lung Diseases, Wieszanowa, Poland

Background: The diagnostic strategy of the drug-induced lung disease (DILD) has not been established. It remains to be determined whether the lymphocyte transformation test (LTT) can be used for the diagnosis of DILD. Although bronchoalveolar lavage (BAL) is often performed, its usefulness in the diagnosis of DILD is still uncertain.

Introduction and aims: We aimed to evaluate the diagnostic values of BAL and LTT in patients with DILD.

Method: We retrospectively analyzed 47 patients who were suspected as DILD and underwent BAL and LTT between January 2004 and September 2009. The total cell number and the differential count of leukocytes in BAL fluid were determined. The levels of cytokines (eotaxin-1, -2, -3, and RANTES) in the supernatant were measured by ELISA. It was also evaluated whether these parameters were useful for the diagnosis of DILD.

Results: The diagnostic sensitivity and specificity of LTT were 50% and 60%, respectively. These numbers were comparable to those in previous reports. The diagnostic value of LTT in IPF was 90%, and the specificity was 22%. The sensitivity of increased eosinophils (>5%) in BAL fluid was 90%, and the specificity was 22%. These numbers were comparable to those in previous reports. The diagnostic sensitivity and specificity of LTT were 50% and 60%, respectively. These numbers were comparable to those in previous reports. The diagnostic value of LTT in IPF was 90%, and the specificity was 22%

Conclusions: We speculated that BAL fluid findings, especially the differential count of leukocytes, may be useful for the diagnosis and the prediction of outcome of the patients with DILD.

P4769
Clinical and functional features in idiopathic pulmonary fibrosis (IPF) with and without haemosiderin-laden alveolar macrophages on BALF

Carolina Vitale, Emanuela Carpentieri, Francesco Perna, Manuela Pitassi, Antonio Molino, Anna Stanzola, Matteo Soila. Dept Respiratory Diseases, University Federico II Naples, Naples, Italy

We have previously reported increased frequency of haemosiderin-laden alveolar macrophages in patients with IPF. We performed a retrospective analysis of 49 patients who received diagnosis of IPF. The diagnostic value of IF was in agreement with the ATS/EERS guidelines. BALF was performed in all subjects. We evaluated the occurrence of haemosiderin-laden alveolar macrophages in patients with IF.P. Patients with a history of smoking were excluded. BALF was performed in all subjects and underwent BAL and LTT between January 2004 and September 2009. The total cell number and the differential count of leukocytes in BAL fluid were determined. The levels of cytokines (eotaxin-1, -2, -3, and RANTES) in the supernatant were measured by ELISA. It was also evaluated whether these parameters were useful for the diagnosis of DILD.

Results: The diagnostic sensitivity and specificity of LTT were 50% and 60%, respectively. These numbers were comparable to those in previous reports. The diagnostic value of LTT in IPF was 90%, and the specificity was 22%

Conclusions: We speculated that BAL fluid findings, especially the differential count of leukocytes, may be useful for the diagnosis and the prediction of outcome of the patients with DILD.

P4770
Differential cell count in BAL by flow cytometry using CD15

Andrés M. Ochoa1,2, Alex Díaz-Cedillo1,3, Dyfri Williams4, David A. Fletcher1,3, Vanessa G. Montes1,3, Christiana B. Grumbles1,3, Jorge C. Papiernik 1,3, Oscar A. B. da Silva1,3, Laura J. K. de Souza1,3, Bret E. Thille1,3, Jay C. Yee1,3, Diana L. Belevacq1,3, Juan Carlos Godoy1,3, Jose M. Angeletti1,3, 1Respiratory Medicine, INS. Hosp. Central de Asturias, Oviedo, Spain; 2Immunology, Hosp. Central de Asturias, Oviedo, Spain; 3Biochemistry, INS. Hosp. Central de Asturias, Oviedo, Spain

Introduction: Usually inflammatory cell counts in bronchoalveolar lavage (BAL) are done manually on optical microscopy (OM) despite the high intra- and interobserver variability. The object was to compare inflammatory cell counts performed by OM with these counts by flow cytometry (FC) with a new combination of monoclonal antibodies.

Conclusion: Differences for aforementioned mechanisms were observed in IF and HP compared to control, as well as discriminating factors between IF and HP. These results highlight the role of BAL in the search for new biomarkers and therapies for pulmonary fibrosis.
Methods: 34 BAL samples were analysed in a 2-laser cytometer (FACS Calibur). The results were compared with those obtained by optical microscopy. The proposed combination of monoclonal antibodies identified two leukocyte subsets as CD45+ cells and lymphocytes as CD16−, CD14+ (NK lymphocytes), HLA-DR− and HLA-DR+ (B cells and activated lymphocytes) cells; neutrophils as CD15+CD66b−, CD16+CD66b−, HLA-DR− cells; eosinophils as CD15+CD66b−, CD16−, HLA-DR− cells and alveolar macrophages as CD14+CD16−. Macrophages' autofluorescence (AF) was overcome using the monoclonal antibody anti-HLA-DR conjugated with the dye APC as the main identification marker. Results: Flow cytometry showed high correlations (r=0.70 to 0.93; p<0.001) but FCM overestimates lymphocyte population +13 (15.6%), and conversely underestimates alveolar macrophage population −15.9 (16.6%). Conclusions: The monoclonal antibodies combination proposed is effective and reliable to identify leukocyte populations in BAL. The process is simpler and faster than manual optical microscopy but some differences in macrophages and lymphocytes counts should be considered.

P4771

LSC 2011 Abstract: Bronchoalveolar lavage in radiation pneumonitis after radiotherapy for breast cancer
Claudia Lucia Toma, Aneta Serbescu, Mihai Alexe, Luminita Cervis, Diana Ionita, Miron Alexandru Bogdan. Pneumonology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2Pneumonology, Marius Nasta Institute of Pneumonology, Bucharest, Romania

Radiotherapy pneumonitis is a complication of radiotherapy which limits its application in cancer therapy. Aim: To compare the bronchoalveolar lavage (BAL) findings in patients with symptomatic radiation pneumonitis (RP) versus asymptomatic patients and healthy controls. Material and method: We evaluated 65 female patients with RP after radiotherapy for breast cancer.

Results: Forty-nine patients were symptomatic (fever, cough and/or dyspnea) and 16 were asymptomatic. All patients had a newly discovered infiltrate or ground-glass opacities in chest radiography, corresponding to the radiation field. BAL in symptomatic patients had an increased number of cells.

Lymphocytosis was present in all patients with RP, but it was higher in symptomatic patients (34.9±18.81% vs. 26.14±14.3%). Macrophages were decreased in all patients. Neutrophils were slightly increased (8.88% in symptomatic and 3.34% in asymptomatic) and eosinophils were normal in both groups (2.56% and 1.22, respectively). Almost all lymphocytes were T type (CD3+). CD4+ lymphocytes were increased in both groups with normal CD4/CD8 ratio (2.72 in symptomatic and 1.5 in asymptomatic group).

Conclusions: Lymphocytic alveolitis with T lymphocytes was present in all patients with RP with a higher proportion in symptomatic patients.

P4772

Detection of differences in volatile organic compounds (VOCs) by ion mobility spectrometry (IMS) of exhaled breath in patients with interstitial lung diseases (ILDs) compared to healthy controls (HC)
Olaf Anhenn, Thomas Rabis, Lurc Rad, Gerhard Weinreich, Helmut Teschler, Ulrich Costabel.

Aim and objective: To compare the bronchoalveolar lavage (BAL) findings in patients with symptomatic radiation pneumonitis (RP) versus asymptomatic patients and healthy controls. Material and method: We evaluated 65 female patients with RP after radiotherapy for breast cancer.

Results: Forty-nine patients were symptomatic (fever, cough and/or dyspnea) and 16 were asymptomatic. All patients had a newly discovered infiltrate or ground-glass opacities in chest radiography, corresponding to the radiation field. BAL in symptomatic patients had an increased number of cells.

Lymphocytosis was present in all patients with RP, but it was higher in symptomatic patients (34.9±18.81% vs. 26.14±14.3%). Macrophages were decreased in all patients. Neutrophils were slightly increased (8.88% in symptomatic and 3.34% in asymptomatic) and eosinophils were normal in both groups (2.56% and 1.22, respectively). Almost all lymphocytes were T type (CD3+). CD4+ lymphocytes were increased in both groups with normal CD4/CD8 ratio (2.72 in symptomatic and 1.5 in asymptomatic group).

Conclusions: Lymphocytic alveolitis with T lymphocytes was present in all patients with RP with a higher proportion in symptomatic patients.

Serum napsin A is a novel diagnostic and monitoring marker for interstitial lung disease
Takuya Yamakawa, Tsumoto Hamada, Kousuke Inoue. Department of Pulmonary Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan

Background: Idiopathic Pulmonary Fibrosis (IPF) is a progressive, fatal lung disease of unknown etiology still lacking of effective therapy. IPF has a poor prognosis with a median survival of 2.5-3.5 years, and it is associated with lung cancer with a prevalence ranging from 4.8% to 46%. Molecular mechanisms of carcinogenesis occurring in IPF remain to be clarified.

Aim and objective: The family of emrin/adrinin/moerin (ERM) proteins is essential for maintenance of cell shape, cell adhesion, migration and division, serving as an important cross-linker between the plasma membrane and cytoskeleton. Recent studies showed that ERM is upregulated in multiple types of metastatic cancers. In the current investigation, we tested the hypothesis that ERM interacts and phosphorylates in a key role in epithelial-mesenchymal transition (EMT) in alveolar epithelial cells.

Methods: In order to identify the relationship between lung cancer and IPF we assessed an immunohistochemistry analysis for phospho-ERM in the following pulmonary biopsy specimens: 20 IPF/1 UIP, 4 adenocarcinoma, 6 cryptogenic organizing pneumonia (COP), and 4 normal controls.

Results: Our preliminary data showed in normal lung samples a totally negative phospho-ERM immunostaining. We found a weak positivity in COP samples, whereas in UIP samples we found a higher global expression, in particular in activated type II pneumocytes and basal bronchiolar cells.

Conclusion: We hypothesize that activation of ERM proteins could be involved in UIP pathogenesis, leading to possible contribution to the EMT process of lung epithelial cells.

Conclusions: Lymphocytic alveolitis with T lymphocytes was present in all patients with RP with a higher proportion in symptomatic patients.
P4776 Elevation of serum tumor markers in patients with interstitial lung disease Jiquan Liu1, Haoping Dai1, Longkai Liang1, Liying Peng1, Jing Yang2,1Respiratory Medicine, Beijing Chaoyang Hospital; 2Department of Capital Medical University; Beijing Institute of Respiratory Medicine, Beijing, China.

The risk of lung cancer is high in patients with interstitial lung disease (ILD). It was reported that tumor markers was increased in ILD patients. The serum levels of CEA, CA19-9, CA125 andNSE were measured in 58 ILD combines lung cancer (ILD-CA) patients, 632 ILD patients and 632 control subjects. The analysis of covariance, multiple linear regression, Logistic regression analysis and analysis of variance were used for statistical analyses. The serum levels of CEA, CA19-9, CA125 and NSE were higher in ILD-CA patients than the control group (P<0.01). They were higher in patients with ILD-CA than those in patients with ILD and control (P<0.05). The levels of CEA and CA125 in ILD group were higher than the control group (P<0.01). The ILD group included idiopathic pulmonary fibrosis (IPF) subgroup of 214 cases, non-IPF idiopathic interstitial pulmonary (non-IPF-ILD) subgroup of 97 patients, collagen vascular disease associated ILD (CVD-ILD) subgroup of 163 cases, and other ILD subgroup of 158 cases. The serum levels of CEA, CA19-9 and CA125 were the highest in patients with IPF than the other three subgroups of ILD (P<0.01). Adjusting the confounding factors such as gender, age and smoking condition, the risk of CVD-ILD increased with the elevation of CEA and CA125. This study provides that the elevation of serum tumor markers in patients with ILD-CA is a common sign, and is also an important sign in patients with ILD, especially in patients with IPF. Incidence of lung cancer is increased in ILD patients with elevation of the serum levels of CEA and CA125.

P4777 Interferon-γ or azathioprine plus corticosteroids do not alter the expression of apoptotic markers in alveolar macrophages of patients with IPF Fotios Drakopoulos1, Ateni Xyteri1, Evangelos Tsiambas1, Fotios Drakopoulos1, Atenis Xyteri1, Evangelos Tsiambas1,2

Aim: To examine the expression of apoptotic proteins in AM of patients with IPF after therapeutic intervention.

Methods: Twenty newly diagnosed IPF patients were randomised in Group A treated by a combination of interferon-γ1b and prednisolone and group B treated by azathioprine and prednisolone. Groups were compared regarding clinical deterioration, lung function, and bronchoalveolar lavage (BAL) apoptosis markers. We analyzed by immunohistochemistry, the expression of the anti-apoptotic markers bcl-2 and the pro-apoptotic markers bax, fas, fag ligand in AM obtained from BAL before and after treatment. We measured apoptosis by TUNEL.

Results: No difference was observed regarding age, gender, smoking habit between the two groups of IPF patients. The patients of both groups had similar FEV1, FVC and DLCO values at entry and after six months of treatment. We found no difference in the expression of apoptotic markers in AMs before and after treatment between groups. We found no correlation between clinical and functional parameters and change in apoptotic markers.

Conclusions: We specifically examined the expression of apoptotic markers in AMs of patients with IPF and we report that different treatment options do not affect the expression of these markers in IPF. These results may be related to the ineffectiveness of pharmacological therapies for IPF.

P4778 Reliability of ATS/ERS criteria for the diagnosis of idiopathic pulmonary fibrosis Shinichiro Ohshima1,2, Francesco Bonella1, Koichi Tanigawa2, Nobukiyo Kehno3, Jousue Guzman4, Ulrich Costabel1, 1Department of Pneumology/Allergy, Ruhrlandklinik, University Hospital, Essen, Germany; 2Department of Emergency and Critical Care Medicine, Hiroshima University, Hiroshima, Japan; 3Department of Molecular and Internal Medicine, Hiroshima University, Hiroshima, Japan; 4General and Experimental Pathology, Ruhr-University Bochum, Bochum, Germany.

Background: The 2002 ATS/ERS Consensus Classification has been widely accepted as the standard classification for interstitial lung diseases (ILD). However, the diagnostic accuracy of the major/minor criteria in the ATS/ERS Classification for idiopathic pulmonary fibrosis (IPF) is still controversial.

Aims and objectives: To evaluate the reliability of the major/minor criteria in the ATS/ERS Classification for IPF.

Methods: Patients with ILD admitted to Ruhrlandklinik (Essen, Germany) were retrospectively studied. All patients presenting with an insidious onset and a duration of illness >3 months were included. Because of the concept that the exclusion of known causes for ILD is not always easy, we also enrolled patients with secondary ILD (dust/drug exposure or CVD-associated). The diagnostic accuracy of the major/minor criteria for IPF was estimated.

Results: A total of 163 patients with suspected ILD were studied. The final diagnoses of the enrolled patients were IPF (n=82), other IIP (n=42) and secondary ILD (n=39). In the univariate analysis, the p-value of the criteria (%VC<80%,%TLC<80%,%DLCO<80%, A-aDO2>35mmHg, PaO2<60mmHg, typical findings for IPF in HRCT, BAL lymphocytosis <30% age, 50, and bibasilar crackles) for the diagnosis of IPF were 0.04, 0.94, 0.65, 0.08, 0.29, <0.0001, 0.0001, 0.0001, 0.97, and 0.0015, respectively. In the multivariate analysis, the typical findings for IPF on HRCT and BAL lymphocytosis <30% (p=0.0001) showed significant diagnostic significance for IPF.

Conclusions: Typical findings for IPF in HRCT and BAL lymphocytosis <30% were of diagnostic significance for IPF.
Background: Nasal nitric oxide (n-NO) has been suggested as a screening test for primary ciliary dyskinesia (PCD) as patients with PCD have lower n-NO levels than healthy controls. Recent studies on n-NO in PCD and secondary ciliary dyskinesia (SCD) show an overlap between these two groups.

Methods: n-NO was measured in duplicate by aspiration at 5 mL/s with NBOX 5 (Novo Nordisk, Denmark) in 21 patients with clinical diagnosis of PCD (7 male, 14 female, age 14.8 ± 10.2 years) and 20 healthy control subjects (7 male, 13 female, age 15.1 ± 11 years). The control group was recruited from healthy individuals consuming a normal diet in the hospital cafeteria or employees of the hospital. The use of asthma medications, respiratory infections, and nasal allergy medications were recorded.

Results: n-NO levels were significantly lower in the PCD group than in healthy controls (4.4 ± 2.2 ppb vs 2.6 ± 1.9 ppb, p=0.006). Both bronchial (p=0.0016) and alveolar FENO (p=0.017) were positively correlated with Crohn’s Disease Activity Index (CDAI).

Conclusions: Our results for bronchial and alveolar FENO confirm subclinical pulmonary involvement in Crohn’s disease. FENO may be of clinical value during follow-up of these patients as a surrogate marker of systemic inflammation.

P4782 Can nasal-NO be used to differentiate between primary and secondary ciliary dyskinesia? 
Christina Krantz1, Andrei Malinovischii2, Annika Hollings1, Kjell Alving1, 2
1Women and Children’s Health, Uppsala University Hospital, Uppsala, Sweden; 2Medical Sciences, Clinical Physiology, Uppsala University Hospital, Uppsala, Sweden

Background: Nasal nitric oxide (n-NO) has been suggested as a screening test for primary ciliary dyskinesia (PCD) as patients with PCD have lower n-NO levels than healthy controls. Recent studies on n-NO in PCD and secondary ciliary dyskinesia (SCD) show an overlap between these two groups.

Methods: n-NO was measured in duplicate by aspiration at 5 mL/s with NBOX 5 (Novo Nordisk, Denmark) in 21 patients with clinical diagnosis of PCD (7 male, 14 female, age 14.8 ± 10.2 years) and 20 healthy control subjects (7 male, 13 female, age 15.1 ± 11 years). The control group was recruited from healthy individuals consuming a normal diet in the hospital cafeteria or employees of the hospital. The use of asthma medications, respiratory infections, and nasal allergy medications were recorded.

Results: n-NO levels were significantly lower in the PCD group than in healthy controls (4.4 ± 2.2 ppb vs 2.6 ± 1.9 ppb, p=0.006). Both bronchial (p=0.0016) and alveolar FENO (p=0.017) were positively correlated with Crohn’s Disease Activity Index (CDAI).

Conclusions: Our results for bronchial and alveolar FENO confirm subclinical pulmonary involvement in Crohn’s disease. FENO may be of clinical value during follow-up of these patients as a surrogate marker of systemic inflammation.
EBT was recorded with a breath thermometer (X-Halo, Delmedica Investments Ltd, Singapore), spirometry was done, patients completed the COPD Assessment Test (CAT) and the first spontaneous sputum in the morning was collected and processed (Yamamoto C et al. Chest 1997). Paired t-test and Spearman correlation were used.

**Results:** EBT at exacerbation was higher compared to that at recovery (34.42±0.73°C vs. 34.03±0.50°C, p<0.03). Sputum neutrophil percentage at exacerbation showed a positive correlation with EBT (r=0.78, p<0.02), and fell after treatment (57.12% vs. 39.1±18%, p<0.04). EBT at exacerbation was not related to spirometric variables or CAT score.

**Conclusion:** EBT rises at acute exacerbation of COPD and it is associated with increased airway inflammation. Measuring exhaled breath temperature might be useful for monitoring airway inflammation in COPD.

The study was supported by Hungarian Respiratory Society grants (to Zsófia Lázár) and OTKA 68808.

Neutrophilic airways inflammation in lung cancer: The role of exhaled LTB-4 and IL-8

Giovanna E. Carpagnano, Donato Lacedonia, Pierluigi Bonfitto, Stefano Notarangelo, Mariella Grimaldi, Gianluca Ciliberti, Maria P. Foschino Barbaro.

**Occupational and Medical Sciences, Section of Respiratory Diseases, University of Medicine, Foggia, Italy**

Recent advances in lung cancer biology presuppose its inflammatory origin. In this regard, LTB-4 and IL-8 are known to play a crucial role in neutrophil recruitment into airways during lung cancer.

Notwithstanding the intriguing hypothesis, the exact role of neutrophilic inflammation in tumor biology remain complex and not completely known.

The aim of this study was to give our contribution in this field by investigating LTB-4 and IL-8 in the breath condensate of NSCLC patients and verifying their role in cancer development and progression.

We enrolled 30 NSCLC patients and 25 controls. LTB-4 and IL-8 concentrations were measured in the breath condensate and the blood of all the subjects under study using ELIA kits. Thirty NSCLC patients and ten controls underwent induced sputum collection and analysis.

LTB-4 and IL-8 resulted higher in breath condensate and the blood of NSCLC patients compared to controls. Significantly higher concentrations were found as the cancer stages progressed. A positive correlation was observed between exhaled IL-8 and LTB-4 and the percentage of neutrophils in the induced sputum.

**Conclusion:** The high concentrations of exhaled LTB-4 and IL-8 showed the presence of a neutrophilic inflammation in the airways of NSCLC patients. The treatment of acute exacerbations is of major importance since they have a given impact on the morbidity, mortality and health care costs associated with COPD.

**Objective:** It is well known that the airway inflammation is enhanced at exacerbation. The purpose of this study is to investigate if the volatile organic compounds (VOCs) detected in the exhaled breath of patients with an acute exacerbation of COPD are different from those detected in patients with a stable disease.

**Methods:** Breath samples were collected via a side-stream Teflon tube and measured directly by an ion mobility spectrometer coupled to a multi capillary column (MCC/IMS). VOCs were detected and statistically evaluated in order to discriminate COPD patients with an exacerbation from those with a stable disease.

**Results:** Thirteen COPD patients with an acute exacerbation, 46 COPD patients with a stable disease as well as 51 healthy subjects were included in the study.

Several peaks were found to differentiate in the group of patients with an acute exacerbation compared to the COPD patients with stable disease and with healthy subjects.

**Conclusion:** Our data suggest that specific VOCs can be detected in the exhaled breath of COPD patients with an acute exacerbation indicating possibly the enhanced airway inflammation. The identification of VOCs that characterise the acute exacerbations could be used as diagnostic tool for an exacerbation apart from the clinical criteria.

Targeted eicosanoid lipidomics of induced sputum as compared to exhaled breath condensate in asthmatics

Marek Sanak, Lucyna Mastalerz, Anna Gielcz, Barbara Sokołowska, Natalia Ciegiełska-Woźnick, Andrzej Szczeklik, Medicine, Jagiellonian University Medical College, Kraków, Poland

Eicosanoids are mediators of arachidonic acid pathway. Induced sputum (IS) is a non-invasive material from the lower airways, its sampling is well standardized. Advantage of exhaled breath condensate (EBC) is shorter collection time and low protein content, this is compromised by extreme dilution and inter-individual variation. Both matrices have been introduced for assessment of inflammatory mediators in asthma.

We compared eicosanoids concentration in IS and EBC samples collected according to the current guidelines and estimated redistribution of eicosanoids and their metabolites as a result of sample processing.

EBC was collected from asthmatics using Jaeger ECO Screen I; IS according to the most recent ERS Task Force recommendations. The same validated quantitation mass spectrometry was used for both matrices eicosanoids’ measurements. Random IS samples were split to test enzymatic inhibition during solubilisation. We quantified 29 eicosanoids, including major prostaglandins, leukotrienes, and their metabolites. Average concentration of eicosanoids was 82±[400] times lower in EBC than in IS. IS differed form EBC by higher HETE and undetectable LTC4. Conversion of LTB4 into 5-oxo-LTB4 and increase of tetranor-PGEM was observed during IS solubilisation, non-physiological pH prevented these redistributions only partially.

Although processing of IS shifts eicosanoid profile toward metabolites, significant amounts of mediators are present within detection levels of common immunosays. A strict adherence to the IS collection protocols is recommended to avoid a pre-analytical bias.

In collaboration with U-BIOPRED within the Innovative Medicine Initiative.

**Detection of pseudomonas aeruginosa (Pa) specific peaks by ion mobility spectrometry (IMS) in exhaled breath of bronchiectasis patients**

Thomas Rahns1, Olad Anthen1, Jörg-Ingo Baumbach2, Isabella Kurth1, Gerhard Weinreich1, Helmut Tescher1, Lutz Freitag1, Raid Darwiche1, Uwe Mellies1, Peter-Michael Ruth1, Ute Sommerweck1, 1Dept. of Pneumology - Lung Transplantation, Ruhrlandklinik - West German Lung Centre at the University Clinic Essen, Essen, Germany; 2Department of Microfluidics & Clinical Diagnostics, KIST Europe, Campus E71, Saarbrücken, Germany; 2Dept. of Interventional Pneumology, Ruhrlandklinik - West German Lung Center at the University Clinic Essen, Essen, Germany; 4Dept. of Pediatric Pulmonology, Sleep Medicine and Cystic Fibrosis Center, University Clinic Essen, Essen, Germany; 5Institute of Medical Microbiology, University Clinic Essen, Essen, Germany

**Introduction:** Colonisation or infection of airways from bronchiectasis patients by *Pa* results in chronic inflammation leading to a progressive destruction of the lung and to a decline in lung function. Therefore, more urgent stays for intravenous antibiotic treatment are necessary and the quality of life in these patients is severely limited.

**Objectives:** Aim of our study was to detect and compare volatile organic compounds (VOCs) by IMS in exhaled breath of bronchiectasis patients either colonised or infected by *Pa* with healthy non-smoking controls (hc).

**Methods:** We have analysed VOCs by IMS coupled to a multi-capillary column (MCC) for pre-separation (MCC-IMS) and Analysitk in exhaled breath of bronchiectasis patients either colonised or infected by *Pa* with healthy non-smoking controls (hc).

**Results:** Using IMS for VOC analysis, differences between Pa+ and hc could be found. Different peaks were detected between Pa+ and hc, Pa+ and the samples from asthma patients (Pa-c) as well as Pa+ and Pa-c. VOC analysis from Pa cultures revealed two peaks which could be found in the Pa+ bronchiectasis patients.

**Conclusions:** IMS seems to be a promising method for the non-invasive identification of patients which are colonized or infected with *Pa*. A differentiation between patients with *Pa* colonised or infected with Pa is possible, as well. However confirmation of our findings in a larger study population is needed. The comparison of Pa+ with Pa-c cultures will help to identify peaks caused by the presence of Pa.

**Furthermore, it is required to identify the molecules representing the peaks.**

**P4791**

**Metabolomic analysis of exhaled breath condensate in diagnostics of obstructive airway diseases**

**Faculty of Mechanics and Mathematics, M.V. Lomonosov Moscow State University, Moscow, Russian Federation**

**Introduction:** Metabolomic analysis provides molecular and biochemical profiles of metabolites in different biological fluids.

**Objectives:** The aim of this study was to assess the potential of exhaled breath condensate (EBC) molecular profiling in discrimination patients with COPD and asthma and healthy subjects.

**Methods:** Twenty patients with asthma, twenty patients with COPD and thirty healthy control subjects were enrolled in cross-sectional study. Every subject performed spirometry and EBC collection. EBC samples were analyzed by gas chromatography – mass-spectrometry method (GC-MS). EBC profiles from patients with asthma were separated from patients with COPD and from healthy control subjects using an algorithm based on linear methods of pattern recognition theory.

**Results:** We have detected various profiles of semi-volatile organic compounds (SVOC) in EBC in patients with COPD, asthma and healthy subjects. Mathematical approach to available data revealed 9 SVOC which have been deemed the most appropriate for solving recognition problem (2-phenoxethanol, decanol-1, ethyl 2,3-dihydro-1H-inden-1-ol and others). EBC profiles of healthy subjects can be distinguished from patients with asthma with reliability 75%, healthy subjects from COPD patients with reliability 85% and asthma patients from COPD patients with reliability 83%.

**Conclusion:** Metabolomic analysis of EBC can discriminate patients with asthma and COPD and healthy subjects. We propose that differences in SVOC profiles between asthma and COPD are disease related.

**P4792**

**Discrimination of protein and peptide composition of exhaled breath condensate in patients with pulmonary disease by mass spectrometry**

Anna Ryabokon1, Viktoria Konurova1, Eldar Aanaev1, Alexey Kononikhin1, Kristina Fedorenko1, Eugenie Nikolov1, Sergey Vafalonov1, 1Department of Kinetics and Mechanisms of Enzymatic and Catalytic Reactions, Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, 2Noninvasive Diagnostic Department, Research Institute of Pulmonology, Federal Medico-Biological Agency of Russia, 3Department of Ion and Molecular Physics, Institute for Energy Problems of Chemical Physics, Moscow, Russian Federation

**Objective:** Exhaled breath condensate (EBC) reflects the composition of the airway-lining fluid and may contain biomarkers of diseases of respiratory system.

**Methods:** For the study of exhaled breath condensate (EBC) of patients with obstructive pulmonary disease (COPD) and pneumonia we used 2D-PAGE and MS analysis. Peptides derived from bronchoalveolar lavage fluid (BALF) of 10 COPD (8 M, age 63.3 ± 7.9) were evaluated at baseline (T0) and after 12 weeks (T1) of oral administration of a curcumin based herbal preparation (Curostal®) and compared to healthy non-smoking controls (hc). 876s

Among clinical parameters BSCN score was 4.9±1.0 at T0 and 7.5±1.0 at T1, while FEV1 values resulted slightly but not significantly increased at T1. Conclusions: NMR metabolomic is a sensitive method to explore nutritectic effects of exogenous antioxidant on EBC in patients affected by COPD.

**P4793**

**NMR EBC metabonomics to assess the nutritectic effect in COPD. A pilot study of oral administration of a curcumin based herbal preparation**

Guglielmo de Laurentis1,2, Giovanni Scapagnini1, Deborah Paris3, Dominique Melch3, Mauro Maniscalco1, Andrea Motta1, Sofia Mattos1, Andrea Bianco1, 1Dept. of Respiratory Medicine, University “Federico II” of Naples, Naples, Italy; 2Dept. of Health Sciences, University of Molise, Campobasso, Italy; 3Institute of Molecular Chemistry, National Research Council, Pescocostanzo, Italy; 4Dept. of Medicine, Rehabilitation Center, Santa Maria del Pozzo, Summa Vesuviana, Italy

**Background:** NMR metabolomic of EBC significantly divide healthy from COPD patients, identifying specific profiles linked to cellular oxidative pattern. Curcumin is a recognized anti-oxidant agent in biochemical cellular balance. As it is still unknown of the pattern recognized by NMR metabolomic spectroscopy in COPD is sensitive to exogenous nutrients, in this preliminary open label study we evaluated the effect of daily oral administration of an herbal preparation containing high dosage of curcumin (HPC) on EBC in COPD patients.

**Materials and methods:** 10 COPD (8 M, age 63.3 ± 7.9) were evaluated at baseline (T0) and after 12 weeks (T1) of oral administration of HPC once a day collecting each visit EBC, clinical score (BSCN) and spirometry.

**Results:** We have detected various profiles of semi-volatile organic compounds (SVOC) in EBC in patients with COPD, asthma and healthy subjects. Mathematical approach to available data revealed 9 SVOC which have been deemed the most appropriate for solving recognition problem (2-phenoxethanol, decanol-1, ethyl 2,3-dihydro-1H-inden-1-ol and others). EBC profiles of healthy subjects can be distinguished from patients with asthma with reliability 75%, healthy subjects from COPD patients with reliability 85% and asthma patients from COPD patients with reliability 83%.

**Conclusion:** Metabolomic analysis of EBC can discriminate patients with asthma and COPD and healthy subjects. We propose that differences in SVOC profiles between asthma and COPD are disease related.

**P4794**

**Development of mass spectrometry approaches to quantifying lipid mediators in airway disease**

David Balgoma1, Susanna L. Lundstrom1, Anders Eklund2, Johan Grunewald2, 1Dept. of Respiratory Medicine, Rehabilitation Center, Santa Maria del Pozzo, Summa Vesuviana, Italy; 2Dept. of Health Sciences, University of Molise, Campobasso, Italy

**Background:** Lipid mediators (LMs, such as prostaglandins and leukotrienes) have been extensively studied for their role in both the onset and resolution of inflammation in airway diseases. We report here the development of a state-of-the-art approach for the detection and quantification of lipid mediators in airway disease. Using a data-driven, machine learning approach, we have developed an MS-based method for the rapid and sensitive detection of LMs in airway disease. This method is based on a combination of targeted and non-targeted approaches and is designed to detect a wide range of LMs. Additionally, we have developed a novel approach for the quantification of LMs in airway disease. This approach is based on the use of a multi-plexed MS assay and is designed to detect a wide range of LMs in a single sample. The results of this study demonstrate the potential of MS-based approaches for the rapid and sensitive detection and quantification of lipid mediators in airway disease. These results have important implications for the diagnosis and treatment of airway disease.
the-art quantitative lipodomics-based method for the analysis of LMs using Liquid Chromatography with Tandem Mass Spectrometry (LC-MS/MS).

Aims: Develop a sensitive LC-MS/MS platform to quantify LMs from multiple biological matrices including urine, bronchoalveolar lavage fluid (BALF) and sputum. The method should encompass LMs from arachidonic (AA), linoleic (LA), dihomo-γ-linolenic (DGLA), α-linolenic (α-LA), eicosapentaenoic (EPA) and docosahexaenoic (DHA) fatty acid pathways.

Methods: Pooled BALF from patients with sarcoidosis (n=5) was extracted by Solid Phase Extraction and analytes were quantified by LC-MS/MS (Acquity-Ultima, Waters). The method assessed 87 LMs in combination with 16 deuterated internal standards.

Results: In BALF from sarcoidosis patients, 29 LMs from six fatty acid were detected, but only 8 LMs from each of the AA and LA pathways were quantifiable. The fatty acid origin and biosynthesis pathway of the 29 LMs is shown in Fig. 1.

Conclusions: LC-MS/MS methods for LM quantification are applicable for exploring the etiology and pathology of respiratory diseases as exemplified with BALF from sarcoidosis patients. These methods will be useful in examining inflammatory processes.

P4795
Follow up of lung transplant recipients using electronic nose
Dorottya Kovacs, Andras Bikov, Judit Piko, Zuszsanna Kovats, Zoltan Suto, Veronika Muller, Gabriella Murakozy, Gyorgy Losonczy, Ildiko Horvath.
Pulmonology, Semmelweis University, Budapest, Hungary

Background: The close follow up of lung transplant patients is essential in the recognition of both early and late complications, however today these can be confirmed only by invasive techniques. Analysis of exhaled breath might be promising, as various studies showed relationship between breath components and the development of BOS in lung transplant recipients. Electronic nose is able to analyse the peculiar pattern of breath (breathprint), and it discriminated different lung diseases successfully, however lung transplant patients were not studied yet.

Aim: To investigate the relationship between breathprint and various clinical parameters in lung transplant recipients.

Methods: Sixteen patients following lung transplantation participated in our study (mean age 39±14). The study had a model (N=25 samples) and a validation part (N=35 samples). Hence, in average 3.7±2.5 samples per patient were analysed. During their scheduled follow up at the outpatient clinic exhaled breath collection (N=35 samples). Hence, in average 3.7

Results: Median EWT post 16mins 33 13 mins 57

Conclusions: The analysis of exhaled breath can be useful in the follow-up of patients with obstructive pulmonary disease. The relation with the drug level draws attention to the interfering effect of treatment and to the possibility of monitoring drug level by exhaled breath testing.

P4796
Profiling of sputum inflammatory mediators in asthma and chronic obstructive pulmonary disease
Mona Bafadhel1, Margaret McCormick1, Sharon Saha1, Vijay Mistry1, Susan McKenna1, Paul Dodson2, Andrew Lloyd2, Paul Rugman2, Paul Newbold3,1 Institute for Lung Health, University of Leicester, Leicester, United Kingdom; 2AstraZeneca, R & D, Loughborough, United Kingdom; 3Respiratory Medicine, Sheffield University Hospitals NHS Trust, Sheffield, United Kingdom

Introduction: Asthma and chronic obstructive pulmonary disease (COPD) display features of overlap in airway physiology and pulmonary inflammation. The relationship between mediator expression and airway inflammation was explored within these airway diseases.

Methods: Patients with asthma (54 patients: 21 men) and COPD (49 patients: 36 men) were studied. Clinical characteristics and sputum was collected at entry into the study. A two-step sputum processing method was performed for supernatant and cytopsin preparation. The Mesoscale Discovery and Lumixin platforms were used to measure cytokines, chemokines and matrix metalloproteinase levels.

Results: Analytes sensitive to dithiothreitol (DTT) that had increased recovery in the two step sputum process were IL-1β, 4, 5, 10, 13, IFN-γ, TNFRI, GM-CSF, CCL2, 3, 4, 5, 13 and 17. There was a differential expression in IL-8, TNFRI and TNFRII between asthma and COPD (mean fold difference (95% confidence interval) IL-8, 2.6 (1.3 to 5.4), p=0.01; TNFRI, 2.1 (1.3 to 5.4), p=0.03; and TNFRII, 2.6 (1.2 to 5.6), p=0.02). In neutrophilic and eosinophilic airway inflammation, TNFα, TNFRI, TNFRII, IL-6, IL-8 and IL-5 could differentiate between these phenotypes. However, these phenotypes were unrelated to the diagnosis of asthma or COPD.

Conclusion: Recovery of sputum mediators sensitive to DTT can be improved using a new sputum processing technique. Within airway inflammatory subphenotypes there is a differential pattern of mediator expression that is independent of disease. Whether these inflammatory phenotypes in asthma and COPD confer distinct pathogenesis, therapeutic responses and clinical phenotypes needs to be further evaluated.

494. Pulmonary rehabilitation: looking at alternative approaches and alternative populations beyond COPD

P4797
Pulmonary rehabilitation: First line treatment for respiratory disease
Orla Reddington, Anne Tellford, Victoria Christie, Gail South. Physiotherapy Department, BreathingSpace, Rotherham, South Yorkshire, United Kingdom

Introduction: Breathing Space is a multi-disciplinary primary care centre for the management of respiratory conditions in Rotherham. England. Breathing Space has an emphasis on Pulmonary Rehabilitation (PR) incorporating outpatient pulmonary rehabilitation and an inpatient facility.

Aims: The aim of the research was to establish the effect of PR on Patient Recorded Outcome Measures.

Methods: Data was examined retrospectively between June 2007 and December 2010. All patients underwent field walking tests (Incremental Shuttle Walk Test (ISWT), Endurance Walking Test (EWT) or 6 Minute Walk Test (6MWT)) and CRQ (self report) and HAD questionnaires. PR was provided over 12 sessions in a 6 week period.

Results: 94 patients with Bronchiectasis or Pulmonary Fibrosis were referred for PR. Of these 95% (n=78) agreed to attend PR after assessment. Refer to tables 1 & 2 for results.

Effect of pulmonary rehabilitation on gas exchange, muscle cross sectional area and functional parameters in interstitial lung disease

Balakrishnan Menon1,V.K. Vijayan1, Vishal Bansal2, Brijesh Prajapat1

1Pulmonary Medicine, Vallabhbhai Patel Chest Institute, New Delhi, India; 2Physiology, Vallabhbhai Patel Chest Institute, New Delhi, India

Introduction: Pulmonary rehabilitation has an important role in the management of interstitial lung diseases (ILD). This study evaluates effect of pulmonary rehabilitation on gas exchange, muscle cross sectional area and functional parameters in patients of ILD.

Aims and objectives: To evaluate 6 minute walk distance (6MWD), Mid Thigh Cross Sectional Area on CT (MTCSACT) and Carbon Monoxide Diffusion Capacity (DLCO) before and after pulmonary rehabilitation in patients of ILD.

Methods: Twenty eight patients of ILD were randomly allocated to Control and Test groups. The control group received standard medications for 8 weeks while the test group was given supervised pulmonary rehabilitation along with standard medications for 8 weeks.

Results: Mean values of 6MWD changed from 476.50±61.97 m to 482.64±58.33 m in control group [p=0.369] and from 455.46±63.55 m to 509.78±69.03 m in test group [p=0.015]. Levels of DLCO changed from 11.88±3.87 ml/min/mmHg to 11.92±3.73 ml/min/mmHg in control group [p=0.390] and from 89.81±5.73 ml/min/mmHg to 13.08±6.37 ml/min/mmHg [p=0.004] in test group. Mean values of MTCSACT changed from 9311.21±1918.42 cm² to 9485.21±2083.44 cm² in control group [p=0.066] and from 9485.21±2083.44 cm² to 10303.7±2137.41 cm² in test group [p=0.031].

The difference of means between control and test group after pulmonary rehabilitation was significant for DLCO, MTCSACT, and 6MWD. Positive correlation was obtained between MTCSACT and 6MWD with 0.7, p=0.006.

Conclusion: Pulmonary rehabilitation causes significant improvement in muscle cross sectional area and functional parameters in ILD patients along with significant improvement in gas exchange.

P4799

Pulmonary rehabilitation (PR) outcomes in chronic obstructive pulmonary disease (COPD) compared with interstitial lung disease (ILD)

Victoria Sandrey, Susanna Barr, David Smith. North Bristol Lung Centre, Frenchay Hospital, Bristol, United Kingdom

Background: PR is effective in improving exercise capacity, dyspnea and quality of life in patients with COPD. The benefits in patients with ILD are less well described.

Methods: The records of 24 patients (15 male) with ILD who had completed PR were compared with age (within 2 years) and MRC score (same score) matched COPD patients (19 male) who had also completed PR within the same setting. Incremental shuttle walk distance (ISWT), endurance shuttle walk time (ESWT), level of exercise induced desaturation, chronic respiratory disease questionnaire (CRQD) scores and hospital anxiety and depression (HAD) scores were measured at baseline and on completion of the 8 week programme. The mean changes in each group were compared using a paired t-test.

Results: The mean average age of each group was 68 years, with a mean average MRC score of 3.3. The baseline oxygen saturations in both groups was similar.

Both groups showed improvements in all measured outcomes-most of which were clinically important. There was no statistically significant difference between the groups in any of the outcomes. In addition, the level of exercise desaturation after PR was greater in the ILD group (7.7%) compared with the COPD group (3.0%).

Conclusions: This study shows that PR in patients with ILD produces similar outcomes to those seen in COPD. The exercise induced oxygen desaturation seen in patients with ILD is greater. Outcomes to those seen in COPD. This study shows that PR in patients with ILD produces similar outcomes to those seen in COPD. The exercise induced oxygen desaturation seen in patients with ILD is greater.

P4800

Exercise tolerance and symptoms after standard rehabilitation in emphysema-like COPD patients

Ermesto Cristalli1, Elena Venturelli2, Gianluca Biscione3, Guido Vagheggi4, Andrea Lattoni5, 2Sasha Luccic1, Nicollin Ambrosino1, Franco Pasqua1, Enrico M.Climini1,2, 2Rehabilitation, Ospedale Villa Fimia, Parvallo nfp, Modena, Italy; 3Oncology Haematology Respiratory Diseases, University of Modena, Modena, Italy; 4Pulmonary Rehabilitation, Ospedale San Raffaello, Velleri, Roma, Italy; 5Rehabilitation, Centro Auxilium Vitta, Velleri, Pisa, Italy

In this retrospective analysis on a cohort of 823 COPD patients (age 71±8 yrs, FEV1 56±18% pr.) admitted in 3 centres, we aimed at describing the effect of standard rehabilitation on exercise tolerance and symptoms in the subgroup of emphysema-like individuals, as defined by lung function parameters.

Pre-to-post changes (D) in exercise tolerance (6MWT), Borg dyspnea (D), fatigue (F) and SaO2 nadir (N) on effort, perceived breathlessness (MRC), and quality-of-life (SGRQ) were reported. Propotion of patients reaching the minimally clinical important difference (MCID) in 6MWT, D, F, MRC and SGRQ were also recorded.

Outcomes were then compared between the Emphysema (E, n=283) and the COPD (C, n=540) subgroups.

Lung functions were different by definition when comparing the two groups, with similar age, body mass, exercise tolerance, and breathlessness at baseline. D-6MWD (+72±47 and +62±42 m, p=0.002), D-F (-2±3.1 and -1.9±1.6 points, p=0.002), D-F (+2.8±1.9 and -1.9±1.6 points, p=0.070), and D-N (+1±4.3 and +0.5±1.3 point, p=0.002) were higher, whereas a larger proportion of patients improved at the MCID in 6MWT (62% and 54%, p=0.040) in group E when compared with group C. Using a multivariate logistic regression model, we found that higher normalised PaO2, and lower 6MWT, and FRC at baseline significantly correlated with D-6MWT in the E group (p<0.01).

This study generates the hypothesis that COPD patients with emphysema phenotype are more likely to gain exercise tolerance and perceived symptoms after standard rehabilitation.

P4801

Does better endurance capacity increase physical performance and work participation for patients with obstructive pulmonary disease?

Ulla Pedersen, Siri Skumlien. Physical Department, Glistreeklinikken, Hakadal, Norway

Background: Patients with chronic lung disease have increased risk of unemployment and disability pensioning caused by exacerbations and the complexity of this disease. Multidisciplinary pulmonary rehabilitation could be expected to improve physical performance, work stability and social participation.

Aim: The aim of this study was to evaluate if a 4 weeks’ multidisciplinary vocational pulmonary rehabilitation had an effect on endurance capacity, and whether a change was correlated with degree of physical activity and work participation 1, 6 and 12 months post-rehabilitation.

Methods: 128 consecutive patients were included in this intervention prospective cohort study. Endurance capacity was measured as time to exhaustion during constant work load treadmill walk before and after rehabilitation. Data on post-rehabilitation work relations and physical performance was collected by telephone interview.

Results: The endurance capacity increased from 360 sec to 840 sec (median), p=0.000 during the 4 weeks of rehabilitation. Increase in treadmill endurance time was correlated with physical activity 6 months (r=0.22, p=0.023), but not 12 months post-rehabilitation (r=0.03, p=0.776). There was no correlation between increase in treadmill endurance and work participation 6 or 12 months after rehabilitation.

Conclusion: Patients experiencing the largest improvement in physical endurance after participation in the current rehabilitation model were most likely to continue their physical activity 6 months after rehabilitation, but the effect was lost after 12 months. The degree of improvement in physical condition did not influence work participation.

Physical rehabilitation in asthma management

Natalia Astafeieva,1 Denis Kobzev,2 Inna Gamova,1 Inna Perfilova1

1Department of Clinical Immunology and Allergology, Saratov State Medical University, Saratov, Russian Federation; 2IMI, IMI University Centre, Luzern, Switzerland

**Background:** 50% of asthma patients experience limitations in physical activity and usual lifestyle. Gymnastics can provide significant health benefits and improve quality of life.

**Objective:** To investigate effects of gymnastics on asthma patients, specifically leading to ameliorated lung function.

**Methods:** A prospective, randomized, controlled trial was performed to evaluate the effect of respiratory gymnastics (RG). 85 patients with moderate/severe asthma were randomly assigned to control (CG - 16 persons, standard therapy) or RG (RGTG - 69 persons, standard therapy & RG group) with no significant difference in demographics. Patients were instructed how to practice exercises and examined in 3-6-9-12 months for pulmonary function, cardiopulmonary exercise and control of asthma.

**Results:** 12 month physical rehabilitation (with pharmacotherapy) reduced: the frequency of complaints, clinical manifestations of asthma; symptoms: daytime (from 8.5±3.2 to 4.5±2.7; p < 0.0001) and night (from 54.7±7.1 to 44.6±6.9; p = 0.0001); the consumption of β2-agonists (from 3.2 to 2.1 puffs/week). RGTG group increased: FEV1 (from 1.3 to 1.7 L); PEF (from 338±6.19 to 403±5.18); exercise capacity (W/kg) from 0.85±0.1 to 1.4±0.2. The number of patients with limited physical activity decreased from 86.0±5.0 to 22.0±5.9; p = 0.001. Heart rate and blood pressure recovery time after exercise decreased from 10.4±0.7 to 9.1±0.6 min (p < 0.05). CG changes were much lower (difference between groups was significant, p < 0.001).

**Conclusions:** Individual programs of RG reduced asthma symptoms and the use of bronchodilator medication in patients with asthma, and can be effective as an adjuvant therapy and optimize asthma patients medical treatment.

**P4804**

Obesity in COPD and the response to pulmonary rehabilitation

C.M. Nolan,1 J.L. Canavan,2 A.L. Clark,1 K.A. Ingram,3 R.P. Fowler,1 P. Marks1, M.J. Polkey1, W.D.-C. Man,1 Harefield Hospital Pulmonary Rehabilitation Team,2 Respiratory Biomedical Research Unit, Royal Brompton and Harefield NHS Foundation Trust, Harefield, Middlesex, United Kingdom

The obesity paradox is well recognized in COPD. Obese (OB) patients with COPD may have better survival than the non-OB, yet obesity may impair lung function, increase respiratory load and dyspnea. We hypothesized that OB COPD patients referred to pulmonary rehabilitation (PR) would have reduced exercise capacity and quality of life compared with normal weight (NW) COPD patients, and would respond less well to PR. As BMI<21 is associated with worse prognosis, we defined NW as a BMI of 21-24.9. OB was defined as BMI 30 plus. In 218 patients referred to an 8-week outpatient PR program, we identified 64 NW and 67 OB patients. Baseline and post-PR incremental shuttle walk (ISW), self-report Chronic Respiratory Disease Questionnaire (CQDQ), MRC Dyspnea score (MRC-D), Hospital Anxiety and Depression (HAD) scores and fat free mass (FFM) were recorded. Despite less severe airflow obstruction in OB patients (Median IQR FEV1% predicted: NW = 40 (26, 62) vs. OB = 62 (42, 76); p < 0.0001), median ISW (m) was reduced (NW = 185 (120, 295) vs. OB = 105 (50, 255); p<0.01). CRQD-SR was also significantly reduced (p=0.02) in OB patients. Following PR, there was a significant improvement in ISW, CRQD-SR, MRC and HAD-D in OB patients. No significant difference was seen in pre- to post-PR changes in ISW, CRQD-SR, MRC, HAD and FFM between the 2 groups. Obesity in COPD was associated with less impairment in respiratory function, but worse exercise capacity and quality of life. However OB patients responded equally well to PR as NW patients. The impairment of exercise capacity and quality of life in OB COPD patients may lead to presentation to health care professionals at an earlier stage of lung function impairment and may explain the obesity paradox.

**P4805**

Outpatient vs. home-based pulmonary rehabilitation in COPD: A randomized controlled trial

Julio Cesar Oliveira1, Fernando Sergio Leitão Filho3, Luciana Sampaio3, Ana Carolina Oliveira1, Raquel Hirata2, Dircce Costa2, Claudio Donner4, Luis Vicente Oliveira1, 1Pulmonary Rehabilitation, Lung Institute, Cacacel, PR Brazil; 2Rehabilitation Sciences Master’s Program, Nove de Julho University, Sao Paulo, SP Brazil; 3Medicine Department, Fortaleza University, Fortaleza, CE, Brazil; 4Ambulatorio Diagnostico e Terapeutico Polispecialistico, MONdo Medico, Rorosmanuro, Italy

**Introduction:** Chronic obstructive pulmonary disease (COPD) is a common cause of morbidity and mortality affecting a large number of individuals in both developed and developing countries and it represents a significant financial burden for patients, families and society. Pulmonary rehabilitation (PR) is a multidisciplinary program that results in an improvement in dyspnea, fatigue and quality of life. Despite its proven effectiveness and the strong scientific recommendations for its routine use in the care of COPD, PR is generally underutilized and strategies for increasing access to PR are needed. Homebased self-monitored pulmonary rehabilitation is an alternative to outpatient rehabilitation. In the present study, patients with mild, moderate and severe COPD submitted to either an outpatient or home PR program for 12 weeks were analyzed.

**Methods:** Patients who fulfilled the inclusion criteria were randomized into three distinct groups: an outpatient group who performed all activities at the clinic, a home-based group who performed the activities at home and a control group. PR consisted of a combination of aerobic exercises and strengthening of upper and lower limbs 3 times a week for 12 weeks.

**Results:** There was a significant difference in the distance covered on the six minute walk test (p<0.05) and BODE index (p<0.001) in the outpatient and home-based groups after participating in the rehabilitation program compared to baseline.

**Conclusion:** A home-based self-monitoring pulmonary rehabilitation program is as effective as outpatient pulmonary rehabilitation and is a valid alternative for the management of patients with COPD.

**P4806**

Improvement in skeletal muscle dysfunction after twice-weekly exercise training in COPD patients

Caroline Zambon1, Pilar Cabollero2, Maria Hernández2, Esteban Gorostiaga3, Fabricio Zambon1, Pilar Cabollero2, Maria Hernández2, Esteban Gorostiaga3

1Health Sciences Department, Public University of Navarre, Tudela, Navarre, Spain; 2Respiratory Division, Complejo Hospitalario de Navarra, Pamplona, Navarre, Spain; 3Studies, Research and Sport Medicine Center, Institute of Sport, Government of Navarra, Pamplona, Navarre, Spain

**Introduction:** Skeletal muscle dysfunction is one of the extrapulmonary effects in patients with COPD, resulting in reduced peripheral muscle strength and functional capacity and have been associated to increased mortality risk. It is unknown the optimal frequency of exercise training to optimize the effectiveness of rehabilitation.

**Aim:** To compare the effects of the 12-wk training period of low-volume frequency on maximal strength and muscle power.

**Methods:** Thirty-six moderate to severe COPD men were divided into resistance group (RG, n=14), combined group (REG, n=14) and control (COG, n=8). RG performed a low volume exercise training for 12 weeks. The subjects were tested for maximal strength in the leg press (1RMp), lower limb power at 70%IRM (P70IRMp), maximal strength in chest press (1RMcp) and seated row (1RMgr). Statistical analyses were performed with SPSS.

**Results:** 1RMp increased 28% (from 191±52 to 238±68kg, p<0.001) in REG, 33% (from 189±56 to 250±89kg, p<0.001) in RG and was higher (P<0.05) than in the CG. 1RMcp increased 31% (from 50±12 to 66±18kg, p<0.001) in RG, 35% (from 51±17 to 67±17kg, p<0.001) in REG and was higher (P<0.001) than in the CG. 1RMgr increased (P<0.001) 31% in REG and 41% in RG compared to CG. P70IRMp increased 50% (from 557±290 to 725±258 w, p<0.001) in REG, 33% (from 601±167 to 797±212 w, P<0.001) in RG.

**Conclusions:** Twice-weekly resistance exercise improves lower and upper body maximal strength and lower muscle power in COPD. Once-weekly resistance training is as effective in eliciting improvements in maximal strength and muscle power as twice-weekly resistance training.

Interest of neuromuscular electro-stimulation (NMES) in COPD patients during an ambulatory comprehensive respiratory rehabilitation program

Delphine Nguyen Dang1, Michael Gluck2, Freddy Pimay3, Renaud Lous1, Marc Vanderhornen1, 1Respiratory Diseases, CHU, Liege, Belgium; 2Department of Physic Medicine and Rehabilitation, CHU, Liege, Belgium

**Introduction:** COPD often leads to peripheral muscle atrophy and weakness.
Peripheral muscle electrostimulation: Cardiovascular response in COPD patients and long term effects
Bruno-Henri Marchand, Marine Houle-Pilouquin, Pierre Claude. Respiratory Medicine, Centre Hospitalier Universitaire de Montréal, Montréal, QC, Canada.

Conventional pulmonary rehabilitation (PR) suppose minimal active exercise. Because of the ventilatory limitation, severe COPD patients are not always able to fully participate. Electrostimulation (ESM) of the peripheral muscles helps to prevent total unuse of the patients muscles and could aim to a complete PR program. The long-term benefits of this intervention may be evanescent. The cardiovascular effects of ESM are not known in severe to very severe COPD patients.

We prospectively studied 9 COPD patients (3 females and 6 males, mean age of 65 y/o, mean FEV1 of 0.78 L, 28%) undertaking home-based peripheral muscles ESM. This latter consisted of 5 periods of 20 minutes, 5 times a week and for 3 weeks. Short and long term benefits were measured according to 6MWT and 1RM leg press test. Cardiac frequency (F) and arterial pressure (AP) were registered each 5 minutes during periods 1, 7 and 15. F and AP did not show any significant fluctuations from beginning to end of the ESM period, and there is no difference between periods 1 and 15. 6MWT showed a median change of 14% (p=0.001), and significant improvement of Heart Rate reserve (HRR) of 244 m/s (p=0.002). The 1RM leg press was also improved (192 to 209 p, p=0.004). After, 3/9 patients were able to complete a PR program. At one year, 6MWT and 1RM leg press test were above the baseline values. ESM was well tolerated by the patients, without complication.

Conclusion: Home-based ESM program is a safe procedure and is not associated with significant change in F and AP, and an immediate impact was observed on 6MWT and 1RM leg press test. It could precede a complete PR program in selected severe to very severe COPD patients and be offered in a context of hospitalization.

The effect of BiPAP on maximum exercise capacity in patients with COPD
Ana-Maria Mogu1, Michel De Marche2, Stéphane Delisle2. Jadrinka Spahija1,2. 1School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada; 2Respiratory Health Research Center, Sacré-Cœur Hospital, Montreal, QC, Canada.

Methods: A randomized controlled design was used. Ten stable COPD patients (FEV1; 33±21% pred) performed three symptom-limited incremental exercise tests on a bicycle ergometer while breathing through a mouthpiece, with either no pressure support (PSno), PS of 0 cm H2O (PS0, IPAP & EPAP 4 cm H2O) or 10 cm H2O (PS10, IPAP 14 & EPAP 4 cm H2O) of assist on separate days. Exercise test ended at ventilatory (VL), dyspnea and leg effort (Borg), end-expiratory lung volume (EELV), breathing pattern, O2 uptake (VO2) and CO2 production (VCO2) were measured during exercise.

Results: Peak WL was lower with PS10 (33±16) and PS0 (30.5±13) than PSno (43±19) (p<0.001), there was no difference between PS0 and PS0. Dyspnea at peak exercise was similar with PSno, PS0 and PS10; at isoclair it was lower or PSno compared to PS10 and PS0 (p<0.01). Leg effort at peak exercise was higher with PS10 than PS0 and PS0 (p<0.05), whereas it was not different at isoclair. Tidal volume (VT) and minute ventilation (VE) were highest with PS10 and lowest with PSno both at peak exercise (p<0.001) and isoload (p<0.001). EELV was similar at peak exercise with all three conditions. VO2 and VCO2 were greater with PS10 and PS0 than PSno (both p<0.001), both at peak exercise and isoload.

Conclusion: Use of BiPAP during incremental exercise in the absence of a plateau exhalation valve increases VT and VE at the expense of increasing the VO2 and dyspnea, which in turns reduces peak exercise WL in COPD patients.

Effect of ADL-training for persons with COPD: A randomized controlled trial
Frederik Bjarke Hansen, Anne Marit Mengshoel. Occupational Therapist, Glittrleklinikken, Nakakdal, Norway Department of Health and Society, Faculty of Health Sciences, University of Oslo, Oslo, Norway.

Background: Due to various degrees of breathlessness, fatigue, coughing and increased spasm production, COPD patients have problems performing activities of daily living (ADL). Aim: To investigate if COPD patients experienced differences in performance and satisfaction in performing ADLs at 1 hour compared to 1 hour ADL-training during a 4 weeks pulmonary rehabilitation program.

Methods: A prospective, randomized, single blinded, parallel group design. The control group received Glittrleklinikken’s standard rehabilitation program, which included 1-60 min ADL-training. The experimental group received 4-60 min ADL-training in addition to the standard rehabilitation program. The Canadian Occupational Performance Measure assessed the performance and satisfaction of doing ADL at inclusion (baseline), after four weeks (at discharge) and three months after discharge.

Results: 24 COPD patients (59% women) were included; mean±SD age 69±8 years. FEV1% predicted 35% ± 19). FEV1% predicted change 43±14%, as well as significant change in F and AP, and an immediate impact was observed on maximum exercise capacity (p<0.001), both at peak exercise and isoload.

Conclusion: The patients with COPD participating in a 5 hours ADL-training program evaluated their performance and satisfaction of doing ADL to be better than those participating in a 1 hour program, both at the time of discharge and three months after discharge.

Comparison of efficacy of respiratory rehabilitation in patients with COPD and interstitial lung disease
Atsuhito Nakazawa1, Takeshi Shinozuka1, Eri Hagioawa1, Kaori Tsutsumi2, Takuma Sasaki1, Takashi Ogura1, Hiroshi Takahashi1, Takuma Sasaki2, Takashi Ogura1, Hiroshi Takahashi1. 1Department of Respiratory Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan; 2Department of Rehabilitation Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan.

Objectives: There are few reports describing the efficacy of pulmonary rehabilita- tion (PR) in patients with interstitial lung disease (ILD). We studied whether PR could improve functional status and dyspnea in a group of patients with ILD in comparison with patients with COPD.

Methods: Seventy three outpatients (mean age 71y, male: female = 57:16, ILD: COPD: others = 22: 36: 15) joined a 12-week PR program including exercise training, physiotherapy and education. Six-minute walking test, lung function test COPD: others = 22: 36: 15) joined a 12-week PR program including exercise training, physiotherapy and education. Six-minute walking test, lung function test and quality of life were measured at baseline and 12 weeks after discharge.

Results: We found substantial decrease in SGRQ score from 42.1 to 33.9 (p <0.0409) in total patients. Patients with ILD responded well to the program with the improvement of 6-minute walking distance (318.4 m to 331.6 m) and Borg score (5.2 to 4.4). There was no difference between the level of improvement in patients with COPD and ILD.

Conclusion: Our results show that PR improves both functional status and dyspnea in patients with ILD to the same extent as with COPD. PR should be considered as a standard of care for ILD patients.

Pulmonary rehabilitation in patients with interstitial lung disease – An useful therapeutic option?
Patrick Huppmann1, Bernd Szczepanski2, Martina Boensch2, Sandra Winterkamp3, Ursula Schenken-Kennett2, Claus Neuhoff3, Jürgen Behr1, Klaus Kenn2. 1Medical Clinic I, Division of Pulmonary Diseases, Klinikum Großhadern, Ludwig-Maximilians-University of Munich, Munich, Germany; 2Department of Pneumology, Schoen-Klinik Berchtesgadener Land, Schoenau am Koenigsee, Germany; 3Department Internal Medicine III, BG University Hospital Bergmannsheil, Bochum, Germany.

Introduction: Pulmonary rehabilitation (PR) is recommended for patients with chronic lung diseases by ATS or ERS independent of underlying disease. Data examining the role of PR in patients with interstitial lung disease (ILD) are limited.
so far only a benefit of PR in patients with COPD is widely accepted. Aim of our study is to evaluate an in-patient training in view of functional status and quality of life in COPD-patients. Therefore PR should be considered as a standard of care for patients with ILD.

P4813
Stationary bicycle training at home in COPD patient on LTOT. Is it enough to improve quality of life and exercise capacity? A pilot study
Jacek Nasilowski1, Tadeusz Przybylowski1, Jan Zieleniak1, Ryszarda Chazan1, Pawel Siwiniski2, Przemyslaw Bielen2, Emil Romanski1.
1Department of Internal Medicine, Pneumonology and Allergology, Medical University of Warsaw, Warsaw, Poland; 2Department of Diagnosis and Treatment of Respiratory Failure, National Research Institute of Tuberculosis and Lung Diseases, Warsaw, Poland

Pulmonary rehabilitation improves quality of life (QoL) and exercise capacity (EC) in COPD patients. LTOT with stationary source may reduce daily activities (DA). Aim of study was to assess if self administered training at home improves QoL, EC and reduces symptoms restriction in DA.

Methods: Consecutive COPD pts qualified for LTOT with oxygen concentrator were assessed and randomly assigned to training (TG) or control (CG) groups. Assessment comprised of: cardiopulmonary exercise test (CPET) on cycle ergometer, 6 minute walk test (6MWT), dyspnoea (MRC scale), lung function tests, QoL (SGRQ), DA measured by actigraphy and questionnaire. Training consisted of 30 min. cycling every day for 3 months. In TG adherence to training and its intensity were monitored by memory card. Pts were regularly visited and load was adjusted to patients ability. CG was monitored by phone and encouraged to sustain physical activity.

Results: We studied 33 pts (18M, 15F), mean age 70±9 yrs, mean FEV1 0.9±0.4 (40±13%), mean PaO2 45±4 mmHg. Of 20 pts allocated to TG, 13 pts completed training program. Adherence was satisfactory, pts trained 73±23% of days. TG showed significant improvement in SGRQ (symptoms) and duration of CPET. There was tendency to improve VO2max (p=0.054) and total SGRQ score (p=0.07). Better adherence to training correlated with greater improvement in QoL, VO2max and 6MWT distance. Higher workload reached during training correlated with reduction of symptoms and improvement in 6MWT, dyspnoea (MRC scale). Further analysis is ongoing.

Conclusions: Self cycling at home may improve QoL and EC in COPD patients starting LTOT with stationary source, but has no effect on performance of DA.

P4814
Pilot study of effectiveness of home rehabilitation for homebound patients with severe COPD
David Coulth1, John Sloan2, Dan Willson3, David Coultas1, Gill Perkins2, Lorraine Culley3, Jonathon Grigg3, Mark Johnson2, Narynder Johal1, Logan Manikam4, Melanie McFeeters4, Nocelle Robertson1, Joanne Wilson5, Monica Lakhani6, 1Medical and Social Care Education, University of Leicester, Leicester, United Kingdom; 2Health and Kinesiology, University of Texas-Tyler, Tyler, TX, United States; 3Physical Therapy, Paradigm Rehabilitation and Nursing, Tyler, TX, United States

Introduction: While pulmonary rehabilitation is efficacious, available evidence is not generalizable to patients who are homebound with severe impairment.

Objective: To test the effectiveness of home-based rehabilitation for homebound patients with physician-diagnosed COPD and severe functional impairment.

Methods: Homebound patients, defined as not driving independently and requiring taxing effort to leave home, were enrolled from primary care and pulmonary clinics. Patients were randomly assigned to one of two interventions comprised of education and physical therapy emphasizing either active (A) or strengthening (S). The interventions were delivered over 8 weeks with up to 20 sessions. Pre- and post-intervention outcome measures were collected at 8 and 16 weeks using the Chronic Respiratory Questionnaire (CRQ) and 2-minute walk distance (2MWD).

Results: Of 41 patients enrolled 24 completed the 8 week intervention period with mean age 74.4 (SD 10.7) years, 45.8% female, FEV1 0.75L (30% predicted). Baseline 2MWDs (time, SD) were 56.0m (23.3) and 16.9m (34.0) for groups A and S respectively. After 16 weeks all CRQ domains improved in both groups with the largest improvements in CRQ-dyspnea (A=1.85 [p=0.02] and S=2.21 [p=0.003]). Overall, the proportion of patients reporting clinically significant improvement on CRQ-dyspnea was 80% in group A and 71% in group S. Moreover, 2MWD increased in Group A but declined in Group S.

Conclusions: These results suggest that among homebound patients with severe COPD 8-weeks of either aerobic or strength training are effective for improving quality of life, but aerobic training may be needed to improve walking distance.

P4815
Transparency in evidence-based pediatric asthma guidelines: GRADE and the other considerations
Nicole Bolyuti1, Bart Rottier2, Elaine Vrijlandt3, Johan de Jonge4, 1Pediatrics, Emma Children’s Hospital - Academic Medical Center, Amsterdam, Netherlands; 2Pediatrics, Beatrix Children’s Hospital - University Medical Center Groningen, Groningen, Netherlands; 3Pediatrics, Erasmus University Medical Center - Sophia Children’s Hospital, Rotterdam, Netherlands

Introduction: International evidence-based pediatric asthma guidelines are often not used in clinical practice. In step 3 of pediatric asthma management some guidelines make clear choices for LABA were others give alternative options, but without being transparent in why choices are made. To enhance the usefulness of guidelines, the ATS has chosen GRADE (Grades of Recommendation, Assessment, Development, and Evaluation) as the preferred methodology for rating the quality of evidence and strength of recommendations in clinical practice guidelines.

Objective: Our aim was to develop transparent recommendations on step 3 of asthma management in children.

Methods: We used GRADE to assess the quality of evidence and separately reported other considerations. Final recommendations were formulated on both evidence as well as the other considerations in cooperation with the Dutch Society of Pediatric Pulmonologists.

Results: We found 7 RCTs comparing doubling the dose of ICS versus a combination of ICS and LABA and/or versus LTRA in children with symptomatic asthma despite normal ICS dose. According to GRADE, the quality of evidence was "moderate", both treatments were effective and individual response could not be predicted. Other considerations included safety, convenience and costs. We suggest in children with symptomatic asthma despite ICS, to first double the dose of ICS. If not effective, a combination of ICS and LABA can be prescribed. In case of adverse effects or poor inhalation technique a LTRA can be prescribed.

Conclusion: By using the GRADE approach together with other considerations clear recommendations for step 3 in asthma management were made. This approach might improve implementation.
Aim: To investigate the association between current and long-term asthma control. Methods: Children aged 2-6 yrs, who received a prescription for (ICS) by their general practitioner in the past year and who were still using ICS at the time of inclusion, were followed up for 3 months, during which adherence to ICS therapy was compared to investigate agreement. Results: 106 children (mean age 4.3 yrs) had an ICS prescription over the past year. 95 children could be reached by telephone, 82 of whom were willing to provide information about current ICS use and symptoms of their child. 30 patients (36%) used ICS intermittently during symptomatic episodes, 24 (29%) patients used ICS for non-specific respiratory symptoms such as cough or for intermittent symptoms such as an isolated wheeze episode. 28 children (35%) were using ICS regularly, 21 of whom consented to electronic adherence measurement for 3 months. In these 21 patients, median adherence was 81% [range 34-97%] of prescribed dosages. Conclusion: The low adherence to ICS in population studies of children with asthma may be partly explained by inappropriate prescription of ICS to children with intermittent episodes of wheeze, and non-specific respiratory symptoms such as cough. High adherence to ICS treatment was found in those patients who received ICS therapy in accordance with international asthma guidelines.

P4819
Lack of behavioural problems in preschool children using inhaled corticosteroids with high adherence
Wouter Quak, Ted Klok, Paul Brand. Princess Amalia Children’s Clinic, Isala Klinieken, Zwolle, Netherlands

Background: Parents of young children are frequently worried about the potential side effects of asthma treatment on their child’s behaviour. Aim: To examine whether preschool children using inhaled corticosteroids (ICS) for asthma are more likely to have more behavioural problems compared with healthy reference group. Methods: We included 81 children 2-5 years of age with persistent asthma symptoms who were using ICS. During 3 months follow-up, adherence to ICS treatment was recorded by an electronic logging device (Smartinhales®). The parents completed the Child Behaviour Checklist (CBCL) to assess behavioural problems; results were compared to published reference groups of healthy children. Results: The median (interquartile range) adherence to ICS was 92 (78-97)%. There were no significant differences in CBCL scores (total, internalizing, externalizing problems) between children on ICS and healthy children (all p values > 0.2). Children with asthma were significantly more likely to have somatic complaints (p=0.001) and significantly less likely to have anxious/depressive symptoms (p=0.1) than the reference group. Conclusions: Maintenance treatment with ICS, taken daily as prescribed, is not associated with an increased risk of behavioural problems in preschool children.
Lemonia Tsartsali1, Marios Papadopoulos 1, Evagelia Lagona2, Salivary cortisol for assessment of hypothalamic-pituitary-adrenal (HPA) axis function evaluation. Diurnal SC variation may offer a dynamic response of serum cortisol to ACTH and may provide an alternative to the blood test for HPA axis function evaluation. A significant positive correlation was found between salivary and serum cortisol, beginning with SC at 0' (R:0.398, p=0.003; R:0.401, p=0.002) and SC at 60' (R:0.389, p=0.003; R:0.401, p=0.002; R:0.385, p=0.003; R:0.404, p=0.003) and SC at 0' (R:0.308, p=0.025; R:0.316 p=0.022; R:0.318, p=0.026) and SC at 0' (R:0.389, p=0.003; R:0.401, p=0.002; R:0.336, p=0.001; 30' R:0.402, p=0.002, 60' R:0.303, p=0.041; R:0.368, p=0.009).

Conclusion: The salivary low dose ACTH test yields results that parallel the response of serum cortisol to ACTH and may provide an alternative to the blood test for HPA axis function evaluation. Diurnal SC variation may offer a dynamic evaluation over a day with none intervention.

P4825 The oral corticosteroid sparing effect of omalizumab in patients with severe chronic asthma: Is there a difference when you become 12 years old? Samantha Moss, Michael Mceean, David Spencer. Respiratory Paediatrics, Great North Childrens Hospital, Newcastle upon Tyne, United Kingdom Omalizumab is licensed for treatment of severe persistent allergic asthma over the age of 6 years. In England and Wales, the National Institute of Clinical Excellence recommends omalizumab as a possible treatment for young people over the age of 12, but not before age 6 – 12.

We describe a population of children with severe asthma who have undergone a 16 week open label therapeutic trial of omalizumab.

The dose of oral corticosteroids at the start & end of the trial was documented. Some children completed modified quality of life and asthma symptom control questionnaires before and after the trial.

To date 15 children (13 boys) age 3-11 years, and 19 children (12 boys) age 11-16 years have completed a therapeutic trial in our centre. The baseline IGE was comparable between groups. We were able to reduce the daily corticosteroid dose in 13 children < 12 years (median pre 20, post 10 mg p=0.01) and in 16 children >12 years (median pre 10, post 5 mg, p=0.01). There was a significant increase pre- to post- trial in documented quality of life, using AQLQ (<12 n=8, >12 n=16), and asthma control (<12 n=8, >12 n=15) in all but 1 patient in each group.

In conclusion, the use of omalizumab in children with severe asthma may result in a clinically significant decrease in the use of oral corticosteroids and an improvement in quality of life and a reduction in asthma symptoms. In our practice omalizumab was as effective in children <12 years of age as in the older age group. A placebo controlled randomised control trial of omalizumab using steroid sparing as primary outcome in a paediatric population is urgently required.

P4826 Safety and efficacy of omalizumab in children with allergic asthma Judy Pitts1, Shahad Sheikh2, Karen McCoy3. 1Division of Pulmonary Medicine/Department of Pediatrics, Nationwide Children’s Hospital, Columbus, OH, United States; 2Division of Pulmonary Medicine/Department of Pediatrics, Ohio State University College of Medicine/Nationwide Children’s Hospital, Columbus, OH, United States

Background: Omalizumab (Xolair) is a humanized monoclonal antibody used in the treatment of adults and children over 12 years with moderate to severe allergic asthma. Pediatric studies are few.

Objectives: A retrospective chart review of pediatric patients who received omalizumab in the past 10 years for asthma at Nationwide Children’s Hospital, Columbus, Ohio.

Results: We had 13 patients, M:F 7:6, median age 13 years (range 9-17), median duration of therapy 36 months (range 1 to 59 months). 4 African American and 9 Caucasian, duration of asthma 15 years (9 to 16). Eight are still on therapy. All patients had severe persistent asthma. Twelve patients were receiving combination therapy (ICS and LABA). Only 4 patients claimed compliance with their asthma controller therapy. Five had family history of asthma, 6 had smoking exposure. Mean IGE before starting omalizumab was 249 (range 78 to 2664). Mean BMI was 25.7 and 46% of the patients were above the 100 percentile for BMI. Comparing between one year before and during omalizumab, mean hospital admission/patient/year decreased from 1.7±2.4 to 0.5±1.4 (p<0.05). There was also a trend towards improvement in ED visits from 2.3±3.2 to 1.7±3. Mean FEV1 during one year before omalizumab therapy, at initiation of therapy and during therapy was 91±18, 94±17, and 93±11 and was not statistically different. Two of 13 patients were taken off omalizumab because of serious side effects, one with anaphylaxis and second with dialated cardiomyopathy. Anaphylaxis was noted on first dose and cardiomyopathy was diagnosed in 5th year on therapy.

Conclusion: Omalizumab is add-on therapy in some patients with allergic asthma. Adverse reactions in children are limiting factor.
Methods: A single-blind, placebo-controlled trial was conducted in 60 mild persistent asthma children (5-14 y). Patients were randomly assigned to receive 5mg MT or placebo for 12 weeks. 30 healthy children (5-14 y) were as control. Clinical and laboratory parameters were determined throughout the trial. The mRNA expression of TGF-β1 in PBMC cells, subtypes of FoxP3+CD25− T cells and TGF-β1 in plasma were measured.

Results: After treatment, symptoms were improved with significant increase in pulmonary function in asthmatic, MT superior to placebo (p < 0.05). The mRNA expression of TGF-β1 and TGF-β1 level in asthmatic were lower than in control (0.31±0.07 vs. 0.67±0.2, p < 0.05 and 0.45±0.13 vs. 0.32±0.04, p < 0.05, respectively). Total FoxP3+, CD25− cell and CD25RA FoxP3− were higher in asthmatic (3.8%±1.3% vs 6.05%±1.8%, p < 0.007 and 4.66%±1.00% vs 3.27%±1.03%, p = 0.011, respectively). CD25RA FoxP3− was lower (0.75%±0.13% vs 0.93%±0.26%, p = 0.021). After treatment, CD25RA FoxP3− was increased in MT compared to placebo group (1.16%±0.24% vs 0.89%±0.22%, p < 0.01). TGF-β1 levels had no correlation with those levels of pulmonary function.

Conclusion: The expression of TGF-β1 was low in asthmatic children. Insufficient secretion of TGF-β1 and the deficiency in activating FoxP3+CD25− T cells might play an important role in pathogenesis of asthma. Up-regulation of expression of TGF-β1 and induction of expression of CD25RA FoxP3− in FoxP3+CD25− T cells by MT may be one of the mechanisms by which airway inflammation is inhibited in asthma.

P4829 Did inappropriate delivery systems hamper therapeutic efficacy of di-sodium-cromo-glycate (DSCG)? Time for a reappraisal
Manfred Keller, Oliver Denk, Albert Bucholski, Martin Knoch. Aerosol Research Institute, PARi Pharma GmbH, Graefelfing, Germany

Chymase-positive mast cells located in distal airways play a crucial role in asthma. Up-regulation of expression of TGF-β1 and the defection in activating FoxP3+CD25− T cells might play an important role in pathogenesis of asthma. Up-regulation of expression of TGF-β1 and induction of expression of CD25RA FoxP3− in FoxP3+CD25− T cells by MT may be one of the mechanisms by which airway inflammation is inhibited in asthma.

P4830 Designing a holding chamber mask using anthropometric data and CAD-simulation
Susanne Merk 1, Frank Kummer 2, Kay Behrenbruch 3, Anna Soderholm Labre 4
1 Medical Information, PARi GmbH. Starnberg, Germany; 2 R&D, PARi GmbH, Starnberg, Germany; 3 Human Factors Engineering, Human Ergonomics, Westensee, Germany

Background: A good seal is regarded as critical factor of face-masks for efficient inhalation drug delivery. Dead space, contour, flexibility and acceptance are also important.

Objectives: Evaluate anthropometric data and CAD-simulation to optimise face-masks for inhalation.

Methods: Basic anthropometric data of faces and heads from 32 children (age 1.1-3.5 yrs) were determined with measuring tape and calliper. Data were compared to existing literature data. Frontal and profile photos were taken with and without a mask prototype. Photographmetry was used to generate a 3-D CAD-database comprising the anthropometric and mask related information. The complex interactions between face and mask were then simulated and geometric data for optimised mask design determined. In a subsample (n=8) of the study population, fit of the optimised masks was visually controlled.

Results: Basic anthropometric data of the sample population agreed well with literature values, providing the study population to be representative. CAD-simulation identified the 2D-tightness geometry as inappropriate and was changed to a 3D-shape with soft lip seals. Dead space could be minimised yet leaving enough space for the nose to keep the mask comfortable. Design according to CAD-simulation led to an optimised fit of the face mask. Dimensions went very well with the children’s face structures. Enclosure of mouth and nose were both collision-free and space-saving.

Conclusions: Complex interactions between face and mask could be successfully simulated with a CAD-database. This helped to design face masks (PARi SmartTouch) which now allow for less leakage, more comfortable fit and minimised dead space - supporting efficient aerosol delivery.

P4831 Breath-by-breath delivered dose comparison from three anti-static valved holding chambers with facemasks under simulated pediatric breathing conditions
Wench Li1, Dirk von Hoffen2, Zhen Xu3, Tao Bai4, Kurt Nikander4
1 Department of Pharmaceutical Sciences, University of Maryland, Baltimore, United States; 2 Philips Respironics, Respironics New Jersey, Inc., Parsippany, NJ, United States

Face masks serve as a patient-device interface to facilitate drug delivery from a pressurized metered dose inhaler (pMDI) with an attached valved holding chamber (VHC), and are capable of significantly affecting inhalation drug therapy. A novel horizontal test rig designed for the evaluation of facemask performance under simulated conditions was used to measure delivered dose from ProAir HFA pMDIs (108 µg albuterol sulfate/actuation, Teva Speciality Pharmaceuticals). Three brands of VHC-facemask systems were tested: preproduction OpTiChamber Diamond (Diamond) VHCs with preproduction LiteTouch facemasks (Philips Respironics), AeroChamber Plus Z Stat (Z Stat) VHCs with ComfortSeal facemasks (Monaghan Medical Corp.), and Vortex VHCs with Spinner Duck facemasks (PARi GmbH).

A face replica of a four-year-old child, with a replaceable aerosol filter in the “mouth”, was connected to a breathing simulator (ASL 5000; IngMar Medical Ltd) to simulate a pediatric breathing pattern (Vt=155 mL, f=25 bpm I:E=2:3). Each VHC-facemask system was naturally positioned against the face replica with a constant applied force supplied by a mass of 1.9 kg. Albuterol sulfate was quantified using HPLC after 1, 2, 4 and 8 “breaths” following pMDI actuation.

Table 1. Mean dose recovered on filter (% of nominal dose)

The delivered dose using the Diamond-LiteTouch system, after 1 breath, was significantly higher than the delivered dose using the Z Stat-ComfortSeal or the Vortex-Spinner Duck system after 8 breaths (p < 0.01).
4859  
Physiology is a better predictor of mortality than HRCT findings in patients with fibrotic idiopathic interstitial pneumonia.  
Federica Novellini1,2, Laura Tavani1, Federica Martino1, Stella Cini1, Lorenzo Melosini2, Chiara Romeo1, Fabio Falaschi3, Stefano Solfànnelli3, Alessandro Celi3, Pierluigi Paggiaro1,1, Cardiac, Thoracic and Vascular Department, University of Pisa, Pisa, Italy; 2Radiology Department, University of Pisa, Pisa, Italy  
Background: Prognosis of fibrotic idiopathic interstitial pneumonia (IPF) is influenced not only by the histologic pattern observed in lung biopsy but also by high resolution chest tomography (HRCT) and pulmonary function findings.  
Aims: To evaluate if functional parameters are better predictors of mortality that HRCT findings in patients with fibrotic IPF.  
Methods: We studied 43 patients with fibrotic IPF during a follow-up of 37.2±31.7 months after diagnosis. Baseline HRCT was evaluated for different abnormalities: honeycombing (HC), reticulation, ground-glass, bronchiectasis and total fibrosis score. Pulmonary function was assessed as baseline FVC and change of FVC after 6 months of follow-up (less or more 10%).  
Results: DI, using the dots for HRCT scores, a cut-off of 10% in the HC score differentiated patients with different survival (5-yrs survival 41% vs 90%, p=0.04). Patients with HC > 10% had a longer duration of symptoms (p=0.04), a lower baseline DLCO (% of predicted, p=0.006) and higher fibrotic and bronchiectasis score (respectively, p=0.04 and p=0.001) than the other patients. A baseline FVC < 76% (median value) and a worsening FVC at 6 months (vs stable-improved) were associated with lower survival (baseline FVC: 5-yrs survival 57% vs 78%, p=0.03; FVC change: 21% vs 75%, p=0.005). In a multivariate logistic analysis, taking in consideration clinical, radiological and functional findings, only baseline FVC and FVC change resulted still significant predictors of mortality.  
Conclusion: Functional findings are more important prognostic factors of mortality than HRCT parameters in patients with fibrotic IPF.  
4860  
Six-minute-walk test: Desaturation index in diffuse parenchymal lung disease  
Dina Visca, Angelo De Lauretis, Giuliana Pasqueto, Giuseppina Gioské, Smargiassi Andrea, Riccardo Inchingolo, Francesco Macagno, Giuseppe Maria Corbo, Salvatore Valente. Respiratory Medicine, Internal Medicine, Rome, Italy  
Six minute walk test (6MWT) is widely used in the functional evaluation of diffuse parenchymal lung diseases (DPLD). To date, distance walked is the most studied 6MWT parameter.  
We focused our study on desaturation index (DI) in 6MWT. We retrospectively evaluated serial lung functions of 59 consecutive DPLD patients: 28 idiopathic interstitial pneumonia (IPF), 11 connective tissue disease (CTD), 13 sarcoidosis and 7 other DPLD. DI was calculated as the ratio between the area above the curve, which was created using each peripheral oxygen saturation (SpO2) value obtained every 2 seconds, and the distance walked.  
Composite physiologic index (CPI) was used to assess disease severity. Disease progression (“time to irreversible decline” in either FVC levels of 10% from baseline or DLCO levels of 15% from baseline) was quantified from the date of the first 6MWT available, by using proportional hazards analysis. Of the 59 patients, 38 were females, mean age was 66.3 (±11.8 SD), mean FVC was 90% predicted (±24) and mean DLCO was 55% (±24). Median length of follow up was 24.7 months.  
Among 6MWT parameters, only DI (p=0.02), lowest SpO2 (p=0.001) and SpO2 at 1 minute of recovery (p=0.02) significantly differed between IPF and sarcoidosis. DI showed more correlations with other physiologic variables than distance walked: the strongest one was with DLCO (r=-0.53, p=0.0001). On multivariate analysis, the need for invasive or non invasive ventilation (OR=35; [95% IC: 5-255]), the type of ILD (IPF vs Miscellaneous) (OR=22; [95% IC: 1.4-147]), and high-dose steroids during ICU stay (OR=0.19; [95% IC: 0.04-0.99]) were found to be independent determinants of in-hospital mortality.  
Conclusion: This study highlights the poor prognosis of IPF in ICU particularly if mechanical ventilation is required. DI-ILD and Miscellaneous with comparable severity criteria have a better prognosis than IPF: High-dose steroids appear as a protective factor whatever the type of ILD.  
4861  
Abnormal pulmonary arterial remodelling in patients with combined pulmonary fibrosis emphysema (CPE) and idiopathic pulmonary fibrosis (IPF)  
Elisabetta Balestrieri1, Francesca Lunardi1, Emanuela Rossi1, Nazarena Nannini1, Giuseppe Marulli1, Monica Loy1, Federico Rea1, Fiorella Calabrese2, 1Department of Cardiac, Thoracic and Vascular Science, University of Padova, Padova, Italy; 2Department of Diagnostic Medical Sciences and Special Therapies, University of Padova, Padova, Italy  
CPE is a syndrome with distinct clinical, functional and radiological characteristics. Recent works have demonstrated the impact of pulmonary hypertension (PH) on worse survival but little is known about the morphological and molecular substrates. The aim of our study was to evaluate the arterial remodelling and expression of transforming growth factor beta (TGF-β) in the lungs of patients with CPE compared to IPF without PH. The study was performed on lung samples or native lungs (2007-2010 recruitment period): 7 CPE patients (mean age 59±5.8 yrs), 15 IPF patients (mean age 53±10yrs) and 5 non-implanted donors (mean age 30±10yrs) as a normal control group. In all cases morphometry was used to measure arterial intimal, medial, and total thickening and immunohistochemical evaluation of TGF-β was quantified in macrophages and alveolar epithelial cells. In CPEF, FEV1%pred and FVC%pred were significantly less reduced than in IPF (p=0.004 and p=0.003, respectively), while DLCO%pred was similar. Initial and total thickening were significantly increased in CPEF than IPF (p=0.004 and p=0.03, respectively). A trend of increased alveolar TGF-β expression was detected in CPEF compared to IPF (p=0.07) while its expression in macrophages was similar. As expected, arterial remodelling and TGF-β expression were significantly increased in both IPF (p=0.001; p=0.001 respectively) and CPEF (p=0.004; p=0.003, respectively) compared to controls. In conclusion, our study demonstrated that lungs with CPEF display significant arterial remodelling which may represent pathological substrate for the increased occurrence of PH.  
4862  
Outcome of patients with interstitial lung disease admitted into ICU  
Amandine Vial-Dupuy1,2, Olivier Sanchez1,2, Liath Guetta1,2, Benoît Douvry1,2, Karine Juvin1, Delphine Wermen1, Emmanuel Guertin1, Dominique Israel-Biet1,2, 1Faculté de Médecine, Université Paris Descartes, Paris, France; 2Service de Pneumologie et Soins Intensifs, AP-HP, Hôpital Européen Georges Pompidou, Paris, France; 3Service de Réanimation Médicale, AP-HP, Hôpital Européen Georges Pompidou, Paris, France  
Background: Limited data are available on the clinical course of patients with Interstitial Lung Disease (ILD) and acute respiratory failure requiring admission to ICU.  
Objectives: To investigate the outcome of patients with ILD and acute respiratory failure with special attention to Idiopathic Pulmonary Fibrosis (IPF) or Drug-induced ILD (DI-ILD).  
Methods: Retrospective identification of patients with ILD admitted into ICU between 1993 and 2009. Primary end-point was in-hospital mortality.  
Results: 72 subjects could be included, divided into 3 groups: IPF, n=28; DI-ILD, n=20 and Miscellaneous, n=24. The in-hospital mortality rates were 68, 40 and 25% for IPF; DI-ILD and Miscellaneous, respectively (p=0.008) and reached 100, 64 and 60%, respectively, in those receiving mechanical ventilation (p=0.007).  
On multivariate analysis, the need for invasive or non invasive ventilation (OR=35; [95% IC: 5-255]), the type of ILD (IPF vs Miscellaneous) (OR=22; [95% IC: 1.4-147]), and high-dose steroids during ICU stay (OR=0.19; [95% IC: 0.04-0.99]) were found to be independent determinants of in-hospital mortality.  
Conclusion: This study highlights the poor prognosis of IPF in ICU particularly if mechanical ventilation is required. DI-ILD and Miscellaneous with comparable severity criteria have a better prognosis than IPF: High-dose steroids appear as a protective factor whatever the type of ILD.

The King's brief intestinal lung disease quality of life questionnaire (K-BILD) for patients with IPF and other ILDs  
Amit S. Patel1, Richard Siegert2, Kate Brigland1, Sabrina Bhajwah3, Sujal R. Desai2, Aihol U. Wells2, Irene J. Higginson 1, Surinder S. Birring 1, 1Department of Palliative Care, Policy & Rehabilitation, Cicely Saunders Institute, King’s College London, London, United Kingdom; 2Department of Palliative Care, Policy & Rehabilitation, Cicely Saunders Institute, King’s College London, London, United Kingdom; 3Cardiac, Thoracic and Vascular Medicine, University of Oxford, Oxford, United Kingdom  
We set out to develop a brief ILD specific health related quality of life (HRQOL) questionnaire for patients with idiopathic pulmonary fibrosis (IPF) and other ILDs. Items were generated from patient interviews (n=10), literature review and a multi-disciplinary team meeting. A preliminary questionnaire consisting of 71 items and a 7 point Likert response scale was tested in 173 patients (49 IPF). The following items were removed: 1) floor effect: >60% of participants responded
low and generally similar in both treatments, except for visual symptoms during scores and rescue medication usage (all P > 0.05). Ivabradine produced significantly lower mean HR than placebo in all rate (PEFR), symptoms, rescue medication consumption and adverse events (AEs).

Methods: 161 consecutive patients discussed at the ILD MDT meeting at University Hospital of South Manchester were analysed.

Results: In 69 of 161 cases the MDT agreed with the diagnosis of the referring physician. In 67 of 161 cases a single ILD label different to that of the referring centre was given, and in 25 of 161 cases the ILD delivered a differential diagnosis only. Of 67 patients referred with definite IPF only 40 patients (60%) kept their label of IPF; the remaining 27 patients received a different diagnosis, predominantly non-specific interstitial pneumonias (NSIP). At time of follow (3-6 years after MDT discussion) 52% of patients who kept their IPF diagnosis were alive versus 78% of patients alive where a pre-MDT diagnosis of IPF was changed to a more favourable diagnosis, p < 0.05.

Conclusion: This data is the largest ILD MDT cohort thus far reported and is the first report to clearly link an MDT-based change in diagnosis from IPF to NSIP translating into documented improved survival.

503. COPD: integrated care and rehabilitation

Late-breaking abstract: HR-lowering efficacy and respiratory safety of ivabradine in patients with obstructive airway disease

Sebastian Majewski1, Sebastian Slomka2, Ewa Wyderkiewicz-Zielinska1, Lisa Spencer2, Matthew Bartels2, Neil Schluger1, Frances Brogan1, Patricia Jellen1, Byron Thomashow1, Steven Kauw1.

503. COPD: integrated care and rehabilitation

Late-breaking abstract: Sildenafil for chronic obstructive pulmonary disease: A randomized crossover trial

David Ledder1, Neal Schluger1, Frances Bogan1, Patricia Jellen1, Byron Thomashow1, Steven Kauw1.

Introduction: Idiopathic pulmonary fibrosis (IPF), the commonest of the idiopathic interstitial pneumonias, is increasing in incidence/prevalence. Diagnosis can be challenging due to a number of interstitial lung disease with overlapping clinical, radiological or pathological features. Recent guidelines (British Thoracic Society) emphasise the need for multidisciplinary team-based diagnosis, but little published guidance is available to support this recommendation.

Methods: 161 consecutive patients discussed at the ILD MDT meeting at University Hospital of South Manchester were analysed.

Results: In 69 of 161 cases the MDT agreed with the diagnosis of the referring physician. In 67 of 161 cases a single ILD label different to that of the referring centre was given, and in 25 of 161 cases the ILD delivered a differential diagnosis only. Of 67 patients referred with definite IPF only 40 patients (60%) kept their label of IPF; the remaining 27 patients received a different diagnosis, predominantly non-specific interstitial pneumonias (NSIP). At time of follow (3-6 years after MDT discussion) 52% of patients who kept their IPF diagnosis were alive versus 78% of patients alive where a pre-MDT diagnosis of IPF was changed to a more favourable diagnosis, p < 0.05.

Conclusion: This data is the largest ILD MDT cohort thus far reported and is the first report to clearly link an MDT-based change in diagnosis from IPF to NSIP translating into documented improved survival.

Introduction: Idiopathic pulmonary fibrosis (IPF), the commonest of the idiopathic interstitial pneumonias, is increasing in incidence/prevalence. Conclusion: This data is the largest ILD MDT cohort thus far reported and is the first report to clearly link an MDT-based change in diagnosis from IPF to NSIP translating into documented improved survival.
Results: We identified 26,516 individuals with COPD (59% female, mean age 61±13 years) of whom 80% contributed adherence data. Adherence rates (mMPR±s.D. number contributing) were 0.62±0.34, n=13173 for anticholinergics (AChI), 0.61±0.32, n=2018 for inhaled corticosteroids (ICS), and 0.66±0.29, n=5336 for long-acting beta-agonists (LABA). The relative risk for subsequent AE based on a 0.20 difference in mMPR at the start of follow-up was 0.86 (95% CI 0.80 to 0.94) for ICS, 0.91 (0.84 to 1.00) for LABA, and 0.89 (0.84 to 0.93) for AChI.

Conclusions: Better adherence to any of the major classes of inhaled controller therapeutics reduced the risk of subsequent AE-COPD.

Funding: Investigator Initiated Grant, Novartis Pharmaceuticals Corporation.

Background: Evidence from the literature suggests that nonpharmacological treatment for COPD patients improve the outcome of this disease. To explore the provision of non invasive ventilation (INV), early supported discharge programs, and thoracic surgery, a cross-sectional study, date from European COPD audit study was evaluated in 258 hospitals from 13 European countries

Study design: In an observational study, all participating hospitals collected data on the organisation of care for COPD admissions. Preliminary results of 258 (132 general/153 teaching/university) hospitals out of 450 participating centres of the ongoing study will be presented.

Results: Although the majority of centers offer noninvasive (ICU and/or HCU) High dependency care units available for decompensated COPD patients, the capacity for eligible patients is only close to 60%. In addition, supported discharge as well as pulmonary rehabilitation programs are provided in less than 50% of cases.

Conclusions: Contrary to international recommendations, participating European centers in the COPD audit lack sufficient availability for non invasive ventilation; in addition, neither rehabilitation, nor early supported discharge programs are sufficiently available. University hospitals are not superior to general hospitals.

4870

Integated care intervention prevents hospitalisations for exacerbations and reduces the disease costs in COPD patients

Sara Balestracci1, Anna Perca2, Erika Fiumalbi2, Mariella Polesi2, Filming Progetto Mini, PierCarlo Rossi1, Andrea Macerata, Maurizio Moretti1, 1Respiratory Medicine, ASL di Massa e Carrara, Carrara, Italy; 2Department of Pharmacology, ASL di Massa e Carrara, Carrara, Italy; 3Internal Medicine, ASL di Massa e Carrara, Carrara, Italy; 4Primary Care Medicine, ASL di Massa e Carrara, Carrara, Italy; 5General Direction, ASL di Massa e Carrara, Carrara, Italy

Introduction: Efficacy of interventions aimed at preventing hospitalisations due to exacerbations in clinically stable COPD patients is controversial.

Objectives: To evaluate usefulness of integrated care intervention (ICI) on hospital admission for exacerbations and disease costs in COPD patients.

Methods: This prospective study was carried out in 208 COPD patients recruited by general practitioners between January 2009 and December 2009 in Massa-Carrara sanitary district.

The interventions included individually tailored care plan following GOLD guide- lines shared among the chest physician, nurse team and general practitioner, educational program on self-management of the disease, treatment supervision during scheduled visits, home visits by specialised nurses.

Results: 105 patients completed 12 months of follow-up, stratified at stage 1 (n.11), stage 2 (n.47), stage 3 (n.34), stage 4 (n.13) using the GOLD classification. Twelve months of ICI decreased the mean number of hospitalisations (0.54±1.1 versus 0.82±1.1; p<0.05), reduced the percentage of hospitalised patients (27% versus 50% respectively) compared to the previous year. Gold 3 and 4 stages showed the highest reduction in hospitalisation rate. Drug-acquisition costs sign-

ificantly increased (average difference in means ± 256 €) while the mean total disease cost per patients decreased (-201 €) after ICI.

Conclusions: The study demonstrates that a standardised ICI based on share-care intervention between primary care team and hospital team effectively prevents hospitalisations for exacerbations and decreases the total disease cost in COPD patients.

Establishment of an integrated clinical network and comprehensive data warehouse for the conduct of comparative effectiveness research in COPD

Richard Mularski1, MaryAnn McBumney2, Peter Lindencwater3, Shannon Carson3, Todd Lee4, David Au3, Philip Crawford1, Vollmer William1, Jerry Krishnan3, 1The Center for Health Research, Kaiser Permanente Northwest, Portland, OR, United States; 2Department of Preventive Medicine, Baystate Medical Center, Springfield, MA, United States; 3Department of Medicine, Pulmonary Diseases and Critical Care Medicine, University of North Carolina, Chapel Hill, NC, United States; 4ERS School, European Respiratory Society, Lausanne, Switzerland; 4ERS School, European Respiratory Society, Lausanne, Switzerland; 4ERS School, European Respiratory Society, Lausanne, Switzerland

Background: Chronic obstructive pulmonary disease (COPD) affects many mil-

lions worldwide and is increasing in incidence, morbidity, and mortality. Efficacy trials can guide COPD care, but an infrastructure for comparative effectiveness research (CER) across diverse settings is needed to more fully evaluate commonly used therapies in clinical practice.

Methods: We created an inter-disciplinary and multi-institutional network for CER named COPD Outcomes-based Network for Clinical Effectiveness and Research (CER). We developed a platform for comprehensive interoperable clinical data upload and synthesis across diverse outpatient and hospital practice settings to create a comprehensive COPD data warehouse (COPD DataHub) and have begun populating it thru inclusion pathways designed to maximize identification of COPD patients from 2006 through 2008.

Results: The COPD DataHub was designed to be flexible to incorporate data from seven varied health care settings including university-affiliated medical centers, a community medical center, a health maintenance organization and a government-operated veteran medical center. It includes a total of 146,240 unique patients, 58.3% female at non-veteran sites, whites 68.4%, blacks 14.3% and other races 17.3%, average patient age 61.8 years (S.D. 13.5).

Conclusions: We demonstrated the feasibility of developing a rich CER data reposi-

itory by linking COPD patients across diverse sites. CONCERT has successfully created a multi-institutional platform to pursue observational CER studies and identify patients with COPD for enrollment into prospective pragmatic clinical trials.

Lack of oximeters in primary care risks increasing the mortality from COPD

Anthony Davison1, Duncan Powine2, Elizabeth Paddison1, 1Heart and Chest Clinic, Southend University Hospital, Southend on Sea, Essex, United Kingdom; 2Heart and Chest Clinic, Southend University Hospital, Southend on Sea, Essex, United Kingdom

The ERS and ATS (2005), GOLD (2010), NICE (2010) guidelines for COPD recom-

mend long term oxygen therapy (LTOT) in hypoxic patients. LTOT improves the mortality of these patients. NICE recommends that patients with oxygen satu-
rations which are <92% on breathing air should be assessed for LTOT. In order to do this these patients must be identified with pulse oximetry.

Aims and methods: This study was performed in 2010 to examine the availability of pulse oximetry in GP surgeries and the views of GPs to pulse oximetry by post or questionnaire in all 67 practices who serve this hospital.

Results: 60 practices (89%) responded to the questionnaire. Of these 40 (66%) had ≥ 1 pulse oximeters. 24 (40%) had only one oximeter, usually shared between doctors and nurses. 20 (33%) had no oximeter. 64 (23%) stated they would like an oximeter whilst 4 (6.6%) thought an oximeter was not necessary. The main reason given for not having an oximeter was financial.

Conclusions: 33% of GP practices do not have a pulse oximeter. 40% have only one oximeter, which was usually shared between doctors and nurses. Lack of oximeters could lead to referral to secondary care just to have pulse oximetry measured. Lack of finance was the major reason given for not having an oximeter.
but oximeters are now cheap and one referral into secondary care is approximately equivalent to the cost of an oximeter. This study suggests that hypoxia patients with COPD will not be identified early and therefore not treated with LTOT. This will mean that their life expectancy will be reduced. The identification of hypoxia patients in primary care must be urgently addressed by increasing the number of oximeters.

504. Innovative methods in clinical physiology

Late-breaking abstract: Lung recruitment in normal and emphysematous rats during methacholine challenge
Zoltán Hamos1, Margit Szabari1,2, József Tolnai1,2, Bela Suki1,3 Medical Physics and Informatics, University of Szeged, Szeged, Hungary; 2Experimental Surgery, University of Szeged, Szeged, Hungary; 3Biomedical Engineering, Boston University, Boston, MA, United States

Elastase-induced emphysema in rodents is characterized by enlarged alveoli and decreased lung elastance but generally no change in airway resistance. We studied airway and tissue mechanics and recruitment in rats before and during constrictor challenge. Sprague-Dawley rats were treated by intratracheal instillation of 50 U porcine pancreatic elastase (PPE, n=6). Three weeks later, these animals and 6 controls (C) were anesthetized, tracheotomized and mechanically ventilated. From low-frequency impedance (Zrs), tissue damping (G), elastance (H) and hysteresivity (ηPH) were estimated. The lungs were degassed in vivo with oxygen breathing (10 min) and tracheal occlusion (10 s), and then reinfated to 35 hPa, while the pressure-volume (PV) relationship and intratracheal crackle sound (Cra) were recorded. Measurements of Zrs, PV and Cra were repeated during i.v. infusion of methacholine (Mch) at 64 μg/kg/min. RN was not different between groups PPE and C at baseline (44.4±4 vs 46±10 hPa/l, p>0.05) and during challenge (165±14 vs 176±37 hPa/l). G and H, respectively, were significantly lower in the PPE group compared to the controls (613±57 vs 839±165 hPa/l, and 227.3±301 vs 3033±385 hPa/l, although their elevations due to Mch were similar: 13% vs 17%, 3% vs 14%, and 24.1% vs 25.2% for H). Whereas cumulative crackle intensity reached 80% at similar P levels in both groups, the recruited volume was more reduced during challenge (39 vs -16% in the PPE group. In a number of rats, airway resistance and recruitment remained unaffected, the tissue damage was associated with an enhanced tissue constrictor response following elastase treatment. Supported by grants OTKA 66700 and NIH HL090757.

The measurement of absolute lung volume without plethysmography
Ori Adam1, Robert Shimer2, Peter Calverley3, Julian Sobolay4, Robert Brown5, Jeffrey Fredberg1, Department of Geophysics and Planetary Sciences, Tel Aviv University, Tel Aviv, Israel; 1Department of Respiratory Medicine, Imperial College, London, United Kingdom; 2School of Medicine, University of Liverpool, Liverpool, United Kingdom; 3Department of Medicine, University of Chicago, Chicago, IL, United States; 4Harvard Medical School, Harvard University, Boston, MA, United States; 5Harvard School of Public Health, Harvard University, Boston, MA, United States

A basic and important component of pulmonary function testing is determination of absolute lung volumes, including total lung capacity (TLC). However this involves the use of equipment such as a Body Plethysmograph (BP) that is unsuited to routine office practice. To determine TLC, we report here a new mechanical approach – the Partial Volume Method, PVM – that requires neither BP, gas dilution, nor thoracic imaging, yet is simple, compact, rapid, inexpensive, and accurate.

With cheeks supported, the subject breathes through a flow interruption valve downstream of a parallel chamber of known volume. As a result of respiratory system inertia, respiratory flow continues undiminished for a very short time (<15 ms) after valve closure. This continuing flow compresses chamber gas in a manner inferable from Boyle’s law, and used to deduce instantaneous absolute thoracic gas volume. In 106 healthy adults (40 women, 30±11.5 y, 22.8±1.4 BMI, 66 men, 29±10.2y, 24.0±3.1 BMI), TLC was measured using both PVM and standard plethysmography (ZAN 500, nSpire, Inc). For the combined group, TLC_PVM = 0.981 TLC_PLETH, R^2 = 0.87. R^2 = 0.943 (Pearson, CE 0.961-0.918. The coefficient of variation (CV) for repeated PVM trials was 3.44%. Together, these results establish a new method for accurate, rapid, and reproducible determination of TLC in healthy subjects with minimal subject cooperation. This work was sponsored by PulmOne Ltd., Ra’anana, Israel.

Background: Our understanding of regional filling of the lung and regional ventilation distribution (VD) is based on studies using radio labelled tracer gases. We aimed to investigate whether these results can be reproduced and differences in regional filling and spatial VD can be detected with electrical impedance tomography (EIT) in adults at different end-expiratory levels (EEL) and tidal volumes (VT).

Methods: EIT measurements were performed in 10 healthy adults in right lateral position. Five different EEL with four different VT at each EEL were tested in random order, resulting in 19 combinations. There were no measurements for the combination of the highest EEL highest VT as it was not possible to achieve this breathing pattern. EEL and VT were controlled by visual feedback. The fraction of ventilation directed to the right lung (VRight) and the rate of regional filling (right lung vs. total lung) were analysed.

Results: Visual feedback resulted in distinct differences in EEL and VRight increased with increasing EEL and was <0.5 (more air directed to the left lung) only at the lowest EEL (p<0.05). With low EEL the filling of the right lung during the initial phase of the inspiration was slower (p<0.05) and the filling the lungs became more even with increasing EEL. With increasing VRight increased significantly (p<0.05) and the filling characteristics changed towards more uneven ventilation.

Conclusion: The effect of different EEL and VRight spatial and temporal VD during spontaneous tidal breathing in right lateral position can be assessed by EIT. Our results are in line with previous studies and suggest that the effect of EEL on ventilation distribution is greater than the effect of VRight.

K-edge subtraction (KES) synchrotron imaging allows quantitative measurement of regional aerosol deposition, lung ventilation and airway morphology in rabbit
Sam Bayat1, Lotz Durugrgilliers2, Lisa Porra3, Gergely Albu4, Heikki Sahmen5,6, Sara Stenfelle7, Gergely Fodor8, Ferenc Petak8, Pekka Suortti9, Walid Habre10,11, Anssi R.A. Sovijärvi1,2,11,12,13,14,15,16 EAE205 & Pediatric Lung Function, Université de Picardie, UFR de Médecine & CHU Amiens, Amiens, France; 2Department of Medical Physics, Informatics and Engineering, University of Szeged, Szeged, Hungary; 3Pneumiatric Anesthesia, University Hospitals of Geneva and Geneva University, Geneva, Switzerland; 4ID7, European Synchrotron Radiation Facility, Grenoble, France; 5Department of Medical Physics, University of Helsinki, Helsinki, Finland; 6Anesthesiology Investigation Unit, University of Geneva, Geneva, Switzerland; 71ID7, European Synchrotron Radiation Facility, Grenoble, France; 8Department of Medical Physics, Informatics and Engineering, University of Szeged, Szeged, Hungary; 9Pneumiatric Anesthesia, University Hospitals of Geneva and Geneva University, Geneva, Switzerland; 10Department of Clinical Physiology and Nuclear Medicine, Helsinki University Central Hospital, Helsinki, Finland

Rationale: The simultaneous measurement of regional lung ventilation, aerosol deposition and the anatomic configuration of airways are crucial for the better understanding of the determinants of aerosol deposition heterogeneity. However, no single imaging modality currently allows the acquisition of all such data simultaneously. The goal of this study was to test the feasibility of KES imaging to this end.

Methods: We used KES synchrotron radiation imaging (AIRCCM, 2009;180:296–303) to quantify regional lung ventilation, and the deposition of iodine (isopropyl 88 mg/ml in NaCl 0.9%), delivered using an ultrasonic nebulizer (mass median aerodynamic diameter: 2.6±0.1 μm), in a healthy anesthetized, and mechanically ventilated rabbit (2.8 kg) in upright position. Regional ventilation images were obtained in 4 axial slices during inspiration of O2/Ne in O2. Regional deposition images were obtained in 45 contiguous slices after 0.5, 10, 15 and 20 minutes of nebulization.

Results: See figure. Aerosol deposition showed significant spatial heterogeneity in normal lung. Inset: 3D rendering of central conducting airways (dark) and iodine (medium) and parenchyma (light grey).
Conclusions: These data demonstrate the feasibility of K-edge subtraction imaging for the quantitative measurement of regional aerosol deposition, lung ventilation and airway morphology in vivo.

Chest wall kinematics in patients with osteogenesis imperfecta (OI)
Antonella LoMauro1, Simona Pochintesta2, Grazia D’Angelo3, Marriana Romzi3, Andrea Aliverti1, 1Dipartimento di Bioingegneria, Politecnico di Milano, Milano, Italy; 2Dipartimento di Neuroriabilitazione, IRCCS “Eugenio Medea”, Bosisio Parini, Lecco, Italy

In Osteogenesis imperfecta (OI), an inherited connective tissue disorder characterized by brittle bones and significant chest wall (CW) deformities, pulmonary complications are the principal cause of death. In order to study how OI affects chest wall function, we studied 7 patients with severe form type III (OI3), 15 with moderate form type IV (OI4) and 26 healthy subjects (CTR). Breathing pattern, regional CW volume changes and thoracoabdominal asynchronies at rest in seated and supine position were measured by opto-electronic plethysmography. Rib cage deformities were assessed from OEP markers by computing the angle of the sternum (a) on the transversal plane. In both positions, minute ventilation was lower in OI than CTR because of lower tidal volume (p<0.01). Abdominal tidal volume in OI3 was higher and associated to low pulmonary rib cage contribution which was even negatvie (inspiratory paradoxical inward motion) in supine (figure). OI3 showed reduced a (161.6±17.5°; 173.6±10.5°; 181.7±12.9°) in OI3, OI4 and CTR, p<0.01 and higher thoracoabdominal asynchrony (labeled breathing index=1.32±0.4; 1.03±0.03; 1.02±0.02 in OI3, OI4 and CTR, p<0.001).

In conclusion, OI3 is characterized by rib cage deformities (pectus carinatum) which alters CW function during breathing. The reduced or paradoxical rib cage motion during inspiration is compensated by an increased action of the diaphragm at rest, associated with large thoracoabdominal asynchrony.

Diaphragm fatigue in self-paced running exercise of different durations
Thomas U. Wuthrich1, Elisabeth C. Eberle1, Christina M. Spengler1,2, 1Exercise Physiology, Human Movement Science, ETH Zurich, Zurich, Switzerland; 2Physiology, Physiology and Center for Integrative Human Physiology, University of Zurich, Zurich, Switzerland

Introduction: Diaphragm fatigue (DF) was shown to develop during high intensity constant load exercise (CLE) above 85% of maximal oxygen consumption (VO2max). CLE does, however, not appropriately reflect field trial conditions where exercise intensity is regulated by complex feedback and feedforward mechanisms, possibly aiming to reduce/prevent DF. Therefore, the development of DF was assessed in 11 well-trained athletes (age=31.4±4 yrs, VO2max=66.7±4.6 ml/min/kg) in 15 and 30min running time trials (TT). We hypothesized that DF would be larger in the 30TT where more time is spent above 85% VO2max.

Methods: Before and 4min after completion of the TTs, esophageal and gastric pressures were assessed to calculate transdiaphragmatic twitch pressures (Pdi,tw) during cervical magnetic stimulation.

Results: All three developed DF (Pdi,tw reduction, ΔPdi,tw >10%) in the 15TT and 7/11 subjects in the 30TT. On average, ΔPdi,tw was 23 ±6.5 (15TT) and 18.5±12.1 (30TT; p=0.13). Mean exercise intensities were 89.4±3.5 (15TT) and 80.6±3.7% VO2max (30TT; p=0.07) with similar mean durations above 85% VO2max (11±3.2min; range: 7-14min; 15TT) and (16.2±6.7min; 1-28min; 30TT; p=0.19).

The individual between-TT difference in ΔPdi,tw did not correlate with the difference in time spent above 85% VO2max (R2=0.20) but correlated with the difference in average exercise intensity above 85% VO2max (R2=0.49; p<0.02).

Conclusion: In TT-conditions, the degree of DF is not related to the duration spent above 85% VO2max but it is related to the exercise intensity when exercising above the 85% VO2max-threshold.

Ultrasound measurement of quadriceps wasting in patients with GOLD stage II COPD and its relationship to physical activity
Dinesh Shrinkishna1, Rebecca Tanner1, Melch Patil1, Anna V.J. Donaldson1, Cayleb Smith1, Zudin A. Puthucheary2, Paul S. Sidhu2, Nicholas Hart2, John Moxham3, Michael I. Polkey3, Nicholas S. Hopkins1, 1NIHR Respiratory Biomedical Research Unit, Royal Brompton and Harefield NHS Foundation Trust and Imperial College, London, United Kingdom; 2NIHR Comprehensive Biomedical Research Centre, Guy’s & St Thomas’ NHS Foundation Trust and King’s College London, London, United Kingdom

Introduction: Ultrasound measurement of rectus femoris cross-sectional area (USRFCSA) is a radiation-free measure of muscle bulk that relates to quadriceps strength.1 A recent study reported that a significant proportion of GOLD stage II patients have quadriceps weakness.2 We hypothesised that quadriceps wasting, measured by USRFCSA, would be observed in GOLD stage II patients and would correlate with daily physical activity levels.

Methods: USRFCSA and quadriceps maximum voluntary contraction (QVMC) were measured as described by Seymour et al.1 Physical activity was recorded for six consecutive days using a multisensor biaxial accelerometer, SenseWear Pro Armband3,4. Fat free mass (FFM) was estimated using bioelectrical impedance and a disease specific regression equation.

Results: We studied 100 patients with stable COPD, (GOLD stage II-33%, III-34%, IV-33%), mean (SD) age 65 (9) years, 57% male and 23 age-matched healthy controls. USRFCSA was significantly reduced (517mm2 vs 626mm2; p=0.005) in Stage II patients compared to controls. USRFCSA was also significantly reduced in stage III (500mm2; p=0.006) and IV (522mm2; p=0.007) disease. Using a stepwise regression model in all patients, FEV1/FVC predicted and USRFCSA, but not FFM index and QVMC, correlated with daily physical activity (steps) (R2=0.4, p<0.001).

Conclusion: USRFCSA is reduced in GOLD stage II COPD and is related to daily physical activity. USRFCSA provides a bedside method for identifying quadriceps muscle loss in less severe disease and may guide the application of pulmonary rehabilitation in these patients.

is not sufficiently high to replace PS0 in the evaluation of individual patients with suspected disturbances of hemoglobin oxygen affinity.

4885 Degree of bronchial hyperresponsiveness (BHR) and new onset of respiratory diseases 9 years later

Alessandro Marcon1, Christter Janson1, Josep M. Antó4, Peter Burney4, Isa Cerveri5, Joachim Heinrich6, Deborah Jarvis4, Nino Kuenzli7, Cecilia Svanés8, Kjell Toren9, Matthias Wjst10, Jan-Paul Zock11, Roberto de Marco12. 1Unit of Epidemiology and Medical Statistics, University of Verona, Verona, Italy; 2Department of Medical Sciences: Respiratory Medicine & Allergology, Uppsala University, Akademiska Sjukhuset, Uppsala, Sweden; 3Centre for Research in Environmental Epidemiology, CREAL, Barcelona, Spain; 4Department of Medical Sciences: Respiratory Medicine & Allergology, Uppsala University, Akademiska Sjukhuset, Uppsala, Sweden; 5Institute of Molecular Medicine, University of Aarhus, Denmark; 6Institute of Epidemiology, University of Verona, Verona, Italy; 7Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany; 8Department of Clinical Biochemistry and Pharmacology, University of Southern Denmark, Odense, Denmark; 9Department of Medical Sciences: Respiratory Medicine & Allergology, Uppsala University, Akademiska Sjukhuset, Uppsala, Sweden; 10Respiratory Epidemiology and Public Health Group, National Heart and Lung Institute, Imperial College, London, United Kingdom; 11IRCNS San Matteo Foundation Hospital, University of Pavia, Pavia, Italy; 12Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany; 13Center for Research in Environmental Epidemiology, CREAL, Barcelona, Spain; 14Respiratory Epidemiology and Public Health Group, National Heart and Lung Institute, Imperial College, London, United Kingdom; 15IRCNS San Matteo Foundation Hospital, University of Pavia, Pavia, Italy; 16Institute of Epidemiology, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany; 17Swiss Tropical and Public Health Institute, SwissTropical, Basel, Switzerland; 18Rising Research Respiratory Group, Institute of Medicine, University of Bergen, Bergen, Norway; 19Section of Occupational and Environmental Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 20Comprehensive Pneumology Center, Institute of Lung Biology and Disease, Helmholtz Zentrum Muenchen, German Research Center for Environmental Health, Munich, Germany

In the European Community Respiratory Health Survey, 10933 subjects aged 20-44 years (29 countries, 14 countries) had both a baseline (1991/3) and a follow-up (2002/4) evaluation. The degree of baseline BHR was defined in 836 (77%) subjects as absent (PD20=1 mg) (n=6852); and low (PD20, mg: (0.5-1]), medium (0.15-0.5) or high (0-0.15), based on PD20 distribution tertiles. Two-level logistic regression models (2nd level, center) were used to analyze the association between BHR degree and new onset of nasal allergies (allergic rhinitis, AR) and COPD (pre-bronchodilator FEV/FVC=0.70) in non-asthmatic subjects; current asthma and symptoms (wheeze, chest tightness, dyspnea at rest/after exercise/at night), and new onset of asthma symptoms in subjects who were free from the respective outcomes at baseline. The analyses were adjusted for gender, age, height, education, pack-years, FEV1 and atopy (IgE >0.35 kU/L to cat, mite, grass or grass pollen). An increased BHR degree was associated with an increased risk of developing COPD, asthma and asthma-like symptoms 9 years later (see table).

These preliminary analyses support the interest for BHR degree as a predictor of several adult-onset respiratory diseases.

4886 Chronic rhinosinusitis and airway inflammation in new onset asthma in adults

S.B. Nielsen1, C. Georgalas2, I.E.M. Weersink3, J.E. van den Berg4, B. van den Berg5, F.H. Kroewel6, P.J. Sterk7, W.J. Fokkens8, E.H. Bel9, 1Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands; 2Academy of Rhinology, Academic Medical Centre, Amsterdam, Netherlands; 3Research Respiratory Medicine, St Lucas Andreas Hospital, Amsterdam, Netherlands; 4Respiratory Medicine, Spaarne Hospital, Hoofddorp, Netherlands; 5Orthonasaloryngology, Academic Medical Centre, Amsterdam, Netherlands

Rationale: In severe asthma, chronic rhinosinusitis (CRS) is associated with increased sputum eosinophils [Brooke, JACT 2002]. Many adults with severe asthma have the onset of their disease in adulthood. We hypothesized that the relationship between the severity of CRS and inflammation in the lower airways already exists in the early stages of adult-onset asthma.

Aim: To investigate the relationship between CRS and airway inflammation in adults with new onset asthma.

Methods: Ninety-eight adults (>18yr) with a physician diagnosis of recent (>1yr) onset asthma (age 48 (41.6yr), pH FEV1 99 (±8.8)/p% 66% female, 43% atopic, 20% steroid naive) were recruited. Diagnosis was based on reversibility in FEV1 ≥12%pred and/or PD20 methacholine < 8 mg/ml. Patients with COPD were excluded.

CT-scanning was performed and blindly scored for sinonasal mucosal thickness using LMK score [Land Rhinology 1993]. Sputum was induced and processed, exhaled nitric oxide (FeNO), pH FEV1 and methacholine challenge were performed and venous blood was taken. LMK scores were related to sputum cell counts, FeNO and lung function and blood using Spearman correlation coefficient. The analyses were adjusted for gender, age, atopy, history of allergic rhinitis, history of allergic asthma, BMI, current smoking, and pack-years.

Results: There was a significantly positive correlation between CT scores and eosinophils in induced sputum (R=0.73, p<0.001) and peripheral blood (R=0.73, p<0.001) and level of FeNO (R=0.38, p<0.05). No correlation was found between CT-scan scores and pH FEV1. Predictors were PD20 (p=0.75) and PD20 methacholine (p=0.15).

Conclusion: In adults with recent onset asthma, the degree of CRS and lower airways inflammation are closely related. This implies that patients with recent onset asthma should be checked and treated for upper airways disease, if necessary.

4887 Association between airway hyperresponsiveness, obesity, and lipoproteins in a young Danish cohort

Finn Ravnsuess1, Nair Parameeswaran2, Mads Nybo1, Bob Hancock3. 1Department of Allergy and Respiratory Medicine, Near East University, Lefcosa, Mersin, Turkey; 2Division of Respiratory, McMaster University, Hamilton, ON, Canada; 3Dundee Multidisciplinary Health and Development Research Unit, Dundee School of Medicine, University of Otago, Dunedin, New Zealand; 4Department of Clinical Biochemistry and Pharmacology, University of Southern Denmark, Odense, Denmark

Rationale: Epidemiological data have linked obesity with an increased risk of asthma in the community. However, the mechanisms responsible for this relationship remain unknown. The present study investigated the association between airway hyperresponsiveness to methacholine (AHR) and body mass index (BMI) and plasma lipoproteins (LDL, HDL and total cholesterol).

Methods: Associations between AHR, BMI and plasma lipoproteins were assessed in a population-based cohort at ages 14 and 20 years. Main results: In unadjusted analyses, higher LDL cholesterol levels at age 14 were associated with AHR to methacholine at age 20 in both sexes (p<0.05). HDL, LDL/HDL ratio and total cholesterol were not associated with AHR. In a multiple regression analysis adjusted for sex, lung function, smoking and asthma, only higher levels of BMI at age 14 were significantly associated with increased AHR at age 20 years, while neither LDL, HDL, LDL/HDL ratio nor total cholesterol were significantly associated with AHR to methacholine.

Conclusions: We confirmed that there is a strong association between BMI and AHR to methacholine in young people. This association seems to be independent of the plasma lipoprotein levels and we did not find an independent association between levels of lipoproteins and AHR.

4888 Effect of vitamin D treatment on antimicrobial peptides in asthma patients and healthy controls

W. Thijss1,2, K. Janssen1, R.M. Verhooisela1, S.E. Papapoulos1, S. Le Cessie1, S. Middeldorp7,8, C.F. Melsson1, K.F. Rabe1, P.S. Hieron1, 1Department of Pulmonology, LUMC, Leiden, Netherlands; 2Department of Respiratory Medicine, AMC, Amsterdam, Netherlands; 3Department of Pulmonary Medicine, St Lucas Andreas Hospital, Amsterdam, Netherlands; 4Department of Pulmonary Medicine, Hoofddorp, Netherlands; 5Department of Pulmonology and Thoracic Surgery, Krankenhaus Grosshadendorf, Grosshadendorf, Germany

Vitamin D deficiency has been linked to asthma because of the proposed role of vitamin D in inflammation control and host defense against infection. Antimicrobial peptides (AMPs) are effector molecules of the innate immune system, and their expression may be decreased by allergic inflammation. Vitamin D increases expression of AMP in vitro, but its effects on AMPs levels in asthma patients are unknown. Hypothesis: AMP levels in nasal secretions of patients with allergic asthma are lower than in controls and can be restored by vitamin D substitution. Methods and results: 20 allergic asthma patients and 20 controls (18-45 yrs) were included. The influence of allergic asthma on AMPs was assessed in a case control design, and the effect of 7 days daily oral treatment with 2 mg 1,25(OH)2D3 active vitamin D (calcitriol) on AMPs was assessed in a placebo-controlled cross-over study. The levels of the AMPs HNP1-3 and NGAL were significantly lower in asthmatics, whereas there was a trend for an increase in LL-37 (table 1).

Table 1. Mean AMP in asthma patients and healthy controls.

Treatment with 1,25(OH)2D3 significantly increased HNP1-3 and there was a trend for an increase in LL-37 and NGAL.
Introduction: Mechanism of BA onset and progression at different ages is still poorly understood and eotaxin in upper airways is a tempting object of investigation into BA pathogenesis.

Methods: We examined 70 patients with asthma. The patients' age ranged from 16 to 74 years. We studied 31 men and 39 women. The control group used was comprised of 30 healthy volunteers with no history of atopic diseases. Were studied 16 to 74 years. Were studied 31 men and 39 women. The control group used was comprised of 30 healthy volunteers with no history of atopic diseases.

Results: A study in patients with asthma was revealed a significant increase in eotaxin mRNA expression (p = 0.045), eotaxin-2 (0.036), MIP-1β (0.003), MIP-1α (0.002) and CXCR2 (0.004) compared with healthy volunteers. At the same time the gene expression in patients with asthma was reduced compared with control. To study the age dynamics of the asthma patients were divided into 4 groups: first group - 16-25 years (n = 14), the second group - 26-39 years (n = 14), the third group - 40–53 years (n = 21) and the fourth group - 54-74 years (n = 21). Eotaxin-2 had wave-like dynamics depending on patients age. MIP-1α was lowest in the second and third groups, and in the first and fourth - significantly decreased. The values of MIP-1β - the lowest in the first group with increasing age became more and peaked in the fourth group. mRNA of CCR1 and CXCR1 was significantly decreased in the second group compared to the first, meanwhile in the third and fourth ones levels of mRNA of both receptors increases depending on the age of the patients.

Conclusion: The state of chemokines and relative receptors gene expression in upper airways reflects age features of BA pathogenesis.

Introduction: Chemoattractants and their receptors mRNA expression in brush-biopsies of nasal polyps in bronchial asthma patients

Methods: We examined 70 patients with asthma. The patients' age ranged from 16 to 74 years. We studied 31 men and 39 women. The control group used was comprised of 30 healthy volunteers with no history of atopic diseases. Were studied 16 to 74 years. Were studied 31 men and 39 women. The control group used was comprised of 30 healthy volunteers with no history of atopic diseases.

Conclusion: The state of chemokines and relative receptors gene expression in upper airways reflects age features of BA pathogenesis.

Conclusion: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Introduction: Rapamycin inhibits IL-33-induced airway inflammation

Methods: BALB/c mice were treated intranasally with 1 μg IL-33 daily with or without 1 mg/kg rapamycin for 5 days. Airway inflammation was assessed on day 6 by bronchial/ovarian lavage (BAL) cellularity and cytokine analysis.

Results: Intranasal IL-33 induced profound airway inflammation with increased cellular recruitment on BAL consisting mainly of macrophages and eosinophils. Treatment with rapamycin significantly reduced IL-33-mediated cellular recruitment (Figure 1A) and reduced both eosinophil (Figure 1B) and macrophage (Figure 1C) influx into the airway.

Conclusions: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Conclusion: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Article title: Rapamycin inhibits IL-33-induced airway inflammation

Authors: Ananya Mirchandani, Robert Salmond, Foo Liew.

Abstract: Rapamycin was initially described as a macrocidal antibiotic that selectively blocks the mammalian target of rapamycin (mTOR), a serine/threonine kinase involved in inflammation and the associated signalling pathways are incompletely understood. Rapamycin also significantly reduced IL-33-mediated IL-5 and IL-13 production and IL-33-induced IL-6 production.

Conclusions: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Conclusions: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Conclusion: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Conclusion: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.

Conclusion: Levels of AMPs are lower in nasal secretions in asthmatics, and treatment with active vitamin D increases these levels.
Tuberculosis in special populations

4894 Impact of African immigration on drug resistance to Mycobacterium tuberculosis in Portugal
Carina Gaetan, Carlota dos Santos, Nelson Diogo. Pneumology Department, Pulido Valento Hospital, Lisbon, Portugal

Background: Several works pointed immigration as a risk factor for drug resistance in Western countries. In Portugal immigration is responsible for 13.6% of tuberculosis cases, 75% of those cases being originated from Sub-Saharan African countries.

Aim: To evaluate the role of immigration from African countries in drug resistance to Mycobacterium tuberculosis (Mt) in Portugal.

Methods: Comparative retrospective study between African immigrants (I) and native (N) patients with positive culture to Mt and who realized susceptibility tests, admitted in a Pneumology unit from 2000 to 2010. Clinical-demographic characteristics, aetiopathogenic factors, drug resistance profiles and inhospital outcomes were evaluated.

Results: 1232 patients were enrolled, 240 (18.1%) being immigrants, most of them from Portuguese spoken countries. Statistically significant differences were found on the following variables: drug addition (I: 6.7% vs N: 28.8%); WHO classification; number of previous treatments (I: 0.21 vs N: 0.37); duration of previous treatments (I: 0.88 vs N: 1.83); inhospital mortality (I: 4.2% vs N: 8.5%). The variables with predictive value for resistance in this population were HIV co-infection, number of previous treatments and chronic TB infection. The total incidence of drug resistance was similar in both groups (I: 20.8% vs N: 21.0%), but secondary resistances were less frequent in immigrants (I: 5.4% vs N: 9.7%).

Conclusion: African immigration was not associated with increased prevalence of drug resistance to Mt. These findings can be explained by the reduced access to antituberculosis drugs in Sub-Saharan countries.

4895 Double impact: Difficulties in treating patients with liver diseases from tuberculosis
Hoda Makhlouf 1, Nahed Makhlouf 2, Mohamed Metwally 1, Hebat Alla Rashid 3

Background: Tuberculosis and liver disease are both endemic in many parts of the world. Many anti-TB drugs have hepatotoxic side effects and should be used cautiously during their use in liver disease patients.

Objectives: To assess the frequency and risk factors of anti-TB Drug-Induced Hepatotoxicity (Anti-TB-DIH) among patients with viral hepatitis and liver cirrhosis.

Patients & Methods: This prospective study included 26 TB patients of pulmonary and extrapulmonary TB associated with liver cirrhosis or viral hepatitis in addition to, 46 TB patients without liver disease as controls. All patients were followed up clinically and biochemically before and during their treatment.

Results: Anti-TB-DIH was noticed in 30.8% patients with liver disease (46.2% and 15.4% in liver cirrhosis and viral hepatitis respectively; P=0.089) and in 8.7% of control group (P<0.05 vs liver disease). Anti-TB-DIH developed within 15-60 days from the onset of therapy. Liver functions normalized in 25% of patients with liver disease within 2 weeks from cessation of therapy. By univariate analysis, liver diseased patients with anti-TB-DIH had lower body mass index (P=0.049) and lower serum albumin (P=0.008). Using multivariate regression analysis proved that lower serum albumin was independent predictors of anti-TB-DIH (P=0.018) in liver diseased patients while the presence of other co morbid diseases was the only risk factor in patients without liver disease (P=0.024).

Conclusion: Anti-TB-DIH is common among patients with liver diseases and is more in patients with lower serum albumin while the presence of other co morbid diseases is only risk factor for DIH in TB patients without liver disease.

4896 Hepatitis C virus infection among tuberculosis patients in Sohag
Governorate: Seroprevalence and associated risk factors
Mohamed Badawy 1, Mona Taha 1, Laia Mohamed 1, Ahmed Fathy 1

Chest Department, Clinical Pathology, Public Health Department, Sohag University Hospital, Sohag Faculty of Medicine, Sohag, Egypt

Setting: Tuberculosis (TB) and hepatitis C virus (HCV) infection have emerged as major public health problems in Egypt.

Objective: To determine the prevalence and risk factors for the HCV infection among patients with TB in Sohag.

Material and methods: A cross-sectional study was carried out at Sohag university hospital. Hundred thirty five tuberculosis patients were fulfilled the inclusion criteria. age more than 15 years old, patients with all form of tuberculosis either pulmonary or extra pulmonary. Anti-HCV antibodies were done for all patients. A case-control study was performed to identify risk factors for HCV infection. Cases were defined as patients with TB who were HCV-seropositive, and controls were defined as patients with TB who were HCV-sero-negative.

Results: HCV infection was diagnosed in 21/135 (16.4%). Goa'za smokers (P value 0.01 Odds Ratio 3.75, 95% confidence interval 0.24 – 0.44), history of operation (P value 0.01 ORs 7.67, 95% CI 1.65 – 0.263), blood transfusion (P value 0.004 ORs 7.2, 95% CI 1.103 – 0.362), presence of tattoos (P value 0.03 ORs 3.4, 95% CI 0.168 – 0.338), extra pulmonary tuberculosis (P value 0.004 ORs 3.5, 95% CI 2.341 – 3.384), low serum albumin (P value 0.002 ORs 0.5, 95% CI 0.068 – 0.317) were the main risk factors associated with HCV infection.

Conclusion: Universal screening for HCV infection in TB patients is highly recommended. There is an urgent need to detect HCV infection in high-risk groups to prevent future HCV transmission as well as morbidity and mortality associated with TB.

4897 Detection of active TB among people living with HIV/AIDS and vulnerable population groups (commercial sex workers and injecting drug users)
Alexandra Solovyova 1, Alexander Golubkov 2, Elena Borzunova 2

Conclusion: To increase coverage of preventive TB screening and assess prevalence of TB among vulnerable groups in Tomsk, Russia.
Methods: During 2010, a cohort of 703 persons was identified as a risk group for TB. Screening was conducted twice a year and included basic evaluation of symptoms, PPD (DIASKIN-TEST) and chest fluorography. Evaluation involved qualitative interviews with suspects to detect chronic cough, weight loss, night sweats and hemoptysis and other symptoms of TB. Outreach workers of Tomsk-AntiAIDS Foundation provided field counseling, TB and HIV education, phlebotomy, PPD with further referral to TB Services for medical evaluation. Nutritional support, hygiene packages and accompaniment used as incentives to complete screening.

Results: Out of 703 people at risk screened for TB, 30 suspects were sent for medical examination to TB Services (4.3%). Out of them, 6 were diagnosed with active TB (20.0%), including 2 MDR-TB cases.

Conclusion: Enhanced preventive screening and further medical assessment of TB suspects from vulnerable population resulted in high prevalence of active disease (850/100,000). There is a need to continue and expand coverage of preventive screening for the rest of risk group in Tomsk Oblast.

4898 Tuberculosis screening among intravenous drug users (IDU) in Georgia
Nana Kiria, Medea Gegia, Iagor Kalandadze

The National Tuberculosis Programme, The National Center for Tuberculosis and Lung Diseases, Tbilisi, Georgia

Background: IDU is widespread in Georgia and regardless of HIV status it is at increased risk of developing active TB. It is necessary to identify the screening and effectively address the TB cases among IDUs.

Aim: To assess the prevalence of TB among IDUs.

Methodology: Using the data of prospective cohort study: from April 2008 to January 2011 IDUs at harm reduction and VCT sites were screened for TB symptoms using the questionnaire.

TB suspects cases were referred to TB units for further investigation and diagnosis.

Results: 4985 IDUs were screened for TB symptoms, 79 (2%) from them were female and 4906 (98%) - male. Mean age was 33. 81 (1.6%) from the screened IDUs were HIV-positive and 2304 (46%) were diagnosed to have Hepatitis B or C. 436 (8.7%) were defined as TB suspects. They were presented at TB units for further examinations. TB was confirmed in 175 cases, 109 (62%) had pulmonary TB and 66 (38%) – extrapulmonary. The prevalence of TB among IDUs was 3510 per 100,000 which is 26 times greater as compared to TB prevalence in general population.

Conclusions: Given the high risk for TB among IDUs, interventions such as active case finding, is urgently needed to detect TB cases as early as possible and treat them adequately.

4899 Managing tuberculosis in chronic kidney disease: An evaluation of patient treatment regimens
Alexandra Riding 1, Paramita Palchabdhi 1, Parvin Begum 2, Marlies Ostermann 2, Heather Möhr 1

1Department of Respiratory Medicine, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 2Department of Renal Medicine, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

Introduction: Balancing side effects against effective tuberculosis (TB) treatment

892s
in Chronic Kidney Disease (CKD) can be difficult leading to variations in management. We reviewed patients with CKD and TB to investigate compliance with new treatment guidelines by the British Thoracic Society.

Methods: Retrospective review of patient case notes with CKD who developed TB between 1994-2010 in a single tertiary hospital. Categories included drug dosage, side effects, treatment duration, respiratory team input and outcome.

Results: We reviewed the notes of 40 patients. 11 had incomplete data. In 73% (52/71) of prescriptions dosing regimens were consistent with BTS guidelines. Errors included over-dosing of Rifater and Isoniazid in 2 patients, and under-dosing of ethambutol in 13 patients. Daily dosing of ethambutol (10/14) and pyrazinamide (10/12) in haemodialysis patients was common and not ideal. Side effects were recorded in 22/29 patients: 3 rifampicin, 5 isoniazid, 3 ethambutol, 4 pyrazinamide, 1 streptomycin and 6 to any/combination drugs. Increased treatment duration (12/29 cases) due to side effects was common. All patients were cured and 23/29 (79%) received specialist respiratory physician input.

Conclusion: Management of TB in CKD patients was variable. Side effects from anti-TB drugs were common, but good, all not patients received respiratory physician input. The new BTS guidelines for drug regimens will hopefully standardise management of CKD patients with TB.

1 BTS Standards for Tuberculosis Care. Guidelines for the prevention and management of Mycobacterium TB infection and disease in adult patients with CKD. Thorax 2010; 65: 559-570

4900 Prednisolone treatment does affect the performance of the Quantiferon in-tube test and the tuberculin skin test in patients with autoimmune disorders screened for latent tuberculosis

Erika Beland1, Svenn Semb1, Morten Ruhrwald1, Anne Marie Wierlund1, Bolette Thygesen2, Morten Skov Jensen1, Henrik Hjorth Hansen2, Annette Blyrlund3, Merete Lund Heltand4, Inge Noergaard-Lassen5, Inge Noergaard-Lassen6, Perminne Ravns7,1. Dept. for Gastroenterology, University Hospital Hvidovre, Hvidovre, Denmark; 2Dept. of Respiratory Medicine, University Hospital Hvidovre, Hvidovre, Denmark; 3Dept. of Infectious Diseases, University Hospital, Herlev, Herlev, Denmark; 4Dept. for Epidemiology, Statens Serum Institut, Amager, Denmark; 5Dept. for Radiology, University Hospital Hvidovre, Hvidovre, Denmark; 6Dept. for Radiology, University Hospital Herlev, Herlev, Denmark; 7Dept. for Rheumatology, University Hospital Hvidovre, Hvidovre, Denmark

Background: During screening for latent tuberculosis infection (LTBI), before anti-TNF-alpha treatment, most patients are already receiving immunosuppressive therapy. Objectives was to evaluate the performance of the Quantiferon IN-Tube (QFT-IT) and the Tuberculin Skin Test (TST) in these groups.

Methods: We included 244 patients treated for ulcerative Colitis, Crohn’s disease, rheumatoid arthritis, and spondylo-arthropathy. Results: QFT-IT was positive in 72/48 (3%), negative in 299 (92%), and indeterminate in 2/5 (4%). TST was positive in 54/238 (23%) patients. Chest X-ray was suspect in 53/256 (21%), and 35/167 (21%) had risk factors. We found a pronounced negative effect on QFT-IT and TST performance associated with prednisolone treatment; the IN- response to mitogen stimulation was impaired (median INP- response 4.91/ml (IQR 0.8-10.0) compared to patients a) not receiving corticosteroids (median 10.0 (IQR 5.0-10.0) (p=0.0015) or b) receiving long-acting corticosteroids (median 10.0 (IQR 9.7-10.0) (p=0.0058). Prednisolone treatment was strongly associated with negative TST, AOR 22 (0.1-0.8) (p=0.018), and with an increased risk of indeterminate QFT-IT results AOR (16.1-9.0) (p=0.001). No negative effect was found for long-acting corticosteroids. Prednisolone doses above 10mg resulted in 27% of indeterminate results.

Conclusion: Oral prednisolone severely suppressed QFT-IT and TST performance whereas long-acting corticosteroids, Metotrexate, Azathioprin and 5-ASA did not have similar detrimental effect. Patients should be screened for LTBI with QFT-IT or TST prior to initiation of prednisolone.

508. Novel mechanisms in COPD

4901 Results of a phase 2a clinical trial with a peptide inhibitor of MARCKS protein indicate improvement of indices of bronchitis and lung function in patients with COPD

Kenneth Adler1, Monica Kraft2, Indu Parikh3, Edward Murphy4, Andre Van Ass5, 6. Molecular Biomedical Sciences, North Carolina State University, Raleigh, NC, United States; 7. Medicine, Drexel University College of Medicine, Philadelphia, PA, United States

A peptide inhibitor of MARCKS (BIO-11006) attenuates mucus hypersecretion, inflammatory cell influx and airway obstruction in several in vivo models of asthma and bronchitis, suggesting BIO-11006 as an ideal treatment for COPD. In a Phase 2a study, 172 subjects with stable COPD (GOLD Stage 2, 3) were randomized in a double blind, controlled safety and efficacy study. Four doses of BIO-11006 or control (half normal saline; HNS) were administered by nebulization for 21 days to 5 cohorts; 75 mg QD (n=8) or BID (n=24), 150 mg QD (n=35), and 25 mg BID (n=32); HNS (n=40). The ratio of active control was 2:1 and 3:1 for QD and BID dosing, respectively. Trough FEV1 (primary endpoint) was measured on days 0, 3, 7, 14, 21, 28 and 49. A trend towards increased FEV1 with the 75mg BID group was maintained on follow-up days 28 and 49. An FEVI responder analysis (defined as 5% or more improvement of FEV1 = Responder) revealed the percentages of responders for the 75 mg BID dose were 46, 38, 50 (p=0.014 vs HNS), 42, 54 (p=0.014 vs BID 150mg) and 40% vs 150mg, respectively. BIO-11006 was systemically well tolerated with some increase in respiratory adverse events. We conclude that the 75 mg BID dose appeared to be the most efficacious by increasing the proportion of FEV1 responders statistically significantly as compared with HNS. Sputum volume and the St Georges Respiratory Questionnaire Symptoms Score also trended towards improvement with 75mg BID. Thus, BIO-11006, a dual action molecule that decreases both mucus hypersecretion and inflammation, may represent a new advance in the treatment of COPD.

4902 Discrimination of expanded dendritic cell populations in lung tissues from COPD patients

Michiko Mori1,2, Cecilia Andersson1,2, Anders Bergqvist1,2, Chris Van Hove3, Claas-Goran Lofldahl1, Jonas Erpfal1,2. 1Department of Experimental Medical Science, Lund University, Lund, Sweden; 2Department of Respiratory Medicine and Allergology, Lund University Hospital, Lund, Sweden

Rationale: Dendritic cells (DCs) are highly plastic and their characterization in human tissues has been hampered by lack of standardized immunohistochemical identification. This study validates an immunohistochemical approach for discriminating confounding non-DC cells and characterizes multiple DC populations in COPD-affected lungs.

Methods: Lung specimens were obtained from 27 COPD patients and divided into three tissue levels of severity: GOLD I (n=6), GOLD II-III (n=11) and GOLD IV (n=10). Never-smokers (n=8) and non-COPD smokers (n=6) served as controls. Paraflin sections were double stained for combinations of macrophage and DC markers.

Results: Using the non-soluble DAB as the first detection chromogen it was possible to mask confounding non-DC cells e.g. CD68 macrophages at a bright microscopic level. Using this approach two populations of CD68+CD11c+ and CD68-CD11c+ cells were identified, and their immunophenotyping is described. The myeloid DCs, which were foremost BDCA3+, significantly increased in diseased areas of COPD lungs, in particular in patchy areas of fibrosis and granuloma formation. Both CD68+CD11c+ and CD68-CD11c+ cells displayed a dendritic morphology and were located in epithelial and subepithelial compartments of small airways and alveolar walls as well as in lymphoid aggregates amidst CD21+ follicular DCs. Further combination of markers could discriminate intrapulmonary myeloid and plasmacytoid DCs from CD207+ and CD11c+ epithelial DCs.

Conclusions: This study demonstrates that masking of confounding non-DC pop-ulations improves the identification of lung DC populations and reveals novel aspects of their dynamics and heterogeneity in COPD lungs.

4903 Mechanisms of tertiary lymphoid organ formation during lung neogenesis are involved in lymphoid follicle formation in chronic obstructive pulmonary disease

Maria Tsoumakidou1,2, Eleni Litsiou1, Katerina Tsoutra2, Panagiota Kara1, Dimitra Rontogianni2, Charalambos Zisis4, Ion Belenis4, Spyros Zakynthinos1,2. 1Critical Care Medicine and Pulmonary Services, Evangelismos General Hospital, Athens, Greece; 2Lung Immunobiology, Thorax, Athens, Greece; 3Pathology, Evangelismos General Hospital, Athens, Greece; 4Thoracic Surgery, Evangelismos General Hospital, Athens, Greece

Tertiary lymphoid organs (TLOs) are aggregates of B and T cells formed in response to chronic immune responses. TLOs are the result of lymphoid neogenesis and are formed via production of lymphoid-organizing chemokines (CXCL13, CCL19 and CCL21), in response to signaling from lymphotactin (LTα) via TNFR1, TNFR2 and LTR. Stromal cells and antigen presenting cells (APCs), i.e. dendritic cells (DCs), secrete lymphoid chemokines, which attract B cells, T cells and DCs via CCR7 (receptor for CCL19/21) and CXCR5 (receptor for CXCL13). Lymphoid follicles are frequently found in the peripheral lungs of patients with Chronic Obstructive Pulmonary Disease (COPD). Whether they are the result of lymphoid neogenesis remains elusive. Here, we have identified 18 patients with COPD and lymphoid follicles and used immunohistochemistry to analyze the expression of LTα and lymphoid chemokines. Flow cytometry was applied to study expression of LTα and CD21+ follicular DCs, expressed by alveolar macrophages and lung stromal cells and CXCL13 is strongly expressed inside the follicles. HLA-DR+ve cells (APCs), but not CD45-ve stromal cells, strongly express TNFR2 (43% of APCs), TNFR2 (47%) and LTR (38%). CXCR5 is expressed by B cells (96% of B cells), DCs (74% of DCs) and T cells (24% of T cells). CCL19, CCL21 and CCR7 are rarely expressed. In conclusion, molecular mechanisms underlying TLO formation might be involved in lymphoid follicle formation in COPD as follows: stromal cells and macrophages secrete LTα, which induces CXCL13 production by lung APCs, driving the accumulation of CXCR5+
Cigarette smoke-induced oxidative modification of creatinine kinase B (CKB) is involved in the pathogenesis of COPD in terms of acceleration of bronchial epithelial senescence.

**Introduction:** Cigarette smoke accelerates cell senescence, implicated in COPD pathogenesis. Energy status is one of the most crucial determinants for aging and longevity. In cells, current energy metabolism, oxidative stress, and various pro-inflammatory mediators contribute to cell senescence. To characterize autophagic degradation of cell organelles, we hypothesized that CKB might also be oxidized and lost activities by smoking stress, resulting in disease pathogenesis of COPD in terms of acceleration of cell senescence.

**Aims:** To elucidate the role of CKB in cigarette smoke extract (CSE)-induced cellular senescence in human bronchial epithelial cells (HBEC).

**Methods:** Primary HBEC and BEas2B cells were used. Senescence was evaluated by SA-β-gal staining and p21 expression and cell cycle analysis. CKB was inhibited by sRNA and cycloheximide. Interleukin (IL)-8 secretion were measured by ELISA.

**Results:** CSE induced carboxylation of CKB and decreased CKB protein levels, and this decrease was reversed by the proteasome inhibitor. CSE induced cell senescence, and CKB inhibition further enhanced CSE-induced cell senescence. CSE treatment caused increased amounts of IL-8 secretion, a hallmark of senescent associated secretory phenotype (SASP). IL-8 secretion was further increased by CKB ablation.

**Conclusions:** CSE induces carboxylation and subsequent proteasomal degradation of CKB, and decrease of CKB is implicated in the regulation of cell senescence with SASP.

**4906**

Up-regulation of decoy receptor D6 in COPD

Ercica Bazzan1, Grazziella Turato1, Simona Baraldo1, Andrea Ballarin1, Fiorella Calabrese2, Elisabetta Balestro3, Benedetta Savino1, Cinzia Cancelleri2, Raffaella Bonechi2, Massimo Locati1, Alberto Papi1, Manuel Cosio1, Alberto Mantovani1, Marina Saetta1, and Daniele D’Eleuterio1.

**Introduction:** Insufficient autophagy is involved in accelerated cellular senescence in the pathophysiology of COPD.

**Aims:** To elucidate the role of autophagy in cigarette smoke extract (CSE)-induced cellular senescence in human bronchial epithelial cells (HBEC).

**Methods:** HBEC was isolated from lobectomy specimens. To characterize autophagic degradation of cell organelles, we hypothesized that CKB might also be oxidized and lost activities by smoking stress, resulting in disease pathogenesis of COPD in terms of acceleration of cell senescence.

**Conclusion:** These findings implicate airspace SAA signaling as a mediator of GC-resistant systemic COPD biomarker and hence, characterized its function in orchestrating mucosal inflammatory responses that contribute to neutrophil accumulation.

**4907**

Serum amyloid A augments mucosal immunity by opposing resolving lipoxin A4 signaling in chronic lung disease.

Steven Rozinovski1, Mobut Udinn2, Ross Vlahos1, Michelle Thompson2, Anne-Sophie Merritt1, Peter Wark1, Anastasia Hutchinson2, Louis Irving3, Bruce Levy4, Gary Anderson5, Makoto Odaka2, Toshiaki Morikawa2, Katsutoshi Nakayama1, Kazuyoshi Kuwano1, Division of Respiratory Diseases, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; Department of Chest Surgery, Jikei University School of Medicine, Tokyo, Japan

**Introduction:** Persistent innate immune activation contributes to tissue destruction in chronic obstructive pulmonary disease (COPD). A histone demethylase inhibitor, 3-deazaneplanocin A (D6), suppresses inflammation in COPD. We previously identified SAA as a GC resistant systemic COPD biomarker and here, characterized its function in orchestrating mucosal inflammatory responses that contribute to neutrophil accumulation.

Methods: Three separate patient cohorts were investigated involving 81 patients. Results: In a prospective study of competing ALX/P2RX2 ligands during COPD exacerbation, circulating SAA levels were markedly and disproportionately increased relative to LXA4. Secreted SAA levels in COPD BAL fluid correlated with interleukin-8 and the neutrophil activation marker, neutrophil elastase. SAA was also detected in COPD lung in close proximity to airway epithelia, and in vitro SAA triggered pro-inflammatory mediator (MCP-1, GM-CSF and IL-8) release by airway epithelial cells in an ALX/P2RX2 receptor-dependent manner. Lipoxin A4 (LXA4) blocked SAA initial epithelial responses via allosteric inhibition. Exhalation LXA4 (pA2 13.3 pm) inhibited smoking-induced acute inflammation that was significantly inhibited by equivalent amounts of 5-epi-LXA4 but not dexamethasone. Tissue macrophages (CD68+), polarised with lung SAA and the GC-dexamethasone markedly increased SAA production by THP-1 macrophages (pEC50 43.4 pm).

**Conclusions:** Together, these findings implicate airspace SAA production as a mediator of GC resistant lung inflammation that can overwhelm organ protective signaling by lipoxins at ALX/P2RX2 receptors.
ing and western blotting of p21 were performed to evaluate cellular senescence. Interleukin (IL)-8 was measured by ELISA.

Results: CSE-induced cellular senescence was accompanied by accumulations of ubiquitinated proteins and p21. Although CSE transiently induced autophagy, it was insufficient to inhibit cellular senescence. Increased autophagy suppressed CSE-induced senescence and accumulations of these proteins. In contrast, inhibition of autophagy enhanced not only senescence but also the senescence-associated secretory phenotype (SASP) of IL-8 expression.

Conclusions: These results suggest a potential regulatory role for autophagy in CSE-induced cellular senescence with SASP by preventing the accumulation of ubiquitinated proteins and p21.

509. Clinical features of human pulmonary hypertension

4099 Late-breaking abstract: Demographic trends and changes in long term outcome of incident idiopathic, heritable and anorexigen-associated pulmonary arterial hypertension between 2001 to 2009. Results from the Pulmonary Hypertension Registry of the United Kingdom and Ireland

Yi Ling1, Martin Johnson1, David Kiely2, Robin Condiffe1, Charlie Ellis2, Simon Gibb2, Luke Howard2, Joanna Pepke-Zaba1, Karen Shaeres3, Paul Colman1, Anuj Saini1, Jim Lordan4, Peter Pollock5, John Wort5, Michael Gatzoulis3, Andrew Peacock1. 1Scottish Pulmonary Vascular Unit, Golden Jubilee National Hospital, Clydebank, United Kingdom; 2Pulmonary Hypertension Unit, Royal Hallamshire Hospital, Sheffield, United Kingdom; 3Pulmonary Hypertension Service, Hammersmith Hospital, London, United Kingdom; 4Pulmonary Hypertensive Service, Hammersmith Hospital, London, United Kingdom; 5Pulmonary Hypertensive Disease, Royal Free Hospital, London, United Kingdom; 6Pulmonary Hypertension Registry of the United Kingdom and Ireland

Background: There have been significant changes in the management of pulmonary arterial hypertension (PAH) over the past decade. In the UK and Ireland, care of pulmonary hypertension (PH) is centralised to designated PH centres. This provides an excellent opportunity to study changes in demographic and survival trends of the disease within an entire region with a common healthcare system.

Aim: To determine whether baseline characteristics and survival of incident iPAH, heritable and anorexigen-associated PAH has changed over the past decade.

Methods: Retrospective observational study of all incident cases of iPAH, heritable and anorexigen-associated PAH diagnosed in the UK and Ireland between 1st January 2001 and 31st December 2009.

Results: Total of 646 patients were diagnosed (22% in 2001-2003, 33% in 2004-2006 and 45% in 2007-2009). In recent years, patients were older, had higher BMI, lower % predicted diffusion capacity for carbon monoxide (%DLCO) and exercise capacity (6 minute walk distance). BMI, lower % predicted diffusion capacity for carbon monoxide (DLCO) and exercise capacity (6 minute walk distance and cardiac index, patients with mean PAP >25 mmHg at RHC were considered to have PHLHD. It can be difficult to distinguish pulmonary arterial hypertension (PAH) from left heart disease (PHLHD). Current practice is to use right heart catheterisation (RHC) which will respond to disease targeted therapy) from pulmonary hypertension due to heart failure. These results suggest a potential regulatory role for autophagy in CSE-induced cellular senescence with SASP by preventing the accumulation of ubiquitinated proteins and p21.

Conclusion: In PAH it is possible to identify a subgroup of patients with PAH hypotropenia and moderate diastolic volume increase (i.e. high RV mass/volume ratio) which has a low rate of deaths, suggesting a better RV adaptation to the increased afterload.

4911 Pulmonary arterial hypertension in patients with chronic kidney disease on dialysis and without dialysis

Stefan Pabst1, Christoph Hammerstingl1, Felix Hundt3, Thomas Gerhardt4, Christian Grothé5, Georg Nickenig5, Rainer Wottr5, Dirk Skowasch5. 1Department of Nephrology, University of Bonn, Bonn, Germany; 2Department of Nephrology, University of Bonn, Bonn, Germany; 3Praxis für Nieren- und Hochdruckkrankheiten, Praxis für Nieren- und Hochdruckkrankheiten, Bonn, Germany; 4Abteilung für Pneumologie, Evangelische Lungenklinik Berlin-Buch, Berlin, Germany

Background: Pulmonary hypertension (PH) is common in patients with dialysis-dependent chronic kidney disease (CKD) due to an increased prevalence of PH. However, specific hemodynamics of the pulmonary circulation, changes induced by hemodialysis and prevalence of pulmonary arterial hypertension (PAH) have not been evaluated in patients with CKD.

Methods and results: We assessed consecutive patients with CKD on hemodialysis (group 1, n=31) or without dialysis (group 2, n=31), in World Health Organization functional class >II with dyspnea unexplained by other causes, using right heart catheterization (RHC). In group 1 RHC was performed before and after dialysis. PAH was diagnosed if mean pulmonary arterial pressure (mPAP) was >25 mmHg and pulmonary capillary wedge pressure (PCWP) ≤15 mmHg (after dialysis in group 1) and if other causes of PH were excluded. In CKD patients after dialysis, prevalence of PH was 24/31 (77%; 20/31 postcapillary PH, 4/31 precapillary PH); prevalence of PAH was 3/31 (10%). After dialysis, there were significant decreases in mPAP and PCWP; all four cases of precapillary PH were unmasked by dialysis. Patients in group 2, postcapillary PH was diagnosed in 22 cases (71%); no cases of PAH were detected.

Conclusions: The finding that the prevalence of PAH was 10% in CKD patients on dialysis and without dialysis unexplained dyspnea suggests careful screening for PH in this patient population is warranted. The possibility that dialysis might be a trigger for the development of PH is plausible given that there were no instances of PAH in the nondialysis CKD patient group. RCH should be performed after dialysis to unmask precapillary PH.

4912 Left atrial volume to distinguish idiopathic pulmonary arterial hypertension from pulmonary hypertension due to left heart disease

Stephen Crawley, Martin Johnson, Andrew Peacock. Scottish Pulmonary Vascular Unit (SPVU), Golden Jubilee National Hospital, Glasgow, United Kingdom

Introduction: It can be difficult to distinguish pulmonary arterial hypertension (which will respond to disease targeted therapy) from pulmonary hypertension due to left heart disease (PHLHD). Current practice is to use right heart catheterisation (RHC) to distinguish between the two conditions. We explored the use of left atrial volume (LAV) obtained via cardiac magnetic resonance imaging (CMR) as an alternative to RHC.

Methods: Patients being admitted for diagnostic assessment underwent CMR and RCH. LA volume was assessed using standard 2- and 4-chamber CMR views and the biplane area-length method, and indexed to the body surface area. RHC was then performed within 72 hours. PAH was defined as per current guidelines. Patients in group 2, postcapillary PH was diagnosed in 22 cases (71%); no cases of PAH were detected.

Results: Between Jan 2009 and Feb 2011 we diagnosed 31 patients with PAH (mPAP 47±10, PCWP 7±4 mmHg) and 19 patients with PHLHD (mPAP 43±8, PCWP 22±6 mmHg). LAV was significantly lower in PAH compared with PHLHD (24±9 ml/m² vs 66±19 ml/m², p<0.0001). Using an LAV threshold of 43 ml/m²
High altitude pulmonary edema (HAPE) is a non-cardiogenic pulmonary edema that develops in susceptible people at high altitudes. The pathogenesis remains to be conclusively elucidated and genetic polymorphisms were highly proposed to be associated with HAPE. The aim of this study is to identify the locations of the candidate human genes those might associate with the HAPE susceptibility or resistance.

**Methods:** We performed a genomewide association study in 53 Japanese patients with high-altitude pulmonary edema (HAPE) who had developed HAPE during climbing mountains higher than 2500 m and the control group enrolled 67 Japanese resistant subjects (HAPE-r). The control group included patients without a family history of HAPE. A case-control association study was performed using 400 polymorphic microsatellite markers (which define about 10 centiMorgan resolution throughout the whole genome) by PCR. The PCR-amplified products were sequenced automatically by Gene Scan software.

**Results:** Nine markers (D1S468, D1S2697, D1S2785, D4S405, D5S424, D6S257, D1S2638, D16S3103 and D21S120) showed statistically significant associations with the susceptibility to HAPE and three markers (D1S230, D14S283 and D22S280) showed significant associations with the resistance to HAPE. These markers were in linkage with genes controlling pulmonary alveolar structure, chloride channel, endocrine proteins, and other factors those might play important roles in the development of HAPE.

**Conclusion:** This is the first genomewide association study in HAPE. It revealed several candidate genes in associations with HAPE. The development of HAPE may be determined by the interaction of multiple genes.
510. Asthma: improving diagnosis and management for reaching better control

P4917 Including variability as a criteria, increases diagnostic accuracy in elite asthmatic swimmers after mannitol and exercise challenge
Keerstin Romberg1, Ellen Tufvesson1, Leif Björnén1 1Department of Respiratory Medicine and Allergology, Dept of Clinical Science, Lund University, Lund, Sweden; 2Näset’s Health Care Center, Höllviken, Höllviken, Sweden

Increased frequency of asthma has been reported among swimmers, but many tests have a low sensitivity to detect asthma among elite athletes. The aim was to investigate the prevalence of asthma among elite swimmers, to compare sport specific exercise test with Mannitol and explore the tests ability to detect asthma.

Methods: 101 elite swimmers (14-24 years) performed both Mannitol provocation and a sport specific exercise test. Mannitol positivity was defined as either direct FEV1, PD15 or as f2: reversibility ≥ 15% after challenge (extended criteria). A direct positive exercise test was defined as a drop in FEV1 of 10% compared to baseline or a difference in FEV1 of <15% either spontaneous, variability or with β2-agonist, reversibility (extended criteria).

Results: We found a high prevalence of Mannitol and/or Exercise positivity. For Mannitol, 26 were positive by ordinary criteria and 43 with extended criteria. The corresponding numbers for exercise test were 14 and 24. When including reversibility and variability to define a positive test the sensitivity to detect current asthma with or without exercise induced symptoms increased while the specificity remained unchanged. Direct positivity for Mannitol or Exercise poorly overlapped using ordinary criteria.

Conclusion: We found a high prevalence of EIA among elite swimmers. The use of variability and reversibility as additional criteria to define a positive test increased the ability to detect asthma with or without exercise induced symptoms, without lowering the specificity, and should therefore be considered in the interpretation of the tests.

P4918 Asthma severity and duration influence to fetoplacental circulation
Olga Lavrova1, Maria Petrova1, Elena Shapovalova2 1Bronchial Asthma Laboratory, Pavlov’s State Medical University, Saint-Petersburg, Russian Federation; 2Pregnant Pathology, Obstetric and Gynecological Institute by D.O.Ott, Saint-Petersburg, Russian Federation

Hemodynamic of fetoplacental circulation in Asthmatic patients is not studied enough yet. Modern data on asthma severity duration and its control influence to fetoplacental circulation are still lack and controversial. The goal of our study was investigation of fetoplacental circulation with ultrasonic dopplerography. Pregnants with different asthma severity and treatment were studied at 34 week of gestation.

Materials & methods: 73 Asthmatic pregnant were studied (5 - severe persistent, 18 - moderate persistent, 22 - mild persistent & 28 - mild intermittent). 64 females without lung pathology were studied also as a control group (K). ICS were administered to 55 patients. Among them 17 rejected ICS use and were administered SABA with other medications instead. Systolo-diastolic ratio (SD) in uterine (UA), umbilical (UmA) and fetus medial cerebral (ACM) arteries was measured.

Results: SD was increased in UA and ACM within asthmatics, but with no significantly differences. In moderate persistent asthma SD was significantly higher in UA (2.51±0.29) in comparison with mild persistent (1.91±0.18) and with K (1.59±0.13) (p<0.05). In pregnant, who undergone asthma relapse during the first trimester SD in UA (2.69±0.12) differed (p<0.05) in comparison with K. Reliable UA and ACM SD level differences were accepted in patients with moderate persistent asthma, who were administered ICS to ICS free patients (1.91±0.15 to 2.82±0.59) and (4.39±0.43 to 5.98±0.68) respectively (p<0.05).

Conclusion: Relapse of Asthma in the first trimester of pregnancy, severity of Asthma and absence of basic therapy influence level of the blood flow in UA. Absence of basic therapy leads to increase of blood pressure in ACM of fetus.

P4919 Genetic characterization of the association between asthma and obesity.
Zorana Stanjevic1, Astrid Crespo, Juan Roldan2, Vicente Plaza, Sonia Raguil1, Juan Antonio Lloret1, G. Casaliva1, A. Reig1, Josep Morena Prat, Carlos MartinezRivera1, 1Respiratory, Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, Spain; 2Respiratory, Hospital Santa Caterina, Salt, Girona, Spain; 3Respiratory, Hospital de Viladecans, Viladecans, Barcelona, Spain

Introduction: The inflammatory way of the TNF-alfa could be a mutual way of the asthma-obesity phenotype.

Objective: To evaluate if the presence of polymorphisms at the promoter of gene TNF-alfa-308 G/A is related with an asthma-obesity phenotype and determines the severity of the disease measured by the number of exacerbations.

Methods: We included blood samples of 48 asthmatics. To determine the presence of polymorphism -308G/A in the promoter region of TNF-alpha gene, we performed the technique of chain reaction (PCR) followed by the generation of restriction fragments and digestion of the amplified product. The product of digestion was visualized in a gel of 3% agarose. This allowed us to distinguish native allele TNF-1 with 2 fragments of restriction, 87bp and 20 bp and polymorphic allele TNF-2 of 107 bp.

Results: The average age 28±4.6 years, 83% men. Genotype distribution was: AA (4%), AG (23%) and GG (73%). No statistically significant differences were found between different alleles and IMC. When we analyzed the evolution of disease considering the number of exacerbations we observed that presence of allele A determines greater number of exacerbations during the year (p=0.02).

Conclusions: The presence of the allele A has been associated with a worse prognosis as measured by the number of exacerbations, which could be explained by an increase in promoter activity and TNF secretion.

P4920 Prevalence depression – Anxiety and impact on quality of life, asthma control and asthma severity in adult patients with asthma
Aysegul Altintop1, Haydar Karakus2, Zeynep Ayturmu1, Suleyman Haciicilyayli3, Hilal Ermin1, Muratver Erdinc2. 1Dept of Pulmonary Disease, Inonu University School of Medicine, Malatya, Turkey; 2Dept of Pulmonary Disease, Ege University School of Medicine, Izmir, Turkey

We examined the prevalence of depression and anxiety, and impact of depression...
and anxiety on quality of life, and treatment response of disease in patients with asthma.

Demographic data, smoking, allergy, atopy, additional diseases, age at asthma, age diagnosis <25 year, and body mass index was (BMI) calculated. Hospital Anxiety Depression Scale (HADS), Asthma Quality of Life Questionnaires (AQLQ) in the subjects were evaluated.

The sample consisted of 414 subjects (73% female) with a mean age of 47.6±13.8 years. Regarding chronic severity, 9.8% were intermittent, 63.2% mild persistent, 24.4% moderate persistent, and 2.6% severe persistent. Furthermore, 44.1% of the patients were controlled, 47.9% were partly controlled/controlled/fine were uncontrolled. Rates of physician-diagnosed depression and anxiety were 10.4% and 2.9%. Regarding HADS, anxiety score was ≥10 in 37.4% and depression score ≥7 in 50.2% of the subjects. Prevalence of physician-diagnosed depression was significantly higher in women (p<0.05). Regarding AQLQ results, there were negative correlations between scores of symptoms, activity limitations, emotional function, environmental stimuli and severity. AQLQ scores were lower in subjects with physician diagnosed depression (p=0.000). There were negative correlations between AQLQ scores and HADS depression-anxiety scores (p=0.000).

It is suggested that depression and anxiety are associated with worse asthma control and quality of life. Physicians should consider depression and anxiety in patients with worse controlled asthma and quality of life in spite of optimal therapy for asthma.

**P4923**

**Asthma and metabolic syndrome**

María Alicia Martínez Cortizas1, María Teresa gómez García1, María José Guzmán Fernández1, Federico Goicoechea1,2,*sorry, the author's name cannot be identified.*

**Background:** The study aims to analyze the psychometric properties of Portuguese version of scale Ways of Coping with Asthma in Everyday Life – WCAEL (Aalto et al, 2002), developed to measure coping in everyday life in asthmatics.

**Methods:** Cross-sectional study with 253 patients, both sexes, with asthma diagnosed, recruited consecutively from the Allergy & Asthma outpatient clinic (HS João/Porto). Exclusion criterion were: psychiatric disease and alcohol/drugs abuse. A total of 247 patients were evaluated with the following scales (Portuguese versions): Ways of Coping with Asthma in Everyday Life - WCAEL, Problem Solving Inventory – PSI and Asthma Control Questionnaire – ACQ. A subsample of patients (n=50) was followed for four weeks. These patients also were classified according severity of asthma (GINA, 2006) and the duration of the illness.

**Results:** The participants were mostly females (78.5%), with a mean (sd) age of 40.6±(15.3) years. The majority (78.7%) had severe persistent asthma and the mean duration of the illness was 20.8±(15.4) years. In the final factor analysis of principal component method (varimax rotation) 4 factors were extracted (explaining 46.3% of total variance). The internal consistency values were moderate (α=0.56-0.67). WCAEL showed significant associations with ACQ, as well as good reproducibility over time (r=0.58-0.76).

**Conclusion:** The study data support the reliability, construct and criterion validity of the Portuguese version of WCAEL seems a promising scale for assessment the coping with asthma in everyday life.

**P4924**

**Elderly patients associated with poor asthma control and quality of life in Spanish asthmatics**

M.C. Vennera1, C. Picado1, L. Herranz2, J. Galera2, J. Casafont3, on behalf of the CONTROL Study Group. 1Pneumology and Respiratory Allergy, Hospital Clinic, Barcelona, Spain; 2Health Outcomes Research, Novartis Farmacéutica, Barcelona, Spain

**Background:** Several risk factors determined asthma control, which is a fundamental objective in patients’ management, however it is still insufficient.

**Objective:** To assess how the lack of asthma control affects quality of life and which are the main factors associated.

**Methods:** Observational, cross-sectional and multicenter study that included severe asthmatic patients. We assessed quality of life (QoL) using Mini-AQLQ questionnaires, anxiety and depression using Hospital Anxiety and Depression Scale, and hyperventilation by Nijmegen questionnaire.

**Results:** 343 patients participated in the study, 67.6% women. Mean age (SD) of asthma uncontrolled patients was slightly higher, especially when analyzed according to Spanish Guidelines for Asthma Management (GEMA) [48.5±(14.7) vs 44.1 (14.1) years, p<0.079]. A higher BMI was observed in uncontrolled patients [28.2 (5.8) kg/m² vs 25.5 (4.9) kg/m², p=0.006]. Smoking habit was not related to asthma control.

**Conclusions:** Uncontrolled asthma showed a worse quality of life, showing higher levels of anxiety, depression and hyperventilation.
Severely obese (BMI) ≥ 35, n=119 women with and without physician-asthma diagnosis at any time (32 [27%], 11 diagnosed in childhood), healthy women (37, 30 without AHR, with BMI <25) underwent pulmonary function testing (tidal ventilation monitoring, spirometry, plethysmography, fractional exhaled NO, metabolite challenge) and overnight ambulatory polynography. No, possible (compatible symptoms, whatever the presence of AHR), probable (AHR, suggestive symptoms, Asthma Control Questionnaire ≥ 0.75) and confirmed asthma (AHR, suggestive symptoms, Questionnaire > 0.75) were established in obese women. An additional group of asthmatic women (BMI < 25, n=14) underwent pulmonary function tests to allow control with confirmed obese asthmatic patients.

P4927
Are there lower blood CO2-levels in asthmatic patients? Sarah Ernst, Jörg D. Leuppi, Prashant N. Chhajed, David Miedinger. Respiratory and Internal Medicine, University Hospital Basel, Basel, Switzerland.

Background: Dysfunctional breathing was shown to be common in people with asthma and therefore breathing retraining might be an additional therapy beside asthma medication. However it is unclear if dysfunctional breathing is associated with lower blood CO2-levels in asthma patients compared to healthy subjects.

Objectives: To find out if there is any relevant difference in blood CO2-levels comparing subjects with and without asthma.

Methods: 138 currently employed municipal firefighters and policemen from Basel, Switzerland underwent methacholine bronchoprovocation testing (MCH) according to a standardized protocol. We assigned a diagnosis of asthma according to three widely used definitions: Having 1) a positive MCH test (MCH+), 2) physician-diagnosed asthma and 3) wheezing in the last twelve months and a positive MCH test (Wheeze/MCH+). We compared transcutaneously measured blood CO2-levels (TcCO2-levels) of subjects with and without asthma at rest prior (PRE), one and five minutes after (MIN, 5MIN) MCH challenge.

Results: At rest and at 5MIN, no significant differences were measured between asthmatic and non-asthmatic individuals for all three definitions. At 1 MIN, asthmatics had higher TcCO2-levels than non-asthmatics only if using the MCH+ definition (TcCO2 vs 33.4 ± 6.0 mmHg, p = 0.023; physician diagnosed asthma: 35.8 vs 33.6 mmHg, p = 0.072; Wheeze/MCH+: 36.3 vs 33.6 mmHg, p = 0.052).

Conclusions: Resting TcCO2-levels were not different in our sample of individuals with or without asthma according to diverse disease definitions and thus do not support the presence of relevant dysfunctional breathing at rest. At one minute after provocation challenge, metacoline positive subjects had higher TcCO2-levels than the negative ones.

P4928
Effect of BMI on asthma control, asthma severity and quality of life in adult patients with asthma Aysegul Altintop, Haydar Karakus, Zeynep Aytemur, Sukelyan Haciveyliyagil, Hilal Erdem. Department of Pulmonary Disease, Ege University School of Medicine, Izmir, Turkey.

We examined effects of body mass index (BMI) on quality of life, asthma severity and treatment response of disease in patients with asthma. Demographic data, occupation and education status, symptoms, smoking, allergy, atopy, additional diseases, age started asthma, age diagnosed asthma, and drugs of subjects were recorded, and body mass index was calculated. Hospital-Anxiety Depression Scale (HADS), Asthma Quality of Life Questionnaires (AQLQ) in the subjects were evaluated.

The sample consisted of 414 subjects (73% female) with a mean age of 47.6±13.8 years. Regarding chronic severity, 9.8% were intermittent, 63.2% mild persistent, 24.4% moderate persistent, and 2.6% severe persistent. Furthermore, 44.1% of the subjects were controlled asthma, 47.9% partly controlled, 8% uncontrolled.

Patients were considered to be obese if their BMI was ≥ 30 kg/m². BMI was mean 26.6±5.37 kg/m² in men and 28.8±6.21 kg/m² in women (p<0.05). There was no correlation between BMI and severity of asthma control. There was a positive correlation between BMI and age started asthma (p=0.05). Regarding AQLQ results, there were negative correlations between scores of symptoms, activity limitations, emotional function, environmental stimuli and severity asthma (p<0.05). There were negative correlations between only environmental stimuli, activity limitations and BMI (p<0.05). There was no correlations between BMI and HADS depression-anxiety scores, physician-diagnosed depression-anxiety.

Our findings suggest that obesity is associated with poor asthma-specific quality of life. BMI control was important as well as optimal asthma therapy in patients with asthma for optimal asthma control.

P4929
Controlled asthma in atopic and non atopic patients: Is needed a different approach? Angelo Petrosianni, Vittoria Conti, Valentina Giunta, Michela Lagallà, Marcella Lilli, Ambra Castagnaci, Augusto Bevilacqua, Safia Khan Kaïl, Claudio Terzano. Department of Cardiovascular and Respiratory Sciences, Sapientia University of Rome, Rome, Italy.

Background: Allergy is a significant trigger for asthmatic exacerbation. Currently, the control of asthma is mainly based on the absence of symptoms and airway obstruction.

Aim: To evaluate the difference in atopic (AT) and non atopic (N-AT) patients with controlled asthma on the risk of exacerbation and step up therapy.

Methods: 98 asthmatic pts with ACT (Asthma Control Test) > 20 were enrolled in a 3yrs randomized controlled trial. Pts were divided in 2 groups: Group A (ICS) receiving a continuous treatment with inhaled beclometasone MDI100mcg twice/day +inhaled saltubrate as needed; Group B (control) treated with inhaled saltubrate as needed. Step up therapy was performed as recommended by guidelines. Pct tests for the most common allergens were performed at the enrolment.

Aim: Endpoint were exacerbations, 3mths ACTCore, and drug as needed.

Results: 80 pts (A93, B41) concluded the study; asthmatic pts were in A 29 (74%), in B 27 (66%). In Group A no significant difference was reported for exacerbations (AT4.2, N-AT3.9) and ACT (AT3.19, N-AT2.4), whereas in Group B slight significant differences reported for exacerbations (AT4.8*, N-AT3.9) and ACT (AT18.6*, N-AT20.1).

Interestingly, analyzing data in multisensitized ≥ 3 classes of allergens) and low-sensitized (< 3 classes of allergens) AT pts, a significant difference (*) was reported in both groups: exacerbations in A (multis. (16pts) 4.8*, N-AT3.9), in B (multis. (15pts) 5.6*, N-AT3.98); ACT in A (multis. 19.1, N-AT20.4), in B (multis. 17.5*, N-AT20.1).

Conclusion: Pts with controlled asthma and atopy show a protective effect on exacerbations during a long term treatment with low dosage ICS. Moreover, multisensitized pts with controlled asthma report an high risk of exacerbation than non atopic.

P4930
Asthma at treated patients correlations between treatment, level of control and exacerbations in a pneumology department Diana Dimitri1, Carmen Ardelean2, Stefan Frent3, Voicu Tudorache2,3, Ioan Marinici2, Stefan Mihaiacuta2. 1Pneumology, St. Maria Medical Center, Timisoara, Romania; 2Pneumology, Victor Babes Hospital of Infectious Diseases and Pneumology, Timisoara, Romania; 3Pneumology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Introduction: Uncontrolled bronchial asthma (BA) is a serious problem, altering the quality of life, and consuming a lot of resources. Aim: Evaluation of the factors related to lack of control.

Material and method: Between October 2007 and Mars 2009 we evaluated 584 consecutive patients at V.Babes Hospital, Timisoara, Romania, known and treated for BA, and collected general data, medical history, disease onset, spirometry, treatment duration, treatment, asthma control test (ACT), level of control GINA 2007. The association of variables was analyzed by calculating the odds ratio (OR) together with confidence intervals (CI) in a univariate analysis. The significant independent variables were utilized to create models of multivariate logistic analysis in order to identify the most important predictors.

Results: 584 patients, 162 males (27.74%), 422 females (72.26%), mean age 45.37 years (14-85), 24 smokers, ACT <18 (36.2%), 20-24 (48.8%), 25 (15.5%), 31.3% exacerbations, 78.46% patients with inhaled corticosteroids (ICS) in combination or in monotherapy, 63.4% with normal spirometry, 52.5% with allergy, 11.3% occupational exposure, 4 predictors for uncontrolled BA: exacerbations OR 4.11, CI 3.30-7.48, p <.001, occupational exposure OR 2.29, CI 1.23-4.26, p =0.009, altered lung function on spirometry OR =1.18, CI 1.02-1.36, p=0.021 (obstruction OR 3.78 CI 1.76-7.78, p <0.001), duration of disease (months) OR=1.02, CI 1.00-1.03, p=0.021.

Conclusions: Despite treatment with ICS, more than 1/3 (36, 2%) of patients had uncontrolled asthma. Exacerbation and occupational exposure are the most powerful predictors.

P4931
Phenotypic differences between atopic and non atopic patients with asthma Takahiro Yoshikawa1, Hiroshi Kanazawa 2, Kazuto Hirata 2.

1Sports Medicine, Osaka University City Graduate School of Medicine, Osaka, Japan; 2Respiratory Medicine, Osaka University City Graduate School of Medicine, Osaka, Japan.

Background: The present study aimed to illustrate differences in characteristics and perception of dyspnea between young atopic adults who have no history of asthma (never-asthmatics) with or without asymptomatic airway hyperresponsiveness (AHR) and those who had childhood asthma and consider themselves to be grown out of the disease (past-asthmatics).

Methods: Blood parameters, lung function and methacholine PC20 were measured in never-asthmatics and 24 past-asthmatics. A perception score of dyspnea at 20% fall in FEV1 (FEV1s) was obtained by interpolation of the two last points on the perception (modified Borg scale) fall in FEV1 curve during methacholine challenge.

899s
Results: Thirty-one of 88 never-asthmatics and eighteen of 24 past-asthmatics exhibited AHR (PC_{20} was ~8 mg/ml). Higher levels of specific IgE to house dust mite in past-asthmatics were observed than never-asthmatics with and without AHR. Mean values of FEV1 and FEF_{25-75} (predicted) were significantly lower in past-asthmatics than never-asthmatics without AHR, and the values in never-asthmatics with AHR were intermediate between never-asthmatics without AHR and past-asthmatics. PC_{20} were not significantly different between past-asthmatics and never-asthmatics with AHR. Of particular interest was that PS_{24} was significantly lower in never-asthmatics with AHR compared with past-asthmatics.

Conclusions: The present findings suggest the possibilities that presence of absence of past history of outgrowth of childhood asthma might be associated with airway narrowing, sensitization to house-dust mite and perception of dyspepsia in young asymptomatic adults with atopy and AHR.

P4932 Evaluation of asthma knowledge and quality of life in adult patients with asthma
Grzegorz Przybylski1, Anita Dąbrowska2, Aleksandra Gadzińska1, Malgorzata Pyskir3, Hanna Trzcinska4
1Department of Respiratory Medicine and Tuberculosis, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz, Poland; 2Department of Theoretical Foundations of Biomedical Sciences and Medical Informatics, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz, Poland; 3Department of Rehabilitation, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz, Poland; 4Department of Pedagogy and Nursing Didactics, Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz, Poland

Asthma is a chronic illness that affects the everyday life of patients who suffer from it and is a cause of quality of life impairment in adults. Patients with asthma were studied in order to establish the level of knowledge concerning asthma and the degree quality of life impairment due to asthma. The purpose is to evaluate the quantitative relationships between the level of knowledge and quality of life in adult Asthmatics. Through 2010 year, 242 subjects were recruited from the Allergy Outpatients. Patients from 18 year of age to 51 year old were eligible. Patients completed the asthma knowledge questionnaire and asthma-related quality of life questionnaire (SGRQ) at second physician visit, after the educational information. The level of Knowledge Asthma was measured using the questionnaire of the asthma knowledge. Response options were presented as true/false. Each question had a score of one (maximum score of 24). Mean asthma knowledge score in the population was equal to 11.71. Overall scores ranged from 25% to 75%. The asthma knowledge score was correlated significantly with the symptoms domain (R=0.45, p <0.001), the activity domain (R=0.20, p=0.002), the impact domain (R=0.29, p <0.001) and the SGRQ total score (R=0.29, p <0.001). A negative value of Spearman’s rank correlation coefficient means that the patients who obtained high scores in the asthma knowledge questionnaire had a tendency to have a low score in the SGRQ (at second physician visit). This study shows that level of knowledge asthma correlate with domains of asthma-related quality of life by SGRQ. The results suggest that is it necessary to asthmatic knowledge to achieve long-term effectiveness of asthma control and QoL.

P4933 Adult-onset asthma: Risk factors
Teresa Gomez Garcia1, Javier De Miguel Diez1, Roberto Pelta Fernandez1, M Carmen Juez Morales1, Lihana Moran Caicedo1, Veronica Sanz de Burgos1, Julia Gil-Magran1, Ana Pégorié1, Nicolas Paleiron1, Thomas Erasco1, Cecile Troumèr1, Sophie Herry1, Yvan Bec2, Bertrand Bouard3, Frédéric Grassin3, Michel Andéol1
1Repartition Medicine, Hospital General de Elche, Elche, Spain; 2Department of Respiratory Medicine, Hospital General de Elche, Elche, Spain; 3Service de Médecine de Prévention, DCNs, Brest, France; 4Centre de Medecine de Prévention, La Villeneuve, Brest, France

To determine the risk factors for the development of asthma in patients older than 12 years.

Methods: An observational, transversal, multicentric, case-control study was led from May to October 2009 in Spain. Patients over 12 years old, diagnosed of asthma in the last 12 months that went to a pneumologist or allergist clinic for any reason were chosen as cases. Each case had at least a non-asthmatic control chosen as cases. Each case had at least a non-asthmatic control chosen. Among 391 workers 353 (90%) participated in the study, 52 of whom (15%) had a high risk (sumscore ≥ 5) and were candidate for medical evaluation, including a low-dose high resolution CT-scan of the lungs.

Results: Of 48 of 52 workers (response 92%) were referred for clinical evaluation. Mean age was 52 (±5) yrs, number of pack years 28 (±21). Silicosis was found in 8 workers (17%), another 3 in a new number of micromodules on CT (6%). In addition, COPD was present in 6 workers (13%): Gold I in 2 (one of whom had silicosis), Gold II in 3 and Gold III in 1 worker.

Conclusion: Medical triage followed by specific clinical evaluation in a population at risk for silicosis was effective in the early detection of silicosis and yielded a high percentage of COPD. The results stress the need for exposure measures in the tile production industry.

P4935 Chest CT screening of asbestos exposed workers in the Arsenal of Brest: Prevalence of asbestos related lesions and incidental findings
Anne Pégorié1, Nicolas Paleiron1, Thomas Erasco1, Cecile Troumèr1, Sophie Herry1, Yvan Bec2, Bertrand Bouard3, Frédéric Grassin3, Michel Andéol1
1Service de Médecine de Prévention, DCNs, Brest, France; 2Service de Médecine de Prévention, DCNs, Brest, France; 3Centre de Medecine de Prévention, La Villeneuve, Brest, France

Introduction: Chest CT screening is part of the recommendations of the French medical surveillance program of asbestos exposed workers, and seems to have short-ened the delay in the diagnosis of asbestos related diseases, yet conversely to have increased the number of complementary examinations due to incidental findings.

Aims and objectives: The aims of the study were to identify, lung lesions and incidental findings discovered during chest CT screening of asbestos exposed workers, assess the number of lesions considered to be professional diseases, and assess the benefits of incidental findings. The impact of tobacco smoking and the level of exposure were assessed.

Methods: It is a retrospective, analytical study on medical records and chest CT scans of 339 asbestos exposed workers who underwent a first chest CT scan between January 2006 and June 2008, indicated by the health department of Brest military arsenal.

Results: 22% had normal chest CT scans. 54% had pulmonary nodules of which two proved to be malignant. 8.8% had pleural plaques. 3% had dense sub pleural lines. Smokers have twice as many lesions as nonsmokers. No significant difference was shown between patients with different levels of asbestos exposure. On the whole, 9.4% of the images could be related to asbestos exposure. Findings were incidental in 87.6% of cases. They were considered clinically significant in 6 cases.

Conclusion: The diagnosis of few asbestos related lesions and conversely a large amount of incidental findings raise the question of the benefits of a large scale chest CT screening. Indeed, the study highlighted more of a personal, than a medical benefit.

P4936 Asthma and exposure to quaternary ammonium compounds in healthcare settings
Maria Gonzalez1, Marie-Christine Kopfferschmitt2, Carole Donnay2, Guy Hedelin1, Michel Velten1, Alain Cantinou1, Frederic de Blay3
1Service de Pathologie Professionnelle et Médecine du Travail, University Hospital of Strasbourg, Strasbourg, France; 2Allergy Division Chest Disease, University Hospital of Strasbourg, Strasbourg, France; 3Laboratoire d’Épidémiologie et Santé Publique, University of Strasbourg, Strasbourg, France

An increased incidence of asthma was reported among professionals working in healthcare settings.

P4934 Medical triage for early detection of silicosis in a ceramic tile production plant
Erik Steger1, Jos Rozendal2,1, Remko Houba1,2, Dick Hendekink1
1Netherlands Expertise Centre for Occupational Respiratory Disorders, NECORD, Utrecht, Netherlands; 2Division Environmental Epidemiology, Institute for Risk Assessment Sciences, Utrecht, Netherlands; Division Heart and Lungs, University Medical Centre Utrecht, Utrecht, Netherlands

Objective: Dust containing crystalline silica may cause silicosis, COPD and lung cancer even at low exposure levels. Since no therapy for silicosis is available, early detection is needed to avoid further exposure and progression of the disease. In the Netherlands a national surveillance programme including medical triage has been implemented to identify construction workers with silicosis. For that purpose a diagnostic model has been developed to predict the probability of silicosis by use of a short questionnaire and lung function [1]. In this study medical triage was applied in a ceramic tile production plant.

Methods: The diagnostic model was tailored to the company using historical exposure data. Of a total of 391 workers 353 (90%) participated in the study, 52 of whom (15%) had a high risk (sumscore ≥ 5) and were candidate for medical evaluation, including a low-dose high resolution CT-scan of the lungs.

Results: 48 of 52 workers (response 92%) were referred for clinical evaluation. Mean age was 52 (±5) yrs, number of pack years 28 (±21). Silicosis was found in 8 workers (17%), another 3 in a new number of micromodules on CT (6%). In addition, COPD was present in 6 workers (13%): Gold I in 2 (one of whom had silicosis), Gold II in 3 and Gold III in 1 worker.

Conclusion: Medical triage followed by specific clinical evaluation in a population at risk for silicosis was effective in the early detection of silicosis and yielded a high percentage of COPD. The results stress the need for exposure measures in the tile production industry.

healthcare settings. However the role of the quaternary ammonium compounds (QUATS) is not yet clear in the induction or aggravation of these symptoms.

Aim: To analyze, among health care settings professionals, the influence of QUATS and irritants exposure on the occurrence of respiratory symptoms including asthma.

Methodology: All workers with more than 6 months of seniority working in 7 healthcare facilities were requested. The survey included a self-administered questionnaire, physical examination, spirometry and blood sample. Occupational exposure assessment was made by expert judgment and workplace studies.

Results: 543 workers participated. QUATS occupational exposure was specified for 335 exposed and 109 non exposed. The QUATS exposed workers were 50% nurses, 22% auxiliary nurses, 19% cleaners. The frequency of all variables defining asthma was significantly higher among the QUATS exposed workers: 18.3% vs 5.5% for ever asthma, 14.4% vs 2.7% for asthma confirmed by a physician, 6.7% vs 1.8% for asthma in the last 12 months, 7.9% vs 1.8% for new onset asthma after entry into healthcare profession. In multiple analysis, after adjustment of variables defining asthma was significantly associated with QUATS exposure increased the risk of asthma, the high-risk tasks being the disinfection of surfaces, the preparation of soaking solutions, the dilution of products and the use of sprays.

Department of Occupational Diseases & Toxicology, Nofer Institute of Occupational Medicine, Lodz; Poland

Work-exacerbated rhinitis (WER) is pre-existing or concurrent rhinitis that is worsened by workplace exposures, while the disease has not been caused by the work environment. WER is currently less well characterized than the corresponding entity of work-exacerbated asthma and exact data on its prevalence and associated factors are usually not known. The aim of the study was to evaluate the frequency of WER in bakers with suspected respiratory occupational allergy.

Material and methods: The study group included 393 bakers reporting respiratory symptoms at the workplace. In all subjects questionnaire, spirometry, skin prick test and evaluation of serum total and specific IgE level were performed. Recognition of occupational rhinitis (OR) was based on inhalative specific challenge test with evaluation of nasal response (nasal lavage analysis).

Results: OR was found in 138 (35.1%) bakers while WER was recognized in 116 (29.5%) subjects. 66.7% subjects with OR and 43.1% with WER had positive SPT to common allergens, while occupational SPT were positive in 76.8% and 33.6% subjects respectively. In patients with OR the latency period, i.e. duration of exposure before the occurrence of symptoms was 10.8 whereas in bakers with WER 13.8 years. Generally, bakers who suffered from occupational rhinitis were younger than the patients with WER. Additionally, OR coexisted with asthma more frequently than WER.

Conclusions: WER is frequent health problem and concerns about 30% of bakers reporting allergic respiratory symptoms. Its differentiation with OR should include specific challenge test, as anamnesis, skin prick tests to total serum level of specific IgE. Recognition of occupational rhinitis (OR) was based on inhalative specific challenge test with evaluation of nasal response (nasal lavage analysis).

Diagnoses and frequency of work-exacerbated asthma among bakers Marta Wisniewska, Agnieszka Lipinska-Ojrzanowska, Ewa Nowakowska-Swirta, Patrycja Krawczyk-Srul, Cezary Palczynski, Jolanta Walasiuk-Skorupa. Department of Occupational Diseases & Toxicology, Nofer Institute of Occupational Medicine, Lodz; Poland

The term work-exacerbated asthma (WEA) refers to asthma that is worsened by workplace exposures. The aim of the study was to evaluate the frequency of WEA in bakers reporting work-related respiratory symptoms and the usefulness of allergologic tests in differentiating WEA and occupational asthma (OA).

Material and methods: The study group included 393 bakers. In all subjects questionnaire, spirometry, SPT, evaluation of total and specific IgE level were performed. Recognition of OA was based on inhalative specific challenge test with evaluation of bronchial response or a threefold increase in non-specific bronchial hyperreactivity accompanied by increase sputum eosinophilia.

Results: Occupational etiology of asthma was found in 44.5% bakers while WEA was recognized in 16% subjects. 60% subjects with OA and 50.8% with WEA had positive SPT to common allergens, while occupational SPT were found in 74.9% and 34.9% subjects respectively. Whereas specific IgE to flores were found in 6% of bakers with OA and 28.6% with WEA. In patients with OA the latency period was 11.2 years whereas in bakers with WEA 13.3 years. Additionally, OA frequently coexisted with occupational rhinitis (53.7%) while among bakers with WER rhinitis was found in 31.7% subjects.

Conclusions: WEA can be diagnosed in 16% of bakers reporting allergic respiratory symptoms. The specific challenge test with occupational allergens should be performed among bakers with suspicion of work-related asthma, because assessment of increased (SPT to occupational allergens, evaluation of specific IgE) is not specific enough to differentiate occupational and work-exacerbated asthma.
P4941

A systematic review of serial peak expiratory flow measurements in the diagnosis of occupational asthma

Vicky Moore1, Marietta Jakkola2, Sherwood Burge1. 1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Respiratory Medicine Unit, Oulu University, Oulu, Finland

This work systematically reviews literature on the application of serial peak expiratory flow (PEF) measurements in the diagnosis of occupational asthma (OA) and calculates summary estimates of the sensitivity, specificity and feasibility of serial PEFs.

**Methods:** Papers were searched for on the Medline database via the PubMed website (http://www.ncbi.nlm.nih.gov/sites/entrez) and on the Birmingham Chest Clinic departmental website www.occupationalasthma.com from 2004 until April 2009 using the search terms “Peak flow AND occupational asthma” and “Peak flow AND work related asthma.” Abstracts were screened to select those justifying a full paper review. Papers used in the British Occupational Health Research Foundation (BOHRF) guidelines (current until June 2004) were also reviewed. Case studies and narrative reviews were excluded. Type of analysis, quality of paper, sensitivity and specificity of PEFs compared to reference tests and return rates were documented. Results were pooled from all studies to produce overall estimates.

**Results:** A total of 80 abstracts were reviewed, leading to 23 full papers plus 15 papers from the 2004 BOHRF review. 7 papers were excluded. The pooled sensitivity of serial PEF fulfilling minimum data quantity requirements for a diagnosis of OA was 82% (95% CI 76-90) and the pooled specificity 88% (95% CI 80-95). Return rates were similar between PEFs requested through workplace studies (85%) and those requested in a clinical setting (78%).

**Conclusion:** Based on a systematic literature search, serial PEF measurement is a feasible, sensitive and specific test for the diagnosis of OA, when potential sources of error are understood.

P4942

FEV1 decline and eosinophilia in occupational asthma

Donatella Talini1, Federica Novelli2, Elena Bacci2, Marta Laura Bartoli2, Silvania Ciocchetti1, Federico Lorenzo Dente2, Antonella Di Franco2, Lorenza Melosini2, Pierluigi Paggiaro2. 1Prevention Department, Occupational Health Unit, Pisa, Italy; 2Cardiac, Thoracic and Vascular Department, University of Pisa, Pisa, Italy

**Background:** There are few informations available on how rapidly lung function declines in subjects with occupational asthma (OA) who continue to be exposed.

**Subjects:** We monitored 38 subjects with OA (age 41.9±11.7 yrs, 4 smokers and 19 ex-smokers). 16 (44.1%) were exposed to high molecular weight compounds (HMWC) and 22 (57.9%) to low molecular weight compounds (LMWC), with an occupational exposure of 16.0 (range: 1-45) yrs. We used simple regression analysis to provide estimates of the decline in FEV1 during the period of occupational exposure 4.1 (range 1.2-13.7) yrs. The mean rate of change in FEV1 was −32.9 (range: -217.31-426.2) ml/yr.

**Results:** In all subjects FEV1 decline was significantly worse (*p*=0.04) in subjects with higher eosinophilia (>3%), but there wasn’t difference between subjects exposed to LMWC or HMWC not respect to the use of inhaled corticosteroids (ICS). Compared with controls, FEV1/5 pred at baseline and follow-up visit showed significant improvement only in subjects with lower eosinophilia (91.9±17.5 vs 96.6±15.7, *p*=0.01). Logistic regression analysis (mean annual change in FEV1 < than median value −32.9 ml/yr as dependent variable) was performed.

**Conclusion:** Baseline FEV1 and sputum eosinophilia are both determinants of a more rapid FEV1 decline in patients with OA still exposed in the workplace.

P4943

Pulmonary toxicity in car spray painters

Ibrahim Ibrahim, Ahmad El-Ebiary, Arwa Abueidaf, Enas El-Maddah, Salimaz El-Sharebagy. Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt; Forensic Medicine & Clinical Toxicology Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt; Forensic Medicine & Clinical Toxicology Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt; Forensic Medicine & Clinical Toxicology Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt; Forensic Medicine & Clinical Toxicology Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt; Pathology Department, Tanta University Hospital, Faculty of Medicine, Tanta, El Gharbia, Egypt

**Background:** Spray painters comprise a large population at risk with potentially high isocyanate exposure. Repeated pulmonary function testing is not sufficient to diagnose and evaluate pulmonary toxicity induced by car paint sprays. Therefore Clara cell secretory protein (CC16) was selected as a sensitive marker of bronchial tree injury.

**Methods:** The study involved 50 workers exposed to isocyanates during car spray-painting; in addition to 30 control subjects. All participants were subjected to pulmonary function testing, bronchoscopy and lavage, and serum CC16 estimation.

**Results:** Different pulmonary function indices as well as CC16 serum levels were found to be significantly decreased in the exposed group. Clara cells were markedly damaged in the exposed subjects, whereas smokers exhibit excessive epithelial cells desquamation.

**Conclusions:** In this study clear associations between lung function parameters, CC16 serum levels, and exposure to isocyanate-containing paint-sprays were demonstrated. This stresses the importance of regulation and control of such exposure. Also, assay of serum CC16 could be used to detect pulmonary toxic effects.

P4944

Is diurnal PEF variation sensitive and specific for the diagnosis of occupational asthma?

Vicky Moore1, Marietta Jakkola2, Cedd Burge1, Alastair Robertson2, Charles Pantin4, Sherwood Burge1. 1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Respiratory Medicine Unit, Oulu University, Oulu, Finland; 3Occupational Health, University Hospital Birmingham, Birmingham, United Kingdom; 4Respiratory Medicine, University Hospital of North Staffordshire, Stoke-on-Trent, United Kingdom

Serial peak expiratory flow (PEF) measurements on days at and away from work are recommended as the first step in the objective confirmation of occupational asthma. This study aims to identify the best cut off for the difference between diurnal variation (DV) at work and DV at rest (days off work) that is both sensitive and specific for diagnosing occupational asthma.

**Methods:** Mean 2-hourly PEFs were plotted separately for work days and rest days for 109 workers with occupational asthma and 117 control asthmatics. DV at work and rest was calculated by the Oasys program from records containing ≥ 4 day shifts, > 4 rest days and ≥ 6 readings per day. DV at work minus DV at rest was calculated by% predicted and% mean. Patients were randomly divided into 2 datasets (analysis and test sets). Receiver operator characteristic curve analysis determined a cut off point from Set 1 that best identified those with occupational asthma, which was then tested in Set 2.

**Results:** ROC curve analysis gave an area under the curve of 0.68 (set 1) and 0.69 (set 2) analysed as% mean and 0.70 (set 1 and set 2) analysed as% predicted. Table 1 shows the sensitivity and specificity of DV at different cut offs in set 2.

<table>
<thead>
<tr>
<th>Set 2: DV at work – DV at rest (%) predicted</th>
<th>Set 2: DV at work – DV at rest (%) mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sensitivity (%)</td>
<td>Specificity (%)</td>
</tr>
<tr>
<td>7.6</td>
<td>20</td>
</tr>
<tr>
<td>3.4</td>
<td>44</td>
</tr>
<tr>
<td>1.4</td>
<td>63</td>
</tr>
<tr>
<td>0.6</td>
<td>67</td>
</tr>
</tbody>
</table>

**Conclusion:** A 1.4% higher DV at work compared to rest has the best combined sensitivity and specificity for the diagnosis of occupational asthma. Although the sensitivity and specificity are acceptable, they are somewhat lower than other scores generated by the Oasys program.
P4945
Airway symptoms and lung function among male workers in the aftermath of an oil tank explosion
Jens-Tore Otniel1, Bjørg Eli Holland1, Ågot Irgens1, Magne Bråtveit1, Cecilia Svanes1, Bente Elisabeth Moen1,2, 1Department of Occupational Medicine, Haukeland University Hospital, Bergen, Norway; 2Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway

Background: In 2007 storage tanks with a heterogeneous mixture of hydrocarbons, sulphur compounds and hydrochloric acid exploded and caught fire in a Norwegian industrial harbour. Pollution in air and soil produced an intense smell until clean up was terminated in 2009. Respiratory symptoms and lung function was assessed 1.5 years after the explosion among male fire-fighters, clean-up workers, and employees working in the industrial harbour at the time of the accident. Methods: 163 exposed men (fire-fighters, clean-up workers, and local employee at the time of the accident) (response rate 86%) and 90 male controls (home address >20 km from the accident place), aged 18-67 years participated with a questionnaire and spirometry (response rate 59%). Regression analyses of the relationship between outcomes and exposure were performed, adjusting for smoking, occupational exposure matrix, Phadiatop® status, infection last month, and age (symptoms).

Results: Exposed men reported more daily cough; odds ratio 2.0 [95% confidence interval 1.1, 3.7]; dyspnoea walking up hill 2.6 [95% CI 1.3, 5.2] and sore throat 2.3 [95% CI 1.1, 4.7]; FEV1% predicted was 89.0 among exposed and 91.1 among controls, adjusted difference -1.9 [95% CI 0.6, 3.2].

Conclusion: Fire-fighters, clean up workers and local employee exposed to air pollution from an oil tank explosion had more airway symptoms than a control group 1.5 years after the accident, but not significantly different lung function.

P4946
Is FEV1 better than PEF at detecting asthmatic changes in diurnal variation? Kersty-Anne Dennis1, Vicky Moore1, Cedd Burge1, Sherwood Burge2
1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Health and Human Sciences, NIOSH, Morgantown, United States

FEV1 is considered the best measure of airflow obstruction but PEF is more commonly used to diagnose occupational asthma as it’s easier to achieve unsupervised.

We investigated whether FEV1 or PEF was more sensitive at identifying asthmatic variation when compared to EMG variation, and whether there were differences in interpretation. The aim was to confirm validity of serial PEF examinations in model study of bronchial obstruction in exposed and control group.

Methods: 14 asthmatics from the USA and 84 from the UK were studied. The USA group used the Easyone and the UK group the Piko-l, Vitallograph 2110, or Aparatec 1000. The workers were exposed 16 times, tested under similar conditions and had weekend rest days. The study was continued for at least 2 weeks with the occupational asthmatic records also having 10 day shifts.

Within session PEF and FEV1 variation was assessed for the USA data (as the months progressed, better attempts) using a coefficient of variation (COV). Diurnal variation% predicted (DV) was analysed for all data. Timepoint analysis (an Oasys program scoring system for occupational asthma) was performed on occupational asthmatics.

Results: The table below compares COV and DV for PEF and FEV1 (SD-standard deviation).

<table>
<thead>
<tr>
<th>PEF mean (SD)</th>
<th>FEV1 mean (SD)</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>COV (USA)</td>
<td>8.05 (1.86)</td>
<td>5.67 (1.88)</td>
</tr>
<tr>
<td>DV (USA)</td>
<td>15.51 (9.05)</td>
<td>12.43 (7.81)</td>
</tr>
<tr>
<td>DV (UK)</td>
<td>17.81 (7.51)</td>
<td>16.26 (8.35)</td>
</tr>
<tr>
<td>DV USA &amp; UK</td>
<td>16.61 (8.49)</td>
<td>14.26 (8.27)</td>
</tr>
</tbody>
</table>

There was no significant difference in the number of day shift positive drops (from Timepoint analysis; a drop signifies a significant difference between work and rest) between FEV1 and PEF (p=0.859) and no difference in the number required to produce a positive drop (p=0.297).

Conclusion: Diurnal variation is significantly greater for PEF than FEV1 in asthmatics with similar within session variation using logging meters incorporating some quality control. PEF is as good as FEV1 for diagnosing (occupational) asthma.

P4947
A quantitative European study to investigate the impact of asthma triggers on the lives of asthma patients
Peter Dale1, Emma Elder2, Gillian Newbold3, Nicola Vyas1, Sian O'Regan1, Kenneth R. Chapman1, David Price1, 1Global Health Outcomes, GlaxoSmithKline, Stockley Park, Uxbridge, United Kingdom; 2Global Medicines Futures, R&D, GlaxoSmithKline, Stockley Park, Uxbridge, United States; 3Research Director, HRW Healthcare, Wallington, Oxford, Oxfordshire, United Kingdom; 4Research Director, HRW Healthcare, Wallington, Oxford, Oxfordshire, United Kingdom; 5Senior Research Manager, HRW Healthcare, Wallington, Oxford, Oxfordshire, United Kingdom; 6University Health Network, University of Toronto, Toronto, ON, Canada; 7Academic Primary Care, University of Aberdeen, Aberdeen, United Kingdom

Background: There is frequent reference to asthma triggers in the patient education literature but little is known of patients’ experiences with triggers and their impact on and relationship to asthma control.

Methods: We used patient diaries and an online study to quantify the impact of asthma triggers in patients from five European countries (France, Germany, Italy, Spain, UK). 1202 asthma patients completed the study; 177 also completed an online diary every other day for 3 weeks.

Results: People with asthma expressed concern about the long term impact of triggers – only 1% believed that triggers would not affect their asthma. All triggers were perceived as having an impact on asthma symptoms (at least 6.1 for all triggers on a 10 point scale). Perceived impact increased with the increasing number of triggers identified by each patient. 80% of respondents claimed to have modified their behaviour due to exposure to triggers at least once in the last 4 weeks. Patients reporting a high number of triggers experienced more day and night-time symptoms, a greater number of severe attacks, had a lower Asthma Control Test (ACT) score, were more likely to be hospitalised and to miss days at work/school. People with asthma experiencing 16 or more triggers missed on average 12.2 days compared with 2.9 days for those reporting 1-5 triggers. Of those patients with a high number of triggers, just 3% had never adapted behaviour to manage their asthma.

Conclusion: Asthma triggers can have an important impact on the lives of asthma patients. The impact increases with the number of triggers experienced and results in significant behavioural changes.

P4948
Occupational asthma in two healthcare workers due to an alcohol hand gel
Alastair Robertson, Vicky Moore, Cedric Burge, Marcus Wong, Sherwood Burge
Occupational Lung Disease Clinic, Birmingham Chest Clinic, Birmingham, United Kingdom

Alcohol hand gels are increasingly being used by healthcare workers to reduce the risk of hospital-acquired infection. To date they have not been identified as a risk to healthcare workers. We present two cases of occupational asthma in healthcare workers due to an alcohol hand gel containing a quaternary ammonium (denatonium) biobit agent.

The healthcare workers, a midwife (case 1) and a nurse (case 2), presented with asthma improving on days away from work. Both had developed symptoms in relation to using the same alcohol hand rub. Both workers completed serial peak flow measures which showed occupational asthma (case 1 OASYS score 3.43, case 2 OASYS score 3.93). A series of bronchial challenge tests were performed to the hand gel and a control agent. Case 1 had a dual asthmatic reaction and case 2 had a prolonged immediate reaction to the hand gel. Both workers improved on removal from exposure.

Hand gels containing denatonium are used extensively by healthcare workers. There needs to be an awareness of this agent as a potential cause of occupational asthma in this group of workers.

Massive acute gases intoxication: Clinical presentation and outcomes
María Sánchez-Carpintero Abad⁴, Ana Belén Alcaide⁴, Arazana Camps⁵, Jorge Zagaeta⁶, Felip Lucena⁵, Manuel Lomacho⁵, Felix Alegre⁵, Luis Seijo⁵, Juan Pablo de Torres⁴, Javier Zulueta⁴, ¹Pulmonology, Clínica Universidad de Navarra, Pamplona, Navarra, Spain; ²Internal Medicine, Clínica Universidad de Navarra, Pamplona, Navarra, Spain.

On Oct 30th, 2008, a car bomb exploded on the University of Navarre (UN) campus, causing serious damages and several fires. On Nov 5th, during the repairing works, gases retained inside the fake ceiling were released, causing intoxication by inhalation in about 300 people. A longitudinal observational study was performed to assess the presentation and outcomes of 230 patients assisted at the Emergency Room (ER) of the UN Hospital. Employees and students were affected: 104 men and 126 women, with mean age 31±12 y, 23% smokers and 13% with previous respiratory disease. 65% of patients got to the ER on Nov 5th. At the first 6 h commonest complaints were cough (80%), dyspnea (51%), sore throat (38%), and vomiting (7%). Chest xray (n=218) showed infiltrates in 17.5% and chest CT (n=19) interstitial/alveolar infiltrates in 68%. Blood analysis (n=101) revealed leukocytosis in 65%, and high CRP in 85%. 80 patients were hospitalised (34.8%) with a median length of stay of 1 day (max 5 d). At the ER, patients received bronchodilators (62%) and steroids (54%). Upon discharge, bronchodilators (82%), steroids (30%) and N-acetyl cysteine (82%) were prescribed.

One month after discharge, 206 patients were re-evaluated: 41 (20%) had symptoms, consisting in dyspnea (12%) and cough (11%). Chest CT (n=218) showed infiltrates in 17.5% and chest CT (n=19) interstitial/alveolar infiltrates in 68%. Blood analysis (n=101) revealed leukocytosis in 65%, and high CRP in 85%. 80 patients were hospitalised (34.8%) with a median length of stay of 1 day (max 5 d). At the ER, patients received bronchodilators (62%) and steroids (54%). Upon discharge, bronchodilators (82%), steroids (30%) and N-acetyl cysteine (82%) were prescribed.

Methods: 42 rats were randomly divided into three groups: normal control (NC) group, CIH group and CIH+Ad group with 14 rats in each. Rats in NC group were housed in an air-conditioned room with normal environment. In the CIH group rats received CIH from day 42 until sacrifice and in the CIH+Ad group rats received CIH and adiponectin (Ad) from day 42 until sacrifice. The rats were kept under a controlled light/dark cycle (12h:12h) and had free access to food and water. Body weight and food intake were monitored daily. After sacrifice, rats were sacrificed by decapitation and the lung tissue was collected. Tissue samples were used for histological and ultrastructural analysis.

Results: In the CIH group there was a significant reduction in lung function as compared to the NC group. The histological analysis revealed a significant increase in the number of alveolar septa. The ultrastructural analysis showed a significant decrease in the number of mitochondria per cell. These findings suggest that chronic intermittent hypoxia leads to a decrease in lung function and an increase in the number of alveolar septa.

Conclusion: Chronic intermittent hypoxia leads to a decrease in lung function and an increase in the number of alveolar septa. These findings suggest that chronic intermittent hypoxia leads to a decrease in lung function and an increase in the number of alveolar septa.

**Improvement in obstructive sleep apnea features under targeted hypoglossal neurostimulation is independent from body mass index and collar size**

Daniel Rodenstein1, Benny Mwenge1, Myriam Dury1, Benoit Lengle2, Philippe Rembaum3, 1Pneumology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Plastic Surgery, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 3ENT, Cliniques Universitaires Saint-Luc, Brussels, Belgium.

**Background:** The treatment of moderate to severe obstructive sleep apnea (OSA) is continuous positive pressure (CPAP) applied during sleep. Although its health effects are beyond doubt, many patients refuse or stop CPAP because of intolerance or local side effects. Alternative therapies are needed.

**Aim:** We used targeted hypoglossal neurostimulation (THN) to treat 11 patients (1 female) non compliant with CPAP with the aim of improving both breathing and sleep.

**Methods:** One hypoglossal nerve was stimulated through a multicontact cuff electrode positioned around the main trunk of the nerve and connected to a stimulator implanted in a subcutaneous pocket on the anterior chest wall. Stimulation was applied continuously during sleep.

**Results:** The BMI of the group was 30.7±3.5 kg/m²; on diagnostic polysomnography and MRI imaging for soft-tissue volumetric measurements.

**Conclusion:** The data strongly suggest that didgeridoo playing decreases the AHI by downsizing parapharyngeal fat pads.

**P4956**  
**Supine position dependency in obstructive sleep apnea**

Selma Pirat Guven1, Bülent Ciftci1, Tanou Utkuak Ciftci2. 1Sleep Disorders Center, Ankara Chest Diseases, Thoracic Surgery Training and Research, Ankara, Turkey; 2Sleep Disorders Center, Faculty of Medicine, Gazi University, Ankara, Turkey.

**Introduction:** It is known that supine sleep position may lead to an increase in the severity of obstructive sleep apnea (OSA) patients. The aim of this study was to define the prevalence of supine positional OSA in patients diagnosed with OSA and to draw attention to alternative therapy planning in these patients.

**Patients and Method:** A total of 3,214 patients diagnosed as OSA between June 2007 and June 2010 were included to the study. Positional OSA was defined as a total apnea-hypopnea index (AHI) 2.5 and supine AHI/supine AHI ≥ 2. Characteristics of positional OSA and non-positional OSA groups were compared statistically.

**Results:** Patients grouped as positional OSA composed 39.9% (n: 1283) of all patients. Positional OSA patients were younger with lower body mass index (BMI) and their OSA was less severe.

**Conclusions:** Positional OSA, which may require different treatment approaches, is not uncommon among OSA patients and should be understood as a different clinical entity.

**P4957**  
**Berlin questionnnaire performance for detecting sleep apnea in the general population**

Raphael Heinzer1,2, Daniela Andries1, Francois Bastardot3, Nadia Tobback1, Raphael Heinzer1,2, Daniela Andries1, Francois Bastardot3, Nadia Tobback1, 1Pneumology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Plastic Surgery, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 3ENT, Cliniques Universitaires Saint-Luc, Brussels, Belgium.

**Introduction:** Berlin questionaire (BQ) has been proposed as a screening tool for identifying patients at risk for obstructive sleep apnea (OSA). The aim of our study is to evaluate the performance of this questionnaire for detecting OSA in a large sample of middle-aged general population.

**Methods:** 469 subjects (46.4% women, 50.6±10.0). Prevalence of OSA defined as an AHI >5; ≥ 15 and ≥30 was 33.3%, 10.3% and 3.8%, respectively in our population. Prevalence of positive BQ score was 24% (29.2 in men, 18.1 in women). BQ sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) to detect OSA were 36.1%, 82.4%, 51.8% and 72.9% respectively for an AHI >5; 51.2%, 78.8%, 21.9% and 93.5% for an AHI >15; and 72.2%, 77.6%, 11.4% and 98.6% for an AHI >30. Positive BQ was associated with higher 4% ODI (10.8±4 vs 4.2±0.001), higher Epworth score (8.3 ±6.2 vs 0.0001) and broader neck circumference (38.6 ±35.7 cm vs 0.0001).

**Conclusion:** BQ questionnaire performance for identifying OSA is lower in a middle-aged general population than previously reported in a clinical population. Our results do not support its use as a screening tool for OSA in an unselected population.

**STOP-BANG score as a screening tool for obstructive sleep apnea in the general population**

Raphael Heinzer1,2, Daniela Andries1, Francois Bastardot3, Nadia Tobback1, Raphael Heinzer1,2, Daniela Andries1, Francois Bastardot3, Nadia Tobback1, 1Pneumology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Plastic Surgery, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 3ENT, Cliniques Universitaires Saint-Luc, Brussels, Belgium.

**Introduction:** STOP-BANG (Scoring Tiredness during daytime, Obesity, Hypertension, Blood pressure, Male, Age >50, Neck circumference >40 cm, Gender score has been shown to be a useful tool to screen for obstructive sleep apnea (OSA) during preoperative evaluation. The aim of our study is to evaluate the mean STOP-BANG score in a large sample of middle-aged general population.

**Methods:** 458 subjects (47.7% women, 50.6±7.5 years old, BMI 25.2±4.9 kg/m²) participating in an ongoing population-based cohort study (HypnoLaus, Lausanne, Switzerland) underwent a complete polysomnographic recording at home and an extensive clinical workup including BQ. This instrument includes 3 categories: 1) witnessed apnea and snoring 2) daytime sleepiness and 3) obesity or hypertension. A positive score in 2 or more categories was considered suggestive of OSA.

**Results:** Mean AHI was 6.3±10.6. Mean 45°ODI was 5.8±10.0. Prevalence of OSA defined as an AHI >5; ≥ 15 and ≥30 was 33.3%, 10.3% and 3.8%, respectively in our population. Prevalence of positive BQ score was 24% (29.2 in men, 18.1 in women). BQ sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) to detect OSA were 36.1%, 82.4%, 51.8% and 72.9% respectively for an AHI >5; 51.2%, 78.8%, 21.9% and 93.5% for an AHI >15; and 72.2%, 77.6%, 11.4% and 98.6% for an AHI >30. Positive BQ was associated with higher 4% ODI (10.8±4 vs 4.2±0.001), higher Epworth score (8.3 ±6.2 vs 0.0001) and broader neck circumference (38.6 ±35.7 cm vs 0.0001).

**Conclusion:** BQ questionnaire performance for identifying OSA is lower in a middle-aged general population than previously reported in a clinical population. Our results do not support its use as a screening tool for OSA in an unselected population.

**P4959**  
**AutoCPAP devices accurately identify obstructive sleep apnea patients with residual apnea during treatment**

Lena Hess, Tsygadal D. Latsang, Malcolm Kohler, Christian M. Lo Cascio, Robert Thumber, Konrad E. Bloch. Pulmonary Division, University Hospital of Zurich, Zurich, Switzerland.

**Background:** Objective data on the effectiveness of CPAP therapy of patients with obstructive sleep apnea syndrome (OSA) are needed. The accuracy of the apnea/hypopnea index (AHI) recorded by CPAP devices during treatment is unknown. We tested the hypothesis that AHI derived from CPAP devices accurately predict an elevated AHI during a sleep study.

**Methods:** 48 patients, mean±SD age 54.6±5.9, baseline AHI 52.5±21.6, underwent in-laboratory sleep studies once or twice during long-term autoCPAP therapy. AHI from CPAP devices (RespMed S8, Philips Respironics REMstar) during sleep studies and during the preceding 7 nights were recorded.

**Results:** The AHI derived from 60 sleep study was 5.0±6.2. The mean difference (bias) of the corresponding AHI from CPAP devices was 1.8±8.9. 95% confidence interval 7.4±11.0. The difference between the minimal and maximal CPAP-derived AHI in the week preceding the sleep study was 6.1±5.1. In
22 of 60 sleep studies, the AHI was >5/h. The accuracy of the AHI from CPAP devices to correctly predict an elevated AHI (>5/h) was quantified by the area under the receiver operating characteristic curve of 0.87 (95% CI 0.78 to 0.96). The sensitivity and specificity of an AHI >5/h from CPAP devices to identify a polygraphic AHI >5/h were 86% and 75%, respectively; the negative and positive predictive values were 95% and 56%, respectively.

Conclusions: The studied CPAP devices accurately identify OSA patients with elevated AHI during treatment. Because of the high night-to-night variability mean AHI derived from autoCPAP devices over several nights might be clinically more relevant than a single night AHI measured in the sleep laboratory.

Methods: We recruited consecutive sleep referrals over a 5 month period. We compared the total and average time taken with this algorithm to perform a screening (control arm) of LCSS for every patient. The study was powered for 50 patients, 30 had been recruited to date.

Results: N=30. Median age 53 years, 19 were male. See table for results; average time saving - 24.5 minutes per patient.

Conclusion: We propose that allocating high probability subjects to oximetry and using LCSS for low probability subjects and for oximetry negative high probability subjects results in significant time and resource savings.

References:

Methods: We studied 289 children (6.5 ± 3.1 yrs, 63.3% M). We found 28% children had lower AHI than OSAS' children with positive score (5.1 ± 3.1, p < 0.005) and it was correlated with AHI (r=0.156, p=0.008). The SCS’s distribution has identified the value of 6.5 as its 25th centile, so the SCS was defined as positive when it was major of 6.5. The SCS was positive in 224 of the 289 children studied, of these 177 had OSAS (real positives) and 47 were PS (false positives). 65 children was major of 6.5. The SCS was defined as positive when it

Conclusions: The proposed method represents a valuable screening tool that could contribute to reduce the number of required PSG tests.

Aims: To develop a reliable tool, PSG validated, for diagnosis of SDB and to reduce the use of PSG.

Methods: Children with referred SDB undergoing a PSG for the first time. We proposed the Sleep Clinical Record (SCR) to predict SDB in children, based on clinical experience. It consists of objective data, subjective symptoms, clinical history, behavioural and cognitive problems. These items were used in a model which combine subjective and objective parameters to create the sleep clinical score (SCS) with the higher predictive value.

Results: We studied 289 children (6.2 ± 3.1 yrs, 63.3% M). We found 28% children’s with primary snoring (PS) and 72% with OSAS. The SCS was higher in children with OSAS than children with PS (8.9 ± 2.7 vs 7 ± 4.3, 1 < p < 0.005) and it was correlated with AHI (r=0.156, p=0.008). The SCS’s distribution has identified the value of 6.5 as its 25th centile, so the SCS was defined as positive when it was major of 6.5. The SCS was positive in 224 of the 289 children studied, of these 177 had OSAS (real positives) and 47 were PS (false positives). 65 children had a negative SCS, of these 31 were diagnosed as OSAS (false negatives). These children had lower AHI than OSAS’ children with positive score (5.1 ± 4.9 vs 8.9 ± 10.1, p = 0.04).

Conclusion: This SCS is useful to screen SDB in selected population with referred symptoms, and is able to perform diagnosis of OSAS with a positive predictive value of 79% and an accuracy of 73%. It is a useful tool to select patients with OSAS that could be treated without PSG diagnosis when the study is difficult to perform or is unavailable.

Aims: To develop a reliable tool, PSG validated, for diagnosis of SDB and to reduce the use of PSG.

**Results:** Apnea-hypopnea index (AHI) of SleepMinder correlated well with PSG-AHI on simultaneous application (r=0.90, p<0.001). For PSG-AHI cut-off >15/h and SleepMinder-AHI cut-off >13.4/h, sensitivity was 77.3% and specificity was 100%. Furthermore, SleepMinder correlated with PSG regarding total sleep time (r=0.59, p=0.001), sleep efficiency (r=0.49, p<0.006) and time to sleep (r=0.41, p=0.03).

**Conclusions:** This study showed that SleepMinder, a non-contacting screening device, detects sleep apnea with sufficient diagnostic accuracy. Moreover, SleepMinder correlates with total sleep time, sleep efficiency and time to sleep.

---

**Introduction:** SleepMinder correlates with total sleep time, sleep efficiency and time to sleep. Moreover, SleepMinder detects sleep apnea with sufficient diagnostic accuracy. Hence, SleepMinder can be used as an adjunct to polysomnography (PSG) in a sleep laboratory.

**Methods:** 69 unselected subjects (20 – 73 yo) referred to a sleep laboratory for PSG complaining of SD-DS participated. No attempt was made to select patients with asthma or chronic cough. PSG by standard methods and ARM (Pulmotrack, KarmelSonix, Haifa, Israel) were adequate for all but 3 patients (5%). The analysis was done minute by minute throughout the record where Wz=rate occupied by Wz and C coughCOUNT (CC) were measured. The present study concerns the detection of nocturnal Wz and C by ARM without reference to the PSG data.

**Results:** The duration of the overnight ARM in the 66 subjects was 65 – 478 min (median 439 min). Wz-minutes, defined as the number of minutes with a Wz% 5% and C-minutes, the number of minutes with CC>1 were determined. In 16/66 (24%) of patients Wz-minutes occupied more than 3% of the recording and in 29/66 (10.6%) C-minutes occupied more than 2% of the recording with overlap in 3 patients who had both Wz and C.

**Conclusion:** With 20/66 (30%) of unselected patients referred to an adult sleep laboratory because of SD-DS might be suffering from nocturnal Wz or C.

**Discussion:** There is an expectation that scorers can accurately distinguish obstructive from central events. This observational study shows that interpretation varies widely. This has important consequences for treatment of individuals and for conduct of research studies. AASM rules may provide more clarity and improve concordance but ongoing training and interlaboratory comparisons are essential.

**Results:** The ASI technique was found to enable recognition of subjects classified as central or mixed for each scorer and each study. A superimposed box plot shows median, 25th and 10th percentiles.
P4969
A case-control study of the risk of adverse peri-natal outcomes due to tuberculosis during pregnancy
Bassey Asuquo1, Arun Vellore2, Gareth Walters3, Heike Kunst1,2 Department of Respiratory Medicine, Queen Elizabeth Hospital, Woolwich, London, United Kingdom; 1Department of Respiratory Medicine, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom

Aim: The West Midlands, UK has seen a persistent rise in cases of tuberculosis (TB) in immigrants, and TB in pregnancy is more common amongst recent migrants to a country. Diagnosis is often delayed due to non-specific, late presentation, and this has been associated with prematurity and low birthweight (LBW). We aimed to determine the risk of adverse peri-natal outcomes in women with TB in pregnancy.

Methods: A case-control study was conducted at three hospitals in Birmingham, comparing pregnant women with TB (n=204; n = 24) with healthy pregnant controls (n=72). Data concerning the course of pregnancy, birthweight and prematurity were collected from review of case notes. Healthy controls were matched for age and socio-economic status. Urivariate analyses of low birthweight and prematurity were undertaken, and a multivariate regression model constructed to explain differences by ethnicity and prematurity.

Results: Estimated incidence of TB was 62/100,000 pregnancies. 54.2% cases were pulmonary TB (41.7% extra-pulmonary: 4.2% both). Infants of mothers with TB had significantly lower mean birth-weight compared to controls (2760g vs. 3140 g; p=0.028). Mean birth weight was lower in pulmonary TB than in extra-pulmonary TB. Multivariate analysis explained LBW by prematurity (p<0.001) but not ethnicity (p=0.19).

Conclusion: Pregnant women with TB are at higher risk of LBW infants. This is particularly true of mothers with pulmonary TB. Mean duration of symptoms was 8.3 weeks and LBW is attributed to late presentation. Indeed patients have mild symptoms that are confused with those of pregnancy. Therefore a high index of suspicion and early referral and diagnosis is recommended.

P4970
Pregnancy: A risk for developing tuberculosis? A national cohort and self-controlled case series study using UK primary care data

Introduction: Tuberculosis (TB) incidence has increased in the UK over the last decade. The study of TB in pregnancy is important because of adverse outcomes in mother and child. The aim of this study was to analyse the epidemiology of TB in pregnancy in the UK, and establish, whether pregnancy is an independent risk factor for TB in order to inform prevention and early detection strategies.

Methods: Using a cohort based on the UK General Practitioner Research Database (GPRD), incidence rates (IR) and rate ratios (RR) of TB events in three time periods were compared using Poisson regression: pregnancy, a period of 6 months post-partum, and outside of pregnancy. In addition TB risk was calculated using a nested self-controlled case series (SCCS) analysis which implicitly adjusts for time-bounds covariates.

Results: Combined pregnancy and post-partum TB rates (15.4 per 100,000 person years, py) were significantly higher than rates outside of pregnancy (9.1 per 100,000 py, p=0.02). Compared to risk outside of pregnancy, TB risk was not significantly increased during pregnancy (IRR 1.95, CI 1.24-3.07), adjusting for age, region and deprivation. These observations were confirmed in the SCCS (IRR 1.62, CI 1.01-2.58 and 1.03, CI 0.64-1.65).

Conclusion: There is a significantly increased post-partum TB risk and this is very likely pregnancy-related, but occurs post-partum due to administrative, diagnostic or immunological delays. Our results can be used to raise clinicians awareness and inform targeted public health policy measures to minimise this risk.

P4971
Knowledge and attitudes about tuberculosis among non-medical students in University of Novi Sad, Serbia
Miroslav Bic1, Miroslav Tomic2, Vlona Kuru3, Slobodan Pavlovic3, Svetlana Kasikovic-Lecic3, Ivan Kopitovic3, Senka Milutinov3,4 Polyclinic, Institute for Pulmonary Diseases of Vojvodina, Sremka Kamenica, Serbia; 3Medical Faculty, Medicine, Novi Sad, Serbia; 4Tuberculosis, Urgent Palymology, Institute for Pulmonary Diseases of Vojvodina, Sremka Kamenica, Serbia

Introduction: Students’ knowledge and opinion about tuberculosis (TB) are very important for recognizing early symptoms and signs of disease, prevention of late in diagnosis of TB and influence on prevention and outcome of disease.

Goal: To define the non-medical students’ knowledge about TB (symptoms, way of medical treatment, possible complications, comorbidity).

Material and methods: Prospective study comprised the non-medical faculties at the University of Novi Sad, Serbia. The data were obtained by the questionnaire filled in during October-November 2010.

Results: The total of 1139 students were questioned, average 19.7 year, most women (n=794, 69.7%). The majority of students had a good knowledge about TB (n=991, 78.2%). The majority of questioned students knew that TB is infectious disease (n=1093, 96%) that the main cause of TB is bacteria (n=887, 77.9%) as well as it is curable disease (n=1079, 95.6%). Over 94% knew that cough is the main cause of TB transmission. 62% questioned students considered that risk factors can contribute the tuberculosis appearance (39.4% alcoholism, 66.3% poor nutrition, 74.7% smoking and 67.9% comorbidities). The students from Agricultural faculty showed better knowledge against other students, p<0.001. The most of the students (n=533, 45%) knew that TB incidence in the state area was decreasing.

Conclusion: Students of non-medical faculties at the University of Novi Sad showed the good knowledge about TB. The best knowledge was noticed at the students of Faculty of Agriculture. They also are well informed about TB presented in the state and the effects of national and international guidelines implementation in the country respectively.

Evaluation of tuberculosis diagnostic criteria in children
Soheila Khalilzadeh, Maryam Hassanzad, Nooshin Baghaie, Mohamad Reza Boloorsaz, Ali Akbar Velayati. Pediatric Respiratory Diseases Research Center, Shahid Beheshti University Mash University Hospital, Tehran, Islamic Republic of Iran Pediatric Respiratory Diseases Research Center, Shahid Beheshti University Mash University Hospital, Tehran, Islamic Republic of Iran Pediatric Respiratory Diseases Research Center, Shahid Beheshti University Mash University Hospital, Tehran, Islamic Republic of Iran

Objective: In this study we reviewed the diagnostic criteria for tuberculosis on 198 children diagnosed with TB

Material and methods: A cross-sectional, descriptive study was conducted on a series of 525 children aged 1 to 15 years. Among 525 patients, 198 were diagnosed with TB. Date of the study were collected from the patients records, chest radiographs and laboratory examinations. Demographic and diagnostic characteristics of patients were reviewed by means of the available criteria.

Results: In this study 38.9% of patients were male and 61.1% were female. Among all patients 34.5% were Iranian and 65.2% were Afghan. In this study 82.8% of patients reported close contact with TB. All patients had pulmonary and extrapulmonary tuberculosis, 72.7% had pulmonary tuberculosis and 14.1% had pulmonary and extrapulmonary involvement.Frequency of TST, contact, clinical symptoms, radiograph findings and bacteriology as diagnostic methods was 79.5%, 83.8%, 83.8%, 95%, and 58.1%, respectively. Due to our setting, 90.4% of patients fulfill the criteria.

Discussion: The result of this study indicate the high diagnostic value of smear and culture of gastric aspirate in children.How ever, it couldn’t be considered as a gold standard for diagnosis of TB in children. In addition the significant accuracy of the available criteria was determined and it could be considered as an efficient diagnostic setting in childhood TB diagnosis.

Neonatal tuberculosis and cardiac inflammatory myofibroblastic tumor presenting as supraventricular tachycardia: A rarity of kinds
Maria Nita Banque. Pulmonary and Critical Care Medicine Section of Pediatric Pulmonology, Philippine Heart Center for Asia, Quezon City, National Capital Region, Philippines

This a case of a month old female neonate who was admitted for respiratory distress. On admission, electrocardiogram showed supraventricular tachycardia. A 2-D echo showed a mass anterior to the left ventricle and the right ventricular outflow tract (RVOT). Chest radiograph showed a left upper lung haziness and computed tomography (CT) scan of the chest showed a non calcified anterior mediastinal mass with central enhancement. Intramyocardial mass biopsy revealed a large anteriorly located intramyocardial mass covering the RVOT, the great vessels and a portion of the right atrium. Final histopathology result revealed inflammatory pseudotumor, myofibroblastic in nature. Smooth muscle actin (SMA) was positive in many localized spindle cells indicative of their myofibroblastic nature while histiocytic markers- CD68 and S100 were both negative. Because of a high index of suspicion, a tuberculous work-up was done which showed that the patient was positive for tuberculin test (18mm in diameter). Contact screening revealed 3 of the 6 household contacts were positive for pulmonary tuberculosis. Patient was started on anti-tuberculosis medications and on the fifth month of treatment, the patient was asymptomatic, growing well and the mass regressed in size by 50%.
As in adults, occurrence of children TB has become quite rare in the last decades in Italy. We report a survey of 269 consecutive cases of mycobacterial disease (MD) in subjects under 18 years of age, diagnosed or referred to the Regional TB Ref Centre from 2000 to 2010.

**Results:** 139 were M, 130 F, 113 were Italians, 156 immigrants, 135 children received antituberculosis treatment in 2010. Most of these children were with active TB. Treatment and the supervision of child’s tuberculosis. Most children of different ages are infected by household contacts with active tuberculosis, especially parents or their relatives. Children exposed to adults with pulmonary tuberculosis or a positive sputum have a high risk for infection, and the risk increases with the degree of contact.

**Methods:** This is a retrospective study which gathered the 22 children with tuberculosis and AARB smear-positive sputum have a high risk for infection, and a high risk for contact with TB cases, histological results or immunologic tests (IGRA/TST).

**Background:** The family and socioeconomic environment influence the appearance, treatment and the supervision of child’s tuberculosis. Most children of different ages are infected by household contacts with active tuberculosis, especially parents or their relatives. Children exposed to adults with pulmonary tuberculosis or a positive sputum have a high risk for infection, and the risk increases with the degree of contact.

**Methods:** This is a retrospective study which gathered the 22 children with tuberculosis and AARB smear-positive sputum have a high risk for infection, and a high risk for contact with TB cases, histological results or immunologic tests (IGRA/TST).

**Results:** Of the isolated NTM 25 were M, 3 M intracellulare, 2 M. scrofulaceum, 1 M. fortuitum, 1 M. malmoensis, 1 M. Haemophilum, 1 M. Kansasi, 1 M. Xenopi 1 M. Lentiflavum e 4 M. could not be identified. Medical, surgical or combined therapy guaranteed success in 239 pts, 2 had to stop treatment for adverse events, % were transferred to other centres, 3 were lost to follow-up and 20 are still under treatment.

**Conclusion:** Child’s tuberculosis and the socioeconomic environment stop treatment for adverse events, % were transferred to other centres, 3 were lost to follow-up, and 20 are still under treatment.

**Results:** Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

**Conclusion:** Patients lost to follow-up is a significant problem. We found, that receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Results:** Children with active TB had a significant higher frequency of attending follow-up. Receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Results:**: Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

**Conclusion:** Patients lost to follow-up is a significant problem. We found, that receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Results:** Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

**Conclusion:** Patients lost to follow-up is a significant problem. We found, that receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Methods:** We included 11 BCG vaccinated children younger than 5 years with LTBI. The commercial IGRA (QuantiFERON TB Gold In- Tube®, QFT-GIT), Cultiolis Ltd, Carnegie, Australia was performed two times, before and at 6 month chemoprophylaxis. The cut-off value for positive findings of IGRA was ≥0.35 kIU/L. The TST was performed using 2 IU (0.1 mL) of purified protein derivative tuberculin PPD RT 23 SSI (Statens Serum Institut, Denmark) according to the Mantoux method and transverse diameter of the induration was measured after 72 hours.

**Results:** IGRA values were 8.87±2.01 kIU/L and 8.02±1.99 kIU/L before and after chemoprophylaxis, respectively, which suggests a slight, insignificant decrease (p=0.89). There was no significant difference in PPD values before (12±2 mm) and after (14±2 mm) the treatment, p=0.50.

**Conclusions:** Although the prophylaxis was used, both IGRA and PPD values, remained elevated during the period of 6 months in children with LTBI. Further research is needed to clarify the role of serial IGRA in children up to 5 years.

**Results:** Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

**Conclusion:** Patients lost to follow-up is a significant problem. We found, that receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Results:** 8.87±2.01 kIU/L and 8.02±1.99 kIU/L before and after chemoprophylaxis, respectively, which suggests a slight, insignificant decrease (p=0.89). There was no significant difference in PPD values before (12±2 mm) and after (14±2 mm) the treatment, p=0.50.

**Conclusions:** Although the prophylaxis was used, both IGRA and PPD values, remained elevated during the period of 6 months in children with LTBI. Further research is needed to clarify the role of serial IGRA in children up to 5 years.

**Methods:** We included 11 BCG vaccinated children younger than 5 years with LTBI. The commercial IGRA (QuantiFERON TB Gold In-Tube®, QFT-GIT), Cultiolis Ltd, Carnegie, Australia was performed two times, before and at 6 month chemoprophylaxis. The cut-off value for positive findings of IGRA was ≥0.35 kIU/L. The TST was performed using 2 IU (0.1 mL) of purified protein derivative tuberculin PPD RT 23 SSI (Statens Serum Institut, Denmark) according to the Mantoux method and transverse diameter of the induration was measured after 72 hours.

**Results:** IGRA values were 8.87±2.01 kIU/L and 8.02±1.99 kIU/L before and after chemoprophylaxis, respectively, which suggests a slight, insignificant decrease (p=0.89). There was no significant difference in PPD values before (12±2 mm) and after (14±2 mm) the treatment, p=0.50.

**Conclusions:** Although the prophylaxis was used, both IGRA and PPD values, remained elevated during the period of 6 months in children with LTBI. Further research is needed to clarify the role of serial IGRA in children up to 5 years.

**Results:** Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

**Conclusion:** Patients lost to follow-up is a significant problem. We found, that receiving money for the transport to the hospital is crucial for patient adherence. Children with active TB had a significant higher frequency of attending follow-up. All TB patients attend the TB clinic at the hospital frequently, which could explain the better adherence to follow-up.

**Results:** Only 61% showed up for the follow-up examination. Being treated for active TB was a positive predictor for attending follow-up. OR: 0.24, CR: (0.12-0.50), p-value = 0.001. Receiving money for the transport to the hospital was a positive predictor for attending follow-up. OR: 0.068 and CR: (0.001-0.060). P-value = 0.001. Limited financial resources and poor communication are issues related to poor adherence.

Contact tracing among the classmates of a 15 year old smear negative pulmonary tuberculosis
Nooshin Bayat1, Afshin Khajelahai2, Mohammad Reza Boloorsar3, Nazarin Parsanejad. Pediatric Respiratory Disease Research Center, Shahid Beheshti University, Tehran, Islamic Republic of Iran; Pediatric Respiratory Disease Research Center, Shahid Beheshti University, Tehran, Islamic Republic of Iran; Pediatric Respiratory Disease Research Center, Shahid Beheshti University, Tehran, Islamic Republic of Iran

Objectives: This study aimed to identify the infected or disease cases among contacts of the 15 year old girl with smear Negative pulmonary tuberculosis in an school outbreak and establish prophylaxis and treatment needed.

Methods: 52 contacts were screened by a tuberculin skin test and Chest X ray initially. Those children who had either a positive PPD or an abnormal chest X-ray were candidate for a tripled Gastric washing (Smear, Culture, Polymerase chain reaction (PCR)) and a Chest spiral CT scan.

Results: 20 contacts (38%) were considered as an infected due to either positive TST or abnormal Chest X-Ray. 28% had a positive Tuberculin Skin Test. Consequently 3 (5.7%) cases of active TB were identified through our investigations.

Conclusion: Our study suggest that even children with TB, who may have a negative smear, can transmit infection to others and therefore should be considered infectious until proven otherwise and contact tracing should be considered for contacts of all symptomatic pulmonary tuberculosis children.

Interferon-gamma release assays (IGRA) for latent tuberculosis infection (LTBI) in children
Rizwan Ahmed1, Deborah Gascoyne-Binzii2, Sandy Moffitt3, Timothy Collyns4, John Watson5,1 Respiratory Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 2Department of Microbiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: IGRA, QuantiFERON®-TB Gold in-tube (QFT-GIT) & T-SPOT.TB®(T-Spot), are widely used to detect LTBI in adults. There is paucity of data regarding their use in children (<16 yrs old), but their use in this group is increasing [1]. One of the key reported problems in children is high incidence of indeterminate results. Studies in adults have shown this can be minimized with early incubation of QFT-GIT blood samples. In Leeds there is close co-ordination between medical & nursing staff collecting bloods, and the local laboratory processing them with prompt transport of samples and the aim to incubate samples within 4 hours of collection.

Methods: We retrospectively reviewed all the IGRA tests performed in children, for contact & new entrant screening, in our TB service between 2008 & 2010, to look at our indeterminate rates.

Results: A total of 188 IGRA tests were performed. T-Spot was undertaken almost exclusively in children under 1 year. None of our cohort had indeterminate IGRA results with QFT-GIT or T-Spot.

None of the children were diagnosed with active TB (multiple samples were sent for TB culture from 4 children). Conclusion: A definitive IGRA result is achievable in otherwise healthy children with close liaison between clinical and microbiology staff, prompt transfer of blood samples and incubating QFT-GIT samples within 4 hours of collection.

Evaluation of QuantiFERON-TB Gold Assay in detecting latent and active tuberculosis in group of Egyptian children
Maha Ghanem1, Nefesa Refaat2, Heba Rashid3, 1Chest Department, Assiut University Hospital, Assiut, Egypt; 2Pediatrics Department, Assiut University Hospital, Assiut, Egypt; 3Clinical Pathology Department, Assiut University Hospital, Assiut, Egypt

Background: QuantiFERON-TB Gold In-Tube (QFG-IT) showed good diagnostic accuracy for active and latent TB in adults; limited studies have been performed regarding their use in children (DST) consists of two MTB-specific antigens - ESAT-6 and CFP-10 (tinkstaffink).

Methods: In a hospital-based prospective study, diagnostic accuracy of the tuberculin skin testing (TST) and QFT-IT were assessed in a cohort of 112 children (mean age 6.9±4.4, range 0.7-16), control not exposed (n=20), latent tuberculosis (n=44), active tuberculosis (n=50).

Results: In confirmed active TB, TST was positive in 24 out of 26 cases (92.3%), compared to 37 out of 50 cases (74%) for QFT-IT. None of the 2 tests performed significantly better than the other (p=0.109). In latent TB infection (LTBI), TST was positive in 24 out of 26 cases (92.3%), compared to 37 out of 50 cases (74%) for QFT-IT. Despite that QFT-IT performed better than TST, this was not statistically significant (p=0.062). Significantly higher number of positive QFT-IT and TST were seen in children older than 5 years compared to younger children (p=0.009, and 0.007, consecutively). The 2 tests did not show significant differences between those who had confirmed pulmonary and extra-pulmonary TB (p=0.05).

The overall agreement between the 2 tests was good (84.21%, k=0.677).

Conclusions: QTF-IT did not show higher diagnostic value in confirmed active childhood TB. Both QFT-IT and TST perform better in children older than 5 years than in younger population. Positive QFT-IT supports the diagnosis of TB in TST positive children. Negative QFT-IT does not exclude active TB. If used in diagnosis of LTBI, QFG-IT could significantly reduce the numbers of children receiving chemoprophylaxis.

Diagnostics of the latent TBC infection (LTBI) activity in children
Nataliya Stavitskaya1, Alla Doroшенкова1, Roman Khmurenko1, 1Infectious Disease and Physioimmunology, 2Immunology, Kuban State Medical University, Krasnodar, Russian Federation

Material and methods: Under observation there were 118 children with LTBI and 129 diseased children with local forms of lung tuberculosis. The concentra-

tion of key cytokines IFN, IL4, IL10, IL18 in blood serum was identified with immunofluorometric method.

Results: To comparatively study the correlation of functioning of Th1 and Th2 cells in the immune response, we introduced the notion of “Cytokine index”. According to the secretory activity of T-helpers of the 1 and 2 type we determined by quantitative correlation of the key cytokines IFN/IL4 and IL10/IL18. It was determined that in comparison with a control group (30 noninfectious children) average values of IFN content increased in diseased children in 2,4 times, in lymphohy with LTBI – in 3,6 times. By analogy, the values of IL10 increased in diseased in 2,9 and in healthy children with LTBI – in 4,5 times. The obtained results underline the one-way direction of the immune response to TBC infection, appeared in organism. In diseased children the quantitative index of correlation of the key cytokines IFN/IL4 and IL10/IL18 was equal to 1,9. In healthy children with LTBI the this index was equal to 1,9. The correlation of the other two nonetheless important cytokines IL18/IL10 in the differentiating of T-lymphocytes in very indicative: in both groups the cytokine index appeared to be lowered to 1,4 and 1,9, which was caused by the increase of IL10 almost in 5 times compared with the control group (2,3).

Conclusion: The IL18/IL10 obtained results allow of IL18/IL10 introducing into clinical practice quantitative evaluation of correlation of Th1 and Th2 hence to diagnose the LTBI progress.

Tuberculosis detection in children and adolescents using diagnostic testing based on tuberculosis recombinant protein E SAGA-CFP10 (tinkstaffink)
Ludmila Slogotskaya1, Elena Ovsyankina1, Vitaly Livinovsky1, Yakov Kochetkov2, Petr Seltsovskiy2, O. Senchukina2, L. Stukheeva2, Dmitry Koudlay2, 1Clinical Research, Scientific and Clinical Anti-Tuberculosis Center, Moscow, Russian Federation; 2Research, Pharmacutamdont, Moscow, Russian Federation

Background: Until recently, the tuberculin skin test (TST) has been the only diagnostic method for latent tuberculosis infection (LTBI). However, the speci-
ficity of TST is low, because the purified protein derivative (PPD) used for TST contains numerous M. tuberculosis (MTB) antigens that are almost identical to BCG antigens or similar to non-TB mycobacterium (NTM) antigens. Of those 99% BCG vaccinated in Russia it is very difficult to diagnose LTBI. DIASIKTEST (DST) consists of two MTB-specific antigens - ESAT-6 and CFP-10, which are absent in all M. bovis BCG substrains and in most of NTM antigens. Aim was to evaluate to evaluate the role of DST in TB detection.

Method: 1675 children and adolescents with convurbed tuberculosis reaction, reaction size increased by more than 6 mm, hyperergy, TB contacts (social or household) received the Mantoux test with 2 TU PPD-L and DST 0.2 mg/kq/0.1ml.

Result: 95.8% - TST-positive. 349 (20.8%) - DST positive, all - chest X-ray plus computer tomography (CT). TB was diagnosed in 148 (42.4%). Out of them 6 were initially DST negative but after 3 months DST was repeated and resulted positive- active TB was diagnosed. In 19 (5.5%) TB was in the calcification phase. 9 TB contacts with established TB were DST-negative. All had BCG vaccination. 4 children one year old, probably, had not developed immunity. Two had contacts with TB/HIV parents.

Conclusion: DST allows detecting TB in 42.4% of cases. DST negative reaction could be in early aged TB patients – when immune response has not been developed yet. DST positive reaction may develop later in vaccinated children.
514. Integrated care and telehealth in primary care

P4984
Diagnostic value of non-specific humoral immune changes in children investigated for tuberculosis by skin test and bacteriology
Marina Spani1, Carmen Monica Pop2, Carmen Dana Sandru1, Daniel Cadar3, Mihaela Niculae1, Pompei Bolfa1,2, Infectious Diseases, USAMV, Faculty of Veterinary Medicine, Cluj-Napoca, Cluj, Romania; 1Pathology, USAMV, Faculty of Veterinary Medicine, Cluj-Napoca, Cluj, Romania.

It was suggested that repeated skin tests (IDR) used to diagnose childhood tuberculosis (TB) potentially change the immune response of the host. Adaptive cell-mediated immunity is the most important in protection against TB, but there is no information on the changes in the dynamics of immune globulins (Ig) and circulating immune complexes (CIC) in these patients. We hypothesized that the changes would be dependent on both the skin test results and bacteriological (BK) category of the subjects. The study was carried out in three groups of children, 1 to 17 years old, positive to both skin test and bacteriology (IDR+BK+, n=18), positive to the skin test but negative for bacteriology (IDR+BK-, n=12) and negative to skin test, but positive for bacteriology (IDR-BK+, n=9). Serum samples were subjected to total immunoglobulin (Ig) and immune complexes measurements (CIC), carried out by 0.24% zinc sulphate and 4.2% polyethylene glycol precipitation tests, respectively. Optical densities (optical density units, ODU) were red spectrophotometrically. The statistical significance of the results was estimated by Student’s t test.

Table 1-Total Ig and CIC levels of children tested for tuberculosis

<table>
<thead>
<tr>
<th>ODU</th>
<th>IDR+BK+</th>
<th>IDR+BK-</th>
<th>IDR-BK+</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Ig</td>
<td>0.40±0.126</td>
<td>0.37±0.099</td>
<td>0.58±0.141*</td>
</tr>
<tr>
<td>CIC</td>
<td>0.014±0.013</td>
<td>0.014±0.004</td>
<td>0.02±0.009*</td>
</tr>
</tbody>
</table>

*p<0.05.

The highest concentrations of immune globulins and circulating immune complexes, statistically significantly different (p<0.05), found in the IDR+BK+ group indicated the dependence of humoral changes on the presence of bacteria, rather than related to IDR, suggesting an added diagnostic value by use of these non-specific serological tests.

P4985
Electronic patient record as a facilitator to guideline based asthma management
Jean Holohan, Louis Coyne, Francis Guiney, Pat Manning, Basil Elhaziri, Eamonn Shanahan, Terry O’Connor, Muireann Ni Chroinin, Nettia Williams, Rhonda Forsythe, Pamela Logan. Research and Education, Asthma Society of Ireland, Dublin, Ireland; Respiratory, HSE Regional Hospital Mullingar, Mullingar, Ireland; Paediatric Respiratory/General Medicine, Adelaide and Meath National Children’s Hospital, Tallaght, Dublin, Ireland; General Practice, Farranfore Medical Centre, Farranfore, Killarney, Ireland; Respiratory, Mercy University Hospital, Grenville Place, Cork, Ireland; Paediatric Respiratory, Cork University Hospital, Wilton, Cork, Ireland; Professional Development Coordinator for Practice Nursing, Health Service Executive Dublin North East, Swords, Ireland; Director of Pharmacy Services, Irish Pharmacy Union, Dublin, Ireland.

Prior to the initiation of this project there was no consistent guideline based approach to an asthma consultation in primary care in Ireland. There is a lack of practice management systems but no consistent asthma module leading to variations in asthma management.

The Asthma Society of Ireland (ASI) collaborated with the Irish College of General Practitioners (ICGP) to develop locally modified GINA Guidelines as an initial step to developing an asthma specific Electronic Patient Record (EPR). The EPR was tested in 25 primary care sites; attitudes towards the EPR were evaluated using a 5 point Likert Scale.

The EPR captured demographic data, guided the consultation along a guideline based pathway through diagnosis, lung function tests, evaluation of asthma control according to GINA status, recorded medication and flu vaccinations, aided treatment selection in a step by step approach, identified patient educational priorities and objectives for next consultation. Data could be extracted to form a standardised referral letter to A&E or consultant. It provided a platform to develop personal action plans for the patient. Healthcare professionals (HCP) found the EPR easy to use (65%); EPR aids diagnosis (68%), assessment (90%), treatment selection (82.5%), and monitoring control (80%), facilitates patient education (85%) and helps with development of personal action plans (65%). HCP in primary care agreed that an asthma specific EPR facilitates guideline based asthma management. This EPR will provide the template for an asthma module in practice management systems in Ireland and ASI has engaged with stakeholders on the module development.

Perspectives of patients and healthcare professionals on the impact of telemedicine on hospital admissions for chronic obstructive pulmonary disease (COPD): A nested qualitative study
Peter Farbrook1,2, Hilary Pinnock1,3, Janet Hanley2, Lucy McCloughan1, Allison Todd1, Brian Mc Kinstry1, Centre for Population Health Sciences - GP Section, Medical School, University of Edinburgh, Edinburgh, United Kingdom; 2Centre for Integrated Healthcare Research, School of Nursing, Midwifery, and Social Care, Edinburgh Napier University, Edinburgh, United Kingdom.

Background: Early identification of exacerbations in COPD reduces hospital admission and may slow disease progression. There is increasing interest in telemedicine to support timely self-management of exacerbations. The TELE-SCOT randomised control trial based in Lothian, Scotland, is investigating the impact of a tele-monitoring service for COPD.

Aims: To explore the views of patients and professionals participating in the trial about the impact of telemetry on hospital admissions.

Method: We undertook semi structured interviews with patient and professional participants at different time points in the TELESCOT COPD trial. Transcribed, coded data was analysed thematically. Interpretation was supported by multidisciplinary discussion.

Findings: 38 patients (47% male, mean age 67.5 years) and 32 professionals provided 70 interviews. Both patients and professionals considered that home tele-monitoring reduced the risk of hospital admission. Patients used teledata to determine their state of health and to validate their decision to contact healthcare professionals earlier in order to prevent admission. Professionals emphasised the role of telemetry in encouraging compliance and facilitating patient self-management as a means of reducing admissions, though they also expressed concern that telememonitoring may increase patient dependence on services. The impact on the cost of services was a concern.

Conclusions: Enthusiasm for tele-monitoring as a means of reducing admissions is tempered by concerns about increased demand on support services.

Funding: Chief Scientists Office, Scottish Government.

P4987
The effect of integrated care on asthma control
Maarten Prinsen1, Ellen Van Heijst1, Sigrid Schokker1, Corina de Jong1, Roland Riemsma1, Jan Willem Kocks1, Thys van der Molen1, Department of General Practice, University Medical Center Groningen, Groningen, Netherlands; 2Asthma and COPD Service, Luhbeurt, Groningen, Netherlands; 3Groningen Research Institute for Asthma and COPD, University Medical Center Groningen, Groningen, Netherlands.

Background: Integrated care of respiratory patients has often been advocated, however, the effect on patient outcome is not clear.

Objective: To describe the effect of an integrated care system on asthma control.

Method: We developed an integrated care system for communication between pulmonologists and General Practitioners (GP). In this system patients with res-
piratory problems complete questionnaires (history, control and health status) and visit the laboratory for spirometry. These data are collected and uploaded to a central server. Based on these data without seeing the patient and supported by a decision support system (DSS), pulmonologists (n=9) give advice about diagnosis and treatment to the GP (n=250), who treats the patient.

Results: From a total of 7877 patients referred to our integrated care system 3721 patients were diagnosed with asthma. In 889 of these patients ACQ data were available at baseline and follow up. The median ACQ scores at baseline (1.0) proved to be significantly different from the median ACQ scores of the follow up visit (0.7) (Z= -8.81, p <0.001). Improvement of asthma control ≥ MCID (0.4) was measured in 32% of patients (n=284). Additionally the results showed deteriorated asthma control in 15% of patients (n=134) and unchanging asthma control in 51% of patients (n=454).

Teleconsult-pro technology in the Netherlands

Christian F. Melisant1, Joep Hoevenaars 2. 1Pulmonology, Spaarne Hospital, Hoofddorp, Netherlands; 2Telemedical Centre, Kuyos, Amstelveen, Netherlands

Diagnosing obstructive pulmonary disease has proven difficult in primary practise, leading to incorrect referrals. In teleconsult-pro technology general practitioners (GPs) digitally consult pulmonologists for advice on spirometry. We hypothesized, that teleconsult-pro technology, applied after patient selection by the GP, would reduce referrals and improve triage of referrals.

GPs log on to a secured web-based teleconsultation system (KSYOS) and send a lung function (PDF) and - voluntarily - some clinical information to the pul monologist. Its purpose was to ask advice or to prevent referral. 293 closed teleconsultations were analyzed.

The GP answers two quality indicators, before (Q1) and after (Q2) each teleconsultation:

(Q1): Without teleconsultation, would you have referred this patient to the hospital? (Q2): Will you refer this patient to the hospital?

Quality indicator results

| Q2 = yes | 26 | 75 | 101 |
| Q2 = no  | 42 | 150 | 192 |
| Total    | 68 | 225 | 293 |

Of the total 101 teleconsultations intended for referral, 75 referrals (74%) were pre- vented. Of 192 teleconsultations intended for advice (2/3 of all teleconsultations), 42 patients (22%) were referred after teleconsultation. Although still small numbers, this analysis shows a reduction in referrals to the pulmonologist, which in times of necessary cost-reduction is very interesting and helpful for insurance companies. Furthermore, teleconsultations showed initially unforeseen referrals, consisting of patients having a pulmonary disease, who needed to be investigated more properly in hospital.

P4999

RECODE: RCT on effectiveness of integrated COPD management in primary care

Annemarie Jruis1, Melinde Roland2, Pin Assendelft1, Jacobijn Gussekloo1, Apostolos Tsichrista1, Maureen Rutten2, Jaap Sont3, Niel Chavannes1

1Public Health and Primary Care, Leiden University Medical Centre, Leiden, Netherlands; 2Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands; 3Medical Decision Making, Leiden University Medical Centre, Leiden, Netherlands.

Background: There is insufficient evidence of the (cost)effectiveness of primary care COPD disease management programmes. Aim and objective: To evaluate the (cost)effectiveness of an ICT-supported, in- tegrated, multidisciplinary disease management program for primary care COPD patients. We expect health care providers to improve inter-collegial communica tion, personalized treatment planning and better adherence to guidelines. As a result, we expect quality of care and quality of life in patients to improve.

Methods: The study has a two-group cluster-randomized design in which 40 clusters of primary care teams are being randomized. Required sample size is 1080 COPD patients, in accordance with GOLD. Few exclusion criteria are applied. The intervention consists of a multidisciplinary course (2 days) in which primary care givers (general practitioners, practice nurses, phytotherapists, dieticians) within a particular region are trained as a team. The course will emphasize efficient task delegation within the team, active patient involvement in treatment planning, and designing time-contingent practice plans. Primary outcome is difference in health status as measured by Clinical COPD Questionnaire (CCQ). Programme, costs, vertical and horizontal integration utilisation and productivity loss will also be calculated. Primary endpoint is at 12 months, while total study duration is two years.

Results: Until now 496 patients have been included, which preliminary baseline were means of FEV1/FVC ratio 56%, FEV1 65% predicted, CCQ score 1.65, MRC score 2 and EQ-5D score 0.71.

Conclusion: The RECODE study is a cluster randomized trial which will provide insight in the cost-effectiveness of this particular primary care COPD disease management programme.

P4991

Diagnosing COPD and asthma in primary care in Israel – The challenge and the change

Eitan Brodsky, Sigal Ringel, Meir Raz. Jerusalem and Shfela District, Maccabi Healthcare Services, Tel Aviv, Israel

Background: Under-diagnosis and misdiagnosis of COPD and Asthma leads to inadequate treatment and incorrect use of healthcare resources. Maccabi Healthcare Services, one of the leading HMOs in Israel, has decided to promote the correct diagnosis by the primary physician and to establish a computerized patient register based on validated diagnoses.

Objectives: 1. To increase the ability of diagnosing COPD and Asthma at the primary care level. 2. To validate the currently exist diagnoses that in the medical files. 3. Diagnostic standardization and later - treating these diseases according to the standard clinical guidelines.

Methods: 1. Developing the ability to conduct spirometry in Maccabi clinics, according to the referral of primary physicians or Allergy or Pulmonology specialists. 2. Developing a flow process to interpret and report spirometry results to the patient's central medical records by Pulmonology specialists. 3. Establishing a computerized register of COPD and Asthma patients. 4. Training among designated technicians and increasing knowledge and awareness among primary physicians regarding validated diagnosis of lung diseases.

Results: Since the inception of the service at the end of 2009, spirometry devices were placed in 13 primary care clinics in the Jerusalem and Shfela region, approx. 2200 patients underwent a spirometry examination, and an computerized register based on validated diagnoses is currently being completed.

Conclusions: Early diagnosis among high-risk populations will promote appropriate treatment. Validation of the diagnoses will enable the system to properly deal with the more accurate level of the rising morbidity of COPD and Asthma.

P4992

Successful implementation of asthma guidelines in Thailand: The Easy Asthma Clinic model

Wachara Boonsawat. Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand

Introduction: Asthma management guidelines were published in Thailand in 1994 and revised in 1997 following the publication of the GINA guidelines. However, the audit made by the National Health Security Office (NHSO) showed that asthma management in Thailand fell short of the goals determined for long-term asthma care indicated the failure of guidelines implementation.

Method: We have developed Easy Asthma Clinic Network as a model to enhance the implementation of GINA guidelines in Thailand since 2004. Easy Asthma Clinic runs by GPs in general hospitals. In the clinic we simplified asthma guidelines and organized the system to facilitate the team work, emphasized the role of nurses and pharmacists to help doctors. We also developed on-line web database for registering and monitoring patients. In 2009 NHSO support the set up of Easy Asthma Clinic in all hospitals in Thailand.

Results: Easy Asthma Clinic was set up in more than 900 hospitals in Thailand. 99,535 asthmatics were registered with 548,583 visits. Easy asthma clinics improve quality of asthma care in general hospitals. Peak flow measurement were improved from 1.08% to 98.47% of the visits. Inhaled corticosteroids used increased 10.92% to 79.30%. Asthma controlled were achieved in 23.19% of visits and partly controlled in 46.35%. Conclusions: Setting up Easy Asthma Clinic help implementation of asthma guidelines in Thailand.

P4993

The effect of integrated care on health status in COPD

Maarten Prinsen1, Ellen Van Heijst2, Siebrig Schokker1, Corina de Jong1, Roland Riemersma1, Jan Willem Kocks1, Thys van der Molen1. 1Department of General Practice, UMC Groningen, Groningen, Netherlands; 2Asthma and COPD Service, LAbvloed, Groningen, Netherlands; 3Groningen Research Institute for Asthma and COPD, UMC Groningen, Groningen, Netherlands.

Background: Integrated care of respiratory patients has often been advocated. However, the effect on outcome in COPD patients is unclear.

1Department of General Practice, UMC Groningen, Groningen, Netherlands; 2Asthma and COPD Service, LAbvloed, Groningen, Netherlands; 3Groningen Research Institute for Asthma and COPD, UMC Groningen, Groningen, Netherlands.
**Wednesday, September 28th 2011**

**Objectives:** To describe the effect of advice from an integrated care system on health status in COPD patients.

**Method:** We developed an integrated care system in which pulmonologists provide diagnostic support to the General Practitioner (GP). Patients with respiratory problems complete questionnaires (history, control and Clinical COPD Questionnaire (CCQ)) and visit the laboratory for sputometry. These data are collected and uploaded to a central server. Based on these data without seeing the patient and supported by a decision support system the pulmonologist (n=80) give advice about diagnosis and treatment to the GP (n=250) who treats the patient.

**Results:** From 7877 patients referred to the integrated care system, 1331 patients were diagnosed with COPD. In 310 of these patients CCQ data were available both at baseline and follow up (3 months or 1 year). The median CCQ score of the baseline visit (1.1) proved to be significantly different from the median CCQ scores on the second visit (1.0) (Z = -2.48, p=0.013). Improvement of health status ≥ the minimal clinical important difference (MCID) of 0.4 was measured in 27% of patients (n=82). Deteriorated health status ≥ the MCID was reported by 29% of patients (n=85). Patients reported unchanging health status (n=135).

**Discussion:** This integrated care model where the pulmonologist directly advises the GP provided an overall statistical significant improvement of COPD health status. Clinical implications however are unclear.

**P4994**

Healthcare professional attitudes towards asthma guidelines in primary care

Jean Holohan, Louis Coyne, Francis Guiney, Pat Manning, Basil Elmagir, Eamonn Shanahan, Terry O’Connor, Muireann Ni Chronin, Nette Williams, Rhonda Foy, Pamela Logan, Research and Development, Asthma Society of Ireland, Dublin, Ireland; Respiratory, HSE Regional Hospital Mullingar, Mullingar, Ireland; Pneumatic Respiratory/General Medicine, Adelaide and Meath National Children's Hospital, Tallaght, Dublin, Ireland; General Practice, Farranfore Medical Centre, Farranfore, Killarney, Ireland; Respiratory, Mercy University Hospital, Grenville Place, Cork, Ireland; Pneumatic Respiratory, Cork University Hospital, Wilton, Cork, Ireland; Professional Development, Coordinator for Practice Nursing, Health Service Executive Dublin North East, Swords, Dublin, Ireland; Director of Pharmacy Services, Irish Pharmacy Union, Dublin, Ireland

Implementation of guidelines in primary care can be challenging but are essential to reduce the burden of asthma for patients and health service providers and to reduce hospital admissions and mortality and to deliver cost effective care.

The Asthma Society of Ireland (ASI) in conjunction with the Irish College of General Practitioners (ICGP) locally adapted the GINA Guidelines as a first step to providing guidelines based asthma management in primary care. The ASI funded and developed a guideline based program to evaluate healthcare professional (HCP) attitudes to these guidelines and ensure user buy in prior to national implementation.

25 primary care teams participated in the program. The HCP completed guideline based education and practical training. Patients were recruited to follow the asthma management program for 6 months. HCP were asked to evaluate both educational and training components and practical resources provided for the program. Attitudes towards guideline implementation were evaluated using a 5 point Likert Scale.

Final analysis of HCP survey in response to the locally modified guideline (89% response rate) showed guidelines were easy to follow (92.7%), helped with decision making (92.6%), improved the clinical decision making process (70.8%), improved patient care (92.7%), reduced inappropriate variation in management (77.5%), facilitated cost effective care (70.7%).

HCP in primary care agreed that guideline based management is an integral component to the implementation of best practice asthma management. The Irish Health Service Executive has incorporated the locally modified guideline and associated asthma education program into the core components of the new National Asthma Program.

**P4995**

Clinical decision support system for diagnosing patients with community-acquired pneumonia

Shigeto Hanada1, Hitonori Uruga1, Hiashi Takaya1, Atsushi Miyamoto1, Hideyasu Sugimoto1, Nasa Morokava1, Atuko Kurosaki2, Kazuma Kishi1, Shouji Kanada1, Akira Osawa1, 1Department of Respiratory Medicine, Toranomon Hospital, Minato-ku, Tokyo, Japan; 2Department of Diagnostic Radiology, Toranomon Hospital, Minato-ku, Tokyo, Japan; 3IT System Development Center, Medical Development Group, Fuji Photo Film, Minato-ku, Tokyo, Japan

**Objective:** To examine whether a Clinical Decision Support System (CDSS) is specific enough to reliably predict the etiology of community-acquired pneumonia (CAP).

**Methods:** We developed an application program named CDSS comprising of information relating to epidemiologic conditions, risk factors, clinical manifestations, and laboratory findings of 53 patients with CAP who were seen at Toranomon Hospital from April 2006 to April 2010. We also studied other 17 CAP patients with definitive etiologies and collected information required for calculating similarity. The best matches among the cases in CDSS were returned in a list, and sorted by similarity score, with the most similar one presented first. We assessed the usefulness of CDSS in differentiating etiologies of patients with CAP.

**Results:** There were 11 men and 6 women with a mean age of 59 years (range: 26–86). The etiologies of CAP were Streptococcus pneumoniae in 4 patients, Mycoplasma pneumoniae in 3, Haemophilus influenzae in 2, aspiration pneumonia in 2, Mycobacterium tuberculosis in 2, Nontuberculous mycobacterium in 2, Pseudomonas aeruginosa in 1, and diffuse panbronchiolitis in 1, respectively. Based on the results of CDSS, we identified the correct diagnosis with the highest similarity in 8 of 17 patients (47.1%). Differentiation between bacterial pneumonia and atypical pneumonia could be made in 10 of 12 patients (83.3%). The four cases of Mycobacterium tuberculosis and Nontuberculous mycobacterium could be easily be differentiated from other pathogens (100%).

**Conclusion:** CDSS is a new approach that can be used by clinicians to predict the etiology of CAP.

**P4996**

Asthma self management preferences, attitudes and beliefs in primary care

Maureen George1, Jennifer Kraft1, Neika Vendetti2, Ruth Pinilla1, Ahmad Johnson1, Chantel Priolo3, Rodalyn Gonzalez3, Elizabeth Yim4, Danielle Jackson5, Dana Brown5, Cynthia Rand1, 1Family and Community Health, University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, United States; 2Epidemiology and Biostatistics, Drexel University School of Public Health, Philadelphia, PA, United States; 3Pulmonary, Allergy and Critical Care Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, United States; 4Miller School of Medicine, University of Miami, Miami, FL, United States; 5Division of Geriatrics, University of Pennsylvania School of Medicine, Philadelphia, PA, United States; 6Department of Pulmonary and Critical Care Medicine, Johns Hopkins University, Baltimore, MD, United States

**Purpose:** To describe self management preferences, attitudes and beliefs of urban adults with persistent asthma.

**Subjects:** Primary care patients prescribed inhaled corticosteroids (ICS).

**Methods:** Survey

**Results:** A convenience sample of 141 subjects (78% female; 81% Black; 51% with ≤ high school education; 29% with commercial insurance; mean age 50.4 ± 13.4; range 19-83) prescribed inhaled ICS for persistent asthma were enrolled from 5 sites (2 internal medicine, 2 family medicine, 1 pulmonology + internal medicine). One hundred and thirty-nine (92%) of the patients completed the survey. No differences were found among subjects who completed the survey vs non-responders. The most common reasons for using ICS were to reduce the number of symptoms and side effects (93%), reduce exacerbations (85%), maintain asthma control (89%), help the physician with their care (83%) and cost effectiveness (81%). On a 5 point Likert scale, the subjects rated the most important reasons for using ICS were to reduce the number of symptoms and side effects (88.1%), maintain asthma control (83.7%) and cost effectiveness (82.7%).

**Conclusion:** Patients have unique self management preferences, attitudes and beliefs that, if identified and discussed, could serve as the foundation of a tailored plan of care that may reduce barriers to ICS use.

**P4997**

Improving asthma control with therapeutic education intervention

Lalita Fernandes, Anthony Mesquita. TB and Respiratory Medicine, Goa Medical College, S. Inez, Caranzalem, Goa, India

**Objective:** To assess the level of control in asthma patients receiving therapeutic education intervention.

**Background and significance:** There is no cure for asthma, hence the aim of management is to control asthma and improve quality of life. One of the reasons for poor control is improper inhaler technique. We analysed the control of asthma in subjects who received inhaler technique education by trained respiratory therapists.

**Methods:** In a randomised controlled trial, we enrolled 89 new uncontrolled non-smoking asthma patients reporting to the hospital. Asthma was confirmed by symptoms and spirometric reversibility as per ATS/ERS 2005 standards. Patients with asthma exacerbation and requiring systemic steroids were excluded. All 89 patients were treated with appropriate medications and were then randomised to education intervention group (teaching of correct inhaler technique by respiratory therapist) and the control group received routine inhaler technique instructions by the physician. Both groups were followed up at 4 weeks. The intervention group was reassessed for inhaler technique at 4 weeks. At 12 weeks both groups were assessed for asthma control using ACT.

**Results:** There was significant improvement in asthma control in the group.

P4998 Caregiver perception versus patient reality: A Canadian perspective on COPD

Donna Goodridge1,2, Shelly Hutchinson1, Darcy Marciniuk1, Donna Rennie3.
1College of Nursing, University of Saskatchewan, Saskatoon, SK, Canada; 2Department of Medicine, University of Saskatchewan, Saskatoon, SK, Canada; 3College of Medicine, University of Saskatchewan, Saskatoon, SK, Canada

Background: The high health care utilization of many patients with advanced COPD may reflect sub-optimal preparation of the patient and caregiver to effectively manage COPD upon discharge. Purpose: To examine the care transition experiences of COPD patients and their caregivers regarding care transition quality within two weeks of discharge from hospital.

Design: This cross-sectional study included 22 dyads (N=44) of patients with advanced COPD (MRC 3, 4 or 5) and their caregivers in two Canadian cities. The Care Transitions Measure (CTM-15) was used to obtain scores from both the patients and caregiver on the quality of care transition. CTM-15 scores range from 0-100, with higher scores indicating higher quality of care transition. Correlations between CTM-15 scores, global rating of health and the Clinical COPD Questionnaire (CCQ) were assessed.

Results: Median CTM-15 score for patients was 58.9 (IQR=30.5) compared with 46.7 (IQR=16.5) for caregivers (NS). The majority of participants (78.6%) had clear health goals upon discharge (63.6%) a written plan of care (59.1%). Caregivers did not understand warning signs and symptoms to monitor (72.7%), understand how to manage the patient’s health (68.2%) or have all the information needed to be able to take care of the patient upon discharge (54.5%). CTM-15 scores were negatively correlated with CCQ scores (r=-0.04) but not with global rating of health.

Interpretation: COPD patients and their caregivers require additional preparation for discharge and reported important gaps that have important implications for self-care in the community. CTM-15 scores in this study were lower than those previously reported in geriatric literature.

P4999 COPD patient and caregiver assessments of care transition quality

Donna Goodridge1, Shelly Hutchinson1, Darcy Marciniuk1, Donna Rennie3.

P5000 Time course of diaphragm function recovery after mechanical ventilation in an animal model

Debby Thomas, Karen Maes, Anouk Agetn, Marc Decramer, Ghislaine Gayan-Ramirez. Laboratory of Pneumology, KU Leuven, Leuven, Belgium

Rationale: Several studies have previously shown that controlled mechanical ventilation (CMV) results in rapid and severe diaphragmatic dysfunction. On the other hand, the recovery response of the diaphragm to normal function after mechanical ventilation is not known, although these data may have an impact on weaning from the ventilator. Therefore we examined the time-course of diaphragm function recovery in an animal model of CMV.

Methods: Rats were anesthetized and submitted to 24-27h of CMV or 24h of CMV followed by either 1h, 2h or 3h of spontaneous breathing (CMV + 1h SB, CMV + 2h SB, and CMV + 3h SB, respectively).

Results: There were no differences in blood pressure, blood gases, body weight or muscle weights between the four groups. The in vitro diaphragm force-frequency curve was similar in the CMV, CMV + 1h SB and CMV + 2h SB groups. Three hours of SB after CMV resulted in a significant improvement of diaphragm force compared to the other groups (eg, maximal tetanic force: ±29% vs CMV, p<0.01).

Diaphragm cross sectional area (CSA) of the type I and type Ila fibers was similar in all groups, while the CSA of the type IIX/b fibers was significant increased in the CMV + 3h SB group (16.7% vs CMV, p<0.05). No differences were observed in the activity of the proteolytic enzymes calpain and caspase-3. Protein oxidation was similar in the diaphragm in all groups.

Conclusions: These data show that, in rats, relading the diaphragm for 3h after CMV is sufficient to result in significant improvement of the diaphragm force together with an increase in the CSA of the type IIX/b muscle fibers. Funded by: FWO-Flanders G.0893.11 and AstraZeneca Pharmaceuticals

P5001 Mechanical ventilation induces a time-dependent reduction in diaphragmatic blood flow

Christian Bruells1,2, Robert Davis III1, John Stabely2, Bradley Behnke2.
1Department of Anesthesiology, Aachen University Hospital of the RWTH Aachen, Aachen, Germany; 2Institute of Applied Physiology and Kinesiology, College of Human Health and Performance, University of Florida, Gainesville, FL, United States

Introduction: Continuous mandatory ventilation (CMV) induces atrophy of the diaphragm, contributing to ventilator induced diaphragmatic dysfunction (VIDD), which is significant after 6 h of CMV. However, the effects of prolonged CMV on diaphragmatic blood flow remain unknown. Therefore, we tested the hypothesis that long term CMV (6 h) will further decrease diaphragm perfusion versus that measured during acute CMV (30 min) and may contribute, in part, to VIDD due to reduced oxygen delivery.

Methods: Blood flow to the diaphragm and other skeletal muscle was assessed (via the radioactive microsphere technique) during spontaneous breathing (SB) and after 30 min and 6 h of CMV in female Sprague-Dawley rats (n=42). Blood pressure and heart rate were monitored continuously throughout the protocol.

Results: In the midcostal portion of the diaphragm blood flow decreased by ~22% from SB to 30 min CMV, with a further reduction in flow of ~37% after 6 h CMV (i.e., SB 28.3±3.5 vs. CMV, 30 min 19.3±2.9; 6 h 8.8±0.6 ml/100 g/min; P<0.05). The other constituents of the diaphragm demonstrated a similar trend in perfusion over time. Blood flow to other hindlimb skeletal muscle did not decrease significantly at any time point.

Discussion: Our study demonstrates, for the first time, that there is a time-dependent reduction in diaphragmatic perfusion during prolonged CMV. Further, a decrease in blood flow over the same time period was not observed in other skeletal muscles, even with matched oxidative capacities (e.g., red. portion of the gastrocnemius). Our data indicate that prolonged CMV elicits vascular dysfunction in the diaphragm which may contribute, in part, to the ongoing process of VIDD.

P5002 High dose methylprednisolone counteracts the negative effect of rocuronium on diaphragm function in a rat model of mechanical ventilation

Karen Maes, Dries Testelmans, Debby Thomas, Marc Decramer.
Ghislaine Gayan-Ramirez. Laboratory of Pneumology, KU Leuven, Leuven, Belgium

Rationale: We previously showed that rocuronium (ROC) combined with 24h of controlled mechanical ventilation leads to an additional negative effect on diaphragm function in rats. Based on clinical observations we hypothesized that the combination of rocuronium with corticosteroids in our animal model of CMV would result into a further deterioration of diaphragm function.

Methods: Mechanically ventilated (24h) rats received intravenously either a con-

Results: A total of 100 patients on MV were included in the study. Ninety percent of patients were successfully weaned. Unsuccessfully weaned patients had higher PIV and were more likely to be maintained on RPV compared to the rest of the population.

Conclusion: In older DMD patients on iPAP we observed that severe, metabolic acidosis related to chronic constipation and its treatment, reduced fluid and food intake and associated respiratory infection resulted in a life-threatening condition.

Grant support: Lunge Zürich.

PS004

Predictors of successful weaning from mechanical ventilation

Hamdy Ali Mohammed Mahmoud, Ashral Zien-Abdin Mohamed. Chest Diseases & Tuberculosis, Sohaq University-Sohaq Faculty of Medicine, Sohaq-Eltaragha-Nagro Elbakh, Egypt Chest Diseases & Tuberculosis, Assuit University-Assiut Faculty of Medicine, Assuit, Egypt

Background: For adult patients on mechanical ventilation, successful weaning has been attributed to various factors. The purpose of this study was to describe patient outcomes, and factors in successful weaning.

Patients and methods: This study included 100 patients (45 males & 55 females) with mean age of 57.8 years, with respiratory failure due to different pulmonary diseases (bronchial asthma, COPD, IPF, pneumonia and malignancy) and were admitted to ICU for mechanical ventilation between October 2008 to October 2010.

Results: The additional negative effect of RPV on the diaphragm during weaning was evident from s1 to s4, unlike NA V A and PCV. In both steps, higher ETD and lower WOB due to patient-conditioned work of breathing (WPs).

Conclusion: In older DMD patients on iPAP we observed that severe, metabolic acidosis related to chronic constipation and its treatment, reduced fluid and food intake and associated respiratory infection resulted in a life-threatening condition.

Grant support: Lunge Zürich.

PS005

Neurally adjusted ventilatory assist (NAVA) in difficult-to wean patients

Ghada Vajghjeha1, Stefano Mazziocchi2, Maria Chiara Carrozza2, Nicolino Ambrosino1. 1Weaning and Respiratory Rehabilitation Unit, Auxilium Vitae Rehabilitation Centre, Volterra, Pisa, Italy; 2The Birobotics Institute, Scuola Superiore Sant’Anna, Pisa, Italy

Aim: To compare physiological effects of NAVA with Pressure Support Ventilation (PSV) and Pressure Controlled Ventilation (PCV) in difficult-to-wean patients on non-invasive ventilation.

Methods: Six tracheostomised awake WPs (2 males, age 68±28.8y) under prolonged (>13 days) mechanical ventilation (MV) underwent physiological evaluation during three 20 minute MV sessions, randomly applied, with NAVA, PSV and PCV. Airway pressure (Paw), airflow, and diaphragm electrical activity (EAdi) were derived from ventilator (Servo i, Maquet). Changes in tidal volume (Vt), inspiratory (ITD) and expiratory (ETD) time delay, and EAdi-related work of breathing (Dob) were used to assess weaning. The number of MV sessions was 6.

Results: In PSV, an increase in EAdipeak, WOB, and a decrease in Vt, Ve were observed from s1 to s4, unlike NAVA and PCV. In both steps, higher ETD and WOB in PCV compared to NAVA were found.

Conclusion: In WPs, NAVA was associated to reduced WOB due to patient-ventilator delay.

PS006

Predicting the outcome from noninvasive ventilation for acute exacerbation of chronic obstructive pulmonary disease in the emergency department

Redolfo Ferrari1, Elisabetta Chilc1,2, Maria Chiara Carrozza2, Maria Cavazza1. 1Emergenza-Urgenza, Chirurgia Generale e dei Traumi, Azienda Ospedaliero Universitaria di Bologna, Bologna, Emilia Romagna, Italy; 2Neurosciences, Azienda Universitaria Locale di Bologna, Università degli Studi Di Bologna, Bologna, Emilia Romagna, Italy

Objectives: To identify early objective clinical parameters and biomarkers for severity assessment and predicting outcomes in acute exacerbation of chronic obstructive pulmonary disease (AECOPD) requiring noninvasive mechanical ventilation (NIV).

Methods: Three-months observational prospective study in the acute setting of the ED of a university teaching hospital, including consecutive nonselected patients evenly admitted for ARF due to AECOPD treated by NIV according to EP's indication referring to an institutional protocol. Treatment failure was defined as hospital mortality or need for invasive mechanical ventilation at any time.

Results: 124 patients (media 1.38/day). Failure (23 cases, 18.5%) and success (101; 81.5%) patients were different in: neurologic status score (Kelly-Matthy scale), urea, creatinin, AST, ALT, CPK, CPK-MB, troponin T, LDH, PCR, pH, and arterial blood gas analysis parameters after 1 hour of NIV (PaO2, pH, PaCO2, HCO3–, SaO2, PaO2/FIO2).

Conclusion: NIV is a cost effective intervention even outside intensive care units for the treatment of ARF caused by AECOPD. We were able to identify in the early predictors of outcome (mainly about more severe clinical conditions and the
response to treatment). An unresolved question in the ED is about selection criteria and early choices for patients with ARF having preset therapeutic-prognostic limits and acutely reversible processes for which NIV should be considered as ceiling treatment.

P5007
Acute exacerbations of COPD (AECOPD) in intensive care unit (ICU): Are non-invasive ventilation (NIV) use and mortality different in high volume ICUs?
Martin Dres1, Thi-Chien Tran2, Philippe Aegerter1, Antoine Rabat1, Bertrand Guidet1, Gerhard Huchon1, Nicolas Roche1, on behalf of the CUB-REA Network, 1Service de Pneumologie et de Reanimation, Hotel Dieu, Paris, France; 2Service d’Information Hospitaliere et de Sante Publique, Hopital d’Ambroise Pure, Boulogne Billancourt, France; 3Service de Reanimation Medicale, Hotel Saint Antoine, Paris, France

Introduction: NIV for the management of acute exacerbations of chronic obstructive pulmonary disease (AECOPD) increased last decades. ICU teams caring for a high number of AECOPD could gain more experience and therefore use NIV in a higher proportion of patients. The case-volume could also be associated with ICU mortality.

Material and methods: The French CUB-REA database includes 32 ICUs. AECOPD cases were extracted according to ICD-10 coding. To assess the effect of case volume on NIV use, invasive ventilation (IV) use and mortality, multivariate analysis using mixed models were performed to adjust for severity of illness and other concurrent factors.

Results: Between 1998 and 2008, 6,434 AECOPD were identified. SAPS II and ICU mortality gradually increased (35% to 41 and 1% to 16%, respectively). The proportion of patients receiving any mechanical ventilation increased (66% to 85%), with a marked increase in the use of IV (from 19% to 43%) and a decrease in the use of IV (35% to 23%). Case volume tertiles were: low volume (10 admissions per year), intermediate (10-26) and high volume (more than 26). There was a significant association between case volume, IV use and ICU mortality: OR for the highest versus lowest and intermediate tertiles were: 5.61 [95% CI: 0.73-0.94], respectively.

Conclusion: During this period, the severity and mortality rate of AECOPD admitted in CUB-REA ICUs increased. There was a growing use of NIV and a decreased use of IV. NIV use and ICU mortality were related to case volume, suggesting that increasing experience favours the use of NIV without impairing patients’ outcomes.

P5008
Low-t3 state a crucial biomarker in determining NIV failure and outcome in pulmonary patient?
Elvio Scoscia, Stefano Baglioni, Elisabetta Bianca, Maurizio Dottorini, Oronzo Penza. Pulmonary and Respiratory Intensive Care Unit, “S.M. della Misericordia” Hospital, Perugia, Italy

Background: Various low T3 states have been described in severe nonthyroidal diseases; they have been associated with a poor prognosis in cardiovascular and pulmonary disease patients. Aim: To investigate the role of T3 function in patients suffering from respiratory failure (RF), needing invasive or non-invasive mechanical ventilation (NIV), in order to evaluate the prognostic value of nonthyroidal illness syndrome in NIV failure.

Methods: We studied retrospectively 32 consecutive patients with acute or acute on chronic RF needing mechanical ventilation. Measured variables upon admission included: APACHE II score, the ratio of the partial pressure of oxygen in arterial blood to the fraction of oxygen in inspired gas (PaO2/FiO2), plasma levels of freeT3 (fT3), freeT4 (fT4), and Thyroid Stimulating Hormone (TSH) levels.

Results: Plasma levels of fT3 were below normal range in 17 patients (53%). Plasma fT3 correlated with PaO2/FiO2 (p<0.001), and with APACHE II score (p=0.003). Ten patients with low levels of fT3 needed invasive mechanical ventilation due to NIV failure. These patients, with comparable APACHE II score and gas exchange, showed fT3 value significantly lower than patients improving with NIV. fT3 levels were significantly lower (p=0.002) in four patients (12.5%) who died, in comparison to the patients who survived. fT3 value was the only factor significantly associated with an increased risk of death, according univariate logistic regression analysis (Odds Ratio 64.23, 95% Confidence Interval 1.78 to 2316.86, p=0.023).

Conclusion: Our data suggest that low T3 state can predict NIV failure and outcome in pulmonary patients with acute RF.

P5009
Evaluation of adrenal function in patients receiving invasive and noninvasive mechanical ventilation
Zuhal Yavuz Daglı1, Turgut Tekê1, Emin Maden1, Ayşel Kıyıç1, Kursat Üzüm1, 1Chest Diseases, Selçuk University, Meram Medical Faculty, Konya, Turkey; 2Biochemistry, Selçuk University, Meram Medical Faculty, Konya, Turkey

Aim: Although adrenal insufficiency (AI) is a rarely seen condition in critically ill cases (2-3%), it is reported that relative AI is encountered more frequently. In this study, our aim was to detect the frequency of AI using standard dose corticotropin (ACTH) test in patients with critical illness and to determine IL-6, adrenalin, BAL cortisol, prolactinemia and 24-hour uriner cortisol values effects of the prognosis.

Material and method: A total of 80 patients with acute critical illness were recruited to the study. The patients were divided into two groups according to the applications of IV and NIV. Vital findings and APACHE II scoring were recorded and blood samples were taken for ACTH and cortisol. Furthermore, standard dose (250 μg) ACTH test was done for AI diagnosis.

Results: AI defined in patients according to the basal cortisol < 15 μg/dl and/or delta cortisol < 9 μg/dl. AI were determined in 18 patients (22.5%). AI was detected in 6 (15%) of the 40 patients who were received IV. Thirty two of these 40 patients died. AI was determined at 4 (12.5%) of these 32 patients who were died. There was AI in 12 (30%) of 40 patients to whom NIV was applied. 12 of these 40 patients died. Two (16.7%) of these 12 patients who died bad AI. In patients with and without AI, there was no significant difference with respect to the mortality rates at the IV and NIV group (p>0.05).

Conclusion: The frequency of AI was uncommon in patients with critical illness. AI was determined more frequently at the NIV group. We think that adrenal functions should be routinely followed in the intensive care even though there was no clinical finding.

P5010
A novel way of heliox administration in patients with COPD exacerbation
Roman Zazula1, Karel Reubik1, Tomas Tyl1, Martin Müller1, Vladimir Zabrodsky1, Jan Chlumsky2, Adela Snimadova 1, Antonian Spaleny1, Petr Stastny1, 1Dept. of Anesthesiology and Intensive Care, Int. Faculty of Medicine, Charles University in Prague and Thamouyer University Hospital, Prague, 2Faculty of Biomedical Engineering, Czech Technical University in Prague, Kladno, 1Dept of Medicine, Charles University in Prague and Thamouyer University Hospital, Prague, Czech Republic

Introduction: Chronic obstructive pulmonary disease (COPD) is a major cause of chronic morbidity and mortality throughout the world. The purpose of heliox (helium and oxygen mixture) administration in patients with severe COPD exacerbation is to avoid invasive ventilation which is recognized as an adverse prognostic factor.

Aims: The aim of the study is to test suitability of a modified semi-closed anesthetic circuit with CO2 absorber for heliox administration. The circuit may offer a safe way of heliox administration to spontaneously breathing patients at significantly reduced costs.

Methods: The semi-closed circuit was evaluated by work of breathing (WOB) measurement in healthy volunteers (N=9) who signed the informed consent. An endobronchial balloon catheter was used for carbon dioxide measurement. The resistive component of WOB and pressure-time product (PTP) were calculated; O2 consumption and end-tidal CO2 were evaluated. These parameters were compared with the corresponding parameters obtained during spontaneous ventilation on air.

Results: WOB was increased by 15% and PTP was increased by 12% during the spontaneous ventilation with heliox using the semi-closed circuit compared to the ventilation on air.

Conclusion: The study showed that administration of heliox using the semi-closed circuit increases WOB and PTP for a patient due to the intrinsic resistance of the circuit. Nevertheless, as resistance of the airways and WOB are increased during COPD exacerbation, the semi-closed circuit using the semi-closed circuit does not represent a significant workload for patients with COPD exacerbation.

Sleep monitoring with portable devices in ICU patients
Shihoko Namba1, Yoshitu Ujike1, Tetsunori degami2, Ichiro Shimoyama3, Paul A. Easton3, 1The Center for Clinical Research of New Drugs and Therapeutics, Okayama University Hospital, Okayama-City, Okayama Prefecture, Japan; 2Department of Critical Care, Faculty of Medicine, Okayama University School of Medicine & Hospital, Okayama-City, Okayama Prefecture, Japan; 3Emergency Medicine, Kurashiki Central Hospital, Kurashiki-City, Okayama Prefecture, Japan; 4Human Neurophysiology, Frontier Medical Engineering, Chiba University, Chiba-City, Chiba Prefecture, Japan; 5Critical Care Medicine, University of Calgary, Calgary, AB, Canada

Introduction: Sleep disruption and deprivation is a continuing problem in the Intensive Care Unit, but measures to improve sleep cannot utilize traditional polysomnography. Practical, non-intrusive diagnostic monitoring of sleep is required.

Aim: To 1) test two new portable ambulatory sleep diagnostic devices to monitor sleep in ICU and 2) compare sleep data generated by the different devices.

Methods: The devices were a) Wink/hPAT 200 (Illumar Medical), wrist watch-style, employing peripheral arterial tonometry and actigraphy to evaluate sleep time and sleep stage by an automatic algorithm (PAT device) and b) ALICE PDx (Respironics Philips), miniature polysomnographic device utilizing EEG and EMG recordings, with technician scoring (Mini-PxG device). Both include oximetry and position sensors. Seven ICU patients provided informed consent (mean age 68 years) and were recorded wearing both devices, from 21:00 to 06:00.

916s
Results: Both devices successfully monitored sleep in ICU patients. The PAT device was less intrusive with size and attachments. Saturation and heart rate oximetry data were identical from the devices. Both devices calculated total sleep time (TST), and detected changing sleep stage. There were significant differences in reported values. Mean TST reported was 365 and 507 min., for Mini-PAT and PAT device, respectively, difference 28%. Similarly, REM sleep time was 7.9 and 16.1%TST for the devices, difference 51%. There were large inter-patient variance; some patients showed similar results from both devices.

Conclusions: Portable sleep diagnostic devices can successfully monitor sleep in ICU patients. Devices based on different sensor recordings may generate different calculations of sleep time and stage.

Sleep quality in prolonged mechanical ventilation patients
Dimitra Siope1, Eli Gallatiou2, Evangelia Nena1, Maria Antoniadou1, Evangelia Sarris1, Vasilis Michailidis1, Dimitris Matamis1, Venetia Tsara1, 12nd Chest Department, General Hospital “G. Papanikolaou”, Thessaloniki, Greece; 3Intensive Care Unit, University Hospital, Ioannina, Greece; 4Intensive Care Unit, General Hospital “Papageorgiou”, Thessaloniki, Greece

Intensive Care Unit (ICU) patients recovering from critical illness often present persistent respiratory failure and require prolonged mechanical ventilation (PMV). The aim of this study was to assess sleep quality in PMV patients, during hospitalisation in ICU and in a Respiratory Intensive Unit (RIU).

Patients and methods: A total of 39 PMV patients (13 in ICU and 26 in RIU) were included in the study. All patients were in stable condition, without need for sedation, with GCS > 10. All patients were tracheostomised under mechanical ventilation support at least during the night. A full PSG was performed in all patients during night sleep under PS ventilation.

Results: Sleep efficiency was higher in ICU (82.7±18.3%, RIU 68.4±21.8%, p=0.02) with longer sleep time (SPT ICU 448±62 min. RIU 346±56 min, p<0.001). Duration of stage N2 was 61.4±20.6% in ICU and 48.8±20.5% in RIU, with longer stage N3 in RIU (10.7±15.6%, ICU 5.7±12.6%), but these differences were not statistically significant. Yet, REM sleep duration was longer in RIU (10.3±6.8, ICU 3.7±4.9, p=0.01). Despite pressure support ventilation during night sleep, some breathing abnormalities appeared in RIU patients, with hypoxemia especially during REM (94.4±3.2%, ICU 98.3±6.0%, and apneas or hypopneas (AHI 3.34±11.6h).

Conclusions: Sleep quality was impaired in PMV patients during hospitalisation either in ICU or in RIU, but sleep structure approach normal architecture in RIU. REM sleep breathing abnormalities in RIU patients may require further clinical evaluation in terms of the efficacy of mechanical ventilation mode.

P5013
Swallowing disorders and speech rehabilitation in tracheostomized difficult-to-wean patients
Guido Vagheggini, Adriano Di Paco, Giuseppa Pullarà, Anna Bartolini, Monica Orlando, Eugenia Panait Vlad, Nicolo Ambrosio, Weaning and Pulmonary Rehabilitation Unit, Auxiliar Vita Rehabilitation Centre, Volterra, Pisa, Italy

Background: Swallowing disorders often complicate long-term management of tracheostomised difficult-to-wean patients (DWPs) and may represent a common drawback to the removal of the cannula.

Aims: To evaluate the prevalence of swallowing disorders among DWPs and the restoration of proper swallowing after a weaning and pulmonary rehabilitation program including speech rehabilitation (SR).

Methods: 157 tracheostomised DWPs (83 males, age 69.9±12.5y), consecutively admitted, underwent dysphagia assessment including objective assessment, methylene blue test, and eventually fibroschopy swallowing evaluation.

Results: 74 patients (42 males, age: 70.4±12.5y), were evaluated at risk of aspiration, and underwent SR program. 25 patients, affected by severe ALS, and 15 affected by neurological disorders determining very severe cognitive impairment (GCS<9) were not included in the SR program. 57 (77.0%) out of 74 treated patients recovered swallowing function and were allowed to feed orally; 8 (10.8%) semiliquid, 17 (23.0%) semisolid, 14 (18.9%) homogeneous; 18 (24.3%) solid. In 10 patients compensatory postures were adopted. 13 patients were treated with pancutanous gastrostomy, 4 were discharged with nasogastric feeding tube. 30 patients (40.5%) underwent to tracheostomy decannulation. Length of stay was greater for dysphagic patients (21.7±12.7 vs 33.5±14.4, p<0.001).

Conclusions: Swallowing disorders showed high prevalence among DWPs and are related to an higher length of stay in hospital. Further research are needed in order to determine the burden of swallowing disorders in DWPs and evaluate the effectiveness of their treatment.

P5014
Review of decannulation experience and duration of tracheostomy within the Newcastle upon Tyne Hospitals NHS Foundation Trust
Josephine Nicholas, Christopher O’Brien. Respiratory Paediatrics, Great North Children’s Hospital, Newcastle upon Tyne, United Kingdom

Background: Tracheostomy is increasingly used to manage airway difficulties in paediatric respiratory management. It is important that parents are informed of the likely duration of tracheostomy in different conditions and the prognosis for decannulation.

Aims: The aim of this project was to review the experience of paediatric tracheostomy decannulation in the Newcastle upon Tyne Hospital NHS Foundation Trust (NUTH) Trust over the last 6 years.

Methods: This retrospective review looked at all decannulation episodes in children within the NUTH Trust from January 2005 to December 2010. The notes of the patients identified were reviewed to collect data.

Results: 56 patient episodes were identified, of those, 48 patients were included. The median duration of tracheostomy was 14 months and the median age at decannulation was 26 months. The indications for tracheostomy were: subglottic stenosis (31%), airway malacia (21%), airway mass (13%), airway obstruction (10%) and other (25%). The median duration for these indications were 35, 17.5, 8, 12 and 11.5 months respectively. 81.25% (39) of planned decannulations were successful. Surprisingly 61.54% (24) of successful decannulations had trachy-cutaneous fistulas requiring surgical closure. It appeared that fistulas were associated with patients who were of a younger age at tracheostomy (4.5 vs. 8 months) or who had a longer duration of tracheostomy (20 vs. 12 months).

Conclusions: This review has highlighted likely duration of tracheostomy for the common conditions and prognosis for decannulation. It has also revealed a surprisingly high rate of trachy-cutaneous fistula.

P5015
Prognostic factors for long-term survival in ICU tracheostomized patients
Damien Basille, Eline Maegon, Claire Andrejak, Vincent Joffeumeurs, Pneumologie, CHU Aix-les-Bains, Aix-en-France

Introduction: Few recent studies have evaluated the long-term prognosis of ICU patients who are tracheostomized for their underlying lung disease.

Patients and methods: We conducted a retrospective study from 1997 to 2010 in 82 patients who were tracheostomized during their stay in a medical intensive care unit (ICU). The main objective was the evaluation of long-term survival

Results: Among the 82 patients, 40 (48.8%) have a chronic respiratory failure (16 obstructive, 9 mixed and 15 restrictive with 11 neuromuscular disease). Fifty-nine patients (72%) died (50% before hospital discharge. The median survival time is 188 days. In multivariate analysis using the Cox model, three prognostic factors have been highlighted: 1) the presence of a neurological disease was significantly associated with a better prognosis (OR 0.48 [0.26-0.9], p = 0.022), 2) an age above 65 years (OR = 2.2 [1.17-4.16], p = 0.015) and 3) a Charlson score greater than 2 (OR = 2.05 [1.09-3.86] p = 0.026) were significantly associated with a poor prognosis. GOLD stage IV COPD was not associated with a poor prognosis (OR = 1.93 [0.98-3.81], p = 0.058). Bleeding or respiratory complications were found respectively in 16 (20%) and 7 (9%) patients. Among patients discharged from the hospital, the weaning of mechanical ventilation was obtained in 19 of 46 cases (41.3%).

Conclusion: We found two pejorative prognostic factors (age > 65 years and a Charlson score > 2) and one protective factor (presence of a neurological disease) significantly related to the long-term survival in ICU tracheostomized patients.

Assessment of rapid shallow breathing index as a predictor for weaning in respiratory care unit

Abbas Fadaii¹, Hamid Sohrabpour¹, Saber Sadat Amini¹, Bahador Bagheri², Bahar Taherkahnchi¹. ¹Pulmonology, Shahid Beheshti Medical University, Tehran, Islamic Republic of Iran; ²Pharmacology, Tabriz Medical University, Tabriz, Islamic Republic of Iran

Introduction: Weaning is gradual removal of mechanical ventilator support. Different predictors are used for weaning initiation. This study is designed to investigate the rapid shallow breathing index (RBSI) as a predictor for successful weaning.

Materials and methods: We did this cross-sectional study on 70 patients who had mechanical ventilation for more than 48 hours in respiratory care unit (RCU) in Tehran Labbafi Nejad hospital. We measured RBSI, and then evaluate the value of RBSI for successful extubation.

Results: 63 (90%) Patients had RBSI ≤ 105 (Breath/min/L), among them 49 (77%) patients had successful weaning and did not need re-intubation but the rest had unsuccessful weaning (P=0.001). Weaning index mean for patients with successful extubation was 66±57.2 and for patients with unsuccessful extubation was 76.9±28.1. We could not find a significant difference between means (P=0.433).

Conclusion: Our findings exhibited that RBSI has high sensitivity with low specificity. RBSI ≤ 80 is more reliable than RBSI ≤ 105 as a predictor for weaning.
OPYS1

Immunomodulatory function of chemerin and its receptor ChemR23 in the physiopathology of viral pneumonia and acute lung injury

Benjamin Droescher, Olivier Vosters, Patricio De Nadah, Susphalone Luangsaya, Stephanie Glineur, François Huaux, Daniel Desmect, Paul De Vuyst, Christophe Lamy, Philippe Deleersnijder, and François Vandenabeele

Erasme Hospital, Department of Pneumology, Brussels, BE; 1University of Brussels (ULB), University of Belgium, John F liaison, 1250, Brussels, Belgium; 2University of Liege (ULG), University of Liege (ULG), Department of Pathology, Liege, BE; 3Catholic University of Louvain (UCL), Catholic University of Louvain (UCL), Laboratory of industrial toxicology, Brussels, BE

Background: The role of chemerin (ChemR23) in the modulation of innate and adaptive immune responses is not fully understood. This receptor has been shown to stimulate pro-inflammatory responses in macrophages and dendritic cells, which could be important in viral infections.

Methods: We investigated the role of ChemR23 in the modulation of the immune response to respiratory virus infection in mice. We used wild-type (WT) and ChemR23−/− mice infected with either respiratory syncytial virus (RSV) or influenza A virus (IAV). The immune response was analyzed by measuring cytokine levels, leukocyte infiltration, and pathological changes.

Results: In WT mice infected with RSV, ChemR23−/− mice had reduced leukocyte infiltration and decreased cytokine production compared to WT mice. In contrast, in IAV-infected mice, ChemR23−/− mice had increased leukocyte infiltration and cytokine production. Overall, our data suggest that ChemR23 plays a role in modulating the immune response to respiratory virus infection, with different effects depending on the virus and the stage of infection.

Conclusion: Our findings highlight the importance of ChemR23 in the modulation of the immune response to respiratory virus infection and suggest potential therapeutic targets for the treatment of viral pneumonia and acute lung injury.

OPYS2

Role of Th9 cells in allergic airway inflammation induced by house dust mite

Carla P. Jones, Lisa Gregory, Benjamin Causton, Clare Lloyd, Imperial College, Leukocyte Biology, London, GB

Interleukin (IL)-9-secreting Th9 cells play a key role in the modulation of allergic responses. However, the specific function of Th9 cells in allergic airway inflammation is not fully understood. In this study, we investigated the role of Th9 cells in the allergic response to house dust mite (HDM) exposure.

Methods: We used BALB/c mice sensitized and challenged with HDM to induce allergic airway inflammation. Th9 cell numbers and function were measured in vivo and in vitro, and the role of Th9 cells in regulating allergic airway inflammation was assessed by adoptive transfer experiments.

Results: Th9 cells were increased in the bronchoalveolar lavage fluid (BALF) of HDM-challenged mice, and adoptive transfer of Th9 cells to naive mice induced allergic airway inflammation. Th9 cells were shown to produce IL-9, which is essential for the development of Th2 responses.

Conclusion: Our findings suggest that Th9 cells play a critical role in the development of allergic airway inflammation induced by HDM exposure. Understanding the specific function of Th9 cells in allergic airway inflammation could provide new targets for the treatment of allergic diseases.

Thymic stromal lymphopoietin is a central regulator of anti-viral CD8+ T cell response

Koshiba Yadav1,2, Siebheldt Akele1,2, Aurélien Trompette1,2, Nicola Harris, Benjamin Marsland1,2, and Claire Hoving1,2

1CHUV (Centre hospitalier universitaire vaudois), Service de Pneumologie, Lausanne, Vaud, CH; 2University of Lausanne, Faculty of Biology and Medicine, Lausanne, CH; 3Global Health Institute, EPFL (École polytechnique fédérale de Lausanne), Lausanne, Vaud, CH

Thymic stromal lymphopoietin (TSLP) is an IL-7-like cytokine that is primarily produced by epithelial cells at mucosal surfaces. It has been widely studied in Th2-driven inflammatory disorders such as atopic dermatitis and asthma. Although both viral nucleic acid analogues and pro-inflammatory cytokines associated with active viral infections are potent stimulators of TSLP expression in vitro, its role in antiviral immunity is unknown. To elucidate the role of TSLP in viral infections, we investigated the immune response against influenza A in mice deficient in TSLPR. We found that TSLPR-deficient mice exhibited impaired clearance of the virus at late time points post infection, indicative of a defect in the adaptive immune response. Although priming in the lymph node was unaffected, the virus-specific CD8+ T cell response in the lung was compromised in the absence of TSLPR. This defect was characterized by the reduced frequency of virus-specific CD8 T cells as well as reduced effector functions such as granzyme B expression and interferon γ production. Using mixed bone marrow chimeras and adoptive transfer studies, our data suggest that TSLP affects influenza-specific responses by modulating the function of recruited inflammatory dendritic cells (DCs). Pulmonary DCs isolated from infected lungs of TSLPR deficient mice were defective in inducing proliferation of antigen-specific naive T cells in vitro. Furthermore, in the absence of TSLPR the production and trans-presentation of IL-15 by CD11b+ inflammatory DC was impaired. We propose that TSLP regulates activation of antigen specific cytotoxic T cells at the site of infection by modulation of DC function and suggest a crucial link between TSLP and IL-15 production during infection.

OPYS4

Regulation of allergic airway disease by IL-4/IL-13 activated macrophages and dendritic cells

Natalie Niewoenhuizen, Jayakumar Jaisubash, Frank Kirstein, Ramona Hurdayal, Claire Hoving, Babelle Emaldi, William Hornsll, Frank Brombacher, University of Cape Town, Immunology, Cape Town, Western Cape, ZA

While IL-4Rα and its ligands IL-4 and IL-13 play an important role in mouse models of allergic airway disease, the effects of IL-4 and IL-13 signaling through specific cell types are unclear. The generation of mice with cell specific impairments of IL-4Rα on macrophages/neutrophils (Ly5+IL-4Rα+/-) and dendritic cells/macrophages (CD11c+IL-4Rα+/-) has enabled us to investigate the effect of IL-4/IL-13 signaling on macrophage and dendritic cell function in allergic airway disease.

IL-4Rαlox/−, IL-4RαCre+IL-4Rαlox/−, and Ly5+IL-4Rαlox/− mice were sensitized and challenged with ovalbumin. OVA-challenged IL-4Rαlox/− mice had increased airway resistance and elastance, lung inflammation, and mucus hypersecretion compared to PBS controls. In IL-4Rαcre+ mice, airway resistance and elastance, mucus hypersecretion, Th2 responses and eosinophil infiltration was decreased. However, in both Ly5+IL-4Rαlox/− mice and CD11c+IL-4Rαlox/− mice, airway resistance and elastance were slightly increased. This indicates that IL-4/IL-13 activated macrophages may play a role in downregulating allergic airway disease. Furthermore, lung CD4+ T cells from CD11c+IL-4Rαlox/− mice but not Ly5+IL-4Rαlox/− mice had significantly increased production of the Th2 effector cytokines IL-13 and IL-5 as well as significantly increased lung eosinophils and neutrophils, suggesting an additional role for IL-4/IL-13 activated dendritic cells in downregulating Th2 responses and granulocyte infiltration into the lungs. In summary, we find a role for IL-4/IL-13 signaling through both macrophages and dendritic cells in regulating allergic airway disease in mice.

OPYS5

The influence of glucocorticoids on transcription factor balance in asthma patients

Rotanui Bumbaca1,2, Stephen Durham1, Casen Schmidt-Webber3,4, NHLS - Royal Brompton Hospital, Respiratory Medicine - Allergy, London, GB; 5Elios Hospital Bucharest, Allergy, Bucharest, RO; 6Zentrum für Allergie & Umwelt (ZAUUM), Allergy and Molecular Biology, Munich, DE

Background: Transcription factors are important in T-cell subset differentiation as well as clonal expansion and determine the polarization process towards different T cell phenotypes. Glucocorticoids are important for asthma treatment, potentially by modulating T cell differentiation. We hypothesize that the transcription factor balance could be of predictive value in the treatment of asthma. Our study aimed to profile T-cell transcription factors after 8 week GC-treatment of steroid naïve
asthmatic patients and to test the steroid sensitivity of Th2 versus Th1 and Treg transcription factors (TF) after a treatment period, which is known to control Th2-cell activity and improve clinical symptoms.

Methods: Human CD4+ T-cells isolated from steroid naive atopic asthmatic individuals and decreased significantly following GC treatment. In vitro analysis revealed that Gfi-1 is abundantly expressed in Th2-polarizing conditions in asthma and displays dose-dependent sensitivity to GCs. The current study shows for the first time that Gfi-1 is involved in allergic asthma and may represent a biomarker for assessing Th2-dependent disease and GC-responsiveness.

OP1 Neutrophils augment LPS-mediated pro-inflammatory signaling in human lung epithelial cells

Agnes Boots1,2, Kirsten Gerloff1, Damien van Berlo1, Guido Haenen2, Aalst Bae1, Carin Albrecht1, Roel Schims1,1 J.U.F. Particle Research, Düsseldorf, DE; 2Maastricht University, Pharmacology and Toxicology, Maastricht, NL

The role of polymorphonuclear neutrophils in pulmonary host defense is well recognized. The influence of a pre-existing neutrophilic inflammation on airway epithelial response towards pro-inflammatory triggers, however, is still poorly understood. Therefore, aim of this study is to investigate the effect of neutrophil-induced LPS on pre-existing pro-inflammatory signaling in lung epithelial cells. Human bronchial epithelial cells (BEAS-2B) were incubated with human peripheral blood neutrophils or bone-marrow derived neutrophils from C57Bl/6J wildtype or NADPH-oxidase deficient (p47<sup>−/−</sup>/murine). Upon LPS stimulation, IL-8 production and reactive oxygen species (ROS) generation were measured. Additionally, activation of extracellular regulated kinases (ERK)1/2 and nuclear factor (NF)-κB signaling pathways was analyzed.

Our studies show that neutrophils synergistically increases LPS-induced IL-8 and ROS production by BEAS-2B cells without inducing cytoxicity. The observed IL-8 response to endotoxin increases in proportion to time, LPS-concentration and the number of neutrophils present. Moreover, this synergistic IL-8 production correlated with the chemotactic properties of the co-incubations and significantly depended on a functional neutrophilic NADPH oxidase. The presence of neutrophils also augments LPS-induced phosphorylation of ERK1/2 and IκBα as well as NF-κB RelA DNA binding activity in BEAS-2B.

Our results indicate that the pro-inflammatory effects of LPS towards lung epithelial cells are amplified during a pre-existing neutrophilic inflammation. These findings support the concept that patients suffering from pulmonary neutrophilic inflammation are more susceptible towards pro-inflammatory triggers.

OP2 Angiostatin inhibits neutrophil migration and activation

Gurpreet Aulakh, Baljit Singh. Tel Aviv University, Microbiology and Human Immunology, Tel Aviv, Ramat Aviv, IL

Angiostatin inhibits neutrophil migration and activation

Additionally, activation of extracellular regulated kinases (ERK)1/2 and nuclear factor (NF)κB signaling pathways was analyzed.

Background: A novel immunomodulatory phenotype has recently been identified in human neutrophils that is characterized by diminished chemotaxis in response to fMLP and LPS. ANG also inhibited the signal for phosphorylated p38 MAPK in phagocytosing neutrophils.

Results: ANG inhibited neutrophil rolling flux (<i>p</i>&lt;0.05) in capillary vessels in TNFα-treated cremaster muscles. We conclude that ANG is a novel inhibitor of neutrophil migration and activation. (Funding NSERC Discovery Grant)

OP3 Production of alpha-1 antitrypsin (AAT) by pro- and anti-inflammatory macrophages and dendritic cells

Emily FA. van ’t Wout1, Annerose van Schadewijk1, Nigel D.L. Savage2, Jan Stolk1, Pieter S. Hiemstra1, Guido Haenen2,1 IUF, Particle Research, Düsseldorf, DE; 2Maastricht University, Pharmacology and Toxicology, Maastricht, NL

Acute exacerbations (AE) in COPD have been frequently associated with respiratory infections. However, a causal relationship is debatable as bacteria can also be found in stable patients. To explain this discrepancy, differences in bacterial strain virulence have been suggested. To test this, we examined the virulence of different <i>Haemophilus</i> strains, isolated from COPD patients, either in a stable phase or during an AE.

OP6
Endogenous transforming growth factor beta (TGF-β) influences rhinovirus (RV) replication in primary bronchial epithelial cells (PBECs) by suppressing the innate immune response
Nicole Bedke, David Sammut, Ben Green, Peter Howarth, Stephen Holgate, Dana Davies. University of Southampton, Infection, Inflammation and Immunity, Southampton, Hampshire, GB

RV infection is a major cause of asthma exacerbation in children and adults. PBECs from asthmatics have a deficient IFN response against RV infection, the molecular mechanism of which is unknown. TGF-β is an anti-inflammatory cytokine which is highly expressed in asthmatic tissue and augments RV replication in bronchial fibroblasts by decreasing the innate immune response (Thomas BJ 2009)

Objective: To determine whether the presence of endogenous TGF-β in cultured PBECs from asthmatic patients augments RV replication.

Method: We measured endogenous TGF-β levels in serum-free media from normal and asthmatic PBECs. PBECs from both groups were pretreated with 10 ng/ml neutralizing anti-TGF-β antibodies and infected with RV1B for 24 or 48 hrs. We measured virus titres by TCID50/ml and levels of IFN-β, IP-10 and RANTES protein by ELISA. SOCS-1 and SOCS-3 mRNA levels were quantified by RT-qPCR.

Results: Endogenous TGF-β was higher in asthmatic PBECs than in normal PBECs. Inhibition with a specific antibody to TGF-β in a greater decrease in RV replication in asthmatic PBECs than in normal PBECs. This was accompanied by increased IFN-β protein relative to virus particles. IFN-β and IFN-λ protein levels were upregulated when asthmatic PBECs were treated with anti-TGF-β and polyIC. The antibody significantly decreased SOCS-1 and SOCS-3, which control IFN responsiveness. It had no significant effect on RV-induced IP-10 and RANTES protein production.

Conclusions: Our results suggest that high levels of TGF-β in asthmatics may contribute to a deficient innate immune response to RV infection by decreasing IFN production.

PP101
Critical role of IL-25 in initiation of airway remodeling during a house dust mite driven model of disease
Lisa Gregory1, Carla Jones 1, Simone Walker1, Sara Mathie 1, Charlene DeClercq1, Lawrence Mason 1, Nancy Stedman 1, Edward Lavallie2
1. Imperial College London, Leukocytic Biology; MRC Laboratory of Molecular Biology, Cambridge, Cambridgehire, GB

Airway epithelial cells are key contributors to the innate immune system and intimately involved in allergen recognition and in modulating allergic immune responses. IL-25 is secreted by airway epithelium and is implicated in the regulation of asthma. Using an adenoviral vector to overexpress the TGF-β and activin signalling molecule Smad2 in the airway epithelium enhances airway remodelling and AHR in mice exposed to the environmental allergen house dust mite (HDM). We thus determined whether a neutralising antibody to IL-25 could influence disease pathology induced by HDM following this perturbation of the pulmonary epithelium. AHR was significantly reduced in both the AdSmad2 and AdC (empty vector) mice exposed to HDM. Similarly, peribronchial collagen deposition in HDM treated mice was also reduced (p=0.05). CCL20, a sentinel chemokine that alerts and recruits innate and adaptive immune cells to the lung, was also reduced to baseline values in mice treated with anti-IL-25 even in mice overexpressing epithelial Smad2. Pulmonary levels of the ‘alarmin’ IL-33, known to be important for innate-type mucosal immunity in the lungs and TSLP were also completely abrogated. Elevation in the prototypical Th2 cytokines IL-4, -5 & -13 was reduced following exposure to HDM (p<0.05), however they were still significantly elevated compared to controls. Thus, blocking IL-25 prevented the increase in innate epithelial derived cytokines and reduced the severity of AHR in response to HDM in both control mice and those with an altered, ‘pro airway remodelling’ epithelial phenotype. Understanding allergic innate immunity could potentially lead to new therapeutic targets for the treatment of asthma.

PP102
GOB4/AGR2 deficiency protects against allergic airway disease
Charlene DeClercq1, Lawrence Mason 1, Nancy Stedman 1, Edward Lavallie2
1. Imperial College London, Leukocytic Biology; MRC Laboratory of Molecular Biology, Cambridge, Cambridgehire, GB

Introduction: GoBlet cell gene 4 (GOB4), a.k.a. anterior gradient homolog 2 (AGR2), is a protein disulfide isomerase restrictedly expressed by goblet cells of the airways and the lung.

Objectives: Because GOB4 expression is essential for mucus production in the gut, we hypothesized that it also modulates aspects of allergic airway disease (AAD), including mucus secretion.

Methods: First we focused on a classic model of ovalbumin (OVA)-induced AAD.

In a second set of studies, mice were exposed intranasally (IN) to recombinant murine (rMII-13), which induces a 10-fold increase in GOB4 mRNA expression in the lung. Bronchoalveolar (BAL) lavage and tissue samples were collected 24h and 48h post-rMII-13 or OVA challenge, respectively.

Results: In mice sensitized and challenged with OVA, BAL cellularity was significantly reduced in GOB4 deficient mice compared to wild-type (WT) controls (p=0.009). This was mainly due to lower numbers of eosinophils (p=0.0012) and lymphocytes (p=0.0017). Incidence and severity of intrabronchial mucus accumulation were also lower in tissues from GOB4 deficient mice. In the second protocol, WT mice exposed to rMII-13 developed airway neutrophilia, histiocytic and lymphocytic inflammation, goblet cell metaplasia with intracellular mucus plugs, and vascular mural hypertrophy. In contrast, GOB4 deficient mice exposed to rMII-13 developed neither the airway inflammation nor the morphological changes observed in their WT counterparts.

Conclusion: Our data indicate that, in AAD conditions, GOB4 deficiency protects not only against mucus-driven aspects of the disease but also largely from allergic airway inflammation, making GOB4 an attractive target for the treatment of asthma.

PP103
Steroid-insensitive expression of CCL17 from asthmatic lung macrophages: a driver of severe disease?
Karl J Staples 1, Timothy S.C. Hinks 2, Victoria Gunn 1, Caroline Smith 2, Ratko Dikanovic 1, 2
1. University of Southampton School of Medicine, Division of Infection, Inflammation & Immunity, Southampton, Hampshire, GB;
2. Southampton Respiratory NIHR Biomedical Research Unit, Southampton, Hampshire, GB

Asthma is a complex inflammatory disease of the airways characterised by an increase in the number of CD4+ helper T cells within the lung. The Th2 cytokine IL-4, can also change the phenotype of macrophages. These M2 macrophages are characterised by increased expression of the cell surface marker CD206, as well as being sources of the Th2 cell chemokine CCL17. We hypothesised that it is the macrophage that is the main source of CCL17 in the asthmatic airway.

Using sputum macrophages purified by flow cytometry from the airways of 11 healthy controls and 11 asthmatics, we observed increased expression of CCL17 mRNA (p=0.0311). In contrast, there was no difference in CCL17 expression as assessed by flow cytometry. Furthermore, upon culture bronchoalveolar lavage (BAL) cells from asthmatics released more CCL17 than healthy control cells. Interestingly, this higher expression of CCL17 is also observed in samples derived from moderate asthmatics who were treated with inhaled steroids.

We tested the efficacy of the steroid fluticasone propionate on inhibiting CCL17 release from monocyte-derived macrophages treated with IL-4. We observed that the steroid had no effect on CCL17 release even at high concentrations (10 μM).

In contrast, release of CCL17 was inhibited when the cells were exposed to the PI3-Kinase inhibitor, LY294002 (10 μM).

Taken together, these data indicate that expression of CCL17 in lung macrophages from asthmatics is steroid insensitive and that lung macrophages may be partially responsible for driving the disease. In addition, therapeutics targeting the PI3-Kinase signalling pathway may improve control of the disease in severe steroid-insensitive forms of asthma.

PP104
Short-chain fatty acids are potent modulators of allergic airway inflammation
Aurélien Trompette1,2, Anke Sichelstiel 1,2, Koshika Yadava 1,2
1. CHUV, Laboratoire de Pneumologie, Lausanne, Vaud, CH; 2University of Lausanne, Faculty of Biology and Medicine, Lausanne, Vaud, CH

Introduction: Over the past few decades, there has been a dramatic increase in the prevalence of asthma in westernized countries. Both experimental and epidemiological data indicate that environmental factors, such as an individual’s diet and communal flora can have profound effects upon the susceptibility and progression of inflammatory diseases.

Rationale: There is a growing body of evidence showing that the gut microbiota can influence immune responses. Short-chain fatty acids (SCFAs), end-products of the colonic fermentation of dietary fibers by bacteria, have been shown to exert protective effects upon cardiovascular and intestinal inflammation; however, their impact upon lung inflammation remains to be determined.

Methods: C57Bl/6 mice were given individual SCFAs in drinking water or intraperitoneally 2 weeks prior to and throughout the induction of aFel d1-induced acute model of allergic asthma. As an alternative method, mice were fed a low-fiber diet from birth to reduce circulating levels of endogenous SCFAs.

Results: Mice exposed to SCFAs exhibited reduced airway inflammation, characterized by a significant reduction of infiltrating eosinophils (39.8±6.9% vs. 4.2±5.3%; p<0.01) in the bronchoalveolar lavage, in addition to significantly less systemic Fel d 1-specific IgE and IgG1 antibodies (1.41±0.2 vs. 0.37±0.02 and 1.36±0.1 vs. 0.52±0.2, respectively). Interestingly, mice that were fed a low-fiber diet exhibited an exacerbated airway inflammation when exposed to the Fel d 1 allergen.

Conclusions: Our results show that SCFAs have intrinsic immunomodulatory functions with the ability to dampen lung inflammation in a mouse model of acute allergic asthma.

Changes in the proteome upon dermal sensitization in a mouse model of chemical-induced asthma  

Steven Haenen1, Elke Clynen2, Vanessa De Vooget1, Peter Hoet3, Ben Nemery1,  
Jeroen Vanoorbeek1. 1KU Leuven, Occupational, Environmental & Insurance Medicine - Research Unit of Lung Toxicology, Leuven, BE; 2Haaselt University, BIOMED Research Institute, Diepenbeek, BE  

In follow-up of our studies on proteomic changes in a validated mouse model of immunologically mediated chemical-induced asthma, using tritiated thymidine (TDR) as a sensitizer [1], we evaluated the temporal changes at early time points following dermal sensitization. The identification of biomarkers of sensitization could help to move diagnosis to an earlier (pre-clinical) stage. We explored the proteome of the auricular lymph nodes and serum of mice dermally sensitized to TDI.  

Mice were treated once (day 1) or twice (day 1 and 8) with TDI or with the vehicle (acetone-olive oil, 2:3, control) on both ears. Auricular lymph nodes and serum were collected three days later. Two-dimensional difference gel electrophoresis was used to analyze the differential proteins (p<0.01) of TDI-sensitized mice vs. control mice (p<0.12). Proteome analyses of the auricular lymph nodes resulted in 39 and 86 differential proteins and of serum in 7 and 16 differential proteins, after 1 and 2 sensitizations, respectively. Identification (MALDI-TOF MS) of these proteins mainly showed structural (e.g. vimentin), immune related (e.g. lymphocyte specific protein-1) and oxidative stress related proteins (e.g. peroxiredoxin 6) in both the lymph nodes and the serum.  

Now, a software based pathway analysis of the differentially expressed proteins is performed (Anadate Genomics). This will give more insight in the cellular and molecular events involved in early sensitization, leading to chemical-induced asthma. Possible biomarkers among the differential proteins will be validated.

P2Y2 receptor regulates VCAM-1 membrane and soluble forms and eosinophil accumulation during lung inflammation  

Gilles Vanderstocken1, Benjamin Bondue1, Michael Horckmans1, Larissa De Pooter2, Jean-Marc Roys3, Jean-Marc Roys2, Jean-Marc Roys3, Didier Communs1,  
1Université Libre de Bruxelles, Institut de Recherche Interdisciplinaire en Biologie humaine et moléculaire (IRIBHM), Bruxelles, BE; 2Université Libre de Bruxelles, Institut de biologie et de médecine moléculaires (BIBM), Gosselies, BE; 3Université Libre de Bruxelles, Hôpital Erasme, Bruxelles, BE  

ATP has been defined as a key mediator of asthma. In this study, we evaluated lung inflammation in mice deficient for the P2Y2 purinergic receptor. We observed that eosinophil accumulation, a distinctive feature of lung allergic inflammation, was defective in OVA-treated P2Y2-deficient mice compared with OVA-treated wild type animals. Interestingly, the upregulation of VCAM-1 was lower on lung endothelial cells of OVA-treated P2Y2−/− mice compared with OVA-treated wild type animals. Adhesion assays demonstrated that the action of UTP on leukocyte adhesion through the regulation of endothelial VCAM-1 was abolished in P2Y2−/− lung endothelial cells. Additionally, the level of soluble VCAM-1 reported as an inducer of eosinophil chemotaxis, was strongly reduced in the anti-GR1 antibody (aGR1) or HBSS on day13. On day 15, they received an oropharyngeal cyclophosphamide (CP) or saline on days 11 and 13, or 1 intravenous injection of cyclophosphamide (CP) and aGR1 induced a full neutrophil and eosinophil depletion in both BAL and blood. CP led to a complete disappearance of the TDI-induced AHR, while aGR1 caused only a partial decrease in AHR. CP-injected mice showed an almost full depletion of the auricular lymphocytes, while this was only slightly decreased in the aGR1-injected TDI-mice, mainly caused by depletion of T-lymocytes (CD3+). A decrease of the concentration of IL-3 was detected in the aGR1-injected TDI-mice compared to the HBSS-injected TDI-mice. A decreased total serum IgE was observed only in CP-injected TDI-mice.  

In conclusion, CP and aGR1 are potent neutrophil depletion agents, which clearly influence AHR in our mouse model of chemical-induced asthma. However, because these agents also impact other cells the specific role of neutrophils could not be clarified.  

PP108  
Resolution of house dust mite (HDM) induced allergic airways disease  

Sara Mathi1, Victoria Hammond2, Valerie O’Donnell2, Tracy Hussell3,  
Clare Lloyd4, 1Imperial College London, Leukocyte Biology, National Heart & Lung Institute, London, GB; 2Cardiff University, Department of Medical Biochemistry and Immunology, Tenovus Building, Heath Park, School of Medicine, Cardiff, GB  

The debilitating symptoms of impaired lung function and mucous secretion experience by asthma patients can persist for several days following allergen exacerbation. This persistence may occur due to deficiencies in specific pro-resolving mediators thereby contributing to the propagation of chronic inflammation. The purpose of this study was to characterise the resolution of allergic pulmonary inflammation in mice following 3 weeks of intranasal challenge using HDM. Disease parameters were measured at 4 hours, 7 days and 13 days following cessation of allergen exposure. Airway hyperreactivity (AHR) was sustained at 7 days post challenge compared to PBS treated controls, returning to baseline by 13 days (Resistance at 100μmH<sub>2</sub>O was 5.73 ± 0.41 vs. 3.20 ± 0.19, P<0.05). This was accompanied by persistent levels of Th2 lymphocytes (2.63 ± 10<sup>5</sup> cells/ml and 1.32 ± 10<sup>5</sup> cells/ml vs. 0.79 ± 10<sup>5</sup> cells/ml, P<0.05) and eosinophils (18.9 ± 10<sup>5</sup> cells/ml and 7.16 ± 10<sup>5</sup> cells/ml, vs. 1.8 ± 10<sup>5</sup> cells/ml, P<0.001), returning towards baseline by 13 days. The Th2 lymphocyte numbers did not correlate with the epithelial derived cytokine, IL-33, which returned to baseline by 7 days. Histological analysis of lung sections stained with Periodic-acid Schiff show that mucus persists up to 13 days. The pro-resolving lipid, Lipoxin A4 is expressed in the lung at 4 hours and remained detectable up to 13 days. CD200R is expressed on myeloid cells and has been implicated in the maintence of pulmonary immune homeostasis. Following HDM exposure, expression of CD200R on alveolar macrophages peaked at 7 days and remained elevated at 13 days. These data indicate that distinct molecular pathways may be responsible for induction and maintenance of allergic inflammation and AHR.  

PP109  
Different biochemical properties of house dust mite induce divergent epithelial and inflammatory responses  

S Post, M.C. Nawijn, A.J.M. van Oosterhout, Irene Heijink, 1University Medical Center Groningen, Pathology & Medical Biology, Lab Allergology & Pulmonary Diseases, Groningen, Groningen, NL  

Introduction: Allergic asthma is mainly caused by exposure to aeroallergens like house dust mite (HDM), when transepithelial delivery is facilitated by disruption of the epithelial barrier.  

Objective: We aimed to gain more insight in which biochemical property of HDM is critical for the disruption of barrier function and initiates an inflammatory response.  

Methods: HDM extracts with different biochemical properties were analyzed for their effects on airway/bronchial epithelial barrier function by measuring changes in transepithelial resistance and immunostaining of the functional proteinsZO-1, occludin and E-cadherin. Furthermore, we examined the induction of a pro-inflammatory phenotype of human bronchial epithelium by these HDM extracts, as well as the epithelial remodeling and airway inflammation in vivo in a mouse model.  

Results: We found that the different HDM extracts induced divergent responses. Importantly, the extract with lowest serine protease activity induced the most pronounced effects on barrier function in vitro, and induced an increased production of the pro-inflammatory chemokine CCL20. Remarkably, the same HDM extract induced HDM-specific IgE, a profound epithelial E-cadherin delocalization, goblet cell hyperplasia, cellular inflammation and increased levels of CCL17 and IL-5 in vivo.  

Conclusion: Together, these results indicate that the disruption in epithelial barrier function is independent of serine protease activity, and is essential for allergic sensitization and airway remodeling in vivo.  

PP110  
The role of IL-25 in rhinovirus-induced asthma exacerbations  

Janine Beale, Nathan Bartlett, Sebastian L. Johnson. Imperial College London, Respiratory Medicine, National Heart and Lung Institute, UK  

Rhinoviruses (RV) are the major causative factor of asthma exacerbations (AE). While Th2-mediated inflammation is implicated in asthma, it is unknown how the
immune response to RV infection interacts with Th2 immunity causing an AE. Mast cell-deficient IL-25 is an important regulator of Th2 immunity and plays a role in asthma pathogenesis. We hypothesized that RV infection of the epithelium induces IL-25 production facilitating immunopathogenesis of AE. We measured IL-25 mRNA in mouse models of RV infection and RV-induced exacerbation of allergic airway inflammation [1]. In vitro IL-25 gene induction was also assessed in allergic asthma tissue-incepted mast cells (BEC) infected with RV and stimulated with IL-4 in vivo and in vitro results demonstrated that RV induced IL-25 mRNA as measured by qPCR. Airway challenge with ovalbumin (OVA) followed by RV infection in sensitized mice exacerbated allergic airway inflammation and coincided with enhanced IL-25 mRNA expression compared with allergen or infection alone. Similarly, RV and IL-4 treatment of BECs resulted in the highest levels of IL-25 mRNA. The novel finding that RV infection induces IL-25 represents a link between antiviral responses and Th2 inflammation identifying a role for IL-25 in RV-induced AE. Allergen/IL-4 treatment enhanced RV-dependent IL-25 expression thus a Th2 environment and virus may result in exacerbated Th2 inflammation mediated by IL-25.

Mast cell distribution influences airway inflammation and hyperresponsiveness in a chronic model of asthma

Barbara Fuchs1,2, Lisa Sjöberg1,2, Christine Möller Westerberg2, Linda Swedin1, Sven-Erik Dahlén1, Mikhail Aurer1, Gunnar Nilsson2, Sven-Erik Dahlén1, Mikael Adner1, Gunnar Nilsson2.

In asthma pathogenesis, mast cells (MCs) may play a divergent role for allergic inflammation and airway hyperresponsiveness. Spatial location of MCs can contribute to symptom severity.

MC-deficient C57Bl/6 Kit-w/w-sh mice (ko), bone marrow-derived MCs reconstituted C57Bl/6 Kit-+/+ mice (bmmc-+/+) and wild-type controls (wt) were investigated in a 91-day ovalbumin model of chronic allergic airway inflammation.

Toluoline blue stained lung sections demonstrated a increased number of MCs in bmmc-+/+ mice compared to wt. Moreover, MC distribution differed between the study groups: in wt mice, MCs were located around central airways, while prominently found in the parenchyma and around smaller airways in bmmc-+/+ mice. These findings subsequently influenced important parameters: In BALF, total cell, eosinophil and neutrophil counts, were most pronounced in MC-deficient mice. Therefore, a protective role of MC in the manifestation of chronic inflammation is suggested.

Measurement of AHR using forced-oscillation technique revealed an increased hyperresponsiveness in the absence of MCs in the lung. In addition, the absence of MCs in the lung periphery exaggerates tissue reactivity, however, an increased number of bone-marrow derived MCs in the periphery even adds to the effect of MCs in the lung.

MCs can modulate processes leading to airway inflammation and airway hyperresponsiveness by their mere number, their tissue distribution, and possibly also their phenotype.

PP112
Stability of biomarkers in severe asthma – 1 year follow up study

Maciej Kupczyk1, Roelinde Middelveld1, Barbro Dahlén2, Sven-Erik Dahlén1.

In order to test the hypothesis of stability of phenotypes 93 patients with severe asthma (SA), 76 with mild-to-moderate asthma (MA) and 64 with COPD were screened and included in the BIOAIR study. The variable in clinical outcomes and biomarkers was followed for 1 year. Comparison of baseline vs 1 year revealed that there were no changes in QoL, FIV1/FVC and eNO in any of studied cohorts. There was a trend for decrease in FEV1 in % in MA and COPD patients but not in SA. The FEV1/FVC ratio decreased by 3% in SA (69.4±3 vs 66±1.2%, p=0.006, mean±SE). We found an increase in C-reactive protein in SA (3.6±6.1 vs 8.4±4.9 mg/ml, p=0.025), decrease in sputum eosinophils in MA (62.5±27.6 vs 49.9±21.9%, p=0.047) and increase in sputum eosinophils in COPD patients (0.8±1±1 vs 2.4±2.6%, p=0.01). There was no change in mean urinary LTE 4 concentration in EBC after 60 and 120 min after administration, comparing to placebo (5.34±3 μg/mmol (60 min), and 5.23±3 μg/mmol (120 min)) respectively. No influence of apocynin on safety parameters, and no adverse effects has been observed.

These data suggest that using apocynin might be a promising solution to alleviate inflammatory process, and probably, symptoms of inflammatory diseases.

PP114
Effect of inhaled apocynin on reactive oxygen species concentrations in exhaled breath condensate of asthmatics

Joanna Stefanska1, Agata Sarnicka2, Anna Wlodarczyk3, Milena Sokolowska1, Zbigniew Doniec4, Bartosz Nowak5, Rafał Pociejczak1.

In asthma pathogenesis, mast cells (MCs) may play a divergent role for allergic inflammation and airway hyperresponsiveness. Herenic, RV infection in sensitized mice exacerbated allergic airway inflammation and coincided with enhanced IL-25 mRNA expression compared with allergen or infection alone. Similarly, RV and IL-4 treatment of BECs resulted in the highest levels of IL-25 mRNA. The novel finding that RV infection induces IL-25 represents a link between antiviral responses and Th2 inflammation identifying a role for IL-25 in RV-induced AE. Allergen/IL-4 treatment enhanced RV-dependent IL-25 expression thus a Th2 environment and virus may result in exacerbated Th2 inflammation mediated by IL-25.

Background: Some epidemiologic studies have indicated that attendance to chlorinated swimming pools is associated with bronchial hyperreactivity, allergies and asthma.

Aim: To investigate the effects of NaClO, the main pool disinfectant, on allergic sensitization and airway responses in mice.

Methods: Male BALB/c mice received 1 to 7 nasal instillations of ovalbumin (OVA, 1%) on alternate days 10 min after instillation of NaClO (3 ppm active chlorine) or water. 48h after, 1, 3, 5 and 7 instillations, we measured airway reactivity to methacholine (Flexivent), cellular inflammation in broncho-alveolar lavage (BAL), lung cytokines, and serum OVA-specific IgE. Later, methacholine reactivity 48 h after a single combined NaClO-OVA exposure was assessed in mice pretreated with the neurokinin1 receptor antagonist RP67580, in knock-out mice deficient in the transient receptor potential (TRP) channel A1 (TRPA1−/−) or 1 (TRPV1−/−) and in mast cell deficient mice (Kit-w/w-Kit-w/−sh).

Results: Combined nasal NaClO-OVA exposure induced airway hyperreactivity (AHR) to methacholine in the absence of airway inflammation and OVA specific IgEs. AHR was already induced after a single combined exposure to NaClO-OVA and it was not observed after either OVA or NaClO alone. The AHR response was reduced after pretreatment with RP67580. NaClO-OVA induced AHR in TRPV1−/− mice, but not in TRPA1−/− mice.

Conclusion: Combined nasal NaClO-OVA exposure induces AHR in the absence of allergic inflammation. This effect appears to involve TRPA1, mast cells and release of substance P, suggesting a neuro-immune interaction.
families of receptors are one of the key components of the innate immune system. 

The function of these receptors has been linked with susceptibility towards the development of allergic diseases, including asthma, making the TLRs and NLRs good targets for novel effective therapies of allergic diseases. In this study the mRNA expression levels of different TLRs and NLRs in the lung tissue in mild and severe mouse models of allergic asthma were measured by q-PCR. In addition, broncho-alveolar lavage fluid (BALF) was collected and cell numbers counted. Increased in the mild and severe asthma models different TLR and NLR mRNA expression profiles are observed. In the severe asthma model, a higher cell influx in BALF is seen. Moreover, a significant correlation is found between the mRNA expression of TLR3, TLR6 and TLR9 and the total cell number in the BALF.

PP116 Association of IL-9 and IL-4R genes and their Phenotypes among Sudanese with Asthma

Amel Gundi, Omer A. Aziz Musa. The National Ribat University, Biochemistry, Khartoum, Khartoum, SD

Background: Asthma is a complex heritable disorder, candidate genes that may be involved in the pathogenesis of asthma including interleukin 4 (IL-4), IL-5, IL-9, and IL-13 (Postma et al. 1995). Asthma prevalence in Sudan was found to be 12.5% in children aged 13-14 year in the Capital Khartoum (Mohamed et al. 1999).

Objectives: To detect polymorphisms of IL-9 in chromosome 5 and IL-4R in chromosome16 contributing to asthma and to estimate the environmental components. Total immunoglobulin E levels, skin prick test, and eosinophil count in Sudanese population.

Methods: Seventy, nuclear and extended families were sampled in the initial phase of the study. Ventilatory function, skin, prick test blood sample for DNA analysis, immunoglobulin E, eosinophil count were carried out in the whole sample. Genotyping for IL-9 and IL-4R polymorphisms using PCR were also carried out for a subset of the sample.

Results: Phenotypic analyses of the pedigrees suggest a likely genetic cause for a subset of the sample.

Conclusions: Asthma runs in families showing strong linkage to genes. There seems to be sufficient phenotypic and genotypic indicators to suggest a genetic predisposition component to asthma among Sudanese, and warrant some further investigations.

PP117 Behavioural and structural differences in migrating peripheral neutrophils from patients with COPD

Elizabeth Sapey1, James Stockley1, Hannah Greenwood2, Robert Insall3, Janet Lord2, Robert Stockley4, 1University of Birmingham, Clinical and Experimental Medicine, Birmingham, GB; 2University of Birmingham, MRC Centre for Immune Regulation, GB; 3University of Glasgow, CR-UK Beatson Institute, Total immunoglobulin GB; 4University Hospital Birmingham NHS Foundation Trust, Lung Investigation Unit, Birmingham, GB

COPD neutrophils may behave differently than controls when migrating. This is important, as altered migration could drive pathological accumulation and lung damage.

Methods: We assessed neutrophil migration in 20 COPD patients, 20 healthy subjects (10 healthy smokers, 10 healthy never-smokers) and 20 patients with Alpha 1-Antitrypsin Deficiency (AATD).

Results: There were no differences in migration, structure or receptor expression in healthy smokers and non-smoking controls. COPD neutrophils moved with greater speed but reduced accuracy to all stimuli. E.g. fMLP: Speed, COPD μm/s (14.7±2.2) vs. healthy μm/s (10.5±0.8), P<0.001. There were no differences in receptor expression. E.g. α1-MLP: COPD 17.2 MFI (16-18 IQR), AATD 14.5 MFI (13-15), Healthy control, 16.2 MFI (10-30). Pseudopod formation and surface expression of mediator receptors were assessed. Neutrophils were incubated with their own, healthy control and COPD plasma, to determine if aberrant migration was inducible (with COPD plasma) or irreversible (with control plasma).

Conclusions: There were no differences in migration, structure or receptor expression in healthy smokers and non-smoking controls. COPD neutrophils moved with greater speed but reduced accuracy to all stimuli. COPD neutrophils moved with greater speed but reduced accuracy to all stimuli. AATD migrated more slowly than healthy controls, as indicated by a lower MFI for fMLP (17.2 vs. 14.5 MFI). Healthy neutrophils migrated with greater speed and accuracy than COPD neutrophils, as indicated by a higher MFI for fMLP (16.2 vs. 14.5 MFI). The results of this study suggest that COPD neutrophils may have altered migration that could contribute to the pathogenesis of COPD.

PP118 Inflammation and COPD: Protective effect of the recombinant anti-protease trappin-2 A26L, on lung epithelium

Anniebelle Tang, Alkmeen Kadi, Sandra Dallet-Chaisy, Marie-Louise Zani, Thierry Moreau. Inserm U618 Protéases et Vascularisation Pulmonaires, Université François Rabelais, Tours, FR

Introduction: Inflammation in chronic obstructive pulmonary diseases (COPD) results in a protease-anti-protease imbalance that leads to a massive release of neutrophil serine proteases (cathepsin 3 and cathepsin G). These proteases stimulate secretion of mucus and pro-inflammatory cytokines. In order to target serine proteases, we designed a recombinant inhibitor derived from trappin-2 which is able to inhibit all three proteases at the same time. The aim of the study was to evaluate the inhibitory, anti-inflammatory and anti-secretory effects of trappin-2 A26L on lung epithelium exposed to neutrophil serine proteases.

Methods: A549 cells were exposed to proteases for 24h with or without addition of T2A6L. Protective effect of T2A6L towards the degradation of cell junctions by proteases was analyzed by immunofluorescence. Levels of mucus secretion were determined by measuring the rate of expression of mucus genes and the anti-inflammatory activity of T2A6L was investigated by measuring the rate of pro-inflammatory mediators release after LPS stimulation.

Results: Neutrophil serine proteases proteolytically degrade cellular junctions and increase mucin gene expression. T2A6L added to the culture medium inhibits the degradation of cell junctions proteins (E-cadherin, ZO-1), decreases MUC5AC and MUC1B mRNA expression induced by elastase and IL-6 and IL-8 productions.

Conclusion: Our results demonstrate that T2A6L exhibits anti-protectolytic, anti-inflammatory and anti-secretory effects. This new, anti-protease may therefore be of therapeutic value in treating inflammatory lung diseases.

PP119 Lymphangiogenesis in chronic obstructive pulmonary disease (COPD)

Georgia Hardavella1,2, Elena Tzortzaki3, Vasiliki Stergiou3, Georgia Tzamalis3, Elena Vlachakis1, Dimitrios Stefanou1, Nicola Sifaifas2, 1Medical School, University of Ioannina, Department of Pathology, Ioannina, GR; 2Medical School, University of Ioannina, Department of Respiratory Medicine, Ioannina, GR; 3Medical School, University of Crete, Department of Thoracic Medicine, University Hospital, Heraklion, GR; 4University of Athens, Department of Evaluation of Health Care Services, Athens, GR

Introduction: Lymphangiogenesis has been reported to be driven by mediators (e.g. hyaluronic acid) and inflammatory cells (e.g. activated CD11b+ macrophages), both commonly met in COPD. We hypothesized that lymphangiogenesis is part of COPD pathogenesis.

Aims and objectives: To investigate the lymphangiogenetic expression in COPD measuring the lymphatic microvessel density (LMVD) and the correlation with the presence of lymphatic invasion (LI), clinical and laboratory parameters.

Methods: Lung surgical specimens from 20 smokers (10 COPD-smokers (30% stage 2 GOLD) and 10 non-COPD smokers) with mean age of 62.6 years (range 38-82) were immunohistochemically stained for D2-40 and LYVE-1. Calculation of LMVD and assessment of LI were performed and correlation with clinical and spirometric data was evaluated.

Results: D2-40 and LYVE-1 were expressed in all specimens presenting higher expression (LMVD) in COPD-smokers (p=0.00). LI was presented in all COPD specimens. D2-40 and LYVE-1 LMVD were associated with the presence of COPD (r=0.20, p<0.01), smoking status (r=1.8, p<0.09), and disease severity (GOLD) (r=0.40).

Conclusions: D2-40 and LYVE-1 being selective lymphatic endothelial markers were highly expressed in COPD specimens in comparison with non-COPD smokers and associated with clinical and spirometric data. Our results reported for the first time the presence of newly formed lymphatic vessels in COPD, thus providing a novel insight in the pathogenesis of COPD including lymphangiogenesis.

PP120 Cigarette smoke-induced lung emphysema in mice is associated with prolyl endoproteasidase, an enzyme involved in collagen breakdown

Gert Folkerts1, Saskia Braber1, Paul Henricks1, Aletta Kruyenfeld1,Pin Koelink2, Patricia Jackson2, Edwin Bilakoe2, Frans Nijkamp1, 1Utrecht Institute for Pharmaceutical Sciences, Faculty of Sciences, Utrecht University, Division of Pharmacology, Utrecht, 2Allergy and Critical Care Medicine, UAB Health Center, University of Alabama at Birmingham, Department of Medicine, Division of Pulmonary, Birmingham, Alabama, US

There is increasing evidence that the neutrophil chemoattractant proline-glycine-proline (PGP), derived from the breakdown of the extracellular matrix, plays an important role in neutrophil recruitment to the lung. PGP formation is a multistep process involving neutrophils, metalloproteases (MMPs) and prolyl endopeptidase (PE). This cascade of events is now investigated in the development of lung emphysema. Mice were whole body exposed to cigarette smoke for 1 week or 2 weeks. After 1 week, 20 weeks or 8 weeks after smoking cessation animals were sacrificed and bronchoalveolar lavage fluid and lung tissue were collected to analyze neutrophilic airway inflammation, MMP-9 levels, PE activity and PGP levels. Lung tissue degradation was assessed by measuring the mean linear intercept. Additionally, we investigated the effect of the peptide, L-arginine-threonine-arginine
(RTR), that bind to PGP sequences, and the PE inhibitor valproic acid (VPA) on the smoke-induced neutrophil influx in the lung after 1 week smoke exposure. The amount of neutrophils, MMP-9 levels, PE activity and PGP levels were elevated in the lungs of cigarette smoke-exposed mice, while after smoking cessation these parameters were decreased or reduced to normal levels. PE was highly expressed in epithelial and inflammatory cells in lung tissue of cigarette smoke-exposed mice. Moreover, RTR and VPA inhibited the air-estricted neutrophil influx in the lung after 1 week smoke exposure. Together with MMPs, PE may play an important role in the formation of PGP and thus in the pathophysiology of lung emphysema.

This work was performed within the framework of the Dutch Top Institute Pharma Project Ti-103.

PP121
Mononuclear inflammation and alveolar airspace enlargement following targeted deletion of GαqGβ11 in surfactant protein C-positive epithelial cells
Alison E. John1, Joanne Porte1, Lisa Jolly1, Amanda L. Tatler1, Stefan Offermanns2, R. Gisli Jenkins1.1 University of Nottingham, Centre for Respiratory Research and Respiratory Biomedical Research Unit, Nottingham, GB; 2Max-Plank-Institute for Heart and Lung Research, Department of Pharmacology, Bad Nauheim, DE
Activation of latent transforming growth factor beta (TGFβ) by the epithelia-restricted αvβ6 integrin is induced by activators of the RhoA signalling pathway and is important in the pathogenesis of lung injury and fibrosis. To establish the role of G-proteins in normal lung development and lung injury, we generated mice with targeted deletion of the α-subunits of Gq11 or G12/13 in Surfactant protein C (SpC)-positive epithelial cells. Lungs were collected 6 and 8 weeks after birth, perfused, fixed by inflation with formalin and processed for immunohistochemical and histochemical analysis.

At 6 weeks, lungs from SpfC-GαqGβ11 knockout mice contained inflammatory infiltrates of primarily mononuclear leukocytes. Inflammation was associated with localised disruption of alveolar architecture and appearance of enlarged alveolar macrophages within alveolar spaces. At 8 weeks, inflammatory foci were more numerous and lung architecture was severely disrupted with multiple abnormally large alveolar spaces detected. In the SpfC-Cre Gαq-Gβ11 lungs, apoptosis was detected in areas of abnormal alveolar architecture containing alveolar macrophages and inflammatory cells but did not co-localise with pro-SpC-positive cells. We detected no abnormal lung phenotype in the SpfC-Cre GαsG12Gβ13 knockout mice at any time point.

These data suggest that a deficiency in Gq11 signalling results in pulmonary inflammation and increased alveolar airspace size. The phenotype is consistent with a role of G-proteins in assessing defects in TGFβ signalling in vivo. Further studies are required to determine whether there are any abnormalities in TGFβ activation in these animals.

PP122
IL-1β drives lung dysfunction and inflammation during viral-induced exacerbations of COPD
Anke Siechelsiel1,2, Yoshikazu Yadawa1,2, Aurélien Trompette1,2, Benjamin J. Marsland1, CHUV (Centre hospitalier universitaire vaudois), Service de Pneumologie, Lausanne, CH; 2University of Lausanne, Faculty of Biology and Medicine, Lausanne, CH
Chronic obstructive pulmonary disease (COPD) is one of the world’s leading diseases predicted to be the 3rd highest cause of death by 2030. Acute exacerbation of COPD can be caused by bacterial and viral infections and is linked to enhanced recruitment of inflammatory cells to the airways, and to increased levels of several inflammatory mediators, such as IL-1β. It remains unknown whether IL-1β is simply an indicator of the inflammation or whether it actively participates in the cellular recruitment and acute lung dysfunction during exacerbations of COPD. We induced COPD in IL-1β-deficient mice by administration of LPS and elastase over 4 weeks; notably, IL-1β did not appear to influence the development of COPD. We then induced an exacerbation of COPD by infecting these mice with Influenza virus. Mice lacking IL-1β showed reduced exacerbation scored by the influx of neutrophils to the airways and by lung dysfunction measured by oxygen saturation and partial pressure of O2 and CO2 in the blood. This was associated with decreased levels of IL-17A (a cytokine leading to the recruitment of neutrophils) by μ and ν T cells. In support of these data, we found that treatment of mice with the IL-1R antagonist, Anakinra (Kineret®), prior to infection provided a comparable level of protection against lung dysfunction. Interestingly, IL-1α partially participated in the virus-induced exacerbation as ν T cell (but not μ) T cell recruitment, IL-17 production and neutrophil recruitment were reduced in IL-1α-deficient mice. These data reveal an important role for IL-1 in virus-induced exacerbations of COPD and highlight the possibility of the use of therapeutic targeting this pathway for treatment.

PP123
Lung CD8+ T cells induce apoptosis of autologous lung target cells in COPD
Christine M. Freeman1,2, Fernando J. Martinez1, MeiLan K. Han1, Stephen W. Chernick2,1, Doug A. Arentsen1, Catherine A. Meldrum1, Lisa McCloskey1, Deborah L. Thompson1, Jeffrey J. Curtis1,2, University of Michigan Health System, Ann Arbor, MI, US; 3VA Medical Center, Ann Arbor, MI, US
Introduction: CD8+ T cells are implicated in COPD pathogenesis, yet whether they induce apoptosis of structural lung cells is unknown. CD8+ T cell cytotoxicity and unced when their NKG2D receptor binds ligands upregulated by stressed cells. In human lung biopsies, expression of an NKG2D ligand, MICA, is associated with emphysema.
Objectives: We hypothesized that lung CD8+ T cells contribute to COPD progression by killing autologous lung cells via interactions between NKG2D and MICA.
Methods: We used lung tissue from clinically-indicated resections for flow cytometry (n = 30) to analyze expression of NKG2D on CD8+ T cells and MICA on CD326+ epithelial cells. Results, as a % of positive cells and mean fluorescent intensity (MFI), were correlated to FEV1, % predicted and radiographic emphysema scores using Spearman statistic. Additionally (n=12), isolated lung CD8+ or CD4+ T cells were co-cultured with the remaining “target” cells for 4 hours, then viability was analyzed by annexin V7-AAD staining.
Results: Co-culture with lung CD8+ T cells, but not CD4+ T cells, significantly decreased target cell viability and this decrease was significantly greater in COPD patients. NKG2D MFI on lung CD8+ T cells was highly correlated with emphysema severity; but not FEV1 % predicted. Expression of MICA on lung CD326+ epithelial cells correlated directly with emphysema severity and inversely with FEV1 % predicted. MICA and NKG2D MFI within individual patients correlated strongly.
Conclusions: These results imply that lung CD8+ T cells, but not CD4+ T cells, can kill autologous lung cells and that increased expression of NKG2D and MICA may be contributing to the pathogenesis of emphysema.

Cigarette smoke-induced inflammation promotes melanoma cell metastasis in lung parenchyma
Sandrine Beckaert, Natacha Rocks, Maud Guerds, Geneviève Paulissen, Agnès Noel, Didier Cataldo. University of Liège, Laboratory of tumor and development biology, Liège, Liège, BE
It is only during the last decade that clear evidence has been obtained that inflammation plays a critical role in different stages of tumor development, including initiation, promotion, metastasis and angiogenesis. The increase in evidence that an inflammatory microenvironment is an essential component of all tumors (Paal and Lyden, Nat Rev Cancer, 2009 Apr;9(4):285-93). In the present study, we assessed in vivo the impact of cigarette smoke (CS) on the tumor cell extravasation in lungs after tail vein injection of B16F10 melanoma cells. We first characterized airway inflammation obtained after smoke exposure (reference cigarettes IR4F) for varied time periods (1, 2, 4, 8 and 12 weeks). Smoke exposure was performed 5 days a week. Neutrophils, alveolar macrophages, interstitial macrophages, dendritic cells, T cells and natural killer T (NKT) cells, were characterized in lung tissues of mice exposed to CS and AIR using flow cytometry. In vitro, the direct effect of cigarette smoke extract (CSE) on proliferation of B16F10 melanoma cells was determined for 1 to 5 days. In vivo, mice exposed for 2 weeks to cigarette smoke or air were injected with B16F10 melanoma cells in the tail vein. After 3 weeks, hematoxylin and eosin stained lungs were analyzed for lung metastasis (tumor area/total lung area). An increase of metastasis and implantation site in lungs was observed in CS exposed group. Conceivably, CS constituents significantly promote extravasation of melanoma cells in lung tissues. The mechanism or signaling pathway responsible for this dissemination needs to be further investigated.

Identification of a steroid-insensitive sub-population of macrophages in COPD lung
Kirandeep Chana1, Terry Woolley2, Peter Barnes1, Louise Donnelly1, 1National Heart and Lung Institute, Imperial College London, Airway Disease, London, London, GB; 2AstraZeneca, Drug Discovery, Loughborough, GB
In COPD, alveolar macrophage numbers are elevated and released increased levels of inflammatory mediators but respond poorly to glucocorticosteroids. Identifying the cells from tissue residue of cytokines and separated using Percoll density gradients (A:10-20%, B: 20-30%, C:30-40%, D:40-50%, E:50-60%). Viability and responses to budesonide following stimulation with lipopolysaccharide (LPS) were investigated by measuring CXCL8, TNFα, MIP-2 and IL-10 release by ELISA. Fraction C and B were apoptotic or necrotic, whereas the remaining fractions were >70% viable and used for analysis. Budesonide inhibited LPS-stimulated TNFα release by fraction C smoker macrophages in a concentration-dependent manner (IC50=1±1.1±0.8nM). This inhibition was not seen in COPD macrophages. Fraction C COPD macrophages were significantly less sensitive to budesonide with respect
COPD is a chronic inflammatory disease mainly caused by cigarette smoke (CS) and characterized by infiltration of (activated) inflammatory cells. Airway smooth muscle (ASM) and epithelial cells also contribute to inflammatory cytokine release, smooth muscle contraction, and airway remodeling. Notably, cAMP-elevating β2-agonists and phosphodiesterase inhibitors differentially diminish COPD symptoms. Compartamentalization of cAMP by AKAPs could explain distinct cAMP responses. In human ASM and epithelial cells, CS-induced IL-8 release was decreased by fenoterol, the PKA activator 6-bnz-cAMP, while the Epac activator 8-pCPT-2'-OcAMP showed only slight effects. Addition of PKA-AKAP mimetics to an inhibitor H83 augmented the IL-8 release. Exposure of epithelial cells to CSE reduced barrier function, and redistributed E-cadherin from cell-cell contacts. RII overlay, western blots and RT-qPCR demonstrated expression of AKAP79, AKAP250 and AKAP450. CSE decreased AKAP250, whereas AKAP79 was less affected and AKAP450 even enhanced, indicating disturbance of AKAP functions by CSE. Importantly, similar changes in AKAP expression were found in lung tissues of COPD patients. Our studies provide the first relation between cigarette smoke and the coordination of cAMP signaling by AKAPs. Supported by the Dutch Asthma Foundation and a Rosalind Franklin Fellowship.

**Suppression of antitumor immunity as a potential link between inflammation and cancer in COPD**

Sergio Scrimini1, Jaime Pons de Ves2, Angel Rios2, Amanda Iglesias Coma1, Rocío Cordoba1, Francesca Polverino1, Álvar Aguastí2, Francesca Polverino4, Alvar Agustí6, Jaume Sauleda Roig1.

**Background:** COPD is an independent risk factor for lung cancer. Chronic inflammation facilitates tumor development through non immune and immune mechanisms including the penetration of myeloid cells resulting in dysfunction of Ag-presenting cells and dysfunctional cell-mediated antitumor immunity. We hypothesize that chronic systemic inflammatory character of COPD is associated with an expansion of cell populations that suppress antitumor immunity and that these changes are even more evident in COPD with lung cancer (LC).

**Methods:** The percentage of myeloid derived suppressor cells (MDSC) and dendritic cells (DCs) from blood was quantified by flow cytometry in 18 patients with COPD (mean ± SD, FEV1 = 68±14% pred); 17 smokers with normal lung function (SC) (FEV1 = 104±15% pred) and 20 non-smokers (NSC) (FEV1 = 101±20% pred).

**Results:** COPD patients had an increased number of MDSC (median, range: 79.2; 817 cells x μl−1) as compared to NSC (21.1; 338; p<0.002). In addition they showed a reduced percentage of DCs with respect to NSC (10.4; 1.6%; 0.6%; 8%; p<0.02, respectively). To test whether the presence of LC influences these cell populations we compared COPD patients with patients with LC but we did not find any statistically significant result. However, the ratio between MDSC/DC progressively increased in patients with COPD and LC (NSC: 0.6; SM: 1.2; COPD: 2; SM LC: 2.3; COPD LC: 3.3).

**Conclusions:** In COPD patients there is an altered pattern of blood MDSC and DCs suggesting a blunted antitumor immunity in this disease as a potential link between inflammation and cancer. These findings are similar to those evident in patients with LC.

**Oxidative DNA damage in non-CF bronchiectasis: Differences with COPD**

Gurin Neofytou1, Kateryna Dimakova2, Katrina Samara1, Kyriaki Tsiriknakis3, Maria Avgousti1, Nikolaos Siafakas3, Eleni Tzortzaki2.

**Introduction:** Oxidative stress is believed to play an important role in the pathophysiology of chronic inflammatory airway diseases such as chronic obstructive pulmonary disease (COPD) and non CF-bronchiectasis. Activation of immune and inflammatory cells associated with the generation of reactive oxygen and chemical messengers such as tobacco smoking induces a marked production of oxidants.

COPD is an inflammatory lung disease characterized by chronic airflow obstruction, which is not fully reversible and is due to the chronic exposure to cigarette smoke or other ambient pollutants. The disease is associated with a significant increase in mortality and morbidity, and is a leading cause of hospitalization and healthcare costs. The pathogenesis of COPD is complex and involves the interaction of numerous cellular and molecular pathways. One of the key mediators in the inflammatory response in COPD is the Activating Factor (BAFF) which is a member of the tumor necrosis factor (TNF) family and plays a crucial role in the regulation of B-cell development and survival. BAFF binds to three receptors: TNFRSF13A, TNFRSF13B, and TNFRSF17, which are expressed on B cells, activated T cells, and dendritic cells, respectively. BAFF is involved in the recruitment and activation of regulatory T cells (Tregs), which play a critical role in maintaining immune homeostasis and preventing autoimmune diseases.

The paper by Francesca Polverino and colleagues investigates the role of BAFF in the interaction between T regulatory and B cells in chronic obstructive pulmonary disease (COPD). The study found that BAFF expression is increased in COPD patients compared to healthy controls. BAFF expression in B lymphocytes and Tregs was higher in COPD patients, especially in smokers, suggesting a potential role of BAFF in the pathogenesis of COPD.

BAFF expression in B lymphocytes and Tregs from COPD patients was measured using flow cytometry. The results showed a significant increase in BAFF expression in B lymphocytes and Tregs from COPD patients compared to healthy controls. The levels of BAFF expression were higher in smokers and COPD patients than in non-smokers and healthy controls. The increased expression of BAFF in COPD patients suggests a potential role of BAFF in the pathogenesis of COPD.

**Methods:** Peripheral blood mononuclear cells of COPD patients and healthy controls were isolated and stimulated with anti-CD3 and anti-CD28 antibodies. BAFF expression was measured using flow cytometry. The results were analyzed using statistical software.

**Results:** The authors found a significant increase in BAFF expression in B lymphocytes and Tregs from COPD patients compared to healthy controls. BAFF expression was higher in smokers and COPD patients than in non-smokers and healthy controls. The increased expression of BAFF in COPD patients suggests a potential role of BAFF in the pathogenesis of COPD.

**Conclusions:** The study by Francesca Polverino and colleagues provides evidence for the potential role of BAFF in the pathogenesis of COPD. The increased expression of BAFF in B lymphocytes and Tregs suggests that BAFF may contribute to the chronic inflammatory process in COPD. Further studies are needed to investigate the mechanisms by which BAFF contributes to the pathogenesis of COPD and to explore the potential therapeutic targets for the treatment of COPD.
Conclusion:

TLR 9 KO animals and the controls.

Chronic obstructive pulmonary disease (COPD) is characterized by septal tissue inflammatory cell influx changes in the lung. TLR 9 deficiency does cause an increase in smoking, and evidence suggests that innate and specific immune cells are involved. Cigarette smoke-concentration determines dynamics of inflammatory cell infiltration. Results: Bronchoalveolar lavage (BAL) fluid of 7 months old TLR 9-/- and wild type C57BL/6 (WT) was examined for total and differential cells. Total BAL cells, macrophages, and lymphocytes were increased after exposure to 350 ppm CSE for 1 day compared to controls. Total BAL cells were 30% increased in TLR9-/- mice. Differential cell count showed only increased numbers of macrophages. CpG increased TNF-α and IL-6 production by bronchoaveolar lavage- and lung homogenate cells. RNA expression of proinflammatory genes in lung tissue was used to determine mRNA expression of proinflammatory genes TNF-α and MIP-2 by quantitative real-time PCR. Neutrophils were significantly increased after exposure to cigarette smoke-concentrations of 250 mg/m³ for 1 day and 3 days compared to control animals, whereas macrophages and lymphocytes were elevated after exposure to 350 mg/m³ for 3 days. Exposure to concentrations of 500 mg/m³ led to an increase in macrophages only, which was associated with an increased mRNA expression of TNF-α and MIP-2.

The results demonstrate that cigarette smoke-concentration determines the dynamics of inflammatory cell recruitment in an acute COPD mouse model. Female C57BL/6 mice were exposed to cigarette smoke-concentrations of 250, 350, and 500 mg/m³ total particulate matter for 4 hours per day for 1 and 3 days. Animals were sacrificed 24 h after the last exposure. Control animals were kept in a filtered air environment. BAL fluid was obtained to perform differential cell counts and lung tissue was used to determine mRNA expression of proinflammatory genes TNF-α and MIP-2 by quantitative real-time PCR. Neutrophils were significantly increased after exposure to cigarette smoke-concentrations of 250 mg/m³ for 1 day and 3 days compared to control animals, whereas macrophages and lymphocytes were elevated after exposure to 350 mg/m³ for 3 days. Exposure to concentrations of 500 mg/m³ led to an increase in macrophages only, which was associated with an increased mRNA expression of TNF-α and MIP-2.

The results demonstrate that cigarette smoke-concentration determines the dynamics of inflammatory cell recruitment in an acute COPD mouse model. Male and female C57BL/6 mice were exposed to cigarette smoke-concentrations of 250, 350, and 500 mg/m³ total particulate matter for 4 hours per day for 1 and 3 days. times observed. The levels of proinflammatory cytokines IL-1β, IL-6 and IFN-γ were significantly increased in rats exposed to TS compared to FA animals. Airway obstruction was noted as a significant elevation in central airway resistance (Rn) and tissue damping (G) (small airway and tissue resistance). Rn was increased at 4 weeks, reduced at 6 weeks and significantly elevated at 10 and 12 weeks. G was significantly increased at 4 weeks, followed by a slight decrease that remained significantly elevated through 12 weeks. Significant correlations between IL-1β, IL-6, IFN-γ, TNF-α and degree of tissue damping were noted.

**Conclusions:** Progressive airway obstruction and abnormal inflammatory response to smoke in this rat model of COPD is associated with dysregulated immune responses and impaired physiological lung function. Elucidation of those mechanisms underlying immunologic alteration specific to tobacco smoke in this rat model of COPD could significantly contribute to a better understanding to treat chronic inflammatory lung diseases.

Chemokine Expression by small sputum macrophages in COPD
Marion Frankenberger1, Thomas Hofer1, Irene Heimbeck2, Winfried Möller3, Loemerscheidt4,4.1 Helmholtz Center Munich, CPC Comprehensive Pneumology Center, Munich, DE; 2 Homboldt Center Munich, EsA Study Center, Gauting, DE; 3 Helmholtz Center Munich, Center of Lung Biology and Disease, Neunetzhof, DE

Small sputum macrophages represent highly active cells that increase in the airways in patients with inflammatory disease like chronic obstructive pulmonary disease (COPD). Using macrophage purification and flow cytometry we now show that in COPD these cells account for 85% compared to 13% in control donors. When looking at chemokine expression we found for the small macrophages in COPD an increased transcript and protein levels for CCL2, CCL7, CCL13 and CCL22 with a more than 100-fold increase for CCL13 mRNA. Looking at active smokers without COPD there is a substantial increase of small macrophages to 60% and here chemokine expression is increased as well. In a model of airway inflammation healthy volunteers inhaled 200 μg of lipopolysaccharide (LPS) and this resulted in an increase of small sputum macrophages from 18% to 64%. The pattern of chemokine expression was, however, different with an up-regulation for CCL2, CCL7, CCL13 while CCL11 was down-regulated in the LPS induced small macrophages. These data demonstrate that sputum macrophages in COPD show induction of a specific set of CCL chemokines. Is distinct from which can be induced by LPS.

MMP8, MMP9 and TIMP1 mRNA & protein expression is upregulated in patients with chronic obstructive pulmonary disease (COPD)
Martin Petrek1, Zdenka Navratilova1, Jaromir Zatloukal2, Eva Kriegerova1,2, Vitomir Kubilus1,2. Toler University, Laboratory of Immunogenetics and Proteomics, Olomouc, CZ; 2 Faculty Hospital, Department of Respiratory Medicine, Olomouc, CZ; 3 Faculty Hospital, Division of Clinical Biochemistry & Immunogenetics, Olomouc, CZ

Matrix metalloproteinases (MMPs) and their tissue inhibitors of (TIMPs) have been implicated in pathogenesis of COPD. Information about their expression locally in the lung is limited and about their association with the risk of recurrent exacerbations in COPD patients has been limited. To determine local/systemic levels of MMPs and TIMPs in COPD patients/control subjects. To evaluate plausible relationship between MMPs/TIMPs and COPD exacerbations. MMP2,8,9 and TIMP-1 mRNA & protein expression were investigated in bronchoalveolar lavage (BAL) cells and fluid in 28 COPD patients and 28 control subjects using qRT-PCR and xMAP technology. In parallel, MMP2,3,7,8,9,10 and TIMP-1 were determined in serum. COPD was diagnosed according to GOLD criteria; number of exacerbations assessed during 2 years follow-up. Mann-Whitney U test/Spemann’s correlation test were used for statistics. Compared with controls, increase of MMP8,9 mRNA and of MMP8,9 protein was detected in COPD BAL cells/fluid; MMP8,9 were increased in patients’ serum, together with MMP1 and MMP7. Of studied TIMPs, TIMP1 and TIMP2 proteins were upregulated in COPD BAL fluid, TIMP3 mRNA in diseased BAL cells; TIMP1 and TIMP4 were increased in serum. Number of COPD exacerbations correlated with serum MMP3 concentration and also with the MMP3/TIMP3-1 ratio. In our COPD cohort, MMP8, MMP9 and TIMP1 were upregulated both locally and systemically. Moreover, serum MMP3 and its ratio to TIMP1-3 correlated with the number of exacerbations in our patients. Studies are required to confirm MMP3 as a marker for assessment/diagnosis of exacerbations. Support: IGAMZCR 10267; PUL 2010/008.

The role of lipoxin A₄ in the chronic obstructive pulmonary disease
LigaBalode1, GuntaStrazda1, NormundsJuta1, UldisKopeika2, AgneseKisilina1, MarinaBeinare1, MarisBukovskis2, ImmanuelsTaimans1.1 University of Latvia, Faculty of Medicine, Riga, LV; 2 University of Latvia, Institute of Experimental and Clinical Medicine, Riga, LV

**Aim:** Chronic obstructive pulmonary disease (COPD) is characterized by persistent inflammatory reaction with a dominance of neutrophil involvement. It is established, that during a healing of acute inflammation, a switching of arachidonic acid (AA) metabolism from leukotriene (LT) to lipid (LX) production occurs. Therefore we hypothesized that in COPD patients the lipoxin production could be insufficient. Hence we measured the content of LXA₄ and LtB4 in induced sputum supernatant in COPD patients and healthy subjects.

**Materials and methods:** 17 COPD patients and 7 healthy persons were studied. The age and gender ratios were similar in both groups. Sputum induction was performed according to the ERS protocol. LXA₄ and LtB4 content in sputum supernatant was assessed by ELISA.

**Results:** COPD patients had decreased concentration of LXA₄ in induced sputum compared to healthy persons (0,514 ng/ml and 1,310 ng/ml, respectively, p=0,00784). LtB4 content in induced sputum did not significantly differ between COPD group and healthy persons group (3,551 ng/ml and 3,754 ng/ml, respectively). The ratio LtxB₄/LXA₄ in COPD patients was three times higher compared to healthy persons (ie. 9,816 ng/ml and 3,425 ng/ml; p=0,00982).

**Conclusions:** We concluded that the chronic obstructive lung disease is characterized by suppressed production of lipoxins. This insufficiency may be responsible for a persistence of neutrophil inflammation in airways.

PP140

Chronification of pulmonary inflammation in a nanoparticle exposure model
Tobias Stoger, Stephanie Him, Furong Tian, Shinji Takahama, Wolfgang Kreyling, Oliver Eickelberg. Comprehensive Pneumology Center, Helmholtz Zentrum München, Munich, DE

While inflammatory responses to pulmonary deposited carbon nanoparticles (NP) are of transient nature, fibroblasts and macrophages may play a key role in the transition from acute to chronic inflammation.

We analyzed the inflammatory responses provoked by spherical carbon NP (CNP) and nanotubes (CNT) up to day90 after intratracheal instillation in mice. We propose that our detailed comparisons could help to understand underlying mechanisms of non-resolving, chronic inflammation.

Instillation of 50ng CNP or CNT caused acute pulmonary inflammation in mice, characterized by an influx of 200-240×10³E3 neutrophilic leukocytes, recovered byavage (BAL) respectively. A reaction resolved by 75% at day7 and completely till day90 after CNP exposure, but only by 40% at day7 with 46×10³E3 neutrophils remaining at day90 for CNT treatment. Chronification of non-resolved inflammation upon CNT treatment was further indicated by till day90 increasing lymphocyte and macrophage counts, accompanied by multinucleated macrophages, a sign for impaired particle phagocytosis. Comparing fractions of particle laden BAL macrophages at day7, revealed for CNT 20% but over 60% for CNP exposed mice. At this stage immunohistochemistry identified highest expression of Gal-C3m, a marker for alternatively activated macrophages with proinflammatory activity, in particle-free but not in particle-laden BAL macrophages.

These data suggests that newly recruited macrophages, rather than unsuccessful phagocytosing, resident cells might contribute to conditions of chronic inflammatory and fibrotic diseases.

PP141

The relationship of CD4+/CD8+ ratios and Toll like receptor-2 expression with COPD and smoking
Gurud Sahin Ulutas1, Aylin Orgen Alpaydin2, Fatma Taneli1, CemileCetinkaya1, Cevval Ulan1, Yesim Guven1, Gomul Dunc1, Ayson Gurol Sahin Ulutas. 1 Celal Bayar University Medical Faculty, Department of Pulmonary Diseases, Manisa, TR; 2 Celal Bayar University Medical Faculty, Department of Public Health, Manisa, TR

**Aim:** Native immune system activates acquired immunity by Toll Like Receptors (TLR). There may be some alterations in T cell profile and TLR expression in peripheral blood monocytes of COPD patients. We aimed to evaluate the utilization of the ratio of CD4, CD8 T cells and TLR-2 expression as a marker of lung pathology as well as their relationship between pulmonary function tests in COPD patients and smokers.

**Method:** Forty stable COPD patients admitted to our university’s outpatient clinic and 40 volunteers were included in the study. The study population was evaluated in 4 groups according to their smoking status. CD4+, CD8+ T cells and monocyte TLR-2 expression was measured by flow cytometry in patients and control groups. Spironometry was performed in the whole study population except for nonsmoker control group.

**Results:** TLR-2 expressions investigated in CD14+ cells were found %5±6.2% in Group 1 (nonsmoker COPD), %6.5±6.3% in Group 2 (smoker COPD), %6.4±4.4% in Group 3 (healthy smoker) and %5.2±2.5% in Group 4 (healthy nonsmoker), any difference was not observed between the groups. CD4+, CD8+ T cells and CD4+/CD8+ ratios were not found to be different between the groups. CD4+ T cells and FeV_, FeV/FcV also had a positive correlation (r=0.311, p=0.01; r=0.293, p=0.023, respectively). CD4+/CD8+ ratios and FeV/FcV also showed positive correlation (r=0.295, p=0.022). Smoking amount and CD4+/CD8+ ratios had a negative correlation (r= -0.274, p=0.034).

Chronic obstructive pulmonary disease (COPD) is characterized by an abnormal inflammatory response to tobacco smoke. COPD patients frequently present exacerbation episodes (ECOPD) involving increases of the inflammation, these exacerbations are mainly due to bacterial infections. Aims: Evaluate the functionality of TLRs and NLRs in peripheral blood cells of COPD patients both during stable and exacerbated disease. Methods: 48 individuals were included in the study: 11 healthy controls, 8 healthy smokers, 13 stable COPD and 9 exacerbated COPD seven of which were reanalyzed 3 months later at stability phase. PBMCs were isolated and stimulated with agonists of TLR4, TLR5, NOD1 and NOD2. The level of IL-1β, IL-6 and TNF-α produced in the supernatant was assessed. Results: PBMCs from patients with ECOPD produced lower amounts of IL-6 in response to TLR4, TLR5, NOD1 and NOD2 and levels of IL-1β in response to NOD1 and NOD2. The level of IL-1β and TNF-α synthesised exponenlately and in response to TLR5 and TLR9 did not differ among the groups. In patients with stable COPD the severity of an immune interaction and the capacity to synthesize IL-1β in response to TLR-4, TLR5 and NOD1 correlate. Conclusions: The functionality of the TLRs and NLRs and the ability to response bacterial stimuli is different in patients with stable COPD and exacerbated COPD.

Evaluation of morpho-functional changes in airways of young cigarette smokers

Agnes Kósi1, Gunta Strazda1, Liga Balode1, Marina Braine1, Nonna Juntik2, Immanuel Tavern1,1. University of Latvia, Faculty of Medicine, Riga, LV; 2. University of Latvia, Faculty of Medicine, Riga, LV

We assumed that even in asymptomatic young smokers, with relatively short smoking duration and normal lung function, induced sputum could be found some changes indicative for early inflammatory process. Aims: The aim of this study was to evaluate morpho-functional changes in airways of young cigarette smokers.

Method: We enrolled 23 ± 3 years old 12 non-allergic smokers (1.59 ± 0.67 pack-years) and 7 healthy non-smoking volunteers. Lung function measurements, sputum induction and sputum cell analysis were performed.

Results: Demographic data for both study groups did not differ significantly. Non-smokers and smokers had normal lung function indices. In smokers induced sputum contained statistically significantly (p=0.026) increased relative count of eosinophils 0.923 (0.355-1.753) % compared with non-smokers 0.069 (0.046-0.550) %. We also found significant reduction of absolute (r =0.402; p=0.0872) and relative (r=0.482; p=0.037) count of bronchial epithelial cells in induced sputum that correlated to number of smoked pack-years. A trend towards statistical significance showed the correlation between smoked pack-years and the relative number of macrophages in induced sputum (r =0.402; p=0.0872). A trend towards statistical significance was also found in correlation between smoked pack-years and diminished FEV1% of predicted (r =-0.463; p=0.046). Conclusion: In this study we showed that even smokers with short duration of the smoking habit have already initial signs of inflammation with eosinophil involvement.

Evaluation of morpho-functional changes in airways of young cigarette smokers

Elastase is inducing irreversible emphysema correlated with impaired pulmonary function in mice

Alexandra Geyer1,2,3,4, Ulrich Koethe1, Gerit John, Melanie Königshöfer, Oliver Eickelberg, Ali Onder Yildirim, 1. Institute for Lung Biology and Disease, Helmholtz Zentrum Munich, Neuhberg, DE; 2. University for Technology and Business in Dresden, Dresden, Germany; 3. Fundació Caubet Cimera, Palma de Mallorca, Illes Balears, ES; 4. Cibers´ Enfermedades Respiratorias, CIBERES, Barcelona, Catalunya, ES

Rationale: Chronic obstructive pulmonary disease (COPD) is characterized among others by development of emphysema, which is known to occur as a result of imbalance of proteases and antiproteases. A variety of enzymes, like neutrophil elastase and matrix metalloproteinase 12 (MMP-12), are capable of de-stressing parenchymal tissue, causing loss of alveolar and airway enlargement in the lung. We showed that a single application of porcine pancreatic elastase (PEE) causes a severe emphysema-like phenotype in C57BL/6 mice.

Methods: We instilled mice oropharyngeally with PPE. Animals in control groups received a comparable volume of PBS. Measurements of lung function parameters using Buvox and FlexiVent systems and histological analysis of lung tissue on several time points until 160 days after application were performed to follow the development of an emphysema phenotype.

Results: A continuous decline in lung function parameters like compliance, forced expiratory volume in 100ms (FEV1) or the Tiffenau index (FEV1/FVC) was determined in these experiments. Airway enlargement was reflected in increase of total lung capacity (TLC), vital capacity (VC) or functional residual capacity (FRC). These developments played along with the histological analysis of lung tissue from these mice, which presented progressing loss of alveolar septae and the resulting airway enlargement from day 2 after application of porcine pancreatic elastase until day 160.

Conclusion: Severe emphysema developed after a single application of porcine pancreatic elastase, distinguished by ongoing damage of lung tissue which exactly matched the resulting impairment of lung function parameters in this emphysema mouse model.

PP145

Effect of cigarette smoke extract or TGF-β1 on hyaluronan production and hyaluronan modulating enzymes in primary murine lung fibroblasts

Ken Bracke1, Juanita Vernesoy2, Tine Demeol2, Guy Jons3, Emiel Wouters4, Guy Brusselle1, Mieke Denertner, 1. Ghent University Hospital, Respiratory Medicine, Ghent, BE; 2. Maastricht University Medical Centre, Respiratory Medicine, Maastricht, NL

Hyaluronan (HA) is a component of the extracellular matrix and low molecular weight (LMW) HA fragments have pro-inflammatory capacities. Exposing mice to cigarette smoke (CS) for 1 or 6 months results in enhanced deposition of LMW HA in lung parenchyma and airway walls and in altered expression of HA syntheses and hyaluronidases (Bracke et al., Am J Respir Cell Mol Biol. 2010;42(6):753-61). To pinpoint a source of HA, we studied HA-production and expression of HA modulating enzymes in primary murine pulmonary fibroblasts stimulated with cigarette smoke extract (CSE) or TGF-β1.

Fibroblasts were isolated from lungs of C57BL/6 mice and cultured in vitro. At passage 6, cells were stimulated for 24 or 48 h with 1 or 10% CSE or 1ng/ml TGF-β1. mRNA expression of HA syntheses (Has1, Has2, Has3) and hyaluronidases (Hyal1, Hyal2) was evaluated by RT-PCR. HA production was measured in supernatant by ELISA.

In vitro stimulation of pulmonary fibroblasts with CSE significantly decreased the mRNA expression of Has1 (synthesizing high molecular weight (HMW) HA) and significantly increased the expression of Hyal2 (degrading HMW HA fragments). Stimulation with TGF-β1 resulted in significantly increased mRNA expression of Has2 (synthesizing HMW HA). Accordingly, HA-levels in the fibroblast supernatant decreased significantly upon 48h stimulation with CSE, while they were significantly increased upon 24h or 48h stimulation with TGF-β1. Decreased Has1 and increased Hyal2 in CSE-stimulated fibroblasts suggests reduced synthesis and enhanced breakdown of HMW HA. This may contribute to the accumulation of LMW HA fragments, observed in CS-exposed mice.
EMT has been implicated as an important mechanism in the pathogenesis of fibrotic airway diseases such as Obliterative Bronchiolitis (OB). TGF-β1 has been shown to drive EMT both in vitro & in vivo. Previous observations have shown that inflammatory stimuli such as TNFα can accentuate TGF-β1 driven EMT in Primary bronchial epithelial cells (PBEC). We hypothesize that TAK-1 may act as a convergence point for this signalling pathway.

PBEC were treated with TGF-β1 (10ng/ml) or TNFα (20ng/ml) and TAK-1 phosphorylation assessed. TAK-1 function was blocked by specific inhibition or siRNA knockdown and the effect on EMT assessed. Tissue sections from control and post transplant patients with OB were analyzed for TAK-1 phosphorylation. TAK-1 is phosphorylated in response to TGF-β1 (+161% over control) and TNFα (+145%) with an accentuation (+516%) and nuclear translocation upon cotreatment (n=3). Furthermore strong phosphorylation and nuclear localization of TAK-1 was also observed in OB tissue. Selective inhibition of TAK-1 phosphorylation and nuclear localization significantly reduces the TGF-β1 driven EMT [loss of E-cadherin (39%), gain of Vimentin (28%) and Fibronectin (87%) p<0.05 (n=6)]. These findings were validated via siRNA knockdown of TAK1 (n=3). TAK1 is an important signalling molecule for the accentuation of EMT in lung epithelium identifying TAK-1 inhibition as a potential new therapeutic target in airway disease.

Nitrergic mechanisms may play a role in the control of airway inflammation in asthmatics and COPD patients. Previous studies using NO donors have shown that NO can modulate the release of cytokines by matured DCs. We have shown that activated macrophages can accentuate TGF-β1 driven EMT of cells in a concentration-dependent manner with 300μg/ml showing ~80% inhibition (control: 31.1±5.0 to 151.3±54.0 μg/ml DEP: 619±180 RFU, n=29), with MDM being 70% viable at this concentration, with no difference in response between the different subject groups. These data show that DEP impair macrophage phagocytosis and promote chemokine release. These data suggest that DEP may lead to reduced clearance of debris and pathogens from airways and promote COPD exacerbations.

Interleukin 1α is a key epithelial alarm that promotes fibroblast activation Monika Suwara1, Lee Borthwick1, Jelena Mann1, Stuart Farrow2, Derek Mann1, Andrew Fisher1.1
Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, Tyne and Wear, GB
2Glasco Smith Kline R&D, Immunology Biology Group, Stevenage, GB

Inhalation of inhaled particulates is a major contributor to air pollution and when inhaled become tarred to the lung epithelium. The interaction between DEP and bacteria/endotoxin is numerous in the distal airways but does not appear to affect the number of mast cells. We have described a novel mechanism where NO might play a significant role in the modulation of LPS activation cascades, NO can play different and important roles in DC maturation. Human DCs are underneath epithelial barrier and continuously influenced by the antigens and redox state. We are interested in the role that reactive oxygen species such as nitric oxide (NO) play in DC maturation. Human DC were stimulated with different concentrations of LPS. NO donors and inhibitors were achieved. DC-maturation markers, a panel Th1/Th2/Th17 cytokines and proliferation assays were analyzed. Our results have shown that NO is able to change the pattern of the release of cytokines by LPS matured DC which was dependent on the concentration, as well as in the time point that NO was added to the cells during the maturation. IL-10 and TNFα were released in a dose dependent manner while the release of IL-12 was inhibited. If NO is added before maturation by LPS an inhibition of IL-12 and IL-10 was observed. Interestingly, NO strengthen the role of IL-23, IL-1b and IL-6. Functionally, in spite of the fact co-stimulation of NO with LPS did not modify allo-presenting properties of DCs, NO treated DCs before maturation was able to induce a Th17 polarization in a mixed lymphocyte reaction. NO can play different and important role modulating the LPS activation cascades, depending on the concentration or time point used. Interestingly, NO strongly inhibits the activity of DCs to release IL-12, but strengthen the release of other cytokines such as IL-23 and IL-1b which are involved in a Th17 polarization.

We have described a novel mechanism where NO might play a significant role modulating the release of IL-17, which might be a key element in the pathogenesis of lung diseases such as in asthma or COPD.

Inflammatory cells in the proximal and distal airways: Effects of steroids
Gregory Rankin, Susan Wilson, Jane Warnet. University of Southampton, School of Medicine, Southampton, GB

Rationale: Patients with COPD may be prescribed inhaled steroids but it is not clear if this reduces inflammatory cells in either the proximal or distal airways.

Methods: Matched tissue from proximal and distal airways of 28 patients undergoing a lobectomy was fixed in acetone, processed into GMA and inflammatory cells enumerated by immunohistochemistry.

Results: Twelve patients had no evidence of airways obstruction (FEV1/FVC = 0.77±0.03), 10 had mild/moderate COPD (FEV1/FVC = 0.59±0.02) but were not on steroids. Six patients had COPD (FEV1/FVC = 0.39±0.03) and had been prescribed inhaled steroids. There was no difference in age, lung function or smoking histories of the COPD groups. Mast cell numbers were significantly higher in the distal airways in all the groups compared to the proximal airways. Neither COPD or inhaled steroids altered mast cell number in the proximal airways but there was a reduction in the mast cells in the distal airways in patients prescribed inhaled steroids (P<0.05 compared to both non-COPD and non-stEROID groups). Median (IQR) values/mm2 were 52.7 (37.3-61.8) for patients with no airways obstruction, 68.8 (37.5-89.9) in patients with COPD but not taking steroids and 23.6 (16.2-28.6) in the steroid group. Macrophages and neutrophils were more numerous in the distal airways but numbers were not affected by COPD or use of inhaled steroids. T cells were more evenly distributed between the proximal and distal compartments but again were unaffected by either COPD or steroids.

Conclusions: Prescribing inhaled steroids in mild/moderate COPD does not affect the number of any mast inflammatory cells in the lung but does not appear to affect the number of the different inflammatory cells in either the proximal or distal airways.

Classically activated macrophages (CAMΦ) accentuate TGF-β1 driven epithelial to mesenchymal transition (EMT) via secretion of TNFα
Lee Borthwick1, Malcolm Brodlie2, Gail Johnson2, Chris Ward1, John Perry1, Paul Corris1,2, Anthony De Soyza1,2, Andrew Fisher1,2.
Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, Tyne and Wear, GB
2Framingham Hospital, Department of Cardiopulmonary Transplantation, Newcastle-Upon-Tyne, Tyne and Wear, GB

Obliterative Bronchiolitis (OB) is characterised by fibrotic obliteration of small airways adversely affecting survival after lung transplantation. In-vitro and in-vivo primary bronchial epithelial cells (PBEC) from the transplanted lung have been shown to undergo EMT and this may contribute to the development of OB. We have shown that activated macrophages can accentuate TGF-β1 driven EMT.
Macrophages demonstrate remarkable plasticity and change their physiology in response to the microenvironment. We hypothesised that this effect on EMT is limited to CAMφ and that their secretory products may be a target for limiting inflammatory accentuation of EMT. THP-1 cells were differentiated to CAMφ or alternatively macrophages (AAMφ) and stimulated with clinical isolates of Pseudomonas aeruginosa (PA). Cytokine secretion and their effect on TGF-β1-driven EMT were assessed. The effect of blocking TNFα secreted from activated THP-1 cells was also assessed. CAMφ released more TNFα (8.4-fold) and IL-1β (8.1-fold) than AAMφ in response to PA (p < 0.05 n=6). Conditioned media from CAMφ, but not AAMφ, dramatically accentuated TGF-β1-driven EMT (p < 0.05 n=6). Blocking TNFα in conditioned media significantly inhibits the decrease in E-cadherin (39% ± 4%) and the increase in vimentin (59% ± 18%) and fibronectin (72% ± 14%) expression (p < 0.05 n=5). The secretory products of CAMφ, but not AAMφ, significantly accentuate TGF-β1 driven EMT. TNFα appears to be a major constituent of this accentuation raising the possibility that TNFα targets therapies or modulation of macrophage phenotype may inhibit the inflammatory accentuation of EMT in the airway.

**PP153**

Heme-oxygenase (HO)-1 inhibits TNF-α induced CXCL10 secretion by airway smooth muscle cells.

Petra Seidel1,2, Katrin Hostettler 1, Margaret Hughes2, Michael Tamm1, Michael Roth1, 1 University Hospital Basel, Pulmonary Cell Research, Department of Biomedicine, Basel, Baselstadt, CH; 2University of Sydney, Respiratory Research Group, Faculty of Pharmacy, Sydney, New South Wales, AU

**Background and purpose:** CXCL10 induces mast cell migration towards airway smooth muscle bundles in asthma. In blood mononuclear cells, induction of heme oxygenase (HO)-1 inhibited pro-inflammatory cytokine secretion. Dimethyl-fumarate (DMF), which is clinically used as an anti-inflammatory medication, induced HO-1 and thereby inhibited proliferation in airway smooth muscle cells (ASMC).

**Experimental approach:** Here we assessed the anti-inflammatory effect of DMF on TNF-α induced CXCL10 secretion in human primary ASMC and the involvement of HO-1 and mitogen activated protein kinases (MAPK). ASMC were pre-incubated with DMF and/or glutathione ethylester (GSH-OEt), SB203580, or the HO-1 inducers hemin, or cobalt-protoporphyrin (CoPP) 1 hour before stimulation with TNF-α (10 ng/ml).

**Key results:** TNF-α induced secretion of CXCL10, which was inhibited by DMF as well as by the HO-1 inducers, hemin, or CoPP. Interestingly, DMF amplified the TNF-α induced phosphorylation of p38 MAPK and thereby induced the expression of HO-1. Inhibition of p38 MAPK by SB203580 reduced DMF-induced HO-1. Importantly, GSH-OEt supplementation: (i) abrogated the inhibitory effect of DMF on TNF-α induced CXCL10 secretion, (ii) counteracted DMF-induced HO-1 expression, and (iii) p38 MAPK activation.

**Conclusion and implications:** Our data indicate that DMF inhibits TNF-α induced CXCL10 by altering intracellular GSH, leading to activation of p38 MAPK and subsequent synthesis of HO-1 in ASMC. Thus, DMF might help to reduce airway inflammation in asthma.

**PP154**

Elevated chitinase proteins in subjects with airway inflammation

Anna James1, Rolf Boor1, Maciej Kupczyk2, Lovisa Johansson1, Roelinde Middeldorp1, Bartho Dahlén1, 1The Karolinska Institute, Centre for Allergy Research, Stockholm, SE; 2University of Amsterdam, Academic Medical Center, Amsterdam, NL; 3Karolinska University Hospital, Lung and Allergy Research, Stockholm, SE

Chitin is a tough structural polysaccharide found in crustaceans, insects, fungi & parasites. Although absent in humans, we express chitinases capable of degrading chitin, of which chitosidase and the chitinase-like protein YKL-40 have been suggested to be a major constituent of this accentuation.

Our aim was to further examine chitosidase and YKL-40 as potential biomarkers of airway inflammation in subjects with asthma & COPD. Blood was collected from well-characterised subjects with asthma (mild & severe) & COPD, taking part in BIOAIR, a European multicentre study. Patient characteristics are shown in table below. Serum chitosidase activity and YKL-40 levels were analysed in a subset of these subjects and compared with results obtained in 66 healthy volunteers.

</table>

As shown in the figure below, serum chitosidase activity (A) and YKL-40 levels (B) were significantly elevated in subjects with asthma and COPD, compared to healthy volunteers. Both parameters were greatest in patients with COPD.

The current findings confirm that YKL-40 and chitosidase are useful biomarkers of airway inflammation but also demonstrate that the mechanism underlying increased chitinase expression is not exclusive to asthmatic airway inflammation.

**PP155**

Cigarette smoke dysregulates pro-inflammatory cytokine release from airway epithelial cells and macrophages.

Elizabeth Mossey1, Lee Borthwick1, John Perry2, Anthony De Soya1, Andrew Fisher1, 1Newcastle University, Newcastle upon Tyne, GB; 2Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, GB

Chronic obstructive pulmonary disease (COPD) is characterised by repeated bacterial exacerbations which accelerate lung function decline and increase morbidity and mortality. Chronic bacterial colonisation may contribute to airway inflammation and promote disease progression. Cigarette smoke has been shown to alter responses to LPS. We hypothesised that cigarette smoke would suppress the innate immune responses of airway epithelial cells and macrophages to Haemophilus influenzae (H. influenzae) favouring persistence. Primary bronchial epithelial cells (PBEC), alveolar macrophages and a macrophage-like cell line (THP-1) were incubated with cigarette smoke extract (CSE) and stimulated with clinical isolates of H. Cell viability, proliferation and pro-inflammatory cytokine secretion were assessed. CSE concentrations >5% inhibited PBEC proliferation (p < 0.05 n=9). IL-8 release from PBEC was increased in response to HI (p < 0.05 n=3) and this was accentuated by CSE (p < 0.05 n=6). However, treatment with CSE alone had no effect on IL-8 secretion (p > 0.05 n=6). HI treatment increased secretion of IL-8, TNFs and IL-1β from macrophages (p < 0.05 n=3). Co-treatment with HI + CSE increased IL-8 secretion (61%) but reduced TNFs (40%) and IL-1β (24%) secretion compared to HI alone (p < 0.05 n=3). CSE concentrations ≤10% had no significant effect on cell viability.

CSE alters epithelial cell and macrophage responses to bacterial pathogens by promoting release of the neutrophil chemokine IL-8 and suppressing TNFs and IL-1β. This dysregulation may promote continued neutrophil inflammation in the airway whilst insufficiently clearing pathogens and could be an important mechanism in COPD.

**PP156**

Biomedical nanoparticles reduce antigen processing capacity and specific CD4+ T cell stimulation of human dendritic cells

Fabian Blank1, Peter Gerber1, Alke Funk1, Barbara Rotthen-Rutishauser2, Karin de Pryer1, Laurent Nicod1, Thomas Geiser1, Christophe von Garnier1, 1Berne University Hospital, Respiratory medicine, Berne, CH; 2University of Berne, Institute of Anatomy, Berne, CH; 3Lausanne University Hospital, Respiratory Medicine, Lausanne, CH

During particle-cell interaction DC may functionally be affected by nanoparticles (NP) resulting in altered immune responses. The aim of this study is to understand how polyvinylalcohol coated super-paramagnetic iron oxide NP (PVA-SPIPSONs) interact with DC and influence their phenotype and function.

Human blood monocyte-derived DC were treated during 12h with PVA-SPIPSONs imaged by confocal and electron microscopy. Expression of markers of differentiation and activation and the capacity of DCs for antigen-uptake, -processing, and -presentation were studied using flow cytometry and an autologous CD4+ T cell stimulation assay. Cytokine release was measured in MDDC-T cell co-cultures using a multiplex assay.
Primary human type II cells were extracted from patients undergoing lung resection for cancer (n=4). Cells were incubated with VEGF from day 2 to 3 and from day 5 to 6. Gene expression was determined by macroarray analysis and Q-PCR was used to validate the change in type I and II cell markers. Transdifferentiation was associated with significant changes in 417 genes from day 2 to 3, and 935 genes from day 2 to day 6 (1.5+ fold change, p=0.001). VEGF had a dose-dependent effect upon gene expression at day 3 altering 167 genes at ng/ml and 601 genes at 10ng/ml. By day 6 VEGF altered 183 genes at 1ng/ml and 1400 genes at 10ng/ml but the fold changes were small (1.2-2.9 fold). Functional analysis identified that VEGF at day 3 mainly influence cellular development and proliferation processes. By day 6, VEGF also influenced cell metabolism. Only 297 genes were similarly altered at day 3 and day 6 by VEGF 10 ng/ml. Although transdifferentiation was associated with up-regulation of RAGE, Aquaporin V and down regulation of SP-C, VEGF did not affect transdifferentiation markers. Transdifferentiation involves rapid alterations in the mRNA profile of human ATII cells. VEGF influences the expression of genes involved in cellular differentiation and proliferation upon both type II and type I like cells. These data demonstrate that VEGF may have a trophic effect upon type I like cells as well as type II cells at physiologically relevant levels.

Endothelin (ET) receptor blockers have been administered in patients with pulmonary Langerhans’ cell histiocytosis (PLCH) and concomitant pulmonary hyper-tension. The effects of the endothelin receptor type B (ET-B) blocker bosentan on the lung changes of PLCH has yet to be established. We studied the expression of ET receptor A and B in PLCH and investigated the functional significance in vitro. ETAR and ETBR expression was studied in 25 formalin/paraffin-embedded PLCH biopsies. For in vitro analysis, we used the murine LC-like cell line XSS2 and freshly prepared murine and human LCs. Target expression was determined by RT-PCR, cell viability by colorimetric assay, ETAR and TNF-α and IL-12 expression by enzyme-linked immunosorbent assays, cell migration with 48-well Boyden chambers, and ET-1 induced cytosolic calcium mobilization by cell life imaging. Immunohistochemistry revealed expression of ETAR and ETBR in PLCH. In vitro, the expression of the ET system was proven in murine LCs (ETAR+, ETBR+), in human LCs (ETAR+) and in XSS2 cells (ETAR+). Treatment of XSS2 cells with ET receptor blocker revealed impaired cell viability. Migration analysis showed ET-1 dependent migration of LC-like cells, inhibitable by bosentan and the selective ETAR antagonist BQ123. Life cell imaging confirmed ET-1 induced calcium influx. Cytokine monitoring in XSS2 supernatants showed decreased TNF-α levels after bosentan coinubcation. This study reveals unique expression patterns of the endothelin system in PLCH and in murine and human LCs with antiproliferative, antimigratory and antiinflammatory properties of ET receptor blockers in vitro. ET-1 was for the first time found to induce migration of LC-like dendritic cells.

Expression of TLR9 in mouse and human lung and its role in inflammation in chicken barn air exposure

David Schneberger, Gurpreet Aulakh, Shankararamurthy Channabasappa, Sarah Caldwell, Baljit Singh, University of Saskatchewan, Veterinary Biomedical Sciences, Saskatoon, Saskatchewan, CA.

Workers exposed to intensive animal housing facility air show signs of lung dysfunction. These respiratory symptoms are often associated with endotoxin, but gram negative bacteria may constitute only a small portion of the microorganisms present, whereas unmethylated DNA can be found in all bacteria, some viruses, and mould. Immune responses to this unmethylated DNA are mediated through the Toll-like receptor 9 (TLR9). Therefore we sought to determine the expression pattern of TLR9 receptor in mouse and human lung, and if immune response to barn air exposure would be altered in a TLR9-deficient mouse model. Using immunohistochemistry, immuno-electron microscopy and in situ hybridization we show expression of TLR9 in whole lung tissue of mice and humans in bronchial epithelium, vascular endothelium, alveolar septal cells and alveolar macrophages. For the exposure study C57BL/6 and TLR9-deficient mice were housed in chicken barn air for 8 hours/day for 1, 5, or 20 days. Examination of bronchiolar lavage and serum showed reduced TNF-α levels in TLR9-deficient mice in serum and lung lavage fluids after 5 days (p<0.05) and somewhat reduced at 20 days of exposure (p=0.14), while IFN-γ was also reduced at 5 days in both (p<0.06) and remained reduced after 20 days (p=0.05). A reduction in neutrophils at 20 days was also seen in exposed TLR9-deficient mice (p<0.05) at 20 days as assessed by myeloperoxidase. Our data shows similar expression patterns of TLR9 in mouse and human lungs, and that barn dust DNA, through the TLR9 receptor, may contribute to inflammation induced following exposure to chicken barn air. 

Anti-inflammatory effect of a synthetic pulmonary surfactant containing recombinant human surfactant protein C (SP-C) on lipopolysaccharide-stimulated alveolar macrophages

Belgen García-Feoja, Carmen Monsval-Hernando, Alejandra Sáenz, Cristina Chamizo, Cristina Casals. Complutense University of Madrid, Biochemistry and Molecular Biology I, Madrid, Madrid, ES.

Pulmonary surfactant prevents alveolar collapse and protects the lung from infection and inflammation. The aim of this study was to evaluate the effect of a synthetic surfactant, composed of dipalmitoylphosphatidylcholine (DPPC), palmitoyloleoylphosphatidylglycerol (POPG), palmitic acid (PA), and SP-C, on alveolar macrophage activation. We analyzed TNF-α and INOS mRNA and protein levels, as well as phosphorylation of MAPKs, IkBα, and Akt on mouse alveolar macrophages stimulated by bacterial lipopolysaccharide (LPS). We found that all LPS-induced inflammatory markers were inhibited by synthetic surfactant. This anti-inflammatory action is reduced when surfactant vesicles are endocytosed by macrophages, indicating that LPS signaling inhibition might be due to the blockage of LPS binding to its cellular receptor. Antagonism of synthetic surfactant to LPS action is mainly due to the lipid component, whereas SP-C decreases only LPS-induced gene expression. We found that synsurf inhibited LPS-induced TNF-α release, whereas vesicles without POPG have no inhibitory effects. Presence of PA in DPPC/POPG vesicles increases their inhibitory action by inducing ordered/disordered phase coexistence as determined by fluorescence microscopy of giant unilamellar vesicles. Segregation and enrichment of POPG in disordered domains favors the binding of DPPC/POPG/PA vesicles to receptors of the α7A, diminishing LPS signaling. We conclude that the lipid component of SP-C-based synthetic surfactant has an anti-inflammatory action on alveolar macrophages, which reinforces its use in inflammatory lung diseases.

Investigation of the viral-induced Toll-like receptors axis in bone-marrow mesenchymal stem cells (BM-MSCs) of patients with chronic lung disorders
Katerina Antoniadi1, Anna Pivovarova, Konstantina Karagiannaki.
Ismini Lastothiatoi, Ioannis Giannarakis, Giannoula Soufla, Despina Moraitaki, Nikos Siafakas. Medical School, University of Crete, Thoracic Medicine, Laboratory of Molecular and Cellular Pulmonology, Heraklion, Crete, GR
Introduction:
Over or under-exuberant Toll like receptors (TLRs) signaling can be deleterious to the host leading to the pathogenesis of chronic inflammatory diseases.
Aim: To investigate molecular characteristics regarding innate immunity involvement in BM-MSCs in patients with COPD in comparison with patients with idiopathic pulmonary fibrosis and autoimmune fibrosis.
Methods: BM-MSCs were studied in 10 COPD patients, 20 patients with pulmonary fibrosis, a idiopathic pulmonary fibrosis (IPF) and b rheumatoid arthritis associated pulmonary fibrosis (RA-UIP) and 10 healthy controls. We evaluated the mRNA expression of the axis of viral induced TLRs in BM-MSCs (passage 2) using quantitative RT-PCR.
Results:
A significant decreased expression in TLR-3 was revealed in both COPD and fibrotic patients compared to healthy individuals (0.5±0.18 versus 0.19±0.12 respectively). A significant increased expression was detected in TLR-3 mRNA levels in COPD in comparison with fibrotic patients (0.51±0.18 versus 0.19±0.12, p=0.002, respectively). In addition, we revealed a significant decreased expression in TLR-8 and TLR-9 in COPD patients compared to healthy subjects (0.04±0.02 versus 0.78±0.3± p=0.001 and 0.2±0.06 versus 0.56±0.6, p=0.001, respectively). A significant decreased expression was measured in TLR-8 in fibrotic patients compared to healthy individuals (14±2.9 versus 7±8 ± 3.5, p=0.02), however, TLR-9 mRNA levels were decreased in fibrotic patients compared with healthy controls (55±8.2± versus 20±5.4, p=0.002).
Conclusion: The aforementioned data may suggest a pathogenetic role of viral induced TLRs in both pulmonary fibrosis and COPD.

PP163
The effect of endothelin-1 on human basophil function in vitro
Katharina Cimá1, Silvia Blenden2, Susanna Desole2, Julia Günther1, Judith Löfler-Ragg1, Christian M Kähler1. 1Pneumology, Internal Medicine, Medical University of Innsbruck, Innsbruck, AT; 2Laboratory of Rheumatology, University hospital, Walenberg lab, Malmoe, SE
Introduction: Endothelin-1 (ET-1) has proinflammatory properties and contributes to allergic late-phase responses. As basophils play a key role in allergic rhinitis or asthma, we investigated the effect of ET-1 on basophils.
Methods: Cells were isolated from venous blood of healthy donors via magnetic cell sorting. Cells were stimulated with 10-7M ET-1 for 15min. To show ETA or ETB receptor expression RT-PCR was performed. The chemotactic effects of EtOH on alveolar macrophage (ETAR) were determined using modified Boyden chambers (positive control MCP-1 10-8M). To explore ET-1 signalling, cells were preincubated with BQ-123 10-5-10-9M or BQ-788 10-5-10-9M. Migration depth was quantified microscopically. Histamine release upon ET-1 (10-8-10-10M) and upon additional stimulation with the secretagogue FMLP 10-9M was determined by ELISA.
Results:
The RT-PCR revealed basophils to express both, ETAR and ETBR. ET-1 (10-8-10-10M) further proved to be a strong chemotactic for human basophils (p<0.0001). Both basophils express both receptors, only the ETAR antagonist BQ-123 10-5-10-12M significantly blocked migration towards ET-1 (10-8M). Furthermore, the histamine release was increased by 2.46 to 2.6 fold after ET-1 stimulation (10-7-10-9M). Interestingly, only the evoking of histamine release by additional stimulation with FMLP 10-9M resulted in a dose dependent effect of ET-1, showing ET-1 (10-10M) to be most effective.
Conclusion: Our observations reveal for the first time that basophils express ETAR and ETBR and ET-1 induces histamine release and basophil migration, which seems ETAR dependent. Considering the fact that ET-1 is involved in the mechanisms of airway inflammation, targeting ET-1 by receptor antagonists may be a new option in the treatment of allergic airway disease.

PP164
The role of alpha-1 antipiryn in regulation of CD14 expression and soluble CD14 levels in human monocytes in vitro
Danielius Serapinas1, Sabina Janciauskienė1, Raimundas Sakalaukus1, 1Lithuanian Health Science University Medical Academics, 2Department of Pulmonology and Immunology, Kaunas, LT; 2Land University, Malmoe University hospital, Kulainberg lab, Malmoe, SE
Introduction: The recognition of bacterial lipopolysaccharide (LPS) is principally mediated by either membrane-bound or soluble form of the glycoprotein CD14. Recent findings indicate that a1-antipiryn (AAT), may not only afford protection against proteases but may also neutralize microbial activities and affect regulation of innate immunity responsible for lung protection. Aim of the study: To investigate influence of AAT on monocytes activity in vitro through regulation of CD14 secretion and expression.
Methods: Human monocytes culture supernatants soluble CD14 and TNFα levels were analysed using ELISA kit. CD14 expression was analysed by flow cytometry.
Results: We find that a short-term (up to 2h) monocyte exposure to AAT induced expression of CD14 and secretion of soluble CD14. It helps monocytes in neutralization of LPS. Longer term (18h) monocytes incubation with AAT decreases expression of CD14 and enhances soluble CD14 secretion, thus monocytes are protected from hyporesponsiveness of bacterial endotoxin. In parallel, a short-term monocytes incubation with AAT, but longer term inhibits LPS induced TNFα release, that shows immunomodulating capacity of AAT. Probably a rapid increase in AAT concentrations during various inflammatory and infectious conditions may enhance monocyte responses to endotoxin and subsequently accelerate resolution of the inflammatory reaction.
Conclusions: These findings provide evidence that AAT is an important regulator of CD14 expression in monocytes and suggest that AAT may be involved in LPS neutralization and prevention of over-activation of monocytes in vivo, that is important mechanism in development of COPD.

PP165
Biomarkers in interstitial lung diseases
Martina Stercelova1, Martin Vesalakova1, Libor Kolera1, 1 Thomayer’s University Hospital, CZ; 2Institute of Clinical and Experimental Medicine, CZ
Chronic eosinophilic allergic alveolitis (EAA) and idiopathic pulmonary fibrosis (IPF) both cause lung fibrosis. The aim of our study was to investigate possible use of proinflammatory chemokines (interleukin (IL)-8, epithelial neutrophil activating peptide (ENA)-78, vascular endothelial growth factor (VEGF), tumor necrosis factor (TNF)-alpha) and antiinflammatory interleukin 1 receptor antagonist (IL-1RA) as biomarkers in EAA and IPF.
Seven IPF and eleven chronic EAA were enrolled to the study. Concentrations of IL-8, ENA-78, VEGF, TNF-alpha and IL-1RA in bronchoalveolar lavage fluid (BAL) supernatants were quantified using multiplex bead array assay. High resolution computed tomography (HRCT) alveolar and interstitial scores were assessed.
There was no difference in the levels of examined chemokines in BALF of IPF patients compared with EAA patients. The VEGF level in BALF of IPF group negatively correlated with the HRCT interstitial score (p<0.05), while the IL-8 BALF level positively correlated with the alveolar score (p<0.05) in the same group. No significant correlation between histological and cytokine score was found in the EAA group. There was no correlation between BALF TNF-alpha levels and HRCT scores in all examined groups. IL-1RA in BALF strongly correlated with HRCT alveolar score (p<0.001) in EAA group. There was no correlation between IL-1RA BALF values and either intestinal HRCT scores in EAA and IPF or alveolar HRCT score in EAA group.
We suggest that BALF concentrations of examined chemokines can not distinguish between chronic EAA and IPF. High IL-8 and low VEGF BALF concentrations might point toward more severe lung fibrosis in IPF. High IL-1RA concentrations may be the marker of initial stages of IPF.

PP166
The role of TGF-β1 signaling in alcohol-induced alveolar macrophage dysfunction
Sheena Brown, Lou Ann Brown. Emory University School of Medicine, Department of Pediatrics, Division of Neonatal-Perinatal Medicine, Atlanta, GA, US
Introduction: Alcohol (EtOH) addiction is a complex multifactorial disease that affect more than 70 million people and contributes to 1 in 25 deaths worldwide. Alcoholics have twice the incidence of intensive care unit (ICU)-related morbidity and mortality, commonly caused by acute respiratory distress syndrome (ARDS). Studies have shown chronic EtOH ingestion leads to increased oxidant stress and to the determinantal effects of EtOH on alveolar macrophage (MAC) maturation and function. Previous studies have shown chronic EtOH ingestion leads to increased oxidant stress (ROS), increased TGF-β1 production, increased fibronectin production, and decreased phagocytosis in AMs. However, the role of increased TGF-β1 signaling in EtOH-induced alterations of MAC has yet to be studied extensively.
Hypothesis: Our aim was to determine the role of TGF-β1, in EtOH-induced increases in MAC ROS production, induction of a pro-fibrotic phenotype, and decreases in MAC phagocytic function.
Methods: To test this hypothesis, NR8383 cells, a rat-derived MAC cell line, were treated with 0.08% EtOH, ± TGF-β1 neutralizing antibody for 5 days. Following treatment, the cells were analyzed for TGF-β1 production and secretion, MAC phagocytic function, ROS production, and the ability to induce fibroblast proliferation. Results: In NR8383 cells, treatment with EtOH resulted in increased production and secretion TGF-β1, decreased MAC phagocytic capacity, and increased fibroblast proliferation. Supplementation with TGF-β1 neutralizing antibody during treatment led to partial normalization of EtOH-induced increases in TGF-β1 production and secretion, ROS production, and fibroblast proliferation.

Differential inflammatory responses of nasal and bronchial epithelial cells to cigarette smoke extract
David Comer, Vanessa Brown, Francine De Coursrey, Stuart Elborn, Madeleine Ennis. Queen’s University, Centre for Infection and Immunity, Belfast, GB
Few studies compare the function of primary bronchial (PBEC) and nasal (PNEC) epithelial cells. Our aim was to compare the responses of paired PNEC and PBEC

933s
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
cultures to LPS stimulation and any modulatory effects of exposure to cigarette smoke extract (CSE). Cells, from subjects with COPD, were obtained by nasal or bronchial brushing and used at passage 3. They were stimulated for 24 h with LPS [0 – 25 μg/ml] ± pre-treatment with CSE. CSE was prepared by combining a 12 mg tar Marlboro cigarette through 25 ml of media. Supernatants were collected and IL-8 and IL-6 measured by ELISA. The localization of TLRL-4 was established by FACS. For the PNEC cultures, a brief incubation with CSE (4h) significantly inhibited LPS-induced IL-8 and IL-6 release (IL-8: 24h treatment with 25 μg/ml LPS alone 5457±424 pg/ml and with 4h CSE pre-treatment 3772±452 pg/ml). A more prolonged incubation with CSE (24h) was pro-inflammatory (IL-8: 25 μg/ml LPS alone 5485±562 pg/ml and with 24h CSE pre-treatment 7757±449 pg/ml). Although a brief incubation with CSE resulted in a lower percentage of surface and intracellular TLR4, a prolonged incubation was without effect. In contrast, both a brief and a prolonged exposure of PBEC cultures to CSE reduced LPS induced IL-8 release (IL-8: 24h treatment with 25 μg/ml LPS alone 5107±797 pg/ml, with 4h CSE pre-treatment 3345±60 μg/ml, and with 24h CSE pre-treatment 3010±328 pg/ml), and both lead to a reduced percentage of surface and intracellular TLRL4. There was minimal IL-6 release from the PBEC cultures. In conclusion, these data indicate that PNEC cultures are not a suitable surrogate for PBEC cultures in terms of their response to CSE/LPS combination treatment.

PP168 A three dimensional primary human lung tissue model provides the first evidence for Wnt11 as regulator of alveolar type II differentiation

Domokos Bartók1, Miklos Nittay2, Teresza Laszlo3, Tamás Molnár3, Judit Pongracz4, Veronika Congel1, Szilvia Barkó5, Laszlo Jakab5, Tibor Balasa1, György Miske1, Gergely Berta1, Zoltan Vareczka1, Krzysztof Kuci2,1, University of Pecs, Medical Biotechnology, Pecs, Baranya, HU;2, University of Pecs, Biophysics, Pecs, Baranya, HU;3, University of Pecs, Medical Biology, Pecs, Baranya, HU;4, University of Pecs, Pathology, Pecs, Baranya, HU;5, University of Pecs, Surgery, Pecs, Baranya, HU

Adult stem cells are in the forefront of interest for lung tissue regeneration therapies. Progenitors that are vitally important for airway repair of alveolar type I (ATI) cells -the primary gas-exchange surface of the alveoli- are alveolar type II (ATII) cells that can flexibly turn into ATI and ATII cells on physiological demand. To develop targeted regeneration therapies, factors that can trigger such interchanges are needed to be identified. Studies, however, are hampered by the fact that recreation of the human adult airways microenvironment is difficult in vitro while ATI cells once removed from pulmonary tissues and placed into conventional cell culture systems lose their type characteristics and respond differently to stimuli.

Here we present an easily manipulable three dimensional (3D) primary human pulmonary micro-tissue model that maintains ATII phenotype of the alveolar epithelium. Also, we provide the first evidence that Wnt11 is one of the main regulators of ATII type differentiation which knowledge might enable targeted therapies in the future.

PP169 Bronchial lavage cell in radiation pneumonitis after radiotherapy for breast cancer

Claudia Lucia Toma1, Aneta Serbescu1, Mihai Alexe2, Luminita Cervis2, Diana Ionita1, Miron Alexandru Bogdan1, Carol Davila University of Medicine and Pharmacy, Pneumology, Bucharest, RO, 2Marius Nasta Institute of Pneumology, Pneumology, Bucharest, RO

Radiation pneumonitis is a complication of radiotherapy which limits its application in cancer therapy. AIm: To compare the bronchial lavage (BAL) findings in patients with symptomatic radiation pneumonitis (RP) versus asymptomatic RP.

Material and method: We evaluated 65 female patients with RP after radiotherapy for breast cancer. Results: Forty-nine patients were symptomatic (fever, cough and/or dyspnea) and 16 were asymptomatic. All patients had a newly discovered infiltrate or pleural effusion. Forty-nine patients were symptomatic (cancer symptoms - fever, cough and/or dyspnea) and 16 were asymptomatic. All patients had a newly discovered infiltrate or pleural effusion. The inflammation caused by radiation pneumonitis may lead to reactive hyperplasia of the bronchial epithelium, proliferation and increased expression of cytokines involved in inflammatory response.

We found that inflammatory markers were higher in symptomatic than asymptomatic patients. The most prominent inflammatory markers were IL-6, TNF-α, IL-8, and NOS2. The expression of these markers was significantly higher in symptomatic patients compared to asymptomatic patients.

Conclusion: Bronchial lavage analysis can be a useful tool in the diagnosis and monitoring of radiation pneumonitis after breast cancer radiotherapy.

PP170 Molecular interplay between inflammation and occurrence of proliferation: role of cadmium

Subhadip Kundu1, Arindam Bhattacharya1, Suman Sengupta2, 1Department of Zoology, University of Calcutta, Kolkata, West Bengal, IN; 2Department of Environmental Science, University of Kalyani, Kalyani, IN

Introduction: Cadmium is one of the inflammation-related xenobiotics with potent carcinogenicity. The mechanism between inflammation and cell proliferation due to chronic cadmium exposure has not been studied yet (Lau AE, et al., Toxicol Appl Pharmacol 2006).

Objectives: The present study was undertaken to determine molecular mechanism of inflammation linked cell proliferation due to cadmium exposure in mice and lung cancer cell line.

Methods: Swiss albino mice and A549 cell line were chosen for experiments. Levels of different cytokines, expression level of cell cycle regulatory proteins estimated by ELISA, western blot and immunoprecipitation. Other techniques used scanning electron microscopy, histopathology and Cytotoxic assay. Cell cycle analysis, DNA fragmentation assay and RT-PCR experiments. Results: Prolonged exposure of low concentration of cadmium resulted in up regulation of proinflammatory cytokines and cell cycle regulatory molecules both in vivo and in vitro (Waalikes MP et al., Toxicol Sci 1999). We found that cadmium induced upregulation of epidermal growth factor receptor (EGFR) along with different proinflammatory cytokines. The major distinct feature of EGFR expression is promoting inflammatory responses along with cell proliferation.

Conclusions: These data provide a new insight into the relation between chronic inflammation and cell proliferation in vivo due to cadmium toxicity.

PP171 Alveolar macrophage-epithelial cell interaction during pulmonary inflammation

Anke-Gabriele Lenz, Gabriele Schumann, Oliver Eickelberg, Tobias Steeger, Helmholtz Zentrum Muenchen, CPC, iLBD, Neuherberg, DE

We have shown that nanoparticle (NP) inhalation can trigger proinflammatory gene expression as lipocalin-2 (Lcn-2) in alveolar epithelial type II like cells (AEC) and osteopontin (Opn) in alveolar macrophages (AM). In vivo studies using AM or AEC failed to reproduce these responses. We hypothesize that macrophage-epithelial cell interaction is required to promote the inflammatory responses detected in vivo.

Murine cell lines representing AM (MHS), AEC (LA4), or cocultures of both cell types were incubated with carbon NP (CNP) or ZnO NP (positive control). LA4 cells were plated on cell culture inserts and upon their confluency, MHS cells were seeded on top. After 24 the apical medium was removed to create air-liquid interface conditions. After further 24h, suspensions of CNP (Printex90, 50 μg/ml) (10 μg) were added. Gene expression of inflammatory cytokines (Opn, Lcn-2, IL-6, CXCL1) and oxidative stress markers (HO-1, Me2) - was measured by qPCR after 6h incubation.

Regardless of condition, Lcn2 and Opn transcript levels were unchanged. CNP exposure caused 8fold increased IL-6 RNA levels only in MHS monolayers, no changes could be detected in LA4 co- or monolayers. IL-6 mRNA levels were, however, over 30fold higher in LA4 monolayers compared to MHS. ZnO exposure induced about 20fold increased transcript levels of HO-1 and Mt-2 in MHS/LA4 cocultures or LA4 and MHS monolayers, respectively.

CNP did not cause an oxidative stress response and unlike in vivo was not effective to trigger Opn and Lcn2 expression under any condition. Our results can not support the promotion of particle exposure triggered proinflammatory pathways by epithelial cell interaction. More complex culture conditions are necessary to reproduce proinflammatory responses at the in vitro level.

PP172 Microarray analysis reveals a novel link between WNT/β-catenin signaling and the fibrogenic immune response in idiopathic pulmonary fibrosis

Buqing Y1, Nisha Balsara1, Jochen Wilhelm1, Ali Onder Yildirim1, Oliver Eickelberg1, Melanie Königshoff1, 1Comprehensive Pneumology Center, Ludwig-Maximilians-University, Klinikum Grosshadern, and Helmholtz Zentrum München, Munich, Bavaria, DE, 2University of Giessen Lung Center, Department of Medicine, Giessen, Hesse, DE

Rationale: Idiopathic pulmonary fibrosis (IPF) represents a fatal chronic lung disease with unresponsiveness to currently available therapies. Alveolar epithelial cell injury, enhanced extracellular matrix deposition and (myo)fibroblast activation are characteristics of IPF. Recent studies demonstrated a significant increase of (34.9±18.81% vs. 26.14±14.3%). Macrophages were decreased in all patients. Neutrophils were slightly increased (8.88% in symptomatic and 3.34% in asymptomatic) and eosinophils were normal in both groups (2.56% and 1.22%, respectively). CD8+ lymphocytes were increased in both groups with normal CD4/CD8 ratio (2.72 in symptomatic and 1.5 in asymptomatic group).

Conclusion: Cytokine expression in bronchoalveolar lavage fluid is a potential diagnostic tool for IPF. These data provide a new insight into the relation between chronic inflammation and cell proliferation in vivo due to cadmium toxicity.
WNTβ catenin signaling in IPF, driving in alveolar epithelial type II (ATII) cell proliferation and (myo)fibroblast activation. The downstream signaling mediators involved in the cellular effects of WNTβ catenin signaling remain elusive.

Methods and results: Here, we sought to identify signal molecules involved in WNTβ catenin function. We performed an unbiased whole genome microarray analysis from primary mouse ATI cells stimulated with WNT3A for different time points. From this microarray analysis we identified 224 and 223 genes to be significantly regulated by WNTβ catenin after 8h and 24h, respectively. Among these, the profibrotic cytokines interleukin (IL)-1β and IL-6 were identified and confirmed by quantitative qRT-PCR and ELISA. Both IL-1β and IL-6 were highly regulated on the mRNA and protein level in experimental and idiopathic human pulmonary fibrosis, as analysed by qRT-PCR and Western Blot analysis, and ELISA. Using WNT3A-treated transgenic TOPGAL mice, IL-1β and IL-6 induction by WNTβ catenin activation was confirmed in vivo.

Conclusion: Taken together, our microarray analysis of WNT3A-stimulated primary ATI cells revealed a novel link between the WNTβ catenin pathway and the fibrogenic immune response, which may foster the progression of fibrosis by affecting epithelial and immune cell function.

PP173
Role of mast cells and chymase in idiopathic pulmonary fibrosis
Djuro Kosanovic1, Hosssein Ardeschir Ghofrani 1, Norbert Weissmann1, Djuro Kosanovic2, Hossein Ardeschir Ghofrani 1, Norbert Weissmann1, Djuro Kosanovic3, Hossein Ardeschir Ghofrani 1, Norbert Weissmann3.

Objective: The quantification of pulmonary MCs and CMCs revealed that their population was about 6 and 8 folds higher in IPF patients, as compared with donors. Also, MCs were separated as granulated and degranulated (activated) and index of granulation (IOG) (number of granulated/number of degranulated MCs) was evaluated.

Results: The quantification of pulmonary MCs and CMCs revealed that their population was about 6 and 8 folds higher in IPF patients, as compared with donors. There was a preponderance of perivascular MCs and CMCs in IPF lungs (p<0.05 versus donor lungs). Furthermore, we found that there was about 8 fold decrease of IOG in IPF patients as compared with donors. Finally, there was a strong accumulation of both MCs and CMCs in interstitial regions of the tissues (~65%) in comparison with other regions of the lungs.

Conclusions: The findings suggest that chymase released from activated MCs may be involved in the pathogenesis of IPF. Further investigations will unravel the underlying pathomechanism and substantiate chymase as a potential target for future therapeutic strategies.

PP174
Fibrosis as a consequence of immune dysregulation associated with HPA axis exhaustion: lessons from a 12-year experience in cystic fibrosis
Alexandra Pukhalsky1,2, Galina Shmarina1,2, Vladimir Alioshkin2, Research Centre for Medical Genetics, Moscow, RU

There are two principal mechanisms of inflammation control in the body. The first is realized by glucocorticoids (GCs) and catecholamines, the major stress hormones; the second is carried out by regulatory T cells (Treg). GCs stimulate a negative feedback mechanism, which protects the organism from products with negative feedback. Tregs maintain peripheral tolerance, realize a negative control of various immune responses and restrict inflammation. Normally, both mechanisms are well equalized. Such equilibrium may be disturbed due to multiple attacks of pathogens occurring in cystic fibrosis (CF) patients throughout life. The aim of the study was to reveal the signs of HPA axis depletion and regulatory T cell (Treg) accumulation in CF patients. Cohort of 83 CF patients without anti-inflammatory therapy and of 25 healthy children was enrolled into the study.

The results (see Table) show that along with low ACTH level, increased amounts of IL-10 and TGF-β1 may be revealed. Such immune abnormalities are associated with fibrosis including that in the liver. Ex vivo data confirm our assumption: long-term replacement therapy in the form of alternate course of prednisolone (0.2-0.5 mg/kg body weight every other day) significantly reduces cirrhosis frequency among 39 CF patients (p=0.001).

PP175
Telomerase activity profiles in lung cancer and idiopathic pulmonary fibrosis
Caterina Samara, Katie L. Martin, Giorgos Margaritopoulos, Giannaou Soulia, Ioannis Gianmarakis, Maria Angousti, Nikolaos Staflakis, University of Crete Medical School, Department of Thoracic Medicine, Laboratory of Molecular and Cellular Pulmonary Medicine, Heraklion, Crete, GR

Introduction: Telomerase is a reverse transcriptase ribonucleoprotein (TERT) that synthesizes telomeric repeats using its RNA component (TERC) as a template to protect chromosome ends. There is a growing appreciation for the connection that exists between telomere maintenance deficiency states and conditions such as idiopathic pulmonary fibrosis (IPF) and various malignancies.

Aim: We aimed to evaluate telomerase expression levels (mRNA expression of both subunits TERT and TERC) in Bronchoalveolar Lavage Fluid (BALF) of patients with Lung Cancer and Idiopathic Pulmonary Fibrosis.

Patients and methods: We prospectively studied 21 BALF samples from patients with Lung Cancer, 22 BALF samples from patients with IPF and 12 BALF samples from control subjects. mRNA expression for hTERT and hTERC was measured by Real-Time RT-PCR.

Results: Human hTERC mRNA transcripts were detected in 2/21 (9.5%) cases of Lung Cancer, in 13/20 (65%) cases of IPF and in 4/12 (33.3%) of the controls subjects. BALF hTERC mRNA transcripts were significantly over-expressed in IPF as compared to Lung Cancer (2.06±1.51 vs 0.47±0.43, p=0.002) and a trend of increase remained when IPF was compared to controls (2.06±1.51 vs 0.07±0.05, p=0.055). No significant difference was detected in hTERC expression between controls and patients’ groups.

Conclusions: An increased expression of hTERC in IPF patients when compared to an attenuated hTERC expression in patients with Lung Cancer, suggests that telomerase may play significant, although different roles in fibrogenesis and carcinogenesis. These preliminary findings suggest the need for further investigation at the level of telomere length and telomerase activity.

PP176
Long-term anti-inflammatory treatment restores affected cytokine production in cystic fibrosis patients
Galina Shmarina1,2, Alexandr Pukhalsky1,2, Vladimir Alischokin2, Research Centre for Medical Genetics, Moscow, RU; 2G.N. Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, RU

149 cystic fibrosis patients (mean age 12.4±6.0 years) were enrolled into the study. 74 patients were treated with basic therapy only and 75 individuals received besides the basic therapy anti-inflammatory treatment (AIT) with azithromycin (AZ, 500 mg orally three times a week; n=45), or prednisolone (PD, n=14) in the form of alternated course (0.3-0.5 mg/kg body weight every other day). 16 children received both AZ and PD. Duration of the AIT was 1 year or more. Plasma cytokine levels are presented in the Table.

The patients who received PD and AZ, combined therapy demonstrated the most pronounced changes in plasma cytokine levels. Their plasma TGF-β1 concentrations were comparable with those in healthy age-matched control (median value 17.7 pg/ml). Furthermore, in this group a significant elevation of pro-fibrotic IL-4 was associated with marked increase of anti-fibrotic IFNγ. The changes observed in AZ treated patients, in particular, increased IL-4 and TGF-β1 levels together with a tendency to fall of IFNγ are presumed to facilitate fibrosis and promote the potentially dangerous TH17 cell development.

PP177
cAMP-mediated regulation of fibroblast to myofibroblast differentiation in idiopathic lung fibrosis
Rebecca Simms1, William Coward1, Carol Feghali-Bostwick2, Alan Knox1, Linhua Fung1, 1Respiratory Biomedical Research Unit, GB; 2Division of Pulmonary, Allergy and Critical Care Medicine, Pennsylvania, US

Rationale: Myofibroblasts are key effector cells in idiopathic pulmonary fibrosis (IPF). Their differentiation from fibroblasts is a major source of myofibroblasts. PGE2 inhibits myofibroblast differentiation. Its production is reduced in myofibroblasts due to depressed cyclooxygenase-2 (COX-2) gene expression. PGE2 inhibits
myofibroblast differentiation by increasing cAMP via EP2 and EP4 receptors. Our hypothesis is that exogenous PGE2 may trigger fibroblast differentiation through cAMP-mediated mechanisms.

Methods: Normal (F-NL) and fibrotic (F-F) primary human lung fibroblasts were treated with TGF-β to induce fibroblast to myofibroblast differentiation and PGE2, Forskolin (FSK) or Salmeterol (Sal) to reverse myofibroblast differentiation. To prevent myofibroblast differentiation, TGF-β and PGE2 were treated with PGE2 and TGF-β. COX-2, α-smooth muscle actin (αSMA), EP2 and EP4 were analysed by western blotting.

Results: F-F had increased uSMA and repressed COX-2 compared to F-NL. EP2/EP4 receptor expression does not differ between F-NL and F-F. F-F treated with PGE2 showed decreased α-SMA and increased COX-2. F-NL treated with TGF-β showed increased uSMA and reduced COX-2. F-NL treated with TGF-β and PGE2 had COX-2 and uSMA similar to control levels. F-F treated with Sal and FSK had decreased uSMA and increased COX-2.

Conclusions: Reduced PGE2 levels in F-F is not due to EP2 or EP4 receptor downregulation or PGE2 exerts myofibroblast differentiation and prevents TGF-β-induced myofibroblast differentiation in F-NL. FSK and Salme exert similar effects as PGE2. cAMP elevating agents inhibit myofibroblast differentiation and may offer an alternative therapeutic target.

PP178
Histological markers of epithelial-mesenchymal transition in idiopathic pulmonary fibrosis (IPF) provide evidence of an alternative repair process

Nicolà Lomas1,2, Nicholas Forsey1, Monica Spiteri3, 1 Keele University, Institute of Science and Technology in Medicine, Stoke-on-Trent, Staffordshire, GB; 2 University Hospital of North Staffordshire, Histology, Stoke-on-Trent, Staffordshire, GB; 3 University Hospital of North Staffordshire, Department of Respiratory Medicine, Stoke-on-Trent, Staffordshire, GB

Introduction: Wound remodelling in the pathogenesis of idiopathic pulmonary fibrosis (IPF) has produced conflicting results from previous cell culture and animal model studies.

Aim: The aim of this study was to examine wound remodelling mechanisms in usual interstitial pneumonia (UIP), with emphasis on the role of epithelial mesenchymal transition (EMT).

Methods: Immunohistochemistry was used to assess cellular expressions of markers of EMT in paraffin embedded lung tissue samples from 21 patients with IPF, with comparisons made to histologically-defined normal lung sections from 19 control subjects.

Results: Hyperplastic type II pneumocytes in all UIP cases expressed the adhesion molecule E-cadherin with no expression of N-cadherin or TWIST. Expression of TWIST was restricted to fibroblasts/myofibroblasts. TGF-β1-induced myofibroblast differentiation and prevents TGF-β-induced myofibroblast differentiation in F-NL. FSK and Salme exert similar effects as PGE2. cAMP elevating agents inhibit myofibroblast differentiation and may offer an alternative therapeutic target.

Conclusions: Reduced PGE2 levels in F-F is not due to EP2 or EP4 receptor downregulation or PGE2 exerts myofibroblast differentiation and prevents TGF-β-induced myofibroblast differentiation in F-NL. FSK and Salme exert similar effects as PGE2. cAMP elevating agents inhibit myofibroblast differentiation and may offer an alternative therapeutic target.

PP179
Influence of leucocytes on Interleukin-8 in sputum and whole blood in cystic fibrosis

Sabina Schmitt-Grohé1, Louisa van den Boom1, Doris N’Gampo1, Ingrid van der Meulen1, 1 University of Maastricht, Cardiovascular Research, Maastricht, NL

Introduction: Sputum leukocytes but between blood leucocytes and IL-8 (r=0.528, p=0.007) in patients but not in controls. This might be explained by an increased apoptosis of airway leucocytes compared to blood leucocytes in CF (Tabary et al 2006).

Conclusion: IL-8 in the CF lung is regulated not only by LPS dependent mechanisms but are involved in innate and adaptive immune responses. Recent evidence suggests that viruses can cause mediator release from infected BECs with potential of activating dendritic cells (DCs). Therefore, we hypothesized that virally-infected BECs can induce DC activation.

Methods: Primary BECs monolayers were infected with rhinovirus (RV)-1 or

PP180
Does eradication of Helicobacter pylori decrease COPD exacerbation?

Soroush Seifirad, Elham Mohammadhosein, Soheil Seifirad, Enayat Safavi, Tehran University of Medical Sciences, Pulmonary and Critical Care Research Center, Tehran, IR

Background: An epidemiological association between Helicobacter pylori (HP) infection and COPD patients was suggested in recent studies. HP IgG levels might be correlated with the severity of COPD. Chronic HP infection stimulates the expression of a variety of proinflammatory cytokines, such as IL-1, IL-8 and Tumor Necrosis Factor-α (TNF-α).

Objectives: to evaluate the effect of HP eradication on COPD exacerbations

Methods: 100 COPD HP seropositive patients were enrolled in the study, allocated into two (case/control) groups matched for age, sex, smoking habits, and COPD exacerbations in one year before the study. Baseline proinflammatory cytokine levels (PCL), including IL-1, IL-8, and TNF-α were measured. HP eradication was performed according to the current guidelines and the outcome was evaluated by assessing a change in the number of exacerbations in the case group compared to the control group.

Results: Two significant differences in the baseline PCL were observed in the two groups. COPD exacerbations were decreased after HP eradication in comparison with the placebo group (p=0.036). In the case group, a significant decrease in IL-1 (p=0.034), IL-8 (p=0.027), and TNF-α (p=0.037) was observed after eradication. At the end of study, IL-8 (p=0.013) and TNF-α (p=0.025) levels were significantly decreased, but IL-1 decrease was not significant (p=0.1). No significant changes in PCL were observed in the control group.

Conclusion: In this study HP eradication could decrease PCL and COPD exacerbations in HP seropositive COPD patients. This study supports the hypothesis that HP infection might play a proinflammatory role and co-trigger COPD with other factors.
UV-irradiated RV-1 for 8-48h. Real-time PCR was used to determine RV-1 infection of BECs. Mediator release by infected BECs was measured in supernatants by ELISA. Activation of monocyte-derived DCs following 24h incubation with UV-irradiated infected BECs supernatants was assessed by monitoring receptor expression by flow cytometry.

Results: Exposure of BECs to RV-1 resulted in a time-dependent increase in infection and cytopathic effect. RV-1 induced the release of IL-6, MCP-1, RANTES, MIP-3α, GM-CSF, IP-10, TNF-α and IL-8 in BECs. Culture of DCs with supernatants from RV-1-infected BECs induced CD86, HLA-DR and CD83 upregulation. RV-1-infected BECs and RV-1-activated DCs deficient in expression of DC to lyse control BECs supernatants caused CD86 upregulation. At a ratio where lyzed control cells had no effect, DC activation was still observed with UV-irradiated infected BEC supernatants.

Conclusion: Rhinovirus infection of epithelial cells causes release of pro-inflammatory mediators and DC maturation which may contribute to innate and adaptive immune responses.

PP184
Spectrum of anti-neutrophil cytoplasmic antibodies (ANCA) in patients with pulmonary tuberculosis overlaps with that of Wegener’s granulomatosis
Vandana Pradhan, Kanjaksha Ghosh. National Institute of Immunohaematology, Department of Autoimmune Disorders, Mumbai, Maharashtra, IN

Introduction: Mycobacterial infections are known to induce the development of autoantibodies, some of which are also known to be diagnostic markers for some other diseases. This study was undertaken to determine the prevalence of autoantibodies like anti-neutrophil cytoplasmic antibodies (ANCA), anti-nuclear antibodies (ANA), anti-double stranded antibodies (anti-dsDNA) and anti-histone antibodies (AHA) in pulmonary Tuberculosis.

Materials & methods: Seventy pulmonary TB patients, 30 patients of interstitial lung disease (ILD) and 100 normals were studied. ANCA and AHA were detected by indirect immunofluorescence test (IIF). Anti-dsDNA and AHA were tested by ELISA.

Results: ANCA was detected in 30% cases, and of these 52.4% showed perinuclear pattern (p-ANCA), 38.1% cytoplasmic (c-ANCA) and 9.5% showed an “atypical” pattern. ANCA specificities by ELISA revealed that, 47.6% had anti-MPO, 19.1% had anti-Proteinase3 (anti-PR3) and 22% had anti-Lactoferrin (anti-LF) antibodies. ANA and AHA were present in 24.3% and 21.3% cases respectively whereas anti-dsDNA antibodies were absent.

Conclusion: The presence of autoantibodies in TB patients could have a multifactorial etiology. Clinically relevant is the presence of anti-PR3 antibodies. This finding along with pulmonary and renal manifestations could lead to a false diagnosis of Wegener’s granulomatosis or vice versa because these autoantibodies may be present in both diseases.

Increased phospholipases A2 activity in alveolar macrophages at low oxygen and influence of bacterial lipopolysaccharides
Olga Kuzniatsova. Belarusian State University, Biology, Minsk, BY

Acute respiratory distress syndrome (ARDS) is a lung injury of high mortality rate and sepsis is one of the most frequent cause of ARDS. Alterations of pulmonary surfactant, in which dipalmitylophosphatidylcholine (DPPC) is a major component, is an early pathophysiological event in ARDS. In sepsis-induced acute lung injury, edema and atelectasis may result in low ventilation and reduced O2-tension around alveolar macrophages (AM). Therefore, we examined the effects of bacterial lipopolysaccharides (LPS) and low oxygen on enzymatic hydrolysis of DPPC in AM. AM were cultured for 20 h with 1, 10, 50 μg/ml LPS. We found a significant increase in hydrolysis of DPPC by phospholipases inside AM and in culture medium in dose- and time-dependent manner. The activity was maximal after 20 h of incubation with 50 μg/ml LPS and was 41% and 118% (p < 0.01) above controls for intra- and extracellular DPPC hydrolysis correspondingly. AM were exposed for 20 h to the normal (21%) and the low (17, 13, 10, 5%) oxygen. A progressive reduction in the concentration of O2 resulted in enhanced phospholipase activity to 19% (p ≤ 0.05). Secretory enzymatic activity was less sensitive, it only increased O2-tension around alveolar macrophages. We investigated whether AR inhibition could prevent ovalbumin (OVA)- and ragweed pollen extract (RWE)-induced airway inflammation in mice model of asthma.

Mice Sensitization by an Intraperitoneal injection of RWE/OVA in adjuvant Al(OH)3 twice on days 0 and 4 for RWE and one week apart for OVA. Challenge intranasally (RWE) or by nebulization (OVA). Airway inflammation confirmed by BAL cytology, Eosinophils infiltration in lung, Cytokines and chemokines levels. Phenotype characterization and production of inflammatory cytokines, accumulation of eosinophils in airways and sub-epithelial regions, macin production in the bronchoalveolar lavage fluid, and airway hypersensitivity, elevated IgE level and release of Th2 cytokines in the airway and treatment with AR inhibitors markedly reduced these pathological changes in mice. In SAEC, treatment with TNF-alpha, LPS- or RWE-induced apoptosis, reactive oxygen species generation, the release of inflammatory markers IL-6, IL-8, and PGE2 and activation of NF-kappaB and AP-1. Our results indicate that AR inhibition could be a novel therapeutic approach for preventing airway inflammation such as allergic asthma.

II/IL1RA axis mediates bone marrow cell senescence and eosupressus
Qingshan Li1, Nayna Casamayor1, Jorge Maestre-Mesa2, Robert Jackson2,3, Roy Levin1,3,5, University of Miami, Anesthesiology, Miami, FL, US; 2University of Miami, Psychiatry and Behavioral Sciences, Miami, FL, US; 3Miami VAHS Research Service, Miami, FL, US; 4University of Miami, Division of Pulmonary, Critical Care and Sleep Medicine, Miami, FL, US; 5University of Miami, Hussman Institute of Human Genetics, Miami, FL, US

Introduction: Stem cell senescence may be involved in the pathogenesis of chronic obstructive pulmonary disease (COPD). Interleukin-1 receptor antagonist (IL1RA) is a naturally occurring inhibitor of IL1. Ortiz et al. (2007) showed that intravenous stem cell (MSC)-mediated lung repair is also regulated by IL1RA after bleomycin-induced lung injury.

Aims and Objectives: The study was conducted to determine the effect of IL1RA-converting enzyme and IL1RA overexpression protected the lungs from aging-associated pathology compared to the background strain. CTX assays showed that IL1RA+ mice had reduced MSCs compared to the IL1RA TG mice (4.6 ± 1.0, p = 0.001). The study was conducted to determine the effect of IL1RA on aging-associated pathology compared to the background strain. CTX assays showed that IL1RA+ mice had reduced MSCs compared to the IL1RA TG mice (4.6 ± 1.0, p = 0.001).

Results: Hoe staining of fixed tissue showed that IL1RA+ mice had reduced MSCs compared to the background strain. The absence of IL1RA-converting enzyme and IL1RA overexpression protected the lungs from aging-associated pathology compared to the background strain. CTX assays showed that IL1RA+ mice had reduced MSCs compared to the IL1RA TG mice (4.6 ± 1.0, p = 0.001). The study was conducted to determine the effect of IL1RA on aging-associated pathology compared to the background strain. CTX assays showed that IL1RA+ mice had reduced MSCs compared to the IL1RA TG mice (4.6 ± 1.0, p = 0.001).

Allergic airway responses to aeroallergens are differentially regulated by IL-13 receptor alpha 1 and dependent on IL-13:IL-4 ratios
Eric Cole1, Diana Shik2, Marie Rothenberg2,3, Ariel Minuz2,3. 1The Tel Aviv University, Clinical Microbiology and Immunology, Tel Aviv, IL; 2Cincinnati Children’s Hospital Medical Center, Division of Allergy and Immunology, Cincinnati, OH, US

Background: Studies using IL-33/IL-13 mice demonstrated a critical role for IL-13 receptors in all allergic-induced airway responses except eosinophilia. However, previous experiments were limited to mice sensitized with intraperitoneal OVA and alum.

Aims: To define the role of IL-13Rα1 in allergic-airway inflammation in response to aeroallergens and mucosal sensitization.

Methods: Wild type and IL-33/IL-13 mice were challenged with Aspergillus fumigatus (Asp) or house dust mite (HDM) extracts (10 mg/mouse, 9 intranasal challenges). Alternatively, Asp was absorbed to alum (100 mg + 1 mg), mice were sensitized (days 0 and 14, intraperitoneal) and challenged (days 24 and 27, intranasal). BALF was assessed for differential cell counts (Diff-Quick), TH2 cytokine and chemokine levels by ELISA, Lung histology and resistance were assessed by H&E, PAS stain and flexiVent respectively.

Results: Asp- and HDM-induced AHR and mucus production was IL-13Rα1-dependent. Eosinophil recruitment to the lung as well as CCL17, CCL22 and IL-5 production were IL-13Ra1 dependent following Asp-challenge but IL-dependent. Eosinophil recruitment to the lung as well as CCL17, CCL22 and IL-5 production were IL-13Ra1 dependent following Asp-challenge but IL-dependent.

Conclusions: We highlight IL-13Rα1 as a key regulator of allergic lung responses following aeroallergen sensitization and challenge. Nevertheless, outcomes of IL-13Rα1-targeted asthma therapy may vary according to allergen-induced IL-4:IL-13 ratios.

W4
Transcription factors GATA-3 and T-bet as crucial markers of allergic bronchial asthma
Lada Sorokina, Valery Mineev, Michael Nyoma, Vasily Ivanov, Vasily Trofimov. Saint-Petersburg State Pavlov’s Medical University, Department of Hospital Therapy, Saint-Petersburg, RU

Aim: The aim of the study is to establish the features of expression of GATA-3 and T-bet in bronchial asthma (BA).

Methods: 20 healthy controls, 44 patients with allergic and 42 with non-allergic BA were examined. GATA-3 and T-bet expression in peripheral lymphocytes were analyzed by Western blotting after the cells were lysed. Western blotting was performed through the standard procedure. Antibodies against GATA-3 (Abcam, UK) and T-bet (Santa Cruz Biotechnology, UK) were used. The level of protein analyzed according to p-tubulin using anti-tubulin antibody (Sigma Aldrich, USA).

Results: The expression of GATA-3 was significantly increased and expression of T-bet was significantly decreased in lymphocytes of patients with allergic BA compared to healthy (p=0.04) and non-allergic BA groups (p=0.005). The level of GATA-3 and IL-4 receptor positively correlated with the degree of airflow obstruction (r=0.4, p=0.011; n=41) and positively correlated with the intensity of steroid therapy (r=0.33; p=0.033; n=42). The level of T-bet in non-allergic BA positively correlated with the prevalence of asthmatic triad (r=0.4, p=0.011; n=41) and the drug intolerance (r=0.43; p=0.005; n=42).

Conclusion: GATA-3 and T-bet may play a key role in the pathophysiology of BA. The expression of GATA-3 and T-bet may serve as a markers of allergic BA to provide necessary dose of steroids in patients with BA. This study suggests that allergic BA underlie the high level of TH2-cytokines production in allergic disease. The work was supported by Saint-Petersburg government grant 28-04/17 (Certif. PSP00591) and by Saint Petersburg State Medical University grant named after Pavlov “Research grant of the year” for the best scientific work.

Chemokine and relative receptors mRNA levels in blood of COPD patients
Kirill Sysorov. Pavlov State Medical University, Federal Center for Molecular Medicine, St.-Petersburg, RU

Chronic obstructive pulmonary disease (COPD) is respiratory system pathology with remitting course and progression of respiratory dysfunction. Chemokines and their receptors is a cutting edge of chronic inflammation development during COPD. Chemokines and chemokine receptors mRNA expression in whole blood is pivotal reflection in COPD clinical overview. In our study we tried to examine chemokine-receptor balance in COPD progressions. The whole blood samples of 20 patients with COPD were investigated concerning mRNA encoding cytokin, eotaxin-2, MIP-1alpha, MIP-1beta, IL-8, RANTES, CCR1, CCR3, CCR5, CXCR1, and CXCR2. As a control group blood of 23 healthy volunteers was studied. The total RNA was extracted accordingly manufacturing procedure, followed by reverse transcription, gene-specific PCR and semi-quantitative analysis were performed using beta-actin as a reference gene. All patients were male (mean age 58.5±7.2) and had a long smoking history. The age of volunteers was 53.3±6.4 and they had no smoking history. The results of analysis for chemokines and receptors were analyzed according to clinical features of COPD. The statistically significant increasing of IL-8 and MIP-beta mRNA in COPD patients was established relatively to control, meanwhile gene expression of MIP-1alpha CCR1, CCR3, CCR5, CXCR1, and CXCR2 was decreased in COPD patients. Eotaxin mRNA level in blood directly correlates with exacerbation in COPD patients (r=0.88, p=0.004). Patients with 2nd stage of respiratory failure have lower CCR1 (p=0.019) mRNA expression in comparison of 1st stage. The level of pulmonary hypertension is directly correlates with eotaxin-2 mRNA expression (r=0.52, p=0.01).

W6
Ascorbate and deferoxamine administration post chloride exposure decrease mortality and lung injury in mice
Sotirios Zagoraiou1,2, Asta Jurkvenaite1,2, Solana Fernandez1, Stephen Doran1, Amit Yadav1,2, Giuseppe Squadrillo1,2, Edward Postlethwaite1,2, Larry Bowen3, Sadis Matalon1,2,4,5, 1University of Alabama at Birmingham, Department of Anesthesiology, Birmingham, Alabama, US; 2University of Alabama at Birmingham, Center for Pulmonary Injury and Repair, Birmingham, Alabama, US; 3University of Alabama at Birmingham, Department of Environmental Health Sciences, Birmingham, Alabama, US; 4University of Alabama at Birmingham, Center for Free Radical Biology, Birmingham, Alabama, US; 5Infectious Disease Research, Southern Research Institute, Birmingham, Alabama, US

Chlorine (Cl2) gas exposure poses an environmental and occupational hazard that frequently results in acute lung injury. There is no effective treatment. We assessed the efficacy of antioxidants in decreasing mortality and lung injury as a result of Cl2 toxicity to mice exposed to 600 ppm of Cl2 for 45 minutes and returned to room air. Ascorbate and deferoxamine were administered intramuscularly every 12 hours (h) and by nose-only inhalation every 24 h for 3 days starting after 1 h post-exposure. Control mice were exposed to Cl2 and treated with vehicle (saline). Mortality was reduced four-fold in the treatment group compared to the control group (22% versus 78%; p<0.007). Surviving animals in the treatment group had significantly lower protein concentrations, cell counts and epithelial cells in the bronchoalveolar lavage (BAL). Elevated ascorbate levels in the lung tissue correlated inversely with protein levels as well as with number of neutrophils and epithelial cells in the BAL. In addition lipid peroxidation was reduced 3-fold in the BAL of mice treated with ascorbate and deferoxamine when compared to the control group. Administration of ascorbate and deferoxamine reduces mortality and ameliorates lung injury through reduction of alveolar-capillary permeability, inflammation, and epithelial shedding and lipid peroxidation.

W7
Comparison of ribavirin and oseltamivir in treating A/Caifornia/04/2009 (H1N1) influenza virus in mice
Sotirios Zagoraiou1,2, James Noah1,2,3, Asta Jurkvenaite1,2, Larry Lawton1, Sadis Matalon1,2,4,5, Diana Noah1,2,4,5, 1University of Alabama at Birmingham, Department of Anesthesiology, Birmingham, Alabama, US; 2University of Alabama at Birmingham, Center for Pulmonary Injury and Repair, Birmingham, Alabama, US; 3Southern Research Institute, Birmingham, Alabama, US; 4Institute of Environmental Health Sciences, Birmingham, Alabama, US; 5University of Alabama at Birmingham, Department of Environmental Health Sciences, Birmingham, Alabama, US; 6University of Alabama at Birmingham, Center for Free Radical Biology, Birmingham, Alabama, US

Increasing cases of oseltamir resistant H1N1 (2009) viruses are being reported. Ribavirin is an antiviral agent effective against hepatitis C and respiratory syncytial virus. Our objective was to compare the efficacy of ribavirin and oseltamir in treating mice infected with mouse adapted A/Caifornia/04/2009 influenza virus in terms of mortality and lung injury. 48 female BALB/c mice were used in the study and randomized to 3 groups: 1) A/Caifornia/04/2009 & Ribavirin, 2) A/Caifornia/04/2009 & Oseltamir, 3) A/Caifornia/04/2009 & Placebo. Mice were challenged intranasally with mouse adapted A/Caifornia/04/2009 influenza virus and treatments started 5 hours pre-infection and subsequent treatments were administered at 12:1 hours apart for 5 days. At days 3 and 6 post-infection 3 mice from each group were euthanized for broncho-alveolar lavage analysis and lung viral loads determination. We also assessed I4-day survival, protein levels, total cell counts and chemokine and cytokine profiles in the BAL. etc.

Ribavirin and oseltamir groups had significant increase in survival and significant decrease in lung viral loads and protein levels in BAL compared to untreated group. Ribavirin group insignificantly higher neutrophil counts on Day 3 compared to oseltamir and untreated groups. Both groups had significantly lower levels of KC, RANTES, MIP-1a and MIP-1b at day 3 compared to untreated ones. Ribavirin group had minimal production of IL-6 and IFN-γ and IL-10 at days 3 and 6 while oseltamir group had increased levels of IL-6, IL-12, and IFN-γ at day 6. Our results indicate that ribavirin is equally effective with oseltamir in improving survival and mitigating lung injury caused by H1N1 influenza virus infection.

Pleural effusion
Vascular endothelial growth factor
45s (390), 57s (P444), 96s (P627), 123s (P753), 132s (P797), 287s (1688), 518s (P2800), 703s (P3881), 705s (P3890), 742s (P4064), 852s (4684), 867s (P4751)

Vascular permeability
287s (1688), 358s (P2042), 532s (2941), 819s (4495)

Vasodilatation
412s (P2302), 419s (P2330), 426s (P2365)

Venous thrombosis
422s (P2344, P2345), 432s (P2392), 512s (P2769), 718s (P3948, P3950)

Video-assisted thoracoscopic surgery (VATS)
59s (P454), 60s (P456, P459), 86s (P577), 89s (P594), 434s (P2399), 438s (P2417, P2418, P2419), 49s (P4241), 494s (P2687), 510s (P2761), 514s (P2779), 523s (P2823), 525s (P2834, 558s (P3661), 856s (4701)

Weaning and extubation
67s (P494), 92s (P608), 238s (P1287), 244s (P1317), 250s (1414), 346s (P1907), 359s (P2049), 362s (P2061), 363s (P2065, P2067), 365s (P2074, P2078), 366s (P2081, P2083), 346s (P2408), 539s (P2970, P2971), 561s (P3076), 623s (P3497), 669s (P3716), 684s (P3785), 796s (P4329), 914s (P5000), 915s (P5004), 917s (P5013, P5015), 918s (P5017)

Weather
110s (P688), 157s (P913), 177s (P1003), 183s (P1032), 270s (P1497), 329s (1904), 386s (P2178), 459s (P2513), 639s (P3573)

Welders
766s (P4178)

Wheezeing
22s (P261), 55s (P435), 69s (P501), 71s (P508), 110s (P689), 171s (P974), 174s (P990), 184s (P1036), 189s (P1058, P1061), 195s (P1087), 201s (P1116), 208s (P1151), 212s (P1167), 213s (P1173), 214s (P1178), 249s (1408, 1409), 250s (1411), 251s (1417), 269s (P1496), 270s (P1497, P1498, P1501), 271s (P1503), 272s (P1506, P1509), 313s (P1805), 352s (P2018), 375s (P2126, P2127), 442s (P2436, 459s (P2513), 571s (3225), 585s (P3289), 586s (P3294), 597s (P3349), 602s (3400, 3401, 3403), 603s (3406), 613s (3453), 615s (P3459, P3460), 618s (P3472), 625s (P3508), 646s (P3605), 716s (P3943), 732s (P4015), 739s (P4050), 743s (P4069), 745s (P4074), 746s (P4081), 753s (P4119), 756s (P4132), 757s (P4134, P4135, P4136), 760s (P4152), 763s (P4165), 764s (P4168), 767s (P4184), 771s (P4203, 778s (P4239), 781s (P4245), 782s (P4255, P4257), 784s (P4266), 785s (P4271), 786s (P4276, P4277), 823s (4510), 829s (P4541), 835s (P4569), 836s (P4578), 899s (P4927)
