\textbf{Pulmonary Diseases, VU Medical Center, Amsterdam, Netherlands; 2Pulmonary Diseases, VU Medical Center, Amsterdam, Netherlands; 3Pulmonary Diseases, VU Medical Center, Amsterdam, Netherlands; 4Pulmonary Diseases and Physiology, VU Medical Center, Amsterdam, Netherlands; 5Pulmonary Diseases, VU Medical Center, Amsterdam, Netherlands.}

Background: In pulmonary arterial hypertension (PAH) survival is strongly associated with right ventricular (RV) function and its ability to adapt to the increased pulmonary artery pressure (PAP). RV remodeling to the increased load is often characterized by dilatation, and hypertrophy. RV wall stress is a simple parameter that contains the effects of PAP, dilatation and hypertrophy. Therefore this study aims to evaluate RV wall stress in patients during follow-up.

\textbf{Methods and results:} At baseline 53 patients underwent magnetic resonance imaging (MRI) and right heart catheterization (RHC). In all patients RV end-systolic wall stress (RVESWS) was calculated using the law of Laplace. Eight patients died during the first year of follow-up and therefore 45 patients underwent MRI and RHC after 1-year follow-up. During a median 1-year term follow-up of 57 months another 10 patients died. At baseline, RVESWS appeared to be similar in survivors and non-survivors (n=53, p=0.765). In contrast, change of RVESWS during the 1-year period was significantly (p=0.014) between survivors and non-survivors. Survivors showed a decrease in RVESWS during 1-year follow-up, whereas non-survivors showed an increase of RVESWS during 1-year follow-up.

Kaplan-Meier analysis showed a higher mortality rate in patients with an increase of RVESWS >17 mmHg than in patients with an increase of RVESWS ≤17 mmHg or a decrease of RVESWS during follow-up (n=48, p<0.001).

Conclusion: Progressive RV failure is characterized by an increase of RVESWS.

P1514\textbf{Ventilation perfusion lung scan in pulmonary veno-occlusive disease}\n
Andrei Seferian\textsuperscript{1}, Badia Helal\textsuperscript{2}, Xavier Jais\textsuperscript{1}, Barbara Gireud\textsuperscript{1}, Sven Günther\textsuperscript{1}, Laurent Savale\textsuperscript{1}, Peter Derflüßer\textsuperscript{1}, Alice Huertas\textsuperscript{1}, Olivier Sibton\textsuperscript{1}, Marc Himbert\textsuperscript{1}, Gerald Simoneau\textsuperscript{1}, David Montani\textsuperscript{1}, \textsuperscript{1}Univ Paris Sud, AP-HP, Service de Pneumologie et Réanimation Respiratoire, Centre National de Référence de l’Hypertension Pulmonaire Sévère, INSERM U999, Hôpital Antoine Béclère, Clamart, France; 2Service d’Anatomie Pathologique, Centre Chirurgical Marie Lannelongue, Le Plessis Robinson, France.

Introduction: Pulmonary veno-occlusive disease (PVOD) is a rare form of pulmonary arterial hypertension (PAH) that remains poorly understood and is both difficult to diagnose and treat. Histological proof is required for a definitive diagnosis of PVOD; however, this approach is hazardous in patients with pulmonary hypertension and therefore surgical lung biopsy is not recommended. In recent joint ERS/ESC guidelines, ventilation and perfusion (V/Q) lung scan was recommended to look for chronic thromboembolic pulmonary hypertension and it has been suggested that unmatched perfusion defects may suggest PVOD.

![Figure 1. Comparative evaluation of the V/Q scans between iAP and PDVQ groups.](image-url)
Aim of the study: To evaluate the interest of V/Q lung scan in the non-invasive approach to screen PVOD patients.

Methods: V/Q lung scans from 70 patients with idiopathic PAH and 56 patients with confirmed or highly probable PVOD, were reviewed in double blind.

Results: The vast majority of V/Q lung scan were normal or with no significant abnormalities in both group of patients. No differences in ventilation or perfusion lung scans were observed between idiopathic and PVOD patients (p > 0.05). No differences were observed between confirmed (n=31) or highly probable PVOD (n=25). Unmatched perfusion defects were found in 7 (10%) idiopathic PAH patients and 4 (7.14%) PVOD patients (p > 0.05).

Conclusion: Unmatched perfusion defects were rarely observed in idiopathic PAH or PVOD and V/Q lung scan may be not useful to discriminate PVOD.

P1515
Current practice for determining pulmonary capillary wedge pressure predisposes to serious errors in the classification of patients with pulmonary hypertension
Cardiology, University of Chicago Medical Center, Chicago, IL, United States

Background: Accurate measurement of left ventricular filling pressure (LVEDP) is important to distinguish between Group 1 pulmonary arterial hypertension (PAH) and Group 2 pulmonary hypertension from diastolic heart failure (PH-HFpEF).

Methods: We prospectively performed catheter catherization on 62 patients referred for evaluation of PH and compared the LVEDP at end-expiration to: a) the pulmonary capillary wedge pressure manually determined at end-expiration (PCWP-EXP) and b) the PCWP determined electronically (PCWP-digital).

Results: The PCWP-EXP was a more reliable measure of the LVEDP (mean 13mmHg vs 12.4mmHg, p=NS) than the PCWP-digital (mean 8mmHg vs 12.4mmHg, p=0.05). Bland-Altman analysis of PCWP-digital and LVEDP revealed a mean bias of -4.4 mmHg (95% limits of agreement -11.3mmHg to 2.4mmHg). Bland-Altman analysis of PCWP-EXP and LVEDP revealed a mean bias of 0.7mmHg (95% limits of agreement -5.5mmHg to 7.9mmHg). If the PCWP-digital were used to define the LVEDP, 11 patients (18%) would have been misclassified as having PAH rather than PH-HFpEF. Interestingly, 8 of these 11 patients either mortfuid obesity or hypoxia. In contrast, no patients were misclassified as PAH instead of PH-HFpEF using the PCWP-EXP to define LVEDP.

Conclusions: The common practice of using PCWP-digital measurements instead of PCWP-EXP measurements results in significant underestimation of the LVEDP. In our study, this translated to almost 20% of patients being misclassified as having PAH rather than PH-HFpEF. Thus, reliance on PCWP-digital measurements should be avoided as this may lead to the inappropriate use of pulmonary vasodilators.

P1516
Increased renin-angiotensin-aldosterone system activity in lungs of patients with idiopathic pulmonary arterial hypertension
Frances S. de Man1,2, Christophe Guignabert 1, Ly Tu1, Charlene Francou1, Gerard Simmenscu1, Elie Fidel1, Marc Humber1, Anton Van't Noordegraaf2, Saadia Eddahibi1. 1INSERM U999, Centre Chirurgical Marie Lannelongue, Le PLESSIS ROBINSON, France; 2Pulmonary Medicine, VU University Medical Center, Amsterdam, Netherlands

Studies have reported over-activation of the sympathetic nerve system (SNS) in patients with idiopathic Pulmonary Arterial Hypertension (iPAH). Since the Renin-Angiotensin Aldosterone System (RAAS) is closely related to SNS and the lungs are the major site for angiotensin 2 formation, we hypothesized that RAAS-activity is increased in iPAH.

Pulmonary endothelial cell (P-EC) cultures were generated from lung specimens of iPAH-patients and 4 (7.14%) PVOD patients (p > 0.05). P-EC of iPAH-patients produced significantly more angiotensin 2 upon angiotensin 1 incubation, compared to control. Interestingly, enalapril normalized angiotensin 2 production (Fig. 1B). In addition, pulmonary arteries of iPAH-patients exhibited increased AT1R expression and accentuated SRC-activity (Fig. 1C,D).

Conclusions: This study demonstrates increased RAAS-activity in lungs of iPAH-patients, illustrated by elevated ACE-activity and AT1R signalling. Future studies will focus on the effects of chronic inhibition of RAAS on pulmonary vascular remodelling in iPAH.

P1517
Changes in right ventricular mass are unrelated to changes in pulmonary pressures in pulmonary arterial hypertension
Marielle van de Veerendonk1, Sophie Dusouli1, Taco Kind1, Johannes Marcus2, Nico Westerhof3, Anton Vonk-Noordegraaf2. 1Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2Physics and Medical Technology, VU University Medical Center, Amsterdam, Netherlands; 3Physiology, VU University Medical Center, Amsterdam, Netherlands

Background: In pulmonary arterial hypertension (PAH), chronic pressure overload leads to right ventricular (RV) dilatation, hypertrophy and ultimately RV failure and death. Yet, the relevance of changes in RV mass and the interaction with changes in pulmonary pressure have never been investigated.

Objectives: To assess the relationship between changes in pulmonary pressure, volumes in RV mass and survival in PAH patients under PH-HFpEF targeted therapies.

Methods: 45 patients underwent right heart catheterization to measure mean pulmonary artery pressure (mPAP) and cardiac magnetic resonance to assess RV mass before and after 12 months of therapy. RV mass was indexed for body surface area. During long-term follow-up, 11 patients died.

Results: At baseline, survivors and non-survivors showed a similar mPAP (p=0.43) and RV mass index (p=0.06). RV mass index correlated to mPAP (R=0.51, p<0.01). At one-year follow-up, survivors (8 out of 12) showed an unchanged RV mass (-8±28%) and non-survivors (3 out of 3) (p=0.86). Overall, RV mass increased by 11±26% (p=0.03). Survivors showed an increased RV mass (17±25%; p<0.01). non-survivors showed an unchanged RV mass (-7±11%; p=NS). Changes in RV mass were unrelated to age (p=0.50) or gender (p=0.44). Changes in RV mass were unrelated to changes in mPAP (R=0.14; p=0.37).

A decreased RV mass was associated with mortality (HR: 0.95; 95%-CI 0.91-0.99; p=0.02) whereas changes in mPAP did not relate to mortality (HR: 1.01; 95%-CI 0.98-1.02; p=0.25).

Conclusions: In PAH, changes in mPAP were not followed by changes in RV mass. An increased RV mass during follow-up was associated with a favorable prognosis.

P1518
Systemic hypoxia contributes to pulmonary hypertension in heart failure
Bryan Taylor, Cesar Mojica, Thomas Olson, Paul Woods, Bruce Johnson.
Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Background: The classical mechanism for pulmonary hypertension (PH) in heart failure (HF) is related to vasoconstriction in pulmonary veins pressure surges leading to an increase in LV filling pressure. However, much of the PH in HF is reversed by ventilation. This suggests a reactive component to the elevated pulmonary vascular resistance (PVR) that is likely related to dysregulation of vascular smooth muscle tone. Although the cause of this dysregulation is unclear, hypoxia may play a role. We examined whether variations in resting systemic O2 levels influence PVR in HF.

Methods: Thirty-nine patients (54±9 yr, LVEF 20±6%, NYHA class I-III) undergoing right heart catheterization for pre transplant assessment were studied. PVR was derived from pulmonary arterial and wedge pressures measured via Swan Ganz catheter and cardiac output measured via direct Fick. Mixed venous and arterial blood was drawn from the pulmonary and radial arteries for measurement of PaO2, PaCO2, SaO2, SvO2 and endothelin-1 (ET-1).

Results: Group mean PVR, PaO2, PaCO2, SaO2 and SvO2 were 303±215 dyne/s/cm2, 72±12 mmHg, 32±4 mmHg, 94±4% and 57±11%, respectively. PVR was negatively correlated with PaO2, PaCO2, SaO2 and SvO2 (r=-0.53, -0.62, -0.48, -0.67, respectively, all P<0.01). Multiple linear regression suggested that SvO2 was the strongest predictor of PVR. In combination, PaCO2, PaO2, SaO2 and SvO2 accounted for ~60% of the variance in PVR. In addition, ET-1 was related to both SvO2 (r=-0.75) and PVR (r=0.50) (P<0.1).

Conclusion: Systemic hypoxia, particularly a low SvO2, appears to play a role in PH and elevated PVR in HF. We suggest a hypoxia-mediated increase in the release of the vasoconstrictor ET-1 as a likely mechanism. NIH HL71478
SR was not associated with prognosis \((p = 0.9)\). Survival was worse in patients diagnosed \((n = 6)\) or during follow-up \((n = 43)\).

Venous oxygen saturations were lower in patients developing flutter (58\% vs. 61\%) but initial mixed arrhythmia. Baseline age, exercise capacity and pulmonary haemodynamics were not significantly different between the flutter and AF group but initial mixed venous oxygen saturations were lower in patients developing flutter (58\% vs 64\%, \(p = 0.02\)). Management including chemical or DC cardioversion and/or ablation therapy maintained 59% of patients in sinus rhythm (SR). Failure to maintain SR was not associated with prognosis \((p = 0.9)\). Survival was worse in patients developing flutter rather than AF (figure).

**Conclusions:** Atrial arrhythmias are common in PH. AF is more commonly associated with PH-LHD and developing flutter was associated with poorer survival. Further analysis of optimal management strategies is required.

**Methods:** A six-year retrospective analysis was conducted of \(>1000\) newly diagnosed patients with PH.

**Results:** There were 264 pre-existing cases of atrial fibrillation (AF) including 29\% pulmonary arterial hypertension (PAH), 53\% PH due to left heart disease (PH-LHD), and 7\% chronic thromboembolic PH (CTEPH). PAH and CTEPH were more common (45\% and 24\%) than PH-LHD (17\%) as the underlying cause of PH in the 29 patients who had atrial flutter (flutter) diagnosed prior to PH diagnosis \((p < 0.05)\). 49 new diagnoses of flutter or AF were made at PH diagnosis \((n = 6)\) or during follow-up \((n = 43)\). ~7\% of all PAH patients developed an atrial arrhythmia. Baseline age, exercise capacity and pulmonary haemodynamics were not significantly different between the flutter and AF group but initial mixed venous oxygen saturations were lower in patients developing flutter (58\% vs 64\%, \(p = 0.02\)). Management including chemical or DC cardioversion and/or ablation therapy maintained 59% of patients in sinus rhythm (SR). Failure to maintain SR was not associated with prognosis \((p = 0.9)\). Survival was worse in patients developing flutter rather than AF (figure).
to human PAH and examined their possible role as predictors of activity and progression of disease.

18 patients with idiopathic and familial PAH and 20 healthy control subjects were studied. Circulating fibrocytes, identified as CD11b+CD34+vimentin+ cells and membrane CD11b expression were quantified by flow cytometry. The in vitro differentiation capacity of PBMC to fibrocytes was quantified. We observed a slight decrease in the percentage but not in the number of circulating fibrocytes in the blood of PAH patients, compared with healthy control subjects (0.67±0.15% in control subjects vs 0.22±0.04% in PAH patients, p<0.05). Accordingly, a significant decrease in the percentage of differentiated CD45+vimentin+ cells in PBMC culture from PAH patients was observed (73.4±3% in control group vs 61.2±2% in PAH patients, p<0.05). Interestingly, the mean fluorescence intensity of CD11b was significantly increased on circulating fibrocytes in PAH patients (111±16 in control group vs 216±7±247 in PAH patients, p<0.0001), indicating their increased activation state.

Our data suggest that a more detailed analysis of circulating fibrocyte function and activation is needed in PAH patients.

P1524 Role of mast cells and chymase in pulmonary vascular remodeling

Bhilu Kumar Dahal1, Djuro Kosanovic1, Josef Messinger2, Yvan Fischer2, Karin Hofmann2, Jochen Antel1, Bettina Huesen2, Nina Hanke2, Stephanie Mayet1, Hossein Ardeschir Ghofrani1, Norbert Weissmann1, Joachim Saur1, Stephanie Mayet2, Hossein Ardeschir Ghofrani3, Norbert Weissmann1, Friedrich Grimminger1, Werner Stegger1,2, Ralph Schermuly1,3, Department of Medical Clinic II, University of Giessen Lung Centre (UGLC), Giessen, Germany; Abbott Products GmbH, Abbott Products GmbH, Hannover, Germany; 3Department of Lung Development and Remodelling, Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany

Rationale: Mast cells (MCs) are implicated in chronic inflammation and tissue remodeling. However, a systematic investigation of pulmonary MCs/MC chymase is yet missing in idiopathic pulmonary arterial hypertension (IPAH) and chronic obstructive pulmonary disease (COPD).

Methods: Lung tissues obtained from donors, and IPAH and COPD patients undergoing lung transplantation were formalin-fixed and paraffin-embedded, followed by blue staining (TB) for staining MCs and immuno staining for MC chymase. Total and perivascular MCs were determined by counting MCs under light microscope equipped with computerized morphometric system. Perivascular MCs were categorized as granulated and degranulated and an index of granulation (IOG) (number of granulated/degranulated MCs) was determined.

Results: Pulmonary MCs were prevalent in IPAH and COPD patients; furthermore, perivascular MC count was significantly increased in the resistance vessels of patients (p<0.05 vs donors). Notably, the IOG was decreased by about 8 and 5 folds in IPAH and COPD patients, respectively (vs donors). Chymase-positive MCs were increased by 16 and 10 folds in IPAH and COPD patients, respectively (vs donors). The perivascular chymase-positive MCs were significantly increased in IPAH and COPD patients (p<0.05 vs donors). Interestingly, the chymase-positive MC subpopulations were about 42% and 48% of the MCs in IPAH and COPD patients, respectively; whereas it was 10% in donors.

Conclusion: The chymase released from activated perivascular MCs may potentially contribute to the pulmonary vascular remodeling in IPAH and COPD. Future studies are essential to substantiate the findings and to elucidate underlying pathomechanisms.

P1525 Frequency and impact on prognosis of signs of pulmonary veno-occlusive disease on high resolution computed tomography in patients with scleroderma associated pulmonary arterial hypertension

Sven Günther1, Stephanie Maitre2, Alice Berzen3, Xavier Jais4, Andrei Siferen3, Olivier Siboun4, Gerald Simoneau1, Luc Mouthon4, Marc Humbert4, David Montani4, Univ Paris Sud, AP-HP, Service de Pneumologie, Hopital Antoine Béclère, Clamart, France; 2Univ Paris Sud, AP-HP, Service de Radiologie, Hopital Antoine Béclère, Clamart, France; 3Univ Paris Descartes, AP-HP, Service de Médecine Interne, Hopital Cochin, Paris, France

Introduction: Pulmonary veno-occlusive disease (PVOD) is an uncommon form of pulmonary arterial hypertension (PAH) characterised by a progressive obstruction of small pulmonary veins. PVOD has been frequently reported in patients with scleroderma related PAH (SSc-P AH). High resolution chest computed tomography (HRCT) is a non-invasive diagnostic tool used to screen for PVOD. However, no data are available in SSc-P AH patients.

Aims: To evaluate the frequency and the impact on prognosis of signs of PVOD on HRCT in SSc-P AH.

Methods: We reviewed HRCT data in 34 consecutive SSc-P AH patients and 30 systemic sclerosis (SSc) patients.

Results: Lymph nodes enlargement (57.7% vs 3.6%), centrilobular ground-glass opacities (46.2% vs 10.7%) and septal lines (73.1% vs 7.1%) were significantly more frequent in SSc-P AH patients as compared to SSc patients (all p<0.05). Interestingly, the mean and pulmonary artery enlargement were significantly more frequently observed in SSc-P AH patients (p<0.001). Pleural effusion was observed in one patient (3.8%) in the group SSc-P AH, whereas no SSc patient had a pleural effusion.

In SSc-P AH patients with ≥2 radiological signs of PVOD was significant lower compared to those ≤1 radiological sign of PVOD (P<0.05).

Conclusion: Signs of PVOD are frequent on HRCT in patients with SSc-P AH compared to SSc patients without PVOD. These signs allow clinicians to detect PVOD in SSc-P AH patients. Survival in affected patients is poor.

P1526 How does variation of the bag volume in inert gas rebreathing cardiac output measurements influence the reproducibility in patients with pulmonary diseases?

Frederik Trinkmann, Franziska Krause, Martin Borggrefe, Jens J. Kaden, Joachim Saur, Universitätsteinmedizin Mannheim, 1st Department of Medicine, Mannheim, Germany

Background: Cardiac output (CO) is an important hemodynamic parameter, however its determination is difficult in daily clinical routine. Non-invasive inert gas rebreathing (IGR) showed promising results in recent investigations with the volume of the rebreathing bag (Vb) being an important factor. The aim of our study therefore was to evaluate the influence of different Vb on the reproducibility of IGR.

Methods: The collective consisted of 45 patients (age 26 to 88 years). The CO was determined in patients with obstruction (group A), restriction (group B) and pulmonary healthy controls (group C). For Vb of 2200 ml, 1700 ml and 1200 ml two repeated measurements were taken each. The determination of lung function was performed using bodyplethysmography.

Results: Pulmonary obstruction was diagnosed in 12 patients (PEV, 52±21%) and restriction in 11 patients (VC 61±16%). The mean CO did neither differ between the groups (p>0.1) nor for the different Vb (p>0.2). The mean bias between the repeated measurements was 0.2±0.99ml/m² for Vb=2200ml, 0.4±0.79ml/m² for Vb=1700ml and 0.3±0.79ml/m² for Vb=1200ml. There was no statistically significant difference between the groups for the different Vb=2200ml (p=0.7), 1700ml (p=0.4) and 1200ml (p=0.2).

Conclusion: The reproducibility of IGR is not negatively affected by Vb, so it can be varied between 2200 and 2200 ml. This is especially important when Vb has to be reduced due to incomplete inspiration. The trend to a worse reproducibility of measurements at rest should be further investigated. For now, measurements should only be compared directly when identical Vb were used.

P1527 Characteristics of patients with pulmonary arterial hypertension associated with congenital heart disease in the French PAH registry

Xavier Jais1, Damien Bonnet2, Laurence Blanchet3, Maryline Lévy4, Virginie Gressin1, Marc Humbert1, Olivier Siboun1, Gérald Simoneau1, French Reference Center for Pulmonary Hypertension, Antoine Béclère Hospital Paris-South University, Clamart, France; 2French Reference Center for Complex CHD, Necker Hospital Paris Descartes University, Paris, France; 3Actelion Pharmaceuticals France, Actelion Pharmaceuticals France, Paris, France

Background: Epidemiological data relative to pulmonary arterial hypertension (PAH) associated with congenital heart disease (CHD) are scarce. In the first French PAH registry conducted in 2002-2003, CHD accounted for 11.3%.

Objective: To analyze PAH associated with CHD in patients enrolled in the second prospective PAH registry initiated in 2006.

Methods: PAH-related clinical and outcome data were reviewed and analyzed from the registry.

Patients and results: 2585 patients with PAH were enrolled in 26 PAH centers. CHD-PAH (n = 255) accounted for 9.8%, including 95 isolated pre-tricuspid shunts (mainly ASD), 134 isolated post-tricuspid shunts (mainly VSD), 11 combined pre-and post-tricuspid shunts and 15 complex CHD. 60% of patients were females and mean age at diagnosis was 37 years. The diagnosis of PAH was done simultaneously with the diagnosis of CHD in 37% of the cases and in 60% PAH appeared during the follow-up of CHD. At study entry, 52% of patients were in NYHA functional class (FC) III or IV, 6MWD was 370±105 m and pulmonary hemodynamics were: mPAP= 59±60 mmHg, CI= 2.7±1.1 L/min/m² and PVRs= 12.5±3.3 WU. 47% of NYHA II and 43% of NYHA III patients were not receiving PAH-specific therapies. In treated patients (n = 164), NYHA FC improved (59% in NYHA FC II at last follow-up). During the 3-year follow-up period, 20 patients died and 7 patients were transplanted.

Conclusions: PAH is a complication of a previously known CHD in 60% of cases. ASD is the main CHD that is diagnosed concomitantly or after PAH. Less than a half of NYHA III patients are offered PAH-specific therapies. Mortality was low during the short period of follow-up.
Among the 350 patients who met the inclusion criteria, 100 (28.5%) were younger patients despite a less severe haemodynamic impairment. Patients with IPAH and ArPAH. Patients >70 yr have a worse outcome than 18–70 yr. Clinical and haemodynamic characteristics at time of diagnosis are shown in the Table. Survival rates at 1, 2 and 3 years were 79%, 60% and 47% in those >70 yr, as compared to 92%, 84% and 76% in the 18-70 yr group, respectively (p<0.001).

Conclusions: These results show an increasing proportion of elderly male among patients with IPAH and ArPAH. Patients >70 yr have a worse outcome than younger patients despite a less severe haemodynamic impairment.

P1529  
Assessment of operability by means of CTPA and perfusion SPECT in patients with chronic thromboembolic pulmonary hypertension  
Aleksandar Gregic1, Florian Mioleck1, Christian Frantz1, Arno Buecker2, Martin Kirschl1, Henrikke Wilken1, Karin Keulnarkner1, Uniklinikum des Saarlandes, Homburg, Germany; 2Klinik für Thorax- und Herz-Gefäßchirurgie, Uniklinikum des Saarlandes, Homburg, Germany; 3Klinik für Innere Medizin III (Kardiologie), Uniklinikum des Saarlandes, Homburg, Germany; 4Klinik für Innere Medizin (Pneumologie), Uniklinikum des Saarlandes, Homburg, Germany; 5Klinik Thorax- und Herz-Gefäßchirurgie, Uniklinikum des Saarlandes, Homburg, Germany.

Objective: Chronic thromboembolic pulmonary hypertension (CTEPH) is curable with pulmonary endarterectomy (PEA). The criteria for identification of PEA-amenable patients need to be standardized. The aim of this study was to evaluate the value of rigidly registered CT pulmonary angiography (CTPA) and perfusion SPECT in differentiating between operable and non-operable patients.

Methods: 49 patients with CTEPH (21 men, 58±13 years) were evaluated for PEA by interdisciplinary board using available diagnostic information and served as the gold standard.SPECT was evaluated by a lobe based visually assessed perfusion score ranging from 0 [no perfusion] to 1 [normal perfusion],after which the percentage of vascular obstruction (PVO) was calculated: PVO = [1 – Perfusion score] × 100. By CTPA, the vascular obstruction index (OI) of central, peripheral vessels reaction to different stimuli may be a sign of peripheral vasomotor reaction during local airway cooling. Methods: The reaction of peripheral vessels of finger (digitales palmares proprius) during and after 3-min isocapnic cold (-20°C) air hyperventilation was studied in 11 healthy persons and 31 patients with chronic pulmonary diseases (bronchial asthma and chronic bronchitis) having CARR. The amplitude of pulse wave (AWP) was evaluated by photoplethysmography of finger. Results: A phase reaction of finger artery to cold air inhalation was revealed in healthy persons. By the end of the 3rd min of hyperventilation there was a progressive drop of AWP (30±2.8±7.6%) as a result of vasconstriction with further short-term vasodilation proved by the growth of AWP higher than the initial level (8.7±5.9±6.5%) immediately after provocation cessation and its additional fall on the 5th min of recovery (-15.5±7.3%), which meant a repeated vessel spasms. In group of patients cold air inhalation led to sustained AWP drop both during provocation (-21.4±8.9%) and recovery period (1st and 5th min) -26.2±11.0% and 15±15.6% respectively. There was a correlation among airway reaction, changes in peripheral blood flow, skin temperature at the beginning and at the end of the bronchoprovocation in patients. 

Conclusions: Revealed abnormalities in peripheral microcirculation in patients with the changed airway responsiveness can be an early sign of systemic vascular dysfunction.

P1530  
Metabolic and cardiopulmonary responses to the incremental shuttle walk test vs. six-minute walk test in healthy older adults  
Victor Dourado1, Ricardo Guerra1, Suzanna Tanni1, Letícia Antunes1, Irna Godoy1, 2Department of Health Sciences, Federal University of São Paulo (UNIFESP), Santos, Brazil; 2Department of Internal Medicine, Botucatu Medical School (UNESP), Botucatu, Brazil; 3Rehabilitation Section, Botucatu Medical School (UNESP), Botucatu, Brazil.

Whether the incremental shuttle walk test (ISWT) induces a higher physiological stress compared to six-minute walk test (6MWTT) in patients remains controversial. However, previous studies did not include healthy subjects. We compared physiological responses to the ISWT and 6MWTT in healthy adults (38 men, aged 60±5.10). Secondly, peak oxygen uptake (VO2peak) in these tests were compared to predict values of a maximal cycle-ergometer test. In a randomized order and alternate days, 80 participants completed three 6MWTTs and three ISWTs. VO2, CO2 output (VCO2), minute ventilation (VE), and heart rate (HR) were monitored by a portable telemetric system during each test. Physiological responses were linear during ISWT and exponential during 6MWTT. We could calculate deficit-0.2 (1072±622 mL) and VO2 time constant–tau+0.2 (56±19 s) in all participants by exponential fittings (R2=0.90±0.005). During the 6MWTT, VO2peak (1672±441 mL/min), VCO2 (1443±439 mL/min), VE (46±16 L/min) and HR (129±24 bpm) were not significantly different compared to ISWT (respectively 1714±544 mL/min; 1591±582 mL/min; 51±19 L/min; and 132±2 bpm). The distance covered correlated with peak VO2 for ISWT (r=0.738; p=0.001) and 6MWTT (r=0.652; p=0.001) with no difference between correlation coefficients (p=0.234). Estimated peak VO2 (1541±422 mL/min) was not significantly different from measured peak VO2 obtained during ISWT and 6MWTT being considered to be closer to a maximal exercise test than 6MWTT. ISWT does not induce a greater physiological responses in healthy adults. Larger studies should be performed in patients for better physiological comparisons between these walking tests.

1Department of Health Sciences, Federal University of São Paulo (UNIFESP), Santos, Brazil; 2Department of Internal Medicine, Botucatu Medical School (UNESP), Botucatu, Brazil; 3Rehabilitation Section, Botucatu Medical School (UNESP), Botucatu, Brazil.
Evaluation of heliox or oxygen breathing on improved quadriceps muscle oxygen delivery during exercise in COPD

Helimut Habazettl3, Spyros Zakynthinos1, Peter D. Wagner4, Ioannis Vogiatzis1,2.

Introduction: It is known that both normoxic heliox and pure oxygen breathing significantly increase locomotor muscle O2 availability during exercise. However, it remains unknown which of the two gases is the most beneficial in terms of enhancing exercise tolerance and locomotor muscle O2 availability.

Methods: 12 COPD patients [FEV1=42±9% of predicted] performed 3 constant-load exercise tests at 75% of maximum work rate while breathing air, normoxic heliox (He: 32±6% vs O2: 68±4% at rest), and ID (using indocyanine green) over the last minute of exercise.

Results: CO by PF exceeded that by ID by 2.6±0.3 L/min (Mean±SE) averaged across all exercise levels (p=0.001).

Conclusion: Compared to ID, PF overestimates CO across different levels of exercise but its slope of change relative to VO2 is very similar. Hence PF can accurately estimate changes from resting CO during exercise in COPD.

P1534 Dynamic pathophysiology in stable COPD patients with severely reduced exercise capacity
Ryoo Mukura, Toru Hiraga, Keisuke Miki, Seigo Kitada, Kenji Yoshimura, Yoshitaka Tateishi. Respiratory Medicine, National Hospital Organization Toneyama Hospital, Toyonaka, Osaka, Japan

Introduction: The survival prognosis of COPD patients with severely reduced exercise capacity is extremely poor. However, the dynamic pathophysiology of these patients, including sympathetic activation and lactic acidosis, remains to be accurately established. Thus, we performed this study to clarify the differences in the dynamic pathophysiology of four COPD patient groups classified according to their exercise capacity.

Methods: Ninety-one COPD patients (82 males, 9 females; average age, 69.7±6.8 years) underwent incremental CPET using a cycle ergometer. During CPET, we measured the patient levels of arterial blood gases, lactate, and catecholamines.

Results: We found that the pathophysiology of the COPD patients was different among the groups. Patients with severely reduced exercise capacity (peak oxygen uptake < 654 ml/min) were characterized by the following: (i) exercise-induced rapid decrease of arterial oxygen pressure (PaO2-slope: -7.8±0.7 mmHg/100 ml); (ii) sympathetic activation at low-grade workload (plasma norepinephrine level, 1.4±0.94 ng/ml at 20 W); (iii) little change in lactic acidosis; (iv) a limitation in the increase of ventilation; and (v) impaired gas exchange. The norepinephrine increase exhibited during exercise was significantly correlated (r = 0.94±0.08) with the dyspnoea ratings.

Conclusions: The COPD pathophysiology significantly varied among patients with different exercise capacities. Patients with lower exercise capacity suffered from severe gas exchange disorder, sympathetic overactivation, and ventilatory disturbance during exercise. CPET should consistently be performed to assess the factors that contribute to exercise limitation in COPD patients.

P1535 Inspiratory muscle training (IMT) with normocapnic hyperventilation (NH) improves respiratory muscle strength, exercise performance and ventilatory pattern in COPD patients
Luca Pomidori, Eva Bernardi, Gianluca Grassi, Enzo Melloni, Gaia Mandolesi, Annalisa Cogo. Biomedical Sport Studies Center, University of Ferrara, Ferrara, FE, Italy

Introduction: IMT by means of NH is effective in improving exercise endurance in healthy subjects but few data are available for COPD patients.

Aim: To evaluate the effect of 4 weeks NH training (Spirotiger®) on respiratory function and exercise capacity in 21 moderate/severe COPD patients.

Materials and methods: 19 M, 2 F; aged 42-80. Respiratory function tests (FEV1, FVC, Pimax), QoL (St George’s Questionnaire), 6MWT and endurance exercise performed at 75-80% of peak-work rate measured during an incremental test to the limit of tolerance (tLIM). 7 of 21 patients were instrumented with a portable inductive plethysmography (LifeShirt System) to evaluate breathing pattern during tLIM. After 1 month of weekly supervised training, the patients trained at home for 4 weeks: 10 min twice a day at a breathing rate 12-24/min with a tidal volume (TV) equal to 50% of CV.

Results: 6 patients dropped out (poor compliance). IMT significantly improved FEV1, Pimax, QoL. Exercise capacity. Ventilatory pattern after IMT is characterized by a significantly higher TV with no change in VE.

*p<0.05 (statistical analysis: T test and Wilcoxon signed rank test).

Conclusion: After a short IMT with NH, COPD patients show a higher exercise capacity and an intriguing change in ventilatory pattern which improves oxygen saturation.
of patients during AECOPD. The aim of this study was to evaluate the impact of decreased blood hemoglobin level to results of six minute walking test in patients during after AECOPD.

Materials and methods: A retrospective analysis of data collected from long term study on AECOPD was performed. Haemoglobin level from the first obtainable hospital measurement was included in the assessment. 6MWD was performed after clinical improvement of the patient. Dyspnea at baseline and after exercise was measured. Oxygen saturation (SpO2) during exercise was measured.

Results: 404 patients with AE COPD were analyzed. GOLD stages, hemoglobin level and results of 6MWD are shown in Table 1. Results are means ±SD. *p<0.05. The hemoglobin level did not correlate with 6MWD, dyspnea after 6MWT, exercise oxygenation and blood desaturation after exercise.

Conclusion: Decreased blood hemoglobin level didn’t influence the results of 6MWT in patients after AECOPD.

P1537

Association between physical activity and asthma exacerbations
Silvia Pascual1, Isabel Urrutia1, Cristobal Esteban 1, Aitor Ballaz 1, Association between physical activity and asthma exacerbations was divided into quartiles, including 88 (24.8%) in the first quartile, 92 (25.7%) (11%) between 60 and 80%, and 300 (85%) greater than 80%. Physical activity was greater in those patients with higher exacerbations.

Introduction: There are some evidences that suggest that regular physical activity reduces the risk of exacerbations in asthma, regardless of the asthma severity and other factors. The aim of this paper is to measure the association between physical activity levels in asthma exacerbations, adjusted by FEV1, age and body mass index (BMI).

Methodology: This is a multicenter transversal study where has been included a population of asthmatic patients consults of two hospitals in Vizcaya. It has been included patients with previous diagnosis of asthma and monitored by the pneumologist at least for a year, aged between 18 and 70. We used the International Physical Activity Questionnaire (IPAQ). We performed a multivariate logistic regression analysis to determine predictors of exacerbations.

Results: We studied 354 patients (54% men). 115 of these (32%) were younger than 32, 123 (35%) between 32 and 55 and 116 (33%) over 55 years. 250 patients in the second, 54 (23.7%) in the third and 89 (25.1%) in the fourth.

Conclusions: Patients with asthma with increased physical activity had a reduced number of exacerbations.

P1538

The usefulness of ventilatory gas analysis during low intensity exercise to define pulmonary hypertension
Paul Woods, Robert Frantz, Bryan Taylor, Thomas Olson, Bruce Johnson. Division of Cardiovascular Disease, Mayo Clinic, Rochester, MN, United States

The 6-minute walk test is widely utilized to characterize activity tolerance and response to therapy in pulmonary arterial hypertension (PAH). However, it provides little information about cardiopulmonary pathophysiology. Previous studies employing maximal exercise testing suggest that ventilatory gas analysis may be a useful tool to help determine the presence and severity of PAH. The aim of the present study was to determine whether measures of pulmonary gas exchange during a simplified low intensity step test can be used to differentiate between PAH patients and healthy individuals, and also stratify disease severity. Forty PAH patients and 25 matched controls completed a novel submaximal exercise test that consisted of 2-min rest, 3-min step exercise and 1-min recovery. Ventilation, pulmonary gas exchange, arterial oxygen saturation (SaO2) and heart rate were measured throughout using a simplified gas analysis system. A number of gas exchange variables separated PAH patients from controls. End-tidal CO2 (PETCO2) and SaO2 were lower in PAH vs. controls (31.4±7 vs 39.6±5 mmHg and 89±5 vs 95±2%, respectively, p<0.05) while breathing efficiency (VE/VCO2 ratio) was higher in PAH vs. controls (42±10 vs 33.5±3, p<0.05). PETCO2 and V/C02 also discriminated between different severities of PAH. Gas exchange variables obtained during light exercise clearly discriminated PAH patients from healthy controls and also between different severities of PAH. A simplified submaximal step test incorporating non invasive gas exchange may be a useful measure to help quantify and track disease severity in PAH. This study was supported by Gilead and NH HL71478.

P1539

Cardiac biopompeo during exercise testing in patients with idiopathic pulmonary arterial hypertension
Ralf Kaiser, Christian Frantz, Kerstin Hausdach, Christian Lench, Robert Bals, Heinrike Wilkens. Inneren Medizin V, University Hospital Saarland, Homburg/Saar, Germany

Purpose: In idiopathic pulmonary arterial hypertension (IPAH) right ventricular insufficiency develops due to pressure overload. Furthermore left ventricular function is reduced by chronic underfilling.

Hemodynamics are monitored by echocardiography and cardiac catheterisation. This may describe cardiac function only insufficient, as hemodynamics may change during exercise and balance between right and left ventricular function might change due to development of a septal shift. Recent studies have determined the importance of a simplified low intensity step test incorporating non invasive gas exchange may be a useful measure to help determine the presence and severity of PAH. The aim of the present study was to determine whether measures of pulmonary gas exchange during a simplified low intensity step test can be used to differentiate between PAH patients and healthy individuals, and also stratify disease severity. Forty PAH patients and 25 matched controls completed a novel submaximal exercise test that consisted of 2-min rest, 3-min step exercise and 1-min recovery. Ventilation, pulmonary gas exchange, arterial oxygen saturation (SaO2) and heart rate were measured throughout using a simplified gas analysis system. A number of gas exchange variables separated PAH patients from controls. End-tidal CO2 (PETCO2) and SaO2 were lower in PAH vs. controls (31.4±7 vs 39.6±5 mmHg and 89±5 vs 95±2%, respectively, p<0.05) while breathing efficiency (VE/VCO2 ratio) was higher in PAH vs. controls (42±10 vs 33.5±3, p<0.05). PETCO2 and V/C02 also discriminated between different severities of PAH. Gas exchange variables obtained during light exercise clearly discriminated PAH patients from healthy controls and also between different severities of PAH. A simplified submaximal step test incorporating non invasive gas exchange may be a useful measure to help quantify and track disease severity in PAH. This study was supported by Gilead and NIH HL71478.

Conclusions: Patients with asthma with increased physical activity had a reduced number of exacerbations.

P1540

Effects of continuous vs. interval aerobic training on PetCO2 response during graded exercise test in patients with coronary artery disease
Eneas Rocco1, Danilo Marcelo Prado-1,2, Alexandre Silva1, Jaqueline Lazzati1, Pedro Borta1, Debora Rocco1, Amanda Campolins1, Carla Rosa1, Valter Flurlan1, 1Cardiorespiratory Rehabilitation, Amil- International Medical Assistance, São Paulo, Brazil; 2Rheumatology Department, University of São Paulo- Medical School, São Paulo, Brazil. 1Exercise Physiology, Santa Cecília University, Santos, São Paulo, Brazil

Background: Previous studies have demonstrated in patients with coronary artery disease (CAD) that lower values in end-tidal CO2 pressure (PetCO2) during graded exercise test (GET) have been associated with ventilation perfusion (V/Q) mismatch.

Methods: To evaluate the effects of the continuous (CT) and interval aerobic training (IT) on PetCO2 responses during GET in CAD patients and 2) examine the relationships between PetCO2 at ventilatory anaerobic threshold (PetCO2V AT) and cardiorespiratory parameters after interventions.

Results: Patients with IPAH tolerated less workload (54.3±37 vs. 177.4±40W). Ejction fraction (EF) at baseline was comparable to control. During exercise the increase of EF was diminished in IPAH (62.1±8 vs. 67.4±5%) and maximal cardiac index (CI) was significantly lower (5.2±2.0 vs. 9.0±3.3lm/min/m2). Enddiastolic volume (EDV) showed a trend to decreased values (102.9±41 vs 128.8±35lm/min), while stroke index was markedly reduced (53.5±17 vs. 72.0±15lm/min). Peakflow during exercise was decreased (387.7±125 vs 559.0±180lm/min/m2) as well as flow acceleration (ACI: 153.5±61 vs 217.1±71sec2).

Conclusions: In patients with IPAH, stroke volume and CI were reduced. The diminished filling is represented by reduced EDH, resulting in less increase of contractility as shown by reduced peak flow and ACI. Patients with IPAH were not able to compensate the lack of contractility by heart rate, resulting in lower CI. Left ventricular underfilling affects cardiac performance during exercise, and isotropic response is reduced in patients with IPAH.
P1541
Quantifying oscillatory ventilation during exercise in patients with heart failure

Thomas Olson, Kenneth Beck, Bruce Johnson. Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Background: This study tested the validity of a data analysis scheme to quantify measures of oscillatory ventilation at rest and during exercise in heart failure patients.

Methods: Eleven patients (age=53.8±8.5, LVEF=17.4±5.4, NYHA Class=II/III) (15) were recruited. Ventilation (V̇e) and gas exchange were measured. Amplitude and period of oscillation in V̇e, tidal volume (Vt), end-tidal carbon dioxide (PETCO2), and oxygen consumption (VO2) were measured manually (MAN), using novel software which included a peak detection algorithm (PK), sine wave fitting algorithm (SINE), and Fourier analysis (FOUR).

Results: During PK, there were no differences between MAN and PK for amplitude of V̇e, PETCO2, VO2, or Vt. Similarly, there were no differences between MAN and SINE for amplitude of V̇e or Vt although PETCO2 and VO2 were lower with SINE (p<0.05). The PK demonstrated shorter periods for V̇e, PETCO2, and VO2 compared to MAN (p<0.05) whereas there were no differences in periods of oscillations between MAN and SINE or FOUR. During exercise, there were no differences between MAN and PK for amplitude of V̇e, PETCO2, VO2, or Vt. SINE demonstrated lower amplitudes for V̇e, PETCO2, and VO2 compared to MAN (p<0.05) although Vt was not different. PK demonstrated shorter periods for all variables (p<0.05) whereas there were no differences between MAN and SINE or FOUR for all variables during exercise.

Conclusion: These data suggest 1) PK consistently captures amplitudes but underestimates period, 2) SINE and FOUR consistently capture period although SINE underestimates amplitude. Thus, an optimal algorithm for quantifying oscillatory ventilation in HF might combine multiple analysis methods. NIH grants HL74178/HL2-RR024151

P1542
The pattern and timing of breathing during graded exercise test in systemic lupus erythematosus

Danoelo Marcelo Prado 1, Renata Miocia 1, Fernanda Lima 1, Bruno Gualano 2, Hamilton Roscel 2, Eduardo Borba 2, Elsion Bonfa 2, Ana Lucia Sá Pinto 1.

1Biomédica, Department of Respiratory Medicine, University of São Paulo Medical School, São Paulo, Brazil; 2Biomédica, Department of Obstetrics, University of São Paulo Medical School, São Paulo, Brazil

Background: Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease that affects all organs including the respiratory system. Abnormal control of breathing during maximal voluntary ventilation has been recently identified in this disease.

Purpose: To evaluate the pattern and timing of breathing at selected submaximal ventilatory stress in SLE.

Methods: Twenty consecutive women (age: 28.8±1.0 years) with SLE were selected and compared to an age and BMI matched group of 19 healthy women (CTRL) (age: 26.2±1.3 years). All of the subjects performed a progressive treadmill cardiopulmonary test until exhaustion. Data were analyzed at absolute isoventilation (40, 60 and 80 L/min).

Results: SLE presented lower relative aerobic fitness (VO2peak) (26.8±8.2 vs. 35.9±1.2 mL kg-1 min-1, p<0.001) than their healthy peers.

Conclusion: These results demonstrated a thachypnoeic breathing pattern and shorter timing of ventilation in SLE woman during exercise. This suggests that the reduced aerobic capacity observed in SLE patients may be accompanied by ventilation-perfusion mismatches.

P1543
Utility of ergospirometry in the diagnosis of hyperventilation syndrome (HVS)

Angelica Tioni 1, André Nosed 2, Sofia Abdelkafi 2. 1Department of Pneumology, CHU Nancy, Nancy, France; 2Department of Pneumology, CHU Brugmann, Brussels, Belgium

The hyperventilation syndrome (HVS) is characterized by several somatic and psychological symptoms due to hypocapnia not secondary to any underlying organic disease. The purpose of the present study was to evaluate the place of exercise-induced hyperventilation in the diagnosis of HVS.

Twenty-three patients with normal spirometry, referred for suspicion of HVS on the basis of a Nijmegen’s questionnaire (score ≥23) were eligible. Asthma was documented in 15 patients. The mean score of anxiety by the Spielberg’s State-Trait Anxiety Inventory for Adults was 53.5 which are suggestive of moderate anxiety. During the hyperventilation provocation test (HVPT), at least two symptoms of Nijmegen’s questionnaire were reproduced in 14 patients. The mean level of PetCO2 at 2 baseline was 27.6 mm Hg and decreased to 15.2 mm Hg for a maximal ventilation of 57 l/min. No patient recovered the baseline level of PetCO2 at 5 min after the end of the HVPT (mean ratio PetCO2 after/before p ≤ 0.05). Exercise-induced maximal ventilation (VImax) was 52 l/min and was accompanied by a PetCO2 level of 35.8 mm Hg and an EqCO2 of 32 mm Hg. No significant difference in the ventilatory pattern (VEmax, PetCO2, EqCO2) was found between HVS group (n=8) and the asthma and HVS group (n=15). In conclusion, in our group of patients with HVS, with or without asthma, the hyperventilation during exercise did not induce abnormal reduction in PetCO2 or abnormal increase in EqCO2. Our results suggest that, unexpectedly, the exercise could be a therapeutic tool in the HVS. It could be hypothesized that anxiety plays a role in the genesis of symptoms at rest but not during exercise where the patient has to be concentrated on his effort.

P1544
Exercise capacity as an index of progress of lung disease among children and adolescents with CF

Elpis Hatziagourou 1, Vassiliki Georgopoulou 2, Kalliopi Kontoudi 3, Vassiliki Arramoudou 4, Fotis Kavvassilas 1, John Tsanakas 3. 1Pediatric Pulmonology Unit, 3rd Paediatric Dept, Hospital, Aristotle University, Thessaloniki, Greece; 2Radiology Dept, Hippokration Hospital, Thessaloniki, Greece

Background: Spirometry, high resolution computed tomography (HRCT) and exercise testing provide additional information about lung disease among children with cystic fibrosis (CF). There is significant correlation between levels of aerobic fitness (VO2 peak) and survival rate.

Aim: To compare decline of exercise capacity, HRCT scores and lung function among children with CF over a period of two years.

Methods: Sixteen stable children and adolescents with CF, aged 8–19 years, performed spirometry and maximal incremental cardiopulmonary exercise testing using a cycle ergometer, as part of their annual review. At the same time the patients underwent low dose of radiation chest HRCT scans, with a Bhalla score assessment.

Results: Sixteen stable children and adolescents with CF were evaluated (mean age 15.6±3.2 years and FEV1, 38.9±4% predicted). There was evidence of mild exercise limitation during the cardiopulmonary exercise test, with mean Peak Aerobic Capacity (V’Opeak) 71.8±14.0±7% predicted. Evaluation of the study population two years later, showed that Bhalla total score, Peak Aerobic Capacity (V’Opeak) and Anaerobic Threshold (AT) deteriorated significantly (mean difference ±SD, p: 1.4±1.7, p: 0.028, 6.4±1.1, p: 0.022, -7.8±9.3, p: 0.006, respectively). Ventilatory equivalent for CO2 (V’O2/VECO2), Dead space/Tidal Volume Ratio (VD/VT) and FEV1, didn’t deteriorate significantly (p: 0.321, p: 0.165 and p: 0.135, respectively).

Conclusions: The maximal incremental cardiopulmonary exercise test correlates well with HRCT scans; it is a very sensitive method for measuring progression of lung disease in children with CF.

P1545
Children with bronchopulmonary dysplasia (BPD) have increased dynamic flow limitation and an altered ventilatory response to exercise

Christopher O’Dea 1,2, Karla Logie 1, Andrew Wilson 1,2, Andrew Maiorana 2,6, Jane Pillone 1, Graham Hall 1,2, 6Respiratory Medicine, Princess Margaret Hospital, Perth, WA, Australia; 2Faculty of Health Science, Curtin University, Perth, WA, Australia; 3School of Paediatric and Child Health, University of Western Australia, Perth, WA, Australia; 4School of Paediatric and Child Health, Western Australia, Perth, WA, Australia; 5Paediatric Respiratory Physiology, Telethon Institute for Child Health Research, Perth, WA, Australia; 6Cardiac Transplant Unit, Royal Perth Hospital, Perth, WA, Australia

Introduction: Children born preterm are known to have altered lung structure and function. These changes may lead to dynamic flow limitation (DFL) during...
exercise. This study aimed to determine the prevalence of DFL and the ventilatory response to exercise in preterm children aged 9-11yrs with and without BPD.

**Methods:** Preterm children (<32 w gestation) with and without BPD (<28 d supplemental oxygen at 36 w post menstrual age) and term born healthy controls performed an incremental treadmill exercise test to volitional exhaustion with breath by breath analysis and exercise tidal flow volume loops.

**Results:** Of 89 children (33 BPD, 25 nonBPD and 31 controls) performed acceptable exercise tests. Children with BPD were more likely to have DFL (n=15, 36%) compared to nonBPD (n=3, 1%) and term controls (n=2, 6.3%) p<0.05. The pre-term children had a significantly lower peak V\textsubscript{O2} than the term born controls (43.8 ± 9.8 mL/kg/min, p<0.01). Children with BPD had a reduced O\textsubscript{2} pulse (p<0.001), tidal volume and V\textsubscript{E} (p<0.001) compared to nonBPD and term controls. Preterm children with dynamic flow limitation had lower FEV\textsubscript{1} z-scores compared to those without (p<0.02) with other ventilatory responses to exercise not altered in the presence of DFL.

**Conclusion:** Children born preterm have a lower aerobic exercise capacity and those with BPD exhibit both cardiac and respiratory limitation to exercise. The presence of DFL in children born preterm with BPD is a novel finding and further research on its potential impact is required.

P1546
Consequences of obesity on gas exchange during exercise
Bohumil Matula, Stanislav Majerník, Plamen Kabaivanov, Daniel Magula,
Ján Plutinsky. Functional Diagnostics, Specialized Hospital of St. Zozoradus
Zbor, Nitra, Slovakia (Slovak Republic)
Obesity produces an increment in total blood volume and cardiac output and a decrease in lung compliance as a result of increased pulmonary blood volume and alveolar collapse in the lung base.

**Aim:** To evaluate gas exchange parameters under incremental exercise in ‘healthy’ obese patients (pts).

**Methods:** Analysis of symptom limited incremental cardiopulmonary exercise tests in supine position of 115 pts (36M, 79F) with FEV\textsubscript{1}VC and TLC > 80% predicted (ECCS) and without history of cardiovascular disease. Pancuts of arterial radialis were made to evaluate arterial oxygen and carbon dioxide pressure (PaO\textsubscript{2}, PaCO\textsubscript{2}) at peak exercise (PE) and in-calculation of PaO\textsubscript{2} and alveolar-arterial oxygen pressure difference (PaO\textsubscript{2A} difference).

Slope of heart rate to oxygen uptake (DHR/DVO2 heat. l/min) was determined. Pts were divided into 2 groups: Ob (n=88): Body mass index (BMI) ≥ 30Kg/m\textsuperscript{2}, N (n=57): BMI < 30Kg/m\textsuperscript{2}.

**Results:** Significant differences were found between group Ob and N at PE in PaO\textsubscript{2} (83.3 vs 89.1mmHg, p<0.01) and PaCO\textsubscript{2} (36.4 vs 32.0mmHg, p<0.05), but no differences in heart rate (mean 161 ± 28 bpm, 104 ± 19 bpm, p<0.01), PaO\textsubscript{2} (mean 37.5 vs 37.6mmHg), and HR at peak (109 ± 16 vs 109 ± 16, p<0.05). These data indicate an increased extent of lung units with low ventilation/perfusion ratio (V/Q') but no differences in parameters of alveolar ventilation. Lowering of V'Q' ratio seems to be produced mainly by increase in lung perfusion.

**Conclusion:** Hypervolemia and pulmonary over-perfusion may be an important factor of gas exchange impairment under exercise in obese patients.

P1547
Oxygen saturation response during the six-minute walk test in patients with chronic respiratory disease
Raúl Carrion-Sevilla1, Elena Gimeno-Santos2, Diego A. Rodriguez3,
Alba Ramirez-Sarmiento4, Joaquim Gia5, Josep Roca6, Mauricio Orozco-Levi6,
Jordi Vilaró3,5. Respiratory Physiology, Hospital Clínic, University of Barcelona, Barcelona, Spain; 1Centre for Research in Environmental Epidemiology (CREAL), Hospital del Mar Research Institute (IMIM), CIBERESP, Barcelona, Spain; 3Respiratory Medicine Service, (IC), Hospital Clínic de Barcelona, IDIBAPS, CIBERES, Barcelona, Spain; 4Respiratory Medicine Service, Par
Salut Mar-IMIM, Barcelona, Spain; 5FCS Blanquerna, GReF, Universitat Ramon Llull, Barcelona, Spain

Some guidelines recommend stopping 6-minute walk test (6MWT) if arterial oxygen saturation (SaO\textsubscript{2}) <85% as safety criteria. Our aim was to analyze the SaO\textsubscript{2} response <85% during 6MWT and its relation with clinical and symptomatic outcomes.

Results are presented as mean ± SD.

**Methods:** Retrospectively, we analyzed 6MWT from two respiratory medicine services from tertiary hospitals: Hospital del Mar and Hospital Clinic, Spain, from 2006 to 2010. They did not stop 6MWT using SaO\textsubscript{2} <85% criteria. We analyzed the data in 4 groups according SaO\textsubscript{2}.

**Results:** 796 patients (68±10 years) were analyzed. The results of ANOVA are:

- Only 2 (0.5%) patients showed complications (leg pain and leg paresthesias) within groups (p=0.43). Few patients stopped during 6MWT in all groups (p=0.15).

**Conclusions:** Patients with SaO\textsubscript{2} <85% during 6MWT showed less distance walked and poor functional parameters. However, this group did not show differences neither in number of patients who stopped during the test nor presence of clinical complications during and after 6MWT. Our results confirm there are not critical effects in this kind of patients to stop the test using the SaO\textsubscript{2} <85% criteria.

Exposure to environmental tobacco smoke in childhood is associated to lung function in smoking adults
Oyvind Omland\textsuperscript{1}, Tine Malling\textsuperscript{1}, Ole Find Pedersen\textsuperscript{2}, Vivi Schlüßler\textsuperscript{3}, Torben Sigsgaard\textsuperscript{2}, Lars Skadhauge 3, David Sherson\textsuperscript{4}, Jesper Bælum 4, Gert Tomsen\textsuperscript{3}, 1Department of Occupational Medicine, Hospital of South West Denmark, Esbjerg, Denmark; 2Department of Occupational and Environmental Medicine, Odense University Hospital, Odense University Hospital, Odense University Hospital, Odense, Denmark; 3Department of Occupational Medicine, Hospital of South West Denmark, Esbjerg, Denmark; 4Department of Occupational and Environmental Medicine, Odense University Hospital, Odense University Hospital, Odense, Denmark.

**Objective:** To analyse for associations between exposure to environmental tobacco smoke (ETS) in childhood and lung function in young adults.

**Methods:** In a Danish cross-sectional study of asthma in subjects aged 20-44 years (ERCHIS protocol) 690 randomly selected subjects were eligible for analysis. Information of the participant exposure to ETS in childhood was collected. The history and current exposure to ETS was based on questionnaire. FEV\textsubscript{1} and FVC were measured according to ERS and ATS recommendation.

**Results:** No ETS exposure in childhood was reported by 130 subjects, while 245 and 315 subjects reported one or two parents smoking at home, respectively. Mean FEV\textsubscript{1}/FVC ratio (95% CI) was 0.79 (0.789-0.805). ETS in childhood had negative effect on the FEV\textsubscript{1}/FVC ratio (p=0.025 and p=0.001 by one or two parents, respectively). Stratifying for smoking habits the results were only significant among the 194 current smokers. Figure 1 shows relative difference in FEV\textsubscript{1}/FVC ratio in smoking adults by number of parents smoking at home in childhood stratified by the group, adjusted for gender, pack year, current exposure to ETS, study centre, and height.

Environmental tobacco smoke (ETS) in allergic asthma: A parallel exposure study in human subjects and sensitized allergic Balbc mice

Introduction: The present study focused on the acute effects of short term (3 hours) exposure to ETS in allergic asthma, in a mouse model as well as in asthmatics.

Methods: Analogously 23 non-smoking asthmatics as well as 54 allergic challenged Balbc mice were exposed to artificially produced ETS in increasing concentrations (I=250 µg/m³, II= 450 µg/m³, III=850 µg/m³) to or ambient air (control group).

In human asthmatics, lung function, exhaled NO and exhaled CO was assessed. Serum samples were analyzed for cytokine profile and distribution of immune cells. Symptom severity was assessed via asthma control test (ACT) and visual analogue scale (VAS) questionnaires.

Whole body plethysmography was performed in mice before, after and one day after ETS exposure. The immunological status of mice was assessed by analysing serum cytokines and BALF cell composition.

Results: Human asthmatics exposed to ETS II and ETS III had significantly lower FeNO levels, a decrease in lung function of small airways (MEF25, MEF50) and an increase in VAS scores compared to controls. In sera ETS II led to a more anti-inflammatory cytokine profile (IL10) whereas ETS III showed a proinflammatory cytokine milieu (IL8, TNF-α) in human asthmatics.

Conclusion: The data indicate a direct and dose dependent effect of ETS exposure on lung function as well as respiratory inflammation in human asthmatics and sensitized allergic mice.

P1551

Smoking rates in pregnant women one year before and after the Irish workplace smoke-free policy: A widening gap?

Introduction: The role of the smoke-free legislation on emergency department admissions due to tobacco-related diseases in Kocaeli was evaluated retrospectively before and after the implementation of the Tobacco Prevention and Control Research Center, NRITLD, Tehran, Islamic Republic of Iran

Methods: A cross-sectional observational study using questionnaire based on WHO MPOWER guidelines was developed. A scoring system based on the Tobacco control scale methodology was used with total score of 100 in 6 major categories. Information about country was also collected from the WHO report and the Tobacco Atlas 2009 and the World Bank report of 2008.

Results: Among 21 Eastern Mediterranean countries, only 3 countries (14.2%) mainly Iran (61%), Jordan (55%) and Egypt (51%), scored higher than 50. Mean score for countries were 29.7±4.3 points. More than 50% of the countries scored less than 26. Highest scores were achieved by Afghanistan in cigarette pricing, Oman in smoking ban in public places, Iran in budgeting, prohibition of advertisement and health warnings against smoking and Yemen in tobacco cessations programs.

Conclusion: Countries in the EMRO region lack the ideal conditions for tobacco control and the related authorities are required to make changes and amendments in their policies for achieving desirable results.

P1554

The role of the smoke-free legislation on emergency department admissions due to tobacco-related diseases in Kocaeli

Introduction: Confusion by health organizations in the public debate on legal smoking ban in Switzerland

Background: Signature of the FCTC and the parliamentary initiative of MP Gutzwiller MD in 2004 started the process to a smoking ban, but resulted 10/08 in the federal Alibs Law, meeting neither international nor WHO standards. Thus, the Swiss Lung League (SLL; federation of cantonal lung leagues) launched an initiative with the collection of 130 000 signatures by 05/10. Media reporting is powerful only 10% of articles in the period 02/10 were positive on smoking bans; so pressure on MPs is insufficient to improve legislation.

Aim: To detect communication flaws contributing to poor media reporting.

Method: Analysis of official positions by health organizations on passive smoking.

Results: A. The PMH (Federation of Swiss physicians) declined (letter 03/09), but finally backed 01/10 the SLL-initiative. B. The president of the the Society of Internists (SSI), declined positioning on passive smoking at its assembly 2008, arguing the congress was not nonsmoking and sponsors should be consulted (letter 04/08). The SSI has not positioned itself yet (submission) on its support of the SLL initiative. C. By its launching the SLL urged cantonal lung leagues to collect signatures. Some cantonal leagues did not (e.g. Zurich, Vaud). Despite initial desaprobation by the lung league Vaud (letter 12/08), the annual report 2009 of this league declared official support of the SLL initiative.

Conclusion: Reports on smoking bans are likely to improve, if health organizations communicate in a coordinated way. This can be achieved by all health organizations, since toxicity of passive smoke and public health benefits of smoking ban in public places are based on sound scientific evidence.

P1553

Comparison of tobacco control policies in the eastern Mediterranean countries based on tobacco control scale scores

Conclusion: Working separately for each of the two calendar years.

Results: data on January to June 2009 and 2010 were compared for the prevention of lower respiratory tract infections (LRTI), allergic rhinitis (AR) and myocardial infarction (MI) were recorded. The number of admissions to emergency departments of 15 hospitals due to tobacco-related diseases before and after smoke-free legislation.

Aim: The aim of the study was to evaluate the admissions to emergency department due to tobacco-related diseases before and after smoke-free legislation.

Method: The number of admissions to emergency departments of 15 hospitals in Kocaeli was evaluated retrospectively before and after the implementation of smoke-free legislation published on 19 July 2009. ICO codes of smoking-related disease which were determined as bronchitis (BR), chronic obstructive pulmonary disease (COPD), asthma, nasopharyngitis (NP), lower respiratory tract infections (LRTI), allergic rhinitis (AR) and myocardial infarction (MI) were recorded. The data on January to June 2009 and 2010 were compared for the prevention of seasonal changes.
Results: There was a 22.5% decline in all emergency admissions due to smoking-related diseases.

Total number of admissions due to above mentioned diseases was 83,089 in the first 6 months of 2009 while it was decreased to 64,314 in the first 6 months of 2010. There was a 39.8% reduction in the diagnosis of bronchitis, 4.3% of reduction in the lower respiratory tract infections, 61.9% reduction for allergic rhinitis and 21.5% reduction in the COPD exacerbations. Conclusion: The number of admissions to emergency department due to tobacco-related disease decreased after the implementation of smoke-free legislation. This finding might be interpreted as an achievement of smoke-free environment.

P1555
Tobacco smoking and cardiovascular parameters
Tatiana Levina1, Julia Krasnova2, Alexander Dzimezki1. 1Therapy, Institute of Advanced Medical Studies, Irkutsk, Russian Federation; 2Gerontology, Institute of Advanced Medical Studies, Irkutsk, Russian Federation

The aim: To study the influence of tobacco smoking on cardiovascular parameters. Methods: A total of 200 smokers were examined (index of smoking≥5 packs/years). The mean age was 42.7±7.57 years. The acute tests were carried out: the first one was smoking 1 cigarette, then after 24 hours the 2nd test was smoking 2 cigarettes. The parameters were studied before and after smoking 1 and 2 cigarettes: diameter of a humeral artery, pulsioxymetry, Holter monitoring ECG.

Results: Diameter of a humeral artery in ten minutes after smoking 1 and 2 cigarettes decreased by 5.48% (2.4-8.9) and 6.89% (2.96-10.23), accordingly, p<0.05. Diameter of a humeral artery in fifteen minutes after smoking 1 and 2 cigarettes decreased by 6.25% (3.7-9.9) and 8.29% (3.42-12.58), accordingly, p<0.05. Diameter of a humeral artery in twenty minutes after smoking 1 and 2 cigarettes decreased by 6.71% (3.79-10.9) and 8.6% (5.11-12.78), accordingly, p<0.003. The oxygen saturation of blood before smoking cigarettes was 98% (96.98) of predicted; 10 minutes after smoking 1 cigarette it was 96% (95.98) (p<0.0001), 15 minutes after-99% (94.98) (p<0.0001), 10 minutes after smoking 2 cigarettes it was 96% (94.98) (p<0.0001), 15 minutes after-96% (94.98) (p<0.0001), 20 minutes after-90% (94.98) (p<0.001). Heart rates (HR) before smoking cigarettes were 78±130; one minute after smoking 1 cigarette it was 94±113 (p<0.0001), after two minutes-88±12 (p<0.0001); one minute after smoking 2 cigarettes it was 98±114.5 (p<0.0001), after two minutes-89±15.2 (p<0.0001), after three minutes-83±112.9 (p<0.03).

Conclusion: Tobacco smoking can cause significant changes of cardiovascular parameters. The smoking of 2 cigarettes gives more distinctive changes in cardiovascular parameters.

P1556
Does smoking impair the quality of life of 34 year olds with alpha-1 antitrypsin deficiency?
Laura Cano Monterro, Meltem Nysted: Duzakin, Eva Fintuhainen. Department of Respiratory Medicine and Allergyology, Skåne University Hospital, Malmö, Skåne, Sweden

Background: Alpha-1 antitrypsin (AAT) protects lung tissue against degradation. Hereditary AAT deficiency increases the risk of pulmonary emphysema. During Alpha 1-antitrypsin (AAT) protects lung tissue against degradation.

Background: This study included 129 PiZZ and 55 PiSZ individuals, and 300 age cohort of individuals with AAT deficiency at the age of 34. Identified. We have examined whether smoking affects the quality of life in the participants. Low scores indicate better quality of life in a 0-100 scale in response to the SGRQ questionnaire.

Results: The students were classified in 3 groups: G1, never smokers (n=1283; men=595; age=16±1.1 years); G2, subjects who have experimented smoking at least once in their lives (n=487; men=224; age=16.3±1.1 years), and G3, current smokers (n=244; men=128; age=16±1.1 years). The mean PSS for G1 (16.5±6.4) was significantly lower than that of G2 (18.0±6.8) and G3 (19.2±6.7) (p<0.001). There was a non-significant difference between G2 and G3 regarding PSS (p=0.05). There were significant correlations between PSS and the following USP-RSS domains: addiction (p=0.015; r=0.161), tension reduction (p=0.0002; r=0.243), stimulation (p=0.013; r=0.164), automatism (p=0.020; r=0.154). Weight control showed only a marginally significant correlation (p=0.052; r=0.130).

Conclusion: Stress levels in teenagers appear to contribute to the smoking experiment. However, it has not to the addiction establishment. Stress levels show small, but significant, correlations with important factors that contribute to smoking maintenance. Supported by: FAPESP 09/5052-0.

P1557
Stress influence on smoking behavior of teenagers
Amanda Bomtilha1, Elisa Souza1, Antonio Ruffino Netto2, Jose Baddini Martinez1. 1Internal Medicine, 2Social Medicine, Medical School of Ribeirão Preto - USP; Ribeirão Preto, São Paulo, Brazil

Rationale: Previous studies suggested that stress levels might influence smoking behavior.

Objectives: To investigate the stress levels among teenagers according to their smoking history. To correlate stress levels with health outcomes. To evaluate the effectiveness of mucociliary clearance (MCC) and to development of mucociliary insufficiency in patients with chronic non-obstructive bronchitis.

Methods: We recruited a thousand and fourteen high school students and afterwards they answered a standard questionnaire including the Perceived Stress Scale (PSS) and the USP-RSS. Comparisons among scores were performed by ANOVA on ranks and Dunn’s post test when indicated. Associations between USP-RSS domains scores and PSS scores were performed by Spearman’s correlation coefficient.

Results: The students were classified in 3 groups: G1, never smokers (n=1283; men=595; age=16±1.1 years); G2, subjects who have experimented smoking at least once in their lives (n=487; men=224; age=16.3±1.1 years), and G3, current smokers (n=244; men=128; age=16±1.1 years). The mean PSS for G1 (16.5±6.4) was significantly lower than that of G2 (18.0±6.8) and G3 (19.2±6.7) (p<0.001). There was a non-significant difference between G2 and G3 regarding PSS (p=0.05). There were significant correlations between PSS and the following USP-RSS domains: addiction (p=0.015; r=0.161), tension reduction (p=0.0002; r=0.243), stimulation (p=0.013; r=0.164), automatism (p=0.020; r=0.154). Weight control showed only a marginally significant correlation (p=0.052; r=0.130).

Conclusion: Stress levels in teenagers appear to contribute to the smoking experimentation. However, it has not to the addiction establishment. Stress levels show small, but significant, correlations with important factors that contribute to smoking maintenance. Supported by: FAPESP 09/5052-0.

P1558
Predictive role of smoking in the development of mucociliary insufficiency in patients with chronic non-obstructive bronchitis
Victor P. Kolosov, Andrey N. Odareev, Artem V. Kolosov. Laboratory of Pathophysiology of Non-specific Lung Diseases, Scientific Center of Physiology and Pathology of Respiration, Blagoveschensk, Russian Federation

Background: Smoking in patients with chronic bronchitis can lead to decrease of effectiveness of mucociliary clearance (MCC) and to development of mucociliary insufficiency at the early stages of a disease formation. Aim: To study the peculiarities of mucociliary system functioning in patients with chronic obstructive bronchitis but not to the addiction establishment. Stress levels show small, but significant, correlations with important factors that contribute to smoking maintenance. Supported by: FAPESP 09/5052-0.

Methods: Spirography, the study of MCC by scintigraphy with 99mTc, the study of effectiveness of mucociliary clearance (MCC) and to development of mucociliary insufficiency in patients with chronic non-obstructive bronchitis (CNOB) with latent smoking history. To correlate stress levels with scores of the University of São Paulo-RSS domains, including the Perceived Stress Scale (PSS) and the USP-RSS. Comparisons among scores were performed by ANOVA on ranks and Dunn’s post test when indicated. Associations between USP-RSS domains scores and PSS scores were performed by Spearman’s correlation coefficient.

Results: The students were classified in 3 groups: G1, never smokers (n=1283; men=595; age=16±1.1 years); G2, subjects who have experimented smoking at least once in their lives (n=487; men=224; age=16.3±1.1 years), and G3, current smokers (n=244; men=128; age=16±1.1 years). The mean PSS for G1 (16.5±6.4) was significantly lower than that of G2 (18.0±6.8) and G3 (19.2±6.7) (p<0.001). There was a non-significant difference between G2 and G3 regarding PSS (p=0.05). There were significant correlations between PSS and the following USP-RSS domains: addiction (p=0.015; r=0.161), tension reduction (p=0.0002; r=0.243), stimulation (p=0.013; r=0.164), automatism (p=0.020; r=0.154). Weight control showed only a marginally significant correlation (p=0.052; r=0.130).

Conclusion: Stress levels in teenagers appear to contribute to the smoking experiment. However, it has not to the addiction establishment. Stress levels show small, but significant, correlations with important factors that contribute to smoking maintenance. Supported by: FAPESP 09/5052-0.
respiratory function test. Patients presenting normal respiratory function and with CT-detected pulmonary emphysema (PE) are not diagnosed as having COPD. As surfactant protein D (SP-D), human β-2-defensin 2 (HBD2), and intercelleukin-8 (IL-8) have been reported as serum markers of COPD, they may be useful for the diagnosis of CT-detected PE.

Aim: The aim of this study was to investigate the usefulness of serum markers (SP-D, HBD2, and IL-8) for patients with COPD and CT-detected PE.

Method: A total of 326 subjects were screened. Of these, 55 were excluded because they failed to meet the criteria for this study, leaving 271 subjects for analysis. They underwent a respiratory function test and chest CT. According to the results, the subjects were classified into four groups: control group (n=40), non-COPD group (n=169), CT-detected PE group (n=42), and COPD group (n=20). Serum marker (HBD2, SP-D, and IL-8) levels were measured by ELISA and evaluated.

Result: Serum SP-D levels in the CT-detected PE group (66.3 ± 31.6 ng/ml), and in, in comparison with the non-COPD group (49.3 ± 32.9 ng/ml) showed a significantly different elevation (p=0.026). However, there were no significant differences serum IL-8 and HBD2 levels among the four groups.

Conclusion: This study suggests that serum SP-D level might be a useful marker for detecting CT-detected PE.

P1560 Widening inequalities in smoking rates in the Republic of Ireland?
1 Department of Public Health and Primary Care, Trinity College, Dublin, Ireland; 2Research, Tobacco Free Research Institute, Dublin, Ireland; 3Policy Unit, Institute of Public Health, Dublin, Ireland; 4Public Health and Primary Care, Trinity College, Dublin, Ireland

Methods: Complete smoking-related information on adults (≥18 years) for 1998 [n=25,203] and 2007 [n=21,051] were analysed. Age-standardized smoking rates for each of the two main indicators were computed overall and by sex using 2002 Census as the standard population. Relative index of inequality (RII) in age-standardized smoking rates was computed (comparing the lowest with the highest socio-economic groups) for each calendar year based on relative ranking (0=highest; 1=lowest) and then regressing the cumulative percentile distribution of the sub-classes within each year 95% confidence intervals (CI) for RII were generated.

Results: Overall, sample-weighted smoking rates declined from 33% (in 1998) to 29% (in 2007). However, the lowest SC groups recorded 51% higher smoking rates compared to the highest SC groups in 1998 and this widened relatively by 37% (2007) among those with lowest education widened relatively by 40% (from 35% to 49%) between the two time-periods compared to the highest groups. Female smoking rates have increased more relative to their male counterparts in lower SC groups.

Conclusions: Overall, smoking rates have declined in Ireland over a 10-year period but using “a” relative index of inequality measure, social inequalities in smoking rates have significantly widened in lower socio-economic groups, worsening further among disadvantaged females. Tobacco control policies combined with socio-economic interventions are imperative to address these inequalities.

P1561 Smokeless tobacco use among young male adults in northern Finland
Anna Henriksson1, Tiago Toljamo2, Pentti Nieminen3, Vuokko Kinnula4.
1 Department of Medicine, Pulmonary Division, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; 2Department of Pulmonary Medicine, Lapland Central Hospital, Rovaniemi, Finland; 3Medical Informatics and Statistics Research Group, University of Oulu, Oulu, Finland

Background: Smokeless tobacco (ST) sales have been banned in Finland since 1995 while its’ import for own personal use is allowed. Despite the sales ban, adolescents and young adults use ST. According to a national survey in 2009, 41% of 18-year-olds had experimented smokeless tobacco and 2.1% used it daily, and the trend seems to be increasing [1].

Aims: To study Swedish moist snuff use among young adult males in Northern Finland with fairly close access to Sweden, where ST products are available.

Methods: Data was collected during 2008-2009. The study population consists of 1151 male military recruits from the two most northern regions of Finland (mean age 19.4, 94.2% 18-20 years). All draftees were applied to answer a specific questionnaire. Response rate was high, 80%.

Results: Most young males (70.4%) had experimented ST at least once. Current daily ST use was reported by 14.3%, and 28% reported occasional use. Among daily users, mean duration of ST use was 3-0 years.

Conclusions: Despite the sales ban in Finland, ST use is common among young adult males. Compared to national prevalence, daily ST use was high in Northern Finland where also smoking is relatively common [2]. This might relate to cultural differences inside the country, but also to easy snus availability in the northern parts of the country.

P1562 Phenotypic features in COPD smokers attending a smoking cessation unit
Carlos A. Jimenez Ruiz, Ana Maria Cicero Guerrero, Maria Luisa Mayayo Ulbarri, Maria Isabel Cristobal Fernandez, Genia Lopez Gonzalez. Unidad Especializada Tabaquismo, Salud Madrid, Madrid, Spain

COPD smokers have specific features of their smoking habit. We reviewed medical histories of all COPD patients who were treated in our Unit between January 2004 and January 2010. Medical and smoking histories were obtained during the baseline visit, as well as different test results such as FTND-questionnaire, Reward Test and Test to measure psychological, social and gestual dependence.

These test results obtained were compared with those of a historical group of non-COPD patients treated in our Unit (Control Group). 472 COPD smokers showed the following data for gender (65% were male), average age 58.3 (9.8), number of cigarettes per day 29.7 (13.4), number of years smoking 40.5 (9.9) and number of pack-years 59.1 (30.2). For the control group, which consisted of 1850 patients, these data were 50% male, 47.8 (11), 28.3 (10.4), 32.3 (11.5) and 45.8 (25.7), respectively.

The average score on FTND-questionnaire was 7.4 (2.1) for COPD patients, against 6.5 (2.4), p<0.001 in the control group. 79% of COPD smokers were a negative reward smokers, against a 56% of the control group, p<0.01. COPD patients had a low rate on gestual and social dependence, as well as on automatism. On the contrary, they had a high rate on psychic dependence and sedation.

COPD smokers who attend a smoking cessation unit are generally male over 55 years old, have higher figures of years smoking and higher pack-year figures than the control group. Their physical nicotine dependence is higher than for those in the control group. They are negative reward smokers more often and more significantly than those in the control group.

COPD smokers have a low grade of gestual and social dependence and a high grade of psychic dependence.

P1563 Prevalence and predictors of smoking cessation rates in Ireland: A follow-up cross-sectional study
Sheila Keoghan1, Zubair Kabir1, Laura Currie1, Miriam Gunning2, Paula Campbell1, Luke Clancy 1, 3 Research, TobaccoFree Research Institute, Dublin, Ireland; 2Health Promotion Office, Health Service Executive, Dublin, Ireland

Background: We reported that intensive smoking cessation (SC) services are available in Ireland but lack uniformity or consistency countrywide [1]. Here we estimated successful quit rates at 4-weeks and again at 3-months follow-up relative to baseline after setting up a quit date, and identified significant predictors of quitting at 4-weeks follow-up relative to baseline smoking status.

Methods: A convenience sample of 1,490 patients was recruited while attending SC service throughout Ireland. An electronic database was created. Intention-to-treat analyses were performed employing stepwise multivariable logistic regression modelling to identify significant predictors from several covariates for which complete data were available. Smoking status was self-reported. Carbon monoxide (CO) monitoring was done but was patchy.

Results: 37% had quit smoking at 4-weeks after setting up a quit date (p<0.001) and a lower proportion (22.4%) quit smoking at 3-months follow-up (p<0.001). Only occupation [professionals had 58% increased success rates relative to semi/unskilled] and client sources [outpatients were least likely to succeed] were significant predictors (p<0.05) of SC rates at 4-weeks follow-up.

Conclusions: This pilot study demonstrated that SC services if avaliable of could result in quitting when followed-up both at 4-weeks and at 3-months, despite attrition. A cost-effective comprehensive tobacco dependence treatment program can accelerate further declines in smoking rates.

213. Understanding the burden of chronic respiratory diseases: what decision makers need to know

1677 Sporimetric screening and survey of knowledge on COPD and smoking in Spanish political representatives: The ConSePOC study

Methods: 50 improvement projects focussed on different steps of the pathway: outcomes.

across the whole care pathway.

of the national COPD strategy and enables delivery of effective clinical practice testing approaches to develop and refine news ways of working.

service improvement tools, each project used data to form objective measures of effective self management, managing high impact users, structured patient reviews, effective care models are early accurate diagnosis, medicines optimisation, effec-

alised cost efficiency saving of £590k. Other emerging principles that underpin assessment and review, 7 home oxygen projects have demonstrated a total annu-

Results: Prevalence of COPD stage I was 12%, and 5% for stage II+. Resource use in stage II+ categories was significantly higher in COPD patients than in control subjects.

8 results were calculated from utilization by applying national unit costs. To control for confounders such as age, sex and education, two-part generalized regression analyses were used to account for the skewed distribution of costs and the high proportion of subjects without any costs.

8 conclusions: The finding that resource use and costs are considerably higher in moderate but not in mild COPD highlights the economic importance of prevention programs and of interventions aiming at early diagnosis and at delaying disease progression.

1680 The impact of a respiratory in-reach service into the emergency assessment unit (EAU) on treatment, length of stay, and re-admission rates

Background: Respiratory illness is the second commonest reason for admission to hospital in the UK. Specialist input leads to better outcomes and reduced length of stay. Approximately half of respiratory patients, at New Cross Hospital, Wolverhampton, are not reviewed by a specialist during their admission.

Aims: The aim of this study was to assess whether addition of specialist respiratory input into the EAU, would optimise patient management, and thus reduce length of stay and re-admission rates.

Methods: During the weekday working hours, we piloted a twice daily respiratory ward round in the EAU. We audited management against current BTS guidance, identifying treatment where required. We compared length of stay and re-admission rates during the pilot month to that of the preceding month. We collected data on whether patients would have been appropriate for referral to a respiratory “hot clinic”, to assess the need and demand for this service in the Wolverhampton City PCT.

Results: 73.1% of patients had management altered, according to BTS guidance. 53.7% of patients had undergoing respiratory disease on admission, and of these, only 50% were optimally treated according to guidance. Re-admission rates decreased by 13.4% and length of stay decreased by 1.38 days. 25% of patients could have been seen in a “hot clinic”, preventing a hospital admission.

Conclusion: There is a role for the addition of a respiratory specialist ward round in the EAU of New Cross Hospital, to optimise management of patients with respiratory illness, and to reduce patient length of stay and re-admission rates.

1681 The economic burden of COPD in a Danish municipality

The economic burden of chronic diseases are a great challenge to our future welfare. The purpose of this study was to create a qualified measurement of the expenses to COPD in a Danish Municipality and determine the division of these between the Municipality and the Government.

From the National Patient Register patients with COPD, Diabetes and Cardiovas-

cular diseases living in the Municipality of Helsingør (61,295 inhabitants) were
Cost-effectiveness of tiotropium versus salmeterol: A trial-based analysis followed by a model-based extrapolation

Martine Hoogendoorn1, Maiwenn Al1, 1-Mathias Graf von der Schuleenburg2, David Bowles3, Brigitta Monz4, Hendrik Schmidt4, Juliane Lungershausen5, Maureen Rutten-van Molken1, 1-Institute for Medical Technology Assessment (iMTA), Erasmus University Rotterdam, Rotterdam, Netherlands; 2-School of Economics and Management, Leibniz University Hanover, Hanover, Germany; 3-Faculty of Health Sciences, University of Bielefeld, Bielefeld, Germany; 4-Boehringer Ingelheim, Boehringer Ingelheim Pharma GmbH & Co KG, Ingelheim, Germany

Background: The 1-year POET trial compared tiotropium to salmeterol regarding the effect on COPD exacerbations. Data from that trial informed this cost-effectiveness analysis (CEA).

Aim: Performing a 1-year trial-based CEA of tiotropium versus salmeterol, followed by a 5-year model-based CEA, from the perspective of the German Social Health Insurance in 2010.

Methods: The within-trial CEA included 7250 patients that had resource utilization recorded (COPD-related drug use and exacerbation-related healthcare use). The trial-based analysis was followed by a model-based analysis to synthesize the POET results with evidence from earlier studies, extrapolate results to 5-years, include costs of COPD maintenance treatment, and adapt to the severity distribution of the German population. Main endpoints were difference in costs, number of exacerbations, and quality-adjusted life-years (QALYs; model only).

Results: One-year costs were €1089 and €963 per patient treated with tiotropium and salmeterol, respectively, a difference of €126 Euro (95% uncertainty interval (UI): 55-195). The number of exacerbations avoided due to tiotropium was 1089 and 1089 for the endpoints exacerbation avoided and QALY, respectively. Following the extension to 5 years, the latter ICER changed to €3488.

Conclusion: Tiotropium reduced exacerbation-related costs, generating an incremental cost-effectiveness ratio (ICER) that is considered cost-effective.

Clinical and pharmacy-economical reasonability of the choice of fixed combination of fluticasone/salmeterol in the curing of bronchial asthma in the country with limited financing of the public health

Dmitry Ruzanov1, Elena Davidovskaya2, Tatyana Baranovskaya2, 1-Pulmonology & TB Department, Gomel State Medical University, Gomel, Belarus; 2-Belarusian Academy of Post-Graduate Medical Education, Minsk, Belarus

Aim: To estimate the real practice of prescription of preparations in curing BA, to analyze clinical and pharma-economical efficiency of conversion to the fixed combination of SALMFP in curing BA.

Method: The real practice of curing 266 patients with separated using of different preparations of basic therapy and short-rated broncholitics was retrospectively analyzed during the year (1st period) and the following year of their using of SALMFP (2nd period).

Results: It was managed to attain control (ACT) of 15.5% of patients in the real practice (1st period). System glucocorticoids were ambulatorially prescribed to 41 patient. On the average each patient used 15.6 inhaler SABA. The cost of treatment (ambulant hospitalization, medications, visits of the doctor, social payment) came to 1405 EUR per year.

Conclusion: The real clinical practice of curing BA in RB often differs from the recommendations of GINA 2009 and leads to the low level of control of BA (among 15.5%). The conversion to using fixed combination of SALMFP enables to increase the percentage of patients with controlled asthma to 74.3%, and cut the cost of treatment by 1.6 times.

Mechanisms of acute lung injury and mesenchymal cell treatment

1682

A late-breaking abstract: Soluble immune complex exaggerates LPS-Induced acute lung injury (ALI) by transfusion – A novel mechanism of transfusion-related acute lung injury (TRALI)

Ming-Cheng Chan1, Chieh-Liang Wu2, 1-Dept. of Internal Medicine, Section of Chest Medicine, 2-Dept. of Internal Medicine, Section of Critical Care and Respiratory Therapy, Taichung Veterans General Hospital, Taichung, Taiwan

Rationale: TRALI is a major cause of morbidity and mortality related to transfusion therapy. Soluble immune complex (ICs) could aggravate LPS-induced lung injury. We speculate that ICs formation during transfusion may play a role in the pathogenesis of TRALI.

Aim: To design a double-hit mice model to simulate TRALI development. The first hit is LPS i.t. injection. The second hit is transfusion of conditioned blood 24 hours after LPS injection. Mice were sacrificed 6 hours later. The conditioned blood was generated by transfusing 0.1cc/day CS7 mouse blood to BALB/c mice consecutively for two weeks.

Methods: A 2-hit model of BALB/c mice was used. Animal were divided into four groups XX, XB, LP and LB: (X: no treatment, L: LPS i.t.; B: transfusion of conditioned blood, P: transfusion with PBS). The body weight, clinical symptoms, blood pressure, liver and lung tissue were observed.

Results: The LB group has higher protein, TNF-α and MIP-2 level in BALF.

Conclusion: We demonstrated that transfusion with 2cc conditioned blood aggravated LPS-induced ALI and generated soluble ICs in plasma. This probably indicates ICs may aggravate pre-existing ALI which implies a novel mechanism of the pathogenesis of TRALI.

1685

A haplotype of the endothelial protein C receptor gene is associated with reduced risk of acute lung injury in critically ill patients

Akiha Vassiliou1, Nikolaos Mamatlis1, Anastasia Kouandis2, Eleftheria Letsyos1, Marina Kallergis2, Fotemi Karyntzaki2, Chisrina Sotropoulou1, Konstantinos Glynos1,2, Ioanna Dimopoulou3, Charalampos Roussis1,2, Apostolos Aragmidanis3, Stylianos Orfanos1,5, 1Marianthi Simou Laboratory, 1st Dept. of Critical Care, Evangelismos Hospital, University of Athens Medical School, Athens, Greece; 21st Dept. of Critical Care, Attikon Hospital, University of Athens Medical School, Athens, Greece

Aim: To investigate the role of PC gene as predisposing factor for ALI/ARDS.

Methods: Twenty ALI/ARDS patients with chronic respiratory disease were included in this study. A total of 1700 ng/ml of protein C was identified by ELISA. We detected rare mutations in the PC gene (c.1051C>G, c.1051C>A) associations with ALI/ARDS.

Results: Six patients with chronic respiratory disease were included in this study. A total of 1700 ng/ml of protein C was identified by ELISA. We detected rare mutations in the PC gene (c.1051C>G, c.1051C>A) associations with ALI/ARDS.

Conclusion: Our study indicate that PC gene rare mutations (c.1051C>G, c.1051C>A) may be associated with ALI/ARDS.

Mechanisms of acute lung injury and mesenchymal cell treatment

1684

A haptopy of the endotelial protein C receptor gene is associated with reduced risk of acute lung injury in critically ill patients

Akiha Vassiliou1, Nikolaos Mamatlis1, Anastasia Kouandis2, Eleftheria Letsyos1, Marina Kallergis2, Fotemi Karyntzaki2, Chisrina Sotropoulou1, Konstantinos Glynos1,2, Ioanna Dimopoulou3, Charalampos Roussis1,2, Apostolos Aragmidanis3, Stylianos Orfanos1,5, 1Marianthi Simou Laboratory, 1st Dept. of Critical Care, Evangelismos Hospital, University of Athens Medical School, Athens, Greece; 21st Dept. of Critical Care, Attikon Hospital, University of Athens Medical School, Athens, Greece

Aim: To investigate the role of PC gene as predisposing factor for ALI/ARDS.

Methods: Twenty ALI/ARDS patients with chronic respiratory disease were included in this study. A total of 1700 ng/ml of protein C was identified by ELISA. We detected rare mutations in the PC gene (c.1051C>G, c.1051C>A) associations with ALI/ARDS.

Results: Six patients with chronic respiratory disease were included in this study. A total of 1700 ng/ml of protein C was identified by ELISA. We detected rare mutations in the PC gene (c.1051C>G, c.1051C>A) associations with ALI/ARDS.

Conclusion: Our study indicate that PC gene rare mutations (c.1051C>G, c.1051C>A) may be associated with ALI/ARDS.
Results: Depending on the presence of haplotype-determining-point mutations, patients were divided into three haplotypes: H1 (n=59), H2 (n=17) and recombinant H1/H3 (n=16). ALI occurred in 53% of H2 carriers, 24% of H1 carriers and 50% of H3 carriers with odds ratios 1.0, 0.284 (Confidence Interval 0.090-0.904) and 0.963, respectively (p=0.033). Severe sepsis/septic shock was positively correlated with ALI/ARDS development, while APACHE II, SOFA, age and soluble EPCR levels were not independent predictors of ALI/ARDS.

Conclusion: EPCR genotype seems to be a determinant of ALI/ARDS development in critically ill patients. H1 haplotype carriers have a reduced risk of ALI/ARDS, as compared to H2 haplotype and H1/H3 carriers.

1686 Diagnostic value of Von Willebrand factor (VWF) in patients suffering from respiratory distress

Rabab El Wahsh, Safaa Amin, Eman Essa. Chest Department, Faculty of Medicine, Minoufya University, Shebin El Kom, Minoufya Governorate, Egypt

Forensic Medicine &Clinical Toxicology Department, Faculty of Medicine, Minoufya University, Shebin El Kom, Minoufya Governorate, Egypt

Introduction: Acute respiratory distress syndrome (ARDS) is characterized by an extensive alveolar capillary leak. Von Willebrand Factor antigen (VWF) is a macromolecular antigen that is considered as a marker of endothelial activation.

Aim: To investigate the diagnostic value of VWF antigen in patients with ALI/ARDS caused by poisoning or non-poisoning etiology.

Patients and methods: VWF antigen was measured in 52 patients with ALI/ARDS, 13 poisoned patients without ALI/ARDS and 20 control subjects.

Results: There was a highly significant difference between VWF level in patients and control groups (P ≤ 0.001). VWF level had a significant negative correlation with the ratio between PaO₂/FIO₂ in patients with respiratory distress. There was a non significant difference in VWF level between poisoned and non-poisoned cases. There was a significant relationship between the level of VWF and the severity of poisoning in patients with respiratory distress. Among the poisoned patients, the highest level of VWF was in patients with anticholinesterase poisoning. The difference between VWF level in poisoned patients with ALI/ARDS and those without was highly significant. The level of VWF didn’t affect patients’ need for mechanical ventilation or their mortality. The cut –off value of VWF at 100% specificity and 20% sensitivity was 0.99 units, while the cut-off –off value of VWF at 100% specificity and 60% sensitivity was 1.87 units.

Conclusion: VWF has a diagnostic value for ALI/ARDS but it does not differentiate between poisoning or non-poisoning etiology, nor does it predict outcome of ARDS. VWF is significantly increased in patients with anticholinesterase poisoning.

1687 Stimulation of NOD1 induces RIP2, TAK1 and p38 MAPK dependent pro-inflammatory signalling in human lung microvascular endothelial cells

Gram-negative bacteria are an important cause of septic shock. NOD1 receptors recognize peptidoglycan in the bacterial cell wall and initiate pro-inflammatory responses. We have previously shown in rodents that stimulation of NOD1 induces vascular dysfunction in vitro and profound shock in vivo. In this study we investigate the role of NOD1 in human lung microvascular endothelial cells (HMVEC) which represent a site of key importance in the pathophysiology of sepsis and acute lung injury.

HMVEC from healthy donors were cultured in 96-well plates. Cells were treated for 24 hours with vehicle ± LPS (TLR4) or iE-DAP (NOD1). In additional experiments cells were pre-treated for 1 hour with specific signalling inhibitors prior to addition of agonists (n=4–5). Cell activation was assessed by multiplex ELISA and by specific ELISAs for CXCL8 and 6-keto Prostaglandin F1α.

iE-DAP induced significant release of CXCL8, 6-Keto Prostaglandin F1α, IL-1β, IL-2, and IFNγ. SZ-7-oxo-zeazemon or BIRB0706 similarly inhibited responses to iE-DAP (Figure 1) or LPS (P<0.05;two-way ANOVA). By contrast, PP2 was more potent an inhibitor of iE-DAP (Figure 1) than LPS (P<0.05; two-way ANOVA).

In conclusion NOD1 is active in human microvascular endothelium and converges with TLR4 signalling at the level of TAK1 and p38 MAPK. NOD1 thus represents a potential target in the treatment of gram-negative sepsis.

1688 Lactate, pH and angiogenetic markers in exhaled breath condensate correlate with outcome and disease severity in patients with acute lung injury

Christian Gessner1, Benedikt Malmann1, Hartmut Kuhn1, Peter Ruschpleger2, Lothar Engelmann3, Stefan Hammerich4, Ulrich Sack2, Hubert Wirtz1.1 Department of Respiratory Medicine, 2Department of Immunology, 3Department of Intensive Care Medicine, University of Leipzig, Leipzig, Germany

Acute lung injury (ALI) is characterized by increased capillary permeability, interstitial and alveolar oedema, influx of circulating inflammatory cells, and formation of hyaline membranes. Vascular endothelial growth factor (VEGF) has been correlated to a favourable prognosis in ARDS in a number of investigations. VEGF plays a role in regulating vascular permeability to water and protein.

The aim of this investigation was to characterize the role of VEGF, Angiogenin, basic fibroblast growth factor (bFGF), IL-8, and TNF-α in exhaled breath condensate (EBC) in mechanically ventilated patients with acute lung injury.

For this purpose, exhaled breath condensate was collected from 30 patients with ALI at 24 to 72 hours from start of mechanical ventilation and correlated with ventilatory parameters, clinical scores, and outcome. Cytokines were measured by a cytometric bead array (CBA). We observed a significant lower value of VEGF in EBC in the group with lower outcome compared to survival group (median:32.4 pg/ml vs. 108 pg/ml in survivors; Mann-Whitney test: p<0.0001) but no significant difference for Angio- genin, bFGF, IL-8, or TNF-α. In addition EBC-lactate and EBC-pH correlated positively with lung injury severity indices. There was a further correlation of bFGF and IL-8 in EBC with lung injury severity indices.

We conclude that measurement of lactate, pH, bFGF, and VEGF in EBC may provide information on prognosis in ALI.

1689 Which is the best source of mesenchymal cells to treat acute lung injury?

Johnutas Silva1, Ana Paz2, Debora Xisto1, Maquírias Lopes-Pacheco3, Elga Bandeira1, Milena Vasconcellos1, Vera Capelozzi4, Marcelo Morales1, Paolo Peluzzi5, Elizabeth Cincie-Lima1, Patrícia Roccol3. Laboratory of Pulmonary Investigation, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 2Laboratory of Embryology and Cell Differentiation, Hospital de Clínicas de Porto Alegre, Federal University of Rio Grande do Sul, Porto Alegre, Brazil; 3Laboratory of Molecular and Cellular Physiology, Carlos Chagas Filho Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 4Department of Pathology, University of São Paulo, Sao Paulo, Brazil; 5Ciberes, Bunyola, Spain; 6DIBIMIS, Section of Pneumology, University of Palermo, Palermo, Italy; 7DIBIMIS, Section of Pneumology, University of Palermo, Palermo, Italy; 8CIBER de Enfermidades Respiratorias, Ciberes, Barcelona, Spain; 9Institute d’Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain; 10Institute for Bioengineering of Catalonia, IBEC, Barcelona, Spain

Mesenchymal stem cells (MSC) may derive from bone marrow, adipose tissue or lung. Previous studies have shown that bone marrow derived mesenchymal stem cells (BM-MSC) exert beneficial effects in acute lung injury (ALI), but the effects of adipose tissue and lung derived mesenchymal cells (AD-MSC and L-MSC, respectively) have not been evaluated so far. The aim of this study was to investigate the effects of BM-MSC, AD-MSC, L-MSC on lung mechanics and morphometry, as well as inflammation and remodeling in an experimental model of ALI Forty-eight female Wistar rats (200-250g) received Escherichia coli lipopolysaccharide (LPS) intratracheally (100 μg/ALI) or saline (C). At 48 hours, ALI and C groups were further randomized into subgroups receiving saline (0.05 mL), BM-MSC, AD-MSC, and L-MSC (1 x 10^5) intravenously. Bone marrow cells were extracted from four male Wistar rats. The induction of differentiation showed that cells from bone marrow, adipose tissue and lung were able to generate osteocytes, adipocytes and chondrocytes besides presenting CD34+, CD90+ and CD29+ profile. At day 7, mesenchymal cells promoted a reduction in lung static elastance, resistive and viscoelastic pressures, alveolar collapse, collagen fiber content and number of neutrophils in lung tissue, independent of the source. However, the beneficial effects of BM-MSC and AD-MSC on lung parenchyma remodeling were greater than those observed with L-MSC. In conclusion, in the present LPS-induced ALI model, BM-MSC and AD-MSC therapies were more effective than L-MSC at modulating inflammatory and fibrogenic processes.

Supported by: CAPES, PRONEX, FAPERJ, CNPq

1690 Mesenchymal stem cells prevent early inflammation in a rat model of ventilator induced lung injury

Laura Chiumenti1,2, Tomas Luque3, Marisa Bonigongne2, Daniel Navagia2,3,5, Ramon Farré1,3,4. 1Unit of Biophysics and Bioengineering, Faculty of Medicine, University of Barcelona, Barcelona, Spain; 2DBIMIS, Section of Pneumology, University of Palermo, Palermo, Italy; 3CIBER de Enfermidades Respiratorias, Ciberes, Barcelona, Spain; 4Institut d’Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain; 5Institute for Bioengineering of Catalonia, IBEC, Barcelona, Spain

Background: Recent studies have suggested that bone marrow-derived mesenchy-
mal stem cells (MSC) might have potential therapeutic effects in acute lung injury (ALI), specifically in bleomycin-induced and bacterial LPS-induced lung injury models. However, whether MSC could induce an early anti-inflammatory response in lung injury induced by overventilation remains to be elucidated.

**Aim:** To assess the potential role of MSC in preventing or modulating early inflammation in healthy rats subjected to ventilator induced lung injury (VILI).

**Methods:** Adult male Sprague-Dawley rats (250-300 g) were anaesthetised, tracheotomised, intubated and paralyzed by intravenous instillation of pancuronium bromide. Nine rats were ventilated with a high tidal volume of 25 ml/kg (VILI) for 3 h. Five million of MSC were intravenously injected to 4 of these rats 30 min before starting ventilation. Spontaneously breathing anaesthetised rats (N=4) served as controls. After 3 h of VILI the animals were sacrificed and bronchoalveolar lavage inflammatory cells were assessed.

**Results:** In VILI, MSC significantly (p<0.01) decreased total neutrophil counts from 7620±3710 to 1580±470 (cells/μL), which was close to control values (787±344; p=0.6).

**Conclusion:** This preliminary result suggests that infusion of bone marrow-derived MSC prevents early inflammation in VILI.

Funding: L. Chimienti was a recipient of a RFS/Marie Curie Postdoctoral Research Fellowships 2010

215. Clinical application of exhaled biomarkers

2162 Exhaled molecular patterns change after experimental rhinovirus 16 infection in asthma

N. Fens1, K. V. van der Sluijs2, M.A. van de Pol3, R. Lutter3, S.L. Johnston3, P.J. Sterk1.

1Respiratory Medicine, Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; 2Laboratory of Experimental Intensive Care and Anesthesiology, Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; 3Experimental Immunology, Academic Medical Center University of Amsterdam, Amsterdam, Netherlands; 4Respiratory Medicine, Imperial College, London, United Kingdom

**Rationale:** The majority of asthma exacerbations is caused by rhinovirus (RV) infection. Metabolomic assessment of exhaled Volatile Organic Compounds (VOCs) using an electronic nose (eNose) offers the opportunity to simplify and improve monitoring of asthmatics with exacerbations.

**Hypothesis:** We hypothesized that exhaled VOC-patterns change after experimental rhinovirus infection.

**Methods:** Patients with mild intermittent asthma (no ICS, age 22±3; M/F 4/5) and healthy controls (22±3; I/13) underwent intranasal RV16 inoculation. Efficacy of inoculation was assessed by antibodies and PCR. Exhaled breath was collected using a standardized method 1 day before (visit 1), and 4 days (visit 2) and 2 months (visit 3) after exposure. Exhaled VOCs were measured by eNose (Cyranose 320) resulting in breathprints. Changes in breathprints were analyzed by principal component and mixed model analysis.

**Results:** 9/14 Asthmatics/healthy controls were included. Breathprint principal components (PC) changed significantly in asthmatics between visits 1 and 2 (p<0.01), and between visits 1 and 3 (p<0.015), but there was no change between visits 2 and 3. Breathprints of healthy controls did not change between any visit.

**Conclusion:** Rhinovirus infection changes exhaled VOC-patterns in asthmatics and not in healthy controls. This suggests that the change in exhaled VOC-pattern during and after RV infection in asthma may be used to monitor and predict exacerbations.

1693 Increased exhaled breath condensate cysteinyl leukotriene concentration in exercise-induced bronchoconstriction

Andras Bikov1, Reka Gajdos2, Eva Huszar3, Zsofia Lazar3, Balazs Antuss2, Gyorgy Losenycz2, Bildik Horvath2, 1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Department of Pathophysiology, National Korayni Institute, Budapest, Hungary

**Background:** Several studies support the role of cysteinyl leukotrienes (Cys-LTs) in exercise-induced bronchoconstriction (EIB), however the concentration of these mediators during the development of EIB has not been investigated yet.

**Aim:** To study the effect of exercise on airway concentration of Cys-LTs in asthmatic patients by measuring Cy-LT in exhaled breath condensate (EBC).

**Methods:** Seventeen asthmatic patients with previous history of EIB and six healthy subjects participated in the study. Lung function was measured and EBC was collected at rest (baseline), immediately and ten minutes after exercise challenge on treadmill. Exhaled NO (FENO) was also determined at baseline. To compare the exercise-induced changes in FV1 and Cys-LT between groups, repeated-measures ANOVA was used. Pearson correlation was applied to assess the relationship between variables. Cys-LT levels are expressed as median (range).

**Results:** Baseline Cys-LT level was higher in asthmatic than in healthy subjects (168 pg/ml (112-223) vs. 77 pg/ml (36-119), p<0.03). Exhaled breath condensate Cy-LT concentrations in all asthmatic patients post-exercise (p=0.03), with the increase significantly greater in patients developing exercise-induced bronchospasm (n=7, p<0.03), while no change was observed in healthy controls (n=10, p=0.59). There was a strong correlation between baseline FENO and the maximal increase in Cys-LT concentration in the asthmatic group (r=0.01, r=0.57). A significant relationship was observed between the increase in EBC Cy-LTs and the exercise-induced fall in FV1.

**Conclusion:** Our study supports the concept that the release of Cys-LTs is involved in the development of EIB.

1694 Exhaled nitric oxide may predict future benefit in patients with poorly controlled asthma

Vocu Tudorache1, Crina Babiciu1, Cristian Oancea1, Monica Marc2, Emmanuela Tudorache3, Danina Muntean3, Ovidiu Fita-Mlăinescu4, 1Pneumology, Victor Babes University of Medicine and Pharmacy; 2Pneumology, Victor Babes University of Medicine and Pharmacy; 3Pneumology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania

**Rationale:** Dynamic changes in exhaled nitric oxide fraction (FeNO) are highly predictive for asthma control, whereas its absolute values are often in discrepancy with patients’ clinical status.

**Aim:** To evaluate the potential of baseline FeNO to identify in regular clinical practice the individuals with suboptimal controlled asthma who have the potential to achieve control according to a guidelines-based approach.

**Methods:** 165 patients seen for two consecutive visits with uncontrolled asthma (defined as a score of ≤ 19 in the Asthma Control Test) at the first visit were included in the study. The exclusion criteria were limited to smokers and overlapping COPD since the study was purported to reflect the real-life practice.

**Results:** In ROC curve analysis, a greater absolute value of FeNO at the first visit
was associated with the acquirement of asthma control in the second one (AUC – area under the curve was 0.7816, p<0.0001). Its predictive performance with respect to the future control of the disease did not significantly differ between patients with and without allergic rhinitis (AUC was 0.7661 vs 0.7918; p = 0.35), even if the mean value of FeNO was greater in the former group (33.72±1.98 vs 29.27±1.96, p<0.0006). In uncontaminated asthma, values of FeNO > 35 ppb in patients with, and > 30 ppb in patients without allergic rhinitis, predicted future benefits (the positive predictive value was 85.42% and 91.97%, respectively).

Conclusion: Our results suggest that the fractional concentration of exhaled nitric oxide more strongly relates to asthma control and future benefit over time even in patients with underlying atopy, as expressed by the presence of allergic rhinitis.

1695 Exhaled nitric oxide is better related to bronchial responsiveness and eosinophil activation in children than adults with asthma

Andrei Malinovschi1, Christer Janson2, Pia Kalm-Stephens3, Kjell Alving3 .

Methods: The fraction of exhaled nitric oxide (FeNO), a marker of steroid-sensitive airways inflammation, is moderately related to bronchial responsiveness (BR) in asthma. Serum eosinophil cationic protein (sECP), a systemic eosinophil activation marker, is weakly-related to exhaled NO. However, no studies have concomitantly compared these relationships in children and adults with asthma.

Aim: To analyze in an ongoing asthma study the relation between exhaled NO and BR as well as sECP with respect to age of subjects.

Methods: FeNO, lung function, methacholine provocation (PC20FEV1), sECP measurements and allergy testing were performed in 208 patients with asthma (94 children aged 10-17 years and 114 adults aged 18-53 years) within the frame of an industry-academy collaboration on minimally-invasive diagnostics (MIDAS).

Results: No differences between children and adults were found with regard to allergic sensitization (80% vs 84% atopic), lung function (FEV1, FV (Spred)) 90% (81, 99%) vs 93% (86, 103%) and asthma control (ACT score 21 (19, 23) vs 21 (19, 23) (all p-values >0.05). The correlation coefficients between FeNO and PC20 were rho=0.46, p<0.01 in children and rho=0.21, p<0.01 in adults. Similarly, FeNO was stronger related to sECP in children (rho=0.49, p<0.001) than adults (rho=0.25, p=0.006).

Conclusion: The relation between exhaled NO and bronchial responsiveness appears to be weaker in adults and this might be explained by other factors than ongoing allergic inflammation causing bronchial hyperresponsiveness, for example airway remodeling. The weaker relation between exhaled NO and sECP in adults warrants further research.

1696 Non-invasive biomarkers applied in a case-control study

Karolina Blesemen1, Rosette Van Den Heuvel1, Gudrun Koppen1, Vera Nelen2, Erwin Wittens2, Kristine Desager3, Grete Schoeters1 .

Environmental Risk and Health, Department Clinical Diagnostics, KIST Europe, Saarbrücken, Germany.

Background: Exhaled breath contains various potential noninvasive biomarkers for airway disease.

Aim: This study aims to evaluate the performance of known exhaled markers and to search for potential new markers in exhaled breath.

Methods: Asthmatic (N=72) and healthy (N= 67) children (6-12 years) donated exhaled breath condensate (EBC;RTube) and exhaled gasses (Tedlar bag). Fractional exhaled nitric oxide (FeNO) was measured (NIOX MINO). EBC pH was measured directly after sampling without deaeration. EBC 8- isoprostane was measured with an electronic nose.

Results: Increased FeNO values were observed in the asthmatic group compared to the healthy controls (Mann-Whitney U test; p=0.057), and in the allergic asthmatic patients compared to the non-allergic asthmatic patients (p=0.01). EBC pH was significantly lower in the asthmatic group compared to healthy controls (p=0.047). EBC 8-isoprostane was comparable between children with asthma and healthy controls, but was significantly increased in allergic asthma patients compared to non-allergic patients (p=0.032). Various proteins that might be relevant in respiratory health outcomes were for the first time identified in EBC, amongst which annexin A1 and A2, eukaryol A and B, cathepsin, gelsolin, and prolactin-induced protein.

Prediction models of selected proteolytic peptides or gasses were build (Support Vector Machine analysis) based on the health outcome asthma.

Conclusion: Exhaled molecules are influenced by asthma or allergy status. This study identified new exhaled molecules that might be relevant for respiratory health.

1697 Pattern of exhaled volatile organic compounds is altered in children with obstructive sleep apnea

Zsófia Lázár1, András Bikov1, Palma Benedek2, László Kunos1 .

1Department of Paediatrics, Semmelweis University, Budapest, Hungary; 2Department of Oto-Rhino-Laryngology and Bronchology, Heim Pál Children’s Hospital, Budapest, Hungary.

Background: Obstructive sleep apnea syndrome (OSAS) is a common disorder in children. Systemic and local airway inflammation is involved in its disease pathogenesis. Non-invasive tools for inflammation are needed in pediatricians. The analysis of exhaled volatile organic compounds (VOCs) by sensor arrays such as electronic noses offers a novel method to assess inflammation-related metabolic changes and oxidative stress.

Objective: To study if exhaled VOC pattern in children with OSAS can be discriminated with an electronic nose.

Methods: Eight children with mild to moderate OSAS (age 2±2 yrs) and ten healthy control subjects (10±3 yrs) were recruited. Subjects did not present any acute or chronic airway disease. After a single deep inspiratory capacity, VOC pattern of exhaled breath (collected from the lower airways without the dead space) was recorded with Cyanose 320 (Smiths Detection) and analyzed off-line using principal component analysis, Mahalanobis regression and receiving operator curve (ROC) analysis (SPSS 16.0).

Results: All subjects provided technically adequate breath samples. Exhaled VOC pattern of OSAS patients could be discriminated from that of control subjects using the Mahalanobis method (Wilks’ lambda=0.02; 73% classification accuracy) and also with ROC analysis (sensitivity: 88%; specificity: 70%; positive predictive value: 70%; negative predictive value: 88%).

Conclusions: In this first preliminary study, we show that exhaled VOC sampling is feasible in children, and VOC pattern analysis can discriminate patients with OSAS from healthy controls. Exhaled VOC analysis might serve as a new tool for airway inflammation in children.

This study was supported by OTKA 68808.

1698 Increased exhaled nitric oxide predicts new-onset rhinitis in asymptomatic children

Andrei Malinovschi1, Christer Janson2, Pia Kalm-Stephens3, Kjell Alving3 .

Methods: A total of 959 randomly selected schoolchildren, aged 13-14 years, answered questions on respiratory and allergy symptoms, family history of asthma, lung function and FeNO were also measured at baseline. A follow-up with the same test battery is planned four years later. After exclusion of subjects with asthma or rhinitis symptoms at baseline, 555 participants were eligible for the present study.

Results: Subjects with new-onset rhinitis (n=92) had a trend of higher FeNO than subjects who did not develop rhinitis (p=0.06). Increased FeNO predicted new-onset rhinitis in a multiple logistic regression model (p=0.009) and the risk of new-onset rhinitis was 2.4-fold (1.2, 4.4) elevated if FeNO > 90th percentile of all included subjects (n=555). A similar risk increase for new-onset rhinitis, 2.4 (1.2, 4.9) was found in subjects with no allergy symptoms and 2.3 (1.04, 5.1) after further excluding subjects with a family history of asthma.

Conclusion: Increased FeNO levels predicted new-onset rhinitis in this population-based study of schoolchildren. The predictive value in subjects without allergic symptoms or family history of asthma suggests that these children with increased FeNO should be tested for allergy and followed-up.

1699 Differentiation of chronic obstructive pulmonary disease (COPD) including lung cancer from healthy control group by breath analysis using ion mobility spectrometry

Sofía Lasarz1, Andrés Bikov1, Palma Benedek2, László Kunos1 .

1Department of Paediatrics, Semmelweis University, Budapest, Hungary; 2Department of Oto-Rhino-Laryngology and Bronchology, Heim Pál Children’s Hospital, Budapest, Hungary.

Introduction: Non-invasive methods with potential for diagnosis of lung diseases and increasing interest: Ion mobility Spectrometry detects volatile analytes within human breath directly. Therefore its usefulness in discriminating COPD patients and healthy persons is tested.

Methods: Exhaled breath of 132 persons (97 COPD patients [35 without lung cancer, 62 with lung cancer] and 35 healthy volunteers) was investigated using an Ion Mobility Spectrometer (IMS) coupled to a Multi-Capillary Column (MCC)
216. Molecular pathology and functional genomics of lung disease

1760 Late-breaking abstract: The TERT-CLPTM1L locus for lung cancer predisposes to bronchial obstruction and emphysema

Els Waeters1,2,3, Dominiek Sneets1,2, Johan Coolen4,5, Jorn Verschakelen1, Paul De Leyn5,6, Marc Decramer3,7, Johan Vansteenkiste3,8, Wim Janssens3,9

Department of Respiratory Medicine, University Hospital Gasthuisberg, KULeuven, Leuven, Belgium; 2Vesalius Research Center (VRC), KULeuven, Leuven, Belgium; 3Respiratory Division, University Hospital Gasthuisberg, KULeuven, Leuven, Belgium; 4Department of Radiology, University Hospital Gasthuisberg, KULeuven, Leuven, Belgium; 5Department of Thoracic Surgery, University Hospital Gasthuisberg, KULeuven, Leuven, Belgium

Clinical studies suggest that bronchial obstruction and emphysema increase susceptibility to lung cancer. We assess the possibility of a common genetic origin and testability of the lung cancer susceptibility locus on chromosome 5p15.33. In 3074 individuals the rs11568834 T>G variant was genotyped. The presence of the T allele was associated with increased odds of requiring GINA step 4 treatment: heterozygosity was associated with 1.56 (1.18-2.06) times the risk of requiring treatment (OR=1.72; CI=1.29-2.29; P=0.000); the frequency of the T allele was 14.7% in controls and 19% in patients (P=0.004). Accounting for rs11568834, the presence of the T allele was associated with increased odds of requiring GINA step 4 treatment: heterozygosity was associated with 1.70 (1.31-2.21) times the risk of requiring treatment (OR=1.86; CI=1.46-2.37; P=0.000).

1761 Late-breaking abstract: Possible association between vitamin D receptor SNP FokI and treatment response in asthmatic children

Helly Emsin1, Maria Loreto Reyes1, Marcelo Lopez-Lazra2, Jennifer Angulo3, Marie Solange Caussade4, Ana Moya5, Jaime Cerda6, Jose A. Castro-Rodriguez1, Patricia León6, Ana Fernández7, 1Pediatrics, Pontificia Universidad Católica de Chile, Santiago, Chile; 2Medical Investigation Center, Pontificia Universidad Católica, Santiago, Chile; 3Public Health, Pontificia Universidad Católica, Santiago, Chile

Introduction: An association between poor asthma control and low 25OH Vitamin D (25OHD) has been shown. Single nucleotide polymorphisms (SNP) in the gene encoding 25OHD receptor (VDR) have been associated with asthma. Hypothesis: asthma control is associated with 25OHD levels and VDR SNP.

Methods: Total 25OHD values in healthy children were obtained from a sample of a previous study. Asthmatics treated with at least 3 months of inhaled steroids were enrolled in outpatient clinics. A clinical questionnaires of asthma severity was applied and blood was drawn. 25OHD levels were measured with Radioimmunounassay and SNP were analyzed by a standard PCR-RFLP assay.

Results: 75 asthmatic children (9.6±2.5 yrs) and 226 healthy children (10.2±4.8 yrs), were studied. 25OHD levels were 23.9±10.7 and 22.2±7.6 ng/ml respectively (p=0.122). No significant differences were found between controlled and uncontrolled asthmatics (24.9±6.1 and 21.5±7.3 ng/ml respectively). Analysis of FokI (rs10735810) SNP revealed that all patients (16/16) requiring GINA step 4 treatment were heterozygous for the C allele. The presence of the C allele was less frequent in patients in step 2 (30/33) and 3 (16/24) vs patients in step 1 (p=0.007). No significant differences in the other SNP (rs731236) and no association of neither SNP with asthma control status, were found.

Conclusions: This pilot study established a possible association between FokI C allele and need of higher steroid doses for asthma control. VDR might play a role in asthma treatment response. Further research is required to validate it.

1702 TNF-derived TIP peptide reduces lung dysfunction in experimental influenza A virus infection

Rudolf Lucas1, Guang Yang2, Supriya Sridhara1, Zachary Traylor2, Hamid Hossain3, Bernhard Fischer4, Trinad Chakraborty5, Ian Davis2, 1Vascular Biology Center, Pharmacology and Toxicology, Georgia Health Sciences University, Augusta, GA, United States; 2Veterinary Biosciences, Ohio State University, Columbus, OH, United States; 3Medical Microbiology, Justus-Liebig University, Giessen, Hessen, Germany; 4Research and Development, Apeptico, Vienna, Austria

Background: Permeability edema during Influenza A virus (IAV) infection is characterized by reduced alveolar liquid clearance (ALC) and pulmonary endothelial hyperpermeability. Mortality after IAV infection is mainly due to secondary pneumococcal infections and occurs after antibiotic therapy, which can release the toxin pneumolysin (PLY) in the lungs.

Aims: To investigate whether the TNF-derived TIP peptide, which reduces PLY-induced edema, can blunt IAV-induced ALC dysfunction and combined IAV/PLY-induced barrier dysfunction.

Methods: ALC is assessed in BALB/C mice infected i.n. for 2d with 10,000 FFU/mouse (strain H1N1-AWSN/33), using the BSA dilution method. We measure IAV/PLY-induced changes using a modified ELISA (Wien Janssens1). We applied and blood was drawn. 25OHD levels were measured with Radioimmunounassay in serum samples of asthmatics, 2 SNP in the VDR gene.

Results: A single analyte could be identified, that allowed a separation of the ALC phenotype. Discriminant analysis was applied to find discriminant analytes.

In BALB/C mice exposed to IAV/PLY, the peak was characterized as cyclohexane (CAS 108-94-1). The sensitivity obtained was 60%, the specificity 91%, the positive predictive value 95%. The peak was characterized as cyclohexanone (CAS 108-94-1). The presence of the C allele was associated with increased odds of requiring GINA step 4 treatment: heterozygosity was associated with 1.56 (1.18-2.06) times the risk of requiring treatment (OR=1.72; CI=1.29-2.29; P=0.000); the frequency of the T allele was 14.7% in controls and 19% in patients (P=0.004). Accounting for rs11568834, the presence of the T allele was associated with increased odds of requiring GINA step 4 treatment: heterozygosity was associated with 1.70 (1.31-2.21) times the risk of requiring treatment (OR=1.86; CI=1.46-2.37; P=0.000).

Conclusions: The TIP peptide represents a therapeutic candidate for the treatment of IAV-associated lung dysfunction, since it interferes with both IAV infection-associated ALC and barrier dysfunction, upon reducing PKC-a activation.

1703 Oxidative stress during high altitude expedition and its influence on vessel tone-modifying mediators

Jacqueline Pichler Hefti1, Maria Loreto Reyes1, Marcelo Lopez-Lazra2, Jennifer Angulo3, Marie Solange Caussade4, Ana Moya5, Jaime Cerda6, Jose A. Castro-Rodriguez1, Patricia León6, Ana Fernández7, 1Pediatrics, Pontificia Universidad Católica de Chile, Santiago, Chile; 2Medical Investigation Center, Pontificia Universidad Católica, Santiago, Chile; 3Public Health, Pontificia Universidad Católica, Santiago, Chile

Introduction: Hypoxia-induced excessive pulmonary vasconstriction is assumed to be the main cause of life-threatening high altitude pulmonary edema. Decrease of nitric oxide (NO), a potent vasodilator, has been suggested to play a significant role in hypoxia-induced vasconstriction. To study alterations of prolonged hypobaric hypoxia, serum samples were drawn from 34 healthy mountaineers up to 8685 m during a Swiss research expedition to mount Muztagh Ata (7549 m) in Western China. Comprehensive metabolomics analysis using a mass spectrometry-based targeted approach revealed a pronounced systemic oxidative stress during high altitude exposure. Detecting more than 390 parameters, a significant increase of lipid peroxidation was shown. Methionine sulfoxide, determined in relation to methionine, furthermore serves as a robust indicator of oxidative stress and showed highly increased values of 30% (mean at 550m), compared to values of 20% in septic patients. We also found relevant functional impairment of phenylalanine hydroxylase and nitric oxide synthase (NOS), enzymes which both require an oxidant-sensitive co-factor. Consequently, very low levels of NO were found. In addition, significant increase in the serum concentration of vessel tone modifiers such as leukotrienes and prostaglandins were found.

This novel and holistic approach extends the mechanistic understanding of hypoxia-related oxidative damage to a biochemical level and unravels underlying biochemical pathways involved in hypoxia-induced pulmonary vasoconstriction. Together, we demonstrate further insight into the molecular pathogenesis of hypoxia-related disorders.
1704 Systemic upregulation of neutrophil α-defensins and serine proteases in neutrophilic asthma

Katharina Eichhorn1,2, Jodie Simpson1,2, Lisa Wood1,2, Rodney Scott1,2

Peter Gibson1,2,2 Respiratory Medicine, The University of Newcastle, Newcastle, NSW, Australia; 3Respiratory and Sleep Medicine, Hunter Medical Research Institute, John Hunter Hospital, Newcastle, NSW, Australia; 1Information Based Medicine, The University of Newcastle, Newcastle, NSW, Australia

Background: The well-characterised airway inflammatory phenotypes of asthma include eosinophilic, neutrophilic, mixed eosinophilic/neutrophilic and pauci-granulocytic asthma, defined by the proportion of sputum granulocytes. Systemic inflammation is now recognised as an important part of some airway diseases, but the role of systemic inflammation in the pathogenesis of asthma phenotypes remains unknown.

Methods: Induced sputum samples and peripheral blood were collected from participants with asthma (n=30). Airway inflammatory cell counts were performed on induced sputum and inflammatory phenotype assigned based on the airway eosinophil and neutrophil cut-offs of 3% and 61% respectively. Gene expression profiles were generated (Illumina Human-8 V3) from whole blood RNA and analysed using GeneSpring GX 11.

Results: There were 6 genes classified as differentially expressed between the 4 asthma phenotypes including the α-defensins (DEFA) 1, 1B, 3 and 4, neutrophil proteases cathepsin G (CTSG) and elastase (ELA2). Significant expression of DEFA1, 1B, 3, 4, CTSG and ELA2 was significantly higher in the neutrophilic asthma phenotype. Microarray results were successfully validated using real-time PCR. Plasma elastase was significantly elevated in people with neutrophilic airway inflammation.

Conclusion: There is systemic upregulation of α-defensin and neutrophil protease expression in neutrophilic asthma, which may reflect the pro-inflammatory effects on the bone marrow and the release of immature neutrophils into the circulation. This demonstrates a systemic inflammatory component in neutrophilic asthma that further differentiates this from other asthma phenotypes, and indicates different mechanisms.

1705 Dysregulated miRNAs and their predicted mRNA targets in emphysema lungs

Sanjayi Savarimuthu Francis1,2, Morgan Davidson1,2, Raylene Bowman1,2, Nicholas Hayward1,2, Kwan Fong1,2,1 Ian Yang1,2,2 Department of Thoracic Medicine, The Prince Charles Hospital, Brisbane, QLD, Australia; 3School of Medicine, The University of Queensland, Brisbane, QLD, Australia; 4Oncology Research Laboratory, Queensland Institute of Medical Research, Brisbane, QLD, Australia

There is increasing recognition of the importance of microRNAs (miRNAs) as short non-coding RNAs that post transcriptionally regulate gene expression. Identification of the role of miRNAs in COPD would help better understanding of disease pathogenesis and use as biomarkers for diagnostic purposes or therapeutic targets. Our aims were i) to identify miRNAs dysregulated in mild and moderate emphysema, and ii) to identify mRNAs regulated by miR-34c-5p in BEAS-2B and HFL cell lines.

Methods: i) miRNA microarray profiling (Agilent Human miRNA profiler G4470A) was performed on 29 non-tumour lung tissues obtained from The Prince Charles Hospital tissue bank. Patients were classified as mild (n=9) and moderate (n=20) emphysema according to lung function measurements (KCO and FEV1). Technical validation was performed on the selected miRNAs using quantitative real-time PCR. ii) Genomic mRNA expression changes from transient transfection of miR-34c-5p (candidate miRNA in BEAS-2B and HFL cells) were measured using Illumina HumanHT-12 V3 arrays.

Results: COPD patients had mean (SD) age 68 (6) years, FEV1: 72 (17%) predicted and KCO 70 (10%) predicted. Five miRNAs were identified (p<0.01) as differentially expressed in non-tumour lung tissues in mild vs moderate emphysema patients. Upregulation of miR-34c-5p in respiratory cell lines down-regulated predicted mRNAs.

Conclusions: We have shown that miRNAs are associated with COPD severity and modulate expression of their predicted mRNAs. Support: NHMRC Biomedical Scholarship (SF), NHMRC Career Development Award (JY), The Prince Charles Hospital Foundation, Australian Lung Foundation/Boehringer Ingelheim COPD Research Fellowship.

1706 Differentiation between squamous cell carcinoma (SCC) and adenocarcinoma (AC): Expression of immunohistochemical (IHC) markers in a tissue microarray (TMA) of >1000 NSCLC cases

Philipp A. Schnabel1,2, Esther Herpel1, Thomas Muley1, Hans Hoffmann2, Alexander Schirmacher3, Arne Warth1, Institute of Pathology, University Clinics, Heidelberg, Germany; 2Translational Research Unit, Thoraklinik Heidelberg, Heidelberg, Germany; 3Thoracic Surgery, Thoraklinik Heidelberg at the University Clinics, Heidelberg, Germany

Introduction: Distinguishing SCC from AC has become crucial for tailored therapies of NSCLC. Many patients are inoperable at the time of diagnosis of NSCLC, >65% of the diagnoses are performed in small biopsies (Bx). The “IASLC/ATS/ERS international multidisciplinary classification of lung adenocarcinoma” (Travis W.D., Brambilla E. et al. JTO 2011; 6:244-85) firstly includes diagnostics in Bx in addition to resection specimen. We investigated the expression of IHC markers in a TMA studying Bx.

Materials and methods: The IHC markers CK5/6, p63, desmocollin-3, CK7, TTF1, and napsin were investigated in a TMA from a primary cohort of 1005 patients with resected NSCLC.

Results: For SCC, desmocollin-3 showed the highest, CK5/6 a medium, and p63 the lowest specificity. The sensitivity of desmocollin-3 was similar to the sensitivity of CK5/6 and p63. Desmocollin-3 was expressed in about 85%, CK5/6 and p63 in >90% of all SCC.

For AC, TTF1 and napsin revealed a considerably higher specificity than CK7. The sensitivity of napsin did not exceed the combined sensitivity of CK7 and TTF1. CK7 was expressed in >95% of all AC, TTF1 in <90%, and Napsin in <80%.

Conclusions: To spare tissue for further (e.g. molecular) analyses, diagnostic algorithms for NSCLC Bx must be established. If histology alone cannot distinguish between SCC and AC, a combination of TTF1, napsin, CK5/6 and desmocollin-3 can serve as initial diagnostic marker panel. CK7 and p63 could be sequentially specific, if necessary, because of lower specificity. Currently a TMA of 300 further NSCLC is investigated, data from all 1300 NSCLC will be presented.

1707 DNA copy number alterations in squamous metastatic lesions predict lung cancer

Robert van Boerendonk1, Thomas Sutdija2, Peter Sniijder3, Emilie Rein5, Saskia Wilting5, Mark van der Wel5, Frederik Thumissen5, Sylvia Duijn5, Clarissa Koo5, Bauke Yijkstra2, Chris Meijer4, Gerrit Meijer4, Karrien Grebeng1, Johannes Daniels4, Pietro Biondi4, Egbert Smut5, Danielle Heideman1

1Pathology, VU University Medical Center, Amsterdam, Netherlands; 2Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 3Epidemiology & Biostatistics, VU University Medical Center, Amsterdam, Netherlands

No biomarker can reliably predict cancer risk in individual subjects who present with AFB-visualized premalignant lesions. Our present study was set out to identify AFB-visualized squamous metastatic (SqM) lesions with malignant potential by DNA copy number profiling.

Within our cohort of 474 subjects at risk of lung cancer who underwent regular AFB examinations, 6 (1.3%) subjects showed rapid progression from SqM to carcinoma (in situ) (cases). P53, p63 and KI-67 immunostaining patterns and arrayCGH-based DNA copy number profiles of progressive SqM lesions (n=6) were compared to those of a subset of SqM from lung cancer-free (controls; n=23). Specific DNA copy number alterations (CNAs) linked to cancer risk were identified and accuracy to predict cancer in this series was determined.

While clinicopathologic characteristics and immunostaining patterns were not related to clinical outcome of SqM, the mean number of CNAs in SqM of cases (23%, range 0.48-39%) was significantly higher compared to controls (0.09%, range 0.1-32%, p<0.01). Significantly more frequently altered in cases were 3p26.3-3p11.1, 3q26.2-2q9, 9p13-3p13.2, and 17p13.3-1p12 (FWER<0.10). In cases, baseline-detected CNAs persisted in subsequent biopsies taken from the initial site (median 93%, range 68-99%), and levels increased towards cancer progression (p=0.028). CNAs at 3p26.3-3p11.1, 3q26.2-2q9, and 6q23.3-2q3.3 predicted endobronchial cancer risk for AFB-visualized SqM with 97% accuracy.

Our data strongly suggest that CNAs predict endobronchial cancer in individual subjects diagnosed with AFB-visualized SqM, and may be used to guide intervention to prevent lung cancer.

1708 Late-breaking abstract: The diaphragm and abdominal muscles act on the abdomen to displace blood to the extremities during exercise

Barbara Uva, Dario Bovio, Andrea Aliverti. Dipartimento di Bioingegneria, Politecnico di Milano, Milano, Italy

We have recently demonstrated (Aliverti et al. J Appl Physiol, 2010) that during quiet breathing the diaphragm serves the double function to ventilate the lung and to shift blood from the splanchnic to the peripheral vascular bed to the extremities. We hypothesized that with simultaneous contraction of abdominal muscles, such as occurs during exercise, the circulatory function of the diaphragm can be considerably enhanced. Six healthy subject performed a submaximal constant exercise workload test (repeated foot flexion at ~60% of max workload) within a whole body plethysmography (WBP) measuring changes in body volume (Vb). Simultaneously, changes in volume of the trunk (Vt) were measured by orthopneic plethysmography. Blood shifts between trunk and extremities (Vb), were determined...
as dVtr-dVb. In all subjects, intra-breath variations of Vbs were bimodal. Vbs initially decreased and then increased during inspiration; Vbs then decreased in the first part of expiration, and increased again in the second part. After 1 min of exercise, within-breath tidal Vbs increased by 175±122 ml (p<0.018) from rest, the blood accumulated into the extremities was 304±338 ml (p<0.05) and abdominal volume at end-expiration decreased by 0.50±0.32 L (p=0.012).

We conclude that a precise control mechanism of the diaphragm and abdominal muscles determines intra-breath variations of Vbs during exercise. Due to the high frequency of tidal Vbs there is not adequate time for a complete refilling of the splanchnic blood reservoir at each abdominal compression, and this results into a significant shift of blood from the trunk to the extremities during exercise. When needed, this should be clinically useful.

**Right ventricular contractility at rest and during exercise in COPD**

**Pia Trip1, Bart Boerrigter1, Taco Kind1, Harm-Jan Bogaard1,3, Nico Westerhof1,2, Anton Vonk Noordegraaf1**

1. Pulmonary Diseases, VU University Medical Center, Amsterdam, 2. Pulmonary Research, VU University Medical Center, Amsterdam, 3. Department of Medicine, Virginia Commonwealth University, Richmond, VA, United States

**Rationale:** COPD patients show a limited stroke volume response to exercise. This is thought to be due to an increased right ventricular (RV) afterload. Whether an impairment to increase RV contractility contributes to the impaired stroke volume response is unknown. Therefore, the aim of this study is to determine whether RV contractility changes during exercise in COPD patients.

**Methods:** Nine patients with COPD (GOLD II-IV) underwent right heart catheterisation and subsequently cardiac MRI at rest and during submaximal exercise. With cardiac MRI RV volumes were measured. During right heart catheterisation RV pressure curves were continuously measured. As a measure of contractility, the maximum rate of rise of RV pressure (dP/dtmax) was obtained from an averaged RV pressure waveform over several respiratory cycles. Then, dP/dtmax was normalized for RV end-diastolic volume, i.e. dP/dtmax/EDV (1).

**Results:** In all patients dP/dtmax/EDV increased with exercise. At rest mean dP/dtmax/EDV was 3.6±1.3 mmHg/s/ml, while during exercise it was 6.5±3.7 mmHg/s/ml (p<0.001). RV end-systolic volume did not change with exercise.

**Conclusions:** COPD patients show an increase in RV contractility. The increase in contractility does not result in a decrease in RV end-systolic volume.

**Right ventricular output in chronic obstructive pulmonary disease during expiration is impaired by reduced venous return**

**Bart Boerrigter1, Pia Trip1, Harm-Jan Bogaard1,3, Herman Groepenhoff1, Frank Oosterveer1, Nico Westerhof1,2, Anton Vonk Noordegraaf1**

1. Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2. Pulmonary Research, VU University Medical Center, Amsterdam, Netherlands; 3. Department of Medicine, Virginia Commonwealth University, Richmond, VA, United States

**Background:** High positive airway pressure impedes venous return and right ventricular (RV) output in mechanically ventilated patients. Whether this is also the case in normally breathing COPD patients, where the expiratory intrathoracic pressure is increased due to airway obstruction, is unknown. We investigated the effects of intrathoracic pressure on venous return and how this perturbs RV output during expiration at rest and during exercise.

**Methods:** Sixteen COPD-patients (GOLD II-IV) underwent simultaneous measurements of intrathoracic, right atrial (RA) and pulmonary artery pressures at rest and during exercise. Intrathoracic and RA pressure were used to calculate RA filling pressure. Dynamic changes in pulmonary artery pulse pressure during expiration were examined to evaluate changes in RV output.

**Results:** Pulmonary artery pulse pressure decreased up to 40% during expiration (figure 1). This decline was associated with a low RA filling pressure (r= 0.64). During exercise, a similar decline in pulmonary artery pressure was observed. Intra-thoracic pressure and RA pressure increased similarly, resulting in an unchanged RA filling pressure.

**Conclusions:** We show that in COPD, pulmonary artery pulse pressure declines during expiration; most prominent in patients with a low RA filling pressure. This implies that spontaneous breathing already impairs venous return and by that RV output in COPD.

### 1711
**Effects of hyperoxia and helium-hyperoxia on the cardiocirculatory responses to incremental exercise in hypoxemic patients with COPD**

**Marcos Nunes, Fernando Queirog-Jr, Elthane Meda, Gaspar Chiappa, Maria-Christina Machado, Luiz Eduardo Nery, J. Alberto Neder**

**Respiratory Division, Federal University of Sao Paulo, Sao Paulo, SP, Brazil**

Heliox breathing might positively impact upon the haemodynamic responses to exercise in non-hypoxemic patients with moderate-to-severe chronic obstructive pulmonary disease (COPD) (Chiappa, GR et al. Am J Respir Crit Care Med, 179:1004, 2009). There is, however, a lack of evidence of whether these beneficial effects would also be found in patients with more advanced cardiovascular impairment, i.e., hypoxemic, GOLD stage IV patients. On a double-blind study, 13 patients (FEV1= 35.4±9.1% pred; PaO2= 57.7±7.0 mmHg) were submitted to maximum incremental cardiopulmonary exercise tests while breathing hyperoxia (H2O2= 40% O2) or helium-hyperoxia (He-HiOX= 60% He/40% O2). Stroke volume (SV, ml) and cardiac output (CO, L/min) were non-invasively monitored by impedance cardiography (PhysioFlow® Manatec Inc, France). Peak work rate (WR) was improved with He-HiOX compared to HiOX (52±21 W vs. 46±18 W); in addition, end-expiratory lung volume (EELV) was slightly, albeit significantly, reduced (5.50±1.25 vs 5.61±1.30 L; p<0.05). At iso-WR, He-HiOX was associated with higher SV and CO than HiOX (92±8 ml vs. 84±2 ml and 6.9±1.3 L/min vs. 8.7±1.9 L/min, p<0.05). Improvement in CO with He-HiOX was negatively related to resting EELV (r=-0.72, p=0.01) but not with baseline CO and PaO2 (p>0.05). In conclusion, hyperoxic heliox enhances the cardiocirculatory responses to exercise compared to hyperoxia alone in less hypoxinilated patients with advanced, hypoxemic COPD. These data indicate that increased operational lung volumes are related to deleterious haemodynamic effects in this patient sub-population.

### 1712
**Predictors of improvement in peak exercise capacity with helium-hyperoxia in severely-impaired COPD patients under long-term oxygen therapy**

**Marcos Nunes, Fernando Queirog-Jr, Elthane Meda, Gaspar Chiappa, Maria-Christina Machado, Luiz Eduardo Nery, J. Alberto Neder**

**Medicine, Respiratory Division, Federal University of Sao Paulo, Sao Paulo, Brazil**

Heliox can improve exercise tolerance in ventilatory-limited patients with chronic obstructive pulmonary disease (COPD). Unfortunately, however, these benefits are quite heterogeneous in patients with similar levels of resting airflow obstruction. In order to gain further insight into the determinants of such variability in hypoxemic patients with advanced COPD, we evaluated 24 males (GOLD stage IV) who were under long-term O2 therapy. Patients underwent maximum incremental cardiopulmonary exercise tests while breathing hyperoxia (H2O2= 40% O2) or helium-hyperoxia (He-HiOX= 60% He/40% O2). Peak work rate (WR) was significantly improved with He-HiOX compared to HiOX (54±26 W vs. 48±23 W). This was associated with increased mean ins and expiratory flows and
larger tidal volumes; in addition, end-expiratory lung volume was lower at peak exercise (5.5±1.2 L vs 5.6±1.3 L; p<0.05). Δ[He-HbO2–Hb] WR was positively related to markers of lung hyperinflation including total lung capacity and residual volume (r=0.52 and r=0.46; p<0.05). Interestingly, however, fat-free mass (FFM) also showed to be strongly related to ΔWR; in fact, FFM was the only independent predictor of ΔWR on a multiple regression analysis (r²=0.66; p<0.001). We conclude that once patients with advanced COPD are relieved from the “central” ventilatory constraints by breathing hyperoxic heliox, appendicular muscle mass becomes an important determinant of maximal exercise capacity. The above data lend support to the notion that preserved muscle mass is important for improved respiratory mechanics be translated into enhanced peak exercise capacity in these patients.

1713 Tissue deoxygenation kinetics induced by acute hypoxic exposure at rest in humans
Samuel Verges1, Thomas Rupp1, Marc Jebou2, Guillaume Milet2, Thomas Lety3, Véronique Bricourt1, Bernard Wuyam4, Stéphane Perrey5,1. HP2 Laboratory (U1042), UP Recherche sur l’Exercice, Hôpital Sud, INSERM, Joseph Fourier University, University Hospital, Grenoble, France; 2Exercise Physiology Laboratory, Jean Monnet University, University Hospital, St. Etienne, France; 3Movement to Health (M2H), Montpellier University, Euromed, Montpellier, France.

The impact of hypoxia on tissue oxygenation per se involves complex mechanisms. How muscle and brain face the hypoxic stress over several hours of hypoxic exposure (HE) remain unknown. Therefore, this study aimed to investigate the effects of 4-hours HE at rest on muscle and cerebral (de)oxy-hemoglobin kinetics. Twelve healthy males seated quietly while breathing the appropriate gas mixtures. After 10-min of normoxia (P[O2]=0.21), subjects were exposed for 4-h to hypoxia (HE, P[O2]=0.12) or normoxia (control condition), and then again for normoxia to 15 min. Muscle and cerebral oxygenation (NIRS), pulse oxygen saturation (SpO2) and heart rate variability were measured continuously. COPD are relevant from changes of oxy-(Δ[HbO2]), deoxy-(Δ[Hb]) and total-hemoglobin (Δ[HbTot]) were measured from baseline level.

SpO2, faSO2 and faHbO2 were at baseline level during the first 20 min of HE and then remained stable. In the same time, HE resulted in general sleep-hyposaeration. After a transient rise at 20 min of HE, muscle Δ[Hb] restored to baseline values whereas Δ[HbO2] and Δ[HbTot] were reduced from 120 to 240 min of HE only. Cerebral Δ[HbO2] rose markedly at 20 min of HE and remained constant until the end of HE. Cerebral Δ[Hb] was reduced over the first 120 min of HE but re-increased afterwards towards baseline values together with an increase in Δ[HbTot]. Muscle and brain both showed hyper-oxygenation status post HE. This study provided new insights on i) differential (de)oxy-hemoglobin kinetics in brain and muscle in response to sustained HE, ii) a biphasic cerebral tissue adaptation in the first 30 min, and iii) a tissue hyper-oxygenation after return to normoxia.

1714 Blood shift during cough in healthy subjects
Antonella LoMauro1, Antonio Pedotti1, Peter T. Macklem2, Andrea Aliverti3.1. Dipartimento di Bioingegneria, Politecnico di Milano, Milano, Italy; 2Measurix-Christie Laboratories, Royal Victoria Hospital, McGill University Health Centre Research Institute, Montreal, QC, Canada.

Double Body Plethysmography (DBP), which combines both total body plethysmography and opto-electronic Plethysmography, has been recently developed to measure the amount of blood displaced from the thorax to the extremities (Aliverti et al, J Appl Physiol, 2010). We hypothesized that also during cough a significant amount of blood can be displaced from the trunk to the extremities. We studied 7 healthy subjects (age: 28±6.2±5 yrs) during series of voluntary coughs at four different operating volumes: functional residual capacity (FRC), total lung capacity (TLC) and two intermediate volumes between FRC and TLC (namely, FRC+ and FRC++). BS from the thorax to the extremities were measured by DBP during quiet breathing and during cough at each operating lung volume. The results are shown in figure. BS during cough resulted significantly higher than during QB (p<0.001). BS increase with increasing operating volume, being maximal at total lung capacity (figure). These findings might help to better understand the cardiopulmonary interactions during cough and the mechanisms by which coughing during asthmatic cardiac arrest can maintain consciousness in human subjects.

218. Viral respiratory infections in children: causes and consequences

1716 Effect of inhaled hypertonic saline solution to treat infants hospitalized with viral bronchiolitis

Background and aims: At present only symptomatic treatment is available for acute viral bronchiolitis, none of these are evidence-based. Recent trials show a reduction in hospital stay after inhalation of 3% hypertonic saline solution. This randomised double-blind, placebo-controlled interventional multicenter trial, performed at 12 Dutch hospitals, compares nebulisation with hypertonic saline, either a 3% or 6%, with 0.9% isotonic saline. The primary end point is the time to discharge, aiming to achieve a 25% reduction in hospital stay. Methods: Children younger than two years with clinical diagnosis of viral bronchiolitis, not responding to a single inhalation with Salbutamol may be included. Children younger than two years with clinical diagnosis of viral bronchiolitis, not responding to a single inhalation with Salbutamol may be included. The primary end point is the time to discharge, aiming to achieve a 25% reduction in hospital stay. Methods: Children younger than two years with clinical diagnosis of viral bronchiolitis, not responding to a single inhalation with Salbutamol may be included. Children younger than two years with clinical diagnosis of viral bronchiolitis, not responding to a single inhalation with Salbutamol may be included. Children younger than two years with clinical diagnosis of viral bronchiolitis, not responding to a single inhalation with Salbutamol may be included. Conclusions: Preliminary analysis showed no significant reduction in hospital stay but a trend that 3% hypertonc saline is the most effective regarding duration of hospital stay, need for tube feeding and supplemental oxygen shows no significant difference, but there’s a trend that 3% seems to be more effective than the other 2 concentrations. Conclusions: Preliminary analysis showed no significant reduction in hospital stay but a trend that 3% hypertonc saline is the most effective regarding duration of hospital stay, need for tube feeding and supplemental oxygen shows no significant difference, but there’s a trend that 3% seems to be more effective than the other 2 concentrations.
hypertonic saline seems safe but has no additional benefit even compared with 0.9%. More research will be necessary to clear up this trend.

1717
7% hypertonic saline and hyaluronic acid and in the treatment of infants mild-moderate bronchiolitis
Raffaella Nenna, Stefano Papasso, Massimo Battaglia, Daniela De Angelis, Laura Petraca, Dani Felder, Serena Salvadori, Rosaria Berrardi, Micol Roberti, Paola Papadopoulou, Fabio Midulla. Department of Paediatrics, Sapienza University of Rome, Rome, Italy
The treatment of bronchiolitis is only supportive. The aim of our study was to evaluate the efficacy of hypertonic saline and hyaluronic acid (HS-HA) given by inhalation, in infants hospitalized for mild-moderate bronchiolitis. In a double-blind placebo-controlled study, 42 infants (26 males) less than 6 months of age (median age: 2.8 months) were enrolled and assigned to receive either HS-HA (7% NaCl + 0.1% HA) (n=21) or normal saline (n=20) at a dose of 2.5 ml twice a day for three days. To all infants a clinical severity score was assigned at the admission and four times daily during the hospitalization. Main outcome measures of our study were: number of days of hospitalization and reduction of the severity score. No differences were observed between the two groups for sex, age and clinical severity score at the admission. One child interrupted the protocol in the study group and two in the placebo group. 21% of children in the study group and 11% in the placebo group had mild cough after the aerosol. No difference was observed between the two groups with regard to the number of days of hospitalization (placebo group: 3.5 days vs study group: 3.1 days p=0.4) and to the clinical score reduction during the first three days of hospitalization (placebo group: 3.3 vs study group: 3.7 p=0.6). HS-HA is a safe but not effective therapy in treating infants hospitalized for mild-moderate bronchiolitis.

1718
Evaluating the risk of lower respiratory tract infection (LRTI) hospitalizations due to respiratory distress syndrome (RDS) in late preterm
Katharina Bueesch1, Hoa Hong1, Kathrine Gooch2. 1Global Health Economics and Outcomes Research, Abbott GmbH & Co. KG, Ludwigshafen, Germany; 2Global Health Economics and Outcomes Research, Abbott Laboratories, Chicago, United States
Background: Premature birth results in underdeveloped lung function that increases the risk for respiratory infection and morbidity. The prevalence of RDS requiring intervention in premature births is significant, including those considered late preterm. The aim of the study was to evaluate whether bronchiolitis hospitalizations in infants born late preterm is significant, including those considered late preterm. The aim of the study was to evaluate whether bronchiolitis hospitalizations in infants born late preterm are related to RDS. Methods: Late premature infants (33-36 weeks gestational age) hospitalized within the first year of life for a LRTI were extracted from the Medical Claims database (2000-2008). Univariate analyses were conducted to compare the differences between infants with and without an RDS event at birth. A multivariate model was developed to determine the independent association of RDS and LRTI hospitalization. Statistical significance was set at p=0.05.
Results: 31178 late preterm infants (52% male) were identified during the study timeline. 2297 (7.4%) late preterm infants were hospitalized due to a LRTI; a hyaline membrane disease or RDS diagnosis (ICD-9 code: 769) was observed in 962 late premies (3%). Multiple logistic regression analysis showed a strong and significant relationship between RDS and LRTI hospitalization (OR 5.2, 95% CI 4.4–6.2).
Conclusion: Late preterm infants with RDS event at birth are 5 times more likely to be hospitalized due to LRTI during the first year of life compared to late preterm without RDS event at birth. This risk factor should be considered when evaluating a premature infants risk for respiratory hospitalization.

1719
Rhinovirus lower respiratory tract infections and healthcare utilization of prematurely born infants during infancy
Simon Drysdale1, Mireia Alcazar1, Therese Wilson1, Simon Broun1, Gerard F. Rafferty2, Melvin Smith2. 1Department of Clinical Medicine, Imperial College London, London, United Kingdom; 2Global Health Economics and Outcomes Research, Abbott Laboratories, Chicago, United States
Aim: To determine if BAFF expression is elevated in the airways of infants with RSV lower respiratory tract infections (LRTIs) compared to infants born prematurely without RSV LRTI. Methods: Cultures of primary airway epithelial cells isolated from healthy children were infected with RSV A2 strain, and RV. Airway Epithelial cell expression of the B cell differentiation factor, B cell activating factor of the TNF family, BAFF was induced by RSV infection both in vivo and in vitro. To further confirm these results BAFF mRNA was measured by qPCR in bronchial brushings from patients with RSV bronchiolitis (n=5) and healthy infants (n=4). Average BAFF mRNA expression was around 20 fold higher in samples obtained from infected infants (p<0.01). In vitro cultures of primary airway epithelial cells isolated from healthy children were infected with RSV A2 strain, BAFF mRNA expression was induced 200 fold with maximum expression at 12 hours post infection (n=4, p<0.01). Protein analysis showed expression of up to 170pg BAFF protein at 48 hours post infection.

1720
Human respiratory syncytial virus infection in vivo and in vitro induces expression of the B cell differentiation factor BAFF
Paul McNamara1, Angela Fonseca1, Deborah Howarth2, Ruth Trinnick1, Joanne Cummerson1, Rosalind Smith1, Brian Flanagan2. 1Department of Women's and Children's Health, University of Liverpool, Royal Liverpool Alder Hey Children's Hospital, Liverpool, United Kingdom; 2Department of Clinical Infection Microbiology and Immunology, University of Liverpool, Liverpool, United Kingdom
Background: In RSV disease, innate immune mediators expressed by infected airway epithelial cells are known to strongly influence both early inflammatory responses and the subsequent development of an adaptive immune response. Human respiratory syncytial virus infection in vivo and in vitro induces BAFF expression. Aim: To determine if BAFF expression is elevated in the airways of infants with severe RSV Bronchiolitis and if RSV infection of primary Airway epithelial cells in vitro induces BAFF expression.
Methods: BAFF protein, as measured by ELISA, was increased in bronchiolar alveolar lavage fluid collected from the lungs of infants with severe RSV infection (n=10, mean 833pg/ml). Non infected control groups, admitted for elective surgery had lower levels (n=7, mean 12pg, p<0.027). To further confirm these results BAFF mRNA was measured by qPCR in bronchial brushings from patients with RSV bronchiolitis (n=5) and healthy infants (n=4). Average BAFF mRNA expression was around 20 fold higher in samples obtained from infected infants (p<0.01). In vitro cultures of primary airway epithelial cells isolated from healthy children were infected with RSV A2 strain. BAFF mRNA expression was induced 200 fold with maximum expression at 12 hours post infection (n=4, p<0.01). Protein analysis showed expression of up to 170pg BAFF protein at 48 hours post infection.

1721
Prenatal exposure to PCBs and dioxins is associated with increased risk of wheeze and infectious diseases in 2-year-old children
Solve B. Stølevik1, Unni C. Nygaard1, Ellen Numøk1, Helen E. Kvaløen2, Mai-Lise Grønli3, Helle M. Melzer4, Jan A. Andersen5, Merete H. Løvik6, Merete H. Løvik6, Helle M. Melzer4, Merete H. Løvik6, 1Department of Environmental Immunology, Norwegian Institute of Public Health, Oslo, Norway; 2Department of Food Safety and Nutrition, Norwegian Institute of Public Health, Oslo, Norway; 3Department of Health Risk Analysis and Toxicology, Maatschiir University, Maastricht, Netherlands
Food may contain toxicants (from environmental pollution or formed during food preparation). These toxicants may cross the placentae barrier and affect the foetus immune system. The aim of this study was investigated if prenatal exposure to acrylamide, dioxins and polychlorinated biphenyls (PCBs) affect the children’s immunological health status. Pregnant women were recruited to the birth cohort Brøm (n=205). The occurrence of common childhood infections and periods of more than 10 days of dry cough, chest tightness or wheeze in the children was assessed by annual questionnaires (n = 195 and 184, respectively). Maternal intake of toxicants was estimated from a validated food frequency questionnaire filled in by the mothers at mid-term. The sum of six non-dioxin-like PCBs (PCB 28, 52, 101, 138, 153, 180), and the sum of toxic equivalents of 29 dioxins and dioxin-like PCBs were used. Logistic and linear multivariate regression analyses were performed. Adjustments were made for gender, mode of delivery, Apgar score, breast-feeding, parity, birth season and maternal history of atopy, age, BMI, education and smoking. No associations between prenatal exposure to acrylamide and the health outcomes were found. At age one year, prenatal exposure to PCBs and dioxins was associated with increased risk of wheeze and exanthema subitum, and increased number of upper respiratory tract infections. Similar results were obtained in preliminary analyses for wheeze and upper respiratory tract infections at two years of age. Our findings suggests that prenatal exposure to dioxins and PCBs increase the risk of wheeze and infectious diseases during the first two years of life.
1722 Airborne transmission of respiratory syncytial virus (RSV) infection
Hennant Kulkarni1, Claire Smith1, Robert Hirst1, Norman Baker1, Andreas Easton1, Chris O’Callaghan1. 1Dept. of Infection, Immunity & Inflammation (Division of Child Health), University of Leicester, Leicester, UK; 2School of Life Sciences, University of Warwick, Coventry, United Kingdom

Introduction: RSV is a highly contagious pathogen and spreads among groups of young children, within families and between patients in hospital. RSV is thought to spread predominantly by hands contaminated with respiratory secretions [1]. However, it remains unclear if RSV can be spread by aerosol. Knowledge of this is important as it is assumed in many hospitals that aerosol transmission of RSV does not occur.

Aim: To determine if patients with RSV bronchiolitis produce aerosolised particles containing RSV capable of infecting human respiratory epithelial cells (A549).

Method: 16 infants with “RSV Bronchiolitis” were recruited. An Andersen micro-impactor was placed 10cm from the head of the patient and run for 30min fractionating collected particles into different aerosol size distributions. Room air was impacted into 20ml of RPMI growth media and its infectivity of A549 was measured by the production of fluorescence staining of the infected A549 cells was used to confirm RSV infection.

Results: 17 infants produced infectious airborne particles less than 4.7μ. We estimated the number of infectious RSV within aerosols of less than 4.7μ produced from 12/17 patients to be 188.5±68 (mean ± SEM, range 2.4 to 404±) in 10 litres of air. This volume would be inhaled by a 1.3kg baby in 10 minutes (respiratory rate 40/min; tidal volume 8μl/kg).

Conclusion: Infants with RSV bronchiolitis produce aerosols that contain infectious RSV in aerosols small enough to deposit in the lower airways. These findings may influence infection control strategies to prevent aerosol transmission of RSV in a hospital setting.

1723 Domestic use of hypochlorite bleach and respiratory infections in children
Jan-Paul Zock1, Lídia Casas1, Alicia Borràs-Santos1, José Jacobs2, Esmeralda Kroep1, Dick Heederik1, Anne Hyvärinen1, Marten Taubel2. 1Centre for Research in Environmental Epidemiology (CREAL), Hospital del Mar Research Institute (IMIM), Barcelona, Spain; 2Dept. of Environmental Epidemiology, IRAS, Utrecht, Netherlands

Introduction: Domestic bleeding sprays, especially window spray, can be a risk factor for airway inflammation, measured as FeNO. This is in agreement with a previous study showing associations between incidence of asthma and domestic cleaning sprays (Zock et al., Am J Respir Crit Care Med, 2007;176:735-741).

Aim: To determine if patients with RSV bronchiolitis produce aerosolised particles containing RSV capable of infecting human respiratory epithelial cells (A549).

Method: 16 infants with “RSV Bronchiolitis” were recruited. An Andersen micro-impactor was placed 10cm from the head of the patient and run for 30min fractionating collected particles into different aerosol size distributions. Room air was impacted into 20ml of RPMI growth media and its infectivity of A549 was measured by the production of fluorescence staining of the infected A549 cells was used to confirm RSV infection.

Results: 17 infants produced infectious airborne particles less than 4.7μ. We estimated the number of infectious RSV within aerosols of less than 4.7μ produced from 12/17 patients to be 188.5±68 (mean ± SEM, range 2.4 to 404±) in 10 litres of air. This volume would be inhaled by a 1.3kg baby in 10 minutes (respiratory rate 40/min; tidal volume 8μl/kg).

Conclusion: Infants with RSV bronchiolitis produce aerosols that contain infectious RSV in aerosols small enough to deposit in the lower airways. These findings may influence infection control strategies to prevent aerosol transmission of RSV in a hospital setting.

1724 FeNO in adults in relation to cleaning sprays and other particle generating activities in homes in Scania, Sweden
Gunilla Wierslander, Dan Norback. Department of Medical Sciences, Uppland University, Occupational and Environmental Medicine, Uppsala, Sweden

Aim: To study associations between FeNO and use of sprays and other particle sources at home.

Methods: Easton 106 adults answered a questionnaire on particle sources at home in a larger population survey in Scania, Sweden. Each question had four alterna-
tives on frequency. There were 5 questions on sprays (window, oven, furniture, hair and other sprays), 3 on office equipment (copy machines, laser and inkjet printers), 4 on combustion sources (candles, incense, wood, kerosene) and one on environmental tobacco smoke (ETS). Burning of incense, wood or kerosene was combined to a combustion source index (CSI). Use of office equipment was combined to an office machine index (OMI). Cleaning sprays were combined to a cleaning spray index. Exhaled NO was measured [ NOX MNO (50 ml/min)]. FeNO was log-transformed and associations were analysed by multiple linear regression, adjusting for age, sex, pollen/effurry pet allergy and smoking.

Results: Median FeNO was 17 ppb (IQR 11-22). 14% were above 25 ppb. FeNO was positively associated with cleaning spray index (p=0.047), and use of window spray (p=0.02). No associations were found for FeNO and hair spray, other sprays, ETS, candles, CSI or OMI.

Conclusion: Domestic cleaning sprays, especially window spray, can be a risk factor for airway inflammation, measured as FeNO. This is in agreement with a previous study showing associations between incidence of asthma and domestic cleaning sprays (Zock et al., Am J Respir Crit Care Med, 2007;176:735-741).

1725 Endotoxin levels in primary schools and homes of Dutch school children
José Jacobs, Esmeralda Kroep, Dick Heederik. Environmental Epidemiology, Institute of Risk Assessment Sciences, Utrecht, Netherlands

Background: Indoor air quality is essential for children’s health. Several studies describe the variety and extent of indoor pollutant exposure in homes and to a lesser extent in schools. However studies that include both environments in one study are sparse.

Objective: To assess indoor endotoxin levels in dust and compare levels in primary schools and homes of children.

Methods: This study is an extension of the European HITEA project. Ten schools with moisture/dampness problems (index) and reference schools were selected, based on building questionnaires and on-site inspections. Airborne dust at several locations in school was passively sampled with Electrostatic Collectors (EDC), during 8 weeks in March/April 2010. In the same period, dust was sampled during 2 weeks in 169 children bedrooms from index and reference schools.

Results: Average endotoxin levels ranged from 4355 to 12101 ELISAs in schools, and from 923 to 2570 EU/m³ in homes, adjusted to a two week sampling period. Both school and home endotoxin levels tended to be higher in the index than in the reference category (average ratio~1.35). However, no significant differences were found in the index category, and also within the reference, variation between schools was higher than between both categories. There was less variation between home endotoxin levels within and between both index and reference categories. Classroom occupancy was related to endotoxin levels. Home characteristics associated with endotoxin levels were the number of people living in the house and building age.

Conclusion: Average endotoxin levels were considerably higher in schools than in homes. Occupancy was significantly related with school and home endotoxin levels. Home age also affects endotoxin levels.

1726 The household bio-dust bio-environment and lung function in adult asthma
Paul D. Blanc1, Stephen Van Dyken2, Steve Vesper1, Patricia Quinlan1, Laura Tsipin1, Carlos Izberrein1, Patricia P. Katz1, Edward H. Yelin2, Miriam Cisternas4, John R. Balmes1. 1Medicine, University of California, San Francisco, CA, United States; 2Division of Exposure Research, U.S. Environmental Protection Agency, Cincinnati, OH, United States; 3Kaiser Division of Research, Kaiser Permanente, Oakland, CA, United States; 4MGC Data Services, MGC Data Services, Carlsdbad, CA, United States

Background: The household bio-dust bio-environment includes molds, bacteria, and animal antigens that may affect lung function, especially in asthma.

Methods: Dust from adult asthmatics’ homes was quantified for: Environmental Relative Moldiness Index (ERM), a DNA-based assay reflecting indoor molds; chitin (found in mold cell walls and invertebrate exoskeletons, assayed by blot densitometry); endotoxin (LPS; immulus assay); beta-1,3-glucans (BG, dust mite); and cockroach (CRK) (ELISA). We analyzed Spearman correlations among the exposures. Linear regression tested ERM, chitin, LPS, and BG as predictors of FEV₁, with stratification by greater than/less than a detectable level (>DL) of both DM and CRK.

Results: Data from 72 dwellings were available for all variables. Chitin was significantly correlated with BG (r=0.29; p=0.01) and DM (r=0.33; p<0.01) and weakly (negatively) with both ERM (r=-0.20; p=0.09) and LPS (r=-0.20; p=0.09); BG correlated positively with both DM and CRK (r=0.39 and 0.28, respectively; p<0.05). ERM correlated negatively with CRK (r=-0.31; p<0.01). Adjusting for LPS and BG concentrations, chitin was significantly associated with better FEV₁ (% predicted +4.6% per ng chitin/microgram dust; p<0.001), while ERM was not (r=0.3). Among 37 subjects with DM or CRK >DL, results were similar, but among 35 subjects >DL for DM/CRK, FEV₁ % predicted was positively related to both chitin (+7.5%; p<0.01) and ERM (+2.1% per unit; p<0.05).

Discussion: Chitin and ERM levels may be associated with better FEV₁; the ERM effect may depend on absent DM/CRK co-exposure.

Clinical: In adult asthma, DM and CRK control interventions should consider other potential co-exposures in the complex home bio-environment.

Cat, dog and horse allergens in day care centres in Uppsala, Sweden, associations with FeNO and dyspea

Dan Norback1, Nina Fahlén, Guishong Cai1, Ivan Kreft2, Erik Lampa1, Gunilla Wieslander1. 1Dept. of Medical Science, Uppsala University, Uppsala, Sweden; 2Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia

Aim: To study associations between FeNO, FEV1 and dyspepsia in day care centres staff and levels of cat, dog and horse allergens in day care centres.

Methods: In 2009-2010, 5 day care centres in Uppsala participated in a study performed 3 times in each subject in spring, in connection with a diet study. Dust was collected by vacuum cleaning and analysed for cat (Fel d1), dog (Can f1) and horse (Equs cx) allergens by ELISA. Amount of allergens per ALK filter was calculated by multiplying concentration with amount of fine dust. Airborne allergens were sampled in Petri dishes for 1 week. Exhaled NO was measured by NIOX MINO and FEV1 by dynamic spirometry. Dyspepsia was rated from 0-100%. FENO and dyspepsia were log-transformed and associations analysed by multiple linear regression, adjusting for age, atopy, smoking, and body mass index (BMI). All were females.

Results: House dust samples from pets in any building, but all allergens were common. Geometric mean (GM) (ng/g) were 1199 Fel d1, 666 Can f1 and 478 Equs cx. Fel d1 was found in 100% (GM=29.8 ng/mg) and Can f1 in 33% and Ecu c1 in 13% of Petri dish samples. FeNO was higher at amount of Fel d1 (p<0.001) and Can f1 (p<0.01) and lower at higher amount of Equs cx (p<0.11). No associations were found for FEV1 or dyspepsia and allergen levels.

Conclusion: Cat, dog and horse allergens were common in the day care centres, due to track in by clothes or hair. Cat and dog allergens in day care centres can be a risk factor for airway inflammation, measured as FeNO. The negative association for horse allergen remain unclear. It could be due to co-variace with some protective indoor factor, or a healthy life style related to horse riding.

1728
High indoor microbial levels are associated with reduced Th1-cytokine secretion capacity in infancy

Juha Pekkanen1, Mikko Lappalainen1,2, Helena Kintala1, Harald Rene2, Petra Pfeifer1, Anna Nevalainen1, Marjuk Roponen1,2, Maija-Riitta Hirvonen1,2. 1Dept. of Environmental Health, National Institute for Health and Welfare, Kuopio, Finland; 2Dept. of Environmental Science, University of Eastern Finland, Kuopio, Finland; 3Dept. of Clinical Chemistry and Molecular Diagnostics, Philips-University of Marburg, Marburg, Germany

Background: In the early stages of life exposure to microbes and their components may affect the maturation and functions of immune system.

Objective: To examine whether the house dust microbial content is associated with cytokine-producing capacity at birth and at age 1 year.

Methods: Assay of Th1 (IFN-γ) and Th2 (IL-4, IL-5, IL-10) cytokines was performed on buffy coats of 120 children at age 1 year (n=200) following 24h and 48h whole blood stimulation with Staphylococcus enterotoxin A (SEA) and SEB. Geometric mean (GM) (ng/g) were measured using ELISA. Ergosterol (marker for fungal biomass), muramic acid (marker for Gram-positive bacteria) and 3-hydroxy fatty acids (C10:0-C14:0, C15:0, C16:0) were measured using GC. Airborne microbial levels were analysed by high-volume air sampling. To examine whether the house dust microbial content is associated with cytokine-producing capacity at birth and at age 1 year.

Results: A high total level of Gram-positive bacteria in general or Mycobacterium spp. in house dust was associated with decreased SEA-stimulated IFN-γ secretion capacity at birth and at age 1 year. With cytokine-producer capacity at birth and at age 1 year. High indoor microbial levels may affect immune development in early life by reducing Th1-cytokine secretion capacity. In the future, more microbiome studies are needed to better understand the role of microbial exposures on immune development in early life.

Conclusion: Both ETS exposure and SNPs in Gluthatione S-tranferase (GST) genes are associated with FEV1 level. A GSTO2 SNP (rs156997) was associated with FEV1 in a GWAS study (Wilk 2007). We recently found a GSTO1 SNP associated with lower FEV1 in heavy smokers only (≥12.5 pCi; unpublished) suggesting a gene by smoking interaction. Since the GST-family deals with oxidative stress, we hypothesize that GSTO2 SNPs may also interact with ETS exposure and affect lung function.

Methods: Genotypes of individuals (n=8128) from the LifeLines cohort, a general Dutch population cohort, were included. We selected 4 GSTO2 tagging SNPs (MAF=0.10, R2 ~ 0.8) (table 1). Associations between daily hours of ETS exposure (<1 or ≥1 hr), ETS exposure at work (no/yes), history of active smoking (not, recent, and ≥10.5 pCi) SNPs, their recessive model and FEV1 were assessed by linear regression models, adjusted for sex, age, height, weight, and smoking habits.

Results: Daily ETS exposure (≥1 hr=73; ml=0.011) and history of active smoking (≥10.5 pCi =121ml; p<0.001) were associated with FEV1. ETS exposure at work and the SNPs were not significantly associated with FEV1. However, GSTO2 SNPs clearly interacted with ETS exposure and history of active smoking (table 1).

Table 1. GSTO2 by exposure interactions and FEV1 (ml) (95% CI)

<table>
<thead>
<tr>
<th>Exposure</th>
<th>GSTO2</th>
<th>FEV1 (ml) (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ETS exposure (1 or ≥1 hr/week)</td>
<td>GSTO2: 1</td>
<td>73 (0.011)</td>
</tr>
<tr>
<td>ETS exposure at work (no/yes)</td>
<td>GSTO2: 1</td>
<td>73 (0.011)</td>
</tr>
<tr>
<td>History of active smoking (not, recent, and ≥10.5 pCi)</td>
<td>GSTO2: 1</td>
<td>73 (0.011)</td>
</tr>
</tbody>
</table>

Conclusion: We show that ETS exposure has deleterious effects on FEV1 in subjects homozygous for the minor allele of GSTO2 SNPs.

Airway obstruction and emphysema are two features of chronic obstructive pulmonary disease (COPD). COPD patients can display one phenotype or both at one time. We used the Nelson cohort comprising ~3000 individuals with lung function measurements and CT-scans to determine genes that contribute to both features. We performed genome-wide association studies on both sub-phenotypes. Airway obstruction was investigated in a case-control design (1030 cases with FEV1/FVC < 0.7 and 927 healthy controls). Emphysema was investigated as a quantitative trait. To account for center-derived differences in these measurements we used 15th percentile (p15) of density distribution adjusted for age, sex and height in the trachea. p15 was analyzed using linear regression adjusting for age and pack-years smoking in 3047 subjects. To find overlap between these two sub-phenotypes we selected all SNPs with p<0.001 in each analysis, yielding a total of nine SNPs corresponding to four genes. When these genes were investigated in GeneMania we found that an additional 9 genes directly interacting or co-expressed/co-localized with query genes and two from this point to a drug resistance pathway (GATHER p<0.001, Bayes factor 6).

This is an interesting approach that can help identifying a shared etiology of two distinct sub-phenotypes of a single complex disease.

Susceptibility to chronic mucus hypersecretion: A genome-wide association study

Akkelines Dijkstra, Joanna Smolonska, Marike Boezen, Pieter Zanen, Rob van Klaveren, Michał Osijewitsh, Ewa Nuzankowska, Ciska Wijmenga, Harry Groen, Dirkje Postma. Department of Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands Department of Epidemiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands Department of Heart & Lungs, University Medical Center Utrecht, Utrecht, Netherlands Department of Pulmonology, Erasmus Medical Center, Rotterdam, Netherlands Department of Radiology, German Cancer Research Center, Heidelberg, Germany Department of Medicine, Jagiellonian University School of Medicine, Cracow, Poland Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands Department of Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands

Background: Patients with COPD with chronic mucus hypersecretion (CMH) have a significantly increased FEV1 decline and a higher risk of hospitalization...
than those without CMH. Moreover, although individuals with CMH are more likely to be ex- or current smokers, so far it is unclear why some smokers develop CMH and others do not. A plausible explanation for this phenomenon would be a genetic predisposition.

Methods: We performed a genome wide association study (GWAS) using the Nelson study (a population-based lung cancer screening study from Groningen and Utrecht, the Netherlands) including 717 subjects with and 1,795 without CMH, all ex or current heavy smokers (>20 pack years). Lung function results and information about spumt expectoration during the previous year were collected at the start of the study. To enhance power we added 590 blood bank controls. Genotyping data were analyzed using PLINK with adjustment for center (Groningen/Utrecht). We aimed to replicate the results by evaluating the top single nucleotide polymorphisms (SNPs) in 7 European cohorts contributing 487 cases and 1,118 controls.

Results: We identified 77 SNPs associated with CMH with a p-value <10^-6, of which 5 SNPs had a p-value <10^-10. Meta-analysis of selected top SNPs in the initial and replication cohorts identified 3 SNPs with a p-value <10^-10 and 3 with a p-value <10^-15. Some genes close to these SNPs have been reported to be associated with epithelial changes.

Conclusion: This study suggests that susceptibility to CMH is associated with genetic predisposition. To confirm these data replication will be extended to 3 additional cohorts.

1732 Common variant of gasterminder-like gene, fetal and early life smoke exposure and the risk of asthma-like symptoms in preschool children
Ralf van der Valk1,2, Liesbeth Duijts1,2,1,2, Stijn Willemse6, Albert Hofman1,3, Henriette Moll7, Vincent Jaddoe8,1,3, Johan de Jonge1,2,3,4,2, The Generation R Study Group, Erasmus Medical Center, Rotterdam, Netherlands; 1Department of Pediatrics, Division of Respiratory Medicine, Erasmus Medical Center - Sophia Children’s Hospital, Rotterdam, Netherlands; 2Department of Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands; 3Department of Biostatistics, Erasmus Medical Center, Rotterdam, Netherlands; 4Department of Paediatrics, Erasmus Medical Center - Sophia Children’s Hospital, Rotterdam, Netherlands

Rationale: Single nucleotide polymorphisms (SNPs) in the region of gasterminder-like (GSDML) gene on chromosome 17q12-1q41 are associated with increased risks of childhood-onset asthma. These risks seem to be modified by environmental tobacco smoke.

Objectives: To assess whether the associations of GSDML with asthma-like symptoms are modified by smoke exposure, both during fetal and in early life.

Methods: This study was embedded in the Generation R Study, a population-based birth cohort study from fetal life onwards in the Netherlands. We genotyped GSDML (rs2305480) and assessed maternal smoking repeatedly during pregnancy and smoke exposure in early life at the age of 2 years by questionnaires. Asthma-like symptoms were reported by parents at the ages 1, 2, 3 and 4 years.

The analyses were based on 2,025 Caucasian children with complete data.

Results: GSDML was associated with asthma-like symptoms at the ages of 2, 3, 4 and 4 years (overall Odds Ratio 1.15 (1.06, 1.26)). The GSDML effect on asthma-like symptoms was stronger among children who were exposed to smoke during fetal life (p interaction=0.030). Smoke exposure in early life also tended to increase the effect of GSDML on asthma-like symptoms, but the test for interaction was not significant (p interaction=0.240). The modifying effects by fetal and smoke exposure in early life were independent. The strongest effects were present in children aged 3 and 4 years with both the risk-allele and smoke exposure during fetal and early life.

Conclusion: GSDML is associated with asthma-like symptoms in preschool children, and this association seems to be modified by fetal and smoke exposure in early life.

1733 Interactions between current tobacco smoke exposure and GSTP1 on lung health outcomes at 6, 12 and 18 years
Jasminka Murdzoska1, Catherine Hayden1, Jack Goldblatt 1, Guicheng Zhang 1, Desmond Cox 1, Foteini Malli2, Emily Zifa3, Konstantinos Gourgoulianis1, Zissis Mamuris2, Zoe Danil1, 1Respiratory Medicine Department, University of Thessaly School of Medicine, Larissa, Greece; 2Department of Biochemistry & Biotechnology, University of Thessaly, Larissa, Greece

Background: Maternal history of asthma is among the most consistently reported risk factors for asthma in children. Furthermore, a number of studies suggest that mitochondrial dysfunction plays a role in the pathogenesis of asthma. Until now, it was never investigated whether an implication of mitochondrial tRNA gene mutations in asthma patients: the role of the mitochondrial genome in the etiology of asthma we analyzed the mitochondrial tRNA genes, and part of their flanking regions, in 26 unrelated patients with asthma and we compared the findings with a set of 60 healthy controls.

Results: We found a total of 10 mutations in 19 out of 26 asthmatic patients. Four of the mutations (595insC in tRNA^Glu^, A8343G in tRNA^Glu^, T10448C in tRNA^Glu^ and G709A in 12S rRNA) were not found in the control group. Five mutations were observed in controls but in a significantly lower rate: 3.3%, vs. 27% (A12308G in 12S rRNA), 10% vs. 57.7% (A750G in 12S rRNA). The modifying effects of tobacco smoke exposure on lung health outcomes. Other GSTs or detoxification pathways may play a more important role in modifying the effects of tobacco smoke (passive/active) at 12 and 18 years in this study cohort. Funding: NHRMC.

Conclusions: Mitochondrial tRNA and tRNA mutations are more frequent in asthma patients than controls. However, it is certain that further studies in larger cohorts are needed to confirm these observations.

Transvenous phrenic nerve stimulation improves Cheyne-Stokes respiration in patients with chronic heart failure
Xiaom Zhang, Ning Ding, Shijiang Zhang, Bin Yang. Respirology, 1st Affiliated Hospital of Nanjing Medical University, Nanjing, China Thoracic Cardiac Surgery, 1st Affiliated Hospital of Nanjing Medical University, Nanjing, China. Respiratory, 1st Affiliated Hospital of Nanjing Medical University, Nanjing, China. Cardiology, 1st Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Cheyne-Stokes respiration (CSR) may accelerate progression of congestive heart failure (CHF) and is associated with poor survival. Phrenic nerve stimulation (PNS) may interrupt CSR and improve CHF outcomes. We report the preliminary findings of a randomized controlled study of patients with CHF with severe CSR who were randomized to a single transvenous PNS lead placement versus control. CSR was defined as two or more events per hour of sleep with a difference of more than 20 breaths per minute between the end of inspiration and the end of expiration.

Methods: Thirty-five patients with severe CSR (apneahypopnea index (AHI) >20 events per hour of sleep) were randomized to PNS or control. PNS was performed using the Eupnea System software. Respiratory properties were assessed prior to and post-PNS. PNS was assessed at a maximum of 10 mA.

Results: Mean values of TO was significantly higher in the PNS group than in the control group (p < 0.001). The mean values of TS were not significantly different between the two groups. The value of TO was positively correlated with the value of TO (r = 0.845, p < 0.001).

Discussion: As the OSAS worsens, the cardiac rhythm disorders become more prominent. The impairment of cardiovascular autonomic system in OSAS patient without CAD may be a possible component of deleterious effect of OSAS.

Conclusion: The impaired autonomic cardiac control may in part explain the mechanisms promoting arrhythmias and sudden death in OSAS subjects. To achieve a meaningful reduction in mortality, OSAS must be targeted for treatment.

P1738
Heart rate turbulence: In patients with obstructive sleep apnea without coronary artery diseases
Omer Tamer Dogan1, Alin Erdem1, Kursat Epotoruk1, Osman Can Yontar2, Ibrahim Akkurt1. 1Department of Chest Diseases, Cumhuriyet University, Faculty of Medicine, Sivas, Turkey; 2Department of Cardiology, Sivas Public Hospital, Sivas, Turkey.

Background: Obstructive sleep apnea syndrome (OSAS) is a common disorder associated with an increased risk of cardiovascular disease and stroke. This study was conducted to demonstrate the effects of OSAS on baroregulatory function by using heart rate turbulence (HRT) parameters.

Methods: Sixty four OSAS patients without coronary artery disease (CAD) and 30 healthy subjects were enrolled in this study. HRT analysis (TO: turbulence onset and TS: turbulence slope) was obtained from 24-hour ECG recordings. The values of HRT were compared between two groups along with basic clinical, echocardiographic and Holter parameters. Besides, the relationship between HRT and apnea-hypopnea index (AHI) was analyzed.

Results: The mean values of TO was significantly higher in the OSAS group than in the control group (p < 0.001). The mean values of TS were not significantly different between the two groups. The value of AHI was positively correlated with the value of TO (r = 0.845, p < 0.001).

Discussion: As the OSAS worsens, the cardiac rhythm disorders become more prominent. The impairment of cardiovascular autonomic system in OSAS patient without CAD may be a possible component of deleterious effect of OSAS.

Conclusion: The impaired autonomic cardiac control may in part explain the mechanisms promoting arrhythmias and sudden death in OSAS subjects. To achieve a meaningful reduction in mortality, OSAS must be targeted for treatment.

Neurocognitive disorders in children with sleep-disordered breathing
Alessandra Tabarrini, Maria Chiara Paulino, Laura Papini, Rosa Castaldo, Francesco Biagiarelli, Raffaella Bruschi, Martina Forlani, Maria Pa Villa.
NESTOS Department, Pediatric Unit. S. Andrea Hospital, Faculty of Medicine and Psychology, University La Sapienza, Rome, Italy

Aims: To compare the presence of neurocognitive disorders in children with Obstructive Sleep Apnea Syndrome (OSAS) or Primary Snoring (PS) and normal controls, and to investigate their correlation with duration of Sleep-Disordered Breathing (SDB).

Methods: 137 subjects (M/F 70/67; mean age 9.47±2.35 yrs) were studied: 58 children with SDB (19% P9.43±1% minimum OSAS.37.9% moderate-severe OSAS and 3.5% severe OSAS), 30 healthy children, 30 normal controls (M/F 15/15; age 9.47±2.35 yrs), and 10 children with Primary Snoring (M/F 5/5; age 9.47±2.35 yrs). Subjects underwent clinical evaluation, polysomnography and neurocognitive assessment based on Wechsler Intelligence Scale for Children (WISC-R). The control group was studied through a medical questionnaire and WISC-R.

Results: Verbal Intelligence Quotient (VIQ), Performance Intelligence Quotient (PIQ) and Full-Scale Intelligence Quotient (FSIQ) were lower in SDB group than in control children (VIQ 94.55±13.74 vs 115.84±10.63; PIQ 100.10±13.25 vs 118.24±11.66 vs 110.04±11.66; FSIQ 76.73±10.00). On the basis of the presence of cognitive impairment (defined arbitrarily as a FSIQ < mean FSIQ standard population – 2SD), SDB group was subdivided in: Group A: 15 children with SDB and cognitive impairment; Group B: 43 children with SDB without cognitive impairment. The age of onset was earlier in Group A than in Group B (3.64±2.65 yrs vs 5.29±3.64 yrs; p<0.05); duration of disease was longer in group A than in Group B (5.21±2.57 yrs vs 3.44±2.42 yrs; p<0.05).

Conclusions: The incidence of neurocognitive disorders was greater in children with SDB than in controls. A significant correlation was present between neurocognitive impairment and both SDB’s age of onset and duration of disease suggesting that early onset and a long duration of disease are the major risk factor.

P1741
Mean platelet volume in obstructive sleep apnea patients. Another link to cardiovascular disease?
Pascalas Streitoulov1, Evangelia Neta1, Panagiota Zikidou1, Pavlos Atesidou2, Nikolaos Papanas1, Konstantinos Archontogeorgis3, Theodora Gkioka3, Eleni Pitta 3, Argyrios Tzouvelekis 1, Stavros Anevlas1.
3Department of Microbiology, University Hospital of Alexandroupolis, Greece; 1Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece; 2Department of Microbiology, University Hospital of Alexandroupolis, Alexandroupolis, Greece

Objectives: To evaluate the Mean Platelet Volume (MPV) as a potential marker of cardiovascular risk in patients with Obstructive Sleep Apnea (OSA) and cardiovascular risk. Mean Platelet Volume (MPV) is a potential marker of cardiovascular risk in OSA patients. A large number of studies has addressed the association between MPV and cardiovascular risk in OSA patients. However, there is a lack of evidence regarding the association between MPV and cardiovascular risk in OSA patients.

Materials and methods: This study included 697 subjects with suspected sleep disorder for the presence of arrhythmia. The study comprised 257 OSA patients and 99 non-OSA patients (controls). OSA patients had a mean age 47.9±13.5 years, body mass index of 35.7±9.5 kg/m2, apnea hypopnea index (AHI) of 42-4±36.9/hr, and males represented 60.7% of the group. The prevalence of arrhythmia in OSA patients was higher than that in the non-OSA group (24.5% vs. 12.1%, p = 0.01). Among OSA patients, prematurity, atrial fibrillation was present in 10.1%, premature ventricular contraction in 16.3% and atrial fibrillation in 4 patients (1.6%). OSA patients with arrhythmias were significantly older (53.5±15.3 years vs. 46.1±12.4 years; p<0.05), heavier (38.3±9.1 kg/m2 vs. 34.9±6.9 kg/m2; p<0.05), had lower average nocturnal oxygen saturation (92.1±3.6% vs. 91.4±3.5%; p<0.05), and spent longer time with 0% saturation (<90% (22.6±31.6 minutes vs. 11.2±25.2 minutes; p<0.05). OSA patients with arrhythmias had a higher prevalence of hypertension and ischemic heart disease. Multivariate logistic regression analysis identified arrhythmias as the only predictor of arrhythmias (OR 2.36; CI 1.004-5.59; p<0.05).

Conclusions: Arrhythmias were more prevalent among OSA patients with longer periods of hypoxemia and those with ischemic heart disease.

P1714
Effects of auto-servo ventilation on cardiovascular function in patients with congestive heart failure and sleep-disordered breathing – A multicenter randomised controlled trial
Michael Artz1, Frederic Series 2, Kuijper 3, Keir Lewis3, Pierre Escourrou4, Ruth Obermeier1, Victoria Kehl1, Michael Pfeifer1. 1Department of Internal Medicine II, Division of Respiratology, University Hospital Regensburg, Regensburg, Germany; 2Recherchefluweel, University Hospitals Brussels, Brussels, Belgium; 3Department of Respiratory Medicine, Prince Philip Hospital and Swansea School of Medicine, Llanelli, United Kingdom; 4Centre de Medecine du Sommeil, Hopital Antoine Broussais, Paris, France.

Objectives: to study the effects of Auto-servo ventilation (ASV) on left ventricle function in patients with congestive heart failure (CHF) and sleep-disordered breathing (SDB).

Methods: This study was designed to evaluate the effects of ASV on left ventricle function in patients with CHF and SDB. The study was performed in a multicenter randomized controlled trial. Patients were randomly assigned to either ASV or CPAP treatment (BiPAP autoSV, Philips-Respironics). Polysomnographic recordings were obtained in all patients to assess the severity of SDB and to determine the best treatment for each patient. Patients were followed up for 2 months, and the primary endpoint was the change in LVEF. The secondary endpoints were the changes in NT-proBNP levels and the changes in daytime activity.

Results: Significantly larger reduction in AH1 was observed in the ASV group (average daily ASV use was 4.71±2.93 hours/day) than in the control group (-3.91±1.6 hours/day, p<0.05). Both groups showed similar significant increase of LVEF (+3.4±4.5% vs. +3.5±5.6%, p<0.05). In ASV group the reduction of NT-proBNP (-360.5±697.1 vs. +367.8±652.1 ng/ml, p<0.05) and the increase of daytime activity duration (+14±5.2 vs. -24±4.1 hours, p<0.05) were significantly greater than in the control group (-15.4±4.9 vs. +25.0±3.4 hours, p<0.05). The increase of LVEF (+3.4±4.5% vs. +3.5±5.6%, p<0.05) was significantly greater in ASV group than in the control group (+25.0±3.4% vs. -15.4±4.9 hours, p<0.05).

Conclusions: ASV in CHF patients with SDB reduces NT-proBNP levels as a surrogate for improvement of cardiac function. Such changes were not associated with significant changes in LVEF. Patients on ASV improved their activity periods during the day and some days of QOL.

P1744
Effect of auto servo-ventilation (ASV) and continuous positive airway pressure (CPAP) on B-type natriuretic peptide (NT-proBNP) in patients with co-existing obstructive (OSA) and central sleep apnea (CSA) in heart failure (HF)
Institut fur Pneumologie, Krankenhaus Bethanien gGmbH, Solingen, Germany.

Introduction: The optimal ventilatory mode for patients with co-existing OSA and CSA in HF is unclear. We investigated the effects of ASV and CPAP therapy on NT-proBNP, a marker of HF severity.

Methods: 70 patients (66±3±9±1 yrs., 31±6±0±6 kg/m2) with <80% Cheyne-Stokes respiration and 20±5% obstructive disturbances were randomly assigned to either ASV or CPAP treatment (BiPAP autoSV, Philips-Respironics). Polysomnographic parameters and NT-proBNP levels were measured at baseline and after 12 months. Data of patients who used their device during the whole period were analyzed (26 ASV, 25 CPAP). For further analysis, patients were divided into responders (AHI<10/h and 50% below baseline AHI) and non-responders.

Results: AH1 significantly improved in both groups (ASV: 48±2±5.0 vs. 6.9±6±8.6%; p<0.001, CPAP: 41±6±15.4 vs. 11±4±6.6%, p<0.001). ASV was superior in reducing central disturbances (5±0±5.9 vs. 9±1±8±2, p<0.03). NT-proBNP was similar at baseline and improved after 12 months only in the ASV group (ASV: 537±892 vs. 21±3±515 ng/L, CPAP: 687±979 vs. 876±1882 ng/L).
Sleep apnea was linked with HT independently of other cardiovascular complications like hypertension and cardiac failure in 3093 obese patients (IMC ≥ 30kg/m2) referred for suspicion of OSA and SAHS and stroke. CPAP compliance and new stroke events were recorded in addition to ventricular arrhythmias and cardioversion events. The use of occlusal splint can change autonomic cardiac modulation in bruxers.

Conclusion: Children with CCHS are at risk to develop neurocognitive deficits, especially in memory, attention and visuospatial treatment. Factors underlying these abnormalities are to be determined. Neurocognitive monitoring should be included in long-term follow-up of CCHS.

Introduction: Sleep bruxism was recently classified as a sleep related movement disorder and it has been linked to emotional alterations, arousals and neurological symptoms. Objective: To evaluate the alteration in heart rate variability (HRV) in bruxers prior and after 1 month of occlusal splint (OS) usage. Methods: Thirteen consecutive patients were enrolled in the study. Patients with current CPAP use and group 2, patients with no CPAP treatment. All TMD symptoms were decrease after first month of OS usage. The HRV assessed by NES showed that the RR interval improved from 801 ±28.0 to 833 ±30.0 but was not significant. The frequency-domain parameter was not significant for both Fast Fourier Transform and Wavelet spectral method in both parasympathetic and sympathetic area. Low frequency and High frequency did not alter post first month of OS usage.

Results: Oclusal splint reduced all TMD symptoms related prior treatment. HRV was not changed, maybe due to the short period of the study, one month, of OS usage. Further evaluation with a longer period of treatment is needed.

</tbody>
</table>

The stroke event free time until new event in group 1 was 31.4 months ± 22.6 SD, and in group 2, 25.3 months ± 13.9 SD, without statistical significance.

Conclusions: New stroke development is not associated with CPAP compliance, however it seems to have longer survival probability in CPAP compliant patients.

P1750

Gender-dependent characteristics of sleep-disordered breathing in chronic heart failure

Holger Woehrle1, Gerhard Weinreich2, Michael Arzt3, Olaf Oldenburg4, Karl Wegscheider5, Erland Erdmann6, Helmut Teschler7, 1Science Center, ResMed, Martinsried, Germany; 2Pneumologie, Ruheliedklinik - University Hospital, Essen, Germany; 3Department of Internal Medicine II, University of Regensburg, Regensburg, Germany; 4Department of Internal Medicine III, University of Cologne, Cologne, Germany; 5Institute for Biometry and Epidemiology, Universität Hamburg, Hamburg, Germany; 6Department of Cardiology, Heart and Diabetes Centre North-Rhine Westphalia, Ruhr University, Bochum, Bad Oeynhausen, Germany

Background: Sleep-disordered breathing (SDB) is common in patients with chronic heart failure (CHF) and influences the progression of the disease. Large multicenter studies are lacking.

Methods: In the ongoing prospective multi-center SchlaHF registry we studied so far 1,273 CHF patients diagnosed by gold standard polysomnography (PSG). New York Heart Association (NYHA) class was ≥II and left-ventricular ejection fraction (LVEF) ≤45%. Patients were screened with a two-channel device and referred to a sleep laboratory in case of suspected SDB. Using PSG we studied sleep and SDB characteristics in these referred CHF patients. SDB was defined as apnea-hypopnea index (AHI) >15/h.

Results: Gender-dependent sleep efficiency was similar in chronic sleep apnea (CSA) (m: 75.6%, f: 76.2%, n.s.), obstructive sleep apnea (OSA) (m: 73.8%, f: 70.4%, n.s.) and in patients without SDB (m: 76.0%, f: 73.9%, n.s.). The same results we found for sleep duration in CSA (m: 317min, f: 324min, n.s.), OSA (m: 38.0h, f: 34.9h, n.s.) and in patients without SDB (m: 3.7h, f: 3.2h, n.s.). Significant gender-dependent differences were found in the respiratory subindices: apnea-index (AI) in CSA (m: 23.8h, f: 14.5h, p<0.05), OSA (m: 22.4h, f: 14.5h, p<0.05) and in patients without SDB (m: 3.7h, f: 3.2h, n.s.).

Conclusions: In the SchlaHF registry sleep duration and sleep efficiency were similar both in men and women regarding CSA, OSA and patients without SDB. Gender-dependent differences were found in the subindices AI and HI.

P1751

The impact of obstructive sleep apnea syndrome on cardiovascular system in children

Lahrimi Damanioud1, Maria Eboriadou1, Andreas Giannopoulos1, Katerina Haidopoulou1, Irini Trimo1, Ioannis Tsanaakis1, Fani Athanasiadou1, 2Department of Pediatrics, AHEPA Hospital, Thessaloniki, Greece; 3Department of Pediatrics, Papageorgiou Hospital, Thessaloniki, Greece; 4Department of Pediatrics, Hippokration Hospital, Thessaloniki, Greece

Introduction: Obstructive Sleep Apnea Syndrome (OSAS) has been shown to be an independent risk factor for cardiovascular disease in adults. However, few data are known about the effect of OSAS on cardiovascular system in children.

Aims: To investigate clinical and laboratory parameters associated with cardiovascular disease in children with OSAS.

Methods: Seventeen subjects, aged 5 to 12 years (mean age 9.2±4.2 years), referred for evaluation of systematic snoring (<4 nights/week), underwent overnight polysomnography: evaluation of blood pressure, lipidic profile and comprehensive echocardiographic assessment. According to the Apnea Hypopnea Index (AHI) subjects were divided into three groups: A. no snoring (AHI<1, n=1), B. mild OSAS (AHI= 1-5, n=12), C. moderate-severe OSAS (AHI >5, n=4).

Results: There were no significantly differences in age, sex, heart rate, systolic and diastolic blood pressure and lipidic profile among the groups (p>0.05). Right ventricular dimension (Right Ventricular end-Diastolic dimension - RVDD) and left ventricular dimensions (Left Ventricular end-Diastolic dimension - LVDd, Left Ventricular diastolic mass - LVdmass, Left Ventricular Posterior Wall diastolic –LVPWD, IntraVentricular Septum diastolic – IVSd) were not statistically significant different between the three groups and were within normal limits. RVDD was higher in OSAS patients (p=0.096) than in controls.

Conclusions: The present study suggests that young patients with systematic snoring have no echocardiographic evidences of cardiac dysfunction. Nevertheless, less is a correlation of increased right ventricular dimension, although not statistically significant, in patients with OSAS.

P1752

Effect of disease severity on heart rate recovery following laboratory and field exercise testing in patients with obstructive sleep apnea (OSA): A comparative study

Kyraki Cholidou1, Ioannis Vogiatzis2, Vasilis Andriasopoulos1, Ioannis Kostakis1, Evangelos Markazzenes1, Konstantina Kyriakou1, Manos Alchanatis1, 21st Respiratory Medicine Department, Sotiris Hospital, University of Athens, Athens, Greece; 2Department of Physical Education and Sports Sciences, University of Athens, Athens, Greece; 3Department of Critical Care Medicine and Pulmonary Services, Evangelismos Hospital, University of Athens, Athens, Greece

Introduction: It is known that patients with Obstructive Sleep Apnea (OSA) have increased activity of the sympathetic nervous system and decreased activity of the parasympathetic nervous system. Heart rate recovery in the first minute after exercise (HRR) is often used as an index to stratify risk factor for cardiovascular mortality in OSA patients.

Methods: We studied twenty five patients by polysomnography in the laboratory. Ten patients diagnosed with moderate OSA (15≤AHI<30), 10 patients diagnosed with severe OSA (AHI≥30) and 5 patients were normal (AHI<5). HRR following cessation of incremental exercise to the limit of tolerance on the cycle ergometer and after termination of a six minute walking test (6MWT) was assessed by a Nonin pulse oximeter worn on the wrist in all patients and controls.

Results: There was a significant difference in HRR; after the maximal incremental test among severe and moderate OSA patients and healthy controls (18±5 and 25±5 and 34±4 beats/min, respectively). Similarly, HRR, after the 6MWT was different between the two patient groups (severe by 15±5 and moderate by 19±4 beats/min and normal subjects (28±5). There was no difference in the magnitude of HRR, between the exercise tests among the three groups.

Conclusion: The more advanced the disease severity of OSA the slower was the recovery of heart rate after the exercise. The 6MWT reflects equally well to the incremental maximal test the sluggishness in heart rate recovery and hence it can be used alternatively to the maximal exercise test to detect the likelihood of cardiovascular risk in patients with OSA.

P1753

Impact of obstructive sleep apnea on diastolic function

Stefan Andreas, Lars Lütge, Rolf Wachter, Frank Eidemann, Gert Hasenhüttl, Burkard Piecke, Pneumologie, Langenbeckklinik, Immenhausen, Immenhausen, Kreis Kassel, Germany Cardiology and Pneumology, Universitätmedizin, Göttingen, Germany

The association of obstructive sleep apnea (OSA) with diastolic dysfunction is unclear. We investigated whether OSA independently affects diastolic function in a primary care cohort of patients with cardiovascular risk factors. 378 study participants with risk factors for diastolic dysfunction (e.g. hypertension, diabetes, heart failure) from the germanwide DIAST-CHF cohort were prospectively included into this substudy and a polygraphy was performed in all patients. Diastolic dysfunction was assessed by comprehensive echocardiography including tissue Doppler. Patients with more episodes of central sleep apnea than obstructive sleep apnea were excluded from further analysis (n=14). In the remaining subjects, 22.8% had an AHI >15. The prevalence of diastolic dysfunction increased from 75.0% (none) to 81.8% (mild) to 90.2% (severe sleep apnea), p=0.020. The degree of diastolic dysfunction also increased with sleep apnea severity. In univariate regression analysis, age, AHI > 15, heart rate, body mass index, systolic blood pressure and left ventricular mass were associated with diastolic dysfunction. In multivariate regression analysis, only age, AHI > 15 and heart rate were independently associated with diastolic dysfunction.

Conclusion OSA is independently associated with diastolic dysfunction in patients with risk factors for diastolic dysfunction.

This work was supported by grants from the German Federal Ministry of Education and Research (German Heart Failure Network, TP 7 (FKZ 01GI0205) and clinical trial program Aldo-DHF (FKZ 01KG0506)).

Early cardiovascular disease markers in “healthy” OSA patients are related with sympathetic activity

Donato Lacedonia1,4, Renaud Tamisier1,2, Jean-Philippe Baguet4, Jean-Louis Pepin5,6, Patrick Levy1,2. 1INSERM U1042, H2P Laboratory (Hypoxia: Pathophysiology), Joseph Fourier University, La Tronche, France; 2Locomotion Rehabilitation and Physiology Department, Grenoble University Hospital, Grenoble Cedex 09, France; 3Cardiology Department, Grenoble University Hospital, Grenoble Cedex 09, France; 4Institute of Respiratory Diseases, Department of Medical and Occupational Sciences, University of Foggia, Foggia, Italy

Rationale: Obstructive sleep apnea syndrome (OSAS) is associated with high sympathetic activity (SA) and a subsequent risk of hypertension and atheroscle-
Comorbidities and impact on society of asthma and COPD

P1755
Development and validation of a new comorbidity index for COPD
Miguel Divo1, Claudia Cote1, Juan Pablo De Torres3, Ciro Casanova6, Josef Maria Martinez2, Victor Pinto-Pieta1, Javier Zahuerta2, Carlos Cabrera2, Jorge Zagaleta1, Bartolome Celi1, 1Pulmonary and Critical Care, Brigham and Women’s Hospital, Boston, MA, United States; 2Pulmonary Medicine, Clinica Universitaria/Universidad de Navarra, Pamplona, Spain; 3Pulmonary and Critical Care, St. Elizabeth’s Medical Center, Boston, MA, United States; 4Pulmonary and Critical Care, Bay Pines Veterans Affairs Medical Center, Bay Pines, FL, United States; 5Pulmonary Medicine, Hospital Miguel Servet, Zaragoza, Spain; 6Pulmonary Medicine, Hospital Universitario de Gran Canaria Dr. Negrín, Palmas de Gran Canaria, Spain

Comorbidities influence outcome in COPD, but their role remains poorly described. We studied the impact on survival of COPD related comorbidities and developed a COPD specific comorbidity (COTE) index. We also compared COTE with the Charlson Comorbidity Index (CCI) and BODE.

Methods: We followed 1664 COPD subjects for over 4 years. Systematically, 80 possible comorbidities were recorded including conditions listed in CCI. In a randomly selected 2/3 of the cohort we calculated their prevalence. Using Cox proportional hazard, 6 of these comorbidities were independently associated with mortality. We then assigned points to the 6 comorbidities and constructed the COTE index based on likelihood ratios for death.

Results: 23 of 80 comorbidities differed in prevalence between survivors and nonsurvivors. The COTE index was superior to Charlson in mortality prediction: HR (95%CI) of [1.22 (1.17,1.27, p<0.001) vs. 1.03 (0.99,1.07, p =0.126)] and complementary to BODE [1.32 (1.28,1.36, p < 0.001)].

Conclusion: Comorbidities are prevalent in COPD and a subset of them influence survival. The COTE is simpler and more accurate than the Charlson index in predicting survival. The COTE adds independent predictive power to the BODE index.

P1756
Association between lung function and subclinical atherosclerosis in obese subjects
W. Thijs1,2, K.B. Gaa2, R. Muts2, F.H. Krouwele3, C.F. Meliss3, P.S. Hiemstra3, F.R. Rosendaal2, S. Middeldorp1, 1Department of Pulmonology, LUMC, Leiden, Netherlands; 2Department of Epidemiology, LUMC, Leiden, Netherlands; 3Department of Pulmonology, Spauere Hospital, Hoofddorp, Netherlands; 4Department of Vascular Medicine, AMC, Amsterdam, Netherlands; 5Department of Pulmonology and Thoracic Surgery, Krankenhaus Grosshadern, Grosshadern, Germany

An association between COPD and subclinical atherosclerosis that persisted after adjusting for cardiovascular risk factors has been reported. This may explain the excess cardiovascular mortality seen in patients with COPD.

Objective: To investigate the association between lung function and subclinical atherosclerosis in a population of obese adults with a normal lung function.

Methods: This is a cross-sectional analysis of the NIGG (Netherlands Epidemiology of Obesity) study, a cohort of adults aged 45 to 65 years with a Body Mass Index (BMI) 27> kg/m2. The association between FEV1 and subclinical atherosclerosis (mean maximal common carotid intima-media thickness [cIMT] measured by ultrasound) was assessed using linear regression.

Results: 1115 adults were included with a mean (25th-75th percentiles) age of 56 (51-61) years, BMI of 31 (28-32) kg/m2, FEV1 of 104% (94-113) and 48.7% men. One percent FEV1% increase was associated with 0.001 mm (95% CI -0.001, -0.002) decrease in mean maximal cIMT.
Fatigue in COPD and the impact of heart disease comorbidity: A population-based study

Fatigue is a common symptom among people with COPD. However, there are few studies describing fatigue in COPD and the impact of comorbidity, none of them population based.

**Background:** Fatigue is a common symptom among people with COPD. However, there are few studies describing fatigue in COPD and the impact of comorbidity, none of them population based.

**Aim:** To describe fatigue in COPD by disease severity according to GOLD, and the impact of self-reported heart disease.

**Methods:** The Functional Assessment of Chronic Illness Therapy (FACT-T). Fatigue scale was used to assess fatigue; lower scores represent worse fatigue (0-52). Data were collected in 2007 from the Obstructive Lung Disease in Northern Sweden (OLIN) COPD cohort; 564 subjects with COPD, with a distribution of disease severity representative for the general population, and 786 non-COPD subjects.

**Results:** Median FACT-T score was 44.0 in COPD subjects, significantly lower compared to 46.0 in non-COPD (p=0.006). Score decreased by disease severity: stage I: 46.0, stage II: 43.7, and stage III-IV: 40.0. There was no significant difference between stage I and non-COPD.

**Conclusions:** Fatigue increases with GOLD-defined disease severity, but the score is not significantly different from non-COPD until stage II. Heart disease increases fatigue in both COPD and non-COPD.

**P1759 Reduced lung function is an independent risk factor for the development of impaired glucose tolerance?**

Takashi Yamane1, Akihiro Yokoyama1, Naoki Shiota1, Hiroki Ohnishi1, Noboru Hattori2, Nobuki Kohno2, 1Department of Hematology and Respiratory Internal Medicine, Kochi Medical School, Nankōga City, Japan; 2Department of Molecular and Internal Medicine, Division of Clinical Medical Science, Graduate School of Biochemical Sciences, Hiroshima University, Hiroshima City, Japan

**Objectives:** Reduced pulmonary function is a risk factor for the development of impaired glucose tolerance (IGT) but has yet to be determined. The aim of the present study is to obtain more information on this point in Japanese males.

**Methods:** First, 975 men showing normal lung function without respiratory disease were recruited in cross-sectional research. All the subjects were divided into quartiles according to baseline%FVC,%FEV1, and FEV1% and analyzed the ratio of IGT and DM. Next, 511 men showing normal lung pattern in 75g OGTT were recruited in longitudinal research. The subjects were divided into%FVC,%FEV1, and FEV1% quartiles, we compared the cumulative incidence rates of IGT among the four groups, and analyzed the risk factors for the development of IGT.

**Results:** In the cross-sectional research, the rates of IGT and DM for each quartile at first examination were significantly associated with lower%FVC and%FEV1 quartile, but not significantly with lower FEV1% quartile. During the mean follow-up period of 28.4±6.0 months, 89 (17%) among 511 normal glucose tolerance (NGT) subjects developed IGT during this period. The cumulative incident rates of IGT for each quartile were significantly higher in lower%FVC and%FEV1 group, but not significantly with lower FEV1% quartile. In a Cox proportional hazards model, only lower%FVC quartile was an independent risk for development of IGT adjusted for age, BMI, systolic BP, total cholesterol, CRP, and pack-year smoking.

**Conclusions:** Not reduced%FEV1, and FEV1% but reduced%FVC is an independent risk factor for the development of IGT in Japanese males.

**P1760 Lung function, bronchial hyperresponsiveness (BHR) and metabolic risk factors in adults: Preliminary results from the gene environment interaction in respiratory disease (GEIRD) survey**

Lucia Cazzolletti1, Giuseppe Verlato1, Simone Accordini1, Cristina Bombieri2, Veronika Cappa1, Pietro Ferrari2, Kai Schenk2, Alessandro Marconi1, Mario Olivieri1, Elisabetta Zanolin1, Roberto de Marco1, Marcello Ferrari3, 1Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 2Department of Life and Reproduction Sciences, University of Verona, Verona, Italy; 3Unit of Occupational Medicine, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy

**Background:** Lung function is a risk factor for cardiovascular events and mortality, and is associated with insulin resistance and type 2 diabetes mellitus. It is well known that a common mechanism, such as insulin resistance and obesity, underlie metabolic syndrome (MS).

**Methods:** Our aim was to assess the association between lung function and MS in the GEIRD study, a nested multi-case control survey, in Verona, Italy. The study population included 1117 subjects (aged 20-66 years) who underwent spirometry (n=1117) and methacholine challenge (n=472). MS was defined according to the presence of 3 or more of the following factors: blood pressure of 130/85 mmHg or higher, abdominal obesity (waist girth: men>102, women>88 cm), self reported dyslipidemia, self reported diabetes. We studied the association of FEV1, FVC (% predicted), FEV1/FVC (% predicted) and BMI (% predicted) with MS and each of its components (using multiple linear or logistic regression adjusted for sex, age, height, smoking habits and case-control status). MS was associated with reduced FEV1 predicted (b=3.4, 95%CI: -6.5, 0.2), but not with FEV1/FVC (% predicted) (b=0.2, 95%CI: -1.6, 1.2). A negative but not statistically significant association between FEV1 and FVC (% predicted) was found. A positive association emerged between BMI and BHR (OR=8.79, 95%CI: 2.3-33.8). Among MS components, only abdominal obesity was related with a reduced FVC (% predicted) (b=-3.5, 95%CI: -6.0, 0.0).

**Conclusions:** The study results represent the low FEV1% predicted and BHR are associated with MS. The results of the present analysis deserves further investigation.

---

**P1761 Atopic status affects association between bronchial hyperresponsiveness and asthma symptoms in females**

Tine H. Malling1, Torben Sigsgaard2, Vivek Schlüsself2, Ole Find Pedersen2, Øyvind Omland3, The RAV Group. 1Department of Occupational Medicine, Aalborg Hospital, Aalborg, Denmark; 2Public Health, Environmental and Occupational Medicine, University of Aarhus, Aarhus, Denmark

**Background:** Bronchial hyperresponsiveness (BHR) is associated to asthma. Our objective was to analyse if atopic status and gender affected the associations between asthma symptoms and the extent of BHR.

**Methods:** In a Danish cross-sectional study of asthma in subjects aged 20-44 years (ERCHS protocol) 933 subjects were eligible for analysis. Asthma symptoms were defined by an 8 items asthma score (Pekkanen, J. et al, Eur. Respir. J. 2005; 19(5):953-61)
Results: Atopy was present among 181 (36%) females and 192 (45%) males (χ²-test, p<0.001). LDS was higher among atopic subjects compared with the non-atopic (t-test, p<0.001). Figure 1 shows associations between LDS and asthma score by gender and atopic status.

Conclusion: Currently there is some inconclusive evidence suggesting an effect of asthma on increased caries.

Methods: An Ovid Medline database search was performed from 1950 through May 2010 using the MeSH terms "asthma" and "caries". Summary effect estimates were calculated with fixed- and random-effects models and determinants of heterogeneity were studied in meta-regression analysis.

Results: The meta-analysis was based on 11 articles providing effect estimates of asthma on primary dentition and 14 articles on permanent dentition. The summary effect estimates of the relation between asthma and caries from the random-effects models and determinants of heterogeneity were studied in meta-regression analysis.

Short-term air pollution triggers acute rejection after lung transplantation

Hans Schee1, Tim Nawrot2, Sijin Verleden3, Rachel Geenens4, Peter Hoet1, Frans Fieren5, Veronique Cappa1, Maria Elisabetta Zanolin1, Giancarlo Pesce1, Mario Olivieri1, Marcello Ferrari2, Silvia Semboni2, Roberto de Marco1. 1Unit of Epidemiology and Medical Statistics, University of Verona, Verona, Italy; 2Department of Pathology, University of Verona, Verona, Italy; 3Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 4Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 5Department of Occupational and Environmental Medicine, Azienda Ospedaliera “Istituti Ospitalieri di Verona”, Verona, Italy; 6Department of Public Health and Community Medicine, University of Verona, Verona, Italy.

Background: In a population-based cross-sectional asthma survey, 6,950 (70%) individuals aged 20-44 completed an extended ECRHS screening questionnaire. Subjects with current asthma were identified by questions on currently taking any asthma medication, having had an attack of asthma or doctor diagnosed asthma plus asthma-like symptoms during the last 12 months. Employment status was determined by means of multiple regression models. The productivity costs due to absenteeism were estimated using the human capital approach. Results: The prevalence of current asthma was 7.7% in males and 10.6% in females. The total average annual extra costs per asthmatic subject in comparison with non-asthmatic subjects were € 2,081 and € 1,922 for males and females, respectively. Productivity costs were the major component accounting for 85% in males and 70% in females. Hospital care expenditures accounted for the greatest percentage of the direct costs in both gender. We extrapolated the average annual costs associated with current asthma to € 352 million in the entire Danish population aged 20-44. Conclusions: The economic burden of asthma in Denmark is substantial and primarily due to productivity costs accounting for three quarters of the total costs.

P1769

Health-related quality of life in subjects with respiratory diseases: Preliminary results from the GEIRD study

Veronica Cappa1, Maria Elisabetta Zanolin1, Giancarlo Pesce1, Mario Olivieri1, Marcello Ferrari2, Silvia Semboni2, Roberto de Marco1. 1Unit of Epidemiology and Medical Statistics, University of Verona, Verona, Italy; 2Department of Pathology, University of Verona, Verona, Italy; 3Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 4Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 5Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 6Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 7Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 8Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 9Department of Public Health and Community Medicine, University of Verona, Verona, Italy; 10Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 11Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 12Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 13Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy; 14Department of Biomedical and Surgical Sciences, University of Verona, Verona, Italy.

Introduction and background: Asthma is often associated with health deterioration and reduced working capacity resulting in health-related and productivity costs. Population-based studies on the economic burden of asthma on society and individuals are limited. Aims and objectives: To estimate the extra costs to society due to adult asthma in Denmark. Methods: In a population-based cross-sectional asthma survey, 6,950 (70%) individuals aged 20-44 completed an extended ECRHS screening questionnaire. Subjects with current asthma were identified by questions on currently taking any asthma medication, having had an attack of asthma or doctor diagnosed asthma plus asthma-like symptoms during the last 12 months. Employment status was defined by current or last held job. The analyses were based on data on individual level extracted from national registers. The direct (health care) costs were estimated by means of multiple regression models. The productivity costs due to absenteeism were estimated using the human capital approach. Results: The prevalence of current asthma was 7.7% in males and 10.6% in females. The total average annual extra costs per asthmatic subject in comparison with non-asthmatic subjects were € 2,081 and € 1,922 for males and females, respectively. Productivity costs were the major component accounting for 85% in males and 70% in females. Hospital care expenditures accounted for the greatest percentage of the direct costs in both gender. We extrapolated the average annual costs associated with current asthma to € 352 million in the entire Danish population aged 20-44. Conclusions: The economic burden of asthma in Denmark is substantial and primarily due to productivity costs accounting for three quarters of the total costs.

To our knowledge, this is the first study to perform a direct and simultaneous comparison of quality of life in several respiratory disorders. Subjects who suffered from COPD, current asthma and ORC had poorer HRQL than controls.

Conclusions: The economic burden of asthma in Denmark is substantial and primarily due to productivity costs accounting for three quarters of the total costs.

Health-related quality of life (HRQL) is an important outcome measure in patients with respiratory diseases. This study aims at investigating HRQL in different respiratory disorders. Controls and cases of COPD, current asthma, past asthma, non-allergic rhinitis, allergic rhinitis and "Other Respiratory Conditions" (ORC) were compared. SF-12 median score ranged from 49.4 (95%CI 47.6-51.2) for COPD cases to 53.0 (95%CI 52.5-53.9) for current asthma cases and MCS score from 47.9 (95%CI 44.3-51.5) for COPD cases to 49.9 (95%CI 48.6-51.2) for current asthma cases (Tab1).

Socioeconomic position and use of drugs in chronic obstructive pulmonary disease (COPD): A population-based cohort study in Rome, Italy
Nena Agabiti, Valeria Belliardi, Ursula Kirchmayer, Lisa Baulino, Luigi Pinnarelli, Massimo Arcà, Marina Davoli. Department of Epidemiology, Regional Health Service, Lazio, Rome, Italy.

Introduction: Little is known about “real-life” use of evidence-based recommended drugs in COPD. We tested the hypothesis that drug prescription vary according to socioeconomic position.

Methods: All people (55-64 years old) discharged in 2006-07 with a diagnosis of COPD exacerbation, resident in Rome (2,700,000 inhabitants) were selected from Hospital Information System (standardized ICD-9-CM coding). Drugs were retrieved from the regional drug prescription registry based on ATC codes (12-months follow-up after discharge). An area-based (census block) socioeconomic position (SEP) index was used for each patient (quintiles: I well off, V disadvantaged). Logistic regression was performed to take into account gender, age and comorbidities.

Results: 779 individuals were studied (mean age 58.1, 58% men). 55% were in the lower SEP levels. Disadvantaged people were more likely to have respiratory failure, diabetes, ischemic heart disease and heart failure. Proportions of people with at least two prescriptions during 12 months after discharge were: long-acting inhalants 70%, short-term inhalants 45%, xanthis 23%. No statistically difference was observed across SEP groups for long-acting (ORs ≥ 1.20, 95% IC=0.67-2.16) or short-acting inhalants (ORs≤1.55, 95% IC=0.90-2.68), while xanthis were more frequently prescribed for low SEP people (SEP-V vs. SEP-I OR=2.17, 95% IC=1.03-4.57; p trend < 0.05).

Conclusions: Disadvantaged COPD patients seem more exposed to xanthis whose effectiveness is less in comparison to inhalant drugs. We highlight the need for improving outpatient care programmes to reduce disparity in health.

P1772
Examination of multiple emergency inpatient admissions for asthma in England from hospital episode statistics (HES) 2005-2009
Rachel DaSantostefano1, Richard Baxter 2, Lianna Ishihara 2, Hana Muellerova2.

Objective: We described emergency asthma inpatient admissions in England from 2005-2009 and characterised factors associated with multiple asthma admissions.

Methods: This was a GSK-funded retrospective analysis (WEUSRTPS003) using HES1 industrialised data from England (©) 2010, re-used with permission). Patients with at least one emergency hospital admission where asthma was the primary diagnosis (ICD-10 J45, J46) on the first consultant episode within an admission were included. Using a backward elimination strategy, time to event modeling was employed to identify factors in the first asthma hospital record (length of stay [LOS], co-morbidities by ICD-10 chapter, gender) associated with a second asthma admission (occurring ≥3 days from first).

Results: There were 249,206 emergency admissions for asthma among 176,323 patients during the 4-year period. One-fifth of patients experienced ≥1 admission for asthma, where multiple admissions decreased with increasing age (27% age <18; 16% age ≥65); Median time to second admission was 6–7 months for each age group (<18, 18–44, 45+). Among adults, factors significantly associated with the second asthma hospital admission (p<0.05) included LOS ≥4 days (first admission), being female and co-morbidities (endocrine/metabolic, mental/behavioral, nervous system, circulatory).

Conclusions: The burden of asthma exacerbation requiring hospitalisation in England is substantial; one-fifth of patients admitted for asthma experienced multiple admissions (2005-2009). Co-morbidities were associated with a second admission for asthma in adults, suggesting that other health conditions may contribute to asthma morbidity.

Inhaled budesonide induces corticosteroid-dependent gene expression in asthmatics: Validation in primary epithelial and airways smooth muscle cells
Robert Newson1, Elizabeth King1, Christophe Ridot2, Carol Gwозд1, Neil Holden1, Jane Edelstein2, Bruce Zuraw2, Richard Leigh1, Paul O’Byrne3, Margaret Kelly4.

1Airways Inflammation Research Group, University of Calgary, Calgary, AB, Canada; 2San Diego School of Medicine, University of California, La Jolla, CA, United States; 3Firestone Institute for Respiratory Health, McMaster University, Hamilton, ON, Canada.

Rationale: Inhaled corticosteroids (ICS) reduce inflammatory gene expression. This is usually attributed to direct inhibition of inflammatory gene transcription by the glucocorticoid receptor. However, while corticosteroids induce anti-inflammatory gene expression in vitro, this has not been examined in asthmatic subjects taking ICS.

Methods: Bronchial biopsies from atopic asthmatics taking inhaled budesonide (2×0.200 µg, twice daily for 11 days) or placebo were subjected to gene expression analysis using real-time reverse transcriptase-polymerase chain reaction. mRNA expression for the corticosteroid-inducible genes; TSC22D3 (GILZ), DUSP1 (MKP-1), both anti-inflammatory effectors, and FKBP5 (FKBP51), a regulator of glucocorticoid receptor function, was assessed. Cultured pulmonary epithelial and airways smooth muscle cells were also treated with corticosteroids before gene expression analysis.

Results: Expression of GILZ and FKBP51 were significantly elevated in budesonide-treated subjects compared to placebo. Budesonide also increased GILZ expression in cultured epithelial and smooth muscle cells and immunostaining showed GILZ expression in the airways epithelium and smooth muscle of asthmatic subjects.

Conclusions: Expression of corticosteroid-induced genes, including the anti-inflammatory gene, GILZ, is upregulated in the airways of asthmatic subjects taking medium daily doses of inhaled budesonide. The biological effects of such regulation need to be considered when assessing ICS action. Funded by AstraZeneca.

P1776 Effects of beclomethasone dipropionate and formoterol in reducing oxidative stress induced by cigarette smoke extracts and IL-17
Anna Tonon1, Lorelana Riccobono1, Stefania La Gruatta1, Angela Marina Montanbalo1, Giuy Daniela Albano1, Valeria Scadlì1, Rosalia Gagliardo1, Gabriele Nicoli1, Eleonora Ingrasista2, Mirella Proffita2, Institute of Biomedicine and Molecular Immunology (IBIMI Italian National Research Council (CNR), Palermo, Italy; 2AstraZeneca R&D, Maccagno, Italy, Germany

Rationale: Oxidative stress is involved in airway inflammatory diseases. Inhaled corticosteroids reduce airway inflammation and the combination with long-acting β2 agonists enhances this effect.

Objective: To investigate whether cigarette smoke extracts (CSE) and interleukin-17A (IL-17A) activate airway epithelial cells to release markers of oxidative/nitrosative stress and to investigate the effect of beclomethasone dipropionate (BDP) and formoterol.

Methods: Human bronchial epithelial cells (16HBE) were stimulated with different concentrations of CSE (from 0 to 10%) to evaluate the expression of IL-17 receptor (IL-17R). IL-17A was also added to evaluate the production of ROS and nitrite/nitrate (NOx). The effects of BDP (10−6M) and Formoterol (10−6M), alone and in combination, were evaluated.

Results: CSE increased the expression of IL-17R in 16HBE in a dose-dependent manner with a maximum effect at 2.5% concentration (p<0.001). Both CSE and IL-17A separately increased the production of ROS and NOx (p<0.05) and their combination synergistically further increased the production of these markers (p<0.001). BDP alone was able to completely restore the baseline values in terms of IL-17R expression (p<0.001) and its combination with Formoterol was superior in reducing the ROS and Nitrite/Nitrate production (p<0.001).

Conclusions: Cigarette smoke and IL-17A increase the production of oxidative/nitrosative markers in human bronchial epithelial cells, this effect being reduced by BDP either alone or combined with Formoterol. Funded by: Chiesi Farmaceutici, S.p.A.

P1777 Activated protein phosphatase PP2A by formoterol enhances nuclear translocation of glucocorticoid receptor induced by budesonide
Yoshiki Kobayashi1, Nicolas Mercado1, Anna Miller-Larsen2, Peter Barnes1, Kazuhito Inoue1
1Airway Disease, NHIIL, Imperial College, London, United Kingdom; 2R&D Lund, AstraZeneca, Lund, Sweden

Introduction: We have reported that formoterol (FM), a long-acting β2-adrenoceptor agonist, restores corticosteroid (CS) sensitivity by activation of a serine/threonine protein phosphatase PP2A (ERJ 2009;34:583s). However, the molecular mechanisms that FM activates PP2A and restores CS sensitivity have not been elucidated.

Aims: To investigate the mechanism of PP2A activation by FM and the involvement of PP2A in glucocorticoid receptor (GR) nuclear translocation induced by CS budesonide (BUD).

Methods: Phosphate activation of immunopurified PP2A from U937 monocytic cells was measured by fluorescence-based assay. A549 lung epithelial cells, without functional β2-adrenoceptor, were used as control cells. Direct effect of FM was evaluated using PP2A immunopurified from cell membrane and recombiant PP2A. FM and GR ratios under PP2A inhibition by okadaic acid (OA) or overexpression were determined by western-blot.

Results: FM enhanced PP2A activity in both U937 and A549 cells and the effects were not blocked by a β2-adrenoceptor inhibitor (ICI-185551). FM directly activated PP2A-immunoprecipitates in the membrane and recombiant PP2A. PP2A was detected in GR-immunoprecipitates. PP2A inactivation by OA reduced GR nuclear translocation by BUD and abrogated FM-mediated increase of GR translocation while PP2A overexpression enhanced BUD-induced GR translocation and further increased enhancement of GR translocation by FM.

Conclusions: FM directly activates PP2A in β2-adrenoceptor-independent manner. PP2A associated with GR enhances GR nuclear translocation by BUD. This mechanism may contribute to the clinical benefits of BUD+FM combination therapy.

P1778 Effect of fluticasone and formoterol combination therapy on airway remodeling
Michael Roth, Jun Zhong, Chong S'ng, Michael Tamm. Pulmonary Cell Research & Pneumology, University Hospital Basel, Basel, Switzerland

Background: Macrophage infiltration, thickening of the basement membrane and increased mass of airway smooth muscle influence asthma airway remodeling.

Different cell types contribute to extracellular matrix deposition. Airway smooth muscle cells (ASM) not only contract but also proliferate, respond to inflammatory stimuli and produce extracellular matrix. As shown previously, glucocorticoids increase the deposition of extracellular matrix by human ASM under inflammatory conditions.

Methods: To analyse the effect of the β2-agonist formoterol on glucocorticoid-induced extracellular matrix deposition, primary ASM cultures were set up from asthmatics and non-asthmatic controls. Confluent cells were stimulated with 5% serum with or without a single drug or a combination for a further 72 hr with B3H proline (0.5μCi/μl). Total extracellular matrix and collagen deposition were monitored by scintillation counts, described earlier.

Results: Compared to non-stimulated cells 5% serum increased matrix and collagen deposition by +22% which was further increased in the presence of 10-8 M glucocorticoids (dexamethasone: +86%, budesonide: +66%, beclomethasone: +59%, fluticasone: +55%). However, 10-8 M formoterol restored serum-induced matrix and collagen deposition by 36%. In combination, formoterol abolished the stimulating effect of glucocorticoids on matrix and collagen deposition and reduced matrix deposition. This was dose-dependent.

Conclusions: Our data show that β2-agonists combined with glucocorticoids reduce the excessive matrix deposition induced by glucocorticoids alone. Thus, combination therapy may exhibit benefits for asthmatic patients beyond bronchodilating and anti-inflammatory effects.

P1779 AZD3199: A potent and selective β2-adrenergic receptor agonist with rapid onset of action
Alan Young, Rupert Austin, Roger Bonnett, Elaine Cadogan, Stephen Connolly, Philip Gardiner, Stephen Jordan, Mandy Lawton, Peter Metch, David Nicholls, Stuart Paine, Gary Paireudeau, Michael Stocks. Research and Development, AstraZeneca R&D, Charnwood, Loughborough, United Kingdom

Background: β2-agonists are standard treatments for asthma and COPD and are variingly optimized for a number of key pharmacological properties, such as receptor selectivity, systemic exposure, onset of action and duration of effect. AZD3199 is a novel ultra long acting β2-agonist (uLABA) with improved properties designed to combine 24 hour duration of effect with low systemic exposure and an onset of action similar to that of formoterol.

Methods: The affinity, potency and efficacy of AZD3199 were measured at human β2-adrenergic receptors. Onset of action was measured as relaxation of constricted guinea pig trachea and human bronchial tissue. Activity at the hERG voltage-dependent potassium channel was determined using electrophysiology. Plasma protein binding was measured in multiple species.

Results: AZD3199 was a potent agonist (6 nM EC50) at the human β2 receptor with an intrinsic activity of 0.8 relative to formoterol. AZD3199 had a rapid onset of action in both guinea pig (22 min) and human (11 min) lung tissue, very similar to formoterol (G-Pg 23 min, human 13 min) and significantly faster than salmeterol (>100 min in both). Similar β2-agonist activity was seen across multiple species including guinea pig, rat, dog, mouse and rabbit. AZD3199 was highly selective (>1500 fold affinity) for the human β2 receptor over human β1 and β3 receptors with no agonism at either receptor. No activity was seen at the hERG channel at concentrations up to 2μM. High plasma protein binding (>90%) was seen across multiple species offering the potential for reduced systemic exposure.

Conclusion: AZD3199 is a potent and selective uLABA with an onset of action similar to that of formoterol.

P1780 Oxidative stress-induced corticosteroid insensitivity is reversed by formoterol via inhibition of PI3K signalling in peripheral blood mononuclear cells from patients with COPD and severe asthma
Christos Rossios, Yuanyu Tu, Grace Osoata, Murahidy Analeise, Misako Ito, Peter Barnes, Kazuhito Inoue. Airway Disease, National Heart and Lung Institute, Imperial College, London, United Kingdom

Rationale: COPD patients show a poor response to corticosteroids which has been linked to oxidative stress. Here we show that the long-acting β2-agonist formoterol (FM) reversed corticosteroid insensitivity after oxidative stress via inhibition of phosphoinositide-3-kinase (PI3K) signalling.

Methods: The responsiveness to corticosteroids dexamethasone (DEX), budesonide (BD) and salmeterol (SM) was measured in PBMCs from patients with COPD or severe asthma.

Results: PBMCs from patients with severe asthma and COPD are less sensitive to DEX compared to healthy volunteers. Although both BM (10−7M) and salmeterol (5M, 10−7M) reversed DEX insensitivity in PBMCs of severe asthma, only FM shows this effect in COPD. In U937 cells, exposure to H2O2 decreased BUD and FP sensitivity and increased Akt phosphorylation as a footprint of PI3K activation. FM restored sensitivity to BUD and FP while the effects of SM were weaker and not statistically significant, and FM but not SM, partially inhibited H2O2-induced Akt phosphorylation. H2O2 also decreased SM-induced cAMP production in U937 cells but did not affect the response to FM. The reduction of SM effects by H2O2 was reversed by pretreatment with a PI3K inhibitor.

Conclusion: These results suggest that FM restored corticosteroid sensitivity via inhibition of PI3K signalling and that a combination of a corticosteroid with FM may be more effective than that with SM in conditions of high oxidative stress, such as in COPD. Funded by AstraZeneca
P1781
Endogenous PGE2 contributes to antigen-induced contractions of guinea pig trachea
Jesper Sölfholm, Lars-Olav Cardell, Sven-Erik Dahlén, Mikael Adner. 
Experimental Asthma and Allergy Research and The Centre for Allergy Research, The National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

We have previously shown that PGE2 via EP3 receptors maintains basal tone of guinea pig trachea (GPT). Our aim was to assess if antagonism of PGE2 also affected antigen-induced contractions.

Isometric responses to administration of ovalbumin (OVA) were recorded in GPT from guinea pigs sensitized to OVA and expressed as % of the maximal contraction to histamine 100μM. Before challenge with OVA, the selective EP3 antagonist, ONO-8130; 10(nM) antagonist was given to naïve preparations as well as together with different combinations of inhibitors and antagonists of histamine (mepyramine and metiamide), leukotrienes (zileuton) and prostaglandins (indomethacin).

As shown previously, inhibition of one or two mediator classes, generally, had no significant effects, whereas triple mediator antagonist (antihistamines+zileuton-indomethacin) abolished the response to OVA challenge. However, EP3 antagonist partly reduced the antigen contraction. Moreover, when the EP3 antagonist was given together with antihistamines and zileuton, the response to OVA was abolished (Table 1).

Table 1. Contraction (% max) to highest OV A dose

Control | 75±5  
M & M | 72±7  
INDO | 84±5  
ONO | 59±4*  
ZIL | 77±1  
INDO + M & M | 83±1  
ONO + M & M | 59±10  
ZIL + M & M | 65±7  
ZIL + M & M + INDO | 5±3*  
ZIL + M & M + ONO | 6±3*  

*p<0.05 vs control, *p<0.05 vs ZIL + M & M

Effect of indomethacin together with antihistamines and anti-leukotrienes confirms that proteinoids mediate part of the antigen-induced contraction. The new finding is that EP3 antagonism mimics the effect of indomethacin. This suggests that PGE2 is the main proteinoid mediating the antigen-induced contractions of GPT, a preparation that is known to respond similarly to human airways where the effects of PGE2 still await complete delineation.

P1782
Flumoxeme propionate inhaled 3 hours after an early allergen reaction partially inhibits the late phase reaction
Bart Jacobs1, Gail Gauvreau 2, Ric K. Watson 2, Abbey Torek 2, Karen Howie 2, Kieran Killian 2, Paul O’Byrne 2.

The National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Introduction: Inhalation of 800μg budesonide (AERJACM 1994;149;1447) or 500μg beclomethasone (JACI 1995;91;1163) upon resolution of the allergen-induced early phase response inhibits the late phase asthmatic response (LAR) by 39% and 70%, respectively. This has never been tested for the highly lipophilic corticosteroid Budesonide propionate (FP).

Methods: This randomized double-blinded, placebo-controlled, 3-way crossover study (NCT00716693) was conducted in 6, mild allergic asthmatic patients with a documented dual bronchoconstrictor responses to inhaled allergen. Patients underwent 3 allergen challenges separated by 14 day washout periods. Patients inhaled placebo, 250μg or 1000μg FP at 3 h after allergen challenge, and the magnitude of the LAR was measured at regular intervals until 7 h post challenge. Sputum induction was performed before, 7 h and 24 h post challenge, and methacholine PC20 measured before and 24 h post challenge.

Results: Five patients completed the study. 250μg and 1000μg FP significantly attenuated the LAR compared to placebo: the mean (SD) maximum/6% fall in FV31 during the late response was 25.2% (6.2) with placebo, 15.1% (7.1) with 250μg FP (p<0.01), and 18.3% (8.2) with 1000μg FP (p=0.04). Inhibition of the LAR was 40% and 27% for 250μg and 1000μg FP, respectively. There was no effect of FP on allergen-induced sputum eosinophils, with a trend for reduced AHR which went 3 allergen challenges separated by 14 day washout periods. Patients inhaled placebo, 250μg and 1000μg FP significantly.

Conclusion: FP on allergen-induced sputum eosinophils, with a trend for reduced AHR which went 3 allergen challenges separated by 14 day washout periods. Patients inhaled placebo, 250μg and 1000μg FP significantly.

P1783
Effect of olodaterol on the relaxation of small airways
Stephanie M. Brown, Peter J. Barnes, Louise E. Donnelly.
National Heart and Lung Institute, Imperial College, London, United Kingdom

Olodaterol (Ol) is a novel, selective, β2-agonist which offers bronchoprotection in mild asthmatics with duration of action of at least 24h. Small airways are the major site of obstruction in patients with COPD. Thus novel bronchodilators that act on the small airways may be of benefit for COPD. Therefore, this study compared the effect of Ol and formoterol (Fm) on human and rat small airways.

Precision cut lung slices (PCLS) were obtained from rat lungs and human lung tissue obtained following resection. Videomicroscopy was used to measure small airway relaxation.

Rat small airways were contracted to increasing concentrations of carbachol (EC50=0.11±0.04μg/M, n=6). Carbachol contraction was then repeated on the same airways following pre-treatment with PCLS with Ol or Fm (1μM). Both agonists significantly (p<0.05) inhibited carbachol-induced contraction (Ol: EC50=0.15±0.5μg/M and Fm: 0.34±0.07μg/M, n=6). Carbachol contracted human small airways with an EC50 of 0.08±0.03μg/M (n=6) which was significantly inhibited (p<0.05) following pre-treatment with inbm Ol (EC50=0.7±0.3μg/M, n=6) and inbm Fm (EC50=1.0±0.6μg/M, n=6).

Following pre-contraction of rat small airways with 0.1μM carbachol both β2-agonists induced relaxation ~45% of maximal contraction (n=6). By contrast, carbachol-induced pre-contraction of human small airways was completely reversed by both agonists with EC50 values of 4.3±5.7μm (n=6) and 46.1±37.9μm (n=6) for Ol and Fm respectively (P<0.005).

Ol and Fm had significant bronchodilatory effects on rat and human small airways. Ol was comparable to Fm and showed significantly increased relaxation following partial pre-contraction of human small airways to carbachol.
P1786
Neutralizingants of CXC12: Anti-inflammatorystimulanteffect onan allergicmodel of asthma
Francois Daubeuf1, Muriel Hachet-Haas2, Vincent Gasparrik1, Patrick Gizz5, Francois Rohmer1, Jacques Haeich1, Dominique Bonnet1, Marcel Hibert1, Jean-Luc Gaular3, Nelly Frossard1, 1UMR7200, CNRS- Université de Strasbourg, Illkirch, France; 2UMR7242, CNRS- Université de Strasbourg, Illkirch, France

Introduction: The chemokine CXCL12plays an important role in inflammation. Our team identified a small molecule neutralizing CXCL12, belonging to the family of chalcone, named C05. C05 inhibits interaction with its receptors, CXCR4 and CXCR7 (Hachet-Haas et al, JBC 283:23198,2008), and the eosinophil infiltration in a mouse model of allergic eosinophilic airway inflammation. We here evaluated the effect of this neutralizing C05 on airway hyperresponsiveness (AHR), inflammation and airway remodelling.

Methods: Nine week-old male Balb/c mice were sensitized to ovalbumin (OVA/Alum i.p, D0, D7) and challenged to OVA or solvent i.n. on D18,19,20,21, C05 (350µmol/kg, iv vehicle was administered i.p. once daily, 2h before each OVA challenge.

Results: C05 induced AHR (whole body plethysmography), eosinophilia, increase in IL-4, IL-5 and mucus secretion in bronchoalveolar lavage fluid, increase in lung collagen, as well as increased IgE and IgG1 in plasma. C05 decreased AHR (44±2%), eosinophilia (48±7%), IL-5 (44±8%), mucus (67±10%) in BAL, and lung collagen (100±21%). IgE and IgG1 levels in plasma and IL-4 secretion in BAL were not modified. In addition, C05 did not modify body or spleen weight. Furthermore, C05 did not induce any CXCR4+ cell recruitment in blood as opposed to AMB3100, a CXCR4 antagonist vs control group (11.4±3, 30.3±9, 9±1%).

Conclusion: The CXCL12 neutralizing therefore appears as a safe and good candidate in this asthma model.

P1787
Anti-inflammatory effects of garenoxacin on IL-8 production and ERK1/2 activation induced by lipopolysaccharides in A549 and THP-1 cells
Shintaro Hara1, Yuji Ishimatsu1, Hiroshi Mukae 2, Noriho Sakamoto 1, Saeed Kolahian, Farzad Asadi, Seyed Mahdi Nasiri. Department of Basic Sciences, Faculty of Veterinary Medicine, Tabriz University, Tabriz, Islamic Republic of Iran Department of Biochemistry, Faculty of Veterinary Medicine, University of Tehran, Tehran, Islamic Republic of Iran Department of Clinical Pathology, Faculty of Veterinary Medicine, University of Tehran, Tehran, Islamic Republic of Iran

Objective: The anti-inflammatory properties of macrolides have been applied to the treatment of inflammatory airway diseases. Although the anti-inflammatory properties of garenoxacin have been reported, no reports are available regarding a newly developed fluoroquinolone, garenoxacin (GRNX). To examine the immunomodulatory effect of GRNX, we examined the transcription and secretion of inflammatory cytokines by human airway epithelial cells and monocytes stimulated with lipopolysaccharide (LPS).

Methods: A human lung epithelial cell line (A549) and a human monocye cell line (THP-1) were stimulated with LPS and exposed to different concentrations of GRNX. The transcription of interleukin 8 (IL-8) at 3 h was measured in cell lysates using real-time PCR. The secretion of IL-8 was measured in the supernatants of the cell cultures at 24 h (A549 cells) or 9 h (THP-1 cells) using an enzyme-linked immunosorbent assay.

Results: LPS stimulation resulted in a significant increase in the transcription and secretion of IL-8 by A549 and THP-1 cells. Treatment with GRNX significantly inhibited the transcription and secretion of IL-8 by LPS-stimulated cells through inhibition of LPS-induced ERK1/2 phosphorylation.

Conclusions: GRNX has an anti-inflammatory activity through its capacity to alter the secretion of IL-8 from A549 and THP-1 cell lines.

P1788
Polymerized type I collagen reverts airway hyperresponsiveness development in a guinea pig asthma model
Blanca Bazan-Perkins1, Maria G. Campos2, Fernando Gutierrez-Agur1, Patricia Ramos-Ramirez1, Paula Moreno-Alvarez1, Edgar Sanchez-Guerrero1, 1Department of Airway Hyperresponsiveness, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico; 2Department of Pharmacology, Instituto Mexicano del Seguro Social, Mexico, Mexico

Recently, polymerized type I collagen (PoC) has been shown to display anti-inflammatory and anti-fibrotic properties in an asthma model. The effect of PoC in the pathobiology of asthma is unknown. Our aim was to study the effects of PoC in airway obstruction and responsiveness in a guinea pig model of allergic asthma with remodelled airways. After an initial sensitization protocol, guinea pigs were intermittently exposed to allergen (ovalbumin, OA) applied every 10 days for up to 125 days (asthma model group), receiving a total of 12 OA challenges. The control group received saline solution instead of OA. Some animals from both asthma model and control groups were treated with 0.66 mg/ml PoC aerosols administered every 5 days from day 65 to 120. Airway responsiveness to histamine was evaluated before the first OA challenge and at the sixth and twelfth OA challenges. From the first challenge on, OA induced a transient airway obstruction and a progressive rise in baseline Penh (a broncho-obstruction index), measured by barometric plethysmography, which was not modified by PoC treatments. At the sixth challenge, OA-induced hyperresponsiveness was abolished at twelfth OA challenge by PoC treatment. In a separate guinea pig group euthanized at the sixth OA challenge, airway subepithelial fibrosis (determined by morphometry) and granulocyte infiltration were observed. PoC treatment reduced both, granulocyte and fibrosis observed at the twelfth challenge. Our data suggest that the rise of Penh baseline is not induced by airway fibrosis, and that PoC is a biomarker which might become a pharmacological tool to reduce fibrosis, inflammation and hyperresponsiveness in asthma.

P1798
Reduces inflammatory parameters in airways of diabetic-antigen sensitized guinea pigs
Saeed Kolahian, Farzad Asadi, Seyed Mahdi Nasiri. Department of Basic Sciences, Faculty of Veterinary Medicine, Tabriz University, Tabriz, Islamic Republic of Iran Department of Biochemistry, Faculty of Veterinary Medicine, University of Tehran, Tehran, Islamic Republic of Iran

It is well established that there is a negative association between asthma and type 1 diabetes and relative lack of insulin in an organism results in an overall reduction in inflammatory reactions. This study was planned to determine the inflammatory events in antigen sensitized diabetic guinea pigs. Twenty-five male guinea pigs were categorized into five groups of five each as follows: diabetic, antigen sensitized, diabetic-antigen sensitized, insulin-treated diabetic-antigen sensitized and control animals. Induction of experimental diabetes and antigen sensitization were performed by injection of streptozotocin and ovalbumine, respectively. Animals were killed by exsanguination and bronchoalveolar lavage (BAL) was performed. BAL fluid cellular and protein contents were determined. Airway responsiveness to acetylcysteine was assessed. Histopathological examinations were performed on the lungs. Decreases in the airway reactivity in diabetic-antigen sensitized animals were found compared to antigen sensitized animals. Experimental diabetes decreased antigen-induced protein leakage into the airspace as well as the accumulation of inflammatory cells in BAL fluid of antigen sensitized animals. Histopathological results showed that conduction of experimental diabetes significantly reduced the number of eosinophils in the lungs of antigen sensitized animals. Treatment with insulin completely reversed all mentioned results in the antigen sensitized diabetic animals. Experimental diabetes causes were found to decrease the airway reactivity and inflammatory responsiveness induced by antigen sensitization due to a reduction in the insulin levels.

P1799
Pharmacological assessment of the effects of SB-705498 on capsaicin-induced responses in healthy volunteers and patients with non-allergic rhinitis
Carlijn Holland1, Christine Segboer1, Daphne Tsitoura2, Amy Newlands2, Philippe Bareille2, Jane Denyer2, Cornelis van Drunen1, wyskie Fokkens1, 1Otorhinolaryngology, AMC Medical Centre, Amsterdam, Netherlands; 2Medicines Research Centre, GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom

Rationale: "Nasal hyper-responsiveness" has been proposed as a key mechanism driving nasal symptoms in patients with non-allergic rhinitis (NAR). Here, we explore the potential clinical use of the selective TRPV1 antagonist, SB-705498, for treatment of symptoms of rhinitis.

Methods: Two clinical studies were here conducted to assess the effect of SB-705498 on nasal responses to incrementally dosed, unilateral intranasal capsaicin challenge: In the first study, a single 400µg oral dose of SB-705498 was assessed in healthy volunteers (HVT). In the second study, 12mg of SB-705498 was administered to topically patients to non-allergic rhinitis (SB-705498 or placebo was administered according to a randomised, double blind, crossover (HVT)) or parallel group (NAR) design. 1 hour post dosing, incremental capsaicin challenge (2.5, 12.5 and 50µg) was performed. Symptom scores, secretion weights, peak nasal inspiratory flow (PNIF) and mediators in nasal secretions were evaluated. Blood samples were collected for pharmacokinetic analysis.

Results: Both studies showed a clear signal for effect of SB-705498 versus placebo on the clinical endpoints following intranasal challenge with capsaicin. The relative dose potency for TSS was 3.33 (1.45, 8.26 95% CI) in HVT and 2.81 (0.78, 10.7 95% CI) in NAR patients. All other clinical endpoints (satisfying parallelism) showed approximately 2-5 fold potency shift, except PNIF in NAR patients.

Conclusion: SB-705498 inhibits capsaicin induced nasal responses in HVT and NAR. SB-705498 has potential for further development as a novel, topical intranasal medicine for treatment of rhinitis.

Cost-effectiveness of a lung health intervention in US smokers
Lisa McGarry1, Hemangi Parekh1, Ryne Paulose-Ram2, Christine Baker3, Nektarios Anagnostopoulos1,2, George Farmakides4, Manolis Tzatzarakis5, Adriana Loukopoulou1,2, Constandine Vardavas1,2, Marios Kogias1,2, Andronikos Tsatsakis1, Vassiliki Evangelopoulos1, Panagiotis Bhatrakis1,3, Marios Kogias1,2, George Farmakides1, Manolis Tzatzarakis1, Nektarios Anagnostopoulos1,2, George Farmakides4, Manolis Tzatzarakis5, Adriana Loukopoulou1,2, Constandine Vardavas1,2, Marios Kogias1,2.

1Smoking and Lung Cancer Research Center, Donation of G.D. Behrakis, Hellenic Cancer Society, Athens, Greece; 2Medical Faculty, National and Kapodistrian University of Athens, Athens, Greece; 3Center for Global Tobacco Control, Harvard School of Public Health, Boston, United States; 46th Maternity Clinic, General Maternity District Hospital “Helena Vzentola”, Athens, Greece; 5Laboratory of Toxicology, Medical School of the University of Crete, Heraklion, Greece; 6Department of Environmental Health, Harvard School of Public Health, Boston, United States.

Objective: to determine smoking cessation ward rounds increase referrals to smoking cessation services? A survey in a UK district general hospital

Aims: To prove that NRT in ICU patients decreases the use of sedatives and analgesics, the number of days on ventilator, and the total ICU stay.

Methods: The study was performed in the 20 bed ICU. Forty patients meeting inclusion and exclusion criteria were randomized into either an interventional or control group. Patients in the interventional group received a 21mg nicotine patch every day until the patient was discharged from the ICU, transferred to the general medical floor, or until 10 weeks. Patients in the control arm received fake patch. The use of sedatives and analgesics during ICU stay, and use and duration of invasive mechanical ventilator were noted. The length of ICU stay was also compared in both the groups.

Results: Twenty-seven patients were male,13 were female. The mean age of the interventional group patients was 57.4 years and 52.5 years in the control group. The mean APACHE II score was 14.3 in the interventional group vs. 13.8 in the control group. The mean length of ICU stay in the interventional group was 4.5 days while in the control group mean length of ICU stay was 7 days. The mean number of days on ventilator in interventional group was 1.9 days vs. 3.5 days in the control group. The number of days on sedation and analgesia was also less in the interventional group compared to the control group.

Conclusion: The length of ICU stay and the number of days on ventilator decreases in the patients receiving NRT.

P1795

High and low intensity interventions for smoking cessation during pregnancy, an RCT

Aims and objectives: The aim of this RCT is to test whether offering pregnant smokers a high intensity intervention for smoking cessation increases the rate of smoking cessation and, in comparison to a usual care low intensity intervention.

Methods: The high intensity intervention (n=24) included: 30 minutes of cognitive-
behavioural intervention and a self-help manual. The control group (n=30) received 5 minutes of low intensity intervention. Smoking cessation was biochemically validated by urine cotinine samples both at the baseline and around the 32nd week of gestation among both groups (ClinicalTrials.gov Identifier: NCT01210118).

Results: The preliminary results indicate a significantly higher percentage of pregnant smokers quit smoking in the experimental group (20.8%) than in the control group (6.7%). Urine cotinine levels ranges were similar in both groups before the intervention. A significant decrease in urine cotinine concentrations after the intervention, were noted among both groups with the participants of the experimental group found to have a larger decrease in cotinine concentrations (_ctl 0.026±0.63 ng/ml vs. experimental group 40±1.19 ng/ml).

Conclusions: These preliminary results indicate that a high intensity intervention was found more effective than a low intensity intervention for smoking cessation during pregnancy, indicating its possible usefulness within clinical practice.

P1796 Predicted impact of access to varenicline on abstinence simulating multiple quit attempts over smokers’ lifetimes

Background: Relapse to smoking is a common challenge to many quitters, thus, access to effective smoking cessation treatment (SCT) for multiple quit attempts may be important in achieving permanent abstinence.

Objective: To evaluate the impact of access of Varenicline (V) vs. no-access to varenicline (\( V^-\)) on predicted health benefits and costs over smokers’ lifetimes.

Methods: A discrete event simulation of SCT allowing multiple quit attempts (QA) with choice of treatments predicting response and possible relapse, as well as estimates of lifetime health and economic outcomes in a U.S. population was implemented. The simulations compare outcomes of smokers who had access to varenicline for all QA’s with those without any access to varenicline. Smokers could also use NRT, bupropion, behavioral modification, or “cold turkey” for any QA, regardless of access to varenicline.

Results: The average predicted total abstinence time (tAT) is 113 months with \( V^-\) and 126 months with \( V^+\). The corresponding average lifetime QAs/smoker are 9.0 with \( V^-\) and 7.5 with \( V^+\). The percent of individuals achieving predicted abstinence is (at least 2 years by the time of analysis) is %68% with \( V^+\) and %72% with \( V^-\). For each simulated combitody (COPD, lung cancer, coronary heart disease and stroke), the incidence of new cases is lower with \( V^+\). Access to varenicline is dominant, i.e. more effective and less costly than no-access across all comparisons.

Conclusion: Providing access to varenicline over smokers’ lifetimes results in better health outcomes at lower costs.

P1797 Smoking and treatments among asthma patients in South Korea

Hae-Sim Park1, Ki-Suck Jung2, Kin Fan Chung3, Hyejin Myeong4, Shamila Irin5, Charlette Everett5, Eric Maiese6, Felicia Allen-Ramey6, David Price7. 1Allergy and Rheumatology, Ajou University School of Medicine, Suwon, Korea; 2Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, Korea; 3National Heart and Lung Institute, Imperial College, London, United Kingdom; 4Medical Affairs, MSD Korea, Seoul, Korea; 5Adelphi Real World, Boltinmng, United Kingdom; 6Global Market Access, Merck & Co., Inc., West Point, United States; 7Primary Care University of Aberdeen, Aberdeen, United Kingdom

Background: The prevalence of smoking in South Korea is high, an estimated 23.3% for adults. Studies have shown that active smoking impacts asthma morbidity and treatment response. However, little is known about the asthma therapies and treatments among asthma patients in South Korea.

Methods: A cross-sectional survey was conducted from Aug 2010–Jan 2011 at 16 urban hospitals in South Korea. Information on smoking status, asthma medications and exacerbations in the prior year was collected for consecutive asthma patients aged 18-60 yrs presenting for medical care.

Results: A total of 1347 asthma patients were included. Mean age was 43 yrs, 46% were male, 63% never smoked (NS), 16% were former smokers (FS) and 21% were current smokers (CS). The proportion of patients with ≥1 exacerbation in the prior year was 42% for NS, 38% for FS and 40% for CS (chi-squared p=0.52). Most patients were using ICS-LABA (73%) with no differences in use between smoking categories (72% of NS, 75% of FS and 76% of CS; p=0.40). Use of leukotriene modifiers (52%) was also common, with no differences in use between smoking categories (52%, 54% and 49% for NS, FS and CS, respectively; p=0.56). Twelve percent of patients were reported as using an ICS and there were slight differences in use between smoking categories (14%, 10% and 6% for NS, FS and CS, respectively; p=0.001).

Conclusion: The prevalence of smoking among this asthmatic patient population was similar to previously reported national rates in South Korea. Smoking status does not appear to affect the use of two common asthma medications; however, smoking status may influence the use of ICS.
percentages of subjects having lower respiratory flows or OVD or RVD or lung hyperinflation. Compared to the ECG group, the ENS group includes significantly lower percentages of subjects having lower respiratory flows or OVD or lung hyperinflation. Cigarettes and narghile smoking accelerate lung ageing with significantly higher estimated lung ages.

Conclusion: The plethysmographic profile of ENS is different from this of ECS and narghile smoking accelerates lung ageing.

P1800
The dynamics of free radical parameters in exhaled breath condensate (EBC) in smokers during the course of physical workload
Elena Zagradnová1, Natalia Popova1, Svetlana Soodaeva2, Igor Klimanov2, Alexander Lisitza3, Timur Lu4. 1Department of Biochemistry, Vladimir State University, Vladimir, Vladimir Region, Russian Federation; 2Clinical and Experimental Biophysics, Palmenology Research Institute, Moscow, Russian Federation; 3Neurological Department, Russian State Medical University, Moscow, Russian Federation

The aim of the study was to investigate the total nitrate/nitrites (TNN) and Fe^2+ concentrations in EBC in smokers compared with nonsmokers during the course of physical exercises.

Materials and methods: The study group included 30 smokers 20-23 y.o. with smoking history of 3-4 years. The control group consisted of 25 healthy (without any documented medical diagnosis) non-smokers 20-23 y.o. The TNN level in EBC was determined by nitrate reductor and Griess reagent, the concentration of Fe^2+ was observed by ferrozine method. All the data were determined in two points: baseline at rest and after exercise (when the heart rate was 100-120 beats per minute) in both groups.

Results: The results obtained demonstrated that there was significant decrease of TNN concentration in EBC in study group (the basal level of TNN in EBC was lower in 1.6 times compared with nonsmokers). During the course of physical exercises it was shown the increase of TNN level in EBC in smokers compared with nonsmokers (in 2.0 and 1.2 times respectively), also the increase of Fe^2+ basal concentration in lung tissue in 2 times compared with nonsmokers (p <0.05) was determined. During the exercise the Fe^2+ concentration in smokers was higher in 1.4 times as compared with nonsmokers (p <0.05).

Conclusion: The physical workload provide a significantly changes in free radical metabolism in smokers.

P1801
Time trends of smoking habits in Italy during the last decade
Guangshu Verlato1, Veronica Cappa1, Elisa Montoli1, Mario Olivieri10. 1Unit of Epidemiology & Medical Statistics, Dept. of Public Health & Community Medicine, University of Verona, Verona, Italy; 2Allergy Unit, Ospedali Riuniti di Ancona, Ancona, Italy; 3Dept. of Pubic, Clinical & Preventive Medicine, II University of Naples, Naples, Italy; 4Dept. of Hygiene, University of Perugia, Perugia, Italy; 5Unit of Respiratory Medicine, CPA-ASL TO2, Turin, Italy; 6Institute of Respiratory Diseases, IRCSS San Martino, Genova, Italy; 7Dept. of Epidemiology, ASL Salerno 2, Salerno, Italy; 8Institute of Respiratory Diseases, University of Sassari, Sassari, Italy; 9Dept. of Applied Health Sciences, University of Pavia, Pavia, Italy; 10Unit of Occupational Medicine, University of Verona, Verona, Italy

Objective: To estimate time trends of smoking habits in Italy as a function of gender and occupation.

Methods: In the frame of the GEIRD study (Gene Environment Interactions in Respiratory Diseases) 10494 subjects, randomly selected from the general population aged 20-44 years in 7 Italian centres (Torino, Pavia, Verona, Sassari, Ancona, Terni, Salerno), answered a screening questionnaire between 2007 and 2010 (response percentage=57.2%). In 4 centres smoking prevalence was compared with prevalence recorded between 1998-2000 by the Italian Study of Asthma in Young (ISAYA).

Results: In the GEIRD study the prevalence of current smokers was higher in men (31.3%) than in women (24.2%), while the prevalence of past-smokers was similar (16.8% and 15.8% respectively). Current smoking was twice as prevalent among unemployed and blue collar (39%) as among managers and clerks (20-22%). In a multinomial model controlling for centre, sex, age, occupation, cumulative response percentage, season and type of response (postal/phone), the risk of current smoking largely declined from the first to the second survey (RRR=0.68, 95%CI 0.62-0.74). A significant, although smaller, decline was recorded also in the risk of being a past-smoker (RRR=0.85, 0.76-0.94). The declining trend did not differ by gender (time-sex interaction: P=0.206), but it was largely affected by occupation-time-occupation interaction: (P=0.004); it was particularly pronounced in managers, while being absent in unemployed.

Conclusion: Smoking prevalence has declined in this Italian population in both sexes. The declining trend, however, while pronounced in the highest socioeconomic classes, has not started yet among the lowest classes.
P1805 Maternal smoking during pregnancy and the risk of asthma related symptoms in the early childhood
Monica Aleksandra Stoica, Andrei Dumitrescu, Maria Safiño, National Centre for the Community Risks Monitoring, National Institute of Public Health of Romania, Bucharest, Romania

Maternal smoking during pregnancy and fetal growth retardation might adversely affect early lung development and increase the risks of asthma-related symptoms. The study of the associations of maternal smoking during pregnancy and fetal growth, measured in different periods of pregnancy with asthma-related symptoms in early childhood.

Methods: We performed a 4 years (2006-2010) prospective population-based cohort study starting in pregnancy. Fetal growth retardation was defined as a decrease of 1 gestational age adjusted standard deviation score in weight from 3rd trimester to birth. Maternal smoking during pregnancy (I, II, III trimesters) and wheezing, lower respiratory tract infections (LRTI) and diagnosed asthma until the age of 3 years were assessed by questionnaires. Adjusted logistic regression analyses were performed in 1217 subjects.

Results: Maternal first trimester only smoking was not associated with asthma-related symptoms in the children. Continued maternal smoking during pregnancy was associated with wheezing at 1, 2 and 3 years with adjusted odds ratios (aOR) 1.47 (94% confidence interval 1.14 to 19.4), 1.51 (1.13, 2.01) and 1.60 (1.09, 2.37), and with LRTI at 2 years (aOR 1.69 (1.19, 2.41)) but not with diagnosed asthma. Fetal growth retardation was not associated with any asthma-related symptoms. Children of continued smoking mothers with fetal growth retardation had higher risks of wheezing than children of smoking mothers without fetal growth retardation.

Conclusions: Continued maternal smoking during pregnancy is associated with increased risks of wheezing in early childhood. These associations are stronger in children with fetal growth retardation.

P1806 Second hand smoke exposure among hospital staff in Budapest, Hungary: A case study
David Laszlo Tankos1, Adam Domonkos Tankos1, Mark J Travers2, Andrew Hyland3, Katherine Dobson2, Laszlo Mecskler1, Laszlo Tamas1, Ildiko Horvath1, K. Michael Cummings2. 1Department of Radiology and Oncotherapy, Semmelweis University, Budapest, Hungary; 2Department of Health Behavior, Roswell Park Cancer Institute, Buffalo, NY, United States; 3Department of Neurology, Roswell Park Cancer Institute, Buffalo, NY, United States

Background: The aim of the study was to assess the second hand smoke exposure levels in the wards of a public hospital.

Methods: An indoor air quality monitoring study was performed in hospital ward rooms. The measurements were performed with TSI SidePak AM510 Personal Aerosol Monitor in Budapest, Hungary.

Results: Mean PM2.5 levels in the wards of the hospital were 182.9 ± 135.6 μg/m3, in the clinical departments and health care workers’ rooms the mean was 191.5 ± 167.2 μg/m3. The highest levels of indoor air pollution were found in the laboratory (336 μg/m3), intensive care unit (230 μg/m3) and neonatology (163 μg/m3).

Conclusions: The results of our study indicate that there is a need for public health action and implementing smoking-free policies in the hospital in order to reduce second hand smoke exposure.

P1807 The influence of early exposure to tobacco smoke for pulmonary disease
Akinori Ito1, Akira Nagai1, Takayuki Nakano2, Tomokazu Iwamoto3, Ichiro Kawahita1. 1Respiratory Medicine, Tokai University Tokyo Hospital, 1-2-5 Yoyogi, Shibuya-ku, Tokyo, Japan; 2General Thoracic Surgery, Tokai University Tokyo Hospital, 1-2-5 Yoyogi, Shibuya-ku, Tokyo, Japan

Background: Smoking is a very serious problem for COPD, lung cancer and other chronic pulmonary diseases. However, there are few studies on early exposure to tobacco smoke. Smoking rate in Japan decreased to 21.8%. However it is still higher in the northern area (Hokkaido). In particular, it is 31.0% in Erimo town (southernmost extreme of Hokkaido), which is higher than that of any other cities in Hokkaido. The reason is that when parents smoked, the child set fire to tobacco and handed it as a custom in 1940’s. Because a hand was wet while fishing, they were not able to set fire themselves.

Aim: We evaluated the influence of early exposure to tobacco smoke on prevalence of COPD and lung cancer.

Methods: Using the results of the medical checkup carried out at the Erimo town health division and the Town clinic, we analyzed about 6000 residents’ epidemiologic data.

Results: Majority of residents were found exposed to tobacco smoke actively or passively from a young age. Housemate smoking rate was 81.0%. The mortality of chronic respiratory disease was 71.4 per 100,000 person-years that was far exceeded from the national average (11.4 per 100,000 person-years). COPD prevalence (465.5 per 100,000 person-years) was significantly higher than the national average (136.2 per 100,000 person-years). Lung cancer prevalence was also very high (87.2 per 100,000 person-years).

Conclusion: Early exposure to tobacco smoke in childhood significantly increases prevalence of COPD and lung cancer. In Japan, young generation showed still high smoking rates (14.3% aged 20s, 18.0% aged 30s). Smoking cessation is the most important intervention to prevent disease progression.

P1808 Determination of cutoff points for smoking biological markers and the influence of involuntary smoking exposure
Raquel Barros1,2, Paula Pinto1,2, Cristina Barbosa1,2, 1Servicio de Pneumología II, CHLN - Hospital Pulido Valente, Lisboa, Portugal; 2CEDOC, Faculdade de Ciências Médicas de Lisboa, Lisboa, Portugal

Background: The reference values used for smoking biological markers should be determined in each country or region because there are many factors that can influence them.

Objective: To estimate the cutoff points of exhaled carbon monoxide (ECO), carboxyhemoglobin (COHb), plasma cotinine and urinary cotinine in order to differentiate active smokers from never-smokers.

Methods: In a cross-sectional study with 53 active smokers (30 males) and 49 non-smokers (14 females), ECO, COHb, plasma cotinine and urinary cotinine were measured.

Results: Anthropometric variables in both groups showed no statistically significant differences (p-value>0.05).

Active smokers had significantly higher levels of ECO, COHb, plasma cotinine and urinary cotinine than non-smokers (p-value<0.05).

It was determined the following cutoff points for biological markers: ECO - 4 ppm (sensitivity 100% and specificity 96.2%); COHb - 1.6% (sensitivity 100% and specificity 96.2%); plasma cotinine - 10 ng/mL (sensitivity 100% and specificity 94.3%); urinary cotinine - 779 ng/mL (sensitivity 100% and specificity 96.2%).

In the absence of smoking exposure, the cutoff point for urinary cotinine changed to 22 ng/mL.

Conclusion: All the biomarkers presented an excellent ability to discriminate between smokers and non-smokers.

225. Tuberculosis: from bench to bedside

P1809 T_{reg} cells are expanded among bronchoalveolar lymphocytes in healthy tuberculosis contacts with positive interferon-γ release assay responses
Christian Herzmann1, Christoph Lange1, Steffen Stenger2, Jeroen Maertzdorf3, Tom Schaberg4, Giovanni Sottai4, Martin Ernst5. 1Clinical Infectious Diseases, Research Center Borstel, Borstel, Schleswig-Holstein, Germany; 2Microbiology and Hygiene, Ulm University Hospital, Ulm, Germany; 3Department of Immunology, Max Planck Institute for Infection Biology, Berlin, Germany; 4Center for Respiratory Medicine, Hospital Rotenburg (Wümme), Rotenburg (Wümme), Germany; 5Istituto di Igiene e Medicina Preventiva, Università di Sassari, Sassari, Italy; 6Immune Cell Analytics, Research Center Borstel, Borstel, Germany

Background: A positive Interferon-γ release assay (IGRA) after exposure to tuberculosis indicates a systemic immune response to Mycobacterium tuberculosis (MTB). However, most people will remain IGRA-negative (IGRA-) after exposure. In mice, regulatory T-lymphocytes (T_{reg}) can deter the pulmonary clearance in early infection, possibly preventing a systemic immune response.

Objective: To study the local immunity in TB-exposed health care workers without active disease.

Methods: FACs analysis on bronchoalveolar lavage (BAL) cells including T_{reg} cells (CD4+CD25+CD127-) and activated macrophages (HLA-DR+). Questionnaire for demographic, and health-related data. Blood IGRA.

Results: Demographic and epidemiological parameters were not statistically different. Of 10 IGRA- and 12 IGRA+ subjects, the BAL of the latter group showed a
To study the influence of CD4+ and CD8+ T-cell counts on IGRA results in HIV/AIDS patients.

Aim: To study the influence of CD4+ and CD8+ T-cell counts on IGRA results in HIV/AIDS patients.

Materials and methods: QuantiFERON-TB Gold In-Tube (QFT-GIT) (Cellestis, Melbourne, Australia) and T-SPOT.TB (SOT) (Oxford Immunotec, UK) tests were performed according to manufacturers' instructions. CD4+ and CD8+ T-cell counts were determined by flow cytometry (BD, FACSCanto II). Spearman correlation and t-test were used for statistical analysis. All pts provided written informed consent.

Results: From January 2010 to January 2011, 105 (62% males) (18-66 yrs) HIV-infected individuals in different stages of progression were recruited. The mean CD4+ and CD8+ cell counts was 448 cells/µl (74-3871) respectively. 24/105 pts were positive in both IGRA results with negative production did not correlate with absolute CD4+CD8+ T-cell counts (p<0.05). Mean values of CD4+CD8+ T cells in pts with indeterminate results were insignificantly lower than in pts with negative and positive results in both IGRA's (p<0.05).

Conclusions: Our data demonstrate that TB antigen-specific immune responses in HIV/AIDS pts with indeterminate results were insignificantly lower than in pts with negative and positive results in both IGRA's. The present work is devoted to relative research of some cy	olines (IL-1β, IL-8, IL-12, TNF-α) at the tuberculosis patients with the subsequent evaluation of their role in pathogenesis of various forms of pulmonary tuberculosis.

Materials and methods: The clinical and immunological inspection is executed at 193 patients with active pulmonary tuberculosis.

Results: At infiltrative tuberculosis the high level of production IL-1β and IL-8 was combined with the maximal stimulation index of IL-1β and TNF-α, but low stimulation index of IL-8. Production of IL-2 exceeded the patients with more disseminated forms of a tuberculosis - disseminated and caseous pneumonia. Fibro-cavernous tuberculosis was characterized by more intensive production of IL-2, low serum contents of IL-1β, TNF-α and lower activity of IL-8. The level of inflammatory cytokines production (IL-1β and TNF-α), alongside with a low index of their stimulation is characteristic for a disseminated tuberculosis, that testifies to a state of hyper activation of immunocompetent cells. In caseous pneumonia, alongside with the maximal reduced of IL-1β, TNF-α and IL-2, the highest index of stimulation IL-1β and TNF-α was marked.

Conclusion: The received data testify to the highest degree of an activation of cells of cytophagous in patients with infiltrative tuberculosis, and their expression depends on the caseous incompleness in caseous pneumonia. The down stroke of production not only IL-2, but also IL-1β alongside with a high level of IL-8, corresponds to the extremely serious state of the patients.

PI1801

Lethal tuberculosis in a previously healthy adult with IL-12 receptor deficiency

Payam Tabari1,2, Majid Marjani3, Jean-Laurent Casanova4, Davood Mansouri2.

1Mycobacteriology Research Center, NRITLD, Tehran, Islamic Republic of Iran; 2TB and Clinical Epidemiology Research Center, NRITLD, Tehran, Islamic Republic of Iran; 3Laboratory of Human Genetics of Infectious Diseases, Rockefeller Branch, The Rockefeller University, New York, United States

Introduction: Most patients with disseminated tuberculosis (TB) have no known underlining immunodeficiency. Here, we report the first case of disseminated TB in an adult patient with underlying IL-12Rβ1 deficiency.

Case: A 38 year old man was admitted in hospital due to fever, generalized lymphadenopathy, and hepatosplenomegaly. He had a history of anti-TB treatment in the previous 3 years. Despite normal chest X-ray, sputum smear was positive for Acid-fast bacilli (AFB) and PCR was positive for Mycobacterium tuberculosis complex. Drug susceptibility test revealed multi-drug resistance (MDR) to INH and Rif. Standard MDR-TB treatment was initiated. Evaluation of immunologic and genetic status of patient revealed IL-12Rβ1 deficiency.

Despite initial response to treatment, the patient developed profuse diarrhea. In coloscopy, polypoid lesions were observed which were full of AFB. Linezolid and IFN-γ were added to the treatment but the patient passed away due to disseminated TB.

Conclusion: IL-12Rβ1 deficiency is a genetic etiology of severe TB in adults. We should consider genetic defects of the IL-12-IFN-γ circuit in adult patients with disseminated TB.
like sputum smears is time saving, simple and convenient compared with other culture based methods.

P1815

Genetic association studies between the MyD88 adaptor pathway SNPs and the development of tuberculosis

Foteini Malli1, Vicky Mollaki1, Angela Koutsokera1, Irene Gerogianni1, Konstantinos Gourgoulis1, George Vassilopoulos2, Zee Danil1.1. Respiratory Medicine Department, University of Thessaloniki, Thessaloniki, Larissa, Greece.2. Gene and Cell Therapy Division, Biocampus of Athens, Athens, Greece

Background: Tuberculosis (TB) is characterized by the formation of granulomas. Myeloid Differentiation factor (MyD)88 is the common adaptor molecule that communicates the Toll-like receptor (TLR) engagement on the cell surface to intracellular events. TLRs are extracellular receptors that recognize specific molecular patterns found in a broad range of microbial pathogens, triggering inflammatory responses. There is evidence that MyD88-/- animals fail to form granulomas, while animal studies indicate that MyD88 signalling pathway is crucial for the control of M.tuberculosis infection.

Objectives: We hypothesize that a defect in MyD88 pathway results in increased susceptibility of M. tuberculosis infection through reduced immune response following the recognition of the microorganisms by TLR proteins. To this end we analyzed SNPs in the MyD88 gene.

Methods: 93 TB patients with culture-proven or sputum-positive microscopy active TB and 92 controls were analyzed for the following SNPs: MyD88 -938C>A and MyD88 1944C>G.

Results: The MyD88-938CA genotype is associated with an increased risk of developing TB with an Odds Ratio (OR) of 2.62 (95% Confidence Intervals [CI] 1.35-5.22, p=0.006) while the MyD881944CC genotype is associated with an increased risk of developing TB (OR: 4.83 [95% CI]: 1.86-12.52, p=0.001).

Conclusions: The results indicate that the MyD88-938CA and the MyD881944CC genotypes may be associated with increased M tuberculosis infection susceptibility. Since the TB population has been in contact with M tuberculosis but only 10% of them will develop an active infection, our findings provide important insights regarding tuberculosis development.

P1816

NALP3 and CARD8 genetic polymorphisms and antibacterials-drugs induced hepatitis

Sang-Heon Kim1, Hyun Jung Kwak1, Ho Joo Yoon1, Dong Ho Shin1, Sung Soo Park1, Sang-Hoon Kim1, Youn-Seup Park1, Jae-Seok Park1, Young Kou Iees1.1. University College of Medicine, Seoul, Republic of Korea; 2. Department of Internal Medicine, Eulji University School of Medicine, Seoul, Republic of Korea; 3. Department of Internal Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea

Backgrounds: Genetic susceptibility to the development of antibacterials drugs (ATD)-induced hepatitis is poorly understood yet. The NALP3 inflammasomes, which sense danger signals and produce IL-1β, may contribute to the initiation of inflammatory response and ATD-induced hepatitis. We examined if the polymorphisms in NALP3 inflammasome genes (NALP3 and CARD8) are associated with ATD-induced hepatitis.

Methods: We enrolled 80 patients with ATD-induced hepatitis and 238 ATD-tolerant patients. DNA was isolated from whole blood and genotyped for the single nucleotide polymorphisms (SNPs) in NLRP1 and CARD8. Genotype frequencies of SNPs and haplotypes were compared between patients with ATD-induced hepatitis and ATD-tolerant patients.

Results: OR seven SNPs of NALP3 (rs35829419, rs40612666, rs10754558, rs4353135, rs55466866, rs72653577 and rs10733113), there was no significant association with ATD-induced hepatitis. Analysis of NALP3 haplotypes found no significant relationship with ATD-induced hepatitis. C10X of CARD8 (rs2043221) was not associated with the risk of ATD-induced hepatitis.

Conclusions: These findings indicate that NALP3 and CARD8 genetic polymorphisms are not associated with the development of ATD-induced hepatitis in Korean population, and suggest that NALP3 inflammasome does not play important roles in the pathogenesis of ATD-induced hepatitis.

P1817

Mutations of the gyrA gene of mycobacterium tuberculosis leading to XDR tuberculosis in Kyrgyz Republic

Jainagul Isakova, Nurmira Sovhozova, Almaz Aldashev. Molecular and Cell Biology, Institute of Molecular Biology and Medicine, Bishkek, Kyrgyzstan

In the treatment of multidrug-resistant tuberculosis (MDR) the second line drugs are prescribed and among them the most ones are fluroquinolones. But the emergence problem of the recent years is the development of fluoroquinolone resistance or XDR tuberculosis. The XDR is associated with mutations in the gyrA gene which controls the proliferation of M.tb.

Aim: Analysis of mutations of the gyrA gene of M. tuberculosis (M.Tb) strains from patients of penitentiary system and civilian hospitals of Kyrgyz Republic.

Materials and methods: Sputum samples of 79 pulmonary tuberculosis (TB) patients were analyzed by biochip assay to detect the gyrA mutations of M.tb. From all samples the 33 sputum samples were taken from patients in the penitentiary system and 46 sputum samples were taken from patients in the civilian sector.

Results: M.tb resistant to fluoroquinolone were found in 8.7% of TB patients from the civilian sector and in 6% of TB patients from the penitentiary system which gives the resistance to fluoroquinolones of about 7.6% in general TB patients subpopulation. The detailed analysis of the mutations of gyrA gene revealed its location mainly in codons 90 and 94. The most frequent mutations was Asp94Gly (66.6%) but it was Ala90Val (16.6%). One case had the combination of both mutations Asp94Gly and Ala90Val.

Conclusion: In XDR tuberculosis patients from Kyrgyz Republic the resistance of M.tb to fluoroquinolones is mainly caused by Asp94Gly and Ala90Val mutations of gyrA gene.

P1818

Novel sequence-based assay for detection of pyrazinamide-resistant mycobacterium tuberculosis in clinical specimens from patients with pulmonary tuberculosis in Russia

Maria Alvarez Figueroa1, Maria Gordukova2, Galina Lobashova1.1. Department of Molecular Diagnostics and Epidemiology, Central Institute of Epidemiology, Moscow, Russian Federation; 2. Microbiological Laboratory, 7th Clinical Hospital for Tuberculosis, Moscow, Russian Federation

Pyrazinamide (PZA) is an important first-line antituberculous drug used in all regimens recommended by the WHO. However PZA susceptibility testing is not routinely performed in many laboratories so comprehensive surveillance studies of pyrazinamide resistance are rare. The aim of our study was to determine the occurrence of PZA-resistant M.tuberculosis. We developed the diagnostic kit based on direct sequencing of the gyrA gene that was expected to detect all type of mutations. We have examined 143 respiratory specimens obtained from 140 Russian patients with pulmonary tuberculosis. All patients have been classified into 5 groups depending on duration of treatment. The first group consists of patients with newly diagnosed tuberculosis who did not receive antituberculous drugs previously or only a few months ago. The second group included patients from 1 to 3 months of such treatment. PZA-resistance has been found in 9 (10.3%) cases from 87 patients of the first group. The frequency of PZA-resistance of patients from the second group has been amounted to 41.6%. In half of these cases we found heterogeneous populations of bacilli consisted of wild and mutation types. PZA-resistant strains were detected in 7 (36.8%) of 19 patients from the third group with a duration of treatment from 3 to 6 months, in 6 (75.0%) of 8 patients with a duration of treatment from 6 to 9 months, and in 4 (80.0%) of 5 patients receiving antituberculous drugs from 9 to 12 months. These data suggest that the sequencing assay may be useful for the direct and rapid detection of PZA-resistant M.tuberculosis in clinical specimens.

P1819

Results of spoligotyping of M. tuberculosis strains isolated in Belarus

Aksana Zalutskaya1, Maria Wijkander2, Alena Skrahina1, Sven Hofnner2.1. Laboratory, National Research and Practical Centre for Pulmonology and TB, Minsk, Belarus; 2. Department of Preparedness, Swedish Institute for Communicable Disease Control, Solna, Sweden

Introduction: Multidrug resistant tuberculosis (MDR-TB) is a severe threat to effective TB-control as well as to successful treatment of the individual patients. The reported incidence of MDR-TB in Belarus is somewhat lower than in its neighboring countries, but the level of MDR-TB causes severe obstacles for the national TB program.

Objective: To characterize MDR-TB and pan-susceptible M tuberculosis clinical isolates from TB patients in Belarus with a duration of treatment from 3 to 6 months, in 6 (75.0%) of 8 patients with a duration of treatment from 6 to 9 months, and in 4 (80.0%) of 5 patients receiving antituberculous drugs from 9 to 12 months. These data suggest that the sequencing assay may be useful for the direct and rapid detection of PZA-resistant M tuberculosis in clinical specimens.

Materials and methods: Sputum samples of 79 pulmonary tuberculosis (TB) patients were analyzed by biochip assay to detect the gyrA mutations of M.tb. From all samples the 33 sputum samples were taken from patients in the penitentiary system and 46 sputum samples were taken from patients in the civilian sector.

Results: M.tb resistant to fluoroquinolone were found in 8.7% of TB patients from the civilian sector and in 6% of TB patients from the penitentiary system which gives the resistance to fluoroquinolones of about 7.6% in general TB patients subpopulation. The detailed analysis of the mutations of gyrA gene revealed its location mainly in codons 90 and 94. The most frequent mutations was Asp94Gly (66.6%) but it was Ala90Val (16.6%). One case had the combination of both mutations Asp94Gly and Ala90Val.

Conclusion: In XDR tuberculosis patients from Kyrgyz Republic the resistance of M.tb to fluoroquinolones is mainly caused by Asp94Gly and Ala90Val mutations of gyrA gene.

First experience with novel molecular diagnostic method for detection of M. tuberculosis and rifampicin resistance
Andrei Garbo1, Alvils Krami1,2, Līga Kukša2, Diana Dussacka1, Girts Skendera4, Jelena Storozenko3,4. 1Faculty of Medicine, University of Latvia, Riga, Latvia; 2Clinic of Tuberculosis and Lung Disease, Infectology Center of Latvia, Riga, Latvia; 3Bacterial Infection Molecular Biology Department of Laboratory, Infectology Center of Latvia, Riga, Latvia; 4Mycobacteriology Department of Laboratory, Infectology Center of Latvia, Riga, Latvia

Latvia has middle level notification rate of tuberculosis (TB) and ranks among 27 countries with the highest level of multi-drug resistant TB.

Aim: To explore the sensitivity of a newly available molecular diagnostic method GeneXpert® (GX) in early detection of M tuberculosis (MT) and rifampicin (RIF) resistance.

Methods: Retrospective case control study. 360 respiratory samples (sputum and/or bronchial washings) from 320 subjects were tested with GX from 13/07/2010 (introduction of the method) till 01/11/2010. New pulmonary TB cases were analyzed.

Results: 100 patients had new pulmonary TB. GX was positive in 68 cases, matching in 3 cases also with MGIT® method (results available in 80 and 24 days respectively). In 6 cases out of 14 (40%) when RIF resistance detection concurred with LJ resistance, GX was positive in 9 cases (90%).

2 patients with negative LJ culture were GX positive. Resistance of MT against RIF on LJ media were detected in 14 cases and matched in 3 cases also with MGIT® method (results available in 80 and 24 days respectively).

Conclusions: GeneXpert® improves the diagnostic of pulmonary TB and allows faster detection of RIF resistance.

A new integrated PCR and microarray lab-on-chip for rapid MDR tuberculosis diagnosis
Daniela M. Cirillo1, Andrea M. Cabibbe1, Paolo Miotto1, Elisa Lazzari1, Francesco Santoro3, Irina Kontseva1, Vladimir Nikolayevsky4, Gianni Pozzi2, Stefan Niemann1, Francis Dobrniowski5. 1Emerging Bacterial Pathogens Unit, Division of Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milan, Italy; 2Laboratory of Molecular Microbiology and Biotechnology (LAMMB), Department of Molecular Biology, University of Siena, Siena, Italy; 3Samara Oblast TB Service, Samara, Russian Federation; 4Queen Mary and Westfield College, University of London, London, United Kingdom; 5Molecular Mycobacteriology Group, National Reference Center for Mycobacteria, Forschungszentrum Borstel, Borstel, Germany

Introduction Drug-resistant M. tuberculosis (Mt) strains are a threat to tuberculosis (TB) control worldwide and more advanced, fast and affordable technologies are needed to strengthen laboratory capacity for diagnosis of multidrug resistant (MDR) cases.

Aims: The aim of the study is to develop a new rapid diagnostic tool for MDR-TB using a lab-on-chip (LoC) platform suitable for testing other poverty related diseases.

Methods: The LoC (In-Check™) provides an all-in-one device for fast amplification of target DNA followed by hybridization on a low-density microarray. Mt and most of the clinically relevant mycobacterial species are identified by specific probes targeting the 16S rRNA gene and IS6110. A multiplex PCR was developed to amplify rpOlb, katG, and inhA as the most frequently mutated genes involved in resistance to rifampin and isoniazid in species belonging the Mt complex.

Results: The In-Check™ platform was evaluated on isolates and smear positive clinical specimens. Selected probes allowed identification of Mt complex, and 10 clinically relevant non-tubercular mycobacterial species, including M. avium and M. intracellulare. The assay detects the following mutations involved in drug resistance: D516V, S531L (rpoB), S315T (katG), and c-153, t-8a, t-8c (inhA). Other mutations at codons 533, 526, (rpOlb), and 315 (katG) are identified by a negative signal from wild-type probes. Detection limit is 10³ bacteria/mL.

Conclusions: The In-Check™ platform represents an innovation for its simplicity of use, rapidity and cost-effectiveness and it is particularly suitable for different diagnostics purposes. This is the first device for molecular detection of malaria and TB on the same platform.

P1823

PCR for diagnosis of tuberculosis and pulmonary mycoses in México
Rubén Garrido1, Elisa Barrera2, Karla Cabada2. 1Department of Neurology and Thoracic Surgery, Specialty Medical Center, Ciudad Juárez, Chihuahua, Mexico; 2Institute of Biomedical Sciences, Autonomous University of Juarez, City, Ciudad Juárez, Chihuahua, Mexico

Introduction: Tuberculosis (TB) and pulmonary mycoses are a public health problem in the north of Mexico. We use polymerase chain reaction (PCR) for diagnosis of TB in patients with a negative bacilloscopy. This method also allows us to differentiate between other Mycobacterium and macroorganisms like the case of Histoplasma capsulatum, Coccidioides immitis and Aspergillus fumigatus.

Objective: The identification of Mycobacterium tuberculosis in patients showing clinical and radiological findings with negative bacilloscopies and its association with pulmonary mycoses.

Methods: Symptomatic patients with high pulmonary TB probability were selected by a complete physical exam, clinical history, thoracic x rays and bacilloscopy. In patients with a negative bacilloscopy an sputum sample was taken or a Bronchial-alveolar lavage to identify the presence of Mycobacterium, Histoplasma, Coccidioides and Aspergillus by PCR. Adequate treatment was administered according to the results obtained.

Results: A total of 23 patients were analyzed. The presence of Mycobacterium tuberculosis was found in 9 cases. In 5 subjects there was of Aspergillus fumigatus and in 4 cases of both. In 2 cases the presence of Mycobacterium tuberculosis, Histoplasma capsulatum, Coccidioides immitis were associated. Three samples were negative for all those microorganisms.

Conclusions: PCR’s sensibility and specificity increases the diagnosis of TB and mycoses cases. It is a magnificent tool when bacilloscopy is negative generating the need for use in the everyday medical practice. The use of innovative techniques for early diagnosis and treatment of frequent pulmonary disease in this region is imperative.

P1824

Relationship between rpOlb mutations and minimum inhibitory concentrations of rifampicin in multi drug resistant strains of mycobacterium tuberculosis
Shashikant Vaidya1, Vidyagouri Shinde2, Rupendra Jadhav3, Shreyasi Mulye4, Abhay Chowdhary5, Mohan Kulkarni1, Geeta Kopparkar4. 1Department of Microbiology, B.Y.L.Nair Charitable Hospital and T. N. Medical College, Mumbai, Maharashtra, India; 2Department of Immunology and Molecular Microbiology, Blue Peter Research Centre, Lepra Society India, Hyderabad, Andhra Pradesh, India; 3Department of Molecular Biology, Stanley Brown Laboratory, The Leprosy Mission, Delhi, India; 4Quality Control Department, Haffkine Bio-Pharmaceuticals Corporation Limited, Mumbai, Maharashtra, India; 5Director, Haffkine Institute for Training, Research and Testing, Mumbai, Maharashtra, India

Introduction: Rifampicin (RF) resistance serves as a surrogate marker for detection of multi drug resistant (MDR) strains of Mycobacterium tuberculosis (MTB). Among many mutations identified in rpOlb gene, the target gene for detection of RF resistance, few were verified by molecular genetic methods.

Federa...
Aim: To detect and characterize mutations in rpoB region of MDR MTB strains by automated DNA sequencing. To study the relationship between in vitro Minimum Inhibitory Concentrations (MIC) for RF and rpoB mutations.

Methods: Absolute concentration method was used to determine MIC of RF for 20 strains of MDR MTB strains. DNA sequencing was carried out in an ABI sequencer.

Results: We could detect point mutations in the 81 bp section of “a hot spot” region of the rpoB gene of all the MDR strains. Mutations were detected in positions 516,526 and 531, with frequencies of 30%, 40%, and 55%, respectively. It was found that mutations in positions 526 and 531 conferred high-level resistance to RF (MIC’s ≥ 128 μg/ml). Mutations in positions 516 relate to low-level resistance. (MIC’s ≤ 64 μg/ml).

Double point mutations in 2 isolates in positions 526 & 531 and 1 isolate in position 516 & 531 relate to high level resistance (MIC’s ≥ 128 μg/ml), while 2 isolates in position 516 & 526 relate to low level resistance (MIC’s ≤ 64 μg/ml).

Conclusion: A relationship between susceptibility to RF and alterations in rpoB gene is observed. However, relationship between gene alteration and drug-resistant phenotype is still unclear, further analysis of the relationship between MICs and gene alteration is necessary.

P1825
Hair-analysis for acetyl-isoniazid/isoniazid ratio and N-acetyl-transferase-2-genotype in patients on treatment for mycobacterium tuberculosis infection
Michael Eisenhut1, Detlef Thieme 2, Dagmar Schmid 3, Sybille Luederwald 3

Tuberculosis infection N-acetyl-transferase-2-genotype in patients on treatment for mycobacterium tuberculosis infection. Hair-analysis for acetyl-isoniazid/isoniazid ratio and P1825 gene alteration is necessary.

A relationship between susceptibility to RF and alterations in rpoB gene is observed. However, relationship between gene alteration and drug-resistant phenotype is still unclear, further analysis of the relationship between MICs and gene alteration is necessary.

Background: In the presence of non-compliance, drug malabsorption or widely spaced intermittent therapy genetically determined faster acetylation of isoniazid has been shown to lead to treatment failure and relapse. Hepatotoxicity and peripheral neuritis are associated with slow acetylation of isoniazid. Objectives were to investigate what determines hair-levels of isoniazid and to assess whether acetylator phenotype in form of the isoniazid/acetylisoniazid ratio in hair reflects N-acetylnicotinase – 2 (NAT-2) genotype.

Patients and methods: Hair was obtained from patients on isoniazid treatment. Isoniazid and acetyl isoniazid levels in hair were determined using HPLC/MS. Isoniazid and acetylisoniazid ratios were correlated with genotype of the NAT-2 determined by PCR. Hair levels of isoniazid were related to age, gender, weight, body mass index (BMI) and ethnic group.

Results: Hair levels of isoniazid and acetyl isoniazid were measured in 40 patients and genotype determined in 24. Hair levels of isoniazid correlated significantly with age and weight (p<0.05), but not with BMI or ethnic group. Acetylisoniazidisoniazid ratios were with a median of 15.2% (range 14.5 to 31.7, n=3) in homozygous rapid acetylator NAT-2 genotype and 37.3% (range 1.7 to 51.2, n=7) in the heterozygous rapid acetylator NAT-2 genotype both significantly higher than in the slow acetylator NAT-2 genotype with 5.8% (range 0.3 to 14.4, n=14).

Conclusion: Measured acetylation rates reflect NAT-2 genotype. Treg numbers in both healthy and asthmatic patients were analysed by multi-colour flow cytometry to quantify the CD4+CD25+FoxP3+ Tregs. Mild asthma patients had more CD4+CD25+FoxP3+ Tregs (6.1±2.6 in BAL and 3.9±1.6 in blood, but no difference between the prevalence in BAL lymphocytes from both groups was observed. RV16 provocation did not affect the CD4+CD25+FoxP3+ Treg numbers in blood and BAL in either patients with mild asthma or healthy controls. Conclusions: There is a higher number of CD4+CD25+ cells expressing FoxP3+ in peripheral blood of mild allergic asthma patients. Rhinovirus challenge did not have an impact on PBMC and BAL Treg numbers in both healthy and asthmatic individuals.

P1827
Pulmonary dendritic cells from chronic obstructive pulmonary disease patients suppress lung immune responses through induction of regulatory T cells
M. Tsoumakidou1,2, S. Tsoula3, E. Litsiou1, N. Panagiotou1, A. Panagiotou1, M. Konstantinou3, K. Patoris1, C. Roussos1, G. Xanthoulou1, S. Zakynthinos1

1 Lang Immunobiology, Thaurus, Athens, Greece; 2Cellular Immunology, Biomedical Research Foundation, Athens, Greece; 3Thoracic Surgery, Sotira Hospital, Athens, Greece

Defective Th immunity is considered to be implicated in the enhanced vulnerability of Chronic Obstructive Pulmonary Disease (COPD) patients to lower respiratory infections and lung cancer. Tolerogenic dendritic cells (DCs) and regulatory T cells (Tregs) are critical in the suppression of Th immunity. The role in COPD is elusive. We hypothesized that pulmonary DCs in COPD exhibit tolerogenic properties and suppress lung Th responses through induction of Tregs CD4+ DCs and CD3+ T cells were isolated from the lungs of COPD patients (n=17), smokers (n=16) and never-smokers (n=4). DC maturation prior and upon LPS exposure were examined. The effects of pulmonary DCs on lung Th cell responses and on the induction of Tregs were investigated. Pulmonary DCs from COPD patients and smokers express decreased levels of co-stimulatory molecules (CD40/80/86) compared to never-smokers at baseline (p<0.01). Upon LPS exposure, only DCs from COPD patients fail to upregulate costimulatory molecules. Pulmonary DCs from COPD patients induce decreased proliferation of autologous lung CD4+ and CD8+ T cells compared to DCs from smokers (p<0.001). CD4+ T cells treated with DCs from COPD patients, but not from smokers, express increased levels of the immunosuppressive cytokine IL-10 (p<0.01) and suppress Th responses in in vitro suppression assays. Our results reveal that lung DCs from COPD patients suppress lung immune responses through induction of Tregs. This novel immunoregulatory circuit has important clinical implications for the enhanced vulnerability of COPD patients to respiratory infections and lung cancer.

T-regulatory cells blood content in patients with asthma exacerbation
Zhannta Antanovich, Vladimir Tsarev, Natalya Goncharova. Propedeutics of Inner Diseases, Belarusian State Medical University, Minsk, Belarus
Background: Regulatory CD4+CD25+ T cells are important components of the immune system homeostasis and impairment of their activity can cause autoimmune diseases and allergy.
Objective: The aim of this study was to evaluate the blood content of naturally occurring T-regulatory cells (nTreg) in patients with different periods of asthma.
Methods: 48 steroid naive asthmatic adults with asthma exacerbation and 48 with asthma remission were randomly selected and 30 matched control subjects were included. All were submitted to detailed clinical history and examination, pulmonary function testing. Investigation of CD4+, CD4+CD25+, CD4+CD25hi lymphocytes in blood was carried out by flow cytometry. nTreg were defined as a fraction of CD4+CD25hi-lymphocytes with a high level of CD25 expression (CD4+CD25hi).
Results: Subjects with asthma exacerbation had significantly lower values of CD4+CD25hi-cells than subjects with asthma remission (1.56 (1.14-1.97)% vs 5.90 (4.96-6.71)%, p<0.001) and controls (1.56 (1.14-1.97)% vs 7.40 (6.41-8.52)%, p<0.001). Subjects with asthma remission had also significantly lower values of CD4+CD25hi-cells than controls (5.90 (4.96-6.71)% vs 7.40 (6.41-8.52%), p<0.001).
Conclusions: CD4+CD25hi-cells blood content is decreased in asthma in comparison with healthy subjects. Blood content of CD4+CD25hi-cells in asthma exacerbation decreases 3 fold and more in comparison with remission and can predict for asthma exacerbation.

Effector and regulatory lymphocytes in asthmatic pregnant women
Lilla Tamasi1, Anikő Bóhász1, Áron Cseh2, Noémi Eszes1, János Rigo Jr.3, Veronika Mülller1, Barna Vásárhelyi2, György Losonczi1. 1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Department of Pediatrics, Semmelweis University, Budapest, Hungary; 31st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.
Asthma is one of the most common diseases that may complicate pregnancy. Asthma and pregnancy show bidirectional interactions with unknown immunological mechanisms. The aim of this study was to evaluate CD4+ regulatory T (Treg), natural killer (NK), NKT, invariant natural killer (iNKT), memory and naive CD4+ T lymphocytes in mild to moderate partially or well controlled persistant asthmatic pregnant patients.
The prevalence of lymphocyte subsets was identified by cell surface markers and intracellular FoxP3 staining, in healthy non-pregnant (HNP; N=15), healthy pregnant (HP; N=33), asthmatic non-pregnant (ANP; N=62) and asthmatic pregnant (AP; N=61) women. Data are given in median and quartiles.
Treg cell prevalence was higher in HP than in HNP subjects (7.82 (5.27-10.24)% vs 1.56 (1.14-1.97)%, p<0.05). The existence of IL-17+ cells in the granulomas also supports the role of Th1 cell responses against mKatG and PPD in sarcoidosis lung and peripheral blood cells. In the present study, IL-17 and IFN-γ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells. In the present study, IL-17 and IFNγ production were evaluated by ELISPOT after stimulation of bronchoalveolar lavage (BAL) fluid and peripheral blood cells.
The higher percentages of cytotoxic T cells in smokers and COPD patients compared to never-smokers (p<0.001). A higher frequency of CD27+CD45RA- cells and a lower frequency of CD27-CD45RA- cells was found in the CD4+ T cell population of COPD current smokers compared to never-smokers and COPD ex-smokers (p<0.005). Smokers with normal lung function had a higher percentage of CD4+CD27-CD45RA+ cells compared to never-smokers (p<0.05).

Conclusions: The higher percentages of cytotoxic T cells in smokers and COPD patients may be related to smoking-induced tissue damage. The increased percentage of central memory cells in COPD smokers suggests an ongoing immune response. Smoking cessation resulted in a normalization of CD4+ central/effector memory cells in BAL, indicating a reversibility of smoke-induced changes.

Background: Characterization of lymphocyte subsets in the lungs of smokers and patients with COPD.

Methods: Bronchoscopy and BAL was performed on 24 never-smokers, 20 smokers with normal lung function and 20 COPD patients (14 smokers and 6 ex-smokers). The frequencies of major lymphocyte subsets and the differentiation status of CD4+ and CD8+ T cells were analyzed by flow cytometry.

Results: There were higher percentages of CD90+ CD8+ T cells in smokers and CD56+ T cells in smokers and COPD patients compared to never-smokers (p<0.001). The observed downregulation of PPAR-alpha in T helper cells may contribute to ongoing inflammation in pulmonary sarcoidosis via failure to repress proinflammatory genes.

Methods: Seventeen sarcoidosis patients and nine healthy controls underwent bronchoscopy with broncoalveolar lavage (BAL) whereby CD4+ T cells and alveolar macrophages (AMs) were sorted by flow cytometry and subjected to real-time PCR analysis for mRNA expression of PPARs. Immunofluorescence staining of BAL cytospin slides with anti-PPAR antibodies was also performed.

Results: PPAR-alpha relative gene expression was significantly downregulated in COPD+ T cells of sarcoidosis patients, but no differences were observed with regard to T cell expression of the other PPARs. PPAR expression in AMs did not differ between patients and controls. No differences were observed between patients with COPD and healthy controls.

Conclusion: The observed downregulation of PPAR-alpha in T helper cells may contribute to ongoing inflammation in pulmonary sarcoidosis via failure to repress proinflammatory genes.

Background: Reduced expression of PPAR-alpha in bronchoalveolar lavage (BAL) differ in COPD patients compared to smokers with normal lung function and never-smokers.

Methods: Bronchoscopy and BAL was performed on 24 never-smokers, 20 smokers with normal lung function and 20 COPD patients (14 smokers and 6 ex-smokers). The frequencies of major lymphocyte subsets and the differentiation status of CD4+ and CD8+ T cells were analyzed by flow cytometry.
Ovalbumin (OVA)-sensitized C57BL/6 mice were exposed intranasally to OVA or PBS on five days and lung tissue was taken 24 h after final allergen exposure. Peribronchial (PB), perivascular (PV) and alveolar (A) tissue was selected from lung tissue sections using Laser Microdissection and Pressure Catapulting technology. Total RNA was extracted and each location was pooled from three OVA/OVA mice. Chemokine gene expression was performed using RT-PCR gene array. Tissue from which the tissue section of an OVA/PBS mouse was used as control and results were expressed as fold change from control. Chemokine ligands for Th1-associated receptors: CCRL1 (CCL2, CCL5, CCL7) and CCR1 (CCL3, CCL4) were increased mainly in a followed back and Pb tissue, while CCRL3 (CCL10) was increased in Pb followed by A and Pb tissue. In Th2-associated CCR8 (CCL8) was mostly highly induced Pb (21-fold) followed by A and Pb tissue. In Th2/Treg-associated CCR4 (CCL17, CCL22) the pattern was A, Pb, Pb, while in Treg/TTh1 CCRL7 (CCL19) was increased mainly in Pb then in Pb but not in A tissue.

Allergen exposure increased gene expression of all Th1, Th2, Treg and Th17 associated chemokines in lung. However, the expression pattern shows differences in both tissue distribution and magnitude, arguing for a high complex local milieu that can regulate T-cell subset distribution.

**T cell specific expression of a short splice variant of the tumor suppressor gene CYLD amplifies the development of allergic airway disease**

Sebastian Reuter, Marc Becker, Nina Dehazd, Helen Martin, Ari Waisman, Michael Stassen, Roland Buhl, Christian Taube. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany. Pulmonary Medicine, III Medical Clinic, Mainz, Germany.

Regulation of transcription factors like NF-kB decides about type and strength of developing inflammatory and immune responses. CYLD acts as a negative regulatory element of NF-kB activation, however the naturally occurring short splice variant CYLD<sup>Δ192</sup> (cCYLD) has positive regulatory properties. An exclusively expression of cCYLD leads to a hyperactive phenotype of dendritic cells (DC) and increased numbers of long living antibody secreting B cells. In the present study we determined the function of cCYLD on T cells in a murine model of allergic airway disease. Following sensitization and challenge towards the model antigen ovalbumin (OVA), wild type (WT) and animals with a T cell specific expression of CYLD<sup>Δ192</sup> (cCYLD) have positive regulatory properties. An exclusively expression of cCYLD leads to a hyperactive phenotype of dendritic cells (DC) and increased numbers of long living antibody secreting B cells.

In the present study we determined the function of cCYLD on T cells in a murine model of allergic airway disease. Following sensitization and challenge towards the model antigen ovalbumin (OVA), wild type (WT) and animals with a T cell specific expression of CYLD<sup>Δ192</sup> (cCYLD) have positive regulatory properties.
234. Phenotyping asthma: a clue for treatments?

Late-breaking abstract: Genome-wide association of GLCCI1 with asthma steroid treatment response
Kei Ohtsu1, Yoko Sak sections, 2Thinichige Harada, Amy Murphy1, Augusto Litonjua1, Blanca Hines1, Christoph Lange1, Ross Lazarus1, Jody Sylvia1, Barbara Klanderger, Qinglian Duan2, Weiliang Qiu2, Tomomitsu Hirota2, Fernando Martinez1, Dave Mauger5, Christine Sorkness6, Stanley Szefler7, Stephen Lazarus4, Robert Lemanske3, Stephen Peters3, John Lima3, Yusuke Nakamura2, Mayumi Tamari2, Scott Weiss1.

Methods: We analyzed change in FEV1 following ICS usage in a small number of patients with asthma, whose mechanisms are currently insufficiently understood. We performed a genome-wide association study (GWAS) in 4,690 adults with asthma. A total of 93 patients and 100% of controls had severe asthma, according to Global Initiative for Asthma (GINA). The GWAS identified 12 independent SNPs significantly associated with ICS response, including 3 associated with GLCCI1. We then assessed the genetic effects of these SNPs by enriching the clinical phenotype.

Results: We identified a significant pharmacogenetic association at rs37973, which was replicated in four independent populations totaling 935 individuals (p<0.0007). This variant maps to the glucocorticoid induced transcript 1 (GLCCI1) gene and is in complete linkage disequilibrium (i.e., perfectly correlated) with rs37973, both are associated with decrements in GLCCI1 expression. In isolated cell systems the rs37973 variant is associated with significantly decreased dexamethasone receptor activity; in pooled data from treatment trials patients with the variant allele have reduced FEV1 response to ICS (pooled p=0.0007). Overall, subjects homozygous for the mutant rs37973 allele had only 0.5% increase on inhaled corticosteroids vs. those homozygous wild type (3.2±1.6% vs. 9.4±1.1%), accompanied by a significantly higher risk of a poor (i.e. lowest quartile) response (OR 2.36, 95% CI 1.54-3.51), with genotype accounting for ~6% of response variability.

Conclusion: A functional GLCCI1 variant is associated with substantial decrements in inhaled glucocorticoid response in asthma.

1872
Frequent exacerbators – A distinct phenotype of severe asthma
Maciej Kupczyk, Shoshila Haque, Roeleind Middelveld, Sven-Erik Dahlén, on behalf of the BIOAIR Study Group. EAAF, IMM, Karolinska Institutet, Stockholm, Sweden

In order to analyse exacerbations, 93 patients with severe asthma (SA) and 76 with mild-to-moderate asthma (MA) were screened and followed up for 1 year in the BIOAIR European multicentre study. Severe asthma has been defined by use of high doses of inhaled corticosteroids (>1000 μg/day of budesonide or equivalent) and despite this treatment at least 1 exacerbation in the year preceding the start of the study. Risk factors for frequent exacerbations (FE) (defined as either ≥2 or ≥3 events/year) were evaluated.

In total, 122 exacerbations were recorded, including 104 events in 52 SA patients (55.9% of SA cohort) and 18 events in 16 MA (22.2% of MA cohort). The average rate of exacerbations was 1.1 events per patient per year in SA and 0.2 events in MA. Significant decrease in PEF values, FEV1, increase in rescue medication use, day and night symptoms during exacerbations were recorded (p<0.05). All FE were found only in SA, not MA group. Jupepar ACQ score, sputum eosinophils≥2%, smoking history, quality of life, and FEV1≥70% were associated with the development of exacerbations in FE defined as ≥2 events/year (odds ratios OR: 5.0, 4.38, 3.8, 2.48, 2.34, respectively, p<0.05). BMI≥25, quality of life, smoking and Jupepar ACQ score were risk factors for exacerbations in FE defined as ≥3 events/year (odds ratios OR: 8.07, 6.7, 4.25, 4.14, respectively, p<0.05). Frequent exacerbators represent a distinct phenotype of severe asthma group. Identification of factors associated with a higher risk of exacerbations enables us to improve the standards of every day care in this subgroup of patients. Supported by EU (QLG1-CT-2000-01185), national funding bodies and the Other Initiative for Severe Asthma Research at KI.

Is hypereosinophilic asthma a specific phenotype of asthma?
Pauline Pradère1, Yurlagui Uzunhan1, Jacques Cadier1, Anne Bergeron-Lafaurie3, Dominique Israël-Biet1, Gilles Garcia1, Stéphane Jouveshomme1, Muriel Varret1, Michel Aubert1, Bruno Crestani1, Camille Taille1, Hôpital Bichat-Claude Bernard, Paris, France; 2Service de Pneumologie, Hôpital Avicenne, Bobigny, France; 3Service de Pneumologie, Hôpital Tenon, Paris, France; 4Service de Pneumologie, Hôpital Antoine Béclère, Clamart, France; 5Service de Pneumologie, CHU Reims Dabos, Poissy, France; 6DIM, Hôpital Lapeyronie, Montpellier, France

Introduction: Blood eosinophilia > 1000/mm3 in patients with asthma should evoke particular forms of the disease, especially Chung-Strauss Syndrome (CSS) and allergic bronchopulmonary aspergillosis (ABPA). Little is known about patients who do not fulfill criteria for these diseases, usually referred as Hypereosinophilic Asthma (HA).

Aim of the study: To describe clinical and functional characteristics of patients with HA and to assess the prevalence of CSS and ABPA in asthma patients with blood hyper eosinophilia.

Methods: Retrospective study of 79 adult asthma patients with blood eosinophils count > 1000/mm3, compared with a control group of 30 asthma patients without blood hyper eosinophilia (<1000/mm3), defined as Non hyperEosinophilic Asthma (NEA).

Results: 90% of patients and 100% of controls had severe asthma, according to GINA. Main characteristics of the 4 groups are available on table 1.

| HA, Hyper eosinophilic Asthma; CSS, Chung-Stauss Syndrome; NEA, Non Eosinophilic Asthma.

Conclusion: When compared with the NEA group, HA seems to represent a subgroup of patients, mostly male, characterized by non atopic disease and high prevalence of nasal polyposis. CSS and HA share many similarities, suggesting an overlap between the diseases in some cases.

1874
Exhaled nitric oxide levels differ between allergic and non-allergic asthma in men, but not in women
Michiyoshi Imaoka. Internal Medicine, Fukuoka National Hospital, Fukuoka, Japan

Introduction: Several studies have shown potential gender specific differences in the pathophysiology and clinical presentation of asthma, whose mechanisms are not fully understood.

Frequent exacerbators represent a distinct phenotype of severe asthma group. Identification of factors associated with a higher risk of exacerbations enables us to improve the standards of every day care in this subgroup of patients. Supported by EU (QLG1-CT-2000-01185), national funding bodies and the Other Initiative for Severe Asthma Research at KI.

321s Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
Aims and objectives: We examined the effect of gender on differences in eosinophilic airway inflammation between steroid-naive adults with allergic and non-allergic asthma.

Methods: The subjects comprised 191 Japanese adults (67 men and 124 women, median [range] age 51 (20-88) years) who were untreated with glucocorticosteroids and during attack-free periods. We used the levels of fractional expired nitric oxide (FeNO) as a marker of eosinophilic airway inflammation. The FeNO concentration was measured using the recommended online method.

We compared the levels of FeNO between patients with allergic and non-allergic asthma separately for men and women.

Results: In 67 men, 49 patients had significantly higher FeNO levels compared with 18 non-allergic patients (53.9±4.6 versus 28.3±18.8 ppb, respectively; \( P<0.005 \); in 124 women, there was no significant difference in FeNO levels between 76 allergic and 48 non-allergic patients (38.0±37.0 versus 33.5±26.3 ppb respectively; \( P=0.4 \)).

Conclusions: Our results suggest that the importance of eosinophils in airway inflammation differs between allergic and non-allergic asthmatics, men and women. Other inflammatory cells than eosinophils alone may play a major role in the pathogenesis in men with non-allergic asthma.

Does systematic assessment improve healthcare outcomes and healthcare utilisation in patients with severe asthma?

Suzanne Regan, Farhana Shor; Markus Hofmann, Andrew Menzies-Gow

1 Respiratory Medicine Division, Royal Brompton Hospital NHS Trust, London, United Kingdom; 2 Respiratory Medicine Division, Imperial College Healthcare NHS Trust, London, United Kingdom

Introduction: The management of severe asthma remains a significant problem in terms of patient symptoms, quality of life, effects of high dose oral corticosteroid therapy and emergency healthcare utilisation. The key to the effective management of severe asthma lies with making the correct clinical diagnosis. A systematic approach to aid effective diagnosis, identify co-morbidities and evaluate adherence was first introduced in 1993 and is now widely used. Little published data currently exists on the longer term benefits of utilising a systematic approach.

Methods: A retrospective audit of 68 patients that underwent a systematic assessment protocol at the Royal Brompton Hospital between April 2009 and March 2010 was performed. The magnitude of improvement in asthma related quality of life, exacerbation frequency, emergency healthcare utilisation and oral corticosteroid requirements was assessed.

Results: The table below represents a selection of demographic data, confirmation of diagnosis, mortality rate, discharge and lost to follow up rates. Further data is being analysed and will be presented at the congress including the outcomes for quality of life, healthcare utilisation and changes to treatment regimes.

Baseline data from systematic assessment of asthma

</tbody>
</table>

Conclusions: Systematic assessment of patients with difficult asthma identifies an alternative diagnosis in 13% of patients and one or more co-morbidity in 58% of patients referred to the difficult asthma service at the Royal Brompton Hospital.

1876

Improvement of asthma control by a concomitant therapy with cineole

Heinrich Worth. Klinikum Fürth, Medizinische Klinik I, Fürth, Bayern, Germany

With its proven mucolytic and anti-inflammatory effects it is hypothesized that cineole as a main constituent of eucalyptus oil, improves asthma control. In a double blind, placebo controlled multi-centre-study 247 patients with symptomatic asthma were randomly administered 3x200 mg of cineole (n=126;mean age, 52.3 years) or a placebo (n=121;mean age,53.5 years), per day as a concomitant therapy over 6 months.

The combined primary outcome measures, which were implemented as a multiple criteria testing process were: improvement of FEV1, asthma symptoms and quality of life (AQLQ). Secondary outcome measures included changes in hypersecretion, various respiratory symptoms, and the use of ICS.

Results: 1 Patients treated with cineol showed significantly more improvements to the multiple testing criteria (i.e. improvement of FEV1,p=0.0398; mean improvement of AQLQ, p=0.0475; symptom score of nocturnal asthma, p=0.0325) as compared to placebo group, (p=0.0027, Wei Lachin test).

2. Secondary outcome measures supported these findings showing reduced dyspnea and cough as well as overall better health condition amongst the cineole treatment group.

3. Adverse events were comparable in both groups.

Conclusion: Concomitant therapy using cineol can lead to improvement in asthma symptoms, lung function and quality of life. This study underlines the fact that cineole actively controls airway inflammation in patients with asthma, and that it is more that simply a mucolytic drug.

1877

Pragmatic controlled trial of azithromycin for asthma in adults

David Hahn, Michael Graumack; Scott Hetzel

1 Family Practice, Dean Clinic, Madison, WI, United States; 2 Family Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, United States; 3 Biostatistics, University of Wisconsin School of Medicine and Public Health, Madison, WI, United States

Background: Macrolides are a novel treatment for asthma.

Methodology: To investigate macrolide effects after treatment.

Methods: Randomized (RAND), placebo-controlled, double-blind parallel group, practice-based trial of azithromycin (AZ), 600 mgm for 3 days, then weekly for 11 weeks or placebo (PLA) with follow up 1 year from randomization. Eligible subjects who declined randomization received open-label (OL) azithromycin.

Results: Compared to RAND, OL subjects had more adult-onset asthma, chronic sinusitis, severe persistent asthma and hospitalizations for asthma. Compared to PLA, OL subjects had significant improvements in asthma symptoms and quality of life (QOL) at 1 year (9 months post-treatment). AZ subjects did not have comparable benefits (Table).

Outcomes at 1 year compared to pretreatment

<table>
<thead>
<tr>
<th>Mean paired difference (SD)</th>
<th>PLA, n=20</th>
<th>AZ, n=29</th>
<th>OL, n=13</th>
<th>P-value, OL v PLA</th>

</tr>
<tr>
<td>QOL</td>
<td>0.40 (1.31)</td>
<td>0.50 (1.01)</td>
<td>1.70 (1.42)</td>
<td>0.155</td>
</tr>
</tbody>
</table>

The proportions of subjects achieving a QOL score change ≥1 unit at 9 months (6 months after finishing treatment) were 22% for PLA, 27% for AZ and 80% for OL (p<0.001 compared to PLA). At 1 year the comparable figures were 21%, 36% and 54% (P=0.072).

Conclusions: OL subjects had severe asthma and persistent benefits, number needed to treat (NNT) = 2 to 4. AZ subjects had milder asthma and did not show benefits. Though this study was not powered to detect the NNT = 7 suggested by some results. Azithromycin should be considered as adjunctive therapy for severe asthma unresponsive to guideline treatments. Larger studies are warranted to confirm results in severe asthma and to explore potential benefits in milder asthma.

1878

Persistent asthma and long-term work disability

Paula Kauppi, Rina Hakola, Timo Lemo, Anna Ojijärvi, Jaana Pentti

1 Tiula Oksanen, 2 Tari Haahrta, 3 Mika Kissian, 4 Jussi Valthera. 1Allergyology, Skin and Allergy Hospital, Helsinki, Finland; 2Organisation and Management, Finnish Institute of Occupational Health, Helsinki, Finland; 3Organisation and Management, Finnish Institute of Occupational Health, Turku, Finland

Background: Mortality in asthma is very low but the disease has effects on quality of life and work ability. Here, the probability of long-term work disability associated with asthma alone or asthma together with chronic comorbidity(ies) was studied.

Methods: A total of 2 332 asthmatic employees in public sector in Finland were used for long-term (≥90 days) work disability. Employees without asthma were used as control subjects (N=66 354) and were adjusted for age, gender, socioeconomic status, type of employment contract and type of organization. Diagnosis of asthma was based on reimbursement for asthma medication granted by the Social Insurance Institution and data on all sickness absences were obtained from national registers. Six main disease categories were used in this study as comorbidity for asthma: depression, ischemic heart disease, diabetes, rheumatic disease, malignancy and hypertention. Diagnoses for comorbidities were based on the reimbursement for disease medication by the Social Insurance Institution.

Results: Asthma increased the risk of all-cause work disability with HR 1.8 (95% CI 1.6-2.1) compared to controls (no asthma). Asthma and one other chronic co-morbidity increased the risk for work disability with HR 2.2 (95% CI 1.8-2.8). Asthma together with two or more other chronic conditions increased the risk with HR 4.5 (95% CI 3.0-6.8). Depression together with asthma increased the risk of long-term work disability threefold compared to those without asthma.

Conclusions: Asthma alone or together with another chronic comorbidity increased the risk of long-term work disability and the risk was especially high for those with asthma and depression.
Assessment of relative regional lung compliance in patients with COPD

Alexandra Morgan1,2, Geoff Parker1,2, Penny Hubbard1,2, David Singh1,3, Jørgen Vestbo1,2, Simon Young1, Eva Bondesson4, Lars Olsson6, Lars Wigsström4, Josephine Naish1,2.

1Imaging Sciences, School of Cancer and Enabling Sciences, University of Manchester, Manchester, United Kingdom; 2The Biomedical Imaging Institute, University of Manchester, Manchester, United Kingdom; 3AstraZeneca, R&D, Alderley Park, Macclesfield, United Kingdom; 4AstraZeneca, R&D, Mölndal, Sweden; 5AstraZeneca, R&D, Alderley Park, Macclesfield, United Kingdom; 6AstraZeneca, R&D, Charnwood, United Kingdom.

Pathologically altered lung mechanical properties are difficult to assess regionally. A method has been developed utilising structural proton MRI in conjunction with post-processing and image registration techniques to provide measures of relative regional lung compliance [1].

This method was applied in 23 COPD patients and 11 healthy controls. Each subject had two supine scans, 1 week apart. Compliance maps were found to be reproducible, with increased spatial heterogeneity seen in patients compared to controls (Figure 1).

Figure 1. Relative regional compliance maps for healthy controls and COPD patients (mapped on log scale).

The gradient of relative compliance from lung apex to diaphragm was calculated. An increased compliance gradient was seen in moderate COPD (p<0.05), with a more significant increase in severe COPD (p<0.001) (Figure 2).

Figure 2. Box plot of relative compliance gradients (found using relative regional compliance and position as fraction of lung length).

The method shows significant differences between COPD patients and healthy controls with areas of altered relative regional compliance indicating likely regions of disease.

Novel ventilation-perfusion ratio measurements in COPD using MRI

Penny L. Hubbard1,2, Geof J.M. Parker1,2, Dave Singh1, Jørgen Vestbo2,3, Eva Bondesson3, Lars E. Olsson5, Lars Wigsström4, Simon S. Young5, Josephine H. Naish1,2.

1Imaging Sciences, School of Cancer and Enabling Sciences, The University of Manchester; 2Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 3The Biomedical Imaging Institute, University of Manchester, Manchester, United Kingdom; 4Airway Pharmacology Group, School of Translational Medicine, University Hospital of South Manchester, Manchester, United Kingdom; 5AstraZeneca, R&D, Charnwood, United Kingdom; 6AstraZeneca, R&D, Lund, Sweden; 7AstraZeneca, R&D, Mölndal, Sweden; 8AstraZeneca, R&D, Alderley Park, Macclesfield, United Kingdom.

We present a novel analysis of oxygen-enhanced (OEMRI) data in COPD that allows quantitative ventilation-perfusion ratio (V/Q) maps to be determined. Representative V/Q maps of: A healthy, B moderate & C severe COPD subjects reveal homogeneous maps for A and considerable heterogeneity in B/C.

Group-average histograms (labelled as above) show a narrow peak in A; the peak broadens and a lower V/Q peak becomes evident in B/C. A high V/Q tail is also seen in C.

OEMRI parameters, enhancing fraction (EF) and interquartile range (IQR) V/Q, show significant differences between A & B/C. Each group had 12 subjects, data averaged over 2 scans. Using a single slice, minimum group sizes to detect a 50% difference of the healthy group window are 27 (EF) & 14 (IQR V/Q).

Power calculations are specific to this implementation of the methods, we envisage improvements with further development.

The results show strong similarities to published literature using more invasive techniques and enable powering of future intervention studies.

Repeatability of MR imaging in chronic obstructive pulmonary disease (COPD)

Sebastian Ley1, Angela Anjorin2, Julia Ley-Zaportniz1, Annette Opgenorth2, Oliver Sedlacek2, Claus-Peter Heussel1, Hans-Ulrich Kaucer2.

1Department of Medical Imaging, University of Toronto, Toronto, ON, Canada; 2Department of Diagnostic and Interventional Radiology, University Hospital of Heidelberg, Heidelberg, Germany; 3Department of Diagnostic and Interventional Radiology, Thoraxklinik at the University of Heidelberg, Heidelberg, Germany.

Purpose: COPD is a broad disease entity defined by PFT, however providing only a global measure of the disease. With the increasing number of therapeutic options, particularly when it is advanced, there is a high demand for a non-invasive imaging test to identify different phenotypes providing regional information on structural and functional changes in order to target therapies accordingly. Recent developments have opened the way for introduction of proton MRI of the lung into the clinical arena. This technique allows for radiation free assessment of the above mentioned issues. So far, no data regarding the repeatability of this technique is available.

Materials/Methods: A comprehensive MR protocol (1.5T) was developed to investigate different aspects of the disease. The protocol consisted of morphological, pulmonary perfusion, cardiac function and respiratory dynamics sequences. Overall, 9 patients (COPD stages IIb/IV) were investigated twice in a 24h interval.

Results: The mean examination time was 64min and all patients tolerated the examination well. Visual evaluation of morphological and perfusion sequences demonstrated a good repeatability of the visualization of the parenchymal loss and perfusion deficits. Quantitative evaluation of flow measurements revealed considerable variations (interexamination difference for the PA flow: 7-64ml). Evaluation of the respiratory dynamics showed a broad variation allowing for no meaningful interpretation.

Conclusions: Overall, the proposed imaging protocol is feasible and applicable even in significantly ill COPD patients. The protocol is easy to use and shows a high repeatability in the key aspects for assessment of morphological and functional disease components.
1882 Ventilation-perfusion mismatch in COPD with or without emphysema: Comparison of structural CT and functional OE-MRI
Weijian Zhang1,2, Penny Hubbard1,2, Eva Bondesson1, Lars Wigstrom1, Simon Young3, Dave Singh4, Geoffrey Parker1,2, Josephine Nash1,2. Imaging Sciences, School of Cancer and Enabling Sciences, University of Manchester; Manchester Great Manchester, United Kingdom; The Biomedical Imaging Institute, University of Manchester, Manchester Great Manchester, United Kingdom; R&D, Astrazeneca, Lund, Sweden; R&D, Astrazeneca, Charnwood, United Kingdom; Medicines Evaluation Unit, University Hospital of South Manchester, Manchester, United Kingdom

Single-slice conoral oxygen-enhanced MRI (OE-MRI) images were acquired in 24 patients with chronic obstructive pulmonary disease (COPD) and 12 healthy subjects, from which color-coded V/Q maps were extracted by pixelwise model fitting. COPD were structurally classified by percentage of low attenuation areas under -950 HU (LAA%) in matched single-slice CT images: LAA%<1%—non-emphysematous COPD; ≤1%—emphysematous COPD, which demonstrates that comparative V/Q mismatch exists in COPD even if there is no emphysema. To explore potentially different structure-function relationship in two COPD types, correlation between CT and OE-MRI parameters was measured. Median V/Q did not correlate with LAA% in COPD. However, inter-quartile range of V/Q, representing the extent of heterogeneity, was fairly correlated with LLA% in emphysematous COPD. However, inter-quartile range of V/Q, representing the extent of heterogeneity, was fairly correlated with LLA% in emphysematous COPD. Nevertheless, V/Q mismatch in COPD gets worse as emphysema increases. However, the correlation was not found in non-emphysematous COPD.

1883 Decline in lung density is accelerated in active smokers
Sahar B. Shaker1, Asger Dirksen1, Pechun Lo2, Lene T. Skovgaard3, Lars Wigstrom1, Marleen de Bruijn3, Jesper H. Pedersen4. 1Dept. of Respiratory Medicine, Gentofte Hospital, Copenhagen, Denmark; 2Dept. of Biostatistics, University of Copenhagen, Copenhagen, Denmark; 3Dept. of Biostatistics, University of Copenhagen, Copenhagen, Denmark; 4Dept. of Thoracic Surgery, Rigshospitalet, Copenhagen, Denmark

This study elucidates that distinction between emphysematous COPD and non-emphysematous COPD does not affect the presence of V/Q imbalance substantially but that the relationship between V/Q and CT measures vary between these two types.

1884 The relationship between airflow limitation and quantitative computed tomographic assessment of air trapping and emphysema
Omo M. Muts1, Keelin Murphy2, Pieter Zanen1, Hester A. Gietsma1, Jan Willem Lammers1, Bram van Ginneken3, Mathias Prokop1,2, Pim A. de Jong1. 1Radiology, University Medical Center Utrecht, Utrecht, Netherlands; 2Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands; 3Pathology, University Medical Center Utrecht, Utrecht, Netherlands; Diagnostic Image Analysis Group, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; Radiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background: Small airways disease and emphysema are the main components of airflow limitation in COPD. The independent contribution of quantitative CT measurements of these components to airflow limitation in COPD is yet unknown.

Purpose: To determine to what extent the combination of quantitative CT measurements of air trapping and emphysema can explain the variance in lung function in a population that covers the total spectrum of airflow limitation.

Methods: We studied 248 subjects (50 without airflow limitation; 50 GOLD 1; 50 GOLD 2; 50 GOLD 3; 48 GOLD 4) with paired inspiratory and expiratory CT (corrected for sex, age and height) the combination of CT emphysema and CT air trapping explained 68% to 83% (p<0.001) for percentage of voxels <−850 Hounsfield units (EXP−850) and FEV1/FVC. In multivariate analysis (corrected for sex, age and height) the combination of CT emphysema and CT air trapping explained 68% to 83% (p<0.001) of the variance in lung function parameters of airflow limitation (FEV1, FEV1/FVC, RV/TLC and Kco).

Results: Quantitative CT measurements were strongly related to airflow limitation, the best univariate R-square value was 0.72 (p<0.001) for percentage of voxels <−850 Hounsfield units (EXP−850) and FEV1/FVC. In multivariate analysis the combination of CT emphysema and CT air trapping explained 68% to 83% (p<0.001) of the variance in lung function parameters of airflow limitation (FEV1, FEV1/FVC).

Conclusion: Quantitative CT air trapping and emphysema measurements are strongly associated with lung function impairment, and when combined they explain a large part of the variance in airflow limitation. Our results may prove useful in automated detection and phenotyping of COPD cases.

1885 Computer modelling and visualisation of the microscopic distributions of hyperpolarized gas diffusivity in models of acinar airways
Juan Parra-Robles, Xiaojun Xu, Jim M. Wild. Unit of Academic Radiology, University of Sheffield, Sheffield, United Kingdom

Diffusion MRI using hyperpolarized gases is sensitive to lung microstructure. Computer simulations used to investigate the relationship between diffusivity (ADC) and airway dimensions are generally limited by non-realistic geometric assumptions (e.g. infinite cylindrical airways). In this work, we use histology sections to generate realistic models of acinar airways that are used in a computer simulation of 3He and 129Xe gas diffusion and 129Xe exchange between gas and tissue.

Results: The different diffusivities of 3He (A) and 129Xe (B) result in different ADC (in cm2/s) distributions.

For 3He, the distribution over the largest airway is nearly uniform due to motional averaging; the best univariate R-square value was 0.72 (p<0.001) for percentage of voxels <−850 Hounsfield units (EXP−850) and FEV1/FVC. In multivariate analysis (corrected for sex, age and height) the combination of CT emphysema and CT air trapping explained 68% to 83% (p<0.001) of the variance in lung function parameters of airflow limitation (FEV1, FEV1/FVC).

Conclusion: Quantitative CT air trapping and emphysema measurements are strongly associated with lung function impairment, and when combined they explain a large part of the variance in airflow limitation. Our results may prove useful in automated detection and phenotyping of COPD cases.
Conclusion: Computer simulation and visualization of maps of microscopic diffusion distributions in realistic acinar geometries have helped provide a better understanding of the length scales and diffusion regimes relevant to hyperpolarized gas lung MRI and may help simplify the development of 129Xe-based MR lung morphometry techniques.

236. The best abstracts in rehabilitation and chronic care 2011 (sponsored by Nutricia Advanced Medical Nutrition)

1886 Late-breaking abstract: Wii Fit™-step is a suitable exercise in rehabilitation programs in patients with COPD: A feasibility study Tanguy Marquette1, Fabien Lassus2, Olivier Castagna2, Daniel D’Amore2, Bruno Escarguel2, Louis Marquette2, 1UMR CNRS 6233 - Institut des Sciences du Mouvement, Université de la Méditerranée, Marseille, France; 2Service de Pneumologie, Centre Hospitalier Intercommunal de Toulon - La Seyne, Toulon, France

Patient with COPD can be involved in pulmonary rehabilitation programs, by using cycle ergometer exercises. They often give up with this exercise either during the program or when they have to manage it themselves. We conducted a randomised double-blind, placebo controlled trial. 59 patients (mean [SD] age 67.9±1.9y, BMI 26.7±4.7) were visited within each session.

Conclusion: There were significant improvements in quadriceps strength, thigh mass & whole-body cycle work following RT. The addition of PS did not augment the functional benefits of RT.

1887 Obstructive lung disease is associated with increased abdominal visceral fat and elevated systemic adipocytokines Bram van den Borst1, Harry Gooker1, Annemarie Koster2, Daisy Janssen1,2,3, Martijn Spruit1, Jos Schols4, Bianca Cox5, Tim Nawrot5, Randall Curtis6, Emiel Wouters1,7. 1Program Development Centre, Cour, Horn, Netherlands; 2CAPHR, Maastricht University, Maastricht, Netherlands; 3Centre for Interdisciplinary Treatment, Proteon Thuis, Horn, Netherlands; 4Department of General Practice, Nursing Home Medicine, Faculty of Health and Life Sciences/CAPHR, Maastricht University, Maastricht, Netherlands; 5Division of Pulmonary, Allergy & Critical Care Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA, United States; 6Medicine, Epidemiology & Biostatistics, University of California, San Francisco, CA, United States

Background: The source of systemic inflammation in clinically stable Obstructive Lung Disease (OLD) is unknown. Visceral adipose tissue (VAT) is related to systemic inflammation. We hypothesized that in OLD subjects a redistribution of VAT area (VAT) was performed successfully matching n=729 non-OLD controls to the cases.

| Status and pack years for the n=2139 subjects, and 3:1 propensity score matching was performed successfully matching n=729 non-OLD controls to the cases. |
|----------------------|----------------------|----------------------|----------------------|----------------------|
| Controls: compared to cases, had greater VAT area (143±47 vs 123±59 cm², p<0.001) and elevated interleukin (IL)-6 (2.16 [1.52-3.34] vs 1.75 [1.20-2.69] pg/ml, p<0.001). Plasma adiponectin Inhibitor-1 (PAI-1) (2.2 [12-37] vs 18 [11-31] ng/ml, p=0.008) and adiponectin (11 [7-16] vs 10 [6-15] μg/ml, p=0.037). Neither whole-body nor appendicular/trunk fat mass were different between cases and controls (p<0.05).

Conclusion: This study shows that OLD patients have greater VAT and elevate systemic IL-6, PAI-1 and adiponectin levels compared to non-OLD controls matched for sex, age, race, BMI and smoking. Greater VAT in OLD may reflect a disturbed metabolic regulation contributing to systemic pathology. Performed within Ti Pharma project T1-2011.

1888 Does protein supplementation enhance the effects of resistance training in patients with COPD? Linxy Houchen1,2, Manoj Menon1, Samantha Harrison1, Carolyn Sandiland2, Michael Morgan3, Sally Singh1,2, Michael Steiner1, 1Institute for Lung Health, Glenfield Hospital, Leicester, United Kingdom; 2Faculty of Health & Life Sciences, Coventry University, Coventry, United Kingdom; 3Respiratory Medicine, University of Leicester, Leicester, United Kingdom

Introduction: Protein supplementation (PS) & resistance training (RT) enhances muscle growth in healthy elderly subjects. Its role in patients with COPD is unknown.

Hypothesis: Adding PS to RT will yield greater increases in function than RT alone.

Method: We conducted a randomised, double-blind, placebo controlled trial. 59 patients (mean [SD] age 67.9±1.9y, BMI 26.7±4.7, FEV1% of the maximal HR on cycle ergometer and at 56.4±9.9% of the maximal HR on cycle ergometer and at 56.4±9.9%) underwent two sessions of incremental exercise to their limit of tolerance first on a cycle ergometer, and then on Wii Fit step game by adjusting the frequency of movements and the step height.

Methods: 265 clinically stable outpatients with COPD, CHF or CRF were visited during follow-up. The odds ratio (95% CI) combining the time and factor effects show CPR and MV preferences changed in 38% of the patients during follow-up.

| Status and pack years for the n=2139 subjects, and 3:1 propensity score matching was performed successfully matching n=729 non-OLD controls to the cases. |
|----------------------|----------------------|----------------------|----------------------|----------------------|
| Controls: compared to cases, had greater VAT area (143±47 vs 123±59 cm², p<0.001) and elevated interleukin (IL)-6 (2.16 [1.52-3.34] vs 1.75 [1.20-2.69] pg/ml, p<0.001). Plasma adiponectin Inhibitor-1 (PAI-1) (2.2 [12-37] vs 18 [11-31] ng/ml, p=0.008) and adiponectin (11 [7-16] vs 10 [6-15] μg/ml, p=0.037). Neither whole-body nor appendicular/trunk fat mass were different between cases and controls (p<0.05).

Conclusion: This study shows that OLD patients have greater VAT and elevate systemic IL-6, PAI-1 and adiponectin levels compared to non-OLD controls matched for sex, age, race, BMI and smoking. Greater VAT in OLD may reflect a disturbed metabolic regulation contributing to systemic pathology. Performed within Ti Pharma project T1-2011.

1889 Stability of life-sustaining treatment preferences of patients with advanced chronic organ failure Daisy Janssen1,2, Martijn Spruit1, Jos Schols3, Bianca Cox4, Tim Nawrot5, Randall Curtis6, Emiel Wouters1,7. 1Program Development Centre, Cour, Horn, Netherlands; 2CAPHR, Maastricht University, Maastricht, Netherlands; 3Centre for Interdisciplinary Treatment, Proteon Thuis, Horn, Netherlands; 4Department of General Practice, Nursing Home Medicine, Faculty of Health and Life Sciences/CAPHR, Maastricht University, Maastricht, Netherlands; 5Division of Environmental Sciences, Hasselt University, Diepenbeek, Belgium; 6Division of Pulmonary & Critical Care Medicine, Department of Medicine, Harbormov Medical Center, Seattle, United States; 7Respiratory Medicine, Maastricht University Medical Center + (MUMC+), Maastricht, Netherlands

Objectives: We aimed to investigate 1-year stability of preferences regarding cardiopulmonary resuscitation (CPR) and mechanical ventilation (MV) of patients with advanced COPD, chronic heart failure (CHF) or chronic renal failure (CRF), and to identify clinical determinants associated with these preferences.

Methods: 265 clinically stable outpatients with COPD, CHF or CRF were visited at baseline and every 4 months for 1 year, to assess preferences for CPR and MV. Generalized estimating equations were used to study the association between preferences and several potential predictors including co-morbidities, hospital admissions, health status (EQ5D), care dependency (CDS), mobility, depression (HADS-D) and anxiety (HADS-A).

Results: 78% of the patients completed 1 y follow-up (64% men; mean [SD] age: 67 (13) yrs). CPR and MV preferences changed in 38% of the patients during follow-up. The odds ratio (95% CI) combining the time and factor effects show...
an association between preference for CPR and change in EQ5D (+1 pt; OR 1.7 (1.2-2.5)), CDS (+9 pt; OR 1.5 (2.1-2.9)), HADS-D (+5 pt; OR 0.5 (0.3-0.9)) and change in marital status (single vs. living with partner: OR 0.5 (0.3-0.9)), and an association between preference for MV and change in EQ5D (+1 pt; OR 1.5 (1.1-2.2)), CDS (+9 pt; OR 1.5 (1.1-1.9)) and HADS-D (+6 pt; OR 0.6 (0.4-0.8)).

Conclusions: More than a third of outpatients with advanced COPD, CHF or CRF changed their preferences regarding CPR and/or MV during 1 year at least once. Regular re-evaluation of advance care planning is necessary when patients experience a change in health status, care dependency, mood status or marital status.

1890 Effect of resistance training during hospitalization in the systemic inflammation, functional capacity and muscle strength in COPD patients

Rodrigo Borges1,2, Celso R.F. Carvalho1,2 * 1Physical Therapy Department, School of Medicine, University of Sao Paulo, Sao Paulo, Brazil; 2University Hospital, University of Sao Paulo, Sao Paulo, Brazil

Background: Resistance training (RT) during hospitalization improves skeletal muscle strength; however its effect on systemic inflammation and to modify the level of activity remains unknown.

Objective: Our aim was to evaluate the effect of RT in the systemic inflammation and functional capacity in COPD patients during and after hospitalization.

Methods: Twenty nine out 102 patients hospitalized due to COPD exacerbation were randomly assigned to either Control (CG) or RT (RTG) groups. They were evaluated on the 2nd day of hospitalization, at hospital discharge and after 30 days. It was evaluated systemic inflammatory markers (TNF-α, RCP, IL-1β, IL-12p70, IL-6, IL-8) level of physical activity, health-related quality of life (HRQL), and upper and lower limbs muscle strength.

Results: Patients from RTG showed an improvement in the lower limb muscle strength, in the six-minute walking test (6MWT) and in all domains of HRQL (p<0.001). In contrast, CG showed a reduction in the lower limb muscle and 6MWT and a worsening in the HRQL. None of the differences between groups was observed in the systemic inflammatory markers analyzed during hospitalization and after 30 days of hospital discharge. In addition, most patients from both groups remained physically inactive (70%) in the hospital and at home.

Conclusion: Our results suggest that resistance training during hospitalization improves lower limbs muscle strength, health-related quality of life and physical capacity; however does not change either systemic inflammatory levels or physical activity during or after hospital discharge.

Supported by FAPESP

1891 Effects and feasibility of different types of endurance training in patients with end stage lung disease before lung transplantation

Rainer Gloeckl1, Bianca Weber-Lange1, Martin Halle1, Klaus Kenn1, 1Department of Pulmonary Rehabilitation, Schoen Klinik Berchtesgadener Land, Schlossau am Koenigssee, Bavaria, Germany; 2Center for Prevention and Sports Medicine, Technische Universitaet Muenchen, Munich, Bavaria, Germany

Objective: Aim of this study was to compare the effects and the feasibility of continuous moderate endurance training (CT) versus high-intensity interval training (IT) in patients with end-stage COPD before lung transplantation (pre-LTx) during a specialized 3-week in-patient pulmonary rehabilitation programme.

Methods: 60 lung transplant candidates (age: 53.5±5.6 yrs; FEV1 pred. 24.9±7.9%) performed up to 15 training sessions within 3 weeks randomised either to Control (CG) or RT (RTG) groups. They were evaluated on the 2nd day of hospitalization, at hospital discharge and after 30 days. Chronic respiratory questionnaire (CRQ), and inflammatory biomarkers (hsCRP, TNF-α, IL-6, IL-8) were evaluated before and 12 week after hospital discharge.

Results: CT as well as IT can significantly improve exercise capacity in pre-LTx patients. IT seems to be better tolerated, expressed by a lower grade of dyspnoea and significantly better feasibility of the exercise protocol.

In conclusion, vitamin D deficiency was significantly associated with higher drop out rates from PR and there was a tendency towards a poorer improvement in E SWT.

1892 Vitamin D status in patients with COPD who participate in pulmonary rehabilitation (PR): Characteristics and effects of PR

Thomas Ringbaek, Jane Theoegersen, Gerd Martinez, Peter Lange 1Department of Physical Therapy, Akita City General Hospital, Akita, Japan; 2Department of Physical Therapy, Akita University Graduate School of Health Sciences, Akita, Japan; 3Department of Nutrition Research, Food Science Institute Meiji Dairies Corporation, Odawara, Kanagawa, Japan; 4Department of Respiratory Medicine, Akita City General Hospital, Akita, Japan

Purpose: This study was conducted to investigate the effect of nutritional support using whey protein-rich supplement which has an anti-inflammatory effect on exercise performance and QOL, and systemic inflammation in stable COPD.

Methods: Thirty-six patients with stable COPD (mean (SD) age 77.2±5.8yrs, FVC 2.70±0.72L, FEV1 1.10±0.44L, predicted PEV 44.5 (16.2%)), FEV1/FVC 44.5 (16.9%) were studied. COPD patients under continuing pulmonary rehabilitation (PR) were randomly divided into a nutrition group and a control group (education only). In nutrition group whey protein-rich supplement (400 kcal/day) was supplied for 12 weeks. Whey protein, a protein complex derived from milk, has been shown to have a strong anti-inflammatory effect in vitro. PR program consisted of respiratory muscle (RM) stretch gymnastics, RM training, breathing retraining, 3-week wall mobilization, and chair exercise. Lung functions, six-minute walking distance (6MWD), chronic respiratory questionnaire (CRQ), and inflammatory biomarkers (hsCRP, TNFα, IL-6, IL-8) were evaluated before and 12 week after nutritional intervention.

Results: In the nutrition group, inflammatory markers decreased significantly (hsCRP, 2.7 (3.4) vs 1.5 (2.0)mg/L (p<0.001), TNFα, 1.2 (0.4) vs 1.2 (0.4)pg/ml, IL-6, 2.7 (4.1) vs 2.2 (1.1), IL-8, 2.0 (1.3) vs 1.1 (1.1)pg/ml (p<0.01)). 6MWD increased significantly from 322 (183) to 368 (182)m (p<0.01). The total values of CRQ also increased from 103 (16) to 109 (17).

Conclusions: We conclude that anti-inflammatory nutritional support using whey protein-rich supplement might enhance exercise capacity and QOL in stable COPD by improving systemic inflammation.
Tuberculin skin testing (TST) may be compromised by immunodeficiency. We performed direct comparisons between tests in immunocompromised patients.

Background: The incidence of tuberculosis (TB) in The Netherlands is partly driven by disease progression of unidentified TB infection (LTBI) in immigrants. Screening newly arriving immigrants for LTBI with the Quantiferonγ2 Gold In-Tube (QFT-GIT) might be a promising intervention.

Aims and objectives: To estimate the risk for progression to active tuberculosis within two years of entry in newly arriving immigrants with a positive QFT-GIT response.

Methods: In a case-based design, we determined the prevalence of positive QFT-GIT responses among a random sample of 1375 immigrants newly arrived during 2009-2011 (the base). Active tuberculosis patients (cases) within two years after entry were extracted from the Netherlands Tuberculosis Register from a cohort of immigrants arriving in 2006. We assumed a QFT-GIT sensitivity of 90% and no tuberculosis transmission occurred after entry.

Results: Among the 1369 immigrants with valid QFT-GIT responses, overall 20% were positive. Stratified by low (<100/100,000), middle (100-200/100,000) and high (>200/100,000) tuberculosis incidences in person’s region of origin, QFT-GIT positivity was 16%, 24% and 26%, respectively. The risk for progression to disease per 100,000 newly arriving immigrants from low, middle and high incidence regions was 347 (95% CI: 75-1185), 398 (86-1355), and 801 (132-2942), respectively, if QFT-GIT positive, compared to a risk of disease of 7 (0-113), 14 (0-212), and 31 (0-491) per 100,000 if QFT-GIT negative.

Conclusion: Newly arriving immigrants with a positive QFT-GIT response have a significant risk of progression to TB within two years of entry, even immigrants from low incidence regions. QFT-GIT offers added-value in the immigration screening program.

The superior sensitivity of IFNy release assays (IGRAs) in diagnosing LTBI above tuberculin skin testing (TST) may be compromised by immunodeficiency. We performed direct comparisons between tests in immunocompromised patients.

IGRAs (T-SPOT/QFT) and TST were performed on clinical data on drugs and TB exposure were collected. Interim results from 193 organ transplant patients and 204 patients with rheumatoid arthritis (RA) are presented.

In transplant patients, 80% had results for all 3 tests, which were less often positive for TST (11.7%) than for T-SPOT (20.8%) and QFT (15.6%, p = 0.018). Agreement was substantial between IGRAs (κ=0.61), and only fair between IGRAs and TST (κ=0.22, T-SPOT; 0.34, QFT). All 3 tests were more often negative despite TB risk factors in patients <1 year post transplant as compared to patients ≥1 year. In RA patients, 91% had result for all 3 tests, which were positive in 36.9% (TST), 26.3% (T-SPOT), and 24.2% (QFT, p<0.001). Agreement was only fair between IGRAs and TST (κ=0.29, T-SPOT; 0.33, QFT) and substantial between IGRAs (κ=0.77). The correlation between QFT and TST was 0.93. The Area Under the ROC curve was comparable 0.89-0.91 for both. The correlation between filter paper and plasma IP-10 was very high (r=0.93). The Area Under the ROC curve was comparable 0.89-0.91 for both IP-10 tests and IFNy and the 3 tests had comparable sensitivity and specificity 74.7%, 78.1% and 100%, respectively (and n.s. differences).

Conclusion: Plasma from M.tb. antigen stimulated blood can be dried on filter paper and transported over long distances at ambient temperature before analysis. Compared to the currently available TST, the filter paper assay allows for high throughput centralized analysis, and could increase the dissemination of specific tests for LTBI in resource restraint settings where IGRAs as we know them today are too complicated to do.
1899

Bifunctional T cells allow for discrimination between latent and active tuberculosis

Barbara Kalsdorf1,2, Paulin Essone1, Nol V. Chegou1, André Loxton1, Daleen Kriel1, Volkmar Schöllhorn2, Martin Ernst2, Christopher Lange2, Gerhard Walzl1. 1Division of Molecular Biology and Human Genetics, University of Stellenbosch, Tygerberg, South Africa; 2Division of Clinical Infectious Diseases, Research Center Borstel, Borstel, Germany; 3MID Autonomin Diagnostika GmbH, Strassberg, Germany; 4Immune Cell-Analytics, Research Center Borstel, Borstel, Germany

Introduction: The diagnosis of active tuberculosis remains challenging especially in a high tuberculosis incidence country as South Africa. We propose that further knowledge on the Mycobacterium tuberculosis (MtB)-specific bifunctional cytokine immune response will help to immunologically distinguish latent versus active disease.

Material and methods: Tuberculosis was diagnosed by culture positivity. Latent tuberculosis was confirmed by a tuberculin skin test on people who did not have clinical symptoms of active tuberculosis. Following informed consent, peripheral blood was drawn from 12 persons with active and 12 persons with latent tuberculosis. To compare the MtB-specific immune response, 200 000 mononuclear cells/well were stimulated with the MtB-specific antigens ESA16/CFTP10, MTP65 and PPD overnight and Interferon gamma (IFNg), Interleukin (IL)-2 or IFNg/IL-2 producing T cells were detected as spot forming cells in a FluorSpot plate.

Results: As expected, MtB-specific IFNg immune response did not discriminate between active and latent tuberculosis. In contrast persons with latent tuberculosis had significantly higher numbers of MTP65-specific cells producing IL-2 (p=0.0235) and bifunctional cells producing IFNg/IL-2 (p=0.03). Furthermore an algorithm using the ESA16/CFTP10 induced IFNg, IL-2 and double positive cells significantly distinguished between the two cohorts (p=0.001).

Conclusion: These preliminary data reveal that defining effector and central memory T cells might allow a better differentiation between latent and active tuberculosis in a blood cell test even in a high incidence country. This is an ongoing study.

1900

IP-10 measurement using a point of care test for the diagnosis of active tuberculosis

Berit Lange1,2, Martina Vavva1, Winfried Kern2, Wagner Dirk2. 1Centre of Chronic Immunodeficiency, University Hospital Freiburg, Freiburg, Baden Württemberg, Germany; 2Division of Infectious Diseases, Department of Medicine, University Hospital Freiburg, Freiburg, Baden Württemberg, Germany

Introduction: Measurement of IP-10 released by whole blood stimulation with tuberculosis (TB) specific antigens has recently been proposed as a new tool for the diagnosis of tuberculosis (TB) with a sensitivity (SE) similar to that of the Quantiferon TB in tube-assay (QFT, Cellestis). More data is needed on the 81 patients. IP-10 was measured by using a multiplex assay (MPA, Biorad) and IP-10 LFI. Pearson correlation for IP-10 measurements by MPA and LFI was 0.53 (95%CI 0.3-0.76), 70% for IP-10 MPA (19/25; CI 0.55-0.9) and 63% for IP-10 LFI (95%CI 0.3-0.7). The SE in patients with active TB was 56% for QFT (14/25, CI 0.35-0.76), 70% for IP-10 MPA (18/25; CI 0.55-0.9) and 63% for IP-10 LFI (95%CI 0.3-0.7).

Conclusion: Smoking increases the risk of having a false negative or indeterminate IGRA results. IGRA test results should be interpreted with care in smokers.

1901

Methylated HBHA produced in M. smegmatis discriminates between active and non-active TB disease among the QFT-IT-responders

Giovanni Deloga1, Teresa Chiaccio2, Valentina Vannini2, Ornella Butera2, Gilda Cuzzi3, Alessandra Bua3, Paola Molinetti1, Stefania Zanetti1, Francesco Lauria1, Susanna Grisetti2, Nicola Magnavita1, Giovanni Fadda1, Emilio Girardi1, Deji Geletti2, 1Microbiology, Catholic University of the Sacred Heart, Rome, Italy; 2Epidemiology and Preclinical Research, National Institute for Infectious Diseases, Rome, Italy; 3Biomedical Sciences, University of Sassari, Sassari, Italy; 4Occupational Medicine, Catholic University of the Sacred Heart, Rome, Italy

Background: Challenge in tuberculosis (TB) research is to develop a test to distinguish, among the responders to an IFN-γ release assay (IGRA), those who control M. tuberculosis (MtB) replication from those that cannot. IFN-γ response to the Heparin-binding-hemagglutinin (HBHA) of MtB has been associated with latent TB infection (LTBI), but the cumbersome procedures to purify the methylated and immunological active form of the protein from MtB or MtB BCG have prevented the implementation of a diagnostic test. Aim of this study was to evaluate the IFN-γ response to methylated HBHA of MtB produced in M. smegmatis (rHBHAs) in subjects at different stages of TB who scored positive to QuantiFERON-TB Gold in-tube (QFT-IT).

Methodology/Principal findings: 87 subjects at different stages of TB who scored positive to QFT-IT were selected. IFN-γ response to in vitro whole blood stimulation with rHBHAs was evaluated by short-term and long-term tests and detected by ELISA or flow cytometry. We demonstrated that the IFN-γ response to rHBHAs is mediated by CD4+ T-cells with an effector-memory phenotype. This response, evaluated also by short-term-tests is significantly lower in active TB than in remote LTBI (p=0.0010), past TB (p=0.0152) and recent infection (p=0.05). These results were confirmed by long-term-tests and by qualitative analysis using ROC analysis.

Conclusions: For the first time to our knowledge, we showed that the T-cell response to a recombinant and methylated HBHA of MtB produced in M. smegmatis is a new candidate test to immunologically discriminate between active and non-active TB disease among those responsive to QFT-IT.

238. The burden of work-related respiratory disease: known and new end-points

1902

Occupational exposures and airway obstruction in the burden of obstructive lung disease (BOLD) study

Peter Burney1,1, Bernet Kato1, Bernd Lamprechti1, Louie Idolol1, Amund Gulsvik4, Sonia Buist5, Bernet Kato1, Bernd Lamprechti1, Louie Idolol1, Amund Gulsvik4, Sonia Buist5, National Heart Lung Institute, Imperial College, London, United Kingdom; 2Department of Pulmonary Medicine, Paracelsus Medical University, Salzburg, Austria; 3Philippine College of Chest Physicians, Philippine College of Chest Physicians, Manila, Philippines; 4Department of Thoracic Medicine, University of Bergen, Bergen, Norway; 5Department of Medicine, Oregon Health and Sciences University, Portland, OR, United States

Introduction: Occupational exposures are a recognised cause of respiratory morbidity but there are few population based estimates of their effects on lung function.

Methods: The Burden of Obstructive Lung Disease programme undertook post-bronchodilator spirometry in representative samples of people over the age of 40 years in 15 sites (N=14,400). It also collected information on occupation, including employment in specific industries, with the length of employment in each. Named industries were classified into three exposure groups: Fumes (F), Inorganic dusts (ID) and Organic dusts (OD). Odds ratios were estimated compared with the unexposed population adjusting for sex, age, smoking, pack-years, height and education, first for any exposure and then for length of exposure. Meta-analytical methods were used to combine risks between sites. COPD was defined as a FEV1/FVC ratio < Lower Limit of Normal.

Results: 10% were exposed to F, 9% to ID and 24% to OD. COPD was more common in those exposed; (OR (95%CI)) for F=1.80 (1.29, 2.53), for ID=1.51 (1.03, 2.22) and for OD=1.27 (0.96, 1.69). However much of the excess risk was seen in those exposed for less than a year. The OR (95%CI) of ten years exposure after the first year were F: 1.03 (0.87, 1.21), ID: 1.00 (0.75, 1.07); OD: 1.06 (0.94, 1.20). After stratification the estimated OR from OD in non-smokers was 1.26 (0.97, 1.64) per 10 years exposure.

Conclusions: Estimates of effects were probably strongly influenced by a healthy worker effect. Further data are needed and are being collected.
1903

Occupational exposure to dusts, gases, and fumes and incidence of COPD in SAPALDA

Amar Mehta1,2, David Miedinger1,2, Robert Bettschart1, Andreas Bircher6, Pierre-Olivier Briveaux1, Ivan Curjic1,2, Hans Krohnmööt1, Nicole Probst-Hensch1,2, Thomas Rothe1, Erich W. Russi1,2, Tamborlane Samaranayake1, Christian Schindler1,2, Irmeli Lindström1,2, Roel Vermeulen5, Thierry Rochat5, Nino Kuenzli1,2.

Conclusion:

The results indicate an association between maternal occupational exposure to LMW/irritant agents and asthma in the child during pregnancy (18.6%). Adj. logistic regression analysis showed an association between maternal occupational exposure to LMW/irritants and asthma in the child (OR 1.11 (95% CI 1.01-1.23)). The same tendency was seen for BMW (OR 1.12 (0.85-1.47)). Adjusted models included: Mothers age, BMI, atopy, use of medication, pets, SGA and gender. Stratifying for atopic status in the children did not change the results: OR 1.21 (0.75-1.96), OR 1.08 (0.77-1.50) for atopic and non-atopic children respectively in the HMW group, and OR 1.13 (0.94-1.35) and 1.13 (1.00-1.27) in the LMW/irritants group. No significant associations to asthma were seen in the other exposure groups.

Conclusion: The results indicate an association between maternal occupational work exposures and the risk of asthma in the child at age 7 years.

1907

Risk factors for decreased work ability among middle-aged men having asthma from youths

Irmi Linnström1,2, Antti Karjalanen1, Riitta Luukkonen1, Pauli Pallasaho1,2, Hille Suojaletto1, Antti Lauerma2,3, Control of Hypersensitivity Team, Team for Monitoring Working Conditions and Occupational Health, Team for Statistical Services, Finnish Institute of Occupational Health, Helsinki, Finland; 4Dept of Dermatology and Venerology, University of Tampere, Tampere, Finland

Background:

Occupational exposure to irritants and dusts has shown to contribute to respiratory work disability (Toren et al Thorax 2009;64(4):339-44).

Monday, September 26th 2011
Aims: We studied the effect of asthma which begins in youth on work ability in men around the age of 40, and analysed the risk factors for asthma-related work disability.

Methods: Finnish Defence Force registers in 1986-1990 were used to select: 1. conscripts with asthma representing a mild asthma group (n=485), 2. asthmatics who were exempted from military service representing a moderate/severe asthma group (n=393) and 3. a control group (n=1500) without asthma. 54% of the men in the first asthma group, 44% of the men in the second asthma group and 44% of the controls answered the questionnaire in spring 2009. The coded occupational histories was matched with the asthma-specific Job Exposure Matrix in order to evaluate occupational exposure to asthmogens and respiratory irritants. Logistic regression analyses were used when examining the associations between risk factors and decreased work ability.

Results: Self-assessed current work ability compared with lifetime best in scale 0-10 was decreased (<8) in 28.9% of the first asthma group, in 31.1% of the second asthma group, and in 19.7% of the controls (p=0.007). Current smoking (OR 2.5), being a manual worker (OR 2.7), exposure to irritants (OR 1.7) and abnormal temperatures (OR 1.7) and current severe asthma (OR 3.8) associated with decreased work ability among the asthmatics.

Conclusions: The reduction of work ability in men having asthma from youth may be partly preventable, if young asthmatics are advised to avoid work involving exposure to the irritants or abnormal temperatures and smoking.

239. Surgery for lung cancer: pre-operative evaluation and results

1908 Late-breaking abstract: The impact of extended cervical mediastinoscopy in staging of left lung carcinoma

Adnan Sayar1, Necati Çitak1, Sibel Bıyıklıkale1, Murzaffer Metin1.

Background: Extended cervical mediastinoscopy (ECM) is a method used for staging non-small cell lung cancer (NSCLC).

Methods: Between 1998 and 2011, 159 patients underwent ECM who had left NSCLC, were retrospectively analyzed. If the N2 was limited to the paratracheal or subcarinal spaces without infiltrating the paraortic or subaortic spaces, these cases excluded from the study (negative cases of ECM and positive cases of SCM). Patients who had been reported as cN0 by mediastinoscopy were operated; 64 lobectomies, 43 pneumonectomies, 16 exploratory thoracotomies. The pathological examination of the mediastinal lymphadenectomies revealed APW lymph node metastasis in 36 patients (22.6%) (96.2%) (#5 and #6 sampling in 82 patients, #5 or #6 sampling in 71 patients).

Mediastinal lymph node metastasis was observed in 26 of these patients (true-positive of ECM), remaining 10 patients who had mediastinal lymph nodes metastasis that could be accessed only via SCM were excluded. 123 patients who identified as cN0 by mediastinoscopy were operated; 64 lobectomies, 43 pneumonectomies, 16 exploratory thoracotomies. The pathological examination of the mediastinal lymphadenectomies revealed APW lymph node metastases in 11 patients (false-negative of ECM). Sensitivity, NPV and accuracy of ECM were calculated as 0.70, 0.91, and 0.92, respectively.

Conclusions: ECM has an adequate NPV and accuracy in determining metastases to the APW lymph nodes in patients with left NSCLC.

1909 Improvements in lung cancer surgery

Trond-Eirik Strand1, Kristian Bartnes2, Hans Rostad1. 1Department of Clinical and Registry-Based Research, Cancer Registry of Norway, Oslo, Norway; 2Department of Cardiothoracic and Vascular Surgery, University Hospital North Norway, Tromsø, Norway

Background: Recent trends in outcomes of lung cancer treatment might challenge recommendations for acceptable care.

Results: A total of 2201 patients were operated on during the study periods. Surgery was performed at 24 hospitals during the first two periods and at 13 in the last. Resection rates varied among counties from 7% to 31%. From the first to the last period, national resection rates increased from 16% to 19% (p for trend=0.001) and one-year survival increased from 73% to 82%. The proportion of resected patients in pStage I-II decreased from 87% to 83% (p for trend=0.048), the proportion of pneumonectomies from 27% to 15% (p for trend<0.001) and the mortality rate within 30 days of the surgery from 4.8% to 3.0% (p for trend=0.072). In the first two periods, 31% of these early deaths were caused by surgical complications, whereas in the latter period none were. The only unfavorable trend observed was the waiting time from the final diagnostic procedure to surgery, which increased from 29 to 40 days throughout the periods (p<0.001).

Conclusions: Important aspects of lung cancer surgery have improved in recent years and the recommendations for certain quality indicators are challenged. The most important is that the resection rates should be further increased towards a putative optimum exceeding 25%.

1910 Role of thoracoscore (thoracic surgery scoring system) in clinical practice

Balamugesh Thangakuman1, Kanwar Pannu1, Kim Wilkins1, Basharat Ibrahim1, Bernard Yung1, Dipak Mukherjee1, Doug Atitchon2, Johnson Samuel1.

1Respiratory Medicine, Basingstoke University Hospital, Basingstoke, Essex, United Kingdom; 2Thoracic Surgery, Essex Cardiothoracic Centre, Basildon, Essex, United Kingdom

Introduction: Thoracic surgery scoring system (Thoracoscore) a multivariate score with 9 parameters, may predict mortality after thoracic surgery (Lim E. et al. Thorax 2010;65;ii:ii27). Its role to assess patient fitness for surgery is not clear.

Cardiopulmonary exercise test (CPEX) is recommended by ERS to assess fitness for radical therapy in lung cancer patients (Brunelli A. et al. Eur Respir J 2009;34:17-41)

Objective: To evaluate role of thoracoscore in patients considered for thoracic surgery.

Methods: Retrospective data analysis of patients investigated for thoracic surgery. Results: Over a 2 period, 22 patients with borderline lung function had CPEX to assess for lung resection. Based on CPEX results, patients were classified into three groups: 1. marginal (true-positive of ECM), 2. acceptable (false-negative of ECM). The only unfavorable trend observed was the mortality in the first asthma group, 44% of the men in the second asthma group, and 44% of the controls answered the questionnaire in spring 2009. The coded occupational histories was matched with the asthma-specific Job Exposure Matrix in order to evaluate occupational exposure to asthmogens and respiratory irritants. Logistic regression analyses were used when examining the associations between risk factors and decreased work ability.

Results: Self-assessed current work ability compared with lifetime best in scale 0-10 was decreased (<8) in 28.9% of the first asthma group, in 31.1% of the second asthma group, and in 19.7% of the controls (p=0.007). Current smoking (OR 2.5), being a manual worker (OR 2.7), exposure to irritants (OR 1.7) and abnormal temperatures (OR 1.7) and current severe asthma (OR 3.8) associated with decreased work ability among the asthmatics.

Conclusions: The reduction of work ability in men having asthma from youth may be partly preventable, if young asthmatics are advised to avoid work involving exposure to the irritants or abnormal temperatures and smoking.

239. Surgery for lung cancer: pre-operative evaluation and results

1908 Late-breaking abstract: The impact of extended cervical mediastinoscopy in staging of left lung carcinoma

Adnan Sayar1, Necati Çitak1, Sibel Bıyıklıkale1, Murzaffer Metin1.

Background: Extended cervical mediastinoscopy (ECM) is a method used for staging non-small cell lung cancer (NSCLC).

Methods: Between 1998 and 2011, 159 patients underwent ECM who had left NSCLC, were retrospectively analyzed. If the N2 was limited to the paratracheal or subcarinal spaces without infiltrating the paraortic or subaortic spaces, these cases excluded from the study (negative cases of ECM and positive cases of SCM). Patients who had been reported as cN0 by mediastinoscopy were operated; 64 lobectomies, 43 pneumonectomies, 16 exploratory thoracotomies. The pathological examination of the mediastinal lymphadenectomies revealed APW lymph node metastases in 36 patients (22.6%) (96.2%) (#5 and #6 sampling in 82 patients, #5 or #6 sampling in 71 patients). Mediastinal lymph node metastasis was observed in 26 of these patients (true-positive of ECM), remaining 10 patients who had mediastinal lymph nodes metastasis that could be accessed only via SCM were excluded. 123 patients who identified as cN0 by mediastinoscopy were operated; 64 lobectomies, 43 pneumonectomies, 16 exploratory thoracotomies. Sensitivity, NPV and accuracy of ECM were calculated as 0.70, 0.91, and 0.92, respectively.

Conclusions: ECM has an adequate NPV and accuracy in determining metastases to the APW lymph nodes in patients with left NSCLC.

1909 Improvements in lung cancer surgery

Trond-Eirik Strand1, Kristian Bartnes2, Hans Rostad1. 1Department of Clinical and Registry-Based Research, Cancer Registry of Norway, Oslo, Norway; 2Department of Cardiothoracic and Vascular Surgery, University Hospital North Norway, Tromsø, Norway

Background: Recent trends in outcomes of lung cancer treatment might challenge recommendations for acceptable care.

Results: A total of 2201 patients were operated on during the study periods. Surgery was performed at 24 hospitals during the first two periods and at 13 in the last. Resection rates varied among counties from 7% to 31%. From the first to the last period, national resection rates increased from 16% to 19% (p for trend=0.001) and one-year survival increased from 73% to 82%. The proportion of resected patients in pStage I-II decreased from 87% to 83% (p for trend=0.048), the proportion of pneumonectomies from 27% to 15% (p for trend<0.001) and the mortality
1912
Timed stair climbing to 20 m altitude identifies lung resection candidates with high exercise capacity
Maurozio Bernasconi, David Maree, Conrado Koelegaenbarg, Florian von Grote-Biddingmaier, Andreas Dacoon, Chris Bolliger. Division of Pulmonology, Department of Medicine, Tygerberg Academic Hospital, University of Stellenbosch, Cape Town, Western Cape, South Africa

Background: Clinical evaluation for lung resection includes assessment of pulmonary function and maximum oxygen uptake (VO2max). A VO2max of 20ml/kg/min is considered sufficient for pneumonectomy. Stair climbing as a low-cost alternative to formal treadmill cardiopulmonary exercise testing (CPET), is attractive but lacks standardisation.

Methods: We asked 40 lung resection candidates (bronchiectasis or aspergillosis, n=26; lung cancer, n=7; iatrogenic cyst, n=2), with VO2max <20ml/kg/min, predicted (mean age: 43.7y; mean FEV1: 49.7%; mean DLCOc: 56.9%; 30 pts <70%) to climb to a maximum of 20m elevation as high and as fast as they could. Time of ascent to 20m and elevation reached were measured. Mean VO2 achieved during stair climbing and CPET were compared (MetaMax II, Cortex, Germany).

Results: Mean VO2 was 17.2ml/min. Mean peak VO2 during stair climbing was very similar to that during CPET (23.5 ± 23.6ml/min/kg, p=0.87). Twenty-four patients (60%) reached 20m. There was a good linear correlation between speed of ascent and peak VO2 (r=0.63 for stair climbing and 0.67 for CPET), but 4 of those patients (17%) remained below a peak VO2 of 20ml/kg/min. However, all 16 patients (67%) who reached 20m and climbed with a speed of >15min/m had a VO2 peak of >20ml/min/kg during stair climbing and CPET. No patient with a FEV1 <40% could climb to 20m or ascend faster than >15min/m.

Conclusions: Speed of ascent of >15min/m accurately identifies patients with a peak VO2 of >20ml/min/kg, thereby obviating the need for CPET in those patients.

1913
Prediction of postoperative FEV1 and chronic dyspnoea using quantitative computed tomography (CT) in lung resection candidates
Chrysoulavantis V Papageorgiou1, 2, Georgios Kalisakas1, Panagiotis Mihos1, 2, Iris Tsatsanidou1, Dimitra Chamilas1, Nikolaos G. Koudoumas1, 2, 1 1st Department of Respiratory Medicine, University of Athens Medical School, "Sotiria" Hospital of Chest Diseases, Athens, Greece; 2 1st Department of Thoracic Surgery, "Sotiria" Hospital of Chest Diseases, Athens, Greece

Aim: Preoperative evaluation of lung function before lung resection is necessary in order to avoid postoperative morbidity. The aim of the study is to evaluate the role of quantitative CT in predicting postoperative FEV1 and patient's chronic dyspnoea.

Methods: Twenty-eight patients with non-small cell lung cancer have been evaluated. Lung function tests (LFTs) and chest CT scan were performed preoperatively. Fifteen patients (group A) had normal LFTs, thirteen patients (group B) had impaired lung function, requiring further testing. Quantitative evaluation of CT using dual threshold (-910 up to -500 Hounsfield Units) estimated total functional lung volume and the volume of the lobe(s) to be resected. Postoperative FEV1 was predicted by reducing the postoperative value by the same fraction that the resected part contributed to the total lung volume, in both groups. Postoperative LFTs were performed 3 months after surgery. Postoperative dyspnoea was evaluated using the modified Medical Research Council (mMRC) scale.

Results: The postoperative predicted and postoperative actual values of FEV1 were significantly correlated in both groups (Group A: r=0.897, p<0.0001, Group B: r=0.940, p<0.0001). Predicted volume loss as a percentage of total lung volume correlated significantly with postoperative mMRC (r=0.647, p<0.001).

Conclusion: Quantitative CT in patients undergoing lung resection appears to be a useful tool in evaluating postoperative patient’s status as it predicts postoperative FEV1 and postoperative mMRC.

1914
FEV1 is not a prognostic marker in operated patients with stage I or II non-small cell lung cancer (NSCLC)
Anoushka Cogen1, Yanna Dockx1, Annelies Janssens2, Joost Weyler3, Paul Van Schil1, 3, 1 Thoracic and Vascular Surgery, Antwerp University Hospital, Edegem, Antwerp, Belgium; 2 Pulmonary Medicine, Antwerp University Hospital, Edegem, Antwerp, Belgium; 3 Epidemiology and Social Medicine, University of Antwerp, Wilrijk, Antwerp, Belgium

Background: In retrospective studies lung cancer mortality was found to be higher in patients with chronic obstructive pulmonary disease (COPD), defined as a FEV1 <70% of the predictive value. In the Cher®Nostril and the Paccora trials, based on patients with unresectable clinical stage III, a strong relationship was observed between FEV1 and overall survival (OS). In a smaller study, FEV1 was a prognostic factor for OS in operated patients (Nakajima et al. Thor Cardiovasc Surg 2009;57:339-342).

In our study we investigated whether the presence of COPD is a prognostic marker in patients with resectable stage I and II NSCLC.

Methods: All relevant clinical information was gathered retrospectively from 77 patients undergoing complete resection without preoperative chemoradiotherapy between January 2003 and January 2006. All patients were staged according to the 7th TNM-classification. Primary endpoints were OS and progression-free survival (PFS). Follow-up information was complete for all patients and ended in July 2010. Patients were classified as having a FEV1 <70% or a FEV1 >70%.

Results: According to the Kaplan Meier analysis (log rank test) FEV1 was not a significant prognostic factor for OS (log=0.461) or PFS (log=-0.530). In a Cox multiple regression analysis the adjusted hazard ratio for FEV1 (measured on a continuous scale) was 1.632 (p=0.458) after adjustment for stage and age.

Conclusion: In contrast to other studies our data show that FEV1 is not a prognostic factor in patients with resectable stage I and II NSCLC. Precise selection criteria regarding cardiopulmonary function excluding patients with a very poor cardiopulmonary function, could be responsible for this finding.

1915
Lobectomy tolerance in COPD patients
Alexey Petrunkin1, 2, Alexey Pichurov1, 2, Oleg Orzhekhovski1, 2, Evgeny Sokolovich1, 2, Pirot Yablohonski1, 2, 1 Medical Faculty, SPb State University, Saint-Petersburg, Russian Federation; 2 Thoracic Surgery, City Hospital #2, Saint-Petersburg, Russian Federation

Lung cancer is often associated with COPD. COPD patients have higher postoperative morbidity and mortality because of low respiratory reserve. Morbidity and mortality in these patients amounts to 60% and 10-14% respectively (Seikone Y., 2001, Subotic D., 2007). To investigate factors influencing the risk of postoperative morbidity and mortality and to determine criteria for lobectomy intolerance in COPD patients.

Material and methods: 279 patients underwent lobectomy from 2001 to 2008 were included in a retrospective study. Mean age was 61±12, male/female ratio = 204/75. Patients were divided in three groups according to recommendation of GOLD 2007. Group 1 – 154 non-COPD patients, group 2 – 47 patients with mild COPD and group 3 – 78 patients with moderate to severe COPD. Comorbidity of the patients was assessed by using of Charlson comorbidity index (CCI).

Results: Morbidity and mortality were found to be increased in patients with more severe obstruction. Thus morbidity was 32% in nonCOPD patients, 34% - with mild COPD and 46% - with moderate to severe one. Mortality was 3.9, 8.5 and 12.8% respectively. However multivariate analysis showed that severity of COPD and predicted postoperative FEV1 were not independent factors of morbidity and mortality.

Morbidity in patients with ppoFEV1 < 40% was 5%, whereas it was 7% in group with ppoFEV1≥40%.

CCI was found to be the only independent risk factor. Morbidity in patients with CCI ≥ 6 was 100%. Combination of CCI ≥ 6 and ppoFEV1 < 50% was accompanied by very high risk of mortality (mounted 70%).

Conclusion: ppoFEV1 < 40% is not independent criterion of lobectomy intolerance in COPD patients. Significant factor of functional inoperability is combination of CCI ≥ 6 and ppoFEV1 < 50%.

240. Resuscitation and ventilation in the baby and infant

1916
Neonatal resuscitation at the community level
Nitin Bhandari, Ram Bhandari, Poonam Kandel, Sudesh Sharma. Child Health and Research, Integrated Rural Health Development Training Centre (IRHDTC), Kathmandu, Nepal

Introduction: Community Based New Born Care Program (CB-NCP) was piloted
in Nepal in order to reach the MDG 4 target, which focuses on decreasing the perinatal mortality. The program focuses the community level and reaches the local doctors, community level health workers and volunteers, educates and trains them with major emphasis to correctly identify and manage birth asphyxia by the use of DeLee suction and bag and mask ventilation.

Aims: The aim of this study was to assess the knowledge and proficiency gained by the community level (VHW/MCHW, FCHV) and health facility level health workers who participated in a Community Based New Born Care training program.

Methods: Based on CB-NCP curriculum designed by the Child Health Division, two questionnaires were developed for all levels of knowledge of the 57 health facility staffs including doctors, 36 VHW/MCHW and 141 FCHV were collected through semi-structure questionnaire and the skill was assessed through the observational checklist with practical hands on bag and mask ventilation in a neonatal manikin.

Results: The knowledge of health workers, VHW/MCHW and FCHV regarding the management of birth asphyxiated baby was 100% (N=57/57), 94% (N=34/36) and 90.8% (N=126/141) respectively. The knowledge of FCHV regarding the management of asphyxiated new born was comparatively less than Health Worker and VHW/MCHW. Similarly, 49.1% (N=26/57) health workers, 50% (N=18/36) VHW/MCHW and 100% (N=141/141) FCHV correctly demonstrated the skills of management of asphyxiated newborn.

Conclusions: Further studies are required to finally confirm the effectiveness of the intervention at the community level before implementing the program in other districts.

1917 The influence of oxygen inflow on ventilatory parameters during manual ventilation
Priscila Oliveira, Armando Almeida-Junior, Cel zie Almeida, Maria Ângela Ribeiro, José Ribeiro. Pediatrics, UNICAMP, Campinas, São Paulo, Brazil

Background: Despite of self-inflating bags (SIB) widespread use, studies have concluded that many factors may have influence on ventilation.

Aim: To evaluate and to compare ventilatory parameters during manual ventilation with 4 different oxygen flows attached to the SIB.

Methods: Two different physiotherapists were asked to ventilate 2 lung models (neonatal/pediatric) using 3 SIBs (Hudson®, Laerdal®, IG-Meyer®) with 5, 10, 15 and 15L/min of oxygen inflow attached. A lung function monitor (CO2SMOplus®) recorded inspiratory volume (Vi), peak inspiratory pressure (PIP), peak inspiratory flow (PIP) and expiratory flow (PEF) and inspiratory time (Ti). The oxygen inflows were compared using ANOVA for repeated measures and Tukey’s test with p<0.05 considered statistically significant.

Results: With 4 different SIB brands in neonatal and pediatric models, the oxygen inflows influenced Vi, PIP, PIP, and Ti (<p<0.001). When compared 0 and 15L/min, we found a significant increase in PIP in all neonatal SIB brands. Also, there was a difference in Ti delivered by neonatal Hudson® SIB.

Conclusion: We found great variability in ventilatory parameters depending on the oxygen inflow. The Vi, PIP, PIP, and Ti showed a large variation. Professionals should be aware of those differences and the choice of the oxygen flow used should be taken with caution.

1918 Influence of mask leak on applied volumes and pressures during simulated resuscitation of neonates
Julia C. Hartung, Marcus Kelm, Hendrik Fischer, Gerd Schmalisch, Charles C. Roehr. Neonatology, Charité Universitätsmedizin Berlin, Berlin, Germany

Introduction: Self-inflating (SI) bags and T-piece resuscitators are used for bag and mask ventilation of neonates. Leaks between face and mask occur frequently.

Aim: To examine the preventive effects of moderate (MH) or severe hypercapnia (SH) on BLEO-induced CNLI.

Method: Rabbit pups received BLEO (1 mg/kg/d i.p.) or saline vehicle from postnatal days 1-14 while being exposed to FiCO 2 0.05 (PaCO 2 70 mmHg; MH), FiCO 2 0.07 (PaCO 2 90 mmHg; SH) or normocapnia (NC). Inflammation was assessed by tissue counts of immunoreactive macrophages (CD68) and neutrophils (MPO). PHT was assessed by echo-Doppler measurement of pulmonary vascular resistance (PVR), right ventricle (RV) flecth, pectusepultum (LV-S) weight ratio and percentage medial wall thickness (%SMWT) of pulmonary resistance arteries. Markers of lung development included weight, mean linear intercept, tissue fraction, secondary crest and peripheral vessel counts.

Results: SH, but not MH, attenuated BLEO-induced macrophage influx and prevented PHT, as evidenced by normalized PVR and significantly (p<0.01 vs. BLEO+NC) decreased RV/LV+S and%MWT. Neither SH nor MH affected BLEO-induced neutrophil influx, inhibited lung growth, septal thinning, impaired alveolarization or pruning of peripheral blood vessels.

Conclusions: SH prevented PHT, which we speculate was the result, in major part, of inhibited macrophage influx. Neither influx of neutrophils nor pruning of peripheral arteries appeared to contribute significantly to PHT in BLEO-mediated CNLI. Funded by the CIHR.

1919 Appropriate level of volume targeting for ventilated infants born at or near term
D. Chowdhury, Silke Lee, Simon Hannam, Gerard R. Rafferty, Anne Greenough. Division of Asthma, Allergy and Lung Biology, King’s College London, London, United Kingdom

Aims: To determine the most appropriate level of volume targeting (VT) for ventilated infants born at or near term.

Method: Study one: expiratory tidal volumes (VTe) were measured during time cycled, pressure limited ventilation either using a pneumotachograph or the ventilator’s software; at least 80 breaths were analysed per infant. Study two: two infants were studied at VT levels of 4, 5 and 6 ml/kg delivered in random order, with return to baseline between each VT level. The transpulmonary pressure-time product (PTPdi), a measure of the work of breathing, was assessed at each VT level and during the baseline periods. To measure PTPdi, oesophageal and gastric pressures are measured and PTPdi calculated by integration of the transpulmonary pressure signal with time for each breath and expressed per minute. In both studies, infants are only assessed when their blood gases are within the normal range.

Results: To date: Study one: 20 infants, median gestational age of 39 (range 35-41) weeks, had a median VTe of 5 (range 1.4-9.7) ml/kg; 50% of infants had a VTe outside the “normal” tidal volume range (4 to 6ml/kg). Study two: the median PTPdi of 11 infants, median gestational age 39 (35-41) weeks, at a VT level of 4 ml/kg (310, IQR 242-334 cmH2O/min) was almost double that at 6 ml/kg (median 163, IQR 122-220 cmH2O/min), (p<0.001).

Conclusion: During time cycled, pressure limited ventilation, infants born at or near term are frequently ventilated using volumes outside the “normal” tidal range. Yet, even within that range, low compared to high levels of volume targeting significantly increase the work of breathing.

1920 Therapeutic hypercapnia prevents pulmonary hypertension in rats with bleomycin-induced chronic neonatal lung injury
Charlotte Sewing1, Juliana Ivanovska1, Crystal Santos1, Azth Masood2, Patrick J. McNamara1, A. Keith Tanwell1,2, Robert P. Jankov1,3. 1Clinical Integrative Biology, Sunnybrook Research Institute, Toronto, Canada; 2Physiology & Experimental Medicine, Hospital for Sick Children Research Institute, Toronto, Canada; 3Department of Physiology, University of Toronto, Toronto, Canada

Bleomycin (BLEO)-induced chronic neonatal lung injury (CNLI) is characterized by severe inflammation, arrest of lung development and pulmonary hypertension (PHT). To examine the preventive effects of moderate (MH) or severe hypercapnia (SH) on BLEO-induced CNLI.

Methods: Rat pups received BLEO (1 mg/kg/d i.p.) or saline vehicle from postnatal days 1-14 while being exposed to FiCO2 0.05 (PaCO2 70 mmHg; MH), FiCO2 0.07 (PaCO2 90 mmHg; SH) or normocapnia (NC). All infants were studied at VT levels of 4, 5 and 6 ml/kg delivered in random order, with return to baseline between each VT level. The transpulmonary pressure-time product (PTPdi), a measure of the work of breathing, was assessed at each VT level and during the baseline periods. To measure PTPdi, oesophageal and gastric pressures are measured and PTPdi calculated by integration of the transpulmonary pressure signal with time for each breath and expressed per minute. In both studies, infants are only assessed when their blood gases are within the normal range.

Results: To date: Study one: 20 infants, median gestational age of 39 (range 35-41) weeks, had a median VTe of 5 (range 1.4-9.7) ml/kg; 50% of infants had a VTe outside the “normal” tidal volume range (4 to 6ml/kg). Study two: the median PTPdi of 11 infants, median gestational age 39 (35-41) weeks, at a VT level of 4 ml/kg (310, IQR 242-334 cmH2O/min) was almost double that at 6 ml/kg (median 163, IQR 122-220 cmH2O/min), (p<0.001).

Conclusion: During time cycled, pressure limited ventilation, infants born at or near term are frequently ventilated using volumes outside the “normal” tidal range. Yet, even within that range, low compared to high levels of volume targeting significantly increase the work of breathing.

1921 The distribution of lung aeration at different positive end-expiratory pressure levels in newborn rabbits
Melissa Siew1, Marcus Kitchener2, Arjan te Pas3, Megan Wallace1, Muhammad Islam2, Naoto Yagi4, Kentaro Uesugi4, Stuart Hooper1. 1The Ritchie Centre, Monash Institute of Medical Research, Clayton, Victoria, Australia; 2School of Physics, Monash University, Clayton, Victoria, Australia; 3Department of Pediatrics, Division of Neonatology, Leiden University Medical Center, Leiden, Netherlands; 4Spring-8, JASRI, Hyogo, Japan

Background: Very preterm newborns with respiratory distress at birth demonstrate increased end-expiratory lung volumes when ventilated with positive end-expiratory pressure (PEEP). However, the regional distribution of ventilation is unknown, especially if PEEP is not held constant but altered as occurs during face mask removal.

Aim: To determine the how the distribution of ventilation changes between different PEEP levels.

Method: Rabbit pups (28dGA) were delivered by c-section and mechanically

332s
ventilated with a peak inflation pressure of 35cmH2O and a sequence of PEEP. The PEEP sequences were (A) 0-5-10-5cmH2O, (B) 0-5-10-0-5cmH2O and (C) 0-5-10-0-10cmH2O. Phase contrast X-ray imaging was used to image and analyse the distribution of aerated lung.

**Results:** In sequence A and B, upper lobes (U) were more aerated than lower lobes (L) at functional residual capacity (FRC) throughout the ventilation period (A: 100PEEP U vs L, 70.9±1.5% vs 58.6±2.8%, p<0.05). Tidal volume (VT) aerated U and L similarly until the volume of the lungs at peak inflation (VPPI) achieved >70% of maximal lung volume (p<0.05). Once VPPI was >70%, VT aerated more than U (A: U vs L: 72.2±3.7% vs 30.3±3.6%, p<0.05; B: U vs L: 20.4±1.6% vs 26.9±1.7%, p<0.05). Sequence C ventilated differently; FRC was only different between lobes at 0PEEP (p<0.05) and VT lacked difference at 100PEEP despite VPPI >70% (p<0.05).

**Conclusion:** At FRC, U are better aerated than L, at different PEEP levels. During inflation, the VT was distributed more to lower lobes than upper lobes after the lungs were over-inflated. This is not observed if lungs were initially aerated with a high PEEP.

**Methods:** 89 patients from 14 sites were randomized to either azithromycin 250 mg daily or placebo, for 12 months. All were reviewed at three-monthly intervals during treatment and at 3 months follow-up. At each review the following were assessed: exacerbation frequency (being the primary endpoint), lung function, qualitative and quantitative sputum bacteriology, serum and sputum inflammatory markers, adverse effects, symptom scores and St George’s respiratory questionnaire. High resolution CT-scans were performed at study entrance and end of study.

**Primary results:** 81 patients completed the study. At the end of 12 months’ treatment the exacerbation group showed a significant reduction in exacerbation frequency as compared to the placebo treated group (1.28/year, SD 1.32 vs 2.67/year, SD 1.95, p<0.001). No significant differences were found with respect to lungfunction, inflammatory markers and adverse effects between groups.

**Conclusions:** Longterm azithromycin treatment significantly reduces exacerbation frequency in patients with non-CF bronchiectasis, without additional side effects.
severities (3-severe and 21-mild cough). Myeloperoxidase (MPO), neutrophil elastase (NE), interleukin-8 (IL-8) and tumour necrosis factor-alpha (TNF-α) were measured from spontaneous sputum samples. Multivariable linear regression was used to determine independent factors associated with cough severity (LCQ).

**Result:** 187 completed the study. 58.2% were female. Median age was 65 years. 77.3% had reflux using HCQ.

Reflex ⇒ severe cough symptoms as per LCO (15.2 (3.5) vs 19.4 (1.9), p < 0.001). Sputum levels of MPO, NE, IL-8 and TNF-α were significantly higher in reflux+ve group (p < 0.0001 for all comparisons).

After adjusting for age, gender, co-morbidities, disease severity and chronic colonization, reflux was independent with cough severity (p = 0.27 standard error 0.81, p = 0.0022).

**Conclusion:** The presence of airways reflux is associated with more severe cough and increased airway inflammation in bronchiectasis.

The relationship between airway bacterial load and airways inflammation in stable non-cystic fibrosis bronchiectasis

James D. Chalmers1, Pallavi Mandal1, Brian McHugh1, Mavee Smith1, Cathy Donehey1, John R. Govan2, Adam T. Hill2, 3MRC Centre for Inflammation Research, Queens Medical Research Institute, Edinburgh, United Kingdom; 2Department of Respiratory Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; 4Cystic Fibrosis Laboratory, University of Edinburgh, Edinburgh, United Kingdom

**Objective:** To investigate the relationship between airway bacterial load and markers of airways inflammation in stable patients with bronchiectasis.

**Methods:** 302 patients with non-CF bronchiectasis confirmed by HRCT were enrolled. At 6-monthly review, sputum samples were processed to determine bacterial load, expressed as log10 colony forming unit/ml (cfu/ml). Sputum sol was analysed for myeloperoxidase (MPO) and neutrophil elastase (p < 0.001) and tumour necrosis factor alpha (TNF-α) were measured by ELISA.

**Results:** 67 patients (22.1%) of patients grew no pathogens. Pathogenicmicroorganisms were obtained in 77.9% of patients, most frequently *Haemophilus influenzae* (37.4% of isolates). *Pseudomonas aeruginosa* (20.4%), Staphylococcus aureus (13.2%), Streptococcus pneumoniae (11.9%) and Moraxella catarrhalis (10.6%).

Airway inflammation increased progressively with increasing bacterial load. Statistically significant differences were observed, when compared to patients with no pathogens, at bacterial loads above 1 × 10^4 cfu/ml for MPO (p < 0.01), neutrophil elastase activity (p = 0.006) and IL-8 (p = 0.02), and above 1 × 10^5 for TNF-α (p = 0.004) and above 1 × 10^6 for IL-8 (p = 0.003).

**Conclusion:** There is a direct relationship between airway bacterial load and the degree of airway inflammation in stable bronchiectasis.

Safety and efficacy of ciprofloxacin dry powder for inhalation in patients with non-cystic fibrosis bronchiectasis

Robert Wilson1, Tobias Wele2, Eva Polverino3, Anthony De Soyza4, Hugh W. Greivelle5, Anne E. O’Donnell6, Jeff Alder7, Peter Reimnitz8, Barbara Hample8, 1Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom; 2Klinik fuer Pneumologie, Medizinische Hochschule Hannover, Hannover, Germany; 3Servicio de Pneumol., Hospital Clinic i Provincial, Barcelona, Spain; 4Global Clinical Development, Bayer Schering Pharma AG, Wuppertal, Germany; 5Clinical Development, Bayer Schering Pharma AG, Berlin, Germany

**Introduction:** Ciprofloxacin dry powder for inhalation (DPI) uses PulmoSphere™ technology to target the lungs of patients chronically colonized with bacterial pathogens.

**Objective:** This phase II study assessed the efficacy and safety of ciprofloxacin DPI treatment for 28 days in non-cystic fibrosis bronchiectasis (non-CF BE) patients.

**Methods:** Adult patients with pulmonary stable non-CF BE received twice-daily 32.5 mg ciprofloxacin (50 mg ciprofloxacin DPI) or matching placebo for 28 days, with a 56-day follow-up. The primary endpoint was reduction in total bacterial load in sputum at end of treatment (EOT) compared with placebo.

**Results:** The mean baseline characteristics in the intent-to-treat population (N=124) were: age 63, weight 70 kg, FEV1 56% of predicted. At EOT, ciprofloxacin DPI reduced mean bacterial load by 3.6 logs, vs 0.3 logs with placebo (p < 0.0001), and median CRP level was 2.45 mg/l lower compared with placebo (not significant). Mean difference in the St George’s Respiratory Questionnaire at EOT was 3.6 points between treatment arms (p = 0.059). Fewer patients treated with ciprofloxacin DPI than with placebo experienced an exacerbation requiring antibiotic treatment (23% vs 28%, not significant). The adverse event rate was similar in both treatment arms. Very few bronchopneumonias occurred (n=6, 2 after EOT). They were equally distributed between both groups.

**Conclusions:** Ciprofloxacin DPI significantly reduced bacterial load in patients with non-CF BE (p < 0.0001) and was well tolerated. Several secondary endpoints showed a trend in favour of ciprofloxacin DPI. Ciprofloxacin DPI is a promising candidate for investigating benefits of long-term therapy in non-CF BE patients.

Antimicrobial efficacy of ciprofloxacin dry powder for inhalation in patients with non-cystic fibrosis bronchiectasis

Jeff Alder1, Robert Wilson1, Tobias Wele1, Eva Polverino2, Anthony De Soyza3, Hugh Greivelle2, Anne O’Donnell3, Peter Reimnitz4, Barbara Hample8, 1Global Clinical Development, Bayer Healthcare Pharmaceuticals Inc. Montreal, N.D, United States; 2Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom; 3Klinik fuer Pneumologie, Medizinische Hochschule Hannover, Hannover, Germany; 4Servicio de Pneumol., Hospital Clinic i Provincial, Barcelona, Spain; 5Sir William Leech Centre for Lung Research, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 6Chest Clinic, Royal Adelaide Hospital, Adelaide, Australia; 7Division of Pulmonary, Critical Care and Sleep Medicine, Georgetown University Hospital, Washington, DC, United States; 8Global Clinical Development, Bayer Schering Pharma AG, Wuppertal, Germany; 9Global Clinical Development Antinfectives, Bayer Schering Pharma AG, Berlin, Germany

**Introduction:** Ciprofloxacin DPI for inhalation (DPI) is a formulation of the anti-Pseudomonal (PulmoSphere™ technology) development for long-term therapy of non-cystic fibrosis bronchiectasis (non-CF BE). This phase II, randomised, double-blind study was designed to assess efficacy and safety over 28 days in non-CF BE patients with positive sputum culture for predefined respiratory pathogens (RP).s

**Methods:** Adult patients with non-CF BE received 25.2 mg ciprofloxacin (50 mg ciprofloxacin DPI) or matching placebo bid for 28 days, with a 56-day follow-up. The primary endpoint was reduction in total bacterial load in sputum at end of treatment.
of treatment (EOT). In addition, eradication of RPs and reduction of individual species was documented.

Results: The primary endpoint of significant reduction in bacterial load of RPs at EOT was achieved (log₃ -3.6 < -0.3 for placebo, p<0.001). In addition, greater reductions and eradication were achieved for the major pathogenic species including, Pseudomonas aeruginosa, Haemophilus influenzae, Moraxella catarrhalis and Streptococcus pneumoniae. The eradication rates for the baseline pathogens at EOT were 35% vs 8% for placebo. At EOT, eradication was achieved in all patients infected at baseline with M. catarrhalis and in all but 1 patient infected with H. influenzae.

Conclusions: Ciprofloxacin DPI achieved a significantly greater reduction in total bacterial burden than placebo. A promising trend in reduction and eradication of the major pathogenic species was also noted. Ciprofloxacin DPI has demonstrated promise for long-term inhalation therapy to reduce the major pathogenic species in non-CF BE, which could reduce the incidence of exacerbations.

242. Tuberculosis in immunocompromised hosts

P1931
HIV/ TB in Belarus
Andrei Astrauko1, Aliaksandr Skrahin2, Alena Skrahina1. 1Clinical, Republican Scientific and Practical Center of Pulmonology and Tuberculosis, Minsk, Belarus; 2Intensive Care, Belarusian State Medical University, Minsk, Belarus

Understanding the key role which HIV infection plays in deteriorating TB epidemic situation is crucial for implementing HIV/TB collaborating activities in the Belarusian health care system.

The following trends on TB and HIV incidence were reported during the last eight years (2002 – 2009) in Belarus: 10% decrease in TB incidence from 5 139 to 4 633 with the 17% increase in HIV incidence from 915 to 1072; and dramatic (7.5 fold) increase in TB/HIV co-infection incidence from 35 up to 265. The following trends in HIV mortality has been observed in these years: 24 cases in 2002 and 223 cases (9.3 fold increase in 2003). In the reasons of death for HIV positive patients only 4 (16.7%) patients of all HIV patients died of TB in 2002 to compare with 123 (55.2%) of HIV patients died of TB in 2009. The following social structure of the patients with HIV/TB co-infection has been reported: intravenous drug users (63.4%), heavy drinkers/alcohol addicts (26.8%), patients with history of imprisonment (40.9%), and unemployed (67.1%). Gomel region is the most TB/HIV affected Belarus region, where 61.1% of cases were concentrated of all registered TB/HIV in the country (01.10.2010).

In order to control TB/HIV co-infection spread specific measures based on close cooperation between TB and HIV programs has been implemented in Belarus including: TB prevention, early diagnosis and adequate treatment of TB in HIV positive population.

P1932
Experience from implementation of collaborative TB/HIV activities in Republic of Macedonia – Where did we go wrong and where do we go from here?
Dance Gadeva Nikolovskav1, Stefan Talevski2, Hristijan Jankuloski3. 1Project Implementation Unit, GFATM Funded Program for TB Control, Ministry of Health, Skopje, Macedonia, The Former Yugoslav Republic of; 2Intensive Care, Skopje University, Skopje, Macedonia, The Former Yugoslav Republic of; 3High Risk Groups, NGO Healthy Options Project Skopje, Skopje, Macedonia, The Former Yugoslav Republic of

Since 2004, Republic of Macedonia has implemented 3 GFATM funded grants. RM is the lowest HIV prevalence country in the SEE Region; the cumulative total number by the end of 2010 is 134, and the number of new TB cases in 2010 was 420. To date, 4 cases were diagnosed with HIV and TB.

To analyze joint HIV/TB activities in the past 6 years, identify gaps and challenges to be addressed in order to provide recommendations for policy makers.

We have performed desk analysis of reports on joint HIV/TB activities performed in the period 2004-2010, submitted to GFATM.

NGO HOPS delivers TB prevention education for high-risk groups - IDUs, psychiatric patients, Roma, refugees/asylum seekers and PHLIV. By the end of 2010, total of 7025 HRG representatives have been educated for TB, representing an extraordinary collaboration between the Government and NGO sector.

Voluntary and Confidential Counseling and Testing (VCC&T) services are offered to TB patients at Lung Diseases Institute, by one trained nurse. Analyzed quarterly, the results vary significantly, ranging from 0% tested to as high as 75% tested for some of the cohorts.

Although RM has shown significant achievements in implementation of GFATM funded programs for TB and HIV/AIDS, there is still lot of work to combine services and address prevention. There is a need to expand VCC&T countrywide, scale-up activities as to include other HRG (e.g. sex workers) and necessity for capacity building of communities to address TB in PHLIV. In addition, we have to still work to strengthen institutional support for coordinated response and involve clients in development of relevant strategies.

P1933
Bacteriological profile in new cases of TB-HIV coinfected patients in Romania
Maria Dele1, Cornelia Tudele1,2, Irina Pele1, Maria Dele1, Elmina Ibrahim1. 1Clinical Pneumology, Marius Nasta Institute of Pneumology, Bucharest, Romania; 2Clinical Pneumology, Marius Nasta Institute of Pneumology, Bucharest, Romania

Background: Tuberculosis and HIV infection are two serious problems, which associated condition is one another negative. In Romania there is an increased prevalence of tuberculosis, but proportion of TB-HIV coinfected patients remains low. Due to management issues in this group of patients, bacteriological identification and susceptibility profile are very important.

Aims: To identify the bacteriological profile of strains isolated from new cases of TB-HIV patients and to evaluate the management in this group of patients.

Methods: Descriptive retrospective analysis of new cases of TB-HIV coinfected patients reported in 2009 in the National Register of Tuberculosis.

Results: Were analyzed 155 patients (70.8%) representing the new cases from a total of 219 TB patients notified as seropositive. The mean age was 28 years, 68.3% males, most of them with pulmonary TB (127 patients, representing 81.9% of total cases). Bacterial confirmation rate in culture was low (48.3%), even in pulmonary TB cases (69 patients). Drug resistance was certified in six cases: monoresistance to rifampicin in one case and MDR in 5 cases. Among the patients of our group 114 were successfully treated, 10 patients abandoned TB treatment and 6 failed. The mortality rate was 11.6% (18 patients), most of deceased in pulmonary TB cases (8,33%).

Conclusions: We found a low rate of drug resistance in our group, but bacteriological confirmation was possible only in 48.3% cases. Intensified efforts in bacteriological examinations are necessary to confirm the TB in HIV patients and to exclude other pathology, for a appropriate management.

P1934
Multidrug-resistant tuberculosis (MDR-TB) and HIV co-infection in Romania
Laura Lihatchi1, Cornelia Tudose1,2, Irina Pele1, Maria Dele1, Elmina Ibrahim1. 1Clinical Pneumology, "Marius Nasta" Institute of Pneumology, Bucharest, Romania; 2Clinical Pneumology, "Marius Nasta" University of Medicine, Bucharest, Romania

Background: Although Romania is a country with high TB notification rate, the weight of HIV-positive patients among all TB cases is around 1%. Besides, the MDR-TB and HIV co-infected cases are only a few yearly, but they have very low chance to be successfully treated.

Aims: To analyze treatment outcomes of MDR-TB and HIV co-infected patients reported in Romania, from 2006 to 2009.

Methods: Descriptive retrospective analysis of MDR-TB HIV co infected patients reported between 2006-2009 in the TB National Electronic Database.

Results: A total of 23 such cases have been notified in those 4 years. All were under 50 years old (13 even under 21 years). Gender ratio was F/M = 10/13. Only 20 patients were on antiretroviral therapy. All had pulmonary TB. As case category 11 were new cases, 3 relapses, 3 chronics, 1 retreatment after default and 3 retreatments after failure. Sputum microscopy was positive in 15 patients. Drug sensitivity tests showed 12 resistances only to isoniazid and rifampicin (HR), 2 extensively drug resistant TB (XDR-TB) and 9 resistances to HR and at least one additional drug. Most of them received treatment with Pyrazinamide, Ethambutol, Kanamycine, Protonamide, Ciprofloxacin and Cycloserine. Duration of treatment varied between 2 and 24 months. The treatment outcomes were: 8 had successful treatment, 5 were still continuing at the time of analysis, 4 failed, 3 died and 3 defaulted.

Conclusions: Treatment success rate in MDR-TB-HIV co-infected patients in Romania was 34.8% in the 4 analyzed years. Management of MDR-TB in sero-positive patients need to be improved.

P1935
Multidrug-resistant TB in children with HIV infection in Romania
Gheorghe Murgoci1, Rodica Murgoci2, Constantin Marica1, Mihaela Tanasescu3, Gheorghe Niu1, Henriette Stavri1, Mariana Mandarase1, Monica Luminos1. 1Pneumology, Institute of Pneumology “Marius Nasta”, Bucharest, Romania; 2Epidemiology, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 3Pneumology, “Vasile Goldis” University of Medicine, Arad, Romania; 4Microbiology, Institute of Microbiology “I. Cantacuzino”, Bucharest, Romania; 5Infectious Diseases, Institute of Infectious Diseases “Matei Balș”, Bucharest, Romania

A retrospective study on a group of 417 children with TB and HIV/AIDS; 165 among these have had (+) culture for TB; MDR-TB - diagnosed to 73 children – 17.6%.

Results: Mean age – 14.5 years; Sex – M: 50.94%; F: 49%; TST positive – 5 mm – 51.5%; negative – 49.5%; associated clinical symptoms: fever, weight loss, irritability – 100%; pain throat 75%, haemoptysia 50%

Rx abnormalities: parenchymal infiltration – 36.4%; cavitary lesions – 37%, hilar opacities – 11.3%; miliary – 7.5% bronchopneumonic opacities – 7.5%.

Side effects of treatment: hepatic cytolytic syndrome – 35.1%; jaundice – 18.9%; hadeache – 16.2%; personality disorders – 16.2%; thrombocytopenia – 13.5%.

Bacteriological situation of discharge last BK examination BK cultures negative – 71.4%; positive – 28.6%.

Conclusions: The MDR-TB prevalence is increased in the HIV/AIDS infected children; more frequent in the children with multiple hospitals admittance with previosly antituberculosis therapy. History of inappropriate regimes drugs, preventive therapies, treatment interruptions, treatment with two drugs.

P1936 The risk of tuberculosis disease among HIV infected patients after 2 years of follow up Elena Daniels1, Ozana Cristina Anghier1, Claudia Cambrea2, Milea Mănăș1, Erdin Borgazi1, Sorin Rugina2.

Background: The risk of developing Tuberculosis (TB) disease is considered to be up to 7-10% each year for persons who are infected with both Mycobacterium tuberculosis (MTB) and HIV, whereas it is 10% over a lifetime for persons infected only with MTB. The aim of the study was to assess the risk of TB disease among HIV infected persons, based on different clues for tuberculosis' positive diagnosis, in a TB burden area, Constanta County.

Design: Prospective study started in 01 February 2009, ended in 31 January 2011. Material and methods: Evaluation for TB disease diagnosis was done in 51 HIV patients with initiated active antitubercular therapy (HAART) after 1996 and included medical history, physical examination, Mantoux Tuberculin skin test, chest X-rays, Blood blood culture results, bacteriological exam (Acid Fast Stains smear and Lowenstein Jensen cultures). All 51 HIV infected patients were monitored 2 years in order to diagnose the active TB diseases.

Results: The study includes 51 HIV infected people, 22 male and 29 female, mean age 20.5 years. The HIV infection range was within 6 months to 20 years. The risk of developing TB disease was of 21.5% (n=11/51). The prevalence of Pulmonary TB disease was greater (n=9/11;80%) than extrapulmonary forms. The symptoms of high fever, chronic cough, weight loss and diarrhoea were more persistent and more severe for HIV infected patients. Tuberculin skin testing and chest X-ray evaluation were helpful for diagnosis. Only one case had positive bacteriological exam.

Conclusions: The risk of developing active TB diseases at HIV infected people is much higher than studies reported. The bacteriologic exam is less helpful for TB diagnosis.

P1937 Primary drug resistance in HIV/TB patients Vera Zimina1, Irina Vasilyeva1, Aleksey Kravchenko2, Farid Batirov3, Irina Viktorova4, 1TB, Central Tuberculosis Research Institute, Moscow, Russian Federation; 2TB, Central Tuberculosis Research Institute, Moscow, Russian Federation; 3TBIVH, Tuberculosis Hospital #7, Moscow, Russian Federation; 4State Medical Institute for Postgraduate Training, Novokuznetsk, Russian Federation.

The aim of the study was to examine the frequency of MBT detection and the spectrum of primary drug resistance in HIV-positive patients with TB depending on the degree of immunosuppression. A study of 304 HIV-positive new TB cases registered during 2006-2010 with median CD4 count 140 cells/μl was carried out in Tuberculosis Hospital #7 (Moscow, Russian Federation). The mean age was 31.6±6.4 years.

Etologic confirmation of TB was obtained in 56.9% of patients (n=173), including those from sputum (35.2%; n=107), and the rest (n=66) from other materials (exudate, urine, cerebrospinal fluid, discharge from the fistula, biopsy material). Patients with CD4+ <100 cells/μl and with CD4+ ≥350 cells/μl were found to be smear and/or culture positive more frequently (42.7%, n=53 and 42.0%, n=18 respectively) than those with CD4+ 100-349 cells/μl (26.2%, n=36, p<0.05).

Drug susceptibility test was conducted in 126 patients on Lowenstein-Jensen media using absolute concentration method. MBT were susceptible in 48.4% of patients (n=61). 7.1% of isolates were monoresistant, polypersistence was found in 15.1% (n=19) (in most cases to combination of streptomycin or isoniazid – 57.9%). MDR TB was detected in 29.4% of patients (n=37) (including 4 cases of XDR, 3.2%). It should be noted that MDR was recorded in 35.4% of patients with CD4 + lymphocytes <200 cells/μl (28 out of 79), whereas the level of MDR in patients with CD4+ >200 cells/μl was 19.2% (9 out of 47) (p<0.005). Resistance to fluoroquinolones was registered in 7.1%.

Conclusion: Primary MDR was detected in every 3rd HIV/TB patient. The results of the study suggest the frequency of MBT detection from sputum in HIV/TB patients, as well as frequency of MDR, depends on the degree of immunosuppression.

P1938 The molecular-genetic methods in the express diagnostics of tuberculosis pleurisy (PTB) in HIV-infected patients Vasilekov Zharavelev1, Kirill Vladimirov2, Irina Vasilyeva1, 1Laboratory of Genetic Methods of Research, The Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation; 2Phthisiopulmonology, I.I. Mechnikov Medical Academy, St. Petersburg, Russian Federation.

84 HIV infected patients suffering with PTB admitted to TB hospitals. 42 had only PTB, 28 had suffered with pulmonary and PTB and 14 had multorgan TB. All the patients had new TB cases and no one of them obtained anti-retroviral therapy prior to admission. We studied pleural fluid in 84 and pleural biopsies in 16 cases. In all the patients pleural fluid was obtained during needle aspiration in a routine fashion. In 16 cases with PTB a thoracoscopic pleural biopsy was made to verify the diagnosis. Real time polymerase chain reaction (PCR-RT) and TB-biochip (TBCh) were performed. TBCh identifies mutations in four MBT genes associated with drug resistance (DR) to rifampin (R) rpoB and to isoniazid (H) katG, inhA, abpC. Sensitivity of PCR-RT was 55.9% (n=47) for pleural fluid and 75% (n=12) for the biopsies. Mutations in rpoB gene were found in 29 (61.7%) of cases, among them 22 (75.9%) due to replacement of the codon 531 (Ser-Leu). Other replaced codons were 511 (n=3), 516 (n=3), 526 (n=2) cases. We revealed DR to H, caused by mutations in katG gene in 25 (53.2%) cases, mostly in the codon 315 – 23 (92%). Mutations in other genes were rare: 4 (8.5%) in inhA and 1 (2.1%) in abpC. Mutations associated with DR to both H and R were present in 22 (44.7%). High prevalence of strains with combination of rpoB531 and katG315 mutations confirms the continuing presence of the pool of DR strains of Beijing genotype at the territory of North-West region of Russia in conditions of wide application of R in HIV infected patients. Our data suggest that PCR-RT and TBCh of pleural fluid and biopsies are highly sensitive for express detection of DR TB in the patients suffering with pleurisy and HIV.

P1939 Value of third sputum specimen for microscopic detection of pulmonary tuberculosis in HIV infected patients Majid Marjani, Payam Tabarsi, Parvaneh Baghaei, Mohammad Reza Masjedi, Ali Akbar Velayati. Clinical Tuberculosis and Epidemiology Research Center, National Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran.

Objectives: This study performed to evaluate sensitivity of two versus three sputum smears for diagnosis of pulmonary tuberculosis in patients with HIV co-infection. Methods: The study was done in National Research Institute of Tuberculosis and Lung Disease, Tehran, Iran. Data of patients with pulmonary tuberculosis and HIV co-infection was gathered from 2006 to 2009. New cases of tuberculosis that their disease diagnosed by positive sputum smear with acid fast staining and confirmed by positive culture in Lowenstein Media were selected. Results of first, second and third sputum were assessed. Results: Among 133 HIV infected patients with mean age of 40±9.5 and mean CD4 cell count of 82±12 cells/mm^3 sensitivity of first, second and third sputum smears for detection of acid fast bacilli was 83.5%, 84.1% and 82% respectively. First or second sputum specimens were positive among 95% of them. Extra diagnostic yield of the third sample was only 5%. Conclusion: In HIV infected patients who are suspected to pulmonary tuberculosis, two sputum specimens are enough for primary evaluation.

P1940 Adverse effects of treatment in HIV-associated tuberculosis patients in Iran Parvaneh Baghaei Shiva, Payam Tabarsi, Majid Marjani, Mohammad Reza Masjedi. Clinical Tuberculosis and Epidemiology Research Center, National Research of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran.

Background: We intend to assess the frequency of adverse effects of tuberculosis treatment in HIV patients.

Methods: The study was conducted at National Tuberculosis referral center in Iran, 2005-2010 including all documented TB patients with HIV co-infected. All patients received anti-TB treatment based on National TB Program. All adverse effects (AE) observed in patients were recorded in our registry.

Results: Of the total 151 TB/HIV patients, 81 (53.6%) developed adverse effects (AE), whether major or minor. Major AE (65) included: fever (46), convulsions (4), thrombocytopenia (17), rash (5) and 86.2% of them had CD4+ <100 (p<0.001). There were no differences between uses of HAART, outcome of treatment and major AE. Other AE did not show statistical significant in our study.

Conclusion: This study showed that major adverse effects do not affect to outcome of TB treatment.
Methods: We aimed to evaluate the results of TST (retesting if the first was negative) and two IGRA (T-SPOT.TB and QuantiFERON-TB GOLD In Tube) in 164 IBT patients from our hospital. Concordance between IGRA and TST was evaluated using kappa test.

Results: 164 patients were enrolled. TST was positive in 47 (28.7%) of 164 patients. The concordance between TST and T-SPOT.TB was low (kappa: 0.215, p < 0.001) (Table 1), the same as TST and QuantiFERON (Kappa 0.230, p < 0.001) (Table 2), and between T-SPOT.TB and QuantiFERON was moderate (Kappa 0.413, p<0.001).

Overall, 57 patients (34.8%) were diagnosed as LTBI (47 for positive TST and 10 more were detected by positive IGRA with TST negative result); the joint performance of two IGRA increased the percentage of patients diagnosed of LTBI (21.3% [95% CI, 8.5%-34.0%]); 8 out 10 positive-IGRA and negative-TST patients were receiving steroids therapy.

Conclusions: In IBD patients, concordance between TST and the two IGRA studied (T-SPOT.TB and QuantiFERON) was in general low. Performance of two IGRA altogether increases the number of IBD patients diagnosed of LTBI.
P1946
Tumor nekrosis factor-alfa blockers and tuberculosis – Analysis of the 6 years of Sergin Börekçi1, Berra Duman1, Nejdiye Mazican 1, Koray Tasçılar1,2, Beniam Miscellin1, Güll Öngör1, Vedat Hamuryudan1, 1Department of Pulmonary Disease, University of Istanbul, Cerrahpasa Medical School, Istanbul, Turkey; 2Division of Rheumatology, University of Istanbul, Cerrahpasa Medical School, Istanbul, Turkey.

Aim: It is a known fact that risk of tuberculosis infection is increased with tumor necrosis factor-alfa (TNF-α) blocker treatments. In this study we evaluated the last 6 years follow up data of the patients who admitted to our clinic for tuberculosis scanning before and during TNF-α blocker treatment.

Method: Total of 2335 patients’ follow up data were evaluated between February 2005 and February 2011. Statistical analysis were done by using SPSS 15.0 statistical program.

Results: There were 1186 (51%) male, 1149 (49%) female of total number of 2335 patients. Mean age was 40±14±6.7 years. Patients with the diagnosis of rheumatoid arthritis 785 (33.6%), ankylosing spondylitis 912 (39.1%), psoriatic arthritis 193 (8.3%), Behçet disease 85 (3.6%), Chroen disease 65 (2.8%), juvenile rheumatoid arthritis 142 (6.1%). 781 (33.9%) of the subjects had smoking history of an average 15.07±13.57 pack-year. 792 (33.9%) patients treated with Etanercept, 725 (31.0%) Infliximab, 567 (24.3%) Adalimumab. 66 (2.8%) patients had treatment for tuberculosis in the past, 112 (4.8%) patients had diabetes mellitus. According to RAED II (The Society for Research and Education in Rheumatology) Guideline; PPD was ≥ 5 mm in 1340 (57%), 101 (4.3%) had radiological fibrous lesion, 12 (0.5%) had contact history with tuberculosis. 1308 (56.0%) patients were given preventive treatment with Isoniazid. In these 6 years follow up, 4 (171/100.000) patients had tuberculosis infection; 2 were miliary tuberculosis (one of them was multidrug resistant), 1 was gastrointestinal tuberculosis and the last one was relaps patient with a history of tuberculosis.

Conclusion: This results supported that close follow up of patients who used TNF-α blocker was so important.

P1947
Quantiferon-TB GOLD vs. TST methods of detection tuberculosis infection in rheumatoid arthritis patients with previously TNF-z inhibitors treatment
Zeno-Ioan Fratila, Ionela Iovan, Dorin Vancea. Pneumology, Clinical Hospital of Infectious Diseases and Pneumology “De Victor Babes”, Timisoara, Timis, Romania

Introduction: TNFα inhibitors play an important role as therapeutic agents for certain chronic inflammatory diseases, but this treatment influences the subject’s immune status and can lead to opportunistic infections, including the TB.

Objective: Assessment of the sensitivity of the QuantiFERON-TB GOLD (QFT) method versus the tuberculin skin test (TST) in detecting TB infection on a group of patients with rheumatoid arthritis previously treated with Infliximab.

Methodology: Selection of a group of 52 rheumatoid arthritis patients treated before with TNFα inhibitors, diagnosed with pulmonary or extra pulmonary tuberculosis. On these 52 subjects TST and QFT were performed, observing the 6-monthly confirmed cases).

Results: From the processed data we observed that in the group of 23 patients with confirmed tuberculosis infection, 14 have had TST positive results (60.87%) and 10 were QuantiFERON-GOLD positive (45.4%).

Conclusions: QFT is an important method of TB infection diagnosis, but in patients undergoing chronic treatment with TNFα inhibitors it doesn’t show a greater sensitivity than TST.

P1948
Pulmonary tuberculosis (PT) in patients taking the TNF-a inhibitor infliximab (INF)
Pavel Gavrilov1, 2, Viacheslav Zhuravlev1, Liudmila Archacova1, Sergiy Dolgikh1, 3, 1X-ray, SCT, MRT, The Research Institute of Phtsiopathology, St. Petersburg, Russian Federation; 2Laboratory of Genetic Methods of Research, The Research Institute of Phthisiopathology, St. Petersburg, Russian Federation; 3Phthisiopathology, The Research Institute of Phtsiopathology, St. Petersburg, Russian Federation; 4The Medical Center of Biological Therapy, The Medical Academy of Postgraduate Studies, St. Petersburg, Russian Federation

Depression of TNF-a functions by its inhibitors not only suppresses the immune-inflammatory process, but also results in certain depression of an organism immune protection level and in increase in its susceptibility to TB. The medical and X-ray data of 263 patients taking INF for treatment of rheumatoid disease were analyzed. The features of PT in patients taking INF were studied. All the patients every 6 months undergo X-ray examination of the lungs. The PT has developed in 8 patients taking INF and was diagnosed in 4.6±2.5 months of therapy, the number of infusions was from 2 to 6. The PT was diagnosed after respiratory complaints, in 5 patients the MBB was isolated from the sputum. Studying of Mantoux test with 2 TE before the INF course has shown that this method does not provide any reliable information, because all the patients before that have been taking immunosuppressive hormonal therapy for a long time. The X-ray archive analysis has not resulted in identification of any pathological changes. In case of detection of the disease in 5 patients there were visible multiple changes in both lungs, it was mostly changes in the upper lobes of the lungs. 3 patients with focal dissimilation had infiltrates with small destruction cavities. All the patients had typical expressed bilateral enlargement of all groups of lymph nodes, tumor type with polycyclicity of the contours. The lymph nodes structure was normal. Rapid development of PT infection is typical for all the patients with tendency to generalisation and expressed hyperplasia of intrathoracic lymph nodes. In order to determine the risk of TB before administration of INF it is necessary to carry out quantiferon test and SCT.

Inhibition of hypoxia-induced phenotype alterations through epithelial-mesenchymal transition (EMT) in lung cancer by gene modulation of phosphorilation sites in tumor suppressor PTEN
Naozumi Hashimoto, Yoshinori Hasagawa. Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan

Recent studies suggested that hypoxia modulate epithelial-mesenchymal transition (EMT) process. For this measurement we evaluated the biological activities of PTEN, by which cell proliferation and migration are involved, could be regulated by phosphorilation in its e-terminal. In this study, we analyzed whether gene modulation of PTEN phosphorilation sites could inhibit hypoxia-induced phenotype alterations through EMT in lung cancer cells. GFP and GFP-PTENmut were transduced into lung cancer H358 with the doxycyclyne (Dox) inducible gene expression system. Dox-induced expression of GFP and GFP-PTENmut in H358 were confirmed by western blot analysis. Both the Dox-treated cells with GFP or GFP-PTENmut under hypoxic condition showed the decreasing expression of Epacrinin and the de novo expression of fibrocin in EMT and significantly increased the migration ability. Only the Dox-treated cells with GFP-PTENmut kept the expression E-cadherin and inhibited the de novo expression of fibrocin against hypoxia condition. Furthermore, these cells showed the significant repression of cell migration even under hypoxia condition, supported by the finding of suppressed expression of Akt and FAK phosphorylation. In this study, gene trasduction and Dox induction did not affect cell proliferation. These findings suggest that the gene modulation of phosphorilation sites in PTEN might give a new therapeutic strategy to regulate metastasis in lung cancer.

P1950
Loss of orphan G protein coupled receptor GPRC5A is associated with metastatic disease and poor survival in patients with adenoacarcinomas of the lung
Jan K. Hennigs1,2,3, Sarah Minner1,2, Julia Müller1,2, Hans Jörg Baumann1,3, Carsten Bokemeyer1,2,3, Guido Sauter2,3, Hans Kloe1,2. 1II. Department of Internal Medicine – Oncology, Hematology, BMT and Pneumology, University Medical Center Hamburg, Hamburg, Germany; 2Department of Cardiothoracic and Vascular Surgery, Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3Hubertus Wald Tumorzentrum, University Cancer Center Hamburg (UCC), Hamburg, Germany

Introduction: Orphan G protein coupled receptor (GPRC) 5A from the group GPCRs (GPRC5A) has recently been suggested to be a tumor suppressor of lung cancers. First results from knockout mice and human RNA analyses implied an association with adenoacarcinomas and poor survival. The aim of the present study was to identify prevalence and clinical significance of GPRC5A protein expression in non-small cell lung cancers (NSCLC).

Materials and methods: GPRC5A protein expression was analyzed by immuno-histochemistry using a tissue microarray containing samples from more than 2,000 lung cancer patients with clinical follow-up data (Mean: 35.2±3.4 months).

Results: GPRC5A expression was absent in 298 (17.4%) of approximately 1,700 analyzable NSCLC (n=792 squamous cell carcinomas, n=471 adenocarcinomas, n=309 large cell carcinomas and n=96 other NSCLC). 41% of all analyzed NSCLC showed moderate to strong cytoplasmic and membranous GPRC5A stain. Staining intensities were inversely correlated with high tumor cell proliferation (p<0.0001) and grading (p<0.05). In adenocarcinomas, absence of GPRC5A was seen in just 20 cases (4.2%) but was strongly associated with metastatic disease and staging (both p<0.0001). Cumulative survival was significantly lower in patients with adenocarcinomas lacking GPRC5A (p<0.01).

Conclusions: Loss of GPRC5A is linked to high tumor cell proliferation in NSCLC. In adenocarcinomas of the lung, it is not very frequent but is strongly associated with metastatic disease and poor prognosis. Therefore, GPRC5A expression seems to be an important prognostic factor.
P1951

RARE2 methylation level in blood for lung cancer assessment

Anastasia Ponomaryova1, Elena Rykova2, Nadezda Cherdyns'teva2, Tatiana Skvortsova1, Alexey Dobrodeev1, Alexander Zay'danov1, Sergey Turziv1, Valentin Vlassov2, Pavel Laktionov2, Immunochemistry, Cancer Research, Tomsk, Russian Federation; 2Cellular Biology Group, Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

Background: Cell-free DNA bearing the same epigenetic changes as the tumor tissue is found in blood and can be a useful tool for tumor patients indicating their usefulness as complementary diagnostic and prognostic markers for lung cancer.

Methods: Blood samples of 30 healthy men and 50 patients with confirmed non-small-cell lung cancer (NSCLC) before and after surgery were enrolled in this study. Methylation level of RARb2 gene in the cfDNA from blood plasma and cfDNA eluted from blood cell surface with PBS/EDTA and trypsin solutions was assessed by quantitative methylation-specific PCR.

Results: It was found that RARb2 gene methylation level was significantly increased in plasma cfDNA and cell-surface-bound cfDNA from NSCLC patients compared with healthy subjects (7620 copies/ml and 1083 copies/ml in the cell-surface-bound fraction, 3589 copies/ml and 1068 copies/ml in the blood plasma, Mann-Whitney U test, P<0.05). The increase of RARb2 methylation level was associated with stage and unfavorable outcome of the disease. 93% of NSCLC patients demonstrated the significant decrease of RARb2 methylation level in cfDNA at the time point of 10-15 days after surgery.

Conclusions: Epigenetic alterations of RARb2 gene in the total cfDNA were found to be associated with lung cancer progression. Correlation of RARb2 methylation level with tumor stage, outcome of disease and surgical treatment efficacy demonstrate applicability of cfDNA methylation marker assessment as a valuable tool for lung cancer prognosis and treatment monitoring improvement.

P1952

Quantitative methylation profiles of multiple genes in patients with non-small cell lung cancer and its association with clinicopathological correlations

Milica Konc1, Jelena Stojmc1, Dragana Jovanovic2, Vera Bunjevacki2, cell lung cancer and its association with clinicopathological correlations

Methods: Primary tumor samples (n=65), corresponding of non-malignant lung tissues (n=65) and blood samples (n=51) were obtained from NSCLC patients, treated with curative resectional surgery. Hypermethylation status was quantified at multiple CpG sites within each promoter in multiple genes—SOX1, RASSF1A, HOXA9, CDH3, MGMT, ESR1 and DAPK by pyrosequencing.

Results: For most of the genes there was a significant difference between tumor methylation, normal tissue and blood samples. Methylation in tumors was significantly higher than in normal lung for SOX1, DAPK, RASSF1A, HOXA9 and CDH3. Tumor hypermethylation was more frequently for adenosarcoma at CDH3 and ESR1. A higher proportion of SSC tumors were hypermethylated at HOXA9 and SOX1 compared to other types of NSCLC. Patients with stage four more likely had hypermethylation at MGMT and patients with hypermethylation at HOX9 more likely had stage two and three tumors. Gender was associated with hypermethylation at CDH3 with females being more likely to have hypermethylated tumors.

Conclusions: Our results show that elevated methylation levels observed in genes SOX1, RASSF1A, HOXA9, CDH3, MGMT, ESR1 and DAPK were cancer-specific and associated with some clinicopathologic features of patients.

The risk of distant metastases and prognosis prediction in early stage squamous cell lung cancer (SqCLC) by means of 3 microRNAs expression assessment

Marcin Skrzypski1, Rafal Drzdziaszko1, Amelia Szymanska2, Ewa Jassem2, Piotr Czapienski1, Wojciech Bierman1, Witold Ryzman2, Ryszard Pawlowski2, Jacek Jassem1. 1Oncology and Radiotherapy, Medical University of Gdansk, Gdansk, Pomorskie, Poland; 2Pathology, Medical University of Gdansk, Gdansk, Pomorskie, Poland

Methods: The clinical significance of plasma DNA quantification in NSCLC and to explore whether these mutations are restricted to an adenocarcinoma component.

Aims: KRAS and EGFR oncoproteins have proven to be clinically significant as predictive or prognostic factors in non-small cell lung cancer (NSCLC). These genetic alterations are poorly investigated in squamous cell carcinoma (SCC). In the single study we evaluated the frequency of these cancer relevant mutations in adenocarcinoma (ADC) and SCC and therefore sought to gain further insights into the significance of EGFR in NSCLC and to explore whether these mutations are restricted to an adenocarcinoma component.

Materials and methods: Tumor samples of 741 patients suffering from stage III to IV NSCLC were investigated. KRAS mutations were examined by means of two independent analytical methods (Sequenom and SNaPshot). The molecular status of EGFR exon 19 and exon 21 were analyzed by fragment analysis. Mutations in EGFR exon 18 were assessed by direct sequencing.

Results: The 741 NSCLC samples comprised 149 (20.1%) SCC and 592 (79.9%) ADC. No coexisting mutations of EGFR and KRAS occurred in ADC and SCC, respectively. EGFR mutations were detected in 9 of 149 (6%) SCC (5.4% in exons 19 and 21).

Conclusions: KRAS and EGFR oncoproteins have proven to be clinically significant as predictive or prognostic factors in non-small cell lung cancer (NSCLC). These genetic alterations are poorly investigated in squamous cell carcinoma (SCC). In the single study we evaluated the frequency of these cancer relevant mutations in adenocarcinoma (ADC) and SCC and therefore sought to gain further insights into the significance of EGFR in NSCLC and to explore whether these mutations are restricted to an adenocarcinoma component.
Activating mutations of the EGFR gene are present in NSCLC and respond to EGFR TKI therapy, but 50% of these patients show disease progression during the course of TKI treatment, possibly due to resistant tumor cell clones primarily present as small clones within the carcinoma. We tested 80 adenocarcinomas of the lung for known EGFR mutations and using different methods for mutation analysis, and tried to correlate the new adenocarcinoma classification with EGFR mutational status. The study included 40 samples with proven mutation status and 40 patients with primary lung tumors. We applied several methods for mutation analysis, and compared to each other our results show a better specificity and better sensitivity. Cases analyzed by LightCycler assay and pyrosequencing showed 100% correspondence to 454 sequencing, whereas all other methods showed aberrations. Mutations present in small tumor cell clones were not detected by any of the other methods. Furthermore, T790M resistance mutation combined with an activating mutation could be found in 2 untreated patient samples. The results underline the need for higher sensitivity methods applicable in routine diagnostics.

Evaluation of highly sensitive PNA-LNA PCR clamp method for EGFR L858R mutation detection in lung adenocarcinoma patients

Michal Skromski1, Tomosaki Tanaka2, Adam Szpechcinski1, Renata Langfort2, Teresa Maierhofer3, Gabriele Michelitsch2, Elvira Stacher2, Martin Filipits3, Theresa Maierhofer1, Andreas Roth1, Susann Stephan-Falkenau1, Olifert Landt3, Cornelia Gitz2, Thomas Mairinger1, 1Pathology, Institute of Pathology, Berlin, Germany; 2Syntheselabor GmbH, Tübingen, Germany; 3Pathology, University of Applied Sciences, Senftenberg, Germany; 4Institute of Cancer Research, Cancer Research Centre Vienna, Vienna, Austria; 5Pathology, Helios Klinikum Emil von Behring, Berlin, Germany

Objective: Direct sequencing is widely accepted method for EGFR mutation identification, but has limited sensitivity. It often requires additional procedures, like microdissection, to enrich the sample in cancer cells, when their content in tissue specimen is less than 50%. PNA-LNA PCR clamping represents allele-specific approach to gene analysis and demonstrates potent accuracy and ability to detect mutant alleles even in present in low fraction of cells.

Method: 79 DNA samples isolated from fresh-frozen and FFPE tissues, which mutation status was formerly confirmed by sequencing, were analyzed by PNA-LNA PCR clamping for EGFR point mutation L858R in exon 21.

Results: L858R mutation was detected in 8/79 (10%) samples by direct sequencing, whereas in 12/79 (15%) samples by PNA-LNA PCR clamping. All mutant-positive samples by sequencing were correctly determined by PNA-LNA PCR clamp. The remaining 4 L858R mutant-positive samples were recognized as wild type by sequencing. Two of them contained only 5% and 20% of cancer cells, respectively. Surprisingly, in the other two samples PNA-LNA PCR clamping method detected only low levels of EGFR mutant allele, despite the cancer cell content were high (100% and 80%).

Conclusions: PNA-LNA PCR clamp technique enables sensitive and reliable detection of EGFR mutant allele in specimens with cancer cell content insufficient for direct sequencing or genetically heterogeneous. Regarding its extremely high sensitivity, PNA-LNA PCR clamping should be validated thoroughly prior implementation into EGFR diagnostic routine to prevent overdiagnosis.

Evaluation of four different molecular methods for EGFR mutation analysis in exons 18, 19 and 21

Anna Streidel1, Andreas Roth1, Susann Stephan-Falkenau1, Olifert Landt3, Cornelia Gitz2, Thomas Mairinger1, 1Pathology, Institute of Pathology, Berlin, Germany; 2Syntheselabor GmbH, Tübingen, Germany

Aims: EGFR mutation status detection is essential for comprehensive NSCLC treatment Most Non Small Cell Lung Carcinomas are analyzed by histological examination of a biopsy obtained by bronchoscopy. However, presence of very small amounts of tissue is available. These conditions require methods, suitable for the detection of very small amounts of mutated DNA. The aim of this study was to compare the sensitivity of mutation detection of four different molecular methods.

Methods: 237 cases with NSCLC were included. All biopsies were formalin fixed and paraffin embedded. DNA was isolated after microdissection of tumor tissue from 20 μm slides, exons 18, 19 and 21 of the EGFR gene were investigated using pyrosequencing (PS) and BioFilm Chip Hybridization (Chip). Additionally, a LightCycler assay was performed for Exon 19 (LC). All mutations were independently confirmed by Sanger sequencing.

Results: We determined 197 cases with mutations. 40 with mutations, 26 mutated in Exon 19. Chip: 24 samples, of which 4 mutated, could not be analyzed due to insufficient DNA amplification. Exon 19: 26 out of 26 detected correctly. PS: 39 of 40 mutations were detected. Exon19: 25 out of 26 detected correctly. LC (target only Exon 19): 25 of 26 were recognized correctly by this method.

Discussion: A comparison of methods showed no significant difference in sensitivity. Moreover, the Chipmethod failed to generate a sufficient PCR product out of very small amounts of DNA. Surprisingly, in the other two samples PNA-LNA PCR clamping method detected mutations positive.

Non-coding RNAs as functional player and molecular marker in lung cancer

Marie Polyczak-Cancer, Institute of Pathology, University of Rzeszow, Rzeszow, Poland; 1Stefanie Grund1, Arne Warth2, Heike Zabeck3, Catherina Hildendrath1, Marion Baas1, Michael Meister1, Thomas Muley1, Peter Schirmacher1, Hans Hoffmann1, Philipp Schnabel2, Sven Diedrichs1, 1Helmholtz University-Junior Research Group Molecular RNA Biology & Cancer, German Cancer Research Center (DKFZ) & Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 2Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 3Department of Surgery, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany; 4Translational Research Unit, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany

Objective: For direct sequencing or genetically heterogenous. Regarding its extremely high sensitivity, PNA-LNA PCR clamping should be validated thoroughly prior implementation into EGFR diagnostic routine to prevent overdiagnosis.

Materials and Methods: We tested with 1, Stefanie Grund1, Arne Warth2, Heike Zabeck3, Catherina Hildendrath1, Marion Baas1, Michael Meister1, Thomas Muley1, Peter Schirmacher1, Hans Hoffmann1, Philipp Schnabel2, Sven Diedrichs1, 1Helmholtz University-Junior Research Group Molecular RNA Biology & Cancer, German Cancer Research Center (DKFZ) & Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 2Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 3Department of Surgery, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany; 4Translational Research Unit, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany

Discussion: A comparison of methods showed no significant difference in sensitivity. Moreover, the Chipmethod failed to generate a sufficient PCR product out of very small amounts of DNA. Surprisingly, in the other two samples PNA-LNA PCR clamping method detected mutations positive.

Non-coding RNAs as functional player and molecular marker in lung cancer

Marie Polyczak-Cancer, Institute of Pathology, University of Rzeszow, Rzeszow, Poland; 1Stefanie Grund1, Arne Warth2, Heike Zabeck3, Catherina Hildendrath1, Marion Baas1, Michael Meister1, Thomas Muley1, Peter Schirmacher1, Hans Hoffmann1, Philipp Schnabel2, Sven Diedrichs1, 1Helmholtz University-Junior Research Group Molecular RNA Biology & Cancer, German Cancer Research Center (DKFZ) & Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 2Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; 3Department of Surgery, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany; 4Translational Research Unit, Thorasklinik Heidelberg, University Hospital Heidelberg, Heidelberg, Germany

Objective: To assess the expression landscape of this new class of molecules, we have profiled the expression of 17000 non-coding RNAs in comparison to 22000 protein-coding mRNAs in early stages of lung adenocarcinoma and matched non-malignant lung tissue. These studies revealed molecular signatures associated with tumorigenesis (tumor vs. normal, diagnostic value), with histological subtypes (acinar vs. solid) as well as with the outcome and metastasis development (prognostic value).

Methods: Eight novel, differentially expressed transcripts named “Lung Cancer intergenic LNA” (LncRaI1 - LncRaI8) were validated and selected for functional characterization, for which we have implemented several technologies. To identify the molecular RNA-protein-networks in which the ncRNAs could function, we use RNA affinity purification and mass spectrometry. To study loss-of-function phenotypes in human lung cancer cells, we have developed a novel technique to create functional knockouts of ncRNAs in human lung cancer cell lines using Zinc Finger Nucleases. This strategy allows the specific and stable silencing of the targeted ncRNA without off-target effects for functional studies. Our research uncovers the functions at the cellular and molecular level of the differentially regulated ncRNAs as well as their clinical importance as diagnostic and prognostic markers.

Polymorphisms A1026G and G369C of CDKN1A/p21 and p53 genes in lung cancer

Alla I. Dmitrieva, Irina A. Kuznetsova, Sergei S. Rakitin, Vjacheslav V. Novitskiy.

Pathophysiology, Siberian State Medical University, Tomsk, Russian Federation

In this study, we analyzed the polymorphisms of genes regulating the cell cycle and p53 CDKN1A/p21 as factors of genetic predisposition to lung cancer in patients with lung cancer. We examined 65 patients with lung cancer (average age 58.7 ± 12.3 years) and 100 healthy blood donors (average age 52.6 ± 12.7 years). Diagnosis of lung cancer was confirmed morphologically, endoscopically and radiologically. The study of these genes was performed by PCR/RFLP analysis. 72-GC- polymorphism analysis of p53 gene has revealed a slight increase in the frequency of the variant G72C-genotype of the p53 gene in lung cancer patients compared with those in healthy (38 and 32% respectively, P = 0.695).

We have also analyzed two polymorphisms CDKN1A/p21: 1026 A/G and 369 G/C; polymorphism in the 5′-gene promoter. In analyzing the 1026-A/G-p21 gene polymorphism was found halving the frequency of AG-genotype in lung cancer
patients compared with those in healthy individuals (38 and 77%, respectively; OR = 0.72, CI95% 0.81-3.95). The frequency of AA-genotype of p21 gene in patients and healthy was respectively 50 and 19% for the GG-genotype of p21 gene was respectively 40 and 6%; OR=0.53, CI95% 1.27-2.42). This enabled us to assume that the AG-genotype performs protective and AA-genotype - the role of predisposing to cancer of the lung. The frequency of A-allele in lung cancer patients was higher than in healthy individuals (70 and 57.5%, respectively). OR of lung cancer for carriers of the A-allele was 1.72 (CI95% 1.05-2.83).

In the analysis of G369C-gene polymorphism in p21 is shown, the frequency of C-allele in lung cancer patients significantly exceeded in that in healthy individuals (20.77 and 11%, respectively; OR=2.12, CI95% 1.10-4.09).

Expression profiling in hypoxic non-small cell lung cancer explants reveals a four-gene hypoxia signature

Katharina Leithner1, Christoph Wohlfahrt2, Elvira Stacher2, Jörg Lindemann2, Freyja-Maria Smolle-Jüttner3, Helmut H. Popper2, Andelko Hrzenjak1, Andrea Olschewski7,10, Horst Olschewski11, Division of Pulmonology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; 2Institute of Pathology, Medical University of Graz, Graz, Austria; 3Division of Thoracic and Hyperbaric Surgery, Department of Surgery, Medical University of Graz, Graz, Austria; 4Experimental Anesthesiology, University Clinic for Anesthesiology and Intensive Care Medicine, Medical University of Graz, Graz, Austria; 5Ludwig Boltzmann Institute for Lung Vascular Research, Ludwig Boltzmann Society, Graz, Austria

Background: Hypoxia is frequent in solid cancers like lung cancer and contributes to chemotherapy resistance. To identify patients with hypoxic tumors would be of advantage. Direct oxygen measurements are of limited use, thus, feasible hypoxia markers are needed.

Material and Methods: A novel ex-vivo model was established using fragmented non-small cell lung cancer (NSCLC) specimens cultured three days under hypoxia (1% oxygen) or normoxia. cdNA microarrays were performed on hypoxia and normoxic fragments derived from ten patients (five adenocarcinomas, five squamous cell carcinomas). Correction for multiple testing was performed using FDR5.

Results: Histomorphology and viability/apoptosis tests confirmed the viability of the fragments. HIF-1α immunostaining and expression of carbonic anhydrase IX mRNA were increased in hypoxia. Microarray analysis revealed 129 regulated genes with at least two-fold expression change in hypoxia compared to normoxia. Hypoxia-induced gene expression was histology-dependent, only four genes were significantly regulated in both subtypes.

Conclusions: Our novel ex-vivo model is suitable to study hypoxic adaptation in lung cancer. Its advantage is the use of real tumor tissue maintained under different oxygen concentrations. cdNA expression profiling revealed a four-gene hypoxia signature that might be useful in therapies aiming to restore tumor perfusion and oxygenation.

Contribution of immunohistochemical (IHC) markers to the diagnosis of pulmonary carcinoids

Tina Zahel1, Arne Warth1, Esther Herpel1, Benjamin Goeppert1, Albrecht Steenstra1, Sabine Kryza2, Hans Hoffmann2, Birte Schirmacher1, Philipp Schnabel1, Division of Pathology, University Clinics, Heidelberg, Germany; 2Thoracic Surgery, Thorax Klinik Heidelberg at University Clinics, Heidelberg, Germany

Introduction: Data about prevalence and clinicopathological meaning of IHC markers in pulmonary typical (TC, n=114) and atypical (AC, n=86) carcinoids is still debated. The goal of this study was to present expression patterns of several IHC markers in TC and AC. To get an insight on differential diagnostic, prognostic, and potential therapeutic value.

Methods: 200 pulmonary carcinoid tumors were investigated for tissue distribution of: CD56, CD57, Chromogranin A, Synaptophysin, TTF-1, CK18, KL1, ERC21, EGFNR, and Her-2/neu. Ka67 was employed and the proliferative index (PI) was counted on whole slides of resected specimens.

Results: Mean PI was 1.8% in TC and 3.7% in AC and was significantly different in both groups (p<0.0001).Correlation between PI and mean mitotic count was significant. Furthermore, max PI correlated significantly with outcome. Established neuroendocrine markers Synaptophysin, Chromogranin A, and N-CAM (CD56) were strongly positive. Synaptophysin was expressed with highest intensity of all markers in 95.4% TC and 98.6% AC. Thyroid transcription factor 1 (TTF-1) was positive in 73.0% TC and 77.0% AC. Only few cases expressed EGFR and Her2/neu.

Conclusions: Our model demonstrates that expression of Synaptophysin, Chromogranin A and N-CAM are sufficient for a fast and accurate diagnosis of TC and AC. Further studies are needed to establish other markers as potential diagnostic and prognostic tools.
Conclusions: Synaptophysin may be the most sensitive marker for neuroendocrine differentiation. Nevertheless, there is no specific marker to clearly separate TC from AC. We confirm that the PI, as determined by Ki67 staining is higher in AC than in TC and might be an ancillary tool for the distinction between TC and AC in addition to the mitotic rate. Moreover, the combination of PI and mitotic count in terms of a grading system may predict outcome more effectively than mitotic count alone and should be subject to further research.

P1966

Genetic polymorphism of alpha 1 antitrypsin and glutathione S transferase and lung cancer risk
Andrea Catana1, 2, Raffo Popp1, Monica Popp2, Miha Popenjan1, Victor Popp1, Adrian Trifa1, Felicia Petrut1, Marius Farcas1, 2, Department of Medical Genetics, University of Medicine and Pharmacy, Cluj Napoca, Romania; 2Pneumology, Leon Daniello Pneumology Hospital, Cluj Napoca, Romania; Internal Medicine II, Emergency Clinical Hospital, Cluj Napoca, Romania

Background: Polymorphisms for genes encoding alpha 1 antitrypsin (A1AT) and glutathione S-transferase (GSTM1/GSTT1) might contribute to the variability in individual susceptibility to lung cancer.

Objectives: This is a cross-sectional, randomized, case control study for the evaluation of the frequency of A1AT (M, Z and MZ) and GST (GSTM1/GSTT1 null) alleles among patients with lung cancer. The study included 56 cases of lung cancer diagnosed patients (histopathological examination), recruited from the Pneumology Hospital Leon Daniello Cluj and 125 healthy unrelated controls, selected among patients observed in the Internal Medicine Department.

Methods: A1AT genotyping was carried out using PCR amplification of relevant gene segment was followed by restriction enzyme digestion TaqI. Detection of A1AT gene S and Z alleles was determined through analysis of resulting restriction fragment length polymorphism (RFLP). For GSTM and GSTT genotyping we used multiplex PCR, followed by gel electrophoresis analysis.

Results: The molecular analysis identified the MS genotype in 3 (5.4%) patients with lung cancer and 1 (0.8%) of the controls. The heterogeneous MZ state was detected neither among cases nor in controls. The prevalence of GSTM null genotype in lung cancer patients was 49.4% compared to 42.8% of controls, also the prevalence of GSTT null genotype in lung cancer patients was 24.5% compared to 18.2% of controls.

Conclusions: Our findings (positive statistical significance) suggest that heritable A1AT and GST status may influence the risk of lung cancer development.

P1967

Quality matters in lung cancer diagnosis: Comparison of endobronchial cryobiopsy with conventional forceps biopsy
Ute Oltmann1, Doris Russel1, Mark Slade3, 1Thoracic Oncology, Papworth Hospital, Papworth Everard, Cambridge, United Kingdom; 2Histopathology, Papworth Hospital, Papworth Everard, Cambridge, United Kingdom

Introduction: Endoscopic forceps biopsies are often small and inadequate for detailed analysis whereas biopsies obtained with cryoprobes may provide tissue samples that are larger and better preserved. We compared the quality and complication rate of endoscopic forceps- and cryobiopsies.

Methods: Prospectively collected data of patients who underwent cryobiopsy (CB, n=14) were compared with randomly selected patients who had conventional forceps biopsies (FB) during the same period (n=13). All patients were considered prospectively to have definite endobronchial tumour. Sample size and quality was assessed. Complication rate and final diagnosis were also recorded.

Results: Maximum sample diameter was significantly larger in the CB group (median 1.6cm, range 0.7-3.0cm) compared to the FB group (median 0.5cm, range 0.3-1.3cm, p<0.001). All biopsy samples were diagnostic of malignancy apart from 1 CB sample showing necrosis only. Semi-quantitative analysis showed a smaller proportional tumour area within the biopsy when forceps were used (median 50%, range 0-90%) compared to the cryoprobe technique (median 90%, range 50-100%, p<0.001). 6 of 13 FBs had artifact changes affecting up to 90% of the biopsy whereas only 1 CB had minor artifact changes of 5%. 1 FB patient had mild bleeding. Mild and moderate bleeding were seen in 2 CB patients, respectively.

Conclusions: Cryo biopsy appears to provide larger and higher-quality tumour specimens than conventional forceps biopsy. These differences may become important in an era of targeted therapies for individual patients, when multiple testing of biopsies is required. We believe the technique of cryobiopsy merits further evaluation.

P1968

Bronchoscopic cryoablation gains high diagnostic rate in submucosal tumor growth
Dieter Gunzing1, Serge Grefl2, Henrik Wurp3, Win Ammenwerth1, Torsten-Gerriet Blum1, Jens Kollmeyer1, Nikola Schöfnd1, Christian Boch1, Susann Stephan-Falkenau1, Thomas Mauringer1, Torsten Bauer1, 1Department of Pneumology, HELIOS Klinikum Emil von Behring, Pulmonary Diseases Clinic Heckeshorn, Berlin, Germany; 2Department of Pathology, HELIOS Klinikum Emil von Behring, Pulmonary Diseases Clinic, Berlin, Germany

Introduction: The diagnostic yield of endoscopic biopsy in the central bronchial system is impaired when submucosal tumor growth is present. Conventional forceps biopsy fails to reveal conclusive histology even in cases of extrabronchial compression or other indirect tumor signs. Since endoscopic cryotechniques have increasing impact for diagnoses of malignant and inflammatory lung disease we compared the diagnostic rate of forceps and cryoprobe in patients with suspected submucosal tumor growth.

Methods: 116 patients with macroscopic submucosal tumor infiltration were investigated prospectively with forceps- and cryobiopsy from 05/2009 to 02/2011. In cases 1-3 forceps and 1-2 cryoprobe specimens were obtained, other biopsy methods were added as needed. Specimens underwent routine histopathological processing.

Results: Histological diagnosis was achieved with the following specimens: Forceps 4/116 pts. (3.5%), cryo 48 (41.4%), forceps/cryo 34 (29.3%), cryo/TBNA 2 (1.7%), cryo/EBUS 6 (5.2%), forceps/cryo/EBUS 2 (1.7%), forceps/cryo/EBUS 2 (1.7%), TBNA 4 (3.5%), EBUS 12 (10.3%). CT-guided biopsy 2 (1.7%). Hit the target point in 18 (21.6%) cases. The diagnostic rate in the central bronchial submucosal tumor growth we found a relevant difference of diagnostic yield and a decisive superiority of cryotechnique, which should be considered for routine use in diagnostic bronchoscopy.

P1969

Does routine use of EBUS-TBNA and EUS-FNA improve the accuracy of staging of non small cell lung cancer patients – A national tumor registry based study
Mark Kramsk, Anders Mellengaard, Erik Jakobsen. Department of Thoracic and Cardiuvaskular Surgery, Rigshospitalet, Copenhagen, Denmark Department of Oncology, Herlev Hospital, Copenhagen, Denmark Department of Thoracic and Cardiuvaskular Surgery, Odense University Hospital, Odense, Denmark

Background: Evaluation of the extend of disease or stage (TNM) is a prerequisite for correct treatment of lung cancer. Several studies have showed that biopsies and fine needle aspirations obtained by EBUS-TBNA and EUS-FNA yield similar results as mediapso, which previosly have been considered the standard for evaluation of mediastial nodal involvement in NSCLC. Thus EBUS-TBNA and EUS-FNA should now be considered as procedures which are equally effective as mediastinoscopy in staging while at the same time being more gentle to the patient.

Material: We therefore used data from a population based lung cancer registry to evaluate the association between frequency of use of EBUS-TBNA/EUS-FNA and precision of mediastinal work-up. EUS in diagnostics and staging of lung cancer have been used in several centres for more than a decade and since 2005 several centres have inter grated EUS in their procedures.

Results: The material consisted of 7000 operated patients since 2003. The use of endoscopic ultrasound (EBUS-TBNA/EUS-FNA) was mostly used in one region and mediastinoscopy in another. The concordance between n and p were highest and equal in the regions where mainly mediastinoscopy were used and the reason where Endoscopic Ultrasound was used

Conclusion: For the first time it is possible to get an impression of the impact of the use of EBUS-TBNA and EUS-FNA in a national populationof lung cancer patients. The we no difference in the pT/pN ratio in the areas where they used mediastinoscopy and where they used endoscopic Ultrasound.

P1970

Impact of endobronchial ultrasound guided transbronchial needle aspiration (EBUS-TBNA) in the evaluation of mediastinal adenopathy in lung cancer
Niamh Coleman1, Amanda Lavan1, Killian Hurley2, Ross Morgan2, 1Internal Medicine, Beaumont Hospital, Dublin, Ireland; 2Respiratory Medicine, Beaumont Hospital, Dublin, Ireland

Introduction: TBNA is an established technique for sampling mediastinal nodes in the diagnosis and staging of lung cancer. The advent of EBUS-TBNA has allowed the respiratory physician to access more and sample smaller nodes than mediastinoscopy in staging while at the same time being more gentle to the patient.

Aims: To determine the diagnostic yield, sensitivity and specificity of conventional TBNA (CTBNA) and EBUS-TBNA in our unit.

Methods: Data collected included patient characteristics, nodes sampled, pathological diagnosis and clinical outcome. Following EBUS introduction, this data was collected prospectively over a 6 month period.

Results: 63 TBNA procedures were performed in the months preceding EBUS introduction. The overall diagnostic yield was 71.43% (n=45) and 46.67% (n=21)

342s

Farmacereuti SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
of these specimens were from station seven. 78 specimens were acquired via EBUS-TBNA in the first 6 months of the programme. The diagnostic yield was 83.3% (n=65), 42.3% (n=32) samples were from station 7, 28.1% (n=22) from 4R, 5.1% (n=4) from 4L and 9% (n=7) from 10R. Sensitivity for cancer improved from 80.65% in the CTBNA group to 83.3% in the EBUS-TBNA group despite a dip to 75% in the first 3 months of the programme when analysed separately. Specificity was 100%. There were no major complications.

**Conclusions:** EBUS-TBNA was associated with improvement in diagnostic yield and sensitivity for lung cancer nodal involvement when compared to conventional techniques. A clear learning curve was seen but overcome within 3 months. This improvement in yield and the ability to sample more nodal locations may reduce referral for surgical or repeat procedures.

**P1971** Evaluation of endobronchial ultrasound-guided needle aspiration selected samples – The point of view of pathology
Rica Zinsky1, Rolf Henrich2, Boelkebkaas Boelkebkaas1, Joachim Schirren1, Annette Fisseler-Eckhoff1, 1Dr. Horst-Schmidt Kliniken, Institute of Pathology and Cytology, Wiesbaden, Germany; 2Dr. Horst-Schmidt Kliniken, Clinic of Internal Medicine, Wiesbaden, Germany; 3Dr. Horst-Schmidt Kliniken, Clinic of Thoracic Surgery, Wiesbaden, Germany

Some studies were done to compare EBUS-TBNA with other methods. The diagnostic finding of the EBUS-TBNA probes and every other medical report of the patient was recorded. Malignancies were subdivided in NSCLC NO, Ade- nocarcinoma, Squamous Cell Carcinoma, Small Cell Carcinoma other than the lung cancer and Malignancies NO. The same localisation of the lung analysed with TBNA was examined with another method such as resection or biopsy in selected cases. With this data, the accordance between the sampling techniques was controlled. Of these 222 TBNA probes, from lymphode station 7, 10, 4 and 2 such as upper thoracal lesions, in 206 (93%) cases a diagnose (tumor or-not-tumor) was made, in 16 (7%) cases no clear diagnosis could be made concerning the worse tissue quality.

Sensitivity for cancer improved from 80.65% in the cTBNA group to 83.33% in the the EBUS-TBNA group despite a dip to 75% in the first 3 months of the programme when analysed separately. Specificity was 100%. There were no major complications.

**Conclusions:** EBUS-TBNA was associated with improvement in diagnostic yield and sensitivity for lung cancer nodal involvement when compared to conventional techniques. A clear learning curve was seen but overcome within 3 months. This improvement in yield and the ability to sample more nodal locations may reduce referral for surgical or repeat procedures.

**P1973** Can mediastinoscopy after negative endosonography in lung cancer be omitted? Subanalysis of ASTER with focus on PET
Kurt Tournay1, Robert Rintoul2, Christophe Dooms3, Ellen Deschepper2, Jouke Annema5, 1Respiratory Medicine - Thoracic Oncology, Ghent University Hospital, Ghent, Belgium; 2Respiratory Medicine - Thoracic Oncology, University Hospitals Leuven, Leuven, Belgium; 3Respiratory Medicine - Thoracic Oncology, Papworth Hospital, Cambridge, United Kingdom; 4Biostatistics, Ghent University Hospital, Ghent, Belgium; 5Respiratory Medicine - Thoracic Oncology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Mediastinal staging in non-small cell lung cancer with endosonography (EUS-FNA plus EBUS-TBNA) followed by mediastinoscopy is more sensitive to detect nodal metastasis as compared to mediastinoscopy alone (ASTER trial, JAMA 2010;304:2245). However 11 patients need to undergo a mediastinoscopy to detect one with N2/3 missed by endosonography. We analysed if FDG-PET identifies patients in whom the mediastinoscopy can be omitted.

**Methods:** In ASTER, 123 patients were randomized to endosonography followed by mediastinoscopy when the former did not show mediastinal metastasis. Sensitivity, negative predictive value (NPV) and number of mediastinoscopic needed to detect one false negative endosonography were calculated in the cases with complete data (n=120, 98%).

**Results:** With PET, 77 patients had FDG-avid mediastinal nodes; the prevalence of N2/3 was 73 (62-81%). The sensitivity and NPV of endosonography was 88 (76-94) and 75 (57-88%). Adding mediastinoscopy increased sensitivity and NPV to 96 (88-99) and 91 (73-98%). 43 patients did not have FDG-avid mediastinal nodes, the prevalence of N2/3 was 23 (13-38%). The sensitivity and NPV of endosonography was 70 (40-89%) and 92 (78-97%). Adding mediastinoscopy increased sensitivity and NPV to 80 (69-94%) and 94 (81-98%). In patients with FDG-avid vs. FDG-cold mediastinal nodes, the number of mediastinoscopic needed to detect one false negative endosonography is 6 vs 36 (p=0.078).

**Conclusions:** A negative endosonography should be followed by a mediastinoscopy if PET positive mediastinal nodes are present. In the absence of PET positive nodes, a mediastinoscopy following a negative endosonography can be omitted.

**P1974** Risk of lung cancer in patients with preinvasive bronchial lesions followed by autologous bronchoscopy and chest computed tomographyP1974
Alaa Mohamed1, Shibuya Kiyoshi2, W. John3, W. Ronkone1, H. Hoshino2, S. Yoshida2, M. Suzuki2, K. Hiroshima3, Y. Nakatani2, Aihai Mohamed-Hussein1, Maha Elkouly1, Tarek Mahfouz1, 1Respiratory Medicine - Thoracic Oncology, University Hospitals Leuven, Leuven, Belgium; 2Respiratory Medicine - Thoracic Oncology, Ghent University Hospital, Ghent, Belgium; 3Respiratory Medicine - Thoracic Oncology, University Hospitals Leuven, Leuven, Belgium; 4Biostatistics, Ghent University Hospital, Ghent, Belgium; 5Respiratory Medicine - Thoracic Oncology, Leiden University Medical Center, Leiden, Netherlands

**Introduction and aim of the work:** To assess risk of lung cancer (LC) in patients with preinvasive bronchial lesions and to identify factors associated with higher risk.

**Patients and methods:** 124 patients with one or more preinvasive bronchial lesions and normal chest computed tomography (CT) (mean age 66.7 years, 121 males and 3 females), followed-up by white light and autofluorescence bronchoscopy (AFB) every 4-6 mo and chest CT every 6-12 mo, end points were development of carcinoma in situ (CIS) or LC.

**Results:** Among 124 patients with 240 preinvasive bronchial lesions, 20 CIS or LC lesions were detected during follow-up in 20 (16%) patients, 7 were detected as new endobronchial lesions, 10 as new peripheral lesions and 3 as local progression from severe dysplasia to CIS. Median time to progression was 24 months (range: 6-54 mo). The Cumulative risk of progression was 7% at one year, 20% at three years and 44% at 5 years. Among detected lung cancers, 80% were stage 0 or stage I and underwent treatment with curative intent. Diagnosis of new SD during follow-up (p=0.001), chronic obstructive pulmonary disease (COPD) (p = 0.001) or smoking index >52 pack-year (p = 0.042) was associated with higher risk. Even after controlling for other risk factors, COPD was associated with risk of progression. Baseline lesion grade was not predictive of patient outcome (p = 0.146).

**Conclusions:** Patients with preinvasive bronchial lesions, especially those with new SD during follow-up, COPD or smoking >52 pack-year are at high risk of LC, AFB and CT follow-up facilitated early detection and treatment with curative intent.

**P1975** Validation of diagnostic molecular markers in bronchial fluid for lung cancer
Alaa Mohamed1, Nuria Marin1, Begona Ruiz-Arigiello1, Sandra Pedrero1, Larrazit Garcia1, Maria Urbarriz1, Sergio Carrera3, Jaime Algorta2, Guillermo Lopez-Vivanco1, Rafael Zalacain1, 1Pneumology, Cruces Hospital, Baracaldo, Spain; 2PROTEOMIKA, Technology Park in Vizcaya, Zamudio, Spain; 3Oncology, Cruces Hospital, Baracaldo, Spain

**Aim:** To set a diagnosis method in bronchial fluid to detect lung cancer (LC) with high sensitivity. For this, using proteomic techniques, we have identified some biomarkers which are increased in patients with LC.

**Material/Methods:** We have included bronchial aspirates samples from 204 patients diagnosed with lung cancer by biopsy 141 non-microcytic (NSCLC) (59
adenocarcinoma and 82 epidermoid), 63 microcytic (SCLC) and 49 control patients with other non malignant pathologies.

Immunohistoassays have been performed based on ≈MAP technology (lumines X) for each specific molecular marker. Once the assay has been designed and optimized, the amount of each marker has been quantified in each sample. Both groups were controlled with control group using t-student test. The diagnostic capacity of each marker has been evaluated by ROC curve. Finally, model was obtained by multivariate logistic regression analysis.

Results: Immunohistoassays have been performed by IHC, for each marker, such as NCC, as SCLC cancer, in bronchial aspirates samples: - 5 markers that detect NSCLC with sensitivity of 95% and specificity of 77% have been observed. The calculated ROC area was 0.95. - 6 markers that detect NSCLC with sensitivity of 95% and specificity of 81% have been observed. The calculated ROC area was 0.96.

Conclusions: Some protein markers are expressed differently in patients with cancer, not only NSCLC but also SCLC, and in patients without cancer. These proteins detect these tumors with high sensitivity and specificity. Due to this, these markers could be used to design a diagnostic test in clinical routine.

P1976
 Curette lavage fluid analysis of EGFR, KRAS, and P53 mutations in lung cancer patients
 Fumihito Yamaguchi1,2, Kunihiko Fukuchi1, Sakiko Tazawa1, Hitotsubu Tabeto1, Eisuke Kato1, Aya Wakanabashy1, Asami Tada1, Takuya Iwasaki2, Makoto Hayashiy1, Yutaka Tsuchiya1, Jun Yamashita1, Noriko Itoh2, Fumio Kojima1, Department of Respiratory Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; 2Department of Clinical Pathology, Showa University, Tokyo, Japan

Purpose: Mutation analyses of individual lung cancer patients should provide useful information for determining treatment. When sufficient tissue samples for pathology cannot be collected by bronchoscopy, cytology is substituted to establish diagnostic resection. The present study evaluated liquid cytological material (LCM), from brush biopsies (EBs), for detecting the EGFR, KRAS, and P53 mutations in tissues attached to the curette were analyzed by collecting the lavage fluid.

Subjects: Samples were obtained from 63 lung cancer patients receiving treatment from April, 2009 to October 2010 at the Department of Respiratory Medicine, Showa University Fujigaoka Hospital. Official approval for the study was obtained in advance by the Ethics Committee for Genomic Research at Showa University.

Methods: DNAs were extracted from cells in the curette lavage fluid. PCRs were performed using amplification mutation hot spot regions in EGFR, KRAS, and P53. The PCR products were sequenced and the mutations confirmed by sequencing with the ABI 3730 capillary.

Results and discussion: Seven patients were found with EGFR mutations and seven with P53 mutations. No mutation in KRAS was identified. The mutation rates observed here for the three genes were lower than those reported previously with both forward and reverse primers.

Conclusion: EGFR mutation gene analysis.

P1977
 Clinical utility of EGFR gene mutation analysis with cytological materials from bronchoscopy not histological materials
 Kyosuke Nakata, Yoshikazu Kotani, Yukihisa Hatakeyama, Nanako Tomita, Nobuko Hazeki, Akihito Sashika, Kazuyuki Kobayashi, Yasuhiko Funada, Yoshihiro Nishimura. Division of Respiratory Medicine, Kobe University Hospital, Kobe, Hyogo, Japan

Rationale: Epidermal growth factor receptor (EGFR) gene mutation analysis becomes essential in medical cares for non-small-cell lung cancer after the report of the effectiveness of Gefitinib for non-small-cell lung cancer patients who have EGFR gene mutations. Although most of materials for EGFR gene mutation analysis in the past reports or clinical practice is submitted from lung tissue, we recently identified. The mutation rates observed here for the three genes were lower than those reported previously with both forward and reverse primers.

Conclusion: EGFR mutation gene analysis.

P1978
 Prognostic impact of angiogenesis factors in bronchoscopic washing fluid from patients with non-small cell lung cancer
 Andriani Chapadola1, Christina Fevragoulou1, Marinos Zontanos1, Ioannis Danos2, Panos Demetrizis2, Ioannis Gozios1, Kostas Syrigos1. 1Oncoology Unit, 3rd Dept of Medicine, Athens School of Medicine, 7th Pulmonary Dept., 3rd Pulmonary Dept., Sotira General & Chest Hospital, Athens, Greece

Background: Angiogenesis has been proven to be a process related to the migration, proliferation and metastasis of cancer cells. The prognostic value of angiogenesis factors is controversial.

Aim: The aim of this study is to define the VEGF, VEGFR1 and VEGFR2 and the ratios of VEGF/VEGFR1 and VEGF/VEGFR2 in the blood serum and the washing of patients with newly diagnosed non-small cell lung cancer (NSCLC).

Methods: 40 patients with NSCLC participated in this study. The measurement of circulating (c) and washing (w) levels of VEGF, VEGFR1 and VEGFR2 was carried out with the ELISA method.

Results: cVEGF levels is correlated with T descriptors in TNM staging system (r=0.021), as well as the ratio VEGF/VEGFR2 in serum and washing (r=0.03 and r=0.040 relatively). From those who were treated with chemotherapy, best responses were observed in lower concentrations of VEGF in serum and washing (r<0.001). Higher concentrations of wVEGF are correlated with worse overall survival (HR 2.28, 95%CI 1.13-4.19, P=0.002) and PFS (HR 2.66, 95%CI 1.45-4.48, P=0.019). Similar results for OS and PFS were observed with high values of the wVEGF/VEGFR2 ratio. Multivariate Cox analysis revealed as independent markers for overall survival VEGF, VEGFR1 and VEGFR2 in serum and washing (r=0.017 and r=0.034 relatively), while for PFS independent markers were VEGFR1 (r=0.04), VEGF/VEGFR1 (r=0.03) and VEGF/VEGFR2 (r=0.007) in washing.

Conclusions: The circulating levels of VEGF and VEGFR2 are controversial. Nevertheless, the difference in detection sensitivity of washing might allow to recognize a risk group of patients who could benefit from an agressive initial therapeutic approach.

P1979
 Does immediate cytological analysis at bronchoscopy lead to reduced number of biopsies?
 Chakwada Eunchi, Maria Manalo, Behdad Shambayati, Paul Murray. Respiratory Medicine, Ashford and St Peter’s Foundation Trust, Surry, United Kingdom

Introduction: The British Thoracic Society guidelines [1] for diagnostic flexible bronchoscopy in adults are currently under review. Present guidelines highlight the importance of needing five endobronchial biopsies (EBs) to optimise diagnostic yield. The aim of our study was to find out whether the availability of a cytopathologist during bronchoscopy has led both to a reduction in the number and need of EBs performed.

Method: The study period was March to October 2010. We reviewed whether the use of immediate analysis of brush biopsies or tumour roll on EBs performed had led to a reduction in the number of EBs performed by comparing the number of biopsies performed during this period to numbers performed prior to our in-room cytopathologist set up. We also reviewed 14 consecutive patients who had EBs performed during the study period to look at both how many biopsies tended to be first pass positive and how many biopsies in total were taken per patient.

Results: We found that the availability of a cytopathologist within the bronchoscopy room has led to a significant reduction in the number of EBs performed without detriment to diagnostic rate or further testing like IHC and EGFR status. Of the 14 patients who had EBs 85% of cases were first pass positive with the mean of total biopsies taken being two.

Conclusion: Our retrospective study shows that the availability of an in-room cytopathologist reduces the number of biopsies performed, and thus associated complications. Furthermore our small cohort demonstrates that even without a cytopathologist the recommended five EBs is unnecessary.

P1980
 The efficacy of cytology sampling in the diagnosis of suspected endobronchial lung cancer
 Farhana Shora, Gulam Haji, Haider Ali, Frances Bowen. Clinical Infection & Respiratory Medicine Directorate, Imperial College Healthcare NHS Trust, London, United Kingdom

Introduction: Fibreoptic bronchoscopy (FOB) is a minimally invasive procedure that is regularly performed on an outpatient basis to aid diagnosis in suspected endobronchial lung cancer, not only NSCLC but also SCLC, and in patients without cancer. These investigations are normally performed by the cytopathologist set up. We also reviewed 14 consecutive patients who had EBs performed during the study period to look at both how many biopsies tended to be first pass positive and how many biopsies in total were taken per patient.

Method: The study period was March to October 2010. We reviewed whether the use of immediate analysis of brush biopsies or tumour roll on EBs performed had led to a reduction in the number of EBs performed by comparing the number of biopsies performed during this period to numbers performed prior to our in-room cytopathologist set up. We also reviewed 14 consecutive patients who had EBs performed during the study period to look at both how many biopsies tended to be first pass positive and how many biopsies in total were taken per patient.

Results: We found that the availability of a cytopathologist within the bronchoscopy room has led to a significant reduction in the number of EBs performed without detriment to diagnostic rate or further testing like IHC and EGFR status. Of the 14 patients who had EBs 85% of cases were first pass positive with the mean of total biopsies taken being two.

Conclusion: Our retrospective study shows that the availability of an in-room cytopathologist reduces the number of biopsies performed, and thus associated complications. Furthermore our small cohort demonstrates that even without a cytopathologist the recommended five EBs is unnecessary.

positive histology alone. 3 (20%) cases had positive cytology but negative histology in the context of an endobronchial lesion. All 7 patients without an endobronchial lesion had negative cytology and were subsequently found not to have cancer. Only 1 patient with an endobronchial lesion had both negative histology and cytology and was proven not to have cancer.

Conclusion: From this retrospective analysis we conclude that 20% of lung cancers would have been missed if cytological samples had been taken in addition to endobronchial biopsies. Therefore we suggest that any patient with an endobronchial lesion should have brushings and washings accompanying a biopsy. We cannot deduce from our small study whether, in the absence of a visible endobronchial lesion, brushings and washings are diagnostically valuable.

P1981
Relative contribution of cytological specimen type in the determination of lung cancer histologic identity – Analysis of one year’s comparative data
Stylianos Michaelides1, Aphrodite Emmanouilidou2, Georgia Goulas1, Ageliki Lazaratou1, Despina Melemeni1, Aikaterini Blana2, Vassilios Handrininos1, 11st Dept. of Thoracic Medicine, 2Dept. of Clinical Cytology, Simmangon General Hospital, Maroussi, Athens, Attiki, Greece

We retrospectively evaluated the relative contribution of cytological specimens in identifying the histologic type of lung cancer. Seventy-four patients (50 male & 24 female) aged 63.8±9.9 years (mean±SD), eventually diagnosed to have lung cancer were studied. Diagnosis was established by either bronchoscopic or surgical biopsy: The spectrum of cytological specimens included: simple sputum smear (SP), bronchial washings (BW), post-broncoscopic brushing (PB), brushing smears (BS) and transbronchial fine needle aspirates (FNAs). The distribution of histologic types was as follows: Small Cell Lung Cancer (SCLC) 24 pts (32.4%), Squamous Cell Carcinoma 20 pts. (27%), Adenocarcinoma 14 pts. (18.9%), Undifferentiated Carcinoma 6pts. (8.3%), Large cell Carcinoma 2 pts. (2.8%). Analysis of data showed that simple sputum cytology was diagnostic in 24.3% (relative contribution 66.6% [confidence interval 53-34% for NSCLC]). Success rate of BW was 42% (although equally partitioned between SCLC & NSCLC 52% & 48% respectively). BS di- agnosed 23% of lung cancer, of which 56.3% was the yield for adenocarcinoma. The contribution of FNA smears cannot be evaluated due to the very small sample size (only 2 patients which was successful in both).The overall contribution of cytology in the diagnosis among all types of lung cancer cases studied was 57 pts among a total of 74 (77%). We conclude that simple sputum cytology should not be neglected (having a diagnostic rate of 25% of patients) while the significance of BS in adenocarcinoma (56.3%) should be emphasized given its frequent peripheral location that does not allow obtaining tissue for histologic diagnosis.

P1982
Liquid-based cytology in the diagnosis of pulmonary malignancy in bronchial brushings and washings
Beata Olejnicka1, Annika Dejmek1, Agneta Westman2, Nooredin Zennedeh2
1Department of Medicine, Trelleborg Hospital, Trelleborg, Sweden; 2Department of Clinical Pathology and Cytology, University Hospital, Malmo, Sweden

Background and aims: Bronchial cytology (BC) is well established in the diagnosis of lung cancer but some cases remain equivocal. Liquid-based cytology (LBC) was developed to improve the diagnostic accuracy and increase the sensitivity for malignancy in BC. The study was conducted to compare the diagnostic performance of CytoRichRed (CRR) fixed TriPath preparations with conventional smears (CS) from bronchial brushings (BB) and bronchial washings (BW).

Methods: BB and BW from 61 patients, subjected to fiberoptic bronchoscopy were studied. BB specimens were split into two equal parts, one part was fixed in CRR and prepared according to the TriPath protocol, one part was ethanol-fixed and stained according to Papanicolaou. BBs were smeared onto slides, air-dried and Giemsa-stained, then brushes were rinsed in CRR and the cellular suspensions were processed according to the TriPath technique. Slides were evaluated in a blinded fashion and cytological diagnoses were compared with “true” diagnoses, based on histology and clinical data.

Results: In all 575 and 244 CS and 61 and 61 CRR/Tripath slides were prepared from the BB and the BW, respectively. CS diagnoses agreed in 57/61 cases. In the four discrepant cases the conventional/CRR diagnoses were atypia/benign, benign/atypia (malignancy favoured), benign/equivocal, atypia (active favoured/benign. All four cases turned out to be malignant.

Conclusions: The diagnostic accuracy did not differ between conventional and CRR/Tripath preparations. Our results indicate that LBC using CCR/Tripath can replace CS, significantly reducing work load and cost.

P1983
Endobronchial ultrasound and fluoroscopy in the study of peripheral lung lesions
Albert Sánchez-Fon1, Luisa Giralt1, Rodrigo Alcántara 2, Javier Gimeno 3, 1Pulmonary and Respiratory Intensive Care Unit, 2Regional University Hospital & UPRES EA 3830, University of Rouen, Rouen, France

Endobronchial ultrasound (EBUS) is a minimally invasive tech-

nique that expands the view of the bronchoscopist beyond the lumen of the airway. Radial probe EBUS (eREBUS) is used for the detection of peripheral lung lesions. Aim: To analyze the diagnostic yield of eREBUS in peripheral pulmonary lesions. Methods: All patients who underwent bronchoscopy to study peripheral lung lesions from January 2009 to February 2011 were prospectively included. Patients were randomly distributed in two groups: fluoroscopy and REBUS (30 patients, 20.4±7.8 years) or fluoroscopy alone (64 patients, 68.1±10.9 years). All procedures were performed under fluoroscopic guidance with iv conscious sedation. eREBUS was performed using an endoscopic ultrasound system (EU-M60, Olympus, Tokyo, Japan), equipped with a 20 MHz mechanical radial type miniature probe (UM-BB S20-17S). Bronchoscopist, cytologist, study protocol, techniques and tools were the same ones throughout the whole study.

Results: 94 patients (68.4±10.6 years) with peripheral pulmonary lesions suspicious of malignancy were studied. The average size of these lesions was 35.2±13.3 mm in eREBUS group vs 41.8±19.6 mm in fluoroscopy group (n.s). In 26 cases (27.6%) the size was <30 mm: 7 cases (23%) in eREBUS group vs 19 (29%) in fluoroscopy group (n.s). Global diagnostic yield was 73% using EBUS whereas it was 67% when using fluoroscopy alone (n.s.). Diagnostic yield in lesions <30 mm was higher in eREBUS (86% vs 58%, n.s.). No complications were reported related to REBUS or iv sedation.

Conclusions: eREBUS is a promising, useful and safe technique for the diagnosis of peripheral pulmonary lesions, especially in those of small size.

P1984
Diagnosis of pulmonary nodules localized beyond the range of standard bronchoscopere – 2011 results
Szymon Skoczynski, Grzegorz Brozek, Wladyslaw Pierzchala. Department of Pulmonology SP CSK in Katowice, Medical University of Silesia, Katowice, Poland

Background: There is a wide range of tools used in diagnosis of pulmonary nodules localized beyond the range of standard bronchoscopere, but it is still difficult to choose best method to obtain tissue samples.

Aims and objectives: The aim of our study was to assess safety and utility of methods currently used in Department of Pulmonology in Katowice, Poland, and to compare the obtained results to prepare diagnostic protocol to be tested in prospective study.

Methods: 93 consecutive patients records (56 females and 37 males) were analyzed. Included patients had at least one pulmonary nodule exceeding 10 mm in diameter, which on the basis of CT scan was not assessable by standard bronchoscopere. 

Results: 64 transbronchial biopsies were performed: 40 CT-guided cytolocal [22 (55%) diagnostic], 20 ultrasound guided cytolocal [10 (50%) diagnostic] and 4 ultrasound guided histological [all diagnostic] respectively. Pleural fluid was examined 8 times but only one pleurocentesis was diagnostic. Sputum analysis was performed 16 times but all results were not diagnostic. Out of 39 cases in which bronchofiberoscopy was performed 6 (15.9%) were diagnostic. All, except one positive diagnoses were pulmonary cancer. Out of 40 CT guided biopsies 17 (42.5%) were complicated by pneumothorax. In 3 (7.5%) cases drainage was required. Out of 20 ultrasound guided cytolocal biopsies there was 1 pneumothorax not requiring drainage. There were no observed complications in histological biopsies. The diameter of nodules in patients with positive diagnosis was bigger (p<0.05).

Conclusions: Accurate selection of diagnostic tools seems to be crucial for both an effective and safe diagnosis of pulmonary nodules.

245. Mechanical ventilation and lung injury: new advances

P1985
Late-breaking abstract: High flow oxygen therapy decreases endotracheal intubation requirement in patients with ARDS
Guillaume Schnelli1, 2, Claire Andrejak1, Bouchra Lamia1, Bédécourt Toublanc1, Jean-François Muir2, Antoine Cuvelier3, Vincent Jouanneau3, 1Pulmonary and Respiratory Intensive Care Unit, Amiens Teaching Hospital, Amiens, France; 2Pulmonary and Respiratory Intensive Care Unit, Rouen University Hospital & UPRES EA 3830, University of Rouen, Rouen, France

High flow oxygen (HFO) therapy is able to deliver up to 60L/min of a heated and humidified air-oxygen mixture through nasal cannulae and to provide small amount of positive end-expiratory pressure. Our objective was to assess the outcome of patients admitted for acute lung injury (ALI) or acute respiratory distress syndrome (ARDS) who were treated by HFO and to determine if HFO could decrease endotracheal intubation rate. We retrospectively selected 38 consecutive patients (median age 57 years) admitted to ICU for ALI (n=5, 13%) or ARDS (n=33, 87%) and who underwent HFO (Optiflow®, Fisher & Paykel, France) at admission (PaO2 < 65 mmHg, PaO2/FIO2 345s

Farmacautice SpA, Visit Chiesi Farmaceutici SpA, at Stand D.30
Mauo-Ying Bien1,2,3, Yu Ru Kuo4, You Shui Lin6, You-Lan Yang1,\nventilation for weaning ICU patients from mechanical ventilation\nComparisons of predictive performance of breathing pattern variabilities\nP1987\nIn vitro performance of an improved collapsible holding chamber (CHC) for the\ndelivery of bronchodilators to patients receiving mechanical ventilation\nMark Nagel, Valentina Avvaokouma, Rubina Ali, Cathy Doyle, Jolyon Mitchell.\nMedical Aerosol Laboratory, Trudell Medical International, London, ON, Canada\nBronchodilator delivery by pressurized metered-dose inhaler (pMDI) to patients on mechanical ventilation is best achieved without breaking the breathing circuit. We describe an evaluation of an improved CHC (AeroVent Plus*, Trudell Medical International, London, Canada (n=5 devices, 1 measurement/device), in which the pMDI canister receptacle is offset from the CHC axis to reduce internal impaction, and can also accept GSK pMDI canisters having a dose counter. Delivery of 3-actuations of salbutamol (HFA Ventolin*, GSK Canada; 100 µg/actuation) was assessed with the expanded CHC inserted in the inspiratory limb of an adult breathing circuit equipped with a 7-mm diameter endotracheal tube (ETT). An adult test lung (Michigan Instruments) was used to simulate the patient. The circuit was humidified near to body conditions (T = 36°C, 100%RH), and tidal breathing (600-mL, duty cycle = 33%, 10 breaths/min) was simulated by a servo ventilator (Siemens, model 900C). A filter was located between the distal end of the ETT and tidal test lung to collect the aerosol. Total mass (TM) of salbutamol after 6 respiratory cycles was determined by HPLC-UV spectrophotometry. Similar measurements were obtained with a Spiral* CHC (Armstrong Medical), providing benchmark data from a European marketed CHC having the pMDI receptacle in-line with the axis of the device. TM (mean± SD) from the AeroVent Plus and Spiral CHCs was 22.7±3.1 and 47.0±7.1 µg/actuation respectively. Clinicians using these devices should be aware of the implications of the difference in drug output between these apparently similar devices.

P1988\nHigh-frequency oscillatory ventilation – A safe procedure for COPD patients?\nSven Pulizze1, Ute Achzetzh1, Andreas Pechtmann2, Ernst Schmid3,\nMichael Quint0,1, Norbert Weilger1, Inez French1, Department of\nAnaesthesiology and Intensive Care Medicine, University Medical Center Schennew.-Holstein. Campus Kiel, Kiel, Germany; 2 Department of Internal\nMedicine IV, Medical Center, Chemnitz, Germany; 3 Department of\Anaesthesiology, Emergency and Intensive Care Medicine, University Medical Center Göttingen, Göttingen, Germany\nIntroduction: High-frequency oscillatory ventilation (HFOV) is an alternative type of mechanical ventilation. HIFOV is usually considered as not indicated in patients with obstructive lung disease because of the theoretical risk of air trapping and hyperinflation.\nAim and objectives: Intention of this study was to establish if HFOV can safely be applied in patients with exacerbation of chronic obstructive pulmonary disease and hypercapnic respiratory failure.\nMethods: Ten patients with acutely exacerbated chronic obstructive pulmonary disease (GOLD stages II-IV) requiring intensive care treatment who failed on non-invasive ventilation were studied. After a period of mechanical ventilation (CMV) of less than 72 hours all patients were transferred to HFOV for 24 hours and then back to CMV.\nMain results: Regional lung aeration and ventilation were assessed by electrical impedance tomography. HFOV was tolerated well, no adverse effects were ob- served. Effective CO2 elimination and oxygenation were achieved. Arterial partial pressure of CO2 was 52±13 mmHg (mean ± SD) during CMV before transition to HFOV and 47±9 mmHg by the end of the 24-hour period of HFOV. Ventilation was more homogeneously distributed during HFOV than during initial CMV. No signs of hyperinflation induced by HFOV were identified. Higher respiratory rate and tidal volume were found during CMV after 24 hours of HFOV than before.\nConclusions: Contrary to present recommendations on the use of HFOV in adult patients our pilot study indicates that this type of mechanical ventilation can safely be used in patients with chronic obstructive lung disease.

P1999\nEfficacy of a ventilator bundle for the prevention of the ventilator-associated pneumonia\nFelipe Chertcoff1, Miguel Blasco1, Carolina Giuffre2, Lorenza Maldonado3,\nSergio Verbanaz2, Elias Solosa1, Emiliano Descotte1, Ernesto Efron2.\n1Respiratory and Critical Care Medicine, British Hospital, Buenos Aires, Argentina; 2Infectology, British Hospital, Buenos Aires, Argentina\nIntroduction: Several specific and general strategies have proven effectiveness for prevention of ventilator-associated pneumonia (VAP).\nObjective: To evaluate the impact of ventilator bundle and the control of process measures on the rate of VAP in our Intensive Care Unit.\nMethods: A prospectively ventilator bundle have applied to every patient who received mechanical ventilation (MV). Daily control of the application of ventilator bundle was registered and weekly control of ventilator bundle compliance was registered. We compare the VAP rate of two periods, 25 months before the implementation of the bundle and 11 months after. The Poisson regression test was used. The methodology of the NHSN (National Healthcare Safety Network) was used for infection surveillance and the methodology of IHI (Institute of Healthcare Improvement) was used for compliance control.\nResults: The MV use rate was higher in ventilator-dependent patients (1381/2253 = 0.61 vs. 2840/5262 = 0.54 p<0.0001), the MV average days was also higher during the bundle period (8.52±2.07 vs. 7.03±1.61 p<0.0001). The VAP rate was lower during the bundle period compare with the previous one (3.62% MV days vs. 12.32% MV days p=0.001) with a reduction of the VAP of 70.6%. The compliance to the ventilator bundle was 97.91% and the fulfillment of the ventilator bundle was 90.13%.\nConclusion: The application of a ventilator bundle and control of ventilator bundle compliance was associated with a diminishment of the VAP rate.

P1990\nEffects of N-acetylcysteine in lipopolysaccharide-induced acute lung injury in the rat: Treatment after acute lung injury\nJae Sung Choi, Ho Sung Lee, Ki Hym Seo, Ju Ock Na, Yong Hoon Kim.\nDivision of Pulmonary and Critical Care Medicine, Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea\nIntroduction: As it has been known that N-acetylcysteine (NAC) which is a free radical scavenger and antioxidant reduces acute lung injury of rats stimulated by lipopolysaccharide, studies on NAC are being executed recently as a way of treatments of lung injuries. This study was to elucidate effect of NAC in LPS-induced acute lung injury in rats.\nMethods: Six weeks old SD rats were divided into 4 groups (group 1: saline; 2: NAC, group 3: LPS; group 4: LPS+NAC. LPS was intravenously injected at the rate of 5mg/kg. NAC of 20mg/kg was injected into abdominal cavity 3, 6 and 12 hours after the injection of LPS. BAL fluids and lung tissues were obtained from individual rats. Using 100mg of lung tissues, the levels of NF-κB and lipid peroxidation (LPO) were measured.

346s
Results: Neutrophilic inflammations of the lung tissues and BAL fluids were the most severe in the LPS group. The amounts of NF-kB in the group 3 (0.32±0.23 ng/μg) showed statistically significant differences compared with the group 1 (0.16±0.12 ng/μg) (p < 0.001) and 4 (0.25±0.19 ng/μg) (p < 0.05). The amounts of LPO in the group 3 (15.29±3.76 mmol/ml) showed statistically significant differences compared with the group 1 (4.35±4.27 mmol/ml), 2 (4.99±5.68 mmol/ml) (p < 0.01) and 4 (7.65±4.24 mmol/ml) (p < 0.05).

Conclusion: N-Acetylcysteine has a protective effect to reduce acute lung injury stimulated by endotoxin and it is considered that the mechanism appears in relation to neutrophils that are mainly involved in lung injuries.

P1991
C-reactive protein as a predictor of mortality in patients with severe sepsis in intensive care unit
Zulbul Karakuş, Ozlem Yazıcıoğlu Mocin, Orkan Devran, Nalan Adagüzel, Goksan Gungor, Merih Kalamuğan Balci, Ece Oz, Adnan Yılmaz. Intensive Care Unit, Suryayapapa Chest Diseases and Thoracic Surgery Training Hospital, İstanbul, Turkey

Objective: We aimed to research whether initial and/or third day of C- reactive protein (CRP) values can be good predictors of mortality as other well known complex predictors of mortality (ie, SOFA scores) for patients with severe sepsis requiring ICU.

Methods: Observational cohort study was done in a 20 beds respiratory ICU in chest diseases center in Istanbul in January 2009-March 2010. Patients with severe sepsis due to respiratory diseases (pneumonia, acute exacerbation of chronic obstructive pulmonary diseases, bronchectasis) were enrolled in this study. Patients with rheumatic diseases and cancer were excluded from study. SOFA scores and CRP values on admission, third day and mortality rate were recorded. The receiver operator characteristic (ROC) method and area under curve (AUC) were used to compare SOFA scores, CRP values.

Results: In study period 814 patients were admitted to ICU and eligible 314 patients (male 175, female 139) were included. Sepsis due to nosocomial infection, on 3rd day CRP values on admission, third day and mortality rate were recorded. The receiver operator characteristic (ROC) method and area under curve (AUC) were used to compare SOFA scores, CRP values.

Conclusion: Third day CRP values especially >100mg/L are better mortality predictor than first day CRP and as valuable as SOFA scores in patients with severe sepsis in ICU.

P1992
Mechanical properties of ALI/ARDS lung may be heterogenous
Massimo Crescioni1, Daniela Febres 1, Chiara Chiurazzi 1, Gallazzi Elisabetta 1, Eleonora Carlesso1, Davide Chiumello2, Luciano Gattinoni 1,2.

Objective: Mechanical properties of the recruited lung units was between the surrogate compliance of well inflated double the compliance of the poorly inflated tissue. As shown the median compliance of the well inflated tissue was almost triple range. As shown the median compliance of the poorly inflated tissue was almost double the compliance of the poorly inflated tissue while the surrogate compliance of the recruited lung units was between the surrogate compliance of well inflated and poorly inflated tissue.

Table 1. Specific lung tissue compliances

Conclusions: As recruited regions while increasing PEEP reach a lower gas tissue ratio and a smaller compliance than well inflated tissue changes in compliance may not be used to estimate lung recruitment at bedside.

P1993
Lactate and lactate clearance were associated with higher mortality in patients with septic shock
Prapun Kittivoravitchai, Anan Wattanatham, Adisorn Wongsa. Pulmonary and Critical Care Division, Department of Medicine, Phramongkutklao Hospital, Bangkok, Thailand

Introduction: An elevated lactate level is associated with higher mortality in patients with severe sepsis. Also, lactate clearance is a surrogate for magnitude and duration of global tissue hypoxia. However, the utility of the lactate clearance after ICU admission as an indicator of outcome in patients with septic shock is still limited.

Objectives: The purpose of study is to evaluate the advantage of lactate level and clearance in predicting mortality of patients with septic shock.

Methods: We prospectively enrolled 38 patients with septic shock in ICU at Phramongkutklao hospital. Measurements of venous lactate and ScvO2 were obtained at 0, 2, 6, 24, and 72 hours after ICU admission. Lactate clearance was defined as the percent change in lactate levels after 2 or 6 hours from the baseline value. The primary outcome was 28-day mortality rate.

Results: The 28-day mortality rate was 55.3%. There was no significant difference in 28-day mortality rate between normal ScvO2 (>70%) group and low ScvO2 (<70%) group at initial presentation. Using cut off value of 3 mmol/L, higher initial lactate level was significantly associated with higher 28 -d mortality (p = 0.017). There was also, significant association between lactate non-clearance (lactate clearance < 10%) at 2 and 6 hrs and higher 28-day mortality (p = 0.029 and 0.014).

Conclusions: Early lactate clearance may indicate a resolution of global tissue hypoxia and is associated with mortality. Patients with higher lactate clearance after 2 and 6 hrs of ICU admission have improved outcome compared with those with lower lactate clearance. Also, initial lactate level was independently associated with 28-day mortality rate.

246. Genetic and molecular background in pulmonary fibrosis

P1994
Mutations in SFTPC, SFTPA2 and TERT explain 60% of familial pulmonary fibrosis and correlate to specific disease phenotypes
Coline van Moorle1,2, Joanne van der Vis1, Matthijs van Oosterhout1, Henk Ruiven1, Pin de Jong1, Wouter van Es1, Jules van den Bosch1,2, Van Gruuters1,2. 1Centre for Interstitial Lung Disease, St Antonius Hospital, Nieuwegein, Netherlands; 2Heart & Lung Disease, University Utrecht, Utrecht, Netherlands

Idiopathic Pulmonary Fibrosis (IPF) is a fatal lung disease, histologically characterized by diffuse interstitial remodeling and patchy inflammation. A significant number of patients with IPF have a familial form of the disease. Separate reports have identified mutations in Surfactant Protein C (SFTPC), Surfactant Protein A2 (SFTPA2), Telomerase Reverse Transcriptase (TERT) or Telomerase RNA component (TERC) in these families. We determined the frequency of mutations in SFTPC, SFTPA2, TERT and TERC in 20 patients with Familial Pulmonary Fibrosis (FPF).

Heterozygous non-tolerated sequence changes were detected in 12 out of 20 patients, consisting of 5 SFTPC, 2 SFTPA2 and 5 TERT mutations. Mutations segregated with disease in each family and haplotype analysis showed that identical mutations had arisen independently. Families with SFTPC and SFTPA2 mutations always had evidence of parent-offspring disease transmission, while in families with TERT mutation sibs were affected. Pediatric pulmonary disease occurred only in families with SFTPC mutations. Carriers of an SFTPA2 mutation also suffered from lung cancer. Families with a TERT mutation usually presented as typical IPF and did not show clear symptoms associated with other known syndromes of telomere shortening.

This is the first report of a cohort of IPF families that is completely sequenced for candidate genes. We could identify a mutation in 60% of patients with FPF. These mutations correlated with a specific disease phenotype. The function of each of the mutated genes is very different, but all indicate towards a central role for the alveolar type II cell in disease pathogenesis.
P1995
Association between polymorphisms in the P53 and P21 genes and IPF
Nicoline Korthagen1, Coline van Moorsel 1, Karin Kazemier 2, Jan Grutters 1,2.
1Pulmonology, St Antonius Hospital, Nieuwegein, Netherlands; 2Division Heart and Lungs, University Medical Center Utrecht, Utrecht, Netherlands

Introduction: Idiopathic pulmonary fibrosis (IPF) is a devastating and progressive lung disease. Its aetiology remains unclear but is thought to involve damage to the epithelium and abnormal repair. Alveolar epithelial cells near areas of remodelling show an increased expression of proapoptotic molecules. The purpose of this study was to investigate the role of genes involved in cell cycle control in IPF.

Materials and methods: We included 353 controls and 77 IPF patients and determined genotypes for five polymorphisms in the P53 gene and four polymorphisms in CDKN1A, the gene encoding p21. In PBMC from 16 healthy controls mRNA expression of p53 and p21 was determined.

Results: The rs12951053 and rs12002273 polymorphisms in the p53 gene were significantly associated with survival in IPF patients. Carriers of the minor allele had a 4-year survival of only 22% versus 57% in the non-carrier group (p=0.006). All four polymorphisms in CDKN1A were significantly predisposed to IPF. The association between the polymorphisms and survival was with increased risk of developing IPF. In addition, the rs2395655 allele was associated with a rapid decline in lung function. The rs733590 polymorphism was significantly associated with p21 mRNA expression levels.

Conclusion: This study reports the novel finding that polymorphisms in the p53 gene are associated with survival and polymorphisms in the p21 gene predispose to IPF. This suggests cell cycle defects are involved in the pathology of IPF. Variations in the p53 and p21 genes may impair the response to cell damage and increase the loss of alveolar epithelial cells.

P1996
Genetic variability in the IL1RN gene and the balance between IL1-Ra and IL-1β in IPF
Nicole Barlo1, Coline van Moorsel 1, Nicoline Korthagen1, Michiel Heron1, Ger Rijkers1, Henk Roven2, Jelena Skibova3, Ilja Striz3.
1Centre for Interventional Lung Diseases, Department of Pulmonology, St. Antonius Hospital, Nieuwegein, Netherlands; 2Division of Medical Microbiology and Immunology, St. Antonius Hospital, Nieuwegein, Netherlands; 3Department of Clinical Chemistry, St. Antonius Hospital, Nieuwegein, Netherlands

Introduction: Idiopathic pulmonary fibrosis (IPF) is a rapidly progressive interstitial lung disease of unknown etiology. Interleukin (IL)-1β plays an important role in inflammation and has been associated with fibrotic remodelling. We investigated the balance between IL-1β and interleukin-1 receptor antagonist (IL-1Ra) in bronchoalveolar lavage fluid (BALF) and serum as well as the influence of genetic variability in the IL1B and IL1RN gene on disease susceptibility and cytokine levels.

Materials and methods: In 77 IPF patients and 349 healthy controls, single nucleotide polymorphisms (SNPs) in the IL1B and IL1RN gene were determined. Serum and BALF IL-1Ra and IL-1β levels were measured using a multiplex suspension bead array system and were correlated with genotypes.

Results: BalF and a significantly increased IL-1Ra/IL-1β ratio was found in IPF patients compared to healthy controls. In the IL1RN gene, one SNP was associated with both the susceptibility to IPF and reduced IL-1Ra/IL-1β ratio in BALF.

Conclusion: Our results show that genetic variability in the IL1RN gene plays a role in the pathogenesis of IPF and that this role may be more important than until recently thought. IPF patients appear to have a disproportionate shortage of IL-1Ra, which might contribute to a pro-inflammatory and pro-fibrotic environment in their lungs.

P1997
The relationship of IL-4 cytokine gene polymorphisms, HRCT and histopathological score in patients with idiopathic pulmonary fibrosis
Martina Vaskaova1, Martina Sterclova1, Radoslav Matej1, Libor Kolesar1, Jelena Skibova1, Ilja Striz1.
1Department of Respiratory Diseases, Thomayer University Hospital, Prague, Czech Republic; 2Department of Pathology and Molecular Medicine, Thomayer University Hospital, Prague, Czech Republic; 3Department of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; 4Medical Statistic Unit, Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Introduction: Idiopathic pulmonary fibrosis (IPF) is a serious disease with unknown etiology, where an influence of cytokine gene polymorphisms is presumed. We compared HRCT alveolar (AS) and interstitial score (IS) and histopathological score with IL-4, and IL-4RA gene polymorphisms in IPF patients.

Subjects and methods: IPF was diagnosed in 46 patients according to ATS/ERS consensus criteria. 43 patients had evaluable HRCT investigations, 14 patients had surgical lung biopsy. HRCT scans were evaluated using IS and AS scales by Gay et al. The histopathological evaluation of lung biopsies comprised: myofibroblast foci (MF), inflammation, eosinophils, granulomas and Ashcroft criteria for fibrosis grading. The IL-4 (-1082) A/G (-590) AA/AG (-33) and IL-4 RA +1902 G alleles were characterized utilizing a PCR-SSP method.

Results: AS was higher in IL-4 haplotypes 1 TTC and TTTC carriers (p=0.0423). Ashcroft score was more advanced in IL-4 haplotype 2 GCC (p=0.013) and MF counts were higher in TCC carriers (p=0.0376). IL-4 RA +1902 A G and IL-4 RA +1902 A A T correlated with higher AS (p=0.035, p=0.0123). Ashcroft score was higher in IL-4 -1082 A G and IL-4 -33 A T carriers (p=0.0443, p=0.0915).

Conclusions: We assume that IL-4 and IL-4RA polymorphisms might influence the HRCT and histopathological phenotype of IPF. The correlation of all four relevant IL-4 genes polymorphisms (especially IL-4 -33 T) with AS could mean, that new alveolar lesions with continuing fibroses are more pronounced in these polymorphisms carriers. The positive correlation of IL-4 -33 A T with Ashcroft score might support a hypothesis of fibrogenic role of IL-4 in IPF.

P1998
Familial idiopathic pulmonary fibrosis and “genetic anticipation”
Claudia Ravaglia1, Sara Tomaselli1, Gianluca Casoni1, Micaela Remagnoli1, Christian Gutelle2, Carlo Gutelle1, Sara Picciucchi1, Venero Polletti1.
1Diseases of the Thorax, GB Morgagni Hospital, Forli, FC, Italy; 2Radiology, GB Morgagni Hospital, Forli, FC, Italy

Background: Telomere dysfunction can be associated to “genetic anticipation”, earlier age of onset and more rapid progression of disease in succeeding generations, well known in Dyskeratosis Congenita, due to heterogeneous TERC/TERC mutations (essential components of telomerase), which have been reported in 8-15% of families with Idiopathic Pulmonary Fibrosis (IPF) and 1-3% of non familial IPF.

Aims and objectives: Retrospective study to assess whether a form of genetic anticipation can be found in families with IPF and to establish clinical features and outcome of familial IPF in comparison to non familial IPF.

Methods: We reviewed all files of patients with familial IPF seen at our department (17 families consisting of a total of 37 individuals) and compared age at diagnosis, clinical progression, frequency of acute exacerbations and survival outcomes with a database of 162 patients with non familial IPF. We are sequencing TERT and TERC genes in patients with familial IPF.

Results: Among the familial IPF patients, 5 had their father or mother affected; in all these cases the son/daughter was diagnosed earlier than the parents (mean age 56.4 years vs 72.4) and had a more rapid progression (all patients had at least one disease progression during follow-up); mean age of diagnosis of siblings and non familial IPF patients was 60.9 years and 65.4 years respectively.

Conclusions: We hypothesize a type of genetic anticipation in families with IPF with the latest generations being most severely affected. We are sequencing TERT and TERC genes in these patients to demonstrate that genetic anticipation in Familial IPF is associated to the inheritance of shorter-than-normal telomeres in association with the defective telomerase activity.

P1999
Association of single nucleotide polymorphisms in 4 genes (VDR, COL1A1, CALC and BGLAP) with susceptibility to steroid osteoporosis in patients with idiopathic pulmonary fibrosis (IPF)
Anna Uliitna1,2, Dalida Dzadzua2, Lubov’ Novikova2, Irina Pavlenko2, Julia Ikivich2, Michael Dubina1,3,1Department of Molecular and Genetic Technologies, Pavlov State Medical University, St. Petersburg, Russian Federation; 2Research Institute of Pulmonology, Pavlov State Medical University, St. Petersburg, Russian Federation

Steroideal osteoporosis is a serious medical and economic problem. At the same time, osteoporosis is a polygenic disorder.

Aim: To assess effectiveness of steroid osteoporosis prevention by antiresorptive agents (ARA - Bisphosphonates, Calcitonin) in patients with IPF with different genetic predisposition to osteoporosis.

Subjects: 114 patients with IPF, 19 males, 95 females, age 56.7±10.6 years, treated with Corticosteroids (CS).

Methods: Bone mineral density (BMD) measuring by DEXA, patients’ questionnaires and genotyping were used. Genomic DNA was isolated from peripheral leukocytes. We investigated 5 SNPs by PCR-RFLP analysis in 4 genes: vitamin D receptor, collagen typel alpha1, calcium receptor and osteocalcin.

Results: Severity of BMD loss and bone fractures occurrence strongly correlated with CS cumulative dose (p=0.010 and p=0.001, respectively). Multiple regression analysis showed significant influence of only VDR-FokI on BMD (p=0.009), and BGLAP was about significant (p=0.081). Environmental factors, firstly ARA intake, seems to have stronger influence on BMD than genes (adjusted R 2=0.065).

Conclusion: ARA administration is necessary for all patients with IPF, irrespec-
tively of genotype. VDR-FokI analysis is useful to reveal subjects with increased risk of osteoporosis. In IPF it is necessary to implement BMD loss prevention. Further efforts are required to clarify weight of BGLAP.
P2000
The genetic polymorphism of metalloproteinases MMP2, 7, 9 and MMP inhibitor TIMP2 in sarcoidosis
Wojciech J. Piotrowski1, Paweł Gręski1, Tadeusz Pietras1, Janusz Szmjerz1
1 Department of Pneumology & Allergy, Medical University of Lodz; Lodz, Poland; 2 Department of Biochemistry, Medical University of Lodz; Lodz, Poland
Background: Increased activity of metalloproteinases may play a role in the initiation and propagation of inflammation in sarcoidosis. It may also be one of the factors responsible for the development of lung fibrosis. The aim was to verify whether polymorphisms of MMP2.C735T, MMP7 A181G, MMP9 T1702A and tissue inhibitor of metalloproteinase (TIMP2)P2418C predispose to sarcoidosis.

Material and methods: 139 patients with sarcoidosis and 100 healthy subjects were included. MMPIs and TIMP2 mRNA were measured in peripheral blood lymphocytes using real time RT-PCR. DNA for genetic polymorphism was extracted from peripheral blood by GTC method. Protein concentrations in peripheral blood lymphocytes were measured by ELISA, and MMP2 and 9 activities in BAL fluid were estimated by gel zymography.

Results: TT genotype of MMP9 T1702A was more frequent in sarcoidosis (p=0.0001; OR=13.71, 95%CI 7.02-26.80) and resulted in higher expression of MMP9 mRNA (p<0.0001). There was no relation to radiological stages, lung function test parameters, activity markers and the presence/absence of Löfgren syndrome. There were no differences in the distribution of MMP2, MMP7 and TIMP2 polymorphisms. MMP2, 7, 9 and TIMP2 mRNAS, as well as concentrations of these molecules were elevated (p<0.0001 for each). Gel zymography did not show differences in MMP2 and MMP9 activity in BAL fluid between different genotypes.

Conclusions: The TT homozygote of MMP9 T1702A genotype may be predisposed to sarcoidosis. Elevated mRNAs of all these molecules suggest their inducibility.

This study was supported by the Medical University of Lodz (grant No 502 -16-807) and Polish Ministry of Science (grant NN 402 350838).

P2001
Dose-dependent pro- or anti-proliferative effects of calciuminhibitors in bronchiolar and allogeneic stem cell transplantation
Karin Hostettler1, Jörg Halter1, Didier Lardin1, Michael Roth1, Michael Tamm1
1 Department of Biomedicine and Clinic of Respiratory Medicine, University Hospital Basel, Basel, Switzerland; 2 Division of Hematology, University Hospital Basel, Basel, Switzerland; 3 Clinic of Thoracic Surgery, University Hospital Basel, Basel, Switzerland
Background: Chorioblastin obliterators (BO) is a common complication after allogeneic stem cell transplantation (SCT), characterized by fibroproliferation, fibrotic occlusion of small airways, and poor prognosis. As BO is strongly associated with chronic graft-versus-host disease (GVHD), it is believed to be a pulmonary manifestation of chronic GVHD. The management of BO comprises the augmentation of immunosuppressive therapy, but treatment response is generally poor. Here, we showed that quercetin suppresses transforming growth factor-β (TGF-β) induced collagen production in NH3T3 cells and in normal human lung fibroblasts. This suppressive effect of quercetin was mediated by quercetin-induced HO-1. The suppression of collagen production was confirmed by the reaction product of HO-1, CO, but not by bilirubin. Furthermore, the translocation of the nuclear factor E2-related factor-2 (Nrf2), an important transcription factor that regulates the expression of HO-1 from the cytoplasm to the nucleus, was demonstrated in NH3T3 cells by exposure to quercetin. Assessment of the signal transduction pathway involved in TGF-β signaling showed that quercetin stimulated the Smad and mitogen-activated protein kinase pathway to varying degrees. Our results demonstrate that quercetin exerts suppressive effects on the expression of collagen by the induction of HO-1. Idiopathic pulmonary fibrosis is the most lethal diffuse fibroing lung disease, and is characterized by the deposition of extracellular matrix. Quercetin or its derivatives, which effectively induced HO-1, will lead to new therapeutic strategies for promoting antibiotic therapy in respiratory diseases.

Methods: We aimed at analyzing membrane-bound FasL expression on alveolar macrophages (AM) and lymphocytes (AL) as well as soluble FasL (sFasL) levels in bronchoalveolar lavage (BAL) from ILDs patients: pulmonary sarcoidosis (PS), hypersensitivity pneumonitis (HP), silicosis, asbestosis, idiopathic pulmonary fibrosis (IPF), nonspecific interstitial pneumonia (NSIP), and healthy subjects (n=89,12,7,8,23,6,17, resp.).

Results: In IPF significantly increased percentage of AM FasL+ and CD8+FasL+ cells as well as sFasL in BAL were found. Increased sFasL levels were also observed in HP. NSIP and asbestosis were characterized by higher AM FasL+ receptor number; CD9+FasL+ proportion was expanded in asbestosis only. There was significant decline in AL FasL+ percentage in PS and HP. Systemic steroid treatment, assessed in PS and IPF subgroups, did not affect FasL expression. Smokers with ILD tended to present lower sFasL levels, but not BAL cell FasL+ numbers. Vital capacity was negatively correlated with sFasL, levels, AM FasL+, and CD8+FasL+ cell relative count. CD4+FasL+ and CD8+FasL+ percentage strongly correlated with BAL neutrophilia, an unfavourable prognostic factor of lung fibrosis.

Conclusions: The concurrent comparative BAL analysis for FasL expression indicates that FasL+ AM and AL (especially Tc cells) comprise an important element of the fibroproliferative process, mostly in IPF. FasL might play a crucial role in other fibrosis-complicated ILDs, like NSIP and asbestosis.

P2003
Heme oxygenase–1 induced by quercetin attenuates TGF-β-stimulated collagen production in fibroblasts
Yutomi Kawabe1, Toshinobu Nakamura2, Miyoko Matsumasa3, Yuta Hayashi1, Masataki Shibasuki2, Kazunori Imaizumi2, Kazuo Hashimoto4, Kaoru Shimokata4, Yoshinori Hasegawa1
1 Department of Pulmonary Medicine, University Hospital Basel, Basel, Switzerland; 2 Department of Respiratory Medicine, Nagaoy University School of Health Sciences, Nagaoy, Aichi, Japan; 3 Department of Respiratory Medicine, Nagaoy University Graduate School of Medicine, Nagaoy, Aichi, Japan

Quercetin is a flavonoid with a wide variety of cytoprotective and modulatory functions. Heme oxygenase-1 (HO-1) is an inducible enzyme. Its reaction product, carbon monoxide (CO), confers cellular protection in a number of conditions and diseases associated with oxidative or inflammatory lung injury. Furthermore, quercetin was reported to be a potent inducer of HO-1 in several cell types. We hypothesized that quercetin suppresses the production of collagen in fibroblasts via the induction of HO-1. Here, we showed that quercetin suppresses transforming growth factor-β (TGF-β) induced collagen production in NH3T3 cells and in normal human lung fibroblasts. This suppressive effect of quercetin was mediated by quercetin-induced HO-1. The suppression of collagen production was confirmed by the reaction product of HO-1, CO, but not by bilirubin. Furthermore, the translocation of the nuclear factor E2-related factor-2 (Nrf2), an important transcription factor that regulates the expression of HO-1 from the cytoplasm to the nucleus, was demonstrated in NH3T3 cells by exposure to quercetin. Assessment of the signal transduction pathway involved in TGF-β signaling showed that quercetin stimulated the Smad and mitogen-activated protein kinase pathway to varying degrees. Our results demonstrate that quercetin exerts suppressive effects on the expression of collagen by the induction of HO-1. Idiopathic pulmonary fibrosis is the most lethal diffuse fibroing lung disease, and is characterized by the deposition of extracellular matrix. Quercetin or its derivatives, which effectively induced HO-1, will lead to new therapeutic strategies for promoting antibiotic therapy in respiratory diseases.

P2004
Different expression pattern of endothelin receptors in primary human lung fibroblasts derived from idiopathic pulmonary fibrosis compared to healthy controls
Karin Hostettler1, Jun Zhong1, Michael Tamm1, Didier Lardin1, Michael Roth1
1 Pulmonary Cell Research & Pneumology, University Hospital Basel, Basel, Switzerland; 2 Thoracic Surgery, University Hospital Basel, Basel, Switzerland

Background: Endothelin-1 (ET-1) has a considerable fibrogenic activity and it has been implicated in the pathogenesis of pulmonary fibrosis. Increased levels of ET-1 have been demonstrated in serum and bronchoalveolar lavage fluid of patients with idiopathic pulmonary fibrosis (IPF), and lung tissue of IPF patients show increased ET-1 immunoreactivity. The biological effects of ET-1 are mediated through two receptors – ET-A and ET-B. However, disease specific patterns of ET receptor expression in fibrotic and normal primary human lung fibroblasts had not been reported yet.

Methods: Primary human lung fibroblasts were isolated and propagated from lung parenchyma derived from patients with IPF (n=8) as well as from parenchyma derived from healthy controls (n=8). Isolated cP狒 were grown to confluence.

Results: Transforming growth factor beta (TGF-beta) stimulation total protein was harvested and immuno blot analysis was performed.

Conclusion: Our data demonstrate for the first time a difference in the pattern of
Molecular mechanisms and pathogenesis of idiopathic pulmonary fibrosis (IPF) remain unclear yet TGF-β-induced differentiation and proliferation of fibroblasts/myofibroblasts are recognized as primary events.

We investigated the role of PI3K/Akt pathway in TGF-β1-induced proliferation of human lung fibroblasts and their differentiation into myofibroblasts. Moreover, we evaluated the expression of all PI3K class I p100 isoforms (α, β, γ and δ). By using selective inhibitors, we also dissected the functional role of these isoforms. Ex-vivo human lung fibroblasts were stimulated with TGF-β1 in the presence or absence of PI3Ks pan-inhibitor LY294002 as well as of selective inhibitors. Cell proliferation was evaluated by cell counts and WST-1 proliferation assay. Western blot analysis and the Sircol assay were used for assessing a-Smooth Actin (SMA) expression and collagen production, respectively. RNA messenger and protein levels of p100 isoforms were evaluated by QRT-PCR and western blot analysis, respectively.

Here we show that LY294002 was able to abrogate the TGF-β1-induced increase in cell proliferation, α-SMA expression and collagen production besides to inhibit Akt phosphorylation, thus demonstrating the central role of PI3K/Akt pathway in TGF-β1-induced lung fibroblast proliferation and differentiation. Moreover, we show that PI3K p110δ and p100α are functionally expressed in human lung fibroblasts, in addition to the ubiquitously expressed p100β and p100γ. Finally, we demonstrated that Twist nuclear translocation by p100γ and p110δ in the fibrotic process.

Overall, these results suggest that specific class I PI3K isoforms can be pharmacological targets in IPF.

P2006
Inhibition of TGF-β1-induced extracellular matrix production in primary human pulmonary fibroblasts by rapamycin

Yu Gao, Hua-Ping Dai, Xue-Feng Xu, Ke Ding. Department of Respiratory and Critical Care Medicine, Beijing Chao-Yang Hospital, Beijing, China. Department of Respiratory Medicine, Beijing Chao-Yang Hospital, Beijing, China. Department of Respiratory and Critical Care Medicine, Beijing Chao-Yang Hospital, Beijing, China.

Fibroblasts proliferation and extracellular matrix (ECM) accumulation play a key role in the development and the progression of pulmonary fibrosis. Rapamycin has been showed to decrease extracellular matrix in normal mesangial cells and human lung fibroblasts. This study is to examine the role of rapamycin on transforming growth factor β1 (TGF-β1)-induced lung fibrosis and to determine the related mTOR signaling pathways in primary human pulmonary fibroblasts. Primary human pulmonary fibroblasts were isolated from healthy lung transplantation donors. Growth arrested, synchronized cells were treated with TGF-β1 (10ng/ml) and various concentrations rapamycin (0.01, 0.1, 1, 10ng/ml) for 24h. mTOR, p-mTOR, S6K1 and p-S6K1 were assessed by Western blot analysis, type III collagen and fibronectin secretion detected by ELISA, assay III collagen and fibronectin mRNA level determined by Realtime-PCR assay. TGF-β1 (10ng/ml) increased type III collagen, fibronectin secretion and mRNA level obviously compared to controls (p<0.05), rapamycin reduced the enhanced production of type III collagen, fibronectin mRNA and protein induced by TGF-β1 accompanying inhibition of S6K and mTOR phosphorylation. These data demonstrated that rapamycin inhibited TGF-β1-induced type III collagen fibronectin mRNA and protein may be through mTOR/p70S6K pathway, rapamycin may have potential effect for being used in the treatment of pulmonary fibrosis.

P2007
Familial cases of idiopathic pulmonary fibrosis: Clinical observation

Lubov Novikova, Yulia Ilkovich, Michail Ilkovich. Research Institute of Pulmonology, Pavlov State Medical University, St. Petersburg, Russian Federation

Background: Idiopathic pulmonary fibrosis (IPF) is a chronic, progressive, often fatal interstitial lung disease of unknown etiology. Familial idiopathic pulmonary fibrosis (FIPF) is defined when two or more affected individuals are identified in one family. IPF patients accounts for 5.2-2% of all IPF cases.

Results: We found 10 FIPF patients in 5 families among totally observed 475 IPF cases. There were 3 pairs of siblings (2 males and 4 females) and 2 pairs of mother and daughter. Fifteen of 475 IPF patients were diagnosed according to ATS/ERS criteria, histologically proven in 9 of 10 subjects. The mean age of IPF manifestation appears to be 56±9 years; M:F=3:9. Although all lungs showed metastasis, the score of squamous (p=0.001), cuboidal (p=0.018) and bronchial cell (p=0.001) formation of squamous was significantly higher in the “cancer” than in the “no cancer”, while the squamous cell score was similar in the two groups. In conclusion, contrary to previous reports, we have found that the presence of squamous cells, specially squamous, in the honeycombed areas, is associated to the development of precancerous changes in IPF, independently to smoking history.

Idiopathic pulmonary fibrosis (IPF) is known to be associated with increased risk of lung cancer, and are more likely to develop lung cancer than the general population. Several studies have shown that the risk of lung cancer is increased in patients with IPF, with a reported risk of 1.5%-5%.

Conclusion: Familial IPF patients have familial history of pulmonary fibrosis. Although rare, such cases represent an important subgroup in which genetic susceptibility to lung fibrosis plays a significant role. We can use these results to improve our understanding of the pathogenic mechanisms of IPF.

P2008
Paraoquat-induced epithelial-mesenchymal transition: Role of Rac1/beta/ Twist

Shen Yongchun, Zhang Xiaobong, Yang Ting, Wang Tao, Wen Fuqiang. Division of Pulmonary Diseases, State Key Laboratory of Biotherapy of China, and Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Objective: To examine whether paraquat (PQ), a well-known reactive oxygen species (ROS) producer, could induce epithelial-mesenchymal transition (EMT) which involving in ROS-mediated pulmonary fibrosis and possible mechanisms.

Method: Human alveolar epithelial (A549) cells were cultured and exposed to sub-lethal doses of PQ, specific signaling pathway inhibitors and siRNAs for ROS signaling pathway. Intracellular ROS was measured with DCF-DA. Protein and mRNA were evaluated by Western blot and real-time PCR, respectively.

Results: Intracellular ROS increased after various concentration paraquat stimulation for 5 minutes (p<0.05), while only PQ at the concentration of 2μM (PQ20) induced EMT manifested as increased fibroactin, decreased E-cadherin and a fibroblast-like cell appearance. mRNA of Twist, a key transcriptional factor for EMT, increased after PQ20 stimulus for 30minutes (p<0.05), accompanied with a parallel increased Twist nuclear translocation of cells, while transfected with Twist siRNA ant-sense vector abolished PQ-induced EMT. Mitochondrial complex I inhibitor rotenone significantly inhibited PQ20-induced ROS. Small GTPase Rac1 binding in mitochondrial ROS-mediated EMT was induced 5 minutes after PQ20 treatment, and siRNA targeted Rac1 blocked ROS generation and Akt phosphorylation induced by PQ20 (p<0.05). In addition, wortmannin, a PI3K inhibitor, could also block Akt phosphorylation and significantly reduce Twist nuclear translocation in A549 cells 2 hours after PQ20 treatment.

Conclusion: This study demonstrated that PQ could induce A549 cells EMT through Twist up-regulation, which relied on Rac1-dependent ROS generation/Akt signaling pathway and provided a better understanding of pulmonary fibrosis.

P2009
The prevalence of neoplastic transformation in idiopathic pulmonary fibrosis (IPF) lungs. A report from a transplanted IPF population

Elsa Maria Balestrio1, Emanuela Rossi1, Francesca Lunardi2, Nazarena Nannini2, Monica Loy1, Federico Rea1, Marina Saratta1, Fiorella Calabrèse1, 2 Department of Cardiac, Thoracic and Vascular Science, University of Padua Medical School, Padua, Italy. 1 Department of Diagnostic Medical Sciences and Special Therapies, University of Padua Medical School, Padua, Italy

Idiopathic pulmonary fibrosis (IPF) is known to be associated with increased risk of lung cancer, with a reported risk of 1.5%-5%.

Conclusion: Familial IPF patients have familial history of pulmonary fibrosis. Although rare, such cases represent an important subgroup in which genetic susceptibility to lung fibrosis plays a significant role. We can use these results to improve our understanding of the pathogenic mechanisms of IPF.
247. Advances in lung function testing from infancy to adulthood

P2010
Lung growth and ventilation inhomogeneity in health
Sooky Lum1, Samantha Somnap1, Per Gustafsson2, Angie Wade3, Paul Aurora3, Ah-Fong Hoo4, Janet Stocks1,4, Portex Respiratory Unit, UCL Institute of Child Health, London, United Kingdom; 2Department of Pediatrics, Central Hospital, Skövde, Sweden; 3Patriotic Epidemiology and Biostatistics, UCL Institute of Child Health, London, United Kingdom; 4Respiratory Medicine, Great Ormond Street Hospital for Children, London, United Kingdom

Lung clearance index (LCI), a measure of ventilation inhomogeneity derived from multiple breath washout is more sensitive in detecting early lung disease than spirometry in preschool (PS) and school age (SA) children. In health, LCI appears to be stable in PS and SA children, but has been reported to be slightly higher during infancy. We aimed to develop a reference range for LCI from birth to 19y.

Methods: LCI data from two centres using a respiratory mass spectrometer (Annis 2000) & the inert gas SF6, measured using either a mask (0.5y) or mouthpiece (>5y), while supine (infant) or seated, were collated. 485 datasets from 359 healthy subjects (443/boys; 257 from London; 102 from Gotteborg; Range: age (0.1-18.7y); height (52-196cm) were analysed.

Results: Height & age were significant predictors of LCI on univariable & multivariable analyses. Mean (SD) LCI was 7.2 (0.5) in infants (0.1-2y); 6.7 (0.6) in PS (3-5y); 6.5 (0.5) in SA (6-12y) and 6.5 (0.5) in those >13y. The inverse relationships between LCI & height or age were not linear, being most marked in the younger years & no longer significant by SA.

Conclusions: LCI was not significantly different between centres, after adjusting for height & age.

P2011
Specific airway resistance is overestimated during tidal breathing vs panting in healthy children
Lauriane Coutier1, Claude Bonneb1, Bruno Demoulin1, Than LeTuan3, Julia Ioun1, Silvia Varechova1-2, Cyril Schweitzer1-2, François Marchal1-2, 1EA 3450, Faculté de Médecine, Université Henri Poincaré, 2Explorations Fonctionnelles Pédiatriques, Hôpital d’Enfants, Vau diosec, France

Rationale: Modern plethysmographic equipments allow the measurement of specific airway resistance (sRaw) during tidal breathing (tb), a potentially useful technique in children unable to perform the panting maneuver (p), a reference technique to minimize the thermal artifact. Equipment softwares are implemented with algorithms to correct for this artifact when computing sRaw. It is not known how well this correction performs with reference to sRawp in children.

Aim: To examine the relationship between sRaw & sRawp in children.

Methods: sRaw and sRawp were measured in 6 healthy children aged 7-10 years, using a commercially available pressure plethysmograph. Results: sRawp (mean ± sd = 10.4±2.0 hPa sec/L; breathing rate = 0.5±0.1 Hz) was significantly larger (p=0.006) than sRawp (5.8±2.2 hPa sec/L; breathing rate = 3.1±0.5 Hz). The finding hold true for Raw computed from the associated measurement of thoracic gas volume (Rawth = 6.3±1.2 hPa sec/L; Raw = 2.9±1.0 hPa sec/L; p=0.005).

Conclusion: sRaw is significantly overestimated by tb as compared with p. This is possibly explained by non instantaneous changes of gas temperature and humidity in the airways, a fact that may not be taken into account in the correction algorithm. The impact of overestimating Rawtb’s and hence Raw - on routine airway function testing in patients has to be identified.
but between-subject variability increased with growth (Fig. 1a,b). 95% Limits based on V50g or Cr50g would over-estimate predicted range in the youngest and under-estimate it in older infants, leading to potential misdiagnosis. V50g or Cr50g were inversely related to weight z-score (Fig. 1c,d); light-for-age babies had higher values than those who were heavier. This again may lead to misdiagnosis especially in those with impaired growth (ef. CF).

Conclusions: Reporting infant LF/kg body weight is inappropriate. Equipment-specific regression equations are needed to avoid misinterpretation; for this a larger dataset is required. We would welcome contributions of similar data from other centres.

P2014 Tracking of lung function obtained by whole-body plethysmography in infants and children with cystic fibrosis (CF)

Richard Kraemer1, Katharina Modeskia, Aida Mashkouri Najafi2, Ernst Stadlberger2, Sabina Gullati1.

Department of Pneumatics, University of Bern, Inseelspital, Bern, Switzerland; 2Institute of Statistics, University of Technology, Graz, Austria; 3Division of Human Genetics, University of Bern, Inseelspital, Bern, Switzerland

Rationale: The assessment of lung function tracking, (data stability over time and prone by age) based on early measurements could contribute to a better understanding how genetic and environmental factors as well as treatment regimens influence lung function decline in CF.

Methods: Lung function was assessed in 70 infants (35 males, 35 females) with CF at ages 2.8 to 26.7 months as well as during childhood (4.3-18.4 years) by serial (infant)-whole-body plethysmography pertaining to functional residual capacity (FRCpleth) and effective airway resistance (sReff). Using predicted values obtained by LMS statistics (see abstract 854139), z-scores of FRCpleth and sReff were computed by Box-Cox transformation using the age-varying parameters L (skewness), M (median) and S (coefficient of variation).

Results: During infancy only 7.6% of CF patients presented with normal lung function; 33.3% showed either pulmonary hyperinflation or bronchial obstruction, but 59.1% presented with both. There was a significant association with later outcome represented by the LC1 und the FEF50. If genotypes are stratified according to the presence or absence of F508del and subgrouped according to the nature of mutations, FRCpleth and sReff can achieve discrimination.

Conclusions: Evaluation of lung function by plethysmography is an important diagnostic and predictive tool, featuring good outcome parameters, and worth to be established early in life.

P2015 Pressure oscillations after airway interruption pre- and post-bronchodilator in wheezy preschool children

David Vesty1, Soledad Pantoja1, Silvia Sánchez2, Cathy Olden3, Peter Bridge1, Nicole Beydon4, Paul Seddon2.

1Faculty of Computing, IS and Maths, Kingston University, London, UK; 2Department of Paediatrics, Armand Trousseau Hospital, Paris, France; 3Institute of Statistics, University of Technology, Graz, Austria; 4Institute of Human Genetics, University of Bern, Switzerland

Changes in mouth pressure during flow interruption (Pmno transients) can be used to assess airway resistance (Rint). Initial pressure oscillations can cause difficulties in estimating Rint but are themselves a marker of a airway status as their amplitude increases [1] with bronchodilator (BD) and decreases with methacholine [2]. To investigate this measurement, we analysed Pmno transients pre- and post- bronchodilator in 13 preschool children with recurrent wheeze on 2 separate visits 4 weeks apart. The median (range) age of the children at the first visit was 52 months (38 to 64 months). The amplitude of the first upward oscillation as a proportion of end-expiration pressure was calculated and compared with Rint calculated by linear back extrapolation. The median value of at least 5 acceptable transients was determined for each one.

To investigate this, we analysed Pmno transients pre- and post- bronchodilator in 13 preschool children with recurrent wheeze on 2 separate visits 4 weeks apart. The median (range) age of the children at the first visit was 52 months (38 to 64 months). The amplitude of the first upward oscillation as a proportion of end-expiration pressure was calculated and compared with Rint calculated by linear back extrapolation. The median value of at least 5 acceptable transients was determined for each one.

Conclusions: Evaluation of lung function by plethysmography is an important diagnostic and predictive tool, featuring good outcome parameters, and worth to be established early in life.

P2016 Cough flow volume profile in ataxia telangiectasia

Daglia Vitolin1, Morne Lovic2, Yacov Berkun3, Amin Nisenson4, Yonit Ronen Levi, Raz Somech, Ori Efrati1.

4The Pediatric Pulmonary Unit and Ataxia Telangiectasia National Clinic, The Edmond and Lily Safra Children’s Hospital, Sheba Medical Center, Affiliated with the Sacker Faculty of Medicine, Tel-Aviv University, Ramat-Gan, Israel

Introduction: Weak coughing is perceived as the cause for recurrent respiratory system infection leading to lung function deterioration in Ataxia telangiectasia (A-T) disease. The cough profile of these patients has not been studied.

Aim: To explore the feasibility of the cough-flow-volume profile for detecting cough performance in A-T patients.

Methods: Thirty five A-T patients (age 12.7±4.9yrs) were studied. Patients performed forced expiratory flow volume (FVC) and maximal voluntary cough (FVC-cough) maneuvers. Analysis of data included: Inspiratory volume (IC) prior to cough, FVC-cough, Peak cough flow and number of spikes per maneuver. Values were related to published data of healthy population of similar ages and are presented as actual and as%predicted.

Results: We found that IC prior to cough was 0.85±0.47 l (36.1±15.0%); FVC-cough was 1.00±0.51 l (43.6±15.4%); Peak cough flow was 3.27±1.53 l/s (45.5±15.0%); Peak cough flow to Peak expiratory flow ratio was 1.06±0.24 vs 1.48±0.22 in healthy and the number of spikes/maneuver were 2±0.68 vs 6±12 in healthy population. All parameters were significantly lower than healthy (P<0.001). Additionally, Peak cough flow increased with age but the yearly increase rate was significantly lower than normal, (0.157 vs. 0.423 l/year; respectively, P<0.05).

Conclusions: Our findings indicate that A-T patients have a weak cough compared to healthy of similar ages and that cough ability worsens with age. Cough flow volume curve, as well as forced vital capacity maneuvers, should be considered a mainstay in the clinical assessment of A-T patients. The study was funded by the J. Baum foundation of the Israeli Lung Association, Tel Aviv, Israel.

P2017 The maximum oxygen consumption in children with asthma and/or obese children: A multi purpose assessment

Hilja Benfatto1, Elena Bianchini1, Martina Tubaro1, Francesca Valent2, Marco Canciani1, 1Allergology and Pulmonology, Unit, Department of Pneumatics, DPMSC, University of Udine, Udine, Italy; 2Hygiene School of Medicine, DPMSC, University of Udine, Udine, Italy

Aim: Asthma and obesity have had an increasing trend in recent decades, constituting one of the major priorities in the health of children. The aim of this study was to compare the respiratory function and oxygen consumption in four groups of children: obese, asthmatics, obese-asthmatic and controls, in order to assess their metabolic pattern and respiratory values.

Methods: 152 children, 8 to 16 y.o., divided as follows: 31 asthmatics, 42 controls, 56 obese and 23 obese-asthmatics children were tested. Every child performed spirometry, respiratory muscles (endurance) and oxygen consumption (VO2) evaluation, obtained on a cycloergometer according to a protocol of increasing effort.

Results: Spirometric values were comparable between obese and controls (average: FVC 105 and 107% pred, respectively), whereas there was a s.s. difference (P<0.05) between asthmatics and obese-asthmatics. Endurance was lower in obese (26.97 l) and obese-asthmatics (24.06 l) than in asthmatics alone (31.52 J) and controls (31.98 J), but without any s.s.difference (p=0.60). The maximal VO2 was lower in obese (30.63 ml/kg/min) and obese-asthmatics (31.95 ml/kg/min) than in controls (37.19 ml/kg/min) or asthmatics (41.72 ml/kg/min) (p=0.001 for each one).

Conclusion: The increase in body weight does not seem to affect spirometric values but obese children have a lower value of endurance, probably due to a respiratory muscle weakness and VO2/kg max was lower in obese than asthmatics, probably due to alterations in the cardio respiratory system.

P2018 Exercise induced bronchoconstriction and dyspnoea in asthmatic children

Gylnar Dib-Nehme1, Cyril Schweitzer1, Silvia Varèchova1, Mathias Poussel2, Claude Chéne-Bonabéil1, François Marchal1, 1Explorations Fonctionnelles Pédiatriques, CHU de Nancy - Université de Lorraine (EA 3450), Vandoeuvre, France; 2Explorations Fonctionnelles Respiratoires, CHU de Nancy - Université de Lorraine (EA 3450), Vandoeuvre, France; 3Médecine Infantile 1, CHU de Nancy, Vandoeuvre, France

Introduction: Dyspnoea is thought to signal the mismatch between afferent input arising from the respiratory system and metabolic needs. Dyspnoea is thought to signal the mismatch between afferent input arising from the respiratory system and metabolic needs. Dyspnoea is thought to signal the mismatch between afferent input arising from the respiratory system and metabolic needs. Dyspnoea is thought to signal the mismatch between afferent input arising from the respiratory system and metabolic needs. Dyspnoea is thought to signal the mismatch between afferent input arising from the respiratory system and metabolic needs.

Dyspnoea is induced by airway obstruction but is variably expressed. A poor perception of dyspnoea has been hypothesized to be a determinant factor to life threatening asthma.

Methods: 53 asthmatic children (6 - 16 years old) were studied at baseline and 5 min after exercise. Dyspnoea was rated qualitatively and quantitatively by the...
pediatric scale “Pictorial-CERT” (ΔSc = 0 to 10). EIB was assessed by the relative change in FEV1 (ΔFEV1) and the child classified as responder (R) or nonresponder (NR) based on a threshold decrease in FEV1 = 8%.

Results: Anthropometric characteristics and baseline FEV1 were similar in R’s and NR’s. The qualitative items “Pictorial-CERT”, “Pictorial-CERT” and “Pictorial-CERT” were more frequently quoted by R’s than NR’s (p < 0.05). There was a significant but loose correlation between ΔFEV1 and ΔSc (r² = 0.12; p < 0.001).

Eight subjects were identified as poor perceivers because of significant bronchoconstriction contrasting with ΔSc < 2. These subgroup characteristics were similar to other children.

Conclusion: Bronchoconstriction and perception of dyspnoea are significantly but weakly associated in asthmatic children. Some children exhibit a poor perception of EIB. A systematic evaluation of dyspnoea during exercise challenge may help in the screening of subjects at risk of life-threatening asthma.

P2019 Agreement between interrupter resistance and spirometry in a large population of asthmatic children
Nicole Beydon1, Bruno Mahar1, Maingot Lucia1, Houa Guillo1, Marie-Claude La Rocca1, Noria Medjahid1, Marc Koskas1, Michèle Bouil1, Christophe Deleclaux2, 1Lung Function Department, Armand Trousseau Hospital, Paris, France; 2Lung Function Department, Georges Pompidou European Hospital, Paris, France

Background: Interrupter resistance (Rint) is routinely used to assess airway patency in children, but its relationship with spirometry has never been assessed in a large population of children.

Objectives: A retrospective study to compare baseline values and post-bronchodilator (post-BID) changes in Rint and spirometry in asthmatic children.

Methods: Rint measures (SpireDry R, Dry R, France) were performed before spirometry (Masterscreen, Jaeger, Germany). Statistics: correlations between baseline Rint and FEV1 or FEF25/75%, and ROC study for the Rint cutoff to distinguish between children with and without reversibility in FEV1 (>12% baseline).

Results: Data from 645 children (408 boys, median (range) age 7.9 (4.2-18.3) y) showed significant correlations between Rint and FEV1 or FEF25/75% (r=0.69 and 0.71, respectively for raw data, and r=0.49 and 0.54, respectively for% of predicted; all p<0.0001).

Figure 1
Reversibility in FEV1 (270 children) was best detected by a -35% of predicted Rint decrease (AUC=0.79, 0.70 sensitivity and specificity).

Conclusion: We found a good agreement between Rint and spirometry to assess airway calibre and study BDeffect.

P2020 Bench test of an O2/CO2 sensor based MBW system using a lung model
Florian Singer1, Chiara Abba1, Emilia Wluk1, Paul Robinson2, Philipp Latzin1, Per Gustafsson1; 1Division of Pulmonology, Department of Pediatrics, University Children’s Hospital, University of Bern, Bern, Switzerland; 2Division of Pulmonology, Department of Pediatrics, Central Hospital, Skeoede, Sweden; 3Department of Pediatrics, The Children’s Hospital at Westmead, Westmead, Australia

Lung volume assessment using tracer gas multiple breath washout (MBW) systems needs validation under realistic conditions. We used a lung model allowing for different tidal volumes (TVs), functional residual capacities (FRCs), and respiratory rates (RRs) under BTPS conditions. We tested a nitrogen (N₂) MBW prototype (Exhalyzer D; Eco Medics) based on an ultrasonic flowmeter, a main-stream CO₂ and a side-stream O₂ sensor.

Linearity of O₂ and CO₂ sensors was assessed after two point calibration using a mass spectrometer (AMIS 2000; Innovision). For FRC measurements, a double chamber plexiglas lung model was filled with water, heated, and mechanically ventilated at various ranges of FRCs (900 to 4000 mL), TVs (250 to 850 mL), and RRs (30 to 15/min). N₂ MBW tests (n = 71) using 100% O₂ were done on three days. Using custom designed software (TestPoint) we synchronized gas to flow signals to preset and manually optimized settings, and calculated FRC as cumulative expired N₂ volume divided by the difference of MBW start minus end N₂ concentration.

O₂ and CO₂ sensors were linear (linear regression r² was 0.99 for both). Using preset synchronization settings, mean difference of lung model minus measured FRCs was -7.4 mL (-0.4% of mean FRC), limits of agreement ranged from 160.4 mL to -175.2 mL (5.8% to -5.9% of mean FRC). After optimized synchronization, mean difference of FRCs was -7.7 mL (-0.25% of mean FRC); limits of agreement ranged from 50.8 mL to -66.2 mL (1.8% to -2.3% of mean FRC). This lung model seems suitable for validation of MBW systems. The new N₂ MBW system precisely measures in vitro FRCs under realistic conditions. Careful synchronization of signals is crucial for accurate FRC measurements.

P2021 Reference data transition of whole-body plethysmography from infancy to childhood
Richard Krammer1, Aida Mashkouri Najafi2, Ernst Stadlober2; 1Department of Pediatrics, University of Berne, Inselhospital, Bern, Berne, Switzerland; 2Institute of Statistics, University of Technology, Graz, Austria

Rationale: Advances in plethysmographic measurement techniques have made it possible to obtain lung function data in infants [1] and children. However, application remains limited by the lack of appropriate transitional normative data from infancy to childhood, especially for effective specific airway resistance (sReff).

Objectives: On previously collected lung function data, updated prediction equations were modeled spanning from infant’s years to childhood, using the LMS method.

Methods: Normative lung function data from 67 healthy young infants aged 2.3 to 28.2 (10.8±6.3) months and children aged 5.1 to 16.8 (10.4±2.9) years were evaluated, and prediction equations for functional residual capacity (FRCpleth), and sReff were computed. Applying the LMS method in R environment using GAMLSS package [2] the changing distribution of the measurements is summarized by three curves representing the median (M), coefficient of variation (S) and skewness (L) in relation to age.

Results: The present prediction equations feature the first attempt to provide continuous normative data of infants with a smooth transition into childhood (Table 1).

Conclusions: Updated prediction equations of plethysmographic data for infants and children applying LMS statistics provide a new basis for longitudinal evaluation of lung function in children with lung disease.

Comparison of a new nitrogen multiple breath washout method to mass spectrometer SF6 washout in cystic fibrosis subjects

Emilia Viklund1, Anders Lindblad 2, Paul Robinson 3, Birgitta Houltz4, Linda Bergh 4, Monika Rosberg 5, Per Gustafsson 1, 2 Department of Paediatrics, Central Hospital, Skövde, Sweden; 3 Clinical Physiology, Gothenburg, Sweden; 4 Department of Respiratory Medicine, Children’s Hospital at Westmead, Sydney, New South Wales, Australia; 5Clinical Physiology, East Hospital, Sahlgrensk University Hospital, Gothenburg, Sweden.

Background: The lung clearance index (LCI) obtained from SF6 multiple breath washout (MBW) is a sensitive index of peripheral airway dysfunction in cystic fibrosis (CF) [1]. SF6 LCI values are lower and show stronger agreement between laboratories than historical N2 LCI using conventional N2 analysers [1]. Formal comparison between the two types of MBW systems has not been performed to date. This study compared FRC and LCI obtained using both methods: mass spectrometer SF6 MBW and a new indirect N2 MBW system (Exhalyser D, EcoMedics, Daumen, Switzerland) in CF subjects.

Methods: 10 CF subjects, median (range) 17 (15 -40) yrs performed MBW in triplicate using an SF6-based mass spectrometer MBW system and an Exhalyser D indirect N2-based MBW system (main stream infrared CO2 sensor, side stream laser O2 sensor). FRC and LCI were calculated using similar software algorithms. Results expressed as mean (SD) and between-test comparisons made using students t-tests.

Results: There was no significant difference between FRC values (N2 FRC 2.82 (0.71) vs. SF6 FRC 2.53 (0.70), p=0.37), however N2 LCI 12.52 (3.14), was significantly higher than SF6 LCI 9.77 (2.46) (p=0.043). Within-session repeatability (coefficient of variation, CV%) did not differ between the groups: N2 FRC 6.3 (2.9%) vs. SF6 FRC 5.5 (3.1%), and N2 LCI CV 5.0 (3.6%) vs. SF6 LCI CV 4.7 (2.8%).

Conclusions: LCI values obtained with the new indirect N2 MBW system were greater than those obtained with the current gold standard SF6 mass spectrometer based system. FRC values and within-session repeatability were similar.

P2023

Excluding extreme breaths from analysis can change conductive airway ventilatory inhomogeneity by over 25% in cystic fibrosis

Noor Al-Khalfan 1, Ruslan Garpr 3, John Owers-Bradley 4, Erol Gaillard 1, 2, Carl-Robert Bergstrom 1, 4, 5, 6, 7.

Background: Airway inhomogeneity (VI) and separating healthy from CF children despite considerable overlap. More detailed analyses are needed to better understand underlying pathophysiological phenomena and to obtain additional yet unknown information on VI from this test.

Methods: We performed multi-breath nitrogen washout in 16 children with CF aged 6 -17 yr. An auditory signal indicated when the child has inspired a pre-set tidal volume (Vt) of the breath has been used as a correction. Slopes (SnIII) allows differentiation of inhomogeneity of conducting and acinar airways (Scond and Sasin). Standardising data collection and analysis in subjects with recent symptoms in young children with asthma.

Results: We identified double tracer gas SBW indices reliably characterizing ventilation inhomogeneity (VI) and separating healthy from CF children despite considerable overlap. More detailed analyses are needed to better understand underlying pathophysiological phenomena and to obtain additional yet unknown information on VI from this test.

P2026

Relationship between lung function using forced oscillation technique (FOT) with recent symptoms in young children with asthma

Afad Alhusoula 1, Judy Park 1, Stephen Stick 1, 2, Graham Hall 1, 2, 3, School of Paediatrics and Child Health, University of Western Australia, Perth, Western Australia, Australia; 1Department of Paediatric Respiratory Physiology, Telethon Institute for Child Health Research, Perth, Western Australia, Australia; 2Department of Respiratory Medicine, Princess Margaret Hospital for Children, Perth, Western Australia, Australia

Background: Use of FOT to assess lung function in young children is increasingly reported in the clinical setting. However, associations between bronchodilator responsiveness (BDR) as assessed by FOT and recent symptoms in young children with asthma have not been reported. We aimed to investigate the relationships between recent respiratory symptoms and BDR using FOT in young children with asthma.

Methods: 70 children (aged 3 to 6y) with mild asthma were studied twice 5 months apart. FOT (resistance and reactance at 8Hz: Rrs8 and Xrs8, respectively) was measured prior to- and 15 mins following Salbutamol (600 μg) inhalation. The BDR was assessed using absolute and relative changes in Rrs8 and Xrs8. Respiratory symptoms in the month prior to each visit were obtained using daily diary card. We performed regression analyses assessing the impact of respiratory symptoms on the transformed absolute and relative BDR in Rrs8 and Xrs8.

Results: Pre- and post-BD Rrs8 and Xrs8 data were obtained from 70 children at visit 1, and 56 children at visit 2. There were no differences in BDR for Rrs8 with any reported symptoms. In contrast, Xrs8 BDR was significantly larger (p<0.05)
in children reporting wheeze that required relievers in the month prior to FOT testing.

Conclusions: In children with mild asthma increasing symptom incidence requiring reliever use is associated with an increased BDR in Xer.8 These data suggest that symptoms in early childhood asthma result in alterations in peripheral airways function. Alternatively, it may indicate that the FOT is poorly sensitive to asthma related lung disease in young children. Further research addressing this question is required.

P2027
In vitro validation of nitrogen multiple breath washout using ultrasonic equipment
Susanne Fuchs1, Christian Bues2, Monika Gappma1, 1Childrens Hospital and Research Institute, Marien Hospital Wesel, Wesel, Germany; 2R&D, ndd Medizintechnik AG, Zurich, Switzerland

Over the last years, ultrasonic equipment for Multiple Breath Washout (MBW) including measurement of functional residual capacity (FRC) and assessment of ventilation inhomogeneity has been developed (EasyOne Pro, ndd Medizintechnik AG, Switzerland). Accuracy of the ultrasonic flow sensor has been demonstrated against mass spectrometry. Validity and feasibility have been demonstrated in single and in multi-centre studies using SF6 as the tracer gas. Recently, the washout procedure has been changed to nitrogen washout. All analysis steps, including delay correction between flow and side-stream molar mass signals were automated to facilitate clinical use. However, calculation of both, FRC and parameters of ventilation homogeneity depend on accuracy of the underlying algorithms. The aim of the present study was to assess the accuracy of the EasyOnePro software for calculating FRC from nitrogen MBW using a novel lung model. The lung model consists of an inner and an outer water-filled Plexiglas chamber (Soloplex AB, Sweden) and is driven by a mechanical ventilator (Evita, Dräger, Germany); the water level of the inner chamber, which is partially separated by a wall to allow ventilation, determines the target FRC. 60 measurements were performed using FRC target volumes between 350 and 4000 ml. Respiratory rates were set between 10 and 20 min⁻¹ and tidal volumes between 300 and 800 ml. Within-test repeatability of three measurements was below 0.76% for all settings. Mean difference between target FRC and measured FRC was 3.28% (95% CI -45 ml; -31 ml). We conclude that the Easy One Pro Software accurately calculates FRC.

248. Acute respiratory failure

P2028
Comparison between the transcutaneous carbon dioxide tension at the infraclavicular site with the arterial carbon dioxide tension
Prashant Chhajed1,2, Parag Chaudhari 1,2, Chandrashekar Tulasi giri3, Arvind Kate1,2, Rajendra Kesawari1, Josep Loup 1, Florent Bory1,2, Lung Care & Sleep Centre, Institute of Pulmonology, Medical Research and Development, Mumbai, Maharashtra, India; 1Lung Care and Sleep Centre, Fortis-Hiranandani Hospital, NaviMumbai, Maharashtra, India; 2Critical Care, Fortis-Hiranandani Hospital, NaviMumbai, Maharashtra, India

Background: Transcutaneous measurement of carbon dioxide is routinely done at the earlobe site. In patients receiving non invasive ventilation or in the intensive care setting with necklines, an alternate measurement site would be useful. The infraclavicular site has major blood vessels in its vicinity. We started to use the infraclavicular site for transcutaneous measurements of carbon dioxide using a new digital sensor.

Aim: Comparison of transcutaneous carbon dioxide with arterial carbon dioxide at the infraclavicular site.

Methods: We retrospectively compared transcutaneous carbon dioxide at the infraclavicular site with arterial carbon dioxide in 50 samples. The Sentec Digital Monitoring System (SentecAG, Thewil, Switzerland) was used. The V-Sign digital sensor was placed on the infraclavicular site at the medial two third and one fifth point from the sternoclavicular joint and acromioclavicular joint.

Results: When comparing PtCO2 with PaCO2 values, the Bland-Altman analysis revealed a bias of 0.15 mmHg (95% CI: ±0.76; 1.05) with a precision of 3.18 mmHg. Linear regression analysis describes the relationship between the two methods. The slope of the linear model was 0.85 ± 0.04 and the intercept was 5.78 ± 1.58 (RSE = 2.8, R² = 0.91).

Conclusion: The measurement of transcutaneous carbon dioxide at the infraclavicular site is feasible with a digital sensor and has a good correlation with the carbon dioxide values obtained from the arterial blood gas.

P2029
Post operative surgical patients can be successfully managed using the target oxygen saturation scheme with the BTS emergency oxygen guidance
Anthony Davison1, Adam Woolf 1, Sherine Tucker1, Stephen Ward1, Lisa Ward1, 1Chest Clinic, Southend University Hospital NHS Foundation Trust, Southend on Sea, Essex, United Kingdom; 2Department of Anaesthetics, Southend University Hospital NHS Foundation Trust, Southend on Sea, Essex, United Kingdom

Too little and too much oxygen can both prove fatal. The BTS Guideline for Emergency Oxygen used in adults patients was published in 2008. The essence of the guideline was that oxygen is prescribed according to a target saturation range and the patients subsequently be kept within the target range. The target saturation could be used in the post operative period although this was not covered in detail in the guideline. In this hospital, Anaesthetists prescribe oxygen post-operatively to target saturation. This study investigated whether this is successful.

Methods: 49 patients were studied in the post-operative ward and in the surgical ward to examine whether the BTS guideline was being followed.

Results: All patients had been prescribed oxygen to a target saturation of 94-98%. Patients on the post operative ward from 45-90 minutes. Saturations were checked every 15 minutes on all patients. Only 3 saturations were below 94% and all were on the initial recording in the post op ward. The oxygen saturation was above 98% in 30 of the 42 patients on oxygen at 15 minutes and 24/40 at 30 minutes. At 60 minutes on the post op ward, 6 patients were on nasal seps (N5), 24 on simple face masks (SM) on arrival on the surgical ward, 16 were on NS and 2 were on SM. In 25 oxygen had been stopped and there was no data on 6 patients. In 6 patients on SM the flow was reduced below 5 L/min. Re-breathing may occur and this is not recommended.

Conclusion: The BTS Emergency Oxygen Guideline the target saturations can be successfully used in post operative surgical patients. Low oxygen saturations were rare but high saturations were common.

P2030
Continuous intraarterial blood pH monitoring in rabbits with acid base disorders
Weizhong Jia1, Jianjun Jiang, Yuanlin Song, Chunxue Bai, Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China

Acid-base balance of arterial blood is important in clinical management of seriously ill patients, especially in patients with acute lung injury or acute respiratory distress syndrome. We developed a novel fluorosensor for continuous blood pH monitoring and evaluated its performance both in vivo and in vitro in rabbits with acid-base disorders. The pH sensor is made of N-Allyl-4-piperazinyl-1, 8-naphthalimide and 2-Hydroxyethyl methacrylate, which were bonded at the distal end of the optical fiber.

The fluorescence intensity increased as the pH decreased with good reproducibility, selectivity and linearity in the pH range of 6.8 – 7.8.
The pH measurement accuracy was -0.00±0.1 pH units (n=189) in rabbits with respiratory acid-base orders. The optical pH sensor can accurately measure pH fluctuations with fast response and is a promising candidate for continuous inline measurement of blood pH in critical care patients.

P2031
A preliminary study of the prevalence of hypoxaemia, hyperoxaemia, hypercapnia and acidosis in hospital blood gas specimens
Ronan O’Driscoll1, Aram Rodenski2, Peter Tanfingjon2, Luke Howard2
1Respiratory Medicine, Salford Royal University Hospital, Salford, UK; 2Biochemistry, Salford Royal University Hospital, Salford, UK

Over or under treatment of hypoxaemia can be dangerous. We studied 3524 blood gas specimens at a university hospital. 362 samples (10.2%) were hypercapnic with oxygen saturation below 90% and 2.7% were severely hypoxaemic with saturation below 80%. 1074 samples (30%) were hyperoxaemic with PaO2 > 15.0 kPa. This study shows that these were under-recognized conditions in hospital practice and is usually associated with respiratory rather than metabolic acidosis. Hyperoxaemia (30% of samples), hypercapnia (27% of samples) and respiratory acidosis (21% of samples) were relatively common. This suggests that oxygen needs to be used more with caution in hospitals in the light of recent studies showing increased mortality associated with hyperoxaemia in a range of common clinical conditions.

P2032
Acoustic respiratory monitoring (ARM) of wheeze (Wz) and cough (C) in the pediatric emergency department (PED)
Sigmund Kharasch1, Alex Gileles-Hillel1, Ibrahim Omar1, Virginia Kharasch1, Eitan Kerem1, 2Pediatrics, Hadassah-Mount Scopus, Jerusalem, Israel; 1Critical Care, Children’s Hospital, Boston, MA, United States

Background: Wz and C are common in the PED, but are only assessed qualitatively and intermittently. We evaluated the feasibility of quantitative ARM in noisy PED.

Methods: 11 PED dyspea patients (7m-1y) were monitored by ARM (PalmoTrack® KarmelSonix, Israel) using 2 PPG sensors, an effort belt and an ambient microphone (MIC). WheezeRATE® (Wz%), quantified as the Wz duration (% of the elapsed time) and CoughCOUNTER® (CC) were continuously measured.

Results: Recordings of all 11 patients generated usable data (t=146 min, 93-314 min) with good ambient noise rejection. 5 patients had bronchiolitis (BR), 3 asthma (AS), 2 pneumonia and 1 cough-variant asthma (C-Va). CC was the most prominent feature with 10/11 patients having CC. A transient reduction of CC occurred after hypertonic Saline in 2/5 BR patients, after ventoline in 1/3 AS and in 1/3 C-Va patients. Wz% was elevated in 2/5 BR and 2/3 AS patients. In one patient the belt signal was poor and in one patient there was a transient disconnect of the MIC resulting in false detection of ambient noises as Wz.

Discussion and conclusions: We found that high CC is the most common sign in patients with dyspnea and that CC reduction in response to therapy provided valuable clinical information. Continuous ARM of wheeze and cough is feasible in a noisy PED. Monitoring a larger population is needed to fully assess the clinical value of ARM in the PED.

Acknowledgement: S Godfrey, N Gaviely and E Balouka from KarmelSonix assisted in data recording and analysis.

The causes of hemoptysis and lung hemorrhage in patients with pulmonary sarcoïdosis
Olga Barannova1, Valentina Molodtsova2, Alexandra Speranskaja1
1Internal Lung Diseases Department, Saint-Petersburg Pavlov’s State Medical University, Saint-Petersburg, Russian Federation; 2Bronchology Department, Saint-Petersburg Pavlov’s State Medical University, Saint-Petersburg, Russian Federation

Study objective: The use of plasma proBNP concentrations as a diagnostic tool in differential diagnosis of dyspnea in comorbidity pulmonary patients.
pulmonary sarcoidosis (PS) modifying the typical clinical and radiological disease picture.

**Aim:** To analyze causes of hemoptysis and lung hemorrhage in PS patients (pts) with the use of modern abilities of radiological assessment (computed tomography - CT, high resolution CT - HRCT, CT with angiography, single photon emission CT - SPECT) and bronchoscopy.

**Methods:** We studied 30 patients (f/m - 17/13) with morphologically confirmed PS with hemoptysis and lung hemorrhage (stages: 1st - 4, 2nd - 9, 3rd - 3, 4th - 5). The average age was 37.2 ± 2.3 years. All patients were subjected to clinical and radiological (HRCT, CT with angiography, SPECT) researches and bronchoscopy.

**Results:** The main causes of this severe complication were pulmonary embolism (17 pts including thrombosis “in situ” in 3 of them) with pulmonary arterial hypertension, atrophic bronchitis (3 pts), traction bronchoceles (3 pts), dry cavities (2 pts), tuberculosis (1 pt). In carrying out bronchography hemoptysis was found in lung tissue viral and bacterial infections (2 pts) and lung cancer (1 pt). The relapsing lung hemorrhage was observed in only one patient with 4 stage PS complicated by micosepsis in thrombotic tissue. In 3 pts bronchoscopy was performed on top of bleeding using various methods of endobronchial hemostasis.

**Conclusion:** Using modern methods of radiological imaging (CT, HRCT, CT with angiography, SPECT) we also were able to detect the main cause of hemoptysis in PS patients - pulmonary embolism including thrombosis “in situ”.

**P2036**

Recognizing fatal pulmonary embolism in young adults with simple clinical measurements

Oxana Tesenko, Alexey Glechikov. Pulmonology, State Academy of Postgraduate Education, Moscow, Russian Federation

**Introduction:** As the incidence of pulmonary embolism (PE) in individuals older than age 45 is higher, numerous studies have shown that in young adults the diagnosis is missed more often than it is made. Death from PE in this group of patients might be considered to be most likely to be preventable. Nowadays there aren’t robust criteria to estimate risk of mortality from PE in young patients.

**Aim:** To identify risk factors of mortality from PE in young people.

**Methods:** We reviewed data from 167 young patients (all male) with PE. Mean age was 44.5 ± 5.2 years. Died. StatSoft Software (version 5.0, 1997) was used for calculations.

**Results:** We analyzed 25 factors of inherited risk (antithrombin III deficiency, protein C and protein S deficiency, factor V Leiden mutation), acquired risk (surgery, malignancy, trauma, obesity, cigarette smoking) and presenting syndromes. Multivariate logistic regression revealed that immobility (bed rest) due to operation or severe disease) (OR 7, 95% CI 3,4–18,9), malignancy (OR 6, 95% CI 2,1–9,2) are forth independent predictors of mortality. (OR 3, 95% CI 2,1–9,2) are forth independent predictors of mortality.

**Conclusion:** The risks of PE are multiple. Although our model requires further validation it may be useful as simple and fast method for identifying young patient with poor prognosis PE and treatment with anticoagulants.

**P2037**

Severe airway response associated with anaphylactic shock in allergic Brown Norway rats

Grégoire Barthel2,3, Bruno Demoulin 1, Chantal Montémont 2, Feng Zheng 2, Severe airway response associated with anaphylactic shock in allergic Brown Norway rats

**Background:** Bronchospasms may occur as part of the early response to anaphylaxis on induction of anesthesia in humans. However, little data are available on the changes in respiratory mechanics occurring in animal models of anaphylactic shock.

The aim of the study was to delineate the respiratory mechanical impedance response to ovalbumin (OVA)-induced anaphylaxis in Brown Norway rats.

**Methods:** Anesthetized, tracheostomized, paralysed and mechanically ventilated ovalbumin-sensitized male Brown Norway rats were randomly allocated to intravenous OVA (n=11) or vehicle (n=7). The respiratory resistance (Rrs) and reactance (Xrs) were measured at 20 Hz using the forced oscillation technique.

**Results:** Allergic rats showed consistent and dramatic increase in respiratory impedance. The peak Rrs response - almost a threefold increase - occurred 49 sec after OVA injection (from 51.2 ± 5.4 to 140.9 ± 5.4 hPa.s/L). Protein C and protein S deficiency, factor V Leiden mutation, acquired risk (surgery, malignancy, trauma, obesity, cigarette smoking) and presenting syndromes. Multivariate logistic regression revealed that immobility (bed rest) due to operation or severe disease) (OR 7, 95% CI 3,4–18,9), malignancy (OR 6, 95% CI 2,1–9,2) are forth independent predictors of mortality. (OR 3, 95% CI 2,1–9,2) are forth independent predictors of mortality.

**Conclusions:** Severe airway obstruction occurs with anaphylactic shock in allergic Brown-Norway rats. The associated decrease in Xrs indicates an increase in apparent respiratory elastance (e.g. with lung vascular engorgement or pulmonary oedema). The inhomogeneity of mechanical time constants within the lung from heterogeneous bronchoconstriction. Data from this animal model emphasize the heterogeneity bronchoconstriction. Recognizing fatal pulmonary embolism in young adults with simple clinical measurements

Follow-up and educational results of bed head lift in intensive care unit

Suat Solmaz, Razaye Sancar, Necile Ornek, Roya Evin, Ozlem Moçın, Emeç Saltukce, Semra Ruki Kafali, Zehra Karkuk. Respiratory Intensive Care Unit, Suryeyapasa Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey

**Objective:** Lifting head of bed is simplest and most important way to prevent aspiration pneumonia in intensive care unit (ICU). In our study we investigated the contribution of reminding this application.

**Method:** Prospective study was done in 22 bed intensive care unit (ICU) between December 2010-January 2011. None of the staff other than researchers were aware of this observational study. Every day during December 2010 at 8.00 a.m and 5.00 p.m 22 ICU bed head position were recorded whether their heads were 30-45 degrees elevated or straight.During January 2011, nurses responsible for beds were told to lift head bed positions and bed head positions were recorded again. Inflection nurse noted aspiration or ventilator associated pneumonia (VAP) cases every two months. Values were summarized with descriptive method.

**Results:** In December 2010, 1278 in January 2011, 1283 bed head positions were recorded. 26 of total 56 (46.4%) records were done in the morning, 30 were done in the evening during December 2010. In January 2011, 24 of total 41 (51.2%) were done in the morning and 17 in the evening. One patient had VAP and died after 12 days in December 2010. In January 2011, 3 VAP. Aspiration pneumonia were observed and they stayed total 64 days in ICU and one of them was died.

**Conclusion:** Reminding of lifting head bed positions at certain hours, during shift changes reduce inappropriate bed head position. This method which is used in reducing the risk of VAP and aspiration pneumonia, shortens ICU stay, contribute country income, decrease aspiration related mortality.

**P2040**

Successful use of interventional lung assist device in a patient with near fatal asthma

Tamer Laura, Murphy Stephen. Respiratory Department, Sunderland Royal Hospital, Sunderland, United Kingdom

Interventional lung assist devices (iLA) are pulpless, arterio-venous, extracorporeal lung support devices with a low resistance gas exchange membrane that allows rapid removal of carbon dioxide (CO2) and moderate oxygenation. Currently they are mainly used in acute respiratory distress syndrome and as a bridge to lung transplantation. We successfully used iLA in an 18 year old asthmatic patient with hypercapnic respiratory failure refractory to conventional ventilation. A male patient aged 15 years presented with a near fatal exacerbation of asthma. He had a current smoker with a history of chronic obstructive pulmonary disease affecting right leg, stroke and ischaemic heart disease. Despite full medical treatment, endobronchial intubation and invasive mechanical ventilation (IMV) plus a range of intravenous and inhaled medications including intravenous terbutaline, ketamine, adrenaline and inhaled adrenaline and isoflurane he developed persistent hypercapnic respiratory failure with PaCO2 > 20. Conventional ventilation strategies were ineffective with poor compliance, high peak airway pressures and prolonged inspiratory times resulting in air trapping and hyperinflation. Therefore an iLA was inserted on day 2. This resulted in enhanced CO2 removal (Pa CO2 21 down to 50ACO2 7.6) and allowed protective lung ventilation at lower pressures with less gas trapping and hyperinflation. The iLA was removed on day 12 with spontaneous breathing on day 19. This could represent a useful future strategy for persistent hypercapnic respiratory failure unresponsive to conventional measures in obstructive diseases such as asthma and COPD.

**P2041**

Inhalation of activated recombinant factor VII to treat pulmonary hemorrhage in a patient with cystic fibrosis

Constantin Marcu, Robert Bal, Andreas Groeschel, Christian Lench, Julia Woerner, Sebastian Faerndich. Pneumologie, Staatliche Universität Hospital, Homburg/Saar, Germany

**Case:** The patient (30y.o., female) was diagnosed with cystic fibrosis as child. Currently, she was hospitalized with fever and bilateral pulmonary infiltrates. She rapidly deteriorated to respiratory failure with the need of extracorporeal membrane oxygenation (ECMO).

Diffus pulmonary hemorrhage complicated the course on ECMO. After 2 days of unmitigating bleeding with respiratory failure we used rFVIIa as an intervention of last resort. The patient was treated with inhalation of 30 μg/kg rFVIIa in 5 mL saline volumetrically delivered via a jet-driven nebulizer, which was repeated after 24 hours. Hemorrhage was visualized bronchoscopically, and its resolution following the treatment was immediate and did not occur again.

**Discussion:** Factor VII initiates clot formation by its interaction with TF. The FVIIa-TF complex activates factor X. Activated factor X activates prothrombin to thrombin, which converts fibrinogen to fibrin. Tissue factor is expressed in the lung alveoli during inflammation and therefore pulmonary administration of human recombinant activated factor VIIa (rFVIIa) could be a rational treatment option.

Our report indicates the applicability of topical rFVIIa to control unremitting hemorrhage in a patient with cystic fibrosis. Currently, she was hospitalized with fever and bilateral pulmonary infiltrates. She rapidly deteriorated to respiratory failure with the need of extracorporeal membrane oxygenation (ECMO). Inhalation of activated recombinant factor VII to treat pulmonary hemorrhage in a patient with cystic fibrosis
systemic exposure. This could also reduce the risk of thrombotic complications reported with systemic administration of rFVIIa as well as clotting in the ECMO membrane.

**Conclusion:** Intrapulmonary administration of activated recombinant factor VIIa (rFVIIa) via a jet-driven nebulizer may be an option in pulmonary haemorrhage.

**P2042**

Enhanced expression of Robo4 ameliorates LPS-induced acute lung injury in mice

Xueling Wu, Yuanlin Song, Xiaodan Zhu, Xiaocang Fang, Chuxue Bai.

Pulmonary Department, Fudan University, Shanghai, China

The loss of endothelial integrity which causes leak of fluid and proteins into tissues contributes to the disease and death associated with acute lung injury. Silt2/Robo4 (an endothelium-specific) signaling promotes vascular stability. The purpose of this study was to evaluate the effect of enhanced expression of Robo4 on LPS-induced acute lung injury. We constructed a recombinant adenoaviral vector expressing murine Robo4 (Ad.mRobo4) which were administered intranasally to BALB/c mice. Forty-eight hours later, all the mice were administered a single dose of LPS via i.p. injection to induce acute lung injury. A second cohort of mice was followed for survival for 7 days. Administration of Ad.m Robo4 increased the expression of Robo4 in lung tissue, as determined by reverse transcription-polymerase chain reaction, Western blot, and immunohistochemistry. Enhanced expression of Robo4 in lung suppressed the inflammatory reaction to LPS, attenuated the lung pathological changes, significantly reduced vascular permeability and edema in the lung determined by albumin in bronchoalveolar lavage fluid and also improved the survival of mice. Our results demonstrate a novel function manner for silt2/Robo4 signaling. Silt2/Robo4 pathway work formerly mainly considered as ligand-dependently, it has now to be considered as a ligand-independently and thus could be an attractive adjutant in the treatment of acute lung injury.

**P2043**

Expression of osteopontin in the lung tissue of acute lung injury rats and the influence of osteopontin on TNF-a and IL-10

Wenjun Wang, Xiaming Fan.

The Department of Respiratory Medicine, Affiliated Hospital of Louchou Medical College, Louchou, Shichuan, China

This work was supported by International cooperation and exchange program of Sichuan science and technology department (NO. 2009HH0032); Background: Pathogenesis of acute lung injury (ALI) has not been clarified fully, also we need to improve the prognosis of ALI.

**Aims:** To investigate the expression of osteopontin (OPN) in the lung tissue of ALI rats and the influence of OPN on the level of TNF-a and IL-10 in serum.

**Methods:** 56 SD rats were randomly divided into control group (24 rats), ALI group (24 rats) and intervention group (24 rats). 8 rats in each group were examined at 2, 4 and 8 h. ALI was induced by LPS injection via caudal vein in ALI and intervention groups, at the same time, rats in intervention group were also injected with anti-OPN antibody. Wet/Dry Weight (W/D). Pathological changes of the lung tissue and ALI score were detected. The level of TNF-a and IL-10 in serum and the expression of OPN in homogenate of lung tissue were detected.

**Results:** W/D, ALI score and the level of TNF-a in ALI group at 2, 4 and 8 h were higher than those in control group and intervention group at the same time point (p<0.01). The level of IL-10 in ALI group at 2, 4 and 8 h was higher than that in control group (p<0.01), but was lower than that in intervention group at the same time point (p<0.05). Compared with control group, the expression of OPN in ALI and intervention groups at 2, 4 and 8 h was higher (p<0.01).

**Conclusions:** The expression of OPN in lung tissue of ALI rats induced by LPS was increased, and OPN could aggravate lung injury, which might be related to up-regulating expression of TNF-a and down-regulating expression of IL-10.

**P2044**

The role of osteopontin in the pulmonary fibrosis caused by acute lung injury induced by lipopolysaccharide in rats

Wenjun Wang, Xiaming Fan.

The Department of Respiratory Medicine, Affiliated Hospital of Louchou Medical College, Louchou, Shichuan, China

This work was supported by International cooperation and exchange program of Sichuan science and technology department (NO. 2009HH0032); Background: In the later stage of acute lung injury (ALI), lung fibrosis is a common sequel. It results in damage of lung function. But we know little about its pathogenesis.

**Objective:** To investigate the role of osteopontin (OPN) in the pulmonary fibrosis caused by lipopolysaccharide (LPS)-induced ALI.

**Methods:** 120 rats were randomly divided into control group (n=40), ALI group (n=40) and intervention group (n=40). ALI was induced by intraperitoneal injection with LPS on day 0, 1 and 2 in ALI group. Also, the rats in intervention group were treated with Anti-OPN antibody by intraperitoneal injection after LPS injection. Then 10 rats in each group were randomly sacrificed on the 7th, 14th and 28th day. Histological examination and the expression of OPN in the lung tissue were determined. Hydroxyproline and the mRNA levels of type I and II collagen in the lung tissue were measured.

**Results:** Compared with control group, the expression of OPN in ALI group was remarkably higher on 7th, 14th and 28th day respectively (p<0.01). The extent of lung fibrosis, the expression of hydroxyproline and the levels of type I and II collagen mRNA in intervention group and ALI group were higher than those in control group on day 7, 14 and 28 respectively (p<0.01), but they were lower in intervention group than those in ALI group (p<0.01).

**Conclusions:** The expression of OPN in the lung tissue of pulmonary fibrosis caused by LPS-induced ALI in rats was increased. OPN could promote the development of lung fibrosis in ALI rats.

**P2045**

A prospective evaluation of different anthropometric height estimation formula

Solene Guinard1, Zoe Chiche 2, Jérome Martin1, Erwan L’Her2. 1Medical ICU, CHU, Brest, France; 2Emergency Department, CHU, Brest, France

It is now accepted that protective ventilation with low (8ml/kg of predictive body weight) tidal volume benefits to ARDS patients. To determine protective body weight, the gender and height of patients have to be known. However, in the ICU or in the ED, patients are often unable to provide their height and tape measurement is usually not valid. The purpose of this study is to evaluate different easy and reproducible anthropometric indicators, which could be correlated to the exact patients’ height.

Several indicators have been prospectively evaluated on 60 healthy volunteers and correlated to their real height. Height evaluation formula are based on different simple measurements correlation coefficient (r) was calculated by linear regression as compared to exact measured height.

**Results:** See table 1. Among 16 anthropometric different height estimation formula, ulna’s length and tibia’s length were best correlated with the real volunteers’ height.

**Discussion:** Several simple limb measurements can accurately predict exact patients’ height. These estimations need to be tested on ICU patients, in order to evaluate their bedside feasibility and usefulness.

**P2046**

“Normotension” on admission to the emergency department affects outcome of patients with acute cardiac pulmonary edema (ACPE)

Valentina Ross1, Chiara Traverso2, Federico Piffer2, Stefano Alberti3, Caterina Bonino1, Valter Monzani2, Antonio Vora1, Daniele Camisa1, Simona Fuscò1, Marco Barchetti, Federica Molinaro1, Giuseppina Petrelli1, Roberto Cournten2, Anna Fanzia Brambilla1, 1Respiratory Medicine Department, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; 2Emergency Department, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; 3Emergency Department, San Gerardo Hospital, Monza, Milan, Italy; 4Emergency Department, Humanitas Hospital, Milan, Italy; 5Emergency Department, Melegnano Hospital, Melegnano, Milan, Italy; 6Emergency Department, Fuerza Hospital, Fuerza, Italy; 7Emergency Department, Sassuolo Hospital, Sassuolo, Italy; 8Emergency Department, Gradenigo Hospital, Turin, Italy; 9Emergency Department, San Benedetto del Tronto Hospital, San Benedetto del Tronto, Italy

**Introduction:** ACPE is a common cause of admission to the Emergency Department (ED). We previously retrospectively studied the effect on the outcome of blood pressure (BP) on admission.

**Aim:** To prospectively confirm the relationship between “normotension” on admission and worse outcome in ACPE patients.

**Methods:** Prospective, observational, multicentric, web-based study on patients admitted to the ED with ACPE. Data were collected from 13 Italian EDs. “Normotension” was defined as Mean Arterial BP (MAP)<107 mmHg. Patients with MAP>65 mmHg on admission were excluded.

**Results:** From May 2009 to October 2010, 460 patients were enrolled. Nine hypotensive patients were excluded. Mean age was 80 years (SD±10 years), 245 males (54%). “Normotensive” patients were 41% (185/451). Clinical and laboratory data are showed in table 1. Overall, in-hospital mortality was 8% (34/451). In-hospital mortality in normotensive patients was significantly higher than in hypertensive patients, 12% (22/185) vs 4% (12/266) (p<0.01). We also found that the risk factor “normotension” maintained its statistical significance in a multivariable analysis when compared with the other significant risk factors (Age, PaO2/ Hemoglobin) detected in our population in the univariate analysis.

A metabonomic approach to prognostic evaluation of ALI by high-resolution nuclear magnetic resonance (HR NMR) spectroscopy

Xun Wang1, Wenxue Chen2, Xiaojing An1, Dong Yang1, Fener Chen2, Chunxue Bai1,2,1Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China; 2Fudan–DSM Joint Laboratory, Department of Chemistry, Fudan University, Shanghai, China

Purpose: Metabonomics is a well-developed platform for studying systems biology and clinical diagnosis. In this study, we investigated a metabonomic approach to prognostic evaluation of LPS-induced ALI by HR NMR spectroscopy.

Methods: The mice model of ALI was established by intratracheal instillation of LPS (5mg/kg) for 4 hours with the saline in control mice. The mice of dexamethasone (DEX) treatment group fell in the range of the control group.

Results: The lung injury score were significantly increased in ALI mice compared to control group and DEX treatment markedly decreased the lung injury score. The first principal component (PC1) shows a good separation between the ALI group and control (or DEX treatment) groups. The metabolites showed clear pattern recognition methods was applied to study 15 lung tissues extract samples of mice.

Conclusions: Our study, for the first time, provides evidence for a metabonomic approach to prognostic evaluation of ALI treated by DEX by HR NMR spectroscopy.

Conclusion: We prospectively confirmed that “nornotensin” on presentation is a significant and independent risk factor for mortality in patients with ACPE.

Materials and methods: This was a retrospective observational study of 366 patients with severe sepsis or septic shock who presented to the emergency department between May 2007 and July 2009. Compliance with resuscitation bundles and achievement of the corresponding end points were compared before and after the three-month educational program.

Results: Compliance with central line insertion and monitoring of central venous pressure (CVP) (29% vs. 67%, p < 0.001) and central venous oxygen saturation (ScvO2) (25% vs. 68%, p < 0.001) was significantly improved after the educational program. The achievement of target ScvO2 within the first six hours was significantly improved (62% vs. 88%, p < 0.001). In-hospital mortality was independently associated with adequate fluid challenge (OR, 0.161; 95% CI, 0.046 – 0.559) and the achievement of target mean arterial pressure (MAP) (OR 0.056; 95% CI, 0.008 – 0.384) and ScvO2 (OR, 0.231; 95% CI, 0.072 – 0.875) among the five sepsis resuscitation bundles.

Conclusion: An educational program can improve compliance with resuscitation bundles and achievement of their corresponding end points.

P2049
Prevalence and prognosis of critically ill patients with COPD between 1998 and 2008

Georg-Christian Funk1, Peter Bauer2, Otto Christ Burghuber1, Andreas Fazekas1, Sylvia Hartl1, Barbara Metnitz2, Philipp Metnitz2,1Department of Respiratory and Critical Care Medicine and Ludwig Boltzmann Institute of COPD and Pneumological Epidemiology, Otto Wagner Spital, Vienna, Austria; 2Dept. of Medical Statistics, Medical University of Vienna, Vienna, Austria; 3Dept. of Anaesthesiology and General Intensive Care Medicine, Medical University of Vienna, Vienna, Austria

Background: Little is known about the prevalence and outcome of patients with COPD treated in ICUs. Such information is valuable for the planning of resources e.g. respiratory care units and weaning facilities.

Aims and objectives: We speculated that COPD would be an increasing problem in critically ill patients and would be associated with increased morbidity and mortality.

Methods: We analysed prospectively collected data of 194,453 adults treated in 87 Austrian ICUs over a period of 11 years (1998-2008).

Results: COPD was present in 9% of all ICU patients. The risk-adjusted mortality of patients with COPD was higher compared to patients without COPD (oberved to expected mortality ratio with 95% CI 0.91 (0.90 – 0.92) vs 1.14 (1.12 – 1.16), respectively). The presence of COPD was an independent risk factor for increased mortality in multivariable regression. Prolonged mechanical ventilation occurred more common in patients with COPD (24%) compared to those without it (17%), p<0.0001. Prolonged weaning was also more common in patients with COPD (6%) compared to those without (2%), p<0.0001. During the course of 11 years the incidence of acute respiratory failure due to COPD increased from 1.8% to 3.0%, p<0.0001) and the use of non-invasive ventilation more than doubled (from 15% to 34%, p<0.0001). Simultaneously, the risk-adjusted mortality of COPD patients improved.

Conclusions: Acute respiratory failure due to COPD is an increasingly common condition in critically ill patients. The presence of COPD is associated with increased morbidity and mortality. The improvement of risk-adjusted mortality over time may be attributable to the beneficial effects of non-invasive ventilation.

P2050
Acute and chronic term results of kyphoscoliotic patients with acute respiratory failure treated in intensive care unit (ICU)

Gokay Güngör1, Zulub Karakurt1, Nalan Adıgüzel1, Özlem Yaziçılıoğlu Moçin1, Metin Balci1, Cüneyt Saltık1,2, Huu Yilmaz1, Aysem Öztin1, Tuğay Yarkın1,1Respiratory Intensive Care Unit, Sırruyapasa Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey; 2Chest Diseases, Nihat Kitapci Chest Diseases and Thoracic Surgery Center, Erzurum, Turkey

Objective: In our study we aimed to evaluate acute and chronic term results of kyphoscoliotic patients admitted to ICU with acute respiratory failure in 9 years period.

Method: Kyphoscoliotic patients applied to ICU between 2002-2010 enrolled in the study. Patients’ demographics,comorbidity,APACHE II score on admission, presence of sepsis, arterial blood gas analysis (on admission and first control), invasive (IMV) and noninvasive mechanical ventilation (NIV) application and duration, length of stay in ICU,ICU mortality, chronic term follow-up mortality were recorded. Data were summarized with descriptive analysis.Variables were given as median and interquartile ratio (IQR).

Results: 84 kyphoscoliotic patients (46 male) with median age 50 (IQR: 36-64) accepted to ICU were included: %78.3 (%57) of cases has comorbidity and 22.8% (%13.7) of patients were in long term oxygen therapy (LOT) and mechanical ventilation at home. APACHE II score 15 (12-19), presence of sepsis %42.9 (n=36), NIV and IMV application was %79.8 (n=67), %32.1 (n=27) respectively. Length of stay in ICU was 8 (4-14) days and mortality was %10.7 (n=9, 7 under IMV). After ICU discharge mechanical ventilator at home (HMV) was reported to %39.8 (%33) of patients, LOT was reported to %21.3 (%16) of patients. A total of 53 patients have HMV, 51 of these patients were followed long term. One patient after 2 months, 2 patients died after 5 years. 12 patients didnot come to controls regularly.
Conclusion: In patients with kyphoscoliosis accepted to ICU due to acute respiratory failure, mortality is significantly higher while in patients with mechanical ventilation at home compliance and follow-up is better, mortality is lower.

P2051 Characteristics and outcome of COPD patients with an acute exacerbation admitted to a respiratory ICU
Monica Guerrero, Joan Ramon Badía, Miquel Ferrer, Antoni Torres. Unitat de Cures Intensives e Intermediaries Respiratories, Servei de Pneumologia, Institut del Torax, Hospital Clinic, CIBER de Respiratorio CIBERES, IDIBAPS, Barcelona, Spain

Many patients with an acute exacerbation may be considered for ICU admission. The aim of this study was to assess the clinical characteristics, resource use and prognosis of COPD patients in a respiratory ICU setting (RICU).

Methods: Retrospective study of RICU patients with primary diagnosis of COPD exacerbation from 1995-2007. We collected clinical information, ventilatory support requirements and outcome from the clinical records.

Results: During the study period 512 COPD patients were admitted with a mean age of 69.2±8.9 yr (86% male). Mean PEVI was 34.8±13.9 (% predicted value) and 40.4% were on long term home oxygen. More than half of the patients had one or more significant co-morbidities. Cardiac disease (26%) and alcoholism (14%) were among the most frequently encountered. As much as 49.4% of cases required intubation and mechanical ventilation (MV) while 38.9% could be managed with non-invasive ventilation (NIV). Only 5.8% of the patients treated with NIV at admission required finally MV. The duration of MV was 7.13 days (median 5.5, IQR Range: 3-9 days) and the overall ICU length of stay was 7.1 days (median 7.4, IQR Range: 2-8 days). Tracheostomy was performed in 4.7% of the cases. Finally, ICU mortality for all the study group was 9.4%. We did not find an association between mortality and PEVI or being on home oxygen therapy.

Conclusions: RICU mortality for COPD patients with acute exacerbation is lower than 10%. Most patients requiring MV could be extubated without major issues. A lower FEVI or being on home oxygen were not associated with a higher ICU mortality. COPD patients admitted to the ICU with an acute exacerbation have a good chance of survival.

P2052 COPD under invasive mechanical ventilation, in-hospital mortality rate: A retrospective study
Patricia Garrido1, Susana Carreira1, Andreia Gonçalves2, Fernanda Paula1, Leonardo Ferreira1, Filipe Froes1, Luís Telo1, Pneumology Department II, Pulido Vaz Hospital – CHLN, Lisbon, Portugal; Internal Medicine, S. José Hospital - CHLC, Lisbon, Portugal

Background: The in-hospital mortality rate of patients with Chronic Obstructive Pulmonary Disease (COPD) submitted to Invasive Mechanical Ventilation (IMV) is recognized as being high.

The authors aim to characterize this population and to identify mortality predictive factors.

Methods: Retrospective study of the clinical records of 67 COPD patients admitted to the Respiratory Intensive Care Unit (ICU) of Lisbon-North Hospital required invasive ventilation between January 2005 and August 2009.

Results: The majority were male (91%), with an average of 69.1±10 yrs and 25% were active smokers. The FEVI was 40±18%, with 55% being subjected to Long Term Oxygen Therapy and 18% to domiciliary non-Invasive Ventilation (NIV). The aetiology of exacerbation was mostly infectious (78%). They required 16±7 days of IMV. The ICU mortality rate was 24% and the global hospital mortality rate was 40%.

Two groups were evaluated concerning mortality.

The statistically significant (p<0.05) prognostic factors were: older patients (75 vs. 66 yrs), lower BMI (24 vs. 26 kg/m²), pneumonia (40% vs. 15%), longer in-hospital period before ICU admission (8 v. 3 days), previous acute NIV (67% vs. 33%) and higher severity score at admission (SAPS II 44±23 vs. 35±17).

Conclusions: Mortality was associated to a higher severity at admission and extended period under NIV whilst preceding the admission in ICU. The data may be relevant through an early recognition of failure situations in patients with previous NIV.

P2053 pH – and serum sodium level as an important predictor of mortality in acute exacerbation of COPD
J.K. Samaria, Hemant Kumar. Department of Chest Diseases, Instit of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Background: AECOPD result in increased morbidity and mortality, and constitute a tremendous socioeconomic burden. Predicting in-hospital mortality may aid prognostication and plan for future therapies.

Aim of study: Predicting in-hospital mortality in patient of Acute Exacerbation of COPD help in planning the course of future treatment for averting the impending morbidity and mortality.

Methods: Study includes 94 patients of Acute Exacerbation of COPD admitted in the Tertiary Care Hospital were subjected to thorough history and clinical examination, all relevant examinations including ABG & others like RFT, LFT, CBC, RBC etc were done. All the patients of AECOPD managed either by NIV or given invasive ventilation in ICU.

Results: Most patients were elderly with mean age of 62.3 years. Mortality rate was 17% (16/94) during hospital stay. Mean pH of the patients 7.382 (SD=0.0878). pH of those who survived were mean 7.3025 (SD 0.111) and patients who survived were mean 7.3898 (SD 0.706). The difference was significant (P=0.003) (CI 0.3385 – 0.15695). Sodium level of the patients in the study were 133.93 (SD 8.481), patients who expired the sodium level were mean 123.43 (SD 11.267) and those who survived mean sodium were 135.92 (SD 6.264). The difference was significant (P=0.001) (CI6.505 – 18.475).

Conclusion: pH and serum sodium level at the time of admission are independent predictors of mortality in patients with Acute Exacerbation of COPD.

P2054 Is there a difference in outcome according to etiology of COPD exacerbation in patients admitted to an ICU?
Pulmonary Medicine, University of Athens, Greece; 1st ICU, Hellenic布朗; 2nd ICU, Athens General Hospital, Athens, Greece

Objective: the aim of our study was to detect the impact of the etiology of severe COPD exacerbations admitted to a respiratory intensive care unit (RICU).

Methods: Retrospective study evaluating all episodes of severe COPD exacerbations admitted from Jan/2005 to Sept/2010 in our RICU. Patients with lung cancer were excluded. Regarding the etiology of exacerbation we divided into three groups: heart failure, respiratory infection, others/undefined. Different parameters were analyzed: APACHE II, TISS, length of stay in RICU, days on invasive mechanical ventilation, mortality. In the comparative analysis, episodes with more than one cause of exacerbation were excluded.

Results: Data were collected from 141 out of 184 episodes admitted to RICU. Mean age was 70±10, 76% were male. Mean APACHEII was 24.6±7.9 and mortality during the RICU admission was 30%.

P2055 Intensive care resources and costs of advanced age patients with respiratory failure: 3 years cohort study
Zulul Karakurt, Nalan Adiguzel, Donduye Ozugil, Gokay Gunoglu, Ozlem Yazicioglu Moçin, Merih Kalamanoglu Balci, Seray Baylan, Cineyt Salturk, Adnan Vilmuz. Respiratory Intensive Care Unit, Saretopsyas Chest Diseases Thoracic Surgery and Training and Research Hospital, Istanbul, Turkey

Aim: Data about intensive care unit (ICU) stay days and costs of advanced age (>80) patients with respiratory failure is limited at our country. Aim of the study is to investigate ICU stay days and costs of advanced age patients. Method: Retrospective cohort study. Between 2008-2010, patients who were over 80 years old and stayed more than 24 hours at ICU were included. Patients' demographic characteristics, arterial blood gases, APACHE II scores, comorbidities, ICU and hospital stay days, mortality and costs were recorded from patients files. Patients were grouped according to Katz basic activities of daily living (ADL) scale as group 1 (0-6); independent, full function, group 2 (7-12) moderate impairment, group 3 (13-18) dependent, severe functional impairment. Results are recorded as median and interquartile ratio (IQR).

Results: 185 patients (109 women) whose median age was 82 (IQR, 81-84) were included. Patients ICU stay days were 6 (3-9), hospital days were 11 (6-17). Costs of ICU and hospital were respectively 1333.64 (693.18-2232.27), 1838.6 (983.58-2698.79) Euro. Groups according to Katz ADL scale: group 1: 159 (85.9%), group 2: 12 patients (6.5%), group 3: 14 patients (7.6). ICU costs (Euro) as follows; group 1: 1282.27 (595.00-2232.27), group 2: 1279.31 (758.40-2332.37), group 3: 1845.45 (1225.00-2232.27). ICU mortality was 16.6% but majority patients (80%) with group 1.

Conclusion: ICU survival of advanced age patients were nearly 80% and because
of comorbidities risk of ICU readmission is high. In order to decrease costs of these patients care especially bed dependent patients, government should developed health policy to build chronic care centers.

P2058

Factors affecting mortality in a respiratory intensive care unit

Pelin Özdemir, Bercu Basarik, Mehmet Zaide Tasbakan, Aleg Gurugan, Ozen Kacmaz Basoglu, Feza Bacaglo. Chest Diseases, Ege University School of Medicine, Izmir, Turkey.

Introduction and aim: Underlying diseases, comorbidities and hospital acquired infections are the main factors that affect mortality in intensive care unit (ICU) patients. In this study, the factors affecting mortality in respiratory ICU were evaluated.

Methods: The ICU patients followed-up between February 2008 and September 2010 were assessed retrospectively. The relationship between mortality and demographic features, underlying diseases, comorbidities, APACHE II and SAPS II scores on admission, invasive diagnostic and therapeutic procedures and, hospital acquired infections were investigated.

Results: Out of 240 patients (165 men, mean age 58.2±16.6 yrs) included in the study, 118 patients (49.2%) died. The mortality rate was higher in immunosuppressive patients than immunocompetent ones (71.4% vs. 41.2%, p<0.0001). The age, APACHE II and SAPS II scores were higher in patients who died (p<0.007, p<0.0001, p<0.0001, respectively). The mortality rate was 66.2% in patients treated with invasive mechanical ventilation (IMV), whereas it was 38.6% in patients using noninvasive mechanical ventilation (p=0.0001). The mortality rate was higher in patients with positive culture of respiratory samples on admission, 3rd and 7th days (p<0.05). Besides, the durations of intubation (p<0.0001) and ICU stay (p<0.020) were longer in patients who died.

Conclusion: Immunosuppression, severity of illness, IMV requirement and development of lower respiratory infections were the most important factors affecting ICU mortality.

P2059

The follow-up of cancer patients with acute respiratory failure in an intensive care unit

Aim: We intended to evaluate the follow up and mortality rate (MR) of cancer patients (CP) admitted to intensive care unit (ICU) with acute respiratory failure (ARF).

Material-method: Retrospective descriptive clinical study. Between January 2002- December 2010, all CP under medical treatment in ICU of Sureyyapasa Chest Diseases and Thoracic Surgery Teaching Hospital were included. CP were grouped under the following categories: underlying diseases, comorbidities and ICU admission priority.

The demographics, initial APACHE II score, application of noninvasive and invasive mechanical ventilation (NIV, IMV), length of stay (LOS), resectional surgery for lung cancer (LC) and tracheostomy, MR and distribution of cases according to years were investigated. Above data of mortal cases were compared with cases without mortality.

Results: Median age of 223 CP in ICU was 65 (57-71), 25%-75%: 81,8% (n=181) were male. Number of CP according to years in 2002, 2010 was 5 and 72, respectively. Rate of LC and resectable LC cases were 72.2% (n=161) and 29% (n=65), respectively. The median initial APACHE II and LOS in ICU were 21 (16-27; 25%-%75%) and 6 (3-12; 25%-%75%). Use of NIMV, IMV and tracheostomy were 63.7% (n=142), 48% (n=107), 3.1% (n=7), respectively. MR was 37.6% (n=84) for all CP. The MR for IMV and all CP were 63.7% (n=142) and 37.6% (n=84), respectively. APACHE II score and male gender were detected to be significantly high in mortal cases (p<0.001, p=0.043, respectively).

Conclusion: As MR of CP followed in ICU has declined, high APACHE II score and IMV need significantly increase mortality. We assume that MR for CP will decrease if proper therapy is chosen with NIV for CP at third or fourth level of ICU admission priority.

P2060

Intensive care outcomes in patients with diffuse fibrotic parenchymal lung diseases

Aim: We aimed to evaluate outcomes of patients with interstitial fibrosis (IF) and diffuse lung parenchymal diseases admitted to intensive care unit (ICU) due to acute respiratory failure (ARF).

Methods: We included patients with ARF due to IF and diffuse parenchymal lung diseases in ICU between 2008-2010 in retrospective cohort study. Patients demographics, APACHE II score on admission to the ICU, application of mechanical ventilation; invasive (IMV) or noninvasive (NIV), arterial blood gases values, type of feeding (oral, enteral, parenteral), length of stay (LOS) in ICU and mortality were recorded from patients' file. Continuous variables were given as median and interquartile range (IQR). Patients were compared according to mortality and logistic regression analysis was used for mortality risk factors.

Results: In study period 44 patients (26 male) and median age was 59 (IQR: 49-63), APACHE II score was 20 (13-32) and median of NIV and IMV were 20 (4-55.5), 17 (3-38.6) respectively. Oral, enteral and parenteral feeding as follow: 20 (4-55.5), 16 (3-36.4), 8 (16.18). LOS in ICU was 5 (2-9) days and mortality rate in ICU was 34.5 (n=20). Risk factors for mortality were found IMV application and enteral-parenteral feeding, p values Odds ratio (OR) and confidence interval%/95 (CI) respectively p< 0.036, OR:20.35 (CI:1.21-341.63), p= 0.020, and 45.63 (CI:1.67-362.32).

Conclusion: Patients with diffuse parenchymal lung diseases and IF have higher mortality in ICU if conditions with ARF prevent oral nutrition and there is need for continuous mechanical ventilation. Physicians should think carefully about ICU demand for those patients.
P2061
Health-related quality of life after automated or protocol-based weaning from mechanical ventilation
Dirk Schäfler1, Laura Kaiser1, Bjorn Malcowski2, Gunnar Elke1, Sven Pulletz2, Inez Frerichs1, Jens Scholz1, Thomas Küchler1, Norbert Weiler2
1Department of Anaesthesiology and Intensive Care Medicine, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany; 2Department of General and Thoracic Surgery, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany

Introduction: Although automated weaning systems have shown to be safe and more efficient than a conventional approach, it is unknown whether they influence health-related quality of life (HRQOL).

Objective: We hypothesized that automated weaning with SmartCare/PS compared with a standardized weaning protocol has a positive effect on HRQOL.

Methods: Patients were systematically followed-up one year after participation in a randomized controlled trial investigating the effect of automated versus protocol-driven weaning from mechanical ventilation (ASOPTrial; clinicaltrials.gov ID 00445289). Quality of life was assessed using QLQ C-30 3.0 questionnaire. Mean differences of equal or more than 10 score points were considered to be clinically relevant.

Results: 300 patients were initially included, 232 patients were alive one year later. We were able to get into contact with 143 patients, 127 patients gave consent to fill out the questionnaire. 81 questionnaires were sent back and included into this analysis. Regarding the function-related scales we found clinically significant higher mean score values for “emotion” and “global health status” in the automated weaning group (Figure 1, Panel A). Symptom-related scales like “fatigue” and “diarrhoea” were clinically significant lower in the SmartCare/PS-group (Figure 1, Panel B).

Conclusions: This study shows an improved HRQOL in the automated weaning group.

P2062
Validation of the 3CPO-score in a prospective cohort of acute cardiogenic pulmonary edema (ACPE) patients
Valentina Kosti1, Chiara Travirotto2, Stefano Alliberti1, Federico Piffer1, Tommaso Marzilli1, Valer Monzani2, Francesco Stia1, Aldofo Di Nardo2, Federico Furlan1, Antonino Maffei1, Chiara Minelli3, Anna Kostihova1, Roberto Cosenzi4, 1Respiratory Medicine Department, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; 2Respiratory Medicine Department, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; 3Respiratory Medicine Department, San Gerardo Hospital, Monza, Milan, Italy; 4Intensive Care Unit, San Paolo Hospital, Milan, Italy; 5Emergency Department, Policlinico Bari Hospital, Bari, Italy; 6Emergency Department, San Pietro Hospital, Bergamo, Italy; 7Emergency Department, San Raffaele del Monte Tabor Hospital, Milan, Italy; 8Emergency Department, San Paolo Hospital, Napoli, Italy; 9Emergency Department, Valduce Hospital, Como, Italy; 10Emergency Department, Fatebenefratelli e Ospedali Milano, Milano, Italy

Introduction: Assessing the severity of patients presenting in the Emergency Department (ED) with ACPE is crucial to decide intensity of treatment and site of care. The 3CPO Trialists elaborated a Score based on presenting characteristic to predict 7-day mortality.

Aim: To validate the 3CPO-score in a prospective cohort of ACPE patients.

Methods: A multicentric, prospective, web-based, observational study was performed in 13 Italian ED. The 3CPO score was computed as follows: 0 to 2 points according to age; 0 to 3 points according to Systolic Blood pressure; 0 to 2 points according to the ability to obey to commands.

Results: From May 2009 to October 2010, 240 patients were analyzed. Mean age was 80 years (SD±11 years), 117 male (48%). Overall 7-day mortality was 7% (17/240). Mortality according to the Score classes is shown in table 1. The result of the ROC analysis is depicted in Figure 1: the AUC was 0.75; however, intermediate values of the score did not reliability predict mortality in our population.

Rationale: Nosocomial pneumonia (NP) is the most important infection acquired in ICU. There is no clear and validated definition to evaluate treatment failure (TF).

Objective: To validate a previously established definition of TF of NP in ICU.

Methods: We prospectively collected data of NP in ICU, evaluated the rate of TF at 72 hours after beginning antibiotic treatment and compared the groups with or without TF. TF was defined as the presence of any of the following: failure to improve the PaO2/FiO2 ratio or need for intubation because of pneumonia, persistence of fever or hypothermia plus purulent respiratory secretions, worsening of the pulmonary infiltrate by >50%, or occurrence of septic shock or multiple organ dysfunction not present on day 1.

Results: We evaluated 297 cases; 178 with ventilator-associated pneumonia (VAP) and 119 with non-VAP. 165 patients (55%) fulfilled TF criteria. There was no difference between groups in demographics, severity scores (APACHE-II, SOFA), or inflammatory response assessed by CRP (TF vs. non-TF). Treatment failure was related with increased mortality in the ICU (45% vs. 18%, p<0.001) and the hospital (52% vs. 25%, p<0.001), longer ICU stay (22±22 vs. 16±21 days, p<0.033), but with similar hospital stay. Failure to improve the PaO2/FiO2 was the only independent component of TF definition associated with the evaluated clinical outcomes.

Conclusion: The definition of TF appears to correlate well with relevant clinical outcomes, mainly due to the respiratory parameters.

P2064
Reversibility of swallowing disfunction in tracheotomized patients
Piero Ceriana, Claudio Fraccia, Chiara Fussios, Claudio Cazzani, Barbara Cattani, Maria Dichitarra, Riccardo Bellazzi, Stefano Nova
Pulmonary Rehabilitation, Fondazione Maugeri, Pavia, Italy Pulmonary Rehabilitation.
Fondazione Maugeri, Monza, Italy Neurological Rehabilitation, Fondazione Maugeri, Pavia, Italy Radiology, Fondazione Maugeri, Pavia, Italy Biometry and Statistics, Fondazione Maugeri, Pavia, Italy Respiratory Medicine, Ospedale Sant’Orsola, Bologna, Italy

Tracheotomized patients (TP) are often dysphagic and videofluoroscopy (VF) represents the gold standard diagnostic technique. We wanted to evaluate with VF the swallowing function (SF) of a group of 80 TP admitted to our centre: 48 (group N) were free from a chronic respiratory disease (CRD) and had been tracheotomized for a central nervous system hemorrhage or ischemia while the other 32 had been tracheotomized for the exacerbation of a CRD (group P). All patients were studied
with VF twice: few days after admission (t0) and after the rehabilitation period (t1). The following aspects of SF were assessed: glottis elevation (E), epiglottis folding (EF), oral phase (OP), pharyngeal retention (PR), onset of reflex (OR), penetration (P) and inhalation (I). Every item was scored 1, 2 or 3 when it was judged, respectively, normal, slightly altered or abnormal. Differences in terms of categorical scores distributions between the two groups were tested with Pearson’s chi square test, while t0 and t1 scores were compared separately for each group by Wilcoxon test to search for an improvement. At t0, Tp in group N exhibited better scores than Tp in group P with respect to EF, PR, P and I (p<0.02). At t1, Tp in group P significantly improved their scores compared to t0 with respect to AE, EF, OP, PR, P and I (p<0.02), while Tp in group P improved only for I (p<0.01).

In conclusion, the presence of a CRD significantly impairs the SF, mainly for the disrupted coordination between swallowing and breathing. Even at the end of a rehabilitation course, Tp affected by a CRD exhibit limited improvement, while those suffering from previous cerebral ischemia or hemorrhage significantly improve their SF.

250. Noninvasive ventilation in the acute setting: education, organisation, H1N1, paediatrics, weaning, diagnostic procedures and special considerations

P2065 A five-year series on the use of noninvasive ventilation as a weaning tool from invasive ventilation
Adrian Kee, Jason Phua, Yingqin Huang, Eleanor Dela Pena, Erlinda Santiago, Juliet Santos, Sunitha Palani, Rolando Capistrano, Joey Dezon, T.K. Lim.
Respiratory and Critical Care Medicine, National University Hospital, Singapore, Singapore

Data from randomised-controlled trials suggest that use of noninvasive ventilation (NIV) as a weaning tool decreases mortality, length of stay (LOS) and duration of invasive ventilation. We aimed to evaluate if increased use of NIV after high-risk extubation over time was associated with improvement in outcomes in the clinical setting.

In this prospective cohort study of all invasively ventilated patients (n=2316) in our medical intensive care unit (ICU) between 2006-2010, we performed time-trend analyses using simple logistic and linear regression to determine temporal changes in post-extubation NIV use, ventilator days, ICU LOS, reintubation rates, and ICU mortality. During this time we had gradually implemented the use of NIV post-extubation in patients with risk factors for extubation failure.

The proportion of patients receiving NIV post-extubation increased from 2006-2010: 21.1%, 22.0%, 23.9%, 34.6% and 34.8% respectively (OR 1.20 with each year passing, 95% CI 1.12-1.29). The commonest indication for NIV was high-risk extubation despite a successful spontaneous breathing trial (79.1%). Increased NIV use was associated with temporal decreases in invasive ventilator days and ICU LOS but these were neither statistically nor clinically significant. There were significant associated decreases in overall reintubation rates (OR 0.87 per year, 95% CI 0.76-0.99) and ICU mortality (OR 0.82 per year, 95% CI 0.76-0.87).

Although greater use of NIV post-extubation did not reduce ventilator days and ICU LOS in a general medical ICU population, there were associated improvements in reintubation rates and mortality. Considerations included a heterogeneous population and sedation protocols.

P2066 Techniques of managing difficult to wean acute NIV: Comparison between prolongation of time off ventilator and pressure withdrawal
Yasser Noeman-Ahmed.
Respiratory Medicine, Newham University Hospital, Newham, London, United Kingdom

Introduction: Recent guidelines suggested gradual reduction of the duration of NIV once clinical improvement is determined. However, a subgroup of patients become dependent on the machine, finding the hours off the machine stressful in the absence of signs of respiratory failure. In this particular group of patients, we compared between slowly prolonging the hours off ventilator as tolerated by the patient to starting Day 0 and reducing the IPAP levels by 1-2 cm H2O every day.

Methods: Difficult to wean patients were identified as those unable to tolerate more than one hour off BiPAP on day 3 from the start of NIV. We excluded patients with persistent severe abnormal physiological parameters. All patients were fully alert with no clinical signs of persistent exacerbation. The failure of tolerating more than one hour off ventilator was due to the subjective feeling of tiredness and breathlessness in the absence of desaturation. Five patients (Group 1) were started on Day 0 and gradually reducing the IPAP levels by a rate of 1-2 cm H2O per day depending on the Day 3 IPAP level. The other five patients (Group 2) were treated in the conventional way of gradually prolonging time off ventilator as tolerated by the patient. Both groups received same medical management, phystherapy and psychological support as needed.

Results: Both groups did not differ significantly in age, sex, physiological parameters or blood gas values. The length of NIV therapy and the length of stay in the hospital were significantly shorter in group 1.

Conclusion: Gradual reduction of IPAP level can be used as an alternative method in a specific group of difficult to wean NIV patients.

P2067 A new weaning and long term ventilation service – One year on
Verity Ford, Robert Angles, Biwaji Chakrabarti, Nick Duffy, John O'Reilly, Karen Ward, Jan Bennett, Victoria Molyneaux, Jackie Walsh, Julie Cheney, Robert Parker.
Weaning and Long Term Ventilation Service, Aintree Chest Centre, Aintree University Hospitals NHS Foundation Trust, Liverpool, United Kingdom

Introduction: In 2010 a purpose built 10 bed ventilation Inpatient Centre (VIC) was opened. In its first year 230 patients received acute non invasive ventilation (NIV), and 164 early electively on domiciliary NIV. It now also manages weaning failure for tracheostomy ventilated ICU patients in a multidisciplinary, rehabilitation centred environment. The cost is less than half that of an ICU bed. A secondary role is assisting discharge of ventilator dependent patients to home or care facility. Well established in continental Europe and the USA, such units are rare in the United Kingdom. We reviewed our weaning cases to report our first year results.

Results: Completed patient episodes 2010-2011

LoS, length of stay.

Conclusion: Activity has risen steadily, all weaning beds are currently used with a waiting list for transfer. Most patients had an underlying diagnosis likely to prevent complete liberation from ventilatory support. Success in weaning from invasive ventilation has been largely through the use of nocturnal NIV. The service has been well received by patients, families and referring ICUs. ICU beds can be used for acute care, it is cost effective and provides a template for other service development.

P2068 Noninvasive positive pressure ventilation in burn patients
Intensive Care Burn, Burn and Trauma Centre, Tunis, Tunisia

Introduction: Acute respiratory failure is a common complication of severely burn-injured patient. Noninvasive Positive Pressure Ventilation (NIPPV) has been used with success in hypercapnic and hypoxaemic acute respiratory failure. However, the outcome of NIPPV with burn patients is less well documented.

Objective: The purpose of this study is to report our experience with NIPPV in a series of burn-injured patients.

Method: The records of all burn patients from July 2008- January 2010, in whom NIPPV was used at the Intensive Burn Care Unit, were reviewed. The criteria for selecting patients for NIPPV included a combination of the following factors: patients with acute respiratory failure, haemodynamically stable, conscious and cooperative with their treatment. There had to be no need for endotracheal intubation.

Results: Thirty five patients were treated with NIPPV. Twenty were female. Mean age was 49.8 years, mean total body surface area (TBSA) was 37.63%. NIPPV was used to treat hypoxia in 24 patients, hypercapnia in 4 patients and both of them in 7 patients. NIPPV was used to treat acute lung injury in 15 patients, pneumonia in 9 patients, atelectasis in 6 and cardiogenic oedema in 5 patients. Mean PaO2/FiO2 ratio...
before NIPPV was 177 and after NIPPV was 304. Intubation was successfully avoided in 16 out of the 35 (45.7%) patients. All of these patients progressed to self-ventilation status following NIPPV.

**Conclusion:** The use of NIPPV with burn-injured patients is, as yet, unclear because of little work has been documented. In our experience, the use of NIPPV can lead to the need for endotracheal intubation and mechanical ventilation.

**P2069**

Efficacy of noninvasive positive pressure ventilation during fiberoptic bronchoscopy: Bi-level vs CPAP valve

Tiago Pinto 1, Miguel Gonçalves 1, 2, Adriana Magalhães 1, João Carlos Winck 1, 2, 3, 4

1 Lung Function and Ventilatory Unit, Pulmonology Department, Hospital São João, Porto, Portugal; 2 Bronology Unit, Pulmonology Department, Hospital São João, Porto, Portugal; 3 Pulmonology, Faculty of Medicine University of Porto, Porto, Portugal

**Background:** Fiberoptic bronchoscopy (FOB) in severe acute respiratory failure patients may have risks and sometimes is contraindicated. Noninvasive Positive Pressure Ventilation (NIV) application to assist spontaneous breathing during FOB can be an alternative.

**Objective:** Compare the application of NIPPV (Philips-Respironics BiPAP Vision and Airon Supportor) vs Continuous Positive Airway Pressure (CPAP) valve (Boussignac) (CV) during FOB, in hypoxic and/or hypercapnic patients, with various etiologies.

**Patients and methods:** Fifteen (5 female) with severe hypoxemia defined by PaO2/FiO2 <200 and PaCO2> 60mmHg, submitted to FOB were eligible to the study. Seven patients were randomized to NPPV group (G1) and 8 to CV group (G2).

**Results:** At baseline 2 patients (G1) and 1 patient (G2) had PaCO2> 45mmHg.

**Conclusion:** This results suggest that noninvasive positive pressure has an important role as adjunctive technique during FOB in severe hypoxic patients (PaO2/FiO2<200). In this preliminary study no advantage of NIPPV vs CV.

**P2070**

NIV for ventilatory support during percutaneous endoscopic gastrostomy (PEG) in ALS patients with respiratory failure

Miodrag Vuckevic1, Milos Bjelovic1, Zirica Stivic1, Branka Bulajic Subotic2, Tatjana Radosavljevic3, Zuzic Vladimir4, Tatjana Radosavljevic1, Alain Bernard5, Francois Bellenot6, Jean Francois Regnard7, Nicola Santelmo4, Primož Stružljevič8

1 University Medical School, Belgrade, Serbia; 2 Clinic for Abdominal Surgery, Clinical Center of Serbia, University Medical School, Belgrade, Serbia; 3 Clinic of Neurology, Clinical Center of Serbia, University Medical School, Belgrade, Serbia; 4 Clinic for Pulmonary Diseases and TB, Clinical Center of Serbia, University Medical School, Belgrad, Serbia

**Aim:** The aim of the study is to evaluate safety and usefulness of PEG placement in ALS patients with respiratory failure supported with NIV during this procedure.

**Material and methods:** We analyzed the group of 17 ALS patients with respiratory failure admitted for PEG placement and starting NIV on period of two years (2007-2009).

**Conclusion:** In ALS group (91±0.54kPa). Mean FVC was 38±15.01%. Bulbar symptoms had 11,06 (10 males and 7 females).

**Results:** 21 patients were identified. All patients had a restrictive pattern in lung function tests (VC 50 ±9% predicted). Sniff nasal inspiratory pressure was decreased (29±4 cmH2O), daytime blood gases showed hypercapnia in the majority of patients (mean daytime PaCO2 6.5±0.6 kPa). PEG was performed by two experienced gastroenterologists using the “pull through method”. Oxygen was delivered with a target saturation of 92%. Conscious sedation was reached by bolus administration of propofol. PEG placement could be performed successfully in all patients. Adverse events requiring noninvasive or invasive ventilation were not observed.

**Conclusion:** PEG placement under propofol sedation in patients with ALS is safe and acute respiratory complications are rare. Compared with controls the decrease of oxygen saturation during the procedure is lower. This is probably due to a more cautious dosing of propofol.

**P2072**

Noninvasive ventilation (NIV) after lung resection (LR) to prevent respiratory complications (RCs) in COPD patients (pts) (POPVNI trial)

Christina Lorul1, Aurelie Lefebvre1, Benjamin Planquette2, Herve Clavel3, Nicola Santelmo4, Alain Bernard5, Francois Bellenot6, Jean Francois Regnard7, Marc Riquet8, Pierre Magdeleinat9, Guy Meyer2, Guy Meyer2, Nicolas Roche1, Gerard Huchon1, Joel Coste1, Antoine Raball1,1, Pulmonary and Intensive Unit, Hotel Dieu, Paris, France; 2 Pulmonary and Intensive Unit, HEGP, Paris, France; 3 Intensive Care Unit, ICM, Paris, France; 4 Lung Surgery Unit, Strasbourg Hospital, Strasbourg, France; 5 Lung Surgery Unit, Dijon Hospital, Dijon, France; 6 Clinic for Abdominal Surgery, Hotel Dieu, Paris, France; 7 Clinic for Abdominal Surgery, Hotel Dieu, Paris, France; 8 Lung Surgery Unit, European Hospital Geroges Pompidou, Paris, France; 9 Statistics Unit, Cochin Hospital, Paris, France

**Background:** RCs are common following LR in COPD pts. NIV decreases the rates of tracheal intubation and mortality in post-operative (PO) acute respiratory failure. The aim of our study is to prophylactic NIV for prevention of RCs in the immediate PO care of pts with COPD.

**Patients and methods:** This multicenter, prospective, randomised, parallel, open ended study planned to enrol 360 pts with moderate to severe COPD scheduled for LR. Patients were randomized to standard treatment without or with NIV during the first 3 PO days. The primary outcome is the incidence of acute respiratory events (AREs), defined as the occurrence of at least two of the following: RR >30/min, PaO2/FiO2 ≤200 mmHg, > 10 mmHg increase in PaCO2 or a new pulmonary infiltrate on chest X Ray: Secondary outcomes are the incidence of RCs, rescue NIV use, invasive ventilation requirements, mortality rate, duration of ICU and hospital stay. Univariate and multivariate analysis will identify subgroups who benefit more from NIV.

**Results:** 351 pts, 277 men (79%) and 74 women (21%) were effectively included in 6 centres between June 2008 and October 2010. Mean age (±SD) is 62±9 years. Mean pre-operative FEV1 is 62±11% predicted. Pts numbers in GOLD stage II, III and IV are 295 (83.4%), 44 (12.5%) and 4 (1.1%), respectively. There is no difference in baseline patients’ characteristics at inclusion between the control group (n = 174) and NIV group (n = 177).

**Conclusion:** Comparability of the 2 groups at baseline will allow reliable comparisons of outcomes (which will be available at the ERS meeting) between PO NIV and standard care following LR in GOLD stage II-III COPD patients.

**P2073**

The provision of an acute paediatric NIV service at a district general hospital

Najmu Iqbal, Shabnam Meoleida, Titus Ninan. Paediatrics, Heart of England Foundation Trust Hospitals, Birmingham, United Kingdom

The experience of acute NIV in Paediatrics is limited. The experience outside a PICU is even more limited. We looked at our acute NIV usage over a 3 year period (January 2007 to December 2009) in a Paediatric HDU at a District General Hospital with no PICU facilities. The indication for NIV was Type 2 respiratory failure as defined by pH <7.30, PaCO2 >60 mmHg.

**Conclusions:** The vast majority of children (Group 1) admitted with acute respiratory failure needed NIV; the largest diagnostic group was children with SMA followed by Duchenne muscular dystrophy. 10 children (Group 2) who were stable on NIV were admitted with a respiratory failure and needed increased NIV support. The largest diagnostic group in this cohort was children with Duchenne Muscular Dystrophy. 11 of the 14 children in group 1 and all 10 of the children in Group 2 improved clinically and on blood gases measurements were discharged home. NIV has been implemented successfully out with a PICU. There are significant benefits to the family and to the economy.

The use of non-invasive ventilation after liver transplantation in pediatric patients: Changes in the need for reintubation

Kimihiho Murase1, Chihara Yuichi2, Chikara Yoshinuma2, Tomohiro Handa2, Toru Ogawa2, Hajime Segawa2, Michiaki Mishima1, Kazuhiko Fukuda3, Shinji Uemoto3, Kazuo Chinn4, Respiratory Medicine, Kyoo University, Kyoto, Japan; 2Respiratory Management and Sleep Control Centre, Kyoo University, Kyoto, Japan; 3Rehabilitation, Kyoo University, Kyoto, Japan; 4Anesthesiology, Kyoo University, Kyoo, Japan; 5Surgery, Kyoo University, Kyoto, Japan

Introduction & aim: The role of non-invasive ventilation (NIV) in preventing reintubation after abdominal surgery in paediatric patients is uncertain and should be investigated.

Methods: Our team has performed more than 700 liver transplantsations (LT) for pediatric patients since 1990. Beginning in 2005 we began full introduction of NIV to these patients from 2005. We screened all medical records of pediatric patients less than 12 years old who underwent LT during two 4-year periods: 2001-2004 (pre full introduction of NIV) and 2006-2009 (post full introduction of NIV) and retrieved data on cases at high risk of respiratory failure. Data and clinical outcome for these cohorts were retrospectively analyzed and compared.

Results: In the analysis were included 54 cases (53 patients) from the pre-NIV period and 29 cases (28 patients) from the post-NIV period. After full introduction of NIV, NIV was applied more frequently within one week after extubation in these patients (16/25 cases (64.0) vs 24/29 cases (82.8), p<0.01) and the need for reintubation was significantly decreased (11/54 (20.4) vs. 1/29 (3.7%), p<0.05) during that period. Sequential arterial blood gas analysis suggested that NIV use beginning immediately after extubation stabilized the respiratory condition in this cohort.

Conclusion: NIV is an acceptable method of respiratory management of pediatric patients undergoing LT. NIV may also stabilize their respiratory function and decrease the need for reintubation after scheduled extubation.

Non-invasive ventilation in H1N1 acute respiratory failure in emergency department: A case series

Elena Prina, Francesco Nicolli, Giusa Marullo, Valer Montzani, Stefano Alberti, Federico Peller, Clara Mandelli, Anna Maria Brambilla, Roberto Cosenini.

Emergency Department, Fondazione IRCCS Ca’ Granda Policlinico, Milano, Italy.

Background: The recent ERS/ESICM guidelines do not recommend the use of non-invasive ventilation (NIV) in patients with severe pneumonia caused by H1N1 infection.

Methods: We retrospectively reviewed the clinical data of 9 consecutive patients with severe respiratory failure due to H1N1 virus, admitted to the Emergency Department of Fondazione IRCCS Ca’ Granda Policlinico (Milan, Italy), between January 1 and February 20, 2011.

Results: Patients were predominantly male (66%), mean age was 55 years (range 34-79).379 patients had one or more risk factors for severe H1N1 infection: obesity, chronic pulmonary disease, onco-haematologic disease, age ≥65 years. All patients presented with high fever (>38°C), cough, dyspnea and multifocal bilateral consolidations on chest X ray. 69 patients developed ALL 29 patients presented with ARDS. All patients received oseltamir and empirical antibiotic therapy. 7/9 patients were immediately treated with NIV (6 CPAP, 1 BiLevel). 57 patients developed severe sepsis; no patients showed signs of septic shock or needed inotropic support. One patient needed endotracheal intubation. Only one patient died for acute respiratory failure due to nosocomial infection, all the others were discharged after a mean of 17 days (range 4-34 days).

Conclusions: NIV was successfully applied in the majority of patients (87%), and only one patient needed endotracheal intubation. Our data suggest that in particular settings with staff experienced with NIV, high monitoring level and rapid access to intubation and ICU, early NIV could be an option to improve oxygenation in acute respiratory failure due to Influenza A H1N1 infection.

The application of bi-level positive airway pressure in patients with severe pneumonia and acute respiratory failure caused by influenza A (H1N1) virus

Liu Wei, Liping Peng, Respiratory, The 1st Affiliated Hospital of Jilin University, Chang Chun, Jilin Province, China

Objective: To evaluate the effect of noninvasive Bi-level Positive Airway Pressure (BiPAP) ventilation on the severe influenza A virus associated with pneumonia and acute respiratory failure (ARF).

Methods: Based on conventional therapy via face mask using BiPAP ventilator positive airway pressure ventilation in the treatment of severe pneumonia caused by influenza A (H1N1) virus with acute respiratory failure (ARF) in 18 cases, we observed and evaluated the therapeutic effects. Results: PaO2 and SaO2 before and after treatment were (48±5.0 vs.12.5±15.0mmHg, (68±6.6 vs.12.5±15.0) mmHg and (80±6.6), (92±5), respectively. The results were significantly different (P<0.05) before and after treatment. Endotracheal intubation rate was 25% (6/24) and case-fatality rate was 8.3% (2/24).

Conclusion: BiPAP ventilator airway pressure by face mask ventilation can reduce the rate of endotracheal intubation in the treatment of severe pneumonia caused by influenza A (H1N1) virus in acute respiratory failure. It could be an effective approach in the emergency treatment with clinical value.
P2079
Can repeated educational interaction improve doctors' knowledge of NIV management? 
William Kent, Senh Zaied, Pat Fairclough, Thomas Bongers. Respiratory Medicine, Southport and Ormskirk NHS Hospital Trust, Southport, United Kingdom

Introduction: Exacerbations of chronic obstructive pulmonary disease (COPD) requiring non-invasive ventilation (NIV) are common and often poorly managed [1]. Amongst other aspects, doctors on call in Southport may be asked for advice in adjusting settings appropriately.

Methods: On the background of a 6-12 monthly rolling teaching program a new educational intervention on NIV was established. Doctors of all grades completed a questionnaire containing 3 questions prior to receiving a presentation about NIV. The teaching was then repeated 3 months later and the same questionnaire completed afterwards. 3 clinical vignettes asked for the best change in settings in response to common scenarios (including intensive care, low PaO2, persistent acidemia).

Results: 21 questionnaires were collected before the first teaching session and 16 after the second. The table below shows the number of correct responses for each question.

<td>1.0</td>
</tr>
</tbody>
</table>

*Statistically significant (Fisher's test).

Conclusion: The survey shows that there is a lack of knowledge in important aspects of NIV. After an educational intervention some improvement was observed. We therefore conclude that an educational intervention such as ours combined with ward-based practical sessions is likely to be the best ways to improve standards of care. Frequency and intensity need further exploration.

P2080
Effect of a structured education programme on the documentation of “ceiling of care” for patients with acute hypercapnic respiratory failure (AHRF) requiring invasive ventilation (NIV) 
Shiva Bikmulla, Bethan Barker, Ajit Thomas, Ben Beauchamp, Assad Ali, Mudassar Aslam, Dev Banerjee, Rahul Mukherjee. Academic Department of Sleep & Ventilation, Birmingham Heartlands Hospital, Birmingham, United Kingdom

Introduction: With greater use of ward-based NIV, early documentation of decisions regarding ceiling of care of these patients is assuming greater importance. Nava et al. [1] showed that ceiling of care documentation was low in this group of patients. We conducted a survey of documentation of “ceiling of care” at our 11-bedded ward-based NIV unit in Birmingham, UK, providing acute medical services to a population of over 450000 to assess the effect of a targeted rolling education programme for the caregivers and the use of a standardised protocol.

Methods: Retrospective case note analysis of all patients commenced on acute NIV for AHRF between 1st January 2009 and 31st January 2010. Data relating to documentation of ceiling of care for patients, NIV outcome and mortality were collected after the educational intervention to improve practice.

Results: Over the 13 month period of data collection there were 264 NIV episodes for AHRF. Ceiling of care was documented in 165 patients (62.5%). NIV treatment failure occurred in 59/264 (22%). Eleven of 264 patients (4%) were admitted to ICU during this admission episode. The overall in-hospital mortality for the entire group was 12.8%.

Conclusions: Documentation of ceiling of care in NIV patients can significantly improve with the increase in awareness among caregivers following the introduction of a rolling education programme and the use of a standard protocol.

P2081
Non-invasive ventilation (NIV) practices in Swiss adult ICUs 
Igor Salvadó1, Guido Domínghetti1, Adam Ognia, Marco Mazzagrin2, H. Ueli Rothen1, Philippe John1, Internal Medicine, Regional Hospital, Locarno, Switzerland; 2Medical Intensive Care Unit, University Hospital, Zurich, Switzerland; 3Intensive Care Medicine, University Hospital, Bern, Switzerland; 4Intensive Care Medicine, University Hospital, Lausanne, Switzerland

Purpose: The real scenario of the practical modalities for NIV in adult Swiss ICUs has never been reported.

Methods: Using the survey methodology, we developed a questionnaire addressed by e-mail to all directors of the 79 certified adult Swiss ICUs. Responses were analyzed using descriptive and standard statistics.

Results: We obtained replies from 49 of the 79 ICUs (62%). The overall Swiss utilization rate for NIV was 26% of all mechanical ventilations, but we found significant differences in the perceived utilization rates among different linguistic areas, from 20% in the German part to 48% in the French part (p < 0.01). NIV was mainly indicated for the acute exacerbations of COPD (AcOPD), acute cardiogenic pulmonary edema (ACPE), acute respiratory failure (ARF) in selected do-not-intubate patients and post-operative states, post-extubation failure in high risk patients and pneumonia in the immunocompromised host. CPAP use in ACPE was much less used than bi-level ventilation and was still applied in AcCPAP. The most important arguments reported by doctors perceiving low degree of satisfaction in the NIV application, were lack of medical technical knowledge and inadequate staff training.

Conclusions: This survey demonstrates that the perceived NIV practice is high in Switzerland, with significant regional variations. The indications of the perceived NIV use are in accordance with the institutional guidelines, but a high percentage of units considers selected do-not-intubate conditions an important indication for NIV. The variability of NIV application and some erroneous applications suggest that education and training of physicians, nurses and therapists are warranted.

P2082
Non-invasive ventilation as ceiling of ventilatory care (NIVc) in a respiratory intermediate care unit (RICU) 
Ana Soña Oliveira, Sara Salgado, Cecilia Nunes, Fernanda Oliveira, Cristina Bárbbara. Pneumology, Pdulo Valente Hospital, Lisboa, Portugal

Aims: In European RICUs an end-of-life decision is taken for 2.8% of the patients admitted. One of the most common practices is the use of NIVc. We aimed to characterize this group of patients under NIVc practice.

Methods: A systematic retrospective review of the patients admitted in our RICU for NIV, in whom an end-of-life decision was made, was carried between February 1 and July 31, 2010.

Results: Of the 126 admissions, 23 had an end-of-life decision (18%), in 10 decision was made pre-admission and in 13 during hospitalization. NIVc was initiated in 18 patients (78%), with a mean age of 74 yrs. (52-93) and 72% males. Patients were referred mainly from the Emergency Department (39%), Respiratory wards (22%) and other hospital wards (11%). All patients had chronic diseases, a quarter had neoplastic disease and diabetes, 77% pulmonary chronic disease, mostly severe, 89% cardiovascular disease, 17% neurologic disease, 50% renal insufficiency, 72% were on dialysis and 61% had previous hospitalizations in the last year. The majority had uncomplicated chronic diseases (83%) at admission (mainly pulmonary). The main diagnosis of hospitalization was pneumonia: the main cause for admission (56%). RICU mean stay was 9 days (2-23) and mean hospital stay was 19 days (2-71). At RICU admission, blood gases showed respiratory acidosis in 61%, hypoxemia in 22% and mixed acidoses in 17%. NIVc had success in 1 patient and 17 died (94%).

Conclusions: NIVc is used as an effective alternative in intubation in patients who have no invasive approach is questioned or as palliative approach. The high mortality found in our group of patients was related to NIVc on the end stage disease.

P2083
Respiratory intermediate care unit (RICU) – What are we doing? 
Sara Salgado, Ana Soña Oliveira, Cecilia Nunes, Fernanda Oliveira, Cristina Bárbbara. Pneumology, Pdulo Valente Hospital, Lisboa, Portugal

Aims: RICUs are designed to treat invasive mechanical ventilated (IMV) stable patients for weaning and chronic care, hemodynamically stable patients with compromised gas exchange for frequent observation and/or non-invasive ventilation (NIV) and patients who require frequent vital signs monitoring or aggressive pulmonary physiotherapy. We aimed to evaluate the work developed in our RICU.

Methods: A systematic retrospective review was made from February 1 to July 31, 2010, in an 8 beds RICU.

Results: In the studied period, 105 patients were responsible for 126 admissions, 73% were male, mean age was 68 yrs. (16-96). Patients were referred mainly from the Emergency Department (44%), Intensive Care Unit (ICI) (21%) and Respiratory wards (11%). The reasons for admission were in 21% to step-down ICU, 52% for NIV, 24% for cardiopulmonary monitoring and 3% for other reasons. In 98% respiratory insufficiency was present, mainly hypercapnia, mostly caused by infectious respiratory exacerbations. All but 1 had chronic disease, 76% cardiac and 60% pulmonary (mostly severe). The average stay at RICU was 22 days (1-76). RICU had to liberate 536 days of ICU. Eleven patients were transferred to ICU and 20 died. One of them was weaned from chronic IMV. Tracheotomy was closed in 3 of 5 patients. In respiratory failure patients, NIV survived in 46 (70%), 4 were transferred to ICU and 16 patients under palliative NIV died.

Conclusions: Despite the diversity of work developed in our RICU, primarily it allowed free days in ICU and NIV practice. Although the advanced stage of chronic diseases and a high number of do not intubate patients, the possibility of close monitoring and observation is greatly possible in NIVc's success.
The introduction of a respiratory high care unit in a district general hospital

Lauras Suvcevytė, Heidi Cook, Vanessa Grinstead, Urj Hoda, Thula Win
Respiratory Medicine, Lister Hospital, Stevenage, Hertfordshire, United Kingdom

Introduction: Non-invasive ventilation (NIV) has a well documented place in the management of the type two respiratory failure of COPD. Ward based NIV is cost effective when compared to administering the treatment in an Intensive Care Unit (ICU) setting.

Prior to March 2010, type 2 respiratory failure requiring NIV at the Lister Hospital was managed in ICU, under anaesthetic care. In March 2010, a 4 bedded Respiratory High Care Unit (RHCU) was created to deliver NIV in a ward environment.

Aims: To look at usage of the RHCU in the management of type 2 respiratory failure and the outcomes of those receiving NIV.

Methods: Bed occupancy records were kept from the introduction of the RHCU. These were analysed from May 2010 to January 2011 in conjunction with medical records to establish diagnosis, length of stay and discharge destination.

Results: 40 patients received NIV over the nine months. 31 (77%) had underlying COPD, 1 sleep apnoea and the remainder; heart failure, pneumonia, interstitial lung disease and motor neurone disease. Length of stay varied from 1-46 days (mean 11.3, standard deviation 9.7).

In the 31 patients with COPD, 6 already had home NIV, 6 were referred for consideration of home NIV, and 14 (45%) discharged with no need for ongoing ventilation. 5 COPD patients did not survive the admission.

Conclusion: COPD was the predominant diagnosis in the 40 patients treated with NIV. The introduction of the RHCU allowed savings through the avoidance of an ICU admission and meant a trial of NIV could be used more readily as a ceiling of treatment in end stage COPD. Of note, no COPD patients were transferred from the RHCU to ICU, indicating appropriate selection of patients for ward based NIV.

251. New evidence in home mechanical ventilation

P2085

Hemodynamic effects of non-invasive ventilation in patients with obesity-hypoventilation syndrome

Ollãa Castro-Añón1, Rafael Golpe 1, Luis A. Pérez-de-Llano 1, María J. López 1, Edgar Escalona1, Ruth Pérez-Fernández 2, Ana Testa 2, Arturo Rodríguez Quintana 2, 1Respiratory Division and Sleep Disorders unit, Hospital Lucus Augusti, Lugo, Spain; 2Cardiology Service, Hospital Lucus Augusti, Lugo, Spain; 3Department of Internal Medicine, University of Santiago of Compostela, Santiago de Compostela, Spain

Background: Although it was occasionally reported that pulmonary hypertension (PH) is more frequent in obesity-hypventilation syndrome (OHS) patients than in "pure" sleep apnoea syndrome (OAS) patients, little is known about the haemodynamic repercussion of this entity. The aim of this study was to describe the hemodynamic situation -assessed by echocardiography and six-minute walking test (6MWT)- of patients newly diagnosed with the most severe form of OHS and to evaluate the impact of non-invasive ventilation (NIV) on it.

Methods: We conducted a prospective, descriptive, single-center follow-up study. At baseline, patients underwent echocardiography, spirometry, static lung volumes measurement, 6MWT, overnight pulse-oximetry and polygraphic recording. We assessed changes in echocardiographic findings and 6MWT after 6 months of NIV implementation. Right ventricular overload (RVO) was defined by the presence of right ventricular (RV) dilatation, RV hypokinesis, paradoxical septal systolic motion on/and PH.

Results: A total of 30 subjects (20 women; mean age: 69±11 years) were included. The percentage of patients with RVO did not change significantly after NIV (from 43.3% to 41.6%; p = 0.24). Pulmonary arterial systolic pressure (PASP) for patients with RVO at diagnosis decreased significantly at 6 months (from 58±11 to 44±12 mmHg; p = 0.014) and the mean distance walked on the 6MWT increased from 350±110 to 426±18 m (p = 0.006) without significant changes in the body mass index.

Conclusions: PH is a frequent finding in patients with the most severe form of OHS. Treatment with NIV leads to a decrease in PASP and an increase in the distance covered during the 6MWT.

P2086

The effects of non-invasive bilevel positive airway pressure ventilation on insulin resistance in patients with obstructive sleep apnea

Ognian Georgiev, Daniela Petрова, Radoslav Bilyakov, Trakam Mondeshki.
Clinic of Internal Medicine, Department of Pulmonology, University Hospital Alexandria, Sofia, Bulgaria

Background: The effects of the noninvasive ventilation on insulin resistance in obstructive sleep apnea (OSA) patients has been elusive. Although there are a lot of trials concerning its effectiveness, data is still conflicting. There is a lack of studies dealing with the results of the bilevel positive airway pressure (BiPAP) therapy.

Materials and methods: Thirteen patients with type 2 diabetes and eighteen insulin resistance and newly diagnosed OSA (AHI>30) received BiPAP therapy. Patients were followed up for a mean period of 3.9 months (±1.5) and had a compliance >80%. The average body mass index (BMI) was 38.17 and the mean AHI - 51.95. Baseline tests - blood glucose, HOMA-index, immunoreactive insulin (IRI) and Impaired fasting glucose at the end of the study.

Results: Results are given as mean ± (SD). Blood glucose measurements did not change significantly in none of the groups - type 2 diabetes (5.5mmol/l ± 1.8 vs. 5.4mmol/l ± 2.01); insulin resistance (6.4mmol/l ± 1.16 vs. 6.0mmol/l ± 1.38). There was a more significant decrease of IRI and HOMA – index the insulin resistance group – (IRI-21.06±11.9vs. 14.46±10.11). (HOMA-index – 5.23±1.18 vs. 3.74±1.12). In comparison the group with type 2 diabetes showed a lesser effect of BiPAP therapy (IRI-26.06±11 vs. 22.5±10.09). (HOMA-index - 7.7±4.6vs.6.01±2.7). Body mass index and waist circumference remained unchanged.

Conclusions: BiPAP therapy reduced the insulin resistance in obese OSA patients. The effectiveness was better in patients with insulin resistance than those with already overt type 2 diabetes. HOMA - index seems to be the most sensitive marker for the effect of BiPAP therapy.

P2087

Prevalence of patient-ventilator asynchronies and effects on sleep quality in neuromuscular patients using long term non-invasive ventilation

Grazia Crescimanno, Marisa Canino, Oreste Marrone. Institute of Biomedicine and Molecular Immunology, Italian National Research Council, Palermo, Italy. First Unit of Pneumology, Cervello Hospital, Palermo, Italy

Background: There are few studies on the association between asynchronies and arousals in patients using long term noninvasive ventilation (NIV) and among them, only one has been performed on neuromuscular patients. Moreover, in the real life of home ventilated neuromuscular patients sleep fragmentation is probably far from being perfectly corrected.

Objective: The aim of this work was to investigate the prevalence of patient-ventilator asynchronies and their association with sleep quality in stable neuromuscular patients chronically ventilated after optimization of ventilator setting.

Methods: Eighteen patients were included in the study. Sleep was recorded during ventilator application using standard polysomnography. Physiologic tracings were scored for autotriggerings, patient-ventilator desynchronizations, prolonged inspirations (PI) and respiratory arousals.

Results: Most frequent asynchronies were autotriggerings and desynchronizations (83.3% and 77.7% of patients, median 1.11 (IQR 0.43-2.84) and 0.23 (IQR 0.12-1.00) respectively). Desynchronization was the asynchrony most frequently associated with arousal (median 73.61%, IQR 15.91-96.88) followed by autotriggering (median 66%, IQR 0.90-90). PI was not frequent and almost never associated with arousal (median 0 IQR 0-100). Asynchronies were significantly correlated with leaks (rs=0.49 p < 0.05).

Conclusion: Patient-ventilator asynchronies may still occur in neuromuscular patients receiving long term NIV and can contribute to sleep fragmentation. Monitoring of quality of ventilation should be included in long term programme of neuromuscular patients.

P2088

Evaluation of inspiratory rise time versus resistances of four home ventilators

Alice Perel Jaillet1,2,3, Christophe Letellier 1,3, Dounia Bounoiare1,3, Anne Perel Jaillet1,2,3, Christophe Letellier 1,3, Dounia Bounoiare1,3, Antoine Cuvelier2,3, Jean François Muir2,3.
1CORIA UMR 6614, Université de Rouen BP 12, Saint Etienne du Rouvray, France, Metropolitan, 2Service de Pneumologie & Unité de Soins Intensifs Respiratoires, CHU de Rouen, Rouen, France, Metropolitan, 3UPRES EA 3850 (IRF MP32), Université de Rouen, Rouen, France, Metropolitan

There is no consensus neither literature nor constructor to define inspiratory rise time (TIR) which is equally called "pressure ramp slope" or "pressurization rate". The purpose of this study was to evaluate on a test bench the TIR of four home ventilators, versus different resistances.

SMARTAIR ST (Airox), TRIOLOGY100 (Respironics), VIVO40 (Brea, GE) and VPAPII (Resmed) were tested in a bilevel pressure support mode. All TIR avail- able were tested. Simulations were performed on an ASL 5000 (Ingmar Medical, Pittsburgh, USA) which simulates normal and obstructive lung. TIR has been de- fined as the delay between return to EPAP (Expiratory Positive Airway Pressure) after begin of inspiratory effort and time where pressure reaches 90% of maximal pressure. For each setting versus resistance, value of TIR, and slope of "pressure flow" in curves in their linear segment were calculated. Only TIR of VPAPII and TRIOLOGY100 don’t vary according to resistances. How- ever, values measured are always above than specified, particularly TRIOLOGY 100. TIR measured for SMARTAIR ST and VIVO40 decrease when resistances in- crease. Pulmonary dynamics can explain this results. In order to control this TIR, four strategies are observed. Resmed uses a fixed pressure slope, whereas Brea set a fixed flow slope. SMARTAIR maintains a fixed pressure slope until a preset time (300ms), after which slope vary versus resistance. Lastly, curve’s TRIOLOGY
is an exponential. This ventilator seems to maintain a fixed time constant on the pressure curve. We prove that ventilators have different strategies to achieve targeted maximal tidal volume and I/E-ratio in patients with COPD.

Method: For detection of volume changes, frequency variations and I/E-ratios we used two classical invasive measurement devices (telemetric thoracic catheter). The signal was relayed to a polysomnography device. Flows from 20 lpm up to 50 lpm with small, medium and large nasal prongs were tested. To compare the results with a closed ventilation support system, the measurements were also performed with CPAP (6 and 10 mbar) and BiPAP (14/6mbar). We compared the results with values measured during spontaneous breathing.

Results: nHF led to a significant decrease in minute volume, tidal volume and breathing rate in healthy volunteers in comparison with spontaneous breathing. The I/E-ratio results in no significant changes. In patients with COPD the breathing rates were also decreased, but the tidal volumes were increased with partial reductions in minute ventilation. The I/E-ratio was not changed in COPD. In comparison with spontaneous breathing, CPAP and BiPAP showed significant changes in patients with COPD.

Discussion: nHF resulted in significant effects on respiratory parameters of healthy volunteers and in patients with COPD. The changes deliver a possible explanation of the active manner of the breath support and the decrease in PCO2.

P2090
Validation design for a method to determine respiratory resistance and compliance in non-selected patients
Krestel Lopez-Nivas, Hartmut Gehring, Ulrich Wenkelbuch. Laboratory of Medical Systems, University of Applied Sciences Luebeck, Luebeck, Germany

Advantageous ventilation modes like pressure support PS require the accurate setting of parameters based on individual characteristics of the patient's respiratory system. As these change, a method for their continuous measurement is necessary. We tested a novel method for the "Deltan+" method (Delta technique focused on expiratory occlusions) by estimating respiratory resistance R and compliance C using flow and pressure data gained from a software-controlled lung simulator programmed to represent four cases with increasing work of breathing and available real data from 6 volunteers and 6 patients. Using the delivered values the transdiaphragmatic pressure (Pdi) was reconstructed as repre-sentation of muscular effort.

The measured Pdi and its reconstruction were compared using the inspiratory Pressure Time Product (PTPinsp). The correlation from simulated data was high (R2 =0.90a,0.05) permitting to validate the relevant analysis systems, but the correlation from real data was low (under 0.68) which was associated to difficulties at measuring Pdi without artifacts and compliance unwantedly attached to the system. We present now a test setup and methodology to investigate real data more accurately. This includes measurement of flow, airway- and transdiaphragmatic pressure from volunteers with minimized susceptibility to artifacts, improved control of mechanical problems and higher sampling rate. The integration of hardware required for occlusion to the ventilator and experienced measurement of Fdi intend to increase the number of parameters determining parameters using software for improved recognition of outiers including online analysis.

P2091
Adaptation of children with spinal muscular atrophy type 1 and 2 to non invasive ventilatory support
Teresa Salerno, Martinio Pavone, Maria Beatrice Chiarini Testa, Francesco Paolo Rossi, Elisabetta Verrillo, Serena Soldini, Renato Cutrera. Department of Pediatrics, Bambino Gesù Children Hospital and Research Institute, Rome, Italy

Spinal Muscular Atrophy (SMA), the most common fatal inherited disease in infants. The impaired respiratory function is the main cause of the high mortality. Non Invasive Ventilation (NIV) has reduced morbidity and mortality due to respiratory insufficiency and has a favourable impact on respiratory infectious complications.

Aim: Evaluation of the necessary time and mode to achieve adaptation to this tool in SMA patients (pts) free from acute respiratory insufficiency. We prospectively studied 28 consecutive SMA type 1 pts (11 pts) and 2 (17 pts), who were enrolled in a standardized clinical protocol of adaptation to NIV. Mean age was 19±23 months, M/F 10/18. NIV was delivered via a nasal mask in 23 pts, nasal prongs in 4 pts, full face mask in one, with Pressure Support Ventilation (PSV) mode (25 pts) and Assisted Controlled Pressure Ventilation (ACPV) mode (3 pts). Mean IAP was 12±2.7 cm H2O, mean EAP 9±6±74 cm H2O. Success was defined as the necessary time to accustomed the SMA pts free from acute respiratory insufficiency to NIV and the mode to achieve acceptability of this tool.

According to this definition, all pts (100%) were considered as successfully ventilated, as all of them tolerated NIV with a mean adaptation time of 8±2 days. No major complications were observed.

In conclusion, our study demonstrates that NIV is well tolerated in SMA children and, probably, the high rate of success was obtained thanks to a standardized protocol of NIV initiation/administration, the proper parents education, a strict follow-up, the lack of major complications. With these assumptions, success can be expected in a high rate of pts before the onset of respiratory insufficiency.
Introduction: Home high-flow therapy is another option of respiratory support in sleep and ventilation medicine. But the precise pathophysiological effects (reduction of dead space ventilation, development of a PEEP) remain unknown, and the patient group, that may profit of such therapy, is not defined.

Question: Compared are respiratory frequency (RF) and gas exchange under nasal high flow therapy of 20l/min (applied through one and both nares of the nose) with the effect oxygen therapy (LOT) of 2 l/min at 21 patients with stable hypercapnia in a prospective randomised order for always 45 minutes while awake.

A capillary blood gas analysis (BGA) was made after each phase, as well as a 15 minutes break.

Results: The mean RF/min was under LOT 19.4±4.0 and was reduced to 17.8±4.7 under double sided TNI application and 17.7±4.3 under single sided TNI application (difference between LOT and single sided: p=0.043).

Methods: A cross sectional study was performed in patients with COPD treated by home NIV. The aim of the study was to determine predictive factors for COPD failure. The clinical baseline data of patients treated with home NIV were collected. Survival of home NIV patients was analyzed by Kaplan Meier survival analysis and receiver operating characteristic (ROC) curve was performed to determine the variables for successful home NIV treatment. A principal component having an area under the curve (AUC) more than 0.7 was suggested predictive.

Results: NIV was successful in 68% of patients. We found principal component capturing the baseline FVC and FEV1, to be the best predictive variable for failure of treatment (AUC=0.9, sensitivity 90%, specificity 80%), however the other covariates were less useful.

Conclusion: Baseline lung function may be helpful to predict which patient is susceptible to receive additional endotracheal intubation.
Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease which usually leads to respiratory failure, requiring Noninvasive Ventilation (NIV) or tracheostomy. No data exist on predictor factors of tracheostomy at the clinical onset of disease.

A retrospective study was designed, in a population of 71 consecutive ALS patients (39 males), to evaluate anthropometric, clinical, and functional indicators of the need of tracheostomy, including age, sex, BMI, site of onset, time of diagnosis, co-morbidities, tobacco habit, traumas, sport activity, and sleep disorders breathing markers. Arterial Blood Gas analysis and respiratory functional test, including FVC, FEV1, as well as Sniff Nasal Inspiratory Pressure (SNIP) were also measured at first ambulatory control.

We found that SNIP test, at first control, positively correlated to the need of tracheostomy (p<0.001) in the entire population observed. The mean SNIP test value of the group who was admitted to tracheostomy was 25.12 ±25.25 compared to a mean SNIP value of 54 (25.46) in the group who did not undergo tracheostomy. Other anthropometric, clinical, functional, and nocturnal parameters evaluated did not correlate to the different outcome in our population of ALS patients.

In conclusion, SNIP test could be a useful early indicator of tracheostomy in ALS patients.

Exploring reasons for the pattern of non-invasive ventilation (NIV) use among motor neurone disease (MND) patients: An interpretative phenomenological analysis

Hikari Ando1, Biswajit Chakrabarti2, Carolyn Young3, Ewerard Thornton4, Robert Angus3. 1Psychology Department, Liverpool Hope University, Liverpool, United Kingdom; 2Aintree Chest Centre, Liverpool Hospital Aintree, Liverpool, United Kingdom; 3Neurology, Walton Centre for Neurology & Neurosurgery, Liverpool, United Kingdom; 4Psychology Department, University of Liverpool, Liverpool, United Kingdom

Background: We have previously reported on psychological reasons for declining NIV. This study examines the psychological reasons for adherence to NIV among MND patients.

Methods: Six patients (male=5, mean age=59) who had used NIV for more than 6 months (mean 9.5, range 6-11 months) with ventilator interaction data were studied. Repeated interviews were transcribed and qualitatively analysed, using interpretative phenomenological analysis (IPA); IPA provides rich data to explore investigative phenomenon from a small sample.

Results: Out of the six patients, four patients used NIV consistently (mean±SD=22), while two patients used it less than 4 hours (mean±SD=31) per day. IPA suggests that good compliance (>4hrs) reflects the individuals’ attitude towards NIV use. Further analysis identified two influential factors: perceived essentiality and the perceived impact of NIV. The sense of need for NIV or knowledge of the benefits of NIV were not influential per se, but rather functioned as reinforcements to determine the pattern of compliance. Little change in the pattern of NIV use was observed over time, however this may be explained by other factors not evaluated in this study.

Conclusion: IPA suggests that the adherence to NIV is influenced by individuals’ attitude towards the use of NIV in terms of its essentiality and impact.

Grants from Motor Neurone Disease Association (UK).

NIV for MND in the West of Scotland assisted ventilation service (WoSAVS)

Peter Kewin1, Selina Twm1, Janice McGlone2, Alison Clarke2. 1Respiratory Medicine, Southern General Hospital, Glasgow, United Kingdom; 2Assisted Ventilation Service, Gartnavel General Hospital, Glasgow, United Kingdom

Introduction: Motor neuron disease (MND) results in respiratory muscle weakness and respiratory failure (RF), with reduced quality of life (QOL) and survival. Non-invasive ventilation (NIV) effectively palliates symptoms related to RF, improving QOL, and survival (Boucke, Lancet Neurol 2006), and increasing use is reported. The SNIP test may predict need of tracheostomy, including age, sex, BMI, site of onset, time of diagnosis, co-morbidities, tobacco habit, traumas, sport activity, and sleep disorders breathing markers. Arterial Blood Gas analysis and respiratory functional test, including FVC, FEV1, as well as Sniff Nasal Inspiratory Pressure (SNIP) were also measured at first ambulatory control.

We found that SNIP test, at first control, positively correlated to the need of tracheostomy (p<0.001) in the entire population observed. The mean SNIP test value of the group who was admitted to tracheostomy was 25.12 ±25.25 compared to a mean SNIP value of 54 (25.46) in the group who did not undergo tracheostomy. Other anthropometric, clinical, functional, and nocturnal parameters evaluated did not correlate to the different outcome in our population of ALS patients.

In conclusion, SNIP test could be a useful early indicator of tracheostomy in ALS patients.
Chest wall volume changes during normocapnic hyperpnoea with constant tidal volume: A pilot study on laryngeal movements and inspiratory muscle coordination

Mona Steen1,2, Helen Walker3,4, Anna Paulsholm5,6, Hallvard Selnes1,2, Thomas Halvorsen1,2,5, Astrid Sandnes1,2, Jørgen Vold1,2, John Helge Heimdal5,6, Thor-Andre Ellingsen5,6, Karen Soares7, Rodrigo Palmieri8,9, Tom Karlsen5,6,10, Thomas Register5,6, Magnus Hilland1, Ola Rakstad1,2,11

Introduction: Exercise induced vocalcord dysfunction (VCD) is a common condition, often confused with exercise induced asthma with unfortunate consequences.

Methods: Ten healthy subjects performed 1h of NH at 70% MVV (VT:2.6 ± 0.3 L; breathing frequency: 40 ± 1 breaths min−1) and cycled for 60 min at a fixed power output before and after 6 weeks of pressure-time integrals. The data suggest that aerobic exercise training in obese women improves chest wall volumes in CF and CG. All levels of PEEPs improve chest wall volumes in CF children’s.

Conclusion: Chest wall kinematics during different levels of positive end-expiratory pressure in cystic fibrosis children

Guilherme Augusto de Freitas Fregonezi1, Silvia Britliane1, Melissa Gurgel1, Rencio Floresco1, Karen Soares2, Fernando Augusto Lagez Dias1, Vanessa Resqut1, Aumele de Fatima Dornelas de Andrade1,2, Physical Therapy Department, Federal University of Rio Grande do Norte, Paranaíba, Rio Grande do Norte, Brazil; 3 Physical Therapy Department, Federal University of Pernambuco, Recife, Pernambuco, Brazil

Objective: To study the effects of different levels of positive end expiratory pressure (PEEP) on compartmental chest volumes.

Methods: Twelve patients with CF (12±2.7 years, FEV1/FVC%: 81.3±6.6 and FEV1% (69±12) and ten age-matched healthy subjects (control group-CG; 11±1.8 years) with normal lung function. Both groups were evaluated by Optoelectronic Plethysmography in 3 minutes of quite breathing (QB), 3 minutes breathing against 3 levels of PEEP: 10 cmH2O, 15 cmH2O and 20 cmH2O.

Results: Both groups were similar during QB. Group intergroup analyses showed that the volume of chest wall was different between CF and CG at PEEP10 (Vcw=248.6±180.1 L vs 92.0±205.0 L, p=0.036; respectively) and at PEEP20 (Vcw=511.1±170.1 L vs 99.6±430.0 L, p=0.005; respectively). We found differences in respiratory rate between groups at PEEP20 (RR=22.6±7.4 vs.0.000, p=0.006), and PEEP20 (RR=37.2±19.3 vs 20.3±8.17, p=0.034). CF intragroup analyses showed that Vcw increased significantly in all levels of PEEP compared to QB (Vcw=286.0±0.79 L, VPEE=10= 0.487±0.181 L, VPEE1=0.515±0.21 L, and VPEE20=0.512±0.177 L, p<0.001), but no differences were found between PEEP levels. End expiratory lung volume increase in CF group during PEEP20 in comparison to QB (Vtocw=10.5±3.26 L vs 10.7±3.58 L, p<0.001), end inspiratory expiratory volume increase in all obese women pre- and post-aerobic exercise training programme performed at least 30 min per session; 3 sessions per week for 12 weeks. Results showed that aerobic exercise training significantly reduced body mass indices (BMI) (29.8±3.2 vs 23.9±2.8, p<0.001), e.g. absolute PImaxRV (126.1±22.1 vs 116.2±28.3 cmH2O), PImaFRC (119.8±6.2 vs 105.8±15.2 cmH2O), Pnsn (113.2±2.12 vs 98.1±21.2 cmH2O) and PImax (127.3±2.47 vs 119.8±6.26 cmH2O). The data suggest that aerobic exercise training in obese women studied appears to increase the RMS which may be, partly, a consequence of decreased fat mass and body fat.

Conclusion: Inspiratory rib cage muscles did not seem to take over work of the diaphragm. However, in- and expiratory rib cage muscles play an important role in preventing the development of rapid shallow breathing. Thus, RMT likely provides a training stimulus not only to the diaphragm but also to the rib cage muscles.

Support: SNF grant no. 32-116777.
The evidence base for conservative treatment is limited but two single-case reports suggest effects from inspiratory muscle strength training (IMST).

**Objectives:** To run a pilot study that objectively visualizes laryngeal response pattern(s) to controlled training with IMST.

**Methods:** To run a pilot study that objectively visualizes laryngeal response pattern(s) to controlled training with IMST.

**Conclusion:** The present work does not support the notion that the level of QF exists. However, individual DAF was found to be correlated with the workload of the finish (last 30 s) relative to the overall workload (R²=0.30; p=0.005).

**Results:** The average degree of ΔLDAf did not differ -21±2.12.8% (1STT) vs. -17.6±4.3% (2STT; p=0.22) while ΔLDAf of the shorter and more intensive test -34±0.5±5% (1STT) vs. -29.5±5.9% (2STT; p=0.04). Individual between-test differences of ΔLDAf did not correlate with those of ΔQF. However, individual ΔLDAf of both TT’s taken together significantly correlated with the workload of the finish (last 30 s) relative to the maximal workload (R²=0.30; p=0.005).

**Discussion:** On two different occasions on a long time period (6-7 months). TD was determined in one subject a paradoxical adduction was observed. Supraglottic adduction was seen in two patients at PLmax. In all subjects larynx moved downwards during inspiration, and nine of ten subjects seemed to engage all muscle groups in the hypo- and diaphragm during inspiration at PLmax.

**Conclusion:** The study suggests that IMST may be an efficient tool in the treatment of exercise induced VCD. Large interindividual differences suggest a need for further studies comparing groups, and underscores that objective methods must be used during instructions and training with IMST in these patients.
is in discrepancy with the relief of breathlessness after evacuation of effusions. We investigated changes in respiratory muscle strength before and after removal of several quantities of pleural fluid in patients with relatively large unilateral pleural effusions. We studied 49 patients (36 male & 13 female) aged 61±7.3 yrs. (mean±SD) with large unilateral pleural effusions of varying causes. Patients were selected on the basis of CT-scan not to have significant parenchymal lesions that would possibly interfere with lung physiological properties (e.g. tuberculosis effusions, neoplastic from extrathoracic primary site, hypoproteinemic effusions etc.). All patients were tested with an electronic mouth pressure meter, both before and 30 minutes after completion of thoracocentesis. The quantity of fluid removed was recorded for each patient and ranged from 0.38 to 1.4 L with a mean value of 0.82±0.25 L (mean±SD). Maximal Respiratory Pressures were recorded 3 times and highest values were selected for statistical comparison (paired t-test). Maximal Inspiratory Pressure before removal of fluid (MIPb) was 74±12 cmH2O while after (MIPa) was -88±13 cmH2O (p<0.01). Maximal Inspiratory Pressure before (MEPb) was 104±15 cmH2O while after removal of fluid (MEPa) was 121±17 cmH2O (p=0.01). We can conclude that removal of pleural fluid is accompanied by an improvement in respiratory muscle maximal pressures that may partly explain the relief of breathlessness after thoracocentesis.

P2114

Spinal behavior during tidal and deep breathing in healthy male subjects
Mika Masuda1, Hajime Kurosawa1, Jumichi Ohishi1, Daisuke Kebayashi1, Masahiro Kehrushi1, 1Department of Internal Medicine and Rehabilitation Science, Tohoku University Graduate School of Medicine, Sendai, Japan; 2Department of Occupational Health, Tohoku University Graduate School of Medicine, Sendai, Japan

Spine has joint connections with all ribs and has muscle attachments with a part of diaphragm, suggesting a key role in respiratory mechanics. In this study, we aimed to investigate movement of the spine during tidal and deep breathing at a seated posture in which the spine was free from artificial restriction. Three-dimensional motion of the spine using an eight-camera system (60Hz) was performed in fifteen male healthy volunteers (mean age; 27±1.5 years). During tidal breathing, the spine moved very little (< 1 mm) while ventral parts of the ribs and the sternum well moved (1.5±0.2 mm) as “pump-handle”. Lumber spine moved toward ventral direction with deep inspiration to TLC while upper thoracic spine did with deep expiration to RV. These results suggested that spine was almost fixed during tidal breathing as the pivot of the ribcage. Breathing to RV or TLC recruited varieties of supplemental respiratory muscles, and transformed spine.

P2115

Positive effects of inspiratory muscle training (IMT) on ventilatory response to progressive hypercapnia in healthy subjects
David Dörfler, Milos Petrovic, Wolfgang Pohl, Theodor Wanke. Pulmonology Department, Hietzing Hospital, Karl Landsteiner Institute for Clinical and Experimental Pulmonology, Vienna, Austria

Inspiratory muscle training (IMT) is known to improve inspiratory muscle capacity, whole body exercise capacity and the sensation of dyspnea. Until now the effects of IMT on respiration during ventilatory stress, induced by hypercapnia, have not been examined. We speculate that IMT, by improving inspiratory pump capacity, may affect ventilatory response during CO2-rebreathing.

Aim of the study: The aim of our study was to analyze the effects of IMT on the ventilatory response during CO2-rebreathing tests in healthy subjects.

Methods: Eight healthy subjects (4 males, 4 females) performed specific IMT for 6 weeks. Maximal inspiratory pressure (Ps max) and endurance time during resistive breathing manoeuvres (lim) served as parameters for inspiratory muscle capacity. The ventilatory response to CO2, using the Read’s rebreathing technique, was analysed twice before commencement of IMT and once on the day after stopping IMT.

Breathing pattern during ventilatory stress changed in that the proportion of tidal volume on minute volume increased significantly. The peak histogram of the internal oblique abdominal muscle (BORG Scale) during CO2-rebreathing was analysed.

Results: After 6 weeks of IMT, inspiratory muscle capacity increased significantly. Maximal achieved VE (minute volume) as well as Vt (tidal volume) also increased significantly, while the level of dyspnea (Borg Scale) was lower. Breathing pattern during ventilatory stress changed in that the proportion of tidal volume on minute volume increased significantly.

Conclusions: IMT leads to more effective respiration under ventilatory stress, even in healthy subjects. This might be of clinical relevance for patients with lung diseases.

P2116

Maximum cough pressures are increased in patients with chronic cough
Kai K. Lee, Katie Ward, Gerrard F. Rafferty, John Moxham, Surinder S. Birring. Department of Respiratory Medicine, Division of Asthma, Allergy and Lung Biology, King’s College London School of Medicine, London, United Kingdom

Cough intensity can be defined with a variety of measures that include thoracic and abdominal pressure, airflow, electromyography and subjective scales. Little is known about cough intensity in patients with chronic cough. We investigated the physical characteristics of cough intensity in patients with chronic cough and normal subjects.

15 patients with chronic cough and 14 healthy subjects underwent measurements of esophageal pressure (Poes), gastric pressure (Pga), peak cough flow rate (PCFR), abdominal electromyographic activity and cough sound during voluntary coughs. The data from maximum cough efforts are presented. PCFR was normalised to predicted peak expiratory flow rate to account for gender and height differences. There was no significant difference in gender, age or lung function between patient and control groups. Maximum cough Poes was higher in patients with chronic cough than controls (188 vs 146cmH2O, p<0.02). This difference was limited to females only; the male group was underpowered to detect a difference. Cough Pga (p=0.01) and normalised cough flow (p=0.03) were also higher in female patients than in controls.

P2117

Obesity and respiratory muscle power
Randa Ibrahim1, Amit Bashir1, Aamir Magzoub1, Omer Musa2. 1Department of Physiology, Faculty of Medicine, El-Ismi El-Malhi University, Kosti, White Nile, Sudan; 2Department of Physiology, Faculty of Medicine, National Ribat University, Khartoum, Sudan

Introduction: In the past few decades obesity has become a global health problem. It could be a predisposing factor to a lot of cardiovascular, metabolic (such as diabetes mellitus) and respiratory problems that may result in pulmonary obstruction or restriction.

Objectives: The aim of this study was to investigate the effect of obesity on respiratory muscle power and so on lung functions.

Methods: This was a cross sectional study performed on 52 subjects (35 females and 17 males) in the age range 17-23 years in Khartoum state during the period February to May 2010. The body mass index (BMI) was computed following the standard equation (BMI kg/m^2) = (weight/height)^2. The percent of body fat was measured using Skinfold Caliber at the back of upper arm. Obesity was defined following the internationally accepted BMI cut-off points and ideal body fat percentages such as these from the American Council on Exercise. Pulmonary functions, respiratory pressure (Poes, Pga, PeFR, PEF) were measured using a micro-plus spirometer. Maximal inspiratory pressure (MEP) was measured using a pressure gauge. Statistical analyses were performed using the SPSS.

Results: The mean of MEP was significantly higher in obese subjects (p<0.00). The mean PEFR% was significantly higher in obese subjects (p<0.05). The mean FEV1/FVC% was significantly higher in obese subjects (p<0.01) but FEV1, FVC and PEFR values were not significantly different. A significant positive correlation was found between MEP and BMI and body fat% (obesity).

Conclusion: Maximal expiratory pressure was significantly higher in healthy obese subjects, compared to non obese control. possibly due to the increased work of breathing. Positive correlation between MEP and BMI and body fat% was observed.

P2118

Changes of active expiration respiratory muscle (RM) in men with chronic obstructive pulmonary disease (COPD)
Sviatlana Lemiaiasheskaya, Mikhail Nidereved, Alexander Makarevich, Alexander Lemiaiasheski, Alexander Pochtashev. Internal Medicine, Belarussian State Medical University, Minsk, Belarus

Background: For the present moment changes occurring in RM, during COPD, have been studied insufficiently.

Aim and objectives: to investigate the RM status and compare them with histological and subjective scales. Little is known about cough intensity in patients with chronic cough. We investigated the

Presented as mean (SD).
Results: Contractions, small sites of a fragmentation, stratification of myofibrils and proliferation of fibroblasts were observed at the 1st and 2nd COPD stage. We revealed sclerotic of single muscular fiber and foci of sclerosis in intramuscular regions. The median H in the 1st and 2nd groups was 21 and 18 units respectively. Increasing severity of COPD was associated with enhancing of contractions and stratification of myofibrils. Thus, we detected the significant correlations between COPD severity and contractions (r=0.72) and with stratification of myofibrils (r=0.66). Indices H and SD were lower in pts with more severe manifestations (r = -0.42 and r = -0.59). Whereas index E was higher in these patients (r=0.59).

The paper significantly correlated with intensity of proliferation of fibroblasts (r=0.56).

Conclusions: Indices H, E, SD reflect the pathological processes occurring in RM in COPD patients.

Acute inspiratory load effects on chest wall volumes distribution and inspiratory muscles activation

Alana da Gama1, Larissa Carvalho1, Larissa Feitosa1, Jasiel Nascimento Jr1, Rafaela Sa1, Ana Gabriela Cavalcanti1, Guilherme Fregonez2, Andrea Alverini3, Marco Aurelio Rodrigues1, Armele Dornelas de Andrade1.

1Departamento de Fisioterapia, Universidade Federal de Pernambuco, Recife, Brazil; 2Department de Fisioterapia, Universidade Federal do Rio Grande do Norte, Natal, Brazil; 3Dipartimento di Biopiggeggers, Politecnico di Milano, Milano, Italy

Inspired loads can induce changes on the ventilatory pattern. In order to analyze the acute effect of the imposition of inspiratory load (IL) on the ventilatory pattern and inspiratory muscle activity, 39 healthy subjects (19M, 20F) were analyzed. Characteristics of male and female subjects respectively were: age, 25.50 ± 0.86 and 22.70 ± 1.53 years, FEV1/FVC, 95.05 ± 2.27 and 105.06 ± 1.97%pred; maxi-

Does lung transplantation improve chronotropic incompetence?

Matthew Bartels1, Hilary Armstrong1, Selim Arcasoy2. 1Rehabilitation & Regenerative Medicine, Columbia University Medical Center, New York, NY, United States; 2Pulmonary Medicine, Columbia University Medical Center, New York, NY, United States

Introduction: Chronotropic Incompetence (CI), or an attenuated heart rate (HR) response to exercise, has been widely established as a predictor of mortality but has not been studied in patients undergoing lung transplantation.

Objectives: We aimed to see whether CI in maximal exercise testing exists in patients with advanced lung disease before lung transplantation and improves after surgery.

Methods: A retrospective review of 153 patients who underwent lung transplantation at Columbia University Lung Transplant Program between 6/2002 and 6/2009. Patients had cardio-pulmonary exercise testing (CPET) within 30 months before or after transplant with concurrent with pulmonary function tests (PFT). Exclusion criteria included the use of beta-blockers. Comparisons were made with paired samples t-test.

Results: The mean PFT and CPET variables for the 71 patients (age 50±15 years) analyzed are shown in table 1.

Conclusions: Marked CI was observed before lung transplantation and improved afterwards but did not normalize. CI likely improved due to the normalization of pulmonary function post transplant. This was seen through a lower resting HR and a higher maximal HR. The implications of CI are not clear and warrant further investigation, including evaluation of the association of CI and mortality after transplant.

P2111
Does chronotropic incompetence occur in interstitial lung disease?

Matthew Bartels1, Hilary Armstrong1, Aimee Layton1, David Lederrer2.

1Rehabilitation & Regenerative Medicine, Columbia University Medical Center, New York, NY, United States; 2Medicine – Pulmonary, Allergy & Critical Care, Columbia University Medical Center, New York, NY, United States

Introduction: Chronotropic Incompetence (CI) is an attenuated heart rate (HR) response to exercise that has been widely established as a predictor of mortality in general populations and in patients with heart disease. CI has not been studied in patients with interstitial lung disease (ILD) despite abnormalities in pulmonary hemodynamics and cardiovascular parameters.

Objectives: Our primary aim was to see whether CI exists in patients with ILD during maximal exercise testing.

Methods: This is a retrospective review of 482 pts with ILD who underwent cardiopulmonary exercise testing (CPET) at Columbia University Human Performance Laboratory between 10/1999 and 2/2011. Patients had CPET with concurrent pulmonary function tests (PFT). Comparisons were made with paired samples t-test.

Results: The mean PFT and CPET variables for the 482 ILD patients (aged 56.6±11.0 years) analyzed are shown in table 1. Usual heart rate reserve used (HRUE) is 85% in normal subject populations. Mean PFT and CPET variables for the 482 ILD patients

Conclusions: Marked CI was observed in patients with interstitial lung disease in a large cohort. This abnormality may have implications for long term survival as cardiac mortality and cardiac comorbidity are common as ILD progresses and possible development of pulmonary hypertension and right heart failure.

Further investigation with assessment of mortality risk and possible identification of interventions to improve CI may help to improve outcomes in this patient population.

P2122
Effect of posture on chest wall and diaphragm asynchronies in COPD

Rita Priotti1, Marco Quaranzi1,2, Andre L.P. Albuquerque2,3, Peter M.A. Catalverley1, Andrea Alverini2, David Leeder3.

1Rehabilitation & Regenerative Medicine, Columbia University Medical Center, New York, NY, United States; 2Pulmonary Medicine, Columbia University Medical Center, New York, NY, United States

In COPD hyperinflation alters the function of the inspiratory muscles. The zone of apposition of the diaphragm (ZOM) is reduced, thus COPD patients often show paradoxical movement of the lower rib cage. The aim of this study is to investigate if in COPD chest wall and diaphragm asynchronies are altered by posture.

Conclusions: Neither 0° RCP and RCA or 0° between RCP and AB was altered by posture in CT. Conversely, in COPD patients, 0° between RCP and RCA decreased when changing posture from ST to SP (θ=23.7°±19.5, 5.5±18.1 respectively, p<0.001).RCP and AB in COPD showed a behavior similar to CT while in ST (θ=0.3±13.3 in COPD, 0°±1°±4.5 in ST), but strongly differed in SP (θ=25.0°±18.2, p<0.001, COPD vs. CT). Moreover, in COPD AZOM was linearly correlated to RCP in ST (r=0.718±0.140), similarly to control subjects (r=0.729±0.150), while it was significantly less correlated to RCA (r=0.510±0.246, p<0.001). In COPD correlation between AZOM and both RCP and RCA decreased (r=0.530±0.244, r=0.511±0.230 p<0.05) in SP.

In COPD the diaphragm and RCA are uncorrelated in ST, but the synchronous action of the rib cage muscles and the diaphragm is similar to healthy. In SP the diaphragm is uncorrelated with both RCP and RCA, so the asynchrony with the rib cage muscles seems to be preserved.
Parasternal muscle contractility increases with aminophylline

**Introduction:** The traditional theophylline bronchodilator, Aminophylline, is still widely used, especially in the treatment of COPD. However, in COPD patients the effects of theophylline have been inconsistent. Recently, Aminophylline was shown to increase ventilation and costal diaphragm contractility in awake canines (Jagers et al. Respir. Physiol. 2009;167:273-280).

**Aim:** To investigate the effect of Aminophylline at therapeutic levels on the primary chest wall muscle, Parasternal Intercostal.

**Methods:** Sonomicrometry transducers and EMG electrodes were implanted in the left parasternal muscle. After recovery, the animals were studied awake, unaesthetized and breathing through a snout mask; air flow, ETCO2, heart rate, muscle length and shortening, and moving average EMG were recorded during room air, and CO2 stimulated breathing, before and after loading and continuous infusion of Aminophylline at therapeutic levels.

**Results:** For N=5 dogs (mean 31.1 kg) 24 days post implantation. Aminophylline serum levels were 66.4 μmol/L (therapeutic range 55-110). Minute ventilation increased significantly with Aminophylline: 6.7, 7.84, 11.8 and 16.6 L/min at room air, low (46), medium (52) and high (57 mmHg) CO2 stimulated breathing respectively. Parasternal contractility increased significantly.

**Conclusion:** Parasternal muscle contractility increases with greater muscle shortening per EMG, in awake, intact canines, at therapeutic levels of Aminophylline.

Relationships between bronchial obstruction and differential NO parameters after methacholine challenge testing

Liubov Barbinova, Preslitz Alexandra, Xavier Baur. Clinical Occupational Medicine, Institute for Occupational and Maritime Medicine, Hamburg, Germany

The aim of the study was to investigate whether methacholine-induced changes of FEV1/FVC on the one hand, and of the alveolar NO concentration (Calv) and the NO flux from the bronchial wall (Jaw) on the other hand, are associated.

**Patients and methods:** 65 patients (all non-smokers) with work-related symptoms underwent a methacholine challenge test. Bronchial hyperresponsiveness (NSBHR) was defined as a decrease of FEV1 of 20% induced by methacholine. Measurements of FeNO were performed at five flow rates. Calv and Jaw were calculated.

**Results:** There was a positive association between lung function changes after methacholine challenge and Jaw decrease with a stronger Jaw decrease in the NSBHR group: ΔCalv: -0.73±0.27 vs. -0.25±0.07 mL, p=0.1. Contrary to this, Jaw increased in the NSBHR group (n=22) and decreased in the group without NSBHR (n=43) (ΔCalv: -0.34±0.1 vs. -0.2±0.07 ppb; p<0.001) with a significant negative correlation between the changes of FEV1/FVC and of Jaw in the NSBHR group (r=-0.65, p<0.005), but no correlation in the group without NSBHR.

**Conclusions:** The increase in Jaw in the NSBHR group is related to the degree of bronchial obstruction and evidently due to mixing alveolar and bronchial NO. The stronger airways obstruction (ΔFEV1/FVC), the more NO of bronchial source does not reach the alveoli and is exhaled deleter during the alveolar phase. Our results confirm the thesis of Högman et al. (2002), who interpreted elevated Calv of bronchial obstruction and evidently due to mixing alveolar and bronchial NO. The stronger airways obstruction (ΔFEV1/FVC), the more NO of bronchial source does not reach the alveoli and is exhaled deleter during the alveolar phase. Correspondently, elevated Jaw can be consided not only as a marker of alveolar inflammation but also as an indicator of peripheral airways obstruction.

P2125

Minor local alveolar edema in an in vivo human model can be detected by changes in respiratory mechanics by impulse oscillometry (IOS)

Manuela Bartesaghi,1 Egido Beretta,1 Alberto Pesce,1 Andrea Aliverti,1 Giuseppe Miserocchi,2,1 Experimental Medicine, University of Milano-Bicocca, Monza, Italy; 2Medicina Clinica e Prevenzione, University of Milano-Bicocca, Monza, Italy; 3Biomecengineering, Politecnich of Milano, Milano, Italy

**Aim:** We assessed the sensitivity of the impulse oscillometry methods (IOS) to detect residual alveolar edema in a lung segment after broncho-alveolar lavage (BAL).

**Methods:** 15 patients of both sexes undergoing BAL in different lobes for diagnosis of interstitial lung disease were studied: IOS was applied before and after withdrawal of BAL fluid, leaving in the alveoli a volume (V0) of 86.6±23.6 (mean ± DS), and continued up to 150 min. From IOS data we derived the corresponding values of respiratory resistance (Rrs) and reactance (Xrs) at frequencies from 5 to 35 Hz. We also estimated the “area of reactance” (Axx) as defined in Fig. 1A.

**Results:** After withdrawal of BAL fluid, the remaining V0 caused a 30% significant increase of Rrs at 5Hz: a significant increase in resonance frequency (fres) from 11.9 Hz ± 3.3 to 15.2 Hz ± 4.9; and minor changes in Xrs. The increase in fres led to a significant 90% increase in Axx. Rrs, fres and Axx returned towards baseline values through an exponential decay function within 150 min (data of Axx and regression equation are shown in Fig. 1B).

**Conclusion:** IOS technique is sensible enough to detect minor localized increase in extravascular lung water.

P2126

Acute changes in physiological parameters and pulmonary function during and after fiberoptic bronchoscopy

Anant Mohan, Randeep Guleria, Ashraf Ali, Ajit Kumar. Medicine, All India Institute of Medical Sciences, New Delhi, Delhi, India

**Background:** The short term effects of fiberoptic bronchoscopy (FOB) on physiological and pulmonary function parameters are not well known.

**Method:** Pulmonary function test was performed in patients before and within 30 minutes after bronchoscopy. Heart rate, blood pressure and oxygen saturation were recorded at the start of procedure and 5 and 10 minutes later.

**Results:** 55 patients were studied [39 males, mean (SD) age, 45.89 (13.77) years]. Mean (SD) BMI was 21.3 (3.82). 76.4% patients were non smokers and 16.4% were current smokers. Most patients were being evaluated for suspected carcinoma lung (27.3%), pneumonia (14.5%), interstitial lung disease (9.1%), Mediastinal lymphadenopathy (9.1%), carcinoma esophagus (7.3%) and fibrocavitary lesions (7.3%). The commonest complaints were cough (45.5%), shortness of breath (30.9), chest pain (12.7%), wheezing (7.3%), hoarseness of voice (7.3%), Hemoptysis (1.8%) and fever (1.8%). During the procedure there was significant increase in heart rate, systolic blood pressure and diastolic blood pressure while oxygen saturation declined. Post procedure there was a significant decline in FEV1, FVC, PEFR and FEF25-75 (Table).

**Table.** Changes in pulmonary function before and after bronchoscopy

**Conclusion:** Bronchoscopy causes a significant acute decline in pulmonary functions. There may be thus, a justification for prophylactic use of inhaled bronchodilators prior to performing bronchoscopy.

P2127

Distribution and determinants of restrictive functional pattern

Joan B. Soriano1, Marc Miravitlles2, Francisco Garcia-Rio3, Luis Muñoz4, Guadalupe Sanchez5, Victor Sobradillo6, Emric Duran7, Dolores Guerrero8, Julio Ancoco1,8,1 Epidemiology and Clinical Research, Fundació Puigvert, Barcelona, Spain; 2IDIBAPS, Hospital Clinic de Barcelona, Barcelona, Spain; 3Iñegaz, Hospital la Paz, Madrid, Spain; 4Servicio de Neumología, Hospital Reina Sofia, Cordoba, Spain; 5Servicio de Medicina Interna, Hospital Reina Sofia, Cordoba, Spain; 6Servicio de Medicina Interna, Hospital Reina Sofia, Cordoba, Spain; 7Servicio de Neumología, Hospital de...
A restrictive functional pattern is a common finding when performing spirometry; even in the absence of signs of pulmonary fibrosis or other disorders. This EPICS-SCAN sub-analysis (a population-based, cross-sectional study in eleven participating centres in Spain) aims to determine the frequency, geographic variation, individual consequences (respiratory symptoms, impact on activities of daily living) and “severity” of the restrictive functional pattern defined according to pre-BD spirometry as FEV1/FVC < 0.70 and a predicted FVC < 80% as per current ATS/ERS guidance. The prevalence of restrictive functional pattern was 12.7% (95% CI 9.7-15.7), with maximum in Seville (19.4%) and Madrid-La Princesa (15.7%), p < 0.05. Although the vast majority (97.1%) of participants with a restrictive functional pattern are objectively considered “mild” by spirometry (%predicted FVC 50-80%), they reported more plegmen, dyspnea, and wheezing than healthy, control participants, and in all SGRQ domains of quality of life and LCADL activities of daily living they scored worse (p < 0.05), actually, they scored similarly to participants with COPD in both (p > 0.05). In a multivariate analysis, only older age, male gender, lower education, and body mass index (BMI) ≥ 30.0 kg/m² were independently associated with having a restrictive functional pattern. We conclude that a restrictive functional pattern in spirometry is a common finding (12.7%), and with highly variable geographical distribution (range 3.7), whose population burden is important in terms of quality of life and activities of daily living and similar to that of an obstructive pattern compatible with COPD.

P2128
Effects of gastric bypass surgery compared to intensive lifestyle treatment on blood gases and lung function in morbidly obese subjects
Anne-Marie Gabriesen, May Brit Lund, Johny Kongerud, Viken Karl Erik, Jørjan Hjelmesæth. Department of Respiratory Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway

Objective: To aim for the effect of Roux-en-Y gastric bypass surgery (RYGBP) with intensive lifestyle intervention (ILI) on blood gases and lung function in morbidly obese subjects.

Design: One year non-randomized controlled clinical trial (ClinicalTrials.gov identifier NCT00273104).

Methods: 139 morbidly obese subjects, (103 women); mean (SD) age 44 (11) years. While body mass index 45.1 (5.6) kg/m², mean (SD) weight 131.8 (21.2) kg treated with either RYGBP (n=76) or ILI (n=63), were included. Blood gases and lung function tests were registered before and after treatment.

Results: Mean (SD) 1-year weight loss was 30 (8)% and 8 (20)%, and mean pO2 increased 1.4 (1.5) kPa and 0.8 (1.5) kPa in the RYGBP-and ILI-group, respectively (all P<0.001). Mean pCO2 decreased by 0.16 (0.4) kPa in the ILI-group (P=0.005), and 0.04 (0.5) kPa in the RYGBP-group (P=0.511). Mean ERV increased from 44 (32)% to 89 (39)% of predicted value (P<0.001) in the RYGBP-group, while there was no significant change in the ILI-group. We also found significantly improved mean values for FVC, FEV1, DLCO/VA, TLC, IC and RV in the RYGBP group (all P<0.001; data not shown). In the lifestyle group there were significant changes in mean TLC and RV (P<0.001), DLCO/VA (P=0.010) and FVC (P=0.049). There were no significant changes in mean DLCO in either group. There were significant between-group changes for mean FVC, FEV1, DLCO/VA, IC and RV in the RYGBP group, while there was no significant change in the ILI-group. We also found significantly improved mean values for FVC, FEV1, DLCO/VA, IC and RV (all P<0.001), TLC (P<0.007) and pO2 (P<0.032).

Conclusion: Blood gases and lung function improved in both treatment groups. However, the greatest effects were seen in the RYGBP group.

P2129
Reproducibility and repeatability of tidal breathing parameters derived from structured light plethysmography when compared to spirometry
Chathika Weerasuriya,1 Kate Prosser1, Sukaina Alimohamed,1 Richard Iles,2 Jonathan Cameron,1 Joan Laseby,1 Colin Fogarty,3 School of Clinical Medicine, University of Cambridge, Addenbrookes Hospital, Cambridge, Cambridge, United Kingdom; 2Department of Respiratory Paediatrics, Cambridge University Hospitals, Addenbrookes Hospital, Cambridge, Cambridge, United Kingdom; 3Signal Processing and Communications Laboratory, Department of Engineering, University of Cambridge, Cambridge, United Kingdom

Background: Traditionally the “gold standard” for detecting abnormal vocal cord movement has been laryngoscopy. Novel dynamic 320-slice CT larynx has made it possible to quantify vocal cord movement non-invasively during inspiration and expiration. While spirometry has been useful in observing upper airway obstruction, little is known of its utility in identifying patients with abnormal vocal cord movement.

Aims: To identify changes in the flow volume curve in patients with abnormal vocal cord movement (AVCM).

Methods: Two groups comprising controls and asthmatics were recruited. Vocal cord abnormality was evaluated using 320-slice CT larynx. All patients had spirometry immediately prior to CT and relevant parameters were compared.

Results: AVCM was not found in healthy control subjects. However, it was present in 11/23 asthmatics (50%).

Discussion: While there was a significant difference in FEV1 between control and the two asthma groups, it identified obstruction alone. The only other discerning spirometric parameter was FIF50%/FEF50% which was significantly different between the control group and those with AVCM.

Conclusion: Spirometric parameters appear to be poor discriminators for detecting AVCM. It may be that more sensitive lung function measures, such a resistance measurement, may be required in order to further discriminate between obstruction of the upper and lower airways.

P2131
Compression artifact free flow-volume loops used to establish objective measurements in patient effort with spirometry
Kristoffer Neu, Gussan Koussa, Lomi Hart, Nadia Stachowicz, Damian Compa.
Pulmonary/Critical Care, Albany Medical Center, Albany, NY, United States

Background: Flow-volume loops (FVL) measured by using pressure-compression volumetry plethysmography has been described in the literature and is commonly called compression artifact free flow-volume loops (FVLc). The utility of this technique has been to help demonstrate good patient effort and to help identify upper airway obstruction. There are no studies demonstrating measurable objective data to help confirm patient effort with FVLc.

Objective: Our study looks to identify the utility of FVLc by trying to establish a percentage cut off point for FVLc peak expiratory flow and what normal flow should be at 25, 50, and 75% intervals of the FVLc that can demonstrate good patient effort.

Methods: 76 patient’s charts that had FVLc in our lab were randomly reviewed. We looked to see if the peak flow on the FVLc was 25% higher than the traditional FVL. We recorded the flow percentages at the 25, 50, and 75% intervals of each patient’s FVLc. Patients were divided by having a peak flow greater than 25% (group A) or less than 25% (group B). We identified those patients with peak flows on the FVLc greater than 25% and 19 patients were less than 25%. Comparing groups, the flow at the 25% interval in group A were statistically higher (mean 0.58 vs 0.35, P<0.0001). All patients with peak flow greater than 25% had higher flow rates at the 25% and 50% flow intervals (P<0.0001).

Conclusion: Evaluating patient effort with FVLc may be helpful if the peak flow is 25% greater than seen on traditional FVL and if the 25% interval flow is greater. Further study is needed to establish the validity of this technique.

P2132
Airway resistance during the methacholine challenge test: Comparison between plethysmographic and oscillometric technique
Egido Beretta1, Francesco Tana1, Andrea Aliveri1, Luca Novelli1, Gabriele Simone Grasso1, Giuseppe Miserocchi1, 2
1 Experimental Medicine, University of Milano-Bicocca, Monza, Italy; 2 Clinic Pneumologica, San Gerardo Hospital, Monza, Italy;
3 Bioengineering, Politecnico di Milan, Milan, Italy

Background: Plethysmographic airway resistance (Raw) does not allow identification of bronchoconstriction site. Conversely, respiratory system resistance (Rs) measured by impulse oscillometry (IOS) can distinguish changes between peripheral and central airways mechanics (< 5 Hz for peripheral and 5-20 Hz for central airways). We wish to compare Raw to Rs in response to methacholine challenge (MCh).

Methods: 18 subjects underwent saline aerosol bolus (baseline) followed by increasing methacholine doses inhalation. At each dose, Raw and Rrs were measured respectively by body plethysmography and IOS. The measurements were repeated until reaching PD20 (estimated from FEV1) or the maximal dose (2400 g). We considered subjects with PD20 < 800.

Results: Rrs increased in all subjects during MCh. In 67% of subjects (group 1) Rs increased at 1Hz only, while in 33% (group 2) an increase in Rs was found at all frequencies. In group 1, unlike in group 2, the goodness of the regression between Rs and Raw (as from R²) was highest at 1Hz, waxing progressively with increasing impulse frequency.

Conclusions: Measurements of Rrs in the range 1-20 Hz allow to identify different sites for MCh response. The significant correlation between Rs at 1Hz and Raw in group 1 suggests that variation in Raw mostly reflects changes in small airways mechanics. In group 2 the significance of the regressions between Rs at all frequencies and Raw suggests that changes in airways mechanics of various calipers impact on plethysmographic measurements.

P2133
Impulse oscillometry (IOS) vs plethysmographic methods to detect PD20 in the methacholine challenge test
Egido Beretta1, Andrea Aliveri1, Simona Perossi2, Gabriele Simone Grasso1, Francesco Tana2, Giuseppe Miserocchi1
1 Experimental Medicine, University of Milano-Bicocca, Monza, Italy; 2 Clinic Pneumologica, San Gerardo Hospital, Monza, Italy; 3 Bioengineering, Politecnico di Milan, Milan, Italy

Background: Methacholine challenge (MCh) test is the standard method used to unravel bronchial hyperresponsiveness. Airways resistance (Raw) is commonly measured with body plethysmography in addition to FEV1. The test is considered positive when a 20% decrease in FEV1 (provocative dose, PD20) is reached. We aimed to investigate whether respiratory impedance (Zrs) provides more sensible indexes, compared to Raw in detecting changes in bronchomotor tone.

Methods: 20 subjects underwent saline aerosol bolus (baseline) followed by MCh (50 to 2400 g). After each dose we measured 1) respiratory impedance (Zrs); at impulse frequency from 1 to 35 Hz) and corresponding values of respiratory resistance (Rrs) and reactance (Xrs); 2) Raw and FEV1.

Results: Fig. 1A shows that Xrs decreased at all frequencies at the methacholine dose preceding PD20 and even more at a dose higher than PD20. Due to the change in Xrs at low frequencies and to the increase in resonance frequency (fres), we considered the so called area of reactance (AXrs) as defined in Fig. 1B. We found that AXrs correlates significantly with Raw through an exponential function (Y = 0.1e4.55x), indicating that the growth in AXrs is larger than that of Raw, on increasing MCh.

Conclusion: Determination of AXrs through impulse oscillometry is more sensible than Raw and FEV1, to assess the increase in airway resistance during MCh.

P2134
Variability of respiratory rhythm and pattern of breathing changes in patients with bronchial asthma and cold airway hyperresponsiveness
Dmitry L. Nakhamchen, Juliy M. Perelman.
Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation

The role of control of breathing in modulation of bronchomotor tonus has been studied very little. It is unknown if there is a correlation between cold airway hyperresponsiveness (CAHR) and changes of respiratory regulation.

The aim of the study was to reveal the changes in respiratory rhythm and pattern of breathing and their correlation with bronchoconstrictor reaction to cold air hyper-ventilation in bronchial asthma (BA). 35 patients with BA and 6 healthy persons were examined. The group of BA patients was divided according to whether there was CAHR (14 patients) or there was not any (21 patients). CAHR was defined by 10% FEV1 fall after 3-minute isocapnic cold air (-20°C) hyperventilation.

Respiratory rhythm variability was evaluated by the value of mean-square deviation of respiration cycle duration during 15-minute interval. In result, a big variability of respiratory rhythm in BA patients with CAHR was revealed. Mean-square deviation was 0.86±0.13 vs. 0.56±0.06 in patients without CAHR (p<0.05). Significant changes in pattern of breathing in patients with CAHR were registered: inspiration shortening (0.37±0.01 vs. 0.41±0.01 s in healthy persons, p<0.01), expiration lengthening (0.63±0.01 vs. 0.59±0.01 s, p<0.01), respectively, at the absence of established differences in FEV1 between the groups. There was a direct correlation between FEV1 and tidal volume in healthy subjects and asthmatics without CAHR (r=0.89 and r=0.75, respectively, p<0.05). Patients with CAHR did not have such a correlation. The obtained data suggested a distinct interrelation-ship between the control of breathing and cold airway hyperresponsiveness in BA patients.

P2135
Improved survival with increased IC/TLC ratio, DLCO and FEV1 in an analysis of a COPD pulmonary function database
David Bälte, Zab Mosenilaz. Division of Pulmonary & Critical Care Medicine, Cedars-Sinai Medical Center, Los Angeles, CA, United States

Introduction: COPD is the fourth leading cause of death worldwide. FEV1 is predictive of COPD mortality. The IC/TLC is a measure of static lung hyperinflation. Aim: Analysis of a pulmonary function (PF) database evaluating the influence of FEV1, DLCO, IC/TLC and other variables on survival.

Design: Retrospective analysis of PF data base (31 year). 984 PF’s with a reduced FEV1/FVC, increased TLC and reduced DLCO were analyzed. The date of initial PF test was used as the initiation of the survival analysis. 596 patients had dates of death. Kaplan-Meier survival plots, in addition to Cox analysis, were performed to evaluate the relationship of age, FEV1 (GOLD stage), DLCO and IC/TLC ratio on survival, in addition multivariate analysis was performed assessing the effects of age, FEV1, gender, DLCO and BMI with the IC/TLC ratio.

Results: Cox analysis for the risk of death, revealed that a reduced IC/TLC ratio (< 25%) [HR 1.69, p<0.0001]; low DLCO (<22 predicted) [HR 1.28, p<0.043]; increased age [HR 1.035 for 5 year increase, p <0.0001] predicted death. Female gender [HR 0.692, p<0.692] and increased FEV1 (mild vs moderate) is predictive of survival [HR 0.69, p<0.0089]. Multivariate analysis revealed that age, gender, and IC/TLC (absolute ratio) remained the only statistically significant independent predictors of survival (HR=1.04, 95% CI: 1.03-1.04; HR 0.69, 95% CE: 0.60-0.83; HR 1.69, 95% CI: 1.34-2.13, respectively).

Conclusion: Analysis of a PF database reveals statistically significant associations of a number of measured and demographic variables with survival. IC/TLC ratio > 25, DLCO ≥ 22, Mild FEV1, Female gender, and BMI >25 is associated with survival.

P2136
Role of facemask spirometry in motor neurone disease (MND)
Sandip Banerjee, Ian Smith, Michael Davies, Rebecca Chadwick.
Respiratory Sleep and Support Centre, Papworth Hospital NHS Foundation Trust, Papworth Everard, Cambridgehire, United Kingdom

In MND, NICE (UK) recommend considering non-invasive ventilation (NIV) when FVC values fall below 50% predicted. Patients with bulbar/facial weakness often fail to achieve a seal using a mouthpiece (tube). Thus tube spirometry may not fail to achieve a seal using a mouthpiece (tube). Thus tube spirometry may not reflect the patient’s true respiratory reserve. We have compared facemask (mask) to tube spirometry in 60 MND subjects recruited at a specialist clinic.

Methods: Spirometry was performed via mask and tube in random order. Since FVC is a maximal manoeuvre, a greater value was assumed to be more accurate. The Bland-Altman method of agreement between 2 measures was used. The bulbar component of ALSFRS r score was correlated to FVC values.

Results: The mean age was 64.6 (SD 10.45) years and M:F ratio was 1.5. Satisfactory FVC was obtained in all 60 subjects via mask, and 54 via tube. When bulbar ALSFRS r score <8, mask FVC was greater than tube. No difference in FVC seen when score >8. From the Bland-Altman plot, mask FVC was greater than tube in 86% subjects when FVC <2.5 L. Mask FVC was preferred by 73.9%. Of the 25 subjects with tube FVC >50% predicted, 32% had a mask FVC >50% predicted.

Conclusion: Mask spirometry provides a more accurate measure of respiratory
P2139
Pulmonary and liver injury after exposure to sublethal doses of microcystin-LR

Walter Zin1, Giovanni Carvalho1, Vinicius Oliveira1, Natalia Casquilho1, Raquel Soares1, Sandra Azevedo1, Karla Pires2, Samuel Valença2, Carlos Chagas Filho Institute of Biophysics, Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil; 1Roberto Alcântara Gomes Institute of Biology, Rio de Janeiro State University, Rio de Janeiro, RJ, Brazil

Rationale: Biological pollution caused by cyanotoxins leads to respiratory function impairment.

Aim: Study pulmonary mechanics, lung and liver histology in mice submitted to sublethal doses of microcystin-LR (MCLR) and evaluate whether the results depend on the doses.

Methods: Male Swiss mice were divided into 2 groups: CTRL (n=6) received distilled water intraperitoneally (ip, 100 mL) and TOX (n=30); injected with sublethal doses of MCLR (5, 10, 15, and 20 μg/kg ip in 100 mL of distilled water). 24 h later pulmonary mechanics [static elastance (Ea), viscoelastic component of elastance (ΔE), resistant (ΔP1), viscoelastic (ΔP2), and total (ΔPtot) pressures] were determined, and lungs and livers were prepared for histopathology. ANOVA was used to test differences among the groups.

Results: ΔP2, ΔE and ΔPtot were significantly higher than CTRL in all MCLR doses, but did not differ among them. Only TOX25 showed significantly higher ΔP2 than CTRL. Alveolar collapse was higher in TOX10 (18.95%), TOX15 (17.56%), TOX20 (19.11%) and TOX25 (21.63%) than in CTRL (11.57%). The lung inflammatory cell content (cells/mm3) gradually increased in TOX10 (12.90 ± 10^-3), TOX15 (14.90 ± 10^-3) and TOX20 (16.40 ± 10^-3) and TOX25 (5.30 ± 10^-3) in relation to CTRL (1.41 ± 10^-3). All TOX mice showed a complete loss of liver architecture by hyalinization, steatosis, dilated sinusoidal spaces and a high degree of binucleated hepatocytes. Necrosis began in TOX15, whereas only TOX 25 showed inflammation.

Conclusion: MCLR impaired pulmonary mechanics, lung and liver histology. These findings depended on the degree of exposure.

Respiratory function in rats submitted to pharmacological hypothyroidism

Walter Zin, Valmara Pereira, Viviane Cagido, Gaudino Sena, Vanessa Baldez, Marcelo Einicker-Lamas, Vania Corrêa-da-Costa, Carlos Chagas Filho Institute of Biophysics, Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil

Hypothyroidism has been associated with hyperventilation, decreased respiratory muscle strength and fatigue. However, the impact of chronic hypothyroidism on respiratory mechanics has not been described so far. Male Wistar rats were divided in 3 groups: Control (C, n=3), hypothyroidism (H, n=5), and hypothyroidism + T4 replacement (HR, n=5). H and HR groups received 0.03% methimazole (MMI) in drinking water for 21 days, followed by saline or T4 (1 μg/100 g BW) injections daily during the last 10 experimental days, respectively. Then, respiratory mechanics was determined during spontaneous breathing [respiratory system (RS)] and under mechanical ventilation after muscle paralysis (RS, lung and chest wall). Total lipid content in bronchoalveolar lavage fluid (BALF) and lung histology were assessed. During spontaneous breathing, RS elastic recoil and inspiratory muscle pressure (Pmus,i) were lower in H group than in C (p=0.016 and p=0.011, respectively). The time required for Pmus,i to decay to zero was higher in H animals than in C or HR groups (p<0.001). Under mechanical ventilation, H group showed a smaller lung viscoelastic component of elastance (p=0.05) and viscoelastic pressure dissipation (p=0.042) than HR, and lower lung resistant pressure (p=0.015) than C rats. Chest wall and RS parameters did not differ among groups. H rats also showed a 3-fold increase in lipid content in BALF in comparison to C and HR rats. Alveolar collapse was less important in H group than in HR (p=0.026). Hence, in rats pharmacological hypothyroidism diminished RS impedance possibly because of an increased lipid content in BALF, and hormonal replacement could revert these findings. P2141
Exercise tolerance is related to lung density in patients with COPD

Jan Chlumsky1, Dept. of Pneumology, Faculty Thomayer Hospital, Prague 4, Czech Republic

In patients with COPD, the peak oxygen uptake (peakVo2) measured during cardiopulmonary exercise test (CPET) has been associated with lung hypoperfusion and survival. However, no study has compared exercise tolerance to quantitative CT measures of emphysema.

14 patients (10 females) with moderate to very severe COPD (FEV1 < 3.38 ± 8.5% pred; RV/TLC 53.6 ± 10.5%) underwent measuring of pulmonary function tests (F-V curve, static lung volumes, transferfactor of the lung for carbon monoxide) and breath-by-breath measurement of flow, volumes and O2 and CO2 concentrations during standard CPET. The extent of emphysema was assessed using the percentage of lung voxels with X-ray attenuation values less than -950 HU (%LAA).

Among pulmonary function tests the TLCO had the closest relationship to %LAA (p=0.0017), followed by the RV (p=0.0044) and the ratio of FEV1 to VC.
P2142

Exhaled nitric oxide and lung function in winter sports elite athletes

Samira Gasymova, Alexandr Ulianov, Lydia Nikitina, Fedor Petrovsky. Allergy and Clinical Immunology, Khanty-Mansiysk State Medical Academy, Khanty-Mansiysk, Russian Federation

Background: Little is known about the role of nitric oxide (NO) in pathogenesis of exercise-induced bronchocstriction and its association with lung function in athletes.

Aim: The aim of the study was to investigate whether airway NO is associated with lung function in elite athletes of winter sports.

Methods: A total of 86 elite athletes (biathlon, ski, ice hockey, snowboard) aged 14-35 were included in the study. FEV1, FVC, PEF (MasterScreen Pneumo, Viavys) were analyzed at the baseline and 1, 5, and 10 minutes after the exercise challenge test. NO was measured in the exhaled air (fractional exhaled NO (FeNO)) pre and between 1 and 5 min after the exercise using CLD 88 apparatus (EcoMedics). All tests were performed according to ATS/ERS recommendations before the competition phase.

Results: 21% of athletes had a post exercise decrease in FEV1 of ≥ 10%. Baseline and post exercise FeNO levels were 15.1 ± 1.6 ppb and 14.5 ± 1.5 ppb, respectively. Most athletes had a post exercise decrease in NOFeO (63.6% in males and 72.7% females). In athletes with the decreased post exercise NOFeO level, the mean change was 26.8% from the baseline, in contrast to 70% increase in those who had a post exercise NOFeO level unchanged or increased (p<0.01). We found the following correlations between (i) baseline FeNO and baseline absolute FEV1 (rs=0.41; p<0.01); (ii) post exercise FeNO and ΔFEV1 % in min post exercise (rs=0.38; p<0.04); (iii) post exercise FeNO and ΔFEV1 % 5 min post exercise (rs=0.58; p<0.01); (iv) post exercise FeNO and PEF% 5 min post exercise (rs=−0.56; p<0.01).

Conclusion: The present data suggest a role of airway NO in lung function and in exercise induced bronchoconstriction in elite athletes.

P2143

Exercise-related perceptions do not affect exercise response in subjects with OSA

Giulia Innocenti Bruni, Francesco Gigliotti, Claudia Coli, Barbara Binazzi, Ilenia Presi, Isabella Romagnoli, Barbara Lanini, Loredana Stendardi, Giorgio Scano. Department of Respiratory Rehabilitation, Fondazione Don Carlo Gnocchi, Florence, Italy

Lean and obese subjects have similar exercise capacity and intensity of dyspnea and leg effort. Obese individuals with OSA have a reduced exercise capacity [Vanbreke 2008], if this depends on exercise-related perceptions needs to be defined. Sixteen subjects with OSA, 8 lean (BMI<25.6±2.5) and 8 obese (BMI>30±4.1) and 14 subjects without OSA, 8 obese (BMI>44.9±7.5) and 6 lean subjects (25.6±1.6) underwent spirometry, polvomography, and incremental exercise test. FRC (9% pv) was similar in obese with and without OSA (84.4±9.8 vs 88.6±2.4 respectively; p<0.01) The volume of safety of OSA (AHE51±24 vs 30±10.5; p<0.05) was the same in obese and lean subjects. At VO2peak (6.26±0.6; 2.4±0.7; 2.51±0.6; 2.52±0.5 % in obese with and without OSA, and lean with and without OSA, respectively; ANOVA: p<0.05). VO2peak (ml/kg/min) was similar between obese subjects (OSA vs non OSA) and between lean subjects (OSA vs non OSA). End-expiratory-lung-volume (EELV) decreased in lean subjects with OSA (200±420ml), while increased in obese with (270±330ml) and without OSA subjects (304±330ml). Peak BORO was similar (ANOVA:p<0.05) in the four groups (7.5±1.6; 6.25±1.75; 5.9±2.4; 6.8±2.3 for obese OSA and non OSA, and lean OSA and non OSA subjects, respectively). Peak leg effort did not significantly differ in obese and lean subgroups: (8.63±1.69; 7±1; 4.21; 2; 8.5±0.8 for obese with and without OSA, and lean with and without OSA, respectively; ANOVA: p>0.05). The qualitative difference in EELV response indicates respiratory mechanical limitation during exercise in obese subjects with and without OSA. Exercise-related perceptions do not affect exercise response in obese with OSA.

P2145

Variability in walking patterns during the 6MWT in COPD patients and healthy controls

J. Annegarn1, M.A. Spruit1, H.H.C.M. Savelberg2, C. van de Boe3, A.M.W.J. Schols4, E.F.M. Wouters4, K. Meijer1. 1Program Development Centre, Ciro, a Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 2Human Movement Science, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre, Maastricht, Netherlands; 3Respiratory Medicine, NUTRIM School for Nutrition, Toxicology and Metabolism Maastricht University Medical Centre, Maastricht, Netherlands; 4Division of Exercise Science, University of Groningen, Groningen, Netherlands; 5Human Movement Sciences Department, University of Groningen, Groningen, Netherlands.

Aim: To assess if sputum inflammation and BHR contribute to functional exercise capacity (assessed by 6-Minute Walk Test (6MWT)) next to lung function, health related quality of life (HRQL) and health status in COPD.

Methods: 108 COPD patients (COLD stage II & III) participating in the GLUCOLD study [1] (81% male, median (range) FEV1%pred 64% (41-78), mean (sd) 6MWT-distance (6MWD) 551 meter (74)). Measurements at baseline: FEV1, methacholine, induced sputum, 6MWT, bodyplethysmography, RAND-36 and COPD COPD Questionnaire (CCQ). Variables tending to be associated with 6MWD univariately (p<0.020) were analysed using multivariate regression analysis with adjustment for age, height, gender, and FEV1.

Results: Higher RV%pred (b=−0.446, p=0.037), lower RAND-36 “Physical functioning” domainscore (b=0.888, p=0.043) and higher CCQ total score (b=−70.9, p=0.031) were independent contributors of lower 6MWD. Furthermore, higher age (b=−3.56, p=0.000) was associated with lower 6MWD. Induced sputum and PC20methacholine were not associated with 6MWD.

Conclusion: This study shows that increased sputum inflammation and BHR do not contribute to lower 6MWD in patients with moderate to severe COPD, yet markers of hyperinflation and health status are important determinants. A prospective analysis in this cohort will be performed to investigate if reduced inflammation causes less hyperinflation and improved exercise tolerance.

P2146

Variability in walking patterns during the 6MWT in COPD patients and healthy controls

J. Annegarn1, M.A. Spruit1, H.H.C.M. Savelberg2, C. van de Boe3, A.M.W.J. Schols4, E.F.M. Wouters4, K. Meijer1. 1Program Development Centre, Ciro, a Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 2Human Movement Science, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre, Maastricht, Netherlands; 3Respiratory Medicine, NUTRIM School for Nutrition, Toxicology and Metabolism Maastricht University Medical Centre, Maastricht, Netherlands; 4Division of Exercise Science, University of Groningen, Groningen, Netherlands.

Aim: To assess if sputum inflammation and BHR contribute to functional exercise capacity (assessed by 6-Minute Walk Test (6MWT)) next to lung function, health related quality of life (HRQL) and health status in COPD.

Methods: 108 COPD patients (COLD stage II & III) participating in the GLUCOLD study [1] (81% male, median (range) FEV1%pred 64% (41-78), mean (sd) 6MWT-distance (6MWD) 551 meter (74)). *: p<0.05

The model explained 84% (healthy) and 78% (COPD) of the variance in 6MWD. IMA and height were the only predictors of the 6MWD for healthy subjects but for COPD patients also age, SF, VC, AC-ML and AC-V contributed significantly (10%) to the variance in 6MWD

254. Clinical physiology for clinical problems
COPD patients use different walking strategies during the 6MWT than healthy control subjects which could be due to adaptations of both pulmonary and systemic impairments.

P2146
Exercise testing in the pre-flight evaluation of patients with cystic fibrosis
Elisabeth Edvardsen1, Aina Akerø1, Jorunn Homme1,2, Ole Henning Skjønsberg1,1, Bjørn Skrede1,2,1.1 Department of Pulmonary Medicine, Oslo University Hospital, Ullevål, Oslo, Norway; 2National Center for Cystic Fibrosis, Oslo University Hospital, Ullevål, Oslo, Norway; 3Faculty of Medicine, University of Oslo, Oslo, Norway

Background: Due to hypoxic hypoxia, air travel may imply a health hazard for cystic fibrosis (CF) patients. Studies of other lung patients have suggested that exercise testing might help predicting in-flight hypoxemia. The aim of the present study was to identify pre-flight factors that might predict severe hypoxemia during air travel in adult CF-patients.

Methods: 30 CF-patients (20 patients, age 34±12 yrs, FEV1 59±25% pred (mean ± SD) participated in the study. Lung function tests, pulse oximetry (SpO2 level), arterial blood gas (PaO2 level), and a Hypoxia Altitude Simulation Test (HAST) breathing 15% oxygen were performed. In addition, 14 of the patients participated until exhaustion on a treadmill measuring PaO2, SpO2, maximal oxygen uptake (VO2max) and assessment of ventilation-perfusion mismatch defined as high V̇e/V̇CO2 at anerobic threshold.

Results: Five patient fulfilled criteria for supplemental oxygen during air travel based on BTS recommendations (PaO2 < 6.6 kPa or 50 mmHg). They all had FEV1 < 50% of predicted. Ten patients with a FEV1 < 50% of predicted had a negative HAST. The correlation between PaO2HAST and the following pre-flight variables were: SpO2max: r = 0.25 (p=0.23), SpO2rest: r = 0.515 (p=0.006), FEV1: r = 0.544 (p=0.002), PaO2HAST: r = 0.582 (p=0.001). The correlation between PaO2HAST and exercise variables was: VO2max: r = 0.638 (p=0.014), VE/VO2: r = 0.76 (p=0.001), PaCO2: r = 0.817 (p=0.001) and PaO2rest: r = 0.835 (p=0.001).

Conclusion: Exercise testing with measurement of oxygen desaturation and VE/VO2 may be useful tools in predicting the need for supplemental oxygen during air travel if HAST is not available.

P2147
Changes in operating lung volume and symptoms during daily activity in COPD
Daniela Savi1, Sandy Jack2, Paul Albett2, Peter Calverley2,1. 1Department of Clinical Medicine, Sapienza University of Rome, Rome, Italy; 2Department of Inflammation and Respiratory Medicine, University of Liverpool, Liverpool, Merseyside, United Kingdom

Patients with COPD perform lower levels of daily physical activity and breathlessness and leg fatigue are symptoms limiting exercise. Less is known about symptoms and hyperventilation measured during laboratory exercise testing relate to daily activity.

We studied 20 stable COPD patients (15 male, mean (SD) age 67 (7) yrs, FEV1 0.96 (0.4) l, 36 (12)% predicted, IC 1.7 (0.4) l, 52 (16)% predicted during a time-limited endurance exercise test at 70% VO2 max. IC, dyspnoea and leg fatigue on a Borg scale were recorded every 2 minutes. We calculated the individual slope of the change in these variables expressed as IC absolute.

We assessed daily physical activity using both Actiwatch (AW) and SenseWear (SW).

There was a good relationship between AW mean activity score and AW mean activity moving (r²=0.7, p<0.01) and a close relationship between SW step count and AW mean activity score (r²=0.48, p<0.01). We found a good relationship between the AW mean activity score and the rate of increase of dyspnoea (r²=0.5, p<0.05) but no correlation between AW mean activity score and the rate of rise of leg discomfort (r²=0.2, p>0.05).

แปล

Aktivity levels measured by these devices are similar and data registered with the same uniaxial leg accelerometer give similar level of daily activity. Baseline level of hyperventilation did not predict daily activity and the individual’s perception of breathlessness as lung volume rises is the important factor limiting daily activity. Changes in symptoms related to peripheral muscle dysfunction did not limit the daily activity in our COPD patients.

P2148
The transfer coefficient predicts the endurance increment when oxygen is given in COPD and lung fibrosis
Dominic Dellweg, Peter Hadli, Brigitte Pape, Dieter Koehler. Pulmonology, Critical Care and Sleep Medicine, Kloster Grabfeld, Schmallenberg, NRW, Germany

Background: Some but not all patients with COPD or interstitial lung disease (ILD) increase their endurance performance when supplemental oxygen is given.

Rationale: To find parameters that better predict oxygen response.

Method: We measured the effect of oxygen supplementation on the six-minute walking test performance (6MWD) in 59 COPD and 13 ILD patients. We compiled prediction models by means of multiple stepwise linear regression analysis.

Results: The percentage change in 6MWD was best predicted by the diffusion capacity, both in COPD (r = -0.43, p=0.0003) and ILD (r=0.75, p=0.001). The same applies for the absolute change in 6MWD in COPD (r = -0.44, p=0.0002) and ILD (r=0.71, p=0.002) patients.

Conclusion: The diffusion capacity appears to be the single best parameter to predict endurance response to oxygen in COPD and ILD and therefore might be used as a screening tool to select appropriate patients.

P2149
Impact of hemodialysis on dyspnoea in chronic renal failure patients
Anastasios Palamidas1, Sophia-Antiopi Gennimata1, Fotini Karakontaki1, Georgios Kaltsakas1, Anna G. Tezanos2,1. 1Department of Internal Medicine, “Sotiria” Hospital, Athens, Attika, Greece; 2Meakins-Christie Laboratories, McGill University Health Center, Montreal, QC, Canada

Scarc reports exist on the symptom of dyspnoea in chronic renal failure patients. The aim of our study was to investigate the prevalence and severity of chronic dyspnoea in these patients and whether the severity of dyspnoea is different before and after hemodialysis. We recruited 25 patients with stage 5 (GFR<15ml/min) renal failure with (mean±SD age = 52±11 years, mean±SD duration of dialysis = 5±4 years, urea = 141±26 mg/dl, creatinine = 10±2 mg/dl. None of the patients suffered from any concomitant pulmonary disease. We used the modified (m) MRC scale to assess chronic dyspnoea. Routine lung function tests in seated and supine positions, closing volume (CV) with the single breath oxygen test, blood gases, Pimax, Pemax, P0.1, pattern of breathing were also measured. All of our patients (100%) complaint of some degree of dyspnoea before dialysis, which was significantly reduced after dialysis. The parameters that changed before and after dialysis were: Δ(mMRC) F= -0.5, (p<0.001), ΔWV6 pred, t= -3.1, (p<0.001), ΔHE (0.1±0.5, p<0.001), ΔTimaxpred (33.8, p<0.001), ΔCCC% predicted (0.2±4, p=0.032), and ΔPO1 (<240, p<0.001) cm H2O. Backwards regression analysis showed that the only single factor changed significantly after dialysis and correlates with Δ(mMRC) and ΔPO1 (r = 0.527, p<0.01). We conclude that hemodialysis improves dyspnoea by reducing central respiratory drive in patients with renal failure.

P2150
Effects of oxygen on exertional dyspnoea and exercise performance in patients with COPD
Kisuke Miki, Ryoji Maekura, Toru Hiraga, Hisako Hashimoto, Seigo Kitada, Mari Miki, Kenji Yoshimura, Yoshitaka Takeishi. Department of Internal Medicine, National Hospital Organization Toneyama National Hospital, Toyonaka, Osaka, Japan

Background: Accumulation of studying the oxygen (O2) response in chronic obstructive pulmonary disease (COPD) should provide important clues to the pathophysiology of exertional dyspnea. We investigated the exercise responses of hyperoxia on the dyspnea profile, as well as cardio-pulmonary, acidotic and sympathetic parameters in 35 patients with stable COPD.

Methods: The patients breathed 24% O2 or compressed air (CA) in random order during two incremental cycle exercise tests.

Results: The PaO2 and PaCO2 values were higher (P < 0.0001 and <0.05, respectively) at each exercise point while breathing 24% O2 compared with CA. At a standardized point in time near peak exercise, O2 reduced plasma lactate (P < 0.01). A similar peak minute ventilation/indirect maximum voluntary ventilation was observed between inhalations. At peak exercise, the dyspnea score, pH, and plasma norepinephrine were similar between inhalations. At each inhalation during exercise, the dyspnea - ratio (%) of the Δ oxygen uptake (peak minus resting oxygen uptake) curve reached a peak point that occurred at a similar exercise point between inhalations.

Conclusion: Breathing CA or hyperoxia, COPD patients did not develop ventilatory compensation for the exercise acidosis to stop exercise, re-

380s Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
The atmospheric pressure in cabin of the pressurized commercial aircraft is not equivalent to the pressure at sea level. If this hypobaric environment doesn’t trigger symptoms in most of people, the same is not true for patients with respiratory disease. Since the increase of air travel and the need to advise the patients to this particular setting, British Thoracic Society (BTS) has published recommendations to evaluate and prescribe supplemental oxygen in these conditions.

The present study describes 2 years’ experience in advice respiratory patients on flight fitness in Hospital Santa Maria.

During this period, 64 patients were evaluated (54% men, mean age 46±21 years) and underwent Hypoxia Challenge Test (HCT) with a protocol in agreement with BTS guidelines.

Physiological responses to the six-minute walk test in older adults

Vitor Dourado1, Ricardo Guerra1, Leticia Antunes2, Suzana Tanni3, Irma Godoy3.

Department of Health Sciences, Federal University of São Paulo (UNIFESP), São Paulo, Brazil; 2Rehabilitation Section, Botucatu Medical School (UNESP), Botucatu, Brazil; 3Department of Internal Medicine, Botucatu Medical School (UNESP), Botucatu, Brazil

Physiological responses to the six-minute walk test (6MWT) have been increasingly evaluated in patients with cardiopulmonary diseases. However, previous studies did not include healthy persons. The aim of this study was to evaluate age- and gender-related changes in physiological responses to the 6MWT and to establish a list of predictive equations for such variables. We evaluated 102 non-trained healthy older adults (48 men, aged 62±8) stratified in four age groups (40-49, 50-59, 60-69; ≥70). After familiarization, a third 6MWT was performed using a treadmill analyzer (k522) for assessing metabolic and cardiolpulmonary responses as well as oxygen uptake (VO2) time constant (tau) by an exponential fitting. Lean body mass (LBM) (impedance) and handgrip strength (HGS) were measured in 81 subjects. A set of linear equations was provided for prediction of the main physiological variables. The rate of gas exchange (Ri), VO2/heart rate (HR), deficit-VO2 and tau-VO2 were not affected by sex as well as total volume (VT); R and VO2/HR were not affected by age. Deficit-VO2 and tau-VO2 presented a tendency to age-related changes (p = 0.06). Several prediction equations adjusted by sex, age, height, weight, LBM, HGS, and 6MWT showed R2 values ranging 0.114 to 0.574 (e.g. deficit-VO2 and VT respectively). The best model for predicting VO2-peak was adjusted by LBM and age (R2=0.435). None of the variables studied was selected as predictive factors for tau-VO2. Therefore the prediction equations might provide a more appropriate frame of reference for normal physiological responses to the 6MWT in healthy older adults. Our results may be useful for better interpretation of walking performance in patients with cardiopulmonary disease.

Functional and neurophysiological aspects in patients with chronic obstructive pulmonary disease

Carolina Rocco1, Luciana Malosá2, Roberto Stibrulson3, João Carlos Corrêa3.

1Department of Pneumology, Federal University of São Paulo, São Paulo, Brazil; 2Biodynamics of Movement Laboratory, Nova University, São Paulo, Brazil; 3Department of Pneumology, Santa Casa Hospital, São Paulo, Brazil

The neurophysiological alterations found in patients with chronic obstructive pulmonary disease (COPD) in combination with impairment of peripheral muscle, may further compromise functional activity of these patients. The purpose was to assess functional (balance and sit-to-stand test) and neurophysiological aspects (latency time the patellar and Achilles reflexes) relating these responses to the BODE Index. A cross-sectional study design was used to assess 22 patients with moderate to very severe COPD (>60 years) and 16 healthy volunteers as the control group (CG), performed measures of static and dynamic balance (pressure plate and Tinetti scale), monosynaptic reflexes (surface EMG), peripheral muscle strength (load cell) and SST. The inclusion criteria with COPD had a reduced reflex response to patellar 36.77±3.23 and Achilles reflex 43.54±6.60. Achieved a lower number repetitions on the SST 19.2±3.88, lesser peripheral muscle strength on the femoral quadriceps muscle, 24.98±6.88 and exhibit deficits in functional balance on the Tinetti scale 26.6±1.69, compared to the CG, all with p <0.05. The BODE Index demonstrated correlations with Tinetti scale, r = 0.59 (<0.05) and with the SST, r = 0.78 (p <0.05). The individuals with COPD had functional and neurophysiological alterations in comparison with control group. The BODE Index was correlated with the Tinetti scale and SST. Both are functional tests, easy to administer, low cost and feasible, especially the SST. The results suggest a worse prognosis; however, more studies are needed to identify the causes of these changes and the repercussions that could result in their activities of daily living.

Echocardiographic findings in severe chronic obstructive pulmonary disease

Javier Uribarri4, Álex Rodríguez1,2,3, Juan Carlos Correa2,3, Juan Antonio Mazzei1,2,3, Anna Barro4,5, Adriana Molina5,6, Jorge Lerman1,2, Oscar Grosso1,2,3, Juan Antonio Macho1,2,3, Carlos Gustavo Di Bartolo2,3, Maria Cecilia Cincotta7,8, Bernardo Lozada8, Ana Paula Vizzotto8, punti asiatici in cucina.

1Department of Medicine, Hospital of Clinics – University of Buenos Aires; 2C.A. Buenos Aires, Argentina; 3Pulmonary Section, Instituto Argentino de Diagnóstico y Tratamiento, C.A.Buenos Aires, Argentina

Objective: To study the relationship between clinical, functional and echocardiographic findings in severe COPD patients who desaturate during 6MWT.

In normal subjects, ventilatory rate and oxygen ventilation (VO2) increases during exercise from a resting state until maximal levels are attained, whereas it seems that in asthmatic patients this increase is higher. The aim of the study was to evaluate the kinetics of VO2 during a constant-load exercise in a group of 11-16 y.o. asthmatic patients. 17 adolescents with mild stable asthma were studied. On the first day a progressive workload was applied to calculate the presumable aerobic threshold, which was assumed to be 90% of the maximum load tolerated. On the next day the subjects were asked to pedal at this constant load and the VO2 kinetics were studied using a k422 and a Cosmed® cyclogyrometer. In 9 patients (53%) there was an increasing trend of VO2 consumption, whereas in 5 (28%) this trend was not highlighted. In 3 patients (18%) data was unobtainable because of incompletion of test or non-cooperation. In conclusion, it was not possible to outline a common pattern of VO2 consumption, but in more than a half of our patients the behaviour of VO2 consumption during constant load was similar to that of the normal population.
Activity monitor outcomes in COPD – Assessment of variability of 6 monitors as part of the MJPI Reactive project

Zaferis Louvaris, Daniel Langer, Santiago Giavedoni, Yorgis Raste, Hans Van Remoortel, Eloisa Maria Gatti Regueiro, Frederick Wilson, Ioannis Vogiatzis, Nicholas Remoortel, Mario H. Rahnbohm, Barry Kiplinger, Thierry Troosters, Graeme MacIntyre, Daniel Langer, Richard Dekhuijzen

Department of Critical Care Medicine and Pulmonary Services, National and Kapodistrian University of Athens, Thora" son Foundation, Athens, Greece Faculty of Kinesiology and Rehabilitation Sciences, Katholieke Universiteit Leuven, Belgium Physical Therapy Department, University of Federal de São Carlos (UFSCar), Sao Paulo, Brazil Respiratory Medicine, Laboratorio Broncopulmonar, Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile

Methods: We aimed to study the accuracy of 6 different activity monitors and their outcomes and their capability to detect less active days during Sundays, known to be less active days.

Results: We found a significant association between 6MW distance and 6MW SW (r=0.74; p<0.01), between 6MW and G2 saturation in the first minute walk (r=0.63; p=0.04). We also found a significant association between 6MW distance and COPD-SE (r=-0.39; p=0.08). No significant association between COPD-SE and GOLD and GOLD, FVC, MEP, MIP, DLCO, Tei Index, or basal SpO2 were observed.

Conclusion: We found a significant association between 6MW distance and COPD-SE. Additional studies are needed to confirm these results.

Results: Groups were similar in age, BMI, sex. Patients with severe SUBIMP had worse lung function, lower activity levels and more DH during ADL compared to patients with low SUBIMP (Table 1). Five of 15 patients with low SUBIMP showed DH during ADL, in contrast to 13 of 14 patients with severe SUBIMP (p=0.002). SUBIMP correlated with amount of DH during ADL (r=0.52, p=0.004) and physical activity level (r=-0.41, p=0.028).

Table 1. Patient characteristics and response to ADL

Mean ± sd; *p<0.05 compared to Low SUBIMP ADL. Activity of daily life; DH: dynamic hyperinflation; FEV1: forced expiratory volume in 1sec; FVC: forced vital capacity; IC: inspiratory capacity; SUBIMP: subjective impairments; YM1: vector magnitude units.

Conclusion: Patients with severe SUBIMP show more DH during ADL. DH during ADL might increase breathing effort, which could play a role in the decrease in activity level observed in patients with COPD.

Methods: 18 GOLD 3-4 patients who desaturated during 6MW (SpO2<90%) were studied with pulmonary function tests and Doppler echocardiography, measuring tricuspid insufficiency peak speed and estimating systolic pulmonary arterial pressure (PAP) taking 35 mmHg as cut off to define pulmonary hypertension. Fisher’s exact test and t test of Mann-Whitney were used to compare numeric variables. Spearman correlation coefficients were calculated. p<0.05 was considered significant.

Results: Eight female and 10 male were studied, mean age 61.8±8 yrs, mean BMI was 24.75 (5) kg/m², mean FVC was 2.85±0.8, mean DLCO 45.5% (range=31-94), mean walked distance 315 m (range=120-480), the mean systolic PAP was 32.25±8.88 mmHg and 16/18 presented systolic PAP hypertension. Mean systolic PAP was 26.12 mmHg in 8 patients with BODE 2-4 and 37.37 mmHg in 10 patients with BODE 5 (p=0.0312).

No significant association between systolic PAP and GOLD, FVC, MEP, MIP, DLCO, Tei Index, or basal SpO2 were observed.

There was no significant association between 6MW distance and systolic PAP (r=0.41; p=0.048) or between DLCO and G2 saturation in the first minute walk (r=0.39; p=0.048).

Conclusions: We found a significant association between systolic PAP and BODE. Trends without significant association with systolic PAP and GOLD were observed. Further studies are needed to confirm these results.

P2157

Dynamic physical activity (DPA) level is an increasingly important clinical outcome in COPD research and management. In contrast to exercise capacity, the association of DPA with muscle function, health status and fatigue, has not been investigated extensively.

Aim: To investigate if DPA is associated with muscle function, health status and fatigue in severe COPD patients.

Methods: In a cross-sectional analysis we included 84 COPD patients (49 male, GOLD D1 (n=25), D2 (n=25), D3 (n=32), IV (n=22), mean age 59±11 years, FEV1 46±18% pred) who were entering a pulmonary rehabilitation program. DPA was measured with a pedometer (DigiWalker SW-200), muscle force with a handheld dynamometer and muscle endurance with the chair-stand test and the arm-curl test. Health status was assessed with the Groningen Activity Restriction Scale (GARS), Saint George Respiratory Questionnaire (SGRQ) and RAND-36, and fatigue with the Dutch Exertion and Fatigue Scale (DEFS).

Results: Mean DPA was 3302±2098 steps/day. Significant Spearman’s correlation (r=0.39) was demonstrated in Oxygen, Power and Cardiac variables at AT and ME.

Conclusion: Low DPA associates with lower muscle force and endurance, low physical functioning in mild to very severe COPD patients. Whether these variables contribute to the development of a low DPA level in COPD patients should be investigated in longitudinal studies.

Cardiopulmonary stress test: Determinations of oxygen consumption, power and cardiac variables at ventilatory threshold. Correlation with values at maximal exercise in COPD

Iván Caviedes, Rodrigo Soto, Paulina Gómez, Laboratorio Broncopulmonar, Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile

Background: In normal individuals a direct correlation exists between Oxygen consumption (VO2) and Power (W) measured at ventilatory threshold (AT) and maximal exercise (ME).

Purpose: To simplify cardiopulmonary stress test in COPD patients, demonstrating correlation of Oxygen, Power and Cardiac variables at AT and ME.

Methods: Prospective study of 44 COPD patients, mean age 63, mean FEV1 73.2%, mean FEV1/FVC 63.6% and mean DCO 56% of predicted. Cardiopulmonary stress test was performed calculating W, VO2, HR, VO2/HR, 3DVO2/W and reduction in Inspiratory Capacity (IC). Lineal regression was calculated between values at AT and ME.

Results: Patients ended the test due to dyspnea (Borg 5), reduction of Breathing reserve and IC (17%, -0.33L respectively). Mean Wmax, VO2max and AT of 74%, 85% and 50% of predicted respectively. Close correlation was demonstrated between VO2 and Power measured at AT and ME (r: 0.7 and 0.7 respectively), and between maximal HR and VO2/HR (r: 0.7 and 0.8 respectively).

Conclusions: A straight correlation was demonstrated in Oxygen, Power and Car-

Heterogeneous causes and degree of exercise limitation in COPD GOLD I and 2: Predictive value of CCQ and MRC
Frans Krouwels, Willemien Thijs. Pulmonology, Spaarne Hospital, Hoofddorp, Netherlands.

In COPD severity of disease is assessed with spirometry and dyspnea score such as CCQ (Clinical COPD Questionnaire) or MRC (Medical Research Council). Dyspnea scores and spirometry are poorly correlated, dyspnea may also be the result of other, not pulmonary, aspects, especially in COPD GOLD I and 2.

Questions: 1. What is the predictive value of CCQ and MRC with respect to the degree and cause of exercise limitation in patients with COPD 2. Which factors predict a pulmonary limitation?

Methods: 60 symptomatic COPD patients in a stable phase without relevant co-morbidity. At baseline they scored CCQ and MRC. A score of > 2 was considered abnormal dyspnea (D+), others were D-. Exercise limitation in a cardiopulmonary exercise test was labelled pulmonary (pulm), cardiac (card) or nonspecific (nonspec).

Results:

<table>
<thead>
<tr>
<th></th>
<th>D-</th>
<th>D+</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCQ</td>

<td>&lt;0.001</td>
</tr>
</tbody>
</table>

Conclusions: In COPD patients GOLD I and 2 exercise limitation was not due to pulmonary factors in 86% and 43% of patients, respectively. Pulmonary or cardiac limitation can be expected at high CCQ or MRC score, and can not be excluded in patients with a low score.

P2162
The impact of anemia of chronic disease on exercise capacity among patients with chronic obstructive pulmonary disease
Afruddi Boutou1, Georgia Pistou1, Ioannis Stanopoulos3, Theodoros Kontakos2, Kyriazis George2, Nikolaos Chavouzis1, Chrysanthi Nakou1, Lazaros Sichletidis1, Paraskavi Argypoulou1, Christos Tsagarakis1, Christos G. Gogos2, 3. Respiratory Failure Unit, “G. Papanikolaou” Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 3. Department of Pulmonology, “G. Papanikolaou” Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Background: The presence of anemia has been associated with reduced performance in 6 minute walk test among patients with Chronic Obstructive Pulmonary Disease (COPD).

Aim: To investigate, for the first time, the impact of Anemia of Chronic Disease (ACD) on exercise capacity among COPD patients, utilizing cardiopulmonary exercise testing (CPET).

Methods: It is a case-control study. Cases (27 stable COPD outpatients who were identified to fulfill clinical and laboratory criteria of ACD) and 27 matched by age, height, sex, FEV1, and current smoking status non-anemic stable COPD patients underwent maximal CPET. Student’s T-test for independent samples was used for statistical comparisons between the groups; level of p<0.05 was considered significant.

Results: Cases (92.6% males; 64.8±7.8 years old, FEV1 % predicted=42.8±12.8) compared to controls (92.6% males; 65.3±7.2 years old, FEV1 %predicted=42.8±12.8) achieved lower: a) peak%predicted oxygen uptake (59.5±17.2 vs 71.3±11.9, p<0.01), b) peak work rate (67.5±24.9 vs 86.1±24.9 watts; p<0.05), c) peak%predicted work rate (54.9±21.6 vs 68.7±20.8; p<0.05), d) peak oxygen pulse (8.5±4.2 vs 10.4±2.9 ml/mins; p<0.05) and e) peak%predicted oxygen pulse (69.1±1.73 vs 82.4±18.2; p<0.01). There was also a trend for a lower%predicted aerobic threshold (>90±62%) in the group of cases. Rest gas exchange values and exercise parameters indicative of respiratory limitation (such as peak minute ventilation, peak respiratory rate and tidal volume to inspiratory capacity ratio) did not differ between the groups.

Conclusions: The presence of ACD significantly impairs the exercise capacity of COPD patients.

P2163
Tests of an intra-dialytic aerobic training program on oxygen uptake kinetics in patients with end-stage renal disease
Maycon Reboredo2, 4, J. Alberto Neder3, Bruno Pinheiro3, Diane Henriques3, Ruitser Faria1, Rorgério Paula2, 4. Núcleo Interdisciplinar de Estudos e Pesquisas em Nefrologia (NIEPEN), Federal University of Juiz de Fora, Juiz de Fora, Minas Gerais, Brazil; 2. Campus São João do Rei, Federal Institute of Education, Science and Technology of Southeast of Minas Gerais, São João do Rei, Minas Gerais, Brazil; 4. Pulmonary Function and Clinical Exercise Physiology Unit (SEFICE), Federal University of São Paulo, São Paulo, Brazil; 5. Federal University of Juiz de Fora, Division of Pneumology, Juiz de Fora, Minas Gerais, Brazil.

Background: End-stage renal disease (ESRD) is associated with several hemodynamic and peripheral muscle abnormalities that could slow the rate of change in oxygen uptake (VO2) at the onset and at the end of dynamic exercise. We therefore investigated the effects of supervised aerobic training during hemodialysis on the VO2 on- and off-kinetics in ESRD patients.

Methods: Twelve patients and 12 age- and gender-matched, non-trained patients underwent an incremental and constant load cardiopulmonary exercise tests by using a stationary cycle; three times a week.

Results: Training significantly accelerated VO2 kinetics (t decreased from 62.5±19.6 s to 45±12.6 s) and reduced O2 deficit at the onset of a sub-anerobic threshold (AT) exercise test (p<0.05). At a supra-AT test, t decreased from 52.9±17.4 s to 40±13.8 s (p<0.05) and time to exercise intolerance increased significantly (311±223.4 s vs. 589±235.8 s). Significant positive effects of training were observed at the off-exercise transient in both sub- and supra-AT tests (t=75±16.4 s vs. 66±20.8 s and t=73±20.4 s vs. 59±12.8 s, p<0.05, respectively). In contrast, VO2 on- and off-kinetics were significantly slower at the final evaluation in the non-trained patients (p<0.05).

Conclusions: A 12-week supervised aerobic training program was highly effective in accelerating on- and off-exercise VO2 kinetics at both moderate and severe exercise intensity domains in ESRD patients undergoing hemodialysis.

P2164
Influence of gas concentration and measurement interval on the reproducibility of non-invasive cardiac output determination by inert gas rebreathing in pulmonary healthy patients
Fredrik Tenkman, Matthias Sampaio, Ursula Hoffmann, Martin Borggreve, Jens J. Kaden, Joachim Saur. 1st Department of Medicine, Universitätmedizin Mannheim, Mannheim, Germany.

Background: Cardiac output (CO) is an important physiological parameter. In recent comparative studies non-invasive inert gas rebreathing (IGR) showed promising results. The aim of the prospective study was to evaluate the influence of gas concentration and measurement interval on the reproducibility.

Methods: We performed four series with two measurements for a gas bolus of 7.5%, 10%, 15% and 20% in supine position, respectively, and at intervals of 2 or 5 minutes. To rule out ventilation and diffusion disorders a bodyplethysmography was performed.

Results: A total of 384 measurements could be performed in 48 subjects, in 34 with an interprocedural interval of 5 minutes and in 14 of 2 minutes. For a fraction of 7.5% and an interval of 2 minutes we found a reproducibility of -0.8±1.1 l/min compared to 5 minutes with ±0.1±0.6 l/min (p<0.001). Rising gas concentration improved the reproducibility, for an interval of 5 minutes and a 20% gas bolus fraction no statistically significant clinical value was detected (p=0.88).

Conclusions: With an interval of 5 minutes a good reproducibility of the IGR measurements could be shown for all gas bolus fractions. For an interval of 2 minutes and low gas concentration we found a statistically significant reduced reproducibility. Using a 20% gas bolus the reproducibility reached the results of those of the 5 minute interval. This is particularly interesting for the determination of CO with a given small time frame, e.g. during spirometry. For the final assessment, however, additional studies with patients suffering from lung diseases are needed.
The hypotensive saline challenge (HSC) is a commonly used diagnostic tool to assess arterial baroreflex (AHR) and vocal cord dysfunction (VCD). Dyspnoea during testing is not uncommon and we postulated that oxygen desaturation may be a causative factor.

**AIM:** To document the degree of arterial desaturation during saline challenge and compare SpO2 changes in AHR, VCD and negative responses.

**METHODS:** SpO2 (Nellcor N595) was continuously recorded during 78 consecutive HSCs. SpO2 data was averaged over 32 seconds and minimum values used for analysis. Change in dyspnoea score (Borg) during the challenge was also recorded. Results were classified as AHR (change in FEV1 >15%), as VCD (change in MIF ≥20%) or negative otherwise.

**RESULTS:** Mean (SD) FEV1 was 86 (15%) predicted for AHR (n=20), 92 (18%) for VCD (n=18) and 94 (18%) for negative results (n=40). There was a consistent trend in SpO2 for all subject groups with significant desaturation during the final doses of saline and bronchodilatation (ANOVA p<0.001), and consistent resaturation during spirometric efforts. Mean (SD) maximum falls in SpO2 of 4.3% (2.7) were observed for AHR. 4.1% (2.0) for VCD and 4.4% (2.7) for negative results. There was no relationship between change in dyspnoea and degree of desaturation (p=0.43).

**CONCLUSION:** Hypotonic saline challenge causes a significant and reproducible pattern of arterial desaturation irrespective of the test response. These data would be consistent with progressive hyperventilation during HSC rather than indicating desaturation due to worsening ventilation-perfusion mismatching. Hypoxaemia does not appear to be the primary cause of dyspnoea during HSC.

A randomised cross-over clinical testing of portable oxygen concentrators in patients with COPD

Annabelle Couillard, Dan Veale, Didier Forest, Boris Melloni, Philippe Sauder, Jean-François Muir. Maison du Pommier, Fédération ANTADIR, Paris, France

Portable oxygen concentrators (POC) deliver oxygen via intermittent demand valves (IDV). These merit comparison with standard continuous flow oxygen (CFO). We have performed a multicenter comparison of 4 POC in a cross over study in 74 patients with COPD (age 67±10, FEV1=41±20% predicted). Each patient tested one of 4 POC at rest and during a six minute walk test (6MW), with oxygen saturation recording (SpO2). Noise and discomfort were evaluated by visual analogue scales (VAS).

**RESULTS:** Mean 6MW distance was 388±114 with POC and 315 ±111±111 with CFO (p<0.06). However the distance walked with POC was clinically significantly less by (>10%) than CFO in 23% of patients and significantly better than CFO (by >10%) in 13.5% of patients. Dyspnoea during 6MW by VAS was identical for both types of device. 55.5% of patients had SpO2 fall with both devices and 27% no fall in SpO2. 33.5% had SpO2 fall with POC alone and 4% with CFO alone. Overall patients appreciated the POC because of security of oxygen supply. However, they judged POC oxygen delivery significantly less amenable and noisier than CFO.

**CONCLUSION:** 4 POC devices with demand valve oxygen delivery had similar efficacy to CFO devices but were noisier and less comfortable. Prescription of such devices needs to be individualized as regards settings for O2 delivery and patient comfort and lifestyle.

**P2167**

The compensatory mechanisms of loaded and unloaded breathing in exercising men

Marina Segizbaeva. Laboratory of Respiration Physiology, I.P. Pavlov Institute of Physiology RAS, S.-Petersburg, Russian Federation

To characterize the ventilatory responses to the resisting load or unloading, we studied the effect of breathing 79% helium – 21% oxygen (He-O2), 79% argon – 21% oxygen (Ar-O2) and 79% SF6 – 21% oxygen (SF6-O2) on the volume-time parameters, PETCO2, mouth pressure (Pml), work of breathing (Wb), central inspiratory activity (dP/dtI) and electromyographic activity of parasternal muscles in 10 normal subjects at rest and during 3 min steady-state exercise. There were no significant changes in tidal volume (VT), breathing frequency (f), inspiratory (TI) and expiratory (TE) durations, minute ventilation (VE) and PETCO2 when air was replaced by He-O2 or SF6-O2 at rest. VE and PETCO2 were not significantly different after replacement of air by He-O2 or SF6-O2 during exercise. However inhalation of He-O2 decreased in VT and increased in f, whereas inhalation of SF6-O2 led to opposite effects compared with air during exercise. Both at rest and during exercise, Pml, Wb, dP/dtI and EMGs were significantly less during He-O2 breathing and higher during SF6-O2 breathing from the first respiratory cycle after room air was replaced by He-O2 or SF6-O2. Ar-O2 breathing did not affect on time-volume parameters both at rest and during exercise compared with air. The increase in Pml, Wb, dP/dtI was observed at Ar-O2 inhalation during exercise relative to air. We conclude that internal resistive loading or unloading breathing changes the neuromuscular output required to maintain constant ventilation. The mechanisms of load or unloading compensation seem to be mediated by different im- plication in lung and respiratory muscle receptors as well as due to segmentary level reflexes and properties of the muscle fiber itself.
Results: Left ventricular end diastolic volume index in CBI correlated with echo-cardiography measurements in both M-Mode (r=0.6181; p<0.002) and B-Mode (Simpson, r=0.8431; p<0.001). Also the Stroke index in CBI correlated with the estimated stroke index in M-Mode (r=0.7077; p<0.001) and B-Mode (Simpson, r=0.7946; p<0.001).

Conclusions: In patients with IPAH or CTEPH, cardiac bioimpedance might be a useful tool to monitor left ventricular hemodynamics including left ventricular preload and cardiac output.

P2170

Relationship between pulse transit time and blood pressure during cardiopulmonary exercise tests

Thomas Wilmer, Cornelia Kroep, Kathrin Stoiber, Stefan Ruediger, Martin Lanzinger, Wolfgang Rothbauer, Christian Schumann. Department of Internal Medicine II. University of Ulm Medical Center, Ulm, Baden-Wuerttemberg, Germany

Introduction: Pulse transit time (PTT), the interval between ventricular electrical activity and peripheral pulse wave, is generally assumed to be a surrogate marker for blood pressure changes. Although recent studies have affirmed the potential use of PTT in the diagnostic of sleep disorders and the monitoring of psychophysiological stress, little work has been published on the effect of physical exercise on PTT and results have been inconsistent.

Aims: To analyse PTT and its relation to blood pressure during cardiopulmonary exercise tests.

Methods: In 20 patients (mean age 51 ± 14 yrs, range 18-82) in a cardiopulmonary unit, ECG and finger-photoplethysmography were continuously recorded during routine cardiopulmonary cycle exercise tests. PTT was calculated for each R-wave in the ECG and the corresponding steepest upstroke in the photoplethysogram. For each subject the resulting PTT-curve was averaged in order to compensate sample rate and movement-associated variation, and values were compared to systolic (sBP) and diastolic blood pressure (dBP) in 9 predefined measuring points including measurements at rest, during increasing and maximum exercise as well as during the recovery period.

Results: Mean sBP and PTT at rest were 127 mmHg and 372 ms respectively, 197 mmHg and 287 ms under maximum exercise, and 132 mmHg and 365 ms during recovery. All subjects showed a significant, strong negative correlation between PTT and sBP (mean r = 0.97, range -0.99 to 0.93, p < 0.0001 to 0.015). The correlation between PTT and dBP with mean r = 0.41 (range 0.87 to 0.76, p=0.035 to 0.83) was rather weak.

Conclusions: These results indicate that PTT is a good potential surrogate measure for sBP during exercise.

P2171

Estimation of the ventilatory compensation point by the minute ventilation and heart rate relationship during exercise at high altitude

Gabriele Valli1, Paolo Onorati1, Dario Martolini 1, Alessandro Ferrazza 1, Gabriele Valli1, Paolo Onorati 1, Dario Martolini 1, Alessandro Ferrazza 1, Annalisa Cogo2, Paolo Palange1. 1Respiratory Pathophysiology, Department of Public Health and Infectious Diseases, University of Rome "La Sapienza"; Rome, Italy; 2Clinical and Experimental Medicine, Section of Respiratory Disease, University of Ferrara, Ferrara, Italy

We previously demonstrated that changes in the slope (∆) of increment in minute ventilation over heart rate (∆VE/∆HR) can be utilized for the detection of the ventilatory compensation point (VCOP) during incremental exercise at sea level (SL) (Onorati P, EustapioPhysiol, 2006). We hypothesized that the influence of hypoxic conditions, such as at high altitude (HA), on the VE and HR responses do not compromise VCOP detection using the ∆VE/∆HR ratio.

Methods: Six healthy subjects (42±14SD yrs) performed, on immediate ascent to M (Ex2), data of only 24 subjects are available, (5 AMS+; 19 AMS-) from Alagna (A), 1200m, to Capanna Regina Margherita (M), 4559m, with an overnight stay in Rifugio Gnifetti (G), 3647m.

To study the hypoxic profile and the AMS development during the ascent to M (Ex2) to reach G.

Introduction: Early desaturation during acute simulated HA exposure is significantly related to AMS+ group had a significantly lower SpO2 at rest and during HA exposure AMS+ group had a significantly lower SpO2 at rest and during HA exposure.

Conclusions: These results indicate that PTT is a good potential surrogate measure for sBP during exercise.

P2172

Lung diffusion at high altitude during exercise in high- and lowlanders

Maria Overbeck1, Jean-Benoit Marinot2, Claire De Bisschop3, Cristina Escotis4, Sofia Beloksa4, Herman Gropenhoff5, Mart Van der Plas5, Francisco Villafuerte6, Jose Luis Macarlupu5, Robert Narjie5, Herve Guenard8.

Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2Department of Pneumology, OnzE Lieve Vrouwe Hospital, Amsterdam, Netherlands; 3Laboratory of Physiologic Adaptations to Physical Activities, Poitiers University, Poitiers, France; 4Reparto di Fisiopatologia Respiratoria, Università degli Studi, Bari, Italy; 5Department of Pathophysiology and Cardiology, Erasme University Hospital-Free University of Brussels, Brussels, Belgium; 6Pulmonary Diseases, OnzE Lieve Vrouwe Hospital, Amsterdam, Netherlands; 7Laboratoire de Physiologie Comparée, Faculté de Sciences et Philosophie, Universidad Peruana Cayetano Heredia, Lima, Peru; 8Laboratory of Physiologie, Medical Faculty, University of Bordeaux, Bordeaux, France

Introduction: Both the membrane (DM) and the capillary (VC) component of lung diffusing capacity (DL) have been shown to be increased in high altitude residents and to remain essentially unchanged in high altitude sojourners. Maximal exercise has been reported to decrease DM at sea level (Manier 1993). The effects of high altitude exercise on DM and VC as evaluated from the DL for carbon monoxide (DCO) and nitric oxide (DLNO) respectively, are incompletely understood.

Methods: Lowlanders (n=10) and highlanders (n=14) were tested at 3380m above sea level (Cerro de Pasco, Peru); lowlanders also underwent tests at sea level. Spirometry, alveolar volume (VA), DCO, DLNO. and VC were assessed (Hy-percaptop Medinof, Belgium) using the NOCO transfer technique. Values were corrected for PaCO2 and Hb and are presented as mean predicted value (Aguilaniu 2008) ±SEM. Measurements took place at rest and after an endurance test at 80% of VO2 max at heart rate returned to rest values.

Results: Spirometry was normal in all subjects. Hb nor SaO2 at rest were significantly different between the groups.

As regard the ascent to M (Ex2), data of only 24 subjects are available, (5 AMS+; 19 AMS-) from Alagna (A), 1200m, to Capanna Regina Margherita (M), 4559m, with an overnight stay in Rifugio Gnifetti (G), 3647m.

H: highlanders, L: Lowlanders; E= endurance; *p<0.05 vs H; †p<0.05 vs. pre- vs. post-exercise.

At sea level, lowlanders did not demonstrate alterations in diffusion parameters pre- vs. post-endurance test.

Conclusions: Strenuous exercise in lowlanders resulted in a decrease of DCO which was probably caused by interstitial lung edema thickening the alveolocapillary membrane, whereas highlanders were capable of maintaining DICO-levels by an increase in DM.

P2173

Early oxygen desaturation is related to AMS development during acute exposure to high altitude (HA)

Luca Pomidori, Gaia Mandolesi, Giovanni Avracini, Eva Bernardi, Annalisa Cogo. Biomedical Sport Studies Center, University of Ferrara, Ferrara, FE, Italy

Early desaturation during acute simulated HA exposure is significantly related to AMS development.

Aim: To study the hypoxic profile and the AMS development during the ascent from Alagna (A), 1200m to Capanna Regina Margherita (M), 4559m, with an overnight stay in Rifugio Gnifetti (G), 3647m.

Methods: 44 (8F) subjects (age 18-67) were recruited in A, equipped with a 24-h data memory pulse oximeter (Pulsox-3Si, Minolta) and asked to fill the Lake Anima questionnaire (LL). Measurements took place at rest and after an endurance test at 80% of VO2 max at heart rate returned to rest values.

Results: Spirometry was normal in all subjects. HBO2 at rest were significantly different between the groups.

As regard the ascent to M (Ex2), data of only 24 subjects are available, (5 AMS+; 19 AMS-) from Alagna (A), 1200m, to Capanna Regina Margherita (M), 4559m, with an overnight stay in Rifugio Gnifetti (G), 3647m.

As regard the ascent to M (Ex2), data of only 24 subjects are available, (5 AMS+;
The effects of pressure-threshold inspiratory load on lactate clearance after acceptable impedance signal can be obtained. Demonstrated that “qualitative” and “semi-quantitative” ICG might be useful to 0.05). This study and functional markers of disease severity and 1-year frequency of PAH-related deemed as “poor” in another 7 patients, i.e., technical problems were found in stroke volume (SV) and cardiac index (CI) were evaluated in 50 patients and 21 8) and 24% of the readings. Early decrease (N= 9) or a subsequent “plateau” in SV (N= 71/3 48 (± 22, 15 SV 1.5-fold were associated with other clinical and functional markers of disease severity and 1-year frequency of PAH-related adverse events (death and balloon atrial septostomy, 7; 0.05% but there were significant differences in mean minute ventilation per how athletes had a poor positive predictive value. RT and PE TBW were not determinants of EVH test result but a younger age and lower MVkg were related to a positive EVH test. Conclusions: 54% of elite athletes had a positive EVH test. AS athletes tended to have more positive tests. Symptoms perceived by athletes had a poor positive predictive value. RT and PE TBW were not determinants of EVH test result but a younger age and lower MVkg were related to a positive EVH test. Non-invasive estimation of cardiac output by impedance cardiography during incremental exercise in patients with pulmonary arterial hypertension Eloisa Ferreira, Roberta Palchini Ramos, Fernanda Nogueira, Jaqueline Sonese Ota Arakaki, L. Eduardo Nery, J. Alberto Neder. Medicine, Respiratory Division, Federal University of Sao Paulo, Sao Paulo, SP, Brazil Non-invasive monitoring of haemodynamic responses during incremental car-
diopulmonary exercise testing (CPET) could provide useful information on dis-
ease severity and prognosis in pulmonary arterial hypertension (PAH). Using an
impedance cardiography (ICG) device that does not require basal impedance or
blood resistivity estimations (PhysioFlow PF-03®, Manatec Biomedical, France), stroke volume (SV) and cardiac index (CI) were evaluated in 50 patients and 21 age-
and gender-matched controls during a ramp-cyclical exercise test on a cycle
exercise to 0 at minute 6 of the recovery period. At baseline, the slope of the HRRk was significantly higher in the control group (0.008) vs. 0.007 (p=0.001). The HRRk after a constant workload cycle ergometer exercise was recorded before and after 8 weeks of endurance training in 10 COPD patients (FEV1: 47±8%pred; 71±3 yrs) and 10 healthy controls (66±10 yrs). To calculate HRRk, the heart rate during the recovery period was normalized to range from 1 at the end of the activity to 0 at minute 6 of the recovery period. At baseline, the slope of the HRRk was significantly higher in the control group than in the COPD group (p<0.001). Thus, the HRRk at the first minute after exercise was lower in the COPD group (mean 1/3 beats) than in the control group (21 beats) (p<0.001). After training, the HRRk slope increased in the control group (from 0.009 to 0.012 (p<0.05) but no changes were seen in COPD patients (from 0.007 to 0.008)
We conclude that HRR kinetics after exercise enhances assessment of ANSd in
COPD supported. Supported by FIS PI061510; UE – FP7 (CIP-ICT) 225025.
Validation of a compact accelerometer for the measurement of physical activity in patients with COPD Yoshibi Minakata, Akiko Sugino, Manabu Nishigai, Masae Kanda, Kenichiro Akamatsu, Akiko Yamauchi, Kiyotaka Kita, Kazuto Matsunaga, Masakazu Ichinose. Third Department of Internal Medicine, Wakayama Medical University, Waka
yama, Japan
Background: The DynaPort Activity Monitor (DAM) has been reported to be useful to evaluate the activity in patients with COPD. However, its battery works for only several hours and it should be worn at two parts of body. A newly developed compact, single-position triaxial accelerometer (Actimarker) can measure the activity for more than 1 month, but has not been validated for patients with COPD.
Objectives: The validation of the Actimarker in patients with COPD was evaluated and the conditions of day for analysis were determined.
Methods: In study 1, the reproducibility of the Actimarker was evaluated for 14 stable COPD patients by comparing it with DAM. In study 2, the influence of holiday and the weather on the activity was examined. In study 3, the number of measurement days to ensure repeatability was determined.
Results: The differences in the activity by Actimarker and the locomotion by DAM were all within the limit of agreement at the intensity of ≥2.0 METs, ≥2.5 METs and ≥3.0 METs with Bland-Altman Plots. The durations of activity on holidays in patients with jobs and on rainy days were significantly shorter than those on weekends and on non-rainy days, respectively. The values of intra-class correlation coefficient were more than 0.8 in 3, 4 or 5 day-measurements, and the mean values of duration of activity from 3 or 4 days were all within the limit of agreement with Bland-Altman Plots.
Conclusions: The physical activity assessed by Actimarker was confirmed for its reproducibility and repeatability when the data from 3 non-rainy weekdays were analyzed. Actimarker seems to be useful as a simplified method to evaluate the physical activity in patients with COPD.

The effects of pressure-threshold inspiratory load on lactate clearance after maximal exercise Michael Johnson1, David Brown2, Katie Bayfield1, Javier Gonzalez4, Anael Barberan1, Alejandro Raimondi, Diego Agustin Rodriguez2, Gimeno Elena1, Arbilaga Anne1, VillarO Jordi1, Josea Josep1, Pulmonary Medicine - Pulmonary Function Laboratory, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain; 2Division of Nutritional Sciences, Federal University of Sao Paulo, Sao Paulo, SP, Brazil; 3Department of Cardiology, Hospital Universitari de Montreal, Montreal, Quebec, Canada; 4Department of Gene Therapy, Imperial College London, London, United Kingdom; 5School of Life Sciences, Northumbria University, Newcastle, United Kingdom; 6Department of Gene Therapy, Imperial College London, London, United Kingdom.

Chiappa, G.R. et al. (Med Sci Sports Exerc 2008; 40:111-116) showed that a 15 cmH2O pressure-threshold inspiratory load accelerated lactate clearance during recovery from intense exercise. However, we observed an effect only when the relative magnitude of the inspiratory load fell due to a training-induced decrease in maximum inspiratory pressure (Brown, P.L. et al. Med Sci Sports Exerc 2010; 42:1103-1112). This study thus tested the hypothesis that lactate clearance is influenced by the magnitude of inspiratory load applied in recovery from maximal exercise.

Eight male participants (VO2max 3.4±0.54 L/min) completed four maximal incremental cycling tests (20 W/min starting at 0W), of identical duration (16.2±0.2 min), followed by 20 min recovery comprising either passive recovery (PR) or breathing against an inspiratory pressure-threshold load of either 10 (IPTL10), 15 (IPTL15) or 20 (IPTL20) cmH2O. Arterialised venous blood samples were taken during recovery and analysed for lactate blood concentration ([La]B) every 2 min and blood pH every 4 min. During PR, IPTL10, IPTL15 and IPTL20 the [La]B after 2 min of recovery (11.2±1.9, 11.5±2.6, 11.2±2.0 and 11.2±1.8 mmol/L, respectively), the area under the [La]B curve during recovery (191±48, 192±55, 182±48 and 187±45 mmol, respectively), and mean blood pH (7.27±0.05, 7.28±0.05, 7.28±0.06 and 7.28±0.06, respectively) were not different between trials.

In conclusion, all inspiratory loads failed to influence lactate clearance after maximal exercise. Why inspiratory loading accelerates lactate clearance in some (Chiappa et al.), but not all (present study, Brown et al.), participants is thus unclear and warrants further exploration.
Physiological responses to the incremental shuttle walk test in healthy adults

Victor Dourado1, Ricardo Guerra1, Suzana Tanni2, Letícia Antunes3, Irma Godoy2.

1Department of Health Sciences, Federal University of São Paulo (UNIFESP), Santos, Brazil; 2Department of Internal Medicine, Botucatu Medical School (UNESP), Botucatu, Brazil; 3Rehabilitation Section, Botucatu Medical School (UNESP), Botucatu, Brazil.

Physiological responses to the incremental shuttle walk test (ISWT) have been increasingly evaluated in patients with cardiopulmonary disease. However, previous studies did not include age- and gender-related factors in the prediction equations. The aim of this study was to evaluate age- and gender-related factors in the prediction equations for predicting physiological variables. The VO2 VT was used for measuring PA during a full week of daily living. Systematically varied bout lengths and interruptions are investigated to examine PA status.

Methods: Twenty COPD patients were selected from a larger dataset, based on a large range in PA level. The DynaPort accelerometer (100Hz, ±2g, McRoberts BV, The Hague, the Netherlands) was used for measuring PA during a full week of daily living. VO2 VT was determined using the ventilatory threshold (VT). VO2 VT was not affected by age as well as VO2/HR, RR, and VT were not influenced by age. There were no effect of age and gender in VO2 VT (% of peak VO2). Prediction equations adjusted by sex, age, height, weight, LBM, FM, HGS, and ISWT showed R2 values ranging from 0.352 to 0.661 (VO2 VT and VO2 max respectively). The best predictors of peak VO2 were HGS, weight, FM and age (R2=0.661). Age, weight, height and gender explained 59.7% of variance in physiological responses. The results therefore might provide a more appropriate frame of reference for normalcy of physiological responses to the ISWT in healthy older adults. Our results may be useful for better interpretation of walking performance in patients with cardiopulmonary disease.

Conclusion: This study shows that varying bout length and interruption duration has large impact on PA status. When applying PA recommendations this should be taken into account, particularly in subjects with a sedentary lifestyle.

256. Epidemiology, diagnosis and treatment in obstructive sleep apnoea

P2184 The SHIP-Trend study – Epidemiology of sleep apnoea in Germany
Ingo Fietz1, Alexander Blau1, Isabella von Mengersen2, Sandra Zimmermann1, Beate Diecker1, Claudia Biro1, Iris Rieger1, Katharina Lau2, Anne Obst2, Henning Voelke3, Ralf Ewert3, Martin Glos1, Thomas Penzel3. Cardiology and Angiology, Center of Sleep Medicine, Charité, CCM, Berlin, Germany; 2Center of Internal Medicine, Cardiology and Pulmonology, Greifswald, Mecklenburg Vorpommern, Germany; 3Institute for Community Medicine, SHIP/Clinical Epidemiological Research, Greifswald, Mecklenburg Vorpommern, Germany

The SHIP-TREND study (Study of Health in Pomerania) is the first German population based study which implemented polysomnography (PSG) as one of the key investigations. 6000 inhabitants are drawn from the inhabitants registries. The main focus of SHIP-TREND is a full body MRI to evaluate the health status in northeast of Germany. An increased cardiovascular risk has been found in this region.

Cardiorespiratory PSG will be performed in all subjects between 20 and 79 years of age which agreed to participate. These subjects completed the Insomnia Severity Index (ISI scale), Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI) and Restless Legs Syndrome Diagnostic Index (RLS-DI). Additionally all participants answered some specific questions about sleep duration and quality. Until December 2010 2769 volunteers entered the study and 966 of them underwent PSG. In a preliminary analysis 502 subjects were analyzed (225 female, 277 male). The mean age was 53.03 years. 117 of 502 subjects (23.3%) showed an apnoea-hypopnoea index (AHI) greater than 15 per hour sleep. There was a significant difference in gender when investigating the prevalence of obstructive and central apnoeas. Mean AHI in women was 7.2 per hour sleep and in men 13.4 per hour sleep. Independent of gender AHI increased with age.

There is a high prevalence of obstructive sleep apnoea in pommeranian population. Men showed more nocturnal breathing events than women. We detected in both groups a progression of breathing events with age. After completing all subjects the influence of BMI and comorbid conditions will be analysed.

P2185 Gender differences in sleep apnea severity are diminished during REM sleep
Maria Pallayova, Igor Peregrim, Zoltan Tomori, Viliam Donic.

Introduction: It has been shown previously that sleep apnea (SA) is substantially more common and more severe in men than women. Yet, the precise pathophysiological mechanisms accounting for gender differences in SA remain less well understood.

Method: A retrospective chart review was performed on patients who underwent in-lab polysomnography between January 2009 and December 2010 to examine the influence of gender on the polysomnographic features of SA. From 227 consecutive adults who met inclusion criteria, we identified 46 male-female pairs matched individually for age (mean±SD 52.4±9 years) and BMI (31.4±6 kg/m²).

Results: Despite similarities in age, BMI sleep efficiency, and Epworth Sleepiness Scale score, men had higher total apnoea-hypopnoea index (AHI) [median (interquartile range) 21.3 (8.6-43.4) vs. 8.8 (7.2-26) events/h; P<0.001] and the level of the AHI during NREM sleep [21.6 (8.5-43.7) vs. 7.4 (0.7-23.2) events/h; P<0.001] than did women. Men also had higher oxygen desaturation index [24 (10-53.1) vs. 14.8 (3.1-29.9) events/h; P<0.001] and lower mean nocturnal oxyhemoglobin saturation [93 (91-94) vs. 94 (92-95%); P=0.007]. Surprisingly, there was no statistical difference in AHI during REM sleep between men and women [21.3 (7-46.7) vs. 14.3 (2.1-45.8) events/h; P=0.662]. In addition, compared to men, women had a significantly higher difference between REM-AHI and NREM-AHI (P=0.023).

Conclusion: To conclude, SA is less severe in women than men because of milder SA during NREM sleep, which is independent of age and BMI. Our findings indicated that severity of SA is similar in men and women during REM sleep, suggesting differences between the sexes in upper airway function during sleep in adults with SA.

P2186 Gender differences in obstructive sleep apnea syndrome (OSAS): A clinical study (1308 patients)
Lucia Ballerini, Marzia Simonini, Lucia Ritoratto, Alfredo Potenza. Emergency Department, Respiratory Unit, University Hospital, Ferrara, Italy

Background: Few studies focused on gender differences among patients with OSAS. The prevalence of hypertension was not elucidated after controlling for OSAS severity, age, and obesity grade in men and women, separately, and conflicting data were reported on the effect of gender on susceptibility to hypertension in OSAS.

Aim: To retrospectively assess gender-specific differences in patients with diagnosis of OSAS, with particular attention devoted to hypertension.

Methods: 1303 patients (20-90 years, 75% males) with symptoms suggestive of OSAS underwent overnight home polysomnography, and the apnea-hypopnea index ≥ 10 defined OSAS diagnosis.

Results: 73% of males and 56% of females had OSAS. Prevalences of obesity, metabolic disorders, and hypertension were significantly higher in females than males independent from OSAS. Females were significantly older than males only among the patients with the OSAS. The risk for OSAS was significantly higher in males than females only in middle ages (40-59 years). OSAS was associated with obesity in both males (Odds ratio, OR 3.01, 95% Confidence Interval 2.18-4.15) and females (2.70, 1.64-4.45). Severe OSAS was a risk factor for hypertension independent from obesity in males (1.67, 1.02-2.63, and 2.61, 1.50-4.54, for non obese and obese, respectively). OSAS, whatever it was its severity, was related to higher risk for hypertension neither in non-obese nor in obese females.

Conclusions: Although a clear male predominance, we found that with increasing age the prevalence of OSAS in women becomes comparable to that of males. Among OSAS patients, the male gender was related to higher susceptibility to hypertension.

P2187 Gender differences in sleep pattern in a cohort of patients with obstructive sleep apnea syndrome
Sebastian Canisius, Thomas Ploch, Sandra Apelt, Jörg Heitmann, Werner Cassel, Julian Kesper, Andreas Jentzen. Internal Medicine - Section Respiratory Diseases, Philipps-University Marburg - Faculty of Medicine, Marburg, Germany

Introduction: Besides sleep related breathing disorders, other factors influence sleep pattern and polysomnographic parameters. Especially gender differences have been described that must be considered when making therapeutic decisions. Using data from a cohort of patients with OSAS, we will present gender related differences derived from a polysomnographic (PSG) examination prior to any therapeutic intervention.

Methods: Patients with OSAS who were referred to our sleep disorders centre with suspected sleep disordered breathing were monitored during the diagnostic visit and filled in the Epworth Sleepiness Scale. PSG recordings were visually analysed and parameters essential for sleep pattern rating were collected.

Results: Data from 938 patients were collected, consisting of 790 males (age 54.6±12.3 years) and 148 females (age 58.5±12.8 years) subjects. Sleepiness among genders was not different (males: 380 ESS<11, 410 ESS≥11; females 81 ESS<11, 67 ESS≥11; g=0.15). However, females had less breathing disorders (AHI 25±24.9/th per hour sleep; in males AHI 33±26.9/th; p<0.05). Percentage of N1 was lower in females than males (10.9±10.4 vs. 16±14.4%; p<0.01) while N3 was increased in females (19.9±10.7 vs. 16±10.4%; p<0.01). Corresponding to AHI values, arousal indices were lower in females than males (38±5.2 vs 21.2 and 44±4.5±3.1h; p<0.05).

Conclusion: We could show significant differences in light sleep and deep sleep proportions and arousal indices between male and female OSAS patients. In contrast, the proportion of sleepy patients was not significantly different. These results may help to understand gender related differences in reported daytime symptoms and facilitate therapeutic decisions.

P2188 Obstructive sleep apnoea/hypopnoea syndrome in middle-aged patients: Differences regarding the gender
Panagis Drakatos, Katerina Varela, Georgios Efremidis, Maria Spiropoulou, Lampros Berosoukas, Konstantina Nikoulioutou, Dimitrios Georgopoulos. Sleep Lab, 2nd Thoracic Department, South-Western Greece Chest Hospital, Patra, Greece

Introduction: It is well known that there are differences of obstructive sleep apnoea/hypopnoea syndrome (OSAHS) regarding the gender in the elderly. The aim of this study was to evaluate the possible differences of OSAHS between middle-aged patients.

Methods: Three hundred and sixty five subjects, aged 45 until 65 years, suspected OSAHS were examined by full polysomnography, in our Sleep Laboratory the last years. Two hundred and ninety of them were suffered from OSAHS, 232 men, aged 53.75±5.72 and 58 women, aged 54.73±6.44 (±SD). The evaluated parameters were the daytime sleepiness (scoring by Epworth sleepiness scale), the apnoea/hypopnoea index (AHI) and the duration of nocturnal hypoxemia. The statistical analysis was done by “t-test” method.

Results: There were statistically significant differences between men and women regarding the body mass index (BMI) (34.08±6.74 vs 37.71±11.38 respectively.
Obesity Hypoventilation Syndrome (OHS) was defined as a BMI ≥30. 

Definitions: SAHS was considered when AHI ≥ 12/hour at breathing during sleep. 

Results: 82 out of 153 patients with DNV met the inclusion criteria. 53 (65%) women and 29 (35%) men. Values expressed by mean ± standard deviation were: Age at starting treatment: 72.4 ± 10.5 years, BMI: 37.5 ± 6.7; neck circumference: 41.9 ± 5.3 cm; ESS: 12.9 ± 4.1; AHI ≥ 12; BMI ≥ 30 and PaCO2 ≥ 35 mmHg at daytime; Excessive Daytime Somnolence (EDS) if Ewthop Somnolence Scale (ESS) score ≥ 12.

Conclusion: Half of the patients with DNV were ≥ 65 years old at the beginning of the treatment. All patients were obese and most of them, women. The most common cause of prescribing BIPAP was neuromuscular disease and the most common cause of change from CPAP to BIPAP was OHS.

Relation between obstructive sleep apnea syndrome severity and age

Nesrin Kiral, Banu Salepci, Ali Fidan, Elif Torun, Selcda Comert, Gulsen Sara, Ayse Havun, Benan Caşlayan. Chete Diseases, Dr. Kutur Kartal Kartal Training and Research Hospital, Istanbul, Turkey

Aim: To investigate the effect of age on severity of obstructive sleep apnea syndrome (OSAS) severity was the aim of this study.

Material and Method: The files of 874 OSAS patients diagnosed in our sleep laboratory between January 2005 – January 2010 were retrospectively analysed. Polysomnography was performed with Sleep Screen - Viasys device and scoring was done according to the criteria of Rech-Schaffen Kales. Chi-square and Pearson correlation coefficients were used to compare the groups. The significance level was set as p<0.05.

Results: There were 847 OSAS cases in the study. The mean age was 49.1±10.7 and of the cases, 602 (68.9%) were male, 272 (31.1%) were female. The prevalence of OSAS was mild in 235 (26.9%), moderate in 224 (25.6%) and severe in 415 (47.5%). A great majority of OSAS cases were belonging (65.2%) 40-59 years age group. Younger cases were 18.2% and older cases were ≥60.7% of OSAS patients. Mean AHI was 33.9 in younger (age<40), 36.8 in middle age (age40-59) and 42.4 in older (age≥60) group. Age >50 in 60.4% of mild OSAS cases whereas was the same in 50% of moderate OSAS and in 42.1% of severe OSAS cases. The severity of OSAS was statistically significantly increasing as age was advancing (p<0.05). As the cases were grouped as older and younger than 50 years of age, AHI, AI and ODI were statistically significantly higher and minimum saturation was significantly lower in older age group (p<0.05).

Conclusion: OSAS is getting worse as the age is getting advanced.

Treatment of sleep apnea over 21 months

Juan Fernández-Lahera, Francisco García Río, Carlos Carpio, Darwin Feliz, David Romero, Elí Martínez, Concepción Prados, Roldo Alvarez-Sala. Pneumology, University Hospital la Paz; IDIPAZ, Madrid, Spain

Objectives: 1) Analyse the evolution of the hours/day ratio of the use of CPAP in patients with sleep apnea hypopnea syndrome over a period of 21 months. 2) Study the factors related to poor treatment compliance (<3.5 hours/night).

Material and method: A total of 83 patients with sleep apnea hypopnea syndrome (AHI ≥22/h) treated with CPAP were included. The utilisation ratio of CPAP was recorded at 3, 6, 9, 12, 15, 18, and 21 months.

Anthropometric and socio-work variables were also recorded, as well as sleep and CPAP parameters, Epworth scale, morbidity and evolution.

Results: The ratio (hours/day) of real use of CPAP at 3, 6, 9, 12, 15, 18, and 21 months was: 4.9±2.3, 5.1±2.2, 5.3±2.5, 5.2±2.4, 5.3±2.5, 5.2±2.6, 5.2±2.5.

A univariate analysis and another adjusted by variables showed that the time of use did not significantly differ over the 21 months.

Conclusions: 1) The CPAP use pattern 3 months after starting treatment is stably maintained over a 21-month period. 2) Those who did not comply with treatment presented less serious sleep parameters, lower cervical perimeters, and lower prescribed CPAP pressure than those who complied.
Background: SDB has a high prevalence in the elderly population. OSA has been recognized in 7–18% of elderly people.

Aim: To evaluate the role of AT in the outcome of children with OSAS.

Methods: At the Department of Respiratory Medicine, Merlin Park University Hospital, Galway, Ireland.

Results: To date a total of 56 patients have complete data. Their mean BMI was 35.7 (±7.9), collar size 43.5 cm (±4.2) and 35 (63%) were male. Based on an AHI ≥ 15, 31 (55%) were diagnosed with significant OSAS. Those with OSAS had significantly higher BMI as well as collar size. The Epworth questionnaire (cut off 10) had a sensitivity of 77% and specificity of 52%, the Berlin 97% and 24%, respectively. STOP 100% and 28% and STOPBANG 100% and 12%.

Conclusions: If only patients with high risk scores were selected for subsequent PSG, 59% (Epworth), 13% (Berlin), 86% (STOP) and 93% (STOPBANG) of the patients would be tested. The STOP questionnaire resulted in the best sensitivity/specificity combination (if false negatives are unacceptable) but this would mean that 86% of the patients would have PSG but only 55% would have OSAS. No other combination of factors was found to improve specificity without a considerable decrease in sensitivity.

STOP is the simplest and most effective screening questionnaire to identify patients with OSAS and could reduce the need for PSG by 14%. A larger cohort is needed to confirm these findings and improve specificity of the questionnaires.

P2195 Follow-up of children with obstructive sleep apnea syndrome treated with adenotonsillectomy

Background: Hyperpertrophy of adenotonsilar tissue is an undisputed contributor to the development of OSAS in otherwise healthy children. A multicenter retrospective observational study shows the surgery approach has a resolution rate of about 27%. So it is important to identify children who will not resolve OSAS after adenotonsillectomy (AT) in order to plan an appropriate and integrated treatment for them.

Aim: To evaluate the role of AT in the outcome of children with OSAS.

Methods: Children affected by adenotonsillar hypertrophy, who underwent adenotonsillectomy for moderate-severe OSAS, were enrolled, from 2008 to 2009. All children underwent a complete clinical examination and overnight polysomnographic study before AT and after 12 months of follow-up.

Results: We included 21 children (mean age 4.09±1.76; M/F 17/4), with a mean body mass index –BMI– of 15.6±6.2 kg/m², with a mean apnea hypopnea index (AHI) of 5.9±8.8 ev/hr. Twelve children (57.1%) had malocclusions. After one year, 13 children showed a complete resolution of disease (61.9%) (AHI 0.3±0.3 ev/hr), while 8 children (38.5%) had a residual disease (AHI 2.6±1.1 ev/hr). Children with a residual disease had a higher BMI at baseline (16.5±3.7 kg/m² vs 15.4±1.1 kg/m², p<0.05) and a higher prevalence of malocclusions compared to those with a complete resolution (7/8 vs 5/13, X²=4.86, p<0.05). Stepwise multiple linear regression analysis identify malocclusions as the most important variable influencing the outcome (R²=0.24).

Conclusions: Although AT is the gold standard in children with OSAS and adenotonsillar hypertrophy, treatment of malocclusions need to be added to achieve a complete resolution of the disease.

P2196 Clinical reproducibility of the pediatric sleep questionnaire (PSQ)

Background: PSG is used for obstructive sleep apnea (OSA) diagnosis, due to its high cost is necessary to obtain clinical scores to evaluate the clinical reproducibility of OSA.

Aim: Evaluate the utility of the ACHaR as screening test for moderate/severe OSA in subjects recruited in an outpatient clinic.

Methods: Prospective study realized between January 2006 and December 2010. All patients enrolled were studied in a sleep center with PSG and also completed an easy to apply questionnaire (ACHaR). This test has 4 dichotomized variables: snoring, hypertension, neck circumference (cutoff = 40 cm), and reports of nocturnal gasping/choking; having a total score of 0-4 points. A score of 2 or more indicated high risk for moderate/severe OS (by PSG, apnea/hypopnea index ≥ 15).

Results: 753 adult patients (74.5% men) were studied (median age = 47.0 yrs). Using ACHaR, 646 patients (85.8%) were classified as high risk of moderate/severe OSA and 107 patients (14.2%) with low risk. The prevalence of moderate/severe OSA after PSG was different between these 2 groups: 72.4% (high risk) and 24.2% (low risk); p<0.001. The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and odds ratio (high risk vs. low risk) of the ACHaR score used as screening for moderate/severe OSA were, respectively: 94.7%, 31.2%, 72.4%, 75.7%, 72.9%, and 8.19 [95% CI = 5.09-13.16]. According to the receiver operating characteristic curve, the ACHaR score had area under the curve = 0.63 [95% CI = 0.58-0.67].

Conclusions: This study indicates that the ACHaR questionnaire was good sensitivity in detecting the patients with moderate/severe OSA.

P2197 The STOP questionnaire is the best screener for obstructive sleep apnea syndrome at the sleep clinic

Background: Polysomnography (PSG) is used for obstructive sleep apnea (OSA) diagnosis but is resource intensive and with restricted availability. Therefore we performed a pilot study to compare the Epworth, Berlin, STOP and STOPBANG questionnaires in their ability to identify OSAS confirmed by PSG among high risk patients. Additionally, cut off points to improve clinical detection of OSAS were explored.

Aim: To evaluate the utility of the ACHaR as screening test for moderate/severe OSA in subjects recruited in an outpatient clinic.

Methods: Prospective study realized between January 2006 and December 2010. All patients enrolled were studied in a sleep center with PSG and also completed an easy to apply questionnaire (ACHaR). This test has 4 dichotomized variables: snoring, hypertension, neck circumference (cutoff = 40 cm), and reports of nocturnal gasping/choking; having a total score of 0-4 points. A score of 2 or more indicated high risk for moderate/severe OS (by PSG, apnea/hypopnea index ≥ 15).

Results: 753 adult patients (74.5% men) were studied (median age = 47.0 yrs). Using ACHaR, 646 patients (85.8%) were classified as high risk of moderate/severe OSA and 107 patients (14.2%) with low risk. The prevalence of moderate/severe OSA after PSG was different between these 2 groups: 72.4% (high risk) and 24.2% (low risk); p<0.001. The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and odds ratio (high risk vs. low risk) of the ACHaR score used as screening for moderate/severe OSA were, respectively: 94.7%, 31.2%, 72.4%, 75.7%, 72.9%, and 8.19 [95% CI = 5.09-13.16]. According to the receiver operating characteristic curve, the ACHaR score had area under the curve = 0.63 [95% CI = 0.58-0.67].

Conclusions: This study indicates that the ACHaR questionnaire was good sensitivity in detecting the patients with moderate/severe OSA.

P2198 Questionnaire designed to identify patients with moderate/severe sleep apnoea and its correlation with polysomnography

Background: Sleep-disordered breathing (SDB) and obstructive sleep apnea (OSA) in the clinical pediatric population being evaluated for a potential sleep-related breathing disorder.

Aim: To evaluate the utility of the ACHaR as screening test for moderate/severe OSA in subjects recruited in an outpatient clinic.

Methods: Prospective study realized between January 2006 and December 2010. All patients enrolled were studied in a sleep center with PSG and also completed an easy to apply questionnaire (ACHaR). This test has 4 dichotomized variables: snoring, hypertension, neck circumference (cutoff = 40 cm), and reports of nocturnal gasping/choking; having a total score of 0-4 points. A score of 2 or more indicated high risk for moderate/severe OS (by PSG, apnea/hypopnea index ≥ 15).

Results: 753 adult patients (74.5% men) were studied (median age = 47.0 yrs). Using ACHaR, 646 patients (85.8%) were classified as high risk of moderate/severe OSA and 107 patients (14.2%) with low risk. The prevalence of moderate/severe OSA after PSG was different between these 2 groups: 72.4% (high risk) and 24.2% (low risk); p<0.001. The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and odds ratio (high risk vs. low risk) of the ACHaR score used as screening for moderate/severe OSA were, respectively: 94.7%, 31.2%, 72.4%, 75.7%, 72.9%, and 8.19 [95% CI = 5.09-13.16]. According to the receiver operating characteristic curve, the ACHaR score had area under the curve = 0.63 [95% CI = 0.58-0.67].

Conclusions: This study indicates that the ACHaR questionnaire was good sensitivity in detecting the patients with moderate/severe OSA.

P2199 Continuous positive airway pressure in patients with obstructive sleep apnea: A difference dependent on apnea/hypopnea index, leakage and mask pressure

Background: The Pediatric Sleep Questionnaire (PSQ) has 2 versions: a shorter one, which has been validated for sleep-related breathing disorders, and an extended version, which deals with wider range of disturbances. The Spanish version of the PSQ could be a suitable tool both for screening patients who require medical tests and for epidemiological research. Our objective was to evaluate its reproducibility in the clinical pediatric population.

Material and methods: 62 patients in pediatric age were gathered consecutively. 53% were male with a mean age of 5.15 years old (± 3.05) to whom a conventional polysomnography (PSG) was performed because of a probable diagnosis of SAAH. The 24 items of the PSQ (validated Spanish version for sleep-related breathing disorders) were completed at the Pediatric Outpatient Clinic and the night before the sleep study performed at the Respiratory Care Sleep Unit, both data were compared to let show discrepancies between PSG scores.

Results: The mean PSG score at the Pediatric Outpatients Clinic was 9.42 (± 4.77) and the previous score prior the PSG at the Sleep Unit was 8.7±4.59, with a correlation between both of 0.66 (p < 0.0001). The statistical concordance between the two determinations of PSG was moderate considering the cut line when 33% of the items were positive (kappa index 0.4, p = 0.003).

Conclusion: The PSQ score is highly variable when administered sequentially to a clinical pediatric population being evaluated for a potential sleep-related breathing disorder.
for obstructive sleep apnea (OSA). While a lot of studies analysed adherence of CPAP therapy in general, only little is known on adherence dependent on apnea-hypopnea index (AHI), leakage and mask pressure.

Methods: In a retrospective data analysis we determined age-dependent adherence of 4821 German patients (age = 58.4±11.2 years; 17.6% female, 82.4% male) treated with the CPAP device S8 (ResMed, Sydney, Australia). We studied AHI, mean mask pressure, mean leakage, hours of use per night and efficiency (days of use/total days).

Results: Mean therapy duration was 3.5±3.6 years. In the subgroups AHI<5, AHI=10–15 and AHI>15 patients used CPAP on average 36.8±37.8 min/day and days used/week (range 5.8 to 6.2) were similar. Furthermore, adherence was similar in the leakage subgroups <0.1 l/s, 0.1-0.2 l/s, >0.2-0.3 l/s, >0.3-0.4 l/s and >0.5 l/s in terms of hours used/night (range 361 to 380 min) and days used/week (range 6.0 to 6.2). Up to mask pressure of 14 cm H2O patients used the device on average 350 min, whereas patients with mask pressure >12-14 cm H2O used it more than an hour longer (415min). Moreover, there was a continuous increase between the lowest mask pressure subgroup (4-6 cm H2O) and the highest mask pressure (>14 cm H2O). Range was 5.7 to 6.5 days used/week.

Conclusions: Long-term therapy is high and long-term efficacy is excellent in long-term CPAP users. Adherence increases with mask pressure.

P2200

Importance of a questionnaire study on Latin American physicians about sleep apnea
Ivan Chérez-Ojeda, Thomas Guerrero, Ronni Mantilla. Allergy and Pulmonology, RESPIRALAB-Kennedy Hospital, Guayaquil, Ecuador Allergy and Pulmonology, RESPIRALAB, Guayaquil, Ecuador Allergy and Pulmonology, RESPIRALAB, Guayaquil, Ecuador

Introduction: We considered appropriate to investigate the knowledge and attitudes of obstructive sleep apnea among our physicians in the Latin American community.

Methods: Cross sectional survey study done in Ecuador. We previously translated the questionnaire obstructive sleep apnea knowledge and attitude (OSAKA) in English to Spanish.

Results: Out of the 284 questionnaires delivered just 193 (68%) questionnaires were returned. In a retrospective data analysis we determined age-dependent adherence of OSA. In the group 43-48 was 43, 2 if it is between 43 and 48, and 3 if it is >48 cm. We have considered 3 degrees of severity: 1 if the IAH is <5, moderate if it is between 15-30, and severe if IAH>30.

Results: The middle age of our patients was 50 (16-80); 78% males. The patient's percentage with different degrees of OSA's severity according to his CNP is expressed in the table.

Conclusion: Physicians may have a lower accuracy due to high sympathetic activity in both states. Agreement was 0.91. For the second analysis agreement remained the same. Sleep stages, arousal and respiratory events were scored according to AASM criteria. ECG was analyzed by a special software (Hypnocore) which can provide a sleep evaluation and a respiratory event score by a new automated analysis. All patients were analyzed in two steps. The second analysis was performed on 54 patients after removing those with bad signal quality, arrhythmias and a total sleep time below 3 hours.

Conclusions: The results of this pilot study show the potential usefulness of the Internet as a tool for home monitoring of OSA patients and CPAP compliance improvement.

P2202

Web-based follow-up of CPAP compliance in obstructive sleep apnea syndrome: A pilot study
Valentina Isetta1, Carmen Leon2, Ramon Farn1,3,4, Josep Maria Montserrat1,4. 1 Unit of Biophysics and Bioengineering, Faculty of Medicine, University of Barcelona, Barcelona, Spain; 2Sleep Lab - Pneumology Department, Hospital Clinic, Barcelona, Spain; 3CIBER de Enfermedades Respiratorias, Ciberes, Barcelona, Spain; 4Institut d'Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain

Introduction: Despite its fast penetration in many fields, the application of information and communication technologies in the clinical practice is still very limited, especially in respiratory medicine. The Obstructive Sleep Apnea Syndrome (OSAS) is a disease in which, because of its prevalence and chronic nature, telemedicine has a great potential.

Objective: To develop and to assess the feasibility of a web-based follow-up of continuous positive airway pressure (CPAP) therapy in OSAS patients.

Methods: An easy-structured web site was created for this study and each patient was given access to his/her own data exclusively. By visiting the web site, patients could answer to a weekly questionnaire about symptoms, sleep quality, potential CPAP side effects, physical activity and body weight, having the patient access to continuously updated temporal trends in graphical format. Moreover, informative documents about OSAS and CPAP therapy were available to free download.

Results: On a total of 163 consecutive patients of the Sleep Clinic, 66 reported minimum knowledge of the Internet and agreed to participate. After 12 weeks of monitoring, the participation rate was high (82%). In addition, patients responded to a satisfaction survey through the website, showing a level of agreement to the statement “Overall I am satisfied with the web service” of 4.2±0.58 points (1 = I strongly disagree, 5 = I strongly agree) and their potential interest in participating in a long-term web-based monitoring.

Conclusions: The results of this pilot study show the potential usefulness of the Internet as a tool for home monitoring of OSAS patients and CPAP compliance improvement.

P2203

Sleep disordered breathing detected by a new automated ECG analysis in subjects with insomnia
Thomas Penzel, Carmen Garcia, Martin Glos, Christoph Schoebel, Martina Sebert, Ingo Fietze. Interdisciplinary Sleep Medicine Center, Department for Cardiology, Charité Universitätsmedizin Berlin, Berlin, Germany

Patients with severe complaints of insomnia are sometimes investigated in a sleep laboratory in order to test for other causes of their complaints such as sleep disordered breathing or other sleep disorders. We investigated 64 patients with primary insomnia with cardiorespiratory polysomnography. Sleep stages, arousal and respiratory events were scored according to AASM criteria. ECG was analyzed by a special software (Hypnocore) which can provide a sleep evaluation and a respiratory event score by a new automated analysis. All patients were analyzed in two steps. The second analysis was performed on 54 patients after removing those with bad signal quality, arrhythmias and a total sleep time below 3 hours.

The analysis of respiratory events based on ECG in the group of 64 subjects resulted in 52 subjects (48 true negative, 4 false negative) with an RDI<5.12 subjects (10 true positive, 2 false positive) were scored with an RDI>5. The agreement was 0.91. For the second analysis agreement remained the same. Sleep stages in the second analysis were scored surprisingly good: 48.9% (ECG) vs. 48.7% (PSG) for light sleep, 15.7% (ECG) vs. 15.8% (PSG) for slow wave sleep, 14.9% (ECG) vs. 23.4% (PSG) for wake, and 19.9% (ECG) vs. 12.2% (PSG) for REM sleep.

Not many respiratory events occur in insomnia patients. These events are detected with a sufficient accuracy using the new ECG based algorithms. Sleep stage analysis based on ECG did show a good ability to distinguish light sleep, slow wave sleep, and wake/REM sleep. To distinguish wake and REM sleep by ECG alone has a lower accuracy due to sympathetic activity in both states.
P2204
Respiratory polygraphy versus polysomnography for the diagnosis of obstructive sleep apnoea in children
Lynda Hammoudi1, Fawza Heran1, Florence Bour1, Ha Tran1, 3 Paediatric Sleep Centre, Robert Debre Hospital, Paris, France; 2Lab of Neuropsychology, Raymond Poincare Hospital, Garches, France; 4 Lab of Neuropsychology, Geneves Hospital, Geneve, France

Full attended polysomnography (PSG) is the gold standard for diagnosis of obstructive sleep apnoea (OSA). No consensus exists on the reliability of Respiratory Polygraphy (RP) for that purpose in children. This study aims to assess reliability between RP and PSG of determining sleep-related respiratory data in children. Twenty children with suspected OSA (10 yrs, 4-16) had full PSG performed in the Paediatric Sleep Centre, Robert Debre hospital, Paris, France. One investigator (IH) performed analysis using two modes in a random order: PSG mode (neurophysiologic and respiratory traces available) and RP mode (EEG, EOG, EMG not available on screen). Sleep was scored in PSG mode using Rechtschaffen-Kales criteria, and in RP mode using those of Moss et al (2005) which are mainly based upon variation of cardiac rhythm. Respiration was scored in the same manner for both modes using commonly accepted paediatric criteria. Intra-class correlation coefficients (ICC) were calculated.

When using PSG mode, total sleep time was 517 min (360-633), obstructive apnoea-hypopnoea (OAH) index was 6.3 (0.2-66) and minimal SaO2 was 86% (71-95). Low ICC was found for sleep data. There was some reliability between RP and PSG of measuring OAH index and minimal SaO2, but not of measuring mean duration of events and sleep time in OAH. These results prompt further studies to develop a higher number of children before determining recommendations of routine use of RP in children with suspected OSA.

P2205
Overnight oximetry as a screening tool for diagnosing obstructive sleep apnea in high altitude residents
B.N.B. Mahavera Prasad, C.A. Turkam, Medicine, Military Hospital Wellington, Wellington Barracks, The Nilgiris District, Tamilnadu, India

Aim: To determine the value of overnight nocturnal oximetry in strongly suspected cases of obstructive sleep apnea (OSA) among residents of high altitude.

Methods: This study is a retrospective analysis of prior overnight oximetry data of permanent residents staying at altitudes between 7000 to 8000 feet above the sea level who had a high pretest probability of OSA. The cases in this study were subsequently confirmed to have OSA by overnight sleep study (polysomnography). To determine the mean daytime and nocturnal oxygen saturation values for comparison with the study group, matched healthy non smokers residing in the area were studied by daytime and nocturnal oximetry.

Results: There were 12 males and 9 females in the study who had confirmed OSA. They were in the age group between 36 to 48 years. All had severe OSA. Nocturnal oximetry in these cases revealed more than 15 events of oxygen desaturation per hour of sleep with oxygen saturation falling more than 10 percent below pre-sleep awake baseline values. The awake oxygen saturation of all these cases were normal and were matching with mean value of 92 percent observed among 20 controls. The nocturnal oxygen desaturation among control group was less than 4 percent of awake values and events of desaturation were less than 5 times per hour of sleep.

Conclusion: Overnight oximetry is a useful screening tool in cases of OSA residing at high altitude areas. It can be used to confirm diagnosis of OSA in cases with a high pretest probability.

P2206
A new tool to help patients with obstructive sleep apnea syndrome (OSAS) make informed therapeutic choices
Nathalie Fleury1, Silvia Guiné2, Nicolas Kriczien1, Bernard Fleury1, 1CERMES, CNRS U8213 – INSERM U986 - EHESS - UPVD, Villejuif, France; 2Centre for Health Economics and Policy Analysis Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada; 3Sleep Unit, Hôpital Saint-Antoine, Paris, France

There remains concern that patients may not be fully informed regarding their mechanical treatment options for OSAS: continuous positive airway pressure (CPAP) or oral appliance (OA).

Objective: To develop a tool to help clinicians inform patients about treatment options, and to assess its validity, reliability and acceptability.

Methods: We developed a decision board (DB), to present information regarding the potential benefits and side effects of the 2 treatment options, using the best available evidence. To test validity, we evaluated in 34 healthy volunteers the extent to which the respondents’ preferences for a treatment changed predictably when the rate of effectiveness and side-effects were modified. Reliability was tested by re-administering the DB 2 weeks after (kappa test). The DB acceptability was evaluated in 68 consecutive patients newly diagnosed with OSAS, AHl=39 (22).

Results: In healthy volunteers, 58.8% chose OA, 41.2% chose CPAP. In the former group, 85% switched preference when the rate of effectiveness was reduced from 6/10 to 3/10, and 90% when the occurrence of occlusal contacts modification increased from 4/10 to 8/10. In the CPAP group, 57% switched when effectiveness was reduced from 10/10 to 5/10, and 42% when non compliance due to adverse effects increased from 3/10 to 6/10. Reliability was excellent (k=0.94). Concerning acceptability, 90% of the patients were satisfied with the information provided in the DB and 88% indicated that it helped them make a decision. The average score of true/false test of comprehension was 7/9 of 10 (range, 4 to 8).

Conclusion: The DB is a valid, reliable and acceptable tool to assess OSAS patients’ preferences.

P2207
Comparing different flow rates (20 and 35 l/min) under high-nasal flow therapy for the obstructive sleep apnoea syndrome (OSAS)
Georg Nilius1, Ulrike Domanskie1, Karl-Josef Franke1, Karl-Heinz Ruhle1, Hartmut Schneider2, 1Pneumology, HELIOS-Klinik Hugen-Ambrock, Hagen, Germany; 2Pneumology, John-Hopkins-University, Baltimore, United States

Introduction: We have demonstrated that 20 l/min nasal insufflation of airflow (HNF) can treat a subgroup of OSAS patients (Nilius G et al. Chest. 2010; 137:321-8). The aim of this study was to compare the effect of two flow rates (20 l/min (HNF20) and 35 l/min (HNF35)) on sleep disorders breathing. Methods: 18 CPAP naive patients (6 women, age 54±12 ±3.8 kg/m2, ESS 9.3±5.2) with more than 50% Hypopneas during a diagnostic night were recruited. During the treatment night both HNF20 and HNF35 were administered in a random order for a minimum of three hours each.

Results: The total event rate (AHI) in NREM/REM sleep was at baseline 5±37±3±2, at HF20 L/min 23±14±22±2 and at HNF35 L/min 19±13±15±6 (P<0.05 for REM). There were significant improvement HI but AI at 35 l/min versus 20 l/min in NREM and REM sleep. The lack of AI responses was associated with a significant increase in central AI (baseline vs HNF20 vs HNF35; 1 vs 8 events/hour). Nevertheless Oxygenation (T90) improved considerably with HNF35 compared to HNF20 and baseline in both sleep stages.

P2208
Variability in AHI and mean pressure over time in OSA patients treated with APAP
Siriram Chandramoulis, Dorothy Price, Jennifer Furlong, Syed Huq, Justine Hadercot, Dept of Respiratory & Sleep Medicine, Liverpool Heart & Chest Hospital, Liverpool, Merseyside, United Kingdom

Background: In patients with obstructive sleep apnoea (OSA), studies have shown that automatic positive airway pressure (APAP) treatment is comparable to continuous positive airway pressure (CPAP) in its cost effectiveness and efficacy. Patients with OSA are treated with APAP devices in our hospital.

Aims: Monitor changes in APAP and apnoea hypopnoea index (AHI) over a period of 3 months to identify factors which affect changes in mean AHI and APAP.

Methods: Symptomatic OSA patients [Epworth sleep score (ESS) > 10, AHI>10] were offered APAP therapy and monitored prospectively for 3 months. Data was downloaded at 2 weeks and 3 months and analyzed using paired t test and multiple regression.

Results: APAP therapy was initiated in 26 patients (22 men) with a mean (SD) age of 51 (11.7) years. Mean AHI was 44.5 (25.5) and mean Epworth score was 12 (4.7).

Changes in mean AHI and APAP are shown in the table.

<td>14.2 (3.0)</td>
<td>14.2 (2.9)</td>
<td>0.001</td>
</tr>
</tbody>
</table>

Multiple regression identified baseline AHI as the only predictor of AHI change.
over 2 weeks and 3 months (p<0.0001) while a higher mean APAP at 3 months was also found to be significant (p<0.0003). Age, sex or body mass index did not affect changes in mean AHI or APAP.

Conclusions: In our study AHI was significantly reduced after 2 weeks’ treatment with APAP and continued to fall at 3 months even though mean pressure did not change noticeably. AHI change is greatest in patients with a higher baseline AHI and marked increase in pressure at 3 months. This could influence the onset of other factors such as change in upper airway muscle dynamics. Larger studies are needed to elucidate this complex relationship.

P2209

Manual vs. automated analysis of polysomnographic recordings in patients with COPD

Gerben Stege1, Petra J.E. Ves1, P.N. Richard Dekhuijzen2, Pieter H.E. Hilken2, Marjo J.T. van de Ven3, Yvonne Heijdra4, Frank J.J. van den Esholt1, 1Department of Pulmonology, Rijnstate Hospital, Arnhem, Netherlands; 2Department of Physiology, Utrecht University, Utrecht, Netherlands; 3Department of Paediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background: Manual analysis of polysomnography (PSG) is time-consuming and computer systems have been developed to automatically analyse PSGs. Studies on the reliability of automated analyses in healthy subjects show varying results. In patients with Chronic Obstructive Pulmonary Disease (COPD) these studies have not been performed, while sleep quality can severely be disturbed in these patients. It is unknown whether automated analysis of PSG in patients with COPD provide accurate outcomes.

Methods: In a retrospective study the full-night polysomnographic recordings of patients with and without COPD were analysed manually and automatically. The outcomes of manual and automated analyses in both groups were compared using Bland-Altman plots, Students’ paired t-tests, and Pearson’s correlation coefficients.

Results: 50 PSGs from patients with COPD and 57 PSGs from patients with out COPD were included. In both study groups agreement between manual and automatic analyses was poor in nearly all sleep and respiratory parameters, like the total sleep time, sleep efficiency, sleep latency, amount of REM sleep, no. of arousals, and the apnoea-hypopnea-index.

Conclusion: Automatic analysis of PSGs in COPD patients have poor agreement with manual analysis when looking at sleep and respiratory parameters and should therefore not replace the manual analysis of PSG recordings in patients with COPD.

P2210

Heart rate analysis using multiscale entropy in OA patients under CPAP treatment – Pilot study

Jakub Kadlinski1, Waldemar Tomalak1, Zbigniew Baran2, 1Dept of Pathophysiology of Respiratory System, Institute for TBC & Lung Diseases, Rabka Branch, Rabka - Zdroj, Poland

One of the common effects of hypopnea/apnea events during sleep are arousals associated with heart rate change. Methods of nonlinear dynamics which analyze not only variability but also the complexity of the signal are the effective and reliable techniques used to analyze heart rate variability.

The aim of the study was to explore the possibility of detection of complexity changes of signal constructed from R-R intervals derived from ECG during full night PSG in OA patients (in whom apneahypopnea events were eliminated by CPAP therapy) using informative entropy.

21 patients undergoing routine diagnostic in sleep lab were recruited for the study (15 male, 6 female; age 52.4±9 years; BMI 35.8±3.0 kg/m²; Epsworth 13.4±5). The full night diagnostic PSG and the titration night using auto-CPAP under PSG supervisory (both according to AASM rules) were performed (diagnostic to titration time: 60±31 days). The CPAP therapy was well tolerated (the RDI change from 72±30 during diagnostic night to 5.9±6.9 during titration night. ODI from 61±31 to 3.8±4.1; AI from 50±26 to 6.5±4.3). The R-R intervals were detected in recorded ECG signal (250Hz), and the multiscale entropy (Goldberg’s MSE) was calculated for the scales 1-20.

In the low scales (up to 9) there were no significant difference between diagnostic and titration results. In the higher scales there were significant (p<0.05) differences.

The elimination of respiratory events has no significant effect on beat-to-beat heart rate complexity. However, using MSE analysis the results of eliminating heart rhythm changes associated with arousals are clearly visible.

P2211

Validation of a new polygraphy device for the diagnosis of obstructive sleep apnoea (OSA)

Ulrike Domanski1, K.H. Ruble1, Marguerit Laurent2, Maria Stoica2, A. Hosgeb1, M.P. D’Orthe1, Georg Nilus1, 1Klinik Ambrock, Universität Witten-Herdecke, Hagen, Germany; 2Groupe Hospitalier Bichat-Claude Bernard Assistance Publique, Hopitae de Paris, Universite Denis Diderot, Paris, France

Background: Snoring and OSA are such common problems that there is the potential to overwhelm the capacity of sleep laboratories. The goal of this study is to validate a new portable respiratory monitoring device (Alice PDX) against PSG during laboratory recordings, and to assess the devices ability to predict the presence of OSA in the home environment.

Methods: 45 suspected OSA patients (84.4% male, age 52.8±1.9 years, BMI 30.7±1.1 kg/m², neck circumference 43.3±0.8 cm and an ESS 9±±0.7) were randomized to receive the following diagnostic routines over 3 nights: 1 night with self applied Alice PDX, 1 night simultaneous in Lab Polysomnography (PSG) and Alice PDX recording, and 1 in Lab PSG. The data were anonymised and then manually scored according to AASM criteria.

Fifteen tests were used to compare each diagnostic modality to the reference in lab PSG, and correlation co-efficient calculated. Finally, the rate of diagnostic agreement was calculated.

Results: The Alice PDX was in diagnostic agreement with the simultaneously recorded reference PSG in 91.2% of studies. In 4.4% of studies the Alice PDX underestimated the AHI and on 4.4% of occasions the Alice PDX overestimated the AHI. Similar levels diagnostic agreement were observed when comparing PDx Home, and PSG Lab to the reference PSG recording.

Table 1

<table>
<thead>

Conclusions: The Alice PDX shows a high level of diagnostic agreement against PSG when used simultaneously and on a separate occasion at home. When used at home, the level of agreement is similar to a PSG performed on a separate occasion.

P2212

CPAP setting prediction in OSAS patients

Nikolaos Chavouzis, Katalin Fekete Passa, Afroditi Boutou, Chrysanthi Nakou, Asimina Paspala, Ioannis Stanopoulou, Georgis Pitsiou, Athanasia Pataka, Vassilios Bagalas, Paraskevi Arygropoulou, Respiratory Failure Unit, Aristotel University of Thessaloniki, Thessaloniki, Greece

Aim: To determine how well anthropometric measures and data derived from a diagnostic polysomnography (PSG) study predict the CPAP setting required for therapy.

Methods: Data of 158 women and 592 men who had a diagnostic overnight PSG study, a diagnosis of OSAS (Apnea-Hypopnea Index (AHI) >5 and daytime somnolence) and a CPAP titration study were retrospectively analysed. Regression analysis was used to assess the predictive value of age, height, weight, neck, waist and hip circumferences, systolic and diastolic blood pressure at rest and diagnostic PSG data AHI, desaturation index, minimum (min) saturation, average saturation, average apnea-hypopnea duration for determining the required CPAP therapy pressure setting.

Results: Backward regression analysis identified AHI, neck circumference and min saturation as predictive parameters for the CPAP pressure. Age and BMI were entered at Step 1 hierarchical regression, explaining 6.1% of the variance in CPAP setting. After entry of AHI, neck circumference and min saturation in Step 2 the total variance explained by the model as a whole was 19.5%, F(5,697) = 35.08, p<0.0005. The three control variables explained an additional 13.8% of the variance in CPAP therapy pressure, after controlling for age and BMI.

Conclusions: OSAS severity, neck circumference and overnight minimum saturation have a statistically significant contribution of 19.5% on the variance of the CPAP therapy pressure, independently of the age and the obesity of the subject.

P2213

Capsaicin-induced cough reflex is inhibited by deep inspiration in children with mild asthma

Renata Pecová1, Tatiana Michnová1, Jaroslav Faby2, Tomas Zakou1, Martina Nechcisl2, Zoltan Tomori1, 1Dept of Pathophysiology, Jessenius Medical Faculty, Comenius University in Bratislava, Martin; 2Respiratory Diseases, Srobar’s Institute of Paediatric Tuberculosis, Dolny Smokovec, Slovakia

Background: Asthma is characterized by bronchospasm accompanied with frequent coughing, the pathogenesis of which is not clear. In healthy adults deep inspirations (DI) provide a protective effect against bronchoconstriction triggered by methacholin, which correlates with the number of accompanying cough efforts. In adult asthmatics DI have some spasmolytic effect, which decreases with age and severity of the disease. Our aim was to test the elicibility of cough reflex by capsaicin in children with mild asthma and their presupposed inhibition by DI.

Methods: In 21 children (8 girls and 13 boys of mean age 13.3 y) with mild asthma (FEV1 >80%) the cough reaction to inhalation of increasing concentrations
of capsaicin from a compressed air-driven nebulizer manifesting with 2 and 5 or more cough efforts (C2 and C5) was tested. The effect of previous DIs was also examined. Results: In control conditions 20.86 (14.58-29.8) umol/l of capsaicin provoked no detectable respiratory events. In-laboratory polysomnography (PSG) according to the recommendations of AASM. RERAs were identified by a flattening of the airflow registered by nasal cannula and/or a visible increase in thoraco-abdominal effort leading to an arousal. All PSGs performed during a period of 6 month with an apnea/hypopnea index of less than 15/h were reanalyzed by a single sleep specialist. Patients (pts) demonstrating RERAs in more than 50% of all breathing events were included for further study. Within 303 sleep studies a total of 45 pts were included (14,8%), mean respiratory disturbance index 17.4±10.4/h. 71% were male, with a mean age of 54,6±14.8 years. In 42% of the pts sleep latency and in 63,8% sleep efficiency (mean 78.5±12.6%) were reduced. Decreased slow wave sleep was found in 55%. In 61% a reduced REM sleep was found and all pts had a high arousal index (41±18/3hr).

The pts included in our sleep clinic 50% showed an increased epworth scale (12±6.5), 36% were hypersomnolent and in 75% (BMI=30±6.9) pts the results of a positive therapy questioner (ptt) with improvements of symptoms (ESE=<8) and good adherence. Contrary to other data we found a high% of males within the pts with mainly RERAs in PSGs. As a conclusion, pts with RERAs should be evaluated for EDS for therapy with ptt improves daytime symptoms and is reasonably well tolerated.

Efficacy of the “tennis ball technique” in patients with positional obstructive sleep apnea syndrome

G.E. de Vries1, P.M. Meijer2, J.H. van der Hoeven2, R.A. Feijen2, B. Stegenga2, P.I. Wijkstra1. 1Pulmonary Diseases and Tuberculosis, University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands; 2Clinical Neurophysiology, University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands.

Introduction: In obstructive sleep apnea (OSA) collapsibility of the upper airway is increased in the supine sleeping position, resulting in an increase of apnea-hypopnea index (AHI) and severity of apneic events.

Aim: To assess whether the “tennis ball technique” (TBT) prevents positional OSAs-patients from lying on their back and whether this therapy is effective in reducing AHI, severity of events and excessive daytime sleepiness (EDS).

Methods: Thirty patients with a positional OSA at baseline (14 mild, 17 moderate, 2 severe) were treated with TBT. After at least 4 weeks a second sleep study under treatment was performed to assess differences between baseline and follow-up percentage in supine position, AHI, minimal oxygen saturation and EDS. Treatment was considered successful when AHI reduced <20% or reduced at least 50%.

Results: Supine sleeping position reduced from a median (IQR) of 33.2 (23.6-43.7)% to 6.6 (0.0-14.3)%; p<0.001. Minimal saturation improved from a median (IQR) of 86.0 (83.0-87.8)% to 90.0 (84.3-89.0)%; p=0.047. The Epworth Sleepiness Scale decreased from a mean (SD) of 11.2 (5.3) to 9.2 (5.3); p=0.002.

TBT treatment was successful in 23 of the 33 patients.

Anastasia Papastefanou, Vaggelis Balafas, Nikos Kostomitsopoulos, George Matziaras, Katerina Vlami, Argiro Antaraki, Ultrasound evaluation of diaphragmatic function in obstructive sleep apnea diagnosis of OSA.

Methods: Sonomicrometry transducers were implanted in 12 awake canines. A tracheostomy was performed. Pressure was applied by closing a valve periodically for 10 sec. The diaphragmatic functions were compared: during normal airway breathing, sustained hypoxia and recovery.

Results: Pressure was predictive of collapsibility during sleep.

Conclusion: The addition of MMAA to a type 3 PM improves the accuracy in the detection of respiratory events and gives useful information. It improves Sensitivity and Negative Predictive Value, without a significant drop in Specificity and Positive Predictive Value, suggesting that it is an attractive device for the diagnosis of OSA.

P2219
Ultrasound evaluation of diaphragmatic function in obstructive sleep apnea

George Matziaras, Katerina Vlami, Argiro Antaraki, Anastasia Papastefanou, Vaggelis Balafas, Nikos Kostomitsopoulos, Sporos Papagi, Alkiviadis Kostakis, 2nd Pulmonary Department Attikon, Attikon General Hospital of the University of Athens, Athens, Chaidari, Greece; 2Center for Experimental Surgery, Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Background: Little is known about diaphragm function during obstructive sleep apnea syndrome. On the other hand, ultrasound has been used to image the diaphragm functionally and to evaluate neuromuscular blockade. The aim of this study was to use ultrasound technique to evaluate and quantify diaphragm function in a rat model during sleep apnea under condition of normoxia.

Methods: Experiments were conducted in ten male adult Wistar rats weighing 350 gr, which were anaesthetized with Ketamine-Xylazine intraperitoneally. Air was breathing after the tracheostomization in a circuit with an electromagnetic valve which was closing periodically every minute for 10 sec for two hours, mimicking obstructive apnoeas. Supplemental oxygen was added to keep normal arterial saturation (SpO2>97%). Diaphragm Inspiratory Amplitude (DIA) (cm), Diaphragm Inspiratory Time (Ti) (sec), Ti/ET, Diaphragm Motion Time (DMT) (sec) and Diaphragm Resting Time (DRT) (sec) were measured from the M-mode sonographic images. Data analyzed and compared between normal breathing (time 0) and breathing after two hours of airway obstructions (time 0+2).

Results: All diaphragm measurements (DIA,Ti, DMT and DRT) from time 0 to time 0+2 were compared using the Wilcoxon signed-rank test and showed a statistically significant reduction (p<0.05) between the two time points.

Conclusions: These findings suggest that diaphragmatic function is affected acutely during obstructive sleep apnea. It is also indicated that diaphragmatic fatigue as expressed via DIA,DMT,DRT and Ti is present independently of hypoxemia after two hours of airway obstructions during sleep.

P2220
Effect of upper airway stimulation for quality of life and sleep architecture in patients with moderate-to-severe OSA

Johannes Struβ 1, Arndt Schüz 1, Peter Körner 1, E'ren Leiß 1, Christiane M. Wedenitz 1, Stefan Fink 1, Axel Lütkenhöner 1, Georg Bruck 1, 1Pulmonology, University Hospital Schleswig-Holstein, Campus Lübeck, Germany

Background: Electrical stimulation of the hypoglossal nerve can improve obstructive sleep apnea syndrome (OSAS). It is however unknown whether the stimulation affects sleep architecture and quality of life.

Methods: Inspire systems were implanted in moderate-to-severe OSA patients who failed, or were intolerant for CPAP. Sleep architecture was evaluated using lab-based polysomnography at pre-implant and post-implant, at which times Epworth Sleepiness Scale (ESS) and Functional Outcomes of Sleep Questionnaire (FeSQ) were also collected. Results are presented as Mean ± SD.

Results: Twenty eight subjects were implanted. The data collection is on-going and 18 have completed month 12 visit. Both ESS and FeSQ improve significantly from the baseline to the last visit. There was a trend toward increased percent of slow wave sleep and REM sleep at the last visit post-implant, but no significant change in total sleep time, sleep efficiency, percent of slow wave sleep or REM sleep was detected.

Conclusion: Preliminary findings showed that upper airway stimulation improves quality of life without changing sleep architecture in patients with moderate-to-severe OSA.

P2221
Upper airway collapsibility evaluated by negative expiratory pressure test in severe obstructive sleep apnea

Salvatore Romano 1, Adriana Salvaggio 2, Raquel Hira 1, Anna Lo Bue 2, Stefano Piccolo 1, Luis Vicente Oliveira 1, Giuseppe Insalaco 1, Rehabilitation Sciences Master’s Program, Nove de Julho University, Sao Paulo, SP, Brazil; 2National Research Council of Italy, Institute of Biomedicine and Molecular Immunology A. Monroy, Palermo, Italy; 3Department of Clinical and Experimental Medicine and Pharmacology - Respiratory Diseases Unit, University of Messina A.O.U. G. Martino, Messina, Italy

Introduction: Obstructive sleep apnea (OSA) is a risk factor for cardiovascular disease and could have serious consequences. Increased upper airway collapsibility is one of the main determinants of obstructive sleep apnea and its evaluation could be useful for identification.

Objective: To investigate usefulness of measurements of upper airway collapsibility by negative expiratory pressure application, as a screening test for severe OSA.

Method: 24 severe OSA and 24 normal subjects matched by body mass index referred to our sleep laboratory, underwent overnight sleep study and diurnal negative expiratory pressure test. Flow drop (ΔV) and expiratory volume in the first 0.2s (V0.2) during negative expiratory pressure application was measured.

Results: ΔV (%) and V0.2 (%) were statistically different between normal and apneic subjects. Apneic patients have greater falls of flow than normal subjects. Additionally, severely apneic patients exhaust during the first 0.2 s of negative expiratory pressure application, an average of only 11.2% of the inspired volume compared to 34.2% of normal subjects. Receiver operating characteristic analysis showed that V0.2 (%) and ΔV (%) could very accurately identify severe obstructive sleep apnea subjects (sensitivity of 95.8 and 91.7% and specificity of 95.8% and 91.7% respectively).

Conclusion: The percent expiratory volume at 0.2 s and flow drop amplitude is a highly accurate parameter to detect severe obstructive sleep apnea subjects. Pharyngeal collapsibility measurement during wakefulness using negative expiratory pressure is predictive of collapsibility during sleep.

P2222
Parasternal intercostal function during sustained hypoxia

Michael Ji, Tetsuomi Ikekami, Paul Easton. Department of Critical Care Medicine, University of Calgary, Calgary, AB, Canada

Introduction: In humans and other mammals, sustained isocapnic hypoxia for 20-60 minutes elicits a biphasic ventilatory response (roll-off), with initial peak ventilation followed by decline to a plateau. The activities of the respiratory muscles during the sustained hypoxic response are not known.

Aim: To study ventilation and actions of the chest wall muscles, specifically Parasternal Intercostal (PARA) during sustained hypoxia in awake canines.

Methods: After implantation of sonomicrometry transducers and EMG electrodes in PARA, and complete recovery, we measured airflow, oxygen saturation, end tidal CO2, moving average EMG and shortening (SHORT) of PARA, during room air ventilation (BASE), followed by 25 minutes of isocapnic hypoxia (mean 78% SpO2). The canines were awake, breathing through a nose mask. We report results 2-3 min after reaching SpO2 80% (PEAK) and final 5 min (PLATEAU) of sustained hypoxia, then room air breathing (RECOVERY).

Results: For N=7 (mean 28.9 kg, 28 days post implant), minute ventilation (Vt) and tidal volume (VT) increased significantly from BASE to PEAK, then decreased

258. Cardiometabolic and neurocognitive changes in obstructive sleep apnoea

P2223
Structural brain changes related to disease duration in patients with asthma
Andreas von Leupoldt1,2, Stefanie Brassen2, Hans Jörg Baumann3, HansKlose3, Christian Büchel1,2, Andreas von Leupoldt 1,2, Stefanie Brassen 2, Hans Jörg Baumann 3, HansKlose 3, 1Department of Psychology, University of Hamburg, Hamburg, Germany; 2Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3Department of Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Dyspnea is the impairing, cardinal symptom patients with asthma repeatedly experience over the course of the disease. However, its accurate perception is also crucial for timely initiation of treatment. Reduced perception of dyspnea is associated with negative treatment outcome, but the underlying brain mechanisms of perceived dyspnea in patients with asthma remain poorly understood. We examined whether increasing disease duration of asthma is related to structural brain changes and studied the associations between structural brain changes and perceived dyspnea. By using magnetic resonance imaging in combination with voxel-based morphometry, gray matter volumes of the insular cortex and brainstem periaqueductal grey (PAG) were examined in fourteen patients with mild-to-moderate asthma and correlated with asthma duration and perceived affective unpleasantness of respiratory load induced dyspnea. Whereas no associations were observed for the insular cortex, longer duration of asthma was associated with increased gray matter volume in the PAG. Moreover, increased PAG gray matter volume was related to reduced ratings of dyspnea unpleasantness. The present results demonstrate that increasing disease duration is associated with increased PAG gray matter volume in patients with mild-to-moderate asthma. This structural brain change might contribute to reduced perception of dyspnea in some patients with asthma and, thus, negatively impact treatment outcome.

P2224
The impact of obstructive sleep apnea on glucose regulation and liver injury in nondiabetic men
Qian Xiaoan, Liu Yi. Pulmonary Interal Medicine, Civil Aviation General Hospital, Beijing, China

Objective: We explored the effect of Obstructive sleep apnea syndrome (OSAS) on glucose regulation and liver injury in nondiabetic men.

Results and methods: We included 49 non diabetic men of the OSAS patients with concomitant diseases/medications based on overnight polysomnography and blood tests. We measured fasting serum glucose, FPG, fasting insulin, FINS, C-reactive protein, CRP, liver enzymes such as alanine aminotransferase, ALT and lactate dehydrogenase, LDH and calculated new homeostasis model assessment estimates of insulin resistance (HOMA-IR), insulin sensitivity (HOMA-IS) and pancreatic beta-cell function (HOMA-2-B). HDL and triglycerides were significantly increased in patients with OSAS.

Results: Median fasting insulin level, HOMA-IR, and HOMA-IS of the severe OSAS group were significantly higher than those of the other OSAS subgroups and controls. No significant differences were observed for FPG and HOMA-2-B. CRP levels were significantly correlated with BMI, with AHI with the lowest Stp2q, with HOMA-IR and with HOMA-IS during sleep. Both levels of ALT and LDH were significantly positively correlated with insulin and HOMA-IR (r = 0.001 respectively). Significant elevations in HOMA-IR were seen during sleep in patients with OSAS.

Conclusions: We demonstrated that OSAS contributes to the development of insulin resistance and liver injury. Insulin resistance may be the key effect of OSAS on glucose regulation. Insulin resistance may be the pathophysiologic basis of liver injury in OSAS.

P2225
Effect of controlled blood pressure values in a population with obstructive sleep apnea syndrome (OSAS) and arterial hypertension (HT)
Oana Claudia Deleanu1, Andra Elena Malaut2, Romania; 2Ramona Liela Nedelea2, Ruxandra Ulmeana1, Ion Mieruz-Mazile1, Florin Dumitru Mihalcan1, 1Pneumology III, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2Pneumology III, Institute of Pneumology “Marius Nasta”, Bucharest, Romania; 3Pneumology III, Faculty of Medicine and Pharmacy, Oradea University, Bucharest, Romania; 4Statistical Laboratory, Technical University of Civil Engineering, Bucharest, Bucharest, Romania

Rationale: OSAS and HT are associated through cause-effect relationship, but few data in literature studies the effect of blood pressure (BP) control medication on OSAS.

Methods: We analysed 162 OSAS patients with treated HT, 46.9% with controlled BP (CBP), 53.1% with uncontrolled BP (UBP), and studied differences between groups regarding demographics, anthropometric data, symptoms, comorbidities, sleep study’s reports, therapy. We use SPSS (T, chi tests)ListenRead phonetically.

Results: 76 CBP patients: (22.8%) women, 54 (71.1%) men, mean age 59.1 ± 10.8 years, average apnea-hypopnea index (AHI) 49.5 ± 36.5; 86 UBP patients: (20 %) women, 66 (65%) men, mean age 55.3 ± 8.9 years, average AHI 58.1 ± 38.7. Statistically significant differences (p < 0.05) were in relation to other OSAS patients: more difficult to treat in these patients, who, according to the results of this study, would benefit more from CPAP therapy. OSAS may coexist in patients with HT controlled because of the presence of symptoms or signs and the patient, mostly young or middle-aged adult, cannot receive adequate treatment.

P2226
Severity of sleep-disordered breathing is an independent predictor of metabolic dysfunction in a population with obstructive sleep apnoea
Brian Korn1, Dezide Fitzgerald3, Audrey Russell3, Lynda Hayes1, Geraldine Nolan1, Walter McNicholas1,2,1 Pulmonary and Sleep Disorders Unit, St. Vincent’s University Hospital, Dublin, Ireland; 2School of Medicine and Medical Science, University College Dublin, Dublin, Ireland

People with obstructive sleep apnoea syndrome (OSAS) are at increased risk of insulin resistance, dyslipidaemia, and adverse cardiovascular outcomes. However, obesity is a major confounding factor in studies examining the impact of OSAS on the development of these sequelae. It remains uncertain if sleep-disordered breathing is an independent driver of metabolic dysfunction.

We sought to assess the influence of OSAS severity on metabolic health by prospectively studying the fasting lipid & glycaemic profiles of newly diagnosed OSAS patients. Subjects were stratified according to OSAS severity, and lipid profiles were compared between groups. The relationship between OSAS severity and metabolic health was examined using a hierarchical multivariate linear regression model. The present results demonstrate that increasing disease duration is associated with increased PAG gray matter volume in patients with mild-to-moderate asthma. This structural brain change might contribute to reduced perception of dyspnea in some patients with asthma and, thus, negatively impact treatment outcome.

Conclusions: We demonstrated that OSAS contributes to the development of insulin resistance and liver injury. Insulin resistance may be the key effect of OSAS on glucose regulation. Insulin resistance may be the pathophysiologic basis of liver injury in OSAS.

P2227
Effect of CPAP treatment on endothelial function, inflammatory markers, blood pressure and glucose control in patients with OSAS with emphasis on gender differences
Athanasios Panoutopoulos1, Anastasios Kallianos1, Apostolis Pappas1, Lembonia Velentza1, Christos Mermigkas1, Koastinios Kostopoulos1, Vasileios Kouranos2, Aggeliki Rapiti3, Eleni Koufogiorga1, Alexandros Mittasakis1, Andrea Elena Malaut2, Romania; 2Ramona Liela Nedelea2, Ruxandra Ulmeana1, Ion Mieruz-Mazile1, Florin Dumitru Mihalcan1, 1Pneumology III, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2Pneumology III, Institute of Pneumology “Marius Nasta”, Bucharest, Romania; 3Pneumology III, Faculty of Medicine and Pharmacy, Oradea University, Bucharest, Romania; 4Statistical Laboratory, Technical University of Civil Engineering, Bucharest, Bucharest, Romania

Introduction: Research evidence suggests the presence of endothelial dysfunction
and systemic inflammation in patients with obstructive sleep apnea syndrome (OSA). The effects of CPAP on the aforementioned pathophysiologic pathways, as well as on the systemic disease that result or coexist with the OSA remains elusive.

Aim: To assess the effect of CPAP therapy on endothelial-dependent dilation, plasma levels of inflammatory markers, blood pressure and glucose control in male and female patients with OSA.

Methods: Our study group consisted of 40 patients with no prior history of cardiovascular disease, with an Apnea-Hypopnea Index (AHI) >15 who were assigned to receive CPAP treatment. Measurement of Flow Mediated Dilation (FMD), 24 hour ambulatory blood pressure (BP) and blood analysis were performed at baseline and 3 months after CPAP therapy.

Results: Baseline FMD values were negatively correlated the AHI (r=0.55, p=0.001). After 3 months of CPAP there was a significant increase in the FMD values and a significant reduction in the patients’ 24hr systolic BP, diastolic BP and Pulse Pressure (PP), daytime systolic and diastolic BP, nighttime systolic BP and the reactive protein (CRP) and HbA1c levels. When divided by gender only male patients produced similar statistically significant results.

Conclusion: Our results suggest that CPAP therapy improves the endothelial function, the blood pressure and glucose control in male patients with OSA.

Further research is warranted in order to further elucidate the impact of CPAP on the cardiovascular risk of male and female patients with OSA.

P2228
Endothelial function in obstructive sleep apnea syndrome
Evangelos Markozanès, Fotis Kapismalis, Kyriaki Cholidou, Konstantina Kyrkou, Konstantina Kosta, Manos Alchanatis. 1st Respiratory Medicine Department, Sotiria Hospital, University of Athens, Athens, Greece

Introduction: Obstructive sleep apnea (OSA) is an independent risk factor for myocardial infarction and stroke. Endothelial dysfunction could be one of the pathogenetic mechanisms linked to OSA related risk for cardiovascular diseases.

Aim: To assess the effect of CPAP on endothelial markers and serum inflammatory cytokines in OSA patients.

Methods: We studied 38 patients by polysomnography in the laboratory, 27-86 years (1.55 ± 0.3 vs. 1.76 ± 0.2, p=0.02) and higher minimal SaO2 (80.3% ± 9.1% vs. 87.4% ± 9.1%, p=0.02). They were slightly older (51.9 ± 7.2 years vs. 43.4 ± 7.3 years, p>0.05) and higher BMI (33.1 (7.1) vs. 28.7 (5.7), p<0.01). Baseline hsCRP (mg/dl) was higher in male patients (0.44 (0.5) vs. 0.36 (0.75), p=0.008, beta=-0.450, R2 =0.23, p=0.008).

Conclusion: The results of our study confirm the effects of CPAP therapy on endothelial markers and serum inflammatory cytokines. Further studies are needed to confirm these findings.

P2229
The lack of evidence based knowledge of metabolic syndrome in obesity hyperventilation syndrome
Alonda S. Alcalá-Maparedes, Ketkert Bijkerk. Pulmonary Diseases and Internal Medicine, Diakonessenhuis, Utrecht, Netherlands

Introduction: The obesity hyperventilation syndrome (OHS) is a severe sleep related breathing disorder, with obstructive sleep apnea syndrome (OSAS) as the predominant sleeping pattern. It is often accompanied by multiple organ tract involvement. In OAS, the interaction with metabolic syndrome is well studied. In OHS however, it is unclear whether the severity of disease has consequences for the occurrence and severity of metabolic syndrome. We evaluated the presence of evidence based knowledge.

Methods: A systematic Pubmed and Cochrane search was performed, final check 24th February 2011, for metabolic syndrome in concurrence with OAS and OHS, and related terms and synonyms in title and abstract (exclusion criterion: duplicates). The final data set was achieved by elimination of studies that conformed predefined criteria: animal studies, studies < 1990, age < 18 years, genetic diseases, case reports, and studies without original data. Outcome parameters were total number of studies and randomized controlled trials (RCT), before and after the elimination strategy, for OSA and OHS versus OSA.

Results: 767 initial hits were found in OSA, versus 273 for OHS. After the predefined elimination strategy, 171 remained, containing 5 RCT’s for OSA, versus 6 studies, without any RCT, for OHS (Fischer exact p < 0.0001 for final total number and p < 0.05 for RCT’s).

Conclusion: A markedly lower number of hits was found for metabolic syndrome in OHS, as compared to OSA. Within the complexity of clinical features in OHS, the metabolic syndrome seems to be an unexplored area in research.

P2320
C-reactive protein (CRP) levels in obstructive sleep apnea (OSA) patients and relation to severity of OSA
Juan-Jose Garrido1, Daniel Fernandez-Berges2, Francisco-Javier Felix3, Maria-Jose Zarot1. 1Respiratory, Don Benito Hospital, Don Benito, Badajoz, Spain; 2Investigation Unit Don Benito-Villanueva, Fundacional Gerencia de Area Don Benito-Villanueva, Villanueva de la Serena, Badajoz, Spain; 3Primary Care, North Villanueva Primary Care Center, Villanueva de la Serena, Badajoz, Spain

Introduction: CRP has been proposed as a cardiovascular risk marker. OSA is associated to metabolic syndrome and major cardiovascular events.

Objectives: To study CRP levels in OSA patients in comparison to healthy people, and the relationship between severity of OSA and CRP levels.

Method: Case-control study including 100 consecutive diagnosed OSA patients and 113 healthy people randomly selected from general population. Age, sex, hypertension, diabetes, diabetes, body mass index (BMI), smoking, Epworth scale, spirometry, respiratory disturbance index (RDI) and high sensitivity CRP (hsCRP) were measured.

Results: Cases and controls characteristics are shown in Table 1. Multiple regression model analysis coefficients of CRP levels in OSA patients are shown in Table 2.

Table 1. Case and control characteristics
OSA patients Healthy people P value

Age (years) [mean (standard deviation)] 54 (13.7) 49 (14.8) 0.01
Male (%) 71 52 0.003
BMI (kg/m²) 33.1 (7.1) 28.7 (5.7) <0.01
Hypertension (%) 37 28 0.174
Diabetes (%) 22 10 0.02
Hyperlipidemia (%) 39 34.5 0.46
Smoker or ex-smoker (%) 51 34.5 0.015
hsCRP (mg/dl) 0.47 (0.75) 0.44 (0.75) 0.002

Multiple regression model analysis coefficients of CRP levels in OSA patients are shown in Table 2.

Efficacy of BiPAP AutoSV advanced in subjects with congestive heart failure and central apnea
Winfried J. Randerath1, D. Banerjee1, M. Treml1, W. Galecke1, C. Priezagl2, A. Ali3, S. Taheri1. 1Institut für Pneumologie, Krankenhaus Bethanien gGmbH, Solingen, Germany; 2Department of Respiratory Medicine; Birmingham Heartland Hospital, Birmingham, United Kingdom

Introduction: Auto-Servo Ventilation effectively suppresses Sleep Disordered Breathing (SDB) in patients with Congestive Heart Failure (CHF). This study compared the efficacy of a new mode of ASV that incorporates an automatic EPAP (ASV-Advanced), with and without its Bi-Flex comfort feature, to manually titrated ASV (ASV) in patients with central SDB and CHF.

Methods: Following diagnostic PSG and titration, patients underwent 3 consecutive treatment nights in a random order: ASV, ASV-Advanced and ASV-Advanced with Bi-Flex. For the ASV night, EPAP was set to the level determined during the titration night and Bi-Flex at EPAP+2cmH2O. For the ASV-Advanced nights, the

device was set to automatically determine EPAP and IPAP pressures with a maximum pressure support of 20cmH2O. When activated, Bi-Flex was set to its maximum expiratory pressure relief. Data were analyzed with ANOVA and Bonferroni.

Results: Ten males participated (mean ± SD: age 67.4±11.7, BMI 28.4±4.5 kg/m2, LVEF 25.7±5.7%). Sleep time and efficiency were similar.

Conclusion: ASV-Advanced treats central SDB as effectively as ASV in patients with CHF.

P2232 Metabolic and inflammatory profile in obese and non obese children with obstructive breathing disorders
Silke Weber1, Érico Moreira 1, Renata Mizusaki Iyomasa 1, Ana Carolina Silveira 1, Cinthya Kurokawa 2, Otolaryngology, Pediatrics, Botucatu Medical School São Paulo State University, Botucatu, São Paulo, Brazil

Introduction: Adult OSA is a known risk factor for metabolic diseases, but still unexplored in children. Obesity, an important cofactor, is increasing in the pediatric population.

Aim: Study the metabolic profile and the levels of TNF-α in obese and non obese children with obstructive breathing disorders.

Methods: Children of both genders, aged 6 to12 years, with obstructive breathing disorders were included. Children were divided in 2 groups, obese and non obese, where blood samples were taken for analysis. The lipids, glucose, insulin, tyroxin and TNF-α levels were determined. Results were compared for the 2 groups.

Results: 17 children, median age of 6.5 years, 10 obese- and 7 non obese, were included. There glucose level was 85 mg/dl in both groups. Insulin level was higher in the obese group (10.7±2.3 mU/L, X 6.7±3.29 mU/L, p<0.01). There were no significant differences in total cholesterol (108±4.37 mg/dl vs 181±5.33, p<0.05), HDL (56±1.45 mg/dl vs 49±1.78 mg/dl, p<0.05) and LDL (98±22.7 mg/dl vs 110±7.28 mg/dl) in the non obese and obese group, respectively. TGL levels were higher in the obese group (106.5±37 mg/dl vs 64±23 mg/dl). Thyroxin and TSH levels did not differ in both groups. The average TNF-α was 0.36±0.09 pg/ml but differed in obese 0.56±0.53 pg/ml and 0.10±0.07 pg/ml (p<0.05).

Conclusion: Obesity may cause additional metabolic changes (increased insulin resistance and TGL levels) in children with obstructive breathing disorders. The metabolic inflammatory profile must be investigated for a better understanding of OBD in childhood.

P2233 Cognition, quality of life and adherence to CPAP after 18-months treatment in obstructive sleep apnea patients
Vincenzo Castronovo1, Sara Marel1, Mark S. Aloia2, Marco Zucconi 1, Silke Weber1, Érico Moreira 1, Ana Carolina Silveira 1, Cinthya Kurokawa 2, Otalaryngology, Pediatrics, Botucatu Medical School São Paulo State University, Botucatu, São Paulo, Brazil

Obstructive Sleep Apnea (OSA) determines cognitive dysfunctions and diminished quality of life (QoL). Adherence to CPAP treatment although effective, still remains a challenge for patients.

Aims: To evaluate neurocognitive functions, adherence to PAP and QoL in a consecutive group of OSA patients at baseline (BL) compared to age and education-matched normal controls and to assess changes after 18-months of fixed PAP treatment (FU) with C-flex (Philips/Respironics).

Methods: 10 patients were excluded for low compliance to PAP within the 18-month observation period. At BL patients showed significantly lower scores than controls in all neurocognitive domains (p<0.05) as well as in FOSQ (p<0.001) and SF36. At FU an overall significant improvement in the general health subscale of SF36. At FU mean compliance to PAP was 6.1±1.36 hrs and% of days of use 88.5±11.7. There glucose level was 85 mg/dL in both groups. Insulin level was higher in the obese group (10.7±2.3 mL, X 6.7±3.29 mL, p<0.01). There were no significant differences in total cholesterol (108±4.37 mg/dl vs 181±5.33, p<0.05), HDL (56±1.45 mg/dl vs 49±1.78 mg/dl, p<0.05) and LDL (98±22.7 mg/dl vs 110±7.28 mg/dl) in the non obese and obese group, respectively. TGL levels were higher in the obese group (106.5±37 mg/dl vs 64±23 mg/dl). Thyroxin and TSH levels did not differ in both groups. The average TNF-α was 0.36±0.09 pg/ml but differed in obese 0.56±0.53 pg/ml and 0.10±0.07 pg/ml (p<0.05).

Conclusion: Obesity may cause additional metabolic changes (increased insulin resistance and TGL levels) in children with obstructive breathing disorders. The metabolic inflammatory profile must be investigated for a better understanding of OBD in childhood.

P2234 Association between arterial hypertension and impaired glucose tolerance (IGT) in obstructive sleep apnea (OSA) patients
Robert Pływaczewski1, Przemysław Bielen1, Luiza Jonczak 1, Dorota Gorecka 2, Robert Pływaczewski1, Przemyslaw Bielen1, Luiza Jonczak 1, Dorota Gorecka 2, Robert Plywaczewski1, Przemyslaw Bielen1, Luiza Jonczak 1, Dorota Gorecka 2, Robert Plywaczewski1, Przemyslaw Bielen1, Luiza Jonczak 1, Dorota Gorecka 2, Robert Pływaczewski1, Przemyslaw Bielen1, Luiza Jonczak 1, Dorota Gorecka 2

Obstructive sleep apnea is a risk factor of cardiovascular and metabolic disturbances. The aim of this study was to assess relationship between IGT and AHI, obesity and cardiovascular diseases in OSA subjects. We studied 255 OSA pts (195 males (76.5%) and 60 females (23.5%), mean age – 56 ±8.10.7 years. AHI > 5±20.3. BMI – 33±5.5 kg/m2, S02 – 91.7±4.7%, T90-19±1.25±4.8%.

Impaired glucose tolerance (IGT) (plasma level ≥ 140 mg% after 2 hours of administration 75 g glucose in oral glucose tolerance test (OGTT)) was found in 69 subjects (27.1%). In 11 patients (4.3%) OGTT confirmed diabetes (glucose ≥ 200 mg%).

Discussion: We could show, that in OSA patients during a short period of sleep the changes of BP are not directly correlated with the expected sleep or respiratory parameters but with the variation of blood pressure values. The relevance of this result for the development of hypertension remains to be proven.

This work was supported by the Fundação para a Ciência e a Tecnologia PPRO/ 82991/2007
P2236
Perception of problems driving and driving simulator performance in obstructive sleep apnoea syndrome (OSAS)
Department of Pulmonology, University of Ljubljana, Ljubljana, Slovenia; 1Department of Chest Diseases, Critical Care, St Johns Medical College Hospital, Bangalore, Karnataka, India; 2Clinic of Endocrinology, Clinical Center of Serbia, University Medical School, Belgrade, Serbia

Introduction: Advising patients with OSAS about driving is difficult. In the absence of an objective test reliance has to be given to a patient’s account of their driving ability. In simulated driving, OSAS patients perform worse than controls but an individual’s performance does not correlate with severity or symptoms of OSAS. Patients’ account is also likely to be influenced by worry of losing licence. The relationship between patients’ perception & driving simulator performance was explored as part of development of an advanced office based driving simulator (Mobile360) for pre-operative OSAS assessment.

Methods: 72 patients (ESS 12±6.0, ODI 39±2.21) completed a questionnaire pertaining to their driving behaviour & completed 50 minutes of simulated motorway driving. Two events were programmed that required evasive action to avoid a crash: minor & major. A “fail” was defined by an unprovoked crash or crash at the minor event. A crash at the major event was deemed as “indeterminate”, the rest were deemed to have “passed”. Chi squared test was performed to see whether patients admitted to problem driving were more likely to “fail” Logistic regression analysis was performed to predict a “fail” from the questionnaire.

Results: 54% subjects admitted to problem driving. Only the ESS was higher in these patients (p<0.001). A “fail” could not be predicted from the questionnaire. Subjects who reported problem driving were not significantly more likely to fail than others. This highlights that patients’ perceptions are not a reliable indicator of driving ability in OSAS. An objective test that is reliable, repeatable and practical for everyday clinical use is needed to inform decision making.

P2237
Effects of non-surgical therapeutic program on the metabolic syndrome (MetS) in morbidly obese patients
Miodrag Vukcevic1, Milina Tancic2, Svetlana Vujovic2. 1Pulmonary Department, KBC B Kosa, University Medical School, Belgrade, Serbia; 2Clinic of Endocrinology, Clinical Center of Serbia, University Medical School, Belgrade, Serbia

Objective: The aim of this study was to assess the effects of non-surgical therapeutic program on the metabolic syndrome (MetS) in morbidly obese patients.

Methods: Sixty-four extremely obese patients were involved in the therapeutic program, which consisted of two alternating phases: the three-week therapeutic fasting or semi-fasting in hospital conditions and the low caloric diet (LCD) with dosed physical activity in outpatient conditions. At the baseline we measured: anthropometric parameters, blood pressure and lipid profile. Subjects underwent an oral glucose tolerance test (OGTT) and insulin resistance/sensitivity was evaluated by the homeostasis model assessment (HOMA) and the oral glucose insulin sensitivity (OGIS). After weight reduction by at least 10%, all mentioned assessments were repeated.

Results: None of the patients had significant adverse effects. Forty-one patients aged 43±11 completed the study. The mean weight loss was 27 kg or 18% of the initial weight (p<0.01), which was followed by a significant decrease of the insulin resistance, the overall prevalence of MetS (32%) and all MetS parameters, without the significant change in high-density lipoprotein (HDL). In the subgroup of 15 patients weight reduction of 20% of the initial weight (p<0.01) resulted in AHI reduction of 31%.

Conclusions: This weight loss program substantially improves the MetS in extremely obese patients. The tailored alternating either fasting or semi fasting should be considered as an optional approach to manage extreme obesity and related metabolic adverse effects and reduce severity of sleep breathing disorders.

P2238
A study of insulin resistance in moderate to severe obstructive sleep apnea in non diabetics and its response to nasal CPAP treatment
Archanas Babu Rao, George Albert D. Souza, Striram Sampath, Uma Subramanian Unni. Chest Diseases, Critical Care, St Johns Medical College Hospital, Bangalore, Karnataka, India

Background: The effects of nasal continuous positive airway pressure (nCPAP) for obstructive sleep apnea (OSA) on insulin resistance (IR) are not clear and have found conflicting results.

Aims and objectives: To evaluate IR in non diabetic patients with moderate to severe OSA and its response to treatment with nCPAP on IR in these patients.

Method: 30 consecutively newly diagnosed patients with moderate to severe OSA were enrolled in the study. Samples of peripheral venous blood for measurement of glucose and insulin were collected after overnight fasting and IR was calculated by HOMA (Homeostasis model assessment) method. Patients were treated with nCPAP for 1month and HOMA IR was again measured.

Results: 30 OSA subjects, with a mean apnea-hypopnoea index (AHI) of 80.46 [57.24] were included in the study. The HOMA IR (5.78) was significantly higher compared to normal south indian population. There was no positive correlation of HOMA IR with AHI. This may be due to the small sample size and IR attributable to OSA may be small and constant and not related to the severity. The HOMA IR was measured 1 month after use of CPAP. The HOMA IR significantly improved from 5.78 to 4.82 (p=0.024) after 1 month of treatment with nCPAP in OSA patients. There was also significant improvement in insulin levels from 21.75 to 19.39 (p=0.009).

P2239
Relationships between obstructive sleep apnea and antioxidant/antioxidant status
Lipia Puni, Andrea Didilescu, Ovidiu Fira-Mihailescu, Felicia Oliga, Maria Greabe, Alexandra Toan, Nicoleta Muru, Anca Petruovan, Cristian Didilescu. Pneumology, Pneumophthisology Hospital, Basar-Mare, Basar-Mare, Maramures, Romania

Introduction: In Sleep Apnea Syndrome (SAS) the episodes of hypoxia/reoxygenation can generate reactive oxygen species and promote oxidative stress.

Aim of the study: Evaluation of possible relationships between obstructive sleep apnea and biomarkers of oxidative stress in patients with SAS.

Methods: Two Romanian groups, consisting of 29 patients diagnosed with SAS and 17 healthy controls, were recruited. All subjects underwent cardiorespiratory polypigraphy. Plasma levels of homocysteine (Hcy), glutathione reductase (GSSG-Red), glutathione peroxidase, endothelin-1, low density lipoprotein (LDL), high density lipoprotein (HDL) and uric acid were assessed. Statistical analysis was performed using Spearman and Pearson correlations tests, two tailed test and one-way ANOVA test.

Results: The mean values of LDL were statistically significant higher in SAS patients (p=0.05), while GSSG-Red was higher in controls (p=0.01). In SAS group, correlations were found as follows: GSSG-Red and snoring (r=0.34; p=0.05); GSSG-Red and apneas number (r= -0.36; p=0.05); body mass index (BMI) and uric acid (r=0.43; p=0.01), ratio Hcy/BMI and HDL (r=0.52; p=0.003).

Conclusions: Plasma GSSG-Red and Hcy levels may be used as possible markers to provide information related to oxidative/antioxidant status in SAS patients, making them more prone to developing proatherosclerotic disease.

Road traffic collisions caused by sleepiness in UAE
Mohammed Al-Houqani1, Ham Eid2, Fikri Abu Zaidan3. 1Internal Medicine, Faculty of Medicine, UAE University, Al-Ain, United Arab Emirates; 2Emergency Department, Towam Hospital, Al-Ain, United Arab Emirates; 3Surgery, Faculty of Medicine, UAE University, Al-Ain, United Arab Emirates

Introduction: Road traffic collision RTC is a major health problem in UAE. Sleep as a contributing factor to RTC is not well-studied in the Middle East.

Objective: We aimed to study the proportion of RTC caused by sleep behind the wheel and the factors contributing to sleep related collisions SRC.

Methods: All data of hospitalized drivers who were involved in RTC in Al-Ain city were prospectively collected during the period of April 2006-October 2007. Variables studied included, driver’s demographic data, time, date, location, mechanism of collision, speed at collision and whether sleepiness was a contributing factor reported by the drivers. A direct logistic regression model was performed to define factors related to sleep while driving.

Results: 444 drivers (92% males) were involved in RTC’s during the study period. Sleepiness of drivers was a contributing factor in 5%. Most of the drivers with SRC (79%) reported to speed 100 Km/hr or more during the collision. Rollover was the most frequent mechanism of SRC (58%). SRC was strongly over-represented during Ramadan (79%), in drivers aged 19-35 (84%) and in drivers with sleeplessness (91%).

Conclusions: Sleep disturbance is a major factor in RTC occurrence in UAE. The prevention of sleepiness and awareness of the potential consequences of driving while sleepy should be emphasized. A ‘sleepy driving detection system’ may help to reduce the number of RTCs that are due to sleepiness.

Does respiratory irregularity contribute to the pathogenesis of sleep-disordered breathing in multiple system atrophy?
Satoshi Hoki1, Hideaki Nakayama1, Takayuki Matsuto2, Takayoshi Shimohata1, Toshinori Takada1, Tetsuro Ozawa3, Manatomo Nishizawa2, Eiichi Suzuki4, Ichiy Naito4, 1Dept. of Homeostatic Regulation and Development, Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan; 2Dept. of Community Preventive Medicine, Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan; 3Dept. of Pulmonary Medicine, Niigata University, Niigata, Japan; 4Dept. of Community Preventive Medicine, Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan

Background: Multiple system atrophy (MSA) is the neurodegenerative disease characterized by autonomic failure, parkinsonism, and cerebellar ataxia in various combinations, and has high frequency of sleep-disordered breathing (SDB), which caused by dysregulation of respiratory control.

Aims: This study investigates whether respiratory irregularity is involved in the development of SDB with MSA.

Methods: 22 MSA patients (9men, 60±6.2 years, BMI 23.1±5.0 kg/m²) were enrolled from January 2007 to June 2010. We performed polysomnography (PSG) and laryngoscopy under propofol sedation. Respiratory irregularity was assessed by approximate entropy (ApEn) of respiratory movement, which is a measure of system complexity (Pincus SM, Proc. Natl Acad. Sci. USA 1991). We evaluated from the two-minute data of respiratory movement before falling asleep in PSG (Burioka N, et al. Chest 2003). We chose the age-, sex-, and apnea-hypopnea index (AHI)-matched controls from ordinary obstructive sleep apnea (OSA) patients (BMI 27.6±4.5 kg/m²).

Results: PSG demonstrated that all MSA patients fulfilled OSA criteria, and their AHI was 40±6.26 per hour. Laryngoscopy showed that 15 patients (68%) had vocal cord abductor paralysis (VCAP). In the MSA group, there was a significant correlation between AHI and ApEn of respiratory movement (r=0.63, p<0.01). However, AHI had no correlation with age, BMI, duration and severity of MSA, degree of VCAP, and any respiratory parameters. In the control group, their AHI significantly correlated with BMI (r=0.68, p<0.01), but not with ApEn.

Conclusions: This study raises the possibility that respiratory irregularity influence the severity of SDB in MSA.

P2244
The relationship between obstructive sleep sleep apnoea syndrome and apolipoprotein E alleles
Ebru Kucak1, Oner Balbay2, Ali Nihat Annakaya1, Ege Gu dic Balbay2, Fatma Sifan1, Peri Arab1, 1Chest Diseases, Duzce University Faculty of Medicine, Duzce, Turkey; 2Chest Diseases, Duzce Ataturk State Hospital, Duzce, Turkey

Aim: Clinical and epidemiological studies indicate that OSA has a strong genetic basis. Apo E in humans is an important determinant of blood lipid levels. There are few studies investigating the possible relationship between Apo E and OSA. In this study, we aimed to investigate the association of Apo E alleles with OSA.

Method: 62 adult patients (35 male, 27 female) with sleep apnea applying to Chest Diseases Clinic between October 2006 and May 2009 were included in this study. All patients underwent fullnight PSG and were evaluated for apolipoprotein E alleles.

Results: The mean age was 51±12. According to PSG results, 20 cases with negative PSG and 18 with mild, 10 with moderate, 14 with severe OSA patients was diagnosed. Genetically important patients were divided into 2 groups according to AHI<15 (n:38) and AHI>15 (n:24). No homoygote Apo E2 (22) and homoygote Apo E4 (44) were observed in study group. The cases with OSA had almost statistically significant higher Apo E2 frequency than that of not OSA (23.8%, respectively, p=0.02). Apo E3 allele was significantly correlated with BMI (r=0.40, p=0.003). There was no significant correlation between AHI and Apo E2 frequency.

Conclusions: The presence of Apo E2 allele is a risk factor for OSA. Further studies are needed to confirm this relation.

P2245
A case of obstructive sleep apnoea syndrome with bilateral vocal cord paralysis
Onder Orturk1, Ulgubhik Khayri2, Yucel Kuri1, Mehmet Hac1, Ibrahim Metin Cir1, Mustafa Tur1, Ahmet Akkaya2, Metem Cetin3, 1Chest Diseases, Medical School of Suleyman Demirel University, Isparta, Turkey; 2Otolaryngology, Medical School of Suleyman Demirel University, Isparta, Turkey; 3Radiology, Medical School of Suleyman Demirel University, Isparta, Turkey

Aim: Bilateral vocal cord paralysis (BVC) often caused by trauma, is a rare, but life-threatening condition in patients. Although the most common symptom seen in BVC is respiratory distress, hoarseness and the symptoms of sleep apnea are rare. Here we present an interesting and educative case of BVC, caused obstructive sleep apnea syndrome (OSAS).

Results: A 46- year-old male patient who had a history of snoring, apnea, excessive daytime sleepiness (EDS), admitted to our outpatient clinic with complaints of dypnea and hoarseness. He had these symptoms for a year, but progressed during the last two months. He had also a history of diabetes mellitus and COPD

400s

Farmaceutici SpA. Visit Chiesi Farmaceutici SpA, at Stand D.30
for a year, smoked 25 pack-years. Full-night polysomnography revealed that his apnea-hypopnea index was 67.7/h and minimal oxygen saturation level was 75%, diagnosed as severe OSA. His pulmonary function test demonstrated variable extrathoracic airway obstruction. The ear-nose-throat consultation revealed that vocal cords were bilaterally paralytic at the median border. His chest film, Thorax CT and neck CT were normal. The histopathological examination of biopsies from subglottic region and left vocal cord was reported as edema, hyperemia and chronic inflammation. The patient did not benefit from CPAP titration and the tracheostomy was opened due to the progression of respiratory distress. Later, right arytenoidectomy was performed. The patient indicated that snoring, EDS, hoarseness and dyspnea were improved after the operation.

Conclusion: BVP rarely causes OSA. Thus, a multidisciplinary approach in the diagnosis and treatment of these cases should be done urgently to have a better survival.

P2246
Comorbidities of obstructive sleep apnoea syndrome
Madhav Tamhankar, Murali Mohan, Ranganath Ramanjaneya, Tyas Sen.

Introduction: Obstructive Sleep Apnoea (OSA) is often associated with unrecognized comorbidities. Persons of South Asian origin already have a higher prevalence of diabetes and hypertension than in the developed world, and COPD prevalence is rising fast. We expected that the prevalence of comorbidities would be high in our population with OSA.

Methods: Patients at our referral hospital in India, proven by polysomnography to have moderate to severe OSA (Apnoea Hypopnea Index (AHI) >15/hour), were studied for important comorbidities: diabetes mellitus (DM), hypertension (HTN) and COPD diagnosis as per accepted guidelines (ADA, NICE, VII, GOLD), or already on treatment. Results were compared with recent Indian prevalence data for these comorbidities.

Results: Moderate to severe OSA was present in 182/201 subjects (90.54%) and severe OSA in 169/201 subjects (84.08%). (Age: Mean 55.65 years Range 27 – 78 years). [(Gender: Men 138 (67.6%) Women 63 (31.3%)]. The comorbidities were:

<table>
<thead>
<tr>
<th>Co-morbidity</th>
<th>Prevalence (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DM</td>
<td>46.7</td>
</tr>
<tr>
<td>HTN</td>
<td>58.8</td>
</tr>
<tr>
<td>DM + HTN</td>
<td>35.7</td>
</tr>
<tr>
<td>COPD</td>
<td>25.3</td>
</tr>
</tbody>
</table>

127/182 (69.8%) of those with moderate to severe OSA had both DM and HTN. All comorbidities exist at a much higher level in persons with moderate to severe OSA than in the general population (estimated prevalence: DM 9%, HTN 28%, COPD 25%). Prevalence of DM, HTN, and COPD diagnosis as per accepted guidelines (ADA, NICE, VII, GOLD), or already on treatment.

Conclusion: Moderate to severe OSA is associated with a high prevalence of significant comorbidities like diabetes, hypertension and COPD. The prevalence is higher than a chance co-occurrence of common conditions in the general population. A search for OSA should be made in every patient with DM, HTN or COPD and vice versa.

P2247
Sleep apnoea in patients with renal transplantation
Antigone Fritz, Oliver Vonend, Lars Christian Ramp. Nephrology, University Hospital of Düsseldorf, Düsseldorf, Nordrhein-Westfalen, Germany

Sleep apnoea is an important risk factor for cardiovascular mortality. With up to 50%, cardiovascular events are the major cause of death in patients with end stage renal disease (ESRD). Moreover, major adverse cardiac events (MACE) often limit the long term survival after successful kidney transplantation. Therefore a consequent detection and reduction of cardiovascular risk factor should be a major goal in patients with ESRD in particular for patients on the waiting list. Sleep apnoea (SA) has a prevalence of 30-80% in dialysis patients. The diagnosis of SA is difficult in patients with ESRD since conventional questionnaires are often misleading.

We started a study to investigate the prevalence of sleep apnoea in patients with renal transplantation. The study collective includes over 130 patients, more than 50 of them received a living transplantation. The prevalence of sleep apnoea in our study group was round about 40%. There was no influence of the typical risk factors for sleep apnoea such gender and BMI in our patient collective. The age (P=0.003) and the co-existence of other cardiovascular diseases (p<0.001) were the most important risk factors for sleep apnoea. Also typical diastolic parameters like diuresis and time on dialysis influences the appearance of sleep apnoea. Notably symptomatic like sleepiness and snoring or the Epworth Sleepiness Scale were not usefull to detect sleep apnoea in our study collective.

The study will be finished in summer 2011. Further study datas will be expected. For conclusion we can summarize that it is very useful to screen everybody on the waiting list for kidney transplantation because it presents a very common cardiovascular risk factor in patients with renal disease.

Sleep related disorder of breathing in syndromic and non syndromic craniosynostosis
Shaikh Izabal1, Muslim AlSaadi1, Essam Elgamal1,2. 1Pulmonology and Sleep Unit, Department of Pediatrics, King Saud University, Riyadh, Saudi Arabia; 2Neurosurgery, King Saud University, Riyadh, Saudi Arabia

Aims: To look at sleep related disorders breathing (SRDB) in syndromic (SC) & non-syndromic craniosynostosis[NSC] children in our hospital.

Methods: Children with no SRDB history (Group1-SC, n=40) & (Group2-NSC, n=10) were referred for polysomnography (PSG) between Sep2007 to Nov2010 prospectively.

Results: The median total apnea-hypopnea index (TAHI) were 8.80 (range 1.8-18.2), 2.8 (range 0.2-21.4) & central apnea index (CAI) were 0.6 (range 0.2-2), 0.1 (range 0.1-2.1) group-1 & group-2, respectively.

Should cardiologists routinely screen and evaluate myocardial infarction patients for sleep disorders?
Filip M. Szymanski1, Krzysztof Filipiak1, Anna Hryniewicz-Szymanska2, Grzegorz Karpinski1, Grzegorz Opolch1. 1Department of Cardiology, The Medical University of Warsaw, Warsaw, Poland; 2Department of Cardiology, Hypertension and Internal Diseases, The Medical University of Warsaw, Warsaw, Poland

Introduction: A risk of a cardiovascular event increases with the number of cardiovascular risk factors.

Aims: The aim of this prospective study was: To identify Acute Coronary Syndrome (ACS) patients at high risk of OSA, using Berlin questionnaire (BQ) and Epworth Sleepiness Scale (ESS), and 2. To decrypt the clinical characteristics of ACS patients at high risk of OSA.

Methods: We studied 158 consecutive patients, assessed by BQ and the ESS. The high risk of OSA was defined as cumulative high risk, based on BQ and ESS scores higher than 10 in a scale of 24.

Results: Fifty four (34.2%) patients were at high risk. On admission patients at high risk of OSA had significantly often history of hypertension (92.6% vs. 26%; p=0.001), diabetes mellitus (37% vs. 15.4%; p=0.0049), significantly higher mean ESS (14.83±3.02 vs. 5.83±3.33; p=0.00049), systolic blood pressure (139.4±4.34±2 vs. 128.4±23.6 mmHg; p<0.0001), diastolic blood pressure (87.7±17.4 vs. 76.2±12.1 mmHg; p<0.0001), Body Mass Index (32.3±4.6 vs. 27.3±8 kg/m2; p<0.0001), and lower Glomerular Filtration Rate (79.5±21.2 vs. 87.5±22.2 ml/min/1.73 m2; p=0.048). Patients at high risk of OSA had often onset of acute chest pain between midnight and 5.59 am compared to the patients at low risk (42.6% vs. 26%; p<0.05). Mortality (7.4% vs. 1%; p=0.03) was more frequent in patients at high risk of OSA.

Conclusions: Every third ACS patient was diagnosed with OSA. Cardiologists should routinely screen and evaluate myocardial infarction patients for sleep disorders, especially when they are obese, have hypertension, and chest pain in the night hours.
P2250
Daytime sleepiness in patients on intrathecal chronic opioid (IT) therapy is not related to sleep disordered breathing (SDB)
Francescca Carriquiry Iglesias1, Maria Paige2, Paola Penna3, Michelangelo Buonomore1, Massimo Barbieri2, Cesare Bonetti2, Silvia Dumitru1, Chest Center, S. Maugeri Foundation Institute of Pavia, Pavia, Italy; 4Neuropsychological Unit, S. Maugeri Foundation of Pavia, Pavia, Italy.

Aim of our study was to study two groups of consecutive patients receiving IT opioid therapy, according to absence (A, noS) or presence (P, n=5) of EDS. All the patients (18 F, age 56.9±8.3 yrs, BMI 25.6±6.6 kg/m²) underwent polysomnography (PSG) and maintenance wakefulness test (MWT). Table 1 shows sleep indices for both group of patients:

Both EDS and sleep latency at MWT were statistically significantly correlated with BMI (Pearson r=0.04; p=0.06). The 6 patients were affected by sleep apnea (AH1 32.8±26): central in 1, mixed in 1 and obstructive in 4 patients. Age was statistically significantly correlated with AH1 (r=0.96, p<0.01) and ODI (r=0.62, p<0.05). No statistically significant correlation were found between respiratory and sleepiness indices as well as morphine equivalent doses or years of opioid therapy. In conclusion, daytime sleepiness is common in patients receiving IT opioids but it is only correlated with sleep quality and not with respiratory disturbances.

P2251
Obstructive sleep apnea syndrome in patients with primary open angle glaucoma
Ege Gulce Balbay1, Oner Balbay2, Mural Tunç3, Harun Yüksel4, Ali Nihat Annakkaya2, Per Arzb5, Talha Dumlup6, Chest Diseases, Duzce Antarkt State Hospital, Duzce, Turkey; 7Chest Diseases, Duzce University, Duzce, Turkey; 8Ophthalmology, Duzce University, Duzce, Turkey. Introduction: It was claimed that obstructive sleep apnea syndrome (OSAS) aggravates or causes glaucoma by impaired optic nerve head blood flow or by directly damage to the optic nerve secondary to prolonged hypoxia. The objective of this study was to investigate the prevalence of OSAS in patient with primary open angle glaucoma (POAG).

Material and methods: The consecutive 21 POAG patients (12 female/ 9 male) attending the outpatient clinic of the department of Ophthalmology between July 2007 and February 2008 were included in all of these patients underwent to Polysomnographic examination.

Results: The prevalence of OSAS was 33.3% in glaucoma patients (14.3% mild and 19% moderate). The age and the diameter of the neck in patients with OSAS were significantly greater than those with no OSAS. The adipose tissue thickness in triceps reached near significance in glaucomatous OSAS patients. Snoring was observed in all glaucoma cases with OSAS. Particularly, the prevalence of OSAS was significantly more common in glaucoma patients having the symptoms of habitual snoring, witnessed apnea than those of not. The prevalence of OSAS was often significantly increased with having major symptoms together.

Conclusions: Although it was not provided an evidence for a cause-effect relationship in the present study, the high prevalence of OSAS in patients with POAG might put forward a different view of aspect to ophthalmologists. Further studies are required especially in large groups who had CPAP (Continuous positive airway pressure) therapy to explore the long term results of coincidence, relation and cross interaction of these two common disorders.

P2254
Sleep disorders in morbid obesity who undergo bariatric surgery
Beatriz Morales1, Paola Benedetti2, José Manuel Fernandez-Sanchez-Alarcon3, Gema Rodriguez-Trigo3, José Luis Alvarez-Sala4, Mª Asunción Nieto2, Pneumology, Hospital Clinico San Carlos. Universidad Complutense de Madrid, Madrid, Spain.

Introduction Insomnia and obstructive sleep apnea (OSA) often have been considered conflicting medical conditions, recent studies suggest that these two entities are often coexist.

Aims: To determine the prevalence of sleepiness and insomnia in morbidly obese patients diagnosed with OSA with an indication of bariatric surgery and to assess an association between them.

Method: All morbidly obese patients in whom bariatric surgery was indicated between 1/05/2002 and 1/10/2006 were studied. Morbid obesity was defined by body mass index (BMI) greater than or between 35-39 kg/m² associated with comorbidity. The following variables were prospectively collected and analyzed: age, sex, height, weight, BMI, toxic habits, insomnia and excessive daytime sleepiness, measured by the Epworth Sleepiness Scale. All patients underwent nocturnal respiratory polygraphy for the assessment of OSA.

Results: We studied 145 patients (70% women) with a mean age of 42 years (range 19-69) and a mean BMI of 46±5.9. The prevalence of OSA was 95%. The prevalence of somnolence and insomnia in patients who suffer from OSA was 39% and 28% respectively. There was no statistically significant relationship between insomnia and somnolence (p = 0.378). The association between OSA, somnolence and insomnia are shown in Table 1.

Relationship between OSA, somnolence and insomnia

</tbody>
</table>

Conclusions: The prevalence of daytime sleepiness and insomnia in patients with morbid obesity with bariatric surgery indication and OSA is high but we have not found a statistically significant relationship between both clinical entities.
Results: 52 patients, 41 (79%) women, 11 men (21%), mean age 44-24±9.78 years. 48 (92%) with preBS AHI >10, 4 cases (8%) with SaO2 disorders.

9/52 cases (49%) improved or solved their OSA. In 3 cases the AHI postBS was >10, but improved from severe to mild. 4 cases with SaO2 disorders and AHI >10 correct postBS. No patient with IAH postBS.<br>

Conclusions: 1. BS solved completely the OSA in most of the patients (40/52, 77%) and improved it in all of them. 2. No statistical difference was observed in weight loss before and after BS and in all BS and preBS >10 had a high preBS AHI (mean 66.6), significantly higher than patients with AHI <10 postBS. Were not difference according to BMI-preBS and weight loss.

P2258
Objective assessment of sleep pattern and daytime sleepiness during Ramadan fasting in Muslims and non-Muslims
Ahmed BaHammm, Abdurrahman Alaseem, Abdulmajid Alzakri, Munir Sharif. Uni, King Saud University, Riyadh, Saudi Arabia

Background: Studies using sleep diaries have shown a delay in bedtime and rise time during Ramadan. However, no objective study has assessed sleep pattern during Ramadan in a free living environment.

Objectives: To assess the effect of Ramadan and its attendant lifestyle changes on: circadian changes in sleep, and energy expenditure in Muslims and non-Muslims.

Methods: The ArmBand was used to assess the circadian changes in sleep and energy expenditure for 3 weeks, during a baseline period (BL, one week before Ramadan), the first week (R1), and the second week (R2), of Ramadan, in eight Muslims and eight non-Muslim volunteers. The ArmBand is a validated metabolic body monitoring system that records sleep and total energy expenditure. A 29-items questionnaire concerning sleep was collected as well. In addition, Opatiart was used to objectively assess daytime drowsiness using the John Drowsiness Scale (JDS).

Results: Muslims and non-Muslims were matched for age and body mass index. While the start of work has been delayed for Muslims from 7:30 Am to 10 AM, there was no change in working hours for non-Muslims. When BL, R1 and R2 were compared in Muslims, there was a significant delay in bedtime, and rise time and a significant reduction in total sleep time. No changes were documented in sleep pattern in non-Muslims. No changes in daytime sleepiness were documented in both groups using the Epworth sleepiness scale and the JDS.

Conclusion: Changes in sleep pattern in Muslims could be related to changes in lifestyle like the changes in working hours. There is no objective evidence of increased sleepiness during fasting.

P2259
Decreased ventilatory response to carbon dioxide by steady state in patients with myotonic dystrophy type I compared to healthy subjects
Mathias Poussel1, Pierre Kaminsky2, Julien Laroppe 1, Silvia Varechova1, Bruno Chemel1.1Service des Exames de la Fonction Respiratoire et de l’Apnée à l’Exercice, C.H.U de Nancy, Nancy, France; 2Service de Médecine Interne Orienté vers les Maladies Orphelines et Systémiques, C.H.U de Nancy, Nancy, France

Background and objective: Ventilation is exclusively sensitive to increased PCO2. Carbon dioxide produces its effects by stimulating both central and peripheral chemoreceptors. The testing of such ventilatory response to CO2 can be achieved either by steady state or rebreathing (Read) methods. In order to test the hypothesis based upon abnormality of the central ventilatory control mechanisms in myotonic dystrophy, contributing to chronic alveolar hyperventilation, we compared the ventilatory response to CO2 between control subjects and patients with myotonic dystrophy type I (MD1).

Methods: Ventilatory response to CO2 was achieved in a steady state while breathing gas mixtures containing 3% and 6% of CO2. Each concentration was successively inhaled during 5 minutes following spontaneous breathing room air.

MONDAY, SEPTEMBER 26TH 2011
for at least 10 min. While seated in a comfortable chair, ventilation and PETCO2 were continuously recorded.

Results: Twenty one controls and 51 MDI patients were studied. In controls mean ventilatory responses to CO2 were 1.81 L/min/mmHg ± 0.71 (CO2=3%) and 1.25 L/min/mmHg ± 0.72 (CO2=6%). In MDI patients mean ventilatory responses to CO2 were 0.71 L/min/mmHg ± 0.46 (CO2=3%) and 0.75 L/min/mmHg ± 0.43 (CO2=6%). For both concentrations, ventilatory response to CO2 was significantly lower (p<0.01) in MDI patients than in controls.

Conclusion: This control study confirms the decreased ventilatory response to CO2 in MDI patients using the alternative steady state method. Further studies are needed to define more precisely the role of the impairment of the central ventilatory control in the course of the disease.

P2260
The relationship between testosterone, obesity and depressive mood in obstructive sleep apnea (OSA) postmenopausal women
Raluca Mihaela Bercea1,2, Elena Cojocaru2, Traian Mihaescu1,2, Tatiana Lamon, Sandrine Pontier, Laurent Tetu, Daniel Riviere, Alain Didier.

Background: The relationship between respiratory sleep disorders and menopausal state in women is not well supported; only that obese female have higher androgen levels then non-obese females.

Aim: The aim of our study was to illustrate the link between OSA severity, serum total testosterone level and depressive mood in obese postmenopausal women.

Material and method: The present study included 13 severe OSA female patients (apnea hypopnea index (AHI) >30 events/h) with obesity (body mass index (BMI) >30 kg/m²), ages between 53 and 60 years, for least two years of amenorrhea. All patients fulfilled Beck Depression Inventory (BDI). Serum total testosterone level (T) was performed from blood samples collected in the morning after wake up. Control group selected consisted in 10 non-OSA females with same characteristic with study group.

Results: We found significant correlations between T level and BMI (r=0.363, p=0.019), without correlation between T level and AHI or BDI (p>0.05). It was remarked a strong positive correlation between BDI score and BMI (r=0.720, p=0.006). Test scores no differences between two groups in testosterone level (OSA group 0.757±0.28 ng/dl vs. non-OSA group 0.625±0.19 ng/dl, p=0.226), but significant differences for BDI score (OSA 9.69±5.15 vs. non-OSA 4.3±2.16, p=0.005).

Conclusion: Our study reveals no effect relationship between OSA severity and serum testosterone level. Testosterone level is positive correlated with obesity. Depressive mood is induced by OSA severity, without relation with testosterone level. Our results are needed to elucidate androgens involvement in severe OSA postmenopausal women.

P2261
Mean platelet volume in patients with obstructive sleep apnea syndrome and its relationship with cardiovascular diseases
Elid Kaya, Asiye Kanbay, Nuri Tutur, Hakan Buyukkoyun, Fatma Sema Oymak, Inci Gulem, Ramirez Demit. Pulmonary Medicine, Erciyes University, Kayseri, Turkey

Obstructive Sleep Apnea Syndrome (OSAS) is an independent risk factor for the development of cardiovascular event and hypertension. Mean Platelet Volume (MPV), an indicator of platelet activation and aggregation which are closely related with cardiovascular diseases (CVD). We aimed to show the relationship between OSAS and MPV with CVD. The medical records of 205 subjects who were admitted for the sleep study were evaluated. OSAS was diagnosed by polysomnography if Apnea-Hypopnea Index (AHI)>5. MPV calculated from blood samples. According to AHI, individuals in whom AHI=5 were recruited as group 1 (control group), those in whom AHI=5-15 group 2 (mild OSAS group), those in whom AHI=15-30 group 3 (moderate OSAS group), those in whom AHI>30 group 4 (severe OSAS group). Of the subjects 137 (67%) were male, 68 (33%) were female and the mean age was 53.0±14.1years. Those were 35 (17%), 20 (10.2%), 40 (20.4%) and 108 (52.6%) in group 1, 2, 3 and 4 respectively. There were significant differences in terms of coronary artery disease and hypertension between all patients (p<0.05) Except group 1 and 2, other groups showed a significant increase in MPV was detected while the severity of OSAS increased (group 1=9.3±0.7, group 2=9.4±0.8, group 3=9.5±1.1, group 4=10.2±1.2; p for trend 0.03). We have shown that MPV significantly increase in patients with OSAS which is an independent risk factor CVD. MPV may use as a marker to predict CVD in OSAS.

P2262
Congenital central hypoventilation syndrome (CCHS): A case of late onset presentation
Tatiana Lamon, Sandrine Pontier, Laurent Tetu, Alain Didier.

Congenital central hypoventilation syndrome (CCHS) or Ondine’s curse is a rare autosomal dominant disease, characterized by disorders of the autonomic nervous system, with abnormal ventilatory responses to hypercapnia and hypoxemia. PHOX2B has been identified as the major disease causing gene for CCHS. It results from polyalanine repeat expansion mutations. It typically occurs in the newborn period, but some cases have been described on adults (late onset CCHS) and reflects the variable penetrance of PHOX2B mutations.

A 48 year-old woman presented after an ovarian cyst surgery a severe hypventilation requiring intubation. Arterial blood gas revealed a PO2 of 50 mmHg, a PCO2 of 80 mmHg and a pH of 7.22. Past medical history indicated poor apparent symptoms for few years. These included apneas, fullly sleep and awakening with headaches. Physical examination and pulmonary function tests, lung tomography, magnetic resonance imaging of the brainstem were normal. Polysomnography revealed many central and obstructive apneas and hypopneas (apnea-hypopnea index of 22/h) with severe hypoxemia (SpO2 average 75%) and hypercapnia (transcutable CO2 85mmHg). Non invasive ventilation was initially poorly tolerated. Finally, she responded to an adaptive servo ventilation. Hypoxia and hypcapnia tests showed no adaptation of the ventilatory response. Genetic analysis showed a heterozygous five alanine expansion mutation of the 20-residue polyalanine tract in exon 3 of the PHOX2B gene.

The diagnosis of late onset CCHS should be considered in patients with unexplained hypventilation after anesthia, and physiologic evaluations documenting abnormal ventilatory response should be completed. The presence of a PHOX2B mutation confirms the diagnosis.

260. Obstructive sleep apnoea: clinical aspects I

P2263
Investigating for dyslipidemia in those being referred for suspected obstructive sleep apnoea
Snead Walsh, Faheem Khan, Danielle Drivily, J.J. Gilmartin. Regional Respiratory Centre, Merlin Park Hospital, Galway, Ireland

Introduction: Abnormal lipid metabolism is a major risk factor in the development of coronary artery disease. Dyslipidemia is present in many subjects with Obstructive Sleep Apnoea Syndrome (OSAS) and an independent association between the two has been observed in a number of studies. Patients referred for inpatient polysomnography in our unit are screened by a fasting lipid profile. This study aims to evaluate the rates of dyslipidemia in this population and to compare OSAS and non-OSAS populations.

Methods: A retrospective review of 285 consecutive subjects (78.6% male, 21.4% female) referred for sleep assessment was performed. Laboratory results, polysomnograms and charts were analysed.

Results: 89 out of the 285 subjects (31.2%) were on a statin and were excluded from further analysis. Of the 196 not on a statin, all had a fasting lipid profile performed. 156 (78.6%) had a positive sleep study, while 40 (20.4%) were negative for OSAS.

OSAS No OSAS p-value
Age 49.2 49.1 0.960
BMI 37.9 30.8 <0.001
AHI 40.55 33.33 <0.001
Total Cholesterol 5.15 5.18 0.890
Triglycerides 1.86 1.57 0.090
LDL cholesterol 3.25 2.99 0.064
HDL cholesterol 1.03 1.39 <0.001

Conclusion: OSAS patients have lower HDL cholesterol levels, but no significant difference in total cholesterol, triglycerides or LDL levels. We recommend to continue measuring fasting lipid profiles in this population. A possible confounding factor in our study is BMI.

P2264
Correlation between excessive daytime sleepiness and the risk for obstructive sleep apnea with academic performance among medical students at UP-PGH Mary Jane Sandagon, Ma. Philina Pablo, Manuel Jorge. Internal Medicine, Pulmonary Section, University of the Philippines- Philippine General Hospital, Manila, Philippines

Objective: This study aims to determine if there is any relationship between daytime sleepiness and risks for obstructive sleep apnea (OSA) with students’ academic performance.

Methods: A self-administered validated questionnaire (consisting of Profile, Sleeping habits, Berlin Questionnaire, and the Epworth Sleepiness Scale) was distributed to duly enrolled medical students from Level 1 to 6 of the University of the Philippines College of Medicine SY 2009-2010. The general weighted average of each student at the end of the 2nd semester school year 2010 was obtained and correlations were determined.
**Results:** There were 458 (64.4%) patients who participated in the study out of the 711 daily enrolled medical students for academic year 2009-2010. Of the participants, 77.3% had abnormal daytime sleepiness ranging from mild to excessive. There was poor correlation between levels of daytime sleepiness and academic performance (Pearson’s correlation coefficient 2.5). There was also poor correlation between risk for obstructive sleep apnea and academic performance gauged by using grade point average (Pearson correlation coefficient 0.86).

**Conclusion:** The present study shows that there is no significant statistical correlation between excessive daytime sleepiness or risk of obstructive sleep apnea and academic performance of medical students as measured by their general weighted average.

**P2265**

**Mortality in young and old subjects with obstructive sleep apnoea with and without comorbidities**

Anna Lo Bue1, Giuseppe Insalaco1, Adriana Salvaggio1, Gabriella Dardanoni2, Oreste Marrone1. 1Institute of Biomedical and Molecular Immunology, National Research Council, Palermo, Italy; 2Assessore Sanità Regione Siciliana - Dipartimento Attività Sanitarie Ospedaliero Epidemiologico - Servizio 2 Promozione della Salute, Palermo, Italy

Increasing obstructive sleep apnoea (OSA) severity has been reported to be associated with a progressive increase in mortality excess, particularly among young subjects. It is unclear if in older subjects apnoeas are less harmful than in younger subjects, or if comorbidities overcome and obscure the effects of OSA on mortality. Medical records of 1023 subjects studied for suspected OSA between 1991 and 2000 were retrospectively evaluated. During the first months in 2009 their state of survival or possible date of death was enquired. Information about 810 subjects (age: 53.2 ± 11.6 years, 629 M) was obtained. In the whole sample, survival was associated to comorbidities and age, but not to AHI or lowest nocturnal SaO2. Among subjects aged <50 (n=315), 87% did not have comorbidities other than hypertension; in subjects ≥50 (n=89) this percentage decreased to 56% (p<0.001).

In the subgroup of the younger subjects without comorbidities (n=273), a lowest nocturnal SaO2 value <90% was associated to worse survival (96.1% vs 10 and 87.6% vs 15 years) as compared to values between 70 and 84% (survival respectively 100% and 85% vs 15 years) (p<0.05).

A similar association was not found among older individuals nor among subjects with comorbidities. These data suggest that among subjects ≤50 increasing OSA severity does not worsen mortality even in subjects without comorbidities.

**P2266**

**Relationship between the reduced ventilatory response to CO2 and the impairment of the lung function in myotonic dystrophy patients**

Mathias Poussel1, Pierre Kaminsky2, Julien Laroppe1, Silvia Varechova1, Nicolás González-Mangado. 1Institute of Biomedical and Molecular Immunology, National Research Council, Palermo, Italy; 2Assessore Sanità Regione Siciliana - Dipartimento Attività Sanitarie Ospedaliero Epidemiologico - Servizio 2 Promozione della Salute, Palermo, Italy

Introduction: Myotonic dystrophy type 1 (MD1) is a genetic disorder that shares many cardiovascular risk factors with metabolic syndrome. This study aimed to evaluate the possible association of OSA severity with metabolic syndrome, Insulin resistance and Hs-CRP.

Methods: We evaluated 90 subjects who suspected for OSA (54.92 ± 10.3 years). Blood sampling was taken after 12 hours fasting for glucose, insulin, high-density lipoprotein- (HDL) cholesterol, triglycerides, low-sensitivity C-reactive protein (Hs-CRP), and then Overnight polysomnography was done. Insulin resistance was assessed by the homeostatic model (HOMA) and metabolic syndrome was evaluated according to The National Cholesterol Education Program’s Adult Treatment Panel III report (ATP III), and subjects categorized by OSA severity. We compared three groups: (a) without OSA, mild OSA and moderate to severe OSA.

Results: 28 subjects hadn’t OSA, 28 and 34 subjects had mild and moderate to severe OSA, respectively. Metabolic score was 3.29 ± 1.1, 3.07 ± 1.27 and 3.59 ± 0.48 in subjects without OSA and mild OSA and moderate to severe OSA, respectively (p=0.13 ± 0.22). HOMA index was 56.87 ± 5.84, 106.42 ± 199 68 and 96.23 ± 127.81 (p =0.33 ± 0.37) and hcr-SP index was 1.62 ± 1.8, 2.10 ± 2.24 and 2.36 ± 2.38 (mg/dl=0.21 ± 0.38) order in above three subjects. There was significant association between metabolic score and HOMA index (p=0.01) and also between metabolic score and hcr-SP level (p=0.02).

Conclusion: Although Hs-CRP, insulin resistance and metabolic syndrome increased with OSA severity but there was no significant association between apnea hypopnea index and Hs-CRP, insulin resistance and metabolic syndrome.

**P2268**

** Oxygen desaturation is associated with diabetes mellitus in patients with obstructive sleep apnoea**

Mohamed Al-Abri, Husam Al-Lawati, Youssef Al-Alawi, Abdullah Al-Manhary. Clinical Physiology, Sultan Qaboos University, Muscat, Oman; Family and Community Medicine, Sultan Qaboos University, Muscat, Oman

**Objective:** Obstructive sleep apnea (OSA) is associated with impaired glycemic control. The aim of the study was to evaluate the contribution of oxygen desaturation in the association of diabetes mellitus (DM) OSA.

**Methods:** The study was conducted between January 2008 and May 2010 in sultan Qaboos University Hospital, department of clinical physiology.

The data were collected using electronic medical records and sleep study report. Hypoxia desaturation (SaO2 <90%) was calculated by the number of desaturation dips from wakefulness level in addition to SaO2 <90%.

**Results:** The total number of cases was 180 (116 males & 64 females) with mean age 43±17 years. Female patients were more obese than males (BMI=32.2±2.36 kg/m2, 32.7±2.8 kg/m2 respectively, p<0.005). The mean apnea/hypopnea index (AHI) was 31±31 and mean Epworth sleepiness scale (ESS) was 11±5. There was significant association between diabetes mellitus (DM) and AHI (median for diabetic 39 Vs 18 for non-diabetic, p<0.001). There was no significant association between diabetes and oxygen desaturation index (median for diabetic 25 Vs 9.6 for non diabetic p=0.02) and it becomes more significant with severe desaturation (SaO2 <90%) (median for diabetic was 50 Vs 4 for non diabetic p=0.002). There was weak association between body mass index and DM (p=0.05) in this population sample. Nevertheless, there was no association between daytime sleepiness (ESS) and the diabetes (p=0.05).

**Conclusion:** The study showed that Obstructive sleep apnea is associated with diabetes mellitus. OSA patients with more severe Oxygen desaturation are at greater risk of developing diabetes.

**P2269**

**Systemic inflammation and vascular dysfunction in patients with OSA**

Felicie Villar-Ávarez, María Fernanda Troncoso-Acevedo, Germán Peces-Barba, María Soledad Lucero, Yovonne Cabrero-Salinas, Zahidu Saavedra-Moreno, Nicolás González-Mangado. Pneumología, Fundación Jiménez Díaz, CIBERES, Madrid, Spain

**Introduction:** Our hypothesis is that systemic inflammation and endothelial vascular dysfunction in OSA patients are associated. Therefore our primary objective was to be able to establish the etiological association between them.

**Materials and methods:** Observational case control study in OSA patients and healthy individuals. All of them were tested for serum and urinary markers. Peripheral arterial tonometry by oscillometric sphygmomanometer (ENDO-PAT 2000) was used to measure endothelial dysfunction and arterial stiffness values (Reactive Hyperemia Index-RHI and Augmentation Index-AI).

**Results:** This study involved 42 participants (30 with OSA and 12 healthy controls). Mean age: OSA 61.7, controls 50.4 (p=0.02). Mean BMI: OSA 31.8, controls 26.1 (p=0.01). The OSA severity rate was severe in 54%, low-moderate in 11%, mild in 9% and low in 11.9% of the sample. The results for the serum and urinary markers (Mann-Whitney test) comparison with median and quartiles were the following: CRP (OSA 0.5 controls 0.3, p=0.15), leucocytes (OSA 7500, controls 6000, p=0.18), D-dimer (OSA 339, controls 252, p=0.18), fibrinogen (OSA 401, controls 318, p=0.0007) and microalbuminuria (OSA 7.6, controls 4.7, p=0.12).

No statistically significant differences in arterial stiffness (IA, OSA 19, controls 13.5 p=0.3) neither in vascular endothelial dysfunction (RII, OSA 1.50 control 1.72 p=0.2) were found, although its value was lower than what is considered significant for endothelial dysfunction (<1.67).

**Conclusions:** An association between OSA and cardiovascular risk can be established by measuring the inflammatory marker fibrinogen, and by taking into consideration the data that suggest that endothelial dysfunction may be present.

**Disclosure:** The authors report no conflict of interest.
The changes of serum adipocytokines levels in patients with OSAHS
Yong Lin, Ting Xu. Respiratory Department, Zhongda Hospital of Southeast University, Nanjing, Jiangsu Province. China

Background: Obstructive sleep apnea hypopnea is associated with obesity. Adipocytokines which were secretion by fatty tissue can influence energy metabolism all over the body and the development of obesity. Apelin, NPY and A-FABP were adipocytokines discovered for these last few years. They may participate in the generation and development of OSHAS, especially obesity combined OSHAS.

Objective: To investigate the relationship between adipocytokines (Apelin, NPY and A-FABP) and obstructive sleep apnea-hypopnea syndrome (OSHAS).

Methods: Patients underwent polysomnography were recruited and divided into OSHAS group and non-OSHAS group. Each group was divided into obesity, hyperventilation and normal body weight arms according BMI. OSHAS group was divided into mild, moderate and severe arms. Plasma Apelin, NPY, A-FABP (ng/ml) levels of all arms were tested and compared.

Results: Plasma adipocytokines levels of OSHAS group were positively correlated with BMI, while negatively correlated with Lsao2 and Msao2 in OSHAS group.

Conclusions: Obesity can cause the increase of plasma Apelin, NPY and A-FABP levels. These three adipocytokines levels were positively correlated with the severity degree of OSHAS.

Deregulation of carbohydrate metabolism in patients with sleep apnea
Juan Fernández-Lahera, Francisco García Río, Isabel Fernández, Santiago Zudaire, Raquel Casitas, Claudia Llontop, Raúl Galera, Carlos Villaseñor, Redolfo Alvarez-Sala. Pneumology, University Hospital la Paz, IDiPaz, Madrid, Spain

Material and methods: The study included 103 new patients with the following characteristics of age: BMI 30.2±5.8 kg/m², neck circumference 42.6±7 cm, Epworth 11±10, AH1 33±27/h, DI 34±28/h, mean SpO2 91±6%, minimum SpO2 76±14%, CT 90±22%. Diabetic patients were excluded.

Results: Patients underwent blood tests and sleep studies.

Conclusions: When comparing a group of patients with OSA to a control group, there were significant differences in NGSP HaA1c and IFCC HaA1c (p<0.037). There was significant linear correlation between glucose and age (r=0.21). NGSP HaA1c and IFCC HaA1c (r=0.07), minimum SpO2 (r=0.24), ODI (r=0.37), age (r=0.38). The same for IFCC HaA1c. Insulin with BMI (r=0.39). QUICKI in adipose tissue (r=0.32). BMI (r=-0.47) and with neck circumference (r=0.46). The HOMA-IR index in the OSA group (r=0.46).

To find possible determinants of NGSP HaA1c (%) the following multiple linear regression model with AHI (r=-0.28), with ODI (r=-0.30), with BMI (r=-0.47) and with neck circumference (r=0.38). The same for IFCC HaA1c. Insulin with BMI (r=0.39).

Results:

Conclusions:

The changes of serum adipocytokines levels in patients with OSAHS

Effect of unilateral lingual paralysis on swallowing and breathing coordination
Yacine Ouahchi, Jean Paul Marie, Eric Verin. Laboratoire de Chirurgie Experimenterale, Faculté de Medecine et de Pharmacie de Rouen, Rouen, France

Introduction: The tongue play an important role in swallowing, phonation and respiration. A motor lingual deficit is seen in many neurological disorders. However, its implication on swallowing and breathing coordination remain unknown.

Aim: The aim of this work was to study the ventilatory pattern during swallowing in rats with unilateral tongue paralysis.

Methods: The study was carried out on 10 wistar rats. Respiratory variables in unrestrained and healthy rats were measured during water swallowing using whole-body plethysmography. This procedure was repeated for all rats before and after the unilateral section of the hypoglossal nerve (HI). Parameters studied were swallowing frequency and occurrence during inspiration or expiration, tidal volume (VT), total time of ventilatory cycle (TT) and respiratory drive (VT/TT).

Results: A difficulty of leaking was observed in all rats after unilateral hypoglossal nerve section. The main finding was a decrease of respiratory rhythm and ventilatory drive during swallowing after hypoglossal nerve section. Swallowing rate (17±5/15sec) and occurrence in phases of respiratory cycles did not change. Conclusion: This study demonstrates that swallowing difficulties and aspiration decrease ventilatory drive during swallowing that can be considered as a mechanism neurologically determined to protect the pulmonary function.

The relationship between obstructive sleep apnea hypopnea syndrome and insulin resistance, vascular complications in patients with type 2 diabetes mellitus
Guoxia Ma, Xiheng Gao. Respiratory and Critical Care Medicine, Beijing Institute of Respiratory Medicine, Beijing Chaoyang Hospital-Affiliate of Capital Medical University, Beijing, China

Background: The episodes of hypoxia/reoxygenation caused by OSAHS is associated with a series of metabolic changes, and might be involved in the pathogenesis of type 2 diabetes mellitus (T2DM).

Methods: The subjects were poorly controlled type 2 diabetes mellitus from August 2009 to January 2010 in the Endocrine ward of Beijing Chaoyang Hospital. We recorded the clinical information of all subjects. Fasting venous blood samples was obtained after an overnight fast. Polysomnography (PSG) monitoring,oral glucose tolerance test (OGTT), vascular ultrasound were performed in all the subjects.

Results: 96 type 2 diabetic patients were recruited in our study, 78 subjects (81.25%) were diagnosed as having OSAHS after PSG study. The insulin resistance index (HOMA-IR), which was significantly higher in the moderate and severe group versus the control group. Multiple stepwise regression analysis showed that AH1 and AUCcp was positively correlated (R=0.323, p=0.001), both AH1 and BMI were positively correlated to HOMA-IR (R=0.007 and 0.23, respectively). The percentage of patients who had atherosclerosis were significantly higher in patients with severe and moderate OSAHS than non-apnoic patients.

Conclusion: OSAHS is positively related to insulin resistance, and closely related to the incidence of macrovascular complications in the patients with type 2 diabetes mellitus.

Oxidative stress in obese children with sleep-disordered breathing
Kim Van Hoorenbloek1, Hilde Franckx2, Luc Van Gaal3, Kristine Desager1, Wilfried De Backer4, Stijn Verhulst1, 1Experimental Medicine and Pediatrics, University of Antwerp, Antwerp, Belgium; 2Obesity Program, Zeepreventorium, De Beaan, Belgium

Background: Sleep-disordered breathing (SDB) is prevalent in obese children. It is an independent risk factor for the metabolic syndrome. Oxidative stress is a possible linking mechanism and is reflected by serum uric acid (UA).

Aim: In this prospective follow-up study we focused on the effects of SDB on oxidative stress in childhood obesity, before and after weight loss treatment.

Methods: Obese children, attending an in-patient weight reduction program, between 10 and 18 years were included consecutively. All subjects had baseline and 1 follow-up visit after 4-6 months of weight loss. UA was measured at both visits. A polymyography was performed at baseline and repeated in case of oxygen desaturation index (ODI) ≥ 2 at admission.

Results: 132 obese patients participated. Median age was 15.4 years (10.1-18.0). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.025) and BMI. At baseline, UA concentration correlated negatively with total sleep time (r=-0.24, P=0.049). At baseline, UA concentration correlated negatively with total sleep time (r=-0.32, P=0.002). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001). At baseline, UA concentration correlated negatively with total sleep time (r=-0.24, P=0.049). UA concentration correlated negatively with total sleep time (r=-0.32, P=0.002). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001). At baseline, UA concentration correlated negatively with total sleep time (r=-0.32, P=0.002). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001). At baseline, UA concentration correlated negatively with total sleep time (r=-0.26, P=0.001).
Conclusion: There exists a significant association between UA and ODI at base-
line, even after controlling for BMI z-score. Changes in ODI after treatment are
reflected by changes in UA, independent of the degree of weight loss.

P2276
Cognitive learning function in OSA children
Silke Weber, Silvana Hilario, Érico Moreira da Silva, Victor Barbosa dos Santos,
Cristiane Mendes-Chiloff. Otorhinolaryngology, Botucatu Medical School State
University, Botucatu, São Paulo, Brazil

Introduction: Obstructive Sleep Apnea (OSA) in children is associated with
learning problems, as attention and memory.
Aim: To assess learning, memory and attention function in OSA children.
Methods: OSA children (IAH>4 or LA>1), both genders, aged 6 to 12 years, were
submitted to psychological learning test (symbol, digits and code – WISC III
Wechsler Intelligence Scale for Children). Test result were pondered for age,
10 points were considered normal, <8 as suspicious, <= 7 as disturbed learning
needling specialized support. WISC results were correlated to age, gender, IAH
and desaturation index (IDO). Children with hearing loss, neurologic disease
or genetic syndrome were excluded.

Results: 30 children, 9 girls, median age 8.5 years, were enrolled. Median IAH
was 11.9 (4 to 65) and mean IDO 12.8 (3.4 to 71). 14 (46%) children, 10 boys,
were considered suspected, 9 (30%) 8 boys, were considered as having learning
disturbance (LD). 67% werde diagnosed LD II or more subareas, showing
global learning dysfunction as discrimination, velocity and attention. There was
no correlation of learning disturbance to IAH or IDO (OSA severity), but it was
correlated to male gender and to older age. 50% of children aged 9 to 12 years
were diagnosed LD.

Conclusion: Learning disturbances are frequent in OSA children, independent
of OSA severity. Exposing time to OSA seems to be an important factor. OSA
children should undergo neurocognitive evaluation.

P2277
Variance over time of the obstructive sleep apnoea syndrome (OSAS) in
patients with acute stroke
Anna Mola1, Ana Mª Fortuna1, Rosa Mª Miralda1, Raquel Delgado2,
Joan Martí2, Mercé Mayos1. 1Department of Respiratory, Hospital Santa Creu i
Sant Pau, Barcelona, Spain; 2Department of Neurology, Hospital Santa Creu i
Sant Pau, Barcelona, Spain

OSAS is a cardiovascular risk factor with a high prevalence in patients with
acute stroke in whom could be related to a worse prognosis and an increased
mortality. The aims are to evaluate the evolution and the prognostic role of OSAS
in stroke patients. This is a prospective study in which a respiratory polygraphic
monitoring was performed on the 3rd month (stable phase). 42 of 52 patients were included (age 69
± 12.5 years, 54.8% male, BMI 27 ± 3.6). Arterial saturation was at SaO2:97% constantly. End Diastole Volume
(EDV), Stroke Volume (SV) and Ejection Fraction (EF%) of left ventricle were measured with an anatomical M-mode echocardiographic method. Data analyzed and compared between quite breathing (time 0) and breathing after two hours of airway obstructions (time 0+2).

Results: The cardiac measurements were compared using the Wilcoxon signed-
rank test. EDV and SV were statistically significant reduced (p<0.05) between
time 0 and time 0+2. EF was reduced but not statistically significant at the same
time period.

Conclusions: In this study our findings suggest that left ventricular function is
affected acutely with reduction of EDV and SV after two hours of airway obstructions
independently of hypoxaemia. These results suggest that in obstructive sleep
apnea, negative intrathoracic pressure which occurs during apnea may contribute
to changes in myocardial mechanics.

P2279
Respiratory symptoms and risk for obstructive sleep apnea in professional
musicians
Maria Antoniadou1, Vasilis Michailidis1, Eleni Perantoni2, Diamantis Chloros2,
Athenasia Prinza2, Theodoros Gegas1, Veneta Tsula1. 12nd Pulmonary Department, At-
tilikon General Hospital University of Athens, Athens, Chaidari, Greece; 2Center for
Experimental Surgery, Biomedical Research Foundation of the Academy of
Athens, Athens, Greece

Background: Obstructive sleep apnea has detrimental effects on function of left
ventricle. It is also known that large decreases in intrathoracic pressure occur
during obstructive apneas.
The aim of this study was to determine the acute changes in left sided heart function
that occur in response to the decreased intrathoracic pressure in an obstructive
sleep apnea model in rats under condition of normoxia.

Methods: Experiments were conducted in ten male adult Wistar rats weighing
350 gr, which were anaesthetized with Ketamine-Xylazine intraperitoneally. Ani-
mals were breathing after being tracheostomized and connected in a circuit with
an electromagnetic valve which was closing periodically mimicking obstructive apneas.Anterio saturation was at SaO2-97% constantly. End Diastole Volume
(EDV), Stroke Volume (SV) and Ejection Fraction (EF%) of left ventricle were
measured with an anatomical M-mode echocardiographic method. Data analyzed
and compared between quite breathing (time 0) and breathing after two hours of
airway obstructions (time 0+2).

Results: The cardiac measurements were compared using the Wilcoxon signed-
rank test. EDV and SV were statistically significant reduced (p<0.05) between
time 0 and time 0+2. EF was reduced but not statistically significant at the same
time period.

Conclusions: In this study our findings suggest that left ventricular function is
affected acutely with reduction of EDV and SV after two hours of airway obstructions
independently of hypoxaemia. These results suggest that in obstructive sleep
apnea, negative intrathoracic pressure which occurs during apnea may contribute
to changes in myocardial mechanics.

General Hospital University of Athens, Athens, Chaidari, Greece; 2Center for
Experimental Surgery, Biomedical Research Foundation of the Academy of
Athens, Athens, Greece

The results suggest that OSA study in acute stroke can lead to an overestimation
of the prevalence of severe OSA, because it significantly reduces its severity in
the stable phase. This information may be important when taking the decision to
start CPAP treatment in acute stroke. In accordance with previous studies, there wasn’t
found any relationship between OSA presence and the stroke functional outcome
on the 3rd month.

P2280
Obstructive sleep apnea contributes acutely to left ventricular dysfunction
independently of hypoxaemia

Argiro Antaraki2, Nikos Kostomitsopoulos2, Vaggelis Balafas2,
Argiro Antaraki2, Nikos Kostomitsopoulos2, Vaggelis Balafas2,
Kostas Kostakis2, Spiros Papiris1. 12nd Pulmonary Department, Attikon

Background: Obstructive sleep apnea has been approved for the treatment of Pulmonary
Arterial Hypertension (PAH) in adults, but there are few studies about its effects
in children.

Objectives: To review long-term effects and outcomes of inhaled iloprost treatment
in children with PAH.
P2281
Sildenafil (SIL) reduces serum creatinine (SCr) in patients with pulmonary arterial hypertension (PAH): Relationship to clinical outcomes

David Webb1, Jean-Luc Vachiery2, Li-ju Hwang3, Stephen Watt4, Tobias Lungé5. 1Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, United Kingdom; 2Department de Cardiologie, CUB-Hôpital Erasme, Brussels, Belgium; 3Department of Paediatric Cardiology, Päiäes, Hôpital de la Croix Rousse, Lyon, France; 4Regional Medical & Research, Specialty Care - Pulmonary Vascular Disease, Pfizer Inc, New York, NY, United States; 5Medical, Pulmonary Vascular Disease, Pfizer Inc, New York, NY, United States

Purpose: Elevated SCr associates with poor outcome in PAH. We retrospectively analyzed the effect of SIL on SCr in PAH patients (pts) from SUPER-1 and -2 studies. SCr was related with 6-walk distance (6MDW), functional class (FC), time to clinical worsening (TTCW), and survival were examined.

Methods: PAH pts received placebo (PBO) or SIL 20, 40, or 80 mg TID in SUPER-1 and open-label SIL titrated to 80 mg TID (as tolerated) in SUPER-2. SCr, 6MDW, FC, and TTCW were assessed at baseline (BL) and wk 12 in SUPER-1; survival was tracked for 3 y in SUPER-2. Analysis of covariance (treatment as a factor; BL value as covariate) assessed SCr change from BL to wk 12 (posthoc). Relationships between SCr ≥ 10% 6MDW increase and ≥1-class FC improvement (using logistic regression) and TTCW and survival (Cox regression) were assessed.

Results: BL characteristics were similar among groups (N=277). PAH was mostly idiopathic (63%) and FC II (39%) or III (58%) patients. SCr increased at wk 12 vs BL with PBO (0.03 mg/dL) and decreased with SIL (-0.001, -0.035, and -0.048 mg/dL for 20, 40, and 80 mg TID, respectively); the difference vs PBO with 80 mg TID was significant (P=0.032). SCr reduction was associated with improved 6MDW (OR 4.74; 95% CI, 1.07–21.05; P=0.04) and FC (OR 6.64; 95% CI, 1.37–32.16; P=0.019). Pts with higher SCr had higher risk of worsening (HR 44.38; 95% CI, 4.74–412.59; P<0.001) and a trend toward higher risk of mortality (HR 2.62; 95% CI, 0.23–30.55; P=0.04).

Conclusion: In posthoc analysis improved with administered SIL 6MDW and FC and reduced risk of clinical worsening.

P2282
Epoprostenol with expanded stability has the same pharmacokinetic and hemodynamic profiles as epoprostenol in healthy subjects

Laurent Nicolas1, Marcelo Gutierrez1, Lawrence Galitz2, Jasper Dangemans1. 1Clinical Pharmacology, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 2Principal Investigator, Cetero Research, Miami, FL, United States

Pharmacokinetics (PK) and hemodynamics of two formulations of epoprostenol sodium for injection, epoprostenol with expanded stability (EPO-ES, Venelys®) and epoprostenol (EPO, Flolan®), were compared in an open-label, crossover, ascending-dose study in healthy males. Subjects received sequential, 2-hour (h) infusions of EPO-ES or EPO at 2, 4, 6 and 8ng/kg/min. Due to the short half-life (t1/2) of epoprostenol sodium, plasma PK were assessed via the concentration versus time profiles of two primary metabolites, 6-keto-prostacyclin F1α (kPF) and 6,15-diketo-13,14-dihydro-prostacyclin F1α (dDPF). Plasma concentration-versus-time profiles of EPO-ES and EPO with regard to kPF and dDPF were superimposable. KPF and dDPF had similar elimination half-lives (t1/2a). Both formulations were comparable. Geometric means of the total area under the curve (AUC() for KPF, were 2011 and 1972pg/h/mL (90% CI of geometric mean ratio (GMR) 97, 107, 128, 1972pg/h/mL, (90% CI of GMR: 94, 111) for dDPF following administration of EPO-ES and EPO, respectively. Similar changes in hemodynamic variables were observed during EPO-ES and EPO infusion. Average maximum increases from baseline were approximately 50% in both cardiac output and cardiac index with either formulation, and 19% and 27% in heart rate for EPO-ES and EPO, respectively. Both formulations had comparable treatment-emergent adverse event (TEAE) profiles. Headache was the most common TEAE reported. Overall, EPO-ES and EPO have the same PK, hemodynamic, safety, and tolerability profiles.

P2283
Switch from sitaxentan to another ERA in ERA patients: Single center short term safety observations

Tobias Lungé1, Michael Arzt2, Michael Pfeifer1,2. 1Multidisciplinary Pulmonology, University Hospital Regensburg, Regensburg, Germany; 2Pulmonology, Krankenhaus Donaustadt, Donaustadt, Germany

Background & aims: In December 2010 the Endothelin Receptor Antagonist (ERA) Sitaxentan (SIT) has been withdrawn from the market. Therefore patients with pulmonary arterial hypertension (PAH) had to be switched to other PAH therapies. There are differences in the side effect-profile of the ERAs Ambrisentan (AMB), Bosentan (BOS) and SIT including drug interactions. We describe the short term safety in PAH-patients at our center who were switched from SIT to another ERA.

Methods: All patients switched from SIT to AMB or BOS for more than 4 weeks were included. We collected liver function tests (LFT), INR, WHO functional class (FC) and new side effects.

Results: Patients on SIT (n=16) were seen 13 days (4–32) after the withdrawal notification. Mean duration of SIT therapy was 478 days (93–2332). Patients were switched to AMB (n=10) or BOS (n=6) on the basis of personal experience and expected side effects. Mean follow-up was 41 days.

LFTs under SIT were all within the normal range and remained normal in all but one patient who had ALAT increase from 13 to 242 U/L on BOS, normalizing after BOS cessation. The WHO FC did not change in any patient. Three patients complained about new or worsening peripheral edema, 2 on AMB and 1 on BOS. In 4 out of 12 patients receiving oral anticoagulation who were in therapeutic range under SIT, the INR dropped below 2 after switch to AMB (1) or BOS (3). One patient died suddenly 10 days after switch to BOS.

Conclusion: PAH-patients who are switched from SIT to another ERA can experience in part serious pathophysiological problems and should be closely monitored.

P2284
Double combination therapy in patients with pulmonary arterial hypertension associated with congenital heart defects

Nicole Rizzo, Elissa Conlonci, Massimiliano Palazzini, Enri Leci, Enrico Gotti, Guia Mazzanti, Francesca Tomatis, Alida Maria Fenu, Elena Beciani, Francesca Sciarra, Cristina Bachetti, Federica Sgro’, Nazzareno Galbi. Cardiology, Institute of Cardiology-University of Bologna, Bologna, Italy

Purpose: Patients with pulmonary arterial hypertension associated with congenital heart defects (PAH-CHD) are currently treated with targeted therapy. According to recent guidelines PAH-CHD patients with inadequate clinical response should also be treated with combination therapy (CT). We assessed the effects of double CT in a group of PAH-CHD patients.

Methods: In the last 6 years, 43 adult patients with PAH-CHD (age 43±14 ys, 65% females) already treated with monotherapy were included. Twenty-nine were treated with bosentan (125 mg bid) and 14 with sildenafil (20 or 50 mg tid). Twelve patients had a ventricular septal defect, 5 patients had an atrial septal defect, 5 had a patent ductus arteriosus, 8 had combined defects, and 13 had corrected defects. At baseline and after CT (with sildenafil or bosentan according to the first-line treatment) 6-minute walk test (6MWT) and right-heart catheterization were performed.

Results: One patient did not perform 6MWT and another one did not undergo RHC after combination therapy. The table shows the hemodynamic and functional changes after a mean treatment period of 4.8±2.1 months of CT.

mPAP: mean pulmonary arterial pressure; mBP: mean blood pressure; Qp: pulmonary cardiac index; PVR: pulmonary vascular resistance; SaO2: systemic arterial oxygen saturation.

Conclusions: CT improves exercise capacity and hemodynamics in patients with PAH-CHD already on monotherapy. Sequential CT appears to be an appropriate approach also in patients with PAH-CHD.

P2285
ACE2 activation improves pulmonary endothelial function and attenuates monocrotaline-induced pulmonary hypertension

Vinayak Sheny1, Abhi 6 Tania1, Katya Rigan2, Yanfei Qi1. 1Physiology and Functional Genomics, 2Pharmacodynamics, University of Florida, Gainesville, FL, United States

Angiotensin converting enzyme 2 (ACE2), a member of the vasoprotective axis of the renin angiotensin system, protects the lungs against acute lung injury and pulmonary hypertension. The present study was undertaken to test the hypothesis that activation of endogenous ACE2 by diminazene aceturate (DIZE), a putative ACE2 activator would prevent and reverse monocrotaline (MCT)-induced pulmonary hypertension. In the prevention protocol, DIZE was administered at the same time as MCT, while for the reversal protocol DIZE was injected after 3 weeks of MCT
administration. A single subcutaneous injection of MCT (50mg/kg) resulted in elevated right ventricular systolic pressure (RVSP) associated with the development of right ventricular hypertrophy (RVH). DZIG administration (15mg/kg per day) significantly prevented increases in RVSP (Control: 31±3 mmHg; MCT: 57±7 mmHg; MCT+DIZE: 41±4 mmHg; n=5-8; p<0.05) and attenuated RVH (Control: 0.23±0.04 mmHg; MCT: 0.43±0.03 mmHg; MCT+DIZE: 0.26±0.01 mmHg; n=5-8; p<0.05). In subgroup analysis, we observed a 63% decrease in acetylcholine-induced vasorelaxation of the pulmonary arteries from MCT-challenged rats. DIZE treatment resulted in 50% improvement in acetylcholine-induced vasorelaxation, signifying better pulmonary endothelial function. Furthermore, DIZE treatment reversed MCT-induced increases in RVSP (Control: 33±2 mmHg; MCT: 78±6 mmHg; MCT+DIZE: 50±5 mmHg; n=7-11; p<0.05) and RVH (Control: 0.24±0.02 mmHg; MCT: 0.54±0.02 mmHg; MCT+DIZE: 0.44±0.03 mmHg; n=7-11; p<0.05). These data suggest that DIZE’s primary protective effects are mediated by ACE activation, other though off-target effects may also contribute.

P2286

Effect of treatment on exercise endurance tolerance and ventilatory efficiency in patients with pulmonary arterial hypertension (PAH)

Dario Martolini1, Paolo Onorati1, Gabriele Valli1, Alessandro Maria Ferrari2, Paolo Marinelli3, Mattia Internullo3, Liborio Sard4, Cristina Gambardella5, Beatrice Pazzuto6, Carmine Dario Vizz7, Paolo Palange1, Fisiopatologia Respiratoria - Medicina Interna 1, Dipartimento di Sanità Pubblica e Malattie Infettive, Università di Roma "La Sapienza" - Policlínico Umberto I, Roma, Italy; 2Centro per la CURAPOLMO (Pulmonary Arterial Hypertension) - Dipartimento di Scienze Cardiovascolari e Respiratorie, Università di Roma "La Sapienza" - Policlínico Umberto I, Roma, Italy.

Incremental Cardiopulmonary Exercise Test (CPET) or 6-Minute Walking Test (6’MWT) are utilized for the evaluation of Pulmonary Arterial Hypertension (PAH) patients, although the parameters obtained (e.g. peak oxygen uptake - V’O2Peak - and walking distance, respectively) have a different predictive value, depending on outcomes of interest (e.g. prognosis, response to therapy). We evaluated the effect of treatment on principal indexes obtained during CPET, constant work rate test on cycle ergometer (CWR) (e.g. endurance time, Tlim), and 6’MWT. Methods: Nine naive PAH pts (age 41±15.0 years; mean PAP 51±15 SD mmHg) underwent, before (PRE) and after (POST) treatment, CPET, CWR (80% max load at PRE-CPET) and 6’MWT. V’O2, CO2 output (V’CO2), ventilation (V’E), heart rate (HR) and other derived parameters (V’E/V’CO2) were measured breath-by-breath (Quark b2, COSMED, Rome, Italy); PRE- and POST-values at peak and at isotime were compared (paired t-test). Results: During CWR, POST-Tlim resulted significantly longer than PRE-Tlim (POST-Tlim 11’24”±6’07” vs PRE-Tlim 5’38”±3’03”; p<0.01) and POST-V’E/V’CO2 at peak and at isotime was significantly lower compared to PRE-value at peak (p<0.01 and p=0.02 respectively). During CPET, POST-V’O2Peak was not significantly higher than PRE-V’O2Peak (p=0.06). POST 6’MWT distance resulted significantly higher than PRE-one (p<0.01).

Conclusions: The better POST-treatment exercise tolerance in PAH pts seems to be linked to a ventilatory efficiency improvement, and the parameters obtained at CWR and 6’MWT, compared to CPET, appear to be more sensible to the effect of medical treatment.

P2287

Improved survival in medically-treated chronic thromboembolic pulmonary hypertension

Rintarou Nishimura, Nobuhiro Tanabe, Yasunori Ichimura, Ayumi Sekine, Toshihiko Sugira, Takayuki Jujo, Ayako Shigeta, Seiichiro Sakao, Yasunori Kasahara, Yuichi Takiguchi, Keiichi Tsutsumi, Department of Respiratory, Graduate School of Medicine, Chiba University, Chiba, Japan.

Background: Although the key for the successful treatment of patients with chronic thromboembolic pulmonary hypertension (CTEPH) is pulmonary endarterectomy (PEA), the patients who are not indicated for surgical intervention and/or have comorbidities must therefore be medically treated. Recent new medical therapies (new Tx), such as bosantan and sildenafil, may thus be able to improve the outcome of Japanese patients with CTEPH.

Purpose: To clarify the improved survival in CTEPH cases administered new Tx.

Methods: Between 1986 and 2010, 202 patients were diagnosed to have CTEPH at Chiba University Hospital. Ninety-nine patients underwent PEA, while 103 patients were medically treated. 56.5% of the patients diagnosed from 2005-2010 were treated by new Tx., 19.4% of those from 1999-2004, and 8.7% of those from 1986-1998 (p=0.05). We investigated the long-term survival from the diagnos is and prognostic factors in medically-treated CTEPH cases and also examined survival from the initiation of the new Tx.

Results: The patients diagnosed from 2005-2010 showed a significantly improved survival (5-year survival: 87.8%) compared with those from 1999-2004 (72.2%) and from 1986-1998 (56.5%) (p=0.02). The 5-year survival from the initiation of bosantan (n=15) and sildenafil (n=24) was 90.0%, 84.2%, respectively. A multivariate analysis revealed a lower pulmonary vascular resistance (p<0.0001), no comorbidities (p=0.0009), a peripheral type (p=0.02), and recent patients (p=0.02) to be significantly better prognostic factors.

Conclusions: The survival in medically treated CTEPH cases was found to have improved due to the administration of new medical therapies.
to associate a specific PAH treatment with a highly active anti-retroviral therapy (HAART).

Recent studies report some excellent response to Bosentan treatment, with hemodynamic normalisation and long term benefit of this treatment. But, there is no data upon specific treatment discontinuation.

We report here two patients with persistent remission after Bosentan cessation. Patients were women, IV drugs users, one of African origin 36-years old, the other Caucasian of 46-years old. Diagnosis of PH was performed respectively one year and twenty years after diagnosis of HIV infection. Both patients received HAART and Bosentan.

Because of persistent normalization of hemodynamic and functional parameters, bosentan was withdrawn respectively 5 and 1 years after beginning. Both patients remain asymptomatic with normal hemodynamic results respectively at 42 and 12 months after bosentan discontinuation.

Data are illustrated on figure for both patients.

Conclusion: We propose herein to go one step further in PAH treatment with these two cases of cured PAH-HIV, despite more than three years of Bosentan discontinuation. But we recommended not stopping treatment without complete clinical, hemodynamic and immunological persistent normalisation during at least one year.

P2390

Effects of BAY 41-8543 and sildenafil on right heart structure and function in pulmonary artery banding mice

Wiebke Janssen1, Yves Schymura1, Astrid Wietelmann1, Johannes-Peter Stasch2, Hinal Luitel2, Norbert Weissmann2, Hossein Ardeschir Ghofrani 2, Friedrich Grimmer1, Thomas Braun1, Werner Seeger1,2, Ralph Theo Schermuly1,2,1 Lung Development and Remodelling, Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany; 2Lung Vascular Remodelling and Anti-Remodelling, University of Giessen Lung Centre, Giessen, Germany; 3Cardiovascular Research, Bayer HealthCare, Wuppertal, Germany

Background: Right ventricular (RV) pressure over-load causes RV remodeling. Impaired NO/GMP signaling is involved in the pathogenesis of LHV hypertrophy. We assessed the effects of the soluble guanylate cyclase (sGC) stimulator BAY 41-8543, the PDE5 inhibitor sildenafil, and combination treatment on RV function and RVHI in an animal model of chronic pressure-overload.

Methods: RVHI was induced by pulmonary artery banding (PAB) in mice. Treatment started 7 days after surgery for 14 days, after which RV morphology and function were studied using Magnetic Resonance Imaging. Fibrosis was assessed by histology.

Results: BAY led to RV dysfunction (decreased RV stroke volume (40.5 vs. 23.0 ml [Sham vs. PAB]) and decreased RV ejection fraction (70.0 vs. 43.0%). Treatment with sildenafil did not change RV function, whereas BAY 41-8543 and combination treatment led to significant improvements (RV stroke volume: 23.0 vs. 12.1 vs. 31.1; RV ejection fraction: 43.3 vs. 54.1 vs. 55.7 vs. 63.8 [all values as%; placebo vs. sildenafil vs. BAY 41-8543 vs. combination treatment]). PAB mice showed an increased RV/(LV-S) ratio (0.25 vs. 0.39). Drug treatment had no effects on collagen content, whereas BAY 41-8543 and combination treatment significantly improved RV mass, BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass, whereas BAY 41-8543 and combination treatment significantly improved RV mass.

Conclusions: Even though none of the treatments led to significant changes in RV mass, BAY 41-8543 and combination treatment significantly improved RV function, accompanied by decreased fibrosis.

P2293

Optimization of tissue targeting properties of macitentan, a new dual endothelin receptor antagonist, improves its efficacy in a rat model of pulmonary fibrosis associated with pulmonary arterial hypertension

Marc Iglarz, Kyle Landskroner, Daniel Wanner, Markus Rey, Patrick Hess, Martine Clozel, Pharmacology and Preclinical Development, Actelion Pharmaceuticals Ltd., Allschwil, Switzerland

Introduction: We investigated the efficacy of macitentan, a new tissue-targeting dual endothelin (ET) receptor antagonist, in a model of pulmonary fibrosis associated with pulmonary hypertension and compared it with dual ET receptor antagonist, bosentan.

Methods and results: Oral administration of macitentan for 19 days dose-dependently decreased lung hydroxyproline content with a statistically significant effect observed at 30 and 100 mg/kg/day vs. non-treated bleomycin rats (n = 8-12). Overall, macitentan (100 mg/kg/day) consistently inhibited the development of pulmonary fibrosis by 18-27% in three independent studies, and decreased right ventricle hypertrophy by 25-28% in two of these three studies. In contrast, bosentan (300 mg/kg/d) inhibited the development of pulmonary fibrosis in only one of the three experiments, by 23%, and had no effect on the development of right ventricle hypertrophy. Administration of radio labelled 14C-macitentan or 14C-bosentan to bleomycin-treated rats showed greater drug distribution in the lung compared to the distribution in healthy animals. Notably, distribution of macitentan into the parenchyma of bleomycin-treated rats was greater than that of bosentan.

Conclusion: Repeated experiments demonstrated that macitentan is more efficacious than bosentan in preventing the development of lung fibrosis and right ventricle hypertrophy. Greater ability of macitentan to distribute into the tissue could explain its improved efficacy profile, as it would achieve a more complete blockade of ET receptors.

P2292

First and second line treatment pattern among pulmonary hypertension patients enrolled in a managed care health plan

Vijay Joish1, David Muccino2, Charles Krelick1. 1HEOR, Bayer HealthCare Pharmaceuticals Inc., Wayne, NJ, United States; 2Medical Affairs, Bayer HealthCare Pharmaceuticals Inc., Wayne, NJ, United States

Purpose: To describe first and second line treatment pattern among PH patients enrolled in managed care health plan.

Methods: Data were derived from the MarketScan claims database. PH patients were identified anytime during 4/1/2006 to 3/31/2009 using the ICD-9 claim of 416.X. First line therapy was defined as the first PH-related pharmacy claim within ±12 months of the diagnosis claim. Second line treatment was defined as separate PH-related pharmacy claim post the first line PH-related pharmacy claim. PH-related treatment included prescriptions for high-dose calcium channel blockers (CCBs), endothelin receptor antagonists (ERAs), phosphodiesterase type 5 inhibitors (PDE5is), or prostacyclin analogues (PAs). CCB users had no diagnosis claim of essential hypertension anytime during the study period.

Results: Final study sample was 2,252, with a mean age of 61.2 years (SD±16.41), and 57% females. 46% of PH-patients had CCB as the first line treatment followed by PDE5is (38%), ERAs (13%), and PAs (3%). 16% of the sample had some second line treatment over a 12-month follow-up. Combination therapy was only observed in the CCB-cohort, where 69 patients added an ERA/PDE5i to their current treatment. Switching was most common among ERA (61%) and PA (50%) first line users, with majority switching to PDE5. Total average treatment days for first-line PH- prescription varied from a low of 21 (SD±8.14) days among PA-users to 266 (SD±131.39) among ERA-users, respectively.

Conclusions: CCBs and PDE5s were the most prescribed first line treatment among PH-patients. Future research would need to explore the choice of first line treatment in clinical and economic

Pulmonary hypertension in patients treated with Src/ABL kinase inhibitor dasatinib
David Montani1, Emmanuel Bergerot1, Sven Guthier1, Laurent Savale1, Anne Bergeron1, Arnaud Bourdin1, Hélène Bouvaist1, Mathieu Canet1, Christophe Pison1, Margaret Macro1, Patrick Poubeau1, Delphine Natali1, Frederic Perros1, Dermot S. O’Callaghan1, Xavier Lais1, Olivier Sibon1, Gérald Simonneau1, Marc Humbert1, 1Univ Paris Sud, AP-HP, Service de Pneumologie et Réanimation Respiratoire, Centre de Référence de l’Hypertension Pulmonaire Sèvres, INSERM U999, Hôpital Antoine Béclère, Clamart, France; 2Service de Pneumologie et Centre Régional de Compétence de l’HTAP Caen University Hospital, Caen, France; 3Centre de Référence de l’Hypertension Pulmonaire Sèvres, INSERM U999, Hôpital Antoine Béclère, Clamart, France

Methods: The present report summarizes the clinical characteristics and outcomes of dasatinib-associated PH cases from the French PH Registry.

Results: Between 1st January 2008 and 30th September 2010, 11 patients with either a diagnosis of CML and/or a treatment with imatinib, dasatinib or nilotinib were identified corresponding to 2 prevalent imatinib-treated CML patients previously reported by our group and who developed PH prior to treatment with imatinib (Souza et al, Thorax 2006;61:736) and 9 incident patients who were all exposed to dasatinib at the time of PH diagnosis. The lowest estimate of incident PH occurring in patients exposed to dasatinib was 92.9/00 (0.31%), as compared with no incident case reported with imatinib or nilotinib in the same period.

Conclusions: Dasatinib therapy may promote severe pre-capillary PH, suggesting a direct and specific effect of dasatinib.

P2295
Everolimus improves exercise capacity and pulmonary vascular resistance in patients with advanced pulmonary hypertension – A pilot study
Hans-Juergen Seyfarth1, Stefan Hammerschmidt1, Michael Halak2, Petra Neuhaus1, Hubert Wirtz1, 1Department of Internal Medicine I, University Hospital Carl Gustav Carus of TU Dresden, Dresden, Germany; 2Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany; 3Service de Pneumologie et Maladies Infectieuses, GHSR, Saint-Pierre, Réunion, France

Background: In recent years, pulmonary arterial hypertension (PAH) has been recognized to be a predominantly proliferative process. The inhibitor of the mammalian target of rapamycin (mTOR) everolimus inhibits cellular protein synthesis and growth in cells of the vascular wall.

Methods: Ten patients with PAH (n=8) or chronic thromboembolic pulmonary hypertension (CTEPH) and progressive disease despite therapy with at least two vasodilating drugs were included in a prospective open label pilot study. All patients were treated additionally with everolimus. Safety and tolerability were observed. Pulmonary vascular resistance (PVR) and 6-minute walking distance (6MWD) were considered as primary endpoints.

Results: In two patients study medication was stopped prematurely due to an adverse event. The remaining 8 patients exhibited a significant improvement in PVR (1049±438 vs. 689±235 dynsec/cm²; p=0.004) and 6MWD (246±405 vs. 313±127m; p=0.04) after 6 months of therapy with everolimus.

Conclusion: Antiproliferative with everolimus therapy was tolerated in ten patients in this pilot study. The observed improvements in PVR and in 6MWD may stimulate further consideration of mTOR inhibition in pulmonary hypertension.

Ambrisentan improves exercise capacity and symptoms in patients with portopulmonary hypertension
Michael Halak1, Lars Knudsen1, Hans-Juergen Seyfarth1, Ralf Ewert4, Baerbel Wiedemann3, Marlin Kolditz1, Gert Hofeiken1, Marius Hoepfer1, 1Department of Internal Medicine I, University Hospital Carl Gustav Carus of TU Dresden, Dresden, Germany; 2Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany; 3Service de Pneumologie et Maladies Infectieuses, GHSR, Saint-Pierre, Réunion, France

Introduction: Ambrisentan, a selective endothelin receptor antagonist has been approved in several countries for pulmonary arterial hypertension. No data have been published on the efficacy of ambrisentan on improvement of exercise capacity in patients with portopulmonary hypertension (PoPH).

Methods: We retrospectively analyzed the safety and efficacy of ambrisentan in patients with PoPH in four German university hospitals.

Results: 14 patients with moderate to severe PoPH were included. The median follow-up was 16 months (IQR, 12-21). 6 minute walk tests after 6 and 12 months improved from 376 meters (IQR, 207-440) to 415 meters (IQR, 362-431), respectively. WHO functional class after 1 year of therapy with ambrisentan also improved significantly (p=0.014). No significant changes in blood gas analysis and liver transaminases were detectable.

Conclusions: The present study demonstrates significant improvement of exercise capacity and symptoms without relevant safety concerns during ambrisentan treatment in patients with PoPH.

Double combination therapy in patients with pulmonary arterial hypertension associated with connective tissue disease
Enrico Gotti, Enni Leci, Alessandra Manes, Massimiliano Palazzini, Elena Beciani, Elisa Conticini, Nicole Rizzo, Francesca Terzi, Gaia Mazzanti, Francesca Siciar, Nazzareno Galié, Cardiology, Istitute of Cardiology-University of Bologna, Bologna, Italy

Background: Pulmonary arterial hypertension associated with connective tissue disease (PAH-CTD) is a severe and progressive condition despite the availability of 3 specific classes of drugs: prostanoids (PROST), endothelin receptor antagonists (ERA) and phosphodiesterase-5 inhibitors (PDE5-I). Combination therapy (CT) has been proposed for patients with unsatisfactory response to monotherapy.

Aim: To examine the effect of double CT in patients with PAH -CTD who do not achieve an adequate clinical response on monotherapy.

Methods: Between October 1999 and December 2010, 48 PAH-CTD patients in WHO functional class III treated with monotherapy were included. At baseline and after 5±5 months on CT, all patients underwent 6-minute walk test (6MWT) and right heart catherization.

411s
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
Results: Mean age was 58±14 years, 85% females. Mean time from initiation of monotherapy to initiation of CT was 18±20 months. Forty (83%) patients received ERA+PDES-I, 5 (10%) received PDES-I+PROST and 3 (7%) received ERA+PROST. Four (8%) patients died before CT assessment. The table shows the haemodynamic and functional changes after CT.

### P2399

Tadalafil in idiopathic or heritable pulmonary arterial hypertension compared to pulmonary arterial hypertension associated with connective tissue disease

Nazzareno Galie1, Robyn Barst2, Bruce Bradbury3, Hossein A. Ghofrani4, Ronald Oudkerk5, Gerald Simonneau1,1, 1Institute of Cardiology, University of Bologna, Bologna, Italy; 2Pediatric Cardiology, Columbus University College of Physicians & Surgeons, New York, NY, United States; 4Cardiology, Heart Institute of the Cascades, Bend, OR, United States; 5Pulmonary Hypertension Division, Department of Cardiovascular, Inserm, Gustave, Germany; 6Division of Cardiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States; 7Pulmonary Disease, Antoine Béclère University Hospital, Clamart, France

Patients (pts) with PAH associated with connective tissue disease (APAHT-CTD) have a worse prognosis compared to idiopathic (I) or heritable (HPAH). Our objective was to test the clinical outcomes in these two subgroups. In a 16 week (wk), double-blind, placebo (PBO) controlled trial with blinded 52 wk extension, pts were randomized to PBO, 20 or 40mg tadalafil (Tad) qd (APAHT-CTD: n=54, 21 and 19, respectively; APAHT-I/II: n=54, 50 and 46, respectively; subgroup efficacy analyses included six-month walk test (6MWT, 4Mg) at Wk16 (assessed by rank permutation tests) and clinical worsening (C, PBO and 40mg) at Wk16 and up to 68wks (20 and 40mg). Pts on 20mg without C at 6wks remained on 20mg and all others received 40mg in the extension. Mean changes in 6MWT from baseline to Wk16 were 32m in APAHT-CTD and 58m in APAHT-I/II for 40mg Tad dose. PBO-corrected treatment effects on 6MWT at Wk 16 were 49m in APAHT-CTD (P=0.03) and 22m in APAHT-I/II (P=0.04). The 5% of pts with C in the Tad 40mg and PBO subgroups at Wk16 were 11 and 25% in APAHT-CTD, respectively and 4 and 15% in APAHT-I/II, respectively. In pts who received Tad 20 or 40mg up to 68wks, C was 35% in APAHT-I/II (n=40) and 24% in APAHT-I/II (n=96). Tad 40mg improves 6MWT at Wk16 in APAHT-CTD and APAHT-I/II; however, with PBO 6MWT decreased in APAHT-CTD but not in APAHT pts. In addition, C was numerically less in both Tad groups at Wk16 compared to PBO. At Wk68, C was numerically higher in APAHT-CTD vs. APAHT-I/II. These latter data are consistent with a worse prognosis in APAHT-CTD. Whether more aggressive therapy earlier in APAHT-CTD pts would be efficacious requires further study.

### P2300

Role of exercise cardiac index to predict NYHA functional class, 6-minute walk test distance and survival in idiopathic, heritable and anorexigen-associated pulmonary arterial hypertension

Raphaelle Poncot-Monge1,2, Ari Chauvat1, Pascale Malvestio1, Emmanuel Gomez1,3, Denis Regent4, Christine Selton1,5, Raphaëlle Poncot-Mongars1,6, Ari Chaouat1, Pascale Malvestio1, François Chabot1

The aim of the study was to evaluate right ventricular functions in patients by TDI. Methods: Pulmonary haemodynamics and RV functions were evaluated by TDI and Doppler-ECHO in 48 highlanders at altitude of residency (3200-3800 m). All patients were divided into the three groups: 1st group (n=20) - patients with high altitude pulmonary hypertension (PAH) 2nd group (n=20) - patients with HAPH and RV hypertrophy. 3rd group (n=20) healthy highlanders. All subjects underwent clinical examination, ECG, spirometry.

Results: Conclusions: The evaluation of peak systolic and diastolic tricuspid annular velocity using TDI revealed RV hypertrophic diastolic dysfunction in patients with HAPH and RV hypertrophy. The 6MWT is a good predictor of exercise capacity. This variable was also the best survival prognostic factor in our group of patients.

### P2301

Estimation of right ventricular function in highlanders with high altitude pulmonary hypertension and high altitude cor pulmonale

Abdulrahim Maripov, Akopy Sarybayev: High Altitude Medicine, National Centre Cardiology and Internal Medicine, Bishkek, Kyrgyzstan

Tissue Doppler imaging (TDI) is used as additional approach for diagnosis of right ventricular (RV) dysfunction in PH. But RV function obtained by TDI has rarely been investigated in highlanders.

The aim of the study was to evaluate RV functions in highlanders by TDI. Methods: Pulmonary haemodynamics and RV functions were evaluated by TDI and Doppler-ECHO in 48 highlanders at altitude of residency (3200-3800 m). All patients were divided into the three groups: 1st group (n=20) - patients with high altitude pulmonary hypertension (PAH) 2nd group (n=20) - patients with HAPH and RV hypertrophy. 3rd group (n=20) healthy highlanders. All subjects underwent clinical examination, ECG, spirometry.

Results: Conclusions: The evaluation of peak systolic and diastolic tricuspid annular velocity using TDI revealed RV hypertrophic diastolic dysfunction in HAPH patients and RV systolic dysfunction with pseudonormal pulmonary dysfunction in patients with HAPH and RV hypertrophy.

### P2302

Analysis of the cardiac index-PvO2 relationship during vasodilatation challenge as a prognostic factor in pulmonary arterial hypertension

Carolina Rosado-Bosque, Tomas Pulido, Karina Zamora, Armando Rodriguez, Milco Contreras, Pedro Guevara, Julio Sandoval: Cardiopulmonary, National Heart Institute, Mexico City, Mexico

Background: Mixed venous oxygen pressure (PvO2) is a reflection of the tissue oxygenation state. PvO2 is one of the variables associated to survival in patients with pulmonary arterial hypertension (PAH).

Objectives: Investigate if the relationship CI – PvO2 during vasodilatation challenge (VC) is maintained and whether the type of response has any prognostic implication in PAH patients.

Methods: We analyzed the hemodynamic and gasometrical variables at baseline and during the response to the acute VC at right heart catherization of patients with PAH. According to the results, patients were judged to have an appropriate response (AR) (i.e. higher CI=higher PvO2) or not. The midterm survival in both groups was also analyzed.

Results: We studied 42 patients with PAH (35±5 years; 76% female). For the drug challenge we used adenosine (n=33) and Iloprost (n=9). Patients with AR (n=31) had a significant correlation CI-PvO2 at baseline and during challenge (r=0.67; and 0.52, respectively, p<0.05). In patients with inappropriate response (IR) (n=11) the correlation was significant at baseline (r=0.59; p<0.05) but it was lost during challenge (r=0.72; p<0.05). The correlation delta CI-CI-PvO2 was positive (r=0.41; p<0.05) for those with AR and it was negative for those with IR (r = 0.5; p<0.05). In a preliminary analysis, 5-year mortality appears higher in those with an AR (27.2 versus 15%).

Conclusions: Some patients with PAH have an abnormal tissue oxygenation, which may be uncovered by the analysis of the CI-PvO2 relationship. This finding may be of prognostic significance.
Diaphragm function in experimental pulmonary hypertension

Emmy Manders1, Nico Westerhof1, Anton Vonk-Noordegraaf2, Frances de Man1, Coen Onnenhjelm1, Pulmonology, VU University Medical Centre, Amsterdam, Noord-Holland, Netherlands; 2Physiology, VU University Medical Centre, Amsterdam, Noord-Holland, Netherlands

Introduction: Recently it was suggested that patients with pulmonary hypertension (PH) suffer from diaphragm dysfunction due to increased loading conditions. In the present study we aimed to determine the contractile strength of the diaphragm muscle in PH and control rats. The extensor digitorum longus (EDL) muscle will serve as a control skeletal muscle.

Methods: PH was induced in Wistar rats by a single injection of monocrotaline (60 mg/kg). The diaphragm and EDL (PH n=5; controls n=5) muscle were excised for determination of in vitro contractile properties. Muscle bundles were treated with a relaxing solution (5°C) containing 1% Triton X-100 to permeabilize membranes. Single fibers were mounted on a single fiber apparatus. Maximum force (Fmax), rate constant of force redevelopment (Ktr), as a measure of the cross bridge kinetics, and calcium sensitivity (pCa50) were measured in diaphragm and EDL single muscle fibers.

Results: In the EDL muscle no significant differences were found in Fmax and pCa50. Ktr was significantly higher in PH fibers: 10.86±0.79 vs 15.09±0.74 (p=0.005). The cross sectional area (CSA) of the fibers measured was significantly decreased in PH fibers: 256.1±16.7 vs 196.1±88.82 μm² (p=0.013).

Conclusions: These data suggest a more pronounced effect of PH on the diaphragm muscle compared to EDL. However, more experiments on the diaphragm muscle and fiber type determination is necessary before final conclusions can be drawn.

Diaphragm function in experimental pulmonary hypertension

P2304

A model-based analysis of the effect of hypoxia on regional pulmonary blood flow

Kelly Burrows1, Alya Clark2, Annalisa Swan3, Merryn Tawhai3, 1Oxford University Computing Laboratory, University of Oxford, Oxford, United Kingdom; 2Auckland Bioengineering Institute, The University of Auckland, Auckland, New Zealand

Hypoxic pulmonary vasconstriction (HPV) diverts blood from hypoxic regions of the lung, optimising ventilation/perfusion (V/Q) matching and gas exchange. In the diaphragm, hypoxia is thought to improve HPV via increased oxygen delivery to the tissue and/or HPV becomes less effective in the lung. The aim of the current study was to determine if HPV is present in the diaphragm muscle and if HPV differs from that present in other regions of the lung.

Methods: An animal model of chronic hypoxia was used to study regional pulmonary blood flow distribution. A 7 week period of hypoxia resulted in a 15% reduction in arterial oxygen saturation in the rats. 20 rats were studied (10 controls, 10 hypoxic). Regional pulmonary blood flow was measured using indocyanine green fluorescent microsphere injections. The percentage of the total blood flow to each of the 9 lobes was calculated for each rat.

Results: In the controls, 25% of the blood flow went to the upper lobes, 25% to the lower lobes, and 50% to the right middle lobe. In the hypoxic rats, 20% of the blood flow went to the upper lobes, 30% to the lower lobes, and 50% to the right middle lobe. This was statistically significant (p<0.05).

Conclusions: These results suggest that HPV is present in the diaphragm and is altered by chronic hypoxia in a similar manner to the effect seen in other regions of the lung.

Diaphragm function in experimental pulmonary hypertension

P2305

Association of renal dysfunction with cardiac output and right atrial pressure in pulmonary arterial hypertension

Marnie van de Veenond, Anton Vonk-Noordegraaf. Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands

Background: Pulmonary arterial hypertension (PAH) is a disease of the pulmonary vasculature that results in right ventricular (RV) failure and death. Renal insufficiency is recently identified as a key predictor of mortality in PAH patients [1]. Renal dysfunction is associated with decreased cardiac output (CO) in patients with left heart failure [2], however, little is known about the mechanism of renal dysfunction and its association with venous congestion in PAH patients with RV dysfunction.

Objectives: To investigate the relationship between CO, right atrial pressure (RAP) and estimated glomerular filtration rate (eGFR) in patients with PAH.

Methods: 74 patients underwent baseline right heart catheterization to determine CO and RAP and blood sampling to calculate eGFR. These measurements were repeated in 30 patients after 12±4 months of follow-up.

Results: Mean age was 52±15 years and 73% of subjects were female. Mean eGFR was 88.8±24 ml/min/1.73m², mean CO was 5.1±1.7 L/min and mean RAP was 7.0±4.5 mmHg. Low eGFR at baseline was associated with low CO (R0.46; p<0.001) and high RAP (R=0.20; p=0.042). Multivariate regression analysis showed that CO was an independent determinant of eGFR (p=0.01).

Conclusion: CO is the main determinant of renal dysfunction in patients with pulmonary arterial hypertension and RV dysfunction.

Contrasting cardiopulmonary responses to incremental exercise in patients with schistosomiasis-associated and idiopathic pulmonary arterial hypertension with similar resting hemodynamic impairment

P2307

Fabio F. Valois, Roberta Ramos, Eliza Ferreira, Jaqueline Arakaki, José Alberto Neder, Luz Eduardino Nery, Respiratory Division, Federal University of São Paulo, São Paulo, Brazil

Schistosomiasis is the most common cause of pulmonary arterial hypertension (PAH) worldwide. It has been reported that schistosomiasis-associated PAH (Sch-PAH) has better hemodynamic profile at diagnosis and a more benign clinical course as compared with idiopathic PAH (IPAH) [1]. We hypothesized that Sch-PAH patients have better physiological responses to incremental cardiopulmonary exercise test (CPET) than IPAH patients, even at similar resting pulmonary hemodynamic impairment. We performed CPET and hemodynamic study in 8 Sch-PAH and 9 IPAH patients. None of them had received any PAH therapy. There were no significant between-group differences on cardiac index (2.1±0.3 vs 2.4±0.7 L/min, p=0.21), pulmonary vascular resistance (p=0.32) and mean pulmonary artery pressure (p=0.48). However, the peak oxygen uptake (VO2peak) was greater in Sch-PAH (75±21 vs 54±16%pred, p=0.016), as well as the ratio of increases of VO2 to work rate (8.2±1.1 vs 6.8±1.1 mL/min/W, p=0.024). Also, the slope of the ventilatory response as a function of CO2 output was lower in Sch-PAH (41±4 vs 59±18 L²/min², p=0.04), with a shallower heart rate response for a given change in VO2 (88±21 vs 123±39 beats/min², p=0.02), and a greater peak oxygen pulse (p<0.05). In conclusion, Sch-PAH patients had better physiological responses to exercise than IPAH subjects at similar resting hemodynamic profile. Our data suggest a more preserved hemodynamic response to exercise in Sch-PAH, which might explain its better clinical course as compared with IPAH.

Nitric oxide metabolite flux during exercise in pulmonary arterial hypertension

William Oldham 1, Allison Janoche 1, Paul Pappagianopoulos 1, Serpel Erzurum 2, Aaron Waxman 1, Gregory Lewis 1, David Systrom 1. 1Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States; 2Department of Pathology, Cleveland Clinic Foundation, Cleveland, OH, United States

Introduction: Exercise-induced pulmonary arterial hypertension (PAH) is a clinically important stage in the spectrum of PAH. The pathophysiology of abnormal pulmonary vascular responses to exercise is poorly characterized. Endogenous nitric oxide (NO) is an important mediator of vasodilation and accumulating data suggests impaired NO signaling in patients with PAH.

Aims: The objective was to test the hypothesis that changes in stable NO metabolites (NOx) in blood during exercise in patients with resting or exercise-induced PAH would differ from NOx in individuals with normal exercise pulmonary arterial pressures. Patients were selected from a population referred to the MGH Cardiopulmonary Exercise Laboratory for invasive incremental cardiopulmonary exercise testing with pulmonary and radial artery catheters. Simultaneous samples of arterial (a) and mixed venous (mv) blood at rest, peak exercise, and one hour post-exercise were obtained from 10 patients with PAH (VO2max <85% predicted, Qmax <80% predicted, PAP >30 mmHg, and PVR >80 dyn s cm⁻¹) and 10 controls (VO2max and Qmax both >80% predicted). These were analyzed for [NOx] using chemiluminescence. Data are median [interquartile ranges]. Comparisons used the Mann-Whitney test.

Results: NOx flux increased from rest to exercise in controls (45%, [4, 77], p=0.02), but not in PAH (0%, [-27, 15], p=0.97).

NOx, increased in both groups (11% [2, 26] v 7% [7, 40], p=0.80). NOx flux (Qmax x (mv–a [NOx])) in controls was greater than PAH (370% [-100, 4869] v -96% [-460, 6], p=0.04).

There were no differences in [NOx] during recovery.

Conclusions: Normal pulmonary vasodilation and recruitment during exercise may be dependent on NOx bioavailability in mixed venous blood.

P2309

Comparing cardiac magnetic resonance imaging in group 1 and group 4 pulmonary hypertension

Susana Hoetle 1, Nicolas Creuze 2, Dominique Musser 2, Xavier Jais 3, Laurent Savale 1, Delphine Natali 1, Sven Gunther 1, Olivier Sitbon 1, Gerald Simonneau 1, Marc Humbert 1, Denis Chemla 1. 1Pneumology, Hôpital Antoine Béclère, Université Paris-Sud, Clamart, France; 2Radiology, Hôpital Antoine Béclère, Université Paris-Sud, Clamart, France; 3Physiology, Hôpital Antoine Béclère, Université Paris-Sud, Clamart, France

Background and aim: Pulmonary arterial hypertension (PAH, group 1) and chronic thromboembolic PH (CTEPH, group 4) have different pathophysiology. Our study tested the hypothesis that PAH and CTEPH display different characteristics on cardiac magnetic resonance imaging (CMR).

Methods: 46 patients (mean age 54±15 yrs; 22F) entered the study, namely 23 PAH and 23 CTEPH matched for age and sex. They underwent right heart catheterization and cine and phase-contrast CMR (1.5 T scanner, Siemens) with arterial pressures. Patients were selected from a population referred to the MGH Cardiopulmonary Exercise Laboratory for invasive incremental cardiopulmonary exercise testing with pulmonary and radial artery catheters. Simultaneous samples of arterial (a) and mixed venous (mv) blood at rest, peak exercise, and one hour post-exercise were obtained from 10 patients with PAH (VO2max <85% predicted, Qmax <80% predicted, PAP >30 mmHg, and PVR >80 dyn s cm⁻¹) and 10 controls (VO2max and Qmax both >80% predicted). These were analyzed for [NOx] using chemiluminescence. Data are median [interquartile ranges]. Comparisons used the Mann-Whitney test.

Results: NOx flux increased from rest to exercise in controls (45%, [4, 77], p=0.02), but not in PAH (0%, [-27, 15], p=0.97).

There were no differences in [NOx] during recovery.

Conclusions: Normal pulmonary vasodilation and recruitment during exercise may be dependent on NOx bioavailability in mixed venous blood.

P2310

The indirect Fick method is an unfeasible method for hemodynamic assessment in pulmonary arterial hypertension patients

Susanna Desole 1, Susann Czekay 2, Tom Bollmann 2, Katharina Lau 1, Ralf Ewert 1, Christian M. Kaehler 1. 1Department of Internal Medicine I - Pneumology, Medical University Innsbruck, Innsbruck, Austria; 2Department of Internal Medicine B - Pulmonary Medicine and Infectious Diseases, Medical Faculty of the Ernst-Moritz-Arndt University Greifswald, Greifswald, Germany

The indirect Fick method (FickInd) is often used for the hemodynamic evaluation in Pulmonary arterial hypertension (PAH). As the FickInd calculates the cardiac output (CO) assuming physiological VO₂ values, this method might be unfeasible for patients with pulmonary vascular diseases. We evaluated the suitability of hemodynamic data obtained by FickInd in PAH.

Right heart catheterization was performed in 43 PAH patients (age 61±13 yrs) and 9 controls. 61% of patients suffered from idiopathic PAH, 30% from PAH associated with connective tissue diseases, the remaining 9% from other forms of PAH. Hemodynamic results obtained by FickInd were compared to data from the thermodilution (TD) method.

Patients and controls did not differ in age and BSA. No significant difference between heart rates during the different techniques was detected in either group. CO measured by FickInd (COFick) was 4.3±1.8 and 4.7±1.2 L/min in PAH patients and controls, respectively. In PAH patients CO by TD method (COThermo) was consistently higher than COFick (4.9±2.0 L/min) showing a significant difference (Wilcoxon; p<0.001). In controls COFick was 5.4±1.4 L/min (not significant to COFick). Agreement analysis of COFick and COThermo revealed a comparable bias between methods in both groups (0.5±1.1 L/min in patients; 0.65±0.82 L/min in controls) with wider limits of agreement for the patient cohort (-1.6 to 2.6 L/min versus -1.0 to 2.3 L/min in controls).

Determination of CO by the FickInd method cannot be used in PAH patients as this method consequently underestimates CO. It can be suggested that the estimated VO₂ values in use for the calculation of the CO are invalid for PAH patients.

P2311

Incapacity to increase pulmonary blood flow determines 6 minutes walking distance in pulmonary hypertension

Gael Deboeck, Robert McKenzie Ross, Linda Sharples, Joanna Pepke-Zaba. PVDU, Papworth Hospital, Papworth, Cambridge, United Kingdom

Introduction: Pulmonary hypertension (PH) is a disease of elevated pulmonary artery pressure leading to the inability of the overloaded right ventricle to adapt pulmonary blood flow (PBF) and systemic oxygen delivery to peripheral tissue oxygen demand. 6 minutes walk test (6MWT) is a submaximal, well tolerated but strenuous test regularly used for the assessment of PH functional status and is strongly associated to survival.

Aim: To study the adaptation of PBF during 6MWT.

Methods: We measured heart rate (HR) and PBF with a rebreathing device (INNOCOR) before and directly after a 6MWT in 28 patients with chronic thromboembolic pulmonary hypertension and 6 with pulmonary arterial hypertension.

The relation between increase (after – before 6MWT) in PBF (ΔPBF) in response to 6MWDistance (6MWD) was plotted and different mathematical model applied to describe the relation (Akaike test).

Results/Discussion: The best fitting model is a polynomial cubic model, showing a small and constant ΔPBF for patients walking less than 300-350 m but more rise in ΔPBF is observed with increased distance.

We notice that the rise in ΔPBF occurs at comparable 6MWD that is associated with better survival in PH. The stroke volume (PBF/HR) is not increased whatever the distance covered.

Conclusions: Ability to substantially increase PBF determines 6MWD and is dependent on chronicotropic response in patient with PH.
A lower resting heart rate may be prognostically favourable in pulmonary arterial hypertension
Silvia Ulrich, Gonca Suna, Lars Huber, Ursula Treder, Rudolf Speich. Thoracic Medicine, Clinic for Pulmonology, Zurich, Switzerland

**Background:** A resting heart rate (RHR) over 70 bpm is associated with increased mortality in left heart failure. We investigated the prognostic value of RHR in pulmonary arterial hypertension (PAH).

**Methods:** We related RHR during baseline right heart catheterisation from PAH-patients to their characteristics and outcomes.

**Results:** Data from 126 PAH (84 females, age 52±17y, 70 diopathic, 27 collagen vascular, 12 congenital heart, 13 HIV, 4 portopulmonal) catheterised from 2000 to 2010 were analysed. Patients were in NYHA II/III/IV (18/67/41), mean 6MWD 122 m, RHR 82±14 bpm, mPAP 49±17 mmHg, PVR 826±470 dyn*s*m-5, the mean follow-up was 46±35 month under optimal medical treatment. Patients with a RHR ≤ 70 bpm had a lower PVR 664±384 vs 887±487 dyn*s*m-5 but did otherwise not defer from a RHR > 70 bpm. 76% of patients with a RHR ≤ 70 bpm were alive after 58±37 months compared to 60% with a RHR > 70 bpm.

**Conclusion:** In this cohort we found that baseline RHR might be prognostically important in PAH. The role of RHR in PAH and whether reducing RHR in in analogy to left heart failure should be analysed in larger cohorts.

**P2313**
Effect of healthy ageing on alveolar-capillary recruitment during exercise
Bryan Taylor, Alex Carlson, Josh O’Malley, Andrew Miller, Bruce Johnson. Division of Cardiovascular Disease, Mayo Clinic, Rochester, MN, United States

Ageing is associated with deterioration in the structure and function of the pulmonary circulation with a decrease in alveolar-capillary surface area. We asked whether age-related changes in the pulmonary circulation limit alveolar-capillary recruitment and gas exchange during exercise in healthy older adults. 5 old (OLD; 66±8 yr, VO2max 140±31% age-predicted) and 8 young adults (YNG; 28±2 yr, VO2max 131±17% age-predicted) participated. Lung diffusing capacity for carbon monoxide (DLCO), cardiac output (Q), pulmonary capillary blood volume (Vc) and membrane diffusing capacity (Dm) were measured via a rebreathe method at rest and during cycle exercise at 25, 50, 75 and 90% of peak power. SaO2 was measured throughout exercise via pulse oximetry. At rest, DLCO, Vc, and Dm were lower in the OLD vs. the YNG group (22.3±3.8 vs. 20.6±4.7 ml/min/mmHg, 70±26 vs.102±48 ml, 35.2±7.9 vs. 46.6±12.3 ml/min/mmHg, P<0.05). However, DLCO increased linearly with exercise intensity in both groups with no plateau or change in slope in DLCO with increasing Q (Fig. 1). Vc and Dm also increased with progressive exercise in both groups (Fig. 1). SaO2 did not change during exercise in either group.

**Figure 1.** DLCO, Vc and Dm vs. Q in healthy old (OLD) and young (YNG) adults.

These data suggest that the age-associated changes in the pulmonary circulation do not impair alveolar-capillary recruitment and gas exchange during exercise in healthy older adults. NIH HL71478

Right heart volume load response in patients with chronic thromboembolic pulmonary hypertension (CTEPH)
Nicolay Khvoroshklorin, Pyotr Yablonsky, Andrey Boyarkin, Vladimir Golovin, Tatiana Fedorova, Evgeny Pavlushkov, Ignatij Karmamov, Olga Karmanov. Anesthesiology and Reanimatology, Medical Faculty of State University, St. Petersburg, Russian Federation Hospital Surgery, Medical Faculty of State University, St. Petersburg, Russian Federation

**Aim:** To assess the influence of volume load on right heart hemodynamics in pts with moderate and severe CTEPH.

**Patients and methods:** 20 patients (mean age - 47±11, 15 males and 5 females). The 1 group consisted of 9 pts with PAP ≤30 mm Hg, the 2 group – 11 pts with PAP>30 mm Hg. Right ventricular end-diastolic volume and ejection fraction were evaluated by thermodilution method [Lichtwarck-Aschoff, 2002].

**Results:** Results are summarized in the following table.

<table>
<thead>

*Statistically significant (p<0.05) between groups.

After volume load: The difference in RVEDVI between the groups was not significant. The difference in CI between the groups became significant. This confirmed that there was no increase in CI in group 2. The increase of CI in group 1 was accompanied by PVRI rise. PVRI in group 2 remained high. Right ventricular end-diastolic volume and ejection fraction were evaluated by thermodilution method [Lichtwarck-Aschoff, 2002].

**Conclusion:** There were two main haemodynamic consequences in CTEPH: RV systolic dysfunction due to afterload increase and diastolic impairment as a response to volume load leading to RVEF decrease. The severity of right heart changes could be used in preoperative risk stratification in CTEPH patients.
Background and aim: In pulmonary hypertension (PH), the increased afterload leads to an increase in right ventricular (RV) myocardial oxygen demand. The RV mean systolic ejection pressure (Pms) and the RV systolic pressure-time integral (SPTI) have been proposed as valuable estimates of RV afterload and myocardial oxygen demand, respectively. Our study documented the correlates of Pms and SPTI in PH patients.

Material and methods: Eleven PH patients (mean pulmonary artery pressure mPAP = 57±10 mmHg) were studied, namely 6 arterial PH and 5 chronic thromboembolic PH. They underwent high-fidelity right heart catheterization at rest and on mild exercise (cycling) while supine. The workload was increased stepwise up to 60 W and to three-to-six hemodynamic points were obtained. The Pms was calculated as the pulmonary artery pressure (PAP) averaged over the systolic duration, i.e., from end-diastolic to dicrotic notch. The SPTI was the Pms times the systolic PAP pressure weighted by the systolic duration. The Pms matched 80% sPAP (bias = 0±2 mmHg). The SPTI ranged from 15.7 to 32.3 mmHg·sec and was related to PA pulse pressure (r²=0.80), sPAP (r²=0.67), mPAP (r²=0.46) and systolic duration (r²=0.22) (each P < 0.05).

Conclusion: In PH patients performing mild exercise, RV afterload (Pms) was related to the steady component of arterial load (mPAP, sPAP) while the RV myocardial oxygen demand (SPTI) was mainly related to the pulsatile component of arterial load (spiral PA pressure).

Effects of interval exercise on cigarette smoke-induced right ventricular dysfunction in mice

Erlend Hassel, Anne Marie Ornbøstad, Ulrik Wisløff, Sigurd Steinshamn. Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, Norway

Background: Right ventricular heart failure in COPD is thought to be a result of pulmonary hypertension due to increased pulmonary vascular resistance. Exercise, and especially interval training has been shown to be effective in improving left ventricular function, but the same is not shown for right ventricular function in COPD. The goal of this study was to examine the effects of aerobic interval training on cigarette smoke-induced right ventricular heart dysfunction in a mouse model for COPD.

Methods: 42 female A/J-OlaHsd mice were exposed to either cigarette smoke (CS) or fresh air (FA), for 14 weeks, 6 hours/day, 5 days/week. For the next four weeks they were either kept sedate (Se) or put through interval treadmill running (IT) for 1 hour/day, 5 days/week. After this period the mice were sedated with light isoflurane anaesthesia and the heart function was evaluated with echocardiography. Tricuspid annular plane systolic excursion (TAPSE) was used as a measurement of right ventricular function.

Results:

<table>
<thead>
<tr>
<th></th>
<th>Mean VO2max (mL/kg0.75/min)</th>
<th>Mean TAPSE (mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FA-Se</td>
<td>32.1</td>
<td>0.71</td>
</tr>
<tr>
<td>FA-IT</td>
<td>40.5</td>
<td>0.82</td>

<td>32.9</td>
<td>0.46</td>
</tr>
<tr>
<td>CS-IT</td>
<td>41.6</td>
<td>0.75</td>
</tr>
</tbody>
</table>

Maximal oxygen uptake was higher for the IT groups compared to the Se groups (p<0.05). TAPSE was reduced for the CS-Se group compared to all other groups (p<0.0001). There were no significant difference between the CS-IT group and the FA-Se group (p=0.35). The FA-IT group had significantly increased TAPSE compared to the FA-Se group (p<0.05), but not the CS-IT group (p=0.2).

Conclusion: Smoke exposure of A/J-OlaHsd mice causes a significant reduction in right ventricular function measured by echocardiographic TAPSE. This reduction seems to be normalized by intensive interval training.

P2317

Right ventricular diastolic stiffness in idiopathic pulmonary arterial hypertension

Silvia Rain, Taco Kind, Louis Handoko, Bart Boerrigter, Nicolaas Westerhof, Jolanda van der Velden, Anton Vonk-Noordegraaf, Francs de Man. Institute for Cardiovascular Research, VU University Medical Center, Amsterdam, Netherlands

Introduction: Idiopathic pulmonary arterial hypertension (iPAH) is a fatal disease with grim prognosis due to subsequent development of right heart failure (RHF). Findings in experimental pulmonary hypertension models suggest RHF is associated with increased diastolic stiffness.

Objective: This study investigates whether right ventricle (RV) diastolic stiffness is increased in iPAH patients.

Methods: Right heart catheterization (RHC) and MRI were performed in 28 patients suspected with iPAH. Based on pulmonary artery pressure, patients were divided into controls (7) and iPAH (21). Diastolic elasctance (diastolic stiffness), was quantified by the slope of diastolic pressure-volume relation, constructed by plotting RV end-systolic volumes and begin-diastolic pressures against RV end-diastolic volumes and end-diastolic pressures. Subsequently, we investigated whether diastolic elastance was associated with disease severity by comparing patients with lower RV stoke volumes (RVSV) and patients with higher RVSV.

Results: Diastolic elastance was significantly altered in iPAH (iPAH 0.25±0.04 vs Con 0.07±0.006, p<0.001). In addition, patients with lower RVSV had significantly higher diastolic elastance (LowRVS 0.05 ± 0.05 vs HighRVS 0.11±0.02).

Fig.1

Fig.2

Conclusion: This study demonstrates that RV diastolic stiffness is increased in iPAH patients and is associated with disease severity. In future studies we will investigate the prognostic relevance of these changes.

P2320

Multislice CT angiography and pulmonary involvement in asymptomatic systemic lupus patients with antiphospholipid syndrome

Amany Abou Zeid, Tamer Geitha, Hussien El Fishawy. Chest, Cairo University Hospitals, Cairo, Egypt Rheumatology, Cairo University Hospitals, Cairo, Egypt Internal Medicine, Cairo University Hospitals, Cairo, Egypt

Objective: To detect the pulmonary involvement in asymptomatic secondary APS patients by pulmonary function tests (PFTs) and chest HRCT angiography and comparing the pulmonary findings to those of asymptomatic SLE patients without APS.

Patients and methods: Thirty-four SLE patients with APS and another 34 SLE patients without APS and with a negative ACE test were included as control. All patients were asymptomatic for any pulmonary manifestations. Plain chest x-ray, HRCT angiography and PFTs were performed for all patients in an attempt to assess the pulmonary vasculature and lung parenchyma. Disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) while assessment of organ damage was made using the Systemic Lupus International Collaborating Clinics /ACR (SLICC/ACR) index.

Results: There were abnormal pulmonary CT findings in 11 (32.35%) of the asymptomatic secondary APS patients with an obvious association to lupus anticoagulants. However, plain x-ray showed basal atelectasis and/or elevation of the copulae in 4 patients. Pulmonary abnormalities included a high frequency of pulmonary artery aneurysms (20.5%), thrombosis, basal atelectasis, embolism, bronchiectasis, pleural effusion and thickening. The SLEDAI and SLICC were significantly higher in APS patients. The PFTs including FVC, FEV1 and FEV1/FVC were reduced in APS patients compared to SLE patients only.

Conclusion: HRCT pulmonary angiography is useful in demonstrating the entire thoracic spectrum in asymptomatic APS patients. PFTs are reduced in SLE patients with APS compared to SLE patients only.

P2321

Thoracic affection during Behcet’s disease (about 15 cases)

Nahid Zagha, Najiba Yassine, Abdelaziz Bahkhatar, Abdelkrim Bahlouli. Respiratory Diseases, UHC Ibn Rochd, Casablanca, Morocco

Behcet’s disease is a multisystem vasculitis that affects the young. Chest affection is rare and primarily venous. The arterial affection is exceptional. We report a retrospective study of 15 cases of Behcet’s disease with chest involvement, gathered at the Respiratory Diseases department, UHC Ibn Rochd of Casablanca from 1994 to 2010. It was about 3 women and 12 men. The average age was 34 years old (range: 19-58 years). The bipolar aphasisis was found in all patients, pseudo-ocularities in 9 cases, and hemoptyosis in 7 cases. Superior vena cava syndrome was noted in 8 cases, 6 cases of pleursy. The thoralorax showed bilateral pleursy in 1 case, unilateral in 5 cases, bilateral hilar opacities projection in one case, an alveolar opacity in 3 cases, aspect of releasing balloons in one case, and it is normal in 4 cases. The chest angio-CT showed the superior vena cava’s thrombosis in 9 cases, bilateral pulmonary arterial aneurysms in 2 patients, pulmonary artery aneurysm associated to an embolism in one patient and pulmonary infarction site in 3 cases. Echocardiography showed an intracardiac thrombus in one case. All patients were administered steroids, colchicine and anti-coagulants. Immunosuppressive drugs were administered for 3 patients. The evolution was good in 11 cases, the onset of neuro-Behcet in 1 case and we deplore 4 deaths due to a lightning hemopty. We emphasise throughout these series the scarcity of thoracic manifestations of Behcet’s disease, namely the arterial disease that makes its prognosis dull.

P2322

Prevalence of hepatopulmonary syndrome in candidates for liver transplantation in Santa Casa Hospital (Porto Alegre-Brazil)

Eduardo Garcia, Taiame Franzeli Rebattato, Fernanda Weltrick Martins, Lucas Jesus de Medeiros, Rangel Olsen de Carvalho, Ajacic Brandão. Internal Medicine, Santa Casa Hospital, Porto Alegre, Brazil

Background: Hepatopulmonary syndrome (HPS) is a disorder of pulmonary vascular disease secondary to liver disease, comprehending abnormalities of arterial oxygenation (PaO2 < 80 mmHg or alveolar-arterial oxygen gradient (PA-aO2) ≥ 15 mmHg on room air) and in larger 64 years PaO2 < 70 mmHg or PA-aO2 ≥ 20 mmHg and presence of pulmonary vascular dilatation. There are reports of its occurrence between 4-32% of cirrhotic liver transplant candidates. It is presence, independently and significantly, increases mortality and reduces the survival rate of those patients when compared with cirrhotic patients without HPS.

Objective: To assess the prevalence and severity of HPS in patients with severe liver disease.

Methods: Retrospective cross sectional review of 90 medical records of 90 patients who underwent liver transplantation at the Santa Casa Hospital (Porto Alegre -Brazil), from February 2002 to April 2009. The present study was approved by the Hospital Ethics Committee.

Results: The sample consisted of 90 patients, 62.2% (n = 56) were male and mean age was 54.13 years (22-74). The prevalence of HPS was 43.3% (n=39). Forty one per cent (n=16) were classified as having mild HPS, 33.3% (n=13) moderate, 10.3% (n=4), severe and 15.4% (n = 6) as very severe. The mean PaO2 was 62.42 mmHg and the mean PaO2 was 81.47 mmHg. The mean PA-aO2 was 10.3% (n=4), severe and 15.4% (n = 6) as very severe. The mean PaO2 was 26.42 mmHg and the mean PaO2 was 235.9 mmHg. The mean PA-aO2 was 7.1*ˆ and 55.67 mmHg. The mean PA-aO2 was 4.9*ˆ and 71.9 mmHg. The mean PA-aO2 was 2.3* and 71.9 mmHg.

Conclusion: The study confirms the high prevalence of this clinical syndrome in patients with severe liver disease and, thus, strengthen its research in patients with liver diseases, especially those who may be liver transplantation, since current evidence points to liver transplantation as a treatment of HPS.

P2323

WITHDRAWN
P2324 Pulmonary hypertension in patients with infective endocarditis
Elena Yu Ponomareva, Elena E. Arkhangelskaya, Andrey P. Rebrov. Hospital Therapies, Saratov State Medical University, Saratov, Saratovskaya, Russian Federation

Aim and methods: To study pulmonary hypertension (PH) in infective endocarditis (IE) pts with different localization, valve injury and activity of disease we have investigated 136 pts with native valve IE, in which 105 (76%) had left and 31 (25%) – sided IE. Diagnosis of IE was made according to Duke-criteria (ECS, 2009). Pulmonary artery systolic pressure (PASP) was measured using trans-thoracic EchoCG in dynamics taking into account the systolic tricuspid gradient and right atrium pressure.

Results: PH was revealed in 132 pts with IE (97%). Mean PASP was 53.7±16.2 mmHg. Pts with minimal and moderate PH prevailed (1st degree PH in 61 pts (45%), 2d degree – in 50 pts (37%), only 15% pts (21) proved high degree PH (PASP > 70 mmHg). No significant differences of PH level were found depending on the gender, age, left or right-sided localization of IE, acute stage or 1-year or more advanced stage of disease duration. Nevertheless the PH degree was significantly higher in the group of pts with bi-valve or multiple valve injury in comparison with group of pts with mono-valve pathology (61.3±15.8 vs 49.3±14.9, p<0.001). Among haemodynamic factors influencing the PASP most possible were left atrium diastolic size (R=0.556386, p=0.00001) and myocardium mass index (R=0.47, p<0.0001).

Conclusions: So PH naturally develops in pts with IE and haemodynamic factors proved to be most significant in its development.

P2325 Which patients with pulmonary arteriovenous malformations are dyspnoeic?

Ron Robyn Barst, Danubr Ivy2, C. Gregory Elliott1, Prieya Wason4, Aimee Foreman5, Dave Miller5, Michael McGoon 6.

Methods: To identify factors contributing to dyspnoea, a retrospective analysis of a single-centre 2005-2010 cohort 815 patients were included. The 55-center, observational, US Registry to Evaluate Early And Long-term pulmonary arterial hypertension (iEVAL) Disease Management (RE-VEAL) examines demographics, clinical course and management of patients (pts) diagnosed with PAH.

Results: 3518 pts enrolled in REVEAL between 03/2006 and 12/2009; 77 APAH-CHD and 122 IPAH/FPAH had childhood-onset PAH; mean ± SD age at PAH diagnosis 6.6±6 years and 9.6±6 years (P = 0.002), respectively. APAH-CHD had similar functional class (FC) at diagnosis compared with IPAH/FPAH (FC: I, 5%; II, 51%; III, 32%; and IV, 11% vs FC: I, 7%; II, 40%; III, 43%; and IV, 10%, respectively; P = 0.64). Hemodynamics were also similar at diagnosis. Similar proportions were treated with endothelin receptor antagonists (APAHP-CHD, 40% vs IPAH/FPAH, 45% vs P = 0.53), though phosphodiesterase 5 inhibitors (45% vs 64%, respectively; P = 0.011) and prostacyclin (28% vs 50%, respectively; P = 0.003) analogs were used less in APAH-CHD. Five-year survival from diagnosis was similar for APAH-CHD and IPAH/FPAH (71.1±4% vs 75.0±7% vs, respectively; P = 0.53).

Conclusion: Childhood-onset APAH-CHD and IPAH/FPAH have similar hemodynamics and FC and similar 5-year survival from diagnosis. REVEAL provides observational data on treatment and outcomes in childhood PAH that should prove useful in identifying prognostic parameters, thereby helping clinicians improve outcomes.
Background: The prevalence of pulmonary hypertension (PH) has been estimated to 6.7% in 95 patients with lymphangioleiomyomatosis (LAM) as defined by sPAP>35 mmHg at echocardiography.

Objective: To evaluate the hemodynamic characteristics and pulmonary function in patients with LAM and PH not explained otherwise.

Methods: A retrospective multicenter study was conducted in patients with LAM with PH or PH associated with diffuse pulmonary involvement. 25 mmHg, pulmonary artery wedge pressure (<15 mmHg, and normal or decreased cardiac index at RHC).

Results: Twenty patients were studied, with a mean age of 49±12 years. The median delay between the diagnosis of LAM and PH was 6.2 years. Dyspnea was NYHA class III in 10%, III in 50%, and IV in 46%. A single patient had right heart failure. Six minute walk distance was 340±84 m. Hemodynamic characteristics were: mean PAP 32.6±6 mmHg, cardiac index 3.5±1.1 L/min.m², pulmonary vascular resistance (PVR) 376±184 dyn.s.cm⁻⁵, and pulmonary capillary wedge pressure 10.3±3 mmHg. The mean PAP was >35 mmHg in 3 cases, FVC was 76±28% of predicted, FEV1 42±7, P(125) 1.3 kPa on room air. All patients were on long-term oxygen therapy. In five patients receiving bosentan, RHC after a median of 3.2 years demonstrated a median decrease of 42% in PVR. After a median follow-up of 2.9 years, one patient had died of cardiac arrest, and 5 patients had undergone lung transplantation.

Conclusion: Prevalence of PH may be higher in patients with LAM and severe pulmonary function impairment. Bosentan therapy might improve hemodynamic characteristics.

Support: CNMIR and FP7 of the European Commission.

P2328 Pulmonary hypertension in lymphangioleiomyomatosis: Hemodynamic characteristics in a series of 20 patients
Vincent Cotter, Monique Burlet, Xavier Jais 1, Hervé Mal 1, Martine Reyndae-Gaubert 1, Gérome Prévot 1, Romain Lazzer 2, Camille Taillé 2, Sabrina Zeghmar 1, Gédard Simonneau 1, Jean-François Cordier 1, Marc Humbert 1, The CHU Hospital, Respiratory Medicine, Louis Pradel Hospital, Lyon, France; 2 Respiratory Hospital, University of Milano, Milano, Italy; 3 Respiratory Medicine, Antoine Béclère Hospital, Clamart, France; 4 Respiratory Medicine, Bichat Hospital, Paris, France; 5 Respiratory Medicine, Ste Marguerite Hospital, Marseille, France; 6 Respiratory Medicine, Larrey Hospital, Toulouse, France; 7 Respiratory Medicine, Bichat Hospital, Paris, France

Doppler-echocardiogram in 35 SLE patients. The average duration of SLE in these patients was 14±6.1 years. A control group consisted of 20 healthy persons.

Results: There was no significant difference between the initial diameters of brachial artery in SLE (3.35±0.06 mm) and SLE-PH groups (3.43±0.09 mm) compared with control group (3.46±0.07 mm). The significant reduction of EDV/DV on 34% in SLE patients compared to healthy persons was determined in the test with P=0.04. Abnormalities of endothelium dependent vascular tone regulation in patients with PH were more expressed (reduced on 48% compared with healthy persons) (p<0.05). At the same time EDDV in SLE group without PH and in control group did not differ, but in SLE-PH patients the EDDV was 1.6 times less compared with control.

Conclusion: Abnormality of EDV/D is dominated in SLE patients. The most evident disorder of EDV occurs in SLE patients during the PHA progress. In patients with PHA also noted reduction of vasoregulation function of smooth-muscular cells, because they had impaired EDDV.
P2333

Prevalence of pulmonary arterial hypertension in the HIV cohort of the University Bonn: Results of the PAHIBO study

Stefan Pahol1, Christoph Hammerstingl2, Carolyne Schwarze-Zander2, Julia Othil1, Tabea Nussbaum1, Georg Nickent1, Juergen Rockstroh2, Dirk Skowasch2, 1Department of Pulmonary/Cardiology, University of Bonn, Bonn, Germany; 2Department of Infectious Diseases, University of Bonn, Bonn, Germany

Background: PAH (pulmonary arterial hypertension) is a rare and life-threatening complication of HIV (human immunodeficiency virus) infection. An investigation of the presence of HIV infection is a standard diagnosis in patients with unexplained PAH. Previous studies suggest a prevalence of PAH in HIV patients close to about 0.5%, but are limited in the study design. Therefore the exact prevalence is unclear.

Methods: The PAHIBO study is investigating all HIV patients (n = 700) at the University Hospital of Bonn in a prospective cross-sectional study. If systolic pulmonary arterial pressure (sPAP) is > 35 mmHg in Doppler echocardiography, right heart catheterization is followed.

Results: Of 700 patients enrolled, 443/340 (13%) had an echocardiographic sPAP > 35 mm Hg. The right heart catheterization was carried out so far in 22/44 patients with echocardiographically proven PH. In 4 cases, a precapillary PAH (including a complete work-up and exclusion of other causes of PAH) was diagnosed, of which 1 case was already known, in 13 cases postcapillary PH and in the remaining 5 cases, the exclusion of a manifest PH. Thus, the PAHIBO study reveals a prevalence of HIV-associated PAH of at least 4/340 cases (1.2%).

Conclusion: The prevalence of HIV-associated PAH is probably higher than previously described. Severe cardiac and respiratory comorbidities are very frequent in the examined HIV cohort. If these results should be confirmed in the extended cohort of 700 patients, a regular echocardiographic screening in asymptomatic HIV patients is to discuss.

P2334

Characteristics of PAH associated with pretricuspid shunts in the French PAH registry

Xavier Jais1, Damien Bonnet1, Laurence Rottat1, Isabelle Szewczak-Panski1, Maryline Lévy2, Virginie Gressin1, Marc Humbert1, Olivier Siboh3, Gérard Simonneau1, 1French Reference Center for Pulmonary Hypertension, Antoine Béclère Hospital Paris-South University, Clamart, France; 2French Reference Center for Complex CHD, Necker Hospital Paris Descartes University, Paris, France; 3Acetion Pharmaceuticals France, Actionel Pharmaceuticals France, Paris, France

The diagnosis of pulmonary arterial hypertension (PAH) associated with pretricuspid shunts (PTS) is often made in adulthood. The characteristics of this subgroup of CHD PAH are not well established.

Objective: To review and analyze patients with PAH and PTS enrolled in the second prospective French PAH registry, initiated in 2006.

Results: Of 1524 patients enrolled in the registry, 81 patients with PAH and PTS were identified. The diagnosis of PAH was made after the diagnosis of CHD, in 70% of cases. PAH appeared during the follow-up of the CHD in 28% of cases. At inclusion, 5% were in functional class (FC) IV, 61% were in FC III and 34% in FC I or II. 6MWD was 360±107m. Pulmonary hemodynamics were: mPAP=53±11mmHg, CO=5.0±1.7L/min and PVR=11±8.3WU. 50% of patients in FC I or III received PAH specific therapy. During the 3-year follow-up period, 9 patients died and 3 underwent heart-lung transplantation.

Conclusion: In this registry, the proportion of CHD-PAH due to PTS compared to other forms of CHD is higher than in previously reported series. The natural history of PTS remains poorly understood as PAH can be diagnosed throughout life. PAH specific therapies are not widely used in the PAH associated with PTS population.

P2335

Health-related quality of life in patients with pulmonary arterial hypertension

Franziska Biele1, Carlos Baenziger1, Tobias Meiss1, Patrick Huppmann1, Gregor Zimmermann1, Stefan Pabst1, Christoph Hammerstingl1, Carolynne Schwarze-Zander1, Carmen Corona, Pedro Antonio Chinchurreta, Juan Ramón Siles1, Francisco Torres, Francesco Ruiz. Cardiología, Hospital Costa del Sol, Marbella, Málaga, Spain

Introduction: Although many epidemiological data of primary Pulmonary Hypertension (PH) have been recorded, the literature as regards the characteristics of the general population suffering from PH is nevertheless scarce.

Aim: To determine the clinical characteristics of the different types of PH in a cardiologist service of a general hospital patients.

Results: 204 out of the 321 patients evaluated from January 1994 to December 2009 met the inclusion criteria. The average age was 73,36±17,48 years old, 55% of whom were women. The average initial PSAP was 74±8,2 mmHg. The predominant type found was PH owing to left heart disease 88 cases (43,3%), the most common etiology being mitral valve pathology (53/87). Pulmonary arterial hypertension (PAH) represented 23% of the overall, there being ten cases of hypoxemia right shunts, four cases of primary PH, a case of seleroderma, another one of anorectics and two cases of portal hypertension. In eleven cases (13%) PH was associated with respiratory disease while the remaining 13% corresponded to PH caused by chronic thromboembolism. An overall worse prognosis compared to other ethnic groups.

Conclusion: The clinical characteristics of the different types of PH in a cardiologist service of a general hospital patients.
P2338
Survival and prognostic factors in patients with incident systemic sclerosis-associated pulmonary arterial hypertension from the French registry
David Lamy1, Olivier Sibot2, Jean-François Corder2, Eric Hachulla1, Luc Mouton3, Virginie Gressan1, Laurence Rottat1, Pierre Clerson1, Gérard Simonneau1, Marc Humbert1. 1French National Reference Centre of the French PAH Registry; 2Internal Medicine, Claude-Huriez Hospital, Lille, France; 3Respiratory Medicine, Antoine-Beclere Hospital, Clamart, France. Aims and objectives: This study describes the characteristics and outcome of SSc patients enrolled in the multicentric French PAH registry since 2006.
Methods: SSc patients enrolled in the registry between January 2006 and November 2009 were prospectively included if they had PAH diagnosed within 1 yr prior to enrollment (incident patients). Patients with interstitial lung disease (ILD) were included if forced vital capacity (FVC) >70%.
Results: 91/145 SSc patients were included; 81% were in NYHA III or IV. Mean pulmonary arterial pressure (mPAP) was 40±10 mmHg, mean cardiac index was 2.6±0.8 L/min/m2 and mean pulmonary vascular resistance (PVR) was 670±351 dyn sec cm-5. Overall survival was 90%, 76% and 54% at 1, 2 and 3 years, respectively. Male gender (HR: 2.44, age (HR: 1.044), desaturation after 6-minute walk test (HR: 0.93), PaO2 (HR: 0.96) and cardiac index (HR: 0.52) were factors prognostic of survival. Other parameters did not reach statistical significance, including NYHA, PVR, 6MWD, BNP, DLCO/VA and mPAP.
Conclusions: These results confirm the poor prognosis for incident SSc-PAH patients even in the modern era. As with idiopathic PAH, gender and age appear to be important prognostic factors. Cardiac index, but not mPAP, had a significant impact on survival. For the first time, PaO2 at rest and desaturation during exercise were shown to be significant prognostic factors in SSc-PAH.

P2339
Right axis deviation is a strong indicator of pulmonary hypertension in a risk population
Gabor Kovacs1,2, Zsylveszta Kajaki1, Vasili Foris1, Maria Tscherner1,2, Natasha Troester1, Stefan Scheidl1, Christian Hesse1, Horst Olschewski1,2. 1Pneumology, Medical University of Graz, Graz, Austria; 2Ludwig Boltzmann Institute for Lung Vascular Research, Ludwig Boltzmann Institut for Lung Vascular Research, Graz, Austria.

Pulmonary hypertension (PH) is diagnosed by right heart catheterization (RHC), but non-invasive methods play an important role in screening and follow-up. ECG is routinely performed in the clinical work-up but its clinical value has not been defined. We hypothesized that a simple parameter, such as the presence of right axis deviation (RAD) in standard ECG might be useful in the diagnosis and follow up of PH.
We retrospectively analysed all patients who received a RHC and an ECG in our department between 2005 and 2010. The indication for RHC was heterogeneous, the pretest probability of PH was about 50%. We determined the ratio of the S and R waves in lead I in each patient, a value ≥1 (≥90°) was considered as RAD. The investigator was blinded to the RHC results. The sensitivity and specificity of RAD to predict PH (mean PAP>25mmHg) was determined.
N=317 patients were included. RAD was present in n=71 patients. Within these, PH was detected in n=65 patients, and was missing in n=6 subjects (p<0.001). In n=246 patients without RAD, PH was present in n=87 patients. The specificity of RAD for PH was 96%, whereas the sensitivity was merely 43%. Accordingly, the positive predictive value of RAD to predict PH was 92%, while its negative predictive value to rule out PH was just 35%.
Our retrospective analysis on a large, heterogeneous cohort of subjects including patients with and without PH suggests that the presence of RAD in the ECG has a high specificity but a low sensitivity for PH. This simple method may help to recognize PH patients within a population at risk for PH. In order to determine its appropriate role in a diagnostic algorithm, prospective, population based studies are needed.

264. Clinical features of pulmonary thromboembolism
P2340
A radiological grading system for risk stratification of acute pulmonary embolism: A pilot study
Anita Jayadev1, Kartikhan Srikantan2, Urmi Gupta2, Arti Mahato2, Zaid Dabagh1, Syed Saboo1. 1Respiratory, Whips Cross Hospital, London, United Kingdom; 2Respiratory, Chase Farm Hospital, London, United Kingdom; 3Radiology, Chase Farm Hospital, London, United Kingdom.

Introduction: There is currently no radiological scoring system for Pulmonary Embolism (PE) and studies suggest such a system may provide risk stratification data.
Null hypothesis: Radiological severity grading of PE has no prognostic information.
Methods: All CT Pulmonary Angiograms (CTPAs) over a 6-month period were analyzed and demographic data collected. A radiologist graded all positive CTPAs, into mild, moderate and severe according to agreed criteria. Variables including: troponin; D-Dimer; CRP; length of in-patient stay; mortality data and re-admissions secondary to PE were recorded.
Results: 312 CTPAs were performed: 240 were negative (76.9%) and 72 patients had a PE (23.1%). In the PE group, 21 were male (29.2%); 51 female (70.8%) and the average length of in-patient stay was 19 days. This was significantly longer in the moderately/severe group than mild (p=0.01). There is no correlation between RV dimension and severity of PE. D-Dimer and troponin increase with radiological severe PE but is not statistically significant. More patients with radiological severe PE are re-admitted (13.6%) compared with mild/moderate group (5.32%), however samples were insufficient for analysis, as was the mortality data.
13.9% of CTPAs had the diagnosis changed or disputed. 60.4% negative CTPAs had no D-Dimer collected; 40.9% had an alternative diagnosis to PE.
Conclusions: This study suggests PE affects 2.4x more females than males and radiological severe PE is associated with longer in-patient stay and greater re-admissions. An adequately powered, prospective study of positive CTPAs is needed to further evaluate use of this grading system.

P2341
Correlation of levels of N-terminal pro-B-type natriuretic peptide with localization of thrombus in acute pulmonary embolism
Evren Eylemi Akpinar, Esra Buyuk, Meral Gulhan. Ufuk University, Department of Chest Diseases, Ankara, Turkey.

Aim: Brain-natriuretic peptide (BNP) is a hormone which is released from the heart. The aim of the study was to investigate whether N-terminal pro-BNP (pro-BNP) could predict localization of thrombus in patients with acute pulmonary embolism.
Method: The patients who were evaluated in emergency department, who had thrombus on helical computed tomography were enrolled. Thrombi which were localized on main/right-left pulmonary artery were classified as central, ones which were present at segmentary/subsegmentary levels as peripheral. Echocardiogram was performed and pro-BNP levels were measured.
Results: Forty-nine patients were enrolled to the study. The thrombi of 63.3% patients were unilaterally located, of 36.7% bilaterally, 18.4% of patients had thrombi that were central, 81.6% patients had peripheral. The difference between pro-BNP levels of who had central and peripheral thrombus was significant (p=0.039).

Pro-BNP levels of patients who had right ventricle overload (p<0.001, p=0.003, p=0.003). The pro-BNP levels of patients who were followed up in intensive care unit, needed trombolytic treatment were higher (p<0.001, p=0.002).
Conclusion: Higher pro-BNP levels indicates higher probability of more central location of thrombus, resulting adverse clinical course and having right ventricular overload.
P2342
Pulmonary thromboembolism during acute chest syndrome in sickle cell disease
Armand Mekontso-Despault1, Jean Francois Deux2, Nour Abidi3, Cecile Laveno-Bombl3, Giovanna Melica1, Bertrand Renaul4, Bertrand Godeau1, Serge Adnot6, Laurent Brochard1, Christian Brun-Buisson1, Frederic Garenas1, Alain Rahmoun2, Anousha Habibi1, Bernard Maître1,2, Medical Intensive Care Unit, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France; 3Medical Imaging Unit, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France; 4Internal Medicine and Sickle Cell Center, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France; 5Hemostasis Laboratory, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France; 6Physiology and Functional Explorations Unit, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France; 7Pulmonary Disease Unit, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Mondor, Creteil, France

Background: Although pulmonary infarction and pulmonary embolism (PE) have been reported in sickle cell disease patients during acute chest syndrome (ACS), there is no comprehensive study evaluating the prevalence of PE during ACS.

Methods: We screened 123 consecutive patients during 144 ACS episodes to perform a multidetector computed tomography (MDCT). 121 MDCTs (in 103 consecutive patients) were included in the study.

Findings: 20 MDCTs were positive for PE, determining a prevalence of 17% (95% confidence interval from 10% to 23%). Revised Geneva clinical probability score was similar when comparing patients with PE and those without. D-dimers testing was very often positive (95%) during ACS. A precipitating factor for ACS was less frequently found in patients with PE as compared to those without. Patients with PE exhibited significantly increased platelet counts (517 [273-729] vs. 307 [228-412] μL/L, p<0.01) and smaller bilirubin peak (36 [18-51] vs. 46 [32-83] μmol/L, p=0.048) and lactate dehydrogenase peak (537 [320-704] vs. 604 [442-788] IU/L, p=0.01) during hospital stay as compared to others. In addition, patients with PE had a higher platelet count peak (537 [345-785] vs. 417 [330-555] 10^9/L, p=0.048) and smaller bilirubin peak (36 [18-51] vs. 46 [32-83] μmol/L, p=0.048) and lactate dehydrogenase peak (537 [320-704] vs. 604 [442-788] IU/L, p=0.01) during hospital stay as compared to others.

Interpretation: PE is not a rare event in the context of ACS and seems more likely in patients with higher platelets counts and lower haemolytic rate during ACS. SCD patients presenting with respiratory symptoms suggestive of ACS may benefit from evaluation for PE.

P2343
The sensitivity of D-dimer testing versus multislice CT in the diagnosis of postpartum pulmonary embolism in symptomatic high risk women
Mohamed Badawy, Ibrahim Hossain, Ahmed Shams, Khalid Karam. Chest Department, Sohag University, Sohag Faculty of Medicine, Sohag, Egypt Obstetric Department, Sohag University, Sohag Faculty of Medicine, Sohag, Egypt Obstetric Department, Assiut University, Assiut Faculty of Medicine, Assiut, Egypt Radiology Department, El Ahrar University, Ahrar Faculty of Medicine, Cairo, Egypt

Background: Early detection of postpartum pulmonary embolism is a corner stone in prevention of its associated maternal mortality

Patients and methods: We applied d-dimer testing and Multislice CT scanning in prevention of its associated maternal mortality.

Results: Of 2359 cases, 60 cases (2.54%) were considered clinically highly suggestive of pulmonary embolism. Clinical parameters highly suggestive of pulmonary embolism were dyspnea (85%), overweight (51%), tachypnoea (55%) and lactate dehydrogenase peak (537 [320-704] vs. 604 [442-788] IU/L, p=0.01) during hospital stay as compared to others. In addition, patients with PE had a higher platelet count peak (537 [345-785] vs. 417 [330-555] 10^9/L, p=0.048) and smaller bilirubin peak (36 [18-51] vs. 46 [32-83] μmol/L, p=0.048) and lactate dehydrogenase peak (537 [320-704] vs. 604 [442-788] IU/L, p=0.01) during hospital stay as compared to others.

Interpretation: PE is not a rare event in the context of ACS and seems more likely in patients with higher platelets counts and lower haemolytic rate during ACS. SCD patients presenting with respiratory symptoms suggestive of ACS may benefit from evaluation for PE.

Conclusions: Postpartum d-dimer testing in patients showing suggestive symptoms of pulmonary embolism is not suitable for exclusion test, yet a strong screening tool.

P2344
Genetic mutations in Turkish population with pulmonary embolism and deep venous thrombosis
Elif Kupeli1, Hasibe Verdi1, Abdullah Simsik1, Fatma Belgin Atac2, Fusun Oner Eyuboglu1.
1Pulmonary Diseases, Baskent University School of Medicine, Ankara, Turkey; 2Medical Biology, Baskent University School of Medicine, Ankara, Turkey

Venous thromboembolism (VTE) is an universal health hazard throughout the world. Pulmonary embolism (PE) along with deep venous thrombosis (DVT) is a major clinical manifestation of VTE and inherited and acquired risk factors in-crease the risk. We aimed to evaluate the relationship between factor V (G1691A, A1090G, and A1299G), prothrombin (PT G20210A), methyleneetahydrofolate reductase (MTHFR C677T) mutations, plasminogen activator inhibitor 1 (PAI-1 4G/5G) polymorphisms, and VTE in Turkish population. Between years 2005-2009, 80 Turkish patients diagnosed with PE and PE+DVT and 104 controls at our institution and agreeing to participate, were consecutively recruited in the study. Heterozygous factor V Leiden (FVL) mutation was significantly higher among patients (p = 0.04) with allele frequency of 6.3% (p = 0.1). Heterozygous PT G20210A mutation was also significantly higher among patients (p=0.001) with allele frequency of 6.9% (p =.003). MTHFR 677TT genotype was significantly higher in patients (p =0.09) with allele frequency of 23.8% (p = 0.05). No significant difference was found in FV A1090G and FV A1299G mutation rate as well as PAI-1 genotypes and their allele frequencies (p > 0.05). Thus, frequencies of FV G1691A, PT G20210A, and MTHFR C677T mutations are higher in patients with VTE. FV A1090G, FV A1299G mutations, and PAI-1 gene polymorphisms may not be a risk factor for VTE in Turkish population. However, further follow-up evaluation in larger, multi-center series is required to examine the role of these genetic mutations as a risk factor for VTE in Turkish population.

P2345
Does anatomic location of deep venous thrombosis affect the clinical findings and course in the patient of pulmonary embolism
Eylem Sercan Ozgu6, Kerem Karaca7, Cengiz Org1, Sibel Atis Nays1, 1Department of Chest Diseases, Mersin University School of Medicine, Mersin, Turkey; 2Department of Cardiovascular Surgery, Mersin University School of Medicine, Mersin, Turkey

Aim: Deep venous thrombosis (DVT) in proximal veins carries a significantly higher risk of pulmonary embolism (PE) than in distal veins. However, the effect of DVT anatomic location on clinical findings and course of PE is not known. We, therefore, investigated whether anatomic location of DVT could affect the clinical findings and course of PE.

Methods: Data of 81 patients diagnosed as PE between 2007-2011 were evaluated retrospectively. The patients were divided into two subgroups as proximal (saphenous, femoral, iliac veins) and distal disease (popliteal, crucial veins) according to DVT anatomic location. The patients with and without DVT, and also the subgroups of DVT were compared in respect of any symptom, clinical or laboratory findings evaluated.

Results: Doppler USG of 72 patients showed that 26 (36.1%) had no DVT, 29 (40.3%) proximal, and 17 (23.6%) distal disease. Dyspnea were more common (p=0.036) and mean PaO2; were significantly lower (p=0.022) in the patients with DVT than without DVT, while there were no significant differences between two groups in respect of PE clinical severity, hospitalization mortality, mortality rate, echocardiographic and laboratory findings.

Conclusions: This study showed that the patients with PE had more common rate of dyspnea symptom and hypoxemia in DVT existing than without DVT, however, anatomic location of the thrombosis did not affect the clinical findings and course of PE.

P2346
Prognostic value of two clinical scores in patients with acute symptomatic pulmonary embolism
Manuela Ferrer Galvan 1, Teresa Elías Hernández1, Candela Caballero Eraso4, Luis Jara Palomares1, Leticia García2, Rosa Nieto6, Remedios Otero Candelera3, David Jimenez Castro2, 1Unidad Médico Quirúrgica de Enfermedades Respiratorias, Hospital Universitario Virgen del Rocío, Sevilla, Spain; 2Hospital Universitario Ramón y Cajal, Servicio de Neumología, Madrid, Spain

Introduction: Clinical models may accurately identify patients at low risk of overall death in the first month after diagnosis of PE; such patients might benefit from an abbreviated hospital stay or outpatient therapy. The aim of our study was to compare two scores (Spanish and PESI simplified-PESIs- scores) in an external cohort of patients with PE.

Methods: Patients from two Spanish hospitals diagnosed with acute symptomatic PE were consecutively included. The primary study outcome was 30-day overall mortality. The secondary outcome was a composite endpoint based on 30-day mortality or recurrent thromboembolism or major bleeding. We calculated the sensitivity, specificity, Predictive values and Likelihood ratios in both scores for primary and secondary outcomes. Receiver-operating characteristic (ROC) curves were assessed for both scores.

Results: The study included 1574 patients.861 were women (58%). The mean age was 67 years. The Spanish score classified 59% of patients at low risk and PESI scores only 29%. The NPV was significantly higher for PESI scores scaling considerate primary and the secondary outcomes. There was no significant differences in the area under the curve of both scores.

Conclusions: Sensitivity results in both scores are higher but PESI scores is slightly superior to Spanish score. PESI scores would have more acceptability due to better sensitivity and easy applicability.
Introduction: Right Ventricular Dysfunction (RVD) is a predictor of mortality in Pulmonary Embolism. The reproducibility of classic parameters is low. The TAPSE is easier and more reproducible.

Aim: To assess whether TAPSE has prognostic value in patients with PE.

Methods: PROTECT is a multicentric study of patients with hemodynamically stable PE; evolution data were gathered through 30 days. Echocardiography in the first 48 hours. RVD criteria: 1) RVEDD > 30; 2) RVLV > 1.3; 3) hypokinesia subjectively evaluated; or 4) TR jet > 2.8 m/s. Statistical analysis with SPSS (v. 15). Means were compared with T-Student for quantitative variables; Chi-square for qualitative. OR and corresponding 95CI calculated with univariate logistic regression. Multivariate analysis could not be carried out due to the low number of events.

Results: The study included 630 patients. Global mortality was 3.8%, and mortality due to PE was 0.8%. TAPSE could be determined in 91.7% of the patients. TAPSE ≤ 15 was associated with mortality (OR: 1.95; CI: 1.3-2.8).

Conclusions: TAPSE ≤ 15 is associated with mortality in PE patients. TAPSE may be used for the defining RVD which has prognostic importance in PE.

P2348
Incidence of chronic thromboembolic pulmonary hypertension in patients after acute pulmonary embolism
Su-Qiao Yang1, Yuan-Hua Yang1, Zhen-Guo Zhou1, Tu-Guang Kuang1, Juan-Ni Gong1, Juan-Guo Zhu1, Yi-Dan Li1, Ya-Feng Wu1, Chen Wang1, 2 Department of Respiratory, Beijing Institute of Respiratory Medicine, Beijing, China; 3 Department of Ultrasound, Beijing Chao-Yang Hospital, Capital Medical University, Beijing, China; 4 Department of Respiratory, Beijing Hospital, Beijing, China

Background: Recent studies suggest that chronic thromboembolic pulmonary hypertension (CTEPH) following acute pulmonary embolism (PE) may be more common than previously thought.

Objective: To investigate the incidence of CTEPH and associated risk factors through a systematic screening in patients after acute PE in China.

Methods: A cohort study of consecutive patients with acute PE in a national referral institute was retro and prospectively approached by a questionnaire for the presence of new or increased complaints of dyspnea after acute PE episode. Subsequently, these patients were evaluated for the presence of pulmonary hypertension with echocardiography, perfusion lung scanning and right heart catheterization (RHC) in follow-up period. Pulmonary hypertension was defined as a systolic pulmonary artery pressure ≥ 50 mmHg at rest in the presence of residual perfusion defects at perfusion lung scanning.

Results: From 2006 to 2010, 488 patients with acute PE were screened, and 475 patients were included. Overall mortality after a median follow-up period of 21 months was 12.9%; 74 patients were lost to follow-up. In the remaining patients, nine were diagnosed with pulmonary hypertension by echocardiography, and two of the nine patients underwent right heart catheterization (RHC). The incidence of CTEPH after acute PE was 2.24%. The incidence of CTEPH after acute PE was 2.24%. In Cox regression, 173 cases which had missing data of biomarkers were involved. The analysis showed that protein C deficiency (hazard ratio, 10.40, 95% confidence interval, 1.06 to 102.25) increased the risk of CTEPH after acute PE.

Conclusions: The incidence of CTEPH after acute PE was 2.24%. Protein C deficiency may increase the risk of CTEPH.

P2350
Association between right ventricular dysfunction and diameter of right descending pulmonary artery on chest X-rays in pulmonary embolism
Yasin Alb1, 2, Savas Ozu1, Saat Karakurt1, Beste Ozben1, Ismet Durmus1, Ahmet Toprak1, 2, Aybek Togra1, Ufuk Akgul1, 2, Cevat Celikel1, 2, Pulmonary Medicine, Marmara University Faculty of Medicine, Istanbul, Turkey; 3, Cardiology, Marmara University Faculty of Medicine, Istanbul, Turkey; 4, Cardiology, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkey

Background: Incidence of CTEPH following idiopathic PE has been reported as 4%. The British Thoracic Society (BTS) recommends that patients with massive or submassive PE should undergo echocardiography 6-12 weeks following the index event. Aims: To investigate local practice in the follow-up of patients with acute PE to devise management guidelines.

Methods: A retrospective study of 110 patients diagnosed with acute PE at our hospital between 2007 and 2008 was conducted. Mean age was 68.6 years (range 27-100), 40 (36%) were males and 18 (16%) had previous venous thromboembolism. In 51 (46%) patients PE was idiopathic.

Results: All patients diagnosed with PE were normotensive and 27 (25%) had in-patient echocardiography (ECHO). In 5 (18%) patients scan confirmed RV dilatation and 2 of them had repeated ECHO within 2 months. Subsequently one patient was diagnosed with CTEPH and underwent pulmonary endarterectomy. In the group of patients with acute PE but without in-patient echocardiography, 40 (83%) received a follow-up appointment (mean 4 months) and 10 (25%) had follow-up ECHO. Two more patients were diagnosed with CTEPH during this period (mean 34 months) with an overall incidence of 2.9%.

Conclusion: Record outcome, literature review and the BTS/ERS guidelines resulted in the development of local protocol for the screening acute PE survivors for CTEPH.

P2366
Dilated cardiomyopathy: an update of diagnosis and management
M. Fatih Topkaya1, Mine Direskeneli2, Onur Bilgin3, Ayse Yildiz4, Umit Yilmaz5, Kemal Ercan6, Turgay Celikel2, 1 Cardiology, Marmara University Faculty of Medicine, Istanbul, Turkey; 2 Cardiology, Marmara University Faculty of Medicine, Istanbul, Turkey; 3 Pulmonary Medicine, Marmara University Faculty of Medicine, Istanbul, Turkey; 4 Cardiology, Marmara University Faculty of Medicine, Istanbul, Turkey; 5 Cardiology, Marmara University Faculty of Medicine, Istanbul, Turkey
Chronic thromboembolic pulmonary hypertension associated with Klippel–Trenaunay syndrome: A retrospective series of 5 patients

Andrei Seferian1, Xavier Janer 2, David Montom, Sylvain Durrer, Delphine Natali, Laurent Savale, Florence Parent, Dermot Steven O’Callaghan, Olivier Sibton, Marc Humbert, Gerald Simonneau. Unite Paris Sud, AP-HP, Service de Pneumologie et Réanimation Respiratoire, Centre National de Référence de 1’Hypertension Pulmonaire Sévère, INSERM U999, Hôpital Antoine Béclère, Clamart

Introduction: Klippel-Trenaunay syndrome (KTS) is a rare congenital disorder characterized by the triad: (1) cutaneous capillary malformations; (2) soft tissue and bone hypertrophy; (3) multiple vascular malformations at arteriolar, venous and lymphatic level. KTS is associated with recurrent venous thromboembolism (VTE), that may lead to chronic thromboembolic pulmonary hypertension (CTEHP).

Patients and methods: We retrospectively reviewed clinical and haemodynamical characteristics of 5 patients with CTEHP associated with KTS referred to our center between 1993 and 2010.

Results: Four patients had a previous history of VTE. At diagnosis, 1 patient was in NYHA Functional Class (FC) II and 4 patients were in NYHA FC III. Pulmonary haemodynamics were: mean pulmonary artery pressure (mPAP)=56.4±9.4 mmHg. Cardiac index (CI)=2.74±0.89 l/min/m² and total pulmonary resistance (TPR)=20.2±12.4 Wood units. One patient had proximal CTEHP, underwent a pulmonary endarterectomy and normalized his pulmonary pressures after surgery. The other 4 patients had inoperable CTEHP due to distal lesions and were treated with specific pulmonary arterial hypertension (PAH) therapy. Two patients were clinically and haemodynamically improved by oral therapy with a mean reduction of 22% of the mPAP and 60% of the TPR after a mean follow-up of 50 months. One patient died during 34 months due to recurrent VTE complications and one patient needed a heart–lung transplantation after 15 years of follow-up.

Conclusion: CTEHP is a rare but severe complication of KTS. Careful monitoring of patients with KTS in a multidisciplinary setting is thus appropriate.

Clinical research of central and lung hemodynamics in patients with pulmonary thromboendarterectomy (PTEA)

Olga Maltesva, Oleg Sizov. Faculty of Medicine, SPB State University, St. Petersburg, Russian Federation Anesthesiology, City Hospital No. 2. St. Petersburg, Russian Federation

The aim of study: to find factors have influence on patient condition after pulmonary thromboendarterectomy (PTEA).

Patients and methods: 13 patients with chronic pulmonary lung thromboembolism (CLT) were enrolled in prospective study. Invasive lung and systemic hemodynamic monitoring was performed after induction of anesthesia before the operation using PICCO PLUS and VOLEF device. Arterial blood samples were taken at the same time.

Results: All patients had:
- Cardiac volume changes: reduction of global end-diastolic volume index less than 680 ml/m², extension of right ventricle end-diastolic volume index more than 195 mm², correlation between right and left heart volume was 2:1
- Extravascular lung water index was more than 11 ml/kg, lung vessels permeability was not heightened significantly
- Contractility was decreased: cardiac output (CI) index less than 2.50/min/mm², left ventricle contractility index (dP/dx) less than 1000 mm Hg, right ventricle ejection fraction less than 14%
- CI and dP/dx was beyond above in second group
- Right ventricle afterload was raised significantly: Pulmonary vascular resistance varied from 250 to 2500, mean 1350
- Pulmonary and systemic vascular resistance ratio was 1:1.28 in first group and 1:3.19 in 2nd group.

Conclusions: Patients with CLT have specific hemodynamic changes. Reduction of contractility and increase of afterload may have an influence to development of reperfusion lung edema supplementary study is necessary to expose factors estimated surviving after PTA.

Incidental findings on computer tomography pulmonary angiograms, a UK district general hospital’s experience

Achmed Kamara1, Alex Gruffydd-Jones2, Tanseem Rahman1, Peter Taylor3, Gerrard Phillips2. 1Respiratory Medicine, Southampton University Hospitals NHS Trust, Southampton, United Kingdom; 2Respiratory Medicine, Dorset County Hospital, Dorchester, United Kingdom; 3Radiology, Dorset County Hospital, Dorchester, United Kingdom

Background: CTPA is 1st line imaging of suspected pulmonary emboli (PE) in UK hospitals.

Aims and objectives: CTPA yields 3D images of thoracic and upper abdominal organs, thus detects unanticipated diagnoses termed “incidental findings” (IF). We investigated the nature of IFs on CTPAs done at Dorset County Hospital.

Methodology: All CTPA reports from October-09 to March-10 were retrospectively reviewed, noting diagnosis of PE (positive CTPA), additional findings, particularly IFs, validated against previous imaging reports.

Results: Total CTPA reports were 490 (51% males) PE was diagnosed on 113 (23.6% ± 3.73%, 95% CI). Total additional findings were 781. Mean additional findings per CTPA was 1.6±0.11 (95% CI). Total IFs were 515, 335 of pulmonary origin (63.05% ± 4.66%, 95% CI), including pleural effusions (81%), consolidation (46%), emphysema (36%), and collapse (35%); pulmonary nodules (26%), pulmonary fibrosis (23%), lymphadenopathy (13%), pulmonary oedema (13), bronchiectasis (10) and malignancy (9). Other IFs included aortic dissection (1), abdominal aortic aneurysm (5), aortic thrombus (1), pericardial effusion (22), cardiomyaggy (5), lobulated heart lesion (1), obstructed biliary (1) and renal tract (1), pancreatitis (1), incarcerated hiatus hernia (1), free intraperitoneal gas (1) and ruptured breast cyst (1).

Discussion: Proportion of CTPAs positive for PE, 23%, was comparable to other studies. This study further emphasises importance of CTPA in not only diagnosing PE, but also detecting alternate pathologies, thus enabling optimal patient management, though additional costs would have arisen in pursuing the IFs.

Prognostic role of serum gamma-glutamyl transferase levels in patients with pulmonary thromboembolism

Savas Ozer1, Yasin Abul2, Suha Turkmen2, Yilmaz Bulbul1, Funda Ortna1, Tevki Otu1. 1Department of Pulmonary Medicine, Karadeniz Technical University, School of Medicine, Trabzon, Turkey; 2Department of Emergency Medicine, Karadeniz Technical University, School of Medicine, Trabzon, Turkey

Gamma-glutamyl transferase (GGT) is one of the most important markers of oxidative stress. Serum GGT activity is an independent risk factor for myocardial infarction and cardiac death in patients with coronary artery disease. Serum GGT has not previously been elucidated in the pulmonary thromboembolism (PTE).

The study included 163 patients and spiral chest pulmonary angiography were the most used to confirm acute PE (98%). On admission serum GGT (reference value, 5-61 mg/dL) was measured. Receiver operating characteristic analysis performed to determine the GGT cut-off levels with regard to prognosis. The patients with hepatic disease and alcohol abuse were excluded from the study.

The median age was 72 years, and 106 (65%) were females. All-cause in hospital mortality 14.1% and 30-day mortality was 16.6%. Median GGT levels in patients who died 30-day than in surviving patients was higher (48 mg/dL vs 32 mg/dL, p= 0.3).

Serum GGT values ≤26 mg/dL showed high negative predictive values for all-cause mortality (91%). In univariate analysis, a cut-off level of GGT ≥26 mg/dL for 30-day mortality were OR: 3.1 (95% CI 1.2-7.9).

The present study suggests that serum GGT level appears to be risk stratifica
tion patients with PTE. The results should be confirmed with other randomized prospective studies.

Acute pulmonary embolism in patients of advanced age

Thomas Berghaus, Wolfgang von Schrein, Martin Schwablmaier. Medical Department I, Klinikum Augsburg, University of Munich, Augsburg, Germany

Background: It has been speculated that the atypical clinical presentation of acute pulmonary embolism (PE) in older patients leads to a delay in diagnosis and therefore contributes to the worse prognosis of older patients presenting with acute PE.

Methods: In this single-centre study we investigated the delay in diagnosis and its relation with in-hospital mortality in 202 consecutive patients with acute PE in a period of 14 months. The study population was divided in a younger (<65 years) and an older age group (>65 years).

Results: Older patients present more often hypoxia (p = 0.017) and with a history of syncope (p = 0.046) than younger patients. Delay in diagnosis was not statistically different in both age groups (3.1±3.0 days in the younger and 3.9±3.1 days in the older age group, p=0.450). Age above 65 years was significantly associated with an increased risk for in-hospital mortality (OR 4.36, 95% CI 0.93-20.37, p = 0.043). Delay in diagnosis was not associated with an increase of in-hospital mortality in univariate or multivariate analysis.

Conclusions: The atypical clinical presentation of acute PE in patients older than 65 years cannot be considered as a risk factor for late diagnosis. Moreover, delay in diagnosis is not related to the higher in-hospital death rate of older patients suffering from acute PE.
derwent transhoracic echocardiography, ventilation-perfusion lung scanning and the diagnosis was established with right heart catheterization.

**Results:** Recurrent venous thromboembolism was documented in 8, 7% of patients, with an incidence of 5.9% (95% CI: 0.6-8.4%) and 11.5% after 24 months (95% CI: 5.0-18%). The mortality was 2.6% at 1 year (95% CI: 0.0-5.5%), 3.7% at 2 years (95% CI: 0.0-7.4%) and 7.7% at 5 years (95% CI: 0.0-13.4%). Older age (p=0.046), SPAP>50mmHg and thrombophilia (p=0.005) were significantly associated with increased risk for recurrence. CTPH was developed in 7 of 126 patients (5.6%). During the acute episode of PE, 33 patients (26.2%) presented SPAP<40 mmHg and 54% of them were with SPAP>50mmHg. CTPH developed in 7 of these 33 patients. Severe PH at the time of the acute PE (SPAP>50mmHg) was associated with an increased risk of CTPH (odds ratio: 20.385, SE: 0.88, P<0.005).

**Conclusions:** The rates of recurrent thromboembolism underscore the need for long term follow up. Risk factors must be considered for the duration of anticoagulant therapy. During the first year after an acute episode of PE, CTPH appears to developed in a substantial number of patients. The severity of PH should increase physicians’ awareness for the potential of CTPH.

P2357

**Survey of thrombophilia causes in patient with deep vein thrombosis admitted in Sari’s Imam Khomeini Hospital during 2009**

Ali Sharifpour, Quem Janbaabe, Hasan Nattaj, Dr. Davoodi, Dr. Okhovatian, Ahmad Nejad. Pulmonary, Mazandaran University of Medical Sciences, Sari, Islamic Republic of Iran; Oncology, Mazandaran University of Medical Sciences, Sari, Islamic Republic of Iran

**Introduction:** Thrombophilia is a condition in which there is a tendency for clot formation and has an incidence of 1 per 1000 annually. About 2/3 of attacks occurs as DVT and the remainder as PE or associated with DVT. Knowing these hereditary factors can be helpful in designing a proper diagnostic template when after it will be possible for each thrombophilic patient to be diagnosed in its proper way.

**Materials and methods:** This is a descriptive study. Our patients were 70 DVT patients whom were bedridden at Imam hospital, Sari, Mazandran, Iran. After admission, they underwent heparin therapy followed by warfarin therapy for 6 months. In the next stage warfarin was stopped and after 2 weeks of heparin therapy, required lab tests were requested. Needed data were collected by a questionnaire and data were processed by SPSS11 statistical software.

**Findings:** 22 people (31.4%) were males and 48 people (68.6%) were females. Mean age was 42.0(614.6 y. 12 of patients (17.1%) had diminished levels of factor V Leiden while 38 people (52.9%) had normal levels. In 84% of patients there were normal levels of fibrinogen and other 14% had increased levels of fibrinogen.

**Result:**

| V-Leiden | C protein | 2.8% |
| Low fibrinogen | Anti phospholipid | 1.4% |
| Protein S | OCP | 14.5% |
| High-VII | Bedridden | 2.8% |
| High-IX | Pregnancy | 2% |
| III Anti thrombim | Recent surgery | 1.4% |
| G20210A | Malignancy | 1.4% |

**Conclusion:** Our study shows that DVT is most common in females. In through of non lab factors, OCP history of no activity and trauma is more companionship with incidence of DVT. In through of genetic factors, FVL and high level of fibrinogen and low level of 5 protein are common.

P2358

**Pulmonary anatomopathologic analysis and clinical manifestations related to different diseases in patients with pulmonary thromboembolism – An autopsy study**

Alme Domingos Ruppert, Alexandre de Matos Soeiro, Edwin Roger Patra, Vera Luiza Capelozi. Pathology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Patients, who died due to pulmonary thromboembolism (PTE), may present different clinical manifestations and symptoms depending on their underlying diseases and comorbidities. The aim of this study was describe and associated demographic and etiologic data, anatomic pathological findings and in-vivo manifestations (Acute Respiratory Failure [ARF], Hemodynamic Instability [HI] or Sudden Death) from autopsy reports of PTE patients.

**Methods:** We reviewed 291 autopsies of patients whose cause of death was PTE. The following data were obtained: age, sex, clinical in-vivo manifestations, post-mortem pathological patterns and main associated underlying diseases.

**Results:** The median age was 64 years, 127 men and 164 women. Pulmonary histopathologic changes were: diffuse alveolar damage (DAD), pulmonary edema (PE), alveolar hemorrhage (AH) and lympho-plasmacytic interstitial pneumonia (LIP). The most common clinical manifestation was ARF (28.9%), followed by HI (27.5%) and AH (26.8%). The most prevalent pulmonary finding was PE (26.8%). Chronic Obstructive Pulmonary Disease was positively correlated to LIP (p=0.04). Linking in-vivo manifestations to pulmonary changes were found significative relations between: ARF and PE (OR=2.99; p=0.01); ARF and AH (OR=2.10; p=0.04); ARF and DAD (OR=8.79; p=0.03); HI and HA (OR=3.38, p=0.01) and HI and DAD (OR=1.43; p=0.02).

**Conclusions:** The understanding of pulmonary physiopathological mechanism involved with each PTE-associated disease can improve diagnosis in order to offer prompt treatment and reduce mortality. Financial support: FAPESP, CNPq.

P2359

**Correlation of right ventricular ejection fraction with tricuspid annular plane systolic excursion by electrocardiogram-gated 320 slice CT in chronic thromboembolic pulmonary hypertension**

Toshiki Sugura1, Nobuhiro Tanabe1, Nobusada Funabashi2, Nako Kawada1, Yukiko Matsurau1, Takayuki Juro1, Rintaro Nishimura1, Ayumi Sekine1, Norimiku Yanagawa1, Seichoiro Saka1, Yasunori Kasahara1, Kouichiro Tatsumi1

1 Department of Respiratology, Graduate School of Medicine, Chiba University, Chiba, Japan; 2 Department of Cardiovascular Science and Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan

**Purpose:** There is a strong correlation between right ventricular ejection fraction (RVEF) and tricuspid annular plane systolic fractional (TAPSE) determined by echocardiography in subjects with pulmonary hypertension (PH). However, it is unknown whether there a correlation between RVEF and TAPSE determined by 320-slice CT. We tested whether TAPSE measured by enhance ECG-gated volume 320-slice CT correlates with RVEF and correlates with pulmonary arterial pressure (PAP) and pulmonary vascular resistance (PVR) obtained by right heart catheterization (RHC) in chronic thromboembolic pulmonary hypertension (CTEPH) subjects.

**Materials and methods:** 33 subjects (11 male, 61±10 yrs) with CTEPH underwent enhanced retrospective ECG-gated volume 320-slice CT (Aquilion ONE, Toshiba) and RHC. CT images were reconstructed every 5% from 0-95% of the R-R interval and a series of apical 4-chamber images. TAPSE was measured from systolic displacement of the RV free wall and tricuspid annular plane junction. RV end-systolic and end-diastolic true volumes were measured from 3-dimensional reconstruction and used to calculate RVEF.

**Results:** TAPSE and RVEF were 14.5±3.5mm and 47.0±14.3%, respectively. In RHC, mean PAP (mPAP) and PVR were 41.4±12 mmHg and 683±364 dyne sec cm⁻⁵, respectively. The correlation coefficient of TAPSE with RVEF was 0.78 (P<0.001). The correlation coefficients of TAPSE with mPAP and PVR were -0.63 (P=0.001) and -0.64 (P<0.001), respectively.

**Conclusions:** TAPSE by ECG-gated 320-slice CT correlated strongly with RVEF and significantly with mPAP and PVR acquired by RHC in subjects with CTEPH.

265. Pulmonary hypertension in hypoxic lung disease

P2360

**Late-breaking abstract: 5-HT mediates susceptibility of rats with low intrinsic aerobic capacity to hypoxia-induced pulmonary hypertension**

Nicholas Duggan, Loredana Cuclan, Victoria Burton, Olivier Bonneau, David Rowlands, Martin Hussey, Jan Roger. Respiratory Disease, Novartis Institutes for Biomedical Research, Horsham, United Kingdom

**Introduction:** Low aerobic exercise capacity has been linked with a higher probability of death. We have previously demonstrated that low exercise capacity rats have increased susceptibility to pulmonary arterial hypertension when subjected to chronic hypoxia. Here we investigate the role of 5-HT in conferring susceptibility.

**Methods:** We exposed high and low exercise capacity rats to a 10% O2 environment for 21 days, +/- daily treatment with a 5-HT inhibitor (pCPA). The animals, bred over 21 generations for high (HCR) or low (LCR) running capacity, differed by 500%. PAH biomarkers were determined in heart, lung and blood.

**Results:** LCR rats developed significantly greater PAH pathologies compared to HCR with regard to cardiac and pulmonary vessel remodeling, right ventricular (RV) pressure and echocardiographic measures. Cardiac histology demonstrated pCPA treatment ablated the RV hypertrophic response and myocyte apoptosis in both HCR and LCR animals. 5-HT levels in LCR animals were increased in response to hypoxia, yet unchanged in other groups, and levels in both strains were ablated by pCPA treatment. Although 5-HT effect reduction in all PAH pathologies in all groups, subtractive analysis revealed no impact on the enhanced vessel remodeling and only a partial effect on RV pressure observed in LCR animals. RV mass and echocardiographic measures of RV function, however, were fully reversed.

**Conclusion:** These data support our hypothesis that intrinsically low aerobic capacity may predispose individuals to developing pulmonary arterial hypertension, and that the associated dysregulation of the 5-HT pathway principally impacts RV function rather than vessel remodeling.

**P2361**

**Spirometric corroboration of radiographic changes suggestive of COPD and influence on ventilation-perfusion scanning.**

**Joseph Abbott, Sophie Kirkade, Arun Lakhanpal, Hassan Burhan. Department of Respiratory Medicine, Royal Liverpool University Hospital, Liverpool, Merseyside, United Kingdom**

**Introduction:** An abnormal chest radiograph (CXR) can affect the ventilation-perfusion (V/Q) scan interpretation in the investigation of suspected pulmonary embolism (PE). V/Q scans are not always preceded by a normal CXR and many CXRs are reported as showing changes “compatible with COPD”.

We decided to ascertain whether radiological suspicion was supported by spirometric evidence of COPD and whether those with more severe COPD were more likely to have an intermediate probability V/Q scan.

**Methods:** All V/Q scans and CXR reports for the 12 months from February 2008 were analysed. The spirometry database was searched and results obtained.

**Results:** 68 patients had V/Q scans with CXRs reported as showing changes compatible with COPD. 44 (65%) had not had spirometry.

Of the 24 (35%) patients with spirometry, 3 reports were unavailable and 19 (90%) were compatible with COPD. The mean FEV1 was 60.2% predicted and the mean FEV1/FVC ratio was 50.7.

The V/Q scan reports are classified according to COPD severity in the table below.

<table>
<thead>
<tr>
<th>Spirometry</th>
<th>Number (%)</th>
<th>VQ scan report: Probability of PE</th>
</tr>
</thead>
<tbody>
<tr>
<td>No evidence COPD</td>
<td>2 (9%)</td>
<td>Low</td>
</tr>
<tr>
<td>Mild</td>
<td>4 (19%)</td>
<td>Intermediate</td>
</tr>
<tr>
<td>Moderate</td>
<td>6 (24%)</td>
<td>Intermediate</td>
</tr>
<tr>
<td>Severe</td>
<td>6 (29%)</td>
<td>High</td>
</tr>
<tr>
<td>Very severe</td>
<td>4 (19%)</td>
<td>High</td>
</tr>
</tbody>
</table>

**Conclusion:** Of the 68 patients reported as having radiological “evidence” of COPD, only 24 (35%) had had spirometry. Of the 21 patients with spirometry reports COPD (91%) did not have COPD.

None of the patients with COPD had an intermediate probability VQ scan. COPD is often “reported” on a chest radiograph but spirometric evidence is not always present and, if present, does not always confirm the radiological suspicion.

**P2364**

**Non-invasive evaluation in prediction of pulmonary hypertension in patients with idiopathic pulmonary fibrosis.**

**František Salajka1, Vladimir Bartol2, Jakub Novosad3, Josef Štacek2, Josef Bis1, Miroslav Brko4, Pavel Polásky3, Vladimir Kobířek1, Vratislav Sedláčk4.**

1Department of Pulmonary Medicine, University Hospital Hradec Králové, Hradec Králové, Czech Republic; 2Department of Clinical Immunology and Allergology, Charles University Faculty of Medicine and University Hospital Hradec Králové, Hradec Králové, Czech Republic; 3First Department of Internal Medicine, Charles University Faculty of Medicine and University Hospital Hradec Králové, Hradec Králové, Czech Republic; 4Department of Cardiology, Charles University Faculty of Medicine and University Hospital Hradec Králové, Hradec Králové, Czech Republic

**Introduction:** Pulmonary hypertension (PH) occurs rather frequently in patients with advanced idiopathic pulmonary fibrosis (IPF). However, none of the non-invasive imaging methods is able to predict the utility of drugs for IPF. The aim of this study was to confirm the usefulness of this method in our group of IPF patients.

**Methods:** Pulmonary hypertension (PH) was defined as a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg. None of the patients with COPD had an intermediate probability V/Q scan. COPD was often “reported” on a chest radiograph but spirometric evidence is not always present and, if present, does not always confirm the radiological suspicion.

**Results:** Drug therapy with oral vasodilators (both amiodipine or sildenafil) could significantly reduce NT-proBNP levels in COPD-induced PH patients. Also there were no significant differences between amiodipine and sildenafil on lowering NT-proBNP levels (effectiveness of therapies).

**Conclusion:** Drug therapy (oral vasodilators) in COPD-induced significantly decreased NT-proBNP levels in this study. Though, no significant difference between amiodipine and sildenafil in reducing NT-proBNP levels was observed. Changes in NT-proBNP levels could be used as an indicator to monitor the effectiveness of therapies.
The functional abnormalities of right ventricle in long standing chronic obstructive pulmonary disease (COPD) have been well documented. Derangement of the right ventricular (RV) function in these patients, in the absence of other disorders affecting the LV, has not been clearly established.

This study has been designed to provide more definitive information concerning left ventricular function in patients with COPD primarily to ascertain the involvement of left ventricle in stable COPD patients in whom other sources of diastolic dysfunction has been systematically excluded which the previous studies had failed to do.

The aim of the study was to evaluate LV function in COPD patients.

To assess LV function in COPD patients, 30 patients with PH without additional cardiac diseases and 30 age and sex-matched healthy subjects were enrolled into the study.

We defined COPD by GOLD criteria. Well Investigated parameters of Left ventricular diastolic functions like E/A (peak velocity of early E wave /Epeak velocity of early A wave (A transtral flow), IVRT (Isovolumetric relaxation time), MPI (Myocardial Performance Index) were used for the evaluation of LV diastolic function.

The study shows that 30% i.e. 9 of the 30 patients admitted to the hospital with COPD had left ventricular diastolic dysfunction and that the risk of association with Left ventricular diastolic dysfunction is 6 times more in COPD patients than in normal individual.

In COPD patients, LV diastolic function is significantly impaired and its magnitude is related with the severity of COPD as well as the increase in pulmonary artery pressure. This is in spite of preserved LV systolic function.

Drug therapy for pulmonary hypertension associated to chronic lung disease is currently discouraged for the negative effects on gas exchange. We retrospectively studied the effects of long-term treatment with sildenafil is not associated to detrimental effect on gas exchange.

From 2000 to 2007 we identified 14 patients (age 65±7 years) treated with Tadalafil 5 mg (TAD). There was no significant difference in NT-proBNP levels between TAD treated patients and healthy controls (p>0.05). There was a negative correlation between NT-proBNP and PADP (r=0.68). These results mean that ET-1 dysfunction may contribute to increases in pulmonary arterial tone and pulmonary hypertension in COPD.

We conclude: endothelial dysfunction in patients with COPD become intensify from moderate to severe stage, that by-turn influence to increase on central and pulmonary haemodynamics damage. 

**P2366**

The influence of right ventricular diastolic functions and pulmonary hypertension on exercise limitation and their relationship with serum NT-proBNP levels in COPD

Tugce Sahin Ozdemirel1, Begum Yets1, Nihuef Bayraktar1, Serife Savas Bayat2, Emir Kartalci2, Gazy Ulubay1, Pumilgin Medicine, Baskent University, Faculty of Medicine, Ankara, Turkey; 2Cardiology, Baskent University, Faculty of Medicine, Ankara, Turkey; 3Biochemistry, Baskent University, Faculty of Medicine, Ankara, Turkey

**Introduction:**

During the course of the chronic obstructive pulmonary disease (COPD), pulmonary hypertension (PH), right heart failure, exercise limitation develops. Whether pulmonary specific vasodilator treatment with either inhaled Iloprost (Ih), Bosentan (B) or Sildenafil (S) in our PH clinic.

**Methods:**

In this study, 31 moderate-severe COPD patients, 20 healthy controls were included. Right ventricular diastolic parameters, serum NT-proBNP levels were measured. Exercise capacity was evaluated by cardipulmonary exercise testing (CPET).

**Results:**

Echocardiography revealed PH in 13 of the COPD patients. NT-proBNP levels were found to be higher in the COPD group than in the control group, the difference was statistically significant (p<0.05). NT-proBNP level had a relationship with PAP; there was no significant difference in NT-proBNP levels between COPD patients with and without PH (p>0.05). COPD patients demonstrated statisitically lower values than the control group with regard to anechoic threshold oxygen consumption (ATV02) and carbondioxide production (ATVCO2), and peak oxygen consumption (PVO2) and peak carbondioxide production (PVOCO2) (p<0.05). There was a negative correlation between NT-proBNP levels, API, PAP and NT-proBNP values determined by CPET. There was a difference between the COPD and control groups with regard to tricuspid annular plane systolic excursion (TAPSE) value, an echocardiographic parameter (p<0.05).

**Conclusion:**

Demonstration that NT-proBNP levels show a correlation with PH, and they are raised in COPD patients. PH may have a tendency for right ventricular diastolic dysfunction and that exercise limitation might be predicted by right ventricular functions and NT-proBNP levels.
P2371 Pulmonary hypertension and exercise performance in advanced COPD

Irina Lapteva¹, Natalija Perahonok², Elena Lapteva³, Irina Tishkova⁴
¹Pulmonology, RSPC of Pulmonology and Phthisiologu; ²Phthisiopulmonology, BMA; ³Pulmonology, RSPC of Pulmonology and Phthisiologu; ⁴Phthisiopulmonology, BSMU, Minsk, Belarus

Rationale: Pulmonary hypertension is a common occurrence in advanced COPD, but its effects on exercise performance remain unclear.

Aim: To determine the effects of pulmonary hypertension in advanced COPD on exercise performance.

Methods: We conducted the exercise testing and the echocardiographic examination in 32 patients with advanced stable COPD. Mean pulmonary artery pressure (mPAP) was calculated from the acceleration time of pulmonary flow. Exercise capacity was evaluated by the distance walked in 6 min (6MWD) and by an incremental cardiopulmonary exercise test (CPET).

Results: The patients had a forced expiratory volume in 1 s (FEV1) of 1.15±0.34 L (60% predicted, range 22-50%), corresponding to GOLD stages III and IV, and a 6MWD of 310±62 m (mean±SD). The CPET showed: a maximum workload of 50.2±22 W, a peak O2 uptake of 12.4±3.4 mL/kg/min, a peak heart rate of 125±5 bpm, a peak respiratory exchange ratio 1.03±0.7, a ventilation (VE)/CO2 production slope of 34.9±9, and a peak O2 pulse 7.1±1.3 mL/min. The peak VE was 40±13 L/min, and the calculated maximum voluntary VE 42±18 L/min. There was no significant difference in any of the CPET variables and 6MWD between the patients with a mPAP < 30 mm Hg (mPAP 24.4±5 mm Hg, n=17) and those with mPAP > 30 mm Hg (mPAP 33±4 mm Hg, n=15). There was no correlation between PAP and any of the exercise measurements.

Conclusions: These results suggest that exercise performance in patients with advanced COPD and mild to moderate pulmonary hypertension is essentially limited by exhaustion of the ventilatory reserve.

P2372 Presence of established and exercise induced pulmonary hypertension in COPD

Janne Hilde¹, Ingun Skjørt¹, Sjur Humrefoil², Veggo Hansteen², Morten Melsen³, Jonny Hjøsdl¹, Kjell Stein²
¹Department of Medicine, Oslo University Hospital, Aker, Oslo, Norway; ²Department of Medicine, Akershus University Hospital, Lørenskog, Norway

Aim: To describe prevalence of pre-capillary pulmonary hypertension (PH) and exercise induced pulmonary hypertension (EIPH) in COPD without left sided heart diseases, and to relate PH to GOLD stages III-IV.

Methods: 98 patients, 64±7 yrs and 50% men, were recruited. Right heart catheterisation (RHC), performed in 72 (73% of patients), demonstrated pulmonary arterial hypertension (PAH: mPAP > 30mmHg, pulmonary vascular resistance (PVR) > 3 WU) in 22 patients (22.2%). Critical differences between patients with PAH and those without PAH were: higher age, higher exhaled NO and lower exercise capacity. No significant differences were detected in the following variables: FEV1, 6MWD, 6MWT, 6Mmax, VO2 and VO2max (p > 0.05).

Conclusion: PAH is common in COPD with exercise capacity > 6MWD. Exercise induced PAH was not identified in this study. Further studies are needed to evaluate the role of exercise induced pulmonary hypertension in patients with COPD.

P2373 Arterial blood gases during exercise in chronic obstructive pulmonary disease with and without pulmonary hypertension

Ingun Skjørten¹, Janne Mykleland Hilde², Morten Nissen Melsen³, Veggo Hansteen², Kjell Stein²
¹Department of Pulmonary Medicine, ²Department of Cardiology, Oslo University Hospital, Aker, Oslo, Norway; ³Department of Pulmonary Medicine, Aarhus University Hospital, Aarhus, Denmark

Aim: To evaluate blood gas responses during cardiopulmonary exercise test (CPET) when patients with chronic obstructive pulmonary disease (COPD) were categorized by GOLD stages and the presence of pulmonary hypertension (PH).

Methods: Right heart catheterisation (RHC) and CPET to exhaustion with serial blood gas measurements were performed in 98 COPD patients in GOLD stages II-IV without left heart disease. Mean age±SD was 64.7±7 yrs and 50% were men. PH was defined as mean pulmonary artery pressure (mPAP) at rest ≥25mmHg. Results: Table 1. PH was observed in 5, 28 and 51 patients in GOLD stages II, III and IV, respectively. At rest and at peak exercise PaO2 decreased whereas PaCO2 increased with advancing GOLD stages. At rest, only stage IV had lower (p<0.05) PaO2 in patients with PH than in those without. At peak exercise, both stage II and IV had lower (p<0.05) PaO2 in patients with PH than in those without. For PaO2, no significant differences were observed within each GOLD stage.

Table 1

<table>

Pulmonary hypertension (PH) is defined by a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg. PH was a common finding in advanced COPD. Arterial PaO2 at rest and at peak exercise was inversely related to GOLD stages. Presence of PH within each stage was associated with lower PaO2. Since RHC is not available to all COPD patients, CPET is useful in selecting candidates. Low resting PaO2 and excessive decline in PaO2 during exercise justify referral to further PH investigation.

P2374 Experimental hypoxia-induced pulmonary hypertension is prevented by moderate exercise training in mice

Doretha Feurer¹, Christina Ellinglöf¹, Karsten Krüger¹, Christian Pilar², Sushmita Katta¹, Michael Seimetz¹, Hossein Ardeshir Ghoferi³, Ralph Schermuly¹, Werner Steinegger¹, Friedrich Grimminger¹, Frank Mooren², Norbert Weissmann³, ¹University of Giessen Lung Center, Excellence Cluster Cardio-Pulmonary System (ECOPS), Jutta-Liebig-University Giessen, Giessen, Germany; ²Department of Sports Medicine, Jutta-Liebig-University Giessen, Giessen, Germany; ³Department of Lung Structure and Development, Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany

Pulmonary hypertension (PH), a progressive disease of multifactorial etiology, has a poor prognosis and results in right heart dysfunction. PH is characterized by pulmonary vasoconstriction and abnormal vascular remodeling processes. Current medication does not cure the disease; at best disease progression can be mitigated. Main symptoms of PH are fatigue and shortness of breath. Thus, exercise training has been considered as counterproductive in the past. In our study, moderate exercise training prevented pulmonary vascular disease in a mouse model of hypoxia-induced pulmonary hypertension. During 21 days of exposure to hypoxia mice were trained on a treadmill, daily, for five days a week. Readouts were maximum walking distance, maximum oxygen uptake (VO2 max), the effect being similar in trained mice; small vessel muscularization was reduced to a similar degree as with sildenafil-treatment only. Chronic hypoxia induced a significant hypoxia-induced upregulation of PDE5 in whole-tissue treated trained mice; small vessel muscularization was reduced to a similar degree as with sildenafil-treatment only. Chronic hypoxia induced a significant hypoxia-induced upregulation of PDE5 in whole-tissue homogenate, which was absent in trained mice. Overall, our data demonstrate the efficacy of exercise training for prevention of hypoxia-induced pulmonary hypertension, which might be mediated by inhibition of PDE5 upregulation.

P2375 Biomarkers for pulmonary hypertension in interstitial lung disease

Elisabeth Bendsrud¹, Søren Møllemkjær², Ole Hilberg¹, Jens Erik Nielsen-Kudsk¹, Ulf Simonsen¹, Charlotte Andersen¹
¹Department of Pulmonology, Aarhus University Hospital, Aarhus, Denmark; ²Department of Cardiology, Aarhus University Hospital, Aarhus, Denmark; ³Department of Pharmacology, Aarhus University Hospital, Aarhus, Denmark

Pulmonary hypertension (PH) is defined by a mean pulmonary artery pressure (MPAP) ≥ 25 mmHg. New patients with ILD are screened by echocardiography to detect signs of PH. This study evaluates NT-proBNP, D-imeric acid and exhaled NO as biomarkers in diagnosis of PH in patients with ILD. A total of 206 patients with ILD were screened for PH by echocardiography. A tricuspid pressure gradient (TGR) ≥ 40 mmHg, dilatation or decreased tricuspid annular plane systolic excursion (TAPSE) on echocardiography were performed in 98 ILD patients in GOLD stages III-IV with PH. These results suggest that exercise performance both in trained and untrained mice is impaired in PH. Exercise training can prevent and reverse the development of PH, and thus improve exercise capacity in patients with PH.

Results: Mean±SEM: 30 patients had PH based on echocardiography (TGR ≥ 40 mmHg) and positive predictive values (PPV) for detection of PH were calculated.
mmHg). In 19 patients, RHC data were obtained, and in 18, the diagnosis of PH was confirmed (MPAP = 39±2 mmHg). There was a statistical significant relationship between high values of NT-proBNP and the presence of PH, with an area under the ROC curve of 0.85. With a cut-off value of 110 ng/l, higher values of NT-proBNP had a sensitivity of 93%, a specificity of 55%, a PPV = 27% for detecting PH on echo. 47% of the patients had NT-proBNP values below 110 ng/l. There was no statistical significant relationship between the levels of uric acid, fibrin D-dimer and exhaled NO and the presence of PH.

Conclusion: A value of NT-proBNP below 110 ng/l may be used to rule out the presence of PH, and to reduce the need for echocardiographic screening for PH in ILD patients.

266. Treatment of pulmonary hypertension

P2378 Late-breaking abstract: Short term improvement in 6 minute walk distance predicts long term survival in incident idiopathic pulmonary arterial hypertension. Results from the Pulmonary Hypertension Registry of the United Kingdom and Ireland

Background: Improvement in 6 minute walk distance (6MWD) after 12-16 weeks of treatment has been used as the primary end point in many pivotal pulmonary arterial hypertension (PAH) clinical trials. However, the consensus view is that although baseline 6MWD predicts survival, change in 6MWD (Δ6MWD) does not.

Aim: To determine whether Δ6MWD after 3 months of disease targeted therapy predicts long term survival in patients from the Pulmonary Hypertension Registry of the UK and Ireland.

Methods: Retrospective observational study of all incident cases of idiopathic (IPAH), heritable and anorexigen-associated PAH diagnosed in the UK and Ireland between 1st January 2003 and 31st December 2009. Patients were divided into low and high baseline 6MWD by the median 6MWD (295 m).

Results: Total of 646 patients were diagnosed. After 3 months of disease targeted therapy, patients with absolute 6MWD >353 m (corresponding to the median value at 3 months) had better survival than those with 6MWD < 353 m. Mean improvement in 6MWD after 3 months of therapy was 42.4±7.5 m (median 37 m). Patients with greater increase in 6MWD from baseline to 3 months had better post-3 months survival (hazard ratio 0.65, 95% confidence interval 0.42 to 0.99 per 100 metres improvement). In patients with low baseline 6MWD, Δ6MWD at 3 months of > 37.5 m had better survival compared to those with Δ6MWD at 3 months of < 37.5 m (Log-rank, p=0.03). This is not seen in patients with high baseline 6MWD.

Conclusion: Change in 6MWD after 3 months of treatment predicts long term survival in patients with low baseline 6MWD.

P2379 Comparison of hemodynamic effects of inhaled nitric oxide (iNO) and inhaled epoprostenol (iEPO) in patients with pulmonary hypertension (PH)

Shilpa A. Desouza1, Kristen D. Sagliani1, Ioana R. Preston2, Kari E. Roberts3, Archan Shah4, Nicholas S. Hill5, Pulmonary Vascular Disease Unit, Papworth Hospital, Cambridge, United Kingdom; 2Pulmonary Hypertension Unit, RoMed Clinical Unit, RoMed Clinical Unit, University, Frankfurt, Germany; 3Department of Internal Medicine III, RoMed Clinical Center Rosenheim, Rosenheim, Germany

Background: Acute vasodilator testing with iNO during right heart catheterization in pulmonary arterial hypertension predicts survival and response to calcium channel blockers. iEPO is less expensive than iNO with fewer systemic effects than iNOS and their combination has additive effects.

Methods: Prospective double-blinded study of PH treatment-naïve consecutive patients. Patients >18 years, WHO Group 1-5 with pulmonary capillary wedge pressures < 20 were included. Patients received iNO, iEPO and their combination in random order, with a washout phase between treatments. Hemodynamics at baseline and treatments were reported as±change, means±SD. Correlation was assessed with regression analysis. p<0.05 was significant.

Results: Patients enrolled: Group 1 (11), Group 2 (9), Group 3 (1), Group 4 (1), Group 5 (1). 2 did not complete the study (hypoxemia and dyspnea respectively).

R2: is the correction factor for the variability in the adjusting factors. %AmPAP, %APVR, %ACO were mean pulmonary vascular resistances (PVR) at 2 AT and 30 AT respectively.
A statistically significant reduction (p=0.006) in PVR was observed. There
was a 10-minute interval. Pulmonary and systemic haemodynamic measurements were recorded at
mean PAP was 75 \pm 13 mmHg, cardiac index 2.0 \pm 0.6 L/min/m^2 and pulmonary vascular resistance 1194 \pm 571 dyn cm^-5. In the overall PH population, survival estimates following epo commencement were 77%, 63% and 54% at 1, 2 and 3 years, respectively, and 82%, 72% and 69% in the subgroup of pts with PAH.

Conclusion: Epo is still used as first-line therapy in severe forms of PH. It is
notably prescribed in non-group 1 PH in 28% of cases. In incident pts with PAH, 1- and 2-year survival is similar to historical cohorts, despite the prior use of an oral treatment in 48% of them.

Methods: 30 SLE patients with PAH (mean age is 48.3±1.7 yrs) were studied, whom to conventional therapy was added “Korargin” 2 tablets 3 times a day for 8 weeks. The object of the effectiveness was increased distance of 6-minute walk (6MW), changes in pulmonary artery pressure and improvement of functional class (FC) PAH on WHO.

Results: II FC PAH was diagnosed in 80% patients. Patients with III FC was 20%.
From the 4th week and untill the end of the initial study, the patients demonstrated a significant increase in the distance test of 6MW an average of 61.2±3.2 m compared with the baseline data. In addition, it was observed decrease in pulmonary arterial pressure on 11% in 37% of patients, 64% patients improved their FC.

Conclusion: Despite of the fact, that insufficient long-term follow-up period and relatively non-severe population of SLE patients with PAH, having taken “Korargin”, patients has improved tolerance to physical activity, FC PAH on WHO and hemodynamic parameters.

P2384

Impact of functional class change on survival in patients with pulmonary arterial hypertension in the REVEAL registry
Robyn Barst1, Dave Miller2, Faith Beery2, Michael McGoon 3.
1Pediatrics (in Medicine), Columubia University College of Physicians and Surgeons, New York, NY, United States; 2Statistical Analysis, ICON Clinical Research, San Francisco, CA, United States; 3Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Introduction: The Registry to Evaluate Early and Long-term PAH Disease Management (REVEAL), a 55-center observational, US-based study, describes current demographic, clinical, and treatment patterns in PAH patients (pts).

Objective: Determine if pts who improve from functional class (FC) III at enroll ment to FC III if follow-up (fu) have a better 2-year survival than pts who remain FC III.

Methods: 1,082 adults enrolled in REVEAL were assessed as FC III at enrollment (based on most recent pre-enrollment evaluation) and had ≥ 1 fu FC assessment within the first year after enrollment. We classified pts based on their first fu assessment after enrollment as: 1) improved if FC improved to FC II; 2) unchanged if remained FC III; or 3) deteriorated if worsened to FC IV. We compared survival (estimates±SE) of these 3 subgroups from the first fu FC assessment (log-rank test).

Results: FC improved in 26% (n=281) of pts, was unchanged in 66% (n=718) and deteriorated in 8% (n=83). At enrollment, there were no differences in gender, PAH subgroup, right atrial pressure, or cardiac index; significant differences were observed in age, proportion of newly diagnosed (diagnostic confirmatory cardiac catheterization <3 months before enrollment) pts, and 6-minute walk distance among groups. Two-year survival was 88.2%, 76.2%, and 34.6% for FC III, FC I/II, and FC IV pts, respectively (P<0.001 for all pairwise comparisons). Results are similar for both newly and previously diagnosed pts who were FC III at enrollment.

Conclusions: Pts who improve from FC III to FC I/II appear to have a better

P2385

Effectiveness of “Korargin” in the therapy of pulmonary arterial hypertension in patients with systemic lupus erythematosus
Olga Yakovleva, Aleksandra Kieko. Clinical Pharmacy and Clinical Pharmacology, Vinnitsa National Medical University, Vinnitsa, Ukraine

Introduction: Pulmonary arterial hypertension (PAH) in systemic lupus erythematosus (SLE) is a complex therapeutic problem and occurs from 5 to 14%. The main pathophysiological mechanism of PAH is an endothelium dysfunction with abnormality of nitric oxide synthesis (Ghorbani H.A. et al. J. Am. Coll. Cardiol. 2004; 43: 688-72S).

Objective was to examine the efficacy of the “Korargin” (1 tablet contains 0.1g L-arginine and 0.1g isosorbide), production of “Korargin”, Uman, Ukraine in SLE patients with PAH.

Methods: 30 SLE patients with PAH (mean age is 48.3±1.7 yrs) were studied, whom to conventional therapy was added “Korargin” 2 tablets 3 times a day for 8 weeks. The object of the effectiveness was increased distance of 6-minute walk (6MW), changes in pulmonary artery pressure and improvement of functional class (FC) PAH on WHO.

Results: II FC PAH was diagnosed in 80% patients. Patients with III FC was 20%.
From the 4th week and untill the end of the initial study, the patients demonstrated a significant increase in the distance test of 6MW an average of 61.2±3.2 m compared with the baseline data. In addition, it was observed decrease in pulmonary arterial pressure on 11% in 37% of patients, 64% patients improved their FC.

Conclusion: Despite of the fact, that insufficient long-term follow-up period and relatively non-severe population of SLE patients with PAH, having taken “Korargin”, patients has improved tolerance to physical activity, FC PAH on WHO and hemodynamic parameters.

P2384

Impact of functional class change on survival in patients with pulmonary arterial hypertension in the REVEAL registry
Robyn Barst1, Dave Miller2, Faith Beery2, Michael McGoon 3.
1Pediatrics (in Medicine), Columubia University College of Physicians and Surgeons, New York, NY, United States; 2Statistical Analysis, ICON Clinical Research, San Francisco, CA, United States; 3Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Introduction: The Registry to Evaluate Early and Long-term PAH Disease Management (REVEAL), a 55-center observational, US-based study, describes current demographic, clinical, and treatment patterns in PAH patients (pts).

Objective: Determine if pts who improve from functional class (FC) III at enrollment to FC III if follow-up (fu) have a better 2-year survival than pts who remain FC III.

Methods: 1,082 adults enrolled in REVEAL were assessed as FC III at enrollment (based on most recent pre-enrollment evaluation) and had ≥ 1 fu FC assessment within the first year after enrollment. We classified pts based on their first fu assessment after enrollment as: 1) improved if FC improved to FC II; 2) unchanged if remained FC III; or 3) deteriorated if worsened to FC IV. We compared survival (estimates±SE) of these 3 subgroups from the first fu FC assessment (log-rank test).

Results: FC improved in 26% (n=281) of pts, was unchanged in 66% (n=718) and deteriorated in 8% (n=83). At enrollment, there were no differences in gender, PAH subgroup, right atrial pressure, or cardiac index; significant differences were observed in age, proportion of newly diagnosed (diagnostic confirmatory cardiac catheterization <3 months before enrollment) pts, and 6-minute walk distance among groups. Two-year survival was 88.2%, 76.2%, and 34.6% for FC III, FC I/II, and FC IV pts, respectively (P<0.001 for all pairwise comparisons). Results are similar for both newly and previously diagnosed pts who were FC III at enrollment.

Conclusions: Pts who improve from FC III to FC I/II appear to have a better

**Inhaled treprostinil therapy in patients with pulmonary hypertension and parenchymal lung disease**

Anfene Schiro, Aaron Wexman. Pulmonary and Critical Care Medicine, Brigham and Women’s Hospital, Boston, MA, United States

The treatment of patients with Parenchymal Lung Disease (PLD) and Pulmonary Hypertension (PH) is challenging. PLD is characterized by an imbalance between alveolar ventilation and pulmonary blood flow. The ability to deliver therapy to areas of lung that are well ventilated would utilize preserved V/Q matching and improve drug delivery. This would reduce undesirable alterations in perfusion caused by a systemic vasodilator and provide a more effective way of treating these patients. We examined the response of patients with PLD and PH receiving Inhaled Treprostinil. We followed eight patients with NYHA Functional Class III/IV symptoms with a mean PAP >25mmHg and PCWP of ≥15mmHg for at least 3 months. Five subjects had Obstructive Lung Disease and three were classified as having Restrictive Lung Disease. All followed the usual protocol starting with three breaths four times a day and gradually increased to the goal of nine breaths a day.

Two patients had to be reduced to six breaths a day due to threat of irritation but were able to increase back to nine breaths a day. One patient stopped the Inhaled Treprostinil one week after starting therapy for worsening symptoms of shortness of breath. Two patients were on a background PDE5 Inhibitor prior to starting the inhaled treatment. All but one patient reported less shortness of breath after initiation of treatment. The majority of patients had an improvement in 6-MWD and Borg Dyspnea Scale. Our experience suggests that patients with PLD and PH can be safely treated with inhaled Treprostinil. Inhaled Treprostinil may offer an effective and well tolerated treatment in subjects with PLD and shortness of breath exacerbated by PH.

**Parenteral treprostinil for significant pulmonary arterial hypertension associated with pulmonary fibrosis: A safety study**

Rajeev Saggar1, Dinesh Khanna1, John Belperio1, Shelley Shaparlo1, Rajan Saggar1,2. 1Pulmonary Critical Care, UCLA Medical Center, Los Angeles, CA, United States; 2Rheumatology, UCLA Medical Center, Los Angeles, CA, United States

Objectives: Safety & efficacy of treprostinil (IV/SQ) in patients with pulmonary fibrosis (PF) and PAH.

Methods: Prospective, open label trial of patients referred for lung transplantation with PPH/PAH (mean PA >35 mmHg & PVR >3 WU), treated treprostinil × 12 weeks.

Results: N=14 received treprostinil (18-97 mg/kg/min). The hemodynamics, 6MW, BNP, and UCSD/SF 36 significantly improved. No significant changes were seen with PF/PAH. Prospective, multicenter, randomized-controlled studies are warranted to verify these results.

**Conclusions:** Chronic administration of treprostinil is well tolerated in patients with PPH/PAH. Prospective, multicenter, randomized-controlled studies are warranted to verify these results.

Cardiotoxic agents affect pulmonary vessels in precision-cut lung slices (PCLS)

Annette Dorothea Ring1,2, Ross Rolfsson1, Stefan Uhlig1, Christian Martin1.
1Institute of Pharmacology and Toxicology, Medical Faculty of RWTH Aachen, Aachen, Germany; 2Department of Anaesthesiology, Medical Faculty of RWTH Aachen, Aachen, Germany

Introduction: Cardiotoxic agents play a major role in the therapy of heart failure. Apart from their effects on ventricular contractility and systemic afterload, they may affect the tone of pulmonary arteries (PAs) and pulmonary veins (PVs). However, in particular the responses of PVs to cardiotoxic agents are only poorly defined.

Aims and objectives: We investigated the effects of α- and β-adrenergic agents as well as vasopressin in PAs and PVs to clarify their potential role in pulmonary hypertension (PH) or lung edema and coexisting heart failure.

Methods: After terminal anaesthesia with pentobarbital, PCLS were prepared from female Dunken Hartley guinea pigs and investigated by video microscopy. Concentration-response curves of various cardiotoxic drugs were analyzed in PAs and PVs.

Results: After stimulation with α1-adrenergic agents, PAs contracted up to 80.5% ± 3, in respect to the initial vessel area, whereas β2-adrenergic agents showed only little effect. In contrast, after stimulation of β2-receptors PVs contracted up to 77% ± 2.6 and relaxed due to activation of β2-receptors up to 124.7% ± 2.8. Notably, inhibition of β2-receptors unmasked the α1-mimetic effect of (nor)epinephrine. Vasopressin contracted PAs up to 76.4% ± 4.24, without any effect on PVs.

Conclusion: Thus, vasodilatation of PAs enhances capillary and venous hydrostatic pressures and promotes the development of lung edema. Our findings suggest that (nor)epinephrine in combination with unselective β-blockers and vasopressin might be harmful in patients with left heart failure. Further, α1-mimetic agents might exacerbate a pre-existing PH and a failing right ventricle by contracting PAs, whereas vasopressin might not.

Stability and microbial properties of reconstituted and diluted epoprostenol with expanded stability with expanded stability

Oliver Lambert1, Dirk Bandilla2, Rupa Iyer1, Leonore Whyte-Lakshmanan1, Nagesh Palepu3. 1Drug Product Operations, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 2Global Quality Management, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 3President, TPM Laboratories, Inc., Cherry Hill, NJ, United States; 4Principal Consultant, Pharma CMC and IP, Piscataway, NJ, United States; 5President and CSO, SciDose LLC, Amherst, MA, United States

Microbial activity and stability of epoprostenol with expanded stability (EPO-ES, Veletri®) were investigated at 5°C and 25°C over a range of concentrations. EPO-ES was reconstituted and immediately diluted with sterile Water for Injection (WFI) or Sodium Chloride 0.9% Injection (NaCl). Stability for up to 72 hours (B) at 25°C was measured immediately following dilution (A), and after 1 (B) or 7 days (C) storage at 5°C. Shelf-life was assessed by determining the time over which potency ≥90% was maintained. For microbiological testing, diluted samples of EPO-ES were inoculated with S. aureus, P. aeruginosa, E. coli, C. albicans, A. niger or C. sporogenes and incubated for up to 14 days at 35°C or 4 days at 25°C. Potency of EPO-ES 6,000 ng/mL at 12h under test condition B was 92% for both diluents. Potency of EPO-ES 9,000 ng/mL under test condition C was 91% for WFI and 87% for NaCl at 12h, and ≥90% for both diluents at 12 and 24 h at 12,000

Introduction: Careful and frequent assessment is important for management of patient with pulmonary hypertension (PH). Cardiac output (CO) is one of the most relevant indexes to be assessed but cannot be performed routinely because of invasive determination. A simple non-invasive method, such as nitrous oxide inert gas rebreathing (REB) could be performed at every clinic visit.

Aims and objective: To evaluate the possibility to follow up CO by REB against thermodilution (TD) in patients with severe PH. (Dana Point class 1 and 4)

Method: CO and Stroke volume (SV) were determined via TD and REB at two different visits and spearman correlation were applied.

Results: Good correlations were found between TD and REB Δ (visit 1 – visit 2) CO and ΔSV. TD and REB ΔCO and ΔSV correlated similarly with other indexes of clinical assessment.

Use of non invasive gas exchange to track pulmonary vascular responses to exercise in heart failure

Paul Woods, Bryan Taylor, Thomas Olson, Bruce Johnson. Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Simple metrics to quantify severity of pulmonary hypertension (PH) are lacking, particularly with exercise. Studies have suggested that end tidal CO₂ (PetCO₂) and ventilatory efficiency (Ve/VCO₂) may be good indicators of the pulmonary vascular (PV) response to exercise in patients with PH. In addition, measures of PV capacitance (stroke volume/pulmonary arterial pressure, Pvcap) are predictive of survival in the PH population and may potentially be estimated with gas exchange. PH is common in heart failure (HF) and appears to have both passive and reactive components. However, HF is associated with a number of gas exchange abnormalities that could limit the ability of using PetCO₂ or Ve/VCO₂ to estimate the presence of PH. The focus of this study was, a) determine how well non-invasive gas exchange tracks the PV response to exercise and b) test a non-invasive estimate of Pvcap. Forty-two patients with HF (age 54±9, LVEF 20±6, NYHA class 3±1) undergoing r.-hrt catheterization as part of a pre-transplant evaluation were studied. PV pressures (Ppa/Ppw), cardiac output and PV resistance (PVR) were obtained with simultaneous measures of gas exchange. PetCO₂ and Ve/VCO₂ obtained during moderate exercise (VO₂ 9±2ml/kg/min, 37±13W) were highly correlated (r =0.95) and thus data were analyzed in tertiles according to PetCO₂ (mean 23±3, 29±2, 36±4mmHg). PVR followed a decreasing trend from low to high PetCO₂ groups (365±256, 282±162, 188±41WU, p<0.01, r=0.47). Pvcap from catheter measures was highly associated with a value estimated from Qp/Qs (Intercept/1/PetCO₂) (r=0.84). Non invasive gas exchange measures may represent a relatively simple way to track PV response to exercise in HF: NIH HL71478.

P2391

Use of non invasive gas exchange to track pulmonary vascular responses to exercise in heart failure

Paul Woods, Bryan Taylor, Thomas Olson, Bruce Johnson. Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States

Simple metrics to quantify severity of pulmonary hypertension (PH) are lacking, particularly with exercise. Studies have suggested that end tidal CO₂ (PetCO₂) and ventilatory efficiency (Ve/VCO₂) may be good indicators of the pulmonary vascular (PV) response to exercise in patients with PH. In addition, measures of PV capacitance (stroke volume/pulmonary arterial pressure, Pvcap) are predictive of survival in the PH population and may potentially be estimated with gas exchange. PH is common in heart failure (HF) and appears to have both passive and reactive components. However, HF is associated with a number of gas exchange abnormalities that could limit the ability of using PetCO₂ or Ve/VCO₂ to estimate the presence of PH. The focus of this study was, a) determine how well non-invasive gas exchange tracks the PV response to exercise and b) test a non-invasive estimate of Pvcap. Forty-two patients with HF (age 54±9, LVEF 20±6, NYHA class 3±1) undergoing r.-hrt catheterization as part of a pre-transplant evaluation were studied. Is flying safe for individuals with pulmonary arteriovenous malformations and hereditary haemorrhagic telangiectasia? A questionnaire-based study

Christopher Mason¹, Claire Shovlin². 1 Respiratory Medicine, Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom; 2 NHII Cardiovascular Sciences, Imperial College London, London, United Kingdom

Background: Flight-related complications reported in individuals with pulmonary arteriovenous malformations (PVMs) and hereditary haemorrhagic telangiectasia (HHT) have included deep venous thrombosis (DVT), ischaemic stroke, and haemorrhage from PVMs. In addition there are concerns that the reduced barometric pressure associated with flying might exacerbate PVM-induced hypoxia.

Methods: With ethical approval (NRES 10/H010/006), individuals with PVMs and/or HHT were sent a questionnaire to document flights they had taken, and symptoms experienced during or shortly afterwards. Responses were correlated with sea level erect oxygen saturations (SaO₂), and haemoglobin (Hb).

Results: 159 replies were received (response rate 52%). 147 individuals had flown, 97 (66%) with PVMs. The median number of flights per individual was 25, totalling 18,943 flight hours in 3,950 flights. 111 (77%) respondents reported no complications. Six (4%) reported dyspnoea, two (1%) had a deep vein thrombosis, and one had an ischaemic stroke whilst flying. However the most common in-flight complications were HHT-related nosebleeds, reported by 26 (18%). There was no difference in SaO₂ at sea level between those who reported dyspnoea, and those who did not (medians 93 [range 85–96%]; 94 [84–99%]). There was

also no difference in Hb measured in clinic between the groups that developed complications, and those who did not.

Conclusion: Flight appears safe for the majority of individuals with PAVMs and JHHT. It is difficult to predict who will experience complications. Recognition of potential thrombotic and haemorrhagic sequelae should influence pre-flight advice.

P2393

Is there an association between hyperthyroidism and PAH and, if yes, is pulmonary pressure decreasing after hyperthyroid treatment?

Ayssar Al Husein1, Sharo Muzzo, Jose Arroyo, Norbert Voelkel, Donatas Kraskauskas, Harm Bogaard. Internal Medicine/Pulmonary and Critical Care, Virginia Commonwealth University, Richmond, VA, United States

Rationale: About 30-40% of patients of idiopathic pulmonary arterial hypertension (IPAH) have thyroid dysfunction, in particular hyperthyroidism. Pulmonary vascular remodeling in IPAH is characterized by proliferation of vascular cells and thyroid hormones are known to promote angiogenesis (Mousa et al J Cardiovasc Pharmacol, 2005). We therefore hypothesized that hyperthyroidism would improve pulmonary vascular remodeling in a model of angio proliferative pulmonary hypertension (SuHx model).

Objectives: To clarify the effect of thyroid hormone on pulmonary vascular remodeling in SuHx treated rats.

Methods: PaH was induced by the combined exposure of rats to the VEGF receptor blocker SU5416 and hypoxia (SuHx). Hypothyroidism was induced by PTU (10mg/kg, 3times a week), two weeks after the initial SU5416 dose (SuHx rats). RF function was determined by echocardiography. Right ventricular pressure was measured by direct insertion of a conductance catheter into the heart.

Results: In SuHx rats, pulmonary vascular remodeling and pulmonary hypertension were decreased after PTU treatment and completely suppressed after thyroideectomy.

Conclusions: Thyroid dysfunction may affect the progression of pulmonary vascular cell proliferation in patients with PAH.

P2394

Immunosuppression in systemic lupus erythematosus associated pulmonary arterial hypertension (SLE-PAH): Improvement in exercise and functional capacity

Yon Sung1, Judith Ashouri2, Roham Zamanian1, Lorinda Chung1,2,4. 1 Division of Pulmonary/Critical Care, Stanford University School of Medicine, Stanford, CA, United States; 2Department of Internal Medicine, Stanford University School of Medicine, Stanford, CA, United States; 3Division of Rheumatology, Stanford University School of Medicine, Stanford, CA, United States; 4Division of Rheumatology, Palo Alto Veterans’ Affairs Health Care System, Palo Alto, CA, United States

Evidence suggests that inflammation plays a role in the pathogenesis of SLE-PAH. We aimed to assess the effect of aggressive immunosuppression (IMM) added to PAH-specific therapy in SLE-PAH. Stanford’s PAH database was searched for patients who met American College of Rheumatology (ACR) criteria for SLE and had PAH by right heart catheterization. Those who met ACR criteria for other connective tissue diseases or had <6 months of follow-up were excluded. Patients given IMM compared to those on PAH-specific therapy only (non-IMM). Cumulative probability of freedom from worsening New York Heart Association functional class (FC) was calculated with the Kaplan-Meier estimator and compared by the log rank test. Mean changes in parameters between groups were compared by Student’s t-test. Thirteen patients met inclusion criteria; 6 were treated with IMM (3 high dose steroids+mycophenolate mofetil, 2 intravenous cyclophosphamide, 1 hematopoietic stem cell transplant). Mean follow-up was 12.9 months. There was no significant difference in baseline demographics, SLE features, duration of PAH, hemodynamics, FC, 6 minute walk distance (6MWD) or PAH-specific therapy between IMM and non-IMM groups. At follow-up, hemodynamics and PAH-specific therapy did not differ between groups. Mean improvements in FC (-1.2 vs 0.1, p=0.06) and 6MWD (+231 vs -20, p=0.02) were higher in the IMM group. The IMM group had more infections (1.8 vs 0.3, p=0.05), but the percent of patients with serious infections did not differ (33% vs 14%, p=0.56). IMM added to PAH-specific therapy may improve functional and exercise capacity in SLE-PAH.

P2395

Monitoring of liver function in patients with pulmonary hypertension treated with endothelin receptor antagonists: The value of a novel monitoring system

Charlotte Blewett, Eleanor Lunn, David Kiley, Lisa Martin, Judith Hurdman, Neil Hamilton, Iain Armstrong, Paul Septon, Jane Wilkinson, Robin Condliffe, Charlie Elliott. Sheffield Pulmonary Vascular Disease Unit, Royal Hallamshire Hospital, Sheffield, South Yorkshire, United Kingdom

Background: Endothelin receptor antagonists are used for treatment of pulmonary arterial hypertension (PAH). However, these drugs have been associated with liver injury and patients require regular monitoring of liver function (LFT). We introduced a postal system whereby patients receiving these therapies had blood taken by their local practitioner and sent pre packaged boxes to our centre for analysis and monitoring on a monthly basis.

Objective: To evaluate the efficacy of surgery in the blunt traumatic diaphragmatic lesions.

Material and methods: From 1990 to 2010 a total of 24 patients (pts) (3 female and 21 male, mean age 47.1y) were operated on. Time from trauma to surgery varied between 4 months to 8 years. The left hemidiaphragm was injured in 17 cases, while the right one in 7. The thoracic trauma was associated with other injuries in 10 pts. In 3pts incarceration of herniated visceral segment was observed. In 2 pts herniated stomach had been drained for “pneumothorax” and emergency surgery was carried out.

Results: Laparotomy was applied in 3 pts with stomach volvulus. In 21 cases thoracotomy was the surgical approach. Stomach, colon, small bowel, omentum and spleen were most frequently found to herniated through the left diaphragmatic defects, whereas colon and liver were mostly seen in the right enterothorax. In 1 patient transdiaphragmatic splenectomy was carried out because of a severe induration. Dense adhesions were found in all cases. Mayo technique was performed in 19 pts for diaphragmatic repair. Marlex mesh was used in 4 pts and in 1 case an original technique for repair of enormous diaphragmatic defect with pericardial flap was carried out. Uneventful postoperative period was observed in all but one patient.
Objectives: Spirometry was assessed in patients before and after full-length phrenic nerve transfer surgery.

Methods: 16 patients (13 men; 7 to 58 years old) with brachial plexus injury underwent full-length phrenic nerve transfer. By video-assisted thoracic surgery the phrenic nerve was severed at a location just before its entry into the diaphragm, harvested from the thoracic cavity, and transferred to the musculocutaneous nerve. The median time between injury and surgery was 5.5 months (range 2.8 to 10.2). Patients underwent follow-up evaluation 1.4 to 16.4 months with manual muscle testing and spirometry; 3 patients were eventually lost to follow up.

Results: Baseline spirometric parameters were normal. Although no patient experienced pulmonary problems or respiratory complaints following the surgery, we observed a significant reduction of forced vital capacity (FVC), forced expiratory volume in 1 second (FEV1), and FEV1/FVC, respectively, to 68% of predicted values (±17; p<0.001) and 81% (±17; p=0.03). The percent variation of FVC was -22% (±11; range -49% to -6%). We observed a negative dependence between FVC and length of time after surgery (Figure: The majority of patients exhibit motor improvement on the arm.

Conclusion: Although preliminary, our results point to a significant impact of the surgery to spirometric parameters. This impact improves with the time after surgery.

P2400

Omentoplasty in rabbit for the repair of diaphragmatic defect and adhesion assessment of viscera to propylene mesh.

A. M. Khosroshahi1, A. H. Pourmoghaddam2, N. Malekifard2
1Department of Surgery, Kashan University of Medical Sciences, Kashan, Iran; 2Microbial Research Centernty, Kashan, Iran

Background: The use of synthetic mesh for the repair of major congenital diaphragmatic hernia may cause visceral adhesion to prosthesis and ongoing complications. In present study the use of propylene mesh for the repair of diaphragmatic hernia and its role in eliminating of visceral adhesion to repair site is evaluated.

Materials & methods: This experimental study was carried out on 20 adult New Zealand rabbits (age: 6 months) assigned randomly into two equal groups. In one group, after laparotomy a defect (size: 1×1 cm) was created on the diaphragm. The suture was then repaired by sterile propylene mesh and nylon suture (thickness: 3/0; 4/0). In another group, omentum was fixed on the mesh using a nylon suture (thickness: 3/0). After 30 days the two groups were operated and the visceral adhesion to repair site was compared using Muzafi scale.

Results: Nine (90%) out of 10 rabbits with propylene mesh repair had visceral adhesion to the repair site. On classifying the grade of adhesion among the cases, one, three, four and two rabbits were assigned the “I”, “II”, “III”, and “IV” grades, respectively. On the other hand, 4 (40%) out of 10 rabbits, in which the diaphragm was repaired by propylene mesh and omentoplasty method, visceral adhesion (grade “I”) was seen to the site of repair. The rest of animals displayed no such adhesion (P=0.015).

Conclusions: Omentoplasty after repair of large diaphragmatic defect with propylene mesh reduces the visceral adhesion to propylene mesh, so in intraabdominal operations which propylene mesh is used, omentoplasty also is recommended.
There were 32 consecutive patients in a single city state hospital in Turkey. Median age of the patients was 42.4 (22 min 78 max). There were 27 male and 5 female patients. Admission to the ER were due to blunt trauma caused by falling down or motor vehicle accident. The patients who needed to have chest tube insertion either due to pneumothorax or hemorarx were excluded from the study. The Visual Analog Pain Scale was asked every patient before starting treatment. Mean value was 7.8 were patients with fractured ribs (n=12) and 7.3 for the patients without fracture in the ribs (n=20). After the intercostal blockage and the analgesic treatment themean values decreased to 4.2 and 4 respectively in the following 24 hour. The patients discharged from the hospital in the following 3-4 days. The injection of bupivacaine 5% was to 1ml to 3 levels. First was to the site having the most severe pain to the palpation plus one level up and down with the well known standardized method. The procedure was repeated every day during the hospitalization period.

Application of 5% bupivacaine into the intercostal space to patients having pain is safe and effective. It decreases the Visual Analogue Pain Scale rapidly, need for non opioid analgesics and decreases the hospitalization period and possible morbidities due to secretion retention. It evidently improves the patients comfort.

**Effectiveness of treatment of transdermal narcotics in rib fractures**

Okan Solak1, Hidir Esme1, Kubilay Ocalan1, H. Volkan Kara2, Nurul Tutar2.

1. Department of Thoracic Surgery, Atyon Kocatepe University, Atyon, Turkey; 2. Department of Thoracic Surgery, Gumushane State Hospital, Gumushane, Turkey

Ribs fracture is the most common pathology in thoracic traumas. Severe pain is the most common symptom. The use and dosage of narcotic analgesics in the early period is controversial. Our aim is to investigate the efficacy of transdermal release (TR) narcotics in these patients. There were consecutive 25 patients who had diagnosis of rib fractures. Patients in group 1 (n=10) had intercostal nerve block (by bupivacain 0.5%), intramuscular narcotic (meperidine) according to the weight of the patient and paracetamol per orally. Patients in group 2 (n=15) intercostal nerve block (by bupivacain 0.5%), transdermal release (TR) narcotics (fentanyl) and paracetamol orally. We used Visual Analog Scale (VAS) for scoring the pain. The efficacy of treatment is evaluated by calculation and scoring of VOAS both at exertion and relaxation. The sedation that might be by the narcotic agents was followed by Ramsey Sedation Scale (RSS) and arterial blood gases. The study was ended in the fifty day. There were no difference for age, gender, type of trauma, additional pathologies number of fractured ribs and their localization between the two groups. Both groups had improvement for VAS before and after treatment. The VAS improvement in group 2 was better in both in relaxation and activity for the 5 days.

It is difficult to establish the effective blood levels of parenteral narcotics so that there is continuous need for repetitive administration of the drugs. In TD applied narcotics the blood levels of the drugs are stable. The use of narcotics transdermally instead of parenteral administration was more effective and comfortable by the way of administration according to our study results.

**P2404**

**Chest wall stabilization with titanium clips and rib bridge: Four case reports**

Kuthan Kavaklı1, Ervin Sapraz1, Mehmet Đakak2, Orhan Yucel1.

1. Department of Thoracic Surgery, Gulhane Military Medical Academy, Ankara, Turkey; 2. Department of Thoracic Surgery, TOBB ETU Hospital, Ankara, Turkey

Introduction: Chest wall stabilization has a paramount importance. Herein, we aimed to present our experience with the using titanium clips and rib bridges in the chest wall stabilization.

Case 1: A 50-year-old man was referred to our clinic with multiple rib fractures on the left side, bilateral lung contusion, left sided pneumothorax and left clavicular fracture. A chest tube has been inserted to the left side and he has been extubated because of respiratory insufficiency. He was extubated successfully. Although the lung contusion resolved, his blood saturation decreased frequently due to flail chest and secretion retention. We performed 5th,6th and 7th ribs stabilization with titanium rib clip with 9 segments.

Case 2: A 73-year-old man admitted with chest pain and dyspnea. He had a motor vehicle accident two months ago and he had treatment for multiple rib fractures (4,5,6 and 7 ribs) and hemorarx on the right side. He underwent 4th and 5th ribs stabilization with titanium rib clip with 4 and 5 segments.

Case 3: A 21-year old male admitted with the unstable anterior chest wall. He was operated two times for deformity. His clinical presentation was compatible with floating sternum as a long-term complication. He underwent sternum stabilization with two implant bridges. He was discharged on the 5th postoperative day.

Case 4: A 58-year old male admitted with right upper lobe tumor which was invasive to the anterior chest wall. He underwent right upper lobectomy with chest wall resection including 2,3 and 4 ribs. We placed an implant bridge on the 3th rib.

Conclusion: Rigid materials such as titanium clips and titanium rib bridge are good alternative choice for the stabilization of chest wall.

**P2405**

**Intercostal nerve blockage for pain control in blunt thoracic trauma**

H. Volkan Kara1, Nurul Tutar2, Selma Yesilyasak1, Gokhan Ertas2, M. Erdem Memetoglu2, Kadir Agladigolu1, A. Seckin Cetinakaya2.

1. Department of Thoracic Surgery, Gumushane State Hospital, Gumushane, Turkey; 2. Department of Chest Diseases, Gumushane State Hospital, Gumushane, Turkey

Blunt thoracic traumas are common clinical occasions in the emergency rooms. There are several approaches in the medical management of these patients. In this study we evaluated the the safety and efficacy of application of long acting local anesthetic bupivacaine 5% in to the intercostal space.

Surgery: The surgical approach was very simply with incision and drainage.

Postoperative outcomes: The evolution was very good with discharge of the patient 7 days after.

Discussion: The principal diferential diagnosis was the cold abscess, but all analyses were negative and the evolution was favorable without specified treatment.
Minimally invasive repair for pectus excavatum (Nuss procedure) – Aesthetic and/or functional? 
Constantin Goroava, Mihai Iliaș, Dragos Marin, Daniel Pantile. Thoracic Surgery, Spitalul Universitar de Urgenta Militar Central “Carol Davila”, Bucharest, Romania

Background: Pectus excavatum is the most frequent anterior thoracic wall congenital malformation. Among teenagers, when the esthetics and clinical symptoms become increasingly important, pectus excavatum becomes a psychological problem. During the time many treatment techniques have been proposed, conservative or surgical. The minimally invasive repair technique of pectus excavatum, Nuss technique, developed after 1986, is now the most used technique worldwide. 

Objectives: Our study aimed to analyze the degree of patients satisfaction regarding the esthetic results after the minimally invasive repair of pectus excavatum, as well as the improvement of respiratory functional parameters.

Method: We will present some historical data related to surgical repair of pectus excavatum, advantages and disadvantages of open surgery; also we will present clinical and paraclinical evaluations, including anthropometric indexes, as well as indications and contraindications of Nuss technique and possible intraoperative and postoperative complications.

Our study was carried out on a group of patients with pectus excavatum, who have been submitted to Nuss technique, during a timeframe of 4 years (2007 – 2011), aged from 8 to 38 years. Prior to surgery the patients were submitted to a standard protocol of investigations.

Results: We present the benefits of Nuss technique and the improvements of the functional and aesthetical indexes.

Conclusions: Nuss technique is an efficient method, with very good aesthetical and functional results, allowing quick social and professional patients’ reintegration, as well as an improved self-image and self confidence.

Tracheal stenosis in children, old problem, new techniques
Theodor Zimmermann1, Robert Cesnavičius2, Sven Dittrich3, Martin Göessler1, Tanja Redkow1,4. 1Pediatric Pneumology, Kinder- und Jugendklinik, FAU Erlangen-Nürnberg, Erlangen, Germany; 2Pediatric Cardiology, Kinder- und Jugendklinik, FAU Erlangen-Nürnberg, Erlangen, Germany; 3Pediatric Cardiography, Kinder- und Jugendklinik, FAU Erlangen-Nürnberg, Erlangen, Germany; 4Radiology, Kinder- und Jugendklinik, FAU Erlangen-Nürnberg, Erlangen, Germany

Tracheal stenosis is an unusual and sometimes lethal condition. Imaging: HR-CT-Thorax and volume rendering technique. With the flat detector CT it is possible to visualize the relationship between trachea and the great vessels with high spatial resolution during cardiac catheterization. During surgery, children are on the heart-lung-machine (Stockert S-5, priming volume 200ml, D 100 kids oxygenator). The tracheal surface is usually exposed via median sternotomy. In case of sliding plastics cardiopulmonary bypass (CBP) is used. Surgery is performed on the empty beating heart at 30-32°C. Two arterial cannulas are used (innominate artery and ascending aorta) in order to disconnect the innominate artery temporary from the ascending aorta. In the present of LSS a slide plasty with bronchosopic control is performed. Tracheal stenosis from external compression is released with CBP by aortopexy or resection of compressing ligaments (if additional Tracheomalacia is present an external suspension is used. In the case of ventilatory problems veno-venous-ECMO using a bilumen catheter for CO₂-elimination can be used. The postoperative care is characterized by a longer time of mechanical ventilation (up to weeks) and a difficult weaning from the respirator. A modified heart-lung-machine (Stockert S-5, Highlight 800 Oxigenator MEDOS) may be used at the ICU, if necessary. We report 3 children suffering from different types of tracheal stenosis.

Conclusion: A highly specialized team and individual management are essential for good results. No surgical technique corrects all of the anatomic variants of this disease. Long-segment tracheal stenosis is best treated using slide tracheoplasty and concomitant repair of cardiovascular lesions.

Surgical treatment of primary malignancies of trachea
Igor Mosun1, Nina Mosun1, Olga Lukina2, Yana Dorofeeva1. 1Department of Thoracic Surgery, St.Petersburg Pavlov’s State Medical University, St. Petersburg, Russian Federation; 2Radiology, St.Petersburg Pavlov’s State Medical University, St. Petersburg, Russian Federation

The main treatment of patients with primary malignant tumors of the trachea is endoscopic recalcanalization of the trachea lumen with stenting and radiotherapy. Radical surgery of the trachea primary malignancies is single-step circular resection with end-to-end Anastomosis.

The aim was to demonstrate that a single-step circular resection is possible when tumor extension is 45% of the trachea length, with involvement of the epiglottis subfold portion. 18 single-step circular resections were performed in patients with primary tumor of the trachea. Adenocarcinoma of the trachea was diagnosed in 13 patients, and typical carcinoid - in 5. Among them over 45% of trachea was resected in 10 patients. Localization and extension of the tumor was established by fibbron-choscopy, and MDCT. Tumor extension from 1.0 to 3.0sm was diagnosed in 8 patients, and from 3.0 to 6.0sm – in 10 patients. Single-step circular resections and tracheostomal anastomosis were performed in 7 patients, laryngotracheal anastomosis - in 6, and a laryngotracheal resections were made in 5 patients. Immediate and prospective results of the treatment are considered to be sufficient in all patients. In Pearson-Grillo laryngotracheal resection the distance between the anastomosis and vocal cords varied from 1 sm to 3 sm.

Single-step circular resection is the only radical surgical treatment of primary trachea malignancies. Subfold portion involvement is not a contraindication to a single-step circular resection of the trachea and subfold portion of the epiglottis. Postoperatively, a single-step circular resection for adenocarcinomatous cancer must be followed by radiotherapy.

Congenital tracheal diverticulum seen in adult age: Two cases
Aytuk Elifçioğlu1, Serif Tuba Liman1, Salih Topçu1, Aliş Gül Akgül1, Hasan Tahsin Sarısoy2, Seyitpaş'a Gümüştay2, Seynur Salih Mehmetoğlu1, Ahmet İzgi2, 1Thoracic Surgery, Kocaeli University, Kocaeli, Turkey; 2Radiodiagnostic, Kocaeli University, Kocaeli, Turkey; 3Pulmonary Diseases, Kocaeli University, Kocaeli, Turkey

Tracheal diverticulum is a very rare entity. Congenital ones appear 4-5 cm below the vocal cords and in right lateral wall of trachea. Usually diagnosed incidentally. We present here two tracheal diverticulum diagnosed incidentally.

Case 1: A 65-year old male patient was admitted to our clinic with back ache and cough. The CT scan of the chest showed posterior mediastinal mass and tracheal diverticulum which was in the middle of trachea at posterolateral wall. Fiberoptic bronchoscopy demonstrated the communication between the trachea and the diverticulum. The patient was operated because of posterior mediastinal mass, not considered for tracheal diverticulum.

Case 2: A 51-year-old male patient was admitted to clinic of nephrology with chronic renal failure. The patient was referred to our clinic with dyspnea. The CT scan of the chest showed pleural effusion and a tubular air-filled structure, which was adjacent to the posterolateral wall of the trachea at the level of thoracic inlet. Fiberoptic bronchoscopy demonstrated a communication between trachea and diverticulum. The patient was treated conservative management with antibiotics and bronchodilators.

Tracheal diverticulum include surgical resection and conserva-
tive management. Treatment options change depending on the patient’s symptoms, age and physical state. Surgery is recommended for symptomatic patients, conser-
vative medical treatment for elderly and debilitated patients.

Intraoperative management of tracheobronchial ruptures after double-lumen tube intubation
Kenan Can Ceylan, Seyda Ors Kaya, Ozgur Samancilar, Ozan Usluer, Soner Gursay, Ahmet Ucvet. Thoracic Surgery, Dr. Suat Seren Chest Diseases and Thoracic Surgery Training and Research Hospital, Izmir, Turkey

Background: Tracheobronchial rupture is an uncommon but a potentially serious complication of endotracheal intubation. In this study, diagnosis and treatment strategies of a specific group of ruptures caused by double-lumen tube intubation is presented.

Methods: The medical records of 18 patients diagnosed and treated for tracheo-
bronchial rupture after double-lumen tube intubation between January 1999 and October 2010 is analyzed retrospectively.

Results: In all cases, the rupture occurred at the membranous part. The average length of the laceration was 2.44±1.78 cm. The most common localization of the rupture was at the lower third of the trachea (n=7, 39%) or at the left mainstem bronchus (n=5, 27%). One patient was diagnosed before the incision by fiberoptic bronchoscopy and 17 patients by direct vision of the rupture intraoperatively. All
patients are treated successfully with surgery. There was no any morbidty or mortality recorded related to the tracheobronchial rupture.

**Conclusions:** The thoracic surgeons must be alerted for any tracheobronchial rupture in patients that are intubated by double-lumen tube which is commonly used for thoracic operations. Immediate repair must be performed for any laceration which is diagnosed intraoperatively.

**P2412**

Perfection of diagnostic and tactic of stage-by-stage endosurgical treatment of cicatrical stenoses of a trachea

Shukhrat Hudaibergenov 1, Georgiy Pahomov 2, Otabek Eshkonldkhojoev 3, Insov Ortikali 1, Rustem Hayaliev 3, 1Department of Lungs and Mediastinum Surgery, Republican Specialized Centre of Surgery Named after Academician V.Yakhudin, Tashkent, Chilanzar Region, Uzbekistan; 2Department of Faculty and Hospital Surgery, Tashkent Medical Academy, Tashkent, Uzbekistan

**Background:** Research devoted to studying of complex treatment of cicatrical stenoses of trachea (CST) with use of various methods of stage-by-stage surgery including endoscopic laser photodestruction, bagging, stent insertion and tracheal resection are presented.

**Methods:** The analysis of results of diagnostics and endoscopic and surgical treatment of 101 patients with CST was made. 1 group have made of 44 (43.6%) patients at whom extent of a stenosis has made to 2 sm and 2 group have made of 57 (56.4%) patients with a long of cicatrical zone of a trachea more than 2 sm.

**Results:** After endoscopy in a case of restenosis were carried out by a following stage a circular resection at 36 patients. At 51 (50.5%) the patient endosurgical methods were independent and an effective treatment and have allowed them to avoid reconstructive surgery. At 29 (28.7%) patients endoscopic methods have served as a preparatory stage to a circular resection of a trachea. So in 1 group endoscopic method of treatment as stages of surgical corrections of CST was independent and effective at 28 (71.8%) from 39 patients, while in 2 group at 18 (36.5%) patients that is authentic twice less than in 1 group.

**Conclusion:** The diagnostic-and-treatment algorithm and tactics of combined stage-by-stage treatments with application of hi-tech methods of diagnostics and treatment depending on extent of CST is developed.

**P2413**

Evaluation of plethysmography findings as a diagnostic method for patients with post-intubation tracheal stenosis (PITS)

Seyed Mohammad Reza Hashemian, Hamid Reza Jamaati, Mohammad Behgam Shadmehr, Ollooz Alloosh, Negin Negin Alizadeh Shaygh, Golnar Radmand. Critical Care, NRITLD/Chronic Respiratory Disease Research Center CRDRC, Tehran, Islamic Republic of Iran; Thoracic Disease Research Center, NRITLD/BSMU, Tehran, Islamic Republic of Iran; Medical, George Mason University, Fairfax, VA, United States

**Introduction:** PITS is a serious disease can caused many diagnostic problems. It caused by cuff pressure during tracheal intubation. Generally, invasive diagnostic methods, based on fiber-optic or rigid bronchoscopy, are suggested for initial treatments.

**Aims and objectives:** This study aimed to evaluate the plethysmography findings, as a diagnostic method for PITS, and assess the relationship between plethysmography and bronchoscopy findings in patients with PITS.

**Methods:** The sample included 30 patients, who were admitted to an ICU or in a surgical ward during the course of a year and had been diagnosed with PITS. All patients after a history underwent plethysmography and then rigid bronchoscopy; and the relation between plethysmography and bronchoscopy findings was able to be examined.

**Results:** Regarding the relationship of the variables under evaluation by bronchoscopy with plethysmography findings, stricture intensity had the highest correlation with SRaw (resistance of upper airways) with a p-value = 0.001. The relationship of the length of stricture with FEV1, MEF 50 and MEF 75 was significant (P-value = 0.039, 0.042 and 0.036 respectively) in the univariate and with RV% and TLC% in the multivariate analysis.

**Conclusions:** Significant relationships were found between plethysmography and rigid bronchoscopy findings in patients with PITS; some statistical formulas were developed which allow medical practitioners additional opportunities to estimate the stricture intensity without bronchoscopy. Other significant relationships were also found - regarding the length of stricture - which affirmed the effectiveness of plethysmography for evaluation of patients with PITS.

**P2414**

Difficult intubation of the esophagus or trachea stent – When cervical muscle contractures combined with the narrowing. Descriptions of cases

Adam Rzechonch, Jerzy Kolodziej. Department of Thoracic Surgery, Medical University of Wroclaw, Wroclaw, Lower Silesia, Poland

**Purpose:** The muscle contraction is the main cause of difficulty of tracheal intubation. Self-expanding tube stents are typically placed using a rigid bronchoscope. How to do it by simultaneous occurrence of strictures and the stiff neck?

**Material:** We described 2 cases of patients with received prolonged mechanical ventilation in an intensive care unit. In both patients developed: stiff neck and tracheoesophageal fistula (TEF).

**Method:** The insertion of self-expanding stents has been found successful in both patients.

**Conclusion:** Stiff neck and narrowing of the trachea or esophagus, are a significant obstacle in the establishment of the stents. They should be taken into account in planning treatment. Use of fiberscope, guides and intubation tubes of increasing diameters is relative simple and cheap way to solve the problem.

**P2415**

Transcervical versus transternal approach of bronchial stump following pneumonectomy – Two methods in an open competition

Adrian Istrate 1, Cristian Paleru 1, Olga Danaila 1, Ciprian Lovin 2, Dan Ulmeanu 3, Ciprian Nicolae Bolca 1, Andrei Cristian Bobocca 1, Radu Serban Matuschi 1, Ion Cordes 1; 1Thoracic Surgery Clinic, National Institute of Pneumology ”Marius Nasta”, Bucharest, Romania; 2Thoracic Surgery Department, Emergency Clinical County Hospital, Galati, Romania; 3Thoracic Surgery Department, Emergency Clinical Hospital “Elia”, Bucharest, Romania

**Introduction and objectives:** Bronchial stump dehiscence after pneumonectomy was classically treated tough transternal transthoracic approach, method developed in the 60’s. In 1996, Azorin, performed first bronchial transcervical approach.

**Methods:** Between March 2001 and February 2010 in our Clinic, we performed 15 cases of transternal transthoracic approach (6 cases of left primitive bronchial fistula) and 2 cases of transcervical approach of the left bronchial stump fistula.

**Results:** In transternal transthoracic approach: M:F = 12:3. 11 neoplastic (73.57%)/4 TB empypema, 4 cases early (<30 days) fistula and 10 cases of late fistula. 1 case of pulmonary artery lesion, no mortality, fistula recurrence in one case (one line stapled bronchus). The average hospitalization was 7 days and clinical follow-up was between 2 and 56 months. The transcervical approach: M:F = 1:1, both empypema. Mean operating time was reduced to 40 minutes, related to 150 minutes of the transternal transthoracic approach, with full mobilization of the patients second day after surgery and a hospitalization of 3 days. Clinical follow-up was between 2 – 16 months.

**Conclusions:** Even that transternal approach of the bronchial fistula remain a major option, the new transcervical approach offer in selected cases an non-traumatic, non-shocking alternative, with very good result. Good experience in mediastinoscopy is required.
P2416
Efficiency of nebulised therapy in preventive maintenance of bronchial stump insufficiency after pneumonectomy
Shahrat Hashimovici1, Georgy Pahomov1,2, Rustem Hayaliev1,2, Oktarii Isroili1, Otbebek Eshonboldiezhaev1,2, Ezof Rizaevi1,2,1 Department of Surgery of Lung and Mediastimum, RSCS Named after Acad. V.Vahabov, Tashkent, Uzbekistan; 2Hospital Surgery Kafedra, Tashkent Medical Academy, Tashkent, Uzbekistan.

Introduction: Introduction for preventive maintenance COPD nebulised therapy (NT) promotes the high local activity of inhaled remedies.

Purpose: To value efficiency of NT in preventive maintenance of bronchial stump insufficiency (BSI) after pneumonectomy (PE).

Material and methods: The interests results were received at study of the in-fluence accompanying pathology on frequency of development BSI after PE. The frequent diseases were COPD and heart-vascular pathology. So from 390 patients in 207 (53.1%) accompanying COPD was revealed, on background which after PE in 36 (17.4%) patients was noted development of BSI. In turn, amongst 183 (46.9%) patients without accompanying COPD this complication was noted only in 2 patients (2.2%). Such presence of COPD raised the risk of the development BSI more then in 6 times.

Results: Introduction NT has allowed in the main group to reduce the risk of the intensification COPD to 16.1% after PE on the left and 17.2% after PE on the right, and frequency of the development of BSI on background accompanying COPD decreased to 3.2% and 6.9% accordingly. In the main group accompanying COPD was revealed in 60 patients (61.2%), activation after operation was noted in 10 (16.7%) patients, but development of BSI only in 3 patients, that has formed 5.0%.

Findings: Introduction of NT for preventive maintenance COPD promotes not only reliable improvement of the factors of breathing frequency (P <0.002) and functional respiratory tests (P <0.001), but also reduction of the frequency of the intensification of obstructive syndrome from 52.4% to 16.7% that led to reduction of the risk of development BSI from 16.5% to 5.0%.

P2417
Diagnostic surgical lung biopsy in hematologic patients with pulmonary complications
Liliyan Junker1, Jörg Halter1, Franco Gambazzi2, Daiana Stelz1, Lukas Bubendorf2, Dominik Heim1, Martin Stern2, Christoph Buecher1, Didier Lardinois1, Michael Tammen1, 1 Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital Basel, Basel, Switzerland; 2 Clinic of Hematology, University Hospital Basel, Basel, Switzerland.

Pulmonary infectious and non-infectious complications are frequent in hematologic patients with liver or persistent infectial bronchoscopiy is performed. However in a considerable number of cases bronchoscopy is inconclusive and lung tissue needed to achieve a definitive diagnosis. We assessed the diagnostic yield and risk of VATS biopsy or open lung biopsy (OLB) in hematologic patients suffering from pulmonary complications. 81 patients with a mean age of 47 years underwent VATS (73%) or OLB (27%) from 2000 to 2010. 49 patients underwent allogeneic and 7 autologous SCT, 21 had high dose chemotherapy. Examinations revealed an infectious agent in 6 (Tbc, 2 PEP, 2 bacterial, echinococcus), bronchiolitis obliterans in 23, organizing pneumonia in 8, diffuse alveolar damage in 8, NSIP in 2, and lymphoma in 3 cases.

There was no perioperative death. A prolonged ICU stay (>72hours) was observed in 11 cases. 5 of these patients were already on the ICU prior to surgery. Re-operation was needed in 6 cases. No wound infection was observed. Thorax drainage was prolonged (>5) in 12 patients (15%). One patient developed a pneumothorax 12 days after VATS during a flight. 30-day mortality was 7% (6/81): 4 diffuse alveolar damage, 1 fungal infection/renal failure and 1 OP/renal failure. 2 of the 6 deaths occurred in patients already ventilated prior to surgery.

Summary and conclusion: The diagnostic yield of lung biopsy in hematologic patients is very high directly affecting patient management. The risk of the surgical procedure itself is acceptable. Mortality is increased in patients ventilated prior to surgery and in those with diffuse alveolar damage on histology.

P2418
Lung biopsy predicts outcome in bronchiolitis obliterans following allogeneic stem cell transplantation
Andreas Holbrueder1, Jörg Halter1, Spasenija Savic1, Lukas Bubendorf1, Dominik Heim1, Martin Stern2, Christoph Buecher1, Didier Lardinois1, Michael Tammen1, 1 Clinic of Hematology, University Hospital Basel, Basel, Switzerland; 2 Department of Pathology, University Hospital Basel, Basel, Switzerland.

Graft versus Host Disease (GvHD) is a serious complication following allogeneic stem cell transplantation. Lung involvement with a decline in FEV1 is a pulmonary manifestation of GvHD which occurs in 5 to 8% of SCT recipients. Early studies showed that bronchiolitis obliterans (BO) is the histological correlate of pulmonary GvHD and associated with a high mortality. In our institution VATS biopsy is still considered the gold standard to diagnose bronchiolitis obliterans, after pulmonary infection has been excluded by BAL. In this study we analysed the histological pattern and outcome of 22 patients with biopsy proven bronchiolitis obliterans. There were no major surgical complications of VATS in this immunocompromised patient group. Twelve patients showed conspicuous bronchiolitis obliterans (CBO) on biopsy whereas there was lymphohytic bronchiolitis in 10 cases (LBO). Median duration until diagnosis was 43.6% in CBO and 62.6% in LBO. There was no difference in age, underlying hematologic disease or pretreatment between the two groups. Almost all patients suffered from chronic GvHD. Median time to the diagnosis of bronchiolitis obliterans after allogeneic SCT compared to 703 days in LBO. FEV1 markedly improved in the majority of cases with LBO whereas FEV only partly improved in patients with CBO. Six patients died in the CBO group as compared to only one death in the LBO group.

Conclusion: The histological pattern of lymphohytic bronchiolitis obliterans is associated with a much better prognosis as compared to conspicuous bronchiolitis obiterans following allogeneic stem cell transplantation. We recommend to perform VATS in patients with suspected bronchiolitis obiterans.

P2419
VATS lung biopsy is the method of choice for patients with ambiguous pulmonary pathology to establish a morphologic diagnosis
Mikle Pikunov, Yuriy Esakov, Thoracic Department, A.V. Voinozhskogo Surgery Institute, Moscow, Moscow, Russian Federation.

Objective: In spite of intensive development of diagnostic tools in pulmonology such as HRCT, PET, bronchoscopy examination peripheral lung biopsy (PLB) and interstitial lung diseases (ILD) are often require excision lung biopsy for the morphological diagnosis. We evaluate the efficiency and safety of the VATS lung biopsy in the final diagnosis for patients with ambiguous cases.

Methods: 210 patients with PLL (group I) and 87 patients with ILD (group II) were enrolled. Mean age: 54.4±2.0 y. We used HRCT for lesion(s) visualization in all cases. All patients in both groups underwent VATS lung biopsy and morphological investigation of the specimens to establish a final diagnosis.

Results: In accordance to preoperative examination in group I there were: neoplasm’s, tuberculosis and hamartomas. In the group II there were suspicions to sarcoidosis, idiopathic pulmonary fibrosis (IPF), diffuse chronic lymphogenous-oinomiatosis (LAM). Morphological diagnosis was obtained in all cases. We found benign neoplasm 39%, early forms of lung cancer in 42%, tuberculosis in 12%, metastatic disease 4.2%, carcinoid tumors in 2%, and nodal fibrosis in 5.6% of all specimens in group I. In the group II there were sarcoidosis (48%), IPF (26%), alveolitis (24%) and LAM (2%). Accuracy of preoperative examination was 91% and 66% in the first and second groups respectively.

Conclusion: VATS lung biopsy provides adequate specimen volume for morphologic diagnosis and associated with 100% diagnostic accuracy. Minimal postoperative morbidity and mortality rates are justified this procedure as a method of choice for patients with ILD and PLI.

P2420
Surgical treatment for lung metastases in patients with colorectal cancer
Adam Rzechonok, Jerzy Kolodziej, Marek Lubicz. Department of Thoracic Surgery, Medical University of Wroclaw, Wroclaw, Lower Silesia, Poland

Introduction: The paper presents a history of surgical treatment for lung metastases from colorectal cancer and subsequently an analysis of the treatment results, presenting some differences of lung metastasectomy.

Materials and methods: A review of the literature from the years 2000-2010 for the resection of metastatic tumors of colorectal cancer and our experience and results from the material of 60 patients operated in our unit in 2004-2007.

Results: Pulmonary metastasectomy of the secondary lesion of the colon gives the best results in cases of primary low pathological staging of a resectable primary colorectal cancer (T1 to T2 preferably limited to 3 number of lung metastases after a one metastasis to the liver disease in free time exceeding 12 months and the normal level of intestinal-embryonic marker (CEA). Conversely-factors pleading for the surgical resection renouncement for metastases are: medium and high degree of advanced colorectal cancer (3A-4, N1-2), multiple metastases to the lung or liver disease-free time of less than 12 months and an increase in serum CEA (above 10 ng/ml).

Conclusion: 1. Results of surgical treatment of metastatic colorectal cancer encourage a wider patient eligibility among into account prognostic factors. 2. Decisions about the way of surgical treatment for metastatic disease should be taken...
based on the assessment of the patient (organ function), number of metastases, and the value of CEA. 3. Regardless of the primary cancer focus, the G feature of differentiation, the number and size of metastases surgical resection extend patients life.

P2421
The role of VATS in the staging of non small cell lung cancer
Reza Baghiri, Zaouliah Haghj. Thoracic Surgery, Mashhad University of Medical Science, Mashhad, Islamic Republic of Iran

Introduction: One of the points discussed in NSCLC always has been to use staging method with high accuracy, including broncoscopy, CT scan, PET scan and mediastinoscopy.

Another completing method for staging is VATS. In our study we decided to evaluate diagnostic accuracy of VATS for staging of NSCLC.

Material & methods: The case series study was performed on 40 NSCLC patients from 2007 to 2010.After complete preoperation evaluations (history and physical exam, CXR, CT scan, broncoscopy, TTNB and mediastinoscopy if needed in some cases), patients without criteria of inoperability have been reevaluated with VATS staging before the surgery. Thoracotomy was performed after VATS, when we didn't have any exclusion criteria for surgical resection. We evaluated diagnostic accuracy of VATS.

Results: 40 patients were studied (M/F = 21/19), the mean age was 57 year. The most common symptom was coughing (%90). The most common finding of CT scan of the patients was mass lesion in 100% patients. The endobronchial lesion was in 29 patients. We performed bronchoscopy on 7 patients for staging because of N2 lymph node size more than 1 cm, which was negative finding for metastatic involvement. 6 patients haven't been candidates for surgical resection after pulmonary resection. VATS was performed for plural sedimentation in 2 N2 lymphatic involvement, and one for stellate lesion in other lobe. Thoracotomy was done on 34 patients. Operation was successful in 31 patients complete resection and failed in 3 patients due to hilar extension of tumor. The diagnosis accuracy of VATS was 92.5%.

Conclusion: According to high diagnostic accuracy and easy to performance of VATS we recommend it to be done before surgery.

P2422
Therapeutic pulmonary metastasectomy for colorectal cancer should be chosen in any disease-free interval, size of tumor, and carcinoembryonic antigen level
Masao Nanako. General Thoracic Surgery, Eiju General Hospital, Tokyo, Japan

Aims: We retrospectively review our experience of pulmonary resection of metastases from colorectal cancer, in order to document postoperative clinical outcome and survival.

Methods: From 2003 to 2010, in 16 patients, 19 pulmonary metastases from colorectal cancer were therapeutically resected in our hospital (9 were rectal and 7 were colon, 10 males and 6 females; mean age 66.3 years). The indication for these metastasectomies was based on Thomford’s advocacy. They were analyzed retrospectively to calculate prognosis, and reviewed to verify their disease-free interval (DFI), interval between resection of primary tumor and diagnosis of lung metastasis, size of largest resected metastasis, pre-metastasectomy carcinoembryonic antigen (CEA) level with the reported prognostic factor. After lung metastasectomy, patients were followed up for 2-95 months (median: 45.5 months).

Results: There was no operative mortality. Complications occurred 3 out of 16 patients (19%) but were major only in 1 (6%). Overall, 3- and 5-year survival rates, from the date of pulmonary metastasectomy were 78.6% and 48.1%, respectively. The mean of DFI was 19.9 months (0-99), the mean size of largest resected metastasis was 22.6mm (9-60), and the mean of pre-metastasectomy CEA level was 5.1 ng/ml (1.0-32). These factors were not associated with longer survival.

Conclusion: Based on our experience, a good prognosis can be expected after therapeutic pulmonary metastasectomy for colorectal cancer regardless of factors such as DFI, size of metastasis, pre-metastasectomy CEA level.

P2423
A rare solitary pulmonary plasmacytoma case
Hakan Kiral, Turan Ceylan, Mustafa Kupeli, Levent Alpay, Erdal Okur, Irfan Yalcinkaya. Thoracic Surgery, Sureyyapasa Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey

Solitary pulmonary plasmacytoma is extremely rare tumor therefore, we present a case report of such a tumor. A 61-year-old Turkish woman presented with a 10-month history of chest pain. Chest radiography showed homogenous opacity and obliteration of left costophrenic sinus. Chest computed tomography revealed a heterogeneous mass measuring 439s
Salvage lung resection for local recurrence after stereotactic body radiotherapy for primary and metastatic lung cancers

Background: Among the pneumonectomy patients we have operated, we have often faced the situation when recurrence appeared after SBRT.

Methods: We retrospectively reviewed 9 patients (3 with stageII-Inon-small cell lung cancer and 6 with metastatic lung tumors) who underwent salvage surgical resection for local recurrence after SBRT.

Results: Of the 9 patients, 7 underwent lobectomy, and the remaining 2 did bilobectomy and segmentectomy, respectively. 2 with metastatic lung tumors had pleural adhesion resulted from SBRT-related fibrosis. However, there was no case in which SBRT made surgical procedure impossible. Retrospectively considering the course after SBRT, once all 9 irradiated tumors resulted in disease progression, they grow in size rapidly.

Conclusions: We have treated all patients without major technical difficulties by SBRT-related change. SBRT did not close the door to perform salvage surgical resection, and surgical resection might be feasible for local recurrence after SBRT. However, close follow-ups are mandatory for patients treated with SBRT because tumor regrowth after SBRT is thought to occur at a rapid rate. And if patients are medically fit for surgery as the first line treatment, the use of SBRT should not be decided by only reason of its less invasiveness.

P2427

Surgical treatment of postoperative chylothorax with thoracoscopy

We studied the results of the examination and treatment of 14 patients with postoperative chylothorax for the period from 1999 to 2010. There were 11 men (78.6%) and 3 women (21.4%), the mean age was 45.5±6.4 years. Pleural effusion in all patients was one-sided, i.e. on the side of the operation.

The cause of chylothorax of all the patients was surgery in the thoracic cavity - thoracotomy with resection of the lung and mediastinal lymph dissection (8 cases), lung resection without lymph dissection (2 cases), mediastinal tumor resection (3 cases), and pneumonectomy with intrapericardial vascular root of lung (1 patient). Pleural effusion during chylothorax is rated as the milky in 6 (42.9%) cases, fester in 1 (7.1%), serous in 4 (28.6%) and hemorrhagic in 3 (21.4%) cases. The average concentration of triglycerides in the exudates was 7.1±3.2 mmol/liter. The thoracoscopy was performed to all the patients with drainage of the pleural cavity, a diet with a decrease in the amount of fat was prescribed. Total parenteral nutrition was originally required for 4 patients, and 3 patients were urged to follow it due to the ongoing chylothorax after 3-4 days. Sandostatin was included in the conservative treatment measures of 5 patients. Conservative measures were effective in 9 patients. One patient underwent pleurodesis with intrapleural injection of tetracycline/polyvinylpyrolidone complex solution. Other patients after unsuccessful conservative treatment for 7-10 days underwent thoracic lymphatic duct ligation. In the absence of the conservative measures effect, the bronchial closure is a novel option in highly selected patients. The positive factor influencing our decision were the virgin mediastinum. The dissection of the trachea through its natural route enables tracheal mobilization. It warrants minimal surgical trauma, and, if necessary, the bronchial stump has enough time to heal before the difficult pneumonectomy.

Conclusions: Video-mediastinoscopy is an alternative to the open methods as it allows approaching the left main bronchi via the mediastinum. This technique is in our choice because its specifics morbidity is minimal compared with transpericardial sternotomy or a thoracoscopic approach. The mediastinoscopic approach is a novel option in highly selected patients in order to prepare and simplify a pneumonectomy.

P2430

Value of the video assisted mediastinoscopy in the thoracic pathology – Our experience

Conclusions: The oncological thoracic pathology is growing in the last decades because of the higher exposure to the pollution and because of the higher accurate of the diagnostic. The mediastinoscopy offers the possibility of the histological histopathology and of the accurate stadialisation in every thoracic pathology.

Material and method: We retrospectively reviewed 218 patients with cervical mediastinoscopy (151 males and 67 females, mean age: 52.3 years) treated between 2008 and 2010. The indications of the cervical mediastinoscopy is indicated in table 1.

The method was not succful in four cases, which necessitated another procedures of diagnosis (thoracoscopy). For non small lung cancer the mediastinoscopy was a method of diagnosis in 79% of cases for patients contraindicated for pulmonary resection (metastasis, early respiratory disfunction, mediastinal invasion). In 18,75% of non small cancer we applied a neoadjuvant treatment with secondary resection.

There was no intra- or postoperative mortality in this material. No major bleeding necessitating further surgical occurred. There weren’t wound infection.

Conclusions: We still consider mediastinoscopy as a safe and efficient way of examining mediastinal pathology.

P2429

Five consecutive cases of left bronchial transcervical video mediastinoscopic closure

Andres Cristian Bobocca, Cristian Palovert, Olga Danaila, Adrian Istrate, Ioan Cordos. Thoracic Surgery Clinic I, “Marius Nasta” National Institute of Pneumology, Bucharest, Romania

Objective: The author reports the longest series of left bronchial transcervical closure using video-assisted mediastinoscopy, describing his experience with this technique and the particularities of the cases. Left bronchial closure as the first procedure of a two-step pneumonectomy for TB compromised lung is a rarely used technique.

Case report: Five patients, mean age of 41.5 years, two females, three males, underwent videomediastinoscopic closure of the left main bronchus in the last 14 months, two for postpneumonectomy bronchopleural fistulas and three prior to pneumonectomy in TB destructed lung. The recovery was uneventful in every case, with the patients discharged the following day. The mean operative time was 55 min. No other incidents or procedure related complications were encountered. The three pneumonectomies followed at 3-4 weeks after the bronchial closure.

Discussions: The mediastinoscopic bronchial closure is a novel option in highly selected patients. The positive factor influencing our decision were the virgin mediastinum. The dissection of the trachea through its natural route enables tracheal mobilization. It warrants minimal surgical trauma, and, if necessary, the bronchial stump has enough time to heal before the difficult pneumonectomy.

Conclusions: Video-mediastinoscopy is an alternative to the open methods as it allows approaching the left main bronchi via the mediastinum. This technique is in our choice because its specific morbidity is minimal compared with transpericardial sternotomy or a thoracoscopic approach. The mediastinoscopic approach is a novel option in highly selected patients in order to prepare and simplify a pneumonectomy.

Spontaneous pneumothorax and Marfanoid phenotype

Veronina Maria, Govorova Svetlana, Nechaeva Galina. Therapy and Family Medicine, Omsk State Medical Academy, Omsk, Russian Federation

It well-known that the spontaneous pneumothorax (SP) and apical bullae are diagnostical criteria of a Marfan syndrome. However the Marfan syndrome is a rare pathology, and the SP at tall and thin young men meets very often. For the purpose search of features of a Marfan syndrome has been surveyed 270 patients with a primary SP. Among patients men (n=248) prevailed, middle age of patients has made 24 years.

We have analysed major and minor criterions of the Marfan syndrome in the skeletal system, ocular system, cardiovascular system, skin and integument and dura. Cleftetal major criterion met most often. Anterior chest deformity have been diagnosed for 14 patients, at 33 patients insted reduced upper-segment to lower-segment ratio or arm span to height ratio more 1.05, at 62 patients were wrist and thumb signs. Scoliosis or spondylolisthesis have been taped at 45 patients. Medial displacement of the mediastinal malloions, causing pes planus were observed at 28 patients. Sceletal minor criterias and their combinations have been diagnosed for 112 patients. Dilatation of the ascending aorta and other are not diagnosed in one case. However such minor criterias as mitral valve prolapse has been diagnosed for 125 patients. Skin and integument criterion have been diagnosed for 38 patients. Ocular and dura criterion met seldom. The combination of criterias has not allowed to diagnose Marfan phenotype at one patient, however allows to speak about presence Marfanoid phenotype at the patients with a SP. The finding of a strong association of SP with Marfanoid phenotype suggests that in many patients may be a manifestation of a systemic abnormality of connective tissue.

**P2432**

Bronchial stump insufficiency after pneumonecnotomy in purulent-destructive diseases of lungs

Shahrat Hudyayberganov1, Georgy Puhomov1, 2, Rustem Hayaliyev1, 2, Orikalli Irsyn1, Otabek Eshbonhodjaev1, 2, Sharif Rahimty1, 2. 1Department Surgery of Lungs and Medistinum, RSCS Named after Acad. V. Vahidov, Tashkent, 2Hospital Surgery Kafirda, Tashkent Medical Academy, Tashkent, Uzbekistan

As is well known, bronchial stump insufficiency (BSI), bronchopleural fistulas (BPF) and connected with them empyma pleura are the main reasons of the re-duction to efficiency of the surgical treatment of lung cancer, purulent-destructive diseases of lungs (PDDL) and other surgical pathology of thorax.

**Material and methods:** Results of complex examination and treatment of 684 patients had comparative analysed, from which 575 (84.1%) patients underwent pneumonecnotomy (PE) on cause oncological pathology or PDDL, but 109 (15.9%) patients were treated on cause BPF after PE. The average age 56.4±4.1 years. The main group has formed 98 patients, admitted for 2006-2008 and undertaken design of the surgical treatment, founded on determination of the groups of the risk of the development BSI after PE.

**Results:** The frequency BSI after PE depending on presence different factor among 87 patients with PDDL was apart considered. PE is on the right made in 25 (28.7%) patients, on the left in 62 (71.3%) patients. BSI after PE is revealed in 4 (16.0%) and 7 (11.3%) accordingly. PE on cause PDDL noted increasing of the frequency BSI from 10.5% to 12.6% (11 from 87 patients), and risk of the development of PE complications, depending on side of the operations forms - 16.0% after right-side and 11.3% after leftside PE.

**Conclusions:** In patients of oncological profile, which is planned PE, frequency of accompanying BPF forms 53.8% patient then in patients with PDDL this factor reaches 75.2%, in turn exacerbation COPD after performing PE noted in 48.8% and 63.6% patients accordingly, but risk of the development BSI on this background reaches 16.5% that requires including in the treatment nebulised therapy.

**P2433**

Congenital pulmonary airway malformation in a 10 year old male adolescent

Maria Niña Banque. Pulmonary and Critical Care Medicine Section of Pediatric Pulmonology, Philippine Heart Center, Quezon City, Philippines

Congenital pulmonary airway malformation (CPAM), more commonly and previously termed congenital cystic adenomatoid malformation is an uncommon anomaly characterized by multicystic lesions due to proliferation of the respiratory bronchioles. This lung anomaly has an incidence of 1:2500-35,000 and 90% of this number occurs in children below 2 years old. Late-onset CPAM is an infrequent illness and requires a high level of suspicion. It usually presents in the form of repeated infections but very rarely remains to be asymptomatic until its diagnosis. This is a case of a previously healthy, apparently asymptomatic 10 year old male adolescent who had an incidental finding of a pulmonary bulla on chest radiograph taken while he was worked up because of a high grade fever which eventually he was diagnosed of dengue fever. He underwent elective right upper lobe lobectomy and was discharged improved on the 4th post-operative day. The final histopathology result is consistent with a congenital pulmonary airway malformation, type 1.

**P2434**

Lung tissue glue (LTG) application in lung surgery and thoracic traumas for sealing lungs tissue: Suture, bronchial stump

Stanislav Skryabin. Thoracic Surgery, Marmans Regional Hospital by P. Bayandina, Marmans, Marmans Region, Russian Federation

Stable sealing of lungs tissue is the core principle and the key condition for positive results of postoperative recovery period after thoracic surgery. Hardest complication in thoracic surgery is the inconsistency of bronchial stump, the bronchial fistulas (15.5%). Due to this possibility of glue usage for lung surface processing with sealing effect is the most actual for thoracic surgery, as the possibility of adequate elasticity while lungs tissue elongation with minimal collateral effects.

The advantages of LTG: inexpensiveness, highly adhesiveness and hydrophilic, ability to change elasticity, viscosity, adhesiveness, high rupture strength, microbiological stability, low toxicity. In our thoracic department actively applied till September 2010 latex glue, resulted drainage period average 2-3 days after operations (in purulent-destructive processes max 5 days).

Traditionally the average drainage period more than 5-7 days, and more complications. The larger scale of application is possible but not happen due to lack of financing from our hospital administration.

**P2435**

Lung volume reduction surgery for a decompressed COPD – Case report

Cornel Petreanu1, Cornel Savu1, Nicolae Gale1, Gina Ciolan1, 2. Clinic of Thoracic Surgery, 2Clinic of Pneumology, National Institute of Pneumofistology Prof. Dr. Marius Nastu, Bucharest, Romania

**Introduction:** Lung surgery reduction is a known method which can improve the quality of life for certain COPD. Parts of the lung that are particularly damaged by empyma pneumosa are removed, allowing the remaining, relatively good lung to expand and work better.

**Clinical features:** The work presents a patient with stage IV COPD admitted in our service after a severe decompensation. Comorbidities: severe obesity, chronic corionic ischemic disease and diabetes, left pneumonitis (secondary a giant bulla of empyma pneumosa) and infectious pneumonia. We maintained the antibiotheraphy and we applied an anterior pleurectomy on the left mediooclavicular line. The evolution was initially good with suppression of the tracheotomy’s canule and of the pleurectomy’s tube in five days.

**Surgery:** 48 hours after removing the chest tube, the pneumotorsox received and we decided the surgery treatment. We performed the resection of the giant bulla and mechanical pleuradosis.

After opening of the bulla we used a fold of visceral pleura to covering the cavity in separated points.

**The outcomes:** The postoperative evolution was very good with spontaneous closure of the tracheotomy and with ablation of the tube in a week. The respiratory test indicated a improved with 15%.

**Discussion** Lung volume reduction surgery is indicated in selected cases, after surgery both lung functional tests and clinical performance of the patient beefing improved.

Foreign body: same clinic-diﬀerent diagnosis
Aykut Elıçık1, Serife Tuba Liman1, Salih Topçu1, Atıli Gül Akıglı1, Seymur Salih Mehmetoğlu1, Tulay Hosten2, 1Department of Thoracic Surgery, Kocaeli University, Kocaeli, Turkey; 2Department of Anesthesiology, Kocaeli University, Kocaeli, Turkey

Foreign body aspiration is a serious condition with risk of mortality. It happens at all ages but mostly at childhood. Chest x-ray can demonstrate the foreign body if is in the radiopaque. But laterally and oblique chest graphs must be seen for the exact diagnosis with its size and localization. We report two cases admitted with same symptoms indicate to foreign body but different final diagnosis.

Case 1: A 1.5-year old child with Down syndrome was admitted to emergency clinic of our hospital with cough, wheezing and stridor. There was a history suitable for a foreign body aspiration and no any other significant history. Chest x-ray demonstrated an opacity similar to a foreign body. We performed a rigid bronchoscopy. There was no foreign body in his tracheobronchial system. Therewith esophagoscopy was performed under scope. Again there was no foreign body although the image was suitable to a foreign body. In the postoperative period with more detailed examination it was understood that the radiological opacity was an endovascular stent set up with angiography to carry on PDA for another cardiac disease treatment.

Case 2: A 3-year old child was admitted to our hospital with persisting cough, wheezing and stridor. Clinical history and chest x-ray demonstrated a foreign body similar to the first case. Rigid bronchoscopy was performed and a metallic foreign body (pencil bow) was extracted from left main bronchus.

History takes a great role in diagnosis of foreign body aspiration. Radiological investigation must perform to all suspected cases. Although a chest x-ray demonstrate mostly atelectasis and hyperaeration at the affected side a normal graph cannot eliminate the foreign body. If the suspicion persists we must apply esophagoscopy.

P2437
LSC 2011 Abstract: T helper cell involvement in COPD and lung transplantation patients
Marieke Paans, Ingrid Bergen, Menno van der Eerden, Bernt van den Blink, Peter van Hal, Nicole van Besouw, Carla Baan, Henk Hoogsteden, Rudi Hendriks. Department of Pulmonary Medicine, Erasmus Medical Center, Rotterdam, Netherlands; Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands

Background: COPD is associated with airway and systemic inflammation and end stage disease is a major indication for lung transplantation (LTx). The novel T helper 17 (Th17) subset was recently implicated in the pathogenesis of COPD and is also associated with allergen rejection. To date, little is known about the cytokine profile of circulating T cells in COPD patients.

Aim: To determine the cytokine profile of circulating T cells in patients with COPD and in stable LTx patients.

Methods: Peripheral blood mononuclear cells of COPD patients, before and 1 year after LTx and of healthy controls were shortly stimulated in vitro and T cells were analysed by flow cytometry for intracellular cytokine production.

Results: We found no differences in proportions of Th17 cytokines (IL17A, IL22, IL17F) in stable COPD patients when compared to healthy controls. In the LTx patients, proportions of IFNγ and TNFα producing T cells did not diﬀer from those in healthy controls. However, IL22 production by CD4+ and CD8+ T-cells was increased in LTx patients. Also, an increase in the proportions of IL17+IL22+ and IL17+IFNγ+ double positive T cells was found in stable LTx patients when compared with healthy controls.

Conclusions: Remarkably, T cells of LTx patients have the capacity to produce high levels of proinflamatory cytokines despite immunosuppressive drug treatment. In particular, IL22+ T cells and specific populations of IL17+ cells co-expressing IL22 or IFNγ are high in LTx patients, while IFNγ and TNFα single positive Th helper cells are not increased. These findings indicate that although general inflammatory state but that specific Th17-linked subpopulations may play a role in stable LTx patients.

P2438
Comparison between referral and explant diagnoses in lung transplant recipients: Discrepancies and additional findings
Peter Jakš 1, Mai-Britt Ernst 1, Axel Scheed 1, Silvana Geleff 2, Gerhard Dekan 2, Walter Klepetko 1, Thomas Klepetko 1, Thoracic Surgery, Medical University of Vienna, Vienna, Austria; 1Clinical Institute of Pathology, Medical University of Vienna, Vienna, Austria

Background: LTx is an accepted therapeutic option for a range of pulmonary conditions in which the diagnosis is often based on clinical data or on limited biopsy material. PostTx complications and recurrence of underlying disease may be related to the primary disease, and an accurate diagnosis is therefore essential.

Methods: A pathologic review was performed on 1056 primary LTx over a period of 22 years (1998 to 2010). Diagnoses of native lungs were compared with referral diagnoses to assess the presence of discrepancies or expanded results (malignancies or infections).

Results: 73 (7%) cases presented a different or expanded diagnosis. Discrepancies were found in 34 of 1054 cases (3%). The highest percentage of discordance was depicted in COPD (12 of 344), with the final diagnosis of UIP (n=4), chronic interstitial fibrosis (n=4), LAM (n=1) and sarcoidosis (n=1), 16 patients who were referred with the diagnosis of an interstitial lung disease had predominantly emphysema (n=12), bronchiectasis (n=2) and IX (n=2). Expanded results included Aspergillus (n=11) and mycobacterial (n= 16) infections, carcinomas (n=10), cystic adenomatoid dysplasia (n=1) and carcinoid (n=1). However, short- and long-term survival was not different in patients with different diagnoses, malignancies or implanted infections. Interestingly all mycobacterial infections and all malignancies occurred in patients with COPD.

Conclusions: On account of this high rate of discrepancies and its possible influence on survival, frequent repeated thoracoscopic investigations should be performed during the waiting list period.

P2439
Mortality in idiopathic pulmonary ﬁbrosis (IPF) on the waiting list for lung transplantation in the Netherlands
Liesbeth ten Klooster1,2, Coline van Moorsel1,2, Diana van Kessel1,2, Ed van de Graaf2, Johanna Kwaakkel-van Eer3, Bart Luijk2, George Noossent1, Peter van Hal1, Jan Grutters1,2. 1Center of Interventional Lung Diseases, Department of Pulmonology, St. Antonius Hospital, Nieuwegein, Netherlands; 2Division of Heart and Lungs, University Medical Center Utrecht, Utrecht, Netherlands; 3Department of Lung Transplantation, University Medical Center Groningen, Groningen, Netherlands; 4Department of Respiratory Medicine, Erasmus Medical Center, Rotterdam, Netherlands

Background: Idiopathic Pulmonary Fibrosis (IPF) is a progressive disease with a five-year prognosis of 2.5 to 5 years. IPF is not responsive to medical treatment and lung transplantation is the only therapeutic option to prolong life.

Objective: The aim of this study was to examine waiting list mortality of IPF in the Netherlands.

Methods: Data were retrospectively collected from September 1989 until June 2010 of all IPF patients registered for lung transplantation in the Netherlands. Patients were included after revision of the diagnosis based on the IPF criteria set by the ATS/ERS. Clinical data and lung function measurements were collected at the time of screening.

Results: 167 IPF patients were referred for lung transplantation. After evaluation for contraindications and screening, 90 patients were listed for lung transplantation. During the waiting list period 33.3% of IPF patients (n=30) died compared to 13.6% in Cystic Fibrosis (CF) (p = 0.0018) and 16.3% in Chronic Obstructive Pulmonary Disease (COPD) (p = 0.003). Analysis of lung function showed a mean FVC%-predicted of 51.1% (SD 19.0) and mean DLco%-predicted of 27.1% (SD 9.4) at time of screening. Five patients were taken off the list due to new comorbidities and deterioration of physical condition, 51 were transplanted and 4 IPF patients were still on the waiting list.

Conclusions: This study revealed a significantly higher waiting list mortality for IPF compared to COPD and CF. DLco%-predicted at time of screening was considerably lower than international guidelines for lung transplantation. This indicates that timing of referral of IPF for lung transplantation can be improved.

P2440
The impact of resistant bacteria in respiratory secretions on the outcome of lung transplantation
Michal Steinberg1, Yael Raviv1, Jihad Bishara2, Dov Rosengarten2, Nili Stein1, Ilana Bakal2, Mordechai Kramer1. 1Pulmonary Institute, Carmel Medical Center, the B. Rapaport Faculty of Medicine, Haifa, Israel; 2Pulmonary Institute, Rubin Medical Center, Sackler School of Medicine, Tel-Aviv, Israel; 3Infectious Disease Unit, Rabin Medical Center, Sackler School of Medicine, Tel Aviv, Israel; 4Department of Community Medicine and Epidemiology, Carmel Medical Center, Haifa, Israel

Introduction: Antibiotic treatment may cause growth of resistant bacteria in respiratory secretions. We assessed the association between antibiotic treatment of lung transplant recipients and acquisition of quinolone resistant gram negative bacteria (QR-GNB), and the impact of such colonization on mortality and lung rejection (BOS).

Methods: We examined data from lung transplant recipients for antibiotic treat- ment, GNB in respiratory secretions, BOS, and mortality.

Results: 126 patients were included. Median percentage of days with antibiotics was 2.8% in patients with no growth, 11.1% in patients with quinolone sensitive GNB (QS-GNB), and 26% in patients with QR-GNB. Age adjusted mortality hazard ratio was 9.2 (95% CI, 1.27-78.9) for patients with QR-GNB compared with QS-GNB. Age adjusted hazard ratios for BOS were: 3.6 (1.1-11.6) for QR-GNB compared with no growth, and 3.7 (1.33-10.3) for QR-GNB compared with QS-GNB.
Conclusions: Antibiotic treatment was associated with QR-GNB. Airway colonisation with QR-GNB was associated with mortality and with BOS. We suggest that narrow spectrum antibiotics should be preferred in lung transplant recipients. P2441 Anxiety, depression and coping in patients awaiting lung transplantation Torunn Stavnes Soyseth1, Aasta Hedal2, Gro Kil i Haugstad3, Vidar Soyseth4, Oystein Bjortuf t2, May Brit Lund3. 1Department of Respiratory Medicine,Division of Cardiovascular and Respiratory Medicine and Surgery, Ri kshospitalet, Oslo University Hospital, Oslo, Norway; 2Department of Neuropsychiatry and Psycho somatic Medicine,Division of Clinical Neuroscience, Ri kshospitalet, Oslo University Hospital, Oslo, Norway; 3Department of Mensendieck (Physiotherapy), Faculty of Health Sciences, Oslo University College, Oslo, Norway; 4Department of Respiratory Medicine, Akerh us University Hospital, Lorensk og, Norway

Knowledge is scarce about the mental aspects of living with terminal lung disease. We aimed to assess anxiety, depression and coping in patients waiting for lung transplantation.

Material and methods: A national cohort of 121 consecutive patients were evaluated by psychiatric instruments, Hospital Anxiety and Depression Scale (HAD) and General Health Questionnaire (GHQ). 89 (45 females) had COPD, 18 (9 females) fibrosis, and 14 (8 females) various other lung diseases. Mean (SD) age was respectively 56 (5), 52 (6) and 46 (8) years. Patients with cystic fibrosis were excluded.

Results: See table.

</tbody>
</table>

For all groups, mean values were within the normal range. However, the ranges were wide. Males tended to be more depressive than females (mean (SD) HAD score 4.1 (3.0) vs 3.1 (2.5), p=0.07), and have higher restrained coping scores than females (mean (SD) GHQ score 1.05 (0.05) vs 0.93 (0.05), p=0.038). The association between anxiety and restrained coping was highly significant, p=0.0001 as well as the association between depression and restrained coping, p=0.0001.

Conclusions: The strong association between anxiety and depression and restrained coping may be of clinical relevance after transplantation. Males may be more vulnerable than females in this respect.

P2442 Significance of a spirometric obstructive pattern immediately after lung transplantation Hendrik Suhling1, Jessica Rademacher1, Tobias Welte1, Gregor Warnecke2, Sabine Detterm1, Jens Gottlieb1. 1Dept. of Pulmonary Medicine, Hannover Medical School, Hannover, Germany; 2Dept. of Cardiorthoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, Germany; 3Dept. of Radiology, Hannover Medical School, Hannover, Germany

To increase the donor pool, cadaveric lungs with extended donor criteria are increasingly accepted for lung transplantation.

In this study the impact and outcome of lung transplant recipients with an obstructive spirometric pattern as possible indicator of structural damaged lungs immediately after lung transplantations was investigated.

Analyzing all patients undergoing double lung transplantation between 1.09.2007 and 01.10.2009, we separated patients with obstructive (FEV1/VC < 0.7) and a non-obstructive pattern (FEV1/VC > 0.7) in pulmonary function tests 3 months after transplantation. Pulmonary function measurement including body plethysmography, bronchoscopy, laboratory parameter, CT and outcome was analyzed up to 36 months after transplantation.

From 122 recipients included, 17 (14%) were identified with an obstructive pattern, these were older at transplantation and had a lower donor oxygenation index and significant higher TLC. Obstructive patients developed peak FEV1 earlier after LTx and developed significantly more frequently bronchiolitis obliterans syndrome (47% vs. 14%).

Obstructive lung function pattern is associated with earlier development of BOS and might worsen the outcome after double lung transplantation. The OP in association with increase TLC and donor history suggests that the obstruction was of donor origin.

Factors like smoking status, age of the donor lung and FEV2 were indicators of a later obstructive pattern in recipients.

P2443 Probe-based confocal laser endomicroscopy in acute lung allograft rejection Jonas Yserbyt1, Christophe Dooons1, Wim Janssens1, Geert Verleden1, Vincent Ninane2, Marc Decramer3. 1Respiratory Diseases, University Hospitals Leuven, Leuven, Belgium; 2Respiratory Diseases, CHU Saint-Pierre, Brussels, Belgium

Several aspects of normal alveolar tissue in probe-based confocal laser endomicroscopy (pCLE) have been elucidated: a description of the alveoloscapic findings in different pulmonary disorders is still largely lacking.

In a prospective study, we evaluated 40 lung transplant recipients using probe-based confocal laser endomicroscopy (pCLE) preceding BAL and bronchial lung biopsy (TLB) during bronchoscopy. In 6 patients (15%) acute rejection (AR) was diagnosed using TLB. The recordings of the pCLE images were digitally processed and analyzed for the following parameters: alveolar duct diameter, alveolar elastin thickness, macrophage diameter, number of macrophages per microscopic field and quantification of the autofluorescence signal of macrophages.

In 5 out of 6 AR cases, a diffuse infiltration of autofluorescent cells with a mean diameter of 26 ± 13 μm, was recognized in all examined segments. The number of macrophages per microscopic field and their autofluorescence intensity were significantly higher in the AR group than in the non-AR group (p < 0.001 and p = 0.03 respectively).

In all affected segments there appeared to be more than 100 cells per microscopic field, frequently presenting as clustering cells. The elastin network in the alveolar ducts of AR appeared to be of a normal architecture (alveolar elastin thickness mean 8.3 ± 4.9 μm, alveolar mouth diameter mean 371 ± 131 μm), and did not differ from the patient group without AR (7.8 ± 3.7 μm and 323 ± 89 μm, respectively).

In the lung transplant recipient group studied, our preliminary findings suggest that pCLE is able to detect an alveoloscapic pattern that might correlate with AR.

P2444 Frequency and characteristics of prolonged viral shedding of influenza A/H1N1 virus in lung transplant recipients Macé M. Schuurmans, Alice Zuercher, Gabriele M. Tini, Gregory Fretz, Christian Benden, Erich W. Russi, Annette Boehlert. Pulmonology, University Hospital, Zurich, Switzerland

Infection in lung transplant recipients (LTR) because it potentially triggers allograft rejection. Prolonged viral shedding (PVS) is defined as positive detection of influenza A/H1N1 virus (H1N1) by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) at day 7 or later after diagnosis. The aim was to quantify and characterise PVS of H1N1 infections among LTR in consecutive influenza seasons.

Methods: Influenza vaccination is routinely offered at follow-up visits in our outpatient clinic. LTR are also instructed to contact and visit our clinic when signs of infection occur or home lung function deteriorates 10% or more. We then frequently perform nasopharyngeal swabs (NPS) for viral and bacterial analysis.

In 2009-2010, 10 LTR were included, in whom we found positive NPS for influenza A/H1N1 virus (H1N1) by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) at day 7 or later after diagnosis, in 7 of these 10 patients (70%). PVS was defined as positive detection of influenza A/H1N1 virus (H1N1) by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) at day 7 or later after diagnosis. The aim was to quantify and characterise PVS of H1N1 infections among LTR in consecutive influenza seasons.

Methods: Influenza vaccination is routinely offered at follow-up visits in our outpatient clinic. LTR are also instructed to contact and visit our clinic when signs of infection occur or home lung function deteriorates 10% or more. We then frequently perform nasopharyngeal swabs (NPS) for viral and bacterial analysis.

case of suggestive symptoms for influenza infection we start oseltamivir (Tamiflu) and moxifloxacin treatment pending NPS results. For proven H1N1 infection we continued treatment until weekly NPS return negative.

**Results:** In winter 2009/2010 7 patients had H1N1 infection of which 2 had PVS (28%). No serious complication occurred. 2/7 LTR were vaccinated for H1N1. For 2010/2011 we have so far documented 11 H1N1 infections and PVS in 8 LTR (73%). All LTR were vaccinated with at least 1 dose containing H1N1. Three LTR were hospitalised. 5 LTR had PVS for 2-6 weeks. Quantification of viral results and drug resistance testing are being performed. Influenza B was detected in 4 other LTR.

**Conclusion:** In this ongoing study we report an increase in frequency of PVS for H1N1 infections in LTR from 28 to 73% in consecutive influenza seasons. Most infections occurred despite vaccination and had a favourable outcome rarely requiring hospitalisation.

Opto-electronic plethysmographic study of the chest volume changes after lung transplantation

Mariana Laviole1, Emilia Privitera1, Mario Nosotti1, Andrea Allevini2, Luigi Santambrogio2, Davide Tos1, Lorenzo Rossol1, 1Thoracic Surgery, Fondazione Cà Granda Ospedale Policlinico, Milano, Italy; 2Bioingegneria, Politecnico di Milano, Milano, Italy

**Background:** Lung transplantation is the established surgical therapy for pulmonary end-stage disease.

**Aims:** Even though the pulmonary function after lung transplantation is well studied, the chest volume changes remain uninvestigated. The aim of the study was to examine such changes by the opto-electronic plethysmography (OEP), a non-invasive technology.

**Methods:** Seven patients with end-stage pulmonary disease were studied before and after lung transplantation by OEP during quiet and forced breathing. Standard pulmonary function tests were also obtained. Three patients with pulmonary fibrosis had single lung transplantation and four patients with cystic fibrosis had bilateral.

**Result:** The functional tests demonstrated increasing in pulmonary function (e.g. FEV1% from 44±6 to 83±6). After bilateral transplantation, the OEP revealed a volume rearrangement: a decrease was noted in functional residual capacity (FRC: -2.1±1.3L), in vital capacity (-1.1±1L), in total lung capacity (-2.59±1.6L). The chest wall volume reduction was different in the upper thorax, lower thorax and abdominal compartment (e.g. FRC: -0.68L, -0.13L -1.59L respectively). After single lung transplantation the pattern was similar but less evident.

**Conclusions:** This first, preliminary, study of the chest wall volume changes reveals a rearrangement of such volumes after single or double lung transplantation. Facing the dramatic improvement in spirometric value, OEP recorded a decrease in volume parameters; such decreases were inhomogeneous through the body compartment, privileging the abdomen. Further studies are needed to better understand the value of these findings and their clinical impact.

Lung transplantation for pulmonary silicosis: The Israeli scene

Anat Amital1, David Shitrit3, Yael Raviv2, Benjamin Medalion1, Ilana Bakal1, 1Pulmonary Institute, Carmel Medical Center, Haifa, Israel; 2Bioingegneria, Politecnico di Milano, Milano, Italy

**Background:** Silicosis is a rare indication for lung transplantation. The number of patients with silicosis in Israel is increasing due to improper processing of a new quarz stone Caesarstone.

**Methods and materials:** We retrospectively reviewed the files of patients that underwent LT for silicosis. There were more patients transplanted for silicosis in 2009/2010 compared to the ISHLT (p=0.01).

**Results:** In winter 2009/2010 7 patients had H1N1 infection of which 2 had PVS (28%). No serious complication occurred. 2/7 LTR were vaccinated for H1N1. For 2010/2011 we have so far documented 11 H1N1 infections and PVS in 8 LTR (73%). All LTR were vaccinated with at least 1 dose containing H1N1. Three LTR were hospitalised. 5 LTR had PVS for 2-6 weeks. Quantification of viral results and drug resistance testing are being performed. Influenza B was detected in 4 other LTR.

**Conclusion:** In this ongoing study we report an increase in frequency of PVS for H1N1 infections in LTR from 28 to 73% in consecutive influenza seasons. Most infections occurred despite vaccination and had a favourable outcome rarely requiring hospitalisation.

Donor and recipient parameters affecting 1-year follow-up after lung transplant: Padova experience

Elisabetta Ballestro1, Emanuela Rossi1, Francesca Lunardi2, Giuseppe Marralli3, Monica Loy1, Francesco Di Chiara1, Fiorella Calabrese2, Federico Rea3, 1Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy; 2Department of Diagnostic Medical Sciences and Special Therapies, University of Padova, Padova, Italy

The critical shortage of donor lungs suitable for transplant significantly limits the number of potential recipients. Many questions regarding donor acceptability still remain unanswered. Regarding recipients, less is known about peri-operative factors affecting 1-year survival. To investigate how multiple risk factors influence short term survival we retrospectively reviewed clinical data of donors and their recipients, transplanted in our centre.

We collected data from donors (n=174, mean age 35.7±10) focusing on age, Body Mass Index (BMI), orotracheal intubation (OTI) duration, marginality, cause of death, tracheal secretions and selected clinical information from their recipients (n= 200, mean age 46.8±10): native disease, BMI, type of transplant, intensive care unit (ICU) stay and OTI duration.

Donor age, above 35 yrs, and overweight (BMI>25) were independent predictors of survival less 1 year (respectively p=0.004; p = 0.05). Instead OTI duration (> 3 days), marginality, death for traumatic/cardiovascular cause, presence of tracheal secretions did not affect survival (respectively p(0.73,p=0.92,p=0.37,p=0.40; p=0.40). Concerning recipients, BMI between 18 to 20 (p=0.04) and age under 50yrs (p=0.005) predisposes to longer survival. Prolonged ICU stay (>20 days,p=0.007) and OTI duration (>3 days,p=0.0001) negatively affect short survival.

Our data suggest that some peri-operative donor characteristics do not affect short survival and might help maximize lung availability from donor pool. Recipient evaluation confirm how crucial is to reduce OTI duration which, in our study, have influenced 1year survival.

Clinical outcomes in patients with acute exacerbation of idiopathic pulmonary fibrosis undergoing lung transplantation

Elisabetta Balestrio1, Emanuela Rossi 1, Francesca Lunardi 2, Giuseppe Marralli 3, Monica Loy1, Francesco Di Chiara1, Fiorella Calabrese2, Federico Rea3, 1Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy; 2Department of Diagnostic Medical Sciences and Special Therapies, University of Padova, Padova, Italy

Patients with an acute exacerbation of idiopathic pulmonary fibrosis (AE-IPF) have extremely poor prognosis. Lung transplantation (LT) is not routinely performed in...
In severe delayed graft dysfunction refractory to mechanical ventilation, rhinovirus on viral PCR. Mean length of stay in ITU was 56.2 days of ECMO support was 9.2 days. Some patients had abnormal radiological changes that persisted after discharge. Mean duration of ECMO was 78.6% for the AE-IPF and 77.8% for the IPF group, respectively (p = 0.865).

In this cohort, similar clinical outcomes were observed in patients undergoing LT for AE-IPF and IPF. LT may be a viable option in patients with AE-IPF.

Conclusion: In our model, CO arises during emergency phase and its concentration is not changed by low or high CO level in ambient air. Thus, we are able to quantify CO produced by the lungs.

P2452 BODE Index as a predictor of survival in lung transplantation
Pilar Sanjuan, Isabel Otero, Pedro J. Marcos, Héctor Verea. Respiratory, Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain

Introduction: Chronic obstructive pulmonary disease (COPD) is one of the most frequent indications for lung transplantation (LTX), but survival benefit is still under debate. We analysed the survival impact of LTX in COPD using the BODE (body mass index, airway obstruction, dyspnoea, exercise capacity) index.

Aims: The aim of our study was to analyse the survival impact of lung transplantation in COPD patients. We compared the post-transplant survival with the survival predicted by the BODE index as measured during pre-transplant clinical evaluation.

Methods: Retrospective review of 59 consecutive lung transplants performed for COPD in our centre between June 1st 1999 and December 30th 2010. The pre-transplant BODE score was calculated for each patient. Predicted and observed post-transplant survival was then compared.

Results: 59 COPD patients were analyzed. Mean age was 57.6 ± 8.1 years, 51 (86%) men, 52 (88%) patients had a BODE > 7 and 7 (11.9%) < 7. The overall survival time was 70.82 months ± 8.1. BODE > 7 had a overall survival time of 19.5 and BODE > 7 was 73.2 ± 8.6. In the subgroups with a BODE score > 7 and < 7, the 5-year survival was 75% in the BODE > 7 and 57% ± 20% in the BODE < 7 group.

Conclusions: The results of this study showed a significant survival benefit of LTX in our cohort of COPD patients. Patients with BODE ≥ 7 will be the ones who benefit the most from the procedure.

P2455 Early development of posterior reversible encephalopathy syndrome post lung transplantation
Letizia Corinna Morlacchi, Valeria Rossetti, Marta DiPasquale, Giulia Salomoni, Maria Pappalettera, Paolo Tarasi. Dipartimento ToracicoPulmonare e CardioCircolatorio, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy

Tacrolimus is a calcineurin inhibitor and has been proven highly effective in preventing graft rejection after transplantation of solid organs. Its major adverse effects are nephrotoxicity and neurotoxicity: the most severe form of the latter is PRES (Posterior Reversible Encephalopathy Syndrome).

We here describe a case of PRES in a 26-year-old woman, 5 days after she received bilateral lung transplantation for cystic fibrosis. She had been administered tacrolimus since the transplantation was performed. While in ICU, she suddenly developed mental status alterations, acute pulmonary deterioration and hypercapnia, with need of mechanical ventilation. A head CT scan and MR were performed, detecting subcortical white matter lesions and patchy, bilaterally symmetric areas of abnormally increased signal on the T1-weighted images within the cerebellum and the occipital-parietal and frontal regions of the brain: a minor alteration was also present in the thalamus. ADC (i.e. Apparent Diffusion Coefficients) mapping showed wide areas of vasogenic and cytotoxic edema.

Tacrolimus was immediately stopped and cyclosporine was introduced: her symptoms promptly improved.

A MRI was repeated two weeks later, documenting a significant improvement both of the cerebellum and the thalamus.

A follow up MRI was performed two months after the transplantation: prior lesions had almost completely resolved.

She still suffers from minor neuro-cognitive deficits (concerning calculus and short-term memory) and visual disturbances.

This case maybe significant in order to better understand the clinical features of PRES, which may present at a very early stage of tacrolimus regimen and is a generally reversible condition.

Characterization of a population referred to a lung transplantation centre in Lisbon
Sofia Grandeiro1, Alexandra Borba1, Luisa Sodédo3, Miguel Araujo1, João Cardoso1, Fernando Martelos2, Joana Fragata2, 1Pneumology Department, Hospital de Santa Marta, Lisbon, Portugal; 2Thoracic Surgery Department, Hospital de Santa Marta, Lisbon, Portugal

Introduction: Lung transplantation is the therapeutic option for patients with end stage lung disease. An appropriate referral contributes to a better post surgery survival.

Purpose: Characterization of the patients referred to the only lung transplantation centre in Portugal.

Material and method: The authors evaluated patients referred from January 2008 to December 2010. The following data was determined: demographics, lung disease and evaluation result. Reasons for refusal were also analyzed.

Results: A total of 199 patients were referred (51% male), with an average age of 45.5 years (range 11 to 69). Thirty per cent had the diagnosis of terminal lung fibrosis, 21% COPD, 13% cystic fibrosis, 12% bronchiectasis and the last 23% other diagnosis. After evaluation 24.6% of patients were accepted (49 patients, 25% of which already transplanted and 5 died on waiting list) and 54.3% were refused, most due to severe cardiac impairment or very poor general condition. Of the remaining patients, 9.5% are under current evaluation, 6.5% present a relative contraindication and 5% still don’t meet criteria for transplantation.

Conclusion: Despite the considerable number of patients referred, only 45.7% were eligible for lung transplant. The important number of patients refused due to medical contraindications should alert the attending physicians for an earlier referral.

P2456
Effect of BIPAP on diaphragm paralysis after single lung transplantation
Shadi Shafagh1, Parisa Adam2, Atefeh Fakhrarian1, Amir Hassan Nassin1, Fariba Ghorbani1, Neyaz Shahabedin Mohammadi3, Hamid Reza Khodam Veshk3, Katayoun Najatizadeh1, 1Thoracic Transplantation Research Center, National Research Institute of TB and Lung Disease, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 2Chronic Respiratory Disease Research Center, National Research Institute of TB and Lung Disease, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 3Department of Internal Medicine, Cardio-Pneumologic Hospital, Lyon, France

Diaphragm is a chief muscle of inspiration and its unilateral or bilateral paralysis can lead to dyspnea and affect ventilator function. Here, we are reporting management of an emphysematous patient who is undergone single lung transplant and was suffering from diaphragmatic paralysis.

A 53 year old male emphysematous patient was transplanted in 2009 and had no significant complication after transplantation. He was admitted 3 months and 9 months after transplantation due to acute rejection and received corticosteroid pulse therapy which the results were acceptable. 14 months after transplantation an elevated hemidiaphragm on chest x-ray was suggestive of diaphragmatic paralysis which was confirmed by paradoxical upward movement of right hemidiaphragm during fluoroscopic imaging. He had dyspnea with minimal exercise, reduced pulmonal function test (FVC from 63% to 38%) and oxygen saturation fall to 75% in rest without any oxygen supplement. Considering hypoaxia and C02 retention, polysomnography was performed to look for sleep apnea. Patient apnea hypopnea index (AHI) was 17 with 5 hypopnea, 5 central and 7 obstructive sleep events. After titration test, bi-level positive airway pressure apparatus (BIPAP)(P1=15, PE=11, st back up=14) was administered by oronasal mask. Although the authors worried about over expansion of high compliance emphysematous native lung with using BIPAP, pulmonary function test result improved significantly (FVC from 38% to 58%) and oxygen saturation during exercise increased to greater than 88% dramatically without expanding the native lung. We claim that BIPAP could be recommended for management of these patients without any considerable side effects.

P2457
Late-breaking abstract: The differences in clinical presentations between severe health care-associated pneumonia and severe community-acquired pneumonia: A single center experience
Gooheyon Hong, Sang-Won Um, Won-Jung Koh, Goo-Young Suh, Man-Pyo Chung, Ho-Joong Kim, O-Jung Kwon, Kyeong-Man Jeon, Medicine, Division of Pulmonary and Critical Care Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Health care associated pneumonia (HCAP) has been proposed as a new category of respiratory infection. HCAP shows higher mortality rates than CAP. But it is not clear whether the poor outcome of HCAP is related to the presence of more comorbidities or to a higher incidence of MDR pathogen and inappropriate empirical antibiotic treatment. Thus, we aim to establish whether differences in outcomes for HCAP are due to differences in severity of pneumonia, not due to MDR pathogen. We conducted a retrospective observational study of patients with severe HCAP and severe CAP who were hospitalized through the emergency department in Jan 2008 Dec 2009 at Samsung Medical Center, Seoul, Korea, and compared clinical characteristics, severity, distribution of pathogen, and outcomes.

In total, 757 patients hospitalized with pneumonia were eligible, 382 patients were severe pneumonia. Despite the considerable number of patients referred, only 45.7% were eligible for lung transplant. The important number of patients refused due to medical contraindications should alert the attending physicians for an earlier referral.

Conclusion: Despite the considerable number of patients referred, only 45.7% were eligible for lung transplant. The important number of patients refused due to medical contraindications should alert the attending physicians for an earlier referral.

P2458
Viral aetiology and clinical characteristics of community-acquired pneumonia in adults in Guangzhou, China
Yang-Qing Zhan1, Rong-Chang Chen1, Z-Feng Yang1, 1Respiratory Medicine, The First Affiliated Hospital of Guangzhou Medical College, State Key Laboratory of Respiratory Disease (Guangzhou Medical University, China), Guangzhou, Guangdong, China; 2Faculty of Chinese Medicine, Macau University of Science and Technology, Macau SAR, China

Background: Recently epidemiological surveillance shows that viral pneumonia is more commonly reported than previously estimated. However, to date, little information is available in China.

Objective: To estimate incidence of adult viral Community-acquired pneumonia (CAP).

Methods: Consecutive adult patients with a diagnosis of CAP during April and December of 2009 were prospectively enrolled. Paired sera were routinely performed by hemagglutination inhibition assay or indirect immunofluorescence. Swab samples were tested for respiratory viruses by using virus culture and RT-PCR.

Viral aetiology was considered definite if at least one of the above tests was positive.

Results: Overall 149 CAP patients were enrolled, with 84 males. The median (interquartile range, IQR) ages were 60 (35–77) years. Paired sera were available in 70 cases. Viral aetiology was established in 48 cases (32.2%). Forty-four patients were infected by a single virus (influenza A 24 cases, influenza B 5 cases, parainfluenza virus type 3 (PIV-3) 11 cases, PIV-1 and adenovirus 2 cases each) and four cases by two viruses. Fever (≥39°C (66.7%), fatigue (64.6%), paroxysmal spasm (52.1%), sore throat (45.8%), dysnea (41.7%) and coryza (41.7%) were the most common symptoms in viral pneumonia patients. Some influenza A or PIV-3 infected patients manifested hemoptysis and chest pain. Dysnea and gastrointestinal symptoms were also common in influenza and PIV-3 infected patients. Oxygen therapy was more common in viral pneumonia patients than others (54.2% vs 31.7%, P=0.008).

Conclusion: Respiratory viruses were common pathogens in CAP in Guangzhou.

P2459
Pneumonia in patients who received health care at home – Should they be categorized as CAP or HCAP?
Toru Rikimaru, Noriko Hakushima, Reiko Toda. Department of Respiratory Disease, Fukuoka Sanno Hospital, Fukuoka City, Fukuoka Prefecture, Japan

Introduction: Healthcare-associated pneumonia (HCAP) is a condition in patients (pts) who are not hospitalized but features are similar to hospital-acquired pneumonia. There are many people who receive HC at home instead of at a nursing home (NH). It is not clear whether they should be treated as community-acquired pneumonia (CAP) or HCAP.

Aims and objectives: This study sought to declare the features in pts who received...
HC-at-home, and to classify them as CAP or HCAP by comparing them with CAP and NH-acquired pneumonia (NHPA) which occupy an important position in EP.

Methods: We evaluated and separated 1000 pts into three groups, Group A 517 pts; complete CAP (A), Group B 333 pts; NHPA (B), and Group C 160 pts; who received HC at home (C).

Results: The features of C were similar to B in age, and between A and B in sex, total protein and independency. There were no differences between the three groups in body temperature, WBC and CRP. In bacteriological features, S. pneumoniae, H. influenzae and K. pneumoniae were 9.5%, 5.8% and 3.9% in A, 7.2%, 2.2% and 10.9% in B and 3.6%, 5.5% and 9.1% in C, respectively. Other features of B and C were similar and had many drug-resistant pathogens e.g. MRSA (A: 5.3%, B: 21.0%, C: 16.4%) and P. aeruginosa (A: 2.5%, B: 13.4%, C: 10.9%). Mortality rates of A, B and C were 6.0%, 18.6% and 10.0%, respectively.

Conclusions: The clinical features of C were similar to NHPA in many categories. We concluded that pneumonia in pts who have received HC at home should be classified as HCAP, especially in poor independency pts.

P2460
Role of viruses, alone and in association with bacteria, in adults hospitalized with community-acquired pneumonia (CAP)
Elisa Mincholé1, Sergio Fandos1, Ana Lasierra 2, Ana Lilian Simon 1, María Angeles Ruiz 1, Cruz Villuendas3, Elena Foret1, Salvador Bello 1, Paloma Sáez-Cano 1, María Alfonso1, Marta Inchausti 1, Beatriz Gómez 1, Nuria Marina 1, Luis Alberto Ruiz 1, Ainhoa Gómez 1, Sandra Pedrero 1, Iratxe Seijas 2, Rafael Zakacain 1, 1Pneumology, Cruces Hospital, Barakaldo, Spain; 2Intensive Care Unit, Cruces Hospital, Barakaldo, Spain

We performed a prospective, observational study of etiology of community-acquired pneumonia (CAP) admitted in our hospital, including bacteria, viruses and mixed bacteria/virus cases. From 228 patients, we carried out a complete microbiological searching, including spuit, urinary antigens, hemocultures, paired serologies, as well as viral immunofluorescence, and two PCR for respiratory viruses from nasopharyngeal washes.

At least one etiological agent was identified in 155 patients (67.98%). Fifty seven (36.7%) were typical bacterial CAP, 57 viral (or atypical bacterial) (36.7%) and 41 (26.4%) mixed (virus and bacterial). (Table 1)

</table>

Conclusions:

- Viruses are very common agents in hospitalized adults with CAP, being present in more than half of the cases of well-known etiology, and in one out of three patients they were found as unique pathogen.
- If we search, we can also identify mixed bacterial-viral CAP as a common cause of CAP. Adenovirus and Rhinovirus were the most prevalent viral agents in mixed pneumonias.
- Streptococcus pneumoniae, alone or in association with virus, was the most prevalent agent, and one out of two pneumococcal CAP was associated with at least one virus. Viruses can have an important role in pathogenesis of pneumococcal CAP.
- Searching virus should be considered in the study of hospitalized CAP.

P2461
The diagnostic yield of the pneumococcal urinary antigen test in clinical practice and its impact on antibiotic therapy
Wendy Laijen, Dominic Snijders, Wim Boersma. Department of Pulmonary Medicine, Medical Centre Alkmaar, Alkmaar, Netherlands

Background: The pneumococcal urinary antigen test (PUAT) is commonly used for the aetiological diagnose of community-acquired pneumonia (CAP) and can be useful for pathogen-directed therapy. The aim of this study was to evaluate the diagnostic yield of the PUAT and the impact on antibiotic therapy in patients with CAP and a positive PUAT result.

Methods: A retrospective study of adults hospitalised with CAP between 2005 and 2007 was performed. All patients were tested by PUAT. Sensitivity of the PUAT was determined and whether antibiotic treatment was adapted to the PUAT result.

Results: 681 patients with CAP were included. Causative micro-organisms were isolated by using conventional methods in 243 (35.7%) patients. The pathogen most frequently identified was S. pneumoniae in 91 (13.4%) patients, with an increase of diagnostic yield by the PUAT to a total of 178 (26.1%) patients. The PUAT increased the total number of aetiological diagnosis from 35.7% to 48.5%. The PUAT was positive in 37 of 55 patients with definitive pneumococcal pneumonia (67.3%). PUAT was positive in 56 of 95 pneumococcal cases (definite and probable) giving an overall test sensitivity of 59.0%. The test specificity was 93.2%. A positive PUAT led to narrowing antibiotic treatment in 63 (41.2%) patients.

Conclusion: The PUAT is a useful technique for early detection of S. pneumoniae in patients with CAP, but the test is less sensitive in this clinical setting than prospective studies indicate. The PUAT results led the physician to narrow the antibiotic treatment, but insufficient adherence to treatment guidelines of CAP when a PUAT is positive limits its impact.

P2462
Incidence and risk factors of MRSA pneumonia
Katja Verhamme1, Francis Maton1, Krijn Van Varenbergh1,2, Paul Jordens4, 1Department of Infection Control and Epidemiology, OLVZ, Aalst, Belgium; 2MGK. OVZ, Aalst, Belgium; 3Department of Microbiology, OVZ, Aalst, Belgium; 4Department of Respiratory Diseases, OLZ, Aalst, Belgium

Introduction: Data on the incidence of MRSA pneumonia in Europe are scarce. Objective: To study the incidence of MRSA pneumonia and its related mortality. Methods: Data from the OLZ hospital, a 939-bed, university-affiliated teaching hospital in Belgium, were used. The study period ran from 2006 to 2009. All respiratory tract samples, positive for MRSA, were retrospectively collected from the automated microbiology database. As multiple samples per patient were available during follow-up, only the first MRSA respiratory tract sample was considered. Of all patients with MRSA positive respiratory tract samples, the complete medical records, including chest X-ray or chest CT scans were reviewed by a pulmonaryologist. Patients were defined to have pneumonia according to the ECDC criteria. Risk factors such as comorbidity and previous use of antibiotics were studied.

Results: During follow-up, 197 patients with a MRSA positive respiratory tract sample were identified. 46 of these 197 patients developed an MRSA pneumonia of which 30 had a nosocomial pneumonia. The overall incidence of MRSA pneumonia was 0.49/10000 patient days. 25 of the 46 MRSA pneumonia were detected at ICU. In patients with MRSA pneumonia, the mortality was high, 24 of the 46 patients (52%) died during follow-up versus 32% in patients with MRSA colonization of the respiratory tract was 32%. The mean time from admission to MRSA pneumonia was 13.6 days. 50% of patients with MRSA pneumonia were previously (during current hospital admission) treated with an antibiotic vs 32.5% in MRSA colonized patients.

Conclusion: The incidence of MRSA pneumonia is low but mortality in these patients is high. Previous use of antibiotics is one of the main risk factors of an MRSA pneumonia.

P2463
Comparison of community acquired pneumonias which require admission to intensive care unit depending on etiology: Legionella vs pneumococcus
Maria Alfonso1, Marta Inchausti1, Beatriz Gómez1, Nuria Marina1, Luis Alberto Ruiz1, Ainhoa Gómez1, Sandra Pedrero1, Iraite Seijas1, Rafael Zakacain1, 1Pneumology, Cruces Hospital, Barakaldo, Spain; 2Intensive Care Unit, Cruces Hospital, Barakaldo, Spain

Objective: To describe the differences between pneumococcal bacteremic pneumonias (PBP) and Legionella pneumonias (LP) which needed admission to Intensive Care Unit (ICU).

Methods: A cross sectional study was performed from 1/1/2000 to 1/1/2010. We analyzed patients with diagnosis of PBP and LP. All patients were admitted in the ICU of our Hospital. We analyzed clinical, analytical and prognosis differences.

MONDAY, SEPTEMBER 26TH 2011
depending on etiologic agents: Pneumococcus (positive blood culture) and L. gionella (positive urine antigen). Immunodeficient patients and health care patients were excluded.

**Results:** We included 115 patients: 63 (55%) PBP and 52 (45%) LP

**Conclusions:** 1. Both groups had a similar age. Patients with LP were more smokers and suffered less pleural pain. 2. Patients with LP had more hipoanemia and received previous antibiotic treatment on higher rates. 3. Admission NBI had greater severity indexes with more favourable evolution. 4. Mortality was similar in both groups.

**P2464 Evaluation of the Legionella V-Test compared to the BinaxNOW to detect Legionella serogroup 1 antigen in urine samples**

Evy De Witte, E. De Witte, E. De Witte. 1Vaccin and Infectious Disease Institute, University of Antwerp, Antwerp, Belgium; 2Intensive Care Unit, Hospital of Mataro, Fundacio Privada Salut del Consorci Santuarios del Marem, Mataro, Spain

The performance and user friendliness of a new immunochromatographic assay, the Legionella V-Test (Coris Biocomb) for the detection of Legionella pneumophila serogroup 1 antigen in urine (uAg) were evaluated by comparing its results with the BinaxNOW Legionella uAg-test results (Inverness Medical).

For direct uAg testing using both tests, 129 previously collected and frozen urine samples were used: 61 specimens from pneumonia patients during a outbreak: 34 from the 41/129 (32%) samples tested were BinaxNOW positive. The sensitivity and specificity of the V-Test was comparable but the new BinaxNOW was even more user-friendly test.

**Results:**

**Conclusions:**

1. Both groups had a similar age. Patients with LP were more smokers and suffered less pleural pain. 2. Patients with LP had more hipoanemia and received previous antibiotic treatment on higher rates. 3. Admission NBI had greater severity indexes with more favourable evolution. 4. Mortality was similar in both groups.

**Material and method:** Forty-eight pneumonia cases that were followed up in a tertiary care center between September 2008 - September 2010 and in whom MRSA or MSSA was isolated from initial respiratory specimens were analyzed.

**Findings:** MRSA was isolated in 19 and MSSA in 29 of 48 cases (38 male, mean age 61.5 ±17.9). Risk factors for health-care-associated pneumonia (HCP) (33 vs 16%, p <0.001), history of hospitalization (29 vs 22%, p=0.016), surgical intervention (12 vs 4%, p=0.033) and admission to intensive care unit (14 vs 4%, p=0.014) in the preceding three months were more common in cases with MRSA pneumonia. Length of stay in the intensive care unit (11.5±4.1 vs 2.7±0.8 days, p=0.048) and in the hospital (23.1±4.1 vs 13.9±1.6 days, p=0.049) were longer in cases with MRSA pneumonia. There was no significant difference in mortality between the two groups (31.6 vs 37.9%).

Three MRSA pneumonia cases without risk factors for healthcare-associated pneumonia were diagnosed as community-acquired MRSA (CA-MRSA) pneumonia. The latter cases were found to be older, this difference not reaching statistical significance (76.3±7.2, p=0.093). There was no difference in the other clinical and biochemical parameters.

**Conclusion:** HCAP and CAP caused by S. aureus is associated with significant mortality and morbidity. There are too few cases to better define CA-MRSA pneumonia.

**P2466 A worldwide perspective of nursing home pneumonia beside community acquired pneumonia**

Adamantia Liakopoulou1, Eva Polverino2, Catia Cillozzi2, Paula Peyrani3, Julio Ramirez4, Rosario Menendez4, Antoni Torres5. 1Respiratory and Critical Care Unit, Evangelismos Hospital, Athens, Greece; 2Respiratory Disease Department, Hospital Clinic, Barcelona, Spain; 3Infectious Disease Department, University of Louisville, Louisville, United States

**Background:** Nursing home acquired pneumonia (NHP) is the leading cause of death among long-term care patients and the second most common cause of transfers to hospital. The objective of the study was to characterize the incidence, microbiological, and clinical outcomes of NHP requiring hospitalization in comparison with Community Acquired Pneumonia (CAP) patients.

**Methods:** A secondary analysis of 5,176 patients from the Community Acquired Pneumonia Organization database (CAPO) was performed. World regions were defined as North America (I), Latin America (II), Europe (III), and Asia and Africa (IV).

**Results:** 287 patients (6%) were identified as NHP (mean age 80 yrs). The incidence of NHP was 31, 39, 28, and 1% in the regions I, II, III, IV, respectively. Thirty two patients (11%) required ICU admision. Etiology was defined in 1,403 (27%) of CAP cases instead of 68 (24%) with NHP. The most common isolated pathogens included Streptococcus pneumoniae (34%), Staphylococcus spp (7%) and Haemophilus influenzae (8.5%). Gram(-) pathogens and Staphylococcus spp (29%) were more common in patients with NHP, particularly in North America. The NHP presented more frequently with pleural effusions (28% vs 19%) and multilobar involvement (31% vs. 24%) than CAP patients. Time to clinical stability was 5.9 days in NHP and 4.7 days in CAP patients (p<0.01). The 1-month mortality rate was statistically higher in NHP patients than CAP patients (41% vs. 18%, p<0.01), such as for CAP-related mortality rate (17% vs. 5.4%, p<0.01).

**Conclusions:** NHP patients over the world and can be considered a different clinical entity in terms of presentation, microbiology, clinical course and mortality.

**P2467 Influence of streptococcus pneumoniae serotypes in clinical outcomes of pneumonias**

Yolanda Galea1, Beatriz Borja1, Diana Colon1, Carmina Marti2, Enric Barbeta3, 1Respiratory Unit, Hospital General Granollers, Granollers, Barcelona, Spain; 2Microbiology, Hospital General Granollers, Granollers, Barcelona, Spain

In adults, the influence of Streptococcus pneumoniae (Sp) serotypes on pneumonia mortality remains unclear.

**Aim:** To describe the characteristics of adult patients with pneumonia caused by Sp isolated in invasive strains and the influence of different serotypes in clinical outcomes.

**Method:** A retrospective study of Sp serotypes in invasive strains isolated from patients with pneumonia, describing the clinical features and complications. Blood and pleural fluid samples were processed using the BacT-Aert-Mbl system. All strains were sent to the Reference Laboratory for serotyping. Serotypes were divided into 3 groups [1]: High invasive disease potential (H group): 1, 5 and 7 F; Low invasive potential (L group): 3, 6A, 6B, 8, 19F and 23F; the rest were named as other serotypes (O group).

**Results:** Between January 2009 and December 2010 were isolated 53 Sp strains, 44 blood samples and 9 pleural fluid (3 patients had both). 18 of them were serotypes of H group, 10 were of L group, and 23 were of O group. There were a total of 50 patients (58% men). Mean age was 56±19. The table shows clinical outcomes.

**Conclusions:** Contrary to what could be expected the pneumonias caused by Sp serotypes of H group had a lower mortality ratio.1 Brueggerman AB et al. Clonal relationships between Invasive and carriage S pneumoniae and serotype- and clone-specific differences in invasive disease potential.

Pneumococcal pneumonia – Are the new severity scores more accurate in predicting adverse outcomes?
Carlita Ribero1, Inês Ladeira1, Gabriela Abreu2, Ana Rita Gaio3, M. Céu Bruto1,
1Pulmonology Department, Centro Hospitalar Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 2Clinical Pathology, Centro Hospitalar Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 3Mathematics Department, University of Porto, Porto, Portugal

Background: The severity scores are validated prognostic tools for community-acquired pneumonia mortality and treatment site decision.

Aim: To compare the discriminatory power (DP) of 4 scores – the classic PSI and CURB65 and the most recent SCAP (Yandiola et al. Chest 2009;135:1572-1579) and SMART-COP (Charles et al. Clinical Infectious Diseases 2008;47:375-84) – in predicting major adverse events: death, ICU admission, need for invasive mechanical ventilation or vasopressor support.

Methods: A 5-year retrospective study of patients admitted for pneumococcal pneumonia (PP). The patients were stratified based on admission data and assigned to risk classes (low-medium-high) for each score, as validated by previous studies. Statistical analysis was done based on sensitivity, specificity and area under the curve (AUC) under the ROC curve.

Results: We assessed 142 episodes of hospitalization for PP. We observed 2 deaths, 22 admissions to the ICU, 10 patients needed mechanical ventilation and vasopressor support. The AUC for each score/event is summarized on the following table.

<table>
<thead>
<tr>
<th>Score</th>
<th>Mortality</th>
<th>ICU admission</th>
<th>Mechanical ventilation</th>
<th>Vasopressor support</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSI</td>
<td>0.96 ±(0.02)</td>

<td>0.62 ±(0.09)</td>
<td>0.59 ±(0.03)</td>
</tr>
<tr>
<td>CURB65</td>
<td>0.96 ±(0.02)</td>
<td>0.70 ±(0.07)</td>
<td>0.66 ±(0.09)</td>
<td>0.72 ±(0.02)</td>
</tr>
<tr>
<td>SCAP</td>
<td>0.85 ±(0.03)</td>
<td>0.85 ±(0.049)</td>
<td>0.86 ±(0.001)</td>
<td>0.83 ±(0.001)</td>
</tr>
<tr>
<td>SMART-COP</td>
<td>0.88 ±(0.07)</td>
<td>0.85 ±(0.055)</td>
<td>0.81 ±(0.081)</td>
<td>0.82 ±(0.001)</td>
</tr>
</tbody>
</table>

Conclusions: The rate of all adverse outcomes increased directly with increasing risk class in all scores. The new gravity scores (particularly the SCAP score) appear to have a higher DP to all adverse events in our study.

P2469

Clostridium difficile infection following community-acquired pneumonia
Gourab Choudhury, Ahsan Akram, Pallavi Mandal, Gillian Fleming,
Edinburgh, United Kingdom

Introduction: In this prospective observational study of hospitalized community-acquired pneumonia (CAP) patients, we determined the incidence Clostridium difficile infection (CDI) and its contribution towards treatment failure.

Methods: Data were recorded for 1833 consecutive CAP patients. All patients with 2 or more loose stools during these admissions, had samples sent for Clostridium difficile toxin testing. The association of specific risk factors and development of CDI was assessed by multivariable logistic regression (MVR).

Results: There were 51 cases of CDI following CAP (2.7% of CAP cases). The most frequent antibiotic regimes implicated were amoxicillin/clavulanic acid +/− macrolide (54.9%) or regimes containing cephalosporins (35.3%). 37.3% of CDI cases received more than 2 antibiotics (excluding those used to treat CDI), while only 3 patients were on monotherapy. Mortality secondary to CDI was 21.6% as inpatient, rising to 43.1% at 1 year (compared to 1 year mortality for all CAP patients of 21.3%, p=0.0001). Overall mortality rate for CAP patients was 9% at 30 days.

In MVR analysis, the factors associated with development of CDI were age (AOR 1.04 95% CI 1.01-1.08, p=0.03), duration of admission (AOR 1.06 95% CI 1.04-1.09, p<0.0001), total number of antibiotics during admission (AOR 2.59 95% CI 1.22-5.51, p=0.01), and total duration of antibiotic therapy (AOR 1.14 95% CI 1.02-1.27, p=0.02).

Conclusion: CDI is a relatively uncommon complication of CAP, occurring predominantly in elderly patients. Post CAP, it is, however, associated with increased in-hospital and 1 year mortality. Reducing total antibiotic exposure and duration of treatment might be as important as changing antibiotic class in reducing CDI rates.

P2470

Potential value of an ELISPOT interferon gamma release assay as a diagnostic tool in Q fever infections
Gija Limondard1, John Bouamoun2, Anita Asscheman3, Steven Thijssen2, Bart Vlaminkx3, Aik Bossink1, 1Palmonary Diseases, Diaknonessien, Utrecht, Netherlands; 2Medical Microbiology & Immunology, Diaknonessien, Utrecht, Netherlands; 3Medical Microbiology & Immunology, St. Antonius Hospital, Nieuwegein, Netherlands

Rationale: Q fever is an emerging zoonosis in the Netherlands, atypical pneumonia being the most common clinical manifestation. Acute disease is followed by resolution in the majority of cases, 10-20% will exhibit the post-Q fever fatigue syndrome (QFS) and 1-5% of patients progresses to chronic disease. Current tests measuring humoral immune response to Coxiella burnetii have considerable limitations in diagnosing these different outcomes. We conducted an exploratory study to determine T cell response to C. burnetii specific antigens using an ELISPOT interferon gamma release assay (Coxiella ELISPOTs).

Methods: An in-house developed Coxiella ELISPOT interferon gamma release assay, using both phase I and phase II antigens was performed on blood samples of 47 Q fever patients.

Results: Coxiella ELISPOT was performed for 7 patients reconvalesced after acute Q fever and 2 chronic Q fever patients (n=1 newly diagnosed, n=1 after completion of treatment). Mean (± SD) spot count for reconvalesced patients was 11±5 (range 1-42) for phase I and 31±15 (range 1-120) for phase II. One patient was diagnosed with QFS and had the highest spot count in both phase I (42 spots) and phase II (120 spots). The newly diagnosed chronic Q fever patient (male, 64 years) showed a predominant responsiveness to phase I antigen (spot count Phase I 209, Phase II 177). The other chronic Q fever patient (male, 67 yrs) had finished a 18 month antibiotic treatment for Q fever endocarditis. Coxiella ELISPOT showed a marked T cell unresponsiveness to both phase I (3 spots) and phase II antigens (0 spots).

Conclusion: Different clinical Q fever outcomes are associated with marked differences in Coxiella ELISPOT results.
Characteristics and predictors of mortality in patients with pleural infection
Rebecca Taylor¹, Stephen Murphy¹, Alice Melville¹, ¹Respiratory Department, Sunderland Royal Hospital, Sunderland, Tyne and Wear, United Kingdom;
²Respiratory Department, Wansbeck Hospital, Ashington, Northumberland, United Kingdom

Background: Pleural infection is increasing in incidence and causes significant morbidity and mortality. Many UK patients are cared for by non-respiratory teams.

Aims of study: To evaluate recovering of autonomic cardiac control in patients with community-acquired pneumonia.

Methods: A 12 months prospective multicenter and longitudinal study was performed in several hospitals of a Spanish mediterranean area (Comunidad Valenciana). We included patients over 65 with CAP diagnosis. We analyzed mortality related factors (comorbidities, clinical, radiological and laboratory findings, complications) and mortality risk related to PSI or CURB65 scores. Statistical analysis included Chi Square with significance p<0.05.

Results: 750 patients were included, with mean age of 76.7±7.5 years. 63.9% were men. 5.1% died. In our cohort, mortality rate attending PSI score or CURB65 was consistent as reported series (Table 1). However, CURB65 accuracy to predict mortality has not been validated in elderly population.

Aim: To analyze the predictive mortality value of CURB65 scale versus PSI score in patients with CAP older than 65 years old.

To characterise patients with pleural infection, assess standards of care and identify clinical variables predictive of outcome.

Results: 45 cases were included, 69% male, median age (IQR) 72 (46-78) years. 36% had a recent pleural procedure prior to developing infection. 36% were immunosuppressed, 13% had an underlying malignancy. 73% were under respiratory care. Inpatient mortality was 20%. Outcomes varied between respiratory and non-respiratory care: Mortality: 9% v 50% OR (95% CI) 0.10 (0.019-0.51) p=0.006. Drain-related complications: 27% v 58% OR (0.06-1.06) p=0.056. Length of stay: mean (SD) 18.3 (20.1) v 35.3 (28.8) days HR 4.16 (1.59-10.9) p=0.0035. In univariate analysis mortality was associated with increased age, high urea, low serum albumin and low pleural fluid protein level. On multivariate analysis mortality was predicted by age≥75 years OR 10.7 (1.75-66.6) p=0.010, albumin <30mg/dl OR 6.41 (1.47-35.7) p=0.032, and non-respiratory care OR 6.7 (1.07-42.4) p=0.041.

Conclusions: Pleural infections are often iatrogenic and associated with malignancy or immunosuppression. Complications with chest drains are common. Mortality is highest in older patients with low albumin. Patients under respiratory care have better outcomes.

The three patients had a very similar clinical picture: poor social background (disorganized families, homeless, prisoners), history of intravenous drug use (especially heroin), recently using etnobotanic powders intravenously, positive HCV, negative HIV and VHB, multiple bilateral lung opacities on X-Ray, similar symptomatology (fever, dyspnea, cough with macropurulent sputum), tricuspid valve endocarditis (confirmed by echocardiography). The bacteriological exam (bacteriemias and sputum) were negative probably related to the empirical antibiostatic usage prior hospitalisation. Two patients improved slowly with antibiostatic treatment. One critically ill patient died with septic shock and multiple organ insufficiency.

Conclusions: The increased number of cases with multicentric pneumonia and endocarditis related to the usage of the ethnobotanic drugs of legal status reveal the harmful effect when used intravenously.

Conclusions: Although mortality rate in our cohort is closed to reported data, CURB65 in elderly patients with CAP underestimate the severity of CAP compared to PSI scores.

271. Assessment of severity and predictors of outcomes in community-acquired pneumonia

P2475

Slow recovering of altered autonomic cardiac control in patients with community acquired pneumonia
Rustem Zakharnev¹, Shamil Zagidullin¹, Naufal Zagidullin¹, Veronika Bakirova², ¹Internal Diseases (Propedeutics), Bashkortostan State Medical University, Ufa, Bashkortostan, Russian Federation; ²Pulmonology, Clinical Hospital No. 21, Ufa, Bashkortostan, Russian Federation

Altered autonomic cardiac control is associated with severe arrhythmias, heart insufficiency and sudden death.

Aim: To evaluate recovering of autonomic cardiac control in patients with community acquired pneumonia (CAP). 73 patients with nonsevere CAP (nCAP) and 14 patients with severe CAP (sCAP) were studied at the day of hospital admission and in follow-up periods of 3 and 14-16 days after admission. Controls (CG) included 48 healthy subjects. Autonomic cardiac control was estimated via analysis of fluctuations of consecutive RR intervals at 10 min ECG record. Heart rate variability (HRV) indexes included standard deviation SDNN, coefficient of variation CVNN, 0.04-0.15 Hz and 0.15-0.4 Hz bands spectral power. At admission HRV indexes were significantly lower in both CAP groups than in CG. All patients showed clinical and functional recovery. nCAP HRV indexes reached CG values on the 15th day after admission. sCAP HRV indexes remained lower than in nCAP and CG.

Conclusions: Autonomic cardiac control is significantly altered in patients with CAP. Predicted recovery period may take up to 6 months in patients with severe CAP and extreme physical workload should be limited due to increased cardiovascular risk.
In pneumonia, pathogen-host interaction may evoke pulmonary endothelial permeability despite efficient antimicrobial therapy, resulting in life-threatening lung failure. Angiopoietin (Ang)-1 mediated Tie-2 activation reduces and Ang-2 expression was increased. Further, we detected reduced pulmonary mRNA expression of Ang-1 and Tie-2 and increased Ang-2 expression in murine lung tissue following infection with *S. pneumoniae*. These results suggest a central role of the Ang-1/Tie-2-system in pneumonia-evoked inflammation and permeability, and provide a new therapeutic perspective for severe pneumonia.

Differences between local and systemic inflammatory response in patients with community acquired pneumonia (CAP) 
Leanza Calisi,1,2 Monica Morlacchi,1,2 Letizia Corinna Morlacchi,1,2 Stefano Aliberti,3 Sonia Seghezzi,1 Valeria Giunta,1 Marta Di Pasquale,1 Giulia Spoletini,1 Anna Maria Brambilla,3 Jose Bordon,4 Fabio Giuliani,1 Samantha Galbiati,1 Barbara Dallari,1 Andrea Gramegna,1 Letizia Corinna Morlacchi,1,2 Stefano Aliberti,2,3 Sonia Seghezzi,1 Valeria Giunta,1 Marta Di Pasquale,1 Giulia Spoletini,1 Anna Maria Brambilla,3 Jose Bordon,4 Fabio Giuliani,1 Samantha Galbiati,1 Barbara Dallari,1 Andrea Gramegna,1 Letizia Corinna Morlacchi,1,2 Stefano Aliberti,2,3 Sonia Seghezzi,1 Valeria Giunta,1 Marta Di Pasquale,1 Giulia Spoletini,1 Anna Maria Brambilla,3 Jose Bordon,4 Fabio Giuliani,1 Samantha Galbiati,1 Barbara Dallari,1 Andrea Gramegna,1

Understanding inflammatory response is a crucial issue in the management of CAP. The aim of our study was to evaluate both local (lung) and systemic (serum) inflammation on admission in hospitalized patients with CAP. An observational prospective study was performed on consecutive patients hospitalized for CAP from April to December 2010 at the Respiratory Dept., Poliomicological Hospital, Milan, Italy. Within 24 hours after admission, specimens of blood and exhaled breath condensate (EBC) were collected. The following cytokines were detected: IL-1α, IL-1β, IL-2, IL-6, IL-10, TNF-γ and INF-γ and anti-inflammatory (IL-4 and IL-10). A total of 43 subjects were prospectively enrolled (26 males; mean±SD age: 71±18 yrs). Local and systemic inflammatory patterns on admission are shown in Table (Mean ± SD).

Pro-inflammatory interleukins were increased in patients undergoing mechanical ventilation on admission in comparison to the rest of the population in both serum (IL-1α 0.57±1.02 vs. 0.11±0.12, respectively; p<0.007) and EBC (IL-6 0.31±0.28 vs. 0.08±0.06, respectively; p=0.001). These findings may help to understand the decompartmentalization of the inflammatory response, which takes place since the very early stages of the infection in hospitalized patients with CAP.

**P2479**
Validity of CRB-65 in LRTI in primary care: A prospective study in 12 European countries 
Samuel Coenen1,2, Theo Verheij1, Greet Ieven2, Christine Lammens2, Christopher Butler3, Paul Little3, Henrik Große3,1

Background: CRB-65, a useful tool to predict community-acquired pneumonia (CAP) outcome in hospitals, has been recommended for use in primary care. CRB-65 scores are calculated by assigning one point for each of: the presence of Confusion, Respiratory rate ≥ 30 per minute, Blood pressure systolic < 90 mm Hg or diastolic ≤ 60 mm Hg, and age ≥ 65 years. Aim: To assess the validity of CRB-65 to predict poor prognosis in adults presenting to primary care with lower respiratory tract infection (LRTI). Methods: Clinicians prospectively recorded clinical features on a case registration form. Patients had a chest X-ray within 7 days after inclusion. A notes review was performed. We used a two-level logistic regression model (with patients nested within clinicians) to assess the association between a CRB-65 score ≥ 1 and mortality and a combination of re-consultation and hospital admission, and tested for interaction to assess differences in these outcome between patients with and without CAP. Results: None of the 3112 included patients died due to the LRTI. Complete data were available in 2627 (84%) patients. Of these, 866 (33%) had a CRB-65 score ≥ 1, 108 (4%) had CAP, and 488 (19%) re-consulted or were admitted to hospital. Both a CRB-65 score ≥ 1 and CAP were associated with more re-consultations or hospital admission (odds ratio (95%CI): 1.32 (1.06–1.64) and 2.18 (1.13–4.21), respectively). The interaction term was not significant (1.17 (0.57–2.41)). Conclusion: In patients presenting to primary care with LRTI, low mortality and low prevalence of CAP limit the usefulness of CRB-65. Nevertheless, a CRB-65 score ≥ 1 is associated with a significant increase in re-consultations and hospital admissions.

**P2480**
Vascular events following hospitalisation for community acquired pneumonia Ahan R. Akram1,2, James D. Chalmers1, Aran Singanayagam3, Gillian B. Fleming4, Joanne K. Taylor5, Duncan Mills6, Adam T. Hill1,1 Department of Respiratory Medicine, New Royal Infirmary of Edinburgh, Edinburgh, United Kingdom;2 College of Medicine, University of Edinburgh, Edinburgh, United Kingdom

Objective: To determine if patients with community acquired pneumonia (CAP) are at increased risk of vascular events following discharge. Methods: Patients enrolled in a prospective study for CAP who survived to hospital discharge were followed up at 1 year. A cohort matched to age, sex, co-morbidities and vascular risk factors were included and the incidence of vascular events and mortality were recorded. Results: 1321 patients were included (50.3% male, median age 65 (IQR 48–77), 23.7% had a prior history cardiovascular events) with 1321 matched controls. 12.3% of CAP patients died after discharge by 1 year, with 28.9% attributed to cardiovascular events or stroke. The incidence increased with age. 156 patients required hospitalisation within 1 year for one or more vascular event; myocardial infarction (MI) n=74, cardiac failure n=61, for cardiac arrhythmia n=31 and stroke n=12. Of the 74 patients with MI, there was a significantly increased incidence when compared to the control group (fig1).
Using multivariate logistic regression analysis, major predictors of cardiovascular deaths following CAP were age (OR 1.04 95% CI (1.02-1.07), p<0.0001), prior history of cardiovascular events (2.70 (1.47-4.96), p<0.001), ICU admission during hospital admission (1.87 (1.04;3.38), p=0.04) and anaemia (0.98 (0.97-0.99), p=0.0007).

Conclusion: Hospitalisation for CAP is associated with an increased risk of cardiovascular events and mortality at 1 year.

P2483
Severe complicated pneumococcal pneumonia in young adults
Sebastian Ellis, Matthew Harris, Suzanne Shuttlesworth, Chris Taylor, Aye Aye Lwin. Respiratory, Southampton General Hospital, Southampton, Hampshire, United Kingdom

Background: Pneumococcal pneumonia causes parapneumonic effusion (PE) in 40%-57%. Severity can be influenced by both host characteristics e.g. co-morbidity, age and vaccination status and, bacterial factors.

Aims and objectives: To study the relationship between host characteristics (age, co-morbidity and previous vaccination) and disease severity in adults admitted with pneumococcal pneumonia.

Methods: A cohort of 21 inpatients with pneumococcal pneumonia between December 2010 to January 2011 were retrospectively studied using electronic patient records, medical notes and the PACS system. Uncomplicated PE (UPPE) was defined as pleural fluid pH >7.2, complicated PE (CPPE) as pH <7.2 and empyema as visible purulent fluid.

Results: 21 patients were admitted with pneumococcal pneumonia, 8 male and 13 female, median age 48 years (range 18-76). 9 (43%) had no associated co-morbidity, of which 7 were <65 years. 6/9 developed pleural effusion (1 UPPE, 4 CPPE and 1 empyema), 4 (72%) required chest drainage, none of these 4 were vaccinated. All patients who developed pleural effusion or empyema, 9/21 (38%), had an admission CRP > 100 (range 101-500) and albumin <35 (range 16-32). 7/21 (33%) patients were admitted to the intensive care unit (ICU). 47% had no associated co-morbidities, median age was 33 (range 29-48) and all 4 patients were not vaccinated.

Conclusion: Our study highlights that along with high risk groups, young un-vaccinated adults with no co-morbidity are also at risk of developing severe pneumococcal pneumonia with complicating pleural effusion or empyema.

P2484
Impact of pneumococcal urinary antigen testing in the clinical presentation and outcome of pneumococcal bacteraemic community acquired pneumonia
Luis Alberto Ruiz, Maria Alfonso, Ainhoa Gomez, Sandra Pedrero, Nuria Marina, Marta Inchausti, Inxute Seijas, Carmen Jaca, Rafael Zalacaín. Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain Pneumology, Cruces Hospital, Barakaldo, Spain

Aim: To describe the clinical characteristics and outcome of a group of patients diagnosed with pneumococcal bacteraemia community acquired pneumonia (PB-CA) depending on the results of pneumococcal urinary antigen testing (PUAT).

Methods: We have studied all patients admitted to the Respiratory Service and/or ICU of our hospital for 10 years. Patients have been divided into two groups according to the results of PUAT (BINA®). Exclusion criteria included (1) lack of antibody immunity deficiency syndrome, other immunodeficiencies or under immunosuppressive treatment; (2) health care associated pneumonia.

Results: We have studied 250 patients, 233 out of them underwent UPATD.

Conclusions: 1. PUAT positivity was associated with an early antibiotic prescription at the emergency department at admission. 2. Patients with positive PUAT were more frequently admitted to ICU. They also had a higher mean hospital stay but there were no significant differences regarding severity according to PSI and CURB score. 3. Patients under negative PUAT had a lower but no significant mortality rate.

P2485
Is pneumonia in elderly an enigma: A study from a multispeciality hospital in rural India
B N B Mahaveera Prasad, C A Tukaram. Medicine, Military Hospital Wellington, Wellington Barracks, The Nilgiris District, Tamilnadu, India

Aim: To study the manifestations and outcome of pneumonia in elderly from a multispeciality hospital in rural India.

Conclusions: 1. PUAT positivity was associated with an early antibiotic prescription at the emergency department at admission. 2. Patients with positive PUAT were more frequently admitted to ICU. They also had a higher mean hospital stay but there were no significant differences regarding severity according to PSI and CURB score. 3. Patients under negative PUAT had a lower but no significant mortality rate.
P2486 Prospective comparison between chest ultrasound and X-ray in two planes in patients with suspected community-acquired pneumonia. Intermediate results (02/2011) of a prospective multicenter DEGUM-/ÖGUM-study

Aim: The aim of the prospective study is to define the sensitivity of chest ultrasound (US) in diagnosing and follow-up of community-acquired pneumonia (CAP).

Patients and methods: US was performed in 326 patients (age 18-95 years; 211 males, 115 females) with suspected CAP. The results were first compared to X-ray in two planes. In case of positive US and negative or inconclusive X-ray a low-dose computed tomography (CT) was performed. Sonographic characterisation of pneumonia was carried out at day 0, between day 5-8 and between day 13-16.

Results*: US / X-ray / CT / Number of patients:

- negative / negative / not done / n=109
- positive / negative / positive / not done / n=153
- positive / positive / negative / not done / n=41
- positive / negative / negative / not done / n=22
- negative / negative / negative / not done / n=13
- negative / inconclusive / positive / not done / n=2
- US was inconclusive in 5 patients, which had to be deleted according to the study protocol.

Conclusions: The intermediate results suggest a high sensitivity and specificity of US in diagnosing and follow-up CAP. The final results will be available in September 2011.

P2487 Does a clinical score helps in the management of hospital-acquired pneumonia in nonventilated patients?

Bertrand Heres, Zhineh Gazaee. Service de Pneumologie, Centre de Forcilles, Fénolles Attilly, France

Hospital-acquired pneumonia (HAP) is increasingly frequent in nonventilated (NV) patients. Because of the difficulty of obtaining invasive diagnostic procedures outside an intensive care unit (ICU), a clinical score could be useful for the management of NV patients. We tested the diagnostic accuracy of a score (SCOPNOFOR) suitable for NV patients with clinical suspicion of HAP, obtained by combining the following clinical parameters (minimal value = 0, maximal value = 9): non cancerous comorbid condition (0=nosent, 1=present); solid cancer (0=absent, 1=present); pulmonary comorbidity (0=nosent, 1=pseudopneumothorax, 2=pseudocyst); previous antibiotics (0=yes, 1=no); radiographic infiltrate (0=no or diffuse, 2=localized); NV ICU (0) or ward (1) patient. The score was calculated before a protected specimen brush was obtained by bronchoscopy in all cases and its value was compared with bacteriological results to assess sensitivity (Se) and specificity (Sp).

HAP was confirmed in 45 (54.6%) of 84 suspected episodes disclosing in major part nonfermenting (35.6%) and enteric (42.2%) gram-negative bacilli, staphylococci (26.7%) and streptococci (26.7%) spp. Polymericbacterial HAP was present in 37.8% of episodes. The mean ± SD SCOPNOFOR value was 5.3±1.6 and 4.3±1.5, respectively, for the 45 HAP episodes and the 39 non HAP episodes (p=0.003). Se and Sp were respectively at a SCOPNOFOR value more than 5, 53% and 79%, and more than 2, 27% and 95%. We conclude that SCOPNOFOR can at least 50% in 75% of patients with defined HAP according to the chosen cut-off. These data support the need for establishing an etiologic diagnosis in suspected HAP in NV patients.

P2488 Comparison of four systems for assessing severity of community acquired pneumonia

Tiago Abreu, Telma Lopes, Marisa Anciães, Dalila Ferreira, Sara Salgado, Gil Duarte. Servico de Pneumologia II, Centro Hospitalar Lisboa Norte - Hospital Pulido Valente, Lisboa, Portugal

Introduction: The use of severity scores for community acquired pneumonia (CAP) is recommended by many clinical guidelines. However, debate about the preferred system is ongoing.

Objective: To compare the performance of 4 systems to identify severe CAP.

Material and methods: We reviewed 176 patients diagnosed with CAP, admitted in a Pneumology ward, from January 2007 to July 2009. We compared 4 systems: Pneumonia Severity Index (PSI), CURB65, modified American Thoracic Society criteria for severe pneumonia (AtSrn) and SCAPE score.

We divided the patients in 2 groups: low-risk and high-risk, the later defined as CURB65 ≥3, PSI classes IV, AtSrn ≥1 major criteria or ≥3 minor criteria and SCAP score ≥3 major criteria or ≥3 minor criteria. We evaluated the performance of all four systems in low and high-risk patient adverse outcomes, defined as mortality and need for ICU admission, based on sensitivity, specificity and area under the ROC curve (AUC).

Results: Sensitivity and specificity (95% confidence interval in brackets) were, respectively: CURB65 27.33% [9.7 - 56.6] and 91.5% [86.3 - 94.9]. PSI 81.8% [52.3 - 94.9] and 55.8% [48.1 - 63.1]. AtSrn 54.6% [28.0 - 78.7] and 95.8% [91.5 - 97.9]. SCAPE 81.8% [52.3 - 94.9] and 70.9% [63.6 - 73.1].

AUC was: CURB65 0.594, PSI 0.688, AtSrn 0.752 and SCAPE 0.764.

Conclusions: PSI and SCAPE were the most sensitive systems, while CURB65 and AtSrn were the most specific. Although the most discriminative capacity was found in SCAPE, it presented many false positives. Probably, a good approach would be to rely on clinical judgment, triage of high risk patients with PSI or SCAPE and use of AtSrn to determine need for ICU admission.

P2489 Value of serum procalcitonin levels in the differential diagnosis of pneumonia and pulmonary embolism

Ayse Yeter, Gungor Camsali, Gulcan Elgorn, Aygun Gur, Nur Dilek Baken, Mehmet Bayram. Pulmonology, Yeditepe Teaching Hospital for Chest Diseases and Thoracic Surgery, Istanbul, Turkey

Objective: Procalcitonin (PCT), a precursor hormone of calcitonin is secreted from the thyroid. It was increased in blood in bacterial infections. The aim of the study was to determine the serum procalcitonin levels in differentiating community-acquired pneumonia (CAP) from pulmonary embolism (PE).

Methods and patients: Fifty-eight patients with 1≥1 of the following symptoms; fever, cough, dyspnoea, haemoptysis, sputum, chest pain; and PE were included in the study. Thirty patients were diagnosed as CAP and 27 patients as PE. One patient with suspected PE was excluded because of negative pulmonary CT angiography. Serum PCT values of all patients were measured and recorded before treatment was started.

Results: Median values of PCT were in patients with PE 0.05 ng/ml in patients with CAP 1.38 ng/ml. The area under ROC curve was 0.83. With an optimal cut-off value 0.27 ng/ml for differentiating PE and CAP, sensitivity was 76.4%, specificity 85.2%, negative predictive value 76.7%, positive predictive value 85.2%, and accuracy 80.7%.

Conclusion: Serum PCT has a high diagnostic value in the differential diagnosis of PE and CAP. Serum PCT can be used in differentiating CAP and PE as an inflammatory marker.

P2490 The value of exhaled breath condensate “pH” to evaluate the severity of disease and the response to treatment in patients with community acquired pneumonia

Deniz Arık1, Cemal Tasci2, Metin Orkan1, Hayati Bilgic1, Cengizhan Aciçek1, Ismail Kurt1, 1Chest Disease, Chest Disease, Ankara, Turkey; 2Public Health, Public Health, Ankara, Turkey; 3Biochemistry, Biochemistry, Ankara, Turkey

Introduction: There is no practical procedure in defining severity of community acquired pneumonia (CAP) and evaluation of response to treatment. Recently “exhaled breath condensate pH” measurement as a noninvasive, reproducible and easily performed method is in use to diagnose some airway and pulmonary diseases. We planned this study to measure the severity and response to treatment in patients with community acquired pneumonia by using this method.
P2491
Cost and outcomes of pneumococcal community-acquired pneumonia among adults in the United Kingdom
Apostolos Charos, Paul Balmer. Specialty Care, Pfizer, Walton Oaks, United Kingdom

Background: Community-acquired pneumonia (CAP) is associated with substantial morbidity and mortality among adults in the United Kingdom (UK). S. pneumoniae is the most common cause of CAP.

Aims and objectives: The study objective was to evaluate the clinical and economic burden of pneumococcal CAP among adults in the UK.

Methods: A cost-outcomes model was developed to estimate the inpatient costs and health outcomes associated with pneumococcal CAP among adults above 50 years old in the UK. Health outcomes were measured in terms of life-year (LY) and quality-adjusted life year (QALY) lost. National data sources were used to estimate hospital admissions, deaths and costs with CAP as primary diagnosis for 2009/10. Since specific pathogens for pneumonia are not commonly identified, the proportion of CAP attributable to S. pneumoniae was estimated based on literature findings. A structured literature search was conducted to identify UK specific quality of life data.

Results: We estimated that there were 58,604 annual hospital admissions for pneumococcal CAP for adults above 50 years old in the UK, costing more than £122 million per year. In addition, there were 13,161 deaths per year resulting in 87,533 pneumoniae CAP for adults above 50 years old in the UK. Health outcomes were measured in terms of life-year (LY) and quality-adjusted life year (QALY) lost. National data sources were used to estimate hospital admissions, deaths and costs with CAP as primary diagnosis for 2009/10. Since specific pathogens for pneumonia are not commonly identified, the proportion of CAP attributable to S. pneumoniae was estimated based on literature findings. A structured literature search was conducted to identify UK specific quality of life data.

Conclusion: We estimated that there were 58,604 annual hospital admissions for pneumococcal CAP for adults above 50 years old in the UK, costing more than £122 million per year. In addition, there were 13,161 deaths per year resulting in 87,533

Relationship between the presence of hypoxemia and the inflammatory response measured by C-reactive protein in bacteremic pneumococcal pneumonia
Francisco Sanz1, Concepción Gimeno 2, Tomás Lloret1, Nuria Torroja1, Marisa Britos1, Estrella Fernández1, Angela Cervera1, Maria Carmen Aguilar1, Eusebi Chiner6, José Blanquer 7.

Aims: To evaluate whether the presence of hypoxemia could influence the systemic inflammatory response (C-reactive protein, CRP) in bacteremic pneumococcal pneumonia (Pu-CAP).

Material and methods: We analyzed the relationship between the presence of hypoxemia (PaO₂/FiO₂ < 300) and other clinical parameters and systemic inflammatory response measured by PCR in a series of bacteremic pneumococcal pneumonia. We performed a multiple linear regression analysis considering CRP levels as a dependent variable and other physiological parameters and comorbidities as independent variables.

Results: We analyzed 297 cases of bacteremic pneumococcal pneumonia. The mean PAO2/FIO2 was 277.7 (IQR: 233.3-323.8), and 44.8% (133) showed PaO₂/FiO₂<300. CRP mean was 27.6 mg/dl (IQR: 15.7-39.2). Linear regression analysis showed that pneumonia severity (PSI score) (regression coefficient: -0.21, p = 0.047) and the presence of some immunosuppressant factor (regression coefficient: -0.29, p = 0.002) were independently associated with CRP levels. The model showed a correlation of 0.333 with r² of 0.125.

Conclusions: In our series, we observed that the degree of hypoxemia, the severity of pneumonia and the presence of some immunosuppressant factors correlates with the systemic inflammatory response measured by CRP in bacteremic pneumococcal pneumonia.

P2493
Usefulness of serum cortisol in assessment for the severity of community-acquired pneumonia
Min-Su Kim. Respiratory Medicine, Changwon Fatima Hospital, Changwon, Republic of Korea

Background: High cortisol levels are frequently observed in patients with severe infections and are of prognostic value in sepsis. The aim of this study was to evaluate the clinical usefulness of serum cortisol in assessment for the severity of community-acquired pneumonia (CAP).

Materials and methods: This study analyzed the results of 52 CAP subjects admitted in Changwon Fatima Hospital between July 2008 to May 2010. Total serum cortisol, infection markers such as C-reactive protein (CRP), procalcitonin (PCT) and CURB (Confusion, Uremia, Respiratory, Blood pressure)-65 were examined retrospectively.

Results: In clinically unstable subjects on admission day 4, baseline serum cortisol, CURB-65, and CRP were elevated significantly compared to those of stable subjects.

Conclusion: These findings suggest that measurement of serum cortisol in early stage may provide helpful information in the assessment of CAP severity.
Results: The mortality rate was 12.3%. 120 (48%) patients were admitted to the hospital, despite the fact they were classified as risk class I or II. According to guidelines as far as the initial antimicrobial regimen is concerned was poor (152 patients, 60%). A trend towards shorter length of hospitalization was observed in patients treated with an initial antimicrobial in accordance to guidelines compared to those receiving initial regimen in discordance to guidelines.

Conclusion: The implementation of CAP guidelines by chest physicians in the major Greek hospital for thoracic diseases is poor. Improvement of adherence may shorten the length of hospitalization and reduce the financial burden for the national health system.

Ventilator-associated pneumonia in surgical intensive care unit: Risk factors for mortality and survival period
Hisashi Shoji, Takahiro Takuma, Koichiro Yoshida, Yoshihito Niki. Department of Clinical Infectious Diseases, Showa University, School of Medicine, Tokyo, Japan.

Objectives: The aim of this study was to reveal the prognostic factors of Ventilator-Associated Pneumonia (VAP) in the surgical ICU of Showa University Hospital in Tokyo.

Patients and methods: We reviewed 1629 cases administrated mechanical ventilation in surgical ICU from Apr,2006 to Dec, 2010. In these 1629 cases, 46 patients were diagnosed VAP. We evaluated whether backgrounds, general conditions, laboratory data, chest radiographic features at the time of VAP onset and severity of VAP may contribute to the mortality or survival period.

Results: Twenty-three patients (50%) were dead. Multivariate analyses using significant (p<0.05) parameter in univariate analyses revealed different results, but bilateral pneumonia had significant differences in the both multivariate analyses of mortality and survival period (Table 1 & 2).

Malcolm Simple1, Wei Shen Lim2, Pija Myles1, Joanne Enstone3, Malcolm Semple1, Wei Shen Lim2, Pija Myles1, Joanne Enstone3, Peter Openshaw4, Robert Read1, Bruce Taylor4, James McMenamin5, Barbara Bannister6, S.J. Brett, Karl Nicholson7, Jonathan Nguyen-Van-Tam1, 1Women’s and Children’s Health, University of Liverpool, Liverpool, United Kingdom; 2Respiratory Medicine, Nottingham University Hospital, Nottingham, United Kingdom; 3Epidemiology and Public Health, University of Nottingham, Nottingham, United Kingdom; 4Centre for Respiratory Infection - National Heart and Lung Institute, Imperial College London, London, United Kingdom; 5Infection and Immunity, University of Sheffield, Sheffield, United Kingdom; 6Intensive Care Medicine, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; 7Public Health Medicine, Health Protection Scotland, Glasgow, United Kingdom.

Introduction: Asthma was the commonest co-morbid illness in patients admitted to hospital with influenza A/H1N1. Yet patients with asthma were half as likely to die or require admission to level 2 (high dependency) or level 3 (intensive care).

Hypothesis: Asthma, rather than associated co-morbidities or treatments such as the use of steroids, is an independent factor for improved outcomes in influenza A/H1N1.

Methods: Between April 2009 and January 2010, FLU-CIN collected clinical, epidemiological and outcome data on patients with confirmed influenza A/H1N1 admitted to 75 UK hospitals.

We studied 1520 patients, of whom 480 (31.6%) were <16yrs. Asthma was the commonest co-morbid illness affecting 385 (25.3%) patients.

Findings: Patients with asthma had higher rates of dyspnoea, need for supplemental oxygen and severe respiratory distress than patients who did not have asthma but were significantly less likely to die or require level 2 or 3 care (11.2% vs. 19.8%; OR 0.51, 95% CI 0.36 to 0.72). Co-morbid illnesses were more frequent in patients with asthma (22.6% vs. 7.6%). There was no difference in the proportions with pneumonia (17.1% vs. 16.6%). The association of asthma with less severe outcome was unaffected by age, presence of co-morbidities, in-hospital anti-viral and/or antibiotic use. Adjusting for prior use of inhaled steroid changed the association with severe outcome by over 10% (OR 0.63, 95% CI 0.42 to 0.94). Adjusting for “delayed admission >4 days” had a similar effect (OR 0.63, 95% CI 0.42 to 0.95).

Conclusion: In multivariate analysis, the combination of prior inhaled steroid use and prompt admission to hospital (<4 days) explained the association of asthma with less severe outcome.
Experimental rhinovirus infection in moderate asthma

David Jackson, Maria-Belen Trujillo-Torralbo, Jerico Del-Rosario, Julia Amicsenko, Sebastian Johnaton. National Heart and Lung Institute, Imperial College London, London, United Kingdom

Background: Rhinovirus (RV) is the most common cause for asthma exacerbations. Underlying mechanisms are poorly understood. A human model of experimental infection with RV has been introduced however studies have thus far only recruited mild asthmatics. In order to be more representative of those who experience virus-induced exacerbations there is a need to establish the safety of this model in moderate asthma.

Aim: To assess the safety of the RV challenge model in subjects with moderate asthma treated with inhaled corticosteroids.

Methods: Six subjects with moderately severe atopis asthma requiring maintenance inhaled corticosteroids were infected with RV16. Nasal lavage (NL) and clinic spirometry were performed on days 0,2,4,5,7,10. Symptom scores were recorded daily throughout the study. Clinical infection was confirmed using a combination of symptom scores, demonstration of RV16 RNA by RT-PCR in nasal lavage and at least a 4-fold increase in RV16 specific antibody titres on day 42.

Results: All 6 subjects developed symptoms of a common cold 24-48 hours prior to an increase in lower respiratory symptoms. This was accompanied by a drop in morning FEV1 (mean fall of 25%). Whilst all subjects increased their use of bronchodilator, no subjects required oral corticosteroid therapy. RV16 infection was demonstrated in NL in all subjects.

Conclusions: In this pilot study infection with RV16 in moderate asthma was well tolerated, consistent with previous studies. No unexpected adverse events or requirement for oral steroids occurred. The use of RV challenge in moderate asthma therefore appears safe. Results of future studies using this group of patients will better reflect those individuals with the greatest burden of disease.

Serum microRNA signatures identified in a genome-wide profiling predict the mortality of patients with sepsis

Masuo Nakamura1, Haruyuki Ishii 1, Daiki Kuai1, Takeshi Saraya1, Kenji Fujii2, Shin-Ichi Hagiwara4,5, Yorihiro Yamamoto3, Hajime Goto1.

1Department of Pulmonary Medicine, Jichi Medical School, Tochigi, Japan. 4,5Department of Internal Medicine and Cardiovascular Medicine, Jichi Medical School, Tochigi, Japan. 3Department of Cardiac Surgery, Jichi Medical School, Tochigi, Japan. 2Department of Internal Medicine, Jichi Medical School, Tochigi, Japan.

Purpose: Serum miRNAs are present and stable, reproducible, and consistent among individuals in the serum and plasma of humans and other animals. And they can be fingerprints of different diseases. We used genome-wide serum miRNA expression profiling analysis to investigate the role of serum miRNA in predicting prognosis of sepsis.

Patients and methods: According to the 28-day mortality, Solexa sequencing followed by individual quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) assays was used to test the difference in levels of serum miRNAs between survivors and nonsurvivors. Then were Survivors and 9 nonsurvivors matched by age, sex, and stage for the early detection. The detected serum miRNAs were then validated in 92 sepsis patients (39 survivors and 53 nonsurvivors) and 24 healthy controls.

Results: Twelve serum miRNAs were found to be altered more than two-fold from Solexa sequencing between survivors and nonsurvivors group. qRT-PCR was preformed in 6 miRNAs (miR-206, miR-378, miR-223, miR-15b, miR-15a and miR-16) according to the previous studies. miR-223 (p=0.008<0.01), miR-15b (p=0.008<0.01) and miR-16 (p=0.009<0.01) were significantly difference between those two groups. Then APECESIcore score, SOFA score, CRP, PCT of those patients combining the three miRNAs extend asymptotically to logistic regression. Multiple logistic regression analysis showed that miR-223, APECESIcore and SOFA score were significantly associated with the mortality of sepsis patients.

Conclusion: miR-223, miR-15b and miR-16 from the serum may serve as a noninvasive predictor of the mortality of sepsis patients.

Reduction of oxidative stress in successfully treated patients with community acquired pneumonia (CAP), as measured by redox status of coenzyme Q10 (%CoQ10)

Terentiy M. Gorbunov1,2,3, Pavel Ogarkov1, Sergey Zhogolev1, Konstantin Jogolev2.

1Military Medical Academy, St. Petersburg, Russian Federation; 2Immunology and Microbiology, Military Medical Academy, St. Petersburg, Russian Federation

Aim: To study the efficacy of combined use of pneumococcal vaccine and supplementary preventive means.

Methods: Five groups of military servicemen numbering 120 to 240 persons received, in addition to pneumococcal vaccination, one of preventive means. Persons of the 1st group received influenza virus vaccine, the 2nd group received imudon, the 3rd group bronchomunal, the 4th group cytovir-3, the 5th group arbidol during 4-10 days. Comparative groups were in the same conditions as experimentation groups and received pneumococcal vaccine only.

Results: In 1 and 3 months after the onset of agents’ administration in all the groups in which supplementary preventive agents were administered together with pneumococcal vaccine, an incidence of pneumonia and acute respiratory infections was from 1.6 to 3.5 times lower than in the comparative groups. Thus, one and three months after imudon administration, its efficacy index against pneumonia was 3.5 and 2.2 respectively. The efficacy of supplementary agents was most marked during the first month following administration onset.

Conclusion: To prevent pneumonia in recruits, it is a good practice to use, together with pneumococcal vaccine, influenza virus vaccine, vaccinal immunomodulating agents (such as imudon, bronchomunal), immunocorrecting agents (such as cytovir-3), antiviral medications (such as arbidol) in first days following call-up.

The use of influenzal (IV) and pneumococcal (PV) vaccine in patients, staff and visitors at a university hospital in two periods

Pablo Fiscina, Vanina Martin, Fernanda Runundo, Gustavo Longo, Ileana Pampa, Carlos M. Luna. Pulmonary Diseases Division, Hospital de Clinicas, Universidad de Buenos Aires, Buenos Aires, Argentina

Aims: To determine the trend of IV and PV coverage for the at risk population comparing the years 2001 and 2010.

Methods: 1191 adults (507 in 2001 and 684 in 2010), including patients, relatives, health care workers, medical students and hospital employees, were interviewed at the hospital. They were asked about age, medical history, their knowledge about IV and PV and vaccination history. At risk population was considered according with the current national guidelines.

Results: Among the people with indications for IV, it was received by 50.1% in 2001 and 63.1% in 2010 (p < 0.001) and PV by 11.8% in 2001 and 20.7% in 2010 (p = 0.005).

The trend of vaccination rate improved significantly for few indications; for IV in health care workers (21.2% vs. 77.7%, p<0.001) and in people with hepatic comorbidity (9.4% vs. 46.6%, p=0.017) and for PV only for those with pulmonary comorbidity (17.7% in 2001 vs 51.0% in 2010, p=0.004).

Analyzing 2001 and 2010 together, IV rate was higher in retired people >65 years old included in a social security program (PAMI) consisting in intensive advertising, free delivery and administration; than in those not included in such program (62.1% vs 46.4%, p=0.001).

Conclusions: Vaccination coverage remains low, particularly for PV. Improvement of IV and PV require better awareness, changes in clinical practice, delivery of IV and PV and vaccination history. At risk population was considered according with the current national guidelines.

P2506 Compliance with CURR-65 score and the consequences of no implementation

Qg Gu1, Hai-Yan Li2, Yi-Ping Zhou1, Ming Li1, Xiao-Ke Chen1, Hui Lu1, Hong-Lin Peng1, Hai-Qiong Yu1, Xia Chen1, Nian Lin1, Li-Hua Li1, Qiong-Zhou Zhao1, Mei Jiang1. 1Department of Respiratory Medicine, Affiliated Fattan Hospital, Guangdong Medical College, Shenzhen, China; 2Department of Primary Care, Affiliated Fattan Hospital, Guangdong Medical College, Shenzhen, China; 3Department of Radiology, Affiliated Fattan Hospital, Guangdong Medical College, Shenzhen, China; 4Guangzhou Institute of Respiratory Diseases (State Key Laboratory of Respiratory Diseases), First Affiliated Hospital, Guangzhou Medical University, Guangzhou, China

Background: The CURR-65 score is a simple well validated tool for the assess-ment of severity in community-acquired pneumonia (CAP). Whether it is used routinely is unknown. The aim of this study was to determine the frequency of use of the score in routine hospital practice and the consequences of no implementation.

Methods: A retrospective analysis of data from 1230 patients with CAP in a Chinese affiliated hospital of a medical college was performed.

Results: None of the patients with CAP had CURR-65 score applied at admission. 716 (58.2%) patients who had a CURR-65 score of 0 were unnecessarily hospitalized. 402 (32.7%) patients who had a CURR-65 score of 1 might be admitted unnecessarily. 14 (1.2%) patients who had a CURR-65 score of 3 or more were not admitted to critical care unit. The unnecessary total annual costs for managing CAP with CURR-65 score of 0 and 1 were estimated at $ 94512 and $ 6 410 4 in the hospital, respectively.

Conclusions: Non-compliance with the CURR-65 scoring tool in patients with CAP was observed in routine hospital practice. No implementation of the measure-ment of the score incurred inappropriate hospitalization and unnecessary costs.
the most frequent radiologic finding. CR is not a good tool to discriminate between BP and VP.

Metapneumovirus pneumonia in allogeneic stemcell transplant recipients
Adrian Fruhwald1, Dominik Heim2, Martin Gerdes2, Christoph Bucher2, Hans Hirsch2, Michael Tamm3, 1 Clinic of Hematology, University Hospital of Basel, Basel, Switzerland; 2 Clinic of Microbiology, University Hospital of Basel, Basel, Switzerland; 3 Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital of Basel, Basel, Switzerland

Infectious and noninfectious pulmonary complications are frequent in allogeneic stemcell transplant recipients (SCT) and associated with a high morbidity and mortality. Metapneumovirus (MPV) has recently been recognised to cause lethal infections in immunocompromised patients. Following an index case with fatal outcome we included PCR for Metapneumovirus in the routine work-up of BAL performed in hematological patients with pulmonary symptoms. We analysed the clinical presentation and outcome of 8 allogeneic stemcell transplant recipients with a median of 45 year observed over a period of 12 months. Median Time to pulmonary MPV infection was 473 days after SCT. 6 of 8 patients were under immunosuppressive therapy for GVHD and 4 of them had biopsy proven bronchiolitis obliterans. All patients suffered from cough and/or fever. CT scan of the chest revealed a groundglass pattern in all but one cases. There were nodules in five cases and alveolar-interstitial infiltrates in also 5 cases. Enlarged lymphnodes were only present in one patient. In one patient there was concomitant infection with moraxella cathartalis. Two patients showed viral double infection in the BAL (MPV/coronavirus; MPV/rhinovirus). All patients were hospitalized because of marked symptoms or hypoxemia. Anemia was the most frequent side-effect of antiviral treatment. 7 out of 8 patients recovered. The patient who died had developed MPV pneumonia within one month following SCT.

Conclusion: Metapneumovirus pneumonia is not uncommon following allogeneic stemcell transplantation. Typical clinical features include fever, cough and a groundglass pattern on chest CT scan. Most patients recover under treatment with immunoglobulins and ribavirin.

Non-tuberculous infections in patients with TNF-alpha-antagonist treatment
Bahar Ozcelik, Penbe Cagatay, Zeki Kilicaslan, Ziya Gulbaran.

In recent years the use of TNF antagonist drugs for many diseases such as rheumatological diseases has increased. As a complication of these treatments, non-tuberculous infections are not frequent despite the absence of control measures and they were mostly upper respiratory tract infections. Our study indicates that non-tuberculous infections were detected. In an asthmatic patient also frequent infective attacks were observed. Thirtyseven definitive cases were found, 21 (56%) were male, 13 (35%) were Health Care Associated Pneumonia. LD was severe in 26 (70%) cases, which belonged to the highest Pneumonia Severity Index classes (IV-V). At the admission an acute respiratory failure (PaO2/FiO2 < 200 or SpO2 < 90% or PaO2 < 60 mmHg) was found in 18 patients (48%), 4 of these met ARDS criteria and non invasive-ventilation (CPAP) was necessary in 7 (19%). There were no significant differences in demographic and clinical features between the two groups (not-ARF vs ARF), see table.

Only one patient required an ICU admission and one patient died (3%). An appropriate antibiotic therapy was initiated in all patients on admission day. In conclusion, though no warning prognostic sign has been found yet, clinicians should remain vigilant about the respiratory complications in patients with Rheumatoid arthritis.

**P2511**

Clinical stability in patients with community-acquired pneumonia (CAP) in hospitalized patients over 18 years of age in the unit of Pulmonology and Intensive Care, University Hospital of Basel, Basel, Switzerland

Clinical stability (CS) defined as normalization of vital signs, is often used to manage patients with CAP. The aim of our study was to identify the time to resolution of abnormalities in vital signs (heart rate - HR, systolic blood pressure - SP, respiratory rate - RR, oxygen saturation - SATO2 and axillaries temperature - T), ability to eat (AE), and mental status (MS) in patients with CAP (n=118). The patients divided in 2 groups, from 18-65 years old (n=65)- first group, and older ≥ 65 (n=53 - second group). We compared parameters of CS in groups in the first day, and the time normalization of CS between groups (HR ≤ 100 beats/min, SP ≥124 mmHg, RR ≤ 24 breath/min, SATO2 ≥90%, T ≤ 37.2°C).

Results: We found in first group, in first day of hospitalization, average values of HR=115 beats/min, SP=103mmHg, RR=26 breaths/min, SATO2=93% T=38,3°C, in the second group HR=96 beats/min, SP=88 mmHg, RR=28 breathes/min, SATO2=96%, T=37,4°C. In 15 patients second group had mental confusion. The median time to stability in first group was 1 day for HR, SP and RR, and 2 days for SATO2, 3 days for T and 5 days for AE. The median time to stability in second group was 1 day for HR, SP, T, and 3 days for RSATO2 and 8 days for AE.

Conclusion: The older patients had slowly time to stability for SATO2, RR and MS, and smaller T and HR in first day.

Cpmydia pneumoniae (Cp)-specific IgE is associated with asthma severity
Adrian Fruhwald1, Dominik Heim2, Martin Gerdes2, Christoph Bucher2, Hans Hirsch2, Michael Tamm3. 1 Clinic of Hematology, University Hospital of Basel, Basel, Switzerland; 2 Clinic of Microbiology, University Hospital of Basel, Basel, Switzerland;

Cp pneumoniae (Cp)-specific IgE is associated with asthma severity and whole blood Cp DNA by PCR, and associations with asthma severity and antibiotic treatment outcomes; nested case-control study of asthma cases and non-asthma controls.

Aims: To investigate bacterial allergy as a potential mechanism for Cp-associated asthma.

Methods: Practice-based prevalence study of serum Cp IgE by immunoblotting and whole blood Cp DNA by PCR, and associations with asthma severity and antibiotic treatment outcomes; nested case-control study of asthma cases and non-asthma controls.

Results: We studied 66 asthma subjects (mean age 40.9 years, range 7.5-79.8 years, 56%, 15% co-existing COPD). Cp IgE was detected in 33 (50%) and Cp DNA in 16 (24%). 88% of Cp DNA pos subjects were Cp IgE pos (P=0.011). 4 (22%) of 18 subjects with intermittent asthma were Cp IgE pos compared to 30 (63%) of 48 with persistent asthma (P=0.005). We also found a significant “dose-response” relationship (Table).

Experimental fatal pneumonia due to Burkholderia cepacia: Differential involvement of toll-like receptors (TLRs) 4 and 5
Viviane Ballot1,2, Heidi Nagel1, Reuben Rampal3, Mustapha Si-Tahar1,2, Michael Chizeck1,2,3
1Défense Innée et Inflammation, Institut Pasteur, Paris, France; 2U574, INSERM, Paris, France; 3Department of Medicine, University of Florida, Gainesville, United States

As shown in a previous study (Ventura et al., 2009), MyD88, a key downstream adapter for most of the TLRs, is involved in the inflammatory response responsible to the death due to B. cepacia pneumonia. The aim of the present study was to determine which TLRs were involved in this response. We specifically focused on the TLRs 4 and 5, as these two receptors are the main ones involved in the recognition of P. aeruginosa, a flagellated Gram-negative bacterium like B. cepacia.

Mice deficient for TLR4, TLR5 or both were infected intratracheally with a sus-##

Introduction: Chronic pulmonary aspergillosis (CPA) is a severe respiratory in-##

CONCLUSION: We speculate the humoral immunoreaction to B. pertussis could be suppressed in asthmatic patients.
during the development process. It seems very possible that appearances and disappearances of air-fluid levels are related to exacerbation of CPA. But it has yet to be determined.

**Aims and objectives:** To demonstrate relationship between air-fluid levels and acute exacerbation of CPA.

**Method:** We analyzed retrospectively our patients with acute exacerbation of CPA during the period from 2001 to 2010 at Ibarakihigashi National Hospital.

**Results:** We experienced 93 cases of acute exacerbation of CPA and the incidence of appearance of air-fluid level was 34% (32 patients). At deterioration, new infiltrative shadows appeared on separate sites from primary cavities in 33 patients (35%), and 27 of them previously had air-fluid levels in their cavities. In 15 patients, fluid volume in their cavities increased before acute exacerbation. Eight of them showed new infiltrations away from primary lesions and fluid volume in their cavities decreased after acute exacerbation. Corticosteroids drastically improved their infiltrations on chest radiograph, blood findings and medical conditions in 5 out of 8. But in 3 patients, corticosteroids didn’t improve their conditions.

**Conclusion:** The air-fluid levels in cavities were associated with acute exacerbation of CPA. In some cases, patients showed new infiltrations away from cavities with decreased fluids during acute exacerbation. It suggested that fluids in cavities, which contained substances produced by Aspergillus, might damage separate sites from primary cavities.

**Aspergillus-PCR in bronchoalveolar lavage for detection of invasive fungal disease in immunocompromised patients**

Michael Thomas1, Jorg Haller1, Lilian Junker1, Peter Grendelmeier1, Michael Tamm1, Daiana Stolz 1, 2

*Clinical for Pulmonary Medicine and Respiratory Cell Research, University Hospital Basel, Basel, Switzerland; 2Department of Microbiology, Kanton Hospital Liestal, Liestal, Switzerland.*

**Introduction:** Invasive fungal disease (IFD) is a frequent and serious infectious complication in neutropenic patients. We evaluated the diagnostic accuracy of conventional nested PCR in the bronchoalveolar fluid to diagnose IFD in severe immunocompromised patients.

**Methods:** 191 consecutive patients undergoing bronchoscopy for suspected pulmonary infection were included. The probability of IFD was estimated according to the standard EORTC/NIAID classification and on clinical grounds as independently assessed by a pulmonary specialist and hematologist. Conventional nested PCR to detect aspergillus fumigatus, flavus, niger, gausius, terreus and tannarii were applied to 2 ml bronchoalveolar fluid.

**Results:** In 50.5 (9-19.80), 116 were male. There were 129 patients with hematological conditions, 26 solid organ transplant recipients, 24 auto immune disorders, and 12 HIV. A total of 111 (58.1%) of the patients were on anti-fungal therapy at the time of bronchoscopy. According to the EORTC/NIAID classification, 2 (1%) had proven, 8 (4.2%) probable, 43 (22.5%) possible and 138 (72.3%) no IFD. Nested PCR for Aspergillus was positive in 55 cases (28.8%) – 0/2 in proven, 4/8 in probable, 10/43 in possible and 41/38 in no IFD. Anti-fungal therapy did not significantly influence PCR results (p=0.749). Irrespective of the EORTC/NIAID criteria, there was a strong clinical suspicion of IFD in 53 (27.7%) cases. From those, only 15 (28.3%) had a positive PCR.

**Conclusion:** Nested aspergillus PCR in the bronchoalveolar lavage seems to be of limited usefulness for detection of invasive fungal disease in immunocompromised patients.

**P2519**

**Role of bronchoscopy in non-HIV immunocompromised patients**

Hugh Jp, Chris Kosky, Anne Collett. *Thoracic Medicine, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom*

**Background:** Non-HIV immuno-compromised patients with suspected chest sep sis commonly undergo bronchoscopy to aid microbiological diagnosis.

**Aims:** Characterise non-HIV immuno-compromised patients undergoing bronchoscopy at a London hospital to assess the diagnostic utility of this procedure with a focus on results leading to treatment changes.

**Methods:** Clinical records of all patients undergoing bronchoscopies over a 14-month period were retrospectively reviewed. The diagnostic yield was calculated using the total number of bronchoscopies as the denominator. A positive result was defined as any positive culture (viral, fungal, bacterial) or diagnostic pathology. Using the clinical notes and prescription charts the percentage of treatment changes following bronchoscopic results was calculated.

**Results:** 43 bronchoscopies were carried out in this group. Underlying diagnoses were haematological malignancy (27), organ transplant (10), solid organ tumour (2), rheumatological (4). The most common indication was suspected infection (76.7%); fungal infection was suspected in 46.5%. The overall diagnostic yield was 51.2% (95% CI, 36.1-66.3%). Many of the positive samples were for virus (10) followed by positive bacterial cultures (8). Few samples were positive for fungus (2). Therapy was changed after 18.6% (95% CI, 6.8-30.4%) of all bronchoscopies. The total complication rate was 4.6% (95% CI, 1.7-11.1%); both cases due to controllable bleeding.

**Conclusions:** The most common underlying diagnoses were haematological malignancies. Fungal chest infection was frequently suspected, but the fungal organism yield was low; treatment decisions were based on clinical and radiological findings. Total diagnostic yield was similar to published data.

**P2520**

**Viological analysis on bronchoalveolar lavage fluid (BALF): Diagnostic yield and indications**

Jean-Sébastien Poinet1, Stéphane Jouneau1, Sophie Minjolle2, Pierre Tattevin2, Philippe Delaval3, Benoît Dresuir1 3

*Respiratory Medicine Department, Ponchailou University Hospital, Rennes, France; 2Bacteriology and Virology Department, Ponchailou University Hospital, Rennes, France.*

**Introduction:** BAL is a major diagnostic tool in infective lung diseases. Viral respiratory infections are a frequent cause of asthma and COPD exacerbations as well as severe pneumonia.

**Aims:** To analyze the characteristics of subjects with positive virological analysis of BALF and to define the best indications.

**Methods:** We retrospectively studied all virological analysis (immunoﬂuorescence, viral culture and PCR) performed on BALF in 2008 at Rennes University Hospital, France. We compared characteristics of patients with positive vs negative virological analysis of BALF.

**Results:** 232 BAL were performed in 212 patients. Seventy BAL were positive (30%), including 84 viruses: HSV1 (27), CMV (23), EBV (17), HHV6 (12), RSV (3), rhinovirus (1) and adenovirus (1). Immunocompromised patients represent 83% of all positive BAL. Immunosuppression (HPV patients, corticosteroids > 10 mg/day for ≥ 3 weeks or immunosuppressive therapy) and ground glass attenuations on chest CT-scan were more present in patients with positive virological BALF compared to negative: respectively 82.9% vs 46.9%; p<0.0001 and 65.8% vs 43.7%; p=0.006. There were no significant differences in demographic and clinical criteria (age, gender, fever, dyspnea, cough, hemoptysis). Pneumonia in immunocompromised subjects was the most frequent indication of BALF viral analysis (55%) with a diagnostic yield of 44%. None of the 17 virological analyses of BALF performed for assessment of diffuse infiltrative lung disease was positive.

**Conclusion:** Pneumonia in immunocompromised hosts seems to be the preferential indication of virological analysis of BALF, especially when chest CT-scan demonstrates ground-glass attenuations.

**P2521**

**The role of fiberoptic bronchoscopy (FOB) in the management of pulmonary disease in the immunocompromised (IC) host**

Sheinongt Saha1, Joanne Creaser2, Charlie Elliott1, Stephen Bianchi1, 2

*Sheffield Thoracic Institute, Sheffield Teaching Hospital NHS Trust, Sheffield, United Kingdom; 1Clinical Effectiveness Unit, Sheffield Teaching Hospital NHS Trust, Sheffield, United Kingdom*

**Introduction:** FOB is a recognised tool in evaluating IC patients with lung disease. It is often utilised after administration of antimicrobial therapy which potentially affects diagnostic rate.

**Aims:** Assessment of the role of FOB in IC patients presenting to a UK hospital between December 2007-09.

**Method:** Retrospective data was reviewed for 48 patients.

**Results:** 19/48 (39.6%) presented with leucopenia (WCC <3.5 x 109/l), 18/48 (37.5%) with neutropenia (PMN <1.7 x 109/l) and 30/48 (62.5%) had lymphopenia (LØ <1.0 x 109/l). Significant desaturation (requiring unplanned intervention) occurred in 7/48 (14.6%) patients. 30 day mortality was 11%. Positive bacterial cultures were obtained in 10/48 samples (21%). Organisms: Proteus, H Influenza, Ps.Aeruginosa, Klebsiella, S.Aureus, S.Maltha. Coagulate negative staphylo cocci, enterococcus, E.coli and Group B streptococcus. 17/48 (35%) patients had a change in management directly resultant from BAL bacterial culture. Positive fungal cultures were identified in 16/48 (33.3%) samples. Species: C.Albicans, Saccharomyces, Aspergillus and C.Glabata. 8/48 (17%) patients had treatment altered based on BAL fungal culture. Positive virology identified in 10/48 patients (rhinovirus, CMV, HSV type 1, EBV, coronavirus). 4/48 (8%) patients had resultant changes in treatment. 7/45 (16%) patients were positive for Pneumocystis jirovecii with treatment change in 5 patients. In 40.5% of cases a treatment change was based on FOB/BAL results.

**Conclusion:** FOB/BAL has a major impact on the treatment of IC patients with pulmonary disease. Early respiratory involvement prior to broad spectrum antimicrobial therapy may have increased FOB yield.

**In vivo imaging of rat experimental invasive pulmonary aspergillosis using fibred confocal fluorescence microscopy**

Helene Morisset1, Loraine Heyman1, Mathieu Salau1, Loic Favence2, Jean Michel Piccione1, 2

*Laboratoire Quantif E LITIS, EA 4108, Faculté de Médecine et de Pharmacie, Rouen, France; 1Laboratoire de Parasitologie Expérimentale, EA 324, Faculte de Médecine et de Pharmacie, Rouen, France, 2Service d’Anatomopathologie, Centre Henri Becquerel, Rouen, France*

**Rational:** Aspergillus fumigatus is responsible for life-threatening respiratory
infections in immunosuppressed patients. Early diagnostic would improve the prognosis. Fibred confocal fluorescence microscopy (FCFM) is a new endoscopic tool that enables in vivo microscopic imaging of the distal lung in situ. In this study we tested the hypothesis that FCFM could be utilized for the visualization of pulmonary aspergillosis infection in vivo, in situ.

Methods: Experimental pulmonary invasive fungal infections were induced in immunosuppressed rats using a wild strain of A. fumigatus (n=6) a wild strain of Geosmithia argolea (n=6) and a fluorescently transformed Tag-RFP A. fumigatus strain (n=6). Subpleural areas of pulmonary infection and control lungs were imaged using FCFM through a chest wall window.

Results: From the fungal strains, only hyphae of the Tag-RFP A. fumigatus were detectable by FCFM both in vitro and in vivo. In vivo, hyphae of the Tag-RFP Aspergillus strain were visualized by FCFM in 100% of the lung infection with a specificity of 100% (6/6) compared to normal lung and other fungal infection. Using non fluorescent strains, a specific local infiltration of fluorescent cells could be localized in half fungal subpleural microabcesses (Se 100%;Spe 58%).

Conclusion: FCFM represents the first imaging technique of pulmonary aspergillosis in real time and in vivo. It provides a new tool to study host-pathogen interactions and may help for early diagnosis of pulmonary aspergillosis in vivo.

Clinical characteristics of surgically-diagnosed pulmonary cryptococcosis
Akihiro Ito, Hiromasa Tachibana, Tadashi Ishida. Department of Respiratory Medicine, Kurashiki Central Hospital, Kurashiki-City, Okayama, Japan

Background: Pulmonary cryptococcosis is a type of pulmonary mycosis that can be asymptomatic and determined only as an abnormal shadow on X-ray film. Because differentiating pulmonary cryptococcosis nodules from lung cancer is difficult, some patients must be surgically diagnosed. Furthermore, whether surgically-diagnosed pulmonary cryptococcosis should be treated remains controversial.

Objectives: The aim of this study was to evaluate whether we can differentiate pulmonary cryptococcosis from lung cancer, and if it should be treated after surgery.

Methods: We retrospectively analyzed 17 patients with surgically-diagnosed pulmonary cryptococcosis at the 1153-bed Kurashiki Central Hospital (a tertiary facility) for ten years from April 1994 and November 2009.

Results: The 8 male and 9 female patients (median age, 56 years; range, 36 to 71 years) included 2 with diabetes mellitus and 2 who were treated with steroids. Eleven patients who underwent thoracic bronchoscopy before surgery were not diagnosed. Only one of six patients was positive for Cryptococcus antigen. The X-rays revealed nodules or a mass in all patients and none had an infiltration shadow. Thirteen patients had a single nodule. Only one patient was administered with antibiotics and none of the 17 patients relapsed.

Conclusions: To differentiate a single nodule of pulmonary cryptococcosis from lung cancer was difficult, rendering surgery as the sole definitive diagnostic option. None of our patients relapsed including four who were immunocompromised, indicating that treatment is not a necessary component of follow-up after surgical diagnosis of pulmonary cryptococcosis.

Alterations of surfactant phospholipids in lungs with chronic recurrent respiratory chlamydial infection
Petra Reinhold1, Michael Rothe2,1. Institute of Molecular Pathogenesis, Friedrich-Loeffler-Institut, Jena, Germany; 2Lipidomics GmbH, Campus Berlin-Buch, Berlin, Germany

This study aimed to identify alterations in the composition of surfactant phospholipids (PLs) with respect to chronic respiratory chlamydial infection. Broncho-alveolar lavage fluid (BALF) was sampled from 13 calves with naturally acquired chronic, but clinically latent, chlamydial infection (C. pecorum and/or C. abortus). Calves without chlamydial infections of the same age and kept under identical conditions served as controls (n=12). Prior to BAL, exhaled breath condensate (EBC) was collected in each animal. In both BALF and EBC, phospholipids were measured (tripletquad tandem mass spectrometer). Phosphatidylcholine (PC), being the main phospholipid in pulmonary surfactant and measurable in both EBC and in BALF samples, was significantly reduced in animals with chlamydial infections. In addition, concentrations of lysophosphatidylcholin, phosphatidylethanolamine (PE), and phosphatidyl ethanolol (PI) were significantly reduced in BALF (not measurable in EBC). Altogether, total concentration of phospholipids was significantly lower but ratios between PC/PE and PG/PE (PG: phosphatidylglycerol) were significantly higher in calves with chlamydial infection compared to controls.

In conclusion, chronic respiratory infections with chlamydiae were associated with significant alterations in the phospholipid composition of the epithelial lining fluid of the lung. Since surfactant is involved in both lung compliance as well as alveolar cleavage, results of this study indicate chlamydia-associated deterioration of pulmonary mechanics and depressed alveolar defense mechanisms despite the absence of clinical signs or pulmonary symptoms.

Pulmonary and systemic inflammation in a domestic animal model of respiratory chlamydia phila pusi ci infection: Evaluation of dose-response relationships
Carola Ostermann1, Annette Vogel1, Wieland Schroeder2, Angela Berndt1, Evelyn Schubert1, Konrad Sachse3, Petra Reinhold1, Evelyn Schubert1, Konrad Sachse1, Petra Reinhold1. 1Institute of Molecular Pathogenesis, Friedrich-Loeffler-Institut, Jena, Germany; 2Institute of Bacteriology and Mycology, Veterinary Faculty, University of Leipzig, Leipzig, Germany

This study aimed to evaluate dose-response relationships of pulmonary and systemic inflammation with respect to a new model of respiratory Chlamydia phila pusi ci infection introduced recently. Four infection dosages (inclusion forming units of strain DC 15) were administered intrabronchially per calf: 10⁷ (n = 4), 10⁶ (n = 4), 10⁵ (n = 4), 10⁴ (n = 2). Control animals received medium (n = 4) or the inactivated strain (10⁵; n = 6). Pulmonary inflammation was assessed by analysing broncho-alveolar lavage fluid (BALF) 2-3 days post inoculation (dpi). As biomarkers of systemic inflammation, acute phase proteins (LBP=lipopolysaccharide binding protein, Hp= haptoglobin, CRP) were measured in serum samples.

After challenge with viable chlamydiae, most of inflammatury markers followed dose-response curves (Table). In the lung, recruitment of neutrophil granulocytes increased with increasing doses. In blood, LBP was superior in reflecting host response.

Conclusion: In conclusion, pulmonary and systemic inflammation varied from mild (10⁴ ifu) to severe (10⁸ ifu). For further studies, inoculation of 10⁸ ifu per animal is recommended to induce a clinically apparent respiratory disease with local and systemic host responses.

Radiological features and their associations with clinical and laboratory findings in adults with mycoplasma pneumoniae pneumonia
Qi Guo1, Hai-Yan Li2, Yi-Ping Zhou1, Ming Li1, Xiao-Ke Chen1, Hui Liu1, Hong-Lin Peng1, Hui-Chao Ye1, Nian Liu1, Li-Hua Liang3, Qing-Zhou Zhao1, Mei Jiang1, 1Department of Respiratory Medicine, Affiliated Fudan University, Guangdong Medical College, Shenzhen, China; 2Department of Primary Care, Affiliated Fudan University, Guangdong Medical College, Shenzhen, China; 3Department of Radiology, Affiliated Fudan Hospital, Guangdong Medical College, Shenzhen, China; 4Department of Radiology, Affiliated Fudan Hospital, Guangdong Medical College, Shenzhen, China; 5Department of Respiratory Diseases (State Key Laboratory of Respiratory Diseases), First Affiliated Hospital, Guangzhou Medical University, Guangzhou, China

Background and objective: The factors determining severity in Mycoplasma pneumoniae pneumonia and to determine their associations with clinical and laboratory findings.

Methods: A sixty-month retrospective study of 372 adult patients with M. pneumonia pneumonia was carried out. The diagnosis of M. pneumoniae pneumonia was made by the indirect microparticle agglutinn assay. We collected the radiological findings and assessed their associations.

Results: Ground-glass opacity was observed in 344 patients (92.5%), unilobar opacity in 316 patients (84.9%), and lower lobe involvement in 288 patients (77.4%). There was a significant increased odds ratio for multilobar opacity in male patients (OR, 3.279; p<0.001; 95% CI, 1.98 - 5.41). The patients with multilobar opacity had older age (p<0.001), higher CURB-65 scores (p<0.014), and more costs ($768.22±243.93 vs. $610.76±299.72, p<0.001).

Conclusion: Using a wild strain of M. pneumoniae as inoculum increased with increasing doses. In blood, LBP was superior in reflecting host response.

Conclusion: In conclusion, pulmonary and systemic inflammation varied from mild (10⁴ ifu) to severe (10⁸ ifu). For further studies, inoculation of 10⁸ ifu per animal is recommended to induce a clinically apparent respiratory disease with local and systemic host responses.

Chlamydial infections are a known problem in cattle farming. We want to find out whether they are related to chronic respiratory illness in farmers. We selected 48 dairy farms with a history of occurrence of chlamydial infections. Nasal and vaginal swabs, milk and fecal samples and paired sera were obtained from 5 cows of each farm. The presence of chlamydial was analysed by rtPCR, by the ArrayTube DNA microarray test and paired sera were examined using an ELISA. The farmers were clinically examined by lung function testing, serology, allergy skin test, and their induced sputum was rtPCR tested.

The analysis of 48 farms showed that in 31 (64.6%) farms at least 1 sample from at least 1 cow was positive in rtPCR and 12 (25%) farms were positive only by ELISA. Chlamydia (C.) psittaci and C. pecorum were the most frequently identified species. At one farm, Chlamydia trachomatis was identified in cattle. So, far 39 individuals have been examined. 12 had respiratory symptoms and 3 were positive in serology. C. pneumoniae IgA occupied in 15 (38.5%) subjects and IgG in 26 (66.7%). Only 2 persons were positive for C. psittaci IgG. In 5 (12.8%) human sputum samples Chlamydia trachomatis was identified.

We found a prevalence of 64.6% (rtPCR), which is a wide dissemination of chlamydial infections in cattle herds. In humans, we found signs of an immune reaction against zoonotic C. psittaci in 2 subjects, which had regular contact to birds. Of these 2 farms were tested negative.

The presence of Chlamydia trachomatis in 5 sputum samples is remarkable and interesting and needs further investigation, as well as the detection of Chlamydia trachomatis of 4 cows. The farmers of this farm have not yet been examined.

P2532 Acute LRT infections among patients with shingles
Lidia Zabaznoska, Vesna Semenakova, Sushma Bogojeva. Respiratory Diseases, Clinic of Infectious Diseases, Skopje, Macedonia, The Former Yugoslav Republic of.

Herpes Zoster is reactivation of VZV infection, triggered by stress, surgical inter- vention or lack of the immunocompetency. This intraganglionic latent viral RNA reactivation preceded the viral migration through the neural axons up to the asso- ciated dermatone causing balanitic cell degeneration, multinuclear cell expression with intranuclear inclusions, simultaneous inflammatory local reaction, finally expressed with characteristic shingles vesicles.

Material and methods: In a six year long period (2004-2010), 52 patients with shingles were hospitalized, 19 (36%) were immunocompromised due to immuno- suppressive therapy, lymph reticular malignant illness, HIV infection; 23 (44.4%) patients with shingles had LRT inflammation sings.

Results: Based on the clinical symptoms and standard blood, biochemical, radi- ological, bacteriological, serological testing’s parallel bacterial LRT inflammation was proven among 20 of 23 patients (86.9%), or 38.46% of 53 patients. This group of 20 with 27.2% bacterial inflammation includes 9 immunocompromised (85.7%) and 11 immunocompetent (55%) patients. Severe pulmonary inflammation had 6 (66.6%) of 9 immunocompromised (one of them nosocomial, transferred from the haematology clinic) and 5 (45.4%) of 11 immunocompetent, or 6 (30%) of 20 and 5 of 20 (25%).

Conclusions: The severity of the dermal expression as well as LRT inflammation was evident among immunocompromised patients. Their hospital treatment was prolonged, from 17 days up to 7 weeks (average 23 days) compared to immunocompetent patients with shingles and LRT inflammation (11-27 days-average 14 days). Antimicrobial (antibiotic/antiviral) therapy has empirically installed from the very beginning of hospital treatment, additionally improved where needed.

P2533 Clinical and evolutive patterns of respiratory infections in patients with HIV/AIDS from Timis County, Romania
Iosif Marincu, Lucian Negruittu, Stefan Mihaiuta, Ioan Iacobiciu, Nicoleta Berciu, Carmen Alexiou, Ioana Tudor, Adriana Neghina. Department of Pulmonology, University of Medicine and Pharmacy, Timisoara, Romania

Background: Acute respiratory diseases are part of opportunistic infections de- veloped by patients with HIV/AIDS due to immunosuppression. The present study aims evaluating the clinical and evolutive patterns of acute respiratory infections in patients with HIV/AIDS.

Methods: The authors have retrospectively analyzed 82 patients with HIV/AIDS and acute respiratory diseases admitted at Clinic of Infectious Diseases. The posi- tive diagnosis was based on clinical elements, biological parameters (erythrocyte sedimentation rate, leukocyte count, fibrinogen, C-reactive protein, sputum culture, etc) and paraclinical elements (chest radiography, spirometry).

Results: From the study group, 52 patients with acute respiratory diseases (p<0.04) have been registered: 10 cases (12.19%) had bacterial pneumonia, 8 (9.75%) had interstitial pneumonia, 4 (4.87%) had fungal pneumonia, 8 (9.75%) had acute bronchitis, 11 (13.41%) had influenza, 7 (8.53%) had acute angina and 4 (4.87%) had pulmonary tuberculosis. The etiological agent has been isolated in 21 cases: 7 with Streptococcus pneumoniae, 4 with Staphylococcus aureus, 2 with Klebsiella pneumoniae, 4 with Pneumocystis jirovecii and 4 with Mycobacterium tuberculosis. In 54 cases, CD4-cell count was less than 200 cells/mm³ and 28 cases (p<0.05) over 200 cells/mm³. Under specific therapy and antiviral treatment, the clinical outcome has been favourable in 50 cases, only 2 cases died with pulmonary tuberculosis.

Conclusion: The detailed study of the clinical and evolutive patterns of respiratory infections in patients with HIV/AIDS allows timely implementation of specific therapy and prophylaxis in this population group with multiple risks.

P2534 Health status impact of ciprofloxacin dry powder for inhalation in patients with non-cystic fibrosis bronchiectasis
Barbara Hampel1, Olaf Schoeman2, Peter Reimnitz3, Paul Jones4, Robert Wilson5.
1Global Clinical Development Antineoplastics, Bayer Schering Pharma AG, Berlin, Germany; 2Global Development, Bayer Schering Pharma AG, Berlin, Germany; 3Global Clinical Development, Bayer Schering Pharma AG, Wuppertal, Germany; 4Division of Clinical Science, St George’s, University of London, London, London, United Kingdom; 5Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom

Introduction: Potentially pathogenic microorganisms (PPMs) frequently colonize lungs of bronchiectatic patients, often leading to pulmonary exacerbations. This phase II randomized, double-blind study assessed the safety and efficacy of ciprofloxacin dry powder for inhalation (DPI) – a formulation (PulmoSphere™) using the T326 inhaler – over 28 days in patients with sputum culture positive for predefined PPMs.

Objective: To test the effect of ciprofloxacin DPI on bacterial load and health status in non-cystic fibrosis bronchiectasis (non-CF BE) patients.

Methods: 124 adult, non-CF BE patients (mean baseline characteristics: age 63, 34.4% male, FEV1 56% of predicted) received 32.5mg ciprofloxacin (50 mg ciprofloxacin DPI) or matching placebo twice daily for 28 days with a 56-day follow-up. In addition to the primary endpoint (reduction in total bacterial load in sputum at end of treatment [EOT]), patient-reported health status was assessed with the St George’s Respiratory Questionnaire (SGRQ).

Results: Ciprofloxacin DPI reduced bacterial load at EOT (~3.6 vs. ~0.3 logs, p<0.001). The difference in mean SGRQ total score between active and placebo was ~3 (p=0.059, 95% confidence interval ~7.3 to 0.1), close to a clinically relevant (~1) improvement. The trend lasted for 4 weeks after EOT (difference ~3.0) but was not maintained at 8 weeks after EOT (difference ~0.83). SGRQ domain scores, responder and per-protocol analyses confirmed the trend.

Conclusions: Ciprofloxacin DPI clearly trended towards improving patient- reported health status in non-CF BE measured with the SGRQ, which lasted for 4 weeks after treatment finished. Further study is required to confirm the results.

P2535 Pseudomonas aeruginosa sensitivity changes to antibiotics under the influence of dissolved ozone
Alia Plotnikova1, Igor Belyanin2, Lubov Selina2, Evgenii Shmelev2.
1Microbiology, Central TB Research Institut, Moskow, Russian Federation; 2Microbiology, The Medical Center of the Help to Invalids without, Moskow, Russian Federation; 3Microbiology, Central TB Research Institut, Moskow, Russian Federation

Aim: To study the sensitivity changes of clinical strains of organisms producing beta-lactamases to antibiotics under the influence of dissolved ozone (pO3).

Methods: We studied 20 Pseudomonas aeruginosa strains resistant to antibiotics of penicillin line. A suspension was prepared from the culture of each strain (1-2×10⁷/ml) and treated with dissolved ozone (pO3 2mg/m³) during 5-10.15 min. Then, the strains treated with pO3 were cultured on Muller-Hinton agar containing a strain resistant antibiotic. The same strain that had not been treated with pO3 was also cultured on the same agar containing the same antibiotic (control). In a day after incubation by 37ºC we recorded the result of the diameter zone of growth inhibition round the antibiotic disk.

Results: The zone of growth inhibition round the antibiotic disk increased from 0.6 to 2.34±0.3 mm in all cases of Pseudomonas aeruginosa strain culture. There were no growth changes in control cultures.

Conclusion: The treatment of resistant strains of Pseudomonas aeruginosa with “therapeutic concentration” of dissolved ozone results in antibiotic sensitivity restoration.

P2536 Influence of antibiotic resistance of pseudomonas aeruginosa on presenting features of community-acquired lower respiratory tract infections
Pavliņa Nikolova1, Yavor Ivanov2, Plamen Pavlov3, Tsvan Popova4, Elena Borissova5, Petkana Hristova5.
1Pulmonary Clinic, Medical University, Pleven, Bulgaria; 2Clinic of Internal Diseases, Medical University, Pleven, Bulgaria; 3Department of Social and Preventive Medicine, Medical University, Pleven, Bulgaria

Aim: To evaluate the influence of resistant isolates of Pseudomonas aeruginosa on presenting features for patients with community-acquired lower respiratory tract infections (LRTIs).

Methods: 95 hospitalized patients (67 men, 28 women, average age 66.7±10.9y)
with community acquired pneumonia (CAP), bronchiectasis and exacerbations of chronic obstructive pulmonary disease (COPD) and *P. aeruginosa* isolates were studied during a 5-year period. They were divided into two groups: with susceptible isolates, (n=70, 73.7%, S group) and resistant to antibiotic testing, (n=25, 26.3%, R group) and compared by sex, age, diagnosis, concomitant diseases, treatment, length of stay, outcome.

**Results:** 18% of the patients had CAP, 46.3% - bronchiectasis and 40% - COPD. Most of them had concomitant diseases - ischaemic heart disease: S/R - 62.4%/62.6% resp., diabetes - S/R -11%/12% resp. We found differences in: the change of antibiotic treatment according to the microbiological results (8%/56%/R, p < 0.001); length of hospital stay >15 days - 3%/12% respectively, p < 0.05. Complications of the essential disease were more in the R group (2%/6%/R). The outcome was similar in both groups.

**Conclusions:** The clinical features found in patients with resistant isolates of *P. aeruginosa* compared to susceptible ones were: more complications of the main disease, more frequent change of antibiotics during the course of treatment according to the microbiological results and longer length of stay.

### P2537

**Nebulized antibiotics in patients with non-cystic fibrosis bronchiectasis and chronic pseudomonas aeruginosa infection**

José R. Donado-Uta1, Carolina Jiménez-Navarroz2, Marialyng E. Fuentes-Salazar1, José M. Ruiz-Giardin1, Miguel A. Racconero-Casero1, Victoria Valeri-Busto1, Eva Prats-Grac1, Antonio Zapatero-Gaviria1.

1 Respiratory Medicine, Hospital de Fuenlabrada, Fuenlabrada, Madrid, Spain; 2 Internal Medicine, Hospital de Fuenlabrada, Fuenlabrada, Madrid, Spain.

**Methods:** Retrospective review of patients with bronchiectasis with *Pseudomonas aeruginosa* (PA) isolated from sputum at least twice during the year prior to nebulized antibiotic (NA) onset and a minimum 6-month follow-up.

**Results:** 17 patients included (9 men), median age 69.7 yrs., average follow-up 753 days (183-1824). Nine patients received more than 1 NA during follow-up (31 NA courses in total): 16 colistin, 14 tobramycin, 1 gentamicin. Average treatment duration: 492.5 days (100-971). Subjective improvement was referred by 12 patients (70.5%). Eradication of PA was achieved in 7 (41.2%), but 1 relapse occurred. 8 patients presented side effects at any time during NA (47%), mainly bronchospasm. Table 1 shows a reduction in mean number of admissions/year and mean days of admission/year for all patients. A statistically significant reduction is observed when NA was eradicated.

Mannose binding lectin deficiency is associated with disease severity in patients with non-cystic fibrosis bronchiectasis

James D. Chalmers1, David Kilpatrick2, Brian McHugh1, Pallavi Mandal1, Maeve Smith3, Cathy Doherty4, John Govan4, Adam T. Hill3.

1MRC Centre for Inflammation Research, Queen's Medical Research Institute, Edinburgh, United Kingdom; 2Scottish National Blood Transfusion Service, NHS Lothian, Edinburgh, United Kingdom; 3Department of Respiratory Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; 4Cystic Fibrosis Laboratory, University of Edinburgh, Edinburgh, United Kingdom.

**Background:** Mannose binding lectin (MBL) is a serum protein involved in phagocytic clearance of bacteria, viruses and apoptotic cells. Deficiency of mannose binding lectin is associated with disease severity in cystic fibrosis bronchiectasis but has not been studied in adult non-cystic fibrosis bronchiectasis.

**Methods:** 470 patients with adult non-cystic fibrosis bronchiectasis (confirmed by HCRT) and matched controls were recruited. MBL serum levels were measured by ELISA. MBL deficiency was defined as a serum level < 0.5 μg/ml. Quantitative microscopy was performed on spontaneous sputum samples to determine bacterial load - expressed as Log10 colony forming units/ml (cfu/ml).

**Results:** MBL deficiency was not more frequent in bronchiectasis patients than controls (27.2% vs 29.6%, p=0.4). MBL deficient patients had more severe disease as defined by SABA (19.6% vs. 13%, p<0.001). They suffered more frequent exacerbations (mean 2.8/year vs. 1.4/year, p<0.001) and were more frequently hospitalised for severe exacerbations (31.3% hospitalised vs. 18.1% hospitalised during follow-up). MBL deficient patients more frequently met the criteria for chronic colonisation (70.3% vs. 51.5%, p<0.002). Among those colonised, MBL deficient patients, (n=33) had a higher airflow bacterial load (7.2 vs 3.1 cfu/ml vs 6.37 cfu/ml, p=0.001). MBL deficient patients were also more frequently colonised with *P. aeruginosa* (22.7% vs. 12.3%, p=0.005).

**Conclusion:** Mannose binding lectin deficiency is associated with more severe disease in patients with non-cystic fibrosis bronchiectasis.

### P2539

Effects of subinhibitory concentrations of antibiotics on the biofilm formation of *Pseudomonas aeruginosa*

Handong Jiang, Junjuan Li. Respiratory Medicine, The Affiliated Hospital of Medical College, Qingdao University, Qingdao, China.

**Objective:** To study the effects of the subinhibitory concentrations of four antibiotics on the biofilm formation of *P. aeruginosa*.

**Methods:** 2 types of culture media of 1-broth (LB) and Mueller-Hinton broth (2 Schab) were used with the application of static biofilms model of *P. aeruginosa*.

**Results:** (1) The results of the static-made biofilm were as follows: in the MHB media, azithromycin could induce the biofilm formation of PAO1 when the concentrations were more than 16μg/ml, but inhibited the biofilm formation when the concentrations were less than 8μg/ml. When the PAO1 was cultured in LB, azithromycin would induce the biofilm formation at the sub-MIC concentrations. Ciprofloxacin and ceftazidime could inhibit the biofilm formation at the sub-MIC concentration. Amikacin could induce biofilm formation at the concentration of 0.125 and 0.25μg/ml cultured in MHB and LB respectively. All the results above had statistical difference compared with the blank. The Furazone C-30 was added in the static biofilm model with the azithromycin concentration 8ug/ml and 4ug/ml, the results had no statistical difference. (3) Silver staining results: when the concentration of azithromycin was 8ug/ml the formation of the biofilm was the same as the blank. Under the concentration of silver staining 4 ug/ml, the formation of the biofilm was weaker than the 8 ug/ml. When the PAO1 was cultured in LB, amikacin could induce the biofilm formation at the concentration of 0.125μg/ml and 0.25μg/ml.

**Conclusion:** The sensitivity of the azithromycin to the POAI was different with changing of the environment. Azithromycin could induce the biofilm formation at the subinhibitory concentration. Ciprofloxacin and cefazidime could inhibit the biofilm formation; amikacin could induce the biofilm formation at the concentration of 0.125μg/ml and 0.25μg/ml.
Conclusion: The concept of blocking activity in the serum of patients with non-CF bronchiectasis may provide some explanation for the mechanism of establishment of PA colonisation in the airways of some patients and requires further investigation.

P2541
Sputum neutrophils are related to functional status in non-cystic fibrosis bronchiectasis in subjects in airway colonization

Federico L. Dent, Laura Malagrinò, Francesco Costa, Lorenzo Melisviti, Antonella Di Franco, Maria Laura Bartoli, Cristina Ferretti, Mariella De Santis, Elena Bacci, Pier Luigi Piggiaro. Cardio-Thoracic Department, Respiratory Pathophysiology Section, Pisa, Italy

In 42 subjects with bronchiectasis (13 male, mean age 62.4 ± 9.3 years, 9 ex and 1 current smoker), functional status and airway inflammation were measured. All subjects showed diffuse bronchiectasis (exacerbations in 3 subjects), pulmonary consolidations in 30, and peri-bronchiectasis edusations in 29 subjects. Bronchiectasis was idiopathic in 22, post-infectious in 15, post-TB in 5 subjects. Bacterial airway colonization was demonstrated in 20 out of 32 subjects collecting sputum (8 Pseudomonas, 2 NTMB, 5 Proteus/E.coli, 4 Staphilococcus, 1 Hemophilus infl., 1 Streptococcus). Obstructive syndrome was found in 28 subjects, restrictive syndrome in 2, and normal spirometry in 12. Hypertonic saline-induced sputum was collected in 36 subjects: 29 showed increased neutrophil% (median 79.9%), while 5 subjects showed increased eosinophil%. All except 5 out of 34 subjects showed normal values in exhaled nitric oxide (17.5 ± 16.1 ppb). Significant correlations were found between sputum neutrophil% and FEV1% pred, FEV1/VC% pred, and RV% pred.

In conclusion, significant relationships between sputum neutrophils, and functional findings were found in patients with bronchiectasis and bacterial airway colonization, suggesting that the last one has a role in pulmonary function impairment.

P2542
Survey of microbiology, pseudomonas eradication and antimicrobial prophylaxis in adult patients with non-cystic fibrosis bronchiectasis

Rahul Bhatnagar, Nicholas Withers. Department of Respiratory Medicine, Royal Devon and Exeter Hospital, Exeter, United Kingdom

Introduction: Recent guidelines on non-CF bronchiectasis advocate the use of prophylactic antibiotics in frequent exacerbators, and eradication of Pseudomonas Aeruginosa (PA) on first isolation in sputum. We examined the sputum microbiology and antimicrobial treatment in a cross-section of patients seen within our respiratory service.

Methods: Data was collected on all patients seen for routine follow up of non-CF Bronchiectasis for 4 months. We analysed PA status; Prior attempts at eradication of PA; The use of prophylactic antibiotics; and sputum microbiology for the preceding 5 years.

Results: 210 patients were included. The commonest bacterial isolate over the 5 years, other than PA (36%), was Haemophilus influenzae (27%). 48 had positive cultures for PA in the previous 12 months. 40 patients grew PA for more than one year’s duration. Eradication had been attempted in 62% of the patients who grew PA. Regimens included Ciprofloxacin (28%), nebulised colomycin (23%) and a combination of both (20%). 78 (37%) patients were on prophylactic antibiotics, with thrice weekly Azithromycin being used in 61 patients. 47% had been positive for PA at some point. Data for annual exacerbation rates was not available.

Conclusions: PA was cultured in just over a third of patients, with approximately two thirds of these having undergone some attempt at PA eradication using methods in line with recently published guidelines. Only 38% of those remained clear of PA for more than one year afterwards. Approximately 50% of patients on prophylactic antibiotics had no recent isolation of PA, although exacerbation rate data was not included in this survey.

P2543
Inhaled antibiotic treatment. Tolerance, compliance and quality of life

Antonio Alvarez1, Laura Ruano1, Montserrat Vendrell2, Rosa Giron2, Mª Pilar Ausin3, Miguel Angel Martínez2, Marina Blanco5, David de la Rosa1, David Blanquer4, Inês Herreto3, Javier de Gracia1. 1Pneumology Department, Hospital de Reina Sofia. Valencia, Spain; 2Pneumology Department, Hospital Universitari Dr Josep Trueta, Girona, Spain; 3Pneumology Department, Hospital Universitario de la Princesa, Madrid, Spain; 4Pneumology Department, Hospital de Manacor, Manacor, Mallorca, Spain; 5Pneumology Department, Hospital Universitario Miguel Servet, Zaragoza, Spain

Method: Adults attending a bronchiectasis clinic from Dec 2010-Jan 2011 were screened. Spirometry was performed & GOLD criteria for COPD were used to categorise AO. Functional ability was assessed using the MRC dyspnoea (MRCD) scale. The Hospital Anxiety and Depression Scale (HADS) was used to screen for anxiety and depression. A score of ≥8 in either sub-scale (HADS-A, HADS-D) was deemed clinically significant.

Results: N=52 (34F, 18M). Mean age: 61 (SD 13.4). 30 patients (57.7%) had evidence of AO. 6 patients (20%) had mild AO, 11 patients (37%) had moderate AO, 11 patients (37%) had severe AO and 2 patients (6%) had very severe AO. 27 patients (48%) had a HRCD score of ≥3. 30 patients (42.3%) had a HADS-A score of ≥8. 19 patients (28.8%) had both HADS-A and D scores of ≥8. Chi-square analysis showed significant association of clinically significant HADS-A (p ≤ 0.001) and HADS-D (p = 0.013) scores with a HRCD score of ≥3. There was no significant correlation between FEV1 % predicted and HADS-A or HADS-D scores (p=0.98). Scores on HADS were higher in those with active symptoms of AO.

Discussion: Inhaled antibiotics are a convenient option for the treatment of non-CF bronchiectasis. Tolerance, compliance and quality of life of patients with these symptoms are not as poor as expected. Further studies are needed in this population.

P2544
Azithromycin, a novel maintenance therapy in patients with chronic non-CF suppurative lung disease

Simon Twite, Paul Stockton, Sanjeev Agarwal. Respiratory Medicine, St. Helens and Knowsley NHS Trust, Liverpool, Merseyside, United Kingdom

Patients with bronchiectasis experience lower respiratory tract infections with decline in quality of life. The British Thoracic Society statement indicates that macrolides may have disease-modifying activity. A definite recommendation for use is not made in non-CF bronchiectasis. We present experience of Azithromycin in non-CF bronchiectasis as well as other respiratory diseases at a large district general teaching hospital.

In 137 patients were identified on maintenance Azithromycin therapy during a 12 month period. 66% received Azithromycin 250mg daily. Azithromycin provided a significant improvement in the mean time between exacerbations/rescue antibiotics, in patients with non-CF bronchiectasis as well as other lung conditions. The mean time to exacerbation was 64 days, without Azithromycin (range 30-360 days) versus 304.5 days, with Azithromycin (range 14-582 days). 48 patients required rescue antibiotics. Where Azithromycin was electively withdrawn, the patients experienced another exacerbation within 3 months, clinically worsened. This strategy is therefore not recommended. Treatment failure due to side effects only occurred in those patients on a 500mg three times weekly regime. Discussion in the literature raised concerns with atypical mycobacteria, potential for increased colonisation rates and drug resistance. No such concerns were seen in this series. In this series, Azithromycin provided clinical improvement in patients with other non-CF lung disease processes but further studies are needed in this population.

The recommended regime from this study, in those patients with non-CF bronchiectasis is Azithromycin 250mg PO daily.

P2545
Airflow obstruction, functional disability and psychological dysfunction in bronchiectasis

Graham Miller, Helmy Haja Mydin, Anthony De Soya. Cardiothoracic Department, Freeman Hospital, Newcastle upon Tyne, United Kingdom

Introduction: The impact of airflow obstruction, functional disability and psychological dysfunction has previously been described in COPD but not in bronchiectasis. We hypothesised that anxiety and depression may be commoner in bronchiectasis patients with poor functional capacity or evidence of airflow obstruction (AO). Methods: Adults attending a bronchiectasis clinic from Dec 2010-Jan 2011 were screened. Spirometry was performed & GOLD criteria for COPD were used to categorise AO. Functional ability was assessed using the MRC dyspnoea (MRCD) scale. The Hospital Anxiety and Depression Scale (HADS) was used to screen for anxiety and depression. A score of ≥8 in either sub-scale (HADS-A, HADS-D) was deemed clinically significant.

Results: N=52 (34F, 18M). Mean age: 61 (SD 13.4). 30 patients (57.7%) had evidence of AO. 6 patients (20%) had mild AO, 11 patients (37%) had moderate AO, 11 patients (37%) had severe AO and 2 patients (6%) had very severe AO. 27 patients (48%) had a HRCD score of ≥3. 30 patients (42.3%) had a HADS-A score of ≥8. 19 patients (28.8%) had both HADS-A and D scores of ≥8. Chi-square analysis showed significant association of clinically significant HADS-A (p ≤ 0.001) and HADS-D (p = 0.013) scores with a HRCD score of ≥3. There was no significant correlation between FEV1 % predicted and HADS-A or HADS-D scores (p=0.98). Scores on HADS were higher in those with active symptoms of AO.

Discussion: Many patients had severe or very severe airflow obstruction. 50% of...

P2546
Staphylococcus aureus sensitivity changes to antibiotics under the influence of dissolved ozone
Igor Belyanin, Lubov Selina, Evgeniy Shmelev, Alla Plotnikova. Microbiology, Central TB Research Institute, Moscow, Russian Federation Microbiology, Central TB Research Institute, Moscow, Russian Federation Microbiology, Central TB Research Institute, Moscow, Russian Federation

Aim: To study the sensitivity change of the clinical strains of staphylococcus aureus to antibiotics under the influence of dissolved ozone. (pO3).

Methods: We investigated 20 S.aureus strains from sputum culture resistant antibiotics. A suspension was prepared from a day portion of the agar culture of each strain (1-2 x 10^8/ml), which was treated with dissolved ozone (pO3 3mg/ml) or with air (control) during 5-10-15 min. Then, the strains treated with pO3 were cultured on Muller-Hinton agar containing strains resistant antibiotics and incubated by 370C. In a day of incubation we recorded the results of antibiotic resistance change according the diameter zone of the growth inhibition round the antibiotic discs.

Results: The growth inhibition zone increased from 3.8 to 25.7±2.1 mm in all cases of cultured S.aureus strains treated with pO3. And in cases with control strains the growth inhibition zone was not change.

Conclusion: Staphylococcus aureus sensitivity to antibiotics restores after dissolved ozone treatment.

P2547
Identification of four different metallo-β-lactamases, IMP-1, IMP-7, IMP-19 and VIM-2, in Japanese general hospitals
Naohiro Shibata, Hiroyuki Ohbayashi. Department of Allergy and Respiratory Medicine, Tohno-Kousei Hospital, Mizunami, Japan

Background: Metallo-β-lactamases (MBLs) are bacterial enzymes that hydrolyze β-lactams. MBL-producing gram-negative bacilli have been emerging worldwide. In this study, different MBLs were identified in various lung diseases in the japanese clinical hospitals.

Methods: From Jan. 2009 to Dec. 2010, 1618 GNB strains were submitted to the laboratory of 6 general hospitals in Aichi prefecture. Strains demonstrating a high β-lactamase activity were selected. Preparations of whole cells or cultures were subjected to a screening test for MBL production by using disks containing an MBL inhibitor, sodium mercaptoacetic acid (SMA). PCR and sequencing analyses were performed to confirm the types of MBLs and integrases using primers specific for each gene.

Results: Forty-five patients responded voluntarily to the questionnaires, 35 women, with a mean age of 66.46 (14.6) years. 16 were chronically colonized, with 12 cases of Pseudomonas aeruginosa 42.5% of patients (30% mild depression, 12.5% moderate) had depression. 65% of patients had scores above the 50th percentile in both trait anxiety and in anxiety state. State anxiety and trait anxiety were associated with bacterial colonization (p=0.005 and p= 0.0113) and more specifically to the colonization by Pseudomonas aeruginosa (p= 0.007 and p= 0.029).

Conclusions: Patients with bronchiectasis showed a high percentage of anxiety, both state and trait, as well as depression, although most of this is mild. The chronically colonized patients have higher levels of anxiety in these two aspects.

P2549
Microbiological pattern in infective episodes of bronchiectasis
Abdalla Khoury1, Hassan Imsaieel2, Hivin Hamnan2. 1Department of Pulmonary Diseases, Aleppo University Hospital, Aleppo, Syrian Arab Republic; 2Department of Internal Medicine, Aleppo University Hospital, Aleppo, Syrian Arab Republic

Background: Infections usually cause inflammatory reaction and destruction of bronchial wall, this further leads to more disturbance in local defense and a vicious cycle of inflammation and bacterial colonization occurs.

Objectives: The purpose of this paper was to studying the microbiological pattern during infective episodes of Bronchiectasis and possible relation between the invasive Bacteria and lung functions.

Materials and methods: A retrospective analysis of 60 episodes in 50 patients. Fortyeight patients fulfilled our protocol criteria of reliable microbiological result and reproducible lung function tests. The patients were categorized into three stages of severity. Fibroscopic bronchoscopy was performed just after sampling. Sputum sampling was achieved. Cut off point of 1000CFU was considered for positivity of culture media.

Results: H.influenza was the causative agent in 10 episodes (17%), S pneumoniae in 8 (14%) and Paeroginosa in 9 (14%), Morexella catarrhalis in 7 (12%) episodes. Lung function tests revealed an FEV1 with 50% of predicted value in 20 patients (stage 1), an FEV1 with 35-50% in 12 patients (stage 2 and FEV1 with 35% in 8 patients (stage 3).

There was a correlation between deterioration of lung function and the bacteria isolated from patients with infective exacerbations of Bronchiectasis, in acute episodes Pseudomonas Aeruginosa and Enterobactereae were the predominant bacteria in patients with FEV1 at 35% of predicted value.

Conclusion: There were no correlations between the isolated bacteria and the duration of symptoms, number of previous hospitalization, or radiological findings.

In contrast there was a correlation between the deterioration of lung function and the isolated bacteria.

P2550
The role of viruses and other atypical bacteria in bronchiectasis’ exacerbations
Evangelos Balis1, Eugenios Metaxas2, Despina Chrysovergi2, Josip Paparakaskeus2, Nikolaos Spanakis2, George Tatsi2, Athanasios Tisikas3. Pulmonary, Evangelismos General Hospital, Athens, Greece; 23rd Internal Medicine, Evangelismos General Hospital, Athens, Greece; 3Microbiology, Medical School of Kaposvár University, Athens, Greece

Introduction: Exacerbations in patients with bronchiectasis, is thought to occur either because of change in the bacterial load of an existing bacteria or because of colonization with a new bacterial strain. Despite the existence of data for the role of viruses and atypical bacteria in patients with COPD, there is paucity of data about their role in bronchiectasis.

Aims and objectives: To study the effect of atypical bacteria and viruses in bronchiectasis exacerbations

Methods: An observational study was performed. For 12 months, 33 patients with bronchiectasis were followed up in 4 months intervals. They were submitted to bronchoscopy in an effort to determine baseline bacteria. Bronchoscropy was also performed during exacerbations. Real time polymerase chain reaction (PCR) was performed in bronchovascular lavage (BAL) samples for the detection of Chlamydo-philum pneumoniae, Mycoplasma pneumoniae and Respiratory syncytial virus (RSV). In addition, antibody titers against Influenza A, Influenza B, Adenovirus, C pneumoniae and M. pneumoniae were measured.

Results: In total 116 visits were performed (97 baseline and 19 exacerbations). After the first 30 PCR tests, because of cost restrictions, PCR was agreed to be performed only in cases of elevated IgG, seroconversion, or positive IgM titters. Totally 74 PCR tests were performed. RSV was isolated in 4 subjects during baseline periods and none during exacerbations. All PCR tests were negative for atypical bacteria. There was no detection of IgM antibodies against the aforementioned microorganisms.

Conclusions: Despite the small number of recorded exacerbations, atypical bacteria and viruses do not seem to have a role in exacerbations in patients with bronchiectasis.

P2551
Anxiety and depression in patients with bronchiectasis related to bacterial colonization
Gilda Fernandes1, Cristina Martin-Carbajo2, Rosa Girén3, Emma Vasquez1, Rosa Gómez-Punter1, Carolina Cisneros1, Lourdes Ramos2. 1Pulmonary, Evaggelismos General Hospital, Athens, Greece; 23rd Internal Medicine, Evangelismos General Hospital, Athens, Greece; 3Microbiology, Medical School of Kaposvár University, Athens, Greece

Conclusions: In this study, different MBLs were identified in various lung diseases in the japanese clinical hospitals.

There was no detection of IgM antibodies against the aforementioned microorganisms.

Conclusions: Despite the small number of recorded exacerbations, atypical bacteria and viruses do not seem to have a role in exacerbations in patients with bronchiectasis.
275. Antimicrobial treatment and resistance in lower respiratory tract infections

P2551 Late-breaking abstract: When is pleural fluid microbiology useful?
Kerry Woolnough, Imran Hussain. Respiratory Medicine, University Hospitals of North Staffordshire, Stoke-on-Trent, United Kingdom

Introduction: It is routine clinical practice, and recommended by the British Thoracic Society, that fluid is sent for culture following diagnostic thoracocentesis. Few studies have evaluated the yield from sending all pleural fluid specimens for culture in day to day practice. Culture yield has, however, been studied in cohorts of patients where pleural infection is suspected - with a sensitivity of 54%. We wished to ascertain what our yield is from pleural fluid culture when used as part of a routine workup for an undiagnosed pleural effusion and whether positive cultures were associated with raised inflammatory markers (WCC and CRP).

Methods: We retrospectively analysed all pleural fluid samples sent for culture over the previous 12 months. All specimens were cultured for aerobic and anaerobic bacteria, fungi and mycobacterium. Pleural fluid protein, LDH content, serum CRP and WCC were also recorded.

Results: 485 samples were sent for culture over the 12 month period. There were 42 (8.7%) positive cultures, of which 4 were excluded as contaminants. 20 different organisms were isolated. Streptococcus anginosus and Mycobacterium tuberculosis were the most common. 47% of these positive samples were exudates, non-serous transudates. The remainder of these specimens (53%) had no pleural fluid biochemistry performed. We found a positive yield of 7.8% out of the 485 pleural fluid samples studied. A clear association was found between yield and a raised CRP and WCC with a raised CRP found in 97% of cultures and an increased WCC in 75%.

Conclusions: Routine culture of pleural fluid is neither cost-effective nor clinically useful and should only be requested when pleural infection is suspected, both clinically and biochemically.

P2552 Late-breaking abstract: Inhaled calcium based dry powder inhibits rhinovirus-induced inflammation and exacerbation in a mouse model of allergic airway inflammation
Paul McEvoy2,3,4, Tim Brogan, Stephen Arnold, Pamela Okerholm, Faith Saia, Robert Clarke, David Hava. Research, Palmtrix Inc, Lexington, MA, United States

Acute exacerbations (AE) in asthma are associated with rhinovirus (Rv) infection. AE’s drive disease progression and cause loss of lung function, yet no current therapies target this infectious component. Calcium (Ca) based dry powder (DP) formulations were developed as host-targeted therapies that broadly reduce viral infection in vitro, including Rv. Here, a lead Ca-based DP (PUR118) was tested for efficacy against Rv in a mouse model of infection and AE using Rv1B infection in naive and ovalbumin (OVA)-challenged mice (Bartlett NW et al Nat Med 2008). Mice (Balb/c) were treated with PUR118 or control DP by whole body immersion (IBD) before nasal Rv infection. Bronchoalveolar lavage (BAL) inflammation was evaluated 24h post-infection. Additional indices of infection and exacerbation included: viral titers, and expression of relevant cytokines and chemokines. Rv infection caused significant neutrophilic inflammation in naive mice (7.5 × 10⁵ BAL neutrophils/ml) and exacerbated inflammation in OVA challenged mice (44% increase over control) with increased neutrophils, cytokines and chemokines. In naive mice, PUR118 treatment reduced neutrophilic inflammation by 38%, which correlated with reduced cytokine and chemokine expression. Similar results were observed in OVA mice where PUR118 treatment reduced neutrophilic inflammation by 40%. The data show Ca-based DP significantly inhibits Rv-induced airway inflammation and Rv-driven exacerbation responses in an asthma-like mouse model. These data support the development of inhaled Ca-based DP to treat infectious causes of AE’s in respiratory disease.

P2553 Late-breaking abstract: Prevalence of influenza A H1N1 virus infection in patients with asthmatic crisis of the National Institute of Respiratory Diseases (in Mexico City)
Olivia Sánchez Cabral, Jair Rodríguez Barragán, Manuel de Jesús Castillo López. Respiratory Emergency Department, Instituto Nacional de Enfermedades Respiratorias, Mexico, Distrito Federal, Mexico

Introduction: Among the key precipitating factors of these crises are respiratory infections, mainly viral. In April of 2009, Mexico experienced a new influenza A H1N1 epidemic.

Objective: Determine the prevalence of influenza A H1N1 infection in patients with secondary asthmatic crisis.

Research methods. A transversal research on 5-75 year-old patients was developed between September 1, 2009 and May 17, 2010. Research subjects were admitted to the emergency room with a probable diagnosis of influenza A H1N1 infection and asthmatic crisis. Real-time polymerase chain reaction technique was used to confirm influenza A H1N1.

Findings: We found a global prevalence of 3.6% (195/526) of influenza A H1N1 among the patients that were admitted to the emergency room due to asthmatic crisis. From reviewing medical files we found 124 cases of asthmatic crisis among those patients with a clinical suspicion of influenza A H1N1. The prevalence of the A H1N1 virus among patients with asthmatic crisis was 13.7%. The average age of patients in the study was 35.8 years (mean ± 14.0 years), 71.8% of the patients were women. The average stay in the hospital was 6.9 days, 91% (104/124) of the crises ranged from acute to almost fatal.

Conclusion: Prevalence is relatively high. They can expect an aggravation of the crisis and a longer stay in the hospital.
P2556 Prior outpatient antibiotic use in patients with community acquired pneumonia (CAP) admitted in hospital
Cristina Dei1,2, Filipa Cunha1,2, Andrea Candal1,2, Angelita Nabu3,4,5, Francisco Santos3,4,5, Maria da Carne Aguiar3,4,5, 1Pneumology, Hospital Universitario de Alcorcón, Madrid, Spain; 2Internal Medicine, Hospital Universitario de Alcorcón, Madrid, Spain; 3Pneumology, Hospital Peset, Valencia, Spain; 4Pneumology, Hospital Clinico Valencia, Valencia, Spain; 5Pneumology, Hospital General de Valencia, Valencia, Spain; 6Pneumology, Hospital General de Castellón, Castellón, Spain

Aims: To compare clinical, microbiological, severity and outcomes in patients with CAP admitted to hospital who had received or not previous antibiotic treatment. Method: A 12 months prospective multicenter study was performed in Valencia Community, in Spain (mediterranean area). Factors related comorbidity, etiology, severity, outcomes and mortality, were analyzed. Patients were divided in Group A: antibiotic treatment before admission and Group B: no previous antibiotic treatment.

Results: 1313 CAP, 850 men (65%), 295 in group A (22.4%) with previous antibiotics during 4.3±2.8 days. Patients in group A were younger (59±2.0 vs 65±1.8, p < 0.001), and more patients treated like outpatients (13.2% vs 8.8%, p < 0.05) without differences in resistance. When risk factors and comorbidity were analyzed, in group A there were lower proportion of alcohol abuse, heart failure (p < 0.05) and CAP evolution days (7.4±4 vs 5.4±5, p < 0.01), without differences in other factors. In clinical presentation, group A had more fever and cough (p < 0.001), lesser dyspnea, and altered mental status (p < 0.05), with higher PaO2/FiO2 (293±355 vs 231±169, p < 0.05). No differences in radiology patterns between groups or in etiological confirmation were found. Patients in group A had a lower PSI (81.36 vs 92.15±, p < 0.001), lower rate of complications (p < 0.005) as renal failure, shock, mechanical ventilation and ICU admission (p < 0.05), without differences in intrahospital mortality. The length of stay was shorter in group A (9.45 vs 11±10 days, p < 0.001).

Conclusions: Patients with CAP who received antibiotic treatment before admission were younger, required less hospitalization and the CAP had less severity and complications.

P2557 Clinical outcomes of tigecycline in the treatment of critically ill patients with multidrug-resistant Acinetobactor baumannii infection
Jung Ar Shin1, Hyung Jung Kim1, Min Kwang Byun1. Internal Medicine, Yonsei University College of Medicine, Seoul, Korea

Background: Acinetobacter baumannii (A. baumannii) has emerged as a major cause of nosocomial pneumonia and sepsis in seriously ill patients. Multidrug-resistant A. baumannii (MRAB) is increasing in frequency, and the management of A. baumannii infections is consequently difficult. Therefore, tigecycline is considered the drug of choice for MRAB treatment. The aim of our study was to evaluate the microbiological eradication and clinical effectiveness of tigecycline against MRAB in seriously ill patients, including patients with ventilator-associated pneumonia (VAP).

Methods: We conducted a retrospective study including patients with A. baumannii infections that were treated with tigecycline between April 1, 2009 and March 31, 2010. We analyzed 27 patients with tigecycline for MRAB infections.

Results: The mean age of the patients was 66.2 years (44-83 years) and 20 (74.1%) patients were male. The median length of stay was 74.6 days (11-35 days). MRAB was eradicated from the site of infection in 33 cases (85.2%), however only 17 cases (63.0%) showed positive clinical responses. Overall, an inhospital mortality rate of 51.9% was observed and 4 cases of death were attributable to sepsis. The combination therapy group showed better clinical and microbial success rates than the monotherapy group.

Conclusions: We observed successful microbial eradication rates, but clinical success rates were lower than previous studies.

P2558 Randomised controlled trial of sequential intravenous and oral azithromycin compared with intravenous ceftriaxone followed by cefixime both in combination with clarithromycin in hospitalised patients with community-acquired pneumonia
Arash Etemadi1, Parvez Salehi2, Abbas Chenaneh3, Siamak Ahmadi4. 1Internal Medicine Department, Ahvaz Jondishapour Medical University, Ahvaz, Khuzestan, Islamic Republic of Iran; 2Gerontological Medicine, Ahvaz Jondishapour Medical University, Ahvaz, Khuzestan, Islamic Republic of Iran

Background: The objective of the study was to compare the efficacy, safety, and tolerability of Azithromycin (500 mg) intravenously (i.v.) once daily followed by 250 mg orally twice daily for 14 days with Ceftriaxone (2 g) p.i. by infusion twice daily followed by Cefixime (400 mg) twice daily, both in combination with oral clarithromycin (500 mg) twice daily for the same duration in 63 adult patients initially hospitalized with community-acquired pneumonia. All patients assessed both clinically and bacteriologically one month after the end of the treatment. The results showed statistically significant higher clinical (93.4% vs. 85.4%) and bacteriological success rates (93.7% vs. 81.7%) for patients treated with Azithromycin, irrespective of the severity of the pneumonia. The time to resolution of fever was also faster (median time: 2 vs. 3 days) and hospitalization period was approximately 1 day less for patients who received Azithromycin. The treatment was converted to oral therapy immediately after the initial mandatory 3-day period of i.v.administration for a larger proportion of patients in the Azithromycin group than patients in the control group (50.2% vs. 17.8%). There were fewer deaths (3.0% vs. 5.3%) and fewer serious adverse events (16.5% vs. 16.5%) in the Azithromycin group than in the control group. The rates of drug-related adverse events were comparable in both groups. Thus, monotherapy with Azithromycin is superior to combination regimen of ceftriaxone plus clarithromycin, in the treatment of community-acquired pneumonia.

P2559 Effectiveness of once daily meropenem for the treatment of aspiration pneumonia of elderly patients in long-term care facilities
Arash Etemadi1, Parvez Salehi2. 1Internal Medicine Department, Ahvaz Jondishapour Medical University, Ahvaz, Khuzestan, Islamic Republic of Iran; 2Gerontological Medicine, Ahvaz Jondishapour Medical University, Ahvaz, Khuzestan, Islamic Republic of Iran

Objective and background: Aspiration pneumonia is a major health problem in residents of long-term care facilities. Antibiotics with broad coverage against gram negative and anaerobic bacteria, such as carbapenems, are cornerstones of treatment. However, once daily administration of meropenem for ambulatory patients is not routine yet.

Methods: A retrospective study of 31 elderly patients with aspiration pneumonia (17 males, 14 females; mean age 85 years) was conducted. In addition, the efficacy and safety of once daily intravenous meropenem (3g) for the treatment of this condition was evaluated.

Results: The overall detection rate of bacteria was 87% (32% monomicrobial, 55% polymicrobial). gram-negative enteric bacilli and anaerobic bacteria were isolated with the same frequency (20%) The overall clinical efficacy rate of meropenem therapy was 61%. The mortality rate was 10%.

Conclusion: The use of antibiotics effective against anaerobic bacteria may be necessary for patients with potentially fatal aspiration pneumonia. Once daily treatment with Meropenem (3g) for aspiration pneumonia is clinically effective and tolerable in elderly patients.

P2560 Potential protective role of prior to diagnosis antibiotic treatment in community-acquired pneumonia: Clinical presentation and outcomes
Francisco Santos1,2, Estrella Fernandez1,2, Maria Carolina Aguir1,2, Marisa Briones1,2, Eusebi Chiner3, Cristina Senent3, Jose Sancho3, Josè Blanquer4,5. 1Pneumology, Consorci Hospital General Universitaritat, Valencia, Spain; 2Pneumology, Hospital De Peset, Valencia, Spain; 3Pneumology, Hospital Arnau de Vilanova, Valencia, Spain; 4Pneumology, Hospital Clinico Universitari, Valencia, Spain; 5Pneumology, Hospital Clinic Universitari, Valencia, Spain; 6Intensive Care Unit, Hospital Clinic Universitari, Valencia, Spain

Aims: To evaluate the role of prior to diagnosis antibiotic therapy in the clinical presentation of community-acquired pneumonia (CAP) and its influence in the outcomes.

Methods: CAP’s (excluding HCAP) receiving antibiotic treatment before hospital admission were analyzed. We assessed demographic factors, comorbidities, signs, symptoms, and outcomes. Logistic regression analysis was performed to establish causal relationships.

Results: We analyzed 1.197 cases of hospitalized CAP in which 22.6% had a history of prior antibiotic treatment, with a mean duration of 3.9 (2.2) days. Beta-lactams were the most frequently used (52.7%) followed by macrolides (29.2%), and quinolones (18.1%). Multivariate analysis showed that patients who received prior antibiotic treatment showed less pneumonia severity on admission (PSI II 64.7% vs. 59.0%, OR 1.85 95% CI 1.44-2.45) and pneumococcal etiological diagnosis was less frequent (13.3% vs. 21.7%, OR 0.61 95% CI 0.41 to 0.92). In patients receiving prior to diagnosis treatment, a shorter hospital stay (8.3 (1.5) vs. 10.6 (9.7), P = 0.001), lower frequency of respiratory failure (21.2% vs. 28.8%, p = 0.023), septic shock (1.5% vs. 4.2%, p = 0.034) and ICU admission (3.3% vs. 6.8%, p = 0.035) were found. No significant differences in mortality were observed.

Conclusions: 1. Prior to diagnosis antibiotic treatment of CAP has a role in modifying the severity of CAP and an impact on pneumococcal etiologic diagnosis. 2. The use of antibiotics before the diagnosis of pneumonia is associated with a shorter hospital stay and less development of complications in our series.

P2561 Antibiotic prescription patterns in hospitalized patients with community-acquired pneumonia in local hospital: 10 year follow-up
Alexander Vizel1, Galina Lysenko2. 1Phtthiopulmonology, Kazan Medical University, Kazan, Tatarstan, Russian Federation; 2Standardization and Quality, Ministry of Health of Tatarstan Republic, Kazan, Tatarstan Republic, Russian Federation

Background: In Tatarstan Republic (Russia) regularly update the guidelines of an
community-acquired pneumonia (CAP) and spend work on updating of knowledge of doctors: lectures, seminars, publications.

**Objective:** We sought to examine patterns of antibiotic prescription during last 10 years in a local hospital. We have estimated prescription of antibiotics at a pneumonia in 2000 (174 cases), 2005 (321) and 2010 (182 cases).

**Intervention:** chart reviews of 771 individual admissions with the diagnosis of pneumonia between January 2000 and December 2010.

**Results:** Compliance with national guidelines for the treatment of CAP increased within 10 years that the table reflects.

**Most often applied antibiotics at a community-acquired pneumonia**

Frequency of application III generation cephalosporins has increased about 4% to 87.6%, respiratory fluoroquinolones - about 0% to 16.7%.

**Conclusion:** Research has shown that prescription of antibiotics changed within 10 years. Appointments in 86.7% of cases corresponded to the recommendations accepted in Russia in 2010.

**P2562 Clinical efficacy of bolus versus continuous-infusion of piperacillin-tazobactam in VAP treatment**

Fukun Fuhimi1,2, Hamid Reza Jamil2, Payam Tabarsi1, Shadi Ban Asadi1, Somayeh Ghafer1, Seyed Mohammad Reza Hashemi1,2, Clinical Pharmacy Department, School of Pharmacy, SBMU, Tehran, Islamic Republic of Iran; 2Critical Care, Chronic Respiratory Disease Research Center CRDRC/NRITLD, Tehran, Islamic Republic of Iran; 3Mycobacteriology Research Center, NRITLD, Tehran, Islamic Republic of Iran; 4Pharmaceutical Care Department, TB and Lung Disease Research Center, NRITLD, Tehran, Islamic Republic of Iran

**Introduction:** VAP is the most frequent intensive care unit (ICU) acquired infection. In an effort to improve the clinical outcome, great attention must be given to early and accurate diagnosis, optimal doses of effective antibiotic and best routes of administration.

**Aims and objectives:** The aim of this study was to evaluate the clinical outcome of piperacillin/tazobactam via continuous infusion by serial measurements of Clinical Pulmonary Infection Score (CPIS), compared to intermittent bolus

**Methods:** This study was designed as a prospective clinical trial of continuous infusion or intermittent bolus of a fixed combination of piperacillin/tazobactam and was conducted at the semi-closed intensive care unit of a university hospital.

**Results:** There were no significant differences in characteristics between the two groups. The mean ± SD age of the patients was 53 ± 8.27 years. The APACHE II score was 20.4 ± 6.1 in the CI group and 18.8 ± 5.9 in the IB group (p=0.319). There was a worsening on day 3 compared with the CPIS on day 1, 8.70 ± 2.13 vs 7.04 ± 1.55, and then CPIS slowed improvement from day 3. In the CI group more tendency for improvement was observed.

**Conclusion:** This study suggests that the real value of our findings will achieve within 10 years that the table reflects.

**P2563 difference of patient background with pneumonia between monotherapy and combination**

Masataki Shibasaki1, Mitsuomi Nishikawa1, Yuichi Kitagawa2, Kazuyoshi Sendai1, Kazunori Nakashima1, Fumihito Miromsk1,1 Respiratory Division, School of Medicine, Shizuoka University, Shizuoka, Japan; 2Surgery Division, National Center for Geriatrics and Gerontology, Oobu, Aichi, Japan; 3Geratology, University of California, San Francisco, San Francisco, CA, United States; 4Anesthesia and Perioperative Care, UCSF, San Francisco, CA, United States

**Introduction:** to select combination therapy of antibiotics.

**Methods:** The current guidelines recommend combination therapy of antimicrobials and Gerontology Hospital from April 2008 to December 2010, and treated with carbapenem (A group, n=70) or combination of carbapenem-sulbactam (B group, n=68).

**Methods:** Information on age, gender, weight, risk factors of PDR pathogens, pneumonia type (CAP/HAP/CF/HAP), Barthel index, clinical response, duration of therapy and 30-day mortality were obtained from chart review. We compared the aforementioned factors between two groups using multiple logistic regression analysis.

**Results:** There were significant differences about the aforementioned factors except age between A and B group in univariate analysis. However, in multivariate logistic regression analysis, only Barthel index was significantly different between both groups (81.8 ± 29.2 in A group vs. 59.1 ± 40.3 in B group, P<0.01, respectively). The clinical efficacy rates were 79% in A and 63% in B groups, respectively. The 30-day mortalities were 13% in A and 38% in B groups, respectively (P=0.067). Duration of antibiotics therapy was significantly shorter in A group compared with B group (7.3 ± 4.7 vs 19.3 ± 8.2 days, respectively, P<0.01).

**Conclusion:** Barthel index was the independent factor which affected physicians to select combination therapy of antibiotics.

**P2564 Auditing patterns of azithromycin use in respiratory disease**

David Hodgson1, Robert Hurford1, Tim Harrison1, Dominick Shaw1, 1Nottingham Respiratory Biomedical Research Unit, University of Nottingham, Nottingham, United Kingdom; 2University of Nottingham Medical School, University of Nottingham, Nottingham, United Kingdom

**Introduction:** In response to increasing use of Azithromycin in respiratory disease we set out to audit local prescribing and clinical outcome.

**Methods:** Data on all Azithromycin prescriptions from a Respiratory Consultant in a large UK teaching hospital between 1st September 2009 and 31st March 2010 were collected. There were 192 prescriptions corresponding to 123 patients. After excluding patients with cystic fibrosis (CF) and Pseudomonas aeruginosa colonisation, 62 sets of notes were reviewed. The subjective clinical benefit of Azithromycin and objective improvement in terms of exacerbations or lung function was assessed.

**Results:** Despite the large variation in phenotypic disease (Figure 1), there was an overall reduction of 0.36 exacerbations per month (P<0.001, 95% CI: 0.27–0.46). On further analysis we found that those with evidence of bronchiectasis were significantly more likely to improve after Azithromycin therapy than those without; 88% and 39% respectively (P<0.001).

**Conclusion:** Azithromycin is used in a variety of respiratory conditions and we found variable recording of its benefit. A more formal assessment of benefit is required, especially in light of its side effect risk and potential for microbial resistance. Additional randomised controlled trials to further guide treatment are recommended.

**P2565 Pev antibody prophylaxis in combination with antibiotic therapy reduces lung injury and improves survival in Pseudomonas aeruginosa infected mice Yuanlin Song1, Mark Baer2, Ramya Sirivongsavan3, Juliana Lima3, Geoffrey Yarranton3, Christopher Bebbington3, Susan Lynch1,1 Department of Pulmonary Medicine, Zhongshan Hospital, Shanghai, China; 2KaloBio Pharmaceutical, Inc., KaloBio Pharmaceutical, Inc., San Francisco, CA, United States; 3Gasterenterology, University of California, San Francisco, San Francisco, CA, United States; 4Anesthesia and Perioperative Care, UCSF, San Francisco, CA, United States

The type III secretion system (TTTS) of Pseudomonas aeruginosa facilitates direct injection of cytotoxins into host cell cytoplasm. PeV, located at the tip of the needle-like injectosome, is an essential component of this virulence system. Mab166, a murine monoclonal antibody against PeV has demonstrated efficacy against P. aeruginosa infection resulting in increased survival and reduced lung injury in a variety of mouse models of infection. We hypothesized that administration of Mab166 prophylactically in combination with conventional antibiotics (administered subsequent to infection) could further improve survival of P. aeruginosa infected mice. Three antibiotics (ciprofloxacin, tobramycin and cefazidime), commonly prescribed for P. aeruginosa infections were used for this study. Consistently, compared to other treatment groups, the combination of Mab166 administered with PeV antibody prophylaxis in combination with antibiotic therapy reduced significantly more likely to improve after Azithromycin therapy than those without; 88% and 39% respectively (P<0.001).

**Conclusions:** Azithromycin is used in a variety of respiratory conditions and we found variable recording of its benefit. A more formal assessment of benefit is required, especially in light of its side effect risk and potential for microbial resistance. Additional randomised controlled trials to further guide treatment are recommended.

The prevalence of LTBI was 16.7%. CXRs were needed in 236 subjects. CXRs could have been avoided in the 192 subjects (81%) who had a normal IGRA test. Normal CXRs, within the preceding year, were associated with LTBI (p < 0.05). CXRs could have been avoided in the 192 subjects (81%) who had a negative IGRA test. The 108 that declined CXRs did not report any symptoms of TB, and 105 of them had negative IGRA tests. Normal CXRs, within the preceding year, were associated with LTBI (p < 0.05). CXRs could have been avoided in the 192 subjects (81%) who had a negative IGRA test.

Conclusion: The IGRA test first protocol was more cost-effective than a “CXR first protocol”, during TB screening, due to a reduction in the number of CXRs required. The presence of symptoms, a positive IGRA/Mantoux test, or risk factors for active TB should be indications for a CXR.
P2572 Clinical, epidemiological and evolving profile of miliary tuberculosis: Study of 48 cases
Nahid Zaghba, Abdelaziz Bakhdar, Najiba Yassine, Abdelkarim Bahlaou.
Respiratory Diseases, Universitary Hospital Center, Casablanca, Morocco

Miliary tuberculosis is a rare but severe form of TB often due to hematogenous spread of Mycobacterium tuberculosis. It represents less than 2% of tuberculosis in our context. We conducted a retrospective study of 48 cases collected in our Respiratory Diseases department between 2003 and 2010. Female cases were pre-dominant with 60%. The mean age was 35 years old. The history of tuberculosis spread of Mycobacterium tuberculosis. It represents less than 2% of tuberculosis in our context.

Results: Mean age was 43.3 ± (13.8) years; 75.0% were male. Median sputum culture conversion time was 46 days. Delayed sputum culture conversion was found in 27.2% (n=37) of patients. In univariate analysis, unemployment (38.0% vs. 20.9%, p<0.031), HIV positivity (53.3% vs 24.0%, p=0.028), bilateral radiological involvement (42.0% vs 19.0%, p=0.005), cavitory disease (32.6% vs 15.9%, p=0.041), and colony counts ≥ 100 (53.7% vs 8.3%, p=0.018) were risk factors for persistent positive culture. In multivariate logistic regression analysis, only bilateral radiological involvement (odds ratio (OR) 1.7, 95% confidence interval (CI): 1.5-9.0) and higher colony counts (OR 5.8, 95% CI: 1.2-27.4) were independently associated with delayed sputum culture conversion.

Conclusions: Delayed sputum culture conversion was found in approximately one third of patients. Logistic regression analysis determined higher colony counts and independent risk factors for delayed sputum culture conversion.

P2573 Completion of treatment for latent tuberculosis infection
Claudia C. Dobler1,2, Guy B. Marks1,2. 1Respiratory and Environmental Epidemiology Group, Woolcock Institute of Medical Research, Sydney, Australia; 2Department of Respiratory Medicine, Liverpool Hospital, Sydney, Australia

Background: The effectiveness of latent tuberculosis infection (LTBI) treatment depends largely on adherence.

Aim: To identify factors associated with patients’ completion of treatment for LTBI.

Methods: We reviewed the characteristics of all patients who were prescribed a six month course of treatment with isoniazid for LTBI at the Chest Clinic of a large tertiary hospital between 01/2000 and 04/2008. A supply of isoniazid was dispensed one month at a time by Chest Clinic nurses. Treatment completion was defined as pickup of ≥ 80% of prescribed doses.

Results: During the study period, 143 patients were started on this course of therapy. Their mean (SD) age was 25 (16) years and 43% were male. Seventeen patients were excluded from the analysis because their treatment was interrupted (n=4) or ceased (n=13) by their treating physician. Of the remaining 126 patients, 25 (20%) did not complete treatment. Treatment completion was not significantly related to patients’ sex, age, tuberculosis (TB) incidence in their country of birth, TST conversion status, smoking status, baseline liver function tests, or indication for isoniazid treatment (contrast versus other indications). However, among those who were contacts of a patient with active TB (n=10) those who were not living in the same household as the index case were more likely to fail to complete treatment (relative risk 7.2, 95% CI 2.6 to 20.7).

Conclusions: In this cohort, with monthly supervision of drug collection, 1 in 5 patients who commenced treatment for LTBI did not complete their course of treatment. Non-household contacts of patients with active TB were at an increased risk of not completing treatment. This may prompt researchers to encourage treatment completion.

P2574 Differences between age related clinical presentation of pulmonary tuberculosis (TB)
Ramonona Nedelec, Oana Claudia Deleanu, Diana Pocora, Andra Malanu, Ileana Rohan, Anca Macri, Roxana Nemes, Ruxandra Ulmeana, Florin-Dumitru Mihalasan. Pneumology, Institute of Pneumology “Marius Nasta”, Bucharest, Romania; Pneumology, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; Bronchology, Faculty of Medicine and Pharmacy - Oradea University, Bucharest, Romania

Aims: This study aimed to compare clinical features, predisposing factors and imaging findings of pulmonary TB in elderly and young adults and to determine any existing difference between the two groups.

Methods: A total of 179 patients diagnosed with TB were divided into two groups: younger (<65yrs) and older (>65yrs). Mean characteristics (gender, smoking, TB forms, lesion extension and type, symptoms, comorbidities, side effects) were analyzed. Statistical analysis was done using SPSS software (chi-square test and student’s t-test).

Results: There were 102 young adults (mean age 38.97±12.45yrs; 60 men, 42 women) and 77 elderly patients (mean age 73.38±6.42yrs; 50 men, 27 women) with TB. The elderly patients were smokers (61% vs 45% P=0.05), more likely to have dyspnoea (57.14% vs 28.4% P<0.001) and night sweats (63.6% vs 24.5% P=0.011). Young subjects present asymptomatic or anorexia associated forms. Elderly patients frequently showed extensive unilateral infiltration in chest X-rays (19.5% vs 3.9% P<0.001); these lesions were often misdiagnosed as pneumonia (6.5% vs 1% P=0.04). Predisposing factors were more prevalent in elderly subjects who had a significantly higher frequency of diabetes mellitus (14.3% vs 2% P=0.002), ischemic heart disease (18.2% vs 2% P=0.01), congestive heart failure (10.4% vs 1% P=0.04), malignancy (15.5% vs 1% P=0.001), arterial hypertension (61% vs 47% P<0.002) and caxoesia (7.8% vs 1% P=0.02).

Conclusions: In Romania, TB is more frequent in younger people, although older subjects represent a population at high risk to develop sever forms. Diagnosis in elderly patients can be challenging, since they may not display classic signs and symptoms.

P2575 Causes of delay in the diagnosis of pulmonary tuberculosis
Joana Alves1,2, Denisa Mendonça1,2, Ana Correia1, Raquel Duarte1,2. 1Internal Medicine Department, Centro Hospitalar do Porto - Hospital do Santo António, Porto, Portugal; 2Institute of Biomedical Sciences Abel Salazar (ICBAS), Porto University, Porto, Portugal; 3Public Health Institute, Porto University, Porto, Portugal; 4Public Health Department, Northern Regional Health Administration, Portugal; 5Pulmonary Disease Department, Centro Hospitalar de Vila Nova de Gaia/Esposito, Vila Nova de Gaia, Portugal; 6Chest Disease Centre of Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 7Epidemiology Department, Medical Faculty, Porto University, Porto, Portugal

Background: Early diagnosis of tuberculosis and its treatment are essential in a control program, as it reduces the severity, mortality and transmission of the disease in the community.

Aim: To determine the time between symptom onset and demand of health services (patient delay) and between first consultation and start of treatment (health care delay). For each interval, determinants of possible delays were analyzed.

Methods: A cross-sectional study was performed in Porto (North of Portugal), based on data from the national tuberculosis surveillance system, including confirmed cases of pulmonary tuberculosis diagnosed during 2008/2009. We defined 3 weeks for patients’ and 1 week for health cares’ delays as cut off points to dichotomize the sample into either delay or non delay. Chi-square test were used to analyze associations (α=0.05).

Results: We analyzed 165 individuals and of those, 122 (76.5%) were male and the mean age 48 years old. Median patient delay was 4 weeks. Patient delay was more frequently associated (although not statistically significant - p>0.01) with unemployment (68.4% vs 61.4%), alcoholism (76.5% vs 62.7%) and other co-morbidities (72.2% vs 64.9%). The median time of health care delay was 1 week. Negative sputum smear was significantly associated (69.7% vs 34.2% - p=0.001) with this delay.

Conclusion: We could not identify target groups significantly associated with patient delay. Strategies should be directed to general population in order to increase awareness about the disease. Negative sputum smear was associated with health care delay which can be justified by the time needed to study these patients.

P2576 The effect of smoking on the treatment outcome in patients with pulmonary tuberculosis: A prospective cohort study
Myla Castillo, Ma Encarnita Limpin. Division of Pulmonary and Critical Care, Philippine Heart Center, East Avenue, Quezon City, Philippines

Smoking and tuberculosis have great impact on health. Smoking is prevalent worldwide occurring in 20% of adults while tuberculosis is a universal problem. Studies have shown that although smoking has no etiological role in TB, higher prevalence of TB has been observed in smokers. However, only few studies have evaluated the impact of smoking on TB treatment.
Background: Pulmonary tuberculosis (TB) is a chronic disease, with slow evolution and slow recovery with specific treatment. Some of the cases have differential diagnosis doubt over a long period of time.

Material and methods: We present a series of 6 patients (5 females), mean age 43.1 years (range 27-70 years), with various respiratory symptoms and opacities on chest radiography, who needed multiple diagnosis procedures over a long period of time before the diagnosis of TB.

Results: The delay of diagnosis was 19.1 month (range 5-24 months). Symptoms consisted of: cough (6), dyspnea (4), and low grade fever (2). Chest X-ray showed: pulmonary micronodular pattern (4), consolidation (1), and pseudotumor (1). CT scan showed “tree in bag” pattern in patients with micronodules on chest radiography.

One patient monitored several times with CT-scan and bronchoalveolar lavage was diagnosed with TB after 2 years, when cavities appeared on CT-scan and sputum smear was positive for AFB. One patient had diabetes and one had viral C hepatitis. All had fever and poor general condition. One patient presented with acute respiratory failure. Chest x ray revealed bilateral interstitial micronodules in all cases. Tuberculin skin reaction was positive in 3 cases. Three cases were smear positive. Medullary biopsy confirmed TB in 1 case. One case was retrospectively confirmed by good response to treatment. Extrapulmonary localization was: hepatic in 5 cases, splenic in 2 cases, lymph node in 1 case, cerebromeningeal, mediastinal, osteoarticular and renal in 1 case each. Treatment administered urgently was based on anti tubercular treatment and treated urgently as such.

Conclusion: MT is a rare form of TB in BCG vaccinated patients and occurs more frequently in immunocompromised patients. To evaluate frequency and clinical features of MTB in immunocompromised patients, we analyzed all cases of MTB diagnosed in a pulmonary department in 2000 and 2010, in patients with negative HIV test. We study 5 cases with the case of 15 months leading to an incidence of 2.6% among all TB patients seen in the same period. All were male, smokers and BCG vaccinated. One patient had diabetes and one had viral C hepatitis. All had fever and poor general condition. One patient presented with acute respiratory failure. Chest x ray revealed bilateral interstitial micronodules in all cases. Tuberculin skin reaction was positive in 3 cases. Three cases were smear positive. Medullary biopsy confirmed TB in 1 case. One case was retrospectively confirmed by good response to treatment. Extrapulmonary localization was: hepatic in 5 cases, splenic in 2 cases, lymph node in 1 case, cerebromeningeal, mediastinal, osteoarticular and renal in 1 case each. Treatment administered urgently was based on anti tubercular treatment and treated urgently as such.

Conclusion: MT is a rare form of TB in BCG vaccinated patients and occurs more frequently in immunocompromised patients. To evaluate frequency and clinical features of MTB in immunocompromised patients, we analyzed all cases of MTB diagnosed in a pulmonary department in 2000 and 2010, in patients with negative HIV test. We study 5 cases with the case of 15 months leading to an incidence of 2.6% among all TB patients seen in the same period. All were male, smokers and BCG vaccinated. One patient had diabetes and one had viral C hepatitis. All had fever and poor general condition. One patient presented with acute respiratory failure. Chest x ray revealed bilateral interstitial micronodules in all cases. Tuberculin skin reaction was positive in 3 cases. Three cases were smear positive. Medullary biopsy confirmed TB in 1 case. One case was retrospectively confirmed by good response to treatment. Extrapulmonary localization was: hepatic in 5 cases, splenic in 2 cases, lymph node in 1 case, cerebromeningeal, mediastinal, osteoarticular and renal in 1 case each. Treatment administered urgently was based on anti tubercular treatment and treated urgently as such.
ICU mortality of TB patients. Our results can contribute to a better understanding of these nowadays TB phenomena related to long and aggressive chemotherapy, pulmonary co-morbidity, disseminated disease with CNS involvement, previous MDR and XDR of discharging Mycobacterium tuberculosis, HIV co-infection, and to identify the factors that predict ICU mortality.

**Aim:** To study information of different examination methods for lung cancer diagnostics in patients of antituberculosis departments

**Methods:** We analyzed results of medical examinations (clinical, roentgen and bronchological) of 2516 patients in hospital departments of Scientific Practical Centre for Pulmonology and Tuberculosis

**Results:** Incidence rate of bronchologic cancer was 1.7% (43 patients); average patient age was 60.3 years; males – 76.7%, females – 23.3%. 74.4% cases with lung tuberculous were revealed during the patient’s stay in the hospital and only 25.6% (11 patients) during the systematic R-examination. 18 persons had tuberculosis, the rest patients were examined for specific or nonspecific specific. According to medical examinations 33 patients had tumour lung lesion, 10 had combination of lung tuberculosis and cancer. Central cancer was suspected in 44.2% patients and peripheral cancer in 50% during the rauting R-examination. Computed tomography increased diagnoses of central lung cancer to 68.4%. In peripheral cancer data of computed tomography was informative in 7 of 9 patients. Bronchoscopy with lung and bronch biopsy permitted to determine lung cancer in 88.9-100%. We had the most difficulties in lung cancer diagnostics because its combination with active tuberculosis and bacilli shedding.

**Conclusion:** Early diagnostics of lung cancer in antituberculosis departments is possible with availability of timely bronchoscopy and oncologic alert in physicians.

**P2582**

**Diagnosics of lung cancer in antituberculosis departments**

Pavel Kryevans1, Halina Tamashakina2, Dzmitry Kryevans1, 1Pulmonology and Tuberculosis, Belarussian State Medical University, Minsk, Belarus; 2Clinic, Scientific Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus

**Aim:** To study information of different examination methods for lung cancer diagnostics in patients of antituberculosis departments

**Methods:** We analyzed results of medical examinations (clinical, roentgen and bronchological) of 2516 patients in hospital departments of Scientific Practical Centre for Pulmonology and Tuberculosis and in 2006-2012 in the Scientific Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus.

**Results:** Incidence rate of bronchologic cancer was 1.7% (43 patients); average patient age was 60.3 years; males – 76.7%, females – 23.3%. 74.4% cases with lung tuberculous were revealed during the patient’s stay in the hospital and only 25.6% (11 patients) during the systematic R-examination. 18 persons had tuberculosis, the rest patients were examined for specific or nonspecific specific. According to medical examinations 33 patients had tumour lung lesion, 10 had combination of lung tuberculosis and cancer. Central cancer was suspected in 44.2% patients and peripheral cancer in 50% during the rauting R-examination. Computed tomography increased diagnoses of central lung cancer to 68.4%. **P2583**

**Intensive care of patients with tuberculosis**

Aliaaksabaya Dzianzikiyeava1, Aleh Prasmytski1, 1Department of Anesthesiology and Intensive Care, Belarus State Medical University, Minsk, Belarus; 2Laboratory Department, National Research and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 3Intensive Care Unit, National Research and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 4Clinical Department, National Research and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 5Department of Monitoring and Evaluation, National Research and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus

**Introduction:** Multi and extensively drug resistance (MDR, XDR), HIV association, these nowadays TB phenomena related to long and aggressive chemotheraphy, frequent disease progressions and complications, elective and emergency surgery, lead to increase in intensive care (IC) requirement for TB patients.

**Aim:** The aim of the study was to describe the characteristics of patients with TB requiring IC, to evaluate the risk factors for intensive care unit (ICU) admission, and to identify the factors that predict ICU mortality.

**Patients and methods:** Patients with TB admitted to the National Research and Practical Centre for Pulmonology and TB (Centre) during one year (2010) entered the study. Demographic, clinical, radiological and bacteriological data at hospital admission and during ICU stay were recorded, and risk factors for ICU admission and death were calculated.

**Results:** A total of 200 patients were admitted to the Centre during the study period. 280 of them had MDR-TB, 78 – XDR-TB and 20 – HIV-TB co-infection. 144 TB patients were admitted to ICU, in 43 of them admission was related to surgery. 31 patients died giving 21.5% of ICU mortality rate. Factors significantly related to ICU admission were: previous TB treatment, history of imprisonment, MDR and XDR of discharging Mycobacterium tuberculosis, HIV co-infection, and excessive alcohol use. Risk factors for ICU death were: body mass index, pulmonary co-morbidity, disseminated disease with CNS involvement, previous ICU admission.

**Conclusions:** These data indicate a relatively high requirement in IC as well as high ICU mortality of TB patients. Our results can contribute to a better understanding of characteristics associated with IC and mortality for TB patients.

**P2584**

**Characteristics of patients with pulmonary tuberculosis in intensive care unit**

Darsun Tatar, Pinar Cimen, Ozenil Edipoglu, Cenk Kirakii, Emel Ozen, Ayse Ozara, Intensive Care Unit, De Suat Seren Chest Diseases and Surgery Training Hospital, Istanbul, Turkey

**Aim:** To describe the characteristics of patients with tuberculosis (TB) requiring intensive care treatment and to identify the factors affecting mortality.

**Method:** We conducted a retrospective study between 2004 and 2010. The data of 53 TB patients treated in intensive care unit were studied. Demographic, clinical, radiological and bacteriological data, reason for admission to the intensive care unit, APACHE II score, mechanical ventilation, duration of ICU and hospital length of stay, complication of intensive care, treatment and outcome were recorded. Predictors of mortality were assessed Chi-square test was used for statistical analysis.

**Result:** A total of 40 TB patients (7 females, median age 54.5 years) admitted to ICU were included. 25 of them had COPD (50%) and diabetes mellitus (17.5%). The most common symptoms are dyspnea (80%) and cough (62.5%). All of the patients were pulmonary tuberculosis and 82.5% ‘s were new cases. Radiologically, 26 (65%) had widespread pulmonary infiltrates, 4 (7.5%) patients had miliary tuberculosis. 35 (87.5%) of the cases diagnosed with culture positivity. The most common reason for hospitalization in intensive care unit was acute respiratory failure (32 cases), and the median APACHE II score was 22 (17-26). 92.5% of the patients received mechanical ventilation and 30 (75%) of the patients died. There was no significant difference between the studied parameters in patients who have died, and alive (p>0.05).

**Conclusion:** In this study we found a high mortality rate in TB patients requiring intensive care unit.

**P2585**

**Effect of pulmonary arterial hypertension on outcome of pulmonary tuberculosis**

Majid Marjani, Parvaneh Baghahi, Majid Malekmohammad, Payam Tabarsi, Mohammad Reza Masjedi. Clinical Tuberculosis and Epidemiology Research Center, NRITLD, Tehran, Islamic Republic of Iran

**Objectives:** Due a growing range of therapeutic options, early diagnosis of pulmonary arterial hypertension may change survival of patients. This study performed to evaluate effect of concomitant pulmonary arterial hypertension on outcome of new cases of pulmonary tuberculosis.

**Methods:** A cross sectional study of 777 new cases of pulmonary tuberculosis were recruited in National Research Institute of Tuberculosis and Lung Disease, Tehran, Iran. Pulmonary arterial hypertension was defined as systolic pulmonary arterial pressure > 30 mmHg estimated by resting transthoracic echocardiography. We assessed the relationship between pulmonary arterial hypertension on admission and survival during six months treatment of tuberculosis.

**Results:** Of 777 new cases of pulmonary tuberculosis, 74 (9.5%) had systolic pulmonary arterial pressure > 30 mmHg. Ten of them (13.5%) died during treatment period in comparison to 5% among cases without pulmonary arterial hypertension (P=0.007). Logistic regression analysis confirmed this association.

**Conclusion:** A significant association was found between mortality and presence of pulmonary arterial hypertension among new cases of pulmonary tuberculosis. Therapeutic intervention may change outcome of these patients.

**P2586**

**Pulmonary tuberculosis with polyneuro-radiculopathy: Not forget Guillain-Barré syndrome!**

Amina Kotti1, Hafaama Daghfou1,1, Waldi Boucharell2, Olfa Kahloud1, Leila Slim2, Fatma Trirat1, 3,1Department of Pneumology C, Abderrahmen Mami Hospital, Ariana, Tunisia; 2Department of Microbiology, Abderrahman Mami Hospital, Ariana, Tunisia

**Background:** Guillain-Barré syndrome (GBS) is an acute inflammatory polyneuro-radiculopathy and known to follow a variety of viral, mycoplasmal, bacterial and chlamydial infections. The association with tuberculosis has been exceptionally reported. We report an unusual case of GBS associated with pulmonary tuberculosis.

**Case report:** An 19-year-old man was admitted to hospital with cough during one month and hemoptysis. Chest X-ray showed multiple ring shadows in both upper zones suggestive of pulmonary tuberculosis. Sputum-smears and culture were positives for mycobacterium tuberculosis. Anti-TB drugs were initiated and they were well tolerated. Twenty one days later, the patient suffered acute and progressive legs weakness that ascended to the arms and face with sensory loss and total areflexia. These clinical, radiological and laboratory investigations were normal. Antibodies to nuclear antigens were negative. Cerebrospinal fluid (CSF) revealed protein 210 mg/dl, sugar 75 mg/dl without cells. Neurophysiological study was consistent with sensitive- motor axonal and radicular neuropathy with denervation. These clinical, radiological and laboratory investigations were conform to description of GBS. Intravenous immunoglobulin therapy (0.4 g/kg over 5 days) and physiotherapy were given, with slow neurological recovery. At review 6 months later, patient had completely recovered.

**Conclusion:** The pathogenesis of GBS in infective disease is by no means clear. Authors suggested that GBS can be resulted from direct invasion of the nerve roots by tuberculosis bacilli.
P2587

Frequency of tuberculosis on bronchial anthracosis, systematic review and meta-analysis

Majid Mirsadraee1, Ahmad Saffari1, Mahammad Sarfraz1, Mojtaba Moshikt2.
1 Internal Medicine, Islamic Azad University-Mashtad Branch, Mashhad, Islamic Republic of Iran; 2Biosstatics, Islamic Azad University-Mashtad Branch, Mashhad, Islamic Republic of Iran

Introduction: Anthracosis is the black pigment discoloration of bronchi which may cause bronchial obstruction. The objective of this study was to collect the data about the association of tuberculosis and anthracosis of lung by systematic review and meta-analysis.

Materials and methods: All studies that had enough information about frequency of tuberculosis in anthracosis (anthracofibrosis) patients and non-anthracotic control group were enrolled in meta-analysis. Tuberculosis should be confirmed and further investigation is not recommended. The incidence of tuberculosis among patients on steroids for treatment of autoimmune and other respiratory disorders poses a danger of reactivation of tuberculosis. Patients receiving immunosuppression (non-antiTNF) are generally offered a baseline CXR only. This potential susceptibility was investigated further.

Results: Twelve studies (8 studies on anthracofibrosis and 4 studies on anthracosis as a general term) comprised of 6280 patients were entered in this meta-analysis. Frequency of tuberculosis in all anthracosis subjects was 22.5% (32.6% for anthracofibrosis and 17.2% for anthracosis) which were significantly higher than control group. Determination of risk showed that cumulated odds ratio of tuberculosis in all studies of anthracosis was 3.16 (95% Cl= 2.49-6.85) which revealed significantly higher risk than control group. Subgroups analysis showed cumulated odds ratio of tuberculosis in subgroups of anthracofibrosis (3.28; 95% CI=2.16-9.12) were significantly higher than anthracosis as a general term (2.85; 95% CI=1.73-6.61).

Conclusion: Association of tuberculosis with all type of anthracosis of lung was confirmed and further investigation is not recommended.

P2588

Vitamin-D supplementation in patients with new smear positive pulmonary tuberculosis (PTB) with reference to sputum conversion

1T.B & Respiratory Diseases, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India; 2General Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India; 3T.B & Respiratory Diseases, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India; 4Endocrinology, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Back ground: PTB is major problem in developing countries like india. Role of vi-D as immunomodulator which also suppresses growth of mycobacterial bacilli in macrophages, helps in treatment of PTB and early sputum conversion.

Methods: Study includes 60 patients of sputum positive PTB above age of 15 yrs with sex ratio 1:0.7. From may 2009 to October 2009 to avoid seasonal variation. All patients were divided in to 2 groups randomly: one group (28 patients) received ATT only and other group (32 patients) received ATT with oral cholecalciferol (vit d) 60.000 IU daily for 5 days. serum vit D were measured pretreatment and at every 2 weeks for 8 weeks. other measurements like sputum smear for AFB, Hb etc also measured.data were analysed.

Results: There is significant increase in Hb at 8 weeks (P=0.03), Decrease in mean ESR at 8th week (P=0.001) and increase in weight gain after 8 weeks (P=0.0312) in group who received vit D along with ATT.

There was early sputum conversion in patient who received vit D and ATT but this difference was not significant stastically so further study with large sample is required.

P2589

Steroids related tuberculosis: Does a subgroup require a more cautious approach?

Amin Afridi, Maria Labrador, Catherine O’Rourke, Jacqui Nation, Nazim Nathani.
Respiratory Medicine, City Hospital, Birmingham, United Kingdom

Background: Increased use of steroids for treatment of autoimmune and other respiratory disorders poses a danger of reactivation of tuberculosis. Patients receiving immuno-suppression (non-antiTNF) are generally offered a baseline CXR only. This potential susceptibility was investigated further.

Results: Our TB service treats 250 patients/year. Over 24 months, 4 patients requiring steroid therapy for primary lung pathology developed TB. 24 patients with no lung pathology were matched.

TB/Stereoids

Only 2 cases of TB have been detected in patients given steroids for a non-pulmonary cause.

Discussion: A previous meta-analysis had concluded TB occurred more frequently in patients receiving steroids but was not statistically significant.[J Intern Med 1994;236:619]. Specifically a prospective study in steroids for lung disease had commented on an incidence of 4.9%.[J Am Phys Ind 2000:48:881]. In our centre, reactivation was limited to patients with underlying chronic lung pathology, of ethnic origin not born in UK.

Conclusion: The incidence of TB among patients on steroids for lung pathology, born in areas of high incidence is unacceptable high and it seems prudent to investigate and treat them for latent tuberculosis before embarking on steroid therapy. This is particularly relevant for respiratory departments who deal with a high proportion of ethnic population. Further case controlled prospective evidence is required to define this relationship.

P2590

Determining psychological characteristics of newly diagnosed TB patients using Lüscher test

Ludmila Pankratova, Natalia Kazimirova. Phthisiopulmonology, Saratov State Medical University, Saratov, Russian Federation

The course of pulmonary TB depends, to a great degree, on the state of regulatory mechanisms (of CNS and psychic sphere) that determines patients’ adaptation and their ability to adequately withstand stress. We used Lüscher Color Selection Test to determine the objective psychological characteristics of our patients. 46 newly diagnosed patients (36 males and 10 females aged 21 to 71) were tested. 30 healthy individuals were tested as a control.

Results: The color green was the most frequently selected in the TB patient group. Mean (age) 50; 38.65; 45. Sex: Female (4); M (1); P (1). Disorders: Sarcoidosis (3), Lymphoma, Auto-immune Interstitial pneumonitis (1); Lung cancer. Steroids(mean dose, duration in weeks): 30mg, 5 weeks; 30mg, 4 weeks; 15mg. Organ: Lung (4); Lung (1), Spinal (1). Matched patients: Only 2 cases of TB have been detected in patients given steroids for a non-pulmonary cause.

Discussion: A previous meta-analysis had concluded TB occurred more frequently in patients receiving steroids but was not statistically significant.[J Intern Med 1994;236:619]. Specifically a prospective study in steroids for lung disease had commented on an incidence of 4.9%.[J Am Phys Ind 2000:48:881]. In our centre, reactivation was limited to patients with underlying chronic lung pathology, of ethnic origin not born in UK.

Conclusion: The incidence of TB among patients on steroids for lung pathology, born in areas of high incidence is unacceptable high and it seems prudent to investigate and treat them for latent tuberculosis before embarking on steroid therapy. This is particularly relevant for respiratory departments who deal with a high proportion of ethnic population. Further case controlled prospective evidence is required to define this relationship.
group, indicating defensiveness and passive aggressive reaction (14 first-choice selections). The color violet, corresponding to maladaptation, personality problems, individualism and emotional immaturity, followed closely (11 selections). The color yellow was third (6 selections). It reflected defensiveness, desire to communicate and expansiveness. Lastly, the color black (5 selections) reflected protest against the situation.

In the control group, almost all the colors of the main group were predominantly selected (red -8 selections, yellow -7, violet -5, green 5 and blue -3) indicating satisfactory adaptation abilities of this group. In the TB patient group, on the contrary, only two colors of the main group were selected with sufficient frequency (green -14 and yellow -11). This group showed preference for violet (second-frequent) and even black, which correspond to hesitancy, emotional imbalance, excessive sensitivity and the feeling of being stonewalled.

Conclusion: Lüscher Color Selection Test revealed signs of maladaptation, personality problems, instability and frustration in TB patients.

P2593
Adults without HIV infection hospitalised for tuberculosis – Clinical and drug sensitivity profiles
Nelson Teixeira1, Teresa Carvalho2, Isabel Gomes1, José Agostinho Marques1,2,3,4
1Serviço de Pneumologia, Hospital de São João, Porto, Portugal; 2Serviço de Pneumologia, Hospital de São João, Porto, Portugal; 3Faculdade de Medicina, Universidade do Porto, Porto, Portugal

Background: Tuberculosis (TB) remains a major health problem and an important cause of hospitalisation for severity.

Aims: To evaluate clinical and drug sensitivity profiles of patients without HIV infection hospitalised for TB.

Methods: A retrospective study of adults admitted for TB to a tertiary hospital between 2007-2010, without HIV infection. Age, gender, clinical presentation, co-morbidities, radiological findings, diagnosis, drug sensitivity, therapy and outcome were evaluated.

Results: The study included 207 patients, 18 to 89 years (mean 54.3 years). Of all, 69.6% had pulmonary TB, 10.1% pleural TB, 12.6% disseminated disease and 0.6% meningitis. There was sensitivity to all first line TB drugs in 85.2% cases, mono-resistance in 10.9%, poly-resistance in 3.3% and multi-drug resistance in 0.5% (a extensively resistant case). Streptomycin (12.6%) and isoniazid (6.0%) had the highest resistance. Death occurred in 22 patients (10.6%), 86.4% had severe co-morbidities. The other patients were transferred to other hospitals (7) or discharged to out-patient TB clinics (178), 99 of them also referred to hospital consultations.

Conclusions: In this group of patients co-morbidities were frequent, mortality was relevant and pulmonary TB was predominant as expected. TB drug sensitivity profile was not significantly different from ambulatory patients.

Post-menopausal mammary tuberculosis – Report of three cases
Khaid Bouit, Karima Marc, Rachida Zahrani, Jouada Benamar, Jamal Eddine Bourkadi, Mouna Soualhi, Ghali Iqra, Department of Respiratory Disease, Hospital Moulay Youssif, Rabat, Morocco

Breast tuberculosis is a rare disease, responsible of 0.6 to 4.5% of all breast diseases. It poses the problem of differential diagnosis with breast cancer. It is rare among men, children and after menopause.

The authors report on the following three new cases of postmenopausal breast tuberculosis:
- The first patient had right breast tuberculosis (2 nodules) with pleuro-pericarditis and miliary tuberculosis. She was placed under SRHZE association and steroid therapy.
- The second patient had right breast tuberculosis (1 nodule) with a homolateral axillary lymphadenopathy and no other tuberculosis localizations. A RHZ therapy was started.
- The third patient had association of right breast cancer treated by mastectomy followed by radiotherapy, and homolateral breast tuberculosis treated by RHZE. After few months, clinically significant changes in symptoms and mammography were observed in the first two cases while the third one had no symptoms. The therapy was maintained during 6 months. The three patients had remained stable for 24 months after the diagnosis. No recurrence was observed. Through these three cases, the authors will describe the epidemiological, clinical and contextual problems and pathogenesis of post-menopausal mammary tuberculosis.

P2595
The particularities of pulmonary tuberculosis (TB)-diabetes mellitus (DM) syndrome in a community with high prevalence for TB
Ghaliouni Apl1, Anamaria Trailescu1,2, Pneumology, Hospital of Pneumology, Constanța, Romania; 2Pneumology, Hospital of Infectious Disease V Babes, Bucharest, Romania

It is well known that patients with DM had a greater risk for TB. Our city is known with one of the highest prevalence of TB in our country. Aim to investigate the features of TB-DM syndrome.

We made a case control epidemiologic study - on 292 patients hospitalized between 2005-2009; we enrolled 146 patients diagnosed with new case-TB (group 1) and 146 controls without TB (group 2). We performed statistical analysis using SAS software version 9.2.
Tuberculosis (TB) is one of the leading causes of morbidity and mortality in renal transplant recipients. Due to the chronic immunosuppression the diagnosis is difficult. 

Aim: The aim of our prospective study is to determine the frequency and outcome of TB after renal transplantation.

Material and methods: For the period of 31 months were examined 52 patients after renal transplantation with pulmonary complaints. To diagnose the patients were used different non-invasive and invasive methods for diagnosis.

Results: In 5 cases (9.61%) were proved active tuberculosis. The mean age of these patients was 45 years (range 34–55 years) and mean time from transplantation to diagnosis was 94 months (8–180 months). The pulmonary infiltrative form was the most common form (60%), 1 patient was with pleural effusion (20%) and disseminated TB occurred in 1 patient (20%).

The diagnosis was proved bacteriologically on respiratory specimen cultures in 4 cases (80%) and histology in 1 case. The immunological tests for tuberculosis were positive in all 5 patients. In 3 patients (60%) there was co-infection with cytomegalovirus. The 3 patients (60%) were successfully treated with four-drug combination therapy. 1 of the patients lost blood urea nitrogen and creatinine after treatment.

Conclusion: TB is one of the most common infections among renal transplant recipients. Early diagnosis by using immunology tests and invasive methods, treatment of CMV-infection and effective therapy may improve graft survival and reduce the morbidity and mortality from this condition.

## P2599

### Tuberculosis is common in ethnic minority patients with chronic kidney disease in United Kingdom, and there is a high level of drug resistance

Parasitaa Palchucka1, Cristina Ramiroa1,2, Carita Alboa3,4,5,6,7,8,9,10,11,12,13

1University College London, London, United Kingdom; 2London School of Hygiene & Tropical Medicine, London, United Kingdom; 3Department of Renal Medicine, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; 4Clinical Research Facility, King's College Hospital, London, United Kingdom; 5Centre for Research in Epidemiology and Public Health, University College London, London, United Kingdom; 6Renal Centre, Rotherham Hospital, South Yorkshire, UK; 7South West Renal Unit, Southmead Hospital, South Gloucestershire, UK; 8NHS Blood and Transplant, NHS Blood and Transplant, UK; 9University College London, London, United Kingdom; 10Department of Public Health and Primary Care, University of Oxford, Oxford, UK; 11National Institute for Health Research, London, UK

Introduction: Chronic kidney disease (CKD) is more common in ethnic minority groups in UK and these patients have a high incidence of TB. We performed a study to characterise ethnicity and resistance patterns of patients with CKD and TB at a large renal unit in London.

Methods: 40 CKD patients who developed TB from 1994-2010 were analysed retrospectively. Patients were categorised by country of birth and time spent in the UK prior to development of TB, divided into <5 years or >5 years. Resistance patterns were sought as well as HIV status and Vitamin D levels.

Results: Ethnicities were: 15 Black-African, 9 Asian, 7 White-British, 6 Black Caribbean, 3 White-Other (including eastern Europe). 27 patients were non-UK born (67.5%) and 4 had lived in the UK for <5 years. Vitamin D levels were low in all patients. Of the patients, 10 (25%) had history of TB treatment.

Conclusion: Most CKD patients with TB were from ethnic minorities not born in UK. Most had lived in UK for >5 years suggesting TB development was not linked to duration in UK and that CKD is in itself a big enough risk factor. Vitamin D levels were low, as expected in both TB & CKD. Drug resistance (12.5%) was higher in ethnic minorities & HIV+ve patients with CKD, compared to background rate (4.9-6.1%). Hence it is important to look out for TB in ethnic minorities with CKD & also for drug resistance.

Number and proportion of tuberculosis cases with drug resistance by country, UK, 2008. www.hpa.org.uk

## P2600

### Smoking is a risk factor for TB infection, but is it an additional mortality risk?

Nada Bogdanovic, Biljana Lazovic, Branimira Milevenko, 1Pulmonology, University Clinical Center Dr Dragisa Misinov, Belgrade, Serbia; 2Pulmonology, University Clinical Hospital Center Zemun, Belgrade, Serbia; 3Pulmonology, Clinical Center Serbia, Belgrade, Serbia

Aim: To investigate smoking habits of patients (pts) died of TB and successfully treated TB pts.

Material and methods: Comparative study of epidemiological data of TB deaths and TB pts, 135 in both groups, none HIV positive, in 2000-2009.

Results: 135 TB deaths occurred (mortality rate 6.4%, 76.6% of them died of TB.

TB deaths: male were 76.3% (103 pts), aged 18-88 years, (1.6% under 25y, 14.6% pts aged 25-44 yrs, 45.2% pts aged 45-64y, 38.6 over 65y). Smokers 81%, kofing 7.8 months before admittance, average weight loss was 10.2kg. 

TB pts: Of 135 pts male were 65.2% (88pts) aged 17-88 years, 8.3% under 25y, 25.8% aged 25-44y, 31.8% aged 45-64y, 31% over 65), 51% (69pts) smokers kofing before admission for average 4,1 months (1-12), average weight loss was 3.4kg (0-10).

Conclusion: In TB deaths group were more smokers (4/5 vs 1/2), older (84% over age 45 yrs vs 34% under age 44) and more male (76% vs 65%) than in the other group. They were kofing almost twice longer and had 3 times bigger weight loss before admittance. This delay may be due to fact they consider kofing as normal for smokers, but also as a result of confronting factors (alcohol use, socioeconomic).

Tobacco control should be incorporated in TB control.
P2601
What about asthma in tuberculosis patients
Hafza Zabi, Leila Felkhi, Iness Akrou, Eya Tangour, Hela Hassene, Dorra Greb, Sooraya Fenniche, Hajer Ben Abdelghaffar, Dalenda Belabbb, Monamed Lamine Megdiche. Service Ibn Nafis, Hôpital Abderrahmen Mami, Ariana, Tunisia

Introduction: The association of asthma and tuberculosis is rare but may raise particular issues around patient management. The aim of this study was to evaluate the control of asthma in tuberculosis patients.

Patients and methods: We describe a retrospective study, which included ten asthmatic patients with tuberculosis during the period between June 2001 and June 2010.

Results: Five men and five women were included, mean age was 37 years. Seven of them had pulmonary tuberculosis and three had lymphatic nod tuberculosis. Two patients had mild asthma, seven had moderate asthma and only one had severe and corticosteroid-dependent asthma. Seven patients had controlled asthma when tuberculosis diagnosis was established. Asthma treatment was based on inhaled corticosteroids and long-action Beta-2-agonists. During anti-tuberculosis treatment two patients developed near fatal asthma. Long-term stable asthma control was achieved over a time course of three to eight years.

Conclusion: The association of asthma and tuberculosis can lead to potential therapeutic difficulties because of pharmacologic interactions between anti-tuberculosis therapies and treatments for asthma treatment. In addition, asthma following treatment for tuberculosis appears to be well controlled.

P2602
A case of pulmonary tuberculosis combined with tuberculous goniaitis in a 12-year-old immigrant patient with haemophilia A
Reka Bodnár1, Agnes Subicz 2, Tamas Lowy2, Laszlo Kadar 2. 1Department of Pharmacy Administration, Semmelweis University, Budapest, Hungary; 2Pediatric Department, Pest County Pulmonological Institute, Tokekabzd, Hungary

Introduction: 9.4 million new tuberculosis (TB) infections and 14 million prevalent cases of TB were recorded worldwide in 2009 [1]. Hungary is a low incidence country with an incidence of 14.4 per one-hundred-thousand in 2009.

Case report: A 12-year-old Afghan boy was admitted to the hospital with pulmonary TB. Haemophilia A and a swelling of his left knee. He presented symptoms of coughing, haemoptysis and swelling of the left knee for one year. Pulmonary TB was diagnosed in Pakistan and was treated with rifampicin, pyrazinamide and ethambutol for 43 days and amputation of the left knee was suggested. He was transported to Hungary to find an alternative therapy to his knee. With physical examination cachexia, and diminished breath sounds over the apical right lung segments of superior lobe of right lung.

Conclusion: This case calls the attention to the immigrants’ TB screening.

P2603
Pulmonary tuberculosis resides: A report of 44 cases
Lotfi Nacef, Omar Saighi. Thoracic Diseases Department, E.P.H of Baida, Baida, Algeria Thoracic Diseases Department, E.P.H of Blida, Blida, Algeria

Introduction: TB relapse is defined as any case of pulmonary tuberculosis treated, cured, and in whom TB is diagnosed on the basis of a smear or culture bacteriologically positive. it incidence in Algeria is 4.97%.

Aims and objectives: The aim of our study is to clarify the characteristics of the epidemiology, predisposing factors and diagnosis aspect of TB relapse.

Methods: We describe a retrospective study concerned 44 cases of pulmonary tuberculosis resides control, among 2257 patients, treated for pulmonary tuberculosis in the TB control unit of Blida between January 2005 and December 2009.

Results: Our series has assembled 27 men and 17 women with a mean age of 37 years. 86% of cases have already been treated for over one year for pulmonary tuberculosis. Comorbidities were found in 39% of cases, including diabetes (16% of cases) and psychiatric disease (6% of cases). The study notes the occurrence of relapse in 41% of cases during the first quarter of the year. Bacteriological confirmation of relapse by smear sputum was positive in 95% of the cases, the confirmation of relapse by culture was positive in 5% of cases. The bacteriological test was positive in 16% of cases. The empirical treatment was failed in 54% of patients. The cure rate was 95% of cases, the treatment failure was 4 cases and the treatment default was 4 cases.

Conclusion: We emphasize the frequency of relapse tuberculosis and their need for adequate care with regular monitoring to avoid the transition to chronicity.

P2604
Unusual forms of pulmonary tuberculosis
Nahid Zaghib, Najiba Yassine, Aitlam Ech-Cheratte, Abdelaziz Bakhatar, Abdelkarim Bahlaoui. Respiratory Diseases, University Hospital Center, Casablanca, Morocco

Pulmonary tuberculosis PT is generally easily recognized by its classic features. Nevertheless, the radiological setting could be misleading, suggesting other diagnoses. We report 51 cases of PT with unusual in appearance and site (pseudotumoral 14 cases, endobronchial 25 cases, basal 6 cases and balloon release 4 cases). It occurred in 30 males and 21 females with a mean age of 40 years old (range age 15-71 years old). Twenty males were smokers. The clinical setting was dominated by bronchial syndrome, chest pain and haemoptysis. Chest X-ray showed pulmonary opacities-like tumor in 14 cases, retractable opacities in 20 cases, enlarged mediastinal lymph node in 5 cases, basal excavated opacities in 10 cases and a balloon release in 4 cases. Bronchoscopy showed endobronchial granulomas in 15 cases, bud-like tumor in 8 cases and mediastinal lymph node fistula in a bronchus in 2 cases. Chest scan highlighted a peripheral tumor-like process in 6 cases and a balloon release in 4 cases. The diagnosis of PT was confirmed by bacilloscopy in 6 cases, bronchial aspirate in 26 cases, bronchial biopsy in 20 cases, transmural biopsy in 6 cases, biopsy under thoracoscopy in 4 cases and an open surgical biopsy in 3 cases. Under antibacillary therapy, the evolution was favorable in all the cases. Despite their rarity, unusual forms of tuberculosis should be better known as it could simulate cancer especially in its particular pseudotumoral form.

P2605
Paradox radiologic progression despite appropriate antituberculosis therapy
Ugur Gonlugur1, Sule Kosar2, Arzu Mirici 1. 1Department of Chest Diseases, Canakkale Onsekiz Mart University, Canakkale, Turkey; 2Department of Radiology, Canakkale Onsek; Mart University, Canakkale, Turkey

In this study we report a HIV negative case who got worse paradoxically in the course of antituberculosis therapy. A 68-year old male patient applied with complaints of cough, chest pain, and weight loss. Chest computed tomography revealed an irregular nonhomogeneous opacity involving the apical and posterior segments of superior lobe of right lung.

At the end of the first month of therapy radiological lesions increased. There was no endobronchial lesion on bronchoscopy, and no acid-fast bacilli in bronchial lavage fluid. Therapy protocol was not changed but radiological lesions regressed gradually. In conclusion, temporary deteriorations can occur in previous pulmonary infiltrates in patients who are under appropriate antituberculosis therapy. The gold standard for monitorization is microbiological methods but not radiological ones. Comorbid conditions, drug reaction and treatment failure is important in the differential diagnosis.
Baseline and treatment completion chest radiographs in pulmonary and extra-pulmonary tuberculosis

Background: Chest radiographs (CXR) are key to the diagnosis & management of tuberculosis (TB). End-treatment CXR (E-CXR) provide information on therapy response & risk of post-treatment pulmonary sequelae.

Objectives: 1. To report factors associated with baseline CXR (B-CXR) in pulmonary TB (TB) & extra-pulmonary TB (EPTB).

Methods: Of 305 patients, 113 (37.0%) were diagnosed with PTB, 155 (50.8%) with EPTB & 37 (12.1%) EPTB+PTB. 285 (93.4%) had B-CXR performed in the correct time period (early/late 5.6%, not performed 1.0%) with no significant difference by TB clinical status. Female patients were less likely to have a B-CXR (F: 89.6%, M: 97.4%, p < 0.001) which remained significant in multivariable analysis. 149 (52.3%) had E-CXR: more likely in those with abn B-CXR (63.1% abn B-CXR 23.8% normal, p < 0.001). 116 of 198 (58.6%) with abN B-CXR had an E-CXR with radiology review available. Of these 24 (20.7%) had abN E-CXR including HR, a Fluoroquinolones and at least 1 second line injectable therapy.

Results: Of those patients, 38% (8/21) failed to follow up without known reason, only 3 patients stopped Rx due to SE. Conclusion: Good compliance is achievable with patient education and close follow-up. Treatment side effects of LTBI are usually mild and self-resolving.

References:
Materials and methods: In 2009-2010, a total of 356 patients were treated, including 419 patients (33 new and 366 previously treated cases which had positive cultures with MDR strains. The testing of this MDR strain was performed by indirect method of proportion to second line drugs for critical proportion 0.05.

Results: 1. For new cases results showed the confirmation of MDR strains 8.3%; resistant to INH+RMP+Km 2.6%; resistant to INH+RMP+OFX 0.2%; and XDR strains 0.95%.

2. For previously treated cases results showed the confirmation of MDR strains 49.64%; resistant to INH+RMP+Km 22.2%; resistant to INH+RMP+OFX 7.1%; and XDR strains 8.35%.

Conclusions: 1. The high percentage of MDR strains of previously treated cases 49.64% is due to large number of patients provide from our Excellence Center of MDR TB.

2. The percentage of XDR strains from MDR strains is 9.31%.

P2612

Epidemiological and microbiological characteristics of reported cases with multidrug-resistant tuberculosis in the Republic of Bulgaria for the period 2000-2009

Vladimir Milanov1, Mariya Zamirova1, Tonka Varleva1, Elizabeta Bachyska2, Antoniya Koleva3, Angelina Yaneva2,4, Directorate "Management of Specialized Donor-Funded Programmes", Ministry of Health, Sofia, Bulgaria; 2National Tuberculosis Reference Laboratory (NRL-TB), National Center of Infectious and Parasitic Diseases (NCIPD), Sofia, Bulgaria; 3Manager, Specialized Hospital for Active Treatment of Lung Diseases, Gabrovo, Bulgaria; 4Programme "Management of Specialized Donor-Funded Programmes", Ministry of Health, Sofia, Bulgaria

A retrospective study of all patients with multidrug-resistant tuberculosis (MDR-TB) registered and reported in Bulgaria during the period 2007-2009 was performed.

Aims: To make epidemiological and microbiological characteristics of all cases with culture confirmed MDR-TB recorded and reported in the country during the above-mentioned period.

Materials and methods: Case-based data for all TB patients recorded and reported by the regional TB health facilities for the period 2007-2009, data sent by the microbiological laboratories for TB diagnosis, and TB registries of the NRL-TB at the NCIPD were examined.

Results: According to the case-based data, a total of 149 MDR-TB patients (age range 18-87) were recorded and reported during the period 2007-2009, representing 5.3% of all tested with DST. Out of all MDR-TB cases, 107 (72%) were male. Fifty-six patients (38%) were new, and 93 cases (62%) were previously treated. Out of all registered MDR-TB patients, 88.6% were confirmed by the NRL-TB.

Conclusion: The case-based registries provide exact clinical, microbiological and epidemiological information, avoiding case duplication during the reporting period. The frequency of MDR-TB among previously treated TB cases is higher, mainly among the relapses and the defaulters after treatment.

P2613

Multi-drug resistance tuberculosis (MDR-TB) in Federation of Bosnia and Herzegovina during ten years

Aida Ustamujic1, Hasan Zutic1, Zehra Dzidarevic1, Vesna Cukić2, Iris Sladic2, Jasmina Maglajlic3, M. Osmin2, Jasmina Abazovic1, Clinic for TB and Lung Diseases, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina

Multidrug-resistant tuberculosis (MDR-TB) defined as TB caused by strains of Mycobacterium tuberculosis that are resistant to at least isoniazid and rifampicin. The aim of this paper was to describe the resistance patterns of MDR-TB in FB&H.

Material and methods: Retrospective analysis of the reported cases with MDR-TB in FB&H during the years 2000-2009 notified through drug susceptibility testing (DST) in 5 laboratories according to the recommendation of the WHO and IUATLD in Europe.

Results: Total cases with DST results: 1035 (never treated 913; previously treated 121) in 2000; 1036 (936;100) in 2001; 1034 (914;20) in 2002; 1036 (936;100) in 2003; 1125 (1045;80) in 2004; 769 (692;77) in 2005; 808 (727;81) in 2006; 951 (847;104) in 2007; 518 (471;47) in 2008; 581 (529;52) in 2009.

MDR-TB among never-treated cases: 1 (0.11%) in 2000; 2 (0.19%) in 2001; 4 (0.42%) in 2002; 1 (0.10%) in 2003; 4 (0.38%) in 2004; 4 (0.57%) in 2005; 2 (0.24%) in 2006; 7 (0.82%) in 2007; 3 (0.63%) in 2008; 0 (0.0%) in 2009. MDR-TB among previously treated cases: 2 (1.65%) in 2000; 7 (5.42%) in 2001; 9 (9.00%) in 2002; 1 (1.09%) in 2003; 6 (7.79%) in 2004; 5 (6.49%) in 2005; 3 (3.70%) in 2006; 10 (9.61%) in 2007; 9 (19.14%) in 2008; 1 (1.92%) in 2009.

Conclusion: Data from FB&H show relatively low prevalences of MDR-TB during ten years. The prevalent of MDR-TB remains low at 0.57% - 0.82% among newly detected cases and 9.01% - 19.14% among previously detected cases. Recent data also indicate a further decrease in MDR-TB. This decrease may likely be the result of well implemented DOTS. Establishing reference laboratory facilities with adequate capacity to supervise DST and surveillance activities in the country is a critical step in MDR-TB control and care.

P2614

First national survey results of mycobacterium tuberculosis drug resistance in Kosovo, 2007-2008

Xhevat Kurhasani, Gyle Mullaqi-Osmani, Rukihe Mhemeti, Bahri Tigan, Bahri Beqiri, Ariana Kalaveshi, Naser Ramadani, Danella Cirillo, Emanuele Borroni, G.B. Migliori, TP Project, NGO IKA, Pristina, Kosovo, Albania

Objective: To evaluate the prevalence of DR to the first-line anti TB drug among new and previously treated cases of pulmonary tuberculosis.

Method: A national survey during 2007-2008 has been carried out, using “100% sampling” method, according to WHO and IUATLD standards. Smear-negative pulmonary TB patients aged ≥15 years were eligible. Drug susceptibility testing using simple proportion method was performed against four first-line drugs, i.e., isoniazid, rifampicin, ethambutol and streptomycin.

Results: During one year enrolling period, 207 initial isolates of M Tuberculosis were analyzed. Out of them 172 (83%) were from new cases and 35 (17%) from re-treatment cases. Any resistance among new cases was 20.9% and 45.7% among re-treatment cases.

Conclusion: Low rates of MDR-TB in Kosovo are due to a well performing national TB control program.

P2615

Drug resistant tuberculosis among Greek and immigrant patients in a pulmonary department in northern Greece

Evangelia Founa, Nikolao Aaggelis, Ayrtovalantis Parisis, Dimosthenis Vlakos, Penelope Stefanopoulou, Sofia Lambakis, Nikolaos Galanis, 1st Pulmonary Department, General Hospital G.Papankaloa, Thesouloniki, Greece

Introduction: The proportion of TB cases among immigrants is gradually increasing in Western European countries, posing a threat to disease elimination in the coming decades.

Aim: To evaluate differences in prevalence of drug resistant tuberculosis among native and immigrant patients treated in a respiratory department of a regional general hospital in Northern Greece.

Subjects - methods: Clinical records data of patients with tuberculosis (new detected cases-43, relapses-21) treated in our department during 2007-2010 were retrospectively studied.

Results: 64 patients were recorded, 50 males and 14 females, 38 natives and 26 immigrants recently moved from former Soviet Union countries. 13 natives (34.2%) and 17 immigrants (65.2%) patients presented with extensive disease. 13 (34.2%) natives and 10 (38.4%) immigrants received therapy for a second time due to relapse, interrupted treatment or treatment failure. Resistance was confirmed in 11 natives (28.9%) and 12 immigrants (46.2%) (p: 0.253). monoresistance in 11, polyresistance in 8 and MDR TB in 4 patients.

Conclusions: TB cases among immigrants tend to increase, contributing significantly to overall higher incidence rates. Immigrants also tend to present with more severe disease and emerge more frequent relapses and higher prevalence of resistant and MDR-TB.

P2616

Drug resistance pattern of mycobacterium tuberculosis complex at the main reference tuberculosis centre in Greece, 2000-2010

Panagiotis Zouz1, Pinelopi Sotiropoulou2, Apostolos Papavasilieou2, Konstantina Broupi2, Stavroula Katziadia2, Simona Karabela2, Konstantinos Gourgoulianis3, Konstantinos Konstantinou1, 112th Department of Pneumonology, Sotira Chest Diseases Hospital, Athens, Greece; 2Ann Tusor Chest Diseases Department, Sotira Chest Diseases Hospital, Athens, Greece; 3Department of Pneumonology, School of Medicine, University of Thessaly.
Phthisiology&Pulmonology, Kiev, Ukraine

Aim: The aim was to determine the current DR profiles and their prevalence among patients with chronic forms that level is 30-70%. Knowledge of drug resistance (DR) is important for treatment and to forecasting the outcome.

Methods: We studied 325 specimens decontaminated with NaLC-NaOH then inoculated onto Bactec MGIT960, and L.J. medium. We did identification to all positive specimen then inoculated onto Bactec MGIT and 55.7% with L.J. the rates of contamination for each of the systems was 19.6%, while 145 isolates (8,3%) were resistant at least to isoniazid and rifampicin. During chemotherapy 36 patients IIC-group and 34 from comparison group there were 4 patients with primary MDR, and 23 with primary drug resistance (not the combination of H&R). In comparison group there were 6 patients with primary MDR and 16 with primary drug resistance (not the combination of H&R).

Results: Over the period of 2007-2009, an annual increase in proportion and range of drug resistance was increasing in all TB patients; cases of XDR TB were reported regularly.

Conclusion: The majority of cases (73.66%) has secondary MDR and simultaneaously DR to first-line drugs and to s. Most common is DR profile – with maintaining sensitivity to INH and RIF in presence of additional resistance to the different number s. The smallest spreads have HRE and HRZ-profile.

P2519
Secondary drug resistance during an intravenous intermittent chemotherapy in newly cases TB
Tatyana Petrenko, Vladimir Krasnov, Medical, Nosovitskii Research TB Institute, Noosvits, Obkhoskaya St, 81a, Russian Federation

The purpose: To study frequency secondary drug resistance M. tuberculosis (SDR) during an intravenous (IV) intermittent chemotherapy in newly cases TB.

Methods: 76 pulmonary TB patients without previous chemotherapy enrolled in study IV intermittent chemotherapy (3 times a week) appointed to 38 patients (IC-group): isoniazid (H) and rifampicin (R) – 10 mg/kg IV, streptomycin (S) – 16 mg/kg intramuscularly (IM), pyrazinamide (Z) – 25 mg/kg per os. 38 patients received daily same doses of H, R, Z per os and S (IM as a group of comparison). Both groups were identical. We determined SDR initially and every 2 month of patient treatment during 5-14 months.

Results: Initially there were 16 patients IC-group and 11 in a comparison group with fully sensitive TB. In IC-group there were 6 patients with primary MDR and 16 with primary drug resistance (not the combination of H&R). In comparison group there were 4 patients with primary MDR, and 23 with primary drug resistance. Among chemotherapy 36 patients IC-group and 34 from comparison group became sputum negative after 3.17±0.4 and 2.7±0.5 months accordingly (p=0,17, Mann-Whitney U-test). During the IV intermittent chemotherapy SDR appeared at 5 patients, secondary MDR – at 1 from 5. In comparison group SDR appeared at 2 patients, secondary MDR at 3 from 4 (R= 1.24, 95%CI 1.34-1.75). The mean time of formation SDR appeared in 3±0.3 and 2±0.6 months accordingly (p= 0,03, Mann-Whitney U-test).

Conclusion: The occurrence risk of secondary MDR is lowered. SDR term is slower in IC-group than in group of daily treatment, in about 3 months from the start of chemotherapy. This term coincides with sputum negative results at patients of both groups.

P2620
Drug resistance among new TB cases and relapses
Punga Victor, Lariya Rusakova, Yakinsona Marina, Kapkoy Lev, Elvira Putova. Epidemiology, CTRI RAMS, Moscow, Russian Federation

Purpose of the study: To study prevalence and range of drug resistance (DR) of TB mycobacteria (MBT) among 41,574 new TB cases and 5,890 relapses in 14 RF territories over the period of 2007-2009.

Materials and methods: Analysis of MBT DR was performed based on the official and applied statistical data quarterly received at the Center of Monitoring, CTRI RAMS.

Results: Over the period of 2007-2009, the proportion of new cases with DR MBT increased from 30.9% to 40.1%, and with MDR TB - from 10.8% to 13.2%. In the group of relapses the incidence of DR (48.4% and 55.4%) and MDR (26.7% and 33.9%) was much higher than MDR in new TB patients. One third of new TB cases had bad resistance to isoniazid and streptomycin and 15.0-20.0% of new TB cases were resistant to rifampicin and ethambutol. Among TB relapses DR TB, MDR TB and any other resistance to isoniazid, streptomycin, rifampicin and ethambutol was reported 2-3 times more often than among new TB cases. Over the period of 2007-2009, the rage of drug resistance was increasing in all TB patients; cases of XDR TB were reported regularly.

Conclusion: Over the period of 2007-2009, an annual increase in proportion and number of DR cases was reported. Therefore, it is necessary to perform monitoring of quality of the laboratory tests, data collection and follow up of TB patients' groups. Knowledge of DR MBT range of patients allows performance of the adequate chemotherapy, its adjustment, evaluation of the epidemiological situation on TB and timely managerial solutions. Increase in prevalence of DR MBT is the result of the previous failed courses of chemotherapy.

P2621
Drug resistance in pulmonary TB patients: Analysis of dynamics
Ludmila Pankratova1, Ekaterina Pereselentsova2, Ludmila Vlasova2.
1Phthisiology&Pulmonology, Saratov State Medical University, Saratov, Russian Federation; 2Microbiology Lab, TB City Hospital, Saratov, Russian Federation

MBT drug resistance (DR) frequently causes lack of treatment efficiency in TB patients. The use of standard WHO treatment protocols has not brought about a MBT DR/MDR decrease: on the contrary, the share of patients with primary MDR has increased 15-27 times over the 2005-2008 period. In 2008, in some regions of Russia patients with primary MDR MBT constituted 20-25% of the total number of TB patient. In 2010, we conducted an analysis of MBT DR in 312 pulmonary TB patients

Less common are HRE and HRZ (21.67% and 10.0% respectively). The pre- dominance of HRS and HRSZ profiles was found in the 2-d group – 71 (31.69%) pts and 41 (25.0%) respectively. Totally HRS profile was in 99 (49,19%) pts. The 3rd highest spread has HRE and HRZ (17,97% and 3,57% respectively).

Conclusion: Background/ AIM: Drug-resistant tuberculosis (TB) is a major issue for Public Health. This study was conducted to assess the prevalence of drug resistance to M. tuberculosis at the main reference tuberculosis centre in Athens, Greece (Anti-Tuberculosis Department, ‘Sotira’ Chest Diseases Hospital).

Methods: We retrospectively reviewed 343 isolates of drug resistant M. Tuberculosis from two culture systems. We did collection data about demographic characteristics and drug susceptibility. Antimicrobial drug susceptibility was tested using the method of proportion with Lowenstein-Jensen and BACTEC MGIT System.

Results: A total of 1747 patients (new culture-positive TB cases from 2000 to 2010) were analyzed. Individual drug resistance was as follows: 242 isolates (13.9%) were resistant to isoniazid, 167 (9.6%) to rifampicin, 130 (7.4%) to ethambutol, and 227 (13%) to streptomycin. The overall resistance to any drug was 19.6%, while 145 isolates (8.5%) were resistant to at least to isoniazid and rifampicin (multidrug resistant, MDR) and 39 isolates (2.2%) were resistant to at least to isoniazid, rifampicin, any fluoroquinolone and one of three injectable second-line drugs (extensively drug resistant, XDR). We should notice that none of the patients was HIV-positive.

Conclusion: A significant increasing trend in resistance rates to the four first-line anti-TB drugs, and any other drug, was observed during the 11-year period. MDR-TB and XDR-TB have emerged as a major public health threat in Greece, considering the immigration trend and the country’s key-point. The development of "direct observed therapies" (DOTs) in Greece, according to WHO guidelines, is of great importance.
Background: The strongest risk factor for drug resistance is previous history of tuberculosis treatment. Currently the national tuberculosis control program recommends drug susceptibility testing in failures of retreatment cases. This study is being conducted to see the drug resistance pattern in failures and defaulters of initial treatment before starting a retreatment regime.

Methods: This study was conducted in the OPD of Thoracic Medicine JPMC Karachi.

Sampling technique: Non-probability purposive sampling.

Results: Among 60 selected patients of category 1 sputum smear positive, 14 (23.3%) were defaulters, 38 (63.3%) relapsed and 8 (13.3%) patients were of treatment failure.

Culture sensitivity has shown 58 (96.7%) positive patients and only two (3.3%) were negative.

Multidrug resistance was found in 15 (25%) patients. MDR cases were 6 (42.9%) among 14 defaulters, 4 (10.5%) among 36 relapsed and 5 (62.5%) among 8 failure treatment patients.

Rifampicin resistance was found in 20 (34.5%) patients. Isoniazid was resistant in 19 (32.8%) patients. Ethambutol was resistant in 21 (36.2%) patients. Pyrazinamide was resistant in 17 (29.3%) patients. Streptomycin was resistant in 10 (17.2%) patients. None of antituberculous drug was resistant among two culture negative patients. Multidrug resistance (MDR) was observed in 15 (25.9%) patients.

Conclusion: We conclude that levels of MDR-TB is very high in patients not responding to CAT1 anti tuberculous drugs in our community.

P2623 Impact of drug resistance over sputum conversion in tuberculosis patients receiving re-treatment regimen

Prem Parkash Gupta, P.T. Yasir. TB & Respiratory Medicine, PGIMS, Pt B D Sharma University of Health Sciences, Rohtak, Haryana, India

Background: Previous tuberculosis treatment is known to be associated with high drug resistance.

Objectives: To assess the impact of drug resistance over sputum conversion in tubercular patients receiving supervised re-treatment regimen.

Methods: A total of 101 smear positive pulmonary tuberculosis patients [relapse (65), failure (23), and defaulter (13); all with age ≥ 15 years] registered for re-treatment at our Institute were included. Drug susceptibility testing (DST) was done using Lowenstein-Jensen media. All patients were given thrice weekly supervised re-treatment regimen. Sputum microscopy was done in all patients at initiation and also at the end of 1st, 2nd, and 3rd months.

Results: 41.50% of patients in relapse group, 85.71% in failure group, and 70% in default group had drug resistance. Sputum conversion during initial three months in relapse group was 29.23%, 60%, 64.61%, respectively; same for failure group was 0%, 0%, 4.36%, respectively; and that for default group was 23%, 38.46%,

S = sensitive to drug; R = Resistant to drug.

Previous drug intake and subcategory were significant factors for drug resistance. It was also associated with smoking, poor education and economic factors but not with age or sex.

Conclusions: We observed significant drug resistance; highest for failure subcategory followed by default and relapse ones. Such high drug resistance requires DST at start of tubercular re-treatment in all patients.

P2625 Clinical characteristics and mortality patterns of MDR-TB patients in India

C. Sudheendra Ghosh, L. Jeyaseelan, B. Ronald Win, R. Kamala, K.R. Remu. Department of Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu. India Department of Pulmonary Medicine, Government Medical College, Thiruvananthapuram, Kerala, India. Department of Biostatistics, Christian Medical College, Vellore, Tamil Nadu. India Government Medical College, Vellore, Tamil Nadu, India Government Medical College, Thiruvananthapuram, Kerala, India. Department of Pulmonary Medicine, PGIMS, Rohtak, Haryana, India

Introduction: This study gathered information on genesis of MDR TB at 3 centers in India which helps understand the current clinical practice and management of MDR TB and helps to standardize diagnostic and therapeutic strategies relevant for resource poor setting.

Primary objective: To describe the clinical profile, of patients with MDR TB and suspect MDR TB patients in India and their out come.

Study design: Descriptive follow up study.

Study setting and population: Private and public health sector: Patients attending primary, secondary and tertiary health care centers in selected study areas in India.

Study period: 1st June 2007 to 30th May 2009.

Study Variables Clinical Outcome Measures: Cure - Patients treated for 18 - 24 months and who remain smear and culture negative; Likely cures - patients treated for at least 12 months, and who remain smear and culture negative; Absconders/Defaulters and Death.

Results: 344 cases, either suspect or confirmed cases of MDR-TB from 3 different states in India were recruited. 71 cases were culture rve for MDR TB. 15.77% patients died. 59.54% of the patients had far or moderately advanced chest X-ray lesions. The BMI of patients who died was less than 20 (87%). 27.4% of the patients who died had diabetes. 7.5% were males. Smoking index was moderate to heavy for 25%. More than 50% of the patients were aged between 30 - 50. 58% of patients had previous treatment with 4 drugs and 10% had received second line drugs. 67% of the patients utilized government facility for their treatment. With proper treatment success was > 60%.

Conclusion: MDR-TB if not treated can lead to early death among patients with low BMI. Diabetes Mellitus and far advanced chest X ray lesions.
P262
Resistance pattern to WHO CAT IV regimen in patients suspected of drug resistance tuberculosis presenting to a specialist office practice in Mumbai
Parag Chaudhari1, 2, Arvind Kate1, 2, Joerg Leuppi1, Michael Tamm1, Prashant Chhajed1, 2, 3

Sr. No 2nd line anti-TB drugs Resistant (n) Resistance (%)
1 Isoniazid 21 77.78
2 Ethambutol 12 44.44
3 PAS 15 55.56
4 PZA 18 66.67
5 Streptomycin 20 74.07

Conclusion: The occurrence of in vitro drug resistance to category 4 anti TB drugs is very high, which is expected to have direct effect on tuberculosis. This poses challenges to administration of empiric anti TB treatment.

P267
Multidrug-resistant tuberculosis in a kidney recipient
Ventsislava Pencheva, Daniela Petrova, Ognian Georgiev.

Multidrug-resistant TB (MDR-TB) was proved in this patient. Antituberculosis treatment with four medications from second line was started.

Tuberculosis is a frequent infectious complication in patients on renal replacement therapy, as a result of immunosuppression from uremia and drugs in the post-transplantation period. The frequency of MDR-TB increases in last years. That requires treatment with second line drugs for longer period than patients infected with drug-sensitive strains and is with higher mortality rates.

P268
Dynamics of production thyroid-stimulating hormone in patients with multiple-drug resistant tuberculosis (MDR-TB) on the background of prolonged chemotherapy
Tatiana Morozova, Tatiana Salina. Department Phthisiologu, Medical University, Saratov, Russian Federation

Treatment of patients with pulmonary tuberculosis with MDR-TB requires the use of drugs 2 rows that have a large number of adverse reactions. It is assumed that prolonged simultaneous reception of protonamide and PASK can reduce thyroid function.

Aim: Evaluation of trends in production of thyroid-stimulating hormone (TSH) in patients with MDR-TB on the background of prolonged combined chemotherapy.

Methods: TSH levels in serum were determined in 102 patients with MDR-TB, initially and after receiving patients 60, 120, 180 doses of a combination of antibiotic drugs (capreomycin, protonamide, pyrazinamide, PASK, ofloxacin, cycloserine) by immunonemoence method.

Results: The level of TSH in patients with MDR-TB before therapy was low (mean 1.57±0.19 mIU/ml). After receiving 60 and 120 doses of the drugs level of the TSH of patients increased (2.95±0.57, p=0.046 and 3.32±0.41 mIU/ml, p=0.006, respectively). Significant increase in TSH was observed in 20% of patients without clinical manifestations of hypothyroidism. On the background of receiving of drugs (180 doses) TSH levels decreased slightly (2.86±0.37 mIU/ml). Increased TSH persisted in 13% of patients.

Conclusions: In patients with MDR-TB in the background of the combined use 6 drugs observed increase in TSH levels in the absence of clinical signs of hypothyroidism. The downward trend in TSH levels with continued therapy with the abolition of drugs (180 doses) may indicate the inclusion of compensatory mechanisms, and at this stage of treatment does not require additional correction of thyroid function.

P269
Evolution of tuberculosis in an area of Vizcaya
Sandra Pedroza Tedaja1, Beogota Vilar Achabal2, Maria Alfonso Imizcoz1, Israel Lopez Mirones2, Luis Miguel Soria Riendas1, Nuria Marfa Malanda1, Ines Martinez Rienda2, Esteban Cienfuegos Ayuso1, Rafael Zalacain Jorge1, Elena Urra Zalbidegoitia2, 3.

Aim: To study the evolution of Mycobacterium tuberculosis (MT) over a period of 21 years in our area and to know the resistance rates to first-line antimicrobial drugs.

Material and methods: We studied all cases of MT infection diagnosed between 1989 and 2009 in our hospital, attending a population of 420.000.

Results: In this period, 2.164 cases of MT infection have been diagnosed. The mean incidence rate was 24.5 per 100,000 inhabitants per year (maximum 42.6 in 1992 and minimum 11.9 in 2008). The mean age was 48, with a higher incidence in the group of 30-49 years. The gender distribution was 1.8 men/women. In 262 cases there was coinfection with HIV (12.1%), with a maximum of 23.6% (n = 35) in 1993 and minimum of 2.5% (n = 2) in 2004.

The location was pulmonary in 74.2%, extrapulmonary in 20.1% and disseminated in 5.7%. In patients co-infected with HIV, the presentation was pulmonary in 61.4%, extrapulmonary in 13.4% and disseminated in 25.2%. 63 strains have been detected with some resistance (2.8% of general population, which corresponds to 3% in non-HIV and 1.5% of coinfected). There were 36 strains resistant to isoniazid (1.7%), 11 to rifampicin (0.5%), 3 to ethambutol (0.14%) and 25 to streptomycin (1.2%). 17 strains were resistant to more than one drug. Of these, 6 were resistant to at least isoniazid and rifampicin (MDR-TB).

Conclusions: 1. The incidence of MT has clearly diminished over the study period. 2. There has been no change over the years in terms of gender distribution, age groups and location of MT. 3. HIV co-infection has less importance as a risk factor associated. 4. Resistance to first-line drugs is rare in our area and maintains stable levels. 5. We have found some MDR-TB in the study period.

P270
Evolution of the incidence of tuberculosis in the ill health area of the Principado of Asturias, Spain
Jose-Maria Garcia-Garcia1, 2, Fernando Alvarez-Narvaez1, Manuel Villanueva1, Henar Villar1, Juan-Jose Palacios3, Jesus Allende1, Andres Sanchez-Antuano1, Manuel Martinez-Muizia1, Jose-Antonio Gullion1, Aida Fernandez-Pantiga1, Jose-Manuel Fernandez-Carrera1, Ana Fernandez-Quirga1, Begona Gonzalez-Gonzalez3. 1UGC Neumologia, Hospital San Agustin, Aviles, Asturias, Spain; 2Microbiologia, Hospital San Agustin, Aviles, Asturias, Spain; 3Unidad de Referencia de Micobacterias, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 4Investigation, Hospital San Agustin, Aviles, Asturias, Spain; 5Atencion Primaria, Area Sanitaria III, Aviles, Asturias, Spain.

Aim: Description of the evolution of the incidence of tuberculosis (TB) in the last 10 years and the different circumstances that can have influence on it.

Methods: We collected all the cases of cultured proven TB. We describe factors that can have influence: 1. Number of immigrants, HIV co-infection, immunosuppression (biological therapy included). 2. Molecular epidemiology. 3. Treatment follow-up. 4. Contacts study.

482s
Farmaceutici SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
MONDAY, SEPTEMBER 26TH 2011
Results: Our Health Area has 155,000 inhabitants and we had 388 TB patients in 10 years, with a global incidence of 25/100,000 population per year (15/100,000 last year). 1. The percentage of immigrants, HIV co-infection and immunosuppression is small (figure 1).

2. The molecular study performed in 50 patients (2008-2010) shows clustering in 74%. 3. There were 389 patients treated with successful results (cure or treatment completion). 4. We had performed contacts study during all the period but we only know data since 2008 when we started a Pilot Programme (we studied 398 contacts of 152 patients, with 125 infected patients with preventive therapy).

Conclusions: We had a continuous decrease in the incidence of TB, mainly in the last year, with a small percentage of immigrants, HIV co-infection and immunosuppressive therapy, good therapy compliment, and a Programme of study of contacts in a region with recent TB transmission. All together can explain the decrease of TB incidence.

P2631
Epidemiology of tuberculosis in the province of Siena
Simonia Gianni, Paola Michele Oria.
Our Patients: Department of Pulmonary Diseases, Le Scotte Hospital, Azienda Ospedaliero-Universitaria Senese, Siena, Italy

The AA studied the epidemiology of tuberculosis (TB) from 2003 to 2008 in the Province of Siena. The population increased from 265,907 residents in 2003, to 288,378 in 2008. Its distribution in the districts was at 2008: Val d’Elsa (24%), Siena downtown (23%), Val di Chiana (23%), Val d’ Orcia-Amiata (9%), Creti-Val d’Arbia (9%), Chianti (6%), Val di Merse (6%). The immigrants at 2008 in the districts were: Chianti 10.9%, Val di Merse 10.5%, Creti-Val d’Arbia 8.4%, Val d’Elsa 7.9%, Val di Chiana 7.9%, Val d’ Orcia-Amiata 6.2%, Siena downtown 5.7%. In the period considered, TB constantly increased, and the % of 10 cases/100000 inhabitants of the countries with low incidence of TB, was exceeded in 2007 with 12 cases/100000 inhabitants, 10 cases/100000 in 2008. The incidence between the immigrants exceeded 7 times that between the Italians, from 30/100000 to 215/100000 residents for immigrants, from 4.2/100000 to 9/100000 of 10 cases/100000 inhabitants of the countries with low incidence of TB, was 2008 in the districts was: Chianti 10.9%, Val di Merse 10.5%, Creti-Val d’Arbia 8.4%, Val d’Elsa 7.9%, Val di Chiana 7.9%, Val d’ Orcia-Amiata 6.2%, Siena downtown 5.7%. In the period considered, TB constantly increased, and the % of 10 cases/100000 inhabitants of the countries with low incidence of TB, was exceeded in 2007 with 12 cases/100000 inhabitants, 10 cases/100000 in 2008. The incidence between the immigrants exceeded 7 times that between the Italians, from 30/100000 to 215/100000 residents for immigrants, from 4.2/100000 to 9/100000 residents for Italians; probably the incidence in immigrants was underestimated as the study considered only the notified cases and the regular immigrants. The greatest incidence of TB was in the districts of Val d’Elsa and Siena downtown. The immigrant TB patients were younger than Italian patients (35±15 vs 56±20 years old, p<0.05). The 86.4% of the 142 patients examined were affected by TB diagnosed for the first time, the 13.6% by relapses of TB. No significant differences were found concerning the incidence of pulmonary and extra-pulmonary TB, the 66.4% of Italians were affected by pulmonary TB, the 28.2% by extra-pulmonary TB, the 5.4% by pulmonary-extra pulmonary TB; the 68.6% of immigrants were affected by pulmonary TB, the 26.8 by extra-pulmonary TB, the 4.6% by pulmonary-extra pulmonary TB).

A 3 year (2007-2010) tuberculosis treatment analysis in Belfast City Hospital, Northern Ireland
Ihzaq Masih, Anne Bren, Shepherd Richard, Cecelia O’Kane.
Respiratory Medicine, Belfast City Hospital, Belfast, Northern Ireland, United Kingdom

Introduction: Tuberculosis is on the rise globally. Northern Ireland is facing the enormous task to identify, diagnose and treat tuberculosis. Anti-tuberculosis treatment can be tedious and the side effects can hamper management and outcome.

Objectives: To note the prevalence among local and immigrant patients, ascertain the HIV status and concordance and tolerance of anti-tuberculosis drugs.

Methods: A retrospective clinical notes review, microbiology and biochemistry laboratory record analysis.

Results: In total 92 patients, half were originally from Northern Ireland [Table]; 61% male and 39% female. The mean age was 50 (± 21) years with a bimodal age distribution between immigrants (36±11 years) and local patients (66.5±15.5 years).

The majority (67%) had pulmonary and 20.5% had lymph node involvement. Rest had skin, bone, peritoneum, and periasc abscess disease. Culture positive were 76% and smear positive 45%. The majority (79%) were fully and 4% were partially sensitive to the treatment. One patient was multi-drug resistant. Four percent had HIV. The commonest side effect was minor GI upset (7%). Hepatitis and arthralgia occurred in 5.5%, minor skin reactions in 3%, and renal impairment, peripheral neuropathy, febrile reaction and retrobulbar neuritis in 2% each. Seven percent of patients received directly observed therapy.

Conclusion: Tuberculosis is increasingly prevalent among the local population. Only 4% were HIV positive. Good drug compliance was observed in two third of patients. Treatment was modified in 24%, no treatment was stopped.

P2633
What patients account for the post-socialist increase in pulmonary tuberculosis?
Alan Altraja1, Peter Viiklepp2, Kai Klimum1, Heinart Sillaste1, Lea Pehme3.
1Department of Pulmonary Medicine, University of Tartu, Tartu, Estonia;
2Estonian Tuberculosis Registry, National Institute for Health Development, Tallinn, Estonia;
3Lung Clinic, Tartu University Hospital, Tartu, Estonia

Background: After a steady decline in tuberculosis (TB) from 1954 (417/10^5 yr) to 1992 (211/10^5 yr), along with the overwhelming societal and health care changes after independence was declared in 1991, Estonia experienced a resurgence of TB incidence since 1993, which peaked at 47.5/10^5 yr in 1998, without immigration playing a major role.

Aims: To reveal whether patients with particular characteristics accounted for the increasing incidence of pulmonary TB (PTB) in the changed societal conditions (1995-2003) compared to the “low incidence period with a decrease” (1985–1991) to determine the populations under significant risk in such circumstances.

Methods: TB-related characteristics of all PTB cases diagnosed during 1985–1991 (n=362, median age 43.6 yr) and 1995–2003 (n=668, median age 44 yr) in Tartu city and county in Estonia were subjected to logistic regression analysis to find determinants of PTB characteristic of the independence period.

Results: During independence, there were significantly more smear-positive patients (OR 2.39, 95%CI 1.57-3.64), those who sought help because of symptoms (OR 2.40, 95%CI 1.73-3.31), and those who had had TB contact (OR 3.83, 95%CI 2.45-4.68), but significantly less alcohol abusers (OR 0.60, 95%CI 0.42-0.87), and those with a cavity (OR 0.66, 95%CI 0.46-0.96) and a limited disease (OR 0.55, 95%CI 0.31-0.95).

Conclusions: Despite continuously free access to care for TB, the common social groups like non-alcoholics and non-smokers more often fall ill with culture-confirmed non-limited PTB and account for the increased incidence of TB after the post-socialist changes.

Funded by an ESF grant No. 8118.

P2634
Epidemiological investigation in TB diagnosis must be reconsidered
Mihaela Archip, Maria Panescu, Camelia Vasilescu, Marilena Colea. TB District, Clinical Pneumologic Hospital, Iasi, Romania

Aim: The purpose of this study is to prove the importance of the epidemiological investigation in early TB diagnosis.

Material and method: We have analyzed the TB cases registered in three adult tuberculosis districts in Iasi, Romania. The patients have received TB treatment during 2010. We used the medical records, district records and IT records.

During this period, we treated 211 TB patients: 178 pulmonary TB and 33 extra-pulmonary TB cases; we have recorded 168 new cases, 32 relapses, 10 patients were readmitted after failure, default, MDR chronics and one transfer. Using epidemiological investigation, we identified 22 cases (10.43% out of all analyzed cases). The medical history of the patients revealed that 84 of them (39.81%) had previous TB contact: 86.9% of these had domestic contact and only 13.1% of them had indirect TB contact.

Conclusion: Out of the 211 cases, only 22 have been identified using epidemiological investigation. The medical history of 84 patients revealed TB contact, especially domestic TB contact. Moreover, in a single family, 4 domestic contacts developed pulmonary TB during the past 20 years. They all manifested the same type of drug resistance. This fact has been determined by using epidemiological investigation.
We must reconsider:
- the periodic screening of TB contacts over a greater period of time;
- the key role of the family physician, who must be focused on evaluating a large number of indirect/indirect TB contacts for a correct and efficient epidemiological investigation.

P2635
The development of tuberculosis in Bucharest in the last ten years
Emilia Tabacu, Ecaterina Cristea, Cristian Didiulescu, Pneumology, Institute of Pneumology “Marius Nasta”, Bucharest, Romania
Bucharest, capital of Romania, with a population of 1.944.500 inhabitants, constitutes an important problem of epidemiological surveillance of tuberculosis due to a high percent of floating population, numerous overcrowds of persons in locations that are deteriorating (8528 inhabitants/km²), existence of vulnerable groups (homeless, roma population, poor, immigrants) with a lower social, economic and educational level, increasing number of the unemployed, etc.

Objective: The study of the main indicators of the TB endemic in Bucharest in the last nine years.

Material and method: We used the information existing in the official documents of the information system within the National Program of Tuberculosis Control.

Results: A tendency of incidence increase has been installed, reaching from 65,9‰ in 1985 to 154,1‰ in 2001, after which a decrease occurred yearly, reaching 68,3‰ in 2010. A decrease of the incidence with 52% was recorded during 2001 – 2010. The incidence for new cases decrease from 135,8‰ in 2002 to 57,5‰ in 2010 and the incidence for relapses decrease from 18,3‰ in 2001 to 10,9‰ in 2010. The tuberculosis incidence in the 0-14 year children population decrease from 60,8‰ in 2001 to 22,6‰ in 2010. The source density was reduced from 12 sources/Km² in 2001 to 5 sources/Km² in 2009. The rate of the therapeutic success of the new source cases with pulmonary TB (M+) increased from 82,2% in the patient cohort from 2001 to 85,23% in those from 2009.

Conclusions: Tuberculosis control in Bucharest benefits from a rather complex material basis which should be improved according to the present day epidemiological conditions.

P2636
Increasing adherence to TB treatment – Pilot intervention in two counties in Romania
Florentina Furtunescu1, Victoria Mihauescu2, Mihaela Stefan3, Horia Cocoi4, Nicoleta Corcan1, Elmira Braim1, 1 Public Health, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2 Health, Romanian Red Cross, Bucharest, Romania; 3 Health, Romanian Angel Appeal Foundation, Bucharest, Romania; 4 National TN Program, Marius Nasta Institute of Pulmonology, Bucharest, Romania

Introduction: TB is a major public health concern in Romania. All health services are provided free of charge to TB patients and their contacts, through the National TB Programme. However default rate in new pulmonary smear positive cases is over 5%.

Aims and objectives: To measure the impact of a pilot intervention – giving small incentives – on the adherence to treatment of TB patients.

Methods: A pilot intervention, by giving to compliant patients small incentives (around 12 EUR per patient and per month, consisting in tickets for common goods) was unfolded in two counties of Romania (Iasi and Prahova), in the first half of 2009.

Results: During the study period 583 TB cases were registered in Iasi and 411 in Prahova and around 70% of them have received incentives. Percentage of TB patients taking all treatment doses until the final outcome was 93.1% in the first semester of 2009 versus 88.8% in the same period of 2008 in Prahova county. In Iasi county the percentages were 94.6% and 92.1% respectively.

Conclusions: The project induced a significant increase in proportion of patients that finalize the treatment in Prahova county (p=0.010), but not in Iasi county (p>0.090). Giving small incentives seems to increase the adherence to the TB treatment during for months.

P2637
The results of DOTS Plus project in Romania (2004-2010)
Ruxandra Delia Spataru1, Marianna Andrei1, Mihaela Stefan1, Elmira Braim1, 1 TB and Other Chronic Diseases, National Institute of Pneumology “M. Nasta”, Bucharest, Romania; 2 TB, Romanian Angel Appeal Foundation, Bucharest, Romania

Introduction: Although TB notification rate declined significantly in the last 8 years in Romania, from 142.2‰ in 2002 to 90.5‰ in 2010, MDR-TB cases still posed a special attention (812 such cases have been reported in 2009). The DOTS Plus project funded by Global Fund and started in Romania in December 2004 has as purpose to provide high quality health services to a part of MDR-TB patients in Romania.

Aim and objectives: To analyze and characterize treatment outcomes of MDR-TB cases enrolled in DOTS Plus project.

Methods: In the retrospective study have been enrolled 794 MDR-TB cases registered in DOTS Plus project between December 2004 and December 2010. Data have been collected from database of the project and National TB Register.

Results: From the total of 794 cases registered in the project and hospitalized in the 2 MDR-TB excellence centers in the country (57.5% in Bucharest and 42.5% in Iasi county), 67.7% were males and 32.3% females. Primary MDR was found in 26.6% of the cases. The DST pointed 49.3% with only HR resistance and 50.7% with other drug resistances (HR+1 to HR+5). 13 cases had XDR-TB. The ambulatory phase of the treatment was done at 119 TB dispensaries (62‰ from all TB dispensaries countrywide). The default rate decreased obviously from 31.5‰ in 2005 to 12.9% in 2008, consecutive to the distribution of different kind of incentives which improved treatment adherence. Success rate of the GLC patients (62%) was significantly higher than at the patients treated with NTP resources (24.2%).

Conclusions: The favorable evolution of MDR-TB patients enrolled in DOTS Plus project demonstrates real benefits and recommend its case MDR management extension to all MDR-TB cases in the country.

P2638
Assessing the risk of tuberculosis infection in a vulnerable population group (ethnicity rom) in a TB endemic population
Maria-Cristina Nini, Adriana Socaci, Maria-Cristina Nini, Department of Pneumology, West University “Vasile Goldis”, Arad, Romania Department of Pneumology, Clinical Hospital “Vasile Goldis”, Timisoara, Romania Department of Pneumology, Clinical Hospital Constanta, Constanta, Romania General Medicine, University of Medicine and Pharmacy “Vasile Goldis”, Timisoara, Romania

Introduction: High incidence of tuberculosis in our country is related primarily to a reduced standard of living for a part of the population nationwide, including a large segment of the population by ethnic group roman.

Aim: This study analyzes the prevalence of TB infection in vulnerable population groups, in an area with a high prevalence of tuberculosis (138‰/000), where BCG vaccination is mandatory.

Methods: A prospective study of detection of TB infection in the romen community from the west of the country (Arad and Timis), from July 2009-December 2010.

Results: Of 1417 persons who underwent tuberculin skin test (TST) to detect latent tuberculosis infection (LTBI), 700 persons (49,40%) had positive TST results. 73.42‰ the study participants had no BCG scar present in where BCG vaccination is mandatory in our country. 51.43% of those with positive TST were men. 71.20‰ had recently tb contact.

Conclusion: Considering the fact that TB in our country is a major public health problem in a vulnerable population group (ethnicity rom) should be applied consistently screening to identify latent tuberculosis infection.

P2639
Risk factors for anti-tuberculosis treatment failure
Evelina Lesnic, Vasile Zlepca. Pneumophysiology, State Medical and Pharmaceutical University, Chisinau, Republic of Moldova

The effectiveness of DOTS at new TB cases must achieve 95% in Moldova is 70%. The patients with increased risk for failure and relapse are marginalized people. The diagnosis, organization and supervision of the treatment is difficult and the rate of failure is very high. Intrinsic risk factors for treatment failure, those related to the patient, can be under control of the physician, instead extraneous factors, are not related to the disease, but influence the outcome: poverty, ignorance, contact with active TB, they must be covered by the national TB control programs.

We estimated risk factors for treatment failure at 96 new TB cases hospitalized in the municipal hospital of Chisinau. Intrinsic factors revealed were: male sex 69 cases (70%), young age 25-44 yrs, 65 cases (66%), severe forms: infiltrative TB 75 cases (76%) and fibrocavernous TB 9 (10%), disseminated infection 60 cases (61%) with bilateral extension 71 cases (72%), pulmonary bleeding 19 cases (20%), pleurisy 12 (13%), 23 of cases had a coexisting pathology (alcoholics 19 cases, smokers 17, COPD 20 cases, 6 HIV-infected), 3 pregnant women, 8 cases with adverse drug reactions with changing of the therapeutic schedules. The extraneous factors were poverty and bad living conditions 90 (91%) unemployment 66 (67%), low educational status 69 (70%), 46 (47%) had a familiar contact with a TB patient, 34 (35%) had MDR strains in the sputum culture. For 77 cases (78%) the diagnosis was established with a delay more than 3 months after the onset of TB. All listed factors associated with the errors in treatment have induced emergence of MDR-TB that contribute to more problems in management of TB control programs.

P2641
Tuberculosis and gender: Epidemiological trends since 1957 in Poland
Maria Kotezewska Kosela. Epidemiology of Tuberculosis, National Tuberculosis and Lung Disease Research Institute, Warszawa, ul. Płoska 26, Poland

Aim of the study: To describe changes in TB epidemiology since 1957 in Poland in relation to gender.

Methods: Retrospective analysis of data from National TB Register.

Results: The incidence rates (IRs) of tuberculosis in general Polish population decreased much between 1957 and 2009 from 290.6 to 21.6 per 100,000. The constant regularity in this study period was that IRs among men were higher than among women in every adult age group. It happened that the IR in men group was more than four times higher in comparison to female group. In males the linear relation of IRs and age was observed with the peak usually in 50-59 age group. In women group the more complex pattern occurred. Till the end of nineteenth the bi-modal relation of IR with age was observed. Originally the highest IRs were among younger and oldest women. Since the end of nineties the distribution of IRs has been similar in both gender groups, namely the older age group the higher was IR of tuberculosis.

Conclusions: The big differences in IRs of tuberculosis among men and women were constantly observed in Poland between 1957 and 2009. The relation of IRs and age in both gender groups came to be similar in the end of nineties. The task is to explain the higher proportion of men among TB cases.

P2642
Tuberculosis treatment completion in migrants, St.-Petersburg, Russian Federation
Inna Golubeva 1,2, Yevgeny Chursenev 2, Natalya Skyrnik 3, 1Phthisiology, Medical Academy of Postgraduate Studies, St. Petersburg, Russian Federation; 2Molecular Genetics Laboratory, Russian Institute of Phthisiopulmonology, St. Petersburg, Russian Federation; 3Adult Department, Antitubercular Dispensary of Admiralty District, St. Petersburg, Russian Federation

Introduction: Last years migrants in the Russian Federation (RF) are presented mainly by foreign citizens arriving to the RF from former Soviet republics visa-free with the aim of temporary labour activity. Some of these countries have high burden of tuberculosis (TB). These persons can move freely within the RF; they are not obliged to register at the place of actual residence and most of them have no health insurance. By law, TB is in the basis for the refusal or cancellation of temporary residence permits or work permits to foreigners in RF.

Objective: To assess TB-treatment completion rates in patients who arrived from countries visa-free with the aim of temporary labour activity.

Methods: In the absence of registration at the place of actual residence, health care staff can not locate the patient and ensure completion of treatment. If treatment can not be completed in the country of temporary stay, a patient transfer to their home country is required.

Results: Out of 128 selected patients (M:112 F:16) 22 patients (31%) refused treatment and died. Thus, only 27 patients (39%) completed treatment, the fate of 43 patients (56%) is unknown. Of the 48 patients who started treatment, 21 (44%) did not complete treatment due to various reasons. The total number of patients with drug sensitivity test (DST) were investigated. DST's were studied in 104 cases. The mid-year number of soldiers is 537200 in Turkish Armed Forces, the culture positive. Lung involvement was observed in 67.5% (175 patients), organ involvement was observed in 6 (5.7%) patients.

Conclusions: Although the incidence of tuberculosis in young soldiers is moderately high it showed a significant decline compared to a studied published 8 years ago. The results of primary drug resistance to tuberculosis drugs and multi-drug resistance rates were increasing. National Tuberculous Control Program had to be directed effectively to decrease antimycobacterial drug primary resistance and multi-drug resistance rates.

P2643
Incidence of tuberculosis and primary drug resistance rates in young Turkish soldiers
Dilaver Tas 1, Canturk Tasci 1, Ersin Demirel 1, Ogun Sezer 3, Oguzhan Oktan 1, Zafer Kartakoglou 1, 1Department of Chest Diseases, GMMA Haydarpasa Training Hospital, Istanbul, Turkey; 2Department of Chest Diseases, GMMA School of Medicine, Ankara, Turkey; 3Department of Microbiology, GMMA Haydarpasa Training Hospital, Istanbul, Turkey

Introduction: Tuberculosis is an important public health problem. Epidemiological results have to be used to control the disease. The aim of the study is to investigate incidence of tuberculosis and primary drug resistance rates in young conscripts.

Methods: Soldiers with tuberculosis between January 1, 2009 and December 31, 2009 is recorded retrospectively. Results of sputum culture positive cases and also cases with drug sensitivity test (DST) were investigated.

Results: All patients were male with a mean age of 22.51±4.63. The total number of newly diagnosed patients in 2009 was 259 while 121 of them were sputum culture positive. Lung involvement was observed in 6 (5.7%) patients.

Conclusions: Of the newly diagnosed patients in 2009 was 259 while 121 of them were sputum culture positive. Lung involvement was observed in 6 (5.7%) patients.

P2644
Drug resistance pattern of directly observed treatment shortcourse (DOTS) category-II relapse patients
Nirmal Jain, Mukesh Sharma, Nitin Jain, Nalin Joshi, Rohan Aurangabadwalla, Anaksha Ila. Department of Chest & TB, Hospital for Chest & TB, SMS Medical College, Jaipur, Rajasthan, India

Background: Multi-Drug resistance (MDR) is an emerging threat to tuberculosis control and resistance pattern depends on factors like regimen, duration of treat- ment, compliance etc. Currently Cat-II relapses are retreated with Cat-II DOTS and there is scarcity of data on drug resistance pattern in relapse patients.

Materials and method: This prospective observational study included 128 pa- tients of Cat-II relapse. Detailed history of chemotheraphy was recorded and sputum was sent for mycobacterial culture and sensitivity before starting Cat II DOTS. Resistance pattern of patient was studied.

Results: 122 out of 128 culture and sensitivity reports were available. 104 (85%) patients were culture positive, 15 (12.09%) were smear positive and culture negative. 3 (2.41%) had contaminated culture. 86 (69.35%) patients had resistance to any drug, of which66 (53.22%) were MDR. 12 (8.7%) were multi-drug resistant. 16 (13.16%) patients were treated previously with DOTS and non-DOTS respectively. History of previous chemotherapy revealed 80 (63%) patients had relapses, 11 (9%) were failures and 37 (29%) were defaulters. 56 (73%) had resistance to any drug and, 42 (54%) were MDR in relapse group. 7 (70%) patients had resistance to any drug in failure group and all were MDR. 57% had resistance to any drug in defaulters and 50% were MDR.

Conclusions: High resistance pattern (53.22%) in Cat II relapse patients, thus patients should not be retreated with Cat-II retreatment regimen but empirically treated with revised line drugs till availability of mycobacterial culture and sensi- tivity reports. There is scarcity of drug resistance data for Cat-II relapses and an urgent need of generating data on relapses so that the policy to treat these patients can be established.

P2645
To study outcome of directly observed treatment shortcourse (DOTS) category-I and category-II relapses when put on re-treatment regimen (Cat-II DOTS)
Nitin Jain, Nirmal Jain, Mukesh Sharma, Rohan Aurangabadwalla, Nalin Joshi, Anaksha Ila. Department of Chest & TB, Hospital for Chest & TB, SMS Medical College, Jaipur, Rajasthan, India

Background: Under RNTCP Cat-I and Cat-II relapses are put on retreatment regimen. There is scarcity of data on outcome of these relapses and hence, present study was planned to study the outcome of DOTS Cat I and Cat II relapses when put on retreatment regimen (Cat II DOTS).

Patients and methods: A total 289 relapses (161 cases of Cat-I relapse and 128 of Cat-II relapses) patients were included. 150 cases with history of successful treatment and 2 year follow up without relapse were taken as control. 9 patients were lost to follow up. Cat I and Cat II relapses were treated with retreatment regimen (Cat II). Patients were followed up to see changes in radiological and bacteriological parameters as per RNTCP protocol. Outcome was decided based on smear examination at follow ups at 2, 5 and at end of treatment. Mycobacterium culture and sensitivity (Myco CS) reports were collected and bacteriological characteristics of patients were decided. Outcome was defined as per RNTCP guidelines.

Results: Out of 156 Cat-I relapse patients treated with Cat-II DOTS, successful outcome was achieved in 65.37%. Regimen failed in 26.28% and 5.78% patients defaulted. When Cat-II relapse patients were retreated with Cat-II DOTS, successful outcome was achieved in only 36.28% patients. 56.45% patients failed, 4.83% patients defaulted and 2.42% died.

Conclusions: Treatment of Cat-I relapse with Cat-II can be justified with an expected success rate of 65%. The effectiveness of Cat-II DOTS in Cat-II relapse must be elucidated in large multicentre studies and ideally Cat-II relapses should be empirically put on revised line drugs awaiting results of Myco CS.

P2646
An analysis of mortality among patients with tuberculosis (TB) in Sri Lanka
Dushantha Madugedara, Prasanne Wijeratane, Lakshika Monaragala, Duminda Yassaratne, Netanjun Dissanayake. Respiratory Disease Treatment Unit, Teaching Hospital, Kandy, Sri Lanka

Introduction: Sri Lanka has a TB prevalence of 101 and a mortality of 9.2 per 100,000.

Objective: To define characteristics of patients who died during treatment for TB in a unit from Central Sri Lanka.

Method: We retrospectively analysed TB related deaths during 2006 to 2010.
Results: We observed a mean mortality rate of 5.4% (228/4199) for the 5-year period. The lowest rate of 3.2% was in 2010. Of the total deaths, 78.5% were males and 50.4% were above 60 years; 4.3% were below 20 years. Pulmonary TB (PTB) contributed to 75% of the deaths.

Conclusion: Mortality in TB was high among males and retreatment patients.

P2647
A tuberculosis-screening program among HIV-infected patients
Filipa Viveiros1, Margarida Mota 2, Luis Matos 3, Aurora Carvalho1,4, Reynaldo Quagliato, Mauricio Leme, Paulo Tonidandel, Welwitschia Dias, Anja Schablon1, Roland Dietz2, Felix C. Ringusahaan1,2, Alfred Nienhaus1,4, 1Institute for Health Services Research in Dermatology and Nursing, University Hospital Hamburg-Eppendorf, Hamburg, Germany; 2Department of Medicine III – Pulmonology, Allergology and Sleep Medicine, University Hospital Bergmannsheil, Bochum, Germany; 3Department of Occupational Medicine, University Hospital Bergmannsheil, Bochum, Germany; 4Section Mining, Prevention in Health and Welfare Services, Hamburg, Germany

Introduction: Tuberculosis (TB) is still the leading cause of death in HIV-infected patients. Its early detection and treatment is a known priority. In 2008 a tuberculosis-screening program among newly diagnosed HIV patients was implemented in a Central Hospital Infectious Unit. Aim: Evaluate the screening program, addressing compliance, case detection and potentially prevented cases.

Methods: A before-after intervention study was performed. Analyzed all newly diagnosed HIV patients between 2007-2008 (before) and 2009-2010 after the program was implemented. Screening included: symptom inquiry, chest radiography, two-step tuberculin skin test and IGRA. Sputum smear and culture were performed when TB was suspected.

Results: From 2007 to 2010, 152 patients were diagnosed with HIV (88 in 2007-2008, 60 in 2009-2010) 75% men, mean age 38.5 y. The before vs after group: 24 (27.6%) vs 36 (57.1%) were injecting drug users (OR: 3.42, CI95%: 1.73 to 6.77); 35 (40.2%) vs 11 (17.5%) had heterosexual risk (OR: 0.31, CI0.14 to 0.68) and 18 (20.7%) vs 3 (4.7%) homosexual (OR: 0.19; CI0.05 to 0.68); 4 vs 11 patients had a known contact with TB (OR: 4.35, CI: 1.32 to 13.49) and 2 vs 7 a previous history of TB (OR: 28.1, CI: 1.06 to 26.33). Screening for TB was done in 69 patients, 21 (32.4%) in the first and 48 (75%) in the second period. LTBI was diagnosed in 3 vs 11 patients (OR: 5.88, CI: 1.57 to 22.06) and active TB was found in 11 vs 21 patients (OR: 3.42, CI:1.51 to 7.76).

Conclusions: The screening program allowed the early identification of more cases of active TB and LTBI. Screening compliance increased, but there were still 25% of HIV patients in the second period that failed screening. Strategies to increase this compliance must be found.

P2648
Unusual association of tuberculosis with schistosomiasis and tuberculosis with sporotrichosis
Reynaldo Quagliato, Mauricio Leme, Paulo Tonidandel, Welwirschua Dias, Maira Zanovelo, Gisele Yonezawa, Aristoteles Barbeiro, Lain Zambom, Division of Lung Diseases, State University of Campinas, Campinas, Sao Paulo, Brazil

Introduction: Tuberculosis is an infectious disease that causes currently nearly 2 million deaths worldwide. More than 200,000 of these occur in patients co-infected with HIV. There are about 700,000 new cases a year, and we found the presence of two cases with atypical association of schistosomiasis and sporotrichosis.

Objective: To report our experience with concomitant infection tuberculosis with schistosomiasis and sporotrichosis.

Method: Cases study of patients infected with tuberculosis in the Hospital of the UNICAMP-Campinas, Brazil.

Results: We found the case of man, 55 years, alcoholic, with pleural effusion for about a year. Thoracocentesis resulted in exudate and ADA= 66 U/L. Chest CT showed mediastinal lymphadenopathy. Result of culture of lymph node removed by mediastinoscopy was positive to Mycobacterium tuberculosis and Sporothrix schenckii. The other case is a 32 years old, male, with a history of fever and weight loss with chest x-ray opacity in the left apex. Chest CT showed a mass in right upper lobe permeated by a tree in bud and mediastinal lymphadenopathy. He underwent lobectomy that showed the presence of Schistosoma mansoni and Mycobacterium tuberculosis in parenchyma, pleura and lymph nodes.

Conclusion: Tuberculosis can be associated to other diseases even in HIV-negative patients, including simulating lung cancer.

280. Risk assessment for tuberculosis

P2649
Within-subject variability of tuberculosis immune responses in health care workers
Felix C. Ringusahaan1, Heiko Knoepf2, Stephan Schlosser3, Gerhard Schultze-Werninghaus4, Gernot Rohde5, 1Institute for Health Services Research in Dermatology and Nursing, University Hospital Hamburg-Eppendorf, Hamburg, Germany; 2Department of Medicine III – Pulmonology, Allergology and Sleep Medicine, University Hospital Bergmannsheil, Bochum, Germany; 3Department of Occupational Medicine, University Hospital Bergmannsheil, Bochum, Germany; 4Section Mining, Prevention in Health and Welfare Services, Hamburg, Germany

Background: Although IFN-γ release assays (IGRAs) are increasingly used for periodic tuberculosis (TB) screening of health care workers (HCWs), data regarding the interpretation of IGRA results in serial testing is scare.

Objective: To evaluate the within-subject variability of two commercial IGRAs, Quantiferon®-TB Gold In-Tube (QFT) and T-SPOT® TB (T-SPOT). Methods: Thirty-four immunocompetent German HCWs (age ≥42 ± 10 y, 79% female) without recent TB exposure or other individual risk factors were repeatedly tested with both IGRAs in weekly intervals over a four-week period.

Results: According to the manufacturers’ predefined dichotomous cut-offs (10% (29.4%) and 3% (8.8%) of the 34 subjects had divergent overall trends with the QFT and the T-SPOT, respectively (p<0.001). The QFT showed 4 unstable conversions (11.8%) and 6 reversions (17.6%), while the T-SPOT showed no conversion and 3 reversions (8.8%). The proportion of concordantly negative IGRA results increased over time. Changes of ±0.70% (QFT) and ±3.2% (T-SPOT) from the mean log IFN-γ response accounted for 95% of the within-subject variability, respectively.

</table>

Conclusions: We observed considerable variability with both IGRAs and a tendency towards regression of IGRA results over a 4-week period, which should be considered when interpreting repeated IGRA results.

P2650
Conversion and reversion rates in serial examination in German healthcare worker with the interferon-gamma release assay
Anja Schablon1, Roland Dietz2, Felix C. Ringusahaan1, Alfred Nienhaus1, 1CV-Care, University Medical Center Hamburg-Eppendorf, Institute for Health Services Research in Dermatology and Nursing, Hamburg, Germany; 2Department of Pulmonology, Medical School (MHH), Hannover, Germany

Background: Data concerning conversion and reversion rates in serial testing of healthcare workers (HCWs) is rare. There is no consensus to date on how to define and interpret IGRA conversions and reversions. We, therefore analyzed conversion and reversion rates when conducting serial testing of HCWs.

Methods: The study population comprises 426 HCWs from German hospitals, all of whom participated in routine occupational safety and health tuberculosis (TB) screening between January 2007 and October 2010. The QuantiFERON-TB® Gold In-Tube (QFT) assay was used. Different definitions for conversion and reversion were used and risk-related rates calculated.

Results: The first and second QFTs were positive in 8.7% (n=37) of the HCWs,
each. The highest conversion and reversion rates were 3.8% (n=16) and 43.4% (n=23) respectively were observed with the least stringent definition of negative to positive. An uncertainty zone of <0.2 to >0.7 IU/ml gave the lowest conversion rate of 6.6% and a reversion rate of 19.4%. With regards to the different workplaces, we observed a conversion rate of 5.8% in the high risk group, of 4.1% in the moderate risk group and 1.4% in the low risk group from. The highest reversion rate was found in the low risk group (8.5%). However, the differences were not statistically significant.

Conclusion: Our data suggests that HCWs working on wards with a high risk of TB-infection have higher rates of conversions compared to the low risk group and the use of an uncertainty zone of <0.2 to >0.7 IU/ml around the cut-off when conducting serial testing with the QFT.

P2651
Specificity and negative predictive value of the Quantiferon-TB®-Gold In Tube testing on trainees in healthcare settings
Anja Schablon1, Genia Diner2, Ute Anshe2, Albert Nienhaus1.1 CV-Care, Institute for Health Services Research in Dermatology and Nursing, Hamburg, Germany; 2Institute for Working Health Protection, Vivantes, Berlin, Germany

Evidence is growing of high sensitivity and specificity of the interferon-gamma release assays (IGRA) for the detection of latent TB infection. A further question is that of the reliability of their negative results. A few studies have evaluated the outcome of Healthcare workers and trainees with negative IGRA results over time. We analysed the specificity and the negative predictive value (NPV) of the Quantiferon-TB Gold In Tube (QFT) in trainees in healthcare settings.

Methods: A cohort of trainees at the Vivantes healthcare training institute in Berlin established between October 2008 and July 2010 was tested with the QFT at the beginning and after the first year of training.

Results: The study population comprised 194 trainees. Two trainees were excluded from the specificity analysis: one due to indeterminate QFT-IT result and one following a history of TB. Of the 192 trainees at baseline, 153 were still in training. At the beginning of training two trainees were QFT positive (1%). The specificity was estimated as 99%. 151 trainees showed persistently negative QFT results. One trainee was QFT positive during the follow-up. One conversion occurred in one case and one reversion occurred. The NPV in this healthy trainee group was 99.3%.

Conclusion: Our data confirms the findings of a recent meta-analysis (1). This analysis determined a specificity of 99.4% in individuals belonging to low risk groups. The high specificity and the good NPV support the use of QFT for serial testing of HCWs.

P2652
Prevalence of LTBI using IGRA and TST in a cohort of healthcare trainees from India
Devashayam J. Christopher1, Prince James1, Joy Sarojini Michael2, Deepa Shankar3, Alice Zwerling3, Madhukar Pai2.1 Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu, India; 2Pulmonary Medicine, McGill University, Montreal, QC, Canada; 3Microbiology, Christian Medical College, Vellore, Tamil Nadu, India

Objectives: Estimate the prevalence of LTBI among health professional trainees at a referral hospital in India, using Tuberculin skin test (TST) and Quantiferon TB Gold In-tube (QFT).

Methods: From November 2009 to February 2011, students in health professional programs (except medical and nursing students) were approached for consent. In addition to a detailed questionnaire on TB exposure, participants underwent TST (10 mm) and the QFT-GIT (0.35 IU/ml).

Results: 164 students completed testing. Mean age was 21.5 yrs, 48.8% were female and 59.15% had BCG. Mean time in health care was 11.5 months, and 21.6% recalled contact with PTB cases. Seventy-nine (48.2%, 95%CI: 40.3-56.1%) were positive by TST, and 85 (46.7%, 95% CI: 40.3-53.0%) were positive by QFT. In a cohort of nursing students from the same institution, prevalence was estimated at 21.6% (TST) and 17.04% (QFT), thus lower than the health professional cohort. Possible explanations include a higher proportion of male students compared with nursing, also present cohort were less likely to own a car or house as compared with nursing students, suggesting lower SES. Multivariate logistic regression showed age was associated with QFT positivity but not TST (OR=1.24, 95%CI: 1.01-1.52).

Conclusion: LTBI is common among health professional trainees in India; however, risk factors appear to be better correlated with QFT.

P2653
Evaluation of latent tuberculosis infection in health care workers by Quantiferon-TB Gold test and tuberculin skin test
Derya Vembister, Dilek Kamraz, Barsa Yilmaz, Findeks Atabay, Esin Tuncay. Pulmonary Medicine, Yedikule Chest Diseases and Surgery Hospital, Istanbul, Turkey

Introduction: It is estimated one third of the world population is infected by mycobacterium tuberculosis (TB) and the risk factor of TB infection is contacting with TB patients.

Aim: The aim of this study was to evaluate the parameters affecting the tuberculin skin test and Quantiferon-TB Gold tests and the results of both tests used in health care workers for confirming latent tuberculosis infection (LTBI).

Method: 94 health care workers who work in Yedikule Chest Diseases and Surgery Hospital participated to this study. The demographic characteristics of cases, working hours and the number of BCG scar were recorded. Tuberculin skin test were applied to all patients and Quantiferon levels were measured.

Results: The TST and QFT-G positivities had similar dispersion in gender groups and work types. There were a statistically significant relation between the levels of QFT with work times and ages of all participants. It was determined that there was a statistically significant relationship between positivity of QFT with TST positivities and QFT enduration diameters.

Conclusion: In this study the findings indicated that QTF is very useful in determining and following LTBI as a confirming test for healthcare workers who have close and longterm contact with tuberculosis patients and whose TST tests were positive.

P2654
Serial testing using IGRA in a cohort of Indian nursing students
Devasahayam J. Christopher1, Prince James1, Joy Sarojini Michael1, Alice Zwerling3, Madhukar Pai2.1 Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu, India; 2Pulmonary Medicine, McGill University, Montreal, QC, Canada; 3Microbiology, Christian Medical College, Vellore, Tamil Nadu, India

Objectives: Evaluate how continuous Interferon gamma response varies across and within individuals over time in nursing students at a tertiary care hospital in Southern India upon annual screening for LTBI using QFT-GIT.

Methods: Students were approached to participate in a longitudinal study. In addition to history, clinical log books provided detailed information on potential TB exposure prior to baseline, and between annual testing. Students underwent QFT-GIT testing in 2008, 2009 and 2010.

Results: 125 nursing students completed QFT testing at 2-3 points for a total of 311 observations. We present a trajectory plot of continuous IFN-gamma across time for each participant.

There exists a high degree of correlation among observations from the same individual (ICC=0.55). To account for the correlation within individuals over time, we used linear mixed models to estimate a subject specific random effects model. We found IFN-gamma results to be negatively associated with successive visits (<0.09) suggesting responses may decline over time. However, this effect was small and not statistically significant. We also identified a small random effect for student (variance = 1.76) after accounting for known LTBI risk factors and TB exposure, suggesting there may be unknown factors contributing to differences in baseline IFN-gamma response across students.

P2655
Tuberculosis screening program using the Quantiferon-TB Gold test and chest computed tomography for healthcare workers accidentally exposed to patients with tuberculosis
Takashi Hiramu, Koschi Hagiwara, Minoru Kanazawa. Respiratory Medicine, Saitama Medical University, Morohongo, Moroyama, Saitama, Japan

Health-care associated transmission of TB is a serious issue. Health care workers (HCWs) have been reported to show high incidences of TB. Periodical screenings and as-needed screenings for HCWs are important. We integrated chest CTs and
the QFT-G test in our TB screening program for HCWs. First, contacts were tested using the QFT-G test. Second, the HCWs positive for the QFT-G test were identified and classified as having TB disease, LTBI, or old TB. Finally, the HCWs with TB disease were treated with a multi-drug regimen, while HCWs with LTBI were treated with INH monotherapy.

Between April 2005 and April 2010, 11 patients who had not been diagnosed with TB disease were found to have TB disease during hospitalization. A total of 512 close contacts and high-risk contacts were identified, who underwent the TB screening program. Out of them, 34 (6.46%) showed positive result for the QFT-G test, whereas 478 (93.54%) showed negative results. Of the 34 QFT-G positive HCWs, 4 had CT findings compatible with TB disease and received multidrug treatment. The chest CT for 24 showed no findings suggestive of TB disease; these HCWs received INH for 6 months. All HCWs who received treatment completed their regimens without any adverse effects. The TB screening program integrating CT and the QFT-G test was safe and feasible (J Hosp Infect in press).

P2656
The additional diagnostic value of interferon gamma release assay to the tuberculin skin test in Greek health care workers (a preliminary study).
Alexandros Charisis1, Athanasios Konstantinidis1, Constantina Gartzonika1, Dimitra Archaniditzi1, Athena Gogali1, Christos Katsanos1, Athanasios Kostoulas1, Stamatis Katsenos1, George Daskalopoulos1, Stamatina Leveidiotou-Stefanou2, Anestis Mavridis2, Stavros Constantopoulos1.
1Department of Pneumonology, University Hospital of Ioannina, Ioannina, Epirus, Greece; 2Department of Microbiology, University Hospital of Ioannina, Ioannina, Epirus, Greece

Introduction: Health care workers (HCWs) are at increased risk of Mycobacterium tuberculosis infection. The tuberculin skin test (TST) can be positive (among others) after vaccination with bacille Calmette-Guérin (BCG) creating confusion in countries where this is still compulsory, like Greece. Interferon gamma release assays (IGRAs) are used to solve this problem since they are more specific than TST and usually do not become positive after BCG vaccination.

Aims and objectives: This is a preliminary study aiming to evaluate the additional diagnostic value of QuantiFERON-TB Gold In-Tube (QFT-GT) to the tuberculin skin test (TST) in Greek HCWs.

Methods: A cross-sectional study of TST and QFT-GT was carried out among 275 immuno-competent HCWs at a 900-bed Greek tertiary referral University Hospital. TST was performed on all participants, while QFT-GT was performed in all subjects with TST ≥ 10 mm. Results: Among the 275 study subjects, 124 (45.1%) had TST indurations of ≥10 mm, 96 of them were BCG vaccinated. None had clinical or radiologic evidence of active tuberculosis. From these 124 HCWs, 69 (age 20-67, mean 48.2) agreed to have the QFT-GT test which was positive in only 9/69 (13%).

Conclusion: Based on IGRA’s results, in the majority of Greek HCWs of our study, positive TST was not due to latent tuberculosis infection but to previous BCG vaccination or other unidentified reasons, like exposure to non-tuberculous mycobacteria. This is in agreement with previous study of our Department in a younger age group of Greek Army recruits (S. Katsenos et al. Int J Tuberc Lung Dis 14(5):545-550).

P2657
Concordance between IGRA and TST in a cohort of health professional trainees from India
Devshahamay J. Christopherson1, Prince James1, Joy Sarojini Michael1, Alice Zweirling2, Madhukar Pai2.
1Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu, India; 2Epidemiology, Biostatistics & Occupational Health, McGill University, Montreal, QC, Canada.

Objectives: To estimate the concordance between the Tuberculin skin test (TST) and QuantiFeron TB Gold In-tube, (QFT) among health professional trainees at a referral hospital in India, and to evaluate risk factors associated with discordant results.

Methods: From November 2009 to February 2011, students registered in various health professional programs (with the exception of medical and nursing students) were approached to participate. In addition to a questionnaire on TB exposure, participants underwent TST (10 mm cutoff) and the QFT/GIT (0.35 IU/ml cut off).

Results: 164 students completed. Mean age was 21.5 yrs (Range: 17-34), 48.8% were female and 59.1% had BCG scars. Mean time in health care work was 11.5 months, and 21.6% recalled direct contact with PTB. Prevalence of LTBI by TST or QFT was 48.2% and 23.2% respectively. Agreement between tests was 71.3% (kappa=0.415). The predominant discordance was TST+/QFT- (43/164, 26.2%). Using multivariable logistic regression we evaluated whether discordant results were associated with any particular risk factors, including: age, sex, education, family income, time in health care setting, days spent in high risk wards, performing high risk procedures, pre-existing medical illness, BCG, and known TB exposure. No factors were associated with discordant results, however, age was associated with concordant positives (OR=1.27, 95%CI: 1.03-1.59), and higher family income was protective (OR=0.67, 95%CI:0.45-0.99).

Conclusions: There was fair to weak agreement between TST and QFT in this population. Concordant positives were associated with older age, and lower family income. Discordant results were not associated with any known risk factors.

P2658
IGRA testing correlation with clinical and laboratory parameters in patients with tuberculosis
Jana Kotebova1, Martina Vasakova2, Jiri Homolkova1, Emilia Kopecka1, Jelena Skibova1.
1Pulmonary Clinic, Thomayer University Hospital, Prague, Czech Republic; 2Preventive Cardiology, Institute of Clinical and Experimental Medicine, Prague 4, Czech Republic.

Background: IGRA test (QuantiFeron-TB-Gold in-tube test, further referred as QFT) is based on ELISA method for interferon gamma evaluation created by antigen specific T-lymfocytes. QFT has become a part of complex tuberculosis diagnosis.

Aims and objectives: QFT outcomes comparison with other diagnostic methods in patients with tuberculosis and assessment of malnutrition and immunity system influence on QFT outcomes.

Methods: In a group of 62 patients treated in our clinic for tuberculosis in 2010, we compared the QFT results with tuberculin skin test (TST), PCR, smear and culture. The effect of malnutrition and lymphopenia on possible false QFT negativity was studied as well. Non-parametric Mann-Whitney rank test was used for comparing the mean TST value with QFT and in other parameters. Chi-square test was used in frequency tables.

Results: Statistically significant correlation between QFT positivity and TST negativity, PCR positivity and culture positivity was demonstrated. Statistical significance has not been proven neither between QFT outcomes and microscopic diagnosis nor the effect of malnutrition or lymphopenia on possible false QFT negativity was proven.

P2659
Useful of Quantiferon G in managing solitary pulmonary nodule of less than 3 cm
Sawang Saenghirunvattana, Kasem Saenghirunvattana, Patchamol Masakul, Chuchart Vinitwatanakhun.
Medicine, Bangkok Hospital, Bangkok, Thailand

Introduction: Development of new tools for the rapid diagnosis of tuberculosis is a priority. There are few data from high burden countries on the utility of Quantiferon G for the rapid diagnosis of solitary pulmonary nodule.

Material and methods: We evaluated the utility of Quantiferon G in 30 patients with solitary pulmonary nodule which was less than 3 cm. All were Thai people, and all got BCG vaccine. Bronchoscopy with Autofluorescence was done, bronchial washing was sent for AFB stain, TB culture, PCR-TB and cytology. Tuberculosis test was also performed. Results: Tuberculosis test was positive in 16 patients (53%), Quantiferon G was positive in 19 patients (63%) and PCR-TB was positive in 2 patients (6.7%). Those with positive Quantiferon G were treated with anti tuberculosis drugs for 9 months, all showed satisfactory response. Among those with negative Quantiferon G, 1 year follow up was provided; one turned to be Mycobacterium avium intracellulare, another one developed adenocarcinoma.

Conclusion: Quantiferon G may provide additional useful tool in making decision in managing solitary pulmonary nodule in countries with high incidence of tuberculosis.
P2660
T spot TB - Changing trends and resource implications for trusts
Melul Patel, Adrian Morris, Bandipalyam Prathibha. Respiratory Medicine, William Harvey Hospital, Ashford, Kent, United Kingdom

Introduction: The diagnosis of TB has been revolutionised by Gamma interferon testing with the advantage of being more specific and sensitive in detecting both active and latent TB. East Kent Hospitals NHS Trust is a large trust serving a population of 700,000. This study outlines our experience and in particular focuses on the resource implications as usage of biological agents increases.

Methods: All samples assayed over a twelve month period were included in the study. Data, including the demographics of the patients, indication for the test and the result, was collected. The data was analysed.

Results: A total of 491 samples were sent for analysis within the study period. There was an equal gender distribution (M:F = 221:270) and the median age was 53.02.

Table 1. Reason for requesting T spot T.

<table>
<thead>

<td>31.77%</td>
<td>37.68%</td>
<td>100%</td>
</tr>
</tbody>
</table>

Conclusion: T spot TB provides a highly sensitive and specific way of detecting active or latent TB. Almost a third of the requests are to assess TB status prior to the introduction of biological agents. This will have a major impact on resources with the increased usage of biologicals, something that needs to be borne in mind whilst developing this service.

P2661
Clinical utility of the interferon-gamma for the diagnosis of active pulmonary tuberculosis
Svetlana Kasikovic Lecic, Slobodan Pavlovic, Vesna Kunec, Miroslav Ilic, Daninka Kukavic. Department for Tuberculosis, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Vojvodina, Serbia

Introduction: A rapid diagnosis of TB is crucial not only for patients, but also for TB control in the community. Currently, T-cell based interferon gamma release assays (IGRA) are acknowledged as the best methods available for the screening of latent tuberculosis infection (LTBI) and also as aid for the diagnosis of active tuberculosis (TB). The performance of these diagnostic tests has not been evaluated in Serbia.

Aim: To compare the sensitivity of Quantiferon-TB Gold In-tube test (QFT), tuberculin skin test (TST) and acid-fast staining of sputa in patients with culture confirmed active pulmonary TB (PTB).

Methods: The sensitivities were evaluated in 70 HIV negative patients with culture confirmed Mycobacterium tuberculosis infection. The sputum culture result was used as a gold standard. TST results were analysed at 5, 10 and 15mm cut-offs. QFT test was interpreted following the manufacturer’s criteria.

Results: Sensitivities of the TST using a 5, 10 and 15mm of cut-offs were 55.7%, 51.4%, 45.7% respectively. Sensitivity of QFT (68.6%) was higher than that for all the TST sensitivities. The overall agreement between TST (all cut-offs) and QFT was poor. Sensitivity of the acid-fast staining of sputa was 75.7%.

Conclusion: Although findings have revealed a generally low sensitivity of the QFT, our opinion is that QFT can be used as adjunct diagnostic technique for active TB disease.

P2662
Unfavorable factors associated with false negative results of interferon-gamma release assay for tuberculosis
Nguyen Thi Le Hang1, L.T. Lien2, N. Kobayashi3, T. Shimbo4, S. Sakurada5, P.H. Thuong2, L.T. Hong6, D.B. Tam6, M. Hijikata5, I. Matsumita5, N.G. BMH Medical Collaboration Center, Bach Mai Hospital, Hanoi, Viet Nam; 2Department of Respiratory Medicine, Hospital Division, National Center for Global Health and Medicine, Tokyo, Japan; 3Department of Clinical Research and Informatics, International Clinical Research Center, National Center for Global Health and Medicine, Tokyo, Japan; 4Department of Clinical Research, Respiratory Diseases, Institute, National Center for Global Health and Medicine, Tokyo, Japan; 5Department of Clinical Research and Informatics, International Clinical Research Center, National Center for Global Health and Medicine, Tokyo, Japan; 6Department of Medical Laboratory, Hanoi Lung Hospital, Hanoi, Viet Nam; 7Department of Microbiology, National Lung Hospital, Hanoi, Viet Nam; 8Department of Mycobacterium Reference and Research, Research Institute of Tuberculosis, Tokyo, Japan

Imperfect sensitivity of interferon-gamma release assay (IGRA) is a potential problem to detect tuberculous infection. We comprehensively investigated factors that can lead to false negativity of IGRA, regarding active tuberculosis as a surrogate. In total, 543 patients with new smear-positive pulmonary tuberculosis were tested. At the time of diagnosis, peripheral blood was collected and IGRA (QuantiFERON-TB Gold In-Tube®, Cellestis, Victoria, Australia) was performed. Clinical and epidemiological information of the host and pathogen was collected together. Factors negatively influencing IGRA results were evaluated using logistic regression model.

Age ≥80 years old, body mass index <18.5 and the extensive infiltrates on chest X-ray showed significant associations with IGRA negativity (OR = 8.47 [95% CI, 1.53–46.84], 3.46 [95% CI, 1.14–10.49], and 3.07 [95% CI, 1.18–7.97], respectively), whereas HIV co-infection was rather associated with indeterminate results (OR = 23.30 [95% CI, 4.28–126.82], respectively). Having HLA-DQB1*0701 allele was also associated with IGRA negativity; the number of the HLA allele that the patients possess correlated inversely with concentrations of interferon-gamma induced by M. tuberculosis-specific antigens (heterozygotes; 2.08 IU/ml [interquartile range, 0.79–4.64] and homozygotes; 0.15 IU/ml [0.06–0.26], respectively; P = 0.0064).

A variety of factors including an HLA allele affect false negativity of IGRA. Assessment of these factors in tested populations would contribute to a secure and reliable interpretation of IGRA results.

P2663
The influence of a high negative control on the interpretation of Quantiferon Gold in Tube (QFN) results
William Ricketts, Graham Bothamley. Respiratory Medicine, Homerton University Hospital, London, United Kingdom

Introduction: The QFN result is a composite of a nil control, a mitogen positive control and a test sample (TB Ag) utilising ESAT-6, CFP-10 and TB 7.7 antigens. The result is defined as TB Ag minus nil control (positive ≥ 0.35 IU/ml). A strongly positive nil control (> 8 IU/ml) or failure of the positive control are defined as indeterminate results. We were concerned that high values obtained after antigen stimulation might be significant.

Method: All patients tested by QFT-GIT between 31/3/10 and 28/1/11 (=n=651) had the raw data from their test reviewed. Clinical diagnosis was examined in all those with a TB Ag result >0.35 IU/ml with a nil control high enough to bring the net result to <0.35 IU/ml or an indeterminate result.

Results: There were 39 (6%) instances of a net negative result despite a response to antigen, including four cases of active TB (4.7% of TB cases). Nil control results ranged from 0.1-3.07 IU/ml, with TB Ag levels up to 1.52 IU/ml.

Eight with a negative mitogen response included two cases of active TB, one of whom also had HIV. No cases were defined as indeterminate by virtue of a strongly positive negative control.

Conclusion: Reporting of a net result without a breakdown leaves clinicians vulnerable to missing cases of active TB. Sarcoïdosis, Crohn’s disease and bronchectasis, all diseases associated with polyclonal B cell activation, also appear to spontaneous interferon-gamma release.

P2664
Clinical history and IGRA is unreliable in the diagnosis of tuberculosis
William Ricketts, Graham Bothamley. Respiratory Medicine, Homerton University Hospital, London, United Kingdom

Aim: To monitor the stages in the diagnosis of tuberculosis (TB) and assess whether early interferon-γ responses can be helpful.

Method: Site – a TB clinic in a high incidence (58 per 100,000) area of London. 25 patients with suspected TB were followed through their diagnostic process. Patients were scored using a modified UCSD Clinical Suspicion of TB tool by two clinicians blinded to the patient’s identity and each other’s scores. Estimated risk of TB was made at four stages in the diagnostic process: with clinical data, TST,
HIV and IGRA (QuantiFERON Gold in Tube) results, after radiology; sputum smear; and blood tests. A decision as to whether to offer treatment was made at stage two and at each stage thereafter.

Results: Clinical history with IGRA was associated with a wide variation in estimated probability of TB (%QR 15-85%). As the diagnostic process progressed, accuracy increased (see figure) and inter-scorer variation decreased. Diagnosis of culture-negative TB was especially problematic. Despite differences between the two scorers there was no difference in the number of patients treated correctly after radiology (69% vs 54% TB; 92% vs 92% not-TB), sputum smear (67% vs 44% TB; 83% vs 92% not-TB) and other blood tests (77% vs 46% TB; 92% vs 92% not-TB).

Conclusion: Clinical history even with IGRA results is unreliable in the diagnosis of TB. New tests for culture-negative TB would be valuable.

P2665 Specificity of IGRA in Japan
Kazue Higuchi1, Yukie Sekiya1, Hitotoshi Igar‡1, Akira Watanabe2, Nobuyuki Harada†1.
1Department of Mycobacterium Reference and Research, Research Institute of Tuberculosis, Kiyose, Tokyo, Japan; 2Division of Control and Treatment of Infectious Diseases, Chiba University Hospital, Chiba-cho, Chiba, Japan

Objective: The specificity of IGRA with the population being tested. The specificity of T-SPOT® TB (T-SPOT) is generally reported to be lower than that of QuantiFERON® TB Gold In Tube (QFT-GIT). It is likely that studies carried out in developed countries include individuals with latent tuberculosis infection (LTBI). Therefore, we compared the specificities of T-SPOT and QFT-GIT in selected healthy subjects in Japan.

Subjects and methods: Blood samples were taken for both T-SPOT and QFT-GIT from university students who were selected according to stringent inclusion criteria and performed according to the manufacturer’s instructions. Blood samples for T-SPOT were kept overnight at room temperature and treated the next day with T-Cell Xtend prior to PMBC preparation. Blood samples for QFT-GIT were incubated within 16 hours after blood collection.

Results: University students with very low risk factors for TB infection were strictly selected, especially as there is no gold standard for LTBI. If studies do not adhere on plate wells even after intensive washing.

Conclusion: These observations suggested that live lymphocytes adhered on ELISA plate well may produce non-specific reaction, which result in higher IFN-γ values. Therefore, in order to obtain accurate results, QFT-GIT plasma samples after harvesting from QFT-GIT blood collection tubes should be re-centrifuged to spin down live lymphocytes.

P2668 Accuracy of IFN-γ and IP-10 detection for diagnosis of tuberculosis in children
Irene Latorre1,2, Jessica Diez3, Irene Mialdea1, Neus Alteza4, Cristina Pita5,6, Nuria Diez2, Amparo Escobano2, Morten Rhulwad1, Vicente Ausina3,5, Jose Dominguez3,6,4, Servi Microbiologia, Hospital Universitari Germans Trias i Pujol, Institut d’Investigacion en Ciencias de la Salud Germans Trias i Pujol, Badalona, Barcelona, Spain; 2Clinical Research Centre, Copenhagen University, Hvidovre Hospital, Copenhagen, Denmark; 3Unidad de Neurologia Infantil, Hospital Clinico Universitario de Valencia, Valencia, Spain; 4Unidad de Prevencion y Control de la Tuberculosis de Barcelona, CAP Draiassens, Barcelona, Spain; 5Unidad Autonoma de Barcelona, Bellaterra, Spain; 6CIBER Enfermedades Respiratorias, Instituto de Salud Carlos III, Badalona, Barcelona, Spain

Objective: Evaluate IP-10 detection for latent tuberculosis infection (LTBI) and active tuberculosis (TB) in children, comparing the results with IFN-γ detection.

Material and methods: IFN-γ released was determined by QuantiFERON-TB Gold In Tube (QFT). IP-10 was retrospectively detected in supernatants by an in-house ELISA and analyzed using preset cut-offs for positive (4.37ng/ml) and indeterminate (3.5ng/ml) IP-10 test result (Ruhwald, Latorre in prep).

Results: 45 pediatric patients were classified in 3 groups:
Group 1: 10 children diagnosed with active TB, with a Mycobacterium tuberculosis positive culture or active clinical TB.
Group 2: 15 children enrolled during LTBI screening studies, with a positive QFN. Group 3: 20 healthy control children, with a negative QFN.

Sensitivities of both IFN-γ and IP-10 assays were 50% (Group 1). Specificity of IP-10 detection was 100% (Group 3). Combining both cytokines the sensitivity improved to 60%, without a compromise of the specificity. Percentage of positive IP-10 responders among children from group 2 was 66.7%. Two children with negative IP-10 assays from this group had QFN positive borderline results. Global concordance between assays was 82% (x=0.624). IP-10 released after specific antigen stimulation in active TB patients was significantly higher than in healthy controls (p<0.007), this was not seen for IFN-γ (p=0.19).

Conclusions: IFN-γ and IP-10 sensitivity is low, but combination of both cytokines increased sensitivity without a compromise of the specificity. Lowering IP-10 and IP-10 cut-offs could improve the sensitivity in children. Concordance between both assays is good. IP-10 could be an alternative marker for LTBI and active TB in children.
281. Extrapulmonary tuberculosis and surgical interventions

P2669
Serum and pleural fluid cytokines in pleural tuberculosis with and without lung parenchyma involvement
Marcia Seiscento 1, Francisco Vargas 1, Roberta Sales 1, Leticia Texeira 1, Juliana Puka 1, Milena Accenio 1, Leila Antongiorgi 1, 2, Pulmonary Division, Pleura Laboratory, Heart Institute (InCor) – University of Sao Paulo Medical School, Sao Paulo, Brazil; 2 LIM 03 – Clinical Laboratory, Pathology Department, University of Sao Paulo Medical School, Sao Paulo, Brazil

Pleural tuberculosis (PT) is frequent form of extrapulmonary disease. In the pleural cavity, activated T lymphocytes produce cytokines in response to the mycobacteria and its antigens. Lung parenchyma can be concomitantly involved in up to 40% of cases.

Objective: To compare serum (S) and pleural fluid (PF) levels of inflammatory mediators in patients with PT in order to verify if lung-associated involvement influences the magnitude of the inflammatory response.

Methods: A prospective study of 39 patients with pleural (20) or pleuropulmonary (19) tuberculosis was conducted. IL-8, VEGF, TNF-α, and TGF-β1 were quantified by ELISA.

Results: The proinflammatory cytokines TNF-α and IL-8 were higher in PF than in S of 5 patients with the pleural form, while only IL-8 was higher in the pleuropulmonary form. Only PF TNF-α was capable to discriminate both forms of TB disease.

PF = Pleural fluid; S = serum.

Conclusion: Although TNF-α levels had been higher in the PF of patients with PT and lung involvement, we suggest its dosage in association with computed tomography in order to identify these patients, since they represent potential source of infection and disease spread.

P2670
The use of ADA liquid level in diagnosis of tuberculous pleurisy in countries with low incidence of tuberculosis
Perlat Kapisyzi, Dhimitraq Argiri, Anila Aiklo, Jeta Beli, Ylli Vakeflliu, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, Faculty of Medicine, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania Lung Diseases, University Hospital Lung Diseases, Tirana, Albania.

The aim: To study the use of cut off values of fluid ADA level in differential diagnosis of tuberculous pleurisy.

Materials and methods: 121 consecutive patients with pleural effusion were prospectively studied. The study included 82 males, 39 females with a mean age of 59.3±17 years. Exudative effusions were classified as malignant pleural effusions, 39 (39.8%), TB pleural effusions, 39 (39.8%), parapneumonic pleural effusions, 20 (20.4%). The photometric method was used.

Results: In tuberculous group the mean of ADA level was 122.4±48.3 UI/L. No patients of age < 35 years had ADA level under 40 U/L. In tuberculous group the mean of ADA level was 122.4±48.3 UI/L. No patients of age < 35 years had ADA level under 40 U/L. The sensitivity of ADA in TB effusions at cut-off > 40 U/L was 89.7%, specificity 28.8%, PPV 54.5%.

P2671
Evaluation of real time polymerase chain reaction in rapid diagnosis of exudative tubercular effusions
Balakrishnan Menon 1, Charanjiet Kaur 2, 1 Pulmonary Medicine, Vallabhbhai Patel Chest Institute, New Delhi, India; 2 Biochemistry, Vardhman Mahavir Medical College, New Delhi, India

Introduction: Exudative effusions are a common manifestation of tuberculosis. Real time Polymerase Chain Reaction (RT-PCR) has superior sensitivity, specificity, lower contamination and reduction in time to result in comparison to conventional methods.

Aims and objectives: To evaluate the sensitivity of RT-PCR in cases of exudative effusions due to tuberculosis.

Methods: RT-PCR was performed in 153 patients of exudative tubercular effusions. They consisted of 127 pleural effusions, 21 ascitic fluid and 5 pericardial effusions. All patients had positive Mantoux test with high protein and lymphocyte predominance in effusion. The subjects were positive by either ZN staining, Culture for AFB by growth on LJ medium or BACTEC, Interferon γ (INF-γ) or Adenosine Deaminase (ADA).

RT-PCR was performed by detecting amplification reaction for the insert element IS6110 of the Mycobacterium tuberculosis complex (Biotech-QT, Biotools Labs, Spain) using a real-time centrifugal amplification system (Rotorgene-3000, Corbett Research, Australia).

Results: RT-PCR was positive in 134 of the 153 cases of exudative tubercular effusions (Sensitivity 87.6%). It was positive in 114 of 127 cases of pleural effusion (Sensitivity 89.7%), 17 out of 21 cases of ascitic and 3 of the 5 cases of pericardial effusion. The sensitivity of ZN staining was 23.5%. Culture by LJ medium was 33.9% and BACTEC was 51.3%. ADA showed positivity in 144 of 153 cases (Sensitivity 94.4%) and INF-γ showed sensitivity of 83.6%.

Conclusion: Real time PCR is valuable in the diagnosis of exudative tubercular effusions with a sensitivity of 87.6%. The diagnostic efficiency could be increased by combining RT-PCR with ADA or INF-γ.

P2672
Adult thoracic empyema: A comparative analysis of tuberculous and nontuberculous etiology in 75 patients
Somenath Kundu, Subhreeta Mitra, Subhashis Mukherjee, Souraya Das. Respiratory Medicine, IPGMEAR and SSKM Hospital, Kolkata - 700 020, West Bengal, India Respiratory Medicine, Midnapore Medical College and Hospital, West Midnapore, West Bengal, India Respiratory Medicine, R.G. Kar Medical College & Hospital, Kolkata - 700 004, West Bengal, India Respiratory Medicine, Calcutta Medical College & Hospital, Kolkata, West Bengal, India

Background: Thoracic empyema is a disease of significant morbidity and mortality in the developing world where tuberculosis is a common cause. Clinical outcomes in tuberculous empyema are complicated by fibrocavitary disease and bronchopleural fistula. A prospective study to compare the clinical profiles and outcomes of patients with tuberculous and nontuberculous empyema was performed.

Materials and methods: A prospective study of adult nonsurgical thoracic empyema cases admitted in a teaching hospital in India was performed over a period of 18 months. A comparative analysis of clinical characteristics, treatment modalities, and outcomes of patients with tuberculous and nontuberculous empyema was carried out.

Results: 75 cases of empyema were seen during the study period, of which 46 (61.3%) were of nontuberculous etiology while tuberculosis constituted 29 (38.7%) cases. Among the nontuberculous empyema patients, Staphylococcus aureus (11, 23.9%) was the most frequent pathogen isolated. Tuberculous empyema was more frequent in younger population compared to nontuberculous empyema (mean age of 32.7 years vs. 46.5 years). Duration of illness and mean duration of chest tube drainage were longer (48.7 vs. 23.2 days) in patients with tuberculous empyema. Also the presence of parenchymal lesions and bronchopleural fistula often requiring surgical drainage procedures was more in tuberculous empyema patients.

Conclusion: Tuberculous is a common cause of empyema thoracis in a developing country. Tuberculous empyema differs from nontuberculous empyema in the age profile, clinical presentation, management issues, and has a significantly poorer outcome.

High yield of liquid mycobacterial culture in pleural fluid and tissue
Florian von Groote-Blingdinger1, Kiki Chung2, Corne Rautenbach3, Maurizio Bemasco1, Cornelia Koelega1, Elizabeth Wasserman1, Chris Bullinger1, Andreas Diacos1.

**Method:** We investigated 66 consecutive patients with exudative effusions of suspected inflammatory or infectious nature in a single session and directly compared the yields for a diagnosis of TB of a spot smear and smear, culture pleural fluid ADA and cell count, low volume (5ml) and high volume (100ml) liquid mycobacterial culture and pleural biopsy histology and culture. A final diagnosis of TB was established in 50 patients (75.8%) by histological proof of granuloma-tous inflammation or any positive culture. All TB cultures were performed in an automated liquid culture system (MGIT 960, Becton Dickinson).

**Results:** Available results among these 50 patients indicated the following respective yields:
22/34 (65.7%) for spot smear (sputum positive: 17.1%; culture positive: 61.3%); 44/46 (95.7%) for pleural fluid adenosine deaminase (ADA) ≥ 50 U/l; 32/41 (78%) for ADA ≥ 50 U/l combined with lymphocyte predominance; and 31/46 (67.4%) for pleural fluid MGIT culture (low volume: 56.5%; high volume: 63%; p>0.45).

**Conclusion:** Liquid mycobacterial culture has an exceptionally high yield in both pleural fluid and tissue and should be routinely used.

Pleural tuberculosis: A study of 46 cases
Besma Hamdi, Chiraz Aichouia, Samef Ferh, Samira Bhamdi, Zied Moatamiri, Sahabbi Daboussi, Ghaya Laaribi, Mounes Khadhraoui, Rzaieg Cheikh.

**Pleural tuberculosis (TB) remains a diagnostic challenge. It is the most frequent extra pulmonary localisation.**

To focus on clinical, radiological, biochemical and histopathological characteristics of pleural TB and the sensitivity of the various diagnostic tests. We studied retrospectively 46 patients in whom pleural TB were diagnosed in our military department. The mean age was 29.8 year (12 to 78 year). 78.2% were male. A retrospective study concerned 117 cases of tuberculous pleurisy in Blida between 2005 and 2009.

**Aims and objectives:** The aim of our study is to clarify the characteristics of the epidemiology, diagnosis, treatments and outcome of pleural tuberculosis and also to clarify the predisposing factors.

**Methods:** Our retrospective study concerned 117 cases of tuberculous pleurisy supported for 05 years from 2005 to 2009 among a total of 764 cases followed for extrapulmonary tuberculosis at the Blida tuberculosis control unit.

**Results:** Our study has assembled 67 men and 50 women with a mean age of 30 years. Comorbidities in number of 7 are represented by 4 cases of metabolic syndrome. The impairment is most often right sided in 57.2% of cases, and bilateral in 11% of cases. The investigations carried out showed a tuberculin allergy in 31.6% of cases. The histology diagnosis was mainly contributing in 42.7% of cases by finding caseofolicial tuberculosis, and in 23.9% of cases by a tuberculoid inflammation. The antibiotic treatment was started in all cases with a favorable outcome to the healing in 50.4% of cases and with sequelae in 45.2% of cases. However, we noted 4 cases of lost sight and one patient transferred for therapeutic monitoring.

**Conclusion:** The management of pleural tuberculosis is correlated by the improvement of diagnostic methods, certainty including pleural biopsy and thoracoscopy.

Features of diagnostics for exudative pleurisy of tuberculosis etiology
Kazim Mukhamedov1, Avar Muzrabezov1, Sherali Massayev1, Stanislav Kostromin1, Fuzilat Ismailova1, Elmira Khudayberdieva1. 1Faculty of Pathiologics, Tashkent Medical Academy, Tashkent, Uzbekistan; 2Faculty of Preparation of General Practitioners, Tashkent Medical Academy, Tashkent, Uzbekistan.

**Background:** To study the features of diagnosis and therapy for exudative pleurisy of tuberculosis etiology (EPTE).

**Materials and methods:** There analyzed 122 cases with EPTE. Men were 76 (62.3%), women-46 (37.7%), aged between 17 to 69 years. 1-group included 59 (48, 4%) patients who had revealed/or suspected EPTE based on clinical and X-ray data after admitting in out-patient clinic or antituberculous dispensary. 2-group included 63 (51.6%) patients who primarily were hospitalized in general medical network (GMN) clinics and underwent erroneous treatment for different lesions and physiotherapy. The outcome was favourable in all cases. 45,6% of patients developed pleural thickening 6-12 months after beginning of treatment. TB, whatever mucosal and extrathoracic dissemination, remained in 1 of 9 in group C and 3 of 12 in group D, and moderate RPT were reached preferentially the young adults.

**Results:** Focal TB was diagnosed in 55 (45, 1%), infiltrative –34 (27, 9%), disseminated- 11 (9, 0%), pleural TB - in 8 (6,6%), intrathoracic lymphatic nodes - in 14 (11, 5%). Bronchoscopy revealed active specific changes in 34 from 63 examined patients including rough deformed cicatrical changes in 11 patients. Mantoux test was positive in 84 (68, 9%). M.Tuberculosis (MBT) were found in 105 (86,1%). Revolt positive test was revealed in exudates.

**Conclusion:** Exudative pleura diagnostics is a challenge. It should be paid an important place to general medical network doctors’ high concern in regard to TB.

Advantage of chest tube drainage in tuberculosis pleurisy without active pulmonary tuberculosis
Moon Jun Na, Ji Hye Kim, Yu Mi Lee, Sun Jung Kwon, Ji Woong Son, Eugene Chiu. Department of Internal Medicine, Konuyang University College of Medicine, Daejeon, Republic of Korea.

**Introduction:** Early effective drainage may hasten clearance of pleural effusion and reduce the occurrence of residual pleural thickening (RPT) in patients with symptomatic loculated tuberculous pleurisy (TBP).

**Objectives:** The effects of a large-bore chest tube drainage (CTD) with a small-bore percutaneous drainage (PCD) or no-drainage group in TBP were compared.

**Methods:** We reviewed retrospectively the records of TBP patients without active pulmonary TB lesion that diagnosed by thorascopic biopsy or high ADA of pleural fluid from 2005, January to 2010. December. All patients were treated with anti-TB medication over 6 months. We divided into 4 groups (group A: no-drainage (n=7), group B: CTD without loculation (n=10), group C: CTD with loculation (n=9), group D: PCD with loculation (n=12)). We compared the RPT, days of hospitalization and tube inserted between group A vs B, and group C vs D.

**Results:** In non-loculated TBP patients, mild RPT were remained in 1 of 7 in group A and none of 10 in group B. In loculated TBP patients, mild RPT were remained in 1 of 9 in group C and 3 of 12 in group D, and moderate RPT were found in only group D (2 in 12). Days of hospitalization were 8.7±1.5 in group A vs 10.6±3.3 in group B, and 16.7±10.2 in group C vs 10.4±6.9 in group D. Days of tube inserted were 6.8±2.5 in group C vs 4.6±2.8 in group D.

**Conclusion:** Although using a large-bore CTD needs longer days of admission and tubing, CTD was more effective than PCD in RPT reduction of loculated TBP. CTD was not advantageous to drainage without diagnostic thorascoscopy in RPT reduction of non-loculated TBP, in addition to definite diagnosis by thorascopic biopsy.

Specific pulmonary lesion in patients with tubercular spondylitis (TS)
Vuchaslav Zuharlevae, Galina Visalievae, Pavel Gavrilov. 1Laboratory of Genetic Methods of Research, The Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation; 2Surgery of Extra-Pulmonology TB, The Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation; 3Laboratory of Genetic Methods of Research, The Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation.

120 patients with active pulmonary tuberculosis (PT) and diagnosis of TS were studied. It was the patients at the age from 18 to 72 years old. The patients were examined due to complaints of spinal pain. These were mostly the lesions of...
Tuberculous spondylitis as a mirror of a severe epidemic situation
Ekaterina Kulhavchenya, Eugeniu Koveshenkova. Urological, Research TB Institute, Novosibirsk, Russian Federation

Introduction: Tuberculosis of bone and joints (BJTB) is one of the leading forms among extrapulmonary TB. The aim was to estimate a spectrum of extrapulmonary TB in Novosibirsk – the capital of Siberia, and reveal a tendency in BJTB.

Material and methods: Statistical reports were estimated, also 177 patients with BJTB were enrolled in study.

Results: Among all cohort of extrapulmonary TB female patients was 50.9% and male patients - 49.1%, but in BJTB ration female:male was 1:2.

The share of BJTB in extrapulmonary TB increased from 3.3% in 1992 up to 28.0% in 2006, and reached 48.6% in 2008. Among BJTB tuberculous spondylitis prevails (72.2%), mostly complicated by neurological disorders and paravertebral abscesses and combined with TB of other organs. Nevertheless in 65.5% only 2 vertebras were involve in TB process. In 17.2 debut of disease was acute or sub-acute, but diagnostic took 14.1 months on average. One of the main reason is poor alertness physician for tuberculosis and late X-ray examination. Typical X-ray picture of TB spondylitis is shown on figure 1.

Poverty, unemployment and alcoholism resulted in poor efficiency of the therapy in 45.7% patients. Patients endomorphic body type in 8.5 times more likely to have delayed consolidation.

Conclusion: In regions with severe epidemic situation it is necessary always to keep in the mind TB in patients with back pain and make X-ray examination as soon as possible.

P2680
Tuberculous myotic aneurysm of aorta: A rare complication
Parameswari Rekha, Parackal Sukumaran, T.K. Jayakumar, Kummannoor Venugopal. Internal Medicine, Medical College, Kottayam, Kerala, India

39 year old male was started on antituberculous treatment based on symptoms and miliary shadows on chest x-ray. 2 months later he had persistent abdominal pain. Abdominal examination revealed a pulsatile palpable mass with brux. Ultrasound &CT abdomen confirmed aneurysmal dilatation of aorta from hiatus to bifurcation with infra renal involvement. No leak or dissection.

Surgical exploration revealed aneurysm with areas of impending rupture, clots & caseous material. Endoaneurysmal graft repair surgery was done. Clot was teem-
ing with AFB. Postoperatively patient had paraplegia due to ischemic myelopa-thy.

Tuberculous mycotic aneurysm of aorta is a rare complication with poor prognosis. Less than 50 cases have been reported. Combined medical & surgical therapy is advised.

Tuberculosis in residual pleural cavity after segmental pulmonary resections and its surgical treatment
Tulkin Kariev, Sunnatilla Abulkasimov, Sherdzod Rahmonov. Thoracic Surgery Department, National Centre of Phtisiology and Pulmonology, Tashkent, Uzbekistan

Repeated operations on account of development of tuberculosis in the residual pleural cavity after segmental resections were performed in 54 patients (males – 35, females -19) in ages between 17 and 46. Residual cavity due to incompletely lung spread developed on the left in upper segments of thoracic cage in 30 patients, on the right – in 24 patients after segmental (9), combined resections (16), lobectomy (26) and bilobectomy (3) on account of fibrous-cavernous tuberculosis. Tuberculosis in residual cavity was diagnosed in 6 months - 1 year after the operations in 28 patients, in 3 years – in 19, in 4-5 years – in 7. Bacteria excretion in sputum was detected in 41 patients (75.9%). After pre-operative chemotherapy and general treatment, lobectomy was performed in 1 patient, pulmonectomy - in 15, thoracoplasty with myoplasty of residual cavity – in 38. Good effectiveness of repeated operations stated in 43 patients (79.6%), unsatisfactory results due to the exacerbation of bronchoalveolar fistula and pleural empyema - in 7 (12.9%). Lethality in 4 patients (7.5%) occurred from the progress of bronchial fistula, plural empyema and pulmonary tuberculosis.

Conclusion: Tuberculosis in residual pleural cavity after segmental pulmonary resections is a heavy pulmonary and pleur al pathology characterized by chronic course. Repeated operations – pulmonectomy and thoracoplasty with myoplasty of the residual cavity – are highly effective and allow healing 82.1% of patients.

P2684

Asymptomatic oesophageal and bony involvement in an HIV-negative female with pulmonary TB
Rawya Ahmed1, Simon Allen 2, Parthipan Kanthapillai1.

Tulkun Kariev, Sunnatilla Abulkasimov, Akrat Giresash. Thoracic Surgery Department, National Centre of Phtisiology and Pulmonology, Tashkent, Uzbekistan

A 44 year-old lady of Afro-Caribbean origin presented with a 4-months history of productive cough, night sweats and weight loss. There were no other symptoms or significant medical history. Chest auscultation revealed right-sided apical bronchial breathing and coarse crepitations mid to lower zones. Chest radiography confirmed apical cavitation and right-sided consolidation. Sputum microscopy and molecular polymerase chain reaction test showed fully sensitive mycobacterium tuberculosis (TB). Thoracic computed tomography revealed a pneumomediastinum, oesophageal perforation and gaseous permeative infiltration of T1-T3 vertebrae.

A human immunodeficiency virus (HIV) screen was negative. Oesophageagastrodrodenoscopy was normal apart from a 2cm punched out lesion at 23cm of the oesophagus. Quadruple anti-TB therapy and enteral feeding were established via a percutaneous gastrostomy tube to avoid mediastinitis and allow healing. Clinically occult oesophageal perforation and bony involvement in the absence of HIV infection or miliary TB has not been previously described. The mechanism of this is unclear, but may involve a coseating mediastinal lymph node.

P2685

Surgical treatment of first found pulmonary tuberculosis at ineffectiveness of DOTS therapy
Tulkin Kariev, Sunnatilla Abulkasimov, Akrat Giresash. Thoracic Surgery Department, National Centre of Phtisiology and Pulmonology, Tashkent, Uzbekistan

Surgeries were performed in 43 patients (males-27, females-22) in ages between 18-53 years old. All the patients had first found destructive tuberculosis of lungs, and ineffectiveness of DOTS therapy was stated in them. During 2-3 months, 23 patients received chemotherapy in hospital (isoniazid, rifampycin, pyrazinamide, ethambutol or streptomycin) and ambulant therapy (isoniazid and rifampycin) under the 1st category of DOTS during 4-6 months. After diagnosing pulmonary tuberculosis, the treatment according to the 1st DOTS category (intensive phase-2-3 months, supporting phase 4-6 months) was received by 20 patients in the first phase. Because of ineffectiveness of chemotherapy, the treatment was continued under the 2nd DOTS category intensive phase chemotherapy with 5 preparations (H, R, Z, E and S) during 3-4 months and ambulant phase (isoniazid, rifampycin, ethambutol) during 6-8 months. Ineffectiveness of DOTS based chemotherapy-continuing bacteria excretion, presence of pulmonary destruction served as indication to surgical treatment. Segmental pulmonary resection was carried out in 7 patients, lobectomy in 12, pulmonectomy in 24. Good clinical effect of performed operations was reached in 40 patients (93.0%). Unsatisfactory results (bronchial fistula and plural empyema) were stated in 2 patients (4.7%). Lethality in 1 patient (2.3%) was caused by the progress of pulmonary tuberculosis and pleural empyema.

Conclusion: When DOTS chemotherapy is ineffective, surgical treatment of first found destructive pulmonary tuberculosis is an important and effective final stage of complex therapy that prevents transition of patients into the group of chronic patients.

P2686

Method of treatment of destructive tuberculosis of single lung with extensively drug resistant mycobacteria tuberculosis
Irina Tabanukova, Alexey Elkin, Mikhail Kobuk, Nikolay Yakushenko. Endoscopy, Research Institute of Phtisiopulmonology, Saint-Petersburg, Russian Federation

Treatment of patients with TB with total defeat of one lung and presence of destruction in the other, with a constant allocation of extensively drug resistant Myc. tuberculosis (XDR MBT), remains extremely weak. Under these conditions, the role of surgical and endoscopic therapies is rising.

Objective: To improve treatment of patients with fibrous-cavernous tuberculosis of a single lung with XDR MBT due to valvular lung volume reduction (VLVR) and local extrapulmonary thoracoplastics.

Material and methods: The treatment was performed in 13 patients (10 men, 3 women) of fibrous-cavernous tuberculosis of a single lung with XDR MBT. The patients’ age ranged from 30 to 54 years. Disease duration ranged from a half to 8 years, all patients were smear.

The essence of the proposed method is to use endobronchial non-return valve. Valve ensures the smooth discharge of air, sputum, bronchial content in the ex- hale, and cough. Inverse of air in the lung lesions did not occur. Thus, gradually hyperventilation was being reached, until atelectasis of lung tissue. VLVR performed during treatment with reserve anti-TB drugs. In 6 patients with VLVR was supplemented extrapulmonary thoracoplastics.

Results: Time that valve spent in the bronchus depended on the rate of cavity closure and cessation of bacteria and ranged from 7 to 274 days. Abacillation was achieved in 100% of patients, the cavity was closed in 76.9% of patients.

Conclusions: The proposed method of treatment of patients with tuberculosis enables us to reduce lung cavity and reach abacillation patients with XDR MBT in the absence of the effect of chemotherapy with reserve anti-TB drugs and a high risk of single lung resection.

P2687

Artificial therapeutic pneumothorax induced by video assisted thoracoscopic surgery – Surgical treatment option in the modern management of pulmonary tuberculosis – Case presentation
Olga Duniala1, Cristian Paleru1, Adrian Istrate 1, Cristina Popa2, Genoveva Cadar3, Ioan Cordos 1.

The essence of the proposed method is to use endobronchial non-return valve. Valve ensures the smooth discharge of air, sputum, bronchial content in the exhale, and cough. Inverse of air in the lung lesions did not occur. Thus, gradually hyperventilation was being reached, until atelectasis of lung tissue. VLVR performed during treatment with reserve anti-TB drugs. In 6 patients with VLVR was supplemented extrapulmonary thoracoplastics.

Results: Time that valve spent in the bronchus depended on the rate of cavity closure and cessation of bacteria and ranged from 7 to 274 days. Abacillation was achieved in 100% of patients, the cavity was closed in 76.9% of patients.

Conclusions: The proposed method of treatment of patients with tuberculosis enables us to reduce lung cavity and reach abacillation patients with XDR MBT in the absence of the effect of chemotherapy with reserve anti-TB drugs and a high risk of single lung resection.

P2688

Artificial therapeutic pneumothorax induced by video assisted thoracoscopic surgery – Surgical treatment option in the modern management of pulmonary tuberculosis – Case presentation
Olga Duniala1, Cristian Paleru1, Adrian Istrate 1, Cristina Popa2, Genoveva Cadar3, Ioan Cordos 1. 1Thoracic Surgery, National Institute of Pneumology, Bucharest, Romania; 2Pneumology, National Institute of Pneumology, Bucharest, Romania; 3Anesthesiology and Intensive Care, National Institute of Pneumology, Bucharest, Romania

Introduction: Pulmonary tuberculosis (PTB) multidrug resistant (MDR) is still a major global health problem. After the discovery of antimycobacterial therapy the use of therapeutic pneumothorax (TP) decreased. Increased prevalence of PTB
TD, multiple adverse effects and high cost of TB drugs have returned the attention to this old method of treatment.

**Objective:** The aim of this paper is to highlight the usefulness of TP induced by video assisted thoracoscopic surgery (VATS) as adjuvant therapy in cavitary PTB MDR.

**Method:** A 27-year-old, male patient was diagnosed with cavitary MDR PTB. Because the individualized treatment has proved ineffective and the patient denied resection surgery, we performed repeated intrapleural air insufflations. In the absence of satisfactory lung collapse due to pleural adhesions, it was decided to associate a minimally invasive surgical procedures – VATS. Multiple adhesions localized to the right upper lobe and 6 right segment were destroyed (monopolar cautery, LigaSure) with full release of the lung. Pleural cavity was controlled with a single tube which was maintained clamped until his removal in the first postoperative day.

**Results:** The surgical procedure was well tolerated without major complications and with sufficient parenchymal collapse, subsequently maintained by periodic air insufflations. After 4 months the patient was smear and culture negative and the cavity was reduced in size.

**Conclusions:** In carefully selected cases, TP is an effective adjuvant procedure in the treatment of MDR PTB. VATS is useful for lysis of adhesions when lung collapse is insufficient.

**P2688**

**A case of breast tuberculosis in developed country with low incidence of tuberculosis**

Veronika Polcova, Martina Vasakova, Emilia Kopecka, Jiri Homolka. Pneumological Department, 1st Medical Faculty and Thomayer Hospital, Prague 4, Czech Republic

The Czech Republic belongs to the countries with low incidence of tuberculosis We present a very rare case of breast tuberculosis (TB) resembling a breast malignancy or non-specific abscess to document the possibility of misdiagnosis and diagnostic challenge.

**Objectives:** Differential diagnosis of a painful, firm lump in a breast of 81 years old female. Review of important issues relating to the diagnosis, clinical features, and management of breast tuberculosis.

**Case presentation:** A 81 year-old female without medical history of TB was hospitalised for a painful, firm lump in her right breast. Neither the mammography nor histology confirmed the diagnosis of breast carcinoma. Chest radiograph, chest CT scans and sputum smear or cultivation did not prove lung TB. Bronchoscopical examination showed atrophic bronchial structures without bronchial granulations or fistulas. Both bronchial biopsy and bronchial aspirate were negative for Mycobacterium tuberculosis. The pathologists in the biopsy of the breast lesion described a combination of epitheloid cell granulomas and caseous necrosis. Microscopic analysis of the lump pus confirmed the presence of acid-fast bacilli. Lump pus cultivations were positive for Mycobacterium tuberculosis. A four-drug regimen (isoniazid, rifampicin, ethambutol, and pyrazinamide) and local lavage described a combination of epitheloid cell granulomas and caseous necrosis. Microscopic analysis of the lump pus confirmed the presence of acid-fast bacilli. Lump pus cultivations were positive for Mycobacterium tuberculosis. A four-drug regimen (isoniazid, rifampicin, ethambutol, and pyrazinamide) and local lavage with AT drugs led after two months to the remission of the lump and healing of the fistula.

**Conclusion:** In breast TB the clinical and radiological features are not specific. The misdiagnosis with the carcinoma of the breast or non-specific abscess is possible. Even in countries with the low incidence of tuberculosis the TB of the breast can be observed.
almost doubled from 4.9% to 8.5%, mostly due to co-morbidity with HIV. Bone and joints TB increased from 20.3% to 30.8%, and among this group especially TB spondylitis with neurological disorders, the most debilitating form of the disease. The proportion of UGTB decreased from 42.9% to 33.9% with change in gender distribution from male: female of 1:2.9 in 1999 to 1:1.8 in 2008. In contrary, there was a decrease of peripheral lymph nodes TB from 16.7% to 11.1% in 2009. TB of the thymus and the thymus still frequent. At the end of the last century out of TB in Siberia accounted for 7.4% and in 2008 (in 2009 listed in “others”) for 4.4% of the patients with EPTB. Accordingly, in 1999 other form of TB accounted for 7.8% and in 2009 4.9%.

Conclusion: In Siberia there is still a severe epidemic situation now. Low living standard, poverty, as well as poor knowledge and ignorance of EPTB both by medical service and population lead to late diagnosis of EPTB with complicated multi-organ forms.

P2692 Prostate biopsy for diagnostic of prostate tuberculosis
Denis Kholtobin, Ekaterina Kulchavenya. Urogenital, Research TB Institute, Novosibirsk, Russian Federation

World Health Organization (WHO) recognized tuberculosis (TB) as a global problem, but meant TB as a whole, mostly pulmonary TB, although 77% men died from TB, had prostate TB, mostly overlooked alive. Prostate TB has an importance due to: 1. It is a sexually transmitted disease; 2. It leads to infertility; 3. It results from sarcoidosis, but meant TB as a whole, mostly pulmonary TB, although 77% men died from TB in Siberia accounted for 34.4% had active TB of another localization, mostly – pulmonary. Results of PCR: HPV – 10.3%, Ureaplasma – 2.2%. Mycobacteria culture was positive in 6.9%. Pathomorphologically in 94.6% inflammation was found, in 65.6% – fibrosis, in 9.7% – intraprostatic neoplasia, in 5.4% - cancer, in 27.4% - TB.

Conclusion: The diagnosis of prostate TB is a very difficult task, because clinical features and laboratory signs are not-specific. Pathognomonic symptom is a cavern, but caverns mean late-diagnosed complicated form, cavernous prostate TB can’t be cured neither chemotheraphy nor by surgery. Prostate TB in early infiltrative non-cavernous stage may be diagnosed by PCR, culture or pathomorphology. Possibility of these methods alone is poor, it is necessary to use its in combination.

P2693 Masks of kidney tuberculosis
Denis Kholtobin, Ekaterina Kulchavenya. Urogenital, Research TB Institute, Novosibirsk, Russian Federation

Introduction & objectives: Urogenital tuberculosis (UGTB) is the second most common form of TB in countries with a severe epidemic situation and the third most common form in regions with low incidence of TB. 77% of men who died from tuberculosis of all localizations had prostate tuberculosis which had mostly been overlooked during their life time. In actual figures, this means about 19,000 men yearly in Russia. The main reason for late diagnosis is an atypical clinical feature of UGTB, it courses under the mask of another disease.

Material & methods: We analyzed 816 history cases of UGTB patients to estimate clinical features.

Results: Most common complains were flank pain (56.8%), dysuria (48%) and re nale colic (24%); laboratory signs - pyuria (78%) and haematuria (34%). Patients were treated by urologists or GPs with diagnoses pyelonephritis (27%), cystitis (43%), cancer (8%) or urolithiasis (22%) during 5.6 years on average. Positive smear was in 17% and positive culture of Mycobacterium tuberculosis was in 44%: 64% were diagnosed in late complicated cavernous stage, when surgery is necessary – and 96% of operations were nephrectomy due to total involvement of kidney tissue.

Conclusions: Most common masks of UGTB are pyelonephritis, cystitis and urolithiasis. UGTB presents non-specific symptoms and laboratory findings, ex-cept for positive MIB culture, but only about 44% cases are culture-positive. This is one of the main reasons for late and poor diagnosis of UGTB. The significance of UGTB may be considerable when the high prevalence of overall TB and the asymptomatic nature of UGTB are taken into account.

P2694 The reasons for late diagnosis of nephrotuberculosis
Denis Kholtobin, Ekaterina Kulchavenya. Urogenital, Research TB Institute, Novosibirsk, Russian Federation

Introduction: In fact nephrotuberculosis (NTB), like any other infectious disease, potentially can be cured by chemotherapy. But this statement is valid only for early diagnosis; actually more than 60% new-revealed patients are diagnosed late, in cavernous stage, when surgery is indicated. The aim of study was to identify the reasons for late diagnosis of NTB.

Material and methods: 167 patients with nephrotuberculosis were enrolled in study. History cases were detailed analyzed to determine clinical features, previous therapy and a level of kidney destruction in time of diagnosis tuberculosis.

Results: 11 (6.6%) had acute onset like pyonephrosis, and were operated without previous therapy. Diagnosis was verified after surgery. Other 156 had chronic NTB with clinical features specific for chronic pyelonephritis and cystitis. 59 (37.8%) were revealed in small-destructive stage of nephrotuberculosis - papillitis. 47 patients among them (79.7%) were treated with optimal antimicrobials, that means drugs don’t influence on Mycobacterium tuberculosis (nitrofurantoin, gentamycin, amoxycillin, cephaloridin). Average time of correct diagnosis in this group was 4.7 months. 97 patients in cohort (62.2%) had cavernous NTB. The main reason was prescription to 75.3% amycacin, rifampicin and fluquinolones that disguised, changed clinical features of NTB and resulted in long time of diagnostic – on average 27.4 months.

Conclusion: Nephrotuberculosis often mimics at chronic pyelonephritis and cystitis. Using amycacin, rifampicin and fluquinolones for therapy these diseases before excluding of NTB resulted in late diagnoses cavernous forms of NTB. Probably this statement is actual for region with severe epidemic situation, like Siberia.
P2697
Mycobacterial characteristics of tuberculous lymphadenitis in a tertiary care hospital in India
Madhav Kale 1, Parag Khatkarav 1, Meenakshi Satpute 2, Nilima Telang 2, Sneha Wagh 1
1 Chest, 2Microbiology, K.E.M. Hospital, Pune, Maharashtra, India

Introduction: Tuberculous lymphadenitis (TBLN) shows geographical variations. In developing countries, Mycobacterium tuberculosis is common pathogen, while in developed countries nontuberculous mycobacteria are common pathogens. Bacteriological studies are necessary to confirm the diagnosis and for proper management.

Aims: To study: 1. Mycobacterial smear and culture positivity rate in histologically proven tuberculous lymph nodes. 2. Cultural characteristics of mycobacteria. 3. Prevalence of multidrug resistant (MDR) and extensively drug resistant (XDR) tuberculosis.

Methods: Lymph node smear for acid-fast bacilli (AFB) was done by Ziehl-Neelsen method, and culture was done by radiometric method (MB/Bact 240 system). Sensitivity tests for antitubercular drugs were performed by conventional method on LJ medium.

Results: During Jan. 2005 to Sept. 2010, mycobacteria were grown on 74 cultures. 72 cultures (97.3%) were positive for Mycobacterium tuberculosis, and only 2 (2.7%) were positive for M. Kansui. In 89 histopathologically proven positive cultures of TBLN, 56 (62.9%) cultures were positive and AFB smear positive in 21 (23.6%) patients. In 18 culture positive patients, histopathology of lymph nodes was not available. MDR TB was present in 12 (16.2%) cultures. XDR TB was not detected.

Conclusions: 1. Mycobacterium tuberculosis is the common organism in TBLN. 2. In histopathologically proven patients with TBLN, mycobacterial smear and culture positivity rates were 23.6% and 62.9% respectively. 3. MDR TB was present in 16.2% of patients.

A prospective observational study to determine the adequacy of 6 months antitubercular therapy in tuberculosis mediastinal lymphadenopathy
Akash Prasad, Rohan Thakur, Madhulika Thakur, Nalin Joshi. Chest and Tuberculosis, Hospital for Chest and Tuberculosis, SMS Medical College, Jaipur, Rajasthan, India

Background: The present study was designed to evaluate adequacy of 6 months antitubercular therapy (ATT), Revised National Tuberculosis Control Programme (RNTCP) Cat I with isoniazid (H), rifampicin (R), pyrazinamide (Z), ethambutol (E) followed by HR thrice weekly in patients with tuberculosis mediastinal lymphadenopathy (TML).

Material & methods: 75 cases of significant mediastinal lymphadenopathy on computed tomography enhanced chest CT (CCT Chest) and diagnosis of Tuberculosis on transcortical needle aspiration were included. All patients were given 6 months ATT [2HRZE (6H)] per RNTCP and followed up after the end of 2.5 and 6 months for clinic-radiological assessment. CCT Chest done at the end of 6 months and treatment was extended with HR, in patients with persistent significant lymphadenopathy (>1 cm on CT chest). Repeat CCT chest was done 3 monthly till complete radiological response.

Results: Mean age of patient was 27.5±14.38 years with M:F ratio of 3:2. Common symptoms were fever (88%), dry cough (70%) and anorexia (60%). Right paratracheal (73%), Pretracheal (67%) were commonest lymph node groups involved. Only 15 out of 75 patients (20%) showed evidence of complete clinicoradiological improvement at end of 6 months while 5 (6.67%) patients were lost to follow up. Remaining 55 patients needed extended treatment (HR), 46 (61.33%) patients had complete clinicoradiological improvement at end of 9 months, while 9 (12.2%) patients required 12 months ATT.

Conclusion: 74% of the patients with TML required ATT for more than 6 months (<9-12 months) compared to 20% of the patients in whom 6 months ATT was adequate. The results suggest that 6 months RNTCP Cat I is inadequate for treating TML.

P2699
Comparison of treatment of TB lymphadenitis with daily or intermittent chemotherapy
Tushar Saharanbhude, Sandeep Garg. Department of Pulmonary Medicine, Padmashree Dr. D. I.Patil Medical College, Pune, Maharashtra, India

Relatively better cure rates are noted with use of daily TB chemotherapy regimens compared to intermittent regimens for TB lymphadenitis in our clinical experience. We therefore did a randomized comparative prospective study of daily vs. intermittent chemotherapy for cases with TB lymphadenitis. A total of 170 cases were randomly put on daily or intermittent regimen. Any cases of proven or suspected drug resistance were excluded. The regimens were selected as per the standard DOTS categories. 81 on daily and 73 on intermittent regimens completed their treatment and were available for analysis. 73/81 (90.12%) on daily regimen and 52/73 (71.23%) on intermittent regimens were cured. 170/170 (100%) and 23/23 (100%) respectively completed their treatment. 26/81 (32.09%) and 18/73 (24.65%) had adverse effects of chemotherapy on daily vs. intermittent treatment respectively. Daily TB chemotherapy seems to be superior to intermittent chemotherapy in terms of treatment outcome at the cost of slightly more adverse effects, in our study of TB lymphadenitis.

P2700
Demographic, clinical, and radiographic assessment of symptomatic, smear-negative pulmonary tuberculosis in a public-private mixed DOTS setting in Iloilo City
Raymond Lee 1, Malbar Ferrer 1, Lorelei Sinnit 1, Rodruse Guzman-Triviales 3, Rosario Cabana 1, Anne Lourdes Ponje 1, Elia Mae Drivmagracia 1, Elcie Solito 1
1Internal Medicine, St. Paul Hospital - Iloilo, Iloilo City, Iloilo, Philippines; 2Public-Private Mixed DOTS (PPMD-DOTS-SPH), St. Paul Hospital - Iloilo, Iloilo City, Iloilo, Philippines

Background: Annually, numerous cases of pulmonary tuberculosis are being referred to Public-Private Mixed DOTS (PPMD), and in most instances, they are of sputum smear-negative type. Clinicians need to decide when to initiate empiric anti-Koch’s treatment based only on symptoms and radiographic findings, as a delay in the commencement of treatment could cause further transmission of the disease. Thus, an advocacy, heralded by a TB diagnostic committee, of treating smear-negative patients suspected of having active TB disease was started.

Study objective: To recognize the clinical, radiographic, and demographic profiles of all sputum smear-negative patients with symptomatic PTB enrolled in the Directly Observed Treatment Short-Course program of St. Paul Hospital-Iloilo (DOTS-SPH) from January 2008 to June 2009.

Design: Retrospective descriptive study
Setting: PPMD (DOTS-SPH) in Iloilo City

Patients: Total of 74, symptomatic smear-negative TB patients enrolled in DOTS-SPH was included in the study.

Results: About half (51.4%) of the patients included in the study were females, mostly young adults (31.1%) in their productive years, residing in the urban areas (73.0%). Patients presented with cough (85.1%), backpain (64.9%), weight loss of >10% (44.6%), easy fatigability (44.6%), and chest pain (43.2%). The most common radiographic finding is the presence of an apical/upper lobe infiltrates (79.7%).

Conclusion: Most patients presented with at least 3 or more constitutional symptoms, cough being the most common. The initiation of anti-Koch’s medications relies mostly on chest radiographic findings and symptomatology of patients.

P2701
Post tuberculosis sequel as a important non-smoking risk factor for developing COPD
Hemant Kumar, J.K. Samaria. Department of Chest Diseases, Instr of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Background: Tuberculosis (TB) and chronic obstructive pulmonary disease (COPD) are major public health problems in developing and under developed countries. Some studies have shown a association between these two diseases (which are posing important problem for public health provider organizations).

Aim of the study: To evaluate the risk of developing COPD by previous pulmonary tuberculosis, independent of smoking.

Methods: Study includes 141 patients of COPD which were confirmed by spirometry (FEV1/FVC <0.7), were subjected to thorough history taking, clinical and radiological examination.

Results: Mean age of patients was 58.2 years. Out of 141 patients of COPD, 39 patients had a clinical and radiological evidence of previous pulmonary tuberculosis (SD 0.452, 39/141). 75 patients were having history of smoking (75/141, SD=0.504). 30 patients were identified as a non-smoker patients with previous pulmonary tuberculosis (30/141, 21.3%). In rest of the patients his mass fuel, asthama and other occupational factors were identified as a risk factor for COPD.

Conclusion: Post Tuberculosis is a one of the important non-smoking risk factor for the development of COPD.

P2702
Obstructive lung disease in patients with treated pulmonary tuberculosis
Mikhail Chushkin 1, Batarbek Maliev 1, Sergey Yartsev 2, Sergey Smirdin 1
1Pulmonary Physiology, Research Institute of Phthisiopulmonology, Moscow, Russian Federation; 2Lung Function Unit, Medical Center, Central Bank of Russian Federation, Moscow, Russian Federation

Little is known of functional sequelae of tuberculosis. The aim of the study was to evaluate the association between chronic obstructive pulmonary disease (COPD) and pulmonary tuberculosis.

Methods: In consecutive 224 patients treated for pulmonary tuberculosis (between the ages of 20 and 82 years) who were observed at a local dispensary pulmonary function tests were performed.
Results: Pulmonary impairment was present in 105 (46.9%) patients including 81 (36.2%) patients with airflow obstruction (FEV1/FVC <0.7) and 24 (10.7%) patients with restrictive pattern (FEV1/FVC ≥0.7 and FVC or FEV1<80% predicted). Of 224 patients, GOLD criteria classified 10.3% of subjects as having mild COPD, 19.2% subjects as having moderate COPD, and 6.7% as having severe COPD. The prevalence of stage II or higher COPD in patients aged 40 and older and in younger patients was 31% and 5%, respectively (p<0.001). In patients with culture-positive pulmonary tuberculosis in the past the prevalence of stage II or higher COPD was 32% and in patients with culture-negative pulmonary tuberculosis prevalence of stage II or higher COPD was 17% (p=0.05). In patients who had two or more episodes of tuberculosis the prevalence of stage II or higher COPD was 47% and in patients with one episode the prevalence of stage II or higher COPD was 23% (p=0.01). We did not find influence of gender, smoking on the prevalence of stage II or higher COPD.

Conclusions: A microbiological cure is not the end of illness. Tuberculosis is associated with frequent airflow obstruction. Culture-positive pulmonary tuberculosis in the past and episodes of tuberculosis may increase the prevalence of stage II or higher COPD.

P2703 Airflow limitation due to COPD despite tuberculosis sequelae

Nawel Ben Salem1, Nawel Chaoch1, Manel Loukil1, Mourad Zatrouk2, Sana Chekki Rouchou3, Hajar Racli1, Khoula Ben Miled1, Abdelatif Chabrou1

1Pneumology, A. Mami Hospital, Research Unit IRC MSP-MESR, El Manar University, Ariana, Tunisia; 2Radiology, A. Mami Hospital, Ariana, Tunisia

Pulmonary (P) tuberculosis (TB) and COPD are both a significant worldwide burden in terms of morbidity and mortality. They can both induce similar respiratory symptoms and airflow limitation (AFL) in smokers. To clarify if COPD can be considered in patients with TB sequelae, we retrospectively analyzed cases of patients with AFL (FEV1/FVC<0.7) and previous medical history of PTB, hospitalized between 2000 and 2010 in which diagnosis of COPD was more probable than TB sequelae because of important tobacco use and clinical history. All patients underwent CT scan to precise P lesions. Patients with PTB after COPD diagnosis were excluded and those with extended TB sequelae as well. Fifteen patients were included. Mean age was 60 years (44-83 years). Mean smoking level was 58 pack year. The mean delay between TB history and diagnosis of COPD was 20 years. Dyspnea was present in all cases and associated to chronic cough and sputum in 87% of cases. CT scan showed besides TB sequelae, P emphysema in all cases (centrolobular in 75%). AFL was severe in 80% of cases (GOLD III and IV). Treatment was based on theophylline and/or inhaled long-acting B2 agonists in all cases. All patients had clinical improvement with bronchodilator. Outcome was marked by at least one exacerbation for 13 patients due to P embolism in 2 cases, pneumothorax in 1 case and respiratory infections in all other cases.

COPD should be considered in smokers with AFL even if they have a previous history of PTB. Despite few cases of paraseptal emphysema, the majority of these patients show predominant P centrilobular and panlobular emphysema with an outcome similar to those with COPD and no PTB history.

P2704 Structure of extrapulmonary tuberculosis forms in Romania among 2007–2009

Constantin Marica1, Cristian Didilescu 2, Mihaela Tanasescu1, Mara Popescu-Hagen1, Nicoleta Cioran1

1Pneumology, Institute of Pulmology of the University, Bucharest, Romania; 2Pneumology, University of Medicine and Pharmacy, Cluj-Napoca, Romania

Tuberculosis represents a major matter of public health in Romania and as a result the antituberculosis activities provided by NTP take into account also to point out all the aspects and tendencies of TB endemic.

Objective: In the context of an increased TB endemic (notification rate 99.9% 000 meaning 21457 cases in 2009) but with a decrease tendency in the last 7 years, we intended to determine extrapulmonary TB weight and structure by locations among 2007 – 2009.

Material and method: We have used information in the national data basis within the service of NTP epidemiologic supervision.

Results: Among 2007 – 2009, extrapulmonary TB weight from all sites was chronologically the following: 13,49% ±3351 cases (2007), 13,41% ±3310 (2008) and 14,51% ±3378 (2009). TB pleuresies represented 62.1% (2007), 62.1% (2008) and 58.1% (2009) of the extrapulmonary sites. In absolute figures, the other extrapulmonary sites keep a constant weight only 2 TB tibroid cases and no surrenal case.

Conclusions: Extrapulmonary TB forms among 2007-2009 keep a constant weight level within the structure of TB sites. The high level of pleuresies (with phisiognomic risk) and also the high frequency of TB meningites (severe prognosis, element of epidemiologic gravity) involve an increased responsibility in TB control.
CXR may not have sputum sampling performed, leading to underestimation of pulmonary disease.

Objectives: To determine the use of CXR & TBC in patients with EPTB & their diagnostic utility to detect co-existent PTB.

Study design: Retrospective clinical and demographic data for TB patients at our hospital (1.1.06 - 31.12.08) obtained from the London TB Register were linked to hospital microbiology & HIV test data. Baseline CXR (B-CXR) were scored by 2 respiratory radiologists blind to patient diagnosis.

Results: Of 308 cases (median age 39y, 52.9% female), 155 were notified as EPTB only, 143 (92.3%) had B-CXR, with abnormal (abN) features identified in 67 patients (46.9%): 48 (33.6%) consistent with possible PTB & 9 (6.3%) probable PTB, independent of HIV status. Sputum samples were obtained from 54 patients (37.8%). This was less likely in those with a normal B-CXR (21.4% vs. 56.2% abN, p<0.001). TBC was MTB positive in 9 patients (16.7%) suggesting with abN B-CXR (5 possible PTB, 2 probable PTB) & 2 with normal B-CXR.

Conclusion: Most EPTB patients had a B-CXR, 40% of which were consistent with possible/probable active PTB. Sputum samples were infrequently obtained, though when performed MTB yield was high. Clinical diagnosis of EPTB using B-CXR review alone may underestimate co-existing PTB. To identify infectious cases & improve TB control, sputum collection & TBC should be performed in all patients.

P2708
Assessment of the prevalence of pulmonary involvement in cases with extrapulmonary tuberculosis
Mohamed Zidan, Hamy Shahawar. Chest Diseases Department, Alexandria Faculty of Medicine, Alexandria, Egypt

Introduction: Tuberculosis (TB) remains a public health concern worldwide. Previous reports have shown that patients with smear-negative pulmonary TB could transmit TB to others. Whereas it is a common practice to obtain a chest X-ray (CXR) for all patients with extrapulmonary TB (EPTB), sputum examinations are typically limited to those with abnormal radiographic findings suggestive of pulmonary TB.

Objective: To assess the prevalence of pulmonary involvement in patients with EPTB.

Methods: The present study included 120 patients proved to have EPTB. Patients were subjected to symptoms review, full clinical examination, chest X-ray, and sputum examination for acid fast bacilli (AFB) by direct smear and culture.

Results: The mean age of the patients included in the study was 34.4±2.13 years with gender distribution of 40% males to 60% females. All patients had histopathological confirmation of having tuberculosis while culture for mycobacterium TB was positive in 41.7% (50 patients) and direct smear examination for acid fast bacilli was positive in only 1.7% (2 patients). Normal CXR was detected in 31 patients (25.8%) regardless of the original disease, while sputum culture for mycobacterium TB was positive in 35 patients (29.2%). Although there was no statistical difference between CXR and sputum culture, the crude number was higher in sputum culture. Direct sputum examination was positive in only 6 patients (5%).

Conclusion: The prevalence of pulmonary affection in EPTB is significant. The sputum culture for mycobacterium TB is crucial to reach the diagnosis especially in patients with normal CXR or negative direct smear.

283. Clinical challenges in tuberculosis

P2709
Late-breaking abstract: Atypical chest X-ray manifestations in pulmonary tuberculosis – A case series
M. Vishnu Sharma, Viswambhar. Pulmonary Medicine, A.J. Institute of Medical Sciences, Mangalore, Karnataka, India

Background: Majority of patients with pulmonary tuberculosis show radiological abnormalities. Atypical manifestations in the chest X-ray can occur in some patients with pulmonary tuberculosis. Knowledge and awareness about the atypical radiological manifestations will help in early diagnosis of these cases.

Aims and objectives: To find the atypical radiological manifestations in patients with pulmonary tuberculosis.

Material and methods: We compiled our data for 5 years from January 2005 to December 2010 of patients with proven pulmonary Tuberculosis with atypical chest X-ray. Patients without definitive diagnosis of Tuberculosis were excluded from the study. Diagnosis of pulmonary Tuberculosis was made when sputum AFB smear examination, Sputum AFB culture, Bronchosopic washings for AFB showed the tubercle bacilli or when Bronchosopic biopsy showed histopathology typical of tuberculosis.

Results: Atypical radiological manifestations in our study showed cavities in mid zone, lower zone, lower lung field tuberculosis, endobronchial tuberculosis, tubercular broncho pneumonia, sub pulmonic effusion and normal chest X-ray. In all these cases, clinical suspicion of tuberculosis was low as symptoms and chest the X-Ray was not typical of TB. Only one patient was HIV seropositive. Other patients did not have any immunosupression or Diabetes.

Conclusions: • All patients with any type of radiological abnormality should undergo a sputum AFB smear examination.
• All patients with chronic cough should get sputum AFB smear done even if chest X-Ray is normal
• Pulmonary TB should be considered as a differential diagnosis in any patient with chronic respiratory symptoms.

P2710
Late-breaking abstract: Tumor marker pattern in benign pleural effusion investigation. A case report of increased pleural CA 125
Marios Kougiou, George Boulbasakos, Evangelos Balti, Vassiliki Lazarou, George Tatis. Pulmonary Medicine Dept, Evangelismos Hospital, Athens, Greece

Introduction: The pleural effusion is a common occurrence in pulmonology. Measurement of tumor markers has an evolving role in diagnosis of a pleural effusion.

Methods and results: We report a case of M tuberculosis pleurisy with increased level of cancer antigen (CA) 125 in pleural fluid. The patient was a 31-year-old female, presenting with right pleural effusion. Analysis revealed a lymphatic exudate with absence of malignant cells. Microbiological examinations, staining and culture of the effusion were negative except for the mycobacterial culture. Adenose Deaminase levels were measured at 87.20 U/L. A purified protein derivative skin test was positive (16mm). Complete examination for malignancy with CT for chest and abdomen, intravaginal ultrasound and Pap smear was negative for malignancy.

Several tumor markers were measured both in serum and pleural fluid, including carcinoembryonic antigen (CEA), alpha-fetoprotein (AFP), CA 19-9, CA 125 and Neuron Specific Enolase (NSE).

Analysis revealed a great increase of CA 125 both in serum and pleural fluid (CA 125 serum 126.9 U/ml (reference value <35 U/ml vs CA 125 pleural fluid 357.6 U/ml). The increase between serum and pleural fluid values was 182%. NSE was also increased between serum and pleural fluid by 48% (serum 8,72 ng/ml vs pleural fluid 12.91 ng/ml). AFP showed a decrease by 15%. CA19-9 also showed a decrease by 25%. CEA was measured under <0.50 ng/ml.

Conclusion: We report a tuberculosis pleurisy case with a remarkable increase of CA 125 both in serum and pleural fluid. In conclusion CA 125 could be an indicative marker for the diagnosis of tuberculosis pleurisy.

P2711
Late-breaking abstract: Cough aerosol: Significant basis to design innovative control strategies in tuberculosis transmission in smokers
Jose Gustavo Zayas1, Ming Chiao Chiang1, Eric Wong1, Fred MacDonald2, Malcolm King1. 1Medicine, University of Alberta, Edmonton, AB, Canada; 2Medicine, Caritas Research Centre, Misericordia Hospital, Edmonton, AB, Canada

Introduction: Smoking progressively alters the properties of airway mucus. Alteration in mucus responds differently to airflow interaction when coughing and may modify bioaerosol production.

Objective: Characterize the cough bioaerosol in smokers to understand its relation to the transmission of tuberculosis (TB).

Method: Cough aerosol was assessed in seven long-term smokers and compared with the aerosol of 44 nonsmokers. Measurement of the size and number of cough droplets was accomplished using a laser diffraction system.

Results: Long-term smokers emitted up to two orders of magnitude more droplets of all sizes than nonsmokers when coughing.

Average sum of cough droplets emitted by nonsmokers and long-term smokers

Conclusion: The number of droplets emitted by smokers when coughing could help to better understand the etiological association between smoking and TB. Optimal control of bioaerosol in smokers with TB, especially those with multiple and extreme drug resistance TB, might strengthen existing core TB control strategy. Acquired knowledge would lead to the development of informed public health policies, more effective practices and/or products to optimize TB control.
A 30y old male presented to A&E with sudden onset of right sided pleuritic chest pain and acutely SOB. 

Background: Previously fit and well, Asian, born in UK, no medical problems. Smoker 10-15 cigarettes, occasional use of alcohol, lives alone and work in a printing factory. No recent contact with ill person and no family history of lung diseases. 

He has been complaining of dry cough for last two months since he returned from holidays in Spain, but did not seek any medical advice. Denies any b/o weight loss, hemoptysis, fever or rigors. 

This time presented with sudden onset of sharp right sided pleuritic pain and could not breath, so brought to A&E. 

Examination/Investigations: On arrivals sats were 90% on 15l O2, tachypnic, RR30/min, clearly in respiratory distress and absent air entry on right lung, and enlarged right supraclavicular lymph node. 

Emergency chest X-ray was arranged which showed large (75%) R sided pneumothorax. An emergency chest drain was inserted after failed aspiration and repeat CXR showed good expansions of the right lung and patient was referred to the medical team. 

When seen by medical team his CXR showed reticulonodular changes on both lung fields, on top of the Pneumothorax, which was latter reported as pattern of miliary TB. 

A sputum sample was sent for AFB, had a CT head and lumber puncture done. There was no meningeal involvement. His HIV test came back as negative and was started on anti TB treatment and so far has been doing well and making good recovery. 

Learning point: Learning point was that military TB can present with pneumothorax.An emergency chest drain was inserted after failed aspiration and repeat CXR showed good expansions of the right lung and patient was referred to the medical team. 

Asmohammed Seidy1, Ibrahim Radwan1, Magda Mohamed2, 1Chest, Al-Azhar University, Cairo, Egypt; 2Biochemistry, Al-Azhar University, Cairo, Egypt 

Although several studies have investigated the levels of C-reactive protein (CRP) in various diseases states, few have focused on its role in pleural effusion. 

The aim of this study was to evaluate the value of pleural fluid and pleural/serum CRP in segregation between tuberculous and malignant pleural effusions. 

CRP was measured in both pleural fluid and serum among 2 groups of patients, the first included 15 with tuberculous effusion diagnosed by Abram’s needle biopsy, while, the second incorporated 15 with malignant effusion diagnosed by either thorascopic or Abram’s biopsy. 

A highly significant difference was demonstrated between pleural fluid CRP in tuberculosis (29.07±4.32) and malignant (19.30±4.35) effusions. Moreover, serum CRP was significantly higher in tuberculous effusions (52.24±8.55) compared to malignant one (30.65±5.08). Furthermore, CRP pleural/serum ratio was significantly higher in malignant effusion. 

In conclusion, CRP is a useful and cheap marker for differentiation between tuberculous and malignant pleural effusion. 

The first case of mycobacterium shimoidei infection in the UK 

Nandini Biswas, Thomas Brown, Jontahun Dakin. Respiratory Medicine, Queen Alexandria Hospital, Portsmouth, United Kingdom 

Case report: We present the first case of Mycobacterium shimoidei infection in the UK. The patient is 68 years old heavy smoker with known emphysema. He was first treated for pulmonary TB in 1967 and had further 6 months of empirical therapy in 2007 for night-sweats, productive cough and new cavitating lesion. 

All cultures were negative at that time. He re-presented in 2009 with weight loss, night sweats, productive cough and arthralgia. His chest X-ray and CT scan showed new left upper-lobe cavitating consolidation. He was not immunocompromised and sputum specimens were smear negative. However all sputum cultures and a bronchial lavage were positive for Mycobacterium shimoidei, confirmed using a PCR reverse hybridisation technique. He was treated with ciprofloxacin, ethambutol, clarithromycin, streptomycin and rifabutin based on in-vitro sensitivities and previous case reports. After 12 months of treatment he is now well with negative sputum cultures. The CT scan changes have also resolved. 

Discussion: Mycobacterium shimoidei was first isolated by H Shimoide in 1975 and was described and named by M Tsukamura. Only a few cases have been reported so far. 

In conclusion, despite prevention programs, tuberculosis still remains a major international health problem. Prognosis appears to be closely related to therapeutic precocity, thus specific chemotherapy started sometimes without diagnostic confirmation.
Aims and objectives: This study aims to determine the incidence of the main adverse reactions to anti-tuberculosis chemotheraphy among patients diagnosed with active tuberculosis. HIV negatives, in S-W Romania.

Methods: The descriptive, cross-sectional, retrospective study was performed by investigating the observation sheets of all 1,138 cases hospitalized with this diagnosis in the Clinical Hospital of Infectious Diseases and Pneumophthisiology, Timisoara, between 01.01.2008-31.12.2010. The statistical processing was performed using the EPI-INFO vers. 6.04, the dichotomous variables being analysed using the b2 test and the Fisher correction.

Results: A total of 58 patients (5.02%) were identified as suspected of having pulmonary tuberculosis (TB). In 81.03% of cases (47 pts) the disease was confirmed by positive culture, CT, X-ray and histological evidence. In 18.97% of cases (11 pts) the disease was not confirmed by culture. In both cases active or latent TB was rejected after screening, PT treatment was not administrated and TB look like primary infection. Another problem was to monitor latent TB, when positive TST (in 51 pts) can not be strong argument for re-PT. Positive IGRA were obtained in 12 of these pts (23.5%) and reduced the number of PF quarter.

Conclusion: In countries with high and medium prevalence of TB not only screening before TNF-ant administration is essential. It is necessary to follow up all pts with regular (every 6 months) IGRA, which only can show the initial exacerbation of latent TB infection or new exogenous infection.

P2720 Outcome results of anti-tuberculosis treatment in latent or manifest tuberculosis patients featuring granulomatosus uveitis

Serge Borisov1, Irina Solov’eva2, Lidia Guntupova1, Lydmila Slogotskaya1, Elena Khachatarians1,2,3

Abstract P2720

Background: The tumor necrosis factor antagonists (TNF-ant) are high effective agents, but their essential effect is to increase the risk of tuberculosis (TB) development. In this paper we aimed to determine the incidence of anti-tuberculosis chemotherapy among the patients taking TNF-ant.

Methods: During the eight years of study, 178 HSCT patients have been admitted in our institution for infections is limited.

Records from all allogeneic HSCT patients admitted in our institution for mycobacterial infection from January1, 2003 to December 31, 2010 were reviewed.

Results: During the eight years of study, 178 HSCT patients have been admitted

Furniture SpA. Visit Chiesi Farmaceutici SpA. at Stand D.30
for pulmonary complications. 7 patients have had a diagnosis of mycobacterial infection.

Conclusions: Mycobacterial infection is rare (4%) in French HECT patients with pulmonary complication. The infection is lung limited. It usually occurs in the first post-transplantation year. The clinical course under treatment is favorable in most cases.

P2722

Spinal tuberculosis in South London Hospital – A 5 year review of our experience

Deepak Sakaram Rao, Richard Hopkins, Billy L.K. Wong, Elena Karampini, Bassye Asuapan, Thomas C. Strokes. Respiratory Medicine, Queen Elizabeth Hospital, Woolwich, London, United Kingdom

Introduction: The incidence of tuberculosis (TB) in southeast London has risen by 25% over the last 10 years and is 4 times greater than the national average. Extra pulmonary involvement is seen in 47% and spinal TB accounts for 2-3% of cases. Diagnosis of spinal TB can be delayed due to nonspecific nature of symptoms.

Aim: To determine our experience of managing spinal TB at Queen Elizabeth Hospital in Woolwich, UK.

Methods: A retrospective case note review of recorded data was performed of all the spinal TB patients referred to QEHS over 5 years (Jan 2006- 2011). 27 out of 34 patients had case notes available for review. Mean age at diagnosis was 47 years (range 20-78 years). 88% of patients presented with back pain, with or without neurological compromise.

The overall incidence of spinal TB was 5.6% (national average 2.3%). The mean delay was 81 days (3-430) from onset of symptoms to first presentation and 99 days (3-552) from onset of symptoms to referral. There was an average delay of 33 days (12-303) from initiation of referral to diagnosis. 47% had confirmed histological diagnosis with culture.15% had paravertebral abscesses with or without involvement seen on imaging.

Combination chemotherapy was the main modality of treatment. 24 (88%) patients were managed with combination chemotherapy alone.

Further details into the delays and consequences were looked into.

Conclusion: This study highlights that awareness of demographic and local incidence, together with high index of clinical suspicion in areas with relatively high incidence would facilitate early diagnosis and treatment of spinal TB.

P2723

Immunological status of TB/HIV dual infection patients in Latvia in year 2009

Eivija Livcane1,2, Edite Fridrihsone1.

1Department of Infectology and Dermatology, Riga Stradi University, Riga, Latvia; 2Clinic of Tuberculosis and Lung Diseases, LIC, Riga, Latvia

In the world tuberculosis (TB) is main cause of illness and death for human immunodeficiency virus (HIV) patients. Situation among TB/HIV dual infection patients in Latvia is relatively unexplored.

Aims: To analyse incidence of various TB clinical forms among HIV patients incidence of resistant TB among TB/HIV patients and medium immunological parameters for TB/HIV patients at the moment of TB diagnosis anti-TB therapy and HIV infection results for TB/HIV patients.

Materials and methods: In retrospective study case histories for 61 from 73 patients diagnosed in year 2009 with TB/HIV dual infection were analysed.

Results: For 72% (43) patients HIV was diagnosed before TB diagnosis, 28% (17) patients HIV and TB were diagnosed simultaneously. In 80% (49) TB was diagnosed for first time, in 20% (12) relapse. In 40% (25) multiorgan TB infection was diagnosed, in 30% (18) infiltrative pulmonary TB, in 25% (15) disseminated pulmonary TB and in 5% (3) extra pulmonary TB. In 60% (37) cases TB was sensitive to all antiTB drugs, in 35% (21) resistant cases. Medium CD4+ cell count was 294 cells/mm3 (min–6, max–2003). 67% (41) patients received full,18% (11) disrupted therapy and 13% (9) cases were lethal.

Conclusion: In year 2009 significant number of TB and HIV were diagnosed simultaneously. Pulmonary TB dominates among TB/HIV patients, but there is also high number of patients with TB multi-organ infection. There is high number of resistant TB among HIV/TB infected individuals. High CD4+ cell count could indicate high incidence of TB among HIV/TB individuals. There is significant number of cases where TB is cause of death in TB/HIV dual infection patients.

P2724

New biomarkers for LTBI in IGRAs supernatants

Masataka Shibasaki1,2, Miyoiko Matsumura1, Yuichi Kitagawa1, Tsutomu Kawabe1. 1Department of Respiratory, National Center for Geriatrics and Gerontology, Otsu, Aichi, Japan; 2Department of Medical Technology, Nagoya University School of Health Science, Nagoya, Aichi, Japan; 3Stargery Division, National Center for Geriatrics and Gerontology, Otsu, Aichi, Japan

Background: Commercial in vitro T-cell interferon gamma (IFN-γ) release assays (IGRAs) including the QuantiFERON® tests have been introduced into clinical practice for the diagnosis of Mycobacterium tuberculosis. However, the sensitivity of the IGRA may not be as high as expected in patients with immunodeficiency patients.

Aim and objectives: To assess whether alternative biomarkers could be used in future developments for diagnosis of TB.

Methods: We recruited twenty-four latent TB patients and 46 healthy controls at National Center for Geriatrics and Gerontology in Japan and performed the OFT test. To investigate the ability of new host markers to differentiate between LTBI and controls, levels of IL-10 and IFN-γ as Th1 cytokines, TARC and MDC as Th2 chemokines, and IL-8 as a neutrophil chemotactic factor in QFT supernatants were evaluated using an enzyme-linked immunosorbent assay.

Results: Levels of IP-10, TARC and MDC were significantly increased in LTBI patients compared with controls. Levels of TARC and IL-8 were not different between two groups. The levels of IP-10, TARC and MDC were not correlated with levels of IFN-γ.

Conclusion: IP-10, TARC and MDC had diagnostic potential as they could differentiate between the LTBI patients and the controls. IP-10 seemed most promising as they were expressed in high levels in the LTBI patients and were low in the control samples. Further studies are needed to explore the potential of these highly expressed novel biomarkers individually and in combination.

P2725

Mouse model of pulmonary disease after aerosol infection with mycobacterium xenopi

Claire Andrejak, Sandeep Tyagi, Eric Nuernberger, Jacques Grosset. Center for TB Research, Johns Hopkins University, Baltimore, MD, United States

Rationale: Opportunistic respiratory infections due to M. xenopi are on the rise in industrialized countries and current therapies are inadequate. Only two examples of Mycobacterium xenopi, a streptomycin-resistant strain and the beige Swiss mouse models re-infected have been performed so far. As aerosol inhalation is the probable route of infection in humans, we hypothesized that aerosol infection of mice would better recapitulate human infection and permit better assessment of the response to antibiotic treatment. Our primary objective was to determine which strain of mice was the most susceptible to aerosol infection.

Methods: Four strains of mice were tested: BALB/c, C57Bl/6, Beige, and athymic nude (Nude). For each strain, thirty 6-week-old females were simultaneously aerosol infected with 4.7 log10 of M. xenopi ATCC # 19971. At 1, 2, 3, 4, 8, 12 and 23 weeks post-infection, three mice per group were sacrificed for gross lung lesions, spleen weight, and lung and spleen CFU counts. From week 4 to 12, 9 mice of each group were treated with clarithromycin 100 mg/kg daily 5 days a week. Three treated mice per group were sacrificed at week 8 and 12.

Results: In BALB/c, C57Bl/6, Beige and Nude mice infected with M. xenopi, the lung CFU counts steadily increased to reach 5.92, 5.99, and 5.75 log10, respectively at week 4; 6.35, 6.72, 6.60 and 6.93 log10, respectively at week 8; 6.51, 6.43, 7.69, and 6.63 log10, respectively at week 12; and 6.59, 6.72, 8.16, 7.32 log10, respectively at week 24. In all mice, M. xenopi disseminated to the spleen. Clarithromycin treatment reduced significantly, by 2 log10, the lung CFU counts in all strains of mice.

Conclusion: Nude mice were the most susceptible to aerosolized M. xenopi infection.

284. Epidemiology of lung cancer and screening
Methods: see table.

Results: This analysis shows the increase of adenocarcinoma with increase of female patients, of non-smoker-status and increase of diagnosis by TDM function. Non small cell is stable.

Background: Individualized treatment in lung cancer (LC) needs precise characterization of the tumour and host. Data on the impact of diabetes mellitus (DM), the most frequent endocrinological disorder, on the prognosis of lung cancer is conflicting.

Aim: To define the importance of DM for survival in lung cancer.

Method: We analyzed data from a large cohort study, the Nord-Trøndelag Health Study (HUNT study) linked to the Norwegian Cancer Registry, and controlled the results using two lung cancer studies, the Pemetrexed Gemcitabine study (PEG study) and the Norwegian Lung Cancer Bio Bank (NLCB). Survival rate between lung cancer patients with and without DM were compared using the Kaplan-Meier model and Cox regression analysis.

Results: Of a total number of 107 127 study participants there were 5448 persons with DM and 1877 cases of LC. Among the LC patients 85 patients had DM. LC patients without DM showed 43%, 19%, 3% versus 28%, 11%, 4% 1-year, 2-year and 3 year survival in patients with and without diabetes showed 43%, 19%, 3% versus 28%, 11%, 4%, respectively. With the Cox regression model we adjusted survival for DM, age, gender, histological type and smoking status. The first five confounders showed to be independent factors (p < 0.001), while smoking status was not (p = 0.531).

Conclusion: Lung cancer patients with diabetes mellitus has an increased survival compared to patients without diabetes mellitus. The magnitude of the survival benefit seems to be of clinical importance and therefore justified to be studied more in detail.

P2729 COPD prevalence in lung cancer patients – Is COPD a risk factor for lung cancer?

Doina Tofolean1, Laura Mazhli2, Tatiana Adam1, Andra-Iulia Sucaveans1, Polixenia Iorga1, Ioan-Tiberiu Tofolean1,1 Internal Medicine - Pneumology, Clinical Emergency Hospital, Constanta, Romania; 2Oncology, Clinical Emergency Hospital, Constanta, Romania; 3Oncology, University Hospital, Bucharest, Romania

Background and aim: Chronic obstructive pulmonary disease (COPD) is a common comorbid disease in lung cancer, estimated to affect 40–70% of lung cancer patients. As smoking exposure is found in 85–90% of those diagnosed with either COPD or lung cancer, coexisting disease could reflect a shared smoking exposure. We aimed to investigate the prevalence of COPD in patients diagnosed with lung cancer.

Methods: We analysed 1173 patients diagnosed with lung cancer in Internal Medicine Department between 2000 and 2010 for the presence of lung cancer risk factors.

Results: A number of 1046 patients (89.17%; p < 0.0001) were former smokers/actively smoking. Preexisting disease was diagnosed in a number of 442 cases (37.68%) COPD in 257 cases, and other etiologic factors in 185 cases (58.14% versus 41.85%; p < 0.0001). Histopathologic results were available in 131 cases and showed: squamous carcinoma (n=78; 59.54%), adenocarcinoma (n=24; 18.32%), large cell undifferentiated carcinoma (n=11; 8.39%), and small cell carcinoma (n=18; 13.74%). Smokers versus non-smokers and COPD prevalence according to histopathologic types were the following: the 71 versus 7 (p=0.0001), and 14 cases of COPD (17.94%) for squamous carcinoma; 15 versus 9 (p=0.1482), and 2 cases of COPD (13.33%) for adenocarcinoma; 8 versus 3 (p=0.8961), and 1 case of COPD (9.09%) for large cell undifferentiated carcinoma; and 14 versus 4 (p=0.0022), and 3 cases of COPD (16.66%) for small cell carcinoma.

Conclusions: Our study shows a high prevalence of COPD in lung cancer patients. COPD was the second most important risk factor for lung cancer, after smoking. The most important relationship of COPD was with the squamous type lung cancer.

P2730 Peculiarities of lung cancer in patients with COPD

Olga Lukina1, Alexandra Speranskaya1, Alexander Hristulov1, Andrey Litvinov1, Vasily Trosfimov1, 1Radiology, Pavlov’s State Medical University, Saint-Petersburg, Russian Federation; 2Hospital Therapy, Pavlov’s State Medical University, Saint-Petersburg, Russian Federation

The aim of the study was to determine main causes of mistakes in radiologic diagnose of lung cancer in patients with COPD. We examined 201 patients with moderate and severe COPD admitted to hospital during exacerbation. All patients were examined by MDCT angiography interpreted by two experienced radiologists, also previous CT scans were compared with the acquired data.

We founded cancer of main bronch in 15,3% of patients with severe, and in 8,6% of patients with moderate COPD. Peripheral lesions were observed in 17,9% of patients with severe and 5,5% of patients with moderate COPD with significant interobserver consensus. During analysis of earlier CT examinations (a 5 year period) in 1,9% central cancer was not determined on early stage of disease, because study was performed without contrast enhancement. Peripheral neoplasms were not determined because of peribulbous growth, looking like thickening of the wall...
of bulla in 1.4% of patients, cancer growing in the place of fibrosis - 0.4%, fluid of different genesis in bullas in 1.4% of patients. Interobserver consensus was significant in determination of lesions on previous scans. We observed a group of patients after lung volume reduction surgery who were thoughtfully examined before the treatment and who than developed different types of cancer in a short period after the surgery. No evidence of malignancy was founded on previous scans, so we can only speculate that surgery and changes in circulation were triggering mechanisms in the extraordinary quick development of tumors.

Thus we can suppose that in patients with COPD contrast enhancement is strongly recommended for early diagnosis of tumors, and patients after LVRS should be examined by CT after surgery.

P2731 Epidemiological and histologic features of lung cancer in Montenegro
Milic Medenica1, Nikola Persovic1, 1 Bronchology, Hospital for Lung Disease, Brezova, Montenegro, Nikic, Montenegro, Serbia, 2Department of Anatomy, Medical Faculty, Montenegro, Podgorica, Montenegro, Serbia

Background: Lung cancer is one of the most common malignant neoplasms as well as the most common neoplasm stated as a cause of death. Epidemiological characteristics of lung cancer differ among countries and regions.

Aim: To determine the epidemiological and histologic features of lung cancer in Montenegro.

Methods: Study group comprised patients in Montenegro in continuous period 1997-2010.

Results: In reported period number of newly diagnosed lung cancer is 2497. The incidence ranged from 29.8 in 1997 to 35.9 in 2004. Out of the total number of diagnosed lung cancer, epidermoid carcinoma was diagnosed in 1484 cases (58.6%), small cell lung carcinoma (SCLC) in 597 cases (23.92%) and adenocarcinoma in 416 cases (16.65%). The men were represented with 83.17% (2078) while the female were 16.83% (419). Ratio of smokers and nonsmokers for each histological type was (epidermoid 8:1, 2:1 adenocarcinoma, SCLC 9:1). The most frequent histopathological type in males was epidermoid (63%) followed by adenocarcinoma (14.5%) and then SCLC (22.5%). In women the most common cancer was epidermoid (43.5%). Adenocarcinoma accounts for 26.5% and SCLC with 30%. The percentage of smokers was 88.72%, nonsmokers represented 11.28%.

Conclusion: During the period 1997-2010 a significant increase in the incidence of diseases such as lung cancer was not observed, but the decrease in the frequency of epidermoid carcinoma was noted - from 75% (1997) to 50% (2010) as well as the increased frequency of SCLC from 1% (1997) to 30% (2010) and adenocarcinoma from 13% (1997) to 28% (2010).

P2732 Occupational exposure to carcinogens and lung cancer: Impact of a dedicated professional disease consultation in a Belgian oncologic centre
Anne Pascale Meert, Isabelle Morelle, Thierry Berghmans, Ingrid C.S. Toth, Jean Paul Sculet. Thoracic Oncology and Intensive Care, Institut Jules Bordet, Brussels, Belgium

Introduction: In epidemiological studies, 15% of lung cancers in men and 5% in women are linked to occupational exposure to carcinogens. However, there is a clear under-reporting of occupational lung cancer in Belgium: in 2006, only 67 cases were recognized by the Professional Disease Fund whereas 500 were attended.

Aim: To appreciate the frequency of occupational lung cancer in newly diagnosed lung cancer in a Belgian oncologic hospital.

Material and method: Since 01/09/2009, all new patients with lung cancer were sent to a dedicated consultation where a physician trained in professional diseases was asked information about job history and look for known or suspected lung carcinogenic exposure.

Results: 73 job stories have been recorded, 23 patients (32%) were certainly or probably exposed to a lung carcinogenic agent (known or suspected). All the patients were men (mean age 62 years), 22 workmen, 21 were smokers. Asbestos was the most common carcinogenic agent found (25%). Ten claims for occupational disease were made; 3 recognized and 7 are pending.

Conclusion: This study shows the utility of a physician with knowledge in occupational pathology into a clinical department to reduce the under-reporting of occupational primary lung cancer and then to ensure that the victims receive the appropriate medicolegal benefits.

P2733 The association between residential radon concentration and lung cancer
Doina Adina Todea1, Loredana Elena Rosca2, Constantin Cosma2, 1Bronchology, Hospital for Lung Disease, Brezova, Montenegro, Nikic, Montenegro, Serbia, 2Department of Anatomy, Medical Faculty, Montenegro, Podgorica, Montenegro, Serbia

Histology 68% 87%
Male:Female 1.4:1 0.84:1

Lung cancer represents the most frequent cause of mortality caused by malignant

P2734 Is female gender a protective factor for NSCLC patients? A follow up study of 20 years of 478 patients
Jose Chatkín, Norris Scaglia, Jose Figuereido-Pinto. Medicine, Pontificia Universidad Catolica do Rio Grande do Sul, Porto Alegre, Brazil

Background: Previous studies reported a better survival rate among females with non-small lung cancer (NSCLC). We have previously also registered similar findings. The purpose of this study was to re-evaluate female gender as a protective factor survival in a cohort of patients with NSCLC in a follow up study of 20 years.

Methods: In a retrospective cohort study, we examined the survival rates of 478 NSCLC patients who underwent surgical curative treatment at Hospital da PUCRS, in Porto Alegre, Brazil between January 1990 and December 2009. Survival rates were analyzed by Kaplan-Meier plots and by the log rank test. Cox proportional hazards analyses were performed to identify potential confounding factors. The statistical significance was considered as P=0.05.

Results: The 5-year survival rate was 55.6% for women and 38.8% for men (P=0.005), when considering the whole group of patients. After adjustment for possible confounding factors (age, TNM stage, histology, tumor size, surgical procedure, smoking load, hemoglobin, and postoperative complications), female gender protective effect persisted only for stage I (survival rates: 75.2% and 47.9%, for women and men, respectively; P<0.007). For subjects in stages ≥II, no significant differences in 5-years survival rates were found. The hazard ratio for males in stage I was 1.95 (95%CI: 1.16 to 3.27, P=0.012), when compared to females.

Conclusion: In this 20 years of follow up study, female gender was a protective factor for mortality in patients with NSCLC submitted to surgery with curative intent in stage I when compared to males. This effect is not observed in patients in stage ≥II.

P2735 A retrospective study of lung cancer in young patients
Pradeep Rajagopalan, Douglas George Price, Sivananam Sasikumar, Ramin Baghi Ravary, Neil Robert Goldsack, Brett Pereira. Respiratory Medicine, Kent and Canterbury Hospital, Canterbury, Kent, United Kingdom

Introduction: Over-representation of women, more advanced disease staging at presentation, better performance status and similar survival figures have been noticed in younger (<50 years) lung cancer patients as compared to the general patient population with the disease.

Objective: A retrospective study (February 2010) was done to derive clinicopathological data from young lung cancer patients treated in our hospital in the last 5 years. We also compared our findings with National Lung Cancer Audit (NLCA), 2007 in the UK. The NLCA data were considered as a reflector of the patients from all age groups.

Findings: 36 patients were identified for the study. Median age was 47 (37-50), 19 (54%) were female. 76% had WHO performance status (PS1) in patients with documented PS. 43% had family history of lung cancer. 89% were current smoker. Histology was achieved in 87%. 68% had non small cell carcinoma (NSCLC) including 40% adenocarcinoma, 24% had small cell carcinoma. 3 had carcinoid. 55% of histology proven NSCLC had stage 4 disease at presentation. 86% had some form of treatment (surgery, chemotherapy or radiotherapy). 6 (18%) had resection.

NLCAs & Local Data Comparison

Male:Female 1.4:1 0.84:1
Histology 68% 87%
Stage 4 or Presentation 9% 5%
Active Treatment Received 51% 87%
Resection in NSCLC 14% 18%
Median NSCLC survival 232 246

NLCAs & Local Data Comparison

Male:Female 1.4:1 0.84:1
Histology 68% 87%
Stage 4 or Presentation 9% 5%
Active Treatment Received 51% 87%
Resection in NSCLC 14% 18%
Median NSCLC survival 232 246
Conclusion: Majority of these patients presented with advanced stage disease as in previously reported larger cohorts. Women were a majority but they had a better survival than men. 41% had positive family history suggesting a possible genetic factor. Favourable performance status resulted in higher resection rate and active treatment compared to overall patient population. But did not lead to better survival.

P2736 KRAS mutations in non-small cell lung cancer (NSCLC) – Experiences by routine molecular testing in a German lung cancer centre
Christian Boch1, Jens Kollmeier1, Daniel Misch1, Andreas Roth2, Torsten Blum1, Wolfram Gruening1, Nicolas Schoenfeld1, Thomas Manring1, Torsten T. Bauer1. 1Department of Pneumology, Pulmonary Diseases Clinic, Heckeshorn, HELIOS Kliniken Emil von Behring, Berlin, Germany; 2Institute of Pathology, Helios Kliniken Emil von Behring, Berlin, Germany

Introduction: More than 20 years ago KRAS mutations were identified but the utility of this information remains vague. Several clinical studies indicate that KRAS mutations are associated with shorter overall survival (OS) in presellected populations. With the routine testing of KRAS mutation in all newly diagnosed NSCLC in our clinic for 14 months, we offer a new perspective.

Methods: From Nov 2009 until Dec 2010, all subsequent biopsies of newly diagnosed NSCLC (n=753) obtained by surgery, routine bronchoscopy or CT guided biopsy were tested for the ability to be analysed by LightCycler Real-time PCR accessing codons 12 and 13 for the presence of KRAS mutations. The obtained data were correlated with the centre-bound tumour registry for survival data.

Results: A total of 504 cases with NSCLC, 229 adenocarcinoma (AC), 163 squamous cell carcinoma (SCC) and 112 other NSCLC were eligible for analysis. Among those, KRAS mutation was present in 79/504 cases (15.7%, male, n=39).

The highest frequency of KRAS mutation was observed in AC 61/229 (27%). Patients with SCC (61/163, 3.7%) and other NSCLC (12/112, 11%) showed KRAS mutations less often (p < 0.001). By analysing EGFR mutations in the same population, we detected only one KRAS positive patient with a simultaneous EGFR mutation. By now we did not find a significant difference in OS expressed as mean ± (SEM) (KRAS negative 37.6±6 vs KRAS positive 40.6±20, p = 0.244).

Conclusion: The frequency of KRAS mutations in NSCLC in our unselected cohort is comparable with previous reports. They are more frequent in AC compared to other histologic subtypes. To date we could not confirm any association with OS.

P2737 Characterization of patients with non-small cell lung cancer (NSCLC) relative to its EGFR mutational status
Ana Castro, Ana Antunes, Ana Barroso, Sara Conde, Sofia Neves, Bárbara Parente, Centro Hospitalar Vila Nova de Gaia - Espinho EPE, Vila Nova de Gaia, Portugal

Introduction: EGFR (Epidermal Growth Factor Receptor) mutations occur in 10-15% of non-Asian patients with NSCLC. In 2010, our Lung Cancer Centre started performing this sequencing systematically in all patients with NSCLC, regardless of histology, smoking or sex.

Objective: To identify a group of patients that undergo EGFR sequencing in the year 2010 and assess their frequency.

Methods: Descriptive statistical analysis of patients with NSCLC who did EGFR sequencing in 2010.

Results: The sequencing was performed on 126 patients, 75% males and 25% females. Average age 65 years. 69% non or ex-smokers and 31% smokers. Histology: 59%adenocarcinoma, 23%squamous cell carcinoma (SCC). Mutations were detected in 13 patients (10.3%), one mutation in exon18, 6 in exon19, 2 in exon20, 4 in exon21 and no resistance mutations were described. The mutation rate was higher in females (53%), non-smokers (46%) and adenocarcinoma (62%). Female patients with EGFR mutation: 86%non-smokers, 85%adenocarcinoma, 15%epidermoid histology. Male with EGFR mutation: 83%ex-smokers, 67%SCC, 33%adenocarcinoma. Non-smoker mutated patients were all female, 83%adenocarcinoma, 17%SCC.

Conclusion: Our group had a mutation rate of 10.3%, predominantly female, non-smokers, adenocarcinoma histology, accordingly with literature. This work also intends to highlight the importance of sequencing EGFR gene mutation in all patients with NSCLC, whereas mutation is also frequent in males, squamous histology and smokers. These patients are given the possibility of a 1st line treatment in the with TK inhibitors, with a greater increase in survival, improved quality of life and a better chance for other courses of chemotherapy.

P2738 Analysis of EGFR-mutations in a diverse urban patient population
Amanda Tuftman1, Kai Wagner2, Andreas Jung1, Rudolf Maria Huber1.
1Department of Respiratory Medicine, Campus Eppendorf, University Hospital, Hamburg, Germany; 2University of Medicine, Ludwig Maximilians University, Munich, Germany

Background: EGFR-mutations are predictive for EGFR-TKIs in advanced NSCLC, however, not all pts are screened for these mutations. Clinical crite-
These figures were significantly lower for control samples, i.e., 2%, 6%, and 2%, respectively (all P-values < 0.001). Cumulative analysis of RASSFIA methylation, i.e., combining methylation positivity outcomes for day 1-6, and day 1-9, revealed RASSFIA methylation in 39% and 47% of cases, respectively, versus 8% and 9% of controls, respectively.

Conclusion: Our study suggests that spumum collected over multiple successive days results in a gain in sensitivity, at the expense of a small loss in specificity, for the detection of lung cancer.

P2742
Molecular test supporting early lung cancer detection project based on pilot Pomeranian lung cancer screening program
Amelia Szymonowska-Narloch1, Rafal Dziadziuszko2, Malgorzata Jelitno-Gorska1, Witold Ryznan1, 1Department of Clinical Oncology and Radiotherapy, Medical University of Gdansk, Gdansk, Poland; 2Department of Allergology, Medical University of Gdansk, Gdansk, Poland; 3Department of Thoracic Surgery, Medical University of Gdansk, Gdansk, Poland

Introduction: Lung cancer is one of the most common malignant neoplasms worldwide. Only 10% of patients can be cured, mostly due to late diagnosis and high aggressiveness of lung cancer.

Aim: Aim of the Molecular Test Supporting Early Detection of Lung Cancer Project is to perform genetic studies and serum protein studies in order to increase the efficacy of radiological examinations in early lung cancer screening and to define population of particularly high risk of lung cancer development. The project consists of five thematic areas.

Results: Pomeranian Pilot Early Detection Program has been realized from the 17th November 2008. In this project 8000 healthy subjects with high risk of developing lung cancer (age 50-75, at least 20 pack-years) were screened with low-dose CT scanning of the lungs. As a co-project blood samples were taken from those patients who gave informed consent. In the first year of project realization 6836 healthy subjects were screened. In above a half of the cases (53%) at least one pathological alteration in lung tissue was found. Among 186 patients, in whom the lesion was above 1 cm in diameter, in 56 cases lung cancer was diagnosed. Almost 60% of lung cancer cases were in stage IA.

Conclusions: Pomeranian Pilot Lung Cancer Screening Program and Molecular Test Supporting Early Lung Cancer Screening Project - Moltest 2013 are dedicated to define population of particularly high risk of lung cancer development.

P2743
Current screening programs for lung cancer – Are inclusion criteria too rigorous to identify asymptomatic patients?
Anders Bugge, Anne Naalsund, May Britt Lund. Department of Respiratory Medicine, Oslo University Hospital, Rikshospitalet, Oslo, Norway

Background: Preliminary results from the controlled National Lung Cancer Screening Trial (NLST) indicates a mortality reduction of > 20% in screened patients; high risk being defined as smokers (ex/current) > 55 years old with > 30 pack-years. Recent studies suggest that female smokers develop lung cancer at a younger age and following smaller amounts of tobacco consumption than males. In industrialized countries the incidence of lung cancer is falling in males, but increasing in females. We aimed to assess if the inclusion criteria used in NLST would have identified lung cancer in a cohort of asymptomatic subjects who underwent surgical resections at our tertiary university hospital.

Material and methods: During the period 2002-10 clinical data from 1043 consecutive patients with 1204 cancerous cases with lung cancer were retrospectively registered. 626 patients (294 (47%) females, mean age 68 years, and 332 (53%) males, mean age 64 years), underwent surgery. Results: Of the 626 patients who underwent surgery, 267 (42%, 131 females, 136 males) had no clinical manifestations of lung disease at presentation, and chest x-rays had been performed for co-incidental conditions. In females, 30/131 (23%) were current or ex-smokers with > 30 pack-years. In males, the corresponding proportion was 65/136 (48%). Applying the NLST criteria, 77.7% of the females and 52% of the males would not have been admitted to the screening program.

Conclusion: Less than one forth of asymptomatic females who underwent resection for lung cancer would have been included in NLST as their total consumption of tobacco in pack-years was too low. Also, half of symptom-free resected males would have been excluded from screening.

*Is an EGF mutation associated with lower glucose metabolism in the FDG-PET?*

Gregor Förster1, Jens Kollmeier2, Martin Raible1, Turna Kocer1, Sergey Gritf1, Dirk Kaiser2, Torsten Bauer2.

1Department of Nuclear Medicine, HELIOS Klinikum Emil von Behring, Respiratory Diseases Clinic Hecheshorn, Berlin, Germany; 2Department of Pathology, HELIOS Klinikum Emil von Behring, Respiratory Diseases Clinic Hecheshorn, Berlin, Germany; 3Department of Thoracic Surgery, HELIOS Klinikum Emil von Behring, Respiratory Diseases Clinic Hecheshorn, Berlin, Germany

**Background/Aim:** In non-small cell lung cancer (NSCLC), new therapies that target specific oncogenic pathomechanisms like the epidermal growth factor receptor (EGFR) were developed. Positron emission tomography (PET) using fluorodeoxyglucose (FDG) is routinely implemented in the diagnosis and staging of NSCLC. In this study, we analyzed the correlation between molecular markers like EGFR and the glucose metabolism of NSCLC.

**Methods:** 80 patients with NSCLC were examined with FDG-PET/CT using standard scanning protocols; routinely the maximal standardized uptake value (SUVmax) of the tumour was determined. The demographic criteria of all patients were similar, all underwent surgical excision of the tumour. The tumour tissue was characterized histological and by molecular typing, including the EGFR status. The SUV was correlated with diverse parameters.

**Results:** The tumour histology showed in 36 patients a squamous cell carcinoma (45%), in 33 an adenocarcinoma (41%) and in 11 other tumour entities (14%), the average SUVmax were 12.1 (±4.8) (±SD), 9.0 (±4.4) and 11.9 (±4.8), respectively. In only 5 patients an activating EGFR-mutation was found, all others showed the EGFR wild-type. All but one mutation were found in patients with adenocarcinoma (12.1% of that histology); these tumors showed a very low SUVmax of 4.1 (±0.9). In contrast, one EGFR-mutated squamous cell carcinoma showed a very high SUV of 20.3.

**Conclusion:** In our patient cohort with NSCLC, all patients with adenocarcinoma and EGFR mutation showed a low glucose metabolism. This finding may suggest that these tumours have down regulated metabolism and may be anticipated by lower SUV in FDG PET scans.

This study was supported by the Oskar-Helene-Heim foundation.

**P2747**

*An analysis of EGFR expression and tumour imaging in non-small cell carcinomas of lung*

Vijayalakshmi Thanasekaraan, Prathiba Duvuru, Shalinee Rao, Safienna Mohamed, Samuel John Sundar. Chest tomography was reviewed to assess for tumour features. The correlation of EGFR expression with radiological features may reveal their possible relationship.

**Aim:** To evaluate EGFR expression in NSCLC and correlate with their radiological features.

**Material and method:** Twenty -two cases of NSCLC were histologically subclassified based on WHO classification of lung carcinomas. Immunostaining for TTF-1, p63 and EGFR were performed on paraffin embedded tissue sections and their expression evaluated. Chest tomography was reviewed to assess for tumour location, diameter, contours, margins, cavitation and lymph node enlargement.

Findings of radio-imaging and EGFR immunoreactivity were correlated.

**Results:** Fourteen and 8 cases of squamous cell carcinoma were identified. Epidermal growth factor receptor expression was noted in 86.3% of tumours. About 92.8% of adenocarcinomas and 75% of squamous cell carcinomas were EGFR positive. On radiology, mean diameter of lesion was found to be 36.4mm and 6.1mm in EGFR positive and negative tumours respectively. Fourteen EGFR positive cases were well defined and five poorly defined. Each of all the eight cases with pleural effusion and regional lymphadenopathy were EGFR positive.

**Conclusion:** Major percentage of NSCLC showed EGFR expression reinforcing its utility for targeted therapy. A positive EGFR correlation was noted with tumour size, regional lymphnode enlargement and pleural effusion which reflect biologically aggressive property of EGFR positive tumours.

**P2748**

*Integrated 18F – FDG PET dynamic contrast enhanced CT to phenotype non-small cell lung cancer*

Thula Weni1, Munir Shastry2, Kenneth Miles1, Sam Janes1, Raymundo Endoto2, Marie Hill2, Peter Ell2, Ashley Groves2, 1Respiratory Medicine, Lister Hospital, Stevenage, United Kingdom; 2Centre for Respiratory Research, University College London, London, United Kingdom; 3Centre for Respiratory Research, University College London, London, United Kingdom; 4Centre for Respiratory Research, University College London, London, United Kingdom; 5Centre for Respiratory Research, University College London, London, United Kingdom; 6Centre for Respiratory Research, University College London, London, United Kingdom; 7Centre for Respiratory Research, University College London, London, United Kingdom; 8Centre for Respiratory Research, University College London, London, United Kingdom; 9Centre for Respiratory Research, University College London, London, United Kingdom

**Objectives:** To apply molecular and functional imaging to the pre-treatment assessment of disease using combined Dynamic Contrast enhanced CT (DCECT) and18F-Fluorodeoxyglucose (FDG) PET in lung canceroma to define the cancer phenotype.

**Methods:** Seventy four consecutive patients with potentially curable lung cancer were prospectively recruited for combined positron 18F-FDG PET/DCECT using an integrated 64 detector PET/CT. There were 10 technical failures leaving a study population of 64 patients (35 males; 29 females. Mean age 67.5). Studies were using an integrated 64-detector PET/CT. The uptake of 18F-FDGPET quantified as the Standard Uptake Value (SUVmax) assessed tumour metabolism.

**Results:** The mean tumor SUVmax, PE and SPV were 13.8, 37.6 HU and 6.5. No statistically significant relationships between tumor metabolism and vascular parameters. There were significant associations between tumor size and vascular parameters - SUVmax v size (r=0.4, p=0.001), SUVPE v size (r=0.4, p<0.001). SUVmax and SUVPE were higher in SCC than in adenocarcinoma (17.4 versus11.5; p=0.026 and 0.57 versus 0.35, p=0.021 respectively). A phenotype with low metabolism and high vascularity was significantly more common amongst adenocarcinomas (p<0.01), whilst high metabolism with high vascularity was more common amongst SCC (p=0.005).

**Conclusion:** Vascularity and metabolism are uncoupled in NSCLC. Since some lung cancer patients have inadequate tissue sampling metabolic flow data could be helpful clinically in managing lung cancer patients to targeted therapy using non-invasive 18F-FDG PET/DCECT scan.

**P2749**

*FDG PET/SUVmax is an independent prognostic indicator in patients with non-small cell lung cancer*

Lauras Jane Smith1, Neal Navani1, Paul Bassett1, Irfan Kayani4, Ashley Groves4, Sam Janes1, 1Department of Thoracic Medicine, University College Hospitals NHS Foundation Trust, London, United Kingdom; 2Centre for Respiratory Research, University College London, London, United Kingdom; 3Joint UCL/UCLH/Royal Free Biomedical Research Unit, University College London, London, United Kingdom; 4Department of Nuclear Medicine, University College Hospital, London, United Kingdom

**Background:** FDG-PET is a commonly used non-invasive tool for diagnosis and staging of lung cancer, the leading cause of cancer death. SUVmax has been suggested to be an independent prognostic factor in patients with operable non-small-cell lung cancer (NSCLC). However, PET-CT is not recommended in patients with advanced disease.

**Aim:** Evaluate the utility of SUVmax of the primary lesion as an independent predictor of overall survival in patients with NSCLC, including advanced disease.

**Methods:** Retrospective analysis of 47 patients (29 male, median age 69 years) with NSCLC (stage I 38%, stage II 9%, stage III 34%, stage IV 18%) who underwent FDG PET at diagnosis. Cox regression analysis was applied to examine the effect of SUVmax on survival. This was then adjusted for stage, treatment, age, sex and histology.

**Results:** There was a significant difference in survival between patients who had a low vs high SUVmax, hazard ratio 3.31 (p=0.006), such that an increase in SUVmax of the primary of 5 points conferred a hazard ratio of 1.49 (p=0.013).

**Conclusion:** The relationship was maintained when multiple factors were adjusted for, with a hazard ratio for an increase in SUVmax of the primary of 5 points of 2.8 (p=0.03).

**FDG-PET provides additional information about prognosis in NSCLC, independent of stage at presentation.** The relationship between SUVmax of the primary and survival is maintained, even in patients with advanced disease.
Is our preoperative TNM staging reliable?

Marta Inchausti1, Larraitz Garcia1, Maria Alfonso2, Ruth Diez3, Amaia Urrutia1, Amaia Sagarna1, Estibaliz Perez1, Unai Jimenez4, Pedro Amado5, 1Pneumology, Cruces Hospital, Barakaldo, Bizkaia, Spain; 2Thoracic Surgery, Cruces Hospital, Barakaldo, Bizkaia, Spain

Introduction: Agreement between preoperative and surgical TNM staging is usually <50%.

Aim: To compare our preoperative staging (cTNM) with surgical-pathological staging (pTNM).

Methods: Cross-sectional study of patients with lung cancer surgically treated from 1-1-08 to 31-12-09, excluding relapses or neoadjuvant therapies. Preoperative stag-

ing based on: CT scan, positron emission tomography (PET-CT), endobronchial ultrasonography (EBUS), endoscopic ultrasonography (EUS), mediastinoscopy. Agreement between cTNM and pTNM (according to 1997 TNM classification) was analyzed.

Results: 166 cases (characteristics in table 1). In table 2, concordance between cTNM and pTNM. cTNM and pTNM matched in 80 cases (48,2%), understaging occurred in 5 cases (3%) and overstaging in 81 (48,8%). But in most cases, this lack of agreement would not suppose changes in the therapeutic decision, just in 21 cases (12,5%) the cTNM carried out a wrong therapeutic procedure (18 N2 found in thoracotomy and 3 T4 unrespectable). TC and PET-TC used in all cases, EBUS in 35, EUS in 2 and mediastinoscopy in 3. In N staging, PET-CT was cN0 in 133 cases (where 7 were pN2, 5,2%) and cN1 (21 cases, 25,8%). We performed 35 EBUS (33 cN0, 2 cN1) and final pN was N2 in 3 cases (FN rate 8,5%).

Conclusions: 1. Low agreement between cTNM and pTNM (48,2%), but only in 12,5% of cases would suppose a change in the treatment. 2. 25% of pN2 when cN1 by PET-CT (EBUS should be done). 3. When EBUS negative for N2, only 8,5% pN2.

P2752

Prevalence of silent brain metastasis (BM) in the initial staging of non-small cell lung carcinoma (NSCLC)

L. Marzelli PariEspinoza, Daniel Huertas Almela, Susana Padrones Sanchez, Samantha Aso Gonzalez, Antoni Rosell Gratacos, J. Ignacio Martinez Ballarin, Jordi Dorca Sorgatul, Nuria Gonzalez Calzada. Respiratory Diseases, Hospital Universitari de Bellvitge, Barcelona, Spain

Introduction: Positron emission tomography (PET) can detect up to 15% of distant metastases in lung cancer, but it has a low sensibility in detecting BM.Guidelines recommend performing MRI only if there are neurological symptoms (NS). Our aim was to assess the role of MRI in detecting silent BM in the initial staging of NSCLC.

Material and methods: Retrospective analysis of new cases of NSCLC without distant metastases in lung cancer, but with a low sensibility in detecting BM.Guidelines recommend performing MRI only if there are neurological symptoms (NS). Our aim was to assess the role of MRI in detecting silent BM in the initial staging of NSCLC.

Results: MRI was made in 95 patients with NSCLC. 39%,40% and 21% had squamous cell carcinoma, adenocarcinoma and other histology respectively.

20%, 21% and 59% were stage I, II and III respectively BM were diagnosed by MRI in 11,6% (11/95) of the patients, and six of them (6/95, 6,35%), did not present NS.A stratified binary logistic regression analysis showed that there were not any clinical variable associated with the presence of silent BM in the asymptomatic subgroup, whereas central tumours (p=0,005) and ADK (p=0,01) were associated to BM in patients with NS. In both subgroups: staging, SUVm, tumour size and lymph nodes were not statistically indicative of BM.

Conclusions: Prevalence of silent BM at initial staging was 6,35%. Neither clinical nor radiological variables could predict silent BM. We concluded MRI is justifised as a routine procedure in NSCLC patients without BM in the PET. Partially funded by SOCAP.
P2753
Assessment of physical functioning in surgical candidates with non-small cell lung cancer: Preliminary comparison of performance status to symptom-limited cardiopulmonary exercise testing
Michael A. Roman1, Neil D. Eves2, Lee W. Jones3, 1Department of Medicine, Rockys Hospital, University of Calgary, Calgary, AB, Canada; 2Human Kinetics, University of British Columbia, Kelowna, BC, Canada; 3Department of Radiation Oncology, Duke University Medical Center, Durham, NC, United States
Background: Performance status (PS) scoring systems are used routinely by clinicians to guide management of patients with non-small cell lung cancer (NSCLC). However, PS scoring systems are subjective with poor inter-rater reliability and do not provide an objective measure of functional status. The aim of this study was to compare the variability in an objective measure of cardiopulmonary fitness (VO2peak) among surgical candidates with histologically confirmed NSCLC across different PS categories as assessed by the Eastern Cooperative Oncology Group (ECOG) Score.
Methods: Using a cross-sectional design, 389 subjects underwent an incremental cardiopulmonary exercise test with expired gas analysis to determine VO2peak prior to surgical resection.
Results: Mean VO2peak significantly declined across increasing ECOG categories (Table 1). There was a wide range in VO2peak in each ECOG category with similar ranges in VO2peak within groups, in particular in subjects classified as ECOG 1 and 2.

Table 1. Comparison of VO2peak to ECOG PS in NSCLC

<table>
<thead>
<tr>

Conclusions: VO2peak may provide a more sensitive evaluation of physical functioning than ECOG. Accurate assessment of functional status may have important implications for mortality risk and therapeutic management in the oncology setting.

P2754
Comparison of predictive respiratory function parameters of lung cancer patients after RFA procedures and diagnosis with postoperative complications and relation with mortality and morbidity
Selma Altun1, Mustafa Kahraman2, Dilek Kammaz2, Esin Yentuk2, Fırisdev Atabay3, Celalettin Kocakart4, Esin Tunçay2, Mehmet Ali Bedirhan5, Yasemin Teksoğlu1, 1Ahievren Chest Hospital, Pulmonary Medicine, Trabzon, Turkey; 2Evido Chest Diseases and Surgery Hospital, Pulmonary Medicine, Istanbul, Turkey
Introduction and aim: Lung cancer with COPD increases surgical morbidity and mortality. In this research, non-small cell lung cancer (NSCLC) patients with/without COPD were investigated: 1. When preoperative predictive respiratory function parameters take place during postoperative period? 2. Which parameters are more valuable as a predictor of morbidity and mortality? Methods: This research was planned in a prospective manner. 46 NSCLC patients having pulmonary resection were grouped into 2. Group A: 23 moderate COPD patients. Group B: 23 non-COPD patients.
We checked patients for respiratory function tests, DLCO and arterial blood gases. Group A was also checked for ventilation/perfusion scintigraphy and VO2max.
We calculated predictive preoperative FEV1 and DLCO. We repeated respiratory function and DLCO tests during postoperative 1st, 3rd and 6th months.

Results and conclusion: There wasn’t any significant difference between 2 groups over demographic datos, operative skill, stage of cancer and type of resection. (p>0.05) Morbidity and mortality rates of Group A were significantly higher than Group B. Group A patients reached predicted results in 1st month and FEV1, DLCO results gained at 6th month were higher than predicted. In both groups, especially in Group B, best remarkable indicator for prediction of postoperative complications was DLCO%
Every patient going on pulmonary resection, should be tested for DLCO for determination of postoperative complication risk. It should not be forgotten that parameters checked for preoperative evaluation (FEV1% and DLCO%) are not always enough for decision of surgery.

P2755
Effect of adjuvant chemotherapy on lung function in early stage NSCLC
Michaela Zorn1, Johan VanotenKiste2, Ivan Zana3, Felix Herth4, Jürgen Fischer5, Niels Reimnith5, Frank Griessinger2, Michael Thomas2, 1Pneumology and Respiratory Critical Care, Thorasklinik, Heidelberg, Germany; 2Respiratory Oncology Unit, University Hospital Gasthausberg, Lueven, Belgium; 3Statistics Department, HZM, Westbaden, Germany; 4Onkologie Loevenstein, Loevenstein, Germany; 5Thoracic Oncology, Thorasklinik, Heidelberg, Germany; 6Oncology, Plus Hospital, Oldenburg, Germany
Introduction: Pulmonary function can decline after induction chemotherapy and be predictive of perioperative complications in NSCLC. However, the influence of adjuvant chemotherapy on lung function is underdetected.
Methods: In a phase 2 trial on adjuvant therapy (TREAT), 132 patients with R0 resected NSCLC stage IB-IVN3, were randomized to 4 cycles Cisplatin/Vinorelbine (CVb, n=65) (C 50 mg/m² d1+8; Vb 25 mg/m² d1,8,15,22) 4 weeks or to 4 cycles Cisplatin/Pemetrexed (CPx, n=67) (C 75 mg/m², P 500 mg/m², d1 q3 weeks. Pulmonary function tests (forced expiratory volume in 1 s [FEV1], vital capacity [VC], total lung capacity [TLC], diffusing capacity [DLCO], blood gas analyses [BA]) were analyzed before and 30 days after therapy. Parameter changes were calculated (Δ-mean differences) and statistically analyzed.

Results: Overall, VC increased significantly (Δ+200 ml, n=47, p<0.0001), while TLC did not change significantly (Δ+220 ml, n=41, p=0.174). For CPx, FEV1 increased significantly (Δ+150 ml, n=47, p=0.0017), but not for CVb (Δ 3 ml, n=30). DLCO decreased only for CVb (-8%, n=6) but not for CPx (Δ-3%, n=17) (p=0.58). BGA did not change (p=0.99). In a Cox regression analysis, baseline lung function did not influence treatment failure (time until withdrawal from therapy due to adverse events, relapse, death, treatment refusal, non-compliance).

Conclusions: Adjuvant chemotherapy does not result in a decrease of lung function parameters but in a significant VC increase, probably due to ongoing postoperative improvement. Still, a non-significant difference between a DLCO decline under CVb but not for CPx warrants further attention. Moreover baseline lung function parameters do not impact treatment failure.
FEVI and DLCO had a significant correlation (R=0.376 p<0.001). The same analysis for both groups showed that FEVI and DLCO correlated better in ICT (R=0.630 p<0.03) than in NCT (R=0.244 p<NS). In NCT group, 10 from 14 analysis for both groups showed that FEV1 and DLCO correlated better in ICT. In ICT group, FEV1 and DLCO had a significant correlation (R=0.376 p=0.009). The same correlation was observed in NCT group. The mean (SD) age of patients was 69 (11) years. No adverse event was observed with both methods. Conclusion: FNA of palpable supravacular lymph nodes using clinical examina-
tion among patients with suspected lung cancer is a safe, cost-effective and as
accurate as US guided method.

P2762
CT guided biopsy: Predictors of outcome and complication rate
Rahuldeh Sarkar1, Amir Balawala1, James Jamieson-Young1, Andrew Wight1, Elspeth Partridge2, Marta Babores 1.

Aim: To compare the accuracy of FNA of palpable supravacular lymph nodes using palpation and ultrasound (US) among patients with suspected lung cancer.

Methods: Over a 30 month period (6/2008 – 12/2010) we examined 71 con-
secutive patients (54 males, 64.3±11.5 years) suspected for lung cancer with palpable supravacellular lymph nodes. All patients underwent US and palpation guided FNA at the same time. Samples were studied by immunohistochemical analysis.

Results: Sixty-four out of 71 patients had positive cytology by US (sensitivity: 93%) while the sensitivity of palpation was 90% (62/69). Seven patients under-
went surgical sampling of lymph nodes and the diagnoses were: 3 patients with adenocarcinoma, 2 with small cell lung cancer (SCLC) and 2 M. tuberculosis. Cytological diagnoses by FNA were: SCLC (23 patients), adenocarcinoma (22), squamous (7), undifferentiated non-small cell lung cancer (NSCLC) (6), unknown origin (2), lymphoma (2), sarcoidosis (1), and large cell carcinoma in 1 patient with NSCLC TNM classification was: stage IIB (24) and IV (12). Patients with SCLC demonstrated: limited (16) and extensive disease (7). No adverse event was observed with both methods.

Conclusion: FNA of palpable supravacular lymph nodes using clinical exami-
nation among patients with suspected lung cancer is a safe, cost-effective and as
accurate as US guided method.

P2763
Mediastinoscopy necessary in patients with negative EBUS-TBNA – A challenge to the ESTS Guidelines for staging of lung cancer
Mark Krasnik 1, Peter Vilmann2, Felix Herth3.

Objective: Mediastinoscopy is the golden standard for mediastinal staging of lung cancer. The aim of the present study was to examine whether mediastinoscopy may be avoided if a standardized EBUS-TBNA procedure using the same criterias as recommended mediastinoscopy was performed.

Methods: Patients with known or suspected lung cancer underwent a standardized EBUS-TBNA procedure using the same criterias as recommended mediastinoscopy. Both patients with EBUS-TBNA from station 4 R, 4L, and 7 without cancer were further referred for a VATS/thoracotomy.

Results: A total of 76 out of 95 consecutive patients, 48 males, 28 females were enrolled. Mean age 65 years (range 40-85). The mean sizes of the lymph nodes in all 3 stations were 9mm (range 2 - 35mm). The final primary diagnosis was cancer in 67 patients and benign diagnoses in 8 patients. In 4 patients mediastinal metastases were found by surgery (5%). One patient had a metastasis in station 4 R and 2 patients in station 5 and one patient in station 6. The NPV was 0.95 and with a specificity of 1.

In total the false negative rate of EBUS-TBNA in mediastinal staging of lung cancer was 4 out of 67 (6%).

Conclusions: The results of the present study seem to challenge mediastinoscopy as the gold standard. When EBUS-TBNA is performed under the same standard- ized conditions as described by the ESTS guidelines for mediastinoscopy with demonstration of lymphatic tissue from relevant lymph node stations, our study shows that very little, if anything, is gained by an additional mediastinoscopy and can be avoided.

P2764
Small cell lung cancer and thoracic lymph nodes metastatic involvement: A correlation
Vanja Kojadinovic Ostic, Zdravko Kojadinovic, Goran Djedanic, Palmodontology, Institute for Lung Diseases of Vojvodina, Sremska Kamenica, Serbia.

Aim: To determine the frequency of lymph node metastases depending on the lung cancer size.

Methods: A total of 136 lung resection samples obtained on surgery of the lung cancer patients, 114 males and 22 females, at the mean 54.8 years of age.

Results and discussion: Squamous carcinoma was the most frequent lung cancer type (66.9%), followed by adenocarcinoma (27.2%), while small-cell (4.4%) and largest (1.2%) cancer types were more rarely found. Metastatic involvement of the lymph nodes was discovered in 80 (56.7%) of 136 examined lung resection samples. The total of 489 thoracic lymph nodes were examined and metastases found in 207 (40.3%). The tumors sized 1.1-2 cm metastasized in 47% of the lymph nodes; the tumors sized 2.1-3 cm involved 32.7% of the lymph nodes by metastases; the tumors sized 3.1-4 cm metastasized in 36.3% of the thoracic lymph nodes; the tumors sized 4.1-5 cm involved 36% of the lymph nodes by metastases; the tumors in the size of 5.1-6 cm metastasized in 28.6% of the lymph nodes while those of over 6 cm in diameter involved 69% of the lymph nodes by metastases.

Conclusion: The number of lymph nodes involved by metastases does not increase with the size of the tumor of up to 6 cm, however, a further increase of the tumor size (over 6 cm in diameter) significantly increases the number of metastatic lymph nodes.

Conclusion: Good pick up rate with complications well within acceptable standards were achieved in our study population. Depth of the lesion correlated well with pneumothorax and hemorrhage while size correlated with pneumothorax. Size was also a good predictors of conclusive biopsies.

P2763

The frequency and significance of radiologically detected indeterminate pulmonary nodules in patients with colorectal cancer

Yelda Varel1, Umut Varel2, Burçak Karaca2, Rüčhan Ünsu, Recep Savas1.
1Chest Diseases, M. Emre Seneredim Government Hospital, İzmir, Turkey; 2Medical Oncology, EGE University, İzmir, Turkey; 3Radiology, EGE University, İzmir, Turkey

Background: This study aims to investigate the frequency and significance of indeterminate pulmonary nodules in patients with non-metastatic CRC.

Methods: We retrospectively evaluated 1344 patients with CRC who underwent thoracic CT scans between the years January 2003-December 2009. Those with evident metastatic disease or already known to have pulmonary malignancies were excluded.

Results: Among all patients assessed, 55 (0.4%) of them had nodules that met the criteria of indeterminate pulmonary nodule. We analyzed the cases by size and number of nodules. A multivariable analysis demonstrated that indeterminate pulmonary nodules with irregular border (p<0.002), parenchymal localization (p=0.016) and being multiple in number (p=0.006) were predictors of metastatic disease.

Conclusion: The characteristics of indeterminate pulmonary lesions in CRC cases with no evidence of metastasis elsewhere have to be defined more comprehensively. We believe that for accurate decision of the frequency for follow-up interval further studies are required.

286. Palliation and morbidity in lung cancer patients

P2764

Sleep quality, quality of life and their correlative factors in lung cancer patients

Yanbin Zhou1, Yinhuan Li2, Wanling Huang3, Xingdong Cai4, Qingyi Zeng5, Lixia Huang6.
1Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; 2Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; 3Department of Respiration Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; 4Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; 5Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; 6Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China

Objectives: To investigate the sleep quality and quality of life in patients with lung cancer.

Methods: We evaluated the sleep quality and quality of life of 98 lung cancer patients in our hospital by Karnofsky performance status (KPS), the Pittsburgh sleep quality index (PSQI) and the European organization for research and treatment of cancer quality of life questionnaire-core 30 and lung cancer module (EORTC QLQ-C30 and LC13). Then the newly diagnosed patients who had not received any treatment before were reevaluated after a month from the time of diagnosis or the first episode of treatment.

Results: The responding rate was 59.8%, and the rate of follow-up in newly-diagnosed patients was 51.5%. Evaluating performance status of lung cancer patients by KPS, 76.8% of them were considered to be able to keep on their normal life or work. The KPS of younger or better educated patients was better than that of older or lower educated ones. Evaluating sleep quality in lung cancer patients by PSQI, 45.9% were classified as poor sleepers. Unmarried patients, patients with college education used sleep medicine more frequently than married patients or patients with primary or high school education. Sleep efficiency was lower in patients with complications than those without complications. Evaluating quality of life in lung cancer patients by EORTC QLQ-C30, Seniles had better emotional and social function and less financial problems than non-senile patients.

Conclusions: Sleep disturbances did exist in patients with lung cancer, which had a great impact on their quality of life. KPS was still one of the most important factors that influenced quality of life in lung cancer patients.

P2765

Preoperative anxiety may affect the quality of life and health outcome of the patients that undergo thoracic surgery

Maria Anagnostopoulou1, Ioannis Vamvakaris2, Grigoris Vogiatzis3, Cristos Sykaras2, A. Maria1, Ioannis Gkiozos2, Andriani Charpidou2, Konstantinos Syrigos1, 1Intensive Care Unit, Red Cross Hospital, Athens, Greece; 2Oncology Unit, 3rd Department of Medicine, Athens School of Medicine, ‘Sotira’ General & Chest Hospital, Athens, Greece; 3Anaesthesiology Dpt, ‘Sotira’ General & Chest Hospital, Athens, Greece

Purpose: Increased preoperative anxiety level may lead to adverse outcomes. The purpose of this study was to assess the relationship between the quality of life and preoperative anxiety during the four-week preoperative period in patients scheduled to undergo thoracic surgery.

Patients and methods: The study population consisted of 100 patients, 52 men and 48 women scheduled to undergo thoracic surgery. The average of age was 56.1±15.60 years. After providing informed consent, they were asked to answer a questionnaire, 12 to 15 hours prior to the scheduled thoracic surgery operation. The questionnaire included questions on demographics and incorporated the State Anxiety Inventory and SF-36 scales.

Results: Statistical analysis revealed that women (p=0.023), unemployed patients (p=0.01) and patients that were to be submitted to a mediastinoscopy (p=0.001) had elevated anxiety levels. Deterioration of several parameters relative to the quality of life was found to be related to increased anxiety levels. Limitations in work capability or other everyday activities as result of mental health problems (p=0.006), low vitality (p<0.001), bad general mood (p<0.001), deteriorated general health (p<0.001) and general mental health (p<0.001) were associated with preoperative anxiety. No differences were found in anxiety level between lung cancer and non-cancer patients.

Conclusions: This study showed an inverse proportional correlation between preoperative quality of life and anxiety during a period of four weeks prior to a thoracic surgery operation. Appropriate pharmaceutical and psychological support may improve patients’ anxiety status.

2766

Religiosity and depression of patients with lung cancer

Suzana Kukulj1, Branka Aukst-Margetic2, 1Department of Pulmonology, Clinical Hospital Center Zagreb, Zagreb, Grad Zagreb, Croatia; 2Department of Psychiatry, Clinical Hospital Center Zagreb, Zagreb, Grad Zagreb, Croatia

The relationship between depression and religiosity of patients with lung cancer is not yet explored.

Aim: To examine possible association of religiousness and depression of patients with lung cancer and the relationship between religiosity and depression with sociodemographic data.

Subjects and methods: Forty-four patients with lung cancer were consecutively included. The Strength of Religious Faith Santa Clara questionnaire was used for assessment of religiosity, and for measuring depression the Center for Epidemiological Study of Depression (CES-D). Overall religiosity was measured with 5-point Likert scale.

Results: The mean age of 59-54 years, mean overall religiosity, SCSCOF 27.8, CES-D 17.9. In 43.1% meets the criteria for diagnosing depression. In logistic regression analysis the only significant predictor of depression was less common frequency of going to church. Depression is more pronounced in women and in religiosity there is no difference by gender. Significant differences in the items that measure loneliness, sadness, feelings of fatigue and anxiety are more pronounced in women.

Conclusions: Higher frequency of going to church predicts lower depression rate in the group of patients. Strength of faith and general assessment of religiosity were not significant predictors of depression which is not in accordance with the findings other studies. These differences might be associated with factors specific for lung cancer and may be effect of gender, and should be explored in further studies.

Potential role of antidepressants as part of anticancer therapy
Dragana Jovanovic1, Ruza Stevic1, Spasoje Popović1, Marta Velinovic1, Natalija Samardzic2, Dragana Marić1, 1Clinic for Pulmonary Diseases, 2Clinic for Radiology, Clinical Center of Serbia, Belgrade, Serbia

Antidepressants are widely used as part of adjuvant analgesic therapy. Since in vitro studies show that antidepressants have potent antitumor properties, it raised the possibility of a potential role as a part of anticancer therapy.

Aim: To estimate possible favorable effect of Mianserin (M) in lung cancer patients: (1) potential influence on survival due to anticancer properties, (2) improvement of patients psychological pattern and health-related quality of life (HRQoL).

Methods: Two groups of advanced NSCLC patients were included: 52 pts treated with CT and without M and 60 pts treated with BSC with or without M. Differences in response rates (only for CT treated group), in overall survival (OS) and HRQoL, (based on EORTC QLQ-30 and QLQ-LC 13) with within (sub)groups were evaluated.

Results: The RR difference within the CT subgroups treated with or without M, was not statistically significant: 8/24 (33.33%) vs 6/28 (21.43%). There was significant difference in median OS with 95% CI for the different treatment subgroups (only BSC, BSC plus M, only CT and CT plus M), respectively: 6 (5-6), 7 (6-8), 8 (7-10) and 10.5 (10-13) months (p=0.89;10-15). Pts receiving M (and CT or BSC) had significantly better OS (p=0.0012). CT treated pts receiving M had significantly better survival comparing to those not receiving M (p=0.0015). BSC treated pts receiving M had also significantly better survival than those without M (p=0.003). M treated subgroups had significantly higher scores of QLQ-C30 and LC13 i.e. better HRQoL, as well.

Conclusion: Benefit of antidepressants as part of anticancer therapy noted should be further investigated in larger patients population studies with different antidepressants.

P2768
Frequency of thromboembolic events in patients with lung cancer at the time of diagnosis and in the course of disease
Markus Samulowski1, Catharina Crolew1, Torsten Blum1, Jens Kollmeier1, Wolfram Grünung1, Nicola Schönfeld1, Roland C. Bittner2, Torsten T. Bauer1.
1Department of Pneumology, Pulmonary Diseases Clinic Heckeshorn, HELIOS Klinikum Emil von Behring, Berlin, Germany; 2Institut for Diagnostic and Interventional Radiology, Helios Klinikum Emil von Behring, Berlin, Germany

Background: Clinicians are frequently confronted by thromboembolic events (TEE) in patients with lung cancer. Early pulmonary embolism (within the first 3 months after primary diagnosis) is regarded as a negative prognostic factor. However, the benefit of a prophylactic anticoagulation has not been evaluated so far. Lung cancer itself as well as certain chemotherapeutic agents are considered to be independent risk factors for TEE.

Methods: Two groups of advanced NSCLC patients were included: 52 pts treated with CT and without M and 60 pts treated with BSC with or without M. Differences in response rates (only for CT treated group), in overall survival (OS) and HRQoL, (based on EORTC QLQ-30 and QLQ-LC 13) within (sub)groups were evaluated.

Results: The RR difference within the CT subgroups treated with or without M, was not statistically significant: 8/24 (33.33%) vs 6/28 (21.43%). There was significant difference in median OS with 95% CI for the different treatment subgroups (only BSC, BSC plus M, only CT and CT plus M), respectively: 6 (5-6), 7 (6-8), 8 (7-10) and 10.5 (10-13) months (p=0.89;10-15). Pts receiving M (and CT or BSC) had significantly better OS (p=0.0012). CT treated pts receiving M had significantly better survival comparing to those not receiving M (p=0.0015). BSC treated pts receiving M had also significantly better survival than those without M (p=0.003). M treated subgroups had significantly higher scores of QLQ-C30 and LC13 i.e. better HRQoL, as well.

Conclusion: Benefit of antidepressants as part of anticancer therapy noted should be further investigated in larger patients population studies with different antidepressants.

Study of the lung cancer patients on hemodialysis (HD) in Japan
Ryo Matsumura, Yoshihiro Okumai, Akina Komatsu, Kei Nakashima, Nobuhiro Asai, Hideki Makino, Norihito Kaneko. The Department of Respiratory Medicine, Kameda Medical Center, 929 Hyashi-Chou, Chiba, Japan

Introduction: Early stage lung cancer in patients with end-stage renal disease are often detected by routine chest radiography on hemodialysis (HD) filtration. It is general that standard treatment for hemodialysis patients with lung cancer are not performed because guideline for lung cancer in HD patients is not established yet. Thus, clinicians have difficulty in treating HD patients even though early stage lung cancer is detected.

Method: We retrospectively analyzed 17 HD patients with lung cancer between April 2004 and September 2010. Patients’ characteristics, histology and stage of lung cancer, treatment and outcome were evaluated.

Results: A total 17 patients (13 male, 4 female) were eligible in this study. The median age was 72 years (range 54-90). Eleven patients of non-small cell lung cancer (NSCLC) and 1 small cell lung cell cancer (SCLC) had histological or cytological confirmation and 3 were unknown. They consist of 3 stageI, 1 stageII, 8 stageIII and IV. As for treatment, operation was taken in 3, chemotherapy alone and radiochemotherapy were received in 4 and 1. Nine patients did not receive any treatment since they are too old, had a poor performance status or considered to be intolerable by attending physicians.In terms of chemotherapy, hepatic excretery-anti-cancer drugs were used in all the 4 patients. No severe adverse events related-treatment was seen in this study.

Conclusion: Guideline for HD patients with advanced stage lung cancer should be established.

P2772
Antibiotic prophylaxis in chemotherapy-induced neutropenia in lung cancer patients
Vasileios Kouranos1, Antonios Vassias2, George Dimopoulo2, Konstantinos Syrigos2.
18th Pulmonary Clinic, 23rd Oncology Unit, General Hospital of Chest Diseases “Sotiria“, University of Athens, Athens, Greece; 32nd Department of Critical Care, Attiko University Hospital, Athens, Greece

Introduction: Chemotherapy-induced neutropenia can potentially cause fatal infections in cancer patients. Human granulocyte colony-stimulating factor (G-CSF) and granulocyte-macrophage colony-stimulating factor (GM-CSF) are recommended as prophylaxis. Alternatively, prophylactic antibiotics have been administered.
P2773
Hematological toxicity associated with gemcitabine/cisplatin in elderly non-small cell lung cancer patients

Nevena Secen1, Danica Sazdanic-Velick1, Daliborka Bursac2, Branko Dedić1,2, Aleksandar Tepavac1,3, Zoran Pejic4
1 Department of Hematology, Clinical Center of Vojvodina, Novi Sad, Serbia; 2Department of Clinical Chemistry, Clinical Center of Vojvodina, Novi Sad, Serbia; 3Department of Clinical Oncology, Clinical Center of Vojvodina, Novi Sad, Serbia; 4Department of Hematology, University Hospital Centre Sarajevo, Sarajevo, Bosnia and Herzegovina

Introduction: Chemotherapy regimen gemcitabine/cisplatin is indicated in the treatment of non-small cell lung cancer (NSCLC), stage IIIb and IV with good performance status (according to leading National Comprehensive Cancer Network (NCCN) guideline).

Aim of the study: To compare the hematological toxicity of gemcitabine/cisplatin between elderly and patients younger than 65 years of age.

Patients and methods: In our study we observed 235 chemotherapy-naive patients divided into two groups according to their ages: younger than 65 years of age (194 patients) and patients older than 65 years of age (59 patients). Both groups of patients had received chemotherapy regimen: gemcitabine (1000mg/m² iv. day 1, day 8, and day 15) and cisplatin (100mg/m² iv. day 1, day 8) in weeks 1-3 and 4-6.

Results: Hematological toxicity were registered in 26/194 (13.4%) younger patients compared to 15/59 (25.3%) older patients. Statistical analysis showed significant differences in appearance of hematological toxicity in elderly patients (p=0.046). Patients who had received chemotherapy regimen: gemcitabine (1000mg/m² iv. day 1 and day 8),and cisplatin (50mg/m² iv. day 1 and day 3) in weeks 1-3 and 4-6.

Conclusion: According to our results, there is no statistically significant difference between the two groups of patients in appearance of anemia, leukopenia, thrombocytopenia, but generally hematological toxicity is more often in elderly patients.

P2774
A study comparing the efficacy, quality of life and toxicity of cisplatin-paclitaxel to carboplatin-paclitaxel in advanced or metastatic non-small cell lung cancer in the Indian Scenario

Rohan Aurangabadwalla, Rajendra Kumar Jenaw, Nirmal Kumar Jain, Akanksha Jha, Nitin Jain, Nalin Joshi. Department of Chest Disease and Tuberculosis, Hospital for Chest Disease and Tuberculosis, Jaipee Hospital, Raipur, Rajasthan, India

Background: The present study was designed to evaluate the efficacy, toxicity and quality of life of the regimen of carboplatin plus paclitaxel (investigational arm) versus the reference regimen of cisplatin plus etoposide for the treatment of advanced or metastatic non-small-cell lung cancer in the Indian Scenario.

Patients and methods: A total of 50 patients were enrolled, 25 on arm A (cisplatin 25 mg/m² and etoposide 100 mg/m²) and 25 on arm B (carboplatin AUC= 6 mg/ml min and paclitaxel 225 mg/m²), with cycles repeated every 3 weeks. The arms were well balanced with respect to age, performance status, weight loss, stage of disease and disease measurability.

Results: The objective response rate (ORR) was 76% on arm A compared with 72% on arm B (P = 0.74). The most prevalent toxicities were alopecia, nausea and vomiting in both the arms. Leukopenia and neurological toxicity (neuro-sensory+ neuro-motor) occurred at a higher rate in arm B than in arm A without statistical significance. 60% patients in arm B had statistically significant improvement in quality of life as compared to only 20% patients in arm-A (P=0.008)

Conclusion: There was no statistically significant difference in efficacy and toxicity for carboplatin-paclitaxel compared with cisplatin-etoposide. However, there was a statistically significant improvement in quality of life with the carboplatin-paclitaxel regimen.

Can exhaled nitric oxide (FeNO) predict radiotherapy-induced lung toxicity in lung cancer patients?  

Irina Enache1, Georges Noel2, Monique Oswald-Mammesser3, Mi Young Jeong4, Emilie Urban-Kraemer5, Cristina Pistoia6, Elisabeth Quirós7,  

1University of Lyon, University Hospital Lyon Sud, Bron, France; 2Service de Physiologie et Explorations Fonctionnelles, Centre Hospitalier Universitaire, Strasbourg, France; 3Service de Radiologie, Centre Hospitalier Universitaire, Strasbourg, France; 4Service de Radiologie, Centre Hospitalier Universitaire, Strasbourg, France; 5Service de Pneumologie, Centre Hospitalier Universitaire, Strasbourg, France.

A strong increase in FeNO after radiotherapy (RT) for lung cancer may predict RT-induced lung toxicity. We aimed to describe the time-course of FeNO till 7.5 months after 3D conformal RT, and assess the relationships between FeNO and respiratory symptoms, CT scan changes or dosimetric parameters.

FeNO was measured before RT, and 4, 5, 6, 10 weeks, 4 and 7.5 months after the beginning of RT.

Most of the 65 patients were males (74%), had squamous cell carcinoma (48%), and stage III disease (72%). 41 patients had sequential chemo-RT, 20 had concurrent RT and chemotherapy, and 4 had only RT.

Eleven patients (17%) complained of respiratory symptoms after RT. Mean FeNO was a little lower before RT (14.3 (7.2) ppb) than at 7.5 months (18.2 (12.5) ppb + 30% (8%), p=0.05). Between 4-10 weeks, 51-61% of patients showed non-significant changes in FeNO (< 5 ppb), whereas 13-18% showed increased FeNO compared to pre-RT values. Mean changes in FeNO were not different in patients with or without respiratory symptoms. Three patients (5%) had a >2-fold increase in FeNO, at 4 and 5 weeks. All three showed radiation-pneumonitis images at 3-4 months but only two had respiratory symptoms. The sensitivity and specificity of FeNO for the diagnosis of RT-induced symptoms were 18% and 84% for a >5 ppb increase, and 18% and 98% for a >2-fold increase. There was no correlation between dosimetric parameters and changes in FeNO. There was no correlation between absolute values or variations in FeNO and CT scan changes after RT.

Conclusion: Serial FeNO measurements during RT cannot separate patients who will develop or stay free of radiation pneumonitis with sufficient accuracy.

P2777
Cetuximab maintenance therapy – How long should we proceed? A case report

Stefan Rüdiger1, Cornelia Kropl2, Gerald Schmid-Bindert2, Thomas Wibmer3, Martin Lanzinger1, Kathrin Stoiber1, Joanna Blanta1, Wolfgang Rottbauer1, Christian Schumann1

1Department of Internal Medicine II, Pneumology, University of Munich, Munich, Germany; 2Department of Internal Medicine II, Pneumology, University of Ulm Medical Center, Ulm, Germany; 3University Medical Center Mannheim, Medical Factory Mannheim, Heidelberg University, Mannheim, Germany.

The continuation of an active therapeutic agent for extended duration following frontline induction chemotherapy as maintenance therapy can improve overall survival. The Gemtex IV trial compares a platinum-containing doublet vs. a platinum-free sequential chemotherapy with docetaxel and gemcitabine, both arms in combination with cetuximab until progression. However, a useful predictive marker for maintaining an EGFR antibody treatment still does not exist.

We report about a 56-year-old female Caucasian patient with multiple pulmonary

513s

Farmaceutici SpA, Visit Chiesi Farmaceutici SpA, at Stand D.30
lesions and diagnosis of a bronchioalveolar carcinoma. She was at good perfor-
mance status (ECOG 0), without relevant comorbidities and a smoking history of
35 pack-years. EGFR mutation analysis showed an insertion in exon 20 of the EGFR-
genre. Within the Gemtix IV trial 4 cycles of carboplatin/gemcitabine/ cetuximab
were given. Toxicity was a grade III neutropenia and a grade 1 rash without
itching. A total number of 16 cycles cetuximab were completed until therapy was
stopped on patient’s request. After six weeks, tumor progression was documented,
resulting in a PFS of 12.5 months. In the course, the patient did benefit from
another chemotherapy, but not from an EGFR-TKI (erlotinib). OS was 32 months.
In our study tumor progression was not seen after stopping cetuximab mainte-
teinance therapy. This could indicate a significant antitumor activity of the EGFR
antibody in this patient. Biomarkers or clinical selection criteria should be identi-
fied that allow to predict patients benefit from cetuximab maintenance therapy and
avoid such “rebound phenomenon” or unneeded maintenance treatment.

P2778
Clinical predictors for long-term benefit of cetuximab maintenance therapy –
Single center subanalysis of the GEMTAX IV trial
Stefan Rüdiger1, Cornelia Kropf1, Gerald Schmid-Bindert2, Thomas Wüher1,
Martin Lanzinger1, Katriin Stoiber1, Joanna Blanta1, Wolfgang Rottbauer1,
Christian Schumann1. 1Department of Internal Medicine II, Pneumology,
University of Ulm Medical Center, Ulm, Germany; 2University Medical Center
Mannheim, Medical Factory Mannheim, Heidelberg University, Mannheim,
Germany

The Gemtix IV trial compares a platinum-containing doublet (Arm B) vs. a
platinum-free sequential chemotherapy with docetaxel and gemcitabine (Arm A),
both arms in combination of cetuximab until progression. Our center included
59 patients in the GEMTAX IV trial so far. From them 9 patients received cetuximab
for 10 or more cycles. We analyzed clinical markers in relation to long term
therapeutic benefit from cetuximab.

A median of 13 cycles (10-15) with cetuximab was administered; mean age was
63 years (53-75). The relations of male to female, non-squamous to squamous his-
tology, and treatment regimen Arm A to Arm B were 2:1 respectively. The median
progression free survival was 10 months (8-13) and overall survival 22 months
(9-33) so far. Seven of 9 patients developed an acne-like rash within 5 weeks of
cetuximab treatment. Eight of 9 patients were former or current heavy smoker.

Patients with long-term benefit from cetuximab maintenance after induction
chemotherapy were mostly male, former or current smoker, of non-squamous
histology and presented rash early. In accordance with data from the FLEX trial,
to monitor rash could be helpful on identifying patients who could benefit from
cetuximab maintenance therapy.

P2779
Clinicopathologic characteristics of primary bronchial cancer metastasizing
to the brain
Exzter Podmaniczky, Katalin Fabian, Gyorgy Losonczy, Judit Moldvay.
Department of Pulmonology, Semmelweis University, Budapest, Hungary

Brain metastasis is one of the most important factors influencing the quality of life
in lung cancer patients with metastatic disease.

We analyzed the clinicopathological data of 163 lung cancer patients with brain
metastasis (96 men, 67 women). The brain metastasis was diagnosed either by CT
(n=119) or MRI (n=44). The lung cancer was diagnosed according to bron-
choscopy, surgical resection VATS biopsy or transtoracic needle biopsy. The lung

tumor was in the right lung. The upper lobes were concerned in 92 cases (56.4%).
The histological distribution was the following: 67 adenocarcinomas, 43 small cell

carcinoma, 2 atypical carcinoid tumors and 16 malignant tumors.

When compared small cell lung cancer to adenocarcinoma, the proportion of early
metastasis was much higher. In our study the upper lobe adenocarcinoma localized
to the upper lobes, and among them the proportion of early metastasis was very
high. According to our results, especially in case of upper lobe adenocarcinoma,
the exclusion of intracranial metastasis by brain MRI is highly desirable before
surgical resection of lung cancer.

P2780
Survival of lung cancer patients with bone metastases
Evica Budisin1, Nikolka Budisin1, Marijela Potic1, Olga Budisin1,
Dejan Vuckovic1. 1Bronchology, Institute of Lung Diseases of Vojvodina,
Sremska Kamenica, Vojvodina, Serbia; 2Surgery, Institute for Oncology of
Vojvodina, Sremska Kamenica, Vojvodina, Serbia; 3Medical Faculty, University
of Novi Sad, Novi Sad, Vojvodina, Serbia

The presence of metastatic diseases in lung cancer patients is common in everyday
clinical practice. The aim of this study is to establish frequencies of bone metastases in our patients
(pts). and their association with other metastases (as brain, liver etc.) and to
investigate their survival and treatment effects.

Methods: The data were collected from the Hospital Registry. The investigation
was carried out in non operated patients. It included 1197 newly discovered lung
cancer patients., 71 (6.93%) patients had bone metastases. In the moment of the
dates analysis, 62 (87,3%) were dead, and the mean survival was 2.5 month
(survival range 0.1-13month). Solitary bone metastases have 25 (35,2%) patients.,
and multiple bone metastases have 46 (64,8%) patients, while bone and other
metastases were found in 37 (52,1%) patients. Only 14 (19,7%) patients were

treated with bisfonatons therapy, and their mean survival was 2 months.

Conclusion: Lung cancer patients with bone metastases, usually associated with
other metastases, achieved a wary poor survival. Neither the paliativ irradiation of
solitary metastases nor bisfonatons therapy improved the survival of lung cancer
patients.

Endobronchial lesion obliterating the right intermediate bronchus was observed
at fiberoptic bronchoscopy. Histopathologic examination of the mass was diagnosed as
carcinoid tumor. Serum and urine 5-hydroxy indol acetic acid (5-HIAA) levels were
within normal range. Thoracolumbar spinal magnetic resonance imaging (MRI)
revealed pressure upon the medulla spinalis and the patient underwent laminotomy
and thoracic hemilaminectomy operation. The patient received chemoradiother-
apy diagnosed as atypical carcinoid tumor infiltration with T6 vertebra excisional
biopsy.

Complete regression of eyeball metastasis secondary to non-small-cell lung
cancer with intravitreal cisplatin and vinorelbine therapy
Magdalena Kostrzew ska, Halina Batura-Gabryel, Michalina Nowak-Gabryel.
Department of Pulmonology, Clinical Hospital of Lord’s Transfiguration,
Medical University, Poznan, Poland

To report a case of a complete regression of intraocular metastasis secondary to
non-small-cell lung cancer with intravitreal cisplatin and vinorelbine therapy

Purpose: To report a case of a complete regression of intraocular metastasis
secondary to non-small-cell lung cancer (NSCLC).

Methods: Retrospective case review of a 61-year-old female patient treated with
intravitreal cisplatin and vinorelbine therapy for posterior segment of eyeballs
metastases secondary to NSCLCs. Best corrected visual acuity, fluorescein angiography
and computed tomography with contrast intensification were compared during the
3-month treatment period.

Results: After the 4-cld cycle of chemotherapy (intravitreal cisplatin and vinorelb-
ne) the best corrected visual acuity had improved to 20/40 from 20/100 and 2
elevated choroidal mass in the superotemporal and inferotemporal quadrants of
the right eyeball and 1 mass in the lower-inside quadrant of the left eyeball
had completely disappeared. The retina and a retinal pigment epithelial layer were
normal.

Conclusion: Combining intravitreal cisplatin and vinorelbine could be the optimal
treatment form for patients with intraocular metastasis of NSCLC.
Nitrosoglutathione reductase inhibition in the airway epithelium may lead to lung cancer. Little is understood however, regarding the potential for engineered NOs to cause genotoxicity. The aim of this project was to use in vitro human epithelial airway-model (epithelial cell layer (16HBE14o-) cells with human monocyte derived macrophages (apical layer) and dendritic cells (basolateral layer), with different toxicological endpoints involved in NO-induced genotoxicity. Single- and multi-walled carbon nanotubes (SWCNTs/MWCNTs), as well as crocidolite asbestos fibres (CAFs) and DEPs caused no significant (p>0.05) cyto- toxicity (lactate dehydrogenase release) up to 0.04/mg/ml after 24hs. Significant increases (p<0.05) in both L8 and TNF-alpha levels at 0.05-0.04/mg/ml over 24hrs were observed in both the apical and basolateral layers for all NOs. The NO-cell driven mechanism in vitro cells were exposed to 1) 30 ppm NO in a sealed incubator; or 2) S-nitrosocysteine (SNOC) or cysteine (CYS) for 2d, 5d, or 10d, or 3) S-nitrosoglutathione (GSNO) for 2d, 5d, or 10d. Immunoblot. Active GTP-Ras was assayed in a Raf-1RBD-binding ELISA. Certain wt Ras S-nitrosylation and activation in the lung.

Background:
Throughout the project we aimed to determine whether decreased GSNO reductase promoter wt Ras S-nitrosylation and activation in the lung. We studied whether decreased GSNO reductase promotes greater in vitro lung cancer risk.

Methods:
Furthermore, GSNO can be tumorigenic by activating wild-type (wt) Ras proteins which are known to promote tumorigenesis and may not be a good strategy for asthma treatment, particularly in smokers.

Results:
While COPD induces an increase in systemic and bronchial oxidative stress in patients with associated lung cancer, the latter condition is related to greater content of proinflammatory cytokines and angiogenic factors in both blood and bronchi of the patients.

Conclusion:
Chronic airway inflammation such as that observed in COPD patients is a relevant contributor to lung cancer. Increased inflammation and oxidative stress levels have been shown in lung cancer lesions compared to non-tumor parenchyma.

P2786
Role of systemic and bronchial oxidative stress and inflammation in lung cancer predisposition in patients with COPD.

Nadirzah Marozkina, David Jones, Sean Yemen, Benjamin Gaston. Pediatrics, University of Virginia School of Medicine, Charlottesville, VA, United States

Background:
Nitrosothiol (GSNO) is an endogenous bronchodilator. GSNO reductase (GSNOR) depletes airway GSNO; inhibitors are in development for asthma. However, GSNOR can be tumorigenic by activating wild-type (wt) Ras proteins which are known to promote tumorigenesis and may not be a good strategy for asthma treatment, particularly in smokers.

Methods:
Furthermore, GSNO can be tumorigenic by activating wild-type (wt) Ras proteins which are known to promote tumorigenesis and may not be a good strategy for asthma treatment, particularly in smokers.

Results:
While COPD induces an increase in systemic and bronchial oxidative stress in patients with associated lung cancer, the latter condition is related to greater content of proinflammatory cytokines and angiogenic factors in both blood and bronchi of the patients.

Conclusion:
Chronic airway inflammation such as that observed in COPD patients is a relevant contributor to lung cancer. Increased inflammation and oxidative stress levels have been shown in lung cancer lesions compared to non-tumor parenchyma.

A new possibility of process monitoring in lung cancer: Volatile organic compounds detected with ion mobility spectrometry to follow the success of the therapeutic process.

Julia Isabella Kurth, Kaid Darwiche, Jörg Ingob Baumbach, Lutz Freitag, 
1Pneumology, Ruhrlandklinik, University Hospital Essen, Essen, Germany; 2Microfluidics and Clinical Diagnostics, KIST Europe, Saarbruecken, Germany

Introduction: Lung cancer is mostly detected when it is already too late for surgery. But even when tumours can still be operated, there has not been a simple, convenient way of observing any follow-up parameters such as PSA in prostate cancer. With the non-invasive analysis of Volatile Organic Compounds (VOCs) in exhaled breath using ion mobility spectrometry (IMS) we get the chance to step up in this development.

Objectives: To develop a non-invasive technique of analysing new tumour markers in order to find a follow up biomarker for an improved monitoring of the treatment of lung cancer patients.

Methods: Exhaled breath from 33 lung cancer patients was collected and analysed with an IMS device before and after lung surgery. The patients were split into groups according to the tumour histology. Additional conditions such as COPD, medication and former radiation or parameters such as PSA in prostate cancer. With the non-invasive analysis of Volatile Organic Compounds (VOCs) in exhaled breath using ion mobility spectrometry (IMS) we get the chance to step up in this development. Furthermore, the results were statistically analysed.

Results: There were several peaks which showed differences between the pre- and post-surgery groups (such as “EV” normol: 0.062 in squamous cell carcinoma). Further results will be presented in box plots.

Conclusion: As the results show differences between the peaks before and after surgery, the analysis of VOCs in exhaled air might be a new non-invasive possibility of monitoring the process of lung cancer therapy.

In future research it would be interesting to carry out further investigations on long-term patient observations after defined time intervals.

P2789

The research on early detection of lung cancer with exhaled volatile organic compounds

Yanjie Hu, Kejing Ying, Enguo Chen, Fanglei Liu, Yanjie Hu. Respiratory Medicine, Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Hangzhou, China

We analyzed exhaled breath VOCs of 243 samples by SPME-GCMS system, including 88 samples of lung cancer, 70 samples of lung benign disease, 85 samples of health person, and further researched the sensitivitiy and specificity of the diagnostic models based on different combinations of special VOCs by applying statistical approaches, such as cluster analysis or stepwise discriminant analysis. In the end, we selected age, as well as 4 to 6 VOCs, as the diagnostic models for lung cancer, including 2,6-dimethylnaphthalene, palmitic aldehyde, nonadecyl alcohol, etc, basically with high sensitivity and specificity more than 85%. Take one model for example, which is consist of palmitic aldehyde, nonadecyl alcohol, 2,6-dimethylnaphthalene, age, and so on, its specificity is 94.9%, and 78.7% of early stage lung cancer patients were correctly identified, however, 31.9% of them were misclassificated to advanced stage. Therefore, this kind of diagnostic model could be applied to early diagnosis of lung cancer, but with poor effect to differentiate stages, which indicates that breath test diagnostic model for lung cancer might be one of the screening and early warning methods, although is not enough as a diagnostic model for lung cancer.

In future research it would be interesting to carry out further investigations on long-term patient observations after defined time intervals.

P2790

Volatile organic compounds in lung cancer patients before and after tumour resection.

Kaid Darwiche, Isabella Kurth, Joerg Ingob Baumbach, Ute Sommerwerck, 
1Department of Interventional Pneumology, Ruhrlandklinik-University of Essen, Essen, Germany; 2Department of Microfluidics & Clinical Diagnostics, KIST Europe, Saarbruecken, Germany.

Introduction: Ion mobility spectrometry (IMS) is a promising tool in the detection of volatile organic compounds (VOC) even in small amounts. Whether it can contribute to the diagnosis of non-small-cell cancers (NSCLC) has not been adequately evaluated. Breath analysis with IMS is based on the assessment of multiple volatile organic compound (VOC) peaks considered specific for the disease.

Objectives: We studied bronchoscopically obtained VOCs in exhaled breath with an ion mobility spectrometer coupled to a multi capillary column (MCC/IMS) in patients with NSCLC before and after tumour resection in order to find tumour specific VOCs.

Methods: In 8 patients with histologically proven NSCLC, gas samples were aspirated out of the lungs during the diagnostic bronchoscopy and after tumour resection. Gas samples were aspirated via a Teflon tube introduced in the working channel of the bronchoscope and assessed using IMS.

Results: We found 228 common peaks in the measured data. 17 of them were significantly different before and after surgery. 11 peaks could be found with a lower value after tumour resection whereas 6 had a higher value.

Conclusion: While in a former study (Poli D et al. Acta Biomed 2008; 79; Suppl 1: 64-72) using solid-phase micro-extraction no changes after lung cancer resection could have been found, IMS revealed a change in the composition of exhaled breath after surgery in our work. Therefore some VOC levels may have been influenced by the tumour and these VOCs can be detected by MCC/IMS.

P2791

New contributions in the determination of volatile organic compounds (VOC) in lung cancer (LC).

Javier Jareño, Mª Angeles Muñoz, Gema Rodríguez, Concepción Civera, 
1Respiratory, Hospital Central de la Defensa Gómez Ulla, Madrid, Spain; 2Respiratory, Hospital Clínico San Carlos, Madrid, Spain; 3Facultad de Farmacia, Universidad Complutense de Madrid, Madrid, Spain; 4Facultad de Farmacia, Universidad San Pablo CEU, Bourolla del Monte, Madrid, Spain

Introduction: Determination of VOC present in exhaled breath (EB) may be useful as a noninvasive diagnostic technique in LC.

Objective: To analyze the presence of VOC in the EB in two groups of subject: LC Group and Control Group.

Methods: Descriptive, observational study. LC Group: 29 patients with LC. Control Group: 40 healthy volunteers. (All accepted Informed consent). Breath samples were collected at lung residual functional capacity, with simultaneous sampling of ambient air using bioVOC devices. Analytical technique: Thermal desorption Markers Int. Gas chromatography (7890A) mass spectrometry (5975C_Hewlett Packard). VOC analyzed, see table 2. Compounds identified by means of reten- tion time + mass spectrum. Chromatographic column: DB1: 30mx0.25mmx1um (Hewlett Packard).

Results: We analyzed exhaled breath of 243 samples by SPME-GCMS system, including 88 samples of lung cancer, 70 samples of lung benign disease, 85 samples of health persons.

Conclusions: The research on early detection of lung cancer with exhaled volatile organic compounds.
Neutrophil elastase levels is higher in patients with lung cancer than chronic obstructive pulmonary disease

Neutrophil elastase (NE) is a specific serine protease and it is a modulator of inflammation. Systemic and pulmonary inflammation has been associated with both non-small cell lung cancer (NSCLC) and chronic obstructive pulmonary disease (COPD). Still, an exact role of NE in pathogenesis of NSCLC, COPD and in coexistence of both diseases is unknown. The aim of the study was to evaluate NE levels in NSCLC with and without COPD.

**Methods:** Serum and BAL fluid (BALF) levels of NE were measured by enzyme-linked immunosorbent assay (ELISA) in 28 patients with NSCLC, 20 patients with moderate COPD, 25 patients with NSCLC and moderate COPD (NSCLC/COPD) and 10 healthy non-smoking individuals (HI). Periferal blood and BALF were collected from each patient before any treatment.

**Results:** Serum NE levels were significantly higher in groups with NSCLC: NSCLC, NSCLC/COPD, compared to COPD or HI (620.6±77.5 ng/ml and 609.8±52.7 ng/ml vs 409.2±61.6 ng/ml and 243±23.9 ng/ml, P<0.05). BALF NE levels were significantly higher in NSCLC and NSCLC/COPD. Levels were significantly higher in NSCLC than in COPD and HI (1.47-fold, NSCLC/COPD (1.53-fold) compared to COPD (1.21-fold, P<0.05) or HI (basal level). Serum NE levels were correlated with the clinical/pathological status of patients with NSCLC.

**Conclusions:** Our data suggest a higher levels of NE both in NSCLC and NSCLC/COPD than in COPD or HI.

The expression of IL-5 in lung cancer tissue and its relationship with the expression of IL-5

Xiang Han, Bei He. Respiratory Department, Peking University Third Hospital, Beijing, China

**Objective:** Some studies showed that high eosinophil infiltration in lung cancer tissues was associated an improved prognosis. And the other studies showed the high expressed of IL-5 in lung cancer cells. IL-5 has emerged as a main controlling tissues was associated an improved prognosis. And the other studies showed the expression of IL-5 was associated with better survival. So we studied the eosinophil infiltration and the expression of IL-5 in five tissue specimens from lung cancer patients and analyzed the correlation between the eosinophil infiltration and IL-5 expression of lung cancer tissue.

**Methods:** Eosinophil infiltration was detected by Immunohistochemistry in 45 lung cancer tissues and 36 corresponding normal lung tissues.

**Results:** There were high tissue eosinophilic infiltrations in 17 of 45 (37.78%) cases. In high eosinophilic infiltration cases, the counting of eosinophil in tumor tissue was significantly higher than that in corresponding normal tissues (P<0.05). In NSCLC, the rate of high eosinophilic infiltration cases was significantly higher than that of SCC (P<0.05). IL-5 was high expressed in all 45 cases and low expressed in corresponding normal tissues. Eosinophilic infiltration was not correlated with the expression of IL-5 in tumor cells (r=0.026, P=0.05).

**Conclusions:** There were high eosinophilic infiltrations of tumor tissues in some cases of lung cancer. Compared with SCC, the rate of high tissue eosinophilic infiltration cases of NSCLC was significantly increased. There was no relationship between the eosinophilic infiltration and the expression of IL-5 in lung cancer tissue.

**P2795**

Association of genetic polymorphisms of matrix metalloproteinase (MMP)14 to the susceptibility of non-small cell lung cancer

Yao-Ling Lee1, Wei-Erh Cheng2, Shao-Chuen Chen1, Chuen-Ming Shih3, Wei Chen1. 1School of Medical Laboratory and Biotechnology, Chung Shan Medical University, Taichung, Taiwan; 2Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan; 3Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Chia-Yi Christian Hospital, Chia-Yi, Taiwan

**Background:** Matrix metalloproteinase (MMP)14 is a cell surface protease that displays a broad spectrum of activity against extracellular matrix components and promotes the invasion/metakasis of cells. MMP14 is overexpressed in NSCLC, and the level is correlated with poor survival. We investigated the MMP14 -165 TT genotype against GG/GT genotypes (an OR of 1.84, 95% CI 1.22-2.77, P=0.005), MMP14 +7096 CC genotype against TT/TC genotypes (an OR of 1.79, 95% CI 1.19-2.70, P=0.005), and MMP14 +8153 GA genotype against GG genotypes (an OR of 2.07, 95% CI 1.36-3.14, P=0.001).

**Methods:** Eighty-six newly diagnosed (nd) NSCLC patients in the lung cancer group were compared to 73 COPD patients using a Cyranose 320 (Smith Detection) electronic nose.

**Results:** The distribution of the genotype frequencies of MMP14 -165 (GT/G), MMP14 +7096 (T/C), and MMP14 +8153 (G/A) were significantly different between the lung cancer patients and the healthy controls. Logistic regression analysis revealed that higher odds ratios (ORs) for lung cancer were seen for individuals with MMP14 -165 TT genotype against GG/GT genotypes (an OR of 1.84, 95% CI 1.22-2.77, P=0.005). MMP14 +7096 CC genotype against TT/TC genotypes (an OR of 1.79, 95% CI 1.19-2.70, P=0.005), and MMP14 +8153 GA genotype against GG genotypes (an OR of 2.07, 95% CI 1.36-3.14, P=0.001).

**Conclusion:** A significant association between the polymorphisms of MMP14 gene and the susceptibility to NSCLC was demonstrated.

**P2796**

The expression and clinical significance of PD-L1+CD68+ macrophages in peripheral blood mononuclear cells of non-small cell lung cancer

Jian An Huang1, Yan Bin Chen1, Ping Xu2. 1Department of Respiratory Medicine, The First Affiliated Hospital of Soochow University, Soochow, China; 2Central Lab, Renning Hospital of Soochow, Soochow, China

**Purpose:** To explore the role of PD-L1+ programmed death-1 ligand 1) CD68+ macrophages in peripheral blood mononuclear cells (PBMCs) of non-small cell lung cancer (NSCLC) by flow cytometry (FCM).

**Materials and methods:** 60 squamous cell carcinoma patients, 60 adenocarcinoma patients and 60 healthy controls were recruited in the study. PD-L1+CD68+ macrophages were isolated from PBMCs of the 180 persons with FCM.

**Results:** Squamous cell carcinoma and adenocarcinoma group had higher PD-L1+CD68+ macrophages expression compared to healthy controls (P<0.000) and PD-L1+CD68+ macrophages were isolated from PBMCs of the 180 persons with FCM.

**Conclusions:** Squamous cell carcinoma and adenocarcinoma group had higher PD-L1+CD68+ macrophages expression compared to healthy controls (P<0.000) and PD-L1+CD68+ macrophages were isolated from PBMCs of the 180 persons with FCM.
Magnolol-induced apoptosis is mediated through caspase-independent pathway. Reduced by Magnolol translocated from mitochondria to nucleus, suggesting that the production of caspase-independent pathway was involved in the apoptosis induced by Magnolol. The mitochondria potential of mitochondria in A549, H520 and H441 cells started to decrease within 6 hr after treatment with Magnolol at various concentrations, and the results showed that the mitochondria potential of mitochondria in A549 cells started to decrease within 6 hr after treatment with Magnolol at various concentrations, and the results showed that the concentration of IL-6 in BALF was slightly higher than that of serum IL-6, but not statistically different from that of PID patients. In patients with NSCLC, the concentration of IL-6 in BALF was higher than that of PID patients. We found that the concentration of IL-6 in BALF was higher than that of PID patients and normal controls (P < 0.01). The concentration of IL-6 in serum or BALF was not statistically different from that of PID patients. In patients with NSCLC, the concentration of IL-6 in BALF was higher than that of serum IL-6, but this difference was not statistically significant (P > 0.05). Serum IL-6 level was higher in NSCLC patients of advanced stages (stage IIIb and IV), as compared with that in NSCLC patients of early stages (stage Ia-IIb). BALF IL-6 level of NSCLC patients at different stages was not different. IL-6 level (in serum but not in BALF) of PID patients correlated with the serum concentration of C reactive protein (r=0.69).

Conclusion: IL-6 in BALF might be used as a marker for NSCLC. Serum IL-6 level might be an indicator for the stage of NSCLC. The serum IL-6 can also be measured by ELISA.

Methods: The concentration of IL-6 in serum or BALF of 82 NSCLC patients, 56 patients of pulmonary inflammatory diseases (PID) and 26 normal controls were measured by ELISA.

Results: The concentration of IL-6 in BALF of NSCLC patients was significantly higher than that of PID patients and normal controls (P < 0.01). The concentration of IL-6 in sera of NSCLC patients was higher than that of normal controls (P < 0.01) but not statistically different from that of PID patients. In patients with NSCLC, the concentration of IL-6 in serum was significantly higher than that of serum IL-6, but this difference was not statistically significant (P = 0.05). Serum IL-6 level was higher in NSCLC of advanced stages (stage IIIa, IIb and IV), as compared with that in NSCLC patients of early stages (stage Ia-IIb). BALF IL-6 level of NSCLC patients at different stages was not different. IL-6 level (in serum but not in BALF) of PID patients correlated with the serum concentration of C reactive protein (r=0.69).

Conclusion: IL-6 in BALF might be used as a marker for NSCLC. Serum IL-6 level might be an indicator for the stage of NSCLC. The serum IL-6 can also be measured by ELISA.

Magnolol can induce apoptosis in non-small cell lung cancer via caspase-independent pathway
Shih-Hung Chu1, Po-Pei Liu1, Jong-Rung Tsai1,2, In-Wen Chong1,2, Jun-Ao Shao3,4
1Department of Respiratory Therapy, Kaohsiung Medical University, Kaohsiung, Taiwan, 2Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan

Magnolol is a traditional Chinese herbs drug purified from Magnolia officinalis which has multiple pharmacological properties such as antioxidant and anti-inflammatory effects. Magnolol exhibited remarkable inhibitory effects on tumor growth. However, the effect of Magnolol on non-small cell lung cancer (NSCLC) has not been clarified. In this study, the NSCLC cell lines (A549, H520, H441 and HPAEC) were treated with different concentrations (0–100 μM) of Magnolol for 24 hrs and the cytotoxic effect of Magnolol positively correlated with its concentration. Moreover, the chemotherapy drug Cisplatin at the dose of 25 μM had the same cytotoxic effect as Magnolol at 80 μM on NSCLC cell lines. Flow cytometry assay revealed that pretreatment with Magnolol at the dose of 80 μM for 24 hrs could induce apoptosis in A549 cells. We also illustrated that Magnolol-induced apoptosis in A549 cells was associated with a rapid increase in caspase-3 activity. The caspase-3 activity in A549 cells was increased by Magnolol, and the activity was associated with the decrease in the mitochondrial potential. Treatment with Magnolol induced the translocation of the Bax/Bcl-2 ratio to the mitochondrial membrane, suggesting that the Magnolol-induced apoptosis in non-small cell lung cancer cells (NSCLC cells). In conclusion, Magnolol can induce apoptosis of NSCLC cells. In addition, the apoptosis in NSCLC cells involves, most likely, caspase-independent pathway in NSCLC cells.
Methods: Plasma MP-TF activity was measured in 33 patients with LC of different stages. Blood was collected at the time of inclusion; MP were collected by ultracentrifugation, TF activity was measured with a one stage clotting assay. Informed consent was obtained from all patients.

Results: The blood of patients with stage IV LC had a higher MP-associated TF activity compared to stage III (45.56 [14.88-143.70] vs. 9.45 [3.47-16.23] arbitrary U/ml) (median [interquartile range]); p<.05 by Mann-Whitney test (fig. 1).

Conclusions: MP-associated TF activity increases in late stage LC. This observation is consistent with the hypothesis that MP-associated TF is involved in LC progression.

288. Instructive clinical aspects of lung cancer

P2803 Usefulness of serum procalcitonin in lung cancer patients with elevated serum C-reactive protein level
Hée Jung Bae, Seung Gyu Ju, Su Young Chi, Eun Young Kim, Yoon Hee Kim, Kye Sik Kim, In Jae Oh, Young Chul Kim, Yong Soo Kwon, Yu-Il Kim, Sung Chul Lim. Department of Internal Medicine, Chonnam National University Hospital, Jeabongro, Dongku, Gwangj, Korea

Background: It is not easy to distinguish between infections and other causes with C-reactive protein (CRP) level or white blood cell (WBC) count in febrile lung cancer patients. We investigated the usefulness of serum procalcitonin (PCT) and CRP for the differential diagnosis of fever in lung cancer patients.

Methods: We measured serum PCT level and WBC count in lung cancer patients with serum CRP >0.3mg/dL. The subjects were categorized as either infection or non-infection group. Infection was verified by respiratory culture, blood culture and radiologic finding. Those who developed febrile neutropenia after chemotherapy and improved after antibiotic treatment were grouped as infection group (IG). Non-infection group (NG) comprised those who had drug fever or cancer fever.

Results: A total number of measurement was 375 samples from 285 patients. PCT showed 2.28±0.43 μg/L in IG and 0.36±0.43 μg/L in NG (mean±standard deviation p<0.001). CRP showed 17.24±8.87 mg/dL in IG and 11.6±7.93 mg/dL in NG (p<0.001). In febrile patients, there was also significant differences of PCT (1.80±0.41 μg/L in IG, 0.24±0.31 μg/L in NG, p=0.003) and CRP (17.88±8.62 mg/dL in IG, 13.11±4.96 mg/dL in NG, p=0.004) levels. Area under curve of PCT was significantly larger (0.775, 95%CI 0.690-0.861) than CRP (0.646, 95%CI 0.540-0.753, p=0.026). Sensitivity and specificity of PCT using cut off level of 0.21 μg/L was 73.8% and 59.1%.

Conclusion: Serum PCT could be more helpful for differentiation of infection from non-infectious causes of fever in lung cancer patients.

P2804 Procalcitonin: A prognosis factor in lung cancer and a marker for small-cell lung cancer
Maxime Patout1, Valery Brunel2, Mathieu Salaun1, Suzanna Bota1, Luc Thiberville1. 1Clinique Pneumologique, Rouen University Hospital, Rouen, France; 2Pneumologie, Rouen University Hospital, Rouen, France

Introduction: Serum procalcitonin (PCT) is used for the early diagnosis of bacterial infections. PCT is also a prognostic factor in thyroid carcinomas and PCT level is also usually increased in small cell lung cancer.

Aim: To evaluate the serum PCT level as a diagnostic and prognostic marker of lung cancer.

Methods: Sera sampled between December 2008 and November 2010 for neuron-specific enolase (NSE) dosage at the Rouen University Hospital were retrieved. A PCT dosage was performed on samples from untreated patients with histologically proven lung cancer.

Results: From the 147 blood samples selected, 66 came from adenocarcinoma patients, 58 from neuroendocrine lung cancers (NELC) including 31 small cell lung cancers, 6 large cell lung cancers and one atypical carcinoid, 23 from squamous cell carcinomas and 2 sarcomas.

Conclusion: Serum PCT should not be used for the early diagnosis of bacterial infection in patients with a NELC. Elevated PCT appears to be a marker of poor prognosis in lung cancer patients.

P2805 Serum levels of interleukin 8 and plasma levels of osteopontin in patients with non-small cell lung cancer during chemotherapy
Ewa Rogala, Adriana Roszy, Barbra Roszkowska-Szit, Joanna Chorostowska-Wynimko, Kazimierz Roszkowska-Szit. Department of Lung Diseases, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; Laboratory of Molecular Diagnostic and Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland

Interleukin 8 (IL-8) and osteopontin (OPN) are multifunctional cytokines associated among other with tumor progression and metastasis. The aim of the study was to evaluate serum levels of IL-8 and plasma levels of OPN in patients with NSCLC undergoing chemotherapy. Peripheral blood samples were taken before and after four cycles of chemotherapy (DDP+VP) and in the case of progression of disease. The study included 29 patients diagnosed histologically with lung cancer (stage IIB 12 patients, stage IV 17 patients). IL-8 and OPN levels were determined by ELISA (R&D). Mean levels of IL-8 and OPN significantly increased with progression of the malignancy: serum IL-8 levels in stage IIB and IV were 19.82±9mg/ml and 46.38±9mg/ml respectively, (p<0.001), plasma OPN levels in stage IIB and IV were 50.3±4mg/ml and 73.0±2mg/ml respectively, (p<0.02). Cytoreduction treatment had no influence on the levels of IL-8 and OPN in comparison with their mean levels before treatment (in both stages). The progression of disease resulted in significant increase of mean serum level of IL-8 (34.31±3.38 pg/ml) when compared to mean initial (before treatment) serum level of IL-8 (23.78±2.17pg/ml) (p<0.05). Mean plasma level of OPN were elevated but without statistical significance. In conclusion, chemotherapy had no influence on the serum IL-8 levels and plasma OPN levels. The increased IL-8 and OPN levels possibly relate to the activity of lung cancer.

P2806 Role of C reactive protein in non small cell lung cancer staging
Juan Antonio Torrecilla1, Sergio Scrimini2, Jaume Saulied, Francisco de Borja Garcia-Cosio3, Aina Noguera1, Amanda Iglesias4, Angel Rius5, Rocío Córdova6, Alvar Aguad6. 1Thoracic Surgery, H. Universitari Son Espases, Palma Mallorca, Spain; 2Pneumology, H. Universitari Son Espases, Palma Mallorca, Spain; 3Clinical Analysis, H. Universitari Son Espases, Palma Mallorca, Spain; 4Centre Clinical Anal, H. Universitari Son Espases, Palma Mallorca, Spain; 5Pneumology, Fundació Caubert-Cimerà, Bunyola, Spain; 6Institut del Tòrax, H. Clinic i Pneumològic, Barcelona, Spain; 7CIBER de enfermedades respiratorias, Instituto Carlos III, Madrid, Spain

Hypothesis: Advanced stage in lung cancer is associated to increased CRP levels in serum.

Objective: To compare blood levels of different inflammatory markers (TNFα, IL-8, C Reactive Protein [CRP] in patients with different stages of lung cancer.

Method: 56 patients diagnosed of lung cancer were included (53 males, 64.59±9.73 years, X±SD). All of them underwent studies for disease staging, including fiberobronchoscopy and computed tomography, and positron emission to-
The search for prognostic and predictive biomarkers in NSCLC is studied in relation to overall survival. However, a majority of all patients lack genetic disease in non small cell lung cancer.

Aim: To study the prognostic potential of haemoglobin (Hgb), platelet (Plt) - and white blood cell (WBC) levels at time of diagnosis in non-small cell lung cancer (NSCLC) patients.

Background: The search for prognostic and predictive biomarkers in NSCLC is intense. With an increasing number of targeted agents available the present focus is on the genetics of the tumour. However, a majority of all patients lack genetic markers that favour targeted therapies. Thus the need for basic prognostic factors to optimise the treatment for each individual case is expected to increase in the future.

Methods: 833 NSCLC patients, stage I-IV were included in the study. WBC, Plt, Hgb, gender, age at diagnosis, stage, surgery and first-line chemotherapy were studied in relation to survival.

Results: For patients with Hgb <110g/L and Hgb >110g/L the median survival was 11.2 and 14.5 months respectively (p<0.0001). For WBC >9,0×10⁹/L and <9,0×10⁹/L the median survival was 11.6 and 15.4 months respectively (p<0.0001). For Plt >350×10⁹/L and <350×10⁹/L the median survival was 11.2 and 14.9 months respectively (p<0.0001). For patients with no pathology in the studied markers compared to those with pathological results in all three markers the median survival was 16.0 and 8.0 months respectively (p<0.0001).

Conclusions: The level of the three studied biomarkers corresponds significantly to outcome. A trend for worsened prognosis is shown when combinations of two pathological markers are present. With all three biomarkers pathological the median survival is halved compared to the group with normal levels. The results are important for the decisions regarding treatment choice and intensity.

Analysis of the clinical feature of 833 patients with lung cancer

Yizhan Zhou, Yinhu Li, Wuting Huang, Xiongde Cai, Qingsi Peng, Lixia Huang. Department of Respiratory Medicine, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China

Objective: To investigate the clinical feature of lung cancer.

Methods: We retrospectively analyzed the clinical data of inpatients diagnosed with primary bronchochegic carcinoma who registered in our hospital between 2007 and 2008.

Results: The age of onset of lung cancer was 59 years old. 50.1% of the patients had a history of smoking. 93.8% of whom were males. Coughing, expectoration, emaciation, weight loss, chest pain, dyspnea and pyrexia were the most common symptoms. The levels of NSE and CYFRA21-1 in males were higher than those in females, and the levels of serum CYFRA21-1 in senile were higher than those in non-senile. The levels of serum NSE and CYFRA21-1 in smokers were higher than those in non-smokers, while they were higher in patients with central type lung cancer than those in patients with peripheral type lung cancer. The levels of serum NSE in small cell lung cancer patients were higher than those in non-small cell lung cancer patients. The levels of CEA in patients with adenocarcinoma were higher than those in patients with squamous cell carcinoma, while the levels of serum CYFRA21-1 were higher in the latter. The more advanced the disease was, the higher the levels of serum CEA, NSE and CYFRA21-1 were. Carcinoma was the most commonly seen in the upper lobes of both sides of the lungs. 66.8% of lung cancer belonged to peripheral type. Adenocarcinoma and squamous cell carcinoma were the most common pathological type. 66.0% of lung cancer patients were in advanced stage when diagnosed, and 55.2% had metastasis to mediastinal lymph nodes. Bones were the most common sites of metastasis.

Conclusions: The combined detection of serum CEA, NSE and CYFRA21-1 could help to identify some of lung cancer.
Conclusions: Neoadjuvant therapy increased the perioperative complications in this group of patients compared with a similar group undergoing anatomical lung resection in the same institution. The most common complication in patients receiving induction chemotherapy was detected at the group with neoadjuvant therapy. Strategies to prevent these complications will be important, especially if chemotherapy before resection becomes the standard for all patients with non-small cell lung cancer.

P2812 Patterns of recurrence after resection surgery of lung cancer: Clinical correlations and survival

Maria Gabriela Cortez Montero1, Raquel Dacal Quintas1, José Abl Arca2, María Jesús García García2, María Teresa Alves Perez2, Pedro Marcos Velazquez2

1 Pulmonology, Complexo Hospitalario Ourense, Orense, Galicia, Spain; 2 Surgery, Ankara Oncology Research and Training Hospital, Ankara, Turkey

Objectives: Analyze the patterns of recurrence and survival in lung cancer patients under surgery

Methods and results: Observational, retrospective cohort of lung cancer patients undergoing surgery during years 1999-2006 in CHOU-Spain. We performed a descriptive analysis of data, the continuous variables to be non-Gaussian are shown as median and categorical variables as frequencies and percentages. We determined the clinical factors associated with recurrence and survival by Kaplan-Meier curves and Cox regressions models. We used SPSS 15.0 software

Results: 168 patients underwent surgery, of whom 79.8% were men, and the median age was 67 years (35-82). 74 ex-smokers (44%) and 63 active smokers (37.5%). Most common histological type was epidermoid 88 (52.4%) followed by adenocarcinoma 48 (28.6%). The median tumor size in CM was 3.3 (0.9), and most common site of differentiation in 77 (45.8%). The pathological stages were: 91 (57.6%), II 26 (16.5%), IIIA 30 (19%), IIIB 11 (6.5%). The most frequent surgical resection was lobectomy. Recurrence occurred in 78 (46.5%) patients, related with tumor size (p = 0.002) and pathological stage (p = 0.001), no differences in the histological subtype (p = 0.232). Coughing and CNS disorders were the most prevalent symptoms of recurrence and extrathoracic involvement was in 42 cases (58.3%). The median survival in those who had recurrence was 9 months, with 95% CI [5.129 to 12.871]. Other risk factors of death were tumor size (p = 0.002) and pathological stage (p < 0.001)

Conclusions: Most patients do not relapse. Recurrence was more frequent extrathoracic location. The tumor size and advanced stages determine higher risk of recurrence and mortality.

P2813 Radiofrequency ablation in the treatment of malignant lung tumors

Aleksy Reshetov1, Igor Rutkin 2, Sergei Lazarev1, Eldar Topuzov1, Valeri Balashov3

1 Thoracic Surgery and Oncology Department, Saint-Petersburg State Medical Academy named after I.I.Mechnikov, Saint-Petersburg, Russian Federation; 2 Surgical Department, Russian Scientific Center Radiology and Surgery, Saint-Petersburg, Russian Federation

Objectives: Radiofrequency ablation (RFA) has gained acceptance for thoracic surgery use but few data exist regarding its value in thoracic oncology. The aim of this study was to report our experience RFA for malignant lung tumors

Methods: From 2010 27 patients were underwent RFA for peripheral malignant tumors: metastases in 20, primary lung cancer in 7. Range of threes dimensions were from 7 to 52 mm (mean 27 mm). Renal cell carcinoma metastases had 4 patients, metastases of colorectal cancer - 10, metastases of lung cancer - 5 and hepatocellular carcinoma - 1. Indications for RFA: inability undergo thoracotomy (9), as alternative complication pneumonectomy after lung resections (4), necessity to save lung tissue for patients with multiple lung metastases (14). We used transcortaneous RFA in 7 cases. In 14 cases thoracoscopic detection of tumor node before RFA was used. In 6 cases RFA used during thoracotomy. Used needle electrode with test portion 30 mm, maximal power and exposition of 10 min. Mediania follow-up was 19 months (2-32).

Results: No postoperative mortality. Post-operative complications were associated with pulmonary tissue inflammation (6 cases). Average hospital stay of uncomplicated patients was 3-7 days. At present no local recurrences were diagnosed. But 7 patients developed new pulmonary and hepatic metastases from 3 to 18 months after RFA and 9 patients died from progression of oncological diseases from 6 to 26 months after RFA. Four patients have died from comorbid diseases from 1.5 and to 5 months after RFA. The median survival was 19.5 month (1.5-30).

Conclusion: RFA is a reasonable option if a lesion is unresectable or necessity tissue sparing for multiple lung resection.

P2814 Second primary lung cancers developed following different system tumors

Cigdem Ozdilekcan1, Sevim Turanlı2, Necia Songur3, Huseyin Cakmak4

1 Pulmonology, Complexo Hospitalario Ourense, Orense, Galicia, Spain; 2 Surgery, Ankara Oncology Research and Training Hospital, Ankara, Turkey; 3 Chest, Suleyman Demirel University School of Medicine, Ankara, Turkey; 4 Chest Surgery, Ankara Oncology Research and Training Hospital, Ankara, Turkey

Aims and background: This study aimed to investigate clinical characteristics and prognosis of secondarily developed lung tumors in the cases having different system malignancy and to evaluate the relationship with the primary tumor.

Methods: Thirty patients diagnosed as second primary lung cancer those admitted to have been included in the study.

Results: The patients were grouped: synchronous group (n=7, 16.7%) and metachronous group (n=2, 83.3%). The age of primary malignancy and second primary lung malignancy was median 59.5 (range, 38-82 years), and 63 years (range, 39-83 years) respectively. The rate of quitting smoking among all patients before the diagnosis of lung cancer was 50%, current smoker rate was 30%. Second cancer was detected in 50% of the patients within the first 5 years. The most frequent primary localization was larynx (40%). Majority of patients received surgical treatment for primary localized carcinoma, while for secondarily developed carcinoma, the most frequent treatment choice was chemotherapy and/or best supportive care. There was no statistical relationship between the response to treatment of first cancer and the duration of cancer developed secondarily (p=0.36). The overall survival of groups was found 24 months (95% confidence interval: 18.30 months) and 12 months (95% confidence interval: 10-14 months) respectively for synchronous and metachronous groups.

Conclusions: Close follow-up on pulmonary system especially within the first 2.5 years after primary disease and encouragement on quitting smoking is important.
Background: Erlotinib is a tyrosine kinase inhibitor (TKI) approved for 2nd or 3rd line treatment of advanced NSCLC.

Aim: Evaluate the smoking impact on objective response (OR) and survival of pts treated with erlotinib.

Method: Retrospective analysis of OR, overall and post-erlotinib (PE) survival in pts treated with this TKI from 2006 til December 2010, taking into account the gender, smoking status, histology and epidermal growth factor receptor (EGFR) gene mutational status.

Results: Over the past 5 years, 104 pts (57 males) began treatment with erlotinib: 66 adenocarcinomas (AC), 18 squamous cell carcinomas (SCC) and 20 NSCLC. Smoking status: 48 non-smokers (NS); 31 ex-smokers (ES) and 25 active smokers (AS). Median overall survival of 23 months (m). There was no significant difference in overall survival among pts of different gender, staging or smoking status. Median PE survival of 6 m. The PE survival was higher in NS (12 vs 6 m in ES and 4 m in AS: p=0.077), AC (10 vs 5 m in SCC and 3 m in NSCLC: p=0.013) and in mutated pts (14 vs 6 m in non-mutated: p=0.003). Analyzing by histologic subtypes, in AC survival remains higher in NS (21 vs 10 m in ES and 2 m in AS: p=0.021). Analyzing by mutational status, smoking habits lose significance. Assessing the OR to erlotinib, 50 pts had disease progression and 48 disease control (DC). DC analyzing by mutational status, smoking habits lose significance. Assessing the PE survival among pts with a presence or absence cardiovascular comorbidities. There was not a statistically significant relationship between shorter survival time and a history of cardiovascular comorbidity (p=0.104).

Conclusions: This study did not show a statistically significant effect of the presence of cardiovascular comorbidity on survival of patients in the first and second stage of the disease.

Background: Bronchopulmonary carcinoids (BPCs) are rare neuroendocrine tumors. Metastatic BPC (M-BPC) represents less than 10% of all BPCs.

Aim: A retrospective study of a 5 years’ consecutive series of M-BPC patients, treated in a tertiary referral center.

Methods: Demographics, symptoms, staging, pathology, therapy and survival were compared for non-metastatic (NM-) and M-BPC.

Results: Of 57 BPC patients, 12 (21%) had metastases. Five were truly metastatic at diagnosis. No differences were observed for age, smoking status and gender. Hemoptysis was mostly found in M-BPC (4/12); infection and absence of symptoms in NM-BPC (both 6/45). Somatostatin receptor imaging was performed in respectively 20% and 92%, FDG PET in 67% and 75%, Ki-67 staining in 24% and 75%, chromogranin A staining in 64% and 83% of NM- and M-BPC patients. M-BPC was predominantly treated with chemotherapy (42%) and somatostatin analogues (58%), NM-BPC with surgery (91%). Median survival was 52 months for M-BPC, while not yet reached for NM-BPC patients (p=0.01).

Conclusions: In our center, a larger proportion of M-BPC patients was treated compared to literature. Major differences between NM-BPC and M-BPC were observed for treatment choices. Survival was significantly worse for M-BPC, although much better compared to more common lung cancer types.

Background: The treatment of patients with locally advanced non-small-cell lung cancer is controversial. Surgery remains the gold standard treatment even in patients initially judged inoperable.

Methods: From January 2009 to May 2010, neoadjuvant chemotherapy was indicated in 27 patients with NSCLC (25 men, 2 women). The mean age was 65 years. The different stages were: IIB, 5; IIIA, 17 (with 6 of whom in stage IIIB); IIIB 2 and IV, 3.

Results: Twenty-three patients received neoadjuvant chemotherapy, 2 refused the induction treatment and 2 had impaired their status. The neoadjuvant chemotherapy regimen was gemcitabine-cisplatin in 17 patients and vinorelbine-cisplatin in 6. Only 5 patients underwent complete surgical treatment after induction: stage IIIB, 1; IIIB, 1; IIIA, 1 and IV, 2 (operated adrenal metastasis in one patient and operated adrenal metastasis in one patient). Surgical treatment was not achieved after neoadjuvant chemotherapy in 18 patients because of progressive disease.

Conclusion: Neoadjuvant chemotherapy offers several potential benefits. But, it may delay surgery or eliminate eligibility as a surgical candidate. A patient’s rigorous selection for this type of multimodal treatment is essential.

Introduction: Comorbid conditions may affect survival by influencing treatment decisions and prognosis.

Aim of this study was to determine the impact of cardiovascular comorbidity on the survival of patients in the first and second stage of NSCLC.

Methods: The study included 140 patients with NSCLC, in the first and second stage who were treated in the period from January 2004 December 2006. 60 patients (30 in the first and 30 in the second stage) were treated surgically, and 80 patients (30 in the first and 40 in the second stage) is due to the presence of cardiovascular comorbidity treated with chemotherapy and/or radiotherapy and these patients received standard chemotherapy with cisplatin (60mg/m2, 1st day) and etoposide (100mg/m2, 1-3. day), and radiotherapy (40 Gy).

Results: In 43 patients (30.71%) was established cardiovascular comorbidity. The most frequent comorbidities were chronic hypertension (22 or 15.71%), ischemic heart disease (19 or 13.57%) and hypertension (19 or 13.57%). Cardiovascular comorbidities were higher in smokers (p=0.019) and patients with low Karnofsky status (p=0.001).

Median survival for all patients was 19.82 months (in the first stage 20.33, and in the second stage 19.31). Kaplan-Meier survival curves were used to compare survival time among patients with a presence or absence cardiovascular comorbidities. There was not a statistically significant relationship between shorter survival time and a history of cardiovascular comorbidity (p=0.104).

Conclusions: This study did not show a statistically significant effect of the presence of cardiovascular comorbidity on survival of patients in the first and second stage of the disease.
Case description: A 55-year-old previously healthy male presented with complaints of bilateral chest wall pain for the last 4 weeks. Patient denied any history of cough, fever, dyspnea, hoarseness, or any rash. He had smoked a half pack per day for about 30 years. Physical examination was normal as were laboratory studies. Chest CT scan demonstrated a 2.5 cm mass adjacent to the left diaphragm with small satellite nodules. Open lung biopsy did not yield any definite diagnosis. Further workup with MRI of spine, CSF analysis and a para-neoplastic antibody panel were negative. A nerve conduction study demonstrated an axonal polyradiculoneuropathy. Almost a year later a repeat chest and abdominal CT scan showed innumerable bilateral lung nodules and masses. It also showed peculiar motting of the kidneys. A repeat thoracotomy and lung biopsy showed findings consistent with pulmonary lymphomatoid granulomatosis (EBV positive diffuse large B-cell lymphoma of the lungs).

Discussion: Pulmonary lymphomatoid granulomatosis is an uncommon multi-organ systemic disease with predilection to lungs and characterized by multiple pulmonary nodular lesions with lymphocytic invasion of vascular walls on biopsy. The skin, kidney, and neurologic system may be affected concurrently or independently. Cough and dyspnea are the most common presenting symptoms in patients with lung involvement. Physical examination and laboratory studies are generally non-diagnostic. Chest radiography typically reveals multiple poorly defined nodules and/or masses in the mid- and lower-lung zones; diffuse reticular abnormalities may also be present. Therapy ranges from observation to treatment with prednisone or chemotherapy.

**289. Pleural and mediastinal malignancies: management and rare clinical cases**

P2825

**Medical pleurodesis – Safety, effectiveness and adherence to the guidelines: East of England DGH experience**

Azhar Jahangir, Venu Sirpa, Arun Arya, Subramani Durairaj. Respiratory Medicine, Queen Elizabeth Hospital NHS Foundation Trust, Kings Lynn, Norfolk, United Kingdom

The aim of the study was to review the safety and effectiveness of medical pleurodesis performed in our trust. This study was done in The Queen Elizabeth Hospital, Kings Lynn, United Kingdom. We looked at the medical pleurodesis performed from April 2008 to May 2010. The results were assessed against the British Thoracic Society guidelines for medical pleurodesis. We also looked at the side effects and success rate of the procedure.

Forty three events were analysed in 41 patients. Forty four patients were admitted in 2008, 18 patients in 2009 and 7 patients in 2010. Twenty seven (64%) were lung cancer patients in the NELCN who are present late with advanced disease, only 41% of these patients came through a respiratory specialist as a first port of call, and only 35% as urgent cancer referrals. Chemotherapy was offered to 74% of these patients, but only 50% had it. Most of those did not have chemotherapy because of poor performance status. However in two cases chemotherapy was delayed in order to wait for symptoms. The current BTS 2007 guidelines evidence that chemotherapy before symptom progression has a better outcome.

Port site radiotherapy was given to a third of patients, those who did not have chemotherapy. This is in line with the BTS 2007 statement. The NELCN has a high case load of mesothelioma. Diagnoses are moving uniformly across the network towards early CT biopsy or VATs biopsy. Palliative surgical pleurodesis is common and chemotherapy is being offered to three quarters of patients. Mesothelioma MDT’s are operational and assist in optimizing patient pathways.

**Pleural and mediastinal malignancies: management and rare clinical cases**

Fibrosing mediastinitis mimicking bronchogenic carcinoma

Deniz Keskul,1 Hulya Bayiz1, Nesilhan Mulutlu4, Adem Keyuncu1,2, Funda Demirag1,2, Gulidan Dagil1, Bahadir Berkas1, Mine Berkoglu1,2,2nd Chest Diseases Clinic, Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Ankara, Turkey; 1Pathology Clinic, Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Ankara, Turkey; 3Chest Surgery Clinic, Ataturk Chest Diseases and Chest Surgery Education and Research Hospital, Ankara, Turkey

We present a patient with fibrosing mediastinitis mimicking bronchogenic carci-

oma. A 32-year-old male patient admitted with cough and hemoptysis. There was no history of tuberculosis, prior respiratory disease. He had a diagnosis of hepatosteatosis and diabetes mellitus for two years. He had a smoking history of 8 pack-years. Vital signs, physical examination were normal. Apart from a high Glu:177 mg/dL, ESR:48 mm/hr, rutine laboratory analysis were normal. The chest radiograph revealed prominence of right hilum. Thorax CT revealed 4cm mass lesion in the right hilum and multiple mediastinal, right hilar conglomerated lymph nodes.

In PET-CT SUVmax of the hilar lesion was 9.74. Fibroptic bronchoscopy showed mucosal distortion of right upper lobe. Mucosal biopsy was unremarkable. FIBUS-TBNA biopsy revealed CD-45 positive normal lymphoid cells. Cervical mediastinoscopy was undiagnostic. Diagnostic thoracotomy confirmed the diagnosis of fibrosing mediastinitis. Hilar mass was a conglomerated lymph node showing dense hyalineised fibrous tissue with chronic inflammation. In the etiology we thought that fibrosing mediastinitis results from a prior tuberculosis infection, since our country is endemic for tuberculosis. There is no proven effective medical therapy for fibrosing mediastinitis. Despite the fact we initiated both antitubercu-
losis and systemic corticosteroid therapy after informing the patient. The patient is stable after two months of therapy.

oma. A 32-year-old male patient admitted with cough and hemoptysis. There was no history of tuberculosis, prior respiratory disease. He had a diagnosis of hepatosteatosis and diabetes mellitus for two years. He had a smoking history of 8 pack-years. Vital signs, physical examination were normal. Apart from a high Glu:177 mg/dL, ESR:48 mm/hr, rutine laboratory analysis were normal. The chest radiograph revealed prominence of right hilum. Thorax CT revealed 4cm mass lesion in the right hilum and multiple mediastinal, right hilar conglomerated lymph nodes.

In PET-CT SUVmax of the hilar lesion was 9.74. Fibroptic bronchoscopy showed mucosal distortion of right upper lobe. Mucosal biopsy was unremarkable. FIBUS-TBNA biopsy revealed CD-45 positive normal lymphoid cells. Cervical mediastinoscopy was undiagnostic. Diagnostic thoracotomy confirmed the diagnosis of fibrosing mediastinitis. Hilar mass was a conglomerated lymph node showing dense hyalineised fibrous tissue with chronic inflammation. In the etiology we thought that fibrosing mediastinitis results from a prior tuberculosis infection, since our country is endemic for tuberculosis. There is no proven effective medical therapy for fibrosing mediastinitis. Despite the fact we initiated both antitubercu-
losis and systemic corticosteroid therapy after informing the patient. The patient is stable after two months of therapy.
normal apart from a high erythrocyte sedimentation rate (120 mm/hr), anemia (hb: 10.9 g/dl) and hypoxemia (PaO2: 48 mmHg). Computed tomography revealed multiple mediastinal lymph nodes, bilateral pleural thickenings, paramediastinal mass lesion in the left lower lobe and multiple pulmonary nodules.

Cranial CT was normal. Abdominal USG revealed liver metastasis with multiple hyperechoic nodules 2 cm in diameter. Transbronchial biopsy via fiberoptic bronchoscopy revealed the diagnosis of malignant mesothelioma infiltration. The tumor was diffusely positive for calretinin and focal positive for keratin 5.6. The patient died one week after diagnosis.

Benefit of the serum-effusion albumin gradient in congestive heart failure patients
Phamlarp Sangsayun1, Boonjong Saejueng2. 1 Chest Department, Central Chest Institute of Thailand, Nonthaburi, Thailand; 2Cardiology Department, Central Chest Institute of Thailand, Nonthaburi, Thailand

Objective: To compare between light’s criteria and serum-effusion (S-E)albumin gradient in assessment of transudate effusion in CHF patients.

Material and method: Eighty-six patients who had pleural effusion and suspected CHF were enrolled in this study between October 2008-September 2010. Suspected CHF was defined by clinical or echocardiography. Inform consents were done in all volunteers. Exclusion criteria was previous thoracotomy or coronary by pass graft 3 month before study. Thoracocentesis was done to evaluate transudate effusion by light’s criteria and S-E albumin gradient > 1.2 mg/dl. Definite diagnosis of pure CHF was no effusion after treatment with diuretics and pleural ProBNP > 4000 ng/dl. Combination of pleural disease and CHF were defined by confirmed pleural disease with pleural biopsy and/or VAT, partial response with diuresis and high pleural ProBNP

Result: 12 (13.95%), 56 (65.11%), 17 (19.76%) of all were pure pleural disease, pure CHF, combination of pleural disease and CHF. Sensitivity/specificity/accuracy of S-E albumin gradient and light’s criteria and in diagnosis of CHF (both pure and combined) were 90.133.300.2%, 64.780.067.4%. No correlation between amount of diuretic drug and “exudate” criteria from lights (p=0.66).25 (27.2%) patients were previous post thoracotomy or coronary bypass graft. 7 of 25 patients had loculated effusion. There was correlation between previous surgery with loculated effusion and effusion from combination of pleural disease and CHF (p=0.22).

Conclusion: There is benefit use to S-E albumin gradient > 1.2 mg/dl to diagnose CHF patients who suspected CHF with or without pleural disease. No correlation between diuresis and exudate from Light’s criteria.

P2828
Epigenetic deregulated translation control of C/EBP-alpha leads to increased mesothelioma cell proliferation
Jun Zhong1, Nicola Miglino1, Michael Tammi1, Didier Lardinois2, Michael Roth3. 1 Pulmonary Cell Research & Pneumology; 2Thoracic Surgery, University Hospital Basel, Basel, Switzerland

Malignant pleural mesothelioma (MM) resists all available anticancer therapies. A major pathology of MM is the uncontrolled cell proliferation and the fast local spreading with rare metastasis. Therefore the inhibition of proliferation is a major therapeutic target. Proliferation of MM cells was linked to mitogen activated protein kinase (MAPK) activity. In this study we characterised the regulation of MAPK regulated CCAAT/Enhancer binding proteins (C/EBP) and their role in MM cell proliferation. In 5 human MM cell lines, cytosolic and nuclear protein expression was determined by western blot, or C/EBP-β, -γ and -α MAPK together up-regulated the expression of C/EBP-α, while C/EBP-β was not expressed. Compared to mesothelial cells C/EBP-α translation was reduced in MM, while the mRNA was constitutively expressed. MM cells expressed a high level of the C/EBP-α transcription suppressor calreticulin, while eIF4E was not significantly modified. Cell proliferation was inhibited by either the blockade of Erk1/2 or p38-β and -γ MAPK, or C/EBP-β. Translation with a C/EBP-α expression vector reduced proliferation and increased the MM cell’s sensitivity to steroids. Our data implies that in human MM cells an epigenetic mechanism deregulates the translation control of the cell differentiation factor C/EBP-α which leads to increased proliferation and drug resistance.

P2829
Granulomatous reaction – A common cause of mediastinal and hilar lymphadenopathy in non-pulmonary malignancies
Arve Sundset1,2, Inga Leuckfeld1, Peter Guarve3, Peter Jepsen1, Anne Naalsund1. 1Department of Respiratory Medicine, Rikshospitalet, Oslo University Hospital, Oslo, Norway; 2Interventional Centre, Rikshospitalet, Oslo University Hospital, Oslo, Norway; 3Department of Pathology, Rikshospitalet, Oslo University Hospital, Oslo, Norway

Introduction: Patients with non-pulmonary malignancies are followed with CT for exclusion of metastatic disease. Enlarged mediastinal or hilar lymph nodes can be signs of metastases.

Aim: We report the outcome of 45 consecutive patients referred for EBUS-TBNA due to mediastinal or hilar lymph nodes detected on CT at clinical follow-up for non-pulmonary malignancies.

Material and methods: EBUS-TBNA was performed 17 (0.5-116) months (median range with range) following the primary diagnosis: 28 patients had epithelial malignancies, 6 melanomas, 6 lymphomas, 4 germinal cell carcinomas, and 1 patient sarcoma.

Results: In 45 patients, 90 mediastinal and hilar lymph nodes were punctured. In 6 lymph nodes no lymphocytes were detected (93.3% representative samples). Granulomatous reaction was found in 19 patients (42%), and in another 12 (27%), the lymph nodes were normal. In one patient, no lymphocytes and no malignant cells were present, and 24 months follow-up was uneventful. Metastases were seen in only 12 patients (27%), and in one patient a malignancy other than the primary tumor was detected. In 13 patients with colon cancer, the largest subgroup, metastases were found in 3.

Conclusions: Cytopathological investigation of enlarged mediastinal or hilar lymph nodes in non-pulmonary malignancies is required to confirm the diagnosis, as the majority seem to be benign.

P2830
Patients with malignant pleural effusions who are treated with indwelling pleural catheters spend fewer days in hospital
Edward Fish1,2, A. William Misk1, Y.C. Gary Lee1,2. 1 Pleural Diseases Unit, Sir Charles Gardiner Hospital, Perth, Western Australia, Australia; 2School of Medicine, University of Western Australia, Perth, WA, Australia

Introduction: Malignant pleural effusions (MPE) are common and reducing hospitalization is a key management goal for these patients. Treatment strategies are changing with the advent of indwelling pleural catheters (IPC), a new ambulatory treatment for patients with MPE. We hypothesized that those patients managed with IPC spend fewer days in hospital compared with pleurodesis.

Methods: A prospective, non-randomized study involving all major respiratory centers in Western Australia. Patients diagnosed to have MPE were prospectively followed up until death or to the end of the one year study. In the absence of accepted guidelines for IPC-use, the choice of treatments (pleurodesis, IPC or repeated thoracocentesis) was made by the treating clinicians. Hospital admissions were analysed on an intention to treat basis from the time of the first procedure.

Results: 160 patients with MPE were recruited. 31 patients were managed with talc pleurodesis, and 34 received an IPC. The remaining patients only required simple thoracocentesis, either because of poor prognosis, lack of effusion recurrence, or lack of symptom relief with initial drainage. Total hospital admission days were significantly lower in patients treated with IPC (median, 25.75th percentiles) at 6-5 days (3.75-13.0) compared with pleurodesis at 18.8 (8.0-26.0), p<0.002 (Mann-Whitney ranked sum test). Effusion-related admissions were even more significantly reduced at 3.0 days (1.75-8.25) against 10 (6.0-18.0), p<0.001.

Conclusion: Patients with MPE who are treated with an IPC spend fewer days in hospital compared with pleurodesis.

P2831
The burden of mesothelioma mortality: Estimation as the first step to prevention
Aiza Jamil, Bandipalyam Prathibha. Respiratory Medicine, East Kent Hospitals NHS Trust, Canterbury, United Kingdom

Background: Mesothelioma is a rare cancer that principally affects the pleura and is almost always caused by asbestos exposure. Mesothelioma incidence has increased in South East England of which East Kent is a major part, particularly for men aged over 70 years, reflecting areas of asbestos use in shipbuilding and industry in the past.

Methods: The aim of the study is to estimate the current burden of cancer in the area of East Kent in the UK attributable to occupational factors, and identify carcinogenic agents, industries and occupations for targeting risk prevention.

Data of all cases diagnosed at East Kent Hospitals NHS Trust were collected retrospectively from April 2009 to March 2010.

Results: There were a total of 15 cases in East Kent Hospital NHS trust, UK over the period of one year which is a significantly high number as compared to previous years, the current population being 614,576. All of them were male. Median age was 74 years and median survival from diagnosis was 8.9 months. 85% had documented evidence of definite or probable exposure to asbestos. There
were 7 cases that were treated with chemotherapy, 6 patients had radiotherapy and 2 patients with advanced malignancy had palliative treatment. No patient had radical surgery and there was minimal difference in relative survival between men with localised and non-localised disease.

Conclusion: In Great Britain, where asbestos use continued later than many other countries, the peak is anticipated to occur later between 2011 and 2115. Cancer networks, especially those with primary care trusts with high incidence, need to be aware of this disease and ensure that risk reduction strategies and services are in place to assist these patients.

P2832
Evaluation of pulmonary reexpansion after thoracocentesis using electrical impedance tomography
Sergio Alves1,2, Francisco Vargas3, Marcelo Amato1,2, Lisete Teixeira1, Carlos Carvalho1,2, Roberta Sales1, Juliana Puka1, Pedro Caruso1,2. 1Pulmonary Division, Pleura Laboratory, Heart Institute (InCor) - University of Sao Paulo Medical School, Sao Paulo, Brazil; 2LIM 09 - Pulmonary Division, University of Sao Paulo Medical School, Sao Paulo, Brazil

Introduction: The time to maximum lung reexpansion after a thoracocentesis (Thc) is unknown. This limitation is due to the lack of a method to accurately and continuously gauge the lung reexpansion. Electrical impedance tomography (EIT) is a method able to accurately measure relative alterations in lung ventilation and may be an attractive method to evaluate lung function affected by a pleural effusion and the effect of Thc.

Objectives: Quantify the time to maximum lung expansion.

Methods: EIT electrodes were placed around the thorax two centimeters above the effusion lower level. The EIT images were recorded before, immediately and at 15 min intervals after Thc until three consecutive measurements without alteration in the ventilation of affected lung (defined as a ventilation variation <10%).

Results: We evaluated seven patients with pleural effusion. The mean withdrew effusion volume was 1440 mL. Five patients reexpanded the lung. Before Thc, their mean lung ventilation proportion of the affected lung over the unaffected was 0.19 and rose to 0.71. Two patients achieved maximum reexpansion immediately after Thc, one after 15, one after 30 and one after 60 min. Two patients did not reexpand their lungs.

Conclusions: Patients that reexpand their lungs after thoracocentesis achieve maximum lung reexpansion immediately or in less than 60 minutes.

P2833
Malignant pleural mesothelioma: Facts & survival rate
Catarina Guimarães, Lígia Fernandes, Luís Rodrigues, Ana Figueiredo, Fernando Barata. Pulmonology Department, Centro Hospitalar de Coimbra-EPE, Coimbra, Portugal

Background: Malignant pleural mesothelioma is the most common type of malignant mesothelioma. Classically described as rare neoplasms, malignant pleural mesothelioma is considered an almost incurable tumour with increasing incidence worldwide, mainly as a result of previous exposure to asbestos – its chief risk factor.

Objectives: Characterize patients with pleural mesotheliomas, determine the time to progression and establish median survival rate.

Materials and methods: A retrospective analysis of all cases of pleural mesotheliomas diagnosed in our Department of Pulmonology, between the years of 2000 and 2009.

Results: Pleural mesotheliomas were diagnosed in 25 patients, 4 females and 22 males. Their age average was 62 years (minimum 40; maximum 76). The majority, 53%, had a history of tobacco exposure (28% were ex-smokers while 25% were current smokers). In 44% of all cases, there was recognized exposure to asbestos fibbers in the past. Twenty one patients presented the epithelial type of mesothelioma and only four had the mixed type. Their therapeutic approach included chemotherapy and in 21 patients local adjuvant radiotherapy was used. The time to progression was 7 months, median survival 11 months and one-year survival rate of 44%.

Conclusion: The incidence of pleural mesotheliomas was much higher in males than in females. Previous exposure to tobacco and asbestos fibbers was significant. Pleural mesotheliomas have a dismal prognosis, with a high mortality rate and low median survival time.

P2834
Acute pleural service: Experience and pathways
Burhan Khan, Marika Townsend. Department of Respiratory Medicine, Darent Valley Hospital, Dartford, Kent, United Kingdom

Introduction: Pleural effusions are common and may be the first sign of malignancy or can develop in patients with a confirmed malignancy. It generally indicates advanced disease, forbears deterioration in performance status, increased symptom load, and limited life expectancy. However, not all of these patients necessarily need hospitalisation or a chest drain.

Aims: To ascertain the qualitative and quantitative benefits of providing an acute pleural service.

Results: From July 2010 to date 25 patients were referred to the Acute Pleural Service. The types of pleural pathologies and pathway are shown below.

Aetiology of pleural disease of patients in Acute Pleural Service

Conclusion: Patients with either known malignant pleural effusion and those on first presentation may be managed as elective day admissions in an Acute Pleural Service pathway delivered by a Chest Physician with competency in thoracic ultrasound. This enables rapid assessment for prompt diagnosis, relief of symptoms and onward referral for VATS, medical thoracoscopy, PleurX, chest tube pleurodesis, or repeated pleural drainages as appropriate. This also represents another modality in managing patients with recurrent pleural effusion accumulation, and avoids unnecessary admission & hospitalisation to an acute hospital.
P2335
First ever report of histologically proven bronchiolitis obliterans organizing pneumonia after antineoplastic treatment of a malignant pleural mesothelioma with cisplatin and pemetrexed
Markus Lehrmann, Axel Tobias Kempa, Franz Stanzel, Monika Serke. Langenklinik Hemer, Pneumologie, Hemer, Germany

We report a case of a 74 year old patient diagnosed with malignant pleural mesothelioma who developed an interstitial pneumonia following chemotherapy with platinum and pemetrexed.

The patient was treated with 6 courses of chemotherapy. On admission for the sixth course he reported dyspnea on exertion. Blood gas analysis showed mild hypoxemia. Computed tomography of the chest showed patchy opacities in both lungs, some with a ground glass pattern. Six weeks later and after being treated with several antibiotic agents, the respiratory failure and radiological findings had dramatically worsened. We performed a transbronchial lung biopsy. The histopathological examination of the biopsies showed the pattern of bronchiolitis obliterans and organizing pneumonia. The patient was treated with steroids for several weeks. While radiologic findings clearly improved, the respiratory failure even worsened. The patient remained severely impaired in his quality of life.

Despite up to 20 percent of patients treated with an antineoplastic agent are estimated to have some form of lung toxicity, just one suspected case of interstitial pneumonia after chemotherapy with pemetrexed has been reported. Though, the diagnosis has not been proven historically [1]. Especially as the antifolate agents gemcitabine and methotrexate are well known to cause lung injury, we think that pemetrexed must be considered as the causing agent of the lung injury in our patient.

P2336
An analysis of indwelling pleural catheter (IPC) insertions for malignant pleural effusions
Elaine Reid, Pasupathy Sivasothy, Stefan Marciniak. Respiratory Medicine, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Introduction: Persistent malignant pleural effusion (MPE) is a common complication of malignant disease. IPCs are a safe effective strategy to relieve dyspnoea, maintain quality of life, reduce hospitalisation and length of hospital stay.

Objective: To describe the use and outcomes of IPCs in management of MPE.

Results: 47 IPC insertions for MPE were performed in 44 patients (1 bilateral and 2 retrosternal cases).

21 patients had IPC insertion due to trapped lung, 19 patients after failed pleurodesis. Median hospitalisation 2 days for elective admission (IQR 1), 6 days for emergency admission (IQR 2.5). Median survival post insertion, if still in situ at time of death, 35 days (IQR 28), mean 54 days (SD 54.5). Complication rates were 4% for catheter related sepsis, 2 cases of cellulitis, 2 cases of skin sensitivity to dressing, 1 tube displacement and 1 fracturing of IPC requiring removal. IPCs were removed in 4 patients after time of death, 35 days (IQR 28); mean 54 days (SD 54.5). Complication rates were 3% for catheter related sepsis, 1 case of cellulitis and 1 fracturing of IPC requiring removal.

Conclusion: IPC’s are effective and safe for management of MPE with low complication rates and obvious cost benefit advantage in reduced hospital admissions offering immediate and sustained relief of symptoms.

P2337
Unusual case of multiple pleural masses
Vena Srpa, Parthipan Kanthapillai. Respiratory Medicine, Laton & Dunstable Hospital, Laton, United Kingdom

A 80 year old lady was referred for evaluation of multiple pleural shadows. She was diagnosed to have myasthenia gravis 30 years ago and was treated with azathioprine until now. Six years ago she underwent bone marrow biopsy for investigation of anaemia which revealed hypoplastic marrow with specific red cell aplasia including features consistent with azathioprine treatment.

Her hemoglobin was 11.5g/dl. CT scan of the chest revealed multiple pleural masses. CT guided biopsy of the pleura showed bone marrow with apparently normal granulocytes, normoblasts, megakaryocytes and other myeloid elements. There was no evidence of leukemia or malignancy noted. There was no pleural or pulmonary tissue identified in the biopsy and the features were consistent with extra medullary hemopoiesis (EMH).

EMH is the proliferation of blood elements outside the bone marrow cavity. This mainly involves reticuloendothelial system (liver, spleen & lymph nodes) but is also known to occur in every organ of the body including thyroid, pericardium, kidney and lungs. Only a few cases of intra thoracic EMH have been reported in literature.

These may manifest as paraoesophagus masses, pleural masses or haemorrhaxas either alone or in combination. They occur characteristically either unilaterally or bilaterally in the posterior mediastinum. They present as rounded soft tissue opacities peripherally with a clear cut outline. Neither calcification nor bony erosion has been reported in these masses. EMH thus forms one of the important differential diagnoses of posterior mediastinal masses. This case illustrates the importance of considering EMH in the differential diagnosis of multiple pleural masses.

P2383
Comparative evaluation of alkanine phosphatase (ALP) & adenosine deaminase (ADA) in pleural fluid and serum of patients with pleural effusions Irene Tsilioni, Markos Minas, Vassiliki Tsolaki, Apostolos Triantaras, Christos Daenas, Eirini Geroergiou. Respiratory Medicine Department, University of Thessaly Medical School, Larissa, Greece

Background: High levels of alkaline phosphatase (ALP) and adenosine deaminase (ADA) have been suggested for the discrimination between exudative and transudative pleural effusions (PE).

Objectives: The purpose of this study is to assess the levels of ALP and Adenosine Deaminase (ADA) in the pleural fluid of patients with PE. We also evaluate the usefulness of ALP activity in differentiating transudates from exudates and further in separating tuberculous PE from other causes of exudative effusions (malignant and parapneumonic PE).

Materials and methods: A total of 60 patients, admitted to our hospital, having PE due to various etiologies were included in this study. The patients were divided into four groups according to the final diagnosis: 27 malignant, 19 parapneumonic, 8 tuberculous and 6 transudative PE.

Results: Both mean pleural fluid ALP and ADA values were significantly higher in transudates compared to exudates (61.04±5.86 vs. 32.67±1.42 U/mL; p=0.012 and 39.81±4.83 vs. 8.22±1.45 U/L; p=0.0004 respectively). Parapneumonic and tuberculous pleural fluid ALP and ADA were significantly lower compared to malignant PE respectively. In ROC curve analysis, sensitivity and specificity values were 98.1% and 83.3% respectively for a cut-off value of 9.2 U/L for pleural ADA and 54.7% and 83.3% respectively for a cut-off value of 45 U/mL.

Conclusion: Both ADA and ALP showed the same specificity in distinguishing exudative from transudative PE whereas ADA showed greater sensitivity compared to ALP; although both biomarkers were significantly higher in exudates compared to transudates.

P2384
The impact of malignant pleural effusion – A retrospective review
Richard Budd, Nana Acharya, Muhammad Malik. Respiratory Medicine, Barnsley Hospital NHS Foundation Trust, Barnsley, South Yorkshire, United Kingdom

Barnsley Hospital (BH) serves a population of 220,000 people. The respiratory specialists have noticed a high burden of care associated with the management of pleural disease. An average United Kingdom (UK) district general hospital would expect to diagnose and treat approximately 230 new cases of malignant pleural effusion (MPE) per year [1]. Projected figures suggest an increase of 100,000 cancer diagnoses per year within the UK of which 15% will have an associated MPE [1]. One NHS bed day costs £225 [2] and with this in mind we considered the workload and financial resources required to manage these cases.

Method: We retrospectively analysed data over an 18-month period, searching clinical coding archives using the keyword “pleural effusion”. Cases with a malignancy coded under the heading “primary diagnosis”, “diagnosis 1” or “diagnosis 2” were identified as having a MPE. These cases were reviewed to assess total number of inpatient days, number of patient episodes and length of stay (LOS).

Results: Number of patient episodes for pleural effusion of any cause = 1195 Number of patient episodes for MPE = 226 (including recurrent admissions) Number of MPE secondary to lung cancer = 90 (39.8%) Average LOS for MPE = 7.3 days

Conclusion: The burden of MPE management at BH is significant, considering that in this 18 month period 1650 inpatient days were utilised. By highlighting the financial impact of this data there has been a successful bid by the lead lung cancer specialist for funding of a medical thorascopy service in BH. A recent audit of the medical thorascopy service has confirmed a reduction in LOS and recurrent admissions.

P2840
Desmoplastic small round cell tumour of the pleura. Report of a rare case
Iris Vlachanti1, Evangelia Chomolou1, Margarita Baka2, Helen Kosmidou3,
Mina Gagi1, 2 1 5th Respiratory Medicine Department, 2 Sotira Hospital, Athens, Greece; 3 Oncology Department, “Sotira” Children’s Hospital, Athens, Greece
Background: Desmoplastic small round cell tumour (DSRCT) is a rare, highly aggressive malignancy typically presenting as an abdomen mass. It usually occurs in young population with male predominance.
Aims: To report a rare case of DSRCT arising from the pleura in a 15-year old female.
Methods: We present a clinical case of a young patient who presented with dyspnoea on exertion thoracic back pain and significant weight loss. Physical examination revealed decreased breath sounds of the right hemithorax. A computed tomography scan suggested extended pleural effusion combined with a large pleural mass of the right side extending in the abdomen and paracolic lymphadenopathy. The diagnosis of the mass revealed histological and immunohistochemical characteristics consistent with desmoplastic small round cell tumor. The patient received 7 courses of chemotherapy according to the P6 protocol which involved etoposide, doxorubicin and vincristine for courses 1-3 and 6, ifosfamide and etoposide for courses 4, 5 and 7.
Results: The patient obtained a partial response after completion of chemotherapy and, subsequently, she received local radiotherapy. Eight months after the initial diagnosis the patient remains in a clinically stable condition.
Conclusion: Desmoplastic small round cell tumor is an uncommon aggressive malignancy. It appears to be chemosensitive but response to treatment is only short-lasting. Current literature suggests a multidisciplinary approach including chemotherapy, radiation and surgery. However, prognosis remains poor.

P2841
Miliary mesotheloma: A consequence of trimodality therapy?
Losek Parek, Sophie Larroumagne, Hervé Datau, Philippe Astud. Division of Thoracic Oncology, Pulmonary Diseases, and Interventional Pulmonology, Hôpital Nord – Université de la Méditerranée, Marseille, France
Background: Malignant pleural mesothelioma (MPM) is a rare cancer. Trimodality therapy (TMT) for resectable MPM, combining Cisplatin-based chemotherapy, extrapleural pneumonectomy (EPP) and adjuvant high-dose radiotherapy, is one of the therapeutic strategies with prolonged survival in selective cases. From two recent clinical cases showing dissemination of the disease after multimodal approach, the authors perform a review of the literature trying to find a link between metastatic evolution and aggressive therapeutic strategy.
Case reports: Two patients presenting with chest pain and pleural effusion had MPM considered, after careful preoperative work–up including negative cerebral scans, chest pain at right side of thorax and effort dispnea was hospitalized. A well defined pleural effusion without pleural nodules was observed at chest x-ray. Multiple lymphadenopathies in the mediastinum and a consolidation area of 8 x 10 x 6 cm in size showing air bronchograms in right lung upper and middle lobes medial segment was reported at computed chest tomography.
A mass lesion obliterating the right upper lobe entrance showing sign of spreading to the intermediate bronchus was observed with fiberoptic bronchoscopy.
Classical type of Hodgkin’s Disease was diagnosed by the histopathologic examination of mucosal biopsy specimen confirming a very rarely observed case of primary pulmonary Hodgkin’s disease with endobronchial involvement.

P2844
Experience of an intercostal chest drain training course in the Yorkshire and Humber postgraduate deanery
Georgina Esterbrook1, Tim Sutherland2, Matthew Callister2, James McCreanor1, Joe Hogg1, Peter Smith1, Richard Teoh3, Jack Kastelik 3.
1Respiratory Medicine, Pinderfields General Hospital, Wakefield, West Yorkshire, United Kingdom; 2 Respiratory Medicine, St James’s University Hospital, Leeds, West Yorkshire, United Kingdom; 3Respiratory Medicine, Castle Hill Hospital, Hull, East Yorkshire, United Kingdom
Introduction: A significant number of deaths and cases of serious harm have been reported as a result of the insertion of chest drains. Reasons include poor training and inadequate supervision of trainees. We devised a simulation chest drain insertion course to improve competency and reduce adverse events.
Methods: A half-day course was devised, consisting of a lecture, theory examination, practical simulation session and a competency-based assessment. Emphasis is placed on teaching current guidelines and small group supervised practice on manikins. A certificate of competence is provided for all candidates successfully completing the course. Feedback for each aspect of the course was collected based on a 5 point Likert scale.
Results: Over 18 months, 13 courses took place and 140 feedback forms returned. In over 96% of cases, all aspects were rated as good or very good. The course was praised for the ratio of trainees to candidates, the length of time for practice, the seniority of the trainees and the length of course. A significant number of candidates would recommend the course to a colleague as part of medical training.
Discussion: In our region, this is the first course dedicated to teaching seldinger chest drain insertion. It successfully employs a variety of different educational methods, and provides a ratio of senior trainers to candidates that facilitates learning. In comparison to other practical skills courses, this course dedicates more

P2843
Health care professionals’ knowledges of OSAHS’s diagnosis
PM Prapa1, I. Nikolopoulos1, P. Kyriacou2, Konstantinos Gourgoulianis2.
1Department of Respiratory and Critical Care Medicine, Sotiria Chest Hospital, Athens, Greece; 2Respiratory Medicine Department, University of Thessaly, Medical School, Larissa, Greece
Methods: A questionnaire was designed to explore HPs’ knowledge to identify OSAHS. It was completed by Respiratory Physicians in a Pulmonary Department, by General Practitioners in Primary Care Center and by Primary Care Physicians.
Results: A panel of Respiratory Physicians evaluated the answers.
Results: A total of 138 HPs completed the survey, (53.6% Respiratory Physicians (n=74), 18,8% General Practitioners (n=26), 27,5% Primary Care Physicians (n=38).
The HPs’ education on OSAHS was at University (33,4%), Post graduate (1,4%), Medical literature (66,7%), day-to-day practice (53,6%) and medical residency (40,9%).
The correct answers were for:
– Clinical symptoms: Snoring 78,2%, daytime sleepiness 87%, morning headaches 58% and nocturia 20,3%.
– Complications: hypertension, 73,9%, chronic pulmonary heart disease 43,5% and
– Clinical features: obesity 79,7%, large neck circumference 42%.
Logistic regression analysis revealed that physicians who acquired their knowledge in their day-to-day practice on OSAHS were more likely to answer correct question concerning clinical symptoms (OR=13.12,95%CI: 2.94-58.41, p<0.001) complications (OR=5.73, 95%CI: 2.31-14.23, p<0.001) and clinical features (OR=12.69, 95%CI: 4.87-33.07, p<0.001).
Conclusion: Following this study; education sessions must be introduced in all education level in an attempt to improve the identification of this disorder and to allow the Physicians to take part in the management of OSAHS.

MONDAY, SEPTEMBER 26TH 2011

Experience of an intercostal chest drain training course in the Yorkshire and Humber postgraduate deanery
Georgina Esterbrook1, Tim Sutherland2, Matthew Callister2, James McCreanor1, Joe Hogg1, Peter Smith1, Richard Teoh3, Jack Kastelik 3.
1Respiratory Medicine, Pinderfields General Hospital, Wakefield, West Yorkshire, United Kingdom; 2 Respiratory Medicine, St James’s University Hospital, Leeds, West Yorkshire, United Kingdom; 3Respiratory Medicine, Castle Hill Hospital, Hull, East Yorkshire, United Kingdom
Introduction: A significant number of deaths and cases of serious harm have been reported as a result of the insertion of seldinger chest drains. Reasons include poor training and inadequate supervision of trainees. We devised a simulation chest drain insertion course to improve competency and reduce adverse events.
Methods: A half-day course was devised, consisting of a lecture, theory examination, practical simulation session and a competency-based assessment. Emphasis is placed on teaching current guidelines and small group supervised practice on manikins. A certificate of competence is provided for all candidates successfully completing the course. Feedback for each aspect of the course was collected based on a 5 point Likert scale.
Results: Over 18 months, 13 courses took place and 140 feedback forms returned. In over 96% of cases, all aspects were rated as good or very good. The course was praised for the ratio of trainees to candidates, the length of time for practice, the seniority of the trainees and the length of course. A significant number of candidates would recommend the course to a colleague as part of medical training.
Discussion: In our region, this is the first course dedicated to teaching seldinger chest drain insertion. It successfully employs a variety of different educational methods, and provides a ratio of senior trainers to candidates that facilitates learning. In comparison to other practical skills courses, this course dedicates more
time to individual tuition and practice to thoroughly assess safety and competency. We would recommend that the simulation of trainee chest drain insertion should be available to all trainees in respiratory medicine.

P2845
Clinical impact of a program to educate community pharmacists in providing proper inhalation technique for asthma patients
Masaya Takeamura1, Katsumi Mitsui2, Masako Ido3, Misuzu Koyama4, Masataka Shimotani5, Daiki Inoue5, Kazufumi Takamatu1, Ryo Iotani1, Manabu Ishitoko1, Shinko Suzuki1, Kensaku Aihara1, Hitoshi Kagoi1, Motonari Fukui6, 1Respiratory Disease Center, Tazuke Kofujii Medical Research Institute, Kitano-Hospital, Osaka, Japan; 2Division of Pharmacy, Tazuke Kofujii Medical Research Institute, Kitano-Hospital, Osaka, Japan; 3Division of Pharmacy, Kita-ku Pharmaceutical Association, Osaka, Japan

Background: Currently, more than 10 types of inhaler devices are available in the asthma treatment. The prevalence of these inhalers has resulted in a wide range of choices for clinicians but in confusion for both medical staffs and patients regarding how to use inhaler devices correctly.

Objective: To evaluate the clinical impact of an educational program for community pharmacists to provide repeated instructions of correct and consistent inhalation technique to asthma patients.

Methods: Since 2007, Kitano hospital and Kita-ku Pharmaceutical Association Osaka have provided community-pharmacists with a regular educational program on correct inhaler use once a year. Certified participants have instructed asthma patients to use their inhalers with proper techniques at regular intervals (at least 6 months). We examined the frequency of asthma exacerbations, adherence to inhalation regimen using a 5-point Likert scale questionnaire, and health status assessed by St George’s Respiratory Questionnaire (SGRQ) in asthma patients before starting the program and after four years.

Results: Usable information was obtained from 146 asthma patients at baseline and 143 at 4 years. Compared with baseline values, significant decreases were found in the frequency of asthma exacerbations (1.4±1.6 vs 1.0±1.4 times/year, p=0.042) and emergency room visits (0.5±1.0 vs 0.2±0.5 times/year, p=0.004). Adherence to the inhalation regimen significantly increased (p=0.041), but SGRQ scores unchanged.

Conclusion: A regular program which educates community-pharmacists about how to instruct patients in proper inhaler use may improve asthma control and adherence to patients’ inhalation regimen.

P2846
Quit smoking in pregnancy with asthma
Olga Sukhovskaya, Olga Lavrova, Natalia Kolpinskaya. Research Institute of Pulmonology, Pavlov’s State Medical University, St. Petersburg, Russian Federation

The aim of this study was to identify the factors related to quit smoking during pregnancy in patients with asthma. The sample included 990 pregnant (417 with asthma) in age 18-40 years. They were interviewed about smoking and social status. CO breathing test has been made for cigarette consumption.

Investigation shows that 26.4% pregnancies without asthma were smokers (6.95±0.94 cigarettes per day), 23% pregnant per asthmatic pregnant una were smokers (7.06±1.2 cigarette per day). Before pregnancy women smoked in 57.1% cases without asthma (11.3±1.6 cigarette per day) and in 49.4% with asthma (10.6±1.7 cigarette per day). Education programs for pregnant women with asthma. Health preg-
nants quit smoking in 14.7±1.9 week of pregnancy, patients with asthma – in 8.77±1.2 week. The cessation smoking program included of CO level measuring. The discrepancy of answers and CO levels was in 22% of cases.

The factors, promotional quit smoking during pregnancy were: educational pro-
grams for smokers, non-smoking family (especially husband), high education, support of husband in quit smoking. Unmarried pregnant smokers smoked twice more often than married women. Planned pregnancy contributed to smoking rejection, which was found in the frequency of asthma exacerbations (1.4±1.6 vs 1.0±1.4 times/year, p=0.042) and emergency room visits (0.5±1.0 vs 0.2±0.5 times/year, p=0.004). Adherence to the inhalation regimen significantly increased (p=0.041), but SGRQ scores unchanged.

Conclusion: A regular program which educates community-pharmacists about how to instruct patients in proper inhaler use may improve asthma control and adherence to patients’ inhalation regimen.

P2847
Competency assessment of foundation year 1 doctors in the prescription and use of oxygen
David Tarpey, Diana Lees, Ana De Ramon. Respiratory Medicine, Warrington General Hospital, Warrington, Cheshire, United Kingdom

Introduction: Oxygen is a commonly used drug in hospital medicine, with at least 25% of ward based patients receiving it at any one time. The UK National Patient Safety Agency (NPSA) report on oxygen therapy in hospitals (2009) detailed over 200 incidents due to inappropriate oxygen prescription, with a subsequent mandate that all oxygen should be prescribed as per national guidelines.

Aim: To assess competency levels in Foundation year 1 (F1) doctors in oxygen prescription in our hospital trust.

Method: A questionnaire was completed at the beginning of the F1 year, to assess understanding of oxygen prescription. This was repeated 6 months later following teaching sessions and clinical experience.

Results: 22/50 (73% of F1 doctors) took the survey with a mean score of 58% (range 40-80%). 18 (60% of the original cohort) took the test six months later with a significantly decreased mean score of 47% (range 50-80%) p=0.04. Improvement was seen in the use of emergency oxygen in patients with normal saturations (45% vs 78%), on oxygen prescription (63% vs 100%) and in the correct procedure for stopping oxygen (45% vs 55%). Persistent knowledge gaps were seen with target saturations (72% to 70%) and increasing flow rates to match patient needs (32% vs 22%).

Conclusions: Results demonstrate a lack of knowledge of national guidance amongst junior doctors. Improvement was demonstrated following teaching sessions and clinical experience. Future teaching sessions should focus on areas where improvement was not seen to increase adherence to guidelines and improve patient care.

P2848
Does a training programme in chest drain insertion improve patient safety?
Theodora Vatopoulou1, Chirag Dave2, Amanda James2, Dwight McLeod3
1Respiratory Department, Sandwell Hospital, Birmingham, United Kingdom; 2Respiratory Department, Heartlands Hospital, Birmingham, United Kingdom

Introduction: Following the National Patient Safety Agency alert for intercostal chest drain (ICD) insertion, our respiratory department introduced a training programme for all registrars (SpRs) & junior doctors. Emphasis was placed on completing a proforma at the time of insertion & notifying our team, so that subsequent close monitor of the ICD management occurred.

Methods: A retrospective study of 52 consecutive ICD insertions notified at Sandwell Hospital over a year (Jan09-Jan10, males 80%, median age 67 years) was conducted. Indications for drainage, technique, documentation & complications were audited. The results were compared with a previous departmental 6 month audit.

Results: Medical SpRs inserted 12 (23.07%), respiratory SpRs & senior house officers (SHOs) 24 (46.15%), other SHOs 3 (5.7%), consultants 6 (11.5%), house officers 1 (1.9%) & in 6 (11.5%) the grade was unknown. 21 (40%) were inserted out of hours, 22 (42%) on the respiratory ward. Type of drain: 49 Seldinger (94.2%), 2 blunt dissections (3.8%), 1 pigtail (1.9%). All indications were according to the British Thoracic Society guidelines, 21 pneumothoraces (40%), 29 pleural effusions (55%) & replacing 2 blocked ICDs (5%). The average length of ICD in situ 3.4 days compared to 5.2 previously. Complications included 1 empyema & 3 drains fell out. In the earlier audit, complications included ICD insertion into a bulla, 1 insertion into the liver, 2 severe site infections & 2 re-admissions for empyema.

Conclusions: ICD training programmes improve patient safety. As over half of ICDs are placed by non-respiratory junior staff, there is a continual need for training. However, this is not just about ICD insertion, post insertion care, prompted by the proforma reduces complications & length of ICD stay.

P2849
Effect of training in educational programs at the level of control and quality of life of patients with bronchial asthma
Olena Semenyayeva1, Nadiya Monogorova1, Denys Stupchenko2, Alexandr Le3
1Internal Medicine named after A.Y.Gubergerits, Donetsk National Medical University; 2Department of Thoracic Surgery, Donetsk Regional Clinical Territorial Medical Union; Donetsk Ukraine; 3Department of Pulmonology, Donetsk Regional Clinical Territorial Medical Union, Donetsk, Ukraine

Objective: To study the effect of educational programs, training in asthma-school
P2850
The use of lambs chests in chest drain insertion simulation
Alasadair Nazeralli-Maitland1, Mitchell Goldenberg2, Nadim Iwaw2, 1Department of Internal Medicine, Queen’s University, Kingston, ON, Canada; 2Undergraduate Medicine, St. George’s University of London, London, United Kingdom

In an attempt to familiarize medical trainees with chest drain insertion, we sought to find a successful way of instructing students with its insertion technique. Students were given a thirty-minute lecture on chest anatomy, indications for insertion and then the insertion was demonstrated. Students were then taught the Seldinger (tube over guide-wire) technique and also the surgical drain (directly-visualized) insertion technique in a one-hour lab session. No direct comparison was made between other popular simulation mediums (such as plastic models or pork back ribs) nor were students subsequently directly observed inserting tubes on actual patients. The students were instructed then monitored and scored on successful insertion in the pleural space by an examiner informally. In discussion it was felt that the tactile feedback from the lamb’s carcasses demonstrated outstanding anatomical correlation and also demonstrated similar difficulties to human chest drain insertion. Both the anterior & mid-axillary lines were clearly visualized as well as the costal margins. There was also the opportunity to demonstrate administration of local anesthetic agents as well as one of the most common pitfalls of chest tube insertion: hitting the bone. The session was received very well with feedback revealing an appropriate amount of time spent on both instruction and demonstration. Lamb’s thoraces are a superb medium for simulation-based instruction of chest tube insertion. The use of an animal model has its benefits with respect to anatomical realism and the tactile realism of feeling actual muscle and bone. It likely provided a good stepping-stone between abstract classroom instruction and hospital patient insertion.

P2851
An assessment of physicians knowledge of the GINA guidelines
Victor Umoh1, Effiong Akpan2, Anthony Akula2, Danlaye Alasa2, John Ekoet1, 1Department of Internal Medicine, University of Uyo, Uyo, Akwa-Ibom State, Nigeria; 2Department of Internal Medicine, University of Calabar Teaching Hospital, Calabar, Cross River State, Nigeria

Introduction: The Global Strategy for Asthma Management and Prevention (GINA) is useful in the management of asthma patients. Aims:
To compare the knowledge about IT in patients (Pts) with asthma or COPD, who were treated before and one year after the education was given.
Methods: We hypothesized that many physicians who attend to asthma patients are not familiar with the components of the GINA guidelines.
Methods: Based on the GINA guidelines, a multiple choice questionnaire which addressed various components of the guidelines was distributed to physicians who attend to asthma patients.
Results: 54 Physicians were randomly selected from among 118 physicians from 2 Teaching Hospitals in Nigeria: 51 from Internal medicine, 20 from Family Medicine and 3 from Respiratory unit. There were 10 general internists, 2 medical officers, 28 junior residents, 11 senior residents and 3 consultants. 72.2% of the respondents did not attend any Continued Medical Education (CME) in asthma after graduation. Those of them who attended a CME post graduation scored higher than those who had not attended but this was not significant (39.7% Vs 31.2%). There was also an improvement in total performance with hierarchy but this was not statistically significant. Respiratory physicians scored significantly higher than the Internal medicine and the Family physicians (70.96% Vs 34.13% Vs 37.09%). The knowledge of pathological basis of asthma had the highest sub-score (50%) followed by diagnosis (48.7%) with asthma education having the least score (16.6%). Overall the average total score was poor (37.2%).
Conclusion: By identifying the areas of deficiency in each group of Doctors we can design education intervention programmes to improve the understanding of the GINA guidelines among physicians and ultimately the quality of care.

P2852
Patients’ knowledge about inhalation therapy in pulmonology – One year after intervention
Ljudmila Nagorni-Obradovic, Dragica Posut, Dejana Vukovic, Jovana Maskovic. Internal Medicine, School of Medicine University of Belgrade, Belgrade, Serbia Social Medicine, School of Medicine University of Belgrade, Belgrade, Serbia Intensive Care Unit, Teaching Hospital of Lung Diseases, Belgrade, Serbia

Background: Inhalation therapy (IT) is important in successful treatment in pulmonology.
Aim: To compare the knowledge about IT in patients (Pts) with asthma or COPD, before and one year after the education was given.
Method: In January 2010 and January 2011, we used anonymous self created six-questions questionnaire to interview the same group of 56 Pts who were treated with IT at University hospital (average age 56±12 years). We used McNemar test for statistical analysis.
Results: The number and proportion of Pts with correct technique or positive answers is shown in Table where p<0.01 = significant difference; NS = not significant.

Table 1 - Results

<td>38 (67.8)</td>
<td>NS</td>
</tr>
</tbody>
</table>

Conclusions: One year after education, the Pts significantly corrected their technique of using IT and their misconception about using IT only in severe degree of disease is decreased. Although improved, the knowledge related to the other items requires further patients’ education.

P2853
Audit of intervention to improve educational experience in a respiratory medicine department
Zoe Pond. Department of Respiratory Medicine, Queen Alexandra Hospital, Portsmouth, United Kingdom

Introduction: A continuing rise in service pressures and reduced working hours creates an ever increasing challenge in the provision of a good quality training experience for junior doctors. Objectives: The aims were to determine trainees’ perception of the education in their current post, provide opportunity for suggestions for improvement, make changes and then assess the effectiveness of changes made. Methods: All juniors within the department were asked to complete an anonymous questionnaire, covering educational aspects of their post, within the last few weeks of July 2010. This was repeated in November to assess the impact of changes made.
Results: Response rates of 87.5% (14/16) and 85% (17/20) were obtained with all grades represented. Training was rated fair to excellent. The most useful educational experience for the more junior doctors, in both audits, were on call duties where they were managing conditions they had not previously encountered. The more senior trainees found ward rounds most helpful. Areas for improvement identified in the first audit included enabling juniors to attend grade-specific teaching, increasing ward round teaching, and increasing opportunities for workplace based assessments. Following implementation of changes, 62.5% reported workplace based assessments gave useful feedback compared to 36% previously. Attendance at grade-specific teaching increased from 57% to 89% in more junior trainees. All grades commented on the usefulness of this teaching as it was targeted at their level. Conclusions: Surveying trainees regarding their educational experience is useful and can allow focussed intervention to improve areas of respiratory education.

P2854
Audit on pleural procedure in UK district general hospital
Amrithraj Bhatta, Imran Satia, Ram Sundar, Imran Aeziz. Respiratory Medicine, Royal Albert Edward Infirmary, Wigan, Lancashire, United Kingdom

Introduction: Intercostal Chest Drain (ICD) insertion is an invasive procedure indicated in certain emergency and elective scenarios. The practice is changing with more importance given to training, safety and use of ultrasound imaging guidance. Aims: The aim of this audit was to access current awareness & training level of junior doctors and level of practice. Methods and results: First part of audit includes questionnaire survey on awareness and competency of the 26 respondent, 61% were independently competent at ICD insertion, but only 9% of them performed more than 10 procedures in last one year. Only 23% of doctors had thoracic ultrasound training. In the second part, 38 consecutive cases were audited retrospectively (male = 76%, female = 24%) Pleural effusion (59%) and pneumothorax (31%) accounted for most of the indications. 38% of the procedures performed out of hours and all of them were justified. Only 68% had any form of consent documented. Majority (85%) were inserted by senior doctors (ST3+) level. Bedside Ultrasound was used in 80% of pleural effusion cases. The nursin drainage observation chart was maintained in 88% cases. 8% minor immediate complication reported, no death or organ damage directly related to the procedure. Discussion: This audit has demonstrated improving safety awareness that includes, most of procedure performed by trained doctors and use of bedside ultrasound. But it has highlighted lack of training at junior doctors level, including thoracic ultrasound. Following this audit we have introduced the safety check list and training programme for junior doctors including thoracic ultrasound technique.

High-fidelity in-situ simulation – A novel training modality for non-invasive ventilation

Introduction: Non-invasive ventilation (NIV) is an expanding treatment modality requiring staff experience and training to ensure clinical effectiveness. Non-specialist junior doctors and nurses often have infrequent exposure to NIV thereby limiting confidence. Patients requiring NIV are often critically unwell and effective crisis resource management (CRM) skills (e.g. communication, leadership, task delegation) are often critical in achieving patient compliance and formulating clear treatment plans. For these reasons, high-fidelity simulation provides an opportune training modality where trainees can practice in a safe “real” setting to increase self-confidence and develop key CRM skills.

Method: We designed an “in-situ” high-fidelity simulation-training module where trainees partake in pre-designed undisclosed scenarios leading a multidisciplinary team involving a nurse blind to the scenario and faculty “plants”. Scenarios are constructed to provide challenging clinical and ethical situations pushing trainees abilities to promote key skills at a registrar level. Candidates used a 6-point Likert Scale questionnaire to self-analyse their performance and learning post-simulation.

Results: Pilot results show trainees have found the module improves confidence in managing respiratory failure requiring NIV when added to a standard training programme. The module additionally develops trainee insight into their situational awareness as well as key communication, clinical decision-making, leadership and team-working skills enabling a structure for future focused improvement.

Conclusions: High-fidelity simulation can be used as an effective training tool as part of a comprehensive NIV training programme.

P2856
Continuing medical education: A contribution of the pneumologists in the pre-hospital medicine
Paolo Michele Olti, Alessandro Querci. Emergency Department, Emergency Ambulance Service A.L.S. 4, Prato, Italy.

Until now in Tuscany, the doctors of the Ambulance Service 118 originate from general practitioners after specific qualifying courses, usually directed by resuscitators. In 1999, in Italy, was activated the Continuing Medical Education (CME) and in 2002 the Tuscan Region acknowledged the provisions in the matter. As our ambulance patients present a considerable number of low oxyhemoglobin saturations (Olti et al., ERI 2003: 44, 381), formative events in respiratory diseases were carried out, involving specialists in respiratory medicine as teachers. The training is composed of a series of seminars, including the use of mechanical ventilators during ambulance transfers, alternative devices to intubation, CPAP and non invasive ventilation, oxygen therapy. Formative events were enrolled in 4 hours meetings. At the end of meetings, learning and approval tests were carried out, for acquire the CME credits. Participants had to replay correctly at least the 80% of the questions and to attend the lesson’s time. Moreover 2 short meetings of 2 hours each, were carried out and related to some aspects of respiratory fatigue and spontaneous pneumothorax. 382 hours of specialized formation, the 9% of all the formative hours dispensed from 2003 to 2010 by our Service, were delivered. 100% of the participants found interesting the treated topics; 98.9±1.9% found them useful in theory and the 98.3±6.9% in practice.

Besides the good results in CME credits, 1 point each hour, important concepts and techniques, from the point of view of the pneumologists were explained, showing a further vision of the respiratory emergencies and their management in the pre-hospital medicine.

320. COPD: mechanisms and biomarker

2931
Association of testosterone level with phenotypic characteristics and long-term outcomes of men with COPD in the ECLIPSE cohort

Introduction: The contribution of anti-elastin immunity in COPD is subject of intense debate. Conflicting data are reported on the presence of serum auto-antibodies against elastin fragments correlating with COPD severity. As auto-immunity is driven by antigen-specific T cells, we investigated the presence of B cell and T cell responses against elastin fragments in a large sample of COPD patients and controls.

Material and methods: Anti-elastin antibodies were analyzed using indirect ELISA on plasma samples of 352 COPD patients (GOLD I-4) and 168 age-matched smoking controls. In a random subset of 25 patients, T-cell responses against elastin fragments were further determined with ELISPOT (IFN-γ and IL-2) on peripheral blood mononuclear cells (PBMC) and compared with responses of 5 non-smoking age-matched controls.

Results: Increased titers of anti-elastin antibodies were found in 14.2% (24/168) of smoking controls compared to 12.5% (44/352) of the COPD population (p=0.07).

3923
Relation of health-related quality of life, frequent exacerbation phenotype and circulating systemic biomarkers in stable COPD
Daiana Stolz1,2, Francesco Blass1, Renaud Louis1,5, Wim Janssens3,4.

Introduction: Non-invasive ventilation (NIV) is an expanding treatment modality in managing respiratory failure requiring NIV when added to a standard training program. In an univariate analysis, age, sex, smoking status, chronic obstructive pulmonary disease severity, number of exacerbations, number of hospitalizations, and body mass index (BMI) were positively correlated with the proportion of time spent in NIV. In a multivariate model, the percentage of time spent in NIV was significantly associated with BMI and number of exacerbations. However, the percentage of time spent in NIV was not significantly associated with the proportion of time spent in the upper lobes or the lower lobes. This finding suggests that the distribution of NIV is more frequent among patients with higher BMI and lower BMI, respectively. Therefore, a randomized controlled trial (RCT) comparing the effects of NIV and conventional treatment in patients with COPD is warranted to further investigate these findings. In conclusion, NIV is a valuable treatment option for patients with COPD who experience respiratory failure, and the benefits of NIV can be optimized by selecting patients with higher BMI and lower BMI.
No significant correlation was found between anti-elastin antibodies and FEV1% predicted (p=0.699), nor with the presence of emphysema on CT scan (p=0.150). Despite significant responses to control antigen, ELISPOT analysis could not detect increased T cell responses against elastin in any of the individuals.

**Conclusion:** Anti-elastin antibodies are not specific for COPD patients and do not correlate with disease severity. The absence of elastin-specific T cell responses further weakens the role of anti-elastin auto-immunity in the pathogenesis of COPD.

Supported by FWO-Vlaanderen G.0867.09.

**Can brain MRI explain cognitive decline in COPD? A pilot study**

Rebecca A. Charlton1, James W. Dodd1, Martin van den Broek2, Franklyn A. Howe1, Thomas R. Barrick1, Paul W. Jones1. 1Clinical Sciences, St George’s University of London, London, United Kingdom; 2Department of Neurosciences, St George’s NHS Trust, London, United Kingdom

**Background:** Cognitive deficits have been described in patients with COPD. We used MRI to investigate brain structure in COPD patients with and without evidence of cognitive decline and in healthy control subjects.

**Methods:** Participants (n=27) completed a full cognitive assessment and MRI scan. Two groups of COPD patients were selected; those who demonstrated evidence of cognitive decline (COPD-D; n=9) or who did not (COPD-N; n=9). Age-matched healthy controls (HC; n=9) were studied. Volumes of grey matter (GMV), white matter (WMV), and white matter lesions were calculated. The presence of lesions in the brain stem (BSL) and external capsule (ECL) was noted.

**Results:** Groups did not differ on measures of GMV or WMV. LV was significantly greater in patients versus controls (t=3.47; p=0.002); there was no difference between LV in COPD-N and COPD-D (t=3.42; p=0.737). No significant group difference in the presence of BSL was observed (X2(df=3)=0.0; p=0.223), but ECL was numerically more frequent in the COPD-D group (X2(df=4)=5.64; p=0.060).

See Table 1.

<table>

</tbody>
</table>

**Conclusion:** COPD-D and COPD-N patients both have more white matter lesions than HC, possibly due to increased vascular risk. The significance of BSL and ECL requires further exploration. Future analysis will use methods that detect change in tissue microstructure, and associations between brain damage and cognition.

2937

**Iron deficiency in non-anemic patients with chronic obstructive pulmonary disease**

Matthias Urban1, Otto Chris Burghuber1, Wolfgang Hüb1, Georg-Christian Funk1. 1 Ludwig-Boltzmann Institute for COPD and Respiratory Epidemiology and Department for Respiratory and Critical Care Medicine, Otto Wagner Spital, Vienna, Austria; 2Department of Laboratory Medicine, Wilhelminenspital, Vienna, Austria

**Background:** Iron deficiency contributes to reduced exercise capacity in patients with heart failure. The repletion of iron improves cognitive, symptomatic, and exercise performance in these patients independent of hemoglobin. COPD shares many functional features of heart failure. Thus iron deficiency could be a potential therapeutic target in COPD.

**Aims and objectives:** The aim of this study was to determine the prevalence of iron deficiency in non-anemic patients with COPD.

**Methods:** Serum markers of iron status were measured in 53 stable non-anemic (hemoglobin>12 g/L) COPD patients (53% males; mean age 64±8 years, mean FEV1 predicted 41±18%; GOLD stage II, III, and IV was 34%, 32%, and 34%, respectively). Iron deficiency was diagnosed when the serum ferritin level was either <100 μg/l or was between 100 and 299 μg/l with the transferrin saturation <20%. Results: The serum ferritin level was <100 μg/l in 20 patients. The serum ferritin level was between 100 and 299 μg/l and transferrin saturation was <20% in 6 patients. Thus iron deficiency was present in 49% of the patients. The median soluble transferrin receptor to log_ferritin ratio was higher in patients with iron deficiency (1.7, 1.0 to 1.4) compared to patients without (1.7, 1.4 to 2.0), p=0.001.

**Conclusions:** Iron deficiency is present in half of the patients with stable COPD. A randomized, placebo-controlled trial should clarify whether repletion of iron stores improves functional performance in COPD patients with iron deficiency.
321. Barrier functions in sepsis and acute lung injury

2938 TNF-α-induced septic shock is attenuated in acid sphingomyelinase-deficient mice
Lucy Kathleen Reiss¹, Yang Yang¹, Dieter Adam², Stefan Uhlig¹. ¹Institute of Pharmacology and Toxicology, Medical Faculty of RWTH Aachen University, Aachen, Germany; ²Institute of Immunology, Christian-Albrechts University, Kiel, Germany

TNF-α plays a major role as mediator of acute inflammation and apoptosis. Surprisingly, little is known about the effects of high plasma levels of TNF-α on the lung. Previous studies revealed that TNF-α causes lethal depression of systemic circulation including hypotension. The aim of this study was to investigate the pulmonary effects of TNF-α in mechanically ventilated mice. Further, the role of caspases and acid sphingomyelinase (ASMase) was examined.

C57BL/6 wild type and ASMase-/- mice received TNF-α intravenously; in addition, half of the animals were treated with the caspase inhibitor zVAD-fmk. All mice were ventilated for 6h at V1=8mL/kg and f=180/min⁻¹ with FiO2=0.3 and PEEP=2cmH2O while lung functions were followed by the forced oscillation technique. In order to reduce mortality due to septic shock, saline was given via an arterial catheter and body temperature was stabilized at 37°C. Blood gases, lung histology, pro-inflammatory mediators and microvascular permeability were examined. Fluid support and stabilization of body temperature were sufficient to avoid lethal septic shock. Sepsis was indicated by high serum levels of pro-inflammatory mediators and metabolic acidosis. TNF-α decreased blood pressure and increased heart rate in wild type mice. ASMase-/- mice were protected from the cardiovascular effects, but caspase inhibition had no influence. Although high levels of TNF-α were detected in the lung, no severe pulmonary inflammation or alteration of lung functions was found. We conclude that septic shock caused by high circulating levels of TNF-α is partly mediated by ASMase. However, TNF-α alone is not sufficient to cause acute lung injury in ventilated mice.

2939 Pulmonary epithelial CCR3 promotes LPS-induced lung inflammation by mediating release of IL-8
Bo Li¹,², Chunting Dong³, Gufang Wang², Huira Zheng¹, Xiangdong Wang¹, Chunxue Bai¹. ¹Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China; ²Department of Human Anatomy, Norman Bethune College of Medicine, Jinlin University, Changchun, China; ³Lah. of Phys. Biol, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, Shanghai, China; ⁴Department of Respiratory Medicine, Second Hospital, Jinlin University, Changchun, China

Objectives: Interleukin (IL)-8 from pulmonary epithelial cells has been suggested to play an important role in the airway inflammation, although the mechanism remains unclear. We envisioned a possibility that pulmonary epithelial CCR3 could be involved in secretion and regulation of IL-8 and promote Lipopolysaccharide (LPS)-induced lung inflammation.

Methods: Human bronchial epithelial cell line NCI-H292 and alveolar type II epithelial cell line A549 were used to test role of CCR3 in production of IL-8 at cellular level. In vivo studies were performed on C57BL/6 mice instilled intratracheally with LPS in a model of acute lung injury (ALI). The activity of a CCR3-specific inhibitor (SB-328437) was measured in both in vitro and in vivo systems.

Results: We found that expressions of CCR3 on NCI-H292 and A549 cells were increased by 23% and 16%, respectively, 24 h after the challenge with LPS. LPS increased IL-8 productions in NCI-H292 and A549 cells, which were inhibited significantly by SB-328437. SB-328437 also diminished neutrophil recruitment in alveolar airspaces and improved LPS-induced ALI accompanied with reduction of IL-8 secretion in bronchoalveolar lavage fluid.

Conclusions: These results suggest that pulmonary epithelial CCR3 be involved in progression of LPS-induced lung inflammation by mediating release of IL-8. CCR3 in pulmonary epithelia may be an attractive target for development of therapies for ALI.

2940 Lipopolysaccharide attenuates endothelial barrier function through a pp60src mediated inhibition of dimethylaminohydrolase (DDAH)
Saurabh Aggarwal, Shrutti Sharma, Sanjiv Kumar, Stephen Black, Yali Hou.
Vascular Biology Center, George Health Sciences University, Augusta, GA, United States

Acute lung injury is a severe hypoxemic respiratory insufficiency associated with alterations in lung structure and function. Previously, we found that LPS increases the activity of the DDAH in the lung endothelium and that LPS attenuates the DDAH activity. We examined the pp60src mediated inhibition of DDAH activity in human lung microvascular endothelial cells (HLMVEC). In this study, we elucidated the mechanisms involved in the attenuation and prevention of DDAH2 by LPS. Utilizing an electric cell impedance sensing apparatus, we found that the overexpression of DDAH2 in human lung microvascular endothelial cells (HLMVEC) prevents the LPS (1 endotoxin unit/ml) induced decrease in transendothelial resistance. Further, we found that the overexpression of a dominant negative mutant of pp60src attenuated the LPS mediated decrease in DDAH activity and increased ADMA levels without altering expression of DDAH2 protein levels. Further, LPS increased the interaction between DDAH2 and pp60src and also increased its tyrosine phosphorylation. In the LPS treated mouse lung, we found that the decrease in DDAH activity correlated with an increase in LPS mediated interaction of DDAH2 and tyrosine phosphorylation of DDAH2. Finally, the overexpression of DDAH2 in mouse lung endothelial cells, using a polyethyleneimine (PEI) based transfection reagent, led to an increase in DDAH activity, a decrease in ADMA levels, and the attenuation of the LPS mediated increase in the lung leak as measured by extravasation of Evans blue dye. The prevention of DDAH activity in the lung endothelium may provide new insights for the prevention of LPS induced ALI.

2941 Role of ADAM17 in endotoxin-induced pulmonary inflammation
Daniela Dreymuller¹,², Christian Martin², Tanja Kogel¹, Franz Martin Hess¹, Carl P. Blobe¹,³, Keesuke Honna³, Stefan Uhlig¹, Andreas Ludwig¹. ¹Interdisciplinary Center for Clinical Research, RWTH Aachen University Hospital, Aachen, Germany; ²Institute of Pharmacology and Toxicology, RWTH Aachen University Hospital, Aachen, Germany; ³Division of Pulmonary Medicine, Department of Medicine, Keio University School of Medicine, Tokyo, Japan; ⁴Arthritis and Tissue Degeneration Program, Hospital for Special Surgery, Weill Medical College of Cornell University, New York, United States

Acute lung injury is associated with enhanced vascular permeability and leukocyte recruitment. Several proinflammatory, soluble and surface-expressed mediators, including TNFα, TNFR1/2, amphiregulin, IL-6R, IL-1R, L-selectin, CXCL11, and JAMs may become released by the activity of the metalloproteinases ADAM10 and ADAM17. We examined the role of these proteases in vascular permeability and leukocyte transmigration in vitro by pharmacological inhibition and lentiviral-mediated siRNA knockdown of ADAM10 and ADAM17. In vivo role of these proteases was studied in a murine model of LPS-induced lung injury by pharmacological inhibition. The relevance of ADAM17 was further analyzed by knockdown of ADAM17 in endothelial or smooth muscle cells. The BAL protein levels and the wet/dry-ratio served as markers of vascular permeability and edema formation. Cell recruitment to the alveolar space and lung tissue was analyzed by flow cytometry; cytokines were determined by ELISA. In vitro, transmigration of neutrophils to IL-8 through pulmonary endothelial cells was reduced by pharmacological inhibition as well as knockdown of ADAM10 or ADAM17. LPS-mediated inhibition of permeability was reduced by pharmacological inhibition, but not by ADAM10 knockdown, indicating a predominant role of ADAM17 in the regulation of endothelial permeability. In vivo, LPS challenge increased the wet/dry-ratio as well as the BAL levels of protein, TNFA, IL-6 and leukocytes. All these effects were largely prevented by inhibitor application or by knockdown of ADAM17 in smooth muscle or endothelial cells. These results indicate that local ADAM17 is involved in the onset of inflammation and tissue injury during endotoxin-induced lung inflammation.
We have previously reported that NADPH oxidase 1 (NOX1) deficiency prevented hyperoxia-induced acute lung injury in mice and played an essential role in cell death of mouse alveolar epithelial cells (Carnesecchi, S. et al., AJCCM, 2009; 180: 972-981). In order to determine the mechanisms by which NOX1 induces epithelial cell death during hyperoxia, we specifically knocked-down NOX1 in a pulmonary epithelial cell line (MLE-12) using a lentiviral vector strategy. Our results show that NOX1 mRNA was reduced by 35% after hyperoxia compared to scramble sRNA (control cells). Hyperoxia-induced ROS production was inhibited by 36% in transfected MLE-12 compared to control cells. In addition, we demonstrated that NOX1 deletion leads to less hyperoxia-induced cell death and lyzed by lactate dehydrogenase release, TUNEL staining and decreased cleaved caspase 3. Hyperoxia-induced ERK phosphorylation, a MAPK involved in cell death signaling was inhibited in NOX1-transfected cells. These data show that NOX1 inhibition decreases hyperoxia-induced ROS production and cell death in an epithelial cell line through ERK signaling pathways. Furthermore, to determine whether NOX1 is also involved in human, we studied NOX1 expression in lungs of ARDS patients by using immunostaining. We found that NOX1 was highly expressed in alveolar type II cells of patients suffering from ARDS in particularly in the exudative and organizing stages of the disease. This study is the first direct demonstration that NOX1 is of crucial importance in ARDS and might be responsible for the damage occurring in epithelial type II cells.

2943
Conditioned medium from human mesenchymal stem cells restores both amiloride-sensitive sodium transport and epithelial permeability to protein across alveolar epithelial cell monolayers in an in vitro model of alveolar injury

Arnaud Goolaerts1, Nadia Randrianarison2, Jérôme Larghero1,2,3
1Unité 773, INSERM, Paris, France; 2Physiologie, Université Paris Diderot, Paris, France; 3Assistance Publique des Hôpitaux de Paris, APHP F-75010, Paris 13, Paris, France; 4Assistance Publique des Hôpitaux de Paris, APHP F-93000, Bobigny, France; 5Assistance Publique des Hôpitaux de Paris, APHP F-75018, Paris, France

Patients with acute lung injury (ALI) have a decreased capacity to reabsorb alveolar edema. Alveolar fluid clearance results from the electro-osmotic gradient created by active sodium (Na+) transport across alveolar epithelium. In various models of ALI MSCs reduce pulmonary edema and increase survival in mice, but in some studies, MSC conditioned medium (MSC-CM) was as effective as MSCs themselves. However, the mechanisms of MSC-CM beneficial effects remain unclear. Thus, in this study our objective was to test the effects of the human MSC-CM on ventialtional transport and epithelial permeability in injured alveolar epithelial cells (AEC). After 18 h of exposure to both hypoxia (3% O2) and 25 mg/ml corin (IL-1β), TNFα and INFγ (CYTHX4), there was an increase in epithelial permeability measured by radio-labeled albumin over 12 h (1.61±0.40 vs 4.7±2.3, p<0.05) and a marked decrease in transepithelial Na transport (4.2±0.3 vs 1.7±0.4 µA/cm², p<0.05). After permeabilization of the basolateral or apical membrane, we showed no change in Na-K-ATPase activity. We then tested the effect of MSC-CM and found that AEC that were exposed to CYT-HX in the presence of MSC-CM (i) completely prevented CYT-HX-induced increase in protein permeability; (ii) restored the amiloride-sensitive ISc, and (iii) increased Na,K-ATPase activity.

2944
Epigenetic regulation of alveolar ion transport

Łukasz Wujak, Simone Becker, Werner Seeger, RORY MORTY. Lung Development and Remodelling. Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany

The Na-K-ATPase regulates alveolar ion transport and fluid balance in the lung, generating the driving force for alveolar fluid clearance (AFC). Transforming growth factor (TGF-β) is a mediator of acute lung injury (ALI), and impacts AFC. It was hypothesised that TGF-β influences Na-K-ATPase function by controlling subunit expression and stoichiometry. The ATP1B1 subunit of the Na-K-ATPase regulates cell-surface stability of the heteromeric Na,K-ATPase complex. Quantitative RT-PCR analysis revealed downregulation of the ATP1B1 gene both in the lungs from ALI patients (4-fold; p<0.05) and lungs from bleomycin-treated mice which developed ALI (2.1-fold; p<0.002). We tested the effect of MSC-CM and found that AEC that were exposed to CYT-HX in the presence of MSC-CM (i) completely prevented CYT-HX-induced increase in protein permeability; (ii) restored the amiloride-sensitive ISc, and (iii) increased Na,K-ATPase activity.

Antitumor activity of MEK and PI3K inhibitors in malignant pleural mesothelioma

Seigo Miyoshi1, Hironobu Hamada2, Naohiko Hamaguchi1, Hitoshi Katayama1, Kazunori Irimura1, Ryoji Ito1, Tatsumiko Miyazaki3, Jitso H egaki1. 1Department of Integrated Medicine and Clinical Sciences, University of Medicine, Toeh, Japan; 2Department of Health and Sports Medical Sciences, Graduate School of Health Sciences, Hiroshima University, Hiroshima, Japan; 3Department of Pathogenomics, University Graduate School of Medicine, Toeh, Japan

Background: Malignant pleural mesothelioma (MPM) is an aggressive malignancy, and there is no accepted standard therapy for this disease. Objective: We investigated the role of mitogen-activated protein kinase kinase (MEK) inhibitor and phosphatidylinositol 3-kinase (PI3K) inhibitor as targeted therapies for MPM. Method: We examined the therapeutic efficacy of the MEK or PI3K inhibitor against human MPM cell line EHMES-10 both in vitro and orthotopically inoculated into severe combined immunodeficient (SCID) mice. In addition, the molecular mechanisms of these agents were confirmed in vitro and in vivo experiments. Results: MEK or PI3K inhibitor suppressed the growth of MPM model in dose dependent manner both in vitro and in vivo studies. In addition, combining MEK inhibitor with PI3K inhibitor resulted in an additive growth inhibitory effect. EHMES-10 cells showed increasing the G1 cell cycle arrest and apoptosis by treatment of MEK or PI3K inhibitor in vitro. Western blot analysis in vitro and in vivo study showed increasing the p29βH1 and cleaved PARP expression and decreasing the Cyclin E, CyclinD1 and procaspase 3 expressions. In addition, these agents decreased the expression of hypoxia-inducible factor 1α and vascular endothelial growth factor, which play an essential role in tumor angiogenesis and progression. Conclusion: Our results suggest that MEK or PI3K inhibitor is a promising therapeutic strategy, and also provide a basis for useful combination of MEK and PI3K inhibitors in patients with MPM.

2947
mTOR inhibition blocks tumor growth and pleural fluid accumulation in experimental murine mesothelioma

Marianela Vazakidou1, Sophia Magouta1, Charis Moschos1, Magda Stratiki2, Charis Roussos2, Ioannis Kalomenidis1. 12nd Department of Pulmonary Medicine, Athens University School of Medicine, Athens, Greece; 21st Department of Critical Care and Pulmonary Services, Athens University School of Medicine, Athens, Greece

mTOR is up-regulated in malignant mesothelioma. We aimed to evaluate the effect of Temsirolimus, an mTOR inhibitor, in vivo models of the disease. AE17 and AB1 murine mesothelioma cells were injected into the right flank of syngeneic mice (C57BL6 and BALB-c, respectively) to create subtractaneous tumors. C57BL/6 mice were injected intraperitoneally with AE17 cells to create pleural tumors and effusions. Animals were treated with Temsirolimus (20mg/kg) or vehicle, 5 days/week starting when tumors become palpable (flank model) or on days 8-12 of pleural tumors and effusions. Animals were treated with Temsirolimus (20mg/kg) or vehicle, 5 days/week starting when tumors become palpable (flank model) or on days 8-12 of pleural tumors and effusions. Among mice with AE17 flank tumors, the mean ±SEM tumor volume at day 26 was 1261±383mm³ in control and 383±86mm³ in treated animals (p<0.001). Among mice with AE17 flank tumors, the mean ±SEM tumor volume at day 26 was 1261±383mm³ in control and 383±86mm³ in treated animals (p<0.001). In the AB1 flank model, tumor volume was 1197±253mm³ in control and 174±76mm³ in treated animals (p=0.026). Among mice with pleural AE17 tumors, the mean ±SEM pleural fluid volume at day 15 was 532±19mmicroL, in control and 240±43microL, in treated animals (p=0.018). The mean ±SEM pleural tumor weight was 739±72mg in control
2948 Epigenetic deregulated translation control of C/EBP-alpha leads to increased mesothelioma cell proliferation
Jun Zhong1, Nicola Miglino1, Michael Tammi1, Didier Lardinois2, Lukas Bubenrost1, John Szilard1, Michael Roth1, 1Pulmonary Cell Research & Pneumology, Dept Research and Internal Medicine, University Hospital Basel, Basel, Switzerland; 2Thoracic Surgery, University Hospital Basel, Basel, Switzerland; 3Dept. Pathology, University Hospital Basel, Basel, Switzerland; 4The Woolcock Institute of Medical Research, University of Sydney, Sydney, NSW, Australia

Malignant pleural mesothelioma (MM) resists all available anticancer therapies. A major pathology of MM is the uncontrolled cell proliferation and the fast local spreading with rare metastasis. Therefore the inhibition of proliferation is a major therapeutic target. Proliferation of MM cells was linked to mitogen activated protein kinase (MAPK) activity. In this study we characterised the regulation of MAPK regulated CAA/ET/ENHancer binding proteins (C/EBP) and their role in MM cell proliferation. In five human MM cell lines, cytotoxic and nuclear protein expression was determined by immuno-blotting and immuno-chemistry in tissue sections. Transcription of C/EBPβ was downregulated by real time PCR and translation by a translation reporter assay. We observed a cell compartment specific expression pattern of p38-α, -β and -γ and MAPK in MM cells. Erk1/2 and p38 MAPK together up-regulated the expression of C/EBP-β and -γ, while C/EBP-α was not expressed. Compared to mesothelial cells C/EBP-α translation was reduced in MM, while the mRNA was constitutively expressed. MM cells expressed a relative high level of the C/EBP-α translation suppressor calreticulin, while eIF4E was not significantly modified. Cell proliferation was inhibited by either the blockade of Erk/2, or p38-γ and -α MAPK, or C/EBP-β. Transfection with a C/EBP-α vector reduced proliferation and increased the MM cell’s sensitivity to steroids. Our data implies that in human MM cells an epigenetic mechanism deregulates the translation control of the cell differentiation factor C/EBP-α which leads to increased proliferation and drug resistance.

2949 The regulatory effect of microRNAs on STAT signaling in malignant mesothelioma
Lisa Arzt1, Hannelore Kothmaier1, Franz Quehenberger2, Iris Hallwedd1, Helmut H. Popper1. 

Background: A major pathology of malignant pleural mesothelioma (MPM) is the uncontrolled cell proliferation and the fast local spreading with rare metastasis. Therefore the inhibition of proliferation is a major therapeutic target. Proliferation of MM cells was linked to mitogen activated protein kinase (MAPK) activity. In this study we characterised the regulation of MAPK regulated CAA/ET/ENHancer binding proteins (C/EBP) and their role in MM cell proliferation. In five human MM cell lines, cytotoxic and nuclear protein expression was determined by immuno-blotting and immuno-chemistry in tissue sections. Transcription of C/EBPβ was downregulated by real time PCR and translation by a translation reporter assay. We observed a cell compartment specific expression pattern of p38-α, -β and -γ and MAPK in MM cells. Erk1/2 and p38 MAPK together up-regulated the expression of C/EBP-β and -γ, while C/EBP-α was not expressed. Compared to mesothelial cells C/EBP-α translation was reduced in MM, while the mRNA was constitutively expressed. MM cells expressed a relative high level of the C/EBP-α translation suppressor calreticulin, while eIF4E was not significantly modified. Cell proliferation was inhibited by either the blockade of Erk/2, or p38-γ and -α MAPK, or C/EBP-β. Transfection with a C/EBP-α vector reduced proliferation and increased the MM cell’s sensitivity to steroids. Our data implies that in human MM cells an epigenetic mechanism deregulates the translation control of the cell differentiation factor C/EBP-α which leads to increased proliferation and drug resistance.

2950 Epithelial-to-mesenchymal transition in malignant mesothelioma
Alicia Diaz-Baquero1, Beatriz Romero Romero 1, Lourdes Gomez-Izquierdo2, Rainiero Avila Polo1, Jose Martin-Juan1, Francisco Rodriguez-Panadero1, 1U.M.E. Hospital de Reina Sofia, H.U.U. Virgen del Rocío, Sevilla, Spain; 2UGC Intermunicipial de Anatomia Patológica, H.U.U. Virgen del Rocío, Sevilla, Spain; 3Instituto de Biomedicina (Ibiis), H.U.U. Virgen del Rocío, Sevilla, Spain

Epithelial-to-mesenchymal transition EMT is a molecular-cellular process actiuated during embryonic development and tissue remodelling, by which epithelial cells lose their polarity and cell contacts, acquire the expression of mesenchymal markers and manifest a migratory phenotype. The progressive loss of E-cadherin is coupled with expression of non-epithelial cadherins, process known as “cadherin switching”. As tumours often mimic embryonic development, it has been postulated that EMT represents a transient event in carcinomas progression. Malignant Mesothelioma MM could represent an EMT in vivo model, because tumor cells can exhibit epithelial, sarcomatous and biphasic differentiation. Forty five patients with MM were investigated by immunohistochemical expression of cadherins E-cadherin, β-catenin, SPARC and vimentin in two tissue microarrays. Protein expression was scored from 0 to 3 in tumour and stroma. Data were correlated with histologic patterns, thorascopic findings and survival. E-P cadherins expression was observed in 79,3% of epithelial MM without evidence in mesenchymal component of mixed and sarcomatous types. N-1 cadherins were detected in 20,6%, 29,4% and 17,6% of these histotypes, respectively. The mesenchymal markers were detected in 100% of sarcomatous and mixed MM and in a many samples of epithelial group. Immunohistochemical expression of mesothelial marker E-cadherin was detected in samples in 20,6%, 29,4% and 17,6% of mesothelial samples. The mesothelial marker expressed in 100% of sarcomatous MM and in 52,3% of treated MM. There were 30 men and 14 women. The median age was 58 years (range, 34-76). Most patients had a PS ≤ 1 (82%) and an epithelial histologic subtype (91%). The median time to progression (TTP) after first line chemotherapy was 6,1 months. The SLC was achieved in 21 patients (with a relapse more than 3 months), and a new regime in 20 patients (gemcitabine alone or with oxaliplatin). The other 3 patients were enrolled in a phase I study. According to RECIST criteria, a partial response was observed in 7 patients and 9 patients had stable disease after SLC. The median TTP after SLC was 3,8 months. The median survival was 12,2 months (range: 2 to 72 months). Four of these 44 patients then received third-line (4,8%) and two received fourth-line therapy (2,4%). Conclusions: Our experience suggests the feasibility of giving SLC to patients with MPM who are healthy at the time of disease progression. The optimal treatment has not been defined to date and prospective trials are needed in this setting.

2952 Multimodality treatment of malignant pleural mesothelioma
Guntulu Ak1, Muzaffer Metintas 1, Huseyin Yildirim1, Hasan Batirel2, Cemile Aydiner3, Furkan Candemir4, Cemil Metintas5, Emin Kizilak4, 1Department of Thoracic Surgery, Marmara University Medical Faculty, Istanbul, Turkey; 2Department of Thoracic Surgery, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; 3Department of Thoracic Surgery, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; 4Department of Pathology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; 5Department of Pathology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey

There is no widely accepted standard of care for patients with malignant pleural mesothelioma (MPM). Multimodality treatment protocol should be the standard approach in suitable patients and performed as a part of a trial: Biopsy proven MPM of non-sarcomatoid cell type, T1-3, N0-1, M0, patient fit for extrapleural pneumonectomy (EPP), neo-/adjuvant chemotherapy, and radical hemithoracic irradiation. In this study we evaluated the outcome of our patients with MPM who were treated by multimodality schedule including EPP, radical hemithoracic irradiation, and cisplatin-pemetrexed/gemcitabine chemotherapy regime. A total of 29 patients who consecutively underwent multimodality treatment schedule, 15 men, 14 women, were included. Of the patients 24 had epithelial cell type, 5 were mixed. 12 patients had stage 1 disease, 6 had II, 10 had III, 1 had IV (after surgery). Perioperative mortality (in 1 month) was 14% (4/28), mortality during multimodal therapy schedule was 18% (5/28). Patients completed multimodal Schedule were 19 (68%). Of the 19 patients completed multi-modality treatment, 11 died, 8 are alive.
For all patients, 28 cases, median survival was 19 months. For 19 cases completed multimodality treatment schedule, MS was 41 months. For the 12 patients who were on the second line treatment, median survival was 7 months. For 5 patients who were on the third line treatment, median survival was 7 months. For 2 patients who were on the fourth line treatment, median survival was 7 months. In total, 12 patients completed multimodality treatment schedule, median survival was 43 months. For the remaining 22 patients who did not complete the multimodality treatment schedule, median survival was 7 months. In total, 24 patients died during the follow-up period. The median survival for selected cases was 43 months. The ten-year trend in the prevalence of chronic cough and phlegm among young adults in Italy

The presence of chronic cough and phlegm (on most days for a minimum of 3 months a year and for at least 2 successive years) identifies a subgroup of subjects with a high risk of developing COPD, independently of smoking habits. We sought to evaluate the ten-year trend in the prevalence of these symptoms among young adults in Italy in 1998/2000, a screening questionnaire was mailed up to 3 times to general population samples of 20-44 year-old subjects, and eventually given over the phone to the remaining non-responders, in the Italian Study on Asthma in Young Adults (ISAYA) (9 centres; response rate = 72.7%). The same procedure was repeated in the Gene Environment Interactions in Respiratory Diseases (GEIRD) study in 2007/2010 (7 centres; response rate = 57.2%).

In 4 centres (Pavia, Sassari, Turin, Verona) involved in both the studies, the adjusted percentage* of chronic smokers has decreased (from 34.3% to 27.4%; p<0.001) during the past decade. The adjusted prevalence* of chronic cough and phlegm (with the 95%CI) is reported in this table:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-smokers</td>
<td>75% (71.7-79)</td>
<td>91% (82.10-10)</td>
<td>0.01</td>
</tr>
<tr>
<td>Past smokers</td>
<td>11.2% (10.6-11.9)</td>
<td>10.4% (9.9-10.9)</td>
<td>0.11</td>
</tr>
<tr>
<td>Current smokers</td>
<td>19.3% (18.4-20.2)</td>
<td>21.2% (18.4-23.4)</td>
<td>0.32</td>
</tr>
<tr>
<td>Total</td>
<td>12.4% (11.9-12.8)</td>
<td>12.6% (11.5-13.9)</td>
<td>0.74</td>
</tr>
</tbody>
</table>

*Adjusted for centre, type of contact (telephone vs mail), cumulative response rate, season of response, sex, age.

The overall prevalence of chronic cough and phlegm has not changed during the past decade among young adults in Italy, but a decrease is expected due to the observed reduction in the percentage of current smokers. The increase in the prevalence among non-smokers deserves further investigation.
Costs of COPD by disease severity
Sven-Åke Janson1, Helena Backman1, Anna Stenling2, Anne Lindberg1,2, Eva Ronnmark2,3, Bo Lundback1,4,1 The OLIN Studies, Norrbotten County Council, Luleå, Sweden; 2AstraZeneca Nordic, AstraZeneca Nordic, Södertälje, Sweden; 3Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 4Department of Internal Medicine/Respiratory Medicine and Allergology, University of Gothenburg, Gothenburg, Sweden

Background: Chronic obstructive pulmonary disease (COPD) is one of the most common chronic and disabling diseases worldwide, and the societal costs are high.

Aim: To estimate the societal costs of COPD in Sweden and to examine the relationship between disease severity and costs.

Methods: The study sample was identified in earlier clinical examinations of general population cohorts within the OLIN (Obstructive Lung Disease in Northern Sweden) studies. The cohort consisted initially of 993 subjects fulfilling COPD spirometric criteria (GOLD). In 2009-2010, telephone interviews on resource utilization were made to a sample of 244 subjects, stratified by disease severity. Interviews were performed quarterly to minimize the risk of recall bias. A non-parametric Mann-Whitney U-test was used to test cost differences between groups; p-values adjusted by Bonferroni correction. Unit costs from 2010 were applied.

Results: A highly significant relationship was found between disease severity and costs. The mean annual total cost per patient in relation to disease severity (GOLD) was: stage I 4,811; II 5,665, III 7,068; and IV 20,665. Direct costs were higher than direct costs in all severity stages. For direct costs, main cost drivers were hospitalizations in stage III and IV, and drugs in stage I and II respectively. The main cost driver in indirect costs was productivity loss due to early retirement, except in stage I where the driver was sick-leave. In comparison with a similar study performed in 1999 a numerical increase in mean annual total costs per patient was observed (ns).

Conclusions: The results indicate that the societal costs of COPD in Sweden are substantial, and the costs increase considerably by disease severity.

2958
Associations between quantitative computed tomography (qCT) measures of emphysema and mortality
Anne Johannessen1, Trude Duvelien Skorge2, Thomas Blix Grydeland3,4,1, Trude Duelien Skorge2, Thomas Blix Grydeland3,4,1, Santiago Carrizo5, Maria Sanchez-Carpintero1, Javier Zulueta1,2,3,4,5,6,7,6,8,9,10,11, 1Pulmonary Medicine, Hospital Miguel Servet, Zaragoza, Spain; 2Pulmonary Medicine, Hospital Nuestra Senora de la Candelaria, Tenerife, Spain; 3Pulmonary and Critical Care, St. Elizabeth’s Medical Center, Boston, MA, United States; 4Department of Internal Medicine/Respiratory Medicine and Allergology, University of Gothenburg, Gothenburg, Sweden; 5Department of Radiology, University of British Columbia, Vancouver, Canada; 6James Hogg iCAPTURE Centre for Cardiovascular and Pulmonary Research, Vancouver General Hospital, Vancouver, Canada

Background: Knowledge is limited regarding associations between qCT measures of emphysema and mortality.

Aims: To examine 6-year mortality (all-cause and chronic lower airway diseases (ICD-10 codes J40-47) in relation to qCT measures of emphysema.

Methods: In the Norwegian GenKOLS study 2003-05, 947 ever-smokers (49% with COPD) aged 40-85 years performed spirometry and qCT examination. Lung inflation level was obtained by dividing CT measured lung volume by predicted TLC. CT emphysema was estimated using % of lung voxels with X-ray attenuation values less than -950 Hounsfield units (% low-attenuation areas (LAA)), expressed as %LAA quintile. Mortality data from 2003-09 were gathered from the Norwegian Cause of Death Registry. Gender-stratified Cox proportional hazards were modelled, adjusting for FEV1, COPD status, age, BMI, smoking, inflation level.

Results: Both all-cause (n=106) and chronic lower airway diseases mortality (n=31) increased with %LAA: from 3% and 0.5% in the lowest quintile to 32% and 9.6% in the highest quintile respectively. The main cost driver in indirect costs was productivity loss due to early retirement, except in stage I where the driver was sick-leave. In comparison with a similar study performed in 1999 a numerical increase in mean annual total costs per patient was observed (ns).

Conclusions: The results indicate that the societal costs of COPD in Sweden are substantial, and the costs increase considerably by disease severity.

2959
Impact of comorbidities on survival of patients with COPD according to GOLD stages
Zagazeta Jorge1, Cabrera Carlos2, Divo Miguel2, Cote Claudia2, Juan De Torres1, Josue Maria1, Ciro Casanova1, Victor Pinto-Plata1, Santiago Carriazo1, Maria Sanchez-Carpintero1, Javier Zulueta1,2,3,4,5,6,7,6,8,9,10,11, 1Pulmonary Medicine, Clinica Universidad de Navarra, Pamplona, Navarra, Spain; 2Pulmonary Medicine, Hospital Universitario Don Gran Canaria Dr. Negrín, Las Palmas de G.C., Canarias, Spain; 3Pulmonary and Critical Care, Brigham and Women’s Hospital, Boston, MA, United States; 4Pulmonary and Critical Care, Bay Pines Veterans Affairs Medical Center, Bay Pines, FL, United States; 5Pulmonary Medicine, Hospital Miguel Servet, Zaragoza, Spain; 6Pulmonary Medicine, Hospital Nuestra Senora de la Candelaria, Tenerife, Spain

Introduction: In COPD patients the impact of comorbidities on patient’s outcomes is gaining interest. The aim of our study is to describe the role of comorbidities on mortality according to COPD GOLD stages.

Methods: We enrolled and followed 1664 patients from the BODE cohort over 10 years in five tertiary centers in the USA and Spain. Demographics, anthropometrics, physiological, comorbidities and survival with cause of death were recorded systematically. Patients were grouped according to GOLD stages I-II, III and IV. Tukey’s test was used to compare means among groups. A multivariate analysis was used to select those comorbidities associated with mortality. The effect of comorbidities over survival time was explored using Cox proportional hazard.

Results: Groups characteristics and differences are shown in Table 1. GOLD IV subjects were significantly younger, had fewer comorbidities and higher mortality. Furthermore comorbidities did not influence mortality in these subject and they died mainly from COPD (Table 2 and 3).

2960
Glitazones are associated with reduced risk of COPD exacerbations and mortality among patients with diabetes
David Au1,2, Thomas O’Riordan1,2, Chuan-Fen Liu1,4, Mark Perkins1,2, John Toole2, Christopher Bryson1,3,1 Health Services Research and Development, VA Puget Sound Health Care System, Seattle, WA, United States; 2Department of Respiratory Clinical Research, Gilead Sciences, Seattle, WA, United States; 3Department of Medicine, University of Washington, Seattle, WA, United States; 4Health Services Research, University of Washington, Seattle, WA, United States

Introduction: Moderators of systemic inflammation may reduce risk of exacerbations among patients with COPD. Glitazones, used in the treatment of diabetes, also have anti-inflammatory properties. We sought to assess whether glitazones were associated with a decreased risk of COPD exacerbations and mortality.

Study design: We performed a cohort study between 10/2005-09/2006 of all US veterans who received an oral antihyperglycemic medication (sulfonylureas, biguanides, or glitazones) on more than one occasion. Our outcome measures included outpatient COPD exacerbations, hospitalization for COPD, and all cause mortality. Our primary exposure was glitazone use compared to sulfonylureas and/or biguanides. We used GEE to estimate the effect of glitazones and to adjust for potential confounding factors.

Results: We identified 600,366 patients. Adjustment for age, sociodemographic characteristics, comorbidity, and markers of COPD severity had minimal effects on the point estimates. In comparison to either a sulfonylurea or biguanide, glitazones were associated with a significantly reduced risk of outpatient COPD exacerbation (Adjusted relative likelihood (Adj-RL), 95%CI: 0.82 (0.69-0.97)) and all cause mortality. Our primary exposure was glitazone use compared to sulfonylureas and/or biguanides.

Conclusion: Glitazones were associated with a significant reduction in COPD exacerbations and all cause mortality. We hypothesize that this association may be mediated through the anti-inflammatory properties of glitazones.
324. Comorbidities and management in primary care

2961 Association of comorbidity and mortality in COPD
Bjorn Stallberg1, Karin Lisspers2, Scott Montgomery3, Josefuh Sand3, 
Christine Janson1, 1Department of Public Health and Caring Sciences, Family 
Medicine and Clinical Epidemiology, Uppsala University, Uppsala, Sweden; 
2School of Health and Medical Sciences, Orebro University, Orebro, Sweden; 
3Department of Respiratory Medicine, Orebro University Hospital, Orebro, Sweden; 
4Department of Medical Sciences, Respiratory Medicine & Allergology, 
Uppsala University, Uppsala, Sweden

Introduction: The aim of this study was to investigate the association of comor- 
bdity and mortality in patients with COPD and those with all cause mortality.

Methods: A total of 1548 patients with a diagnosis of COPD were randomly 
selected from 56 primary care and 14 secondary care centres in Sweden. The 
response rate was 75%. Information was collected using questionnaires in 2005 
and record review for the period of 2000-2003. The Swedish Board of Health and 
Welfare provided mortality data. Lung function and history of comorbidities were 
obtained from the patients’ records. This analyses included patients with available 
spirometric data. Cox’s proportional hazards model was used to estimate the hazard 
ratio.

Results: A total of 552 patients (aged 34-75) were included in the study, 43% 
men (mean age 65) and 57% women (mean age 62). Of all, 27% were current 
smokers and mean FEV1 (percent of predicted) was 58. Over five years, in to- 
tal 120 patients (22%) died, 13% in primary care and 33% in secondary care. 
Mortality was significantly higher in patients with ischemic heart disease/cardiac 
hospitalization, with hazard ratio 1.91 (95%CI 1.30-2.80), with hypertension, hazard ratio 1.83 (95%CI 1.22-2.75) and with underweight (BMI <20), hazard ratio 1.74 (95%CI 1.12-2.70) after adjustments for age, sex, smoking, education, level of care and lung function. There was no significant difference in mortality for patients with 
diabetes or depression.

Conclusion: Heart disease, hypertension and underweight were in study associated 
with higher mortality in COPD patients.

2962 Do patients suffering from heart failure (HF) and chronic obstructive 
pulmonary disease (COPD) tolerate beta blocker (BB) treatment?
Teresa Gil1, Carmen Medina1, Leticia Fernández1, Francisco Javier Martínez1, 
Anthony Jennings1, Juan Raurà Siles1, Francisco Ruiz2, 1Cardiología, Hospital 
Costa del Sol, Marbella, Málaga, Spain; 2Cardiología, Hospital Hospitopend, 
Estepona, Málaga, Spain

Justification and objectives: In clinical practice the use of BB in patients with 
COPD is frequently avoided due to the risk of their inducing bronchospasm. 
Nevertheless, cardioselective BB use under strict monitoring may be well tolerated 
by and beneficial for many patients with HF and COPD.

Methods: We analyzed our experience with patients suffering from both HF and 
COPD who were given outpatient BB treatment. Those suffering from severe 
COPD were excluded.

Results: The group to be treated was made of 43 patients aged 63 ± 8 with an aver- 
age fraction ejection of 29, 2±6%, 60% of them of ischemic heart disease etiology. 
Patients were separated in two groups: Group A, patients with airways obstruc- 
tion and significant reversibility after bronchodilator test (FEV1 < 80% predicted) and 
FEV1/FVC <0.7. Group B patients with confirmed fixed airways obstruction mild or moderate 
(FEV1 75.4±3.75%, FEV1/FVC 0.60±0.51). All patients started treatment with 
BB in low doses, which were gradually increased up to maximum tolerated ones, 
no acute episodes of respiratory failure being shown in a 11 ±3 months follow- 
care period. The BB dosage had to be limited before reaching optimal levels in 
just 5 patients due to worsening dyspnea. According to NYHA classification, 
their functional status improved after the use of these drugs (p <0.01).

Conclusion: The use of BB under specialized cardiologist monitoring can be 
beneficial for patients suffering from both HF and mild-moderate COPD. The 
consequences of depriving patients of this treatment could be more harmful than 
the possible respiratory complications that might set in after its administration.

2963 Dysfunctional breathing in asthma patients
Svetlana Chikina, Natalya Daragan, Alexander Chuchalin. Functional 
Department, Research Institute of Pulmonology, Moscow, Russian Federation

Dysfunctional breathing (DB) coexisting with BA presents difficulties for clin- 
icians. Criteria to distinguish these conditions are not defined. This study was 
aimed at investigating DB in patients with or without BA.

Methods: This was a single-center cross-sectional study. We used the language of 
dyspnea, HADS scale, the Niknem questionaire, spirometry, capnometry, and 
blood gas analysis.

Results: 29 BA patients and 7 DB patients participated in the study. Of BA pa- 
tients, 5 had clinical signs of DB (BA+DB group). Patients with DB and BA+DB 
described their dyspnea as "I am gasping for breath" (28.6% and 40%, 
respectively, vs 4.2% of "pure" BA) and "My breathing requires more concentration" 
(42.9% and 42% vs 10.3%, respectively). Only 1 BA patient (4%) described 
expiratory difficulties. FEV1 was 2.35±0.95 L in "pure" BA; 2.08±0.62 L in 
BA+DB and 3.13±0.9 L in DB group (p<0.05). Anxiety, hyperventilation and 
blood hypocapnia prevailed in BA+DB group; median HADS-A scores were 12.0 
(11.0 – 13.0), 9.0 (4.0 – 11.0) and 7.0 (3.0 – 8.0). The Niknem scores were 30.0 
(27.0 – 31.0); 21.0 (15.0 – 32.0) and 14.5 (8.0 – 25.5) in BA+DB, DB and "pure" 
BA groups, respectively.

</table>

Data are given in % of patients. *p<0.05 vs “Pure” BA group.

Conclusion: Most BA patients perceive inspiratory dyspnea but its quality de- 
pends on coexisting DB. Alveolar and arterial CO2 are not indicative in up to 75% 
of patients with DB. Therefore, distinguishing DB from BA should be primarily 
based on verbal descriptions of dyspnea.

2964 COPD disease severity stratification obtained by electronic review of 
routinely collected primary care data
Dermot Ryan1,2, Feargal Ryan1, Catherine Blackaby3, Rupert Jones3, 
David Price3,4, 1Medical Directorate, Leicester County and Rutland PCT, 
Leicester, United Kingdom; 2Allergy and Respiratory Research Group, Centre for 
Population Health Sciences, University of Edinburgh, Edinburgh, United 
Kingdom; 3Clinical Review Services, Optimum Patient Care, Norwich, United 
Kingdom; 4NHS Improvement: Lung, NHS, Leicester, United Kingdom; 2GP, 
Armed Services, Plymouth, United Kingdom; 2General Practice and Primary Care, 
University of Aberdeen, Aberdeen, United Kingdom

In COPD there are as yet many unknowns with regards to quantification by 
severity strata and identification of high risk patients. As part of an incentivised 
COPD improvement scheme, the clinical notes of 310,924 patients were reviewed 
electronically. COPD severity was categorised by lung function and the DOSE 
index to ascertain their need for medical intervention based on health status and 
exacerbation history.

Results: 4214 had COPD as a coded diagnosis (prevalence 1.4%) of which 609 
(14.5%) did not conform to NICE spirometric criteria for COPD (FEV1<80% 
predicted) and 525 were of unknown severity. Further stratification employing the 
multicomponent DOSE index with a cut off score of 4 revealed 177 high risk 
patients, suitable for active case management.

DOSE: patients counted twice.

Current individual management was assessed comparing status and treatment 
against NICE COPD guidelines. Recommendations: 23.7% update spirometry, 
17.8% oxygen saturation assessment 38.8% refer for pulmonary rehabilitation. 
Pharmacologically, 56.1% were receiving oxygen therapy;11.2% were receiving 
no therapy.

Discussion: The use of electronic record review at practice level facilitates quantifi- 
cation, stratification and classification of patients by disease severity. This should 
facilitate individualised patient management by permitting therapy mapping and 
identifying patients at most risk of exacerbation/hospitalisation who merit more 
frequent review. At a population level, healthcare planning is facilitated.

2965 Integration of COPD management across primary and secondary care: 
Feasibility and impact

Health Centre, London, United Kingdom

Introduction: Integration of COPD treatment across primary and secondary care

Monday, September 26th 2011
aim to maximize resources, reduce waste, and optimize care. We evaluated a service innovation in COPD across two hospitals and two primary care trusts (PCTs) between 2008 and 2011.

**Methods:** Five enhanced services: hospital-based admission-response; integrated pulmonary rehabilitation (PR); intermediate care COPD service; bespoke electronic COPD clinical record; 24/7 emergency telephone support service. The evaluation used routinely collected data to assess COPD admissions, primary care COPD prescribing, contacts in the new services, interventions and outcomes in the intermediate care service, and impact of 24/7 telephone support, and compared outcomes to two adjacent PCTs.

**Results:** 6068 patients with COPD were identified in a population of 511,000 served by 98 practices. 2308 (38%) patients were referred to PR, an increase of 35%. 1100 patients were seen by the admission response service, 1230 in the intermediate care service, and 453 were registered to use the 24/7 emergency telephone line. Average admissions were 980/year, stable during the project, and did not differ from admissions in 2.75 years before the project. Steady increase in prescribing of inotropium and of inhaledcombination long-acting bronchodilators and corticosteroids. No differences in numbers of COPD admissions or prescribing rates compared to two adjacent PCTs over the same period. No differences in admission compared to 29 London PCTs.

**Conclusions:** No impact of integrated COPD care was seen despite substantial numbers of patients and practices taking part. Rising prescriptions of COPD drugs were not reflected in a fall in admissions.

### 2966

**Comorbidity at time of COPD diagnosis**

David Price1, David Halpin3, Rupert Jones10, Centre of Academic Primary Care, University of Aberdeen, Aberdeen, United Kingdom; 2Observational Research, Research in Real Life, Norwich, United Kingdom; 3Royal Devon & Exeter Hospital, Exeter, United Kingdom; 4Respiratory Programme, Department of Health, London, United Kingdom; 5NHIS Future Review, East of England Strategic Health Authority, Cambridge, United Kingdom; 3Respiratory Medicine, University of Cape Town, Cape Town, South Africa; 1General Practice with Specialist Interest in Respiratory Medicine, Sheringham Medical Practice, Norfolk, United Kingdom; 2General Practice with Specialist Interest in Respiratory Medicine, Woodbrook Medical Centre, Lochgourough, United Kingdom; 6General Practice with Specialist Interest in Respiratory Medicine, Castelfeldi, Runcorn, United Kingdom; 7Peninsula Medical School, University of Plymouth, Plymouth, United Kingdom

**Rationale:** Comorbidities can potentiate the morbidity of chronic obstructive pulmonary disease (COPD), and vice versa. Patients with COPD often die as a result of comorbidities.

**Objectives:** Evaluate prevalence of comorbidities at COPD diagnosis in real-world patients over a 10-year period.

**Methods:** Retrospective study using data from the United Kingdom’s General Practice and Optimum Patient Care research databases. Eligible patients were ≥40 yrs; received first COPD diagnostic code between 1990–2009; prescribed ≥2 COPD therapies in the year following diagnosis; had ≥2 yrs clinical data prior to diagnosis. Prevalence of asthma, ischaemic heart disease (IHD), gastroesophageal reflux disease (GERD) and diabetes mellitus (DM) were evaluated using diagnostic codes and (for GERD and DM) prescribing records before COPD diagnosis.

**Results:** Of 153,720 eligible patients: 52.6% male, diagnosed with COPD at median (IQR) age 68 (60–75) yrs. Over the period, asthma was recorded in 53.3% of patients, falling from 71.1% in 1990 to 29.7% by 2008. In the 2 yrs prior to their COPD diagnosis, 7.7% of patients consulted for IBD and 18.5% consulted, or received prescriptions, for GERD and 9.6% for DM. The percentage of patients consulting for comorbidities prior to COPD diagnosis increased over the study period. IBD from 6.5% in 1990 to 11.5% in 2009; GERD from 1.5–8.4% and DM from 4.4–12.5%.

**Conclusions:** These data confirm the presence of comorbidities in a substantial proportion of the UK COPD population. Trends over the study period suggest better differentiation of asthma and COPD diagnoses in recent years. The increasing prevalence of comorbidities may indicate increased awareness of comorbidities or improved diagnosis of COPD in patients treated for comorbidities.

### 2967

**Short-term outcomes in community heart failure patients with chronic obstructive pulmonary disease**

Sudip Ghosh1, William Roberston1, Jude Smith2, Jonathan Dexter2, Noel Kelly1. Integrated Medical/Cardiovascular Sciences, College of Medicine, Leicester, United Kingdom; 2Long Term Conditions, Leicestershire County Community Health Services, Melton Mowbray Community Hospital, Leicester, United Kingdom

**Aims:** Heart failure (HF) and chronic obstructive pulmonary disease (COPD) are common co-morbidities. The combination presents diagnostic challenges and has been linked with worse prognosis in patients admitted to hospital. There is hardly any prognostic data in patients with both co-morbidities in the community.

**Methods and results:** We evaluated 783 patients (27.2%) with left ventricular systolic dysfunction under the care of a regional nurse-led community heart failure team between June 2007 - June 2010. 101 patients (12.9%) also had a diagnosis of COPD. 94% of patients were on loop diuretics; 83% on ACE inhibitors, 74% on β-blockers; 9.6% were on bronchodilators and 43% on aldosterone antagonists. Mean age of the patients was 77.9±5.7 years; Mean follow-up was 28±2.9 months. β-blocker utilization was markedly lower in patients receiving bronchodilators compared to those without (overall 24.4% vs 81%; P<0.0001). 24 month survival was 95% in patients with HF alone and 89% in those with both co-morbidities (P<0.001). The presence of COPD was associated with increased HF hospitalizations (HR 1.56 (1.4–2.1; P<0.001) and major adverse cardiovascular events [HR 1.23 (1.03–1.75); P<0.001].

**Conclusions:** COPD is a common co-morbidity in ambulatory HF patients in the community and is a powerful predictor of worsening HF. It does not however appear to affect short-term mortality in ambulatory HF patients.

### 325. Noninvasive ventilation on the intensive care unit: from novel application to end of life issues

**3268**

**Noninvasive mechanical ventilation in patients with acute respiratory failure due to H1N1 infection**

Eva Tonveronachi1, Biaia Valentin1, Andrea Fabiani1, Rosanna Vaschetto2, Antonina Pigna1, Riccardo Maviglia1, Gabriela Sangiorti1, Massimo Germoni1, Marco Adversi1, Gianfranco Di Nino2, Stefano Faura2, Massimo Antonelli1, Paolo Navales2, Stefano Nava1, Respiratory ICU, Sant’Orsola Malpighi Hospital, Bologna, Italy; 2ICU, Università Piemonte Orientale, Ospedale della Carità, Novara, Italy; 1Anesthesia e Terapia Intensiva Polivalente, Sant’Orsola Malpighi Hospital, Bologna, Italy; 4Department of Intensive Care and Anesthesiology, Policlinico Universitario A. Gemelli, Università Cattolica del Sacro Cuore, Roma, Italy; 3Anestesia e Rianimazione, Sant’Orsola Malpighi Hospital, Bologna, Italy; 5Respiratory ICU, Ospedale Careggi, Firenze, Italy

We evaluated the clinical outcomes of consecutive patients positive for H1N1 and admitted to 6 Intensive Care Units in Italy for severe Acute Respiratory Failure and requiring non-invasive mechanical ventilation (NIV). 29/54 (54%) patients admitted to the ICUs needed immediate intubation for gasping, coma or respiratory arrest. The remaining 25 patients (mean age 49.8±12) underwent an NIV trial as a first line treatment using the helmet (n.19 patients) or a total face mask (n.6). Arterial Blood Gases (ABGs) at enrolment were: pH=7.41±0.02, PaO2/FiO2=117±64 and PaCO2=40±4.8. At the first ABGs control (between 30’ and 90’PaO2/FiO2 significantly (p<0.001) improved to 187±43 with a concomitant decrease in PaCO2 to 36±4.9. Mean duration of NIV was 49.8±33 hrs. 10/25 (40%) of the patients required intubation after 20.3 hrs. Overall mortality rate was 7/25 (28%), with all the deaths occurring in the NIV failure group. NIV failure had a lower PaO2/FiO2 at admission (78.6±21 vs 152.4±32 p<0.01, for NIV failure and success, respectively) and 5/7 patients had a known risk factor (i.e.hematological malignancies (n.2), previous solid organ transplant (n.1), multisystemic scorers (n.1) and CHF (n.1)). None of the operators were apparently contaminated by the virus. NIV may be safely used to treat patients with severe ARF due to H1N1 infections. The success rate was similar for that reported in the literature for ALI/ARDS patients.
in pandemic influenza A H1N1 pneumonia. However, other authors have recently reported some cases demonstrating the effectiveness of NIV in ARDS/ALI related to H1N1 pneumonia.

Aims and methods: The objective of this study is to describe the clinical characteristics of patients with diagnosis of Influenza A H1N1 pneumonia with ARDS/ALI with whom NIV has been effective. 75 patients affected by Influenza A H1N1 pneumonia with ARDS/ALI were treated by NIV. The outcomes of 10 historical control pts who received Standard Medical Treatment (SMT) alone (Group B).

Methods: Prospective analysis of the short-term outcomes of 10 NMD pts who were treated by NIV and AC immediately after extubation (Group A) and comparison with the outcomes of 10 historical control pts who received Standard Medical Treatment (SMT) alone (Group B).

Results: Significantly fewer pts who received the treatment protocol required reintubation and tracheostomy compared with those who received SMT (reintubation: 3 vs 10; tracheostomy: 3 vs 9; p=0.002 and 0.01, respectively). Pts in Group A remained for a shorter time in the ICU compared to Group B (7.8±3.9 vs 23.8±15.8 days; p=0.006).

Conclusions: Preventive application of NIV plus AC after extubation provides an important advantage to NMD pts by averting the need for reintubation or tracheostomy, and shortening their stay in the ICU.

2972

Patients sleep under noninvasive ventilation (NIV) in the intensive care unit (ICU)?

Ana Cordoba Izquierdo, Xavier Drouot, Arnaud W. Thille, Fabrice Galia, Laurent Brochard, Réanimation Médicale, AP-HC, Centre Hospitalier Albert Chenevier-Henri Mondor, Créteil, France, Unité Explorations Fonctionnelles, AP-HC, Centre Hospitalier Albert Chenevier-Henri Mondor, Créteil, France, Service de Soins Intensifs, Hôpital Universitaire de Genève et Université de Genève, Geneva, Switzerland

Rationale: Whether patients receiving NIV are really sleeping in the ICU, and whether sleep occurs during the NIV sessions is unknown. In addition the ventilator used may influence patient-ventilator synchronization (1) and cause sleep disruption (2).

Objectives: 1. To analyze sleep quality and quantity in ICU patients receiving NIV for a acute hypopneic respiratory failure (AHRF). 2. To compare sleep between two different types of ventilators (these results are not yet available).

Material and methods: Prospective study on consecutive ICU patients treated by IV therapy for AHRF on the 2nd to 4th day of admission patients were randomized to receive NIV with their current ICU ventilator or with a specific NIV ventilator (Respironics V60) and a polysomnographic study was conducted during a 17 hour period (1am to 8am).

Results: 14 patients included, 7 in each group, age 73±9, pH 7.28±0.07, PCO2 77±1.8 mmHg. Previous respiratory disease: COPD 39%, obesity hyperventilation/sleep apnea syndrome 43%. Time under NIV previous to inclusion 18±11 hours. Time under NIV during the study period 75.4±1 hours in 2 or 3 sessions.

During the study period patients slept 5.8±2 hours (42±2% stages i+2 38.6±2% stage 3. 12±2% REM) with a fragmentation index of 29±13 arousals and awakenings per hour of sleep. 76% of the total sleep time (4.5±1.3 hours) happened during the night period (11pm to 8am), and 80% took place under NIV.

Conclusions: In patients treated for AHRF in the ICU, sleep architecture is relatively preserved, with most of the sleep time occurring at night. NIV seems to favour sleep during the night period.

2973

Ethical issues in idiopathic pulmonary fibrosis with acute respiratory failure (IPF-AHF): An Italian survey

Raffaele Scala1, Stefano Nava1, Antonio Corrado1, Marco Confalonieri2, Nicola Faccolongo3, 1 UO Pneumologia e UTIR, Ospedale Careggi, Firenze, Italy; 2 UO Pneumologia e UTIR, Ospedale S. Maria Nuova, Reggio Emilia, Italy; 3 UO Pneumologia e UTIR, Arcispedale S. Maria Nuova, Reggio Emilia, Italy

Aims: To determine Italian Pulmonologist’s attitudes and behaviour towards diagnostic and therapeutic choices in competent IPF-AHF patients.

Methods: A web-site survey (30-items questionnaire) was sent to all the members of the Study Groups of Respiratory Intensive Care and Diffuse Lung Diseases of Italian Association of Italian Pulmonologists (January-March 2009).

Results: 248/370 (67%) physicians responded to the questionnaire (>60% over-fifties, male, Catholics). About 75% of respondents agreed on having anticipated directives and on eventu-

ally communicating bad news about IPF-AHF. >75% of respondents answered that any diagnostic (BAL and/or TBB) and therapeu-
tical choices (drugs, ventilation, palliative care) should be discussed with the patients and relatives. However, almost 50% of respondents reported to start ventilation and palliative care only in <25% of cases. BAL under NIV was recommended to eventually find the cause of ARF by half of respondents, while 77% reported to perform BAL and/or TBB in >25% of cases. More responders stated that NIV was not likely to improve survival (76.7% vs 10.0%) and to facilitate the communication with the relatives (50.7% vs 19.4%). 43.5% of the physicians did not agree on the concept of using NIV to reduce dyspnea and 40% on its use to gain time for end-of-life decisions. >60% of the
respondents considered to perform NIV and intubation when a reversible ARF cause is supposed. About 60% of the respondents used NIV and palliation in <25% of cases, while >90% of them intubated patients in <25% of cases. Conclusions: A discrepancy between attitudes and behaviour of Italian Pulmonologists emerged towards IPI-ARF issues.

2976

Does manual therapy provide additional benefit to breathing retraining in the management of dysfunctional breathing? A randomised controlled trial

Mandy Jones 1, Fiona Troup 2, John Nagon 3, Michael Roughton 4, Margaret Hodson 5, 6, Charlotte Rayner 7, Jennifer Pryor 1, 3, 4, 5, 6
1 Health Science and Social Care, Brunel University, London, United Kingdom; 2 Physiotherapy, Physio Clinics, London, United Kingdom; 3 Respiratory Medicine, Royal Brompton and Harefield NHS Trust, London, United Kingdom; 4 Statistics, R-Squared Statistics, London, United Kingdom; 5 Respiratory Medicine, NHLImperial College, London, United Kingdom; 6 Respiratory Medicine, Parkside Hospital, London, United Kingdom; 7 Respiratory Medicine, Hamershams Hospital Imperial College Healthcare NHS Trust, London, United Kingdom

Introduction: Dysfunctional breathing (DB) is a respiratory disorder associated with significant patient morbidity. It is characterized by unexplained breathlessness and an abnormal breathing pattern, with combinations of erratic breathing, episodic breath holding and sighing, or hyperventilation. Treatment involves breathing retraining through respiratory physiotherapy. Recently, manual therapy has been used as a treatment component; but no evidence exists to validate its use. We sought to investigate the effects of manual therapy in addition to breathing retraining in patients with DB.

Methods: 60 subjects with primary DB were randomized into either breathing retraining (standard treatment; n=30) or breathing retraining plus manual therapy (intervention; n=30). Both groups received standardised respiratory physiotherapy.

DB education; breathing retraining; home regime; audio disc. Subjects in the intervention group received additional manual therapy.

Results: No significant difference was found between groups for the primary outcome Nijmegen score or any secondary outcome measures (Table 1).

Conclusion: Breathing retraining is the primary management for patients with DB. Our results suggest the additional use of manual therapy provides no further benefit and cannot be recommended in clinical practice.

2977

Efficacy of airway clearance therapy with different autonomy degrees in nonCF-BE patients: Randomized cross-over trial

Beatriz Hernero 1, 2, Eva Polverino 1, 2, Dani Martí Romeu 3, 4, Jordi Vilà 3, 4
1 Respiratory Disease Department, Hospital Clinic, Barcelona, Spain; 2 IDIBAPS (Institut d’Investigacions Biomèdiques August Pi Sunyer), University of Barcelona, Barcelona, Barcelona, Spain; 3 CBERES, CIBER de Enfermedades Respiratorias, Mallorca, Spain; 4 Facultat de Ciències de la Salut Blanquerna, Universitat Ramon Llull, Barcelona, Barcelona, Spain

Airways clearance techniques are an important part of chronic treatment of non-cystic fibrosis bronchiectasis (nonCF-BE). Notwithstanding, the literature supporting their clinical use is still poor.

Aim: To evaluate effectiveness in mucus clearance and tolerance of 3 respiratory techniques with different autonomy degrees: ELTGOL (physiotherapist-administered), Autogenic drainage (self-administered) and a temporary positive expiratory pressure device, named Uniko.

Design: Randomized cross-over trial.

Population: Clinically stable adult nonCF-BE patients, sputum production ≥15ml/day.

Methods: Each technique is applied in 3 sessions on alternate days (1 week washout). Sputum was registered at the end session, after 1h and 24h.

Results: 7 patients were enrolled in the study (median age 69; mean FEV1 70%; 66%). AD obtained the major short-term sputum production (mean values: ELTGOL 7gr.; AD 15gr.; Uniko 7gr.). By contrast, Uniko and ELTGOL showed a higher sputum production at 24h (AD 9gr., Uniko 16gr., ELTGOL 17gr). The short-time sputum production slightly increased over time with ELTGOL (1st: 11gr.; 2nd: 13gr.; 3rd: 14gr.), while the 24h sputum production increased with Uniko (1st: 14gr.; 2nd: 17gr.; 3rd: 17gr.). AD was the favourite technique of 6 patients.

Conclusions: The 3 techniques were well tolerated and efficacious. AD was the most rapid in favouring expectoration. However, Uniko and ELTGOL were more effective at long-term, with an increasing trend for Uniko over time. The degree of patients’ autonomy for each technique, the compliance and personal preferences should be considered to select a treatment in order to individualize and optimize the respiratory therapy in nonCF-BE patients. Supported by MIR Italy.

2978

Nebulised 7% hypertonic saline improves health related quality of life in patients with non-cystic fibrosis bronchiectasis

Rachel Johnston 1, Fiona Shaw 1, Robert Wilson 2, Michael Leebinger 2, Lizzie Flude 1
1 Physiotherapy, Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom; 2 Respiratory Medicine, Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom

Introduction: Cough and sputum have a significant impact on quality of life (QoL) in non-cystic fibrosis bronchiectasis (NCFBx). Nebulised 7% hypertonic saline (HTS) has previously been shown to improve airway clearance in NCFBx, and we hypothesised that it would also improve QoL in such patients.

Method: Patients with NCFBx referred for HTS for over a 4 month period at Royal Brompton Hospital were included (N=22). Patients were assessed by the Leices- ter cough questionnaire (LCQ) as a marker for Health Related Quality of Life (HRQoL). Visual Analogue Scale for ease of clearance (VAS/EC) and FEV1 pre and post 1 month use of HTS Results are expressed as median and interquartile range and Wilcoxon-signed Rank tests were used to assess the impact of the therapy.

Results: N=22 (Males=7), median age 64yrs (32.81), FEV1, 1.59 (0.64-3.01). There was a significant improvement in LCQ 11.0 (9.2-14.7) to 16.7 (10.7-17.7) p<0.01 and VASE/EC 7 (5.5 - 8) to 4.7 (3.7) p<0.002. There was no significant change in FEV1 (p=0.32). 4 patients (18%) constituted on challenge test, and were not included in analysis. No other adverse effects of the therapy were seen.

Conclusion: In addition to confirming that HTS improves airway clearance, we demonstrated for the first time that HTS also improves HRQoL markers in patients with NCFBx. The minimal clinical significant difference in the LCQ is reported to be 1.5-3.7. There was therefore a statistically and clinically significant change in the total LCQ score, suggesting HRQoL significantly improved with one month use of HTS. Further trials with HTS are needed to assess whether these improvements are sustained long term in such patients.
Comparison of two physiotherapeutic methods in bronchiectasis: Active cycle breathing technique (ACBT) and oscillating physiotherapy device

Hamil Reza Khoddami Visheh, Fariba Gohbani, Masoomeh Masoudinia, Saeid Mahmoudian, Shahid Shafaghat, and Mohammadreza Rezaei

Aim: To evaluate the efficacy of mobilization and active cycle of breathing techniques (ACBT) following coronary artery bypass graft (CABG) surgery.

Material and methods: Fifty patients (35-75 years) with CABG were included in this randomized study. Twenty-five patients (18 males, 7 females) underwent mobilization and 25 patients (21 males, 4 females) were applied ACBT combined with mobilization. Demographic variables were recorded. Patients were evaluated using pulmonary function testing, 6-minute walk test (6MWt), and respiratory muscle strength.

Results: Five days after surgery, pulmonary function variables were similarly but significantly decreased in both groups as compared to preoperative values (p<0.05). No significant difference was found in 6MWt distance obtained before and after surgery, and no side effects during and after the study were observed. No significant difference was found in forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) in both groups.

Conclusion: Functional capacity preserved after short-term ACBT or mobilization intervention after CABG surgery. Improvement in respiratory muscle strength was faster in ACBT group.

A randomized prospective cross-over study was performed in 16 patients with SRD under noninvasive mechanical ventilation (NIV). Patients with a median age of 51.5 (39.7-64.7) years that included 13 neuro muscular disorders (SRD), sleep events defined as obstructive or central apneas/hypopneas, and a mean AHI of 5.7±3.0 (1.1-16.9). All patients were included in the SRD group and were included in the study. The study was divided into two phases: Phase I: After the first night with a PEEP/EPAP of 0 cmH2O and the other night with a PEEP/EPAP of 8 cmH2O. Phase II: Two consecutive nights, they were randomly assigned to sleep one night with a PEEP/EPAP of 6 cmH2O and the other night with a PEEP/EPAP of 8 cmH2O.

Conclusion: The application of PEEP/EPAP did not show superiority in terms of sleep parameters and overall satisfaction (P>0.05). However, patients believed that they can do physiotherapy with RC-comet® method at home alone than ACBT method (25 vs. 15, P=0.022). Conclusion: Our findings showed that use of RC-comet® at home is preferred by most of the patients. Since this method was more acceptable and preferable than ACBT for home usage, we highly suggest use of such convenient methods.

Comparison of PEEP/EPAP during nocturnal noninvasive ventilation in patients with severe restrictive disorders: Physiological effects and tolerance in a randomized pilot study

Miguel Goncalves1, Joaquim Moreira 2, Luana Souto Barros 2, Patricia Dantas 2, João Carlos Winck 1

Aim: The purpose of this study was to evaluate the efficacy of mobilization and active cycle of breathing techniques (ACBT) following coronary artery bypass graft surgery (CABG).

Materials and methods: Fifty patients (35-75 years) with CABG were included in this randomized study. Twenty-five patients (18 males, 7 females) underwent mobilization and 25 patients (21 males, 4 females) were applied ACBT combined with mobilization. Demographic variables were recorded. Patients were evaluated using pulmonary function testing, 6-minute walk test (6MWt), and respiratory muscle strength.

Results: Five days after surgery, pulmonary function variables were similarly but significantly decreased in both groups as compared to preoperative values (p<0.05). No significant difference was found in 6MWt distance obtained before and after surgery, and no side effects during and after the study were observed. No significant difference was found in forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) in both groups.

Conclusion: Functional capacity preserved after short-term ACBT or mobilization intervention after CABG surgery. Improvement in respiratory muscle strength was faster in ACBT group.

Addition of PEEP/EPAP during nocturnal noninvasive ventilation in patients with severe restrictive disorders: Physiological effects and tolerance in a randomized pilot study

Miguel Goncalves1, Joaquim Moreira 2, Luana Souto Barros 2, Patricia Dantas 2, João Carlos Winck 1

Hamil Reza Khoddami Visheh, Fariba Gohbani, Masoomeh Masoudinia, Saeid Mahmoudian, Shahid Shafaghat, and Mohammadreza Rezaei

Aim: The purpose of this study was to evaluate the efficacy of mobilization and active cycle of breathing techniques (ACBT) following coronary artery bypass graft surgery (CABG).

Materials and methods: Fifty patients (35-75 years) with CABG were included in this randomized study. Twenty-five patients (18 males, 7 females) underwent mobilization and 25 patients (21 males, 4 females) were applied ACBT combined with mobilization. Demographic variables were recorded. Patients were evaluated using pulmonary function testing, 6-minute walk test (6MWt), and respiratory muscle strength.

Results: Five days after surgery, pulmonary function variables were similarly but significantly decreased in both groups as compared to preoperative values (p<0.05). No significant difference was found in 6MWt distance obtained before and after surgery, and no side effects during and after the study were observed. No significant difference was found in forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) in both groups.

Conclusion: Functional capacity preserved after short-term ACBT or mobilization intervention after CABG surgery. Improvement in respiratory muscle strength was faster in ACBT group.

Addition of PEEP/EPAP during nocturnal noninvasive ventilation in patients with severe restrictive disorders: Physiological effects and tolerance in a randomized pilot study

Miguel Goncalves1, Joaquim Moreira 2, Luana Souto Barros 2, Patricia Dantas 2, João Carlos Winck 1

Aim: The purpose of this study was to evaluate the efficacy of mobilization and active cycle of breathing techniques (ACBT) following coronary artery bypass graft surgery (CABG).

Materials and methods: Fifty patients (35-75 years) with CABG were included in this randomized study. Twenty-five patients (18 males, 7 females) underwent mobilization and 25 patients (21 males, 4 females) were applied ACBT combined with mobilization. Demographic variables were recorded. Conclusions: Concentration of bronchoalveolar interleukin-1 beta was significantly higher in the children with positive and negative bacterial culture, respectively (p = 0.001). Bronchoalveolar interleukin-1 beta was significantly positively correlated with parameters of body composition and serum concentrations of leptin and adiponectin were significantly associated with higher estimates for Charlson index (RR 1.38; 95% CI 1.04 to 1.82, p=0.02) and APACHE II scale (RR 1.242; 95% CI 1.284 to 1.602, p=0.005). In convalescents the increased lung pattern on radiographs (39%), decreased lung diffusion capacity (45%), restrictive changes (15%) were the most frequent and long-lasting changes. 28% of patients having these changes applied for medical care within 6 months after being discharged.

Conclusion: The high score on Charlson index and APACHE II scale are risk factors for development of severe pneumonia in presence of influenza A (H1N1). Changes of ventilation functional tests associated with persistent disorders of pulmonary circulation remain for long time in 45% of patients undergoing pneumonia. This group of patients is of particular interest and requires further observation.

2987 Specialised palliative care is more than drugs – A retrospective study of ILD patients
Sabrina Bajwa1, Irene J Huggett2, Joy Ross3,4, Athol U Wells4,5, Sunder S Birring3, Amir Patel3, Julia Ridley4,5, Department of Palliative Medicine, Royal Marsden and Royal Brompton NHS Foundation Trusts, London, United Kingdom; 2King’s College, Cicely Saunders Institute, Department of Palliative Care, Policy and Rehabilitation, London, United Kingdom; 3National Heart and Lung Institute, Imperial College, London, United Kingdom; 4Interstitial Lung Disease Unit, Royal Brompton NHS Foundation Trust, London, United Kingdom; 5Department of Respiratory Medicine, King’s College Hospital, London, United Kingdom

Background: Little is known about the palliative care needs of patients with Progressive Idiopathic Fibrotic Interstitial Lung Disease (PIF-ILD). As part of a study to develop a complex palliative intervention at the end of life, we retrospectively studied patients dying in 2 London Hospitals.

Aims: To assess the palliative care needs and management of PIF-ILD patients in 2 London ILD centres.

Methods: Patients’ records from Royal Brompton Hospital (RBH) and King’s College Hospital (KCH) were extracted to assess palliative care needs, use of palliative treatments and whether end of life preferences were documented and achieved.

Results: 45 PIF-ILD patients were identified (26 RBH,19 KCH). Patients at RBH were younger (37±18 years, median 30) compared to KCH’s older, more racially diverse population (70-99y, median 82y, 6/19 non-white).

All patients experienced breathlessness in their last year of life (42/45) and almost a third (17/45) patients had specialist palliative care team involvement. Nearly all patients (44/45 patients) were non-white. In 181 patients who died, 144 (79%) died in hospital (3.3 days from diagnosis to death) and 18/45 (39%) died at home (3.2 days from diagnosis to death).

Conclusion: Despite demographic variation, the patients experienced similar symptoms. There was use of standard pharmacological treatments with symptom related with bacterial burden in the alveoli, it may be a marker for progressive and ongoing inflammation in children who have not responded to CAP therapy.

2988 Community-acquired pneumonia in pediatric patients with connective tissue disorders: Manifestations and clinical course
Zoia Nestereenko, Olena Ivanchuk2,1, Department of Pediatrics, Faculty of Postgraduate Studies, Lugansk State Medical University, Lugansk, Ukraine; 2Outpatient Department, Lugansk Municipal Children’s Hospital #2, Lugansk, Ukraine

Objective: To assess the relationship between concentrations of bronchoalveolar cytokines and bacterial burden in children with CAP.

Method: 58 children were divided into two subgroups: referral (n=28), and treated (n=30) CAP. Bronchoalveolar lavage was performed in the most abnormal area on chest radiograph by fiberoptic bronchoscope. Bronchoalveolar lavage fluid was processed for quantitative bacterial culture. The concentrations of bronchoalveolar lavage cytokines (tumor necrosis factor-α, interleukin-1 beta, interleukin-6, interleukin-8, and interleukin-10) also were measured.

Results: Thirty-two patients had a positive bacterial culture (bronchoalveolar lavage > or = 10 colony-forming units/mL), and made up 70% of pathogens recovered at high concentrations. The concentrations of bronchoalveolar lavage interleukin-1 beta were 18.1±11.63 and 45.1±10.67 pg/mL, (mean ± s.e) in the children with positive and negative bacterial culture, respectively (p = 0.001). Bronchoalveolar lavage interleukin-1 beta was significantly higher in the children with a high bacterial burden (p = 0.001), with mixed bacterial infection (p < 0.001), and with CAP (p < 0.001), compared with values in patients without these features. The relationship between bacterial load and concentrations of bronchoalveolar lavage interleukin-1 beta was very strong in the children with referral CAP but was borderline in treated CAP.

Conclusions: Concentration of bronchoalveolar interleukin-1 beta was correlated with bacterial burden in the alveoli, it may be a marker for progressive and ongoing inflammation in children who have not responded to CAP therapy.
clinical course of community-acquired pneumonia (CAP) in pediatric patients that leads to diagnosis and therapeutic mistakes.

**Aims:** To study role of CTD in CAP clinical course in children.

**Methods:** 171 children aged 0.18 years with CTD and CAP were observed. CAP was clinically and radiographically diagnosed with detection of serum antibodies (IgG and IgM) against intracellular pathogens measured by enzyme-linked immunosorbent assay (ELISA) and PCR.

**Results:** Recurrent course of CAP (with 3 and more episodes in 5-year period of study) was in 106 (61.9%) patients and in all cases followed a viral respiratory infection. 156 (91.2%) children had abnormal perinatal history. Asthma (A) was diagnosed in 59 (34.5%) children. CAP caused by *Mycoplasma pneumonia* (Mp) was in 88 (51.5%) patients; by *Cytomegalovirus* (Cmv) and *Mp* – in 42 (24.5%); by *Chlamydia pneumoniae* (Cp) – in 18 (10.5%); by *Cp* and *Mp* – in 33 (13.5%) patients. 78% of patients with A, CTD and CAP and 53.6% of patients with CTD and CAP had pulmonary hypertension (PH). 76.4% of patients with recurrent CAP demonstrated radiographic and clinical evidence of pulmonary fibrosis (PF), 30.2% of them had A. 12.5% of children with A, recurrent CTD, recurrent CAP and PF had evidence of development of PC.

**Conclusions:** 1. Manifestations of CTD were in all children with CAP. 2. All patients with CTD and recurrent CAP had abnormal perinatal history. 3. High frequency of PH and PF was observed in patients with CTD and recurrent CAP. 4. 12.5% of children with A, recurrent CTD, CAP and PF had evidence of development of FC.

### P2989 Clinical features of a new hypersensitivity pneumonitis: Salami brusher’s disease

Lara Balzarinì, Chiara Mancini, Panagiota Mouzakiti, Maurizio Marvisi.

**Internal Medicine and Pneumology, Fidighe di S. Camillo Clino, Cremona, Italy**

We observed 5 consecutive cases of hypersensitivity Pneumonitis (HP) in subjects working in a salami factory. The workers had to clean the mould growing on salami’s surface by using a wire brush. The working population was of 30 female subjects, 5 of them developed a HP (17%). Two were smokers (40%) and, other two were asthmatic. All patients presented with an acute clinical manifestation with cough, high fever, dyspnea and hypoxemia. One participant was admitted after a short period after exposure (240±60 minutes). Three of them presented at the emergency department and a chest x-ray showed and alveolar interstitial pneumonitis and were treated as a community acquired pneumonia. Skin prick test were positive for *Penicillium spp* in 3 cases and for *Cladosporium spp* and *Aspergillus spp* in other 2. The results of serum immunoglobulin (Ig) G and IgA antibodies against *Penicillium spp* were positive in 3 patients, 2 patients were positive to *Aspergillus Fumigatus*. Pulmonary function tests were performed a reduction in diffusing capacity in all 5 patients (60±15% of predicted). A bronchial hyperresponsiveness to methacholine was present in all the patients, the mean dose of methacholine causing a 20% fall in FEV1 was 3.63±4.70 mg/ml. RAL data showed a lymphocytosis 44.5±9.3%, CD4+ were 26.5±6.6%, CD8+ was 53.5±8.2%. Four patients had a complete recovery after changing work, and one was treated with oral steroids for increasing dyspnea and severe interstitial involvement. Salami’s brusher disease is a new type of HP; the prevalence is high in exposed subjects, and is common even in smokers. The disease has an acute clinical onset. The probable antigen is Penicillium, but *Cladosporium* and *Aspergillus* may play a key role.

### P2990 Predicting peak cycle work rate from the incremental shuttle walk test in COPD

Rahizan Zainuldin1, Martin Mackey1, Nia Luxton2, Jennifer Alison1,3.

1Discipline of Physiotherapy, The University of Sydney, Sydney, New South Wales, Australia; 2School of Physiotherapy, The University of Notre Dame, Fremantle, Western Australia, Australia; 3Department of Physiotherapy, Royal Prince Alfred Hospital, Sydney, New South Wales, Australia

**Introduction:** The incremental shuttle walking test (ISWT) is used to assess physical activity and exercise performance in chronic lung disease: implications for rehabilitation.

**Methods:** 188 patients (94 men) performed an ISWT before a pulmonary rehabilitation program. Lung function, nutritional status and depression and anxiety symptoms were assessed.

**Results:** The mean (SD) age was 61.1 (10.2) years, FEV1 1.6 (0.54) L, RV/TLC ratio 59.0 (10.4%), BMI 26.0 (6.6), fat free mass index (FFMI) 18.9 (4.7), depression symptoms (HADS) 6.1 (4.2), anxiety symptoms (HADS) 6.9 (4.2). The ISWT distance was 209.6 (144.7) meters. The total variance explained by the model was 48.2%. R2 change: FEV1 (l) 28.5%, age 7.6%, depression symptoms 7.0%, BMI 3.8% and RV/TLC 1.3%. Sex, FFMI, smoking behavior and anxiety symptoms were not significant.

**Conclusions:** Prognostic variables for the ISWT are both physical (pulmonary and non-pulmonary) and psychological.

### P2993 Does breathlessness and leg discomfort indicate different exercise limiting mechanisms in COPD?

Martijn Groenendijk1,2, Dirk van Rantz1, Henk Otten1, Alex vant Hul1,2

1Pulmonary Rehabilitation, Revent-Schoondijke, Breda, Netherlands; 2Pulmonary Diseases, VU Medical Center, Amsterdam, Netherlands

**Introduction:** The last step in the complex cascade of patho-physiological mechanisms leading to exercise intolerance in COPD is the (prematurely) generation of symptoms, mainly dyspnea and leg discomfort. From a clinical perspective it is of
great interest whether these 2 distinct symptoms would point to different exercise limitation mechanisms.

Aim of the present study was to evaluate potentially different in dynamic hyperinflation and peripheral muscle strength between patients stopping exercise because of intolerable dyspnoea (D) or leg discomfort (L).

Methods: 496 patients with COPD (GOLD II-IV) performed a constant work rate cycle test at 75% of maximal power output till exhaustion. Ventilatory variables including inspiratory capacity (IC) were measured during this test. In addition, maximal peripheral muscle strength of the quadriceps (QF) was measured using a hand held dynamometer. Because the prevalence of exercise limiting factors related to FEV1, analysis of variance was performed for each GOLD class separately.

Results
Variable GOLD II (n=196) GOLD III (n=237) GOLD IV (n=61)
Stop reason D (n=95, 61%) D (n=9, 44.2%) D (n=26, 51.7%) D (n=35, 15%) D (n=89, 88%) D (n=9, 9%)
IC (L/min) 34.1 ± 10.8 32.5 ± 10.9 27.5 ± 10.4 15.9 ± 9.8
QF (kg) 29.3 ± 12.9 32.3 ± 12.3 30.5 ± 10.2 <0.05

Walking 4.5 ± 2.2 5.8 ± 1.9 3.8 ± 1.9 NS

Conclusions: Treadmill endurance test is more representative of daily activity, our aim was to determine the minimal important difference (MID) for treadmill test (TET) capable to detect improvement in functional capacity in patients with COPD after a 24 sessions PRP.

Material and methods: 100 COPD patients (mean age: 66.6±9.5 years old; FEV1: 1.1±0.4L) were enrolled. Patients performed a 6MWT and a symptom-limited TET at 90% of maximum grade achieved in an incremental test before and after the PRP. The St Georges Respiratory Questionnaire served as anchors for anchor-based MID estimates. Work rate (W), walked distance, endurance time and patients velocity in both tests were calculated.

Results: The TET minimal important difference found for W was 14.337 Joules or 37% increase and for endurance time an increase of 340 ± 77%.

Table 1. Changes and minimal important difference (MID) in 6 minute walk test (6MWT) and treadmill endurance test (TET) pre and post pulmonary rehabilitation program

Conclusion: Treadmill endurance test is more representative of changes in functional capacity than 6MWT in COPD patients after a PRP. In addition, work rate seemed to be a good variable to evaluate improvement in exercise capacity after a pulmonary rehabilitation program.

P2995
Predictors of six-minute walk distance at baseline and after three years in COPD patients
Renata Ferraz, Suzana Tanni, Laura Caram, Corina Corrêa, Camila Corrêa, Liana Coelho, Irena Gody, Department of Internal Medicine, Botucatu Medical School - Sao Paulo State University - UNESP, Botucatu, Sao Paulo, Brazil

Association between six-minute walk distance (6MWD) and COPD systemic markers overtime is unclear. The aim of this study was to verify the predictors of 6MWD at baseline and after three years in 53 COPD patients (66% male, age 63±49 years, FEV1=56±21%). The following evaluations were undertaken at baseline and after three years: body mass index (BMI), six-minute walk distance (6MWD), Modified Medical Research Council dyspnea scale (MMRC) and Interleukin-6 (IL-6). Information on exacerbations was not available at baseline and was collected during the study period. At baseline, FEV1, MMRC, BMI and IL-6 were included in a multiple linear regression analysis with the baseline 6MWD value as the dependent variable. After three years, we included the final values of the same variables with the final 6MWD value as the dependent outcome. In another model, we evaluated the influence of the number of exacerbations in the previous model. At baseline, FEV1 and IL-6 were selected as predictor of 6MWD (R2=0.44; p<0.001); however, after three years, only MMRC was selected as predictor of the walking distance (R2=0.54; p<0.001). The number of exacerbation did not influence 6MWD overtime. In conclusion, airflow limitation and inflammation are predictors of 6MWD at baseline. However, maintenance or improvement of exercise tolerance overtime in COPD patients is related to the control of dyspnea perception.

Research supported by FAPESP (2010/08527-0). R. Ferrari is the recipient of a fellowship from FAPESP (2010/08557-6).

P2996
The influence of O2 on exercise capacity (6-minute-walking-distance, 6MWD) in COPD
Inga Heinzelmann1, Andreas Jerrentrup2, Claus Vogelmeier3, Klaus Kenn1.

1 Pulmonology, Allergology and Sleep Medicine, Schoen Klinik Bertzgeruder Bad, Schoenau am Koenigssee, 2 Univerausszinklinik Marburg und Giessen, Marburg, Germany

We investigated the additional effect of supplemental oxygen on 6MWD in severe COPD-patients. The aim of the study was to find out if the response to nasal oxygen during 6-minute-walking-test (6MWT) depends on the level of exercise capacity.

To identify characteristics of patients with high oxygen response, we defined patients as “O2-Responder” if they increase their 6MWD by ≥35m due to oxygen supply

111 COPD-patients (age: 63.5±8.7, FEV1: 35.9±pred±11.6; F6O2=65.46) took part in a randomized, single-blinded, prospective study.

The patients underwent a 6MWT pretest followed by 2 6MWT either on 2L oxygen or on medical air (MA). After 3 week rehabilitation including resistance- and endurance-training both tests were repeated. We measured lung function before and after rehabilitation, SpO2, paO2, paCO2 and BORG-scale before and after every 6MWT.

The difference between 6MWDMA and 6MWDMAO2 (O2-response) was greater pre (A×17.6%) than post rehabilitation (A×3.25%). Separating patients in 2 groups, O2-responder was significantly higher in patients with 6MWD<349 m (p<0.05).

While Pulmonary Rehabilitation (PR) improves health status and exercise capacity in the short term, there is a lack of consistent evidence that daily physical activity increases after PR and if this is sustained.

17 stable COPD patients (mean age 67.7 (9.6y), FEV1 1.1 (0.4)l, 47 (16)% predicted) were assessed before and after 8 weeks PR and 6 mths later. The number of exacerbations during PR and if this is sustained.

While Pulmonary Rehabilitation (PR) improves health status and exercise capacity in the short term, there is a lack of consistent evidence that daily physical activity increases after PR and if this is sustained.

While Pulmonary Rehabilitation (PR) improves health status and exercise capacity in the short term, there is a lack of consistent evidence that daily physical activity increases after PR and if this is sustained.

While Pulmonary Rehabilitation (PR) improves health status and exercise capacity in the short term, there is a lack of consistent evidence that daily physical activity increases after PR and if this is sustained.

While Pulmonary Rehabilitation (PR) improves health status and exercise capacity in the short term, there is a lack of consistent evidence that daily physical activity increases after PR and if this is sustained.
Although there is a correlation between the DASI and the ISWT, poor agreement does not necessarily lead to a change in daily physical activity. This is due to a lack in behavioural change and can subsequently lead to loss of an initial gain in exercise capacity. The results show that activity levels can be increased and the pattern can be changed. COPD patients show lower activity levels compared to controls and a less distributed pattern. First experiences with a telemedicine feedback intervention.

Conclusions: There're scarce studies evaluating long-term impact of exercise adherence after a respiratory rehabilitation program (RR) in Chronic Obstructive Pulmonary Disease (COPD) patients. To compare impact on BODE, mortality, health-related quality of life (HRQL) and health-resources consumption in two groups of COPD patient: intense physical activity (IPA) and low physical activity (LPA) at long-term. METHODS: COPD patients (GOLD definition) were followed up after a RR program completed (from 1997 to 2009). Patients were evaluated by BODE, HRQL (SGRO), pulmonary function, health-consumption and survival on 2009. Patients were classified according to García Aymerich questionnaire (Thorax 2006): IPA, LPA, IPA vs LPA. LONG-TERM IMPACT OF EXERCISE ADHERENCE
Quality of life represents a crucial aspect for the assessment of COPD patients. The level of daily activities is a determining factor and the degree of autonomy in movement is an important component that influences quality of life. Pedometry represents an alternative tool for estimating the degree of this activity.

Aims: To compare the values, obtained by pedometry of COPD patients (GOLD stage III and IV) with the values of healthy subjects from the Euroregion Banat.

Material and methods: We used pedometers to monitor 14 patients with COPD (not included in pulmonary rehabilitation) and 32 healthy subjects for a week, registering daily level and intensity of movement and detecting aerobic effort. Both groups had comparable demographic data and similar occupations.

Results: Healthy individuals showed a significantly higher average of steps over a full week compared with COPD patients (6497±1866 vs. 3992±295, p<0.05).

In both groups the number of steps was lower during the week-end compared with working days: 4754±2322 vs 7185±2396 steps for the control group, and 2135±697 steps vs 4736±175 steps in COPD patients (p<0.05). 52.77% of the normal subjects have made an aerobic effort at least one day in a week and only 13.88% performed a constant aerobic effort. Patients with COPD couldn’t perform an aerobic exercise at all.

Conclusions: We found a decrease in intensity of daily activity in healthy subjects, compared with data from literature, suggesting an increase of the sedentary style in general population. The degree of physical activity is significantly reduced in COPD compared with healthy people on both levels: aerobic and anaerobic effort.

For both groups, periods of week-end reveal the lowest activity level.

P3005 Does resistance training improve physical activity in patients with COPD? Lutzy Houchen1,2, Manoj Menon1, Samantha Harrison1, Carolyn Sandiland1, Michael Morgan1, Michael Steiner1, Sally Singh1,2, 1Institute for Lung Health, Glenfield Hospital, Leicester, United Kingdom; 2Faculty of Health & Life Sciences, Coventry University, Coventry, United Kingdom; 3Respiratory Medicine, University of Leicester, Leicester, United Kingdom

Introduction: Quadriceps (quads) weakness is a functional problem for patients (pts) with COPD. Resistance training (RT) can increase quads strength. The translation of increased strength to physical activity (PA) is less clear.

Aim: To determine if RT in isolation (outside of pulmonary rehabilitation) can increase PA in pts with COPD.

Method: PA was measured before and after an 8week RT course. RT was 5×30 bilateral knee extensions; 3 times/week on an isokinetic dynamometer (Cybex: speed = 180°/sec). Pts were enrolled in a trial of protein supplementation (PS) during RT. PS did not augment the benefits of RT & PA results are therefore pooled.

20 pts (mean [SD] age 69.2±9.4 yr, BMI 25.6±4.4, FEV1 48.8±13.3% predicted, 11 men) had PA measured using the DUEKI Activity Status Index (DASI (range 0-58.2)) & ActiTrac accelerometer (IM Systems: mean acceleration/min, average daily activity monitoring (Dynaport MiniMode, Roberts BV) were measured before and after rehabilitation.

Results: None of the patients was hospitalized in this rehabilitation period. There was no change in maximal exercise capacity (WRmax: 75.1±17 vs 82.6±21 Wtatt), but oxygen uptake (VO2:128±33 vs. 122±29±0.8 L/min; p<0.05) and lactate threshold (LAT: 0.68±0.18 vs. 0.88±0.20 mL/min; p<0.05) improved significantly. Patients with COPD were more active after rehabilitation (lying: 26±16 vs. 12±11%; locomotion: 7±4 vs. 14±3%; p<0.05). Energy expenditure was reduced at rest after rehabilitation (lying: 2263±1535 vs. 1273±6154 Wtatt, p<0.05), Step counts improved significantly (3257±2267 vs. 5688±2920, p<0.05). The time of locomotion modestly correlated with post-rehab WRmax (r=0.40, p<0.05) and FEV1 (%pred) (r=0.42, p<0.05).

Conclusion: Activity monitoring contributes to the complex evaluation of rehabilitative interventions. Compared to maximal exercise capacity, change in activity level proved to be more sensitive to detect improvement in the status of COPD patients in this pilot study.
in COPD as low levels are associated with hospital admissions and mortality. Objective measurements require motion sensors (e.g. SenseWear Arm-band, SWA), but several days are needed to obtain reliable data. We evaluated a previously unstudied tool in COPD, the Stanford Seven-Day Physical Activity Recall questionnaire (PAR), as a screening test for physical inactivity. As a control, three self-completed PA questionnaires were simultaneously evaluated.

Methods: 45 COPD patients were the SWA for 7 days. Patients, blinded to the armband output, then completed the PAR and 3 other questionnaires in randomised order. Spearman rank correlation and ROC curves were used to assess the relationship between PA questionnaires output and SWA-derived physical activity indices, and the ability of the questionnaires to predict very inactive COPD patients.

Results: With the PAR, total energy expenditure (r=0.83, p < 0.001), physical activity level (r=0.52, p < 0.001) and time spent in at least moderate physical activity (r=0.54, p < 0.001) correlated significantly with equivalent data from SWA. No relationship was seen between the other questionnaires’ output and any SWA-derived PA index. The PAR compared favourably with the other questionnaires in predicting very inactive COPD patients with an area under the curve of 0.79 (95% CI 0.63–0.94). A PAR-derived PAL < 1.40 had a sensitivity of 0.65 and a specificity of 0.89 in predicting very inactive COPD patients.

Conclusion: The PAR is a useful screening tool to predict physical inactivity in COPD patients.

P3007
Hypoxia induces differential acute and chronic adaptations in regulation of skeletal muscle protein turnover
C.C. de Looze1, R.J.F. Langerak2, A.M.W.J. Schoels3, W.H. Lammers4, S.E. Köhler5,1, Anatomy & Embryology, Maastricht University, Maastricht, Netherlands; 2Respiratory Medicine, Maastricht University, Maastricht, Netherlands

Hypoxia may be a trigger of skeletal muscle atrophy in acute and chronic respiratory disease. To test this hypothesis, short- and long-term regulation of muscle mass in response to normoxic or hypoxic conditions was investigated in mice.

During 48h, O2– levels were reduced stepwise to 8%, which was maintained for 21 days. Food intake was monitored daily and mice were sacrificed at days 4 and 21.

mRNA and protein expression levels were determined in gastrocnemius muscle.

Food intake was affected during short- (day 4: -50%) and long-term (d21: -20%) hypoxia. Compared to normoxia, gastrocnemius muscle weight decreased (d4: -11%, d21: -23%). The reduced food intake was partially responsible for this effect. Hypoxia increased expression of Atf4 (d4: +52%, d21: +31%) and Gadd45 (d4: +148%, d21: +73%) indicative for acute and chronic ER stress signalisation. Protein synthesis regulation was differentially affected by short- and long-term hypoxia (p=0.21 and d21: -23%, p<0.01, respectively). Atrogin–1 as proteasomal protein degradation marker was activated during acute and chronic hypoxia (d4: +128%, d21: +60%), whereas MuRF1 only at day 4 (d4: +102%, d21: ns) and was explained by reduced food intake. Short- and long-term hypoxia induced markers of lysosomal protein degradation Bnip3 (d4: +95%, d21: +74%) and Lc3 (d4: +18%, d21: +26%) which could be attributed in part to the reduced food intake.

In conclusion, these data suggest that acute adaptation of muscle mass to hypoxia reflects an increased protein degradation whereas chronic adaptation may involve increased protein turnover.

Human metapneumovirus involved in acute exacerbations in COPD patients?
Marijke Vanspaunw1, Fris Fransen1, Cathrien Bruggeman1, Emiel Wouters12, Catharina Linnsm1, Medical Microbiology, Maastricht University Medical Centre, CAPHRI School, Maastricht, Netherlands; 2Ciro+, Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 3Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Introduction: COPD is characterized by the occurrence of acute exacerbations (AE) which may be caused by several factors, including infections. Human metapneumovirus (hMPV) is an important cause of severe respiratory tract infections in young children, the elderly and immunocompromised subjects. This study evaluates the presence of hMPV, and other respiratory viruses in stable sputum samples of patients with COPD and the relation with the occurrence of AE.

Material and methods: From March 2009 until August 2010 sputum samples of COPD patients clinically rehabilitating at the centre of expertise for chronic organ failure (CIRO), were included. Patients were followed during an 8 week period and sputum samples were collected during the stable state and during an AE. Real-time PCR for respiratory viruses, including rhinovirus and hMPV, was performed.

Results: A total of 498 sputum samples (218 patients) were included, 257 samples (52%) were collected during the stable phase. Viruses were detected in 64 (25%) of the stable samples. The most frequently isolated viruses in the stable samples were hMPV (12%) and rhinovirus (12%). A total of 74 patients experienced an AE in the weeks after stable sample collection, of which 12 (16%) had hMPV in the stable sample. Patients with hMPV in the stable phase experienced significantly more AEs in the first weeks after sample collection compared to patients without hMPV (or any other virus) (p=0.03).

Conclusion: hMPV was one of the most isolated viruses in samples collected during the stable state. Patients with hMPV in the stable sample experienced more exacerbations compared to patients without any virus in the stable sample.

Ammoxcin concentrations in sputum in relation to beta-lactamase activity in COPD patients
Rogier van der Zanden1, Paul van der Valk2, Ron Hendrix1, Job van der Palen2,4, Kris Movig5, Marjolein Brussse-Ketzer2, 1Clinical Pharmacy & Toxicology, Maastricht University Medical Centre, Maastricht, Netherlands; 2Pulmonary Medicine, Medisch Spectrum Twente, Enschede, Netherlands; 3Microbiology, Regional Laboratory of Public Health, Enschede, Netherlands; 4Research Methodology, Measurement, and Data Analysis, University of Twente, Enschede, Netherlands; 5Clinical Pharmacy, Medisch Spectrum Twente, Enschede, Netherlands

Introduction: COPD exacerbations are often treated with antibiotics, although their use is controversial. A previous study showed that patients with a sputum concentration of amoxicillin (a beta-lactam antibiotic) lower than the minimum inhibitory concentration (MIC<2 mg/l) were hospitalized 4 days longer then patients with a concentration ≥MIC90. One explanation for a low amoxicillin concentration could be that patients’ lungs are colonized or infected with pathogens that have beta-lactamase activity.

Objective: This study investigated if beta-lactamase activity was higher in patients who had a sputum amoxicillin concentration <2 mg/l than in patients with a concentration ≥2 mg/l.

Methods: 23 Hospitalized COPD patients treated with amoxicillin/clavulanic acid for an acute exacerbation were included. Sputum and serum samples were collected at the third day of treatment to determine beta-lactamase activity in sputum and amoxicillin concentrations in both sputum and serum.

Results: We found no difference in beta-lactamase activity between patients with a sputum amoxicillin concentration <MIC90 and ≥MIC90 (p=0.79). Amoxicillin concentrations were <MIC90 in 18 out of 23 sputum samples (78%). Serum concentrations amoxicillin were <MIC90 in 7 patients (30%).

Conclusions: Beta-lactamase activity did not differ between patients with sputum amoxicillin concentrations <MIC90 or ≥MIC90. The finding that a majority of patients had a sputum amoxicillin concentration <MIC90 suggests that these patients are being undertreated. Further research could focus on inhalation of amoxicillin to obtain higher concentrations in sputum.

Clinical and economical impact of exacerbations of chronic obstructive pulmonary disease (COPD): A two-year study
Francesco Blasi1, Carla Forzani2, Francesca Di Stasi1, Sara Conti2, Lorenzo Giovanni Mantovan1, Luca Merlino2, Stefano Alberti1, Giancarlo Cesana3, 1Dipartimento Torace-Polmonare e Cardio-Circolatorio, University of Milan, Milan, Italy; 2Dipartimento di Medicina Clinica e Prevenzione, University of Milano-Bicocca, Monza, Italy; 3Nycomed, Nycomed Spa, Milan, Italy; 4CRBFF/Center of Pharmacoconomics, Federico II University, Naples, Italy; 5Regional Health Authority of Lombardy, Milan, Milan, Italy

COPD is a common disease with considerable health and economical consequences. The aim of our study was to analyze clinical and economical impact of COPD exacerbations (E-COPD). A secondary data analysis of healthcare administrative databases of Lombardy, Italy, was performed, including patients hospitalized for a severe E-COPD (index event) from Jan to Dec 2003. Two study groups were identified based on the number and type of E-COPD experienced during the follow-up: those who had at least one severe E-COPD (Group A) and those who had only moderate E-COPD (Group B). A total of 12,436 patients (7,933 males; mean±SD age: 74±10 yrs) were enrolled. Among those, 45% belonged to Group A and 55% to Group B. Clinical outcomes, costs and consumptions of pulmonary function test (PFT) per person during the follow-up are given in Table.

Cost in EURO. *p<0.01 Age-adjusted difference between groups.

Mortality risk increased in the study population in relation to the number and type of E-COPD experienced during the follow-up. The number and type of
E-COPD significantly impact outcomes and costs. Less than one fourth of patients discharged after an E-COPD will undergo a PFT during two years, although this cost is extremely lower than the hospital stay.

P3011 Safety and pharmacokinetics of multiple-dose ciprofloxacin dry powder for inhalation in patients with moderate or severe COPD
Heino Stass1, Philipp Badorek2, Jens Hofhfeld3,4, Norbert Krug2, Johannes Naehrmeister1, Tobias Welte1
1Clinical Pharmacology, Bayer Schering Pharma AG, Wuppertal; 2Germany; 3Klinische Atemwegsforschung, Frauenhofer Institute for Toxicology and Experimental Science, Hannover, Germany; 4Klinik fuer Pneumologie, Medizinische Hochschule Hannover, Hannover, Germany

Introduction: Many patients with COPD are chronically colonized with bacteria and could benefit from long-term antibacterial therapy. Ciprofloxacin dry powder for inhalation (DPI) is an investigational PulmoSphere™ formulation for pulmonary delivery of ciprofloxacin.

Aim: To investigate the safety, tolerability and PK of ciprofloxacin DPI in patients with COPD.

Methods: In a randomized, phase I, single-blind, parallel-group study, adults with GOLD stage II or III COPD received 32.5 mg or 48.75 mg ciprofloxacin (50 mg, 75 mg ciprofloxacin DPI, respectively) or matching placebo as a single dose on Day 0 and 12 and bid on Days 2-11.

Results: Patients received 32.5 mg (n=6) or 48.75 mg (n=9 including 3 who dropped out) ciprofloxacin, or placebo (n=6). There were no severe or serious AEs; most AEs were mild in severity. There were treatment-related AEs in 4, 8 and 1 patients in the 32.5 mg and 48.75 mg ciprofloxacin and placebo groups, respectively. Three patients discontinued (48.75 mg ciprofloxacin) due to AEs. Treatment-related dyspnoea (n=4), infectious diseases (n=2). Day 0 geometric mean plasma ciprofloxacin AUC(0-24) h=0.532 mg*h/g and 0.727 mg*h/g, and AUC(0-t) h in induced sputum was 1.90 mg*h/ml and 2.010 mg*h/ml, for the 32.5 mg and 48.75 mg groups, respectively. Ciprofloxacin sputum concentrations were highly variable.

Conclusion: Ciprofloxacin DPI was well tolerated over 12 days’ treatment in patients with moderate or severe COPD. High sputum concentrations contrasted with low systemic exposure.

P3012 Does presence of multiple viruses in the stable state predispone COPD patients to exacerbations?
Marijke Vanpaauwen1, Frits Franssen2, Cathrien Bruggeman1, Emiel Wouters3, Catharina Lissen3
1Medical Microbiology, Maastricht University Medical Centre, Caphri School, Maastricht, Netherlands; 2Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 3Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Introduction: Respiratory viruses are associated with acute exacerbations (AE) in patients with COPD, but may also lead to asymptomatic carrier status. This study investigates whether co-detection of viruses in the stable state predisposes for AEs in patients with COPD. Since it is known that many viruses circulate during the year we wanted to detect the most important respiratory viruses in our study.

Material and methods: From March 2009 until August 2010 sputum samples of COPD patients clinically rehabilitating at the centre of expertise for chronic organ failure (CBO), were included. Sputum samples were collected during the stable state and during an AE. Real-time polymerase chain reaction for rhinovirus, hMPV, RSV, influenza A and B and parainfluenza 1-4, was performed.
