P3181
BMI is not the driving factor in position dependent upper airway collapsibility in healthy subjects
Cedric Van Hoekbeke1, Wim Ys1, Samir Vinchurkar1, Jan De Backer1, Oswald Peters, Nasser Nadji1, Wilfried De Backer2. 1Respiratory, Fluid & Airway medicine, Kontich, Belgium; 2Respiratory Medicine, University Hospital Antwerp, Edegem, Belgium; 3Maxillofacial Surgery, A.Z. Monica, Antwerpen, Belgium

Introduction: In obstructive sleep apnea (OSA) patients, the minimal cross sectional area (CSA) of their upper airway (UA) correlates well with the severity of their pathology. However, since there is a correlation between body mass index (BMI) and severity of OSA in a population of OSA patients, it is not known if the minimal CSA is defined by the natural collapsibility of the UA or by the mass of the surrounding tissue. The objective of this study is to evaluate the influence of BMI on the position dependent changes in UA geometry assessed by CT imaging.

Materials and methods: A total of 20 normal subjects where BMI > 25, 6 had a BMI between 25 and 30 and 7 had a BMI < 25 were included. 15 valid CBCT scans could be analyzed as the rotating gantry of the CBCT touched the shoulders of some subjects with a BMI > 30, causing motion artifacts. The supine and upright CT scans were performed using the GE VCT LightSpeed scanner and the upright CBCT scans were performed using the SIEMENS CAT scanner.

Results: BMI was not a predictor for difference between the minimal CSA in a supine and upright posture (R=0.05, p=0.86) as seen in the figure.

Conclusions: It can be concluded that in a healthy population, the BMI has no influence on the position dependent collapsibility of the airway. This means that collapse of the UA in healthy subjects is mostly defined by the natural collapsibility of the subject’s airway.

Clinical and polysomnographic determinants of snoring
Ioannis Koutsourelakis, Emmanouil Vagiakis, Eleni Perraki, Aliki Minaritzoglou, Spyros Zakynthinos. Center of Sleep Disorders, Medical School of Athens University, Athens, Greece

Snoring is considered one of the hallmarks of sleep-disordered breathing but its determinants remain obscure. We aimed to document positional dependency of snoring along with its association with clinical and polysomnographic variables.

Forty-nine OSA patients [41 men; mean apnea-hypopnea index (AHI) 30.9±18.5 events/h] underwent firstly DISE, secondly upper airway surgery, and thirdly follow-up polysomnography to assess surgical outcome. Twenty-three patients (47%) were responders and twenty-nine non-responders (53%). Non-responders had a higher occurrence of complete or partial circumferential collapse at velum, and of complete antero-posterior collapse at tongue base or epiglottis, in comparison with responders. Multivariate logistic regression analysis revealed that, among baseline clinical characteristics and DISE findings, the presence of complete circumferential collapse at velum, and of complete antero-posterior collapse at tongue base were the only independent predictors of upper airway surgery failure. Patterns of collapse on DISE associated with failure. A. complete circumferential collapse at velum. B. complete antero-posterior collapse at tongue base. C. complete antero-posterior collapse at epiglottis.

In conclusion, DISE findings are predictors of upper airway surgery outcome in OSA.

Surgery for obstructive sleep apnea: Sleep endoscopy determinants of outcome
Ioannis Koutsourelakis1,2, Madelene Ravesloot2, Emmanouil Vagiakis1, Spyros Zakynthinos1, Nico de Vries2. 1Centre of Sleep Disorders, Medical School of Athens University, Athens, Greece; 2Department of Otolaryngology, Head and Neck Surgery, Sint Lucas Andreas Ziekenhuis, Amsterdam, Netherlands

Although drug-induced sleep endoscopy (DISE) is often employed in order to determine the site of obstruction in patients with obstructive sleep apnea (OSA) who will undergo upper airway surgery, it remains unknown whether its findings are associated with surgical outcome. This study tested the hypothesis that DISE variables can predict the outcome of upper airway surgery.

Forty-nine OSA patients [41 men; mean apnea-hypopnea index (AHI) 30.9±18.5 events/h] underwent firstly DISE, secondly upper airway surgery, and thirdly follow-up polysomnography to assess surgical outcome.

Twenty-three patients (47%) were responders and twenty-nine non-responders (53%). Non-responders had a higher occurrence of complete or partial circumferential collapse at velum, and of complete antero-posterior collapse at tongue base or epiglottis, in comparison with responders. Multivariate logistic regression analysis revealed that, among baseline clinical characteristics and DISE findings, the presence of complete circumferential collapse at velum, and of complete antero-posterior collapse at tongue base were the only independent predictors of upper airway surgery failure. Patterns of collapse on DISE associated with failure. A. complete circumferential collapse at velum. B. complete antero-posterior collapse at tongue base. C. complete antero-posterior collapse at epiglottis.

In conclusion, DISE findings are predictors of upper airway surgery outcome in OSA.
Importance of Mallampati score as an independent predictor of obstructive sleep apnea

M.S. Kanwar1,2, Ravi Shekhar Jha1, 1Respiratory, Critical Care and Sleep Medicine, Indraprastha Apollo Hospital, Delhi, India; 2Respiratory and Sleep Medicine, Advanced Sleep Disorder Institute, Greater Kailash Part 2, New Delhi, India

Introduction: The Mallampatti Scoring System (MSS) was initially developed as a classification system of oro-pharyngeal opening and has been used to identify patients with potentially difficult intubation. We conducted this prospective study to assess the utility of MSS in diagnosing Obstructive Sleep Apnoea (OSA) and to predict the severity of OSA.

Materials and methods: This prospective study was carried out at a tertiary care sleep referral centre in Northern India. A total of 175 consecutive patients were enrolled and their symptoms and examination findings were noted. A special note was taken of their Mallampati Score Severity. After overnight polysomnography, their Apnea-Hypopnoea Index (AHI) was correlated with the MSS.

Results: The average age of the study population was 47±6.2 years. Average BMI was calculated to be 31.2±8.4 kg/m² and overall AHI was 42±10. MSS was an independent predictor for presence of OSA but there was no significant correlation between severity of MSS and severity of OSA. On average, for every 1-point increase in the Mallampati score, the odds of having Obstructive Sleep Apnea increased more than 2-fold (odds ratio [per 1-point increase] = 2.5; p < 0.05). However with increase in severity of MSS, the AHI did not increase significantly.

Conclusion: MSS is an important predictor for presence and absence of OSA and can be an important screening tool as well as is an important part of pre-test physical examination. However, its role in predicting severity of OSA remains doubtful and needs further study.

P3184 Validation of respiratory inductive plethysmography in people with obesity hypoventilation syndrome
Carly Hollier1,2, Alison Harmer2, Lyndal Maxwell1, Collette Menadue1, Amanda Piper1, Grant Wilson1, 1Respiratory and Sleep Medicine, Royal Prince Alfred Hospital, Sydney, NSW, Australia; 2Faculty of Health Sciences, University of Sydney, NSW, Australia; 3Faculty of Health Sciences, Australian Catholic University, Sydney, NSW, Australia; 4Faculty of Health, University of Canberra, Australian Capital Territory, Australia

The excessive chest and abdominal adiposity present in obesity hypoventilation syndrome (OHS) may reduce the accuracy of respiratory inductive plethysmography (RIP). The aim of the study was to validate RIP measures of ventilation in OHS against a clinical standard (spirometry). Measures of tidal volume (VT) and respiratory rate (RR) were obtained simultaneously from RIP (LifeShirt®) and a spirometer during two 40-minute air-supplemented O2 breathing tests. 16 paired samples were obtained per subject. Using the Bland Altman method, bias was expressed as spirometer-RIP mean difference (MD), and as a percentage. Error was expressed as limits of agreement (LOA) and as a percentage. Differences between groups were assessed with independent samples t-tests. 162 viable paired samples were obtained from 13 subjects with OHS and 197 paired samples were obtained from 13 age- and gender-matched controls. Error of RIP measures was larger in subjects with OHS: VT: MD=3ml (1%), LOA=216 to 222ml (±36%) compared with controls, MD=5ml (1%), LOA=160 to 169ml (±20%); VT: MD=0.2L/min (2%), LOA=4.1 to 4.4L/min (±36%) in subjects with OHS compared with MD=0.1L/min (1%), LOA=1.4 to 1.5L/min (±20%) for controls; and RR: MD=0.2br/min (2%), LOA=5 to 9br/min (±27%) in subjects with OHS compared with MD=0.1br/min (1%), LOA=1 to 1br/min (±12%) for controls. Between group differences were only statistically significant for RR (p<0.05). VT %error correlated strongly with body mass index (r=0.53, p<0.01) and waist circumference (r=0.61, p<0.01). In conclusion, the accuracy of RIP is reduced in people with OHS, limiting its capacity for detecting small changes in ventilation.

P3185 Validation of raised serum bicarbonate for diagnosis of obesity hypoventilation syndrome
Vladimir Macavei1,2, Kristoffer Spurling, Himinder Makker. Sleep and Ventilation Unit, Department of Respiratory Medicine, North Middlesex University Hospital, London, United Kingdom

Introduction: The need for early detection of Obesity Hypoventilation Syndrome (OHS) is clear because delay in the diagnosis and treatment is associated with significant morbidity and mortality.

Objective: To validate previously reported raised serum bicarbonate of 27 mmol/l for the diagnosis of OHS in obese patients attending sleep clinic.

Methods: A retrospective analysis of prospectively collected sleep clinic data on consecutive obese patients referred to sleep clinic from January 2009 to January 2011 to the North Middlesex University Hospital was performed. Subjects with suspected sleep disorders were evaluated according to our clinic protocol and capillary blood gases were measured in obese subjects (BMI>30 kg/m²).

Results: 525 consecutive patients (mean age 51±4.12, 65.71% males, mean BMI 34.59±8.1) were evaluated. A total of 344 (65.52%) were obese (mean age 52.29±12.4, 63.66% males) of which 128 (37.2%) were morbidly obese (BMI>40 kg/m²). 275 (79.94%) obese patients were found to have OHS (AHI > 5 hypopneas) with mean AHI 32.6±23.9 and ESS 11.7±5.8 and OHS was present in 71 (20.63%) with mean PCO2 6.9±1.1 kPa and HCO3- 28.19±7.27 mmol/l.

Obstructive hypoventilation syndrome (OHS) may reduce the accuracy of respiratory inductive plethysmography (RIP). The excessive chest and abdominal adiposity present in Obesity Hypoventilation Syndrome (OHS) may reduce the accuracy of respiratory inductive plethysmography (RIP). with OHS. This study investigated the effect of clinically relevant O₂ concentrations on PCO₂, pH and minute ventilation (Vₑ) in stable OHS patients pre and post treatment with positive airway pressure (PAP), and in controls. In a double-blind randomised crossover study, 14 subjects with OHS and 14 age- and gender-matched controls breathed inspired O₂ fractions (FiO₂) of 0.28 and 0.5, each for 20min, separated by a 45min washout. The OHS group were retested after 3 months of nocturnal PAP. Arterialised-venous PCO₂, and pH, and Vₑ were measured every 5min. Data were analysed with repeated measures ANOVA. In OHS pre-PAP, small rises in PCO₂ of 2.0±1.7mmHg; 3.7±3.2mmHg (both p<0.01) occurred after 1min of breathing FiO₂ 0.28 and 0.5, respectively, with no significant difference between concentrations. pH fell accordingly, with FiO₂ 0.5 inducing mild acidemia (7.34±0.030, p<0.01). Vₑ fell below the room air baseline for both FiO₂ 0.28 (5±11%, p<0.01) and FiO₂ 0.5 (7±20%, p<0.01). The controls responses differed significantly from the OHS group (p<0.01). PCO₂ and pH did not change significantly with either FiO₂ and mild hyperventilation occurred (Vₑ +1.3±19%, FiO₂ 0.28; +12±17%, FiO₂ 0.5). In OHS, O₂-induced PCO₂ rises tended to be smaller after PAP (1.2±2.3mmHg, FiO₂ 0.28; and 0.9±1.7mmHg, FiO₂ 0.5). Commonly used concentrations of O₂ caused hypoventilation, small PCO₂ rises and mild acidemia in stable OHS. When providing supplemental O₂ for people with stable OHS, close monitoring and targeting of O₂ saturations is recommended.

Multiscale entropy analysis of RR time series obtained from polysomnographic recordings in wide age spectrum group

Jjakub Rudlinska, Zhigenei Baran, Waldemar Tomalak. Physiopathology of Respiratory System, Institute for TBC & Lung Diseases, Rabka - Zdrój, Poland

Costs and complication of polysomnography lead to attempts to develop cheaper and simpler methods. The analysis of heart rate seems to be promising, however the heart rate’s dynamics is biased by several physiological factors. The aim of that study was to check influence of age on multiscale entropy (MSE) of RR time series.

64 patients undergoing routine diagnostic in sleep lab were recruited (36 male, 28 female, age 1.5-63 yrs mean 25.2±20 yrs, RDI: 0-4.9 l/h mean 1.9±1.5 l/h). The full night PSG (ASSM 2007) were performed. The R-R intervals were detected in recorded ECG signal (250Hz), and the multiscale entropy (Goldberg’s MSE) was calculated (n=2, r=0.15, scale = 1-20).

We found high correlation between entropy in SE(1) and age (Fig. 1) in adults, however in the children group (age=15) there was no such relation.

**Figure 1**

After removing subjects younger than 15yrs the correlation increase (R=0.58, p<0.001). Using MSE we found significant differences between the lowest and highest quartiles (Fig. 2).

**Figure 2**

We conclude that entropy is biased by age in adults and the lack of such relation in young group needs further investigations.

**P3188**

Effect of nasal CPAP therapy on functional respiratory parameters and cardiopulmonary exercise test in obstructive sleep apnea syndrome

Ozge Oral Tapan, 1 Can Sevinc2, Oya Itil3, Ibrahim Oztura 4, Serkan Nural, Ersin Gunay5, Bilal Halici, Mehmet Unlu. 1Dept of Respiratory Medicine, Orbis Medical Centre, Sittard, Netherlands; 2Dept of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 3Chest Diseases, Dokuz Eylul University, Izmir, Turkey; 4Neurology, Dokuz Eylul University, Izmir, Turkey; 5Physiology, Dokuz Eylul University, Izmir, Turkey; 6Public Health, Dokuz Eylul University, Izmir, Turkey

**Aim:** Nasal CPAP treatment is an effective treatment modality for patients with OAS. It can improve physical and mental functions by reducing daytime hyper-somnolence, arousal index and sleep fragmentations. The purpose of this study was to evaluate whether pulmonary functions, exercise limitation confirmed with CPET and quality of life can be improved after eight weeks of nCPAP treatment.

**Method:** We evaluated our case group with physical examination, SF-36 health survey, body composition analysis before and after CPAP treatment for 8 weeks. Spirometric flow rates, PiP, PiMax, lung volumes and exercise capacities with CPET were measured.

**Results:** 31 of 40 patients (4 female, 27 male) completed the study. The mean age was 53.4±11.46, 51±6.1 of cases had comorbidities and the smoking history rate was 54.8. All of them had exercise limitation before treatment. After treatment there were increases in PiP-PiMax (p<0.05), VO2 peak (p<0.001), Load max (p<0.001), maximal heart rates (p<0.001), all SF-36 scores except pain (p<0.05) and a decrease in systolic blood pressure (p<0.005). We didn’t see any changes in body compositions, spirometric flow rates except FEV1 and lung volumes.

**Conclusions:** OSAS may lead to exercise limitation. nCPAP treatment is effective in reducing exercise limitation, can help to control blood pressure and improves respiratory muscle strength. nCPAP can also improve the quality of life scores in OSA patients without any comorbidities or with comorbidities under control. Our findings may suggest that these results are the improvements in patients’ cardiac function, daytime somnolence and fitness.

**P3189**

End expiratory lung volume as a predictor of obstructive sleep apnea severity

A.J.M. Lebene1, C.P.M. van der Gent2, G.J. de Vries3. 1Dept of Respiratory Medicine, Orbis Medical Centre, Sittard, Netherlands; 2Dept of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

**Background:** One of the contributing factors to upper airway collaps in obstructive sleep apnea (OSA) is reduced end expiratory lung volume (EELV) (Kapur, V.H. et al. Respiratory Care 2010:55). There is evidence for correlation of apnea hypopnea index (AHI) with EELV in supine position. We hypothesized that EELV could affect the severity of OSA.

**Methods:** In an observational study the relationship between EELVₑ and OSA in 59 adult patients of Orbis Medical Centre, Sittard (The Netherlands) was assessed using a regression analysis. EELVₑ was evaluated by helium dilution technique, and severity of OSA by apnea hypopnea index (AHI) based on polysomnography measurements. In addition EELVₑ was compared to other predictors of OSA, Egrowth sleepiness score (ESS), Mallampati-score, body mass index (BMI), and neck- and abdominal circumference, by means of a multiple regression analysis.

**Results:** EELVₑ was a predictor of AHI, R=0.392 (p=0.003). Multiple regression analysis demonstrated that abdominal circumference explained 15.5% of variance of AHI, and together with EELVₑ 23.4% of the variance of AHI was explained. Other predictors were not significant.

**Conclusions:** EELVₑ contributed to the severity of OSA and might therefore be useful to differentiate between high and low risk patients for OSA in screening and diagnostics settings. Abdominal circumference also appeared to predict severity of OSA and had even more impact on AHI compared to EELVₑ.

Inflammatory processes and effects of continuous positive airway pressure (CPAP) in overlap syndrome

Serkan Nural, Ersin Gunay, Bilal Halici, Mehmet Unlu. Department of Chest Diseases, Afyon Kocatepe University, School of Medicine, Afyonkarahisar, Turkey

**Aim:** We aimed to compare serum levels of the inflammatory mediators of C-Reactive Protein (CRP), Tumor Necrosis Factor-α (TNF-α) and Asymmetric-Dimethyl-Arginine (ADMA) in Chronic Obstructive Pulmonary Disease (COPD), Obstructive Sleep Apnea Syndrome (OSAS) and their coexistence called Overlap Syndrome (OVS). Also, we planned to investigate the changes of these mediators with the treatment of continuous positive airway pressure (CPAP) in OSAS and OVS patients.

**Methods:** CRP, TNF-α, ADMA levels were analyzed by ELISA method with the blood samples taken from patients with COPD (N=25), OSAS (N=25) and moderate-severe stage OSAS (N=25) in the morning after polysomnography application and second blood samples taken from OSAS and OVS patients who underwent regular CPAP treatment throughout 3-6 weeks.

**Results:** In comparison of three groups prior to CPAP treatment, ADMA levels in OSAS group were significantly lower than in COPD group (p=0.009), but

OSA is often associated with obesity and metabolic syndrome. The aim of this study was to assess prevalence of hyperuricaemia in OSA patients and relations between elevated plasma uric acid (UA) and OSA severity, obesity and cardio-
vascular diseases. We studied 1144 OSA pts. - AHI > 5.7 mg/dL - BMI = 34.2 ± 6.4 kg/m², mean SaO₂ = 90.8 ± 5.7%, T90 = 26.6 ± 28.9%, Epworth score = 11.3 ± 5.5 points. Hyperuricaemia [males: UA > 7 mg/dL (2005-2007) and > 8.5 mg/dL (since 2008); females: UA > 5.7 mg/dL (2005-2007) and > 6.2 mg/dL (since 2008)] was found in 354 pts (30.9%) (different laboratory methods). Comparison of subjects with hyperuricaemia and normouricaemia is shown in table.

Logistic regression analysis revealed that arterial hypertension, obesity (BMI > 30 vs < 30 kg/m²) and T90 > 30% were independent predictors of hyperuricaemia (OR-1.76; 95%CI – 1.23-2.51; p=0.002, OR-2.47; 95%CI – 1.67-3.65; p<0.001 and OR-1.79; 95%CI – 1.34-2.40; p<0.0001, respectively) after adjusting for NT-proBNP, diabetes, heart failure, coronary artery disease, COPD and stroke. Conclusions: Hyperuricaemia was frequent in OSA patients. Main predictors of hyperuricaemia were obesity, arterial hypertension and diabetes.

CRP (p=0.478) and TNF-α (p=0.137) were similar among groups. On the ba-
sis of before-after CPAP treatment comparison, CRP levels in both OAS and
OSA groups decreased significantly (p=0.02, p=0.046; whereas TNF-α (p=0.980, p=0.144) and ADMA (p=0.321, p=0.282) levels did not display any statistical significant differences.

Conclusion: In OVS group, no significant difference was established in inflamma-
tory mediators when compared to COPD and OSA groups. After effective CPAP treatment, decrease in serum-CRP level in OVS and OAS groups showed that CPAP is an effective treatment method for systemic inflammation. Nevertheless, further investigations examining the differences in ADMA, CRP and TNF-α level in patients with COPD, OAS and OAS are required.

Unintreated OSA is a risk factor for cardiovascular morbidity and mortality. Brain na-
triciuretic peptide (BNP) is a hormone secreted by the ventricles in response to heart failure [1]. We aimed to assess plasma NT-proBNP levels in OSA patients with and without OSA. Comparison of NT-proBNP levels in OSA patients with and without OSA is shown in table.

Logistic regression analysis revealed that heart failure (OR-4.4; 95%CI – 4.09-
4.74; p<0.0001), atrial fibrillation (OR-4.22; 95%CI – 3.89-4.58; p<0.0001), coronary artery disease (OR-2.29; 95%CI – 2.16-2.43; p<0.0001), arterial hyperten-
sion (OR-1.87; 95%CI – 1.75-2.0; p=0.0001) and COPD (OR-1.37; 95%CI – 1.27-
1.47; p=0.0001) were independent predictors of increased NT-proBNP after adjusting for BMI, diabetes, hyperuricaemia and stroke.

Background: Obstructive sleep apnea (OSA) is associated with an increased risk of cardiovascular disease and mortality. One contributory factor may be hemody-
namic stress due to the negative intrathoracic pressure during each apnea. Type-B Natriuretic Peptide (BNP) is secreted by the cardiac ventricles in response to volume expansion and pressure load and we hypothesized that there would be an association between indices of obstructive sleep apnea in the night and levels of BNP in the morning.

Methods: From a community-based sample, 349 women underwent full-night polysomnography, anthropometric measurements and answered a questionnaire about medical conditions and current medication. The morning following the polysomnography, blood samples were drawn for analysis of plasma BNP, C- reactive protein, creatinine and hemoglobin.

Results: There was an increase in mean BNP as the severity of sleep apnea increased, increasing from a mean value of 8.5ng/L among women with an AHI of <5 to 18.0ng/L in women with an AHI of >30. Elevated BNP levels (>20ng/L) were found in 29.8% of the women, while 70.2% had normal levels. The odds ratio was 2.2 for elevated BNP levels for women with an AHI of 5-15 in relation to women with an AHI of <5. For women with an AHI of >30 after adjustment for age, BMI, systolic blood pressure, antihypertensive drugs and creatinine.

mmHg) and severe OSAH (AHI 64.8±15) and otherwise healthy, aged 39.6±11 years, and after adjustment for age, BMI, systolic blood pressure, antihypertensive drugs and creatinine.

mmHg) and severe OSAH (AHI 64.8±15) and otherwise healthy, aged 39.6±11 years, and after adjustment for age, BMI, systolic blood pressure, antihypertensive drugs and creatinine.
**Conclusions:** We found a dose-response relationship between the severity of sleep apnea during the night in women and the levels of BNP in the morning.

Analysis revealed that elevated NT-proBNP level (>125 pg/ml) did not correlate with studied echocardiographic parameters in OSA pts (p>0.05). NT-proBNP level negatively correlated with AHI (r = -0.25, p=0.02). Elevated NT-proBNP concentration indicated at increased risk of coronary artery disease (OR = 12.94, 95%CI = 2.4-68.5, p<0.01).

**Conclusions:** Increased plasma concentration of NT-proBNP was not related to echocardiographic parameters, but it was associated with occurrence of CAD in OSA subjects.

**The relationship between uric acid levels and mean platelet volume and metabolic syndrome in males with obstructive sleep apnoea syndrome**

Ahmet Akkaya1, Önder Oztürk1, Ulugh Bik Khayri1, Mustafa Saygin2, Mehmet Has1,2,1Department of Chest Diseases, Medical School of Süleyman Demirel University, Isparta, Turkey; 2Department of Physiology, Medical School of Süleyman Demirel University, Isparta, Turkey

**Aim:** The aim of our study was to investigate the post-treatment changes in the level of UA and the relationship between serum uric acid (UA) levels and mean platelet volume (MPV) and metabolic syndrome in males with obstructive sleep apnoea syndrome (OSAS).

**Material and methods:** Seventy-nine men who had been performed a single night polysomnography (PSG) (mean AHI=42.59±27.79 events/hour), were included to the study. Demographics characteristics, serum uric acid levels, MPV and PSG results were recorded. We divided patients in two groups according to 75 percentiles of UA levels: 1st with hyperuricemia - UA ≥ 6.86 mg/dL and 2nd with normouricemia - UA < 6.86 mg/dL.

**Results:** There was a statistically positive correlation between UA (6.03±0.13 mg/dL) and AHI (p=0.037), BMI (p=0.013), waist circumference (p=0.027), O2 desaturation % (p=0.047). Subjects with hyperuricemia had higher BMI, HMI, (p<0.05), waist circumference (p<0.01), neck circumference, oxygen saturation index (ODI), O2 desaturation % and triglyceride. The duration of REM decreased and Stage 1 and 3 increased. The UA and MPV were found higher in patients with MS and OSAS and UA levels decreased after CPAP treatments. However, ODI and MPV were included to the model to estimate AHI at stepwise regression analysis (R square 58.9%, p<0.001).

**Conclusion:** This study showed that obesity was the determinant of hyperuricemia and high levels of UA was found with MS and OSAS. The levels were decreased after CPAP therapy. An also, it is thought that high levels UA and MPV are associated with cardiovascular complications in OSAS.

**Adaptive servo ventilation in the treatment of central sleep apnea related to ischemic stroke**

Anne-Kathrin Brill, Regula Rosi, Matthias Gugger, Sebastian Robert Ott.

Respiratory and Sleep Medicine, University Hospital (Inselspital) and University of Bern, Switzerland

**Background:** Adaptive Servo Ventilation (ASV) is a well-established treatment of central sleep apnea (CSA) related to chronic heart failure (CHF). So far, only few studies have evaluated effectiveness and compliance of ASV in patients with CSA of other etiologies. Therefore, we analyzed ASV in CSA following ischemic stroke.

**Methods:** Retrospective analysis of ASV treatment in stroke patients with CSA between 2005 and 2011. Patients with acute stroke (<1 month) or diagnosis of CHF were excluded. Demographic, clinical (including Epworth sleepiness scale; ESS), polygraphic/polysomnographic, ventilator setting and compliance data were collected.

**Results:** Fifteen out of 123 patients treated with ASV suffered from CSA or complex sleep apnea related to ischemic stroke (median time from stroke 11 months). 13/15 patients were pretreated with positive pressure ventilation without clinical success (CPAP: 11/15; BiPAP: 2/15). Indication for ASV was complex sleep apnea in 6 patients, CSA/Chyne-Stokes-Breathing in 5 patients, and mixed sleep apnea in 4 patients. At follow up after 66.3±24.0 days, mean daily use of ASV was 5±4±2.4 h per night. ASV significantly improved AHI (46.7±24.3 to 8.5±12.0, p=0.001). ESS was reduced from 8.7±5.7 to 5.6±2.5 (p=0.08).

**Conclusion:** Our data clearly suggests that ASV is a well-tolerated and clinically effective intervention in patients suffering from CSA related to ischemic stroke. Prospective randomized trials are warranted to establish ASV in the treatment of stroke related central sleep apnea.

**Relationship between NT-proBNP level, echocardiographic parameters and cardiovascular diseases in patients with obstructive sleep apnoea (OSA)**

Anna Czyzak-Gradkowska, Robert Pływaczewski, Monika Targowska, Anna Czyzak, Przemysław Bielen, Pawel Sliwinski.

Department of Diagnosis & Treatment of Respiratory Failure, National IB & Lung Diseases Research Institute, Warsaw, Poland

Brain natriuretic peptide (BNP) is a hormone secreted by the ventricles in response to heart overload. The aim of this study was to assess prevalence of elevated NT-proBNP (inactive form of BNP) level in OSA patients and its relations to echocardiographic parameters and OSA-associated cardiovascular complications. We studied 87 OSA pts, mean AHI was 43±2.1, age - 57.5±10 years, mean plasma NT-proBNP level was 198.5±37.3 pg/ml. Elevated NT-proBNP concentration was found in 34 pts with OSA. Comparison of OSA pts with normal and elevated NT-proBNP level is shown in the table below:

Elevated NT-proBNP level was found in 39.8% OSA subjects. Logistic regression
