470. Smoking tobacco: from second hand to earthquake

4510. Role of genetic factors on smoking habits and secondhand smoke sensitivity: A twin study
Adam Domanouk Tornik1, 2, David Laszlo Tornik1, 2, Zsofia Lazar2, 3, Kungo Karlinge2, 3, Andrea Agnes Molnar1, 2, Zsofi Garami2, 3, Viktor Beczi3, 4, Ilidiko Horvath4. 1Department of Radiology and Oncotherapy, Semmelweis University, Budapest, Hungary; 2Department of Pulmonology, Semmelweis University, Budapest, Hungary; 3Research Group for Immunology and Immunogenetics, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; 4DeBakey Heart and Vascular Center, The Methodist Hospital, Houston, TX, United States

Introduction: The role of genetic factors on nicotine dependence, withdrawal and quitting is well understood; however no information is available on secondhand smoke (SHS) exposure sensitivity. Our aim was to assess SHS exposures, smoking habits and characteristics, smoking regulations at home, during driving and at workplace of monozygotic (MZ) and dizygotic (DZ) twins, and the contribution of genetic factors to SHS sensitivity.

Methods: 161 Hungarian and 50 American adult twin pairs (151 MZ and 62 DZ; mean age 44±17 years; standard deviation/SD) were recruited in this classical twin study.

Results: The overall rate of current, ex and never smokers was 14.6%, 16.4% and 69.2%. MZ twins reported higher rate of everyday and regular smoking for at least one year (p<0.05). 88% of MZ twins were both ex or current smokers, while the number was 70% in DZ twins (p<0.01). Significantly higher concordance was found in the disturbing effect of secondhand smoke in MZ versus DZ pairs (58% vs 94% versus 39 to 79%, p<0.05 to p<0.005) on a self-reported smoke pollution scale between 1-7. Significantly smaller difference was observed in self-reported smoke pollution rate in MZ twins compared to DZ pairs concerning the resting cafes and cafeterias (1.2±1.3 vs 1.8±1.5, p<0.05) which was not present regarding restaurants and cafeterias and transportation facilities.

Conclusions: In conclusion, this study estimated a genetic influence on smoking habits and secondhand smoke sensitivity especially in smoke pollution rate of restaurants and cafeterias.

4512. The effect of passive smoking on body height, body weight, peak expiratory flow rate and motor skills in children
Ivan Pavic1, 2, Pero Pavic1, 2, Slavica Dodig3, Jasna Cepin-Bogovic1, 2, Marinka Krnek1, 2. 1Pulmonology Department, University Hospital “Sestre Milosrdnice”, Children’s Hospital, Zagreb, Croatia; 2Elementary School, Elementary School Trilj, Trilj, Croatia; 3Laboratory Department, Srebrenjak Children’s Hospital, Zagreb, Croatia

Passive smoking is strongly linked to a range of adverse child health outcome. The objectives of the present study were to assess: 1) proportion of school children passively exposed to cigarette smoke; 2) the impact of passive smoking on body height and body weight; 3) the influence of passive smoking on peak expiratory flow rate (PEFR); and 4) on the motor skills in school children. This prospective study included 133 children, 66 males and 67 females, aged from 11 to 14 years. Subjects were divided in two groups depending on parental smoking habits: Group I - children of smoking parents who smoke 10 or more cigarettes per day (88/133=66%) and Group II - children of non-smoking parents (45/133=34%). For the assessment of motor skills 6-minute run test (F-6 test) was used. 88/133 (66.6%) children have been exposed to passive smoking, while 45/133 (34.2%) children came from families of non-smoking parents. There was no statistically significant difference in either height or in weight. The PEFR (L/min) values for Group I were statistically lower [320 (300-370)] than in control group of children [380 (347-405) (P=0.0001). The median F-6 test values for Group I were statistically lower [2 (1-3)] than in control group of children [4 (3-5), respectively (P=0.0001). Children of smoking parents have statistically significant lower grade of motor skills and statistically significant lower PEFR value than children of non-smoking parents. Public health preventive actions should go toward minimizing the exposure of children to passive smoking by counseling the smoking parents that quitting smoking provides enormous health benefits not only to them but also to their children.

4513. Assessment of alveolar clearance with technetium-99m-DTPA radio-aerosol in patients who are active, passive and former smokers: preliminary study
Yavuz Selim Intepe1, 2, Sermin Boerekci2, 3, Aysel Avci1, 2, Serap Erdem1, 2. 1Department of Pulmonology, Depatment of Immunogenomics, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; 2Department of Pulmonology, University Cerrahpasa, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Objective: Smoking is the most important risk factor for pathological changes such as increased inflammation of lungs, fibrosis of airway wall and destruction of alveolar barriers. Recent studies show strong relationship between passive smoking and pulmonary diseases. In our study we investigate alveolar clearance levels in active-passive and former smokers with technetium-99m-DTPA radioaerosol inhalation scintigraphy.

Methods: 82 patients with smoking related complaints to chest disease clinic were taken in study. 52% (63.5) were female and 30% (36.5) were male. Mean age was 51.3±13. Patients were divided into three groups as active smokers and passive. Patients who never smoked and did not expose to passive were accepted as control group. Also patients were divided into subgroups as copd, asthma and healthy control group smokers (7517), nonsmokers 145 (34% and passive were 20 (41%). Mucociliary clearance were evaluated with parameters of T1/2, cap value vs penetration index.

Results: A significant difference was stated in healthy group between smokers and passive (p<0.05) and between smokers and nonsmokers (p<0.04). Also a significant difference was determined in patients of copd and asthma in terms of T1/2 ve cap values between smokers with passive (p<0.04) and former smokers (p=0.02). There was no significant difference between former and passive smokers.

Conclusion: Our study shows that smoking disrupt alveolo-capillar membrane function and increase mucusillar clearnace. In the presence of comorbid dis- eases only active smoking increases clearance. There is also increased clearance in passive smokers compared with nonsmokers.

4514. The relationship between pulmonary function tests and gender among smokers with no respiratory symptoms
Germir Bozoglu1, Berna Duman, Umut Sema, Muselil Benan. Pulmonology Department, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Aim: In some studies, it is shown that there is declines in pulmonary function test due to cigarette consumption. In this study we aimed to investigate the relationship between respiratory function test, cigarette consumption (packet-year) and gender in smoking smokers with no respiratory symptoms.

Methods: Total of 197 files of patients who admit to smoking cessation clinic were evaluated between March 2011-January 2012. 86 cases who have no respiratory complaints were enrolled in this study. Statistical analysis were done by using SPSS 15.0 statistical program. The mean cigarette consumption and pulmonary function test values (FVCVL), FEV1(L1/sn), FEV1/FVC, PEF (L/sec), MEF 5-75 of male and female sex were compared.

Results: 122 patients (42.6% were female, 64 patients (57.4%) were male. Mean age of female was 38.5 ± 9.7, male was 38.3 ± 11.4. The mean cigarette consumption; 26.1 ± 17 packet-year for men, 19.1 ± 16 packet-year for female. There was no statistical difference between female and male according to cigarette consumption and age (p>0.05). The mean values of respiratory functions were: FVC=4702 ml (%102), FEV1=3650 mL/1 (sn (%95), FEV1/FVC%=77, FEV1=8508 mL/sec (%93), MEF 5-75=330 (764%). The mean values of respiratory function test of female patients were: FVC=3286 mL/1 (sn (%94), FEV1=2207 mL/sec (%94), FEV1/FVC=79, PEF=6175 mL/sec (%93), MEF 5-75=2650 (569%). The relationship between pulmonary function test values and gender was not statistically meaningful (p>0.05). Among female, the mean % values of MEF 5-75 were lower than the normal range that shows effected small airways.

Conclusion: Damage to small airways due to smoking begins earlier periods among women.

4515. Health-related effects of smoking on patients with bronchial asthma participating in a disease management program. Results from the DMP asthma in the north Rhine Region, Germany
Anne Weber, Sabine Gross, Bernd Hagen, Jens Kreutschmann, Lutz Altenhofen. DMP Project Office, Central Research Institute of Ambulatory Health Care in Germany, Cologne, Germany

Background and objective: Asthma is one of the most common chronic disorders. In Germany in 2006 a disease management program (DMP) for asthma started, focussing on patient education, standardised documentation and optimisation of quality of care. Smoking is known as a negative risk factor on pathogenesis for asthma. We want to check whether there is also an effect of smoking on selected outcome parameters.

Methods and population: In 2010 there were 85.586 patients and 4.166 physicians, who participated. We conducted descriptive cross-sectional analyses and a logistic regression for all DMP participants. We used standardised medical records providing information on pharmacotherapy, frequency of symptoms and non-medical interventions. A three-step scale has been developed, which is based on different parameters (e.g. Peak Flow Value).

Results: Smokers have a three times lower chance to avoid asthma-related emergency department visits (OR 0.32, CI 95%: 0.11-0.80). Further they suffer more often from daily symptoms (17 vs. 12%) and show less current absence of asthma symptoms (31 vs. 25%). The severity scale show that smokers suffer more often from more severe asthma (Group 1 15%, Group 2 18%, Group 3: 24%). Hence smokers get more often controller medication than non-smokers (67 vs. 64%).

Conclusions: There were worse results for smokers relating health-related parameters, e.g. they suffer more often on asthma symptoms. Therefore efforts on smoke prevention for asthma patients need further improvement. Limitations due to potential selection bias in the DMP population have to be considered.

Earthquake rattled Christchurch residents reach for cigarettes
Lutz Beckert 1, Nic Erekson 1, Bronwen Rhodes 1, Sue Stevenson 1, Veren Dalerdy 2, Department of Medicine, University of Otago, Christchurch, New Zealand; 2Respiratory Medicine, Canterbury District Health Board, Christchurch, New Zealand 

The magnitude 7.1 Canterbury earthquake in September 2010 and associated aftershocks have caused untold damage, drastically changed residents’ living, working, social conditions and taken the lives of 184 people. 

Aim: To assess the impact of the Christchurch earthquakes on changes in smoking status and tobacco consumption of current smokers. 

Methods: Semi-structured interviews in public locations with high pedestrian flow, including two city malls and the central bus exchange. The interviews were carried out 15 months after the first major earthquake. A total of 1001 people were interviewed. 

Results: At the August 2010 point (prior to any earthquakes) 589 (58.9%) had smoked cigarettes or tobacco at some point in their lives; 400 (40.9%) never smoked and three participants (0.3%) were not sure. Of the 319 people who were not smoking in August 2010, 76 (23.8%) had smoked at least one cigarette since the September earthquake. 29 (38.2%) of whom had smoked more than 100 cigarettes. Of the 273 participants smoking in August 2010, 86 (31.5%) had since decreased consumption, 94 (34.4%) had not changed, deletion and 93 (34.1%) increased consumption. Of the 86 people who decreased, six (7.0%) attributed the earthquake and subsequent lifestyle as a reason to reduce smoking. Of the 93 people who increased, 53 (57.0%) attributed the earthquake and subsequent lifestyle changes as a reason to increase smoking. 

Conclusion: The prevalence of smoking in Christchurch has increased in the 15 months following the first major quake in Sept 2010. 28% of people not smoking prior to the earthquakes smoked one or more cigarettes and people smoking prior to the earthquakes increased their consumption.

Eyjafjallajökull 2010: Respiratory morbidity and symptoms following exposure to a volcanic eruption
Hanne Krae Curlein 1, 2, Arna Hauksdottir 1, Unnur Anna Valdimarsdottir 1, Ragnar Gudrun Finnbjornsdottir 1, Gufrun Petursdottir 1, Thorarin Glisason 1, 3, Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland; 1, 2Occupational and Environmental Medicine, University of Iceland, Reykjavik, Iceland; 3Occupational and Environmental Medicine, University, Umeå, Sweden; 4Institute for Sustainability Studies, University of Iceland, Reykjavik, Iceland; 5Respiratory Medicine and Sleep, Landstúlku University Hospital, Reykjavik, Iceland; 6Faculty of Medicine of Iceland, University, Reykjavik, Iceland 

Background: The eruption of Eyjafjallajökull, Iceland 2010 posed an opportunity to study health effects of a volcanic eruption in a society with strong infrastructure. 

The aim of the study was to evaluate the health of the exposed population compared to control population. 

Methods: Six months after the eruption, (fall and winter 2010-11), 1148 exposed South Icelanders and 510 unexposed North Icelanders responded to a questionnaire on recent physical symptoms and questions from the European Community Respiratory Health questionnaire. The data was analyzed using logistic regression adjusted for age, gender, education and smoking status. 

Results: Demographic characteristics and underlying disease rates were similar in the two groups. The exposed group reported more symptoms during the last 4516 Intervention study to evaluate effectiveness of integrated therapy (varenicline plus motivational interviewing) for smoking cessation in diabetic patients
Pasquale Caponetto 1, Biomedical Clinical e Molecular, University of Catania, Italy 

Background: The prevalence of smoking among people with diabetes is similar to that in the general population. For smokers with diabetes, however, the complications incurred are not equal. 

All-cause mortality is increased in smokers with diabetes, and the risk of macro and microvascular complications is also increased (1). 

Aim and objectives: We designed a study to monitor possible modifications in the smoking habits of 40 regular diabetic smokers experimenting and Integrated Therapy (Varenicline plus Motivational Interviewing) focusing on smoking reduction and smoking abstinence. 

Methods: Study participants were invited to attend a total of five study visits: at baseline, week-4, week-8, week-12 and week-24. Number of cigarettes smoked and exhaled carbon monoxide levels were measured at each visit. Smoking reduction and abstinence rates were calculated. Adverse events a were also reviewed. 

Results: Sustained 50% reduction in the number of cigarettes at week-24 was observed in 45% of participants. Sustained smoking abstinence at week-24 was observed in 40% of participants. 

Conclusion: The use of Integrated Therapy (Varenicline plus Motivational Interviewing) improve smoking cessation and reduction s in diabetic smokers intending to quit. 

Conclusions: The results are consistent with our earlier report over the first 1.5 years of life (Karvonen et al. 2009). The results support earlier conclusions that moisture damage not only increases the risk of respiratory symptoms, but is also associated with increased risk of developing new asthma.

4521
Home dampness and mould, β(1,3)-D-glucan in mattress dust and respiratory symptoms in adults from 10 European countries
Jan-Paul Zick 1, Gert Mecklenburg 2, Dan Norback 2, Marco Braggion 2, Maria Alm 3, Simonia Villani 4, Ole Wiklund 4, Lars Lind 2.

Methods: D-glucans in mattress dust samples from 973 randomly selected adults from 22 ECHEL study centres in 10 European countries using an enzyme immunoassay. Information on respiratory symptoms, housing characteristics, dampness and mould was obtained by face-to-face interviews and home visits following a common protocol. Study centre explained 28% of the total variance in glucan concentration with geometric means ranging from 0.40 μg/mg in Reykjavik, Iceland to 1.77 μg/mg in Barcelona, Spain. Damp or mould problems in the previous year were reported by 30% of the participants (range 11-50% across centres) and was significantly associated with a 10% higher glucan level when controlling for centre. Mattresses older than 5 years contained on average 20% more glucan than mattresses less than one year old. The presence of a cat or a dog in the home increased 17-24% the glucan concentration. Nasal symptoms in the previous year (overall 38%) were more prevalent when damp or mould was reported (adjusted Odds Ratio (OR) 1.35; 95% CI 1.00-1.82). However, nasal symptoms were not associated with glucan level (OR 1.00 without indications for heterogeneity across centres). Similarly there was no association of asthma-symptom score with mattress glucan level. In conclusion, β(1,3)-D-glucans are ubiquitous in mattress dust from European homes. Although weakly associated with damp and mould problems there was no evidence that mattress levels of β(1,3)-D-glucans were associated with respiratory health in adults.

4522
Exhaled nitrogen oxide (FeNO) and nasal patency in adults in relation to levels of airborne fungal DNA in dwellings in Lund, Sweden
Gunilla Wieslander 1, Guihong Cai 1, Christina Isaxson 2, Anders Gudmundsson 2.

Background: Questionnaire studies have reported associations between indoor moulds and dampness, asthma and rhinitis. We investigated if levels of fungal DNA in dwellings were associated with nasal patency, tear film stability, and levels of five fungal DNA-sequences were analysed by QPCR.

Methods: Study centre explained 28% of the total variance in glucan concentration with geometric means ranging from 0.40 μg/mg in Reykjavik, Iceland to 1.77 μg/mg in Barcelona, Spain. Damp or mould problems in the previous year were reported by 30% of the participants (range 11-50% across centres) and was significantly associated with a 10% higher glucan level when controlling for centre. Mattresses older than 5 years contained on average 20% more glucan than mattresses less than one year old. The presence of a cat or a dog in the home increased 17-24% the glucan concentration. Nasal symptoms in the previous year (overall 38%) were more prevalent when damp or mould was reported (adjusted Odds Ratio (OR) 1.35; 95% CI 1.00-1.82). However, nasal symptoms were not associated with glucan level (OR 1.00 without indications for heterogeneity across centres). Similarly there was no association of asthma-symptom score with mattress glucan level. In conclusion, β(1,3)-D-glucans are ubiquitous in mattress dust from European homes. Although weakly associated with damp and mould problems there was no evidence that mattress levels of β(1,3)-D-glucans were associated with respiratory health in adults.

Lung function decline in elderly in relation to phthalate metabolites and bisphenol A levels in serum: A 5-year prospective study
Dan Norback 1, P. Monica Lind 1, Gunilla Wieslander 1, Lars Lind 1.

Methods: PIHUS is a cohort, based on a population sample of subjects, aged 70 years in Uppsala, Sweden. Circulating levels of BPA and phthalate metabolites in serum was measured at baseline by LC/MS/MS. Lung function was measured at baseline and after 5 years in 668 subjects. Change of forced expiratory volume in 1 s (FEV1) was calculated. Associations were analysed by multivariate modelling adjusting for height, smoking at 70 and 75 y, pack years of tobacco at 70 y, education level, exercise habits and gender, using ln transformed values for circulating levels, excluding 36 subjects with asthma or COPD at baseline.

Results: BPA median level was 3.75 ng/mL, Monohexyl hexyl phthalate (MEHP) 4.51 ng/mL, monobutyl phthalate (MEHP) 11.6 ng/mL, Monoisobutyl phthalate (MBP) 3.5 ng/mL, and Monoethyl phthalate (MEHP) 1.51 ng/mL, with no gender differences. The annual decline in FEV1 was -55.6 ml/year. MEHP was associated with an additional improvement in FEV1 of 6.6 ml/year (95% CI 3.2 to 9.8) (p=0.001). The association for MEHP was significant in both men and women, while the association for MMP was significant in women only. Discussion: Associations between circulating levels of some phthalates metabolites and the five year decline of FEV1 were found, with MEHP as a risk factor for lung function decline.

4524
Measuring concern about pollution in questionnaire-based environmental surveys
Alessandro Marcon 1,1, Giang Nguyen 1, Marco Braggioni 2, Marta Rava 1, Maria Elisabetta Zanolin 1.

Background: Some recent studies report associations between phthalate exposure and asthma in pre-school children. We investigated if circulating levels of phthalates and bisphenol A (BPA) predicts lung function decline in an elderly population.

Methods: PIHUS is a cohort, based on a population sample of subjects, aged 70 years in Uppsala, Sweden. Circulating levels of BPA and phthalate metabolites in serum was measured at baseline by LC/MS/MS. Lung function was measured at baseline and after 5 years in 668 subjects. Change of forced expiratory volume in 1 s (FEV1) was calculated. Associations were analysed by multivariate modelling adjusting for height, smoking at 70 and 75 y, pack years of tobacco at 70 y, education level, exercise habits and gender, using ln transformed values for circulating levels, excluding 36 subjects with asthma or COPD at baseline.

Results: BPA median level was 3.75 ng/mL, Monohexyl hexyl phthalate (MEHP) 4.51 ng/mL, monobutyl phthalate (MEHP) 11.6 ng/mL, Monoisobutyl phthalate (MBP) 3.5 ng/mL, and Monoethyl phthalate (MEHP) 1.51 ng/mL, with no gender differences. The annual decline in FEV1 was -55.6 ml/year. MEHP was associated with an additional improvement in FEV1 of 6.6 ml/year (95% CI 3.2 to 9.8) (p=0.001). The association for MEHP was significant in both men and women, while the association for MMP was significant in women only. Discussion: Associations between circulating levels of some phthalates metabolites and the five year decline of FEV1 were found, with MEHP as a risk factor for lung function decline.

Abstract printing supported by Chiesi Visit Chiesi at Stand B2.10
traffic, lack of public parks, air pollution, indoor cigarette smoke and chemicals in food. Answers were coded as 0 (don't know/not at all), 1 (a little), 2 (quite a lot), 3 (a lot). Explanatory factor analysis (EFA) and homogeneity analysis were performed. A summed score was computed (range 0-18). The association between a 1-unit increase in the score and potential determinants was estimated by relative risks (RRs), obtained by negative binomial regression.

EFA identified one unique factor, explaining 61% of the variance. The homogeneity analysis revealed its good internal reliability (Cronbach’s α = 0.85) and confirmed the equidistance of the item options response. Item mean scores ranged from 2.0±1.0 (EMFs) to 2.8±0.7 (air pollution). Fathers, indoor-smokers, low educated and non-Italian parents reported less concerns (RRs=0.59, 0.68, 0.38, and 0.82, respectively) with respect to referral groups (p<0.001).

Respondents’ characteristics influence their level of EC. The devised score may be useful in future research to control for EC-related confounding.
