49. Sarcoidosis

169 Concentration of sFas in bronchoalveolar lavage fluid of smoking patients with sarcoidosis
Tomasz Urbankowski, Aleksandra Safianowska, Rafal Krenke, Izabela Knyziak-Medrzycka, Joanna Domagala-Kulawik. Department of Internal Medicine, Pneumonology and Allergology, Medical University of Warsaw, Poland

Sarcoidosis (SA) is a multisystem granulomatous disease of unknown etiology. SA is more prevalent among non-smokers. The postulated protective role of smoking on inflammation in SA remains enigmatic. Fas/FasL, system is assumed to participate in the regulation of immune response and granuloma formation in SA. Soluble Fas (sFas) is known to inhibit Fas-induced apoptosis. In previous study we reported an elevated number of Fas positive cells in the bronchoalveolar lavage fluid (BALF) of smoking sarcoidosis patients.

The aim of this study was to find out whether sFas concentration in BALF differs between ever smoking (S) and never smoking (NS) patients with sarcoidosis. We investigated 57 patients with confirmed SA: 36 NS and 21 S. Total and differential cell count in the BALF samples were performed according to standard methods. The sFas concentration was measured by ELISA.

There were significant differences in BALF composition between S and NS patients. The postulated protective role of smoking on inflammation in SA remains enigmatic. Fas/FasL system is assumed to participate in the regulation of immune response and granuloma formation in SA. Soluble Fas (sFas) is known to inhibit Fas-induced apoptosis.

Results: The sFas concentration was lower in the BALF of S patients compared to NS patients. The sFas concentration in active smokers was significantly lower than among NS (65.6 vs 95.5 pg/mL, p<0.01).

Conclusions: This study shows that smoking is associated with a lower sFas concentration in the BALF of sarcoidosis patients. This finding may have implications for the management of sarcoidosis patients who smoke. Further studies are needed to confirm these findings and to explore the mechanisms underlying the association between smoking and sFas concentration in sarcoidosis.

170 Association study of ANXA11-R230C with sarcoidosis

Jorn Bandel1, Zoe Daniil1, Katerina M. Antoniou2, Antigoni Mamara2, Kotsovi Malti1, Konstantinos I. Gougioulakis1, Anastasios E. Germisas2, Mathaios Speletas2, 1 Respiratory Medicine Department, University of Thessaly, Larissa, Greece; 2Laboratory of Immunology and Histocompatibility, University of Thessaly, Larissa, Greece; 3Respiratory Medicine Department, University of Crete, Heraklion, Greece

Introduction: Recently, a genome wide association study demonstrates that the polymorphism ANXA11-R230C (rs1049550) is strongly associated with sarcoidosis, a chronic granulomatous disease (GD) of unknown etiology. Aim: Considering that also other diseases are accompanied by granulomas formation, as observed in 10% of patients with common variable immunodeficiency (CVID), the purpose of this study was to confirm the association of ANXA11-R230C with sarcoidosis and to examine its possible association with GD in CVID.

Methods: DNA was extracted from peripheral blood of 71 patients with sarcoidosis (M/F:24/47, mean age: 52.5 years, range:20-75), 101 normal individuals (M/F:35/66, mean age: 54.1 years, range:19-76), and 19 CVID patients (M/F:7/12, mean age: 28.1 years, range: 2-60), two of which had granulomatous disease (one with familial CVID history including a sister without GD). A PCR-RFLP protocol was designed to detect ANXA11-R230C and statistical analysis was performed using the SPSS software (ver.-10.0).

Results: The difference in the allele frequency of ANXA11-R230C between patients with sarcoidosis and healthy individuals was not marginally reached to be significant (p=0.073). The allele frequency of ANXA11-R230C in CVID patients was 50.0% and no significant difference between patients with and without GD was observed. However, in the family with CVID, the member with GD carried only the R alleles, associated with granulomas formation, while her sister was heterozygous.

Conclusions: The association of ANXA11-R230C with sarcoidosis was not confirmed, while the emerged contribution of this polymorphism in the granulomas formation in CVID needs to be further clarified.

171 HLA-DRB1 allele distributions in Danish sarcoidosis patients. Increased prevalence of HLA-DRB1*15

Nils Milman1, Claus Bo Svensden1,4, Thomas van Oeveren Hansen4, Lars Ryder3, Klaus Richter Larsen3,1. Department of Rheumatology, Rigshospitalet, University of Copenhagen, Copenhagen O, DK, Denmark; 2Center for Genomic Medicine, Rigshospitalet, University of Copenhagen, Copenhagen O, DK, Denmark; 3Department of Clinical Immunology/Tissue Typing Laboratory, Rigshospitalet, University of Copenhagen O, DK, Denmark; 4Department of Microbiological Surveillance and Research, Statens Seruminstitut, Copenhagen S, DK, Denmark; 5Department of Pulmonary Medicine, Bispebjerg Hospital, University of Copenhagen, Denmark

Background: The MHC class II region appears to play an important role in the development and clinical picture of sarcoidosis, probably due to the influence on the immune response against yet unknown antigen(s). A previous HLA-class II study in Danes has shown that HLA-DR3 antigen is associated with a favorable prognosis and HLA-DR6 with susceptibility to sarcoidosis (Dhm et al, Exp Clin Immunogenet 1991;8:227-321).

Subjects and methods: HLA-DRB1 allele classification was performed by PCR in ethnic Danish patients with biopsy-verified sarcoidosis (n=94). Danish blood donors (n=1046) served as controls.

Results: The prevalence of DRB1*01 was lower and the prevalence of DRB1*15 was higher in sarcoidosis patients compared to controls.

Conclusions: There exist no specific biochemical markers of sarcoidosis. Diagnosis relies on histological examination of tissue biopsy specimens in combination with the exclusion of infection with mycobacteria and other causes of the granulomatous response. Due to the paucity of prognostic markers, we suggest that analysis of HLA-DRB1 (and BTNL2 genotype (Milman et al, Clin Respir J 2011;5:105-11)) should be incorporated in the evaluation of sarcoidosis patients.
3. Evaluation of ANXA11 rs1049550 SNP linkage with sarcoidosis susceptibility

**Introduction:**
Sarcoidosis is a systemic inflammatory disorder that may affect any organ of the body. It is not a valid tool to assess the extent of extrapulmonary organ involvement. Whole-body magnetic resonance imaging (MRI) might be a promising modality to detect extrapulmonary disease activity.

**Aim:** To assess the validity of whole-body MRI with regard to extrapulmonary disease activity in patients with sarcoidosis.

**Methods:** Consecutive patients at the Clinic of Respiratory Medicine, University Hospital Basel, Switzerland, with histologically-confirmed sarcoidosis were prospectively included. All patients underwent whole-body MRI. Pulmonary function tests and the extrapulmonary physician organ severity tool (ePOST) were assessed for each patient.

**Results:** In total 52/4 (38%) patients showed findings of probable or possible sarcoidal origin. 52/4 (21%) showed skeletal lesions, 32/13 (13%) had muscular findings and 1/24 (4%) had enhancement of the cauda equina. ePOST score was significantly higher in those 9 patients with abnormal whole-body MRI-findings (17.3) than in those with normal images (10.6). FVC percentage predicted (%) TLC, %F, and DLCO, %F were significantly lower in those patients with abnormal skeletal enhancement compared to those without skeletal abnormalities.

**Conclusions:** Whole-body MRI depicted manifestations of extrapulmonary sarcoidosis in 38% of cases in an unselected patient sample. Abnormal whole-body MRI findings correlated with high ePOST scores, and might thus be a valid tool to assess extrapulmonary disease activity. Abnormal skeletal findings correlated with decreased lung volumes, and might therefore be a marker of total disease activity.

**HLA-DPB1 and chronic sarcoidosis**

Annika Wennerström1, Annette Pietrangelo2, Jagoda Lasota1, Krista Salli1, Marja-Liisa Lokki1, Olof Selroos1,2, Ueli Studler1

**Background:** Beryllium disease and sarcoidosis have clinical similarities. Beryllium exposure together with the HLA-DPB1 alleles containing a glutamic acid at amino position 69 (Glu69) is associated with beryllium sensitization and chronic sarcoidosis.

**Aim:** To determine whether the same genetic variations of HLA-DPB1 that are found in CBD are associated with chronic sarcoidosis.

**Methods:** HLA-DPB1 was determined in 98 Finnish patients with chronic sarcoidosis not resolved within 2 years and in 150 control subjects. The DPB1 alleles were genotyped with sequence specific primers (Olerup SSP™) and haplotypes were formed with MHC class II and class III markers.

**Results:** 17 different DPB1 alleles were observed. The DPB1*04:02 allele was less frequent in the patients (10.2% vs.20.3%; p=0.003, OR=0.45) than controls. A haplotype with DPB1*04:01, one C4A gene and one C4B gene was increased among sarcoidosis patients (30.9 vs. 22.5% p=0.038, OR=1.5). By studying polymorphic amino acid residues of DPB1, we did not detect an association of Glu69, but a DPB1*04:02 specific amino acid variant was detected at the position 71 (Met) suggesting a protective role for chronic sarcoidosis (p=0.004, OR=0.42).

Furthermore, preliminary SNP analyses of HLA class II and III region showed that the SNP associations are independent from DPB1.

**Conclusion:** We confirm and further describe the contributory role of DPB1 with the risk associated for chronic sarcoidosis. Preliminary results suggest that both DRB1 and certain independent markers in the HLA class II and III region increase the risk for chronic sarcoidosis. However, HLA association analyses are complicated by the extensive linkage disequilibrium (LD) across the HLA region.

**Evaluation of ANXA11 rs1049550 SNP linkage with sarcoidosis susceptibility**

António Morais1,2, Bruno Lima3, Sandra Tafuro1, Maria Peixoto1, Helena Alves1, Natalia Melo1, Patricia Mota1, Agostinho Marques1,2, Luis Delagado4,5.

**Introduction:** A recent genome-wide association detected a strong association between Annexin A11 (ANXA11) polymorphisms and sarcoidosis susceptibility. ANXA11 take part in several biological pathways, namely apoptosis and proliferation.

**Aim:** Evaluation of ANXA11 rs1049550 SNP association with sarcoidosis susceptibility in a Portuguese population and after stratification of clinically distinct disease presentations.

**Methods:** A case-control study included 136 unrelated patients (37.7±12.6 years, 58.8% women) and 92 healthy controls (32.3±7.0 years, 62% women). Allele frequencies were compared with Chi-square (or Fisher exact test when appropriate) and genotype frequencies with Chi-square for trend test. Odds ratios (OR) and 95% CIs were calculated as association measures. Samples were genotyped for ANXA11 rs1049550 CT (R230C) polymorphism using real time PCR with TaqMan genotyping assay.

**Results:** The frequency of ANXA11 rs1049550 T allele was significantly lower in sarcoidosis patients (33.1% vs. controls 46.2%, p<0.01, OR=0.58, 95% CIs=0.38-0.86). An OR=0.44 and OR=0.4 for sarcoidosis was obtained respectively, in the carriers of one (genotype ANXA11 CT) and two (genotype: ANXA11 TT) copies of ANXA11 rs1049550 T allele normalised to the CC wild type genotype (p<0.01). When patients with erythema nodosum (EN) were removed, this association persists only in the group without EN. There was no significant difference among radiological Scadding stages.

**Conclusions:** In this population an association between ANXA11 rs1049550 T SNP and protection to sarcoidosis was observed, confirming previous data in populations from different geographic regions, but only in those patients without EN.

175

**Bosentan for sarcoidosis associated pulmonary arterial hypertension (BoSAPH) was effective in advanced parenchymal lung disease**

Robert Baughman1, Daniel Culver2, Francis Cordova3, Maria Padilla4, Kevin Gobson5, Elysse Lower1, Peter Engel1.

**Introduction:** We reported significant improvement in pulmonary artery mean (PAM) and pulmonary vascular resistance (PVR) for those treated with 16 weeks (wks) of bosentan (BOS) versus no change in those treated with placebo (PLA) for sarcoidosis associated pulmonary arterial hypertension (SAPAH).

**Purpose of the study:** To determine whether patients with advanced parenchymal disease were less likely to respond to BOS.

**Methods:** Patients with SAPH confirmed by right heart catheterization (RHC) were randomized 2:1 to receive either BOS or PLA. After 16 wks of therapy, patients underwent repeat RHC. Patients had forced vital capacity (FVC) and Scadding chest x-ray (CXR) stage.

**Results:** Of the 25 patients treated with BOS, 2 stopped study drug before wk 8. At 16 wks, 23 had repeated RHC. Patients were subgrouped into those with FVC≥70% predicted (FVC≥70%) or below 70% (FVC<70%) and those with CXR stage 0–3 (CXR-0-3) versus stage 4 (CXR-4). The table demonstrates the changes in PAM and PVR. There was significant improvement in PAM and PVR for those with FVC<70% but not for those with FVC≥70%. No changes were seen for the PLA group.

**Means±SD, *P<0.05.**

**Conclusion:** After 16 wks of treatment, bosentan therapy was associated with a significant improvement in PAM and PVR. These changes remained significant for patients with an FVC<70% predicted. SAPH patients with advanced parenchymal lung disease may respond to vasodilatory therapy.
