Methods: A six month project, across three acute hospitals was carried out. All patients admitted with a COPD exacerbation, unless contra-indicated were given self management advice and rescue medication. Guidelines for COPD suggests that patients should be given self-management plan and rescue medication.

Results: 491 patients were recruited. 53.3%, 54.6% and 25.2% of patients received a self management plan and rescue medication across the three hospitals respectively, with a mean of 36.5%. Common reasons for not receiving these were language barriers and concordance issues.

Conclusions: Unified self management plans and rescue medications in COPD reduces 30 and 90 readmission rates by 12.1% and 5.7% respectively.

P2904
Clinical phenotypes in patients with concomitant obstructive sleep apnea and chronic obstructive pulmonary disease
Yui Kusumoki1,2, Ryuko Furutani1, Kumiho Hatton1,2, Takashi Motomi1,2, Koutsu Yamada1,2, Akiko Gemma1,2, Kozo Kida1,2.
1Respiratory Care Clinic, Nippon Medical School, Tokyo, Japan; 2Division of Pulmonary Medicine, Infectious Diseases, and Oncology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Rationale: Concomitant obstructive sleep apnea syndrome (OSAS) and COPD (overlap syndrome, OLS) may result in the presentation of different clinical phenotypes of each disease.

Objectives: To examine the clinical phenotypes of COPD in OLS cases.

Methods: We conducted a prospective cohort study including 204 patients recruited in 8 years. All the subjects underwent the examinations: pulmonary function tests; polysomnography (PSG); blood chemistry tests, including a KL-6 test; nutritional assessments; computed tomography (HRCT) to assess emphysema (LAAV%); and 6-minute walk tests (6MWT). Subjects with symptomatic airflow obstruction were classified as COPD patients, and the apnea-hypopnea index (AHI) was calculated for assessing OSAS. We analyzed the association between the variables recorded during the examinations.

Results: The overall cohort included 138 male subjects and 23 female subjects (mean age, 54.8 years). The mean FEV1/FVC ratio, mean body mass index (BMI), and mean AHI were 0.77, 25.3, and 30.3 respectively. The AHI values were as follows: 0.5 (n = 9), 5–15 (n = 36), 15–30 (n = 50), and >30 (n = 66). The subjects were divided into the OLS group (n = 34), OSAS alone group (n = 118), COPD alone group (n = 0), and neither group (n = 9). The mean age, BMI, and AHI in the OLS were 66.4, 24.5, and 34.7, respectively. AHI was significantly associated with BMI in the OSAS alone group. This association was not seen in the OLS group, in which there was a trend that low FEV1% predicted was associated with low AHI and AHI was significantly associated with KL-6 (p = 0.0002).

Conclusions: We concluded that OLS did not affect the clinical phenotypes of OSAS and COPD.

P2905
Costs and effectiveness of a disease management program for chronic obstructive pulmonary disease
Anna Porcu1, Sara Balestracci2, Marta Polletti2, Giglio Mariagilda2,4, FIMMG Progetto MITO1, Andrea Macurzi3, Pier Carlo Rosii1, Maurizio Montaresi1.
1Respiratory Medicine, ASLI Massa e Carrara, Carrara, Italy; 2Internal Medicine, ASLI Massa e Carrara, Carrara, Italy; 3Medical Direction, ASLI Massa e Carrara, Carrara, Italy; 4Primary Care Medicine, ASLI Massa e Carrara, Carrara, Italy

Introduction: The effect of disease management for COPD is not well established.

Objectives: The effect of integrated care intervention (ICI) on hospital admission was examined and a cost analysis was performed.

Methods: 208 COPD patients recruited by general practitioners in Massa-Carrara sanitary district from January 2009 were followed up prospectively. Interventions included individually tailored care plan following GOLD guidelines, educational program on self-management of the disease, treatment supervision during scheduled reviews, home visits and phone contacts by specialised nurses.

Results: Data from the 2-year follow-up were compared with the year prior to its initiation. ICI decreased the frequency of hospitalization and the mean number of hospitalization days in 1-year follow-up period: these results remained stable after 2 years (table 1). The best clinical results were detected in GOLD 2 and 3 stages. Mean daily cost of pulmonary drugs increased (€ 3.1/patient/year vs € 1.3 in the pre-enrolment year), while mean daily cost of hospitalization decreased from € 5.1/patient/year to € 2.2 (p < 0.001).

Table 1

<table>

Data are mean values. *p<0.001 vs 1yr and 2yr follow-up; **p<0.01 vs 2yr follow-up.

Conclusions: The study shows that a standardised ICI based on share-care intervention between primary care and hospital team in COPD patients effectively decreases hospitalizations for exacerbation and total disease costs after 1 year follow-up; these positive results do not change after 2 years.

P2906
Cardioselective beta-blockers are not only safe in patients with COPD, but may also improve the responsibility of FEV1 to beta-agonist: A meta-analysis of randomized controlled double-blind trials
Yinmeng Ni, Guochao Shi. Department of Pulmonary Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Objective: To assess the effect of cardioselective beta-blockers on respiratory function of patients with COPD
Methods: The EMBASE, MEDLINE, and the Cochrane Controlled Trials Register were searched comprehensively to identify all relevant clinical trials in humans published between 1986 and May 2011. Randomized, blinded, controlled trials that studied the effects of cardioselective beta-blockers on the forced expiratory volume in 1 s (FEV1) and responsibility of FEV1 to beta-agonist in patients with COPD were included in the analysis. Outcomes measured were the FEV1 and the change of FEV1 after the use of beta-agonist. Results: Sample size for the cardio-selective beta-blockers was 85 cases, non-selective beta-blockers 46. The results showed that FEV1 declined 0.14L with the use of non-selective beta-blockers (z = 6.78, p < 0.0001), and with the use of cardio-selective beta-blockers declined 0.03L (z = 2.08, p = 0.04). Non-selective beta-blockers decrease the response to beta-agonist of FEV1 by 13.42% (z = 10.68, p < 0.0001). Cardio-selective beta-blockers produced no significant change in response to beta-agonist of FEV1 (z = 0.46, p = 0.65). A sensitivity analysis was performed to evaluate the effect of excluding a trial which had a great weight and the result showed an opposite result of the responsibility of FEV1 to beta-agonist, although not statistically significant. Conclusion: Our meta-analysis suggests that cardioselective beta-blockers is not only safe in patients with COPD, but may also improve the responsibility of FEV1 to beta-agonist.

P2007
Continuance and effects of self-training at home using a bicycle ergometer with long-term oxygen therapy
Yuji Kusumaki1,2, Risuto Wakabayashi1, Kamikko Hattori1,2, Takeo Ishii1,2, Ryuhe Trub1,2, Koichi Imoto1,2, Komichi Yamada1,2, Koushi Tanaka1,2
1Respiratory Department, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain; 2Department of Internal Medicine, Nippon Medical School, Tokyo, Japan
Rationale: Regular exercise is an important therapeutic modality for advanced chronic obstructive pulmonary disease (COPD). However, daily mobility is severely restricted in patients with COPD. Aim: We evaluated whether self-training at home using a bicycle ergometer with oxygen therapy is an effective therapeutic modality for COPD. Methods: We recruited 129 patients with advanced COPD. After an observation period, each patient was given a bicycle ergometer as per the advice of health care professionals. The patients were instructed to use the ergometer for 20 min each in the morning or afternoon, with oxygen therapy (2L/min), and to maintain the maximum pulse rate at <110 beats/min. Before self-training was undertaken, each patient was examined to assess the effects of the training. We compared the data recorded after 6 months of self-training. Results: The subjects were divided into 2 groups: those using a bicycle ergometer (Group E) and those performing usual exercise (Group U). Group E was further divided into 2 groups: those showing good adherence (Group EG) and those showing poor adherence (Group EP). In Group EG, the mean age, BMI, FEV1%, and walking distance covered in 6 minutes were 72.3, 21.3, 0.4, 42.2, and 43.2, respectively, whereas in Group EP these values were 73.8, 21.1, 4.8, 4, and 407, respectively. The walking distance significantly improved in Group EG. Continuance was 51.4%, and the major reasons for discontinuance were lumbago and arthralgia. Conclusions: Self-training using a bicycle ergometer with oxygen therapy might be useful in select subjects.

P2008
COPD: Disease coping styles
Yania Galketskaya1, Dimitry Pushkarev2, Svetlana Ovcharenko1, Beatrice Volet1
1Faculty Therapy No. 1, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; 2Department of Psychosomatic Disorders and Psychosomatic Problems, Mental Health Research Center of RAMS, Moscow, Russian Federation; 3Psychiatry and Psychosomatics FPPov, I.M. Sechenov First Moscow State University, Moscow, Russian Federation
It is generally known that desadaptative coping plays an important role in deterioration of medical patients’ quality of life (QoL). However, rehabilitation of COPD patients in general is performed uniformly, while individual psychological features of the patient remain ignored. Aim: To identify the basic styles of disease coping in COPD patients. Methods: 43 COPD therapeutic inpatients (male n=36; mean age 65.6±10.4 yr.) were included into the study. All patients were examined by a pulmonologist and clinically interviewed by a psychiatrist. Psychometric scales Beck Depression Inventory (BDI), Temperament and Character Inventory (TCI-125) and NEO-Five Factor Inventory (NEO-FFI), SF-36, Index of Cooperation (IC - developed by Moscow Research Institute of Pulmonology) were also used. Results: Three styles of disease coping were identified: maladaptive denial of physical illness (n=21, 48,8%), health anxiety (n=18, 41,8%), and depression (n=4, 9,3%). Maladaptive denial was comorbid with clinically diagnosed dissocial personality disorder (PD) (n=9, 20,9%), low NEO-FFI Agreeableness and Conscientiousness scores, low TCI-125 Self-Directedness score. Health anxiety and depression were often comorbid with histronic PD (n=7, 16,3%), or avoidant PD (n=4, 6,4%). QoL decrease was prominent in health anxiety and depression groups. Maladaptive denial patients showed relatively fair QoL scores (measured by SF-36), had disturbance of social compliance (measured by IC). Discussion: On the assumption of typology described, we propose developing patient-centered rehabilitation programs, according to the individual COPD patient’s coping style: QoL-oriented program for health anxiety/depression patients, and compliance-oriented for maladaptive denial patients.

P2009
Disease management program for COPD patients with frequent exacerbations
A. Marti1, M. Rivera1, G. Bonet1, R. Hervas1, L. Merlos1, J. Ruiz-Manzano1
1Respiratory Department, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain; 2Centro de Atención Especializada Dr.Robert, SAP Badalona-St.Adrú, Badalona, Barcelona, Spain; 3Centro de Atención Especializada Dr.Barruquer, SAP Badalona-St.Adrú, Badalona, Barcelona, Spain
Objectives: To determine if a disease management program focused on early recognition and self-treatment of COPD exacerbations can reduce hospital admissions due to COPD exacerbation. Methods: We included outpatients with stable COPD who had two or more COPD exacerbations in the previous year. Patients attended an individual education session conducted by a specialized respiratory nurse that included general information about COPD, direct observation of inhaler techniques, smoking cessation counselling and encouragement of regular exercise. Subjects were instructed to recognize signs and symptoms of an exacerbation and to begin action plan medications for symptoms that were substantially worse than usual. Each subject received an individualized written medical action plan and the telephone number to contact the case manager. The nurse made monthly phone calls to patients. Scheduled medical visits were made every three months and after exacerbations. Results: 31 patients were included in the program (94% male; mean age 74 SD 7 years; post-bronchodilator FEV1% predicted 39 SD 11; 100% ex-smokers). The average duration of follow-up was 13.5 (5.5) months. During this period of time a mean of 8 DS 4 phone calls and 5 SD 2 medical visits were made. The frequency of hospitalizations and emergency visits for COPD were lower than the previous year before beginning the program (mean 0.26 SD 0.6 vs. 0.97 SD 1.1, p<0.000). The total COPD exacerbations were significantly lower than the previous year (mean 2.35 SD 1.8 vs. 3.61 SD 1.4; P=0.001). Conclusions: A disease management program focused on early recognition and self-treatment of COPD exacerbations can reduce hospital admissions due to COPD exacerbation.

P210
Daytime risk factors of nocturnal hypoxemia in COPD patients unqualified for long-term oxygen therapy
Yui Wang1, Liang Tiao2, Guochao Shi, Huanying Wan, Xiaoting Cai, Haixing Zhu, Pulmonary Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China
Objective: To identify daytime variables that are predictive to nocturnal hypoxemia among COPD patients unqualified for long-term oxygen therapy (LTO). Methods: Forty-eight stable COPD patients with daytime SaO2 ≥95% were enrolled to this study and regarded as patients unqualified for LTO. Patients were divided into 4 groups depending on daytime SaO2: SaO2≥98%, group 1; SaO2≥97%, group 2; SaO2≥96%, group 3; 90%<SaO2<95%, group 4. All patients underwent lung function examinations during daytime. Their nocturnal oxygen saturations were monitored with overnight pulse oximetry (PO). Results: Daytime oxygen saturation was positively correlated with nocturnal mean SaO2 (r=0.79, P<0.0001), while negatively correlated with time spend with saturation below 90% (TB90) (r= -0.75, P<0.0001). No significant relationship was found between lung function parameters and nocturnal SaO2. Patients with daytime oxygen saturation between 90% and 95% were more likely to have lower nocturnal oxygen saturation and longer TB90 (P<0.05). Table 1. Spearman rank correlation coefficient between daytime SaO2 Variables r P value Nocturnal MSaO2 0.79 <0.0001 TB90 -0.75 <0.0001 ODI 0.28 0.0552
Table 2. K-W test and SNK test among different SaO2 levels of COPD patients Variables r2 P value Multiple comparison Nocturnal LSaO2 0.7585 <0.0059 group 1 vs group 4 TB90 0.9115 0.0020 group 1 vs group 4 ODI 0.3640 0.5030 none
Conclusions: Daytime oxygen saturation may effectively predict the occurrence of nocturnal hypoxemia in stable COPD patients unqualified for LTO. To reduce COPD complications and improve prognosis, we suggest a relative indication of LTO for patients with a high oxygen saturation between 90% and 95% and connected with nocturnal hypoxemia.
P2911
Multiple dimensional analysis of arterial blood gas and pulmonary function in patients with COPD
Takami Takahashi1,2, Hidetsugu Ota1,2, Shigeo Muro1,2, Susumu Sato1,2, Yoshihisa Fuseya1,2, Naoya Tanabe1,2, Yuma Hoshino1,2, Emiko Ogawa2,3, Michiaki Mishima1,2.
1Department of Respiratory Medicine, Kyoto University, Kyoto, Japan; 2Health Administration Center, Shiga University of Medical Science, Shiga, Japan

Introduction: Blood gas analysis is very important and often used to evaluate the hypothesis and hypercapnea in chronic obstructive pulmonary disease (COPD) patients, but little attention has been given to the relationship among blood gas analysis, pulmonary function, body composition and symptoms.

Objectives: To identify the predictor of dyspnea, hypoxemia, hypercapnea in COPD patients, we investigated COPD patients cross-sectionally on multidimensional aspects.

Methods: A total of 309 Japanese COPD patients (334 male, age 71 (64-76), with a smoking history of at least 10 pack-years underwent comprehensive measurements, including medical examination, arterial blood gas analysis, pulmonary function tests, and modified Medical Research Council (MMRC) dyspnea scale. Patients with long term oxygen therapy or non-invasive ventilation were excluded. Possible predictors of MMRC, PaO2 and PaCO2 were analyzed with both univariate and multiple regression methods.

Results: All of PaO2, PaCO2, and MMRC associated significantly with age, various pulmonary function, and/or BMI. In addition, multivariate regression analysis of stepwise manner revealed that PaO2 was able to be explained by %FEV1, %Kco, BMI and age (R^2=0.20, p<0.001). PaCO2 could be explained by %FEV1, %FVC, RV/TLC and age (R^2=0.15, p<0.001). Then MMRC could be explained by %FEV1, %Kco, %FVC, %IC, age and PaO2 (R^2=0.14, p<0.001).

Conclusion: We showed that %FEV1, %Kco and age were important to dyspnea and the estimation of blood gas analysis in COPD patients.

316. Treatment of lung cancer

P2912
Synergistic therapy for NSCLC: Additive preclinical efficacy of interleukin-6 inhibitor madindoline A with crizotinib
Haiyan Ge1,2, Songyi Ni3, Xiaorang Feng3,4, Nuo Xu1, Ying Liu3.
1Department of Respiratory Medicine, Saitama Medical University International Medical Center, Saitama, Japan; 2State Key Laboratory of Respiratory Disease, Zhongshan Hospital, Fudan University, Shanghai, China; 3Respiratory Medicine, The Affiliated Hospital of Nantong University, Nantong, China

Backgrounds and aims: Crizotinib has also demonstrated the development of acquired drug resistance. Despite secondary mutation, resistance of crizotinib may also be influenced by tumor microenvironment. Senescent cells display a senescent-associate secretory phenotype (SASP) involving the production of inflammatory cytokines that alter tumor microenvironment. Here, we analyzed the level of IL-6 and its signaling pathway in NSCLC cells and assessed the efficacy of IL-6 inhibitor madindoline A in combination with crizotinib in vivo.

Methods: We detected senescence, SASP, IL-6/STAT3 and PI3K/AKT/mTOR signaling after crizotinib treatment in the presence or absence of madindoline A. In addition, multivariate regression analysis of inflammatory cytokines that alter tumor microenvironment. Senescent cells display a senescent-associate secretory phenotype (SASP) involving the production of inflammatory cytokines that alter tumor microenvironment. Here, we analyzed the level of IL-6 and its signaling pathway in NSCLC cells and assessed the efficacy of IL-6 inhibitor madindoline A in combination with crizotinib in vivo.

Results: Crizotinib induced tumor cellular senescence with senescent characteristics including increased senescence-associated f-actin cytoskeletal activity and high expression SASPs. Depletion of the key IL-6 signaling component STAT3 by clinical practice obtained from 166 pts who were treated with pemetrexed in the 1st line treatment.

Methods: We retrospectively investigated the clinicopathological characteristics of 26 NSCLC patients who had undergone BEV therapy in Saitama Medical University International Medical Center and Saitama Medical University Hospital.

Results: The patients had a median age of 64 years (range, 33 to 72 years), and 19 males and current smokers. Epidermal growth factor receptor gene mutations were found in 6 patients (23%). Combined with BEV, each half of 26 patients received the chemotherapeutic regimen of either carboplatin/paclitaxel or carboplatin/pemetrexed. Objective response rate was 54% and disease control rate was 96%, and median progression free survival and overall survival were 100 days and 202 days, respectively. Adverse events included 4% of arthralgia, 27% of hyperpertension, 8% of lower gastrointestinal bleeding, 19% of nasal bleeding, and 23% of proteinuria. Using Kaplan-Meier survival curves and logrank tests, therapeutically influenced neither progression free survival nor overall survival, whereas longer overall survival was observed in NSCLC patients treated with pemetrexed-containing chemotherapy after failure of BEV.

Conclusion: Therapeutic response to BEV does not predict survival benefit of BEV-treated NSCLC patients. Meanwhile, it may be a novel therapeutic option for NSCLC patients who have failed BEV treatment.

P2914
Improved results after preoperative concurrent chemotherapy and high dose radiation therapy in selected cases with stage III N2 lung cancer
Kallipisi Athanasiadou1, Evangelos Balls2, Nectarios Alexezopoulos2, Dimitris Liounias3, Maria-Kalliopi Konstantinidou1, Iakovos Tod1, Irini Mavromati4, Argini Psevd4, Lucilla Comis5, Despina Violaki5, Dimitra Romougani6, Ion Bellenis1,2,3, Thoracic Surgery, Pulmonology, 1Oncology, 2Anaesthesiology, 3Pathology, General Hospital “Evangelismos”, Athens, Greece

Objective: Optimal management of stage IIIA-N2 non-small cell lung cancer remains controversial. The use of neoadjuvant chemoradiotherapy can present challenges in the perioperative management of patients undergoing lung resection for non-small cell lung cancer. Preoperative chemoradiotherapy may reduce tumor size and lymph node involvement, and can result in significant fibrosis around key anatomic structures, making dissection difficult and hazardous.

Methods: This is a retrospective study of 40 consecutive patients with T3-1 N2 M0 lung cancer who underwent induction chemoradiation before surgical intervention from January 2005 through December 2011. Induction chemotherapy consisted of cisplatin, etoposide, and concurrent radiotherapy to a mean dose of 54.3 Gy. Lung resection was performed within 6 weeks of completion of chemoradiation.

Results: Twenty-five patients were submitted to pneumonectomy, simple or intrapulmonary one, 10 to lobectomies and 5 either to segmentectomies or atypical resection. R0 resection was achieved in 75% of cases. The median perioperative mortality rate was 2.5% (one died in the lobectomy group). No important morbidity was noted and the overall hospital stay ranged from 7 to 14 days.

Conclusion: Chemoradiation before pulmonary resection in carefully selected patients with surgically resectable stage IIA (N2) non-small cell lung cancer can be performed with low mortality and morbidity and might lead to improved overall and disease-free survival.

P2915
Pemetrexed in the first line treatment in non-smell cell lung cancer (NSCLC): A multicentre prospective analysis of data from clinical practise of Czech Republic
Jana Skrickova1,2, Karel Hejduk2,3, Zbynek Bontlick2,3, Milos Pesek2,3, Vitezslav Kolek1,2, Leona Koubkova2,4, Petr Zlatoukal2,4, Frantisek Salajka2,4, Milada Zemanova2,4, Dimka Sixtova1,4, Jaromir Roubec1,4, Helenia Coupkova2,4, 1Department of Respiratory Diseases and TB, University Hospital, Plzen, Czech Republic; 2Department of Respiratory Diseases and TB, University Hospital, Olomouc, Czech Republic; 3Department of Respiratory Diseases and TB, University Hospital Motol, Prague, Czech Republic; 4Department of Respiratory Diseases and TB, University Hospital Bulovka, Prague, Czech Republic; 5Department of Respiratory Diseases and TB, University Hospital, Brno, Czech Republic; 6Department of Respiratory Diseases and TB, Faculty Hospital, Ostrava, Czech Republic; 7Department of Respiratory Diseases and TB, General Hospital Ostrava, Czech Republic; 8Oncology Department, Masaryk Memorial Institute, Brno, Czech Republic

Background: Pemetrexed is a novel multi-targeted antifolate that is used in the treatment of NSCLC. This analysis presented examines data from Czech Republic obtained from 166 pts who were treated with pemetrexed in the 1st line treatment.

Methods: Pts with advanced NSCLC were treated between 12/2008 and 12/2011 in 10 institutions with pemetrexed 500mg/m2 and cisplatin 80 mg/m2 on day 1 every 3 weeks. We evaluated efficacy and toxicity.

Results: From 166 pts were 47% men and 53% women, median age 62 years. Non-smokers were 32.5%, stop-smokers 26.5% and current smokers 41.0%. Pts 0 was in 18.1%, PS 1 in 76.5% and PS 2 in 5.4%. Stage IV had 86.2% pts. Adenocarcinoma was confirmed in 84.9%. CR was confirmed in 1.5%, PR in 26.3%, SD in 41.6%, 21.9% progressed and 8.8% pts were not evaluated. Major toxicities (grade 3-4) were neutropenia in 10.8%, leucopenia in 4.8%, anemia...
in 6.0% and thrombocytopenia in 1.2%, pts, but the therapy was finished due to toxicity only in 6 (4.4%) patients. Median OS (95% CI) was 12.5 months (7.5; 17.5). Probability of one-year survival was 52.2%. PFS (95% CI) was 3.9 (3.4; 4.5) and probability of 6-months PFS was 38.9%. The best OS survival (13.5 months) was in pts with adenocarcinoma. We don’t find the differences between groups of pts according smoking (p=0.532), sex (p = 0.696) and PS (p = 0.131).

Conclusions: The treatment with cisplatin as the first line treatment was well tolerated (only 4.4% of pts finished therapy due to toxicity), with evidence of antitumour activity in adenocarcinomas. The results from clinical practise of Czech Republic are comparable with the results of registration study.

P2916
Non-small cell lung carcinoma-advanced disease (NSCLC-AD): Effectiveness of subsequent therapeutical lines and predictive factors of poor outcome
Lídia Fernandes, Inês Sanches, Catarina Ferreira, Ana Figueiredo, Fernando Barata. Pneumology, Centro Hospitalar Universitário de Coimbra, Hospital Geral, EPE, Coimbra, Portugal.

Five years observational study (2006-2010) of a cohort of patients with NSCLC-AD (1st line monotherapy excluded). Epidemiology, histology, performance status (PS), therapy, response – disease control (DC) or progression (n-DC), progression free survival (PFS) and overall survival (OS) after each therapy were evaluated.

We also tried to assess predictors for DC and OS.

Results: We included 276 patients, 77.9% men, mean age 63.1 years (±10.9), most of them smokers (36.6%) with PS 1 (89.1%). The most frequent histology was adenocarcinoma (59.8%). Metastasis in L, 2 or 3 organs was found in 65.2%, 31.2% and 3.6% of the patients. All patients were initially treated with a platinum-based duplet; Pemetrexed or Erlotinib or Erlotinib in 2nd-line setting (53.9% of the patients) and Erlotinib in 3rd (15.6% of the patients). There was a progressive reduction of the DC rate along the 3 lines: 71.7%, 67.1% and 51.2%

The median PFS and OS for each line were: 1st: 4.53M ± 0.54, 2nd: 2.89M ± 0.21 and 1st 9.1M ± 0.66, 3rd: 4.47M ± 0.68 and 10.42M ± 3.35. Prognostic factors were: smoking status (HR 1.54, p-value 0.016), the presence of metastasis≥1 organ (HR 1.50, p-value 0.003), PS2 (HR 3.62, p-value<0.001) and n-DC after 1st line (HR 2.71, p-value<0.001). The presence of DC after each line did not predict subsequent DC (p-value 0.05), but the PFS after 1st line correlates with the following PFS (p-value 0.001).

Conclusions: There is an increase in OS and PFS in the 3rd line, probably reflecting the influence of new biological treatments. Strong predictors for a poor outcome were PS 2 and n-DC after 1st line.

P2917
Prevalence and effectiveness of third-line therapy for advanced non-small cell lung cancer (A-NSCLC)
Catarina Ferreira, Lídia Fernandes, Ana Figueiredo, Fernando Barata. Pneumology, Department, Hospital Geral, Centro Hospitalar e Universitário de Coimbra, Portugal.

Background: Systemic chemotheraphy is the main option for A-NSCLC. Few patients receive third-line therapy and in this setting little is known about outcomes.

Objectives: Evaluate demographics, histology, performance status (PS), sites of metastases, toxicity, response (DC or progression), progression-free survival (PFS) and overall survival (OS) in patients with A-NSCLC treated with third-line therapy.

Methods: We reviewed 5 years of clinical practice (Jan 2006 - Dec 2010): 676 patients with A-NSCLC were diagnosed and 330 received systemic chemotherapy. Of these, 44 completed 3 lines.

Results: 73% male, mean age 61.8y (±9.4). Smoking status: 36% non-smokers, 36% former-smokers and 28% active smokers. Histology: 66% adenocarcinoma, 27% squamous cell carcinomas, 5% large cell carcinomas and 2% NSCLC-NOS. Initially all patients had PS 0-1. Main sites of metastases: lung (80%) and bone (43%), with 34% of patients with ≥ 2 metastatic foci. First-line platinum-based duplet: 50% achieved an objective response, 30% had stable disease, PFS 6.4M. Second-line setting (docetaxel/pemetrexed/erlotinib): partial response (PR) 30%, stable disease (SD) 52%, PFS 5.4M. Third-line (erlotinib/pemetrexed): PR 14%, SD 36%, PFS 4.2M. Hematological toxicity: 18% in 1st-line, 16% in 2nd-line and 7% in 3rd-line. None of the hematological toxicities was 16% in 1st-line, 20% in 2nd-line and 14% in 3rd-line. OS was 24.05M.

Conclusions: Third-line therapy was used in 6.5% of the patients. 1st-line platinum-based chemotherapy with new-generation agents like pemetrexed and erlotinib in the subsequent lines had good efficacy with less toxicity and strongly contributed to the 24 months in overall survival in our patients.

P2918
A study on chemotherapy induced intestinal lung disease in patients with unresectable non-small cell lung cancer complicated by combined pulmonary fibrosis and emphysema
Masato Morita, Ryosei Ito, Koichiro Hashimoto, Akira Yamashiki, Tadashi Igishi, Eiji Shimizu. Pneumology, 1st Internal Medicine Department, General and Chest Diseases Hospital, Brabois, Nancy, France; 2Pharmacy, CHU Brabois, Nancy, France; 3Public Health, CHU Brabois, Nancy, France.

Chemotherapy-induced anemia is a frequent complication of LC Platinum-based chemotherapies (CT) particularly impair erythropoietin production. One option for the management of this anemia is the administration of recombinant human erythropoietin (RHE) which stimulates red blood cell (RBC) formation.

We compared the efficacy and safety of two types of RHE: epoetin alpha (Eprex) and epoetin beta (NeoRecombin) in anemic patients with LC. Thirty eight patients (mean age 62.1 years, receiving CT for a LC (stage III and IV) with anemia (hemoglobin level ≤11g/dl) were included: 19 patients in group 1 treated by Eprex 4000IU/week and 19 patients in group 2 treated by NeoRecombin 3000IU/week for 6 weeks. A hematopoietic response was defined as an increase in hemoglobin concentration ≥2g/dl or hemoglobin (Hb) concentration ≥12g/dl in the absence of the RBC transfusion. The mean Hb levels at baseline were identical: 10 g/dl in group 1 and 9.8 g/dl in group 2. Each group was divided into two subgroups (transfused and non-transfused). 15.8% of patients in the first group required a RBC transfusion versus 36.8% in the second group (p=0.26). The mean changes in hemoglobin level during treatment in non-transfused patients were 0.83 g/dl for group 1 (p=0.003) and 0.31 g/dl for group 2 (p=0.13) without statistical difference among groups (p=0.08). While 12.5% patients in group 1 had a significant hematopoietic response, none was observed in group 2. Two patients in group 2 developed thrombotic events.

The tested erythropoietic agents increased the Hb level in anemic patients with LC. In our study epoetin alpha was better in terms of efficacy and safety than epoetin beta.

Docetaxel-related peripheral neuropathy is a dose-dependent event; a retrospective study in a Greek population with NSCLC
Alexandros Kavvadias1, Ioannis Gkiouzos1, Panagiotis Boulas1, Georgios Tooikas1, Konstantinos Syrgos1, 4th Respiratory Department, General and Chest Diseases Hospital “Sotiria”, Athens, Greece; 2Oncology Unit, 3rd Internal Medicine Department, General and Chest Diseases Hospital “Sotiria”, Athens, Greece.

Introduction: Neurotoxicity is the most important non-hematologic toxicity of taxanes. It presents as peripheral neuropathy with tingling, numbness and pain with a “glove and stocking” distribution and influences the daily activities of patients treated with taxanes.

Aim: To record peripheral neuropathy in relation with the dosage of docetaxel in NSCLC.

Method: We retrospectively studied 700 consecutive files of patients from the archive of the oncology unit of our institution in treatment from December 2006 until May 2008. Election criteria includes patients with NSCLC, PS 0-2, any stage, treated with docetaxel in any combination. We evaluated peripheral neuropathy with CTCAEv3.0

Results: We found 105 patients,84 males(80%),21 females(20%), median age 62.94(9.29, smokers 95(90.5%), median dose of docetaxel 74.4(52.7,78.8)mg/m², median aggregate dose 427.13(282.9, dose intensity 32.63(5.88mg/m²/week, median treatment duration 12.6±7.9weeks. Peripheral neuropathy presented in 28 (26.7%) patients, mild or moderate severity, mainly sensory neuropathy in 75%, after 2.64(1.18 cycles. The group of patients who received docetaxel ≥ 80mg/m² presented neuropathy at 37.5% versus 21%(p=0.09). The group with dose intensity ≥37.5mg/m²/week presented neuropathy at 47.1% versus 16%(p=0.001). In the group of aggregate load dose ≥600 mg, 51.6% presented neuropathy versus 16% with <600 mg(p=0.0001). Neurotoxicity was a reversible adverse event in 25 of 28 patients.

Conclusion: Peripheral neuropathy is a dose-dependent adverse event that increases with the accumulation and the dose intensity of docetaxel. Symptoms usually resolve after treatment or by decreasing the dosage.
Tumor-infiltrating lymphocytes (TIL) were isolated from tumor tissue by culturing in 1 out of 6 patients, XAGE-1b induced proliferation in LN XAGE and IFN-γ release in LN XAGE and TIL. In another patient, XAGE-1b induced proliferation (PBMC and LN nsg, but no IFN-γ release). In 3 out of 6 patients, a p53-induced proliferation was observed in LN p53, which was accompanied by IFN-γ release in 2 patients. In one patient, p53 induced TNF-α release in TIL. These preliminary data show T-cell immunity to XAGE-1b and p53 in lung adenocarcinoma indicating that these antigens are potential targets for immunotherapy. More patients are needed to define strength, breadth and phenotype of this antigen-specific response and its relation with antigen expression in the primary tumor.

Elderly lung cancer patients profit from radical mediastinal lymphadenectomy? Kalliopi Athanassiadi1, Vassiliki Karamen2, Irini Mavromiti3, Ilia Samiotis3, Maria-Kalliopi Konstantinoudou1, Despina Viotidak1, Dimitra Riga2, Dimitris Lioumpas1, Dimitris Roudou2, Ion Hellenis1, 2Thoracic Surgery, General Hospital “Evangelismos”, Athens, Greece; 3Anaesthesiology, General Hospital “Evangelismos”, Athens, Greece; 4Pathology, General Hospital “Evangelismos”, Athens, Greece

Objective: The therapeutic impact of a radical mediastinal lymphadenectomy (RLA) associated with a pulmonary resection for lung cancer remains controversial. Our objective is to investigate the impact of radical lymphadenectomy on overall survival compared to the overall survival for elderly lung cancer patients and assess whether the non-performance of an RLA could be justified in the surgical treatment for this group.

Material: We analysed the records of 60 patients aged 75 years and older (41 males, 19 females) who underwent surgery for non-small-cell lung cancer. They were divided into two groups, according to the performance of a radical mediastinal lymphadenectomy, the radical systematic lymphadenectomy (RLA Group, n=36) and the Sampling (SLN group, n=24) groups. A Cox proportional hazards model and the Kaplan-Meier method were used for the survival analyses.

Results: RLAs had no protective effect on mortality; the hazard ratio for the RLA group in comparison to the SLN group was 0.93 in the multivariate analysis. The 3-year survival for the SLN group, was marginally better than that of the RLA group. There was no significant difference in the overall survival between the two groups (p=0.05).

Conclusions: There was no survival benefit for the Radical Mediastinectomy. Although in some reports a significant mediastinal lymphadenectomy is recommended for correct staging, a pulmonary resection with non-performance of radical lymphadenectomy could be an acceptable surgical treatment for the increasing number of elderly lung cancer patients.

P2925

Lung cancer in Berlin – Therapeutic concepts and their impact on survival in patients with NSCLC stage II/III from 2000 to 2008 Torsten Blinn1, Stephan Egginger1, Christian Gogoll1, Christian Grab1, Günter Schöner1, Christian Greil2, Christian Fischer1, 2Thoracic Surgery, Charité, Berlin, Germany; 3Gastroenterology, Charité, Berlin, Germany

Objectives: To evaluate the effect of changing therapeutic concepts on survival times in patients with newly diagnosed NSCLC stage II/III from 2000 to 2008.

Methods: In this retrospective case study, the pooled data of the TZB of pts. with newly diagnosed lung cancer during 2000 and 2008 were analyzed. Pts. were divided into three 3-year groups (G1: 2000-2002, G2: 2003-5 and G3: 2006-8). Results: The total cohort comprised 14,302 pts. For pts. with NSCLC stage II/III, the proportions of pts. with surgery and adjuv. therapy increased in G2 and G3 (Figure 1, see p. 536s). Kaplan-Meier survival analysis could not demonstrate significant differences between G1 and G2/3 in general, but for pts. with NSCLC stage II and III (Figure 2, see p. 536s).

Conclusions: According to the pooled data of the TZB, the analysis of therapeutic concepts spotted an increase of surgery and adjuv. therapy among pts. with NSCLC stage II/III over time corresponding with an improvement in survival in these groups.
P2926
Treatment modalities in lung cancer patients with brain metastasis
Evrica Bagdlij1, Nikola Budisin2, Nensi Lalic1, Danica Sazdanic1, Aleksandra Andelkovic1.1 Oncology, Institute of Lung Diseases Vojvodina, Novi Sad, Vojvodina, Serbia; 2 Surgery, Institute for Oncology of Vojvodina, Sremska Kamenica, Vojvodina, Serbia

Forty lung cancer patients with diagnosed brain metastasis were evaluated at the Institute of Lung diseases at Sremska Kamenica in the period of three years. Duration of survival in such patients was evaluated and compared according to the treatment employed as well as to the histology, number of metastasis and presence/absence of synchronous or other visceral metastasis. Treatment modalities included: irradiation, surgery, and chemotherapy for chest tumor, and for the brain metastasis, and symptomatic treatment. There were 34 male (85%) and 6 female (15%). 72.5% have had solitary metastases, while 27.5% presented with multiple metastasis. Mean survival was 3.2 months from the diagnosis of brain metastasis (range 0-14 months). Irradiation of thorax underwent 57.5%, chest operation (15%). 72.5% have had solitary metastases, while 27.5% presented with multiple metastasis, and symptomatic treatment. Thirty percent were treated only symptomatically. Sixty percent were without other visceral metastasis. Statistical significance in terms of longer survival was found in patients who had solitary compared to multiple metastases p<0.026, in patients with irradiated brain metastasis p<0.015 and in patients operated for brain metastasis p<0.003.

Although prognosis of patients with lung cancer and brain metastasis is gloomy, our investigation suggests longer survival with employed brain surgery or brain irradiation.

Prodomal face of a study: High dose rate endobronchial brachytherapy (HDREB) as a first step introductory treatment of a multimodality therapy approach in non operable NSCLC with endobronchial obstruction
Konstantina Papalla1, Danai Bisritzoglou2, Vasillis Anastasakos2, Athanasios Zetos2, Charalampos Makletos2, Ioannis Katsiilieris1, Georgios Politis2.1 Third Radiooncology, Anticancer Hospital, Athens, Greece; 2 Pulmonology, Anticancer Hospital, Athens, Greece

Introduction: Lung cancer patients frequently present with advanced stage. HDREB has always been used as a palliative treatment option in end-stage disease, and has not yet been thought of as a first-step therapeutic approach of a multimodality treatment strategy. We strongly feel that HDREB could be the method of choice in carefully selected patients with endobronchial obstruction, prior to other treatments.

Aim: HDREB could be used as a first-step, introductory treatment in selected patients with inoperable obstructive endobronchial carcinoma of the lungs.

Methods: A catheter is placed through bronchoscopy in the obstructed lumen. HDREB is delivered in two sessions separated by one week. Bronchoscopy is performed 3 weeks later. Pulmonary function tests are performed before and after HDREB monthly. Evaluation of quality of life is assessed with Saint Georges Respiratory Questionaire. Obstruction score is also evaluated before and after treatment.

Results: Six patients with previously untreated, inoperable NSCLC associated with endobronchial obstruction, were treated with HDREB as an introductory treatment of a multimodality therapeutic approach. We found significant improve- ment on symptoms (cough, dyspnoea, hemoptysis) and intraluminal reduction of the obstruction.

Conclusions: HDREB is a low-cost, semi-invasive, and well-tolerated method that has been applied with a limited palliative purpose, whilst it could provide an improvement of performance status and partial disease regression early enough, giving the patient the opportunity of a better outcome of treatment, overall.

P2928
Non-small cell lung cancer – Advanced disease: Barriers to inclusion in clinical trials and its impact on survival
Claudia Lamas dos Santos, Lugia Fernandes, Ines Sanches, Filipa Cruz e Costa, Fernando Barata. Pulmonology Department, Centro Hospitalar Universitário de Coimbra, CHC, Coimbra, Portugal

Introduction: Inclusion in clinical trials allows patients to submit to innovative therapies and a meta-analysis showed that this may be associated with increased rates of survival.

Aims: Identify reasons that hindered the inclusion of patients in clinical trials of first-line therapy; Compare overall survival (OS) and progression-free survival (PFS) between groups of included and excluded patients.

Methods: This study was conducted over 36 months in a central hospital. Patients with well defined histology and candidates to chemotherapy were considered eligible for clinical trials. Reasons for non inclusion have been detailed. OS and PFS were compared.

Results: We identified 199 eligible patients, mean age 64.9 ± 10.7 years, 75.9% males, 61.8% with non-squamous cell carcinoma. From these 22.1% were included in trials. Among those not included 18.7% had performance status (Zubrod) 2 and 66.5% had other exclusion criteria, mainly heart disease (22.5%), respiratory disease (21.4%), brain metastases (15, 5%) or second malignancy (15.5%). About 15% of patients refused to be involved in trials. Of patients who had performance status 0/1 (N = 170), there was no statistically significant difference in analysis of OS or PFS between those included in trials and the excluded, whether by criteria (Cox Regression: OS p=0.705/PFS p=0.807) or by refusal (Cox Regression: OS p=0.026, PFS<0.000).

Conclusion: Liberalization of exclusion criteria and recognition of causes that lead to refusal are possible determinants of increased participation in clinical trials. Bibliography: CA Stiller(1994). Centralised treatment, entry to trials and survival. Br J Cancer 70,352-362.

Intratumoral injection of plasmid-encoded flagellin inhibits growth of NSCLC-cells in murine lung cancer model
Marek Jankowski1, Tomasz Wandtke1, Piotr Kopinski1, 1 Gene Therapy, Nikolaus Copernicus University, Bydgoszcz, Poland; 2 Clinical Genetics, Nikolaus Copernicus University, Bydgoszcz, Poland; 3 Genetics, Nikolaus Copernicus University, Torun, Poland

Lack of progress in the treatment of NSCLC urges to look for experimental therapeutic methods, such as gene therapy. Currently used therapeutic vectors can cause adverse effects, or have a limited potential to transduce cells. The aim of this work was 1) to construct a vector suited for gene therapy allowing for selective transduction of only tumor cells 2) to assess therapeutic potential of Salmonella flagellin (FlFC).

Engineered plasmid vector was obtained by PCR synthesis. For the purpose of tumor-specific transcriptional activity it was necessary to design a two-step promoter unit system based on telomerase minimal promoter.

Influence of FlFC on NSCLC cells was assessed by measuring proliferation of transfected cells and by phenotyping of maturation markers on DCs incubated with
A549 cells. NSCLC tumors in mice were injected with empty or FliC-coding vector. Tumor growth and survival of the mice were analyzed. FliC-transfected A549 cells had significantly lower proliferative potential. Such cells enhanced maturation of MφDC as suggested by higher expression of CD80 and CD83. NSCLC-inoculated mice administered with a vector containing FliC gene had a significantly longer survival time (p < 0.002) and slower tumor growth (p < 0.001) compared to the control group. Designed two-step promoter unit allows for efficient and tumor-selective expres- sion of therapeutic gene. Results suggest that NSCLC transduction with FliC gene may inhibit tumor growth in vitro and tumors, FliC (Carefusion, Hochberg, Germany) was attached to the tube of the rigid bronchoscope. IOS was performed in real time during interventional procedures under spontaneous breathing. Resistance at Shs (R5) and 20H (R20) measurements were recorded during inspiration and expiration. The cross-sectional area (CSA) at the narrowest segment was recorded using ziostation (Ziosoft, Tokyo, Japan) before bronchoscopic intervention.

Methods: IOS was performed on 14 patients with tracheal stenosis in the endo- scopic suite between April 2009 and December 2011. After patients were intubated with a rigid bronchoscope (FIMER, La Ciotat, France), IOS (Carefusion, Hochberg, Germany) was attached to the tube of the rigid bronchoscope. IOS was performed in real time during interventional procedures under spontaneous breathing. Resistance at Shs (R5) and 20H (R20) measurements were recorded during inspiration and expiration. R5 on inspiration revealed the strongest correlation with the narrowest segment of the cross-sectional area (r = 0.61, p < 0.05). There was little difference between R5 and R20 during inspiration and expiration.

Conclusion: IOS could evaluate airway narrowing in real time during interven- tional bronchoscopy.

Surgical treatment of descending necrotizing mediastinitis
Arkady Visotskiy1, Denys Stupachenko2, Dmitry Vegner1, Vadim Takhtaulov1, 1Thoracic Surgery, Donetsk Regional Clinical Territorial Medical Association, Donetsk, Ukraine; 2Chair of Surgery, Donetsk National Medical University, Donetsk, Ukraine

Surgical treatment of descending necrotizing mediastinitis remains one of the most complex and unresolved problems in thoracic surgery. High level of mortality (up to 70%) is indicative for its actuality. Material and methods: The study based on an analysis of treatment 158 patients with descending necrotizing mediastinitis of following localization: upper anterior – 45, upper posterior – 28, upper total – 20, total anterior – 20, total posterior – 15, total – 30. Results: Surgical treatment undergone 152 patients (six was not operated and died within two hours after admission). Overall mortality was 37.7%, postoperative - 35.5%. The results of clinical application of new methods of draining of anterior and posterior mediastinum are presented. Conclusions: Surgery method remains the main in the treatment of descending mediastinal necrotizing mediastinitis. The results of treatment can be improved by timely diagnostics, adequate mediastinal draining, adequate homeostasis correction, “open” cervical wound treatment, tracheosthomy only in cases of impossibility of intubation.

A rare case of mediastinal inflammatory myofibroblastic tumor
Gabriel Cozma1, Ovidiu Burlacu1, Konstantinos Kanakakis1, Panagiotis Hountis1, Gabriel Cozma1, Ovidiu Burlacu1, Konstantinos Kanakakis1, Panagiotis Hountis1, Monica Marc2, Voicu Voiculescu3, Calin Tuncu1, Iosif Miron1, Alexandru Nicodin1, 1Thoracic Surgery Clinic, Clinical Municipal Hospital, Timisoara, Timis, Romania; 2Pathology Clinic, Victor Babes Hospital, Timisoara, Timis, Romania

The inflammatory myofibroblastic tumor (IMT) or the inflammatory pseudotumor is a rare benign tumor composed of spindle cells that is known to develop in various locations such as lung, skin, breast, gastrointestinal tract, pancreas, bone, epididymis, peritoneum. Mediastinal localisation of the tumor is very rare. We present the case of a 16 years old female with such pathology. Methods: The patient was admitted into our clinic with a history of pain in the right hemithorax, mild dyspnea and irritative cough. The chest x-ray showed a great ascension of the right hemidiaphragm. Abdominal ultrasound revealed the presence of heterogeneous formations, bulk with liver parenchyma dislocation and fluid collection. The Chest CT examination showed a giant formation in the right hemithorax having hypodense mass effect on the liver, trachea, mediastinum and lung parenchyma. A right posterostral approach was used re- vealing a giant tumoral formation (4/13/12 cm) originating from the mediastinum. Total surgical ablation was performed. Results: The postoperative outcome of the patient was good, with no complications and lung reexpansioning. The hospital stay was 7 days. Immunohistochemistry was positive for desmin, VIM, CD 34, CD 68, Ki67, and was diagnosed with inflammatory myofibroblastic tumor. No tumoral recurrence was noticed at the one year and two year follow-up. Conclusions: The mediastinal inflammatory myofibroblastic tumor is a very rare pathology. It can raise a series of problems, from technical problems related to its location. If total surgical ablation is possible the patients have a favorable outcome.

Mediastinal metastases from non-lymphomatous extra-thoracic tumours. A multicenter series of a rare condition
Emilie Canal1, Pierre-Yves Brichon1, Carlos Pages1, Joaquin Pac2, Alain Rind3, Jean-Michel Moreau1, Jesus Loscertales1, Thoracic Surgery, Hospital Universitari Joan XXIII, Tarragona, Spain; Thoracic Surgery, CHU Michallon, Grenoble, France; Thoracic Surgery, Hospital Universitario Carlos Haya, Malaga, Spain; Thoracic Surgery, Hospital de Cruces, Barakaldo, Spain; Thoracic and Cardiovascular Surgery, Clinique Montreal, Carcassonne, France; Thoracic Surgery, Nouvelles Cliniques Nantaises, Nantes, France; General and Thoracic Surgery, Hospital Virgen Macarena, Sevilla, Spain

Introduction: Most mediastinal metastases are from lung, esophagus or medi- astinum itself. Non-lymphomatous extra-thoracic tumours rarely give place to mediastinal metastases. The purpose of this study was to investigate the way this rare condition is managed and its prognosis.

Materials and methods: Thoracic surgeons from 7 different centers in Spain and France put together their series to perform a retrospective study of this kind of mediastinal metastases.

Results: A total of 16 cases was recorded (11 women and 5 men). Age ranged between 32 and 72 years in women (M=49) and between 31 and 76 in men (M=49). Among women, the primaries were: 4 sarcomas, 3 breast, 2 kidney and 2 ovary. Among men, the primaries were: 2 testicular and 1 melanoma, 1 digestive and 1 feochromocytoma. The time between treatment of the primary tumor and the diag- nosis of mediastinal metastasis was 16 months in breast origin (0-24), 84 months in sarcomas (12-132) and 19 months in kidney cases (14-92). Other metastases were rare, only pulmonary in 3 cases of sarcoma and one case of retroperitoneal metastasis in a testicular case. The mediastinal metastases were treated through thoracotomy in 11 patients (9 right, 2 left), 2 right videothoracoscopies and 3 sternotomies. Survival was of 67 months for the already dead patients and 58 months for the still alive patients.

Conclusions: Mediastinal metastases of non-lymphomatous extra-thoracic tumors are more frequent among women, normally the mediastinal metastasis is solitaire except in sarcomas, and their prognosis is not as bad as expected.

Thymic tumours: Diagnostic and therapeutic approach
Sotiria Moutzou1, Konstantinos Kanakakis2, Panagiotis Hountis3, Ioannis Kikinos4, Andriani Charpioulis1, Konstantinos Syrgos2, 1Thoracic Surgery Department, Naval and Veterans Hospital of Athens, Athens, Greece; 2Oncology Unit, 3rd Dept. of Internal Medicine, University of Athens Medical School, “Sotiria” General and Chest Diseases Hospital, Athens, Greece

Introduction: Thymic tumours represent 0.2-1.5% of all malignancies, with an incidence of 0.15 cases per 100,000 populations. We present our experience in the management of patients (pts) with thymic tumours.

Materials and methods: We evaluated retrospectively the records of 16 consecu- tive pts who underwent thymectomy in our department. All but one pts underwent radical thymectomy, through a median sternotomy. The upper and lower thymic poles were traced and all fatty tissue between the phrenic nerves was resected. Diagnostic procedures included contrast enhanced CT of thorax and/or MRI and in the case of 2 pts, F-18 FDG PET-CT was performed. Malignancy grading was present in 2 pts (12.5%).

Results: There were 8 male and 8 female pts (mean age: 42.8 years). The histopathology revealed 11 thymomas, 1 endocrine carcinoma and 4 hyperplasias. Type A thymomas were found in 2 pts (12.5%), AB in 3 pts (18.75%), B1 in 1 pt (6.25%) and B3 in 3 pts (6.25%), while 4 thymomas (25%) were unclassified. The mean diameter of the resected masses was 8.31 cm. Two pts were classified as Masaoka IIA stage (12.5%) and one as Masaoka IIB (6.25%), who received adjuvant radiotherapy. All the others were classified as Masaoka I. All tumours

5375
were totally resected. The 5 year survival was 100%. There was recurrence of the endocrine carcinoma within 5 years. Conclusions: Tumours of the thymus are a heterogeneous group of tumours, ranging from relatively benign thymomas to highly aggressive carcinomas. Surgery continues to be the mainstay of treatment and complete resection of the tumour remains the most important prognostic factor. A recurrence should be completely resected whenever possible, because this approach is associated with good long-term survival.

P2935 Surgical treatment of superior vena cava syndrome caused by thymic carcinoma
Moshey Hubaty1,2, Victor Sokolov2, Vladimir Timmerbaers3, Evgeniy Tarabin1, Sergey Golovinsky1, Duna Ibragimov1,2, Thiencuoadomaiian Surgery, N.V. Skilhosovks Research Institute of Emergency Medicine, Moscow, Russian Federation, 3Cardiovascular Surgery, Heart Transplantation Group, N.V. Skilhosovks Research Institute of Emergency Medicine, Moscow, Russian Federation, 4Anesthesiology, N.V. Skilhosovks Research Institute of Emergency Medicine, Moscow, Russian Federation

Introduction: Thymoma and thymic carcinoma are a rare disease, but they are the most common tumor of the anterior mediastinum in adults. They are asymptomatic until late. There are some potentially life-threatening manifestations of thymic neoplasms like myasthenia gravis and superior vena cava syndrome. The palliative treatment of the medastinal malignancies have poor prognosis and radical surgical therapy is the only option. Resection and reconstruction of the great medastinal vessels in case of involved are technically challenging.

Materials and methods: We report the case of a 63 year-old Caucasian female patient, who presented superior vena cava syndrome derived from a medastinal neoplasm compromising intrinsically and extrinsically the superior vena cava, right and left brachiocephalic vein. After evaluation the patient underwent radical resection of the tumor on blex with the involved vessels and reconstruction with Y-shaped gore-tex graft. Cardiopulmonary bypass wasn’t used. The histological analysis of the surgical specimen was diagnosed as thimic carcinoma, stage III (Yamakawa-Masaoka staging). The patient was discharged after 25 days of hospitalization without chemotherapy and radiotherapy after the operation. Results: The postoperative observation was conducted for a period of 2 and 6 months. There were no signs of recurrent disease or thrombosis of the prosthetic graft. The patient performed his daily chores without difficulty. Conclusion: Extensive resections of the tumor tissue with involved adjacent organs and vessels are feasible, safe, and improve satisfactory survival in invasive thymomas. Radiation therapy and chemotherapy in case of radical resection are not necessary.

P2936 Cryotherapy plus chemotherapy or radiation offers increased survival and quality of life in advanced stage lung cancer patients with endobronchial obstruction: Analysis of 160 patients treated with the rigid bronchoscope
Christos Chatzimoniakos, Peter Michos, Ioannis Gakidis, Evangelos Sepas,
Athanasios Stamatepoulos, Gerasimos Georgopoulos. General Thoracic Surgery, General Hospital of Attica KAF, Athens, Attiki, Greece; General Thoracic Surgery, Sotiria Chest Disease Hospital, Athens, Attiki, Greece

Objective: The objective of this clinical study is to evaluate the efficacy of Bronchoscopic Cryotherapy plus chemotherapy or radiation therapy of patients with advanced stage lung cancer with endobronchial obstruction.

Methods: 160 lung cancer patients with stage IIIA, IIIB, IV and endobronchial tumor, were included in a protocol of three sessions of rigid bronchoscopical cryotherapy. From 2001-2011 142 men (44-82 yrs old) and 18 women (45-66 yrs old) were treated in our Department. After each cryotherapy one cycle of chemotherapy or radiation therapy followed. Patients age, sex, type of tumor, stage, symptoms of dyspnea, cough, hemoptysis, pain plus lung functional studies, performance status and survival time, were recorded. Follow up was at least two years.

Results: Symptoms of dyspnea, cough, hemoptysis and pain improved significantly in 73%, 68%, 69% and 42% of patients respectively (p<0.001). Lung function improved 15-20%, Fev1 from 1.41±0.5 to 1.9±0.57lt, Fvc from 1.5±0.6 to 2.24±0.7lt after treatment (p<0.05). Performance status increased from 62±5 to 75±3 (Karnofsky scale, p<0.05) and from 3.15±0.9 to 2.3±0.5 (WHO scale, p<0.05).

Survival increased considerably to 6-2 months (mean 16+) for stages IIIA, IIIB (Kaplan-Meier, 95% interval). We had 2(1.25%) in hospital deaths.

Conclusions: Bronchoscopic Cryotherapy is a safe palliative method for inoperable lung cancer with endobronchial obstruction and combined with chemotherapy or radiation offers better survival and increased quality of life.

P2937 The effect of locally applied TGF-BETA3 on wound healing and stenosis development in tracheal surgery
Ayakat Elçioğlu1, Serife Tuba Liman1, Betul Arica Yegin2, Asli Gülgü Akgül1, Hakim Erığlık2, Kursat Yildiz2, Sahih Topçu2, Cüneyt Özer3, 1Thoracic Surgery Department, Kocaeli University, Faculty of Medicine, Kocaeli, Turkey; 2Pathology Department, Kocaeli University, Faculty of Medicine, Kocaeli, Turkey; 3Experimental Research Unit, Kocaeli University, Faculty of Medicine, Kocaeli, Turkey

Introduction: Tracheal stenosis constitutes one of the most frequently seen problems in thoracic surgery. Although many treatment modalities to prevent tracheal stenosis have been attempted, an effective method has not been found yet. In this study, TGF-beta/chitosan combination was used for that purpose.

Material and method: A film shaped slow releasing preparation, which contains TGF-beta3 with basal substance of chitosan was created. Thirty “Westar Albino” rats were divided into 3 groups. Full vertical incision was made in the anterior side of trachea between 2 and 5. tracheal rings. Membranous trachea was preserved. Tracheal incision was sutured. Group A was evaluated as control group. In group B, a chitosan based film substance was placed on the incision line. In group C, a chitosan-TGF-β3 combination slow-release film coated substance was placed on the incision line. The rats were sacrificed on 30th day, the tracheas of the rats were excised by cutting between the lower edge of the thyroid cartilage and the upper edge of the 6th tracheal ring together with oesophagus. Histopathализation, fibroblast proliferation, angiogenesis, inflammation and collagen levels were evaluated histopathologically by the same histopathologist (Figure).

Results: It was not found statistically significant difference between three groups. Cold abscesses were observed at the incision area in both TGF3/chitosan combination and chitosan groups and they were thought to form because of chitosan.

P2938 Use of helium and small size endotracheal tubes for surgery of severe tracheal stenoses (STS)
Sylen Alexen1, Danail Petrov. Anaesthesiology and Intensive Care Clinic, University Hospital of Pulmonary Diseases “St. Sophia”, Sofia, Bulgaria

Thoracic Surgery Clinic, University Hospital of Pulmonary Diseases “St. Sophia”, Sofia, Bulgaria

Heliox improves ventilation by reducing density dependent resistance due to high kinematic viscosity and high diffusivity.

Objective: To present our experience and evaluate feasibility to maintain adequate ventilation using Heliox through small size endotracheal tubes during the initial period of operations for STS until the trachea is divided below the stenosis.

Methods: 4 patients with postintubational STS were intubated spontaneously breathing He-O2 (70/30) after topicalization and light sedation. In 3 of them (high stenoses) we used microlaryngeal tubes; for one (low stenosis) we designed double-size tubes.

Results: Results for the period of Heliox ventilation.

P2939 Technical aspects of mini-invasive transcervically right main bronchus approach
Cristian Pălăru1, Ioan Cordon, Olga Danaila, Mihai Dumitrescu, Adrian Istrate.
Thoracic Surgery, National Inst of Pneumology, Bucharest, S3, Romania

We present the mini-invasive transcervical approach of the right main bronchus as operative technique.

We have used this method at a MDR patient for whom we first staple and cut the right main bronchus in order to allow the proper treatment to be administered without the risk of TB spilling. Using a Cooper suprasternal retractor we have open an access to the mediastinum as described by Zielinski for Temla and encircled the right main bronchus and after staped and cut it.

538s
of the stent with at least one pathogen. A total of 11 different pathogens were found; Staphylococcus aureus (6), Alpha haemolytic streptococci (5), Pseudomonas aeruginosa (3), Haemophilus influenzae (2), Coagulase negative staphylococcus (2), Moraxella catarrhalis (1), Non haemolytic streptococcus (2), HRSa (1), Neisseria (1), Clostridium (1), Corynebacterium striatum (1).

Conclusion: Prophylactic control in the form of antibiotic-impregnated stents and modified antibiotics post stent deployment using specific microorganisms may be beneficial in reducing granulation tissue formation.

P2943
Comparative assessment of endobronchial valve lung volume reduction in patients with COPD

Vutim Graneshi1, Mikhail Kozhuk1, Nikolay Ovsyannikov2, Dmitry Petrov2
1General and Thoracic Surgery, Omus State Medical Academies, Omusk, Russian Federation; 2Pulmonology, Omusk City Hospital, Omusk, Russian Federation

Objective: To compare the results of surgical lung volume reduction in patients with COPD with the results of endobronchial lung volume reduction valve.

Methods: Aims: To identify the different endobronchial interventions used in the treatment of airway malignancies at St. George’s Hospital, and document associated complications.

Results: 36 (73%) patients had stent deployment, 7 (14%) had laser ablation with large airway pathology. It is usually well tolerated and rarely contraindicated even for patients with advanced malignant disease.

Aims: To study whether specific microorganisms are associated with granulation tissue formation in patients post endobronchial stent deployment.

Methods: We conducted a retrospective review of all endobronchial stent insertions performed for benign conditions between January 2005- November 2011. Stents used in the procedure were covered and uncovered Ultraflex expandable metal stents (Micro-invasive, Boston Scientific, Watertown, MA). Follow up bronchoscopies determined which patients had developed granulation tissue formation. Biopsies, sputum and lavage were then taken for microbiological analysis. Microsoft excel was used to collect and analyse data.

Results: Thirty patients had endobronchial stents deployed. Ten patients developed granulation tissue proliferation and all of these had bacterial colonisation.

Background: Following endobronchial stent insertion granulation tissue formation may occur, which can occlude the airway. It has been postulated that bacterial colonisation causes granulation tissue formation and its subsequent proliferation.

Aim: To study the effects of antibiotics on the incidence of granulation tissue formation post endobronchial stent deployment.

Methods: Thirty patients had endobronchial stents deployed. Ten patients developed granulation tissue proliferation and all of these had bacterial colonisation of the stent with at least one pathogen. A total of 11 different pathogens were found; Staphylococcus aureus (6), Alpha haemolytic streptococci (5), Pseudomonas aeruginosa (3), Haemophilus influenzae (2), Coagulase negative staphylococcus (2), Moraxella catarrhalis (1), Non haemolytic streptococcus (2), HRSa (1), Neisseria (1), Clostridium (1), Corynebacterium striatum (1).

Conclusion: Prophylactic control in the form of antibiotic-impregnated stents and modified antibiotics post stent deployment using specific microorganisms may be beneficial in reducing granulation tissue formation.

P2944
Endobronchial interventions used in the management of large airway malignancies and their associated complications: An audit

Clara Purgm, Brendan Madden. Cardiothoracic Surgery, St. George’s Hospital Medical School, London, United Kingdom

Introduction: Endobronchial intervention is an expanding specialty involving a Multi- Disciplinary Team, which diagnoses and treats a diverse group of patients with large airway pathology. It is usually well tolerated and rarely contraindicated even for patients with advanced malignant disease.

Aims: To identify the different endobronchial interventions used in the treatment of airway malignancies at St. George’s Hospital, and document associated complications.

Methods: Data relating to endobronchial stenting, laser ablation and forceps debulking, and any short-term complications, were collected from the St. George’s Hospital patient database for 49 consecutive patients with airway malignancy.

Results: 36 (73%) patients had stent deployment, 7 (14%) had laser ablation and 3 (6%) had tumours debulked using forceps. Complications occurred in 9 (18.4%) patients and were granulation tissue formation (3), mucus retention (3), stent migration (2) and bleeding (1). All complications were effectively treated.

Conclusions: Stenting is the endobronchial intervention of choice for the treatment of large airway malignancies at St. George’s Hospital. Although it has the greatest associated complications, they are usually effectively treated. Furthermore, it is safe, well tolerated and achieves good symptomatic relief.

P2945
Lung volume reduction surgery (LVRS) after endoscopic lung volume reduction (ELVRY) in severe emphysema – A case series

Karin Hornemann1, Daniela Gompelmann 2, Felix J.F. Herth2, Claus P Heussel3, Hans Hoffmann1, Ralf Eberhardt1
1Thoracic Surgery, 2Pneumology and Respiratory Care Medicine, 3Diagnostic and Interventional Radiology, Thoraxklinik at the University of Heidelberg, Heidelberg, Germany

Background: LVRS as well as ELVRY can improve patients symptoms, wellbeing and pulmonary function testing. ELVRY can be performed in upper and lower lobe emphysema. LVRS is currently not recommended for patients with very low FEV1 or lower lobe emphysema. LVRS is currently not recommended for patients with very low FEV1 or lower lobe emphysema.

Objectives: Case series to establish if surgical lobectomy after initially successful ELVRY is effective.

Methods: 6 patients (4 female, mean age 60.3 y, mean FEV1 640±214 ml)
with severe lower lobe emphysema received ELVR and showed an initial but not persistent improvement. Hence a lobectomy was performed for surgical lung volume reduction. Pulmonary function tests (PFT), 6-minute-walk-test (6MWT) and dyspnea score (mMRC) were performed 90 days after surgery and safety issues were assessed.

**Conclusion:** In all cases lobectomy of one lower lobe (5 left, 1 right side) was performed for patients with severe lower lobe emphysema for volume reduction. Pulmonary function tests (PFT), 6-minute-walk-test (6MWT) and dyspnea score (mMRC) were performed 90 days after surgery and safety issues were assessed.

**Successful ELVR can be used as a pretest for adequate patient selection.**

Inhaled racemic adrenergic versus saline in acute bronchiolitis, a multicenter randomized double-blind clinical trial

Håvard Ove Skjerpen 1, Jon Olav Gjengstø Hunderi 2, Sabine Kristin Brügmann-Pieper 1, Anne Charlotte Brun 1, Kai-Håkon Carlsen 1, 2, Hanne Engen 1, Leif Eikesdal 3, Marit Halvorsen 1, Jon Lunde 2, Petter Mowinckel 1, Leif Bjarte Rolfsjord 7, Christian Siva 4, Truls Vikin 5, Karin C. Ledupur Carlsen 1, 2, 3, 4, 5

**Department of Paediatric Medicine, University of Tromsø, Tromsø, Norway; 2Department of Paediatric Medicine, Stavanger University Hospital, Stavanger, Norway; 3Department of Paediatric Medicine, Stavanger University Hospital, Stavanger, Norway; 4Klinikk for Pädiatris, University of Tromsø, Tromsø, Norway**

**Background:** The efficacy of inhaled racemic adrenaline (iRA) versus general supportive therapy in acute bronchiolitis in infants is questioned.

**Aims:** To assess efficacy of iRA versus saline and regular vs. on demand therapy in hospitalized infants with acute bronchiolitis.

**Subjects and methods:** A multicenter (n=8) randomized double-blind controlled trial (pharmaceutical company independent) of iRA vs saline further randomised into regular vs on demand inhalations (up to every second hour) included 404 children (<12 months of age (mean 4.2 months), 29.3% boys, with moderate to severe acute bronchiolitis in Norway in 2009-11. A validated clinical score (0-10, 0 best) was used pre-and post inhalation daily. Inclusion required a score ≥ 4. Supportive therapy (oxygen, nasogastric feeding (NG) or ventilatory support) were recorded. The primary outcome was length of stay (LOS) (hours until deemed ready for discharge). Analyses were by intention to treat except for LOS.

**Results:** Infants treated with iRA vs saline had no significant difference in LOS (54.9 (52.8; 57.0) vs. 60.9 (59.2; 62.5) hrs, p=0.14). There was a trend in shorter mean LOS (54.9, 47.9-62.0 vs. 68.1, 60.4-75.7 hrs, p=0.05). Several SNPs with smoking in pregnancy, such as MBL2 region other than MBL2 reached genome-wide significance. We found significant gene-environment interaction of MBL2 SNPs with smoking in pregnancy, such as for the downstream SNPs rs10824787 and rs3821968 (p=0.036 and p=0.044, respectively).

Smoking during pregnancy lowers MBL levels in CB alone and in a joint effect with MBL2 SNPs. Our results may explain a link between genetic and environmental effects on early respiratory morbidity.

**P2947**

Joint effects of smoking during pregnancy and polymorphisms in the MBL2 gene on cord blood levels of mannose-binding lectin

Gülser Düşa 1, 2, Sven Mich 1, 2, Lurern Jan Schlapbach 1, 2, Sabina Gallati 1, Philipp Lauter 1, Michael Kabesch 2, Urs Frey 3, 4

**Department of Paediatrics, Inselspital, University of Bern, Switzerland; 2Department of Paediatric Pneumology, Allergy and Neonatology, Hamann Medical School, Hamann, Germany; 3Paediatric Critical Care Research Group, Mater Children’s Hospital, Brisbane, Australia; 4Department of Paediatrics, University Children’s Hospital (UKBB), University of Basel, Switzerland**

Smoking in pregnancy may affect the developing immune system and is associated with respiratory disease in the offspring. Also levels of mannose-binding lectin (MBL), a soluble innate immune mediator, are related to early respiratory morbidity. Yet, a joint effect of smoking in pregnancy and single-nucleotide polymorphisms (SNPs) in the MBL2 gene on MBL levels in cord blood (CB) is unknown.

MBL was measured in CB in N=221 participants of a birth cohort of unselected, unknown. MBL2 SNPs were quantified with MBL levels in CB. Using the Illumina® MBL2 gene-environment interaction of MBL2 SNPs with smoking in pregnancy, such as for the downstream SNPs rs10824787 and rs3821968 (p=0.036 and p=0.044, respectively).

Smoking during pregnancy lowers MBL levels in CB alone and in a joint effect with MBL2 SNPs. Our results may explain a link between genetic and environmental effects on early respiratory morbidity.
Conclusion: We have characterised biofilm-forming capacity in all 4 H. influenzae isolates from PCM patients. 2 isolates from chronically colonised patients (over 4 years) consistently formed thicker, cell dense and structurally more complex biofilms than the other, more recently isolated, strains. These data suggest that H. influenzae is capable of biofilm formation and that PCM patients, like cystic fibrosis, might harbour bacteria in biofilms.

P2950 Evidence of increased pathogenicity of HRVC compared with HRVA and B: Comparisons between children with an acute lower respiratory illness and controls

Davide Cazzola1,2, Siew-Kim Khor3, Giovanni Ferrari4, Guicheng Zhang2, Wan-Ming Lea, Gary Geelhoed2, Jack Goldblatt2, James Germ2, Joellel Bizzinzo11, Ingrid Liang5, Peter Le Soef2,2, Respiratory Medicine, Princess Margaret Hospital, Perth, WA, Australia; 2School of Paediatrics and Child Health, University of Western Australia, Perth, WA, Australia; 3Telethon Institute for Child Health Research, Centre for Child Health Research, University of Western Australia, Perth, WA, Australia; 4Department of Paediatrics, University of Wisconsin, Madison, WI, United States

Introduction: Recent studies suggest that human rhinovirus group C (HRVC) is more pathogenic in young children than HRVA and B. However, the relative frequency of isolation of these HRV groups between children presenting to an emergency department (ED) with an acute lower respiratory illness (ALRI) and healthy community controls has not been determined.

Aim: To compare isolation rates for HRVA, B, and C between children with an ALRI presenting to ED and health community controls.

Methods: Children aged 0-5 years presenting with an ALRI to the ED of a tertiary paediatric hospital along with healthy children from a local childcare centre were prospectively recruited. A nasal sample was collected at recruitment from which RNA was extracted and reverse transcribed. From cDNA, a 2-step PCR of the HRV 5'NCR was used for HRV detection and molecular typing.

Results: There were no differences in isolation rates for HRVA between ALRI cases and controls. Isolation rates for HRVB were low and slightly higher in controls than cases. For HRVC, not only were isolation rates higher than for HRVA or B, but rates were substantially higher for cases versus controls (48.5 vs 8.7% p<0.001).

Conclusions: HRVC is the most common HRV group causing ALRI in this group of young children, but is relatively uncommon in healthy children. In contrast, HRVA and B were not more common in children with ALRI than controls. These data provide support for HRVC being more pathogenic than HRVA and B.

P2951 RSV hospitalization in Down syndrome in the Canadian Registry of Synagis (CARESS) following prophylaxis (2006-2011)

Ian Mitchell1, Benoîte Côté1,2, Aymée Castonguay1,2, Ian Mitchell1, (CARESS) following prophylaxis (2006-2011)

Background: RSV hospitalization was not different among the groups following prophylaxis. Palivizumab may be efficacious in reducing RSV in DS compared to reported historical untreated controls in a similar Danish cohort of DS patients (untreated; 7.6% vs treated; 1.6% - 77% reduction).

Results: 10,061 infants were enrolled (DS: 299, 3.0%; infants with MD: 1247, 11.0%; infants without congenital heart disease: 8475, 86.9%). Rates of hospitalization for respiratory illnesses and RSV-related hospitalization did not differ among the groups following prophylaxis.

Conclusions: RSV hospitalization in Down syndrome in the Canadian Registry of Synagis (CARESS) following prophylaxis (2006-2011) was not different among the groups following prophylaxis. Palivizumab may be efficacious in reducing RSV in DS compared to reported historical untreated controls in a similar Danish cohort of DS patients (untreated; 7.6% vs treated; 1.6% - 77% reduction).

P2952 Role of probiotics in attenuation of acute respiratory tract infections in preschool and primary school children

Serghei Gerazim1, Orysa Cucur2

1Pediatrics, Liviu National Medical University, Liviu, Ukraine; 2Pediatrics, Ivanovo-Frankivsk National Medical University, Ivanovo-Frankivsk, Ukraine

Background: Probiotics have been shown to reduce incidence, duration and symptom scores of acute respiratory tract infections (ARTIs).

Objective: To study a potential of probiotics in prevention of ARTI in children.

Materials and Methods: 96 otherwise healthy children aged 3-12 years closely contacted to a household with ARTI were randomized to receive 1 g of a powder containing 5 billion CFU of L. acidophilus DDS-1, B. lactis and 50 mg fructooligosaccharide (DDS Junior, UAS Laboratories) (group I, n=48) or rice maltodextrine powder (group II, n=48) once daily for 30 days. During one-month follow-up, we recorded incidence, duration, and clinical course of ARTI using Canadian acute respiratory illness and flu scale (CARIFS).

Results: At baseline groups I and II were comparable on age, number of social contacts, history of attending daycare/school, and history of previous ARTI (85.5% of children in the group I and 90.6% in the group II developed ARTIs, p=0.368). In sick children at group I 50.6% clinical recovery from baseline value of CARIFS occurred on day 6.2(1.9), while in the group II on day 7.2(1.1) (p=0.025). For the group I return to normal health was observed on day 8.5(3.3) vs 10.7(3.9) in the group II (p=0.007). In the group I nasal decongestants, throat preparations, and antipyretics were used for a shorter course than in the group II (2.5(1.2) vs 3.2(1.7) p=0.007; 1.9(1.1) vs 2.9(1.6) p=0.046; 2.7(1.2) vs 3.5(1.5) p=0.049, respectively.

Conclusions: At tendency toward prophylactic potential in limitation of household spread, probiotics have a clear attenuating effect on the clinical course of ARTI in young children and shorten use of flu/cold drugs.

P2953 Active cytomegalovirus infection in non-immunosuppressed children with chronic respiratory disease

María Teresa Romero Rubio1, David Navarro Ortega1, Raquel Lucas Sendra2, Beatriz Almendral1, Olmo Carrión3, Amparo Escrivano Montanés4

1Pediatric Paediatric Pulmonology, Hospital de Denia, Alicante, Spain; 2Department of Microbiology, Hospital Clinico Universitario. Universidad de Valencia, Valencia, Spain; 3Pediatric Pulmonology, Hospital Clinico Universitario. Valencia, Spain; 4Department of Microbiology, Hospital Clinico Universitario., Valencia, Spain; 5Pediatric Pulmonology, Hospital Clinico Universitario. Universidad de Valencia, Valencia, Spain

Cytomegalovirus (CMV) is reactivated in lower respiratory tract in the context of local or systemic inflammatory processes, increasing its morbimortality.

Objective: To set the incidence of acute CMV infection in children with chronic respiratory diseases and no acute exacerbation.

Material and methods: Mixed retrospective-prospective study (May 2009- September 2011) of non-immunosuppressed children who underwent a diagnostic bronchoscopy. The serological test for the CMV was performed using CLIA (Diasorin, Italy).Detection and quantification of DNA in respiratory samples and plasma by PCR QRT-PCR in the m2000RT system (Abbott Diagnostics, USA).

Results: 36 patients (45% male; mean age 5.5 years. Underlying diseases were cystic fibrosis, B, and pulmonary hemosiderosis. 11 patients were IgG positive. CMV DNA detection was 10.7 (3.9) in the group II (p=0.007). In the group I nasal decongestants, throat preparations, and antipyretics were used for a shorter course than in the group II (2.5(1.2) vs 3.2(1.7) p=0.007; 1.9(1.1) vs 2.9(1.6) p=0.046; 2.7(1.2) vs 3.5(1.5) p=0.049, respectively.

Conclusions: At tendency toward prophylactic potential in limitation of household spread, probiotics have a clear attenuating effect on the clinical course of ARTI in young children and shorten use of flu/cold drugs.

P2954 The microbiology of lung disease in ataxia telangiectasia (A-T)

Jayesh Bhatt, Andrew Bush. UK National Ataxia Teleangiectasia Clinic, Nottingham Children’s Hospital, Nottingham, Notts, United Kingdom UK National Ataxia Teleangiectasia Clinic, Nottingham, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom

Background: A-T is a progressive, neurodegenerative disease causing immunodeficiency, an increased risk of malignancy & respiratory system complications, like chronic sinusopulmonary disease, bronchiectesis, interstitial lung disease & aspiration. The high early age mortality is due to cancer & respiratory disease. Little is known about what causes lung infections in A-T (Ped Pul 2010:45:874-59).

Aim: To describe the microbiology of Respiratory tract in patients attending the UK National A-T clinic in order to guide blind antimicrobial therapy, to discuss future studies to improve the evidence base for A-T treatment.

Methods: We prospectively obtained cough swabs or sputum cultures as age...

541s
appropriate & throat swabs for virology. We collected data on new treatment prescribed, current maintenance antibiotic or immune replacement therapy.

Results: 56 children (68 consuls) were seen in the clinic (May 09 to January 12). We could not obtain a sample in some children (Bacteria, n=14; Viruses, n=25).

Conclusions: Our findings are similar to smaller series (n=15) (Acta Pediata 2007;96:1021–24) but with no opportunistic infections; bacterial infection is common and current management is based on deaggravation from other lung diseases. A-T specific evidence based guidelines are urgently needed.

P2955 Host and viral factors predicting severity of rhinovirus-associated wheeze Giulia Cangiano1, Elena Pontetti1, Marie Noelle Krog1, Elisabeth Kromtg1, Mari Giorgiev2, Maria Teresa Barbani1, Laurent Kaiser3, Caroline Tapparel1

Background: Rhinovirus (RV) is a common cause of wheeze in childhood. Person- nal history of atopy, presence of siblings and day care attendance are known risk factors for severe RV-associated wheezing but objective markers predicting disease severity are lacking. We aimed at identifying such markers in a cohort of preschool children hospitalized for RV-associated wheezing.

Methods: Direct immunofluorescence for RV and other viruses was performed on nasopharyngeal aspirates (NPA) within the first 24 hours of hospitalisation of children aged 6-6 years. RV load, interferons (IFN) and cytokines (IL-4, IL-8, IL-15, IP-10) were quantified by RT-PCR and ELISA and related to clinical parameters.

Results: Within a 4-years period (2007-2011), we included 126 children (median (range) age: 1.66 (0.40-5.81) years). Presence of RV was confirmed by RT-PCR in all NPA samples. RV load was inversely related to age (r=0.22, p=0.02) and correlated with the pro-inflammatory cytokines IL-8 (r=0.23, p=0.01) and IL-6 (r=0.35, p<0.001). There was no relationship between RV load or any IFNs cy- tokine level and clinical outcome parameters (clinical severity scores, length of hospitalisation and duration of oxygen therapy). Post-hoc analysis revealed a trend towards higher IL-6 levels of children with prolonged oxygen need (>1 vs. ≤1 days): (135 (5.789) vs.16 (5.244) pmol/L, p=0.07).

Conclusions: In our cohort, RV load and related antiviral and pro-inflammatory responses were not associated with disease severity. This may be due to the wide range of subjects studied. Whether IL-6 levels in NPA may help to predict clinical outcome in subgroups of children with RV-associated wheezing illnesses needs to be evaluated in further studies.

P2956 Modulation effect of beta-glucan isolated from Pleurotus ostreatus in children with recurrent respiratory tract infections

Milos Jeršek1, Peter Banovcin1, Juraj Majtan2, Zuzana Rennerova3, Martin Heřmánek4, Department of Pneumatics, Jessenius Faculty of Medicine, Comenius University in Bratislava, Martin, Slovakia (Slovak Republic); 2Institute of Zoology, Slovak Academy of Sciences, Bratislava, Slovakia (Slovak Republic); 3Immunology and Clinical Immunology Clinic, Bratislava, Slovakia (Slovak Republic); 4Department of Clinical Immunology, St. Elizabeth’s Oncology Institute, Bratislava, Slovakia (Slovak Republic)

Introduction: Recurrent respiratory tract infections (RRTI) present very frequent problem in pulmonologist practice. Several natural preparations have been used for their prevention, but only few of them have scientific evidence for a real clinical efficacy.

Objectives: The aim of the study was to evaluate the preventive effect of Imunoglukan P4H®, syrup containing imunoglukan – beta-glucan from Pleurotus ostreatus, on the frequency of RRTI in children.

Methods: In double-blind, placebo-controlled study, 175 children (5.65±2.39 years) with ≥5 respiratory infections in previous 12 months were studied. Children were treated for 6 months with Imunoglukan P4H® or with artificial syrup with vitamin C (placebo group). During three visits questionnaires were fulfilled and immune parameters in blood were evaluated.

Results: In active group, 36% of the children did not suffer from any respira- tory infection during the treatment compared to 21% in placebo group (p<0.05). Imunoglukan P4H® significantly decreased the frequency of flu and flu-like dis- eases and also lower respiratory tract infections. 65% of physicians evaluated the effect of Imunoglukan P4H® as excellent (significant decreased morbidity) compared to 39% for placebo (p<0.05). We observed a significant modulation effect of Imunoglukan P4H® on humoral and cellular immune response.

Conclusions: Our study provided relevant evidence for preventing effect of Imunoglukan P4H® on the incidence of respiratory infections and revealed its com- plex immunomodulating activity. This is the first double-blind, placebo-controlled study in children with RRTI aimed on the preventive effect of beta-glucans on respiratory morbidity.

P2957 Community-acquired pneumonia in pediatric patients with heritable connective tissue disorders: Novel phenotypic variants

Zoia Nesterenko1, Elena Ivanova2, Department of Pediatrics, SI “Lugansk State Medical University”, Lugansk, Ukraine; 3Polyclinic Department, Lugansk Municipal Children’s Hospital #2, Lugansk, Ukraine

Background: The prevalence of heritable connective tissue disorders (HCTD) changed manifestations of community-acquired pneumonia (CAP) in pediatric patients, leading to diagnostic and therapeutic errors.

Objectives: To study clinical features of CAP in children with HCTD.

Material and methods: 105 patients aged 3-18 years, with clinically, serologically and radiographically diagnosed CAP were followed up for two years. Patients had persistent moderate asthma (A). All pediatric patients had HCTD manifestations.

Results: CAP caused by Mycoplasma pneumonia (Mp) was in 89.1% of patients, by Cytonmegalo virus (CMV) - in 26.7%, by Chlamydophilla pneumonia (CP) - in 21.9%. CAP was caused by association of Mp, Cm and Cm in 38.1% of children. CAP in asinhatic patients occurred with longer duration of respiratory symptoms and bronchial obstruction (11±5.2 days). Pulmonary hypertension (PH) was in 51.7% of patients with CAP and A, with pulmonary fibrosis (PF) in 48.3% of this group of patients. 26.7% of children with PH and PF had CT evidence of em- physematous bullae (EB). Patients with CAP and A received antibiotic treatment (macrolides) (ABT) besides controller therapy for achievement of A control.

Conclusions: 1) Close relationship between CAP, caused by intracellular pathogens, and HCTD is revealed. 2) CAP provoked A exacerbation in 57.4% of patients. 3) CAP in asinhatic patients had more long-term and severe clinical course. 4) PH was diagnosed in 51.7% of patients with CAP, A and HCTD, 48.3% of them had PF. 5) 26.7% of patients with PH and PF had EB. It is advisable to consider CAP associated with HCTD and A as clinical phenotypes of CAP.

P2958 Effect of short-chain fatty acids and pH on aerobic and anaerobic growth of Pseudomonas aeruginosa

Peyman Ghorbani1, Prisila Santhakumar2, Nades Palaniyar1,2,3

Harmut Grasemann1,2,3,4, Department of Laboratory Medicine & Pathobiology, University of Toronto, ON, Canada; 2Department of Health Sciences, McMaster University, Hamilton, ON, Canada; 3Programme in Physiological and Experimental Medicine, SickKids Research Institute, The Hospital for Sick Children, Toronto, ON, Canada; 4Department of Respiratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada

Background: Pseudomonas aeruginosa (PA) is one of the most common pathogens in patients with cystic fibrosis (CF) lung disease. PA and other anaerobic bacteria produce short-chain fatty acids (SCFAs) as byproducts of anaerobic fermentation. SCFAs are more volatile at low pH values, and reports have shown that CF patient sputum in acidic. Recently, we detected SCFAs in the low millimolar range in the sputum of CF patients.

Aim: To determine if SCFAs affect bacterial growth at different pH levels.

Methods: The laboratory strain PA01 and a clinical isolate PAS08 were used for experiments with and without the addition of SCFAs (acetate, propionate, butyrate) at a range of concentrations between 3.125-100 mM and pH values from 5.5-7.0 in tryptic soy broth. Optical density at 600 nm was measured every 30 minutes for a 6 hour period, as well as viable colony counts after the period of incubation. Anaerobic/macro aerobic conditions were generated by sealing microplates with anaerobically-clear PCR film.

Results: Acetate showed a significant inhibition in growth above 50 mM (p<0.05). Acetate at <50 mM showed a significant increase in growth above 12.5 mM acetate (p<0.05). Propionate had the highest inhibition, followed by butyrate and acetate. Anaerobic conditions resulted in lower growth overall and showed similar trends in growth inhibition. Results were consistent for both PA strains tested.

Conclusion: SCFAs increase the growth of laboratory and clinical strains of PA at concentrations found in CF patient sputum, but inhibit growth at high con- centrations. SCFAs produced by anaerobic bacteria may provide an indication of increased virulence of PA.
P2959
Longitudinal microbiology of children with primary ciliary dyskinesia
Woolf Walker1,2, Claire Jackson1,2, Amanda Harris4, Samantha Packham2,
Jane Lucas1,2. 1Primary Ciliary Dyskinesia Research Group, Clinical and
Experimental Sciences, Faculty of Medicine, University of Southampton, United
Kingdom; 2Primary Ciliary Dyskinesia Diagnostic Service, University Hospital
Southampton NHS Foundation Trust, Southampton, United Kingdom

Introduction: Longitudinal changes in the respiratory microbiology of cystic fi-
brosis is well characterised; *Staphylococcus aureus* & *Haemophilus influenzae* are
initially isolated before chronic *Pseudomonas aeruginosa* colonisation. However
there is a paucity of similar microbiological data for primary ciliary dyskinesia
(PCD).

Aims: Longitudinal assessment of respiratory microbiology in paediatric PCD
patients in a UK specialist centre.

Methods: Results of sputum and cough swab microbiology from PCD patients
(aged 2.1–19.3 years old, n=17) between January 2003–January 2012, were re-
viewed. Results were divided into 5-year cohorts corresponding to patient age at
time of sample acquisition (Table 1).

Results: 168/341 (49.1%) cultures were positive. *H. influenzae* was most prevalent
(61/168, 36.3%) followed by *S. aureus* (32/168, 19%), *Streptococcus pneumoniae*
(27/168, 16%) and *P. aeruginosa* (16/168, 9.5%). The predominance of *H. influen-
zae continued throughout childhood apart from in 5–10 year olds where there were
equivalent numbers of *H. influenzae*, *P. aeruginosa*, *S. aureus* & *S. pneumoniae*
(Table 1).

Conclusion: *H. influenzae* is the predominant pathogen in our PCD patients
throughout childhood, particularly >10 years old. The progression to chronic *P.
aeruginosa* colonization seen in CF is not evident in our PCD population.

3074 The second therapeutic intervention in malignant effusion trial (TIME2): A randomised controlled trial to assess the efficacy and safety of patient controlled malignant pleural effusion drainage by indwelling pleural catheter compared to chest drain and talc slurry pleurodesis

Eleanor Mistry1, Helen Davies1, John Wrightson1, Andrew Stanton1, Amar Guhan2, Christopher Davies3, Jamal Graezer3, Richard Harrison3, Anjani Prasad4, Nicky Crosthwaite4, Y.C. Gary Lee5, Robert Miller6, Brennan Khan7, Najah Rahman1,1 Oxford Respiratory Trials Unit, University of Oxford, Oxfordshire, United Kingdom; 2Dept. of Respiratory Medicine, University Hospital of Wales, Cardiff, United Kingdom; 3Dept. of Respiratory Medicine, Great Western Hospital, Swindon, United Kingdom; 4Dept. of Respiratory Medicine, James Cook University Hospital, South Tees, United Kingdom; 5Dept. of Respiratory Medicine, Royal Berkshire Hospital, Reading, United Kingdom; 6Dept. of Respiratory Medicine, Hospital Provincial, Castellón, Spain; 7Dept. of Respiratory Medicine, University Hospital of Wales, Cardiff, United Kingdom; 8Dept. of Respiratory Medicine, Royal Berkshire Hospital, Reading, United Kingdom; 9Dept. of Respiratory Medicine, University Hospital of Wales, Cardiff, United Kingdom; 10Dept. of Statistics, Medical Research Council, London, United Kingdom

Introduction: Malignant pleural effusions (MPEs) can be treated by indwelling pleural catheter (IPC) or chest drain and talc pleurodesis (usual care). This is the first direct, randomised comparison of these techniques as initial therapy assessing patient reported outcomes.

Methods: Randomised trial of IPC versus usual care (1:1) in patients with symptomatic MPE. IPCs were inserted as day cases, followed by patient education and home drainage. Usual care was admission for chest drain and talc pleurodesis in patients with good lung re-expansion. The primary outcomes were daily visual analogue scale (VAS) scores of breathlessness and chest pain over 42 days (100mm line, 0mm = no breathlessness/chest pain, 100mm = maximum breathlessness/pain).

Results: 106 patients were randomised. Dyspnoea improved in both arms, with no significant difference in intensity (mean VAS: IPC 24.4mm (SD 18.9), usual care 24.4mm (SD 17.0), difference 0.16mm, 95% CI -0.6 to 0.96). Dyspnoea decreased by mean 37mm (SD 27.1) IPC arm and 30mm (SD 27.7) usual care arm. Chest pain decreased from baseline in both arms (mean VAS: IPC 20.5mm (SD 18.2), usual care 17.6mm (SD 16.0), difference 5.4mm, 95% CI -3.0 to 13.8, p=0.21). Preliminary analysis demonstrated lower initial hospital stay in the IPC group (median days 0 (IQR 0-1) versus 4 (IQR 2-6)).

Discussion: IPC and usual care are comparable effective treatments for the relief of breathlessness in patients with MPE. The pain profile of IPC and usual care is similar over 6 weeks.

Conclusions: IPC is a useful tool that increases QoL in the palliative management of advanced malignancies with MPE.

3076 Mesothelioma in Sunderland UK 1998-2011: Chemotherapy usage and impact on survival

Joanne Anderson, Susan Pollock, Gemma Probert, Stephen Murphy, Ian Taylor, Kishore Shritharan, Howie Clague. Respiratory Medicine, Sunderland Royal Hospital, Sunderland, United Kingdom

Background: UK and European guidelines on treatment of mesothelioma recommend combination chemotherapy with Cisplatin/Pemetrexed (CP) in patients with good performance status. In Sunderland CP chemotherapy has been the standard treatment for mesothelioma in selected patients since 2006. The aim of this study was to ascertain the usage of CP for mesothelioma and impact on survival.

Method: Study conducted at Sunderland Royal Hospital. Patients diagnosed with malignant mesothelioma between 1998-2011 were included. Data collected: demographics, performance status, comorbidity, histology, treatment. Patients were stratified by date of diagnosis: 1998-2005 and 2006-2011. Factors affecting survival were assessed by Cox’s regression analysis.

Results: N=209, median (IQR range) age 66 (63-77) years, male 81.8%. Histology: Epithelioid 48%; Sarcomatoid 12.6%, Mixed 5.2%, Unspecified 34.2%. Propor- tion treated with chemotherapy 1998-2005 29.3%, 2006-2011 62.9%; OR 3.65 (CI 2.03-6.5). Median (IQR) survival: 1998-2005 8.2 (3.7-19.3) months, 2006-2011 all patients 9.8 (3.7-15.8) months, patients given CP chemotherapy 12.7 (9.8-22.7) months p > 0.05. On regression analysis treatment with CP appeared to confer a survival benefit HR 0.95 (95% CI 0.30) (0.21-0.43). But overall survival was unchanged between 1998-2005 and 2006-2011 HR 0.98 (0.72-1.3).

Conclusion: Most patients with malignant mesothelioma are now treated with carboplatin/pemetrexed combination chemotherapy. However overall survival has not improved significantly and the apparent benefit of treatment may be due to patient selection.

3077 Efficacy and safety of autologous blood pleurodesis versus talc pleurodesis in patients with malignant pleural effusions: Preliminary results

Golden Sari, Hisayen Yildirim, Gunhulo Ak, Muazzer Metintas. Department of Chest Disease, ESOGU Medical Faculty, Eskişehir, Meselik, Turkey

Autologous blood pleurodesis in clinical practice has not been evaluated in the treatment of malignant pleural effusions. The aim of this ongoing study is to determine the efficacy and safety of autologous blood pleurodesis versus talc pleurodesis in patients with malignant pleural effusions.

A prospective, randomized trial was carried out in a single centre. Our study has been conducted since March 2009 and by now comprised 21 patients with recurrent malignant pleural effusions. Patients were randomized to autologous blood and talc pleurodesis group. A blood sample of 3 ml/kg was obtained from the patients' brachial vein and immediately given into the intrapleural space. Four grams of talc mixed in 150 ml of normal saline was administered via tube thoracostomy. Patients were followed up with chest radiographs at 3 days and 1 month after pleurodesis.

Eight patients were randomly assigned to the autologous blood-treated group and 11 to the talc-treated group until January 2012. Two patients were ineligible due to rapid progression of systemic disease and death. The median age was 60.7 years. The success rate was 75% (6/8) in autologous blood group and 82% (9/11) in talc group. There was no statistically difference between the groups in regard to success rates (p=0.574). No severe or life-threatening adverse experiences were noted in the study. Chest pain is the most frequent minor complication in talc group. According to these preliminary results, we have found that pleurodesis using both autologous blood and talc showed high efficacy for controlling malignant pleural effusions.

3078 Time to diagnosis and time to therapy in patients with malignant pleural mesothelioma (MPM) compared to patients with lung cancer in Denmark 2007 to 2011. A quality assurance analysis

Niels-Chr. G. Hansen1, Christian B. Laursen1, Karen Ege Olsen2, Peter Licht3. 1Department of Respiratory Medicine, 2Department of Clinical Pathology, 3Department of Thoracic Surgery, Odense University Hospital, Odense, Denmark

In Denmark patients with pleural diseases are usually first seen by doctors taking care of patients with suspected lung cancer. When “diagnostic packages” were published in 2008 by the National Board of Health a 28 days maximal time to diagnosis and a 42 days maximal time to treatment were stated for lung cancer
as well as for MPM. We wanted to study how well these time frames are fulfilled for MPM. For the 5-year period 2007 to 2011, we have found 146 MPM patients in the pathology registry of Odense University Hospital. This is about 30% of all incident cases in Denmark in the period. MPM was confirmed by histology in 92% of the cases. Five patients died before the final diagnosis was known. Forty-two (30%) of 141 patients were treated by best supportive care. Two patients were lost for follow-up. In the three patients therapy was initiated at progression, but in 94 patients therapy began as soon as possible after the diagnosis. Eighty-three had chemotherapy, 10 had radiotherapy, and one had resection as the first step of the treatment. For the 141 patients the median time to diagnosis was 38 days (range: 6-127 days). Only 30% of the patients were diagnosed within 28 days. The median time to therapy for the 94 patients was 58 days (range: 19-142 days) - 21% were treated within 42 days. Among the 77 MPM patients from our primary uptake area 42% were diagnosed within 28 days and 17 out of 54 (32%) were treated within 42 days. In the same period, 84% of patients with lung cancer from our primary uptake area were diagnosed within 28 days and 74% had started treatment within 42 days. 

3081 A dual-acting muscarinic antagonist, β2-agonist [MABA] molecule (GSK961081) improves lung function in COPD. A randomised trial on moderate and severe COPD subjects. GSK961081 was safe and well tolerated. Introduction: GSK961081 is a dual pharmacophore demonstrating both muscarinic antagonist and beta agonist activities in one molecule (MABA). Recent COPD treatment guidelines have recommended that combining bronchodilators with different mechanisms may increase the degree of bronchodilation for equivalent or lesser side effects (GOLD 2010). Methods: This was a 4-week, multicentre, randomised, double blind, double dummy, placebo and salmeterol controlled parallel group study. Dose ranging across three twice-daily (BD) doses and three once-daily (QD) doses were assessed in moderate and severe COPD subjects. Through FEV1, at day 29 was the primary endpoint. Other efficacy endpoints, included serial FEV1 over 24h, FVC, and rescue salbutamol use. Safety endpoints included heart rate, glucose and QTc. Results: The study recruited 436 subjects. GSK961081 showed statistically and clinically significant differences from placebo in all doses and regimens for FEV1, trough on day 29 (155-277ml p<0.001). The optimal daily dose was 400mcg, either as once (400mcg QD) or as twice a day (200mcg BD) dosing with an improvement in Day 29 trough FEV1 of 21.5ml (95%CI) (-140,290) p<0.001 and 249ml (170,320) p<0.001 respectively. Other efficacy endpoints, including serial FEV1 over 24h, FVC and rescue salbutamol use were assessed. Safety endpoints included heart rate, glucose and QTc.

Rationale: Osteopontin (OPN) is overexpressed in mesothelioma tissue and has been associated with impaired patient survival. However, whether OPN is involved in mesothelioma growth and regulation of tumor-stimulated immune reaction is unknown. Aim: To examine the functional importance of OPN in experimental malignant pleural mesothelioma. Methods: AE17 murine mesothelioma cells which express high levels of OPN, engineered to stably express short hairpin RNAs (shRNAs) targeting the OPN transcript. To mimic pleural mesothelioma we intrapleurally injected syngeneic C57Bl/6 mice with AE17/OPNshRNA or AE17/vector cells. Tumor size and pleural fluid were harvested 15 days post-injection. The presence of pro-tumor cells including CD11b+CD206+ macrophages and CD11b+Gr(+) myeloid suppressor cells were evaluated using FACS. Results: Pleural tumors in mice injected with AE17/shRNAs were significantly smaller than those developed in mice injected with AE17/vector (mean tumor weight 428±41.2mg versus 107±2.25 mg, P<0.05). In addition, animals bearing AE17/shRNAs tumors had significantly less pleural fluid compared to those bearing control tumors (45.8±4.8g/1 versus 41.67±4.52g/1, P< 0.05). Pleural fluid CD206+ macrophages were significantly less in mice with AE17/shRNAs tumors compared to those with AE17/vector. Similarly, pleural fluid CD11b+Gr(+) myeloid-suppressor cells were significantly reduced respectively. Conclusion: OPN promotes experimental pleural mesothelioma growth and formation of malignant pleural effusion. Importantly, OPN substantially contributes in pro-tumor inflammatory cell recruitment in the mesothelioma-affected pleural cavity.

The overall survival of the MPM patients with lower pleural effusion MMP-3 levels was longer than that of those with higher pleural effusion MMP-3 levels. Our data suggest clinical role of pleural effusion MMP-3 levels in malignant pleural mesothelioma. 

3079 Clinical role of pleural effusion MMP-3 levels in malignant pleural mesothelioma

Malignant pleural mesothelioma (MPM) is an aggressive malignant tumor of mesothelial origin associated with asbestos exposure. MPM displays a limited response to conventional chemotherapy and radiotherapy, so early diagnosis of MPM is very important. Malignant tumor progression requires destruction of the basement membrane (BM), which is constructed from extracellular matrix (ECM) materials. Matrix metalloproteinases (MMP) are thought to be important due to their role in ECM degradation and cellular invasion. MMPs are involved in the progression of various diseases, including cancer, atherosclerosis, and immune responses. In particular, MMP-3 is known to play a crucial role in cancer progression and invasion.

In this study, we measured the pleural effusion MMP-3 concentrations of 52 MPM patients and 67 non-MPM patients. We demonstrated that the MPM patients had significantly higher pleural effusion MMP-3 levels than the population with non-malignant pleuritis. This finding suggests that high MMP-3 levels in pleural effusion might be a useful biomarker for diagnosing MPM.

The study also examined the clinical significance of pleural effusion MMP-3 levels. The results showed that patients with higher MMP-3 levels had a significantly shorter survival time compared to those with lower levels. This finding supports the clinical relevance of MMP-3 levels in MPM.

In conclusion, our study reveals that high pleural effusion MMP-3 levels are associated with a poorer prognosis in malignant pleural mesothelioma. These findings underscore the importance of MMP-3 as a potential biomarker and therapeutic target for MPM.

345. New bronchodilators and other novel drugs for asthma and COPD

3082 Lung function effects and safety of fluticasone furoate (FF)/vilanterol (VI) in patients with COPD: Low-nadir dose assessment

Edward M. Kerwin1, Catherine Scott-Wilson1, Lisa Sanfilippo1, Stephen I. Rennard2, Alvar Agusti3, Neil Barnes4, Courtney Crim1, I. Rennard4, Alvar Agusti5, Neil Barnes 6, Courtney Crim 2. 

Clinical Science Centre, Clinical Research Institute of Southern Oregon, Medford, United Kingdom; 2Respiratory Medicine Development Centre, GlaxoSmithKline, Research Triangle Park, United States; 3Quantitative Sciences Division, GlaxoSmithKline, Uxbridge, United Kingdom; 4Department of Internal Medicine, University of Nebraska Medical Center, Omaha, United States; 5Thorax Institute, Hospital Clinic, University of Barcelona, Spain; 6Respiratory Medicine, Barts and the London NHS Trust, London, United Kingdom.

Rationale: FF/VI is in development as a novel once-daily (OD) inhaled corticosteroid/long-acting beta2 agonist combination therapy for COPD.
Objective: To evaluate the efficacy and safety of FF/VI (100/25 and 50/25mcg) vs placebo (PBO), FF (100mcg), and VI (25mcg), given OD as a novel dry powder inhaler for 168 days in moderate-severe COPD patients.

Methods: A multicentre, randomised, PBO-controlled, double-blind, parallel-group study (N=1030 (ITT)). Co-primary endpoints: weighted mean (wm) FEV1 (0-4h). Addition of FF to VI provided numerical improvements only in wmFEV1 (0-4h). Additional endpoints included CRQ-SAS dyspnoea and safety.

Results: Co-primary endpoints: see Figure. FF/VI 100/25 was numerically superior to components on dyspnoea score (treatment differences from PBO =-0.38 vs -0.06 [FF] and 0.14[VI]). On-treatment AEs were more frequent with active treatment (54–60%) than PBO (48%). There were no treatment effects on 24h urinary cortisol, laboratory values, or cardiac monitoring parameters.

Conclusions: Addition of VI to FF produced a clinically significant improvement in wmmFEV1 (0-4h). Addition of FF to VI provided numerical improvements only in trough FEV1. Combination therapy was superior to PBO for both co-primary endpoints. All treatments were well tolerated. Funded by GSK (HESC112206; NCT01053988).

3084 Efficacy and safety of BI 671800, an oral CRTH2 antagonist in controller-naïve patients with poorly-controlled asthma

Objective: To investigate the efficacy and safety of BI 671800 versus placebo and fluticasone propionate (FP) in controller-naive patients with poorly-controlled asthma.

Methods: Adults with asthma (FEV1 < 60% and ACQ >1.5) were enrolled in a randomized, double-blind, parallel arm study comparing BI 671800 50, 200 or 400 mg bid with matching placebo bid or FP 110 μg bid for six weeks. The primary study outcome was change in trough FEV1.

Results: 385 patients were randomised (mean age 37–4 years, FEV1 72%, ACQ 2.9). Changes from baseline in adjusted mean (SE) trough morning FEV1% predicted versus placebo were 3.08% (1.65), 3.59% (1.60) and 3.98% (1.64) for 50, 200 and 400 mg BI 671800 respectively, and 8.61% (1.68) for FP (one-sided p = 0.02 for 200 and 400 mg bid and FP), achieving the primary efficacy outcome for the study. Change in ACQ mean (SE) scores versus placebo were 0.07 (0.11), -0.08 (0.11) and -0.06 (0.11) for 50, 200 and 400 mg BI 671800 bid respectively, and -0.33 (0.12) for FP (one-sided p < 0.025 for FP). No significant imbalance in adverse events, or differences in vital signs or laboratory assessments were observed.

Conclusion: Treatment with BI 671800 was associated with a significant improvement in FEV1 in controller-naive patients with poorly-controlled asthma. BI 671800 was well tolerated at total daily doses up to 800 mg for 6 weeks.

3085 Efficacy and safety of BI 671800, an oral CRTH2 antagonist, as add on therapy in poorly controlled asthma patients prescribed an inhaled corticosteroid

Objective: To investigate the efficacy and safety of BI 671800 administered once daily in controller-naive patients with poorly-controlled asthma prescribed an inhaled corticosteroid.

Methods: Adults with asthma (FEV1 < 60% and ACQ >1.5) were enrolled in a randomized, double-blind, three period, incomplete cross-over study comparing BI 671800 400 mg (1, 2, 4 weeks). Changes from baseline in adjusted mean (SE) trough morning FEV1 (MDI) were -0.08 (0.11), -0.06 (0.11) and -0.33 (0.12) for FP (one-sided p < 0.025 for FP). No significant imbalance in adverse events, or differences in vital signs or laboratory assessments were observed.

Conclusion: BI 671800 is an antagonist of the PGD2 receptor. CRTH2, PGD2 stimulates bronchoconstriction and allergic airway inflammation in animal models. Inhibition of CRTH2 may reduce airway inflamed cells, IL-4, -5, -13, production, serum IgE and airway hyper reactivity.

Objective: To investigate the efficacy and safety of BI 671800 versus placebo and fluticasone propionate (FP) in controller-naive patients with poorly-controlled asthma.

Methods: Adults with asthma (FEV1 < 60% and ACQ >1.5) were enrolled in a randomized, double-blind, parallel arm study comparing BI 671800 50, 200 or 400 mg bid with matching placebo bid or FP 110 μg bid for six weeks. The primary study outcome was change in trough FEV1.

Results: 385 patients were randomised (mean age 37–4 years, FEV1 72%, ACQ 2.9). Changes from baseline in adjusted mean (SE) trough morning FEV1% predicted versus placebo were 3.08% (1.65), 3.59% (1.60) and 3.98% (1.64) for 50, 200 and 400 mg BI 671800 respectively, and 8.61% (1.68) for FP (one-sided p = 0.02 for 200 and 400 mg bid and FP), achieving the primary efficacy outcome for the study. Change in ACQ mean (SE) scores versus placebo were 0.07 (0.11), -0.08 (0.11) and -0.06 (0.11) for 50, 200 and 400 mg BI 671800 bid respectively, and -0.33 (0.12) for FP (one-sided p < 0.025 for FP). No significant imbalance in adverse events, or differences in vital signs or laboratory assessments were observed.

Conclusion: Treatment with BI 671800 was associated with a significant improvement in FEV1 in controller-naive patients with poorly-controlled asthma. BI 671800 was well tolerated at total daily doses up to 800 mg for 6 weeks.
3086 Effects of the novel toll-like receptor 7 (TLR7) agonist AZD8848 on allergen-induced responses in patients with mild asthma
Brian Lekander1, Dave Singh2, Sam Lindgren3, Gun Almqvist1, Barbara Young4, Louis-Philippe Boulet5, Donald Cockcroft3, Beth Davis1, Richard Leigh6, Barbro Dahlén7, Irvin Mayers8, Helen Scheerens9, Romeo Macina9, John Matthews10, Jeffrey Harris11, Paul O’Byrne12, Louis-Philippe Boulet5, Donald Cockcroft3, Beth Davis1, Richard Leigh6, Barbro Dahlén7, Irvin Mayers8, Helen Scheerens9, Romeo Macina9, John Matthews10, Jeffrey Harris11, Paul O’Byrne12.

Abstract: Elevated serum IgE is associated with allergic asthma. Membrane IgE (sIgE) on the prime epitope, present in human IgE-switched memory B cells and plasmablasts. MEMP1972A, a therapeutic antibody specific for M1-prime that depletes M1-prime-expressing cells.

Methods: This randomized, double-blind, controlled study (NCT01196309) assessed the activity of MEMP1972A in adults with mild asthma after allergen inhalation challenge (AIC). Subjects (n=29) were randomized (1:1) to intravenous MEMP1972A (5 mg/kg) or placebo every 4 weeks for 12 weeks. The primary outcome was the area under the curve (AUC) of the late asthmatic response (LAR) at Wk 12. Secondary outcomes included early asthmatic response (EAR). Serum total IgE and allergen-specific IgE were measured to confirm mechanistic activity of MEMP1972A. Other exploratory biomarkers were measured eg sputum and blood eosinophils.

Results: MEMP1972A treatment was well tolerated. At Wk 12, MEMP1972A reduced the LAR AUC by 36% (90% CI -14.6, 69, p=0.21) and the EAR AUC by 26% (6, 43, p=0.046) vs placebo. AIC at screening and Wk 12 induced a >2-fold increase in allergen-specific IgE which was abrogated by MEMP1972A and more than >10-fold increase in sputum eosinophils, which was reduced by MEMP1972A at Wk 12. MEMP1972A reduced total IgE by ~20% at Wk 8, and blood eosinophils by ~45% at Wk 28 vs baseline.

Conclusions: Attenuation of EAR, LAR, serum IgE, pH, PEF, blood sputum and blood eosinophils following AIC is consistent with the mechanism of action of MEMP1972A. Depletion of the M1-prime-expressing B-cell lineage may be effective for the treatment of allergic asthma.
3090 Dynamic preferences for site of death among patients with advanced chronic organ failure
Daisy Jansen1,2, Marjine Spruijl1, Jos Schols3, Emiel Wouters1,4.
The Program Development Centre, CIRO, Vro, Netherlands; 2Department of Elderly Care Medicine, Protee Thuis, Horn, Netherlands; 3CAPHRI, Maastricht University, Maastricht, Netherlands; 4Department of Respiratory Medicine, Maastricht UMC, Maastricht, Netherlands

Background: Being able to die at the preferred site is seen as a key principle of a good death. Aims of this study were to assess 1-year stability and determinants of preferences for site of death among patients with advanced COPD, Chronic Heart Failure (CHF), or Chronic Renal Failure (CRF) and to assess agreement between the actual site of death and the site patients indicated in advance as their preferred site.

Methods: 265 outpatients (105 COPD, 80 CHF; 80 CRF) were recruited. 206 patients (77.6%; 67.2 (13.1) years; 64.1% male) completed 1-year follow-up. Patients were visited at baseline, 4, 8, and 12 months to assess the preferred site of death. Patient characteristics were recorded. A bereavement interview was done with the close relatives of patients who died within 2 years after baseline (n=66, 24.9%) to assess actual site of death.

Results: At baseline, 106 patients (51.5%) preferred to die at home, 61 (29.6%) at the hospital, 21 (10.2%) at a care home or hospice and 18 (8.7%) did not know. Patients living with a partner were more likely to prefer to die at home (OR 3.21 (1.73-5.92)). During 1 year, 61.2% of the patients changed their preference for site of death. During the interview before their death, 34 patients (51.5%) preferred to die at home, 22 (33.3%) at the hospital; 8 (12.2%) at a care home or hospice and 2 (3.0%) did not know. 57.6% died at the hospital, 27.3% at home and 39.4% died at the preferred site (Kappa 0.07, p=0.42).

Conclusions: Although most patients preferred to die at home, the majority died in the hospital. Only 39% of the patients died in the preferred site. However, 61% of the patients changed their preference for site of death at least once during 1 year.

3091 Decrease of physical activity in patients with COPD in the course of the disease
Benjamin Waschki1,2, Miriam Schaper1, Anna-Lena Sack1, Olaf Holtz1, Anne Kirsten1, Thorsten Meyer1, Klaus F. Rabe1, Helge Magnusson1, Henrik Watz1.
1Pulmonary Research Institute at Hospital Grosshansdorf, Member of the German Centre for Lung Research, Grosshansdorf, Germany; 2Hospital Grosshansdorf, Center for Pneumology and Thoracic Surgery, Member of the German Centre for Lung Research, Grosshansdorf, Germany

Methods: We measured total daily energy expenditure, the physical activity level (p.a.) and the number of activity days per week in 343 COPD patients during a median follow-up of 2.8 years (range, 1.8 - 3.5). Total daily energy expenditure was defined as the number of steps divided by resting metabolic rate, and steps per day by a multisensor armband over a period of 5 to 6 consecutive days in 26 patients with chronic bronchitis and 137 COPD patients (GOLD stage 1 - IV) at baseline and at follow-up. Results: During a median follow-up of 2.8 years (range, 1.8 - 3.5), total daily energy expenditure decreased from 2708 kcal (SD 590) to 2518 kcal (SD 536) resulting in an annual rate of decline of 68 kcal (p < 0.001). Physical activity level decreased from 1.57 (SD 0.28) to 1.48 (SD 0.25) resulting in an annual rate of decline of 0.03 (p < 0.001). Steps per day decreased from 6822 (SD 3786) to 5685 (SD 3546) resulting in an annual rate of decline of 418 steps (p < 0.001). The absolute decline of total daily energy expenditure, physical activity level, and steps per day was independent of baseline disease severity. The relative changes of all physical activity parameters were higher in patients with severe and very severe COPD.

Conclusion: Physical activity decreases across all severity stages of COPD in the course of the disease with relative changes being most prominent in severe stages.

3092 A self-management programme of activity coping and education (SPACE) for COPD: 6 week results from a randomised controlled trial
Katy Wag1, Vicki Warrington1, Lindsay Apps1, Louise Sewell1, John Bankaran2, Mick Steiner1, Mike Morgan1, Sally Singh1,2, 1NIHR CLAHRC-LNR Pulmonary Rehabilitation Research Group, University Hospitals, Leicester, United Kingdom; 2Health Sciences, University of Leicester, United Kingdom; 3Health and Life Sciences, Coventry University, Coventry, United Kingdom

Introduction: SPACE for COPD is a self-management programme which individual patients follow independently with telephone support.

Objective: To test the effectiveness of SPACE on health related quality of life (HRQoL) and exercise capacity compared with usual GP care at 6 weeks.

Methods: 184 patients with COPD (101male; mean (SD) age 69(9.19) yrs; FEV1 1.45(0.56) l; BMI 27.3(6.52) were recruited from primary care and randomised to SPACE or usual care. Blinded measurements were taken at baseline and 6 weeks and included Chronic Respiratory Questionnaire-SR (CRQ-SF), hospital anxiety and depression scale (HADS).

Results: See Table 1.

Conclusion: SPACE is effective in improving HRQoL and exercise capacity, when compared with usual care. SPACE could be used to facilitate self-management of patients with COPD in primary care.

3093 Living with COPD: Psychological distress among family carers
Daniela Figueredo1,2, Rafael Gabriel1, Cristina Jácrome1, Alda Marques1, 1Escola Superior de Saúde, Universidade de Aveiro, Portugal; 2Unidade de Investigação e Formação Sobre Adultos e Idosos, Universidade do Porto, Portugal

The impacts of Chronic Obstructive Pulmonary Disease (COPD) in terms of patients’ psychological distress have been well reported. However, COPD also poses several challenges to family carers, as they represent a primary source of support to patients. Yet, the burden of COPD in terms of family carers’ psychological distress remains relatively unexplored. This study aimed to assess the presence of anxiety and depression symptoms among family carers.

A cross-sectional study was conducted with 110 family carers of patients with COPD, in the central region of Portugal. A structured questionnaire based on ICF-checklist was used to collect socio-demographic and subjective health status data; Depression and anxiety were measured with the Hospital Anxiety and Depression Scale (HADS). Descriptive statistics and χ2 tests were applied using PASW Statistics 18.0. Participants’ mean age was 59.9±12±33 years old and was predominantly female (n=78; 71%). The majority were spouses (n=75; 68.2%) and caring for more than 4 years (n=66; 60%). 67.3% of participants presented anxiety symptoms, 37.3% depression symptoms and 28.2% presented both. Subjective mental health was significantly associated with anxiety (p<0.001) and depression (p<0.001). Subjective physical health was significantly related with depression (p<0.001). No other statistically significant associations were found.

Caring for a patient with COPD can impact negatively on the psychological health of family carers. Similar results have been shown in the context of other chronic conditions, such as cancer, dementia or stroke. The results highlight the need of supportive interventions tailored to the particularities of DPOC caregiving in order to prevent burden among family carers.

3094 Reduced exertional dyspnea with supplemental oxygen in patients with COPD – Characteristics of responders and non-responders
Nina Fakvæde Caspergaard, Christine Gudin Karlsen, Anne Edvardsen, Sari Skulstad, Gulliksklinikken, Gulliksklinikken, Haskal, Norway

Introduction: Ambulatory oxygen is recommended for COPD patients who desaturate during activity, and who experience subjective effect of oxygen supplementation. COPD patients with no former oxygen treatment admitted for rehabilitation were referred to extended testing if oxygen saturation measured by pulse oximetry (SpO2) during 6-minute walk test (6MWT) fell below 88%.

Aim: Our study aimed at identifying characteristics that differed between patients who experienced subjective effect of oxygen during constant load treadmill test and those who did not.

Table 1
Methods: Lung function was measured and expressed in % reference values. Two 5 min constant load treadmill tests were performed at a speed just below 6MWT to mimic walking speed in daily activity. Arterial bloodgas samples were drawn before stop. Dyspnea was measured on Borg CR10 scale. Blinded and in random order, patients received oxygen supplement 6 L/min or placebo air administered continuously through nasal catheter.

Results: 27 of 39 patients rated their dyspnoea at least 1 Borg unit lower with oxygen than without. There were no differences in age (64 (8: 65 (6) p=0,56), FEV1 (35 (17); 32 (16) p=0,33), RV (193 (74), 171 (88) p=0,46), TLC (115 (40); 107 (49) p=0,66), DLOCOVA (38 (15); 37 (23) p=0,94), resting pO2 (8.9 (0,6); 8.8 (0,9) p=0,92), nadir pO2 with placebo (6,8 (0,4); 6,5 (0,8) p=0,19), nadir SpO2 during 6MWT (81(3); 78(5) p=0,10) or pO2 with oxygen (kPa) (10,4 (1,3); 10,9 (1,8), p=0,19) between patients with subjective effect and those without.

Conclusion: None of the registered variables were helpful in predicting subjective effect of ambulatory oxygen.

3095
A ten-year survey of long term oxygen treatment (LTOT) in severe COPD: Comparison of the survival during telemetric home monitoring vs standard care
Roberto Dal Negro1, 2, Luca Bonadiman3, Claudio Micheletto3, Silvia Tognella1, 2, Luca Bonadiman1, 2, Luca Bonadiman3, Claudio Micheletto3, Silvia Tognella1, 2, Luca Bonadiman3, Claudio Micheletto3, Silvia Tognella1, 2
Paola Turco2, 3, Respiratory Unit, Ospedale Orlandi, Bassoleengo, VR, Italy; 4Centro Studi Nazionale di Farmacoeconomia e Farmacopediometria, CESFA, Verona, Italy; 5Respiratory Unit, Ospedale Mater Salus, Legnaro, VR, Italy.

Subjects’ survival, is a crucial outcome during long-term oxygen treatment (LTOT). The survival of a cohort of 886 patients suffering from very severe chronic obstructive respiratory disease (COPD) and admitted to long-term oxygen treatment (LTOT) at a home was investigated over the last ten years. Subjects were divided in two groups with matched for age, sex, lung function and daily oxygen use: group A, patients managed according to an usual protocol for home assistance, and group B, patients admitted to a telemetric daily monitoring. Statistics: Wilcoxon’s test was used in order to compare the survival and acute episodes of relapse, and p<0.05 was accepted.

Results: Mean survival had a significantly longer duration (2.5 fold) in subjects telemetrically controlled at home (1239.6 days ± 382.1 vs sd 482.6 days ± 273.9 sd, p=0.001), with a lower incidence of these subjects (17.3 vs 33.0%, and 11.3 ± 21.1% respectively, both p<0.01). When standardization for age, lung function, smoking habit, and comorbidities, females still showed a significantly longer survival when managed according to the telemetric protocol of home LTOT (1166.4 days ± 556 sd vs 1433.7 days ± 656,3 sd, p<0.01).

Conclusions: The telemetric management of home LTOT proves more effective than standard care in terms of patients’ overall survival. Even if further studies are needed, a different females’ psychological approach to this particular model of management and their better acceptance of procedures might presumably contribute to explain the difference observed in the main outcome.

347. Stem cells and progenitors in injury and repair

3096
LSC 2012 Abstract – Effects of stem cells of healthy or acute lung injury donors of recipient injury mice
J.D. Silva1, B. Paredez2, I.M. Araújo1, M.L. Pacheco1, M.V. Oliveira1, G. Safwen1, L. Fascilli3, E.F. Aviss1, H.C.C. Farina-Nets1, R. Goldenberg2, A.C. Carvalho2, M.M. Morales1, P. Peloso1, D.G. Xisto1, 4, 1LIP UFRJ, Rio de Janeiro, Brazil; 2LCMC, UFRJ, Rio de Janeiro, Brazil; 3LFCM, UFRJ, Rio de Janeiro, Brazil; 4The Koch Institute for Integrative Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, United States

Background: The airways of the mammalian lung are lined with specialized epithelial cell types that are the target of airborne toxins and injury. Notch signaling plays an important role in the development of these cells, but its contributions to recruitment, expansion or differentiation of resident progenitor/stem cells in repair of injured lung remains unknown.

Aims & objective: To elucidate the role of Notch signaling in repair of injured airway epithelium.

Methods: We used targeted inactivation of, Notch1, via the epithelial-specific Gata6Cre transgenic line in the embryonic lung epithelium.

Results: Notch1(-/-) mice are viable with intact pulmonary epithelial cell fate determination/differentiation. However, Notch1 was found to be required for normal repair of the injured airway epithelium. Absence of Notch1 reduced the ability of cells distinguished by expression of PDGFRα, a marker of pulmonary neuroendocrine cells, which serve as a reservoir for regeneration of Clara cells.

Blgmecin treatment or influenza virus infection can induce severe damage in distal lung with the loss of large amounts of alveolar type II (AT2) and type I (AT1) cells. During the repair process, new AT2s and AT1s have to be produced to regenerate the damaged alveoli. A recent study showed that the newly generated AT2s were not derived from pre-existing AT2s after blgmecin treatment, indicating the existence of other progenitor cells for alveolar regeneration [1]. We have used a genetic lineage tracing system to follow Clara cells in mice. We show that large numbers of the newly generated AT2s and AT1s are derived from Clara cells after alveoli damage by blgmecin treatment or influenza virus infection. The intermediates between Clara cells and AT2s are SPc-expressing bronchiolar cells (or SEBCs). SEBCs are only observed in damaged area and initially positive for Clara cell marker Clara Cell Secretory Protein (CCSP) and gradually become CCSP negative. Anatomical analysis shows that SEBCs at the tips of bronchioles appear to dilate to regenerate alveolar epithelium in a process similar to that seen during the development of embryonic alveolar epithelium. These findings show that Clara cells are the progenitors to regenerate alveolar epithelium in response to severe lung damage.

3098
Secreted mediators from induced pluripotent stem cells (iPSc) attenuate fibrosis in blgmecin injured rat lung
Anna Gazzaniga1, 2, Iwona Chmiel1, 2, Antonio Gaggero1, 2, Anis Fekri3, Thomas Geiser1
1Division of Pulmonary Medicine, University Hospital, Bern, Switzerland; 2Department of Gynecology, University Hospital, Geneva, Switzerland; 3Department of Pathology, University of Bern, Switzerland; 4Department of Gynecology, Cantonal Hospital, Fribourg, Switzerland

Background: Idiopathic pulmonary fibrosis (IPF) is a progressive interstitial lung disease resulting from deregulated alveolar epithelial repair, after micro injuries. There are no promising treatments available hence; novel methods to regenerate the injured lungs are urgently required. We studied the role of secreted mediators from induced pluripotent stem cells (iPSc) in blgmecin injured rat lungs.

Methods: iPSc cells were generated from human foreskin fibroblasts by transfection of the transcription factors SOX2, OCT4, KL4, and c-MYC, after characterization by immunohistochemistry and RT PCR, the colonies were expanded and the conditioned media (CM) was collected (iPScCM). iPScCM was subjected to proteomics to analyze the contents. Adult male rats (F344) were instilled intratracheally (i.t) with blgmecin at day 7, days later were treated with iPScCM or control media (CM) and sacrificed 7 days after iPScCM or CM treatment.

Results: Proteomic analysis revealed presence of various interesting cytokines and growth factors in the iPScCM, which are involved in regeneration process; the total collagen content after iPScCM treatment was lower than CM group (753±56.12 ug/mg vs 4182±521.8 ug/mg of wet tissue) as measured by hydroxyproline assay. Furthermore, TGFβ1 mRNA levels were also reduced after iPScCM treatment (0.9±0.266 vs 2.4±0.9) (2-ΔΔCt).

Conclusion: Secreted mediators present in the iPScCM attenuate fibrosis in the blgmecin injured rat lungs and may offer a novel therapeutic option for pulmonary fibrosis.

3099
Notch signaling via hairy/enhancer of split-5 (Hes5) & paired-box containing gene 6 (Pax6) controls progenitor cell reservoir for repair of airway injury
Parviz Minoo, Yiming Xing, Pediatrics, University of Southern California School of Medicine, Los Angeles, CA, United States

Background: The airways of the mammalian lung are lined with specialized epithelial cell types that are the target of airborne toxins or injury. Notch signaling plays an important role in the development of these cells, but its contributions to recruitment, expansion or differentiation of resident progenitor/stem cells in repair of injured airways remains unknown.

Aims & objective: To elucidate the role of Notch signaling in repair of injured airway epithelium.

Methods: We used targeted inactivation of, Notch1, via the epithelial-specific Gata6Cre transgenic line in the embryonic lung epithelium.

Results: Notch1(-/-) mice are viable with intact pulmonary epithelial cell fate determination/differentiation. However, Notch1 was found to be required for normal repair of the injured airway epithelium. Absence of Notch1 reduced the ability of cells distinguished by expression of PDGFRα, a marker of pulmonary neuroendocrine cells, which serve as a reservoir for regeneration of Clara cells.

549s
Hairy/Enhancer of Split-5 (Hes5) and a paired-box containing gene 6 (Pax6) were found to be downstream targets of Notch1. Both Hes5 and Pax6 expression were significantly increased in association with Clara cell regeneration in wild type lungs. Ablation of Notch1 reduced Hes5 and Pax6 and inhibited Clara cell regeneration significantly in association with Clara cell regeneration in wild type lungs. Ablation of Notch1 reduced Hes5 and Pax6 expression, and inhibited Clara cell regeneration. Thus, although dispensable in developmental ontogeny of airway epithelial cells, normal activity of Notch1 is required for repair of the airway epithelium. The signaling pathway by which Notch1 regulates the repair process also includes stimulation of Hes5 and Pax6 gene expression.

**3100** Evidence of increased pluripotent cells in adult human lung tissue derived from fibrotic lungs compared to non-fibrotic control lungs

Katrin Hostettler 1,2, Abraham Warzeka 2,3, Michael Tamm 3,4, Didier Lardinois 5, Michael Roth 1,5, 1Department of Biomedicine, University Hospital, Basel; 2Division of Pulmonary Medicine, University Hospital, Bern; 3Clinic of Respiratory Medicine, University Hospital, Basel; 4Division of Thoracic Surgery, University Hospital, Basel, BS, Switzerland

**Introduction:** Tissue-specific multipotent stem cells have been identified in the human lung. However, their role in lung homeostasis or lung disease is not clear.

**Methods:** Primary human lung cells were cultured from fibrotic adult lung parenchyma (n=14) and from non-fibrotic control lungs (n=17). The characterization of different cell types was performed by immunofluorescence stainings.

**Results:** Undifferentiated primary cells grew from adult human lung parenchyma, showing neither a clear epithelial nor mesenchymal morphology/immunofluorescence typing (intermediate cells). When cultured in the respective appropriate media, intermediate cells transformed into mesenchymal cells (positive for fibronectin and smooth muscle actin) or into alveolar epithelial type II cells (positive for E-cadherin and surfactant protein-A). Pluripotency of intermediate cells was proven by positive stainings for Oct3/4 and NANOG. Successful inductive differentiation of adipogenic, osteogenic, myogenic, and chondrogenic differentiation was performed in intermediate cells. Finally, significantly more pluripotent cells were generated from fibrotic lung tissue (n=14) than from non-fibrotic control lungs (n=17).

**Conclusions:** Our data demonstrate that adult human lung contains pluripotent cells which are able to differentiate towards an epithelial as well as a mesenchymal cell type solely by changing their microenvironment. These pluripotent cells might have a pivotal function in lung homeostasis and tissue repair. The observed increased incidence of these cells in fibrotic lung tissue suggests a role in fibrogenesis.

**3101** Adrenaline stimulated mesenchymal stem cells modulate inflammation in lipopolysaccharide induced lung injury

Xiaodan Wu 1, Chunxue Bai 1, Xiangdong Wang 1,2, 1Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China; 2Biomedical Research Center, Zhongshan Hospital, Fudan University, Shanghai, China

**Introduction:** Bone marrow derived mesenchymal stem cells (BMSCs) could modulate inflammation. Adrenergic receptor agonists could increase DNA synthesis and protect oxidative stress in mesenchymal stem cells. We investigated the potential role of adrenaline stimulated BMSCs on lipopolysaccharide (LPS) induced lung injury in vitro.

**Methods:** BMSCs from rats were cultured with adrenaline at 0–100 μM, followed by determination of CCK8. The optimal concentration was chosen for latter study. BMSCs and lung cells from normal or LPS injured rats were co-cultured in a Transwell system (4.5μm pore size) for 36h. The migrated BMSCs were stained by Giemsa. BMSCs and alveolar macrophages were co-cultured with LPS or adrenaline in Transwell (0.4μm pore size) for 6h. The supernatant was collected for cytokines (TNF-α, IL-1β, IL-6, IL-10, IL-13, angiopoietin-1, KGF and IL-11a) analysis by ELISA, and the mRNA expression levels in BMSCs were determined by PCR.

**Results:** Adrenaline at 10 μM promoted proliferation and migration of BMSCs towards injured lung. Adrenaline enhanced the inflammation modulation effects of BMSCs by decreasing TNF-α, IL-1β and IL-6, and increasing IL-10. Adrenaline could also increase angiopoietin-1 mRNA expression of BMSCs.

**Conclusions:** Adrenaline could help BMSCs modulate LPS induced lung injury in vitro, probably through promotion of proliferation, migration and angiopoietin-1 secretion.

**3102** LSC 2012 Abstract – Mesenchymal stromal cells identified in tissue from lung-transplanted patients

**Background:** Chronic rejection expressed as bronchiolitis obliterans (BO) is seen in 50% of lung-transplanted (LT) patients. BO is characterized by extra cellular matrix deposition, where the fibroblast is thought to be a key player. The fibroblast origin is at present not fully known. The fibrocyte is one of the potential origins, and our group has shown that fibrocytes are associated with remodelling in BO. In this study we focused on another origin the mesenchymal stromal cell (MSC).

**Objectives:** Our aims were to examine whether MSC are present in tissue from LT patients and to evaluate whether these cells displays characteristic MSC properties such as adherent clonal growth, multi-lineage potential and a characteristic surface marker profile.

**Methods:** We examined lung biopsy material from LT patients to identify MSCs. Immunofluorescence was used to stain for specific surface markers.

**Results:** MSCs were identified in lung biopsy material from LT patients and the single cell suspension was seeded in colony-forming unit-fibroblast (CFU-F) assays. Isolated MSC were differentiated towards adipocytes, osteoblasts and chondrocytes. Their surface markers was examined by flow cytometry.

**Conclusions:** Our study suggests that MSC are present in lung tissue from LT patients. These cells display colony growth, multipotential and a characteristic MSC surface marker profile.

**3103** LSC 2012 Abstract – TGF-β1 regulates the epithelial supportive capacity of mesenchymal stromal cells

Jonathan McQuater, Rosa McCarty, Ivan Bertocchi. Department of Pharmacology, University of Melbourne, Melbourne, United Kingdom

Despite recent advances in biomarker profiling, prospective isolation and clonogenic assay of putative lung stem cells their regenerative capacity remains ill-defined. On that account we have developed a clonogenic colony-forming assay that has enabled us to identify a population of multi-potent lung epithelial stem cells (EpCAM+CD49f+CD44+CD24−CD104+CD10−) that are able to self-renew and give rise to alveolar and Clara epithelial cell lineages. However, the intrinsic regenerative potential of stem cells is conditional upon their interaction with permissive and restrictive microenvironmental cues. On this note, we have shown that the proliferation and differentiation of lung epithelial stem cells in vitro is dependent on co-culture with endogenous lung mesenchymal stromal cells (EpCAMneg Sca1-1pos), or mesenchyme-derived growth factors including FGF-10 and HGF. On the flip side, we have shown that more differentiated mesenchymal stromal cells (FGE-110f0 SMApos) are unable to support epithelial colony formation. Importantly, we have shown that the capacity of mesenchymal stromal cells to support epithelial stem cells is regulated by TGF-β1 and can be reversed by blockade of SMAD2/3 phosphorylation downstream of TGF-β activation. This data suggests that TGF-β mediated mesenchymal differentiation in chronic lung diseases may obstruct epithelial regeneration.

**348. Act to change tobacco epidemics**

**3104** Stop smoking prevention in the BOLD study

Louisa Gnatiuc, Bernet Kato, Peter Burney. Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom

**Background:** Tobacco smoking is a risk factor for COPD. Stop smoking strategies are associated with slower lung function decline. We used the BOLD data to describe the use of stop smoking prevention across 20 sites.
smoking rate in 12-15 years old Parisian school is sensitive to political

Conclusions: Use of stop smoking prevention is associated with chronic respiratory disease and pack-years smoked, is higher in current smokers than in ex-smokers and in HICs than in LMICs. Understanding factors influencing use and optimising use in current-smokers and LMICs are important.

Smoking rate in 12-15 years old Parisian school is sensitive to political

of the physicians had education about counselling regarding SHS in children. Of those without education, 49.2% wants to be educated.

Conclusion: Dutch physicians insufficiently discuss second-hand smoking in children and lack of time was the most frequent barrier. Child healthcare practices should make more efforts to increase parental awareness and actively contribute to the decrease of SHS in children.

3101

Gain in survival due to smoking cessation in the Italian population

Giulia Carreras1, Andrea Martini1, Giuseppe Gorini2, Laura Carrozzi2, Francesco Pessielli3, Carlo Zerbino1, Franco Falcone1, Giovanni Viegli3,4

1Environmental and Occupational Epidemiology Unit, Cancer Prevention and Research Institute (SPOF), Florence; 2Cardiothoracic and Vascular Department, University Hospital, Pisa; 3General Management, Italian Association of Hospital Pulmonologists (AIPDO) Research, Milan; 4Institute of Clinical Physiology (IFC), National Research Council (CNR), Pisa; 5Biomedicine and Molecular Immunology (IBIM), National Research Council (CNR), Palermo, Italy

Introduction and aim: Smoking is the largest preventable cause of health impairment. An important and challenging task for health professionals is to communicate the health benefits associated with smoking cessation. A simple and effective way could be to compute, for each individual smoker, the number of life years which he/she may gain by quitting smoking. Aim of the study was to estimate gain in life years associated with smoking cessation by using Italian data.

Methods: We computed mortality tables [1] based on Italian data, specific for current and former smokers. Subsequently, the survival curves of former and current smokers were compared to estimate the number of life years gained with quitting smoking at various ages [2], by gender and number of cig. smoked per day.

Results: Based on the implemented statistical model, men and women smoking 10-19 cig. per day and quitting at age 30, 40, 50, or 60 years, gained about 7, 6, or 5, and 5, 4, 3, or 3 years of life, respectively. The gain in life years was higher for men and women smoking more cig. per day (9 years for > 20 cig.) and lower for light smokers (2 years for 1-9 cig.) and related to age of quitting.

3110

Factors influencing dropout of a smoking cessation consultation in patients treated with varenicline

Sergio Campanilha Fernandes, Carla Ribeiro, Regina Monteiro, Ana Antunes, Miguel Guimarães, Ivone Pascual, Pulmonology, Vila Nova de Gaia Hospital Centre, Vila Nova de Gaia, Portugal

Introduction: Smoking cessation clinics have high dropout rates. Reasons are often not clear.

Aim: To determine factors influencing dropout of smoking cessation clinics in patients treated with varenicline.

Methods: Retrospective cohort of patients started on varenicline. Comparative analysis of patients who dropped out (group 1) or not (group 2) our clinic at 4, 12, 24 and 52 weeks according to demographics, attempts to quit smoking, previous diseases, motivation (Richmond) and dependence (Fagerstrom) assessed on first analysis of patients who dropped out (group 1) or not (group 2) our clinic at 4, 12, 24, and 52 weeks. At week 4 dropout was observed in older age (p = 0.018) and individuals with respiratory disease (p=0.045). There was negative relation between motivation and dropout at week 12 (p=0.05) and between dependence and dropout at week 24 (p=0.04). Smoking in the previous appointment increased dropout risk at 24 and 52 weeks (p=0.001 and p=0.001).

Conclusion: Younger individuals with no respiratory disease, less dependent and less motivated tend to dropout more. At week 24 and 52 those who continue smoking and do not adhere to varenicline quit more. Our results may help to identify individuals most likely to abandon programs and improve strategies to address them.

Method: We analyzed patients that were followed in our asthma unit in last 3 months. We totally recruited 141 patients (48 men (34.3%) and 93 women (66.7%); average age = 49.8±16.90 years old). We registered their smoking history and phase, control and crisis of asthma in the last year.

Results: 5 patients (3.5%) were in intermittent asthma, 18 (12.8%) mild persistent, 69 (48.9%) moderate persistent and finally 49 (34.8%) severe persistent. About control we observed 32 patients (22.7%) were well-controlled, 51(36.5%) were partially-controlled and 54 (41.1%) were not-controlled. The smoking history showed 18 patients (12.8%) were active smokers, 25 (17.7%) ex-smokers and 98 (69.5%) non-smokers. If we analyze the smokers ones, 9 (50%) were moderate-persistent asthmatics, 8 (44.4%) severe-persistent and only 1 patient (5.5%) was mild-persistent. Ex-smokers: 10 of them (40%) were severe-persistent, 9 (36%) moderate-persistent and 9 (20%) mild-persistent. About control of asthma, 11 smokers (61.1%) and 12 ex-smokers (48%) were not-controlled. 7 smokers (38.8%) and 9 ex-smokers (36%) were partially-controlled. Only 4 ex-smokers (16%) were well-controlled. Finally, 39 patients (27.7%) visited emergency units in the last year. 14 of them were smokers (35%) and 11 ex-smokers (28%). In the same way, 14 of total smokers (77%) needed emergency units care. So 11 ex-smokers (25%).

Conclusion: Tobacco can affect the asthma management. Smokers and ex-smokers have worse control of asthma than non-smoker people, and they use to have more severe asthma too.

349. Immunologic mechanisms in COPD and asthma

3112

The profile of dendritic cell and T cell response is related to the viral trigger in children with severe asthma exacerbation

Effence Mordaci5,6,1, Sofia Tsousa2, Maria Semitekolou2,3, Francesca Marfell2, Regina Monteiro, Ana Antunes, Isabelle Tille-Leblond1

1Centre d’Investigation Clinique de L’Institut Pasteur de Lille, Lille, France; 2Pneumologie et allergologie Pédiatriques, Hôpital Jeanne de Flandre, CHRU Lille, France; 3Laboratoire de Virologie, CHRU Lille, Lille, France

Viral infection are associated with asthma exacerbations (AE). Activation of dendritic cells (DC) plays a key role in the response to virus and drives the activation and polarization of T cells. Mobilization of Pattern Recognition Receptor (PRR)- Toll Like Receptor (TLR5) RNA helicases (RIG-I, MDA5) are involved. Our purpose was to analyze expression and function of the PRR in DC and to corroborate this with the presence of virus and the T cell response.

Methods: 54 allergic asthmatic children (6-15 y) included during hospitalization for severe AE. Virus identified on nasal secretions by RT-PCR. T cell response determined in blood and induced sputum at the inclusion and in the stable state, 8 weeks later. Mononuclear cells (MNC) stimulated with poly(IC) and with varespland and poly(I:C) and levels of IL-12, IFN-γ, IL-17A measured. Ex- pression of markers of maturation (CD80, CD86) and PRR studied in circulating DC and induced sputum at the inclusion and in the stable state.

Results: Virus were indentified in 60% (Rhinovirus: 82%). A Th1 and Th17 (IFN-γ, IL-17A) response was observed in the Airways and the blood from the infected patients (+V) during exacerbation whereas a Th2 (IL-4) response prevailed in non-infected patients (V-). The stimulation of MNC induced a Th2 and Th17 response for V+ at inclusion, but Th1 in V-. A defect in RNA helicases expression by blood DC was observed in V+ at inclusion, while the expression of the markers of maturation did not differ among both groups.

Conclusion: Viral infection modifies the T cell response during AE and is associated with a defect of RNA-helicase expression in DC. This could contribute to describe new mechanisms in the virus induced AE.

Lung dendritic cells from chronic obstructive pulmonary disease patients induce type I T regulatory cells

Maria Tsoumakidou1,2, Sofia Tsousa2, Maria Semitekolou2, Panagiota Panagiotou1, Anna Panagiotou1, Ellen Litos1, Ioannis Moranos1, Maria Konstantinou1, Antoine Deschamps1, Spyros Zakyntinos1, 2, Georgina Xanthou1, 2, 1Critical Care Medicine and Pulmonary Services, Evangelismos General Hospital, Athens, Greece; 2Cellular Immunology, Biomedical Research Foundation of the Academy of Athens, Greece; 3Thoracic Surgery, Sotira Chest Hospital, Athens, Greece

The high mortality rate and health care costs associated with Chronic Obstructive Pulmonary Disease (COPD) are due to a great extent to recurrent infections exacerbations. Impaired T cell immunity might explain this susceptibility to infections. Mature dendritic cells (DCs) are crucial players in the induction of T cell responses against infectious agents. By contrast, immature DCs induce tolerance by promoting the differentiation of regulatory T cells (Tregs). We have previously shown

5525
that lung DCs of COPD patients express low levels of co-stimulatory molecules, respond poorly to stimulation and display low ability to prime autologous lung T cells and allogeneic naive T cells. Importantly, naïve T cells primed with lung DCs from patients with COPD inhibit T cell proliferation. Here, we have characterized the gene and protein expression profile of these regulatory cells and investigated the mechanism of their suppressive function. Naïve CD4+ T cells primed with lung DCs from COPD patients showed increased gene expression for TGF-β, AHR and GATA3 (assessed by qRT-PCR) compared to T cells primed with lung DCs from smokers without COPD. Accordingly, flow cytometry analysis showed higher IL-10 and Foxp3 intracellular protein expression. These findings suggest that the induced regulatory cells are Tregs type 1. Type 1 Tregs suppress immune responses primarily through IL-10. Indeed, naïve T cells that had been primed with COPD lung DCs failed to inhibit T cell proliferation in the presence of blocking IL-10-10 receptor antibody. Our findings show that lung DCs from patients with COPD induce type 1 Tregs.

3114 Lung B cell-derived CXCL13 is critical for lymphoid follicle formation in chronic obstructive pulmonary disease (COPD). Eleni Litsiou1, Maria Semitekolou2, Ioannis Morianos 2, Aikaterini Tsoutsa 1, Konstantinos Potaris 1, Georgina Xanthou 2, Spyros Zaktakinos 1, Maria Tsoumakidou 5, Critical Care Medicine and Pulmonary Services, Evangelismos General Hospital, Athens, Greece; 2Cellular Immunology, Biomedical Research Foundation of the Academy of Athens, Greece; 3Pathology, Evangelismos General Hospital, Athens, Greece; 4Thoracic Surgery, Evangelismos General Hospital, Athens, Greece; 5Sotiria Chest Hospital, Athens, Greece

Lymphoid follicles (LFs) that have a similar organization to lymph nodes are found in small airways and alveoli in Chronic Obstructive Pulmonary Disease (COPD), but the mechanism of their development is unclear. During lymph node ontogeny, the initiating event to LF formation in COPD is B cell stimulation, leading to LT expression and CXCL13 production. CXCL13 positively feeds back LT, fostering LF formation in COPD-LFs. The BALB/c mice were treated with intranasal house dust mite (HDM) for 24 weeks. Finally, pulmonary Muc5ac mRNA expression was significantly increased upon 4 weeks of CS-exposure, but not upon 24 weeks. Accordingly, protein levels of Muc5ac were significantly elevated in BAL fluid of mice exposed to CS for 4 weeks, but not for 24 weeks. Finally, pulmonary Muc5ac mRNA expression was significantly increased upon both 4 and 24 weeks of CS-exposure, while we found no differences in the mRNA expression of Muc5b. These data demonstrate that 4 weeks of CS-exposure leads to increased expression of ADAM19 and enhanced shedding of neuregulin-1. Binding of neuregulin-1 to the epidermal growth factor receptor (EGFR) plays an ubiquitous role in the ontogeny of LT-expressing lymphoid tissue inducer cells induce lympho- phine production (mainly CXCL13) to LT-receptor-expressing stromal cells. Lymphokines attract haemopoietic cells leading to lymphoid organ development. We examined the role of the initiating event to LF formation from COPD patients with LFs (COPD-LF+), without LFs (COPD-LF-) and never-smokers. Lung CXCL13 was significantly increased in COPD-LF+ compared to COPD-LF- and never-smokers and positively correlated to surface area of LFs. Immunostaining showed CXCL13 expression in B cells of LFs. Flow cytometry indicated that among lung cells, B cells have the highest expression for LT receptors. Ex-vivo, lipopolysaccharide (LPS) and a LT-receptor agonist induced CXCL13 production to whole lung cell cultures have the highest expression for LT receptors. Enzyme-linked immunosorbent assay (ELISA) showed that the initiating event to LF formation in COPD is B cell stimulation, leading to LT expression and CXCL13 production. CXCL13 positively feeds back LT, amplifying its levels and attracting more B cells that organize themselves into LFs.

3115 Dendritic cells’ nerve interaction in allergic airway inflammation Duc Dong Le2,3,4, Sabine Rochlitzer 4, Ulrike Funck2, Hendrik Suhling2, M. de Vries, J. de Vries, M. van der Toorn, A.J.M. van Oosterhout, M.C. Nawijn. University Hospital, Groningen, Netherlands

Introduction: Dendritic cells (DC) play as antigen-presenting cells a decisive role within the allergic airway inflammation. The colocalisation of DC in sensory ganglia has not been explored so far. The aim of the present study is to evaluate possible interactions between DC in sensory ganglia concerning calcitonin gene-related peptides (CGRP)-expression during allergic airway inflammation. Methods: The BALB/c mice were treated with intranasal house dust mite (HDM) extract (32 μg/g) for 5 days a week within a total period of 7 weeks. The jugular-nodose ganglion complex was removed 24 hours after final allergen chal- lenge and histological slices were prepared. Immunohistochemistry was performed to determine the colocalisation of DC by MHC-II and CD11c and neurons by neuronal marker PGP 9.5. Results: Under physiological conditions dendritic cells are found in the vagal sensory ganglia of the mouse and that they were significantly increased during an allergic airway inflammation (DCs/neurons: control 23±8.7/6.1% vs. HDM 49.75±6.194%, p = 0.0083). Additionally, an increased number of CGRP positive neurons in vagal sensory airway ganglia during allergic airway inflammation was found (CGRP+/nerve terminal neurons: HDM 52.07±3.04%/vs. control 21.63±3.799%, p = 0.0001).

Conclusion: The finding of the presence of DC in the airway jugular-nodose gan- glion indicates a role of the DC in these ganglia under physiological conditions. The increased numbers of DC and CGRP-positive neurons in these ganglia suggest the involvement of the pathogenesis of allergic airway inflammation. However, the exact functions of DC and CGRP in allergic airway inflammation remain to be explored in future studies.

3116 LSC 2012 Abstract – The protective role of Pim1 in cigarette smoke induced damage of airway epithelium M. de Vries, R. Gras, L.E. den Boef, M. van der Toorn, A.J.M. van Oosterhout, M.C. Nawijn. Pathology and Medical Biology, Allergology and Pulmonary Disease, UMC, Groningen, Netherlands

Rationale: The main risk factor of developing COPD is exposure to cigarette smoke. CS exposure induces airway epithelial cell damage, release of DAMPs and an innate inflammatory response. We previously observed increased expression of Pim1 in vivo after sub-chronic CS exposure in mice. Pim1 is a serine/threonine kinase involved in cell growth and survival by preventing apoptosis induction through the mitochondrial pathway. We hypothesize that Pim1 plays a protective role in the airway epithelium after CS exposure by phosphorylating BAD and enhancing cell survival. Methods: Pim1 KO mice were exposed to CS twice a day for 4 days. Inflammatory cells and KC levels in BAL were determined. Beas-2b cells were treated with CS extract (CSE) for 4 hours with(out) Pim-inhibitor. Mitochondrial membrane potential (MMP) and apoptosis/necrosis induction were measured by flowcytometry. BAD phosphorylation was determined by Western Blotting. Results: CS exposure induces neutrophilic airway inflammation and increases KC levels in Pim1-KO mice, but not in WT controls. CSE induces a dose-dependent loss of BAD phosphorylation, loss of MMP and necrotic cell death in Beas-2b cells. All of these CSE-induced effects are aggravated by inhibition of Pim1. Conclusion: Pim1 protects airway epithelial cells from CS-induced damage and cell death by phosphorylating BAD and increasing the threshold for apoptosis. In vivo, this protective effect suffices to prevent CS-induced neutrophilic airway inflammation.

3117 LSC 2012 Abstract – Role of ADAM19 and neuregulin-1 in Muc5ac expression in lungs of cigarette smoke-exposed mice Lisa Dupont, Guy Joos, Guy Brusselle, Ken Bracke. Respiratory Medicine, Ghent University Hospital, Ghent, Belgium

Mucus hypersecretion is an important feature of COPD, resulting in chronic cough and contributing to dyspnea by obstructing the airway lumen. Signalling through the epidermal growth factor receptor (EGFR) plays an ubiquitous role in the production of mucins. We hypothesise that A Disintegrin And Metalloprotease19 (ADAM19) stimulates mucin production by shedding of the EGFR-ligand neuregulin-1. C57BL6 mice were exposed to air or cigarette smoke (CS) for 4 or 2 weeks. IHC for ADAM19 on lung tissue sections showed intense staining in bronchial and vascular smooth muscle cells, as well as in endothelium, and a faint stain- ing in bronchial and alveolar epithelial cells. Quantitative PCR analysis of ADAM19 protein expression in the airway wall showed a significant increase upon 4 weeks of CS-exposure, but not upon 24 weeks. Accordingly, protein levels of neuregulin-1 were significantly elevated in BAL fluid of mice exposed to CS for 4 weeks, but not for 24 weeks. Finally, pulmonary Muc5ac mRNA expression was significantly increased upon both 4 and 24 weeks of CS-exposure, while we found no differences in the mRNA expression of Muc5b. These data demonstrate that 4 weeks of CS-exposure leads to increased expression of ADAM19 and enhanced shedding of neuregulin-1. Binding of neuregulin-1 to the EGFR may contribute to the increased expression of Muc5ac. However, especially upon chronic CS-exposure, other EGFR-ligands or alternative mechanisms may be involved in mucin production.
release and cell count of TH1 cells, these effects were enhanced in COPD. LPS effect on IL-2 negatively correlated with FeV1 [% pred.] and was abolished by CL895. In the presence of LPS, blocking MyD88/IRAK was more efficient in restoring IL-2 release in NS vs. COPD, whereas blocking TIRF/IKKc was more efficient in COPD, and miroxiforxacin (MXF) increased IL-2 release and cell count of TH1 cells. MXF effect on IL-2 was enhanced in COPD and correlated to the IL-2-inducing effect of p38MAPK inhibitor SB203580. All effects were p<0.05. LPS and MXF did not induce TH1 cell death.

TH1 response to bacterial infections is impaired in COPD due to a shift from MyD88/IRAK to TIRF/IKKc signalling, which enhances suppression of IL-2 and TH1 growth by LPS. MXF might reinforce IL-2 expression and TH1 growth by blocking p38MAPK signalling. Targeting TLR4 signalling combined with MXF might reduce exacerbation rates.

LSC 2012 Abstract – FOXO transcription factors regulate innate immune mechanisms in respiratory epithelial cells during bacterial infection
Christoph Reisswenger, Frederik Seiler, Philipp Lepper, Robert Bals, Christian Herr. Department of Internal Medicine V, Saarland University Hospital, Homburg/Saar, Germany.

Bacterial pathogens are a leading cause of lung infections and contribute to acute exacerbations in patients with respiratory tract diseases. The innate immune system of the lung controls and prevents colonization of the respiratory tract with bacterial pathogens. Here, we show that FOXO transcription factors regulate innate immune mechanism of respiratory epithelial cells in response to bacterial pathogens such as Haemophilus influenzae and Pseudomonas aeruginosa. Infection with bacterial pathogens led to the activation of FOXO transcription factors in respiratory epithelial cells in vivo and in vitro. siRNA mediated knock down of FOXO3 in bronchial epithelial cells resulted in reduced expression of factors of the innate immune system such as antimicrobial peptides and factors involved in a proinflammatory response. In addition, FOXO3 plays a role in the internalization of bacterial pathogens. These data show that FOXO transcription factors are involved in the cellular response to bacterial stimuli and have a central role in regulating innate immune functions of respiratory epithelial cells.

Ventilatory restrictive impairment in thalassemia patients: Gender differences and correlation with hypogonadism and iron overload
S. Roggero1, L. Zito2, A. Piga1, C. Ciacco3, M. Guglielmo3, M.V. de Vita1, R. Tocchini1. 1Thalassemia Center, University, Turin, Italy; 2Respiratory Disease Postgraduate School, University, Turin, Italy; 3Lung Function and Sleep Laboratory, AOU S. Luigi, Orbausano, TO, Italy.

Background and aim: Ventilatory restrictive (RES) impairment has been described in β-thalassemia, but no evidence exists on the causal mechanism. We investigated relationships among lung function, iron overload and clinical parameters in a homogeneous series of β-thalassemia major adult patients.

Methods: We studied 70 patients (males M/females F 44/35; age 34.5 ± 35 yrs) with β-thalassemia major on regular transfusion and iron chelation. Iron overload was assessed by serum ferritin, liver iron concentration (LIC) by SQUID susceptometry, cardiac iron by MRI T2*. Lung volumes, diffusion capacity, chelator drugs, hypogonadism (H), hypothyroidism and osteopenia were evaluated in stable hematologic conditions.

Results: 30/79 pt (38.5%) [21/44 (47.7%) M and 9/35 (25.7%) F] showed RES, 6 bronchial obstruction with no gender differences (3M:3F). In F LIC was higher 2249±903 vs 1497±553 mgFe/gliver dw; p<0.008 in RES vs normals and correlated with total lung capacity (r=0.40; p<0.03). No differences were present for hypothyroidism, osteopenia or 3 iron chelators. Among RES patients 575M and 88S/F were H. M males showed higher cardiac iron MRI T2* 29.6±12.7 vs 39.6±9.2 ms; p<0.03) but similar LIC in respect to non H, without correlation with total lung capacity. In F cardiac and hepatic iron levels were not different between H and non H.

Conclusions: RES is present in 1/3 of well compensated adult thalassemic (M/F 1:88). Iron (LIC) was higher in RES F vs normals and H males have higher MRI T2*. Different gender impact of H on lung and chest growth, severity and efficacy of replacement therapy can explain data but the involved mechanisms is still unclear.

Coexistent granulomatosis with polyangiitis (Wegener’s) and Crohn disease: A clinicopathologic description of cases
Lazza Vaggion1, Antonio Domenico, Ezio Mark1, Ulrich Specks2, Steven Ytterberg1, Henry Taiebala1, 1Medicine, Mayo Clinic, Scottsdale, AZ, United States; 2Medicine, Mayo Clinic, Rochester, MN, United States; 3Pathology, Massachusetts General Hospital, Boston, MA, United States; 4Pathology, Mayo Clinic, Scottsdale, AZ, United States.

Background: Crohn disease (CD) may lead to various extraintestinal manifestations, including, rarely, respiratory tract involvement. When necrobiosis pulmonar y nodules are present, the differential diagnosis includes granulomatosis with polyangiitis (Wegener’s) (GPA). The respiratory tract manifestations of CD and GPA may mimic each other, complicating the diagnosis and suggesting the possible coexistence of these two conditions.

Aims: To describe the clinical, radiographic and histopathologic features of patients in whom CD and GPA coexist.

Methods: We reviewed the teaching files of the authors and searched the Mayo Clinic medical records for coexistent inflammatory bowel diseases and ANCA-associated vasculitides of the lungs. We reviewed in detail 97 patient charts, and excluded cases of ulcerative colitis and those in whom only one of the diagnoses was present or pathology slides were unavailable. Pulmonary and gastrointestinal biopsies were reviewed for the cases included in the study.

Results: Four cases were identified (2 women and 2 men, age range: 25-62). The diagnosis of CD preceded that of GPA in all cases. Protein-ANCA was positive in two cases, while in the other two PR3- and MPO-ANCA were both negative. Chest imaging showed pulmonary nodules in all cases. Pathology revealed features diagnostic of GPA in all cases with necrotizing granulomatous inflammation and segmental vasculitis. In addition, one case showed capillaritis.

Conclusion: Pulmonary nodules are more frequent in patients with CD, as the presence of granulomatous colitis in patients with GPA should prompt the inclusion in the differential diagnosis of a possible coexistence of CD and GPA.

3122
Arterial hypoxaemia in morbid obesity
Evodry Ayangnuni1,2, Ewa Rosas1, Yolanda Torralba2, Concepcion Gistau3, Felip Burgos1, Josep Roca2, Roberto Rodriguez-Roisin1,2. 1Servicio de Pneumologia, Hospital Clinic of Barcelona, Spain; 2CIBER de Enfermedades Respiratorias, CIBERES, Palma de Mallorca, Islas Baleares, Spain; 3Servicio de Anestesiologia, Hospital Clinic of Barcelona, Spain.

Introduction: Morbid obesity (MO) can be associated with arterial hypoxaemia, mostly to a highly prevalent obstructive sleep apnoea (OSA).

Objective: To determine the prevalence of hypoxaemia in patients with MO before and one year after bariatric surgery (BS) and its correlation with OSA.

Methods: We included 230 patients (44% M, 56% female; BMI, 46.7±2 kg/m2; and, waist-to-hip-ratio, 0.96±0.08). OSA was defined as an apnoea/hypopnoea index (AHI) ≥10.

Results: Before BS, all patients (ERV, 33.4±22%) had spirometry and DLCO within reference values, with normal PaO2 (83±12 mmHg) and PaCO2 (36±3 mmHg) values. One hundred and fifty four (70%) patients had OSA (48%, severe OSA [AHI ≥30]), 66 (43%) with hypoxaemia (PaO2, 70.6±7 mmHg). Patients with OSA had lower PaO2 and higher PaCO2 than those without OSA (p<0.05 each). Thirty out of 230 patients (13%) without OSA had hypoxaemia (PaO2, 74±4 mmHg), whose PVC, FEV1, VC, IC, ERV and DLCO were lower than those in normoxaemic patients (p<0.01 each). Overall PaO2 was correlated with waist-to-hip-ratio (r=0.30, p<0.05). Before BS, age, sex, PVC, ERV and waist-to-hip-ratio were the independent factors associated with hypoxaemia (r2=0.28, p<0.05) (multiple regression analysis). After BS, patients had a 76±18% of excess weight loss with overall improvement in lung function (p=0.01 each) while OSA ameliorated in 65% of them. Post-BS ERV (115±37%) and PaO2 (93±10 mmHg) improvements (p<0.01 each) were associated (r=0.22, p<0.05).

Conclusions: Hypoxaemia continues to be a common finding in MO, mostly in patients with OSA. However, hypoxaemia can also be present without OSA, possibly related to central obesity.

Hypoxic challenge assessments in patients with obesity hypoventilation syndrome
Masoed Ali1, Ian Smith2, Aatul Gulati3, John Shneerson2. 1Heart & Chest Clinic, Southend University Hospital NHS Foundation Trust, Southend-on-Sea, Essex, United Kingdom; 2Respiratory Support & Sleep Centre, Papworth Hospital NHS Foundation Trust, Cambridge, Cambridgeshire, United Kingdom; 3Respiratory Medicine, Colchester Hospital NHS Foundation Trust, Colchester, Essex, United Kingdom.

Background: With worldwide increase in obesity and air travel, more obese people are likely to travel by air in future. No prospective studies have investigated the degree of arterial hypoxaemia during a hypoxic challenge test (HCT) in patients with obesity hypoventilation syndrome (OHS).

Objectives: To investigate the likelihood of a positive HCT in patients with OHS
who are not hypoxicemic at sea level and any possible predictors of desaturation during HCT.

Methods: Ten patients with OHS treated with long term nocturnal non invasive ventilation (NIV) were recruited. Clinically unstable patients and those with COPD were excluded. HCT was part of a detailed assessment and consisted of breathing 15% oxygen via a Douglas bag for 20 minutes.

Results: Mean age 57.4 years (±12.4) and mean BMI 32.8 (±13.3). Seven out of ten had a positive HCT (PaO2 < 6.6 kPa or SpO2 < 85%). Arterial blood gas was attempted in all but could not be taken in two patients. Mean PaO2 before and during HCT were 10.4 kPa (±0.4) and 6.2 kPa (±0.5) respectively. Mean PaCO2 before and during HCT was 5.5 kPa (± 0.8) and 3.5 kPa (±0.8) respectively. Baseline PaCO2 correlated negatively with PaO2 and SpO2 during HCT (r = -0.823, p=0.012 and r = -0.795, p=0.018 respectively). BMI, baseline PaO2 and SpO2, distance walked and minimum SpO2 during BSAT were not significantly correlated with the PaO2 or SpO2 during HCT.

Conclusion: Seventy percent of these patients had a positive HCT despite adequate control of their ventilatory failure. Baseline PaCO2 but not the PaO2 or SpO2 was predictive of a positive HCT. Although these results need to be confirmed in larger studies, we suggest assessment of these patients including a HCT before air travel.

3124 Pulmonary involvement in patients with Marfan syndrome
Isa Ceretti, Angelo Corsico, Bianca Tirone, Federica Albicini, Amelia Grosso, ErncaGini, Andrea Mazzetta, Eti Maria Giulia Di Vincenzo, Roberto Dore, Eleonora Arbustini, Maurizio Lunetti. Foundation IRCCS “San Matteo” Hospital, University of Pavia, Italy

Pulmonary involvement is not generally considered a main feature of Marfan syndrome, particularly in the early days of this disorder caused by mutations of the extracellular matrix protein fibrillin1 particularly affecting vascular, skeletal and ocular systems. However, thanks to the substantial progress in treatments, life expectation of these patients has been dramatically improved in the last 20 years determining changes in different organ systems. The number of patients with a degree of underlying pulmonary pathology may be higher than expected. Clinical history, chest CT, spirometry, lung volumes, and diffusion capacity have been assessed in 64 patients of our national referral center (mean age 32±14 years; M 45%). None of the patients reported chronic respiratory symptoms and only 5% had smokers. Fourteen per cent reported a previous pneumothorax and 2 of them underwent surgery. Three reported bullae and 1 underwent bullectomy. Eleven per cent had radiological signs of emphysema and 32% apical blebs. Twenty-three per cent had aortic thoracic surgery. Forty-five per cent had moderate to severe rib cage abnormalities; 4 of them underwent repeated surgical corrections. Only 37% of our patients showed a restrictive pattern and 19% an obstructive pattern or an isolated diffusion impairment or an isolated hyperinflation. All patients with previous pneumothorax showed an obstructive pattern and diffusion impairment. In conclusion, in the absence of respiratory symptoms, pulmonary abnormalities should be actively detected and monitored and particular attention should be paid to prevent pneumothorax. Our results support the importance of lung volume determination and, when needed, chest CT in Marfan patients.

3125 Lung function abnormalities in patients with heart failure and preserved ejection fraction
Alejandro Lopez-Giraldo1, Rut Andrea2, Patricia Sobradillo2, Carlos Falces1, Laura Sanjuan1, Concepcion Guisat1, Magda Herza3, Josep Brugada4, Alvar Agusti4, 1Pneumology, Thorax Institute, Hospital Clinic, Barcelona, Spain; 2Cardiology, Thorax Institute, Hospital Clinic, Barcelona, Spain

Introduction: Heart failure with preserved ejection fraction (HFPEF) accounts for 40-50% heart failure patients. The aim of this study was to evaluate the prevalence, type and severity of lung function abnormalities among patients with HFPEF.

Methods: In this prospective, descriptive study we included consecutive outpatients with new onset of HFPEF according to the European Society of Cardiology criteria. All underwent a clinical evaluation, chest X-ray, electrocardiogram, echocardiography, brain natriuretic peptide determination, forced spirometry, lung volumes by body plethysmography, single-breath carbon monoxide diffusing capacity (DLCO) corrected for alveolar volume and arterial blood gases.

Results: We included 193 outpatients (68% females), mean age 77 years. Mean body mass index 29.8 kg/m2. 85% had arterial hypertension. 25.4% former smokers (5% women). 19% had hypoxemia (mild 63.3%, moderate 26.6%, severe 10%).

Conclusions: Patients with HFPEF show a high prevalence of lung function abnormalities. Most are underdiagnosed and may contribute to their symptoms. Their pathophysiology is likely multifactorial (smoking, obesity, age, heart function) but requires further research.

3126 Patients with tissue hypoxia with unknown origin
Yoann To1, Kousuke Araki1, Yuta Kono1, Masako To1, 1Allergy and Respiratory Medicine, The Fraternity Memorial Hospital, Tokyo, Japan; 2Laboratory Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan

Background: Dyspnea is common complication in respiratory disease and is mainly caused by hypoxemia due to lung diseases, cardiac diseases or neurologic diseases. Patients with dyspnea without hypoxemia, hypercapnia and clear abnormal chest X-ray findings considered to be a difficult diagnostic problems. We have found a group of some patients who complain dyspnea without hypoxemia (normal SpO2 and PaO2) have high venous oxygen level (PvO2). The aim of this study was to investigate the clinical characteristics of patients who have high PvO2 and normal SpO2.

Methods: Eight patients have dyspnea with high PaO2 with normal SpO2 were enrolled in this study. Patients with any other lung diseases or systemic diseases, abnormal chest X-ray finding or elevation of inflammatory markers were also excluded. Arterial and venous blood gas analysis was performed after 10 minutes bed rest. Tissue oxygen levels (PtO2) was calculated using following equation; PtO2 = PaO2 - PaO2 - PvO2. Serum lactate and pyruvate level were measured by enzyme assay.

Results: PaO2 in patients enrolled (67±12.4 mmHg) was higher than normal range (24-40 mmHg) and PaO2 in patients enrolled was lower (22±17.3 mmHg, normal range: 40-70 mmHg) than normal range. Serum lactate (21.6±7.9 mg/dl) and pyruvate (2.1±0.9 mg/dl) were also elevated compared to normal range.

Discussion and conclusion: The group of patients seem to have dyspnea due to tissue hypoxia. The tissue hypoxia probably raises pyruvate and lactate levels due to activation of anaerobic glycolysis. PtO2 measurement and assessment of tissue hypoxia is need for the patients with dyspnea without hypoxemia. It would be also necessary to explore the cause of tissue hypoxia in the patients.

3127 Lung cancer as a comorbidity in idiopathic pulmonary fibrosis (IPF)
Michael Kreuer1, Svenja Ehlers-Tenenbaum1, Heinrich Wenz1, Hans Hoffmann2, Philipp A. Schnabel3, Claus Peter Heussel4, Michael Puderbach4, Felix J. Hirth2, Arne Warth5, 1Respiratory Care Medicine, Thoraxklinik, Universitätssklinikum Heidelberg, Germany; 2Department of Thoracic Surgery, Thoraxklinik, Universitätssklinikum Heidelberg, Germany; 3Institute of Pathology, Universität Heidelberg, Germany; 4Department of Diagnostic and Interventional Radiology with Nuclear Medicine, Thoraxklinik, Universitätssklinikum Heidelberg, Germany

Introduction: IPF is associated with an increased risk for lung cancer. This might be explained by a contribution of IPF to lung cancer (LC) development or a role of LC in IPF development and/or by shared pathomechanisms causing both IPF and LC. However, data on incidence and reports on treatment related complications are limited.

Methods: In a retrospective monocenter analysis, patients (pts) who were diagnosed between 1/2004-12/2011 with IPF according to the current ATS/ERS guideline were reviewed for the diagnosis of LC.

Results: Of 229 IPF pts, 28 had IPF with LC (12%): 92% male, median age 67 years, median 39.5 pack years, median VC 82% pred., TLC 81% pred, TLCO-SB 35% pred. 75% had NSCLC with stages IA (5%), IB (10%), IIIA (29%), IIIB 35%. Of 229 IPF pts, 28 had IPF with LC (12%): 92% male, median age 67 years, median 39.5 pack years, median VC 82% pred., TLC 81% pred, TLCO-SB 35% pred. 75% had NSCLC with stages IA (5%), IB (10%), IIIA (29%), IIIB 35% pred. 75% had NSCLC with stages IA (5%), IB (10%), IIIA (29%), IIIB 35% pred. 75% had NSCLC with stages IA (5%), IB (10%), IIIA (29%), IIIB 35% pred.

Discussion: LC is a frequent comorbidity in IPF where an interdisciplinary evaluation of therapeutic options is mandatory. However, treatment related complications, especially after surgery are high. Prognosis of operable patients with IPF and LC might be decreased compared to patients either suffering from IPF or with LC alone.

Lung cancer in Berlin – Significant changes in age structure, gender ratio and histologic subtypes from 2000 to 2008

Torsten Blum1, Stephan Eggeling2, Christian Gogoll3, Christian Grab4, Christian Grohé5, Christel Lauer1, Gunda Leschber1, Jens Neudecker6, Wulf Pankow2, Bernd Schicke1, Paul Schneider1, Nicolas Schoenfeld2, Christian Witt5, Anita Jagota7, Lungenklinik Heckerborn, HELIOS Klinikum Emil von Behring, Berlin, Germany; 8Klinik fuer Pneumologie/Klinik fuer Thoraxchirurgie, Vivantes Klinikum Neukolln, Berlin, Germany; 9MVZ, St. Hedwig Krankenhaus, Berlin, Germany; 10Klinik fuer Pneumologie, Gemeinschaftskrankenhaus Havelsehoefe, Berlin, Germany; 11Klinik fuer Pneumologie/Klinik fuer Thoraxchirurgie, Evangelische Langenklklinik, Berlin, Germany; 12Klinik fuer Pneumologie/Klinik fuer Thoraxchirurgie, Choruit, Berlin, Germany; 13Projektgruppe Lungencarcinom, Tumorzentrum Berlin, Germany; 14Klinik fuer Thoraxchirurgie, DRK Klinik Berlin Mitte, Berlin, Germany

Background: The Tumourzentrum Berlin (TZB) analyses the clinical data of lung cancer pts. in Berlin in order to improve patient care by means of joint quality assurance.

Methods: In this retrospective case study, the pooled data of the TZB of pts. with newly diagnosed lung cancer during 2000 and 2008 were analyzed. Pts. were divided into three 3-year groups (G1: 2000-2, G2: 2003-5 and G3: 2006-8).

Results: The total cohort comprised 14,302 pts. (G1: 4,284 pts, G2: 5,049 pts and G3: 4,969 pts). The increase in pt. numbers in G2 and G3 is explained primarily by an absolute increase in pts. aged ≥ 70 yrs., but there was no trend for an increase of younger pts (Figure 1).

Methods: King’s College Hospital, London, UK, has a multiethnic, deprived hospital 2000-2009.

Results: 7,610 patients were enrolled in 119 centres. 6,083 patients (86.3%) had a NSCLC. The main characteristics of NSCLC patients were: mean age, 65.4±11.4 years; 24.4% female; 11.9% non-smokers, 40.5% ex-smokers, 47.6% current smokers; 69.8% performance status 0 and 1. The main characteristics of the tumour were: 53.5% of adenocarcinoma, 31.0% of squamous-cell carcinoma, and 12.9% of large cell carcinoma; 18.1% stage IA to IB, 14.0% stage IIA, 9.5% stage IIIB and 58.3% stage IV. First-line treatments were: curative surgery, 19.0%; radiotherapy alone, 18.7%; combined radio-chemotherapy, 26.1%; and chemotherapy, 61.8%.

Conclusions: In 10 years, characteristics of NSCLC patients changed with a significantly increase (p<0.001) of women, non-smokers, adenocarcinoma histology, and stage IV at diagnosis.

P3129

Proportion of adenocarcinomas of the lung rise from 22 to 42% in a London hospital 2000-2009

Katie Ward1, Deepak Rao1, Nadeem Maddekar1, Katie Hurt1, Itziar Atucha2, Jane Kelly3, Sabine Popmum1, Suninder Birring1, Richard D. Barker1,
1Department of Respiratory Medicine, King’s College Hospital, Denmark Hill, London, United Kingdom; 2Department of Medical Oncology, King’s College Hospital, Denmark Hill, London, United Kingdom; 3Department of Histopathology, King’s College Hospital, Denmark Hill, London, United Kingdom

Background: The proportion of lung cancers that are adenocarcinomas (ACs) is reported to be increasing in Europe. In 2000-2008 the proportion of UK lung cancers typed as AC was 26%. 1 Incidence of lung cancer in females has recently been reported to be increasing in Europe. In 2006-2008 the proportion of UK lung cancer in females was in line with UK data and is not significantly different from the latest UK female incidence.

Methods: King’s College Hospital, London, UK, has a multiethnic, deprived population of 250,000. Since 1999, all lung cancers have been discussed at a multi-disciplinary (MDT) meeting and recorded on a database. Data for histologically confirmed cases of primary lung cancer diagnosed over the period 2000-2008 were analyzed. Pts. were divided into three 3-year groups (G1: 2000-2, G2: 2003-5 and G3: 2006-8).

Results: The total cohort comprised 14,302 pts. (G1: 4,284 pts, G2: 5,049 pts and G3: 4,969 pts). The increase in pt. numbers in G2 and G3 is explained primarily by an absolute increase in pts. aged ≥ 70 yrs., but there was no trend for an increase of younger pts (Figure 1).

*1 degree of freedom.

Conclusion: The trend for increasing proportion of ACs (and decreasing SCCs) was highly significant; the proportion of ACs in our cohort since 2006 is greater than the latest UK figure and numbers of ACs do not appear to have stabilised. 1 The proportion of female cases is in line with UK data and is not significantly changing.

Figure 1

The proportion of pts. with adenocarcinomas has increased over time for all age groups (Figure 2).

Figure 2

Conclusions: The data of the TZB documented significant epidemiologic changes in pts. with lung cancer over time. In contrast to other regions in the world,
there was no increase of younger pts. inspite of a growing proportion of pts. with adenocarcinoma.

P3131 Features of lung cancer in young people: Report of 14 cases
Bianca Marambio Araschly, Claudia Lucia Toma, Ionela Nicolae Belacomi, Stefan Dumitrache-Rujinski, Tudor Constantinescu, Diana Leonte, Miron Alexandru Bogdan. Pneumology 4, “Marius Nasta” Institute of Pneumology, Bucharest, Romania

Introduction: Lung cancer is one of the most common cancers in all ages. Little is known about clinical factors associated with the development of lung cancer in young patients. That is why mistakes are often made in radiological diagnosis of lung cancer in young people.

Method: In this report were included 14 patients admitted in our institute between 2003 and 2012, 8 males/6 females with the mean age of 29 years. Eight patients were non-smokers, 6 patients were smokers (10-65 pack-years). The patients were initially diagnosed with different lung diseases: asthma (2), pneumonia (7), tuberculosis (5). All patients were evaluated with chest X-ray, CT-scan, bronchoscopy.

Results: Patients presented at the doctor for several symptoms: dyspepsia, fatigue, cough in all cases, fever (2), wheezing (2). Ten patients had inflammatory syndrome. The radiological aspects were: lung tumor (11), multiple nodules (2), and atelectasis (1). All patients had negative exams for My. Tuberculosis. The mean delay of diagnosis was 3.5 months. Cancer was confirmed on histological examinations: bronchial biopsy (12), tumor removed during surgery (1), necropsy (1). The type of carcinoma was adenocarcinoma (6), epidermoid (7), macrocellular (1). Six patients died during initial hospitalization, 8 cases were operated and received postoperative chemotherapy. Conclusion: Lung cancer is unfortunately not the first diagnosis taken into account in young people with respiratory problems. The young patient’s condition deteriorates rapidly and the diagnosis of cancer is made when disease is already in an advanced stage. Diagnosis is often delayed and patients might lose the opportunity of curative treatment.

P3132 A retrospective study of lung cancer in young women Hafsia Zaibi, Hager ben Abdellakhfar, Leila Fekih, Dorra Greb, Ines Akrout, Hela Hachime, Soraya Fenniche, Dalenda Belhabib, Mohamed Lamine Megdiche. IBN NAFIS, Abderrahmane Mami Hospital, Ariana, Tunisia

Introduction: Less advanced disease staging at presentation, better performance status and better survival figures have been noticed in younger (<50 years) lung cancer women W1 as compared to older (>50 years) patients with the disease W2.

Aim: To compare clino-pathological features of lung cancer in young and elderly women and to determine any existing difference between the two groups.

Patients and methods: It’s a retrospective study, including 44 women admitted in our department with lung cancer.

Results: There were 15 young women with a mean age of 41 years (20-50 years) and 29 elderly patients with a mean age of 64 years (51-85 years). 26% of first group were current smoker. 26% of W1 had family history of lung cancer vs 3% of W2 (p=0.02). Comorbidities were seen in 5 cases of W1 and in 45% of W2 (p <0.002). Diagnosis delay was 3 months in W1 and 4.4 months in W2 (p=0.04). 94% of younger women had favourable performance status (PS) ≤1. They were more likely to have small cells carcinoma (20% vs 9%), without significant differences in adenocarcinoma rate (46% vs 43%). 20% of W1 had stage I disease at presentation vs 3% in W2 (p=0.05). Younger had more frequently surgical treatment 33% vs 6% (p=0.04). Mean survival time were better in W1 (3 years vs 1.4 years, p=0.03).

Conclusion: Majority of these patients presented with early stage disease. 26% had positive family history suggesting a possible genetic factor. Favourable performance status resulted in higher resection rate and active treatment, which lead to better survival.

P3133 Pathological profile of lung cancer in Tunisia Abdelhamid Ben Amar, Ilhem Tangui, Wajdi Ketata, Sameh Msaad, Abdelkader Ayoub. Pneumology Department, Hedi Chaker Hospital, Sfax, Tunisia

Introduction: Primary lung cancer represents a major public health problem. Its incidence is increasing worldwide and between one in Tunisia.

Aim: The aim of this work is to study the pathological profile of lung cancer in our department.

Methods: A retrospective study on 200 patients treated between 2005 and 2010 for a primary lung cancer.

Results: The average age of our patients was 60 years and the sex ratio was 10. Histological and seventy eight cases of diagnosed patients were smokers or former smokers. Only one woman was smoking and only 14 among the 181 men were non-smokers. The tobacco intoxication average was 48.9 PA. The non-small-cell lung cancer (NSCLC) has represented the majority of primary lung cancer in our study with 165 cases (82.5%) against 35 cases (17.5%) of small-cell lung cancer (SCLC). Only one woman presented a small-cell carcinoma. The study of the distribution of histological types in the NSCLC showed a predominance of adenocarcinoma (47.5% of cases) followed by a lesser incidence of squamous cell carcinoma (28.5% of cases) and large cell carcinoma (3% of cases). The gender analysis has objectified the same frequency profile in the women and men. The adenocarcinoma and squamous cell carcinoma (63% against 21% of adenocarcinoma of squamous cell carcinoma). Other rare histologic types that were found in our study are: large cell carcinoma, one case of adenosquamous carcinoma and one case of pleomorphic carcinoma.

Conclusion: The histological distribution of primary lung cancer shows an increased frequency of adenocarcinoma, which was more frequent than squamous cell carcinoma (47.5% vs 28.5%) while the latter was clearly predominant in 1994 (42.8% versus 15, 3%).
Aamir Khakwani
critical.

survivors can be attributed to similar aetiologies, genetics and the effects of treat-

(n=4). NSCLC cases showed a relatively equal distribution of early (n=8) and

abdomen, brain) for diagnosis and staging. Most histological types of CPPS were

somatic at diagnosis (n=17). All patients performed chest X-ray and CT (chest,

P3136
Second primary lung cancer in clinical emergency hospital of Constanta – A prospective study
Doina Tofolean

–T

Background: More people are living with a diagnosis of cancer than ever before. One of the consequences of surviving cancer is the increased likelihood of being diagnosed with a second primary cancer.

Aim: To determine the frequency of secondary primary lung cancer (SPLC) in clinical practice.

Material and method: A total of 176 patients was diagnosed with lung cancer, between January 2001 and January 2011 in 1st Internal Medical Department of Clinical Emergency Hospital of Constanta; 22 patients (12.50%) were already diagnosed with other cancers. Positive diagnosis of SPLC included chest X-ray, spiral CT, bronchoscopy, EUS+FNAB, CEUS.

Results: Most patients diagnosed with SPLC were initially diagnosed with Hodgkin’s disease (n=4), head and neck cancer (n=3). Gender distribution showed male predominance (n=16). Most patients (n=14) were heavy smokers (>25 Pack Years; P<0.0001). Most patients were symptomatic at diagnosis (n=17). All patients performed chest X-ray and CT (chest, abdomen, brain) for diagnosis and staging. Most histological types of CPPS were NSCLC (n=18; P<0.0001). All cases of SPLC were diagnosed in advanced stages (n=24). NSCLC cases showed a relatively equal distribution of early (n=8) and advanced stages (n=10).

Conclusions: The excess risk of developing a second malignancy among cancer survivors can be attributed to similar aetiologies, genetics and the effects of treatment. As the number of cancer survivors continues to grow, the importance of ongoing medical supervision and screening to detect second primary cancers at an earlier stage and thereby improve the effectiveness of treatment will remain critical.

P3137
The histological confirmation rate of lung cancer in the UK using the NLCA database
Wadee Kablawi, Anna Rich, Richard Hubbard. Division of Epidemiology and Public Health, Clinical Sciences Building, University of Nottingham, City Hospital Campus, Nottingham, United Kingdom.

Background: The optimal histological confirmation rate (HCR) for lung cancer is unknown. However, in the UK, an arbitrary figure of 75% has been recommended by the National Lung Cancer Audit (NLCA) as a benchmark. The aim of this study was to quantify the effect of patient features on the likelihood of having a histological diagnosis of lung cancer.

Methods: Individuals with a diagnosis of lung cancer were selected from the NLCA database from between 01/01/2004 and 31/12/2010. Percentage and odd ratios with 95% confidence interval were calculated to assess the proportion of patients having histology.

Results: Our study included a total of 127,099 individuals with NSCLC. HCR for NSCLC in the NLCA was found to be 66.8%. This however was increasing from 62.2% in 2007 to 72.3% in 2010. The histology in patients aged <65, PS of 0/1 and Charlson Index (CI) of 0 was 89.5%, while 56.8% in patients with the same age and CI but PS of 4. This reduced to 30% in patients with age >75 years and CI of 0 and PS of 4. Increasing age and worsening PS were also associated with a reduced odds ratio, whilst stage and CI had little effect on the likelihood of having proven histology. Individuals from least affluent areas were 23% less likely (adj OR 0.77, 95% CI 0.74 to 0.81, p<0.001) to have histology than patients from most affluent areas.

Conclusion: HCR is crucial in determining the appropriate treatment plan for every patient, especially with the advent of targeted therapies. Our results also show that there is a difference in the histological rate in the sub groups of patients. Therefore achieving 75% HCR in the total population is unreasonable and it should focus on different attainable HCR in sub group of patients.

P3138
Organization and results of the EGFR mutation Spanish quality control program

Material and method: A total of 235 patients, diagnosed with lung cancer by histological and/or cytological bronchoscopic findings(2009-2011), we conducted a correlation between demographic and medical data at the time of diagnosis with the type of histological confirmation of malignancy. In Greece, even though the incidence of lung cancer continues to grow, smoking is confirmed to have the strongest correlation with all lung cancer types. The mean age of first diagnosis is lower than expected from studies conducted in the US.

Introduction: Lung cancer remains in Europe the second most frequent type of malignancy. In Greece, even though the incidence of lung cancer continues to grow, there is not enough epidemiological data. Our aim was to conduct a retrospective epidemiological study using the large pool of data from our Bronchoscopic Unit.

Methods: In a total of 235 patients, diagnosed with lung cancer by histological and/or cytological bronchoscopic findings(2009-2011), we conducted a correlation between demographic and medical data at the time of diagnosis with the type of lung cancer.

Results: The mean age of first diagnosis was between 60-70 years (33%) and the male to female ratio was 3.8:1. There was no significant difference between the three most common histological types (ADCL 24%, SqCLC 21%, SCLC 22%). In the third round 31 spanish centres (25 hospitals, two medicine schools and four private laboratories) sent the complete results. Three mutated (one L858R and two different Del19) and one wild-type adenocarcinomas were selected. No false positive results were reported. There were 11 non-informative and 13 false-negative cases among the 124 analysed. Most of the false-negative results were obtained in centres that used Sanger sequencing in the L858R case where the percentage of neoplastic cells was small.

There is a need to stablish an organized quality control program for molecular testing in lung cancer patients. Pathology societies could be the organizers making routine laboratories perform these tests according to best practices.

P3139
Epidemiological data and correlation with bronchoscopic findings in first diagnosis of lung cancer in the last 3 years in a tertiary Greek hospital
Marcoula Kouvela, Evangelos Balis, Nikolaos Tatsis, Marios Kougias, Marios Georgios Bouthevas, George Giannakos.

Department of Pulmonary Medicine, Evangelismos Hospital, Athens, Greece.

Introduction: Lung cancer remains in Europe the second most frequent type of malignancy. In Greece, even though the incidence of lung cancer continues to grow, there is not enough epidemiological data. Our aim was to conduct a retrospective epidemiological study using the large pool of data from our Bronchoscopic Unit.

Methods: In a total of 235 patients, diagnosed with lung cancer by histological and/or cytological bronchoscopic findings(2009-2011), we conducted a correlation between demographic and medical data at the time of diagnosis with the type of lung cancer.

Results: The mean age of first diagnosis was between 60-70 years (33%) and the male to female ratio was 3.8:1. There is a need to stablish an organized quality control program for molecular testing in lung cancer patients. Pathology societies could be the organizers making routine laboratories perform these tests according to best practices.
P3140
Meeting the referral criteria to the rapid access lung cancer clinic: A 10-year audit
Syed M.H. Kazmi 1, Mohammed Hussain 2, Martin Ledson 1, Colin Smyth 1, Martin Walshaw 1, Respiratory Medicine, Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

Introduction: Although targeting patients with agreed criteria (where the risk of cancer is high) under the “two week wait” rule to fast-track lung cancer clinic allows an efficient and timely diagnosis, the referral of other patients to such services will potentially waste valuable healthcare resources. To look at this further we studied the trends in referral to our dedicated rapid access lung cancer clinic since its inception in 2001.

Methods: We audited referrals in 2001, 2009 and 2011, looking for their compliance with the nationally agreed referral criteria, and their subsequent placement and outcome.

Results: There was an increase in referrals that did not meet the agreed criteria with time.

Of those that did not meet the agreed criteria, in 2001: 10 were returned to the referrer, 18 redirected to a general chest clinic, and 3 were already under specialist care (2009: 15, 51, and 17; 2011: 44, 108, and 12 respectively).

Subsequently 9 (3%) were diagnosed with lung cancer (8 at follow-up and only 1 referrer, 18 redirected to a general chest clinic, and 3 were already under specialist treatment).

Conclusion: These results show that a significant and increasing proportion of referrals are made outside the agreed national criteria and may have been more appropriately referred elsewhere. We are seeking to educate our colleagues to ensure that these scarce and expensive healthcare resources are best used for this unfortunate patient population.

P3141
Timely diagnosis and therapy for suspected lung cancer patients in a 2 day rapid outpatient diagnostic program with integrated FGD-PET and diagnostic CT
Jozef Broekman 1, Bernd Kiers 1, Monika Losoos-Salomon 2, Richard Dekhuijzen 1, Chantal Snijts-van der Graaf 1, Liesbeth Peters-Bax 1, Lioe-Fee De Geus-Oei 1, Hendrikus Van Der Heijden 1, Pulmonary Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 2Pathology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 3Radiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 4Nuclear Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Introduction: Delays in the diagnosis of lung cancer are under debate and may affect outcome. The objectives of this study were to compare delays in a rapid outpatient diagnostic program (RODP) for suspected lung cancer patients with those described in literature and guideline recommendations, to investigate the effects of referral route and symptoms on delays, and to establish whether delays affected stage and outcome.

Methods: We performed a retrospective chart study of all patients with suspected lung cancer, referred to our RODP of our tertiary care university clinic between 1999 and 2009. Patient characteristics, tumor stage and different delays were analyzed.

Results: Of 565 patients with available data, 290 were diagnosed with lung cancer, 48 with another type of malignancy, and 111 patients with a non-malignant lesion. In 112 patients no immediate definite diagnosis was obtained, and in 82 of these the proposed follow-up strategy confirmed a benign outcome. The median first disease delay was 60 days, patient delay - 25±30 days. 39% of patients were previously treated for other malignancy.

Conclusion: In our patient population a surgical procedure is performed in 37.7% of patients with lung cancer. This is higher than the surgical rate of 16.9% according to the audit criteria.

P3142
The use of surgical services in the management of suspected lung cancers
Amar Chakrabarti 1, Martin Hayward 2, Sayed Khan 2, Department of Respiratory Medicine, Barnet and Chase Farm Hospitals NHS Trust, London, United Kingdom; 2Department of Thoracic Surgery, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Introduction: The National Lung Cancer Audit Report 2011 identified an average surgical rate of 14% in England and Wales. This focuses on potentially curative surgery with the exception of mesothelioma and so does not encompass the full breadth of surgical intervention undergone by our patients. This study aimed to describe this spectrum for our patient population in a secondary care setting.

Method: The electronic patient record system was searched for all patients discussed at multidisciplinary meetings in 2010. Data was gathered from letters, operation notes and meeting minutes on the system.

Results: 1172 cases were discussed of which 212 (18%) had confirmed lung cancer. In these, 74 (37.7%) procedures were performed. 1.4% of patients had two procedures. 80.6% had a lobectomy, 4.7% a wedge resection or segmentectomy, 14.6% a VATS drainage of effusion, biopsy and/or pleurodesis (4.2% for mesothelioma) and 5.2% other procedures. For 2.4% there was no diagnosis.

After surgery, histology revealed NSCLC in 52.7%, mesothelioma in 13.5%, SCLC in 2.7%, carcinoid in 1.4% and no malignancy in 6.8%. In 5.4%, a differential diagnosis was given, and in 17.6% there was no data.

All referred patients were discussed at multidisciplinary meetings in 2010. Data was gathered from letters, operation notes and meeting minutes on the system. The delay of diagnostics worsens prognosis of disease.

The purpose: To define factors, associated with a delay of lung cancer diagnostics.

Materials and methods: An analysis of waiting times for 31 patients with lung cancer was undertaken. Males 65%, villagers 61%, mean age 55±14 yrs. Clinical, radiological, laboratory data of all admitted patients were collected. The period from the disease manifestation up to making a hospital diagnosis was 106±68 days, patient delay - 25±30 days. 39% of patients were previously treated of an assumed pneumonia before hospitalization in TB hospital. All patients have been hospitalized with wrong diagnosis “pulmonary TB”, a principal cause - misinterpretation of chest radiogram.

Results: 48% of patients up to making a hospital diagnosis received antituberculous treatment. 55% of patients - smokers.

Conclusion: The results would allow to optimize the diagnostic approaches to such a patients.

P3143
Lung cancer patients in TB hospital: Factors associated with diagnostic delay
Zhanaa Laushkina 1, Pavil Filimonov 2, Elena Pustikarava 2. Pulmonary TB Department, Novosibirsk Research TB Institute, Novosibirsk, Russian Federation

The delay of diagnostics worsens prognosis of disease.

The purpose: To define factors, associated with a delay of lung cancer diagnostics.

Materials and methods: An analysis of waiting times for 31 patients with lung cancer was undertaken. Males 65%, villagers 61%, mean age 55±14 yrs. Clinical, radiological, laboratory data of all admitted patients were collected. The period from the disease manifestation up to making a hospital diagnosis was 106±68 days, patient delay - 25±30 days. 39% of patients were previously treated of an assumed pneumonia before hospitalization in TB hospital. All patients have been hospitalized with wrong diagnosis “pulmonary TB”, a principal cause - misinterpretation of chest radiogram. 48% of patients up to making a hospital diagnosis received antituberculous treatment. 55% of patients - smokers.

Results: Factors associated with increase of diagnostic delay: acute disease beginning (OR 0,34, p=0,03), absent of hematological changes (OR 0,23, p=0,01), nonspecific microbial growth in sputum (OR 0,1, p=0,003). Factors, associated with decrease of a diagnostic delay – old age (OR 2,7, p=0,034), low body weight (OR 2,4, p=0,038), lost of appetite (OR 3,7, p=0,006), dyspnea (OR 3,4, p=0,002), leukocytosis (2,5, p=0,03), ESR acceleration (3,3, p=0,007), lymphopenia (2,5, p=0,043), eosinophilia (3,3, p=0,011), spherical opacity patterns on chest radiogram (5,9, p=0,000), pleural exudates (9,1, p=0,000), presence of atypical cells in sputum (OR 46, p=0,000), biopsy performed (OR 10,5, p=0,000).

Conclusion: The results would allow to optimize the diagnostic approaches to such a patients.

P3144
Risk factors for early mortality in lung cancer
Marta Inchausti 2, Estibaliz Pérez 1, Larratz García 1, Pedro Ansoa 1, Lotra Martínez 2, Amaia Sagara 2, Marta Allonso 2. Pneumology, Cruces Hospital, Barakaldo, Bizkaia, Spain; 2Epidemiology, Cruces Hospital, Barakaldo, Bizkaia, Spain

Aim: To analyze risk factors for mortality due to lung cancer before 1st and 3rd month after diagnosis.

Methods: Revision of all the patients with lung cancer diagnosis in 2 years. Analysis of: demographic variables, smoking status, histological subtype, staging, ECOG, blood analysis, treatments, cause of death. Univariate and multivariable analysis ( Cox regression).

Results: 270 cases, characteristics shown in table 1. In table 2, multivariate analysis. AUC of 0,952 in the 1st month, 0,874 for the 3rd. Among 41 patients who died before the 1st month, 9 (22%) received palliative treatment (6 Radiotherapy [RT], 3 Chemotherapy [QIT]). As death causes: infectious complications in 8 cases (3 QT), respiratory insufficiency 16 cases, rest: tumoral progression and general sepsis.

Conclusions: High percentage of patients die before the 1st month (15%) and 3rd month (29%) after diagnosis. ECOG >2 points, the most impacting factor for early mortality.Other factors: IV TNM stage, low haemoglobin, adenocarcinoma or small-cell histological subtype (1st month mortality) and a high CA125 level
**Conclusions:** Smoking cigarettes is the principal risk factor for causation of LC. Preventive control of smoking appears to be an urgent priority in lung cancer prevention.

Objective: to determine the existence of the eventual causal associations among the cigarette smoking and development and distribution of the lung cancer.

Methods: The investigation was an analytical type of case-control study. It elaborated 185 patients diseased of LC, and the same number of persons without malignant disease (control group-CG). Risk analyses were done using unconditional logistic regression, which provides results in the form of crude odds ratio.

Results: The odds ratios and their 95% confidence intervals (CI) were computed. In the group of patients, there were 67% of current smokers (CS), 23.8% of ex-smokers (ES) and only 9.2% of never smokers (NS), compared to 40.5% of controls (n=1383) 1.4 18.7 79.8

Similar results were observed in the Italian population regarding the T allele frequency in SSC and SSc-ILD in the French population: 10% and 11.1%, respectively.

Background: Combined pulmonary fibrosis and emphysema (CPFE) is characterized by upper lobe emphysema associated with lower lobe fibrosis.

Methods: We retrospectively evaluated 102 consecutive patients who were diagnosed with pulmonary fibrosis after bronchoalveolar lavage (BAL). Cytokine levels and differential cell counts in BAL fluid, pulmonary function, CT scores, and levels of serum markers were compared between patients with emphysema and those without.

Results: Among the 102 patients (14 females, mean age, 68 y/o), 38 showed upper lobe emphysema on CT. In BAL fluid, the levels of ENA-78/CXCL5 and IL-8/CXCL8 were significantly higher in patients with emphysema than in those without. The levels of MCP-1/CCL2, MIP-1a/CCL3, TNF-α, TGF-β1, and neutrophil elastase did not differ between the two patient groups. In patients with emphysema, whereas %VC was greater, FEVI/FVC and %DLCO/VA were lower than in those without emphysema. The composite physiologic index and serum levels of KL-6 and SP-D, markers of interstitial lung disease, were not different between the groups. Levels of CXCL5 and CXCL8 were associated with the...
proportion or absolute number of neutrophils in BAL fluid. In addition, CXCL8 levels were correlated inversely with %VC and %DLCO/VA and positively with the flow of low attenuation on CT.

Conclusion: Elevated CXCL chemokine levels in the airspace might contribute to the emphysematous change in patients with pulmonary fibrosis, which may be associated with the development of CPFE.

P3147
Gene expression profiles of idiopathic interstitial pneumonias: Identification of disease-specific diagnostic markers and molecular therapeutic targets
Nobushia Ishikawa, Noboru Hattori, Masaya Taniwaki, Yasushi Horimasa, Tomoyo Matsuda, Nobuo Kihno. Department of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan

Introduction: Idiopathic pulmonary fibrosis (IPF) and nonspecific interstitial pneumonia (NSIP) are characterized by alveolar epithelial damage and inflammatory responses that lead to fibroblast proliferation and, ultimately, to loss of normal pulmonary architecture and function. Differential diagnosis between IPF and NSIP may be difficult. The molecular mechanisms underlying idiopathic interstitial pneumonias (IPFs) remain unclear.

Aims: This study aimed to elucidate the mechanisms underlying IPFs and identify disease-specific diagnostic markers and molecular therapeutic targets.

Methods: The study included 12 patients with IPFs (IPF; 7 patients; NSIP, 5 patients). RNA was extracted from frozen lung specimens from the study population and was profiled using Illumina Human WG-V 3 BeadChip. Gene ontology functional annotations were investigated in the genes upregulated in IPFs.

Results: Evaluation of 48,000 transcripts in the expression profiles helped identify 1354 transcripts that were commonly upregulated in lung tissues from IPF patients compared to those from normal control subjects. The transcriptional profiles of IPF and NSIP were unexpectedly similar. Lungs with IPF were characterized by increased expression of transcripts associated with cell cycle, cell-to-cell interaction, and p53 signaling pathways, such as MDM2, RB1, RAD21, CFTPR and BAX.

Conclusion: The current data provide valuable information on the molecular mechanism underlying pulmonary fibrosis in IPF patients. Additionally, several potentially promising and novel diagnostic biomarkers as well as therapeutic targets have been identified for IPFs.

P3148
The JAK3 Inhibitor CP-690550 is a potent anti-fibrosis agent in a murine model of pulmonary fibrosis induced by bleomycin
Beixian Zhou, Yingping Fu, Yansheng Wang, Jun Xu. The State Key Lab of Respiratory Disease, Guangzhou Medical University, Guangzhou, China

Rationale: We previously suggested that JAK3, a cytoplasmic tyrosine kinase involved in receptor signaling for cytokines, is a molecular determinant in exacerbated innate immune inflammation. A selective JAK3 inhibitor can alleviate immunopathologic injury. Does it have a potential for treating the lung fibrosis associated with autoimmunity? In the present study, CP-690550, a novel inhibitor of JAK3, was subjected to examination of its effects on lung fibrosis in a murine model of Bleomycin (BLM)-induced pulmonary inflammation.

Methods: JAK3 activity, cytoxia, lung histology and collage deposition were evaluated in mice treated with BLM and CP-690550.

Results: CP-690550 significantly reduced the lung fibrosis and collagen deposition as compared to mice treated with BLM (p < 0.01). Histologically, CP-690550 treatment induced significant reduction in collagen deposition as compared to BLM-treated mice (p < 0.01). Flow cytometry for typing bronchoalveolar lavage fluid revealed a significant reduction in the number of CD3+CD8+ and NKT+ cells in the BLM-challenged mice than control, but no significant changes were detected in the mice treated with CP-690550 compared to BLM-treated mice.

Conclusion: We have previously shown that BLM-derived T cells secrete HGF, regarded as a potent anti-fibrotic cytokine, antagonist of TGFβ, and the promising tool for experimental therapies in lung fibrosis. However, our preliminary results concerning HGF expression in ILD lower airways were not convergent.

Methods: HGF concentration in BAL fluid from pulmonary sarcoidosis (PS), idiopathic pulmonary fibrosis (IPF), extrinsic allergic alveolitis, nonspecific interstitial pneumonia (NSIP), BOOP and eosinophilic pneumonia (n=48, 20, 7, 13, 7, 6 resp.) was assessed by ELISA method. BAL cells were analyzed for intracellular HGF by flow cytometry.

Results: HGF concentration was significantly increased in IPF nonsmokers (317±13.56 pg/ml vs 148±17 in controls, p<0.02, median±SEM). IPF smokers (215±12 vs 141±10, p>0.001) and smokers with advanced PS, t-test, and nonsmokers with increased HGF levels in NSIP and BOOP was observed. HGF concentration was strongly negatively correlated with pulmonary function (VC% pred) and positively, inter alia, with BAL neutrophil and eosinophil relative count as well as with TGFβ levels. Systemic steroid therapy resulted in decline of HGF expression in respective IPF, NSIP and PS subgroups.

Conclusion: Our data seem to disagree with the previously suggested HGF strong anti-fibrotic activity. Its high expression was paradoxically observed in ILD patients with severe lung fibrosis SIIL, our observations might reflect the up-regulated TGFβ enhanced expression aimed at sustaining lung homeostasis.

P3150
Autoimmunity profile in patients with combined pulmonary fibrosis and emphysema (CPFE)
Argyris Tzouvelekis1, Georgios Zacharis1, Anastasia Oikonomou2, Kostantinos Arcontegeorgis1, Andreas Koulelidis1, Panagiotis Boglou1, Marinos Froudarakis1,2. Demosthenis Fotakis1,2.
1Pneumonology, Democracy University of Thrace, Alexandroupolis, Thrace, Greece; 2Radiology, Democracy University of Thrace, Alexandroupolis, Greece; 3Cardiovascular Thoracic Surgery, Democracy University of Thrace, Alexandroupolis, Thrace, Greece

Background: The combination of pulmonary fibrosis and emphysema (CPFE) is a recently defined syndrome, encompassing a distinct radiologic, revealing both upper lobe emphysema and lower lobe fibrosis, as well as lung function profile, with apparently preserved lung volumes contrasting with disproportionately impaired gas exchange. It has also been recently described in the context of connective tissue diseases. Our primary aim was to investigate the autoimmunity profile of patients with CPFE.

Patients and methods: Thirty nine patients, mean age of 66.5 years, 37 men, all smokers, with CPFE based on radiologic and functional criteria (mean FVC: 68.5% pred, FEV1/FVC: 78.2, DLCO: 34.9%pred) were recruited on a retrospective and prospective basis. All patients underwent a thorough investigation of their immunologic profile.

Results: Fourteen patients (36%) had positive anti-nuclear antibodies (ANA). Patients with positive ANA presented with elevated CD20 levels in lung biopsy specimens suggestive of elevated B cell activity. In addition, 6 patients (15%) presented with positive antineutrophil cytoplasm antibodies (ANCA) against myeloperoxidase (MPO) indicative of microscopic polyangiitis. Among the latter three developed respiratory and renal insufficiency and were successfully treated with cyclophosphamide and methylprednisolone whereas the remaining three were switched to azathioprine maintenance treatment.

Conclusions: A significant proportion of patients with CPFE may present with underlying auto-immune disorder which may be recalcitrant. Early identification of these patients using a panel of auto-antibodies may lead to more targeted and potentially effective therapeutic applications.

P3151
Frequencies and dynamics of peripheral immune cell subsets in idiopathic pulmonary fibrosis: Preliminary results and clinical implications
Mariasilia Bocchino1, Domenico Galati2, Marina De Martino1
1Maria Napolitano1,2, Annamaria Trotta2, Anna Stanzol1, Alessandro Sanduzzi1
1Diariemto di Medicina Clinica e Sperimentale, Università Federico II, Naples, Italy; 2UOS Immunologia Oncologica, IRCCS INT Fondazione Pincare, Naples, Italy

Involvement of the immune response in the pathogenesis of idiopathic pulmonary fibrosis (IPF) is not well clarified. Emerging T cell subsets including IL-17 secreting T helper cells (TH17) and regulatory T lymphocytes (Treg) expressing TGF-beta may exert antiinflammatory actions. Distribution and phenotype characteristics of peripheral immune cells along with TH17/Treg dynamics were investigated by multi-parametric flow cytometry in 13 IPF patients (mean age 63 yrs; 13 men) and 10 age- and sex-matched healthy subjects. Propensity for CD20+ B cells and of CD20+ T cells and of B (CD20+) lymphocytes were similar in the two groups. Frequencies of NKT (CD3+CD56+) and NK cells (CD3 CD56+CD16+) were reduced in IPF (p<0.001 for NK cells), the 24% of the latter co-expressing CD16 and CD52a (versus 4.2±3.3; p<0.001). IPF patients displayed higher Treg proportions (CD4+CD25highFoxP3+ (0.71±4.0 vs 0.3±1.3; p<0.05). No differences in the distribution of highly suppressive Treg (CD127-+) were found. Upon stimulation, Treg expression of TGF-beta was similar in the two groups. Conversely, frequencies of IL-17-expressing CD4+ cells were significantly lower in IPF (0.92±0.56 vs 0.21±0.11; p<0.001). This finding was associated with an increased IL-17/IL-17 ratio in IPF (2.8±1.5 vs 0.38±0.2; p<0.001). This study first provides evidence in IPF of a peripheral Treg/TH17 functional imbalance along
Silent microaspiration in idiopathic pulmonary fibrosis: The role of videolaryngoscopy

Emanuela Rossi, Arial Florian, Claudia Rinald, Nazarena Namini, Giuseppe Marulli, Monica Loy, Federico Rea, Fiorella Calabrese, Elisabetta Balestro. Department of Cardiac, Thoracic and Vascular Sciences, University of Padua Medical School, Padua, Italy

A strong association between gastroesophageal reflux (GER) and idiopathic pulmonary fibrosis (IPF) has been reported. A significant proportion of patients may have signs of microaspiration and still remain asymptomatic. Videolaryngoscopy can be a useful tool to detect silent microaspiration, which to date has never been investigated in IPF. The aim of the study was to assess signs of micro-aspiration by videolaryngoscopy in patients with IPF and to relate them with clinical findings. We recruited 20 IPF patients (mean age 52 ± 7 yrs). We investigated the presence/absence of GER symptoms and performed videolaryngoscopy to evaluate abnormal laryngeal findings considered indirect signs of micro-aspiration. Three out of twenty patients (15%) had classic GER symptoms, while 17 (85%) did not report any kind of GER symptoms. Among asymptomatic patients, 5 (25%) had indirect signs of microaspiration at videolaryngoscopy while the remaining twelve had no such signs. Of interest, IPF patients with laryngeal abnormalities at videolaryngoscopy showed a lower FVC% at the diagnosis compared to patients without such abnormalities [46% (45-82) vs 75% (72-87); p=0.03]. Conversely, no differences in age, smoking history and BMI were found between the two groups of patients. In conclusion our study shows that videolaryngoscopy may be a useful diagnostic tool to detect silent microaspiration in patients with IPF even in the absence of GER symptoms. These findings may have important therapeutic implications.

Elevated serum LOXL2 levels are associated with rapid disease progression in idiopathic pulmonary fibrosis (IPF)

Jason Chien, Lixin Shao, Susan Lyman, Joanne Adamikiewicz, Victoria Smith, Thomas O’Roedan. Clinical Research, Gilead Sciences, Inc, Seattle, WA, United States

Background: LOXL2, expressed in fibrotic lung, plays a crucial role in matrix remodeling and fibrogenesis. We hypothesized that elevated serum LOXL2 levels are associated with rapid IPF disease progression.

Methods: Serum samples were collected prior to treatment randomization at selected U.S. clinical trial sites for TARTEMS-IPF. LOXL2 levels were measured using proprietary anti-human-LOXL2 antibodies. Progression free survival (PFS) lung function decline, respiratory hospitalizations (RH) and death served as the primary endpoint.

Results: Subjects with (n=69) and without (n=423) serum samples had similar baseline IPF severity. Among subjects with detectable LOXL2 (n=67), the median LOXL2 level was 31.5 pg/mL. Of interest, 14/5-752.4 pg/mL. Although subjects randomly assigned to receive ambrisentan (n=49) had more severe IPF and higher LOXL2 levels than placebo treated subjects (mean 902.8 pg/mL ± 3172 vs 294 pg/mL ± 288, p=0.026), LOXL2 levels and IPF severity did not correlate. In multivariate analyses that included treatment assignment, 6-minute walk distance and compositive physiologic index, high LOXL2 lev (≥800 pg/mL) in comparison to low LOXL2 levels (<800 pg/mL), were associated with increased risk for disease progression (hazard ratio [HR] 4.95, 95% confidence interval [CI] 1.52-16.18, p=0.008), lung function decline (HR 7.36, 95% CI 1.16-46.74, p=0.034), and RHs (HR 4.85, 95% CI 1.09-21.88, p=0.039).

Conclusion: High baseline serum LOXL2 levels are associated with rapid IPF progression and may reflect disease activity, not severity. Due to potential confounding effects of ambrisentan, these results need to be replicated in other IPF populations.

Hyaluronan synthetase-2 over expression has impact on the evolution and on the prognosis of idiopathic pulmonary fibrosis patients

Edwim Roa Perez1,2, Vera Capolezzi2.1, Pathology, University of Sao Paulo Medical School, Sao Paulo, SP, Brazil

Background: The idiopathic pulmonary fibrosis (IPF) is a terminal illness characterized by unremitting extracellular matrix (ECM) deposition. In this regard, the myofibroblasts and the ECM components such as hyaluronan (HA) have an important role in the fibrosis. We analyzed the expression of HAS1 (HA synthase 1), HAS2, HAS3 and hyaluronic acid receptor (CD44) by epithelial and myofibroblasts cells in patients with IPF and we correlated with a survival.

Methods: HAS-1, HAS2, HAS3 and CD44 epithelial and myofibroblasts expression were evaluated in 27 surgical lung biopsies from patients with IPF in minimal and severe fibrosis by the point-counting technique. Impact of these markers was tested on pulmonary functional tests and follow-up until death from IPF.

Results: HAS2 and CD44 expression were significantly increased and directly associated with severe fibrosis. Myofibroblast HAS2 activity was indirectly associated to DLO/VA (p=0.584; p<0.05). Kaplan Maier curves determined a higher risk of death for patient with high HAS2 (>6.83%) expression than in low expression (Log Rank p<0.05).

Conclusion: The increased HAS-2 activity in epithelial and myofibroblasts cells have impact in the remodeling process and the survival evolution, suggesting that strategies aimed at preventing the effect of this ECM component may have a greater impact in patient’s outcome.

Perceptions, experiences and information needs of patients with idiopathic pulmonary fibrosis (IPF): A qualitative study

Annette Duck1, Lisa Spencer2, Simon Bailey3, Colm Leonard1, Ann-Louise Carses4.1, NWLC, University Hospital of South Manchester, Manchester, United Kingdom; 2Chest Unit, Aintree Hospital, Liverpool, United Kingdom; 3Chest Unit, Central Manchester University Hospital Trust, Manchester, United Kingdom; 4School of Nursing, Midwifery and Social Work, The University of Manchester, United Kingdom

Background: Idiopathic Pulmonary Fibrosis (IPF) is a rapidly progressive lung disease, with median survival of 2-4 years from diagnosis with symptoms that impact on quality of life. There has been little work to date which explores the experiences of these patients, or their family carers, in-depth.

Aim: To understand the experiences, perceptions and information needs of patients with IPF.

Methods: Qualitative study, involving in-depth, audio-recorded, semi-structured interviews, supported by a topic guide (developed from review of the literature and input from patients and clinicians). Seventeen patients with moderate to advanced IPF referred to a tertiary respiratory centre in north-west England, and six of their family carers, were interviewed. Data were analysed using Framework Analysis ( Ritchie and Spencer 1994).

Conclusions: Patients with IPF have many unmet information and support needs. There is an urgent need for improved recognition of these needs, as well as increased availability and accessibility of services.

The correlation of pulmonary function tests and exercise testing with high resolution computed tomography in patients with idiopathic interstitial pneumonias in a tertiary care hospital in south India

Barney Isaac Thomas1, Balamugesh Thangakunam1, Rekha A. Cherian2, Devasahayam J. Christopher1.1, Department of Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu, India; 2Department of Radiology, Christian Medical College, Vellore, Tamil Nadu, India.

Background: Idiopathic interstitial pneumonias (IIP) are a heterogeneous group of diffuse parenchymal lung diseases (DPLD). Although open lung biopsy is the gold standard for its diagnosis, HRCT(High Resolution Computed Tomography) is gradually replacing the former. Repeating HRCT for follow up is costly and involves radiation exposure. Among pulmonary function tests(PFT) and exercise testing, it is unclear which parameter would correlate best with HRCT.

Aim: To find out the correlation of pulmonary function tests and exercise testing with HRCT in patients with IIP.

Methods: Consecutive patients who were diagnosed as IIP were included. PFT and exercise testing parameters were noted. HRCT was scored based on an alveolar...
score, an interstitial score and a total score. Correlation of each of the parameters with HRCT scores were analyzed.

**Results:** A total of 94 patients [85 had Idiopathic Pulmonary Fibrosis(IPF)] were included to obtain a sample size of 105. Forced Vital Capacity, Total Lung Capacity and Diffusion Capacity of the Lung for Carbon Monoxide (DLCO) among PFT parameters and Distance Saturation Product and lowest saturation among exercise testing parameters had significant correlation with the total HRCT score. Among these DLCO corrected was the most correlating with a negative r value of 0.565.

**Conclusion:** In patients with idiopathic interstitial pneumonia, pulmonary function tests and exercise testing had good correlation with HRCT. DLCO corrected was the most correlating parameter.

**P3157**

**Osteoporosis treatment effectiveness in patients with idiopathic pulmonary fibrosis (IPF)**

Yulia Ilievich1, Dali Dzadzua, Lubo Novikova. Pulmonology Department of Postgraduate Education Faculty, Pavlov State Medical University, St. Petersburg, Russian Federation

**Aim:** To assess effectiveness of osteoporosis treatment by Calcium, Vitamin D3 (VD3), Bisphosphonates (BPN), Calcitomin (CTN) in patients with IPF.

**Subjects:** 95 Caucasian patients with IPF, 18 male, 77 female, 55.4±10.9 y.o., treated with glucocorticoids.

**Materials, methods:** Bone Mineral Density was measured by DEXA: Patients were categorized according to T-criterion value. 19 patients (1st group) had T-criterion >-1.5 SD. In this group only Calcium and VD3 were recommended. 24 patients (2nd group) had T-criterion value from -1.5 SD to -2.0 SD. In this group Calcium, VD3 and BPN were prescribed. 20 patients (3rd group) had T-criterion value from -2.0 SD to -2.5 SD. In these cases Calcium, VD3 and CTN were prescribed. 32 persons (4th group) had T-criterion lower than -2.5 SD. These patients received Calcium, VD3, CTN, BPN.

**Results:** Results were assessed in a year. The main criteria were: T-criterion change (ΔT), fractures incidence, presence of bone pain (BP). In the 1st group ΔT was -0.07 SD, 10.5% patients had manifestation of BP. In the 2nd group ΔT was -0.25 SD; one hip fracture occurred; the number of patients with BP decreased from 66.7% to 25.0% (p<0.01). In the 3rd group ΔT was +0.04 SD, no fractures were registered, the number of patients with BP increased from 20.0% to 30.0%. In the 4th group ΔT was +0.11 SD; no fractures were registered, the number of patients with BP decreased from 25.0% to 6.3% (p<0.01).

**Conclusion:** Combination of Calcium and VD3 with antiresorptive agents (both CTN and BPN) is an essential way to prevent and treat osteoporosis in patients with IPF. CTN has an advantage due to its analgesic effect in osteoporotic patients with bone pain.

**Post-marketing surveillance of pirfenidone for idiopathic pulmonary fibrosis in Japan: Interval analysis of 973 patients**

Mika Ito1, Yuka Nii1, Akihiro Nakamura1, Shinichi Kakustani2, Yuki Yoshida2, Takayoshi Yoshikawa1, Pirespa Advisory Board. 1Drug Safety Management Department, Shionogi & Co., Ltd., Osaka, Japan; 2Biostatistics Department, Shionogi & Co., Ltd., Osaka, Japan

**Background:** Pirfenidone (Pirespa®), anti-fibrotic agent, was approved for the treatment of idiopathic pulmonary fibrosis (IPF) in Japan in 2008. We conducted a post-marketing surveillance enrolling all patients with IPF who were administered pirfenidone from Dec 2008 to Oct 2009 to gain understanding, in the clinical setting, of the safety and efficacy of pirfenidone in the treatment of IPF.

**Methods:** The safety was evaluated by comparing the incidence of adverse drug reactions with that reported in Phase II and III trials. The efficacy was evaluated on the change in vital capacity (VC).

**Results:** For this interim analysis, 973 cases were evaluable for safety (male 78.2%, age 69.5±8.4 y.). At baseline, 407 cases (41.8%) were ranked as severity grade IV in Japan (PaO2 at rest <60 Torr) or (PaO2 at rest <70 Torr and 6MWT SpO2 <90%). The incidence of adverse drug reactions was 67.0%. The major adverse drug reactions were decreased appetite (28.6%) and photosensitivity reaction (15.0%). The data on VC were available from 453 cases and the analyses revealed that VC had an increase from 66.7% to 25.0% (p<0.001). In the 3rd group ΔT was +0.11 SD; no fractures were registered, the number of patients with BP decreased from 25.0% to 6.3% (p<0.01).

**Conclusion:** The efficacy of pirfenidone was confirmed by the interim analysis.

**P3159**

**P3161**

**Introduction:** Idiopathic pulmonary fibrosis (IPF) is a poor prognostic fibrotic lung disease with unknown etiologies. Pirfenidone (PFD) was recently reported to decrease the rate of decline in vital capacity and it is anticipated that PFD improves prognosis of IPF patients.

**Aim:** We prospectively examined clinical findings of IPF to predict the effects and adverse effects of PFD.
P3161
Anti-fibrotic effects of nintedanib (BIBF 1120) in primary human lung fibroblasts derived from idiopathic pulmonary fibrosis
Katrin Haustettler1, Eleni Papakonstantinou2, Ioannis Klagas2, George Karakulaklis3, Michael Tammi4, Didier Lardinoux5, Michael Roth1, Jan-Arne Kopp1,6,7
1Department of Biomedicine, University Hospital, Basel, BS, Switzerland; 2Laboratory of Pharmacology, School of Medicine, Aristotle University, Thessaloniki, Greece; 3Clinic of Respiratory Medicine, University Hospital, Besançon, France; 4Pneumology, University Hospital, Lille, France; 5Pneumology, University Hospital, Bichat, Paris, France; 6Department of Biomedicine, University Hospital, Basel, BS, Switzerland; 7Division of Thoracic Surgery, University Hospital, Basel, BS, Switzerland

Introduction: Idiopathic pulmonary fibrosis (IPF) is a progressive lung disease with poor prognosis. One year treatment with the receptor tyrosine kinase inhibitor nintedanib (BIBF 1120) specific for vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR) was associated with a 68.4% reduction in the rate of decline in forced vital capacity in patients with IPF versus placebo, which approached statistical significance.

Aim: To determine the in vitro effect of nintedanib on primary human lung fibroblasts.

Methods: Primary human lung fibroblasts were isolated and propagated from lung parenchyma derived from patients with IPF (n=14). After treatment with nintedanib (0.0001 – 1 μM) enzymatic activity for matrix metalloproteinases (MMP) was assessed in aliquots of the culture medium by gelatin zymography. Gene expression of MMP was measured by quantitative real time PCR. Collagen secretion and deposition was quantitated by the Sircol assay, and cell proliferation was assessed by mechanical cell counting.

Results: Nintedanib significantly inhibited secretion and deposition of collagen by IPF fibroblasts in a dose-dependent manner. Nintedanib significantly increased MMP-2 gene expression and dose dependently stimulated MMP-2 enzymatic activity. The pro-proliferative effect induced by PDGF (10 ng/ml) was completely reversed by nintedanib.

Conclusion: Our data demonstrate a significant anti-fibrotic effect of nintedanib in primary human lung IPF fibroblasts. This work is supported by a non-conditional grant by Boehringer Ingelheim GmbH.

Management of idiopathic pulmonary fibrosis in France: A survey of 1,456 pulmonologists
Vincent Cornet1, Jacques Cadranel1, Bruno Crestani1, Jean-Charles Dalphin1, Philippe Delaval1, Dominique Israel-Biet1, Romain Kessler1, Martine Reynaud-Gaumet2, Dominique Valeyne3, Benoit Wallaert3, Benoît Boassouillon4, Jean-François Cordier4, Laurence Dewachter, Marie Verervynsay, Benoist Rondelet, Jean-Paul Schafranegel, Serge Brimouille, Francois Kerbala, Robert Naicié
Physiopathology Laboratory, Universite Libre de Bruxelles, Brussels, Belgium

It has been suggested that prostacyclin improves patients with pulmonary hypertension through direct myocardioc effects. In an experimental model of acute right ventricular (RV) failure, we previously reported that prostacyclin did not present with significant inotropic effects, but that there might have been a trend as assessed from improved RV-arterial coupling (Kerbala et al. ARJCCM 2007).

Therefore, we further explored the pathobiology of acute RV failure with or without prostacyclin infusion. Dogs were randomized to a sham-(n=8) or to a 90-min pulmonary artery constriction (PAC)-operation (n=15). In 7 dogs with persistent RV failure, prostacyclin was infused 30 min after banding release. After euthanasia, RV tissue was sampled for pathological evaluation. 90-min PAC increased RV gene expressions of interleukin (IL)1β, monocyte chemotactrant protein (MCP)1, IL6, VCA1M1, and decreased expression of IL10. No changes in RV gene expressions of IL1α, macrophage inflammatory protein (MIP)1 and ICAM1 were observed after PAC. Protein expressions of IL1β and IL6 were observed in the failing RV, while IL10 protein expression was decreased. Pro-inflammatory IL6/IL10 and pro-apoptotic Bax/Bcl2 ratios were increased in the failing RV. Increased diffuse macrophage recruitment was observed within the failing RV. Prostacyclin depleted RV gene expressions of IL10, MCP1, MIP1α, VCA1M1 and increased IL10 expression. Prostacyclin decreased RV gene expressions of IL6/IL10 and Bax/Bcl2 ratios, and IL1β protein expression compared to PAC group.

Acute load-induced persistent RV failure appears to be related to an activation of inflammatory processes which seems to be limited by prostacyclin.
Conclusions: Pulmonary hypertension (PH) is a progressive and fatal disease. The gold standard for diagnosing PH and estimating prognosis is the invasive method of right heart catheterization. To date no biomarker is available to prove or exclude the diagnosis of PH.

Aims and objectives: The aim of this study is to identify and validate new biomarkers for PH.

Methods: Plasma from the pulmonary artery banding (PAB) and the monocrotaline (MCT) rat model, and corresponding sham and control animals (n=9), was used for 2D-gel electrophoresis (2D-GE) and MALDI-TOF-MS analysis. Further, plasma changes of interesting candidates were confirmed by ELISA. Human study population consists of patients with idiopathic pulmonary arterial hypertension (n=40), PH associated with collagen vascular disease (n=45), pulmonary venous hypertension (n=44), chronic thromboembolic PH (n=45), and non-PH controls (n=34).

Results: The spot density analysis of 2D-GE and identification by MALDI-TOF-MS revealed 7 proteins significantly changed in PAB vs. sham, and 15 proteins in MCT vs. control group. Complement component 4 (C4) and complement inhibitory factor H (CFH) were upregulated in PAB and MCT. ApoE was changed 15-fold in MCT plasma, but not in PAB. The analysis of human samples revealed no significant difference in mean plasma ApoE between the patient groups (119.4±10.3, 147.6±11.6, 116.8±9.9, 110.2±8.3 μg/ml) and controls (135.3±14 μg/ml).

Conclusions: Despite published data on the role of ApoE in PH and the significant changes in rats, ApoE seems not suitable as biomarker for PH in humans. Other candidates identified by mass spectrometry will be evaluated for their potential as biomarker.
that fibrocytes may cooperate with endothelial progenitors to induce angiogene-
sis. We successfully isolated fibrocytes from blood of IPF patients. The characteriza-
tion of fibrocytes used flow cytometry, real time q-PCR and confocal analysis. We investigated the interaction between fibrocytes and cord blood derived endothel-
ial colony forming cells (ECFC) angiogenic potential in vitro and in vivo in a preclinical model of vascularization.

We showed for the first time the formation of functional microvascular beds in im-
munodeficient mice when human ECFC and fibrocytes isolated from IPF patients were coinoculated in matrigel plugs. Evaluation of implants after 2 weeks revealed an extensive network of blood vessels containing erythrocytes. Secreted media from fibrocytes enhances SDF-1/CXCR4 pathway in ECFC in vitro. Blocking CXCR4 in vivo in implants significantly inhibited blood vessel formation. Finally, we confirmed the relevance of these data by showing that vessels close to fibrotic areas in biopsy specimens from IPF patients expressed high levels of CXCR4, in contrast to control lungs. Circulating fibrocytes might be involved in vascular remodelling process observed in patients with fibrotic disease and should represent a useful biomarker for fibrosis progression.

miR-16 modulates human pulmonary artery smooth muscle cell phenotype

Premana Tamang2, Parvatharatna, Gurukumar Kollongod Ramanathan, Richard F. Lockey, Narasiah Kolliputi. Allergy and Immunology, Department of Internal Medicine, University of South Florida, Tampa, FL, United States

Introduction: Pulmonary artery hypertension (PAH) is progressive fatal disease characterized by excessive proliferation of human pulmonary artery smooth muscle cells (hPASMC) and formation of small pulmonary arteries, leading to severe pulmonary hypertension and right ventricular failure.

Objective: Serotonin mediates hPASMCs proliferation through serotonin trans-
porter (5HT). Recently micro RNAs have been identified to be involved in patho-
genetics of miR-16 targets SERT and Cyclin D1. Our previous results show that miR-16 is down regulated in hypoxic PAH mice. We hypothesize that overexpression of miR-16 can alter PAH phenotype. In the present study, we investigated the phenotypic consequences of overexpression of miR-16 in hPASMCs in vitro.

Methods: hPASMCs were commercially obtained and cultured according to manufacturer instructions. Cells were transfected with plasmid containing miR16 and over-expressed SERT or CyclinD1. Cells were treated with increasing concentrations of serotonin (3H-thymidine) and apoptosis (Hoechst nuclear staining; DNA fragmentation ELISA) assays were performed.

Conclusions: miR-16 overexpression down regulates SERT and CyclinD1 levels. Most importantly miR-16 modulates hPASMC phenotype which is a major hallmark in PAH, implicating a potential therapeutic role in PAH.

Macrophage migration inhibitory factor (MIF) promoter polymorphisms are associated with favorable hemodynamic indices in systemic sclerosis-associated pulmonary arterial hypertension

Todkorn1, Daniel Booth2, Noah Lechtzin1, Nicholas Rafael2, Li Guo2, Kathleen Burns2, Reda Girgis1, Ari Zaiman1, Stephen Mathai1, Laura Hummers1, Traci Houston1, Rachel Dumco1, Paul Hasson1. 1Division of Pulmonary & Critical Care Medicine, Department of Medicine, Johns Hopkins University, Baltimore, MD, United States; 2Division of Allergy & Clinical Immunology, Department of Internal Medicine, Johns Hopkins University, Baltimore, MD, United States; 3Division of Rheumatology, Department of Medicine, Johns Hopkins University, Baltimore, MD, United States

Rationale: Inflammatory mediators are increasingly associated with pathogen-
esis in pulmonary arterial hypertension (PAH). We have previously observed a 3.7-fold increase in serum levels of the pro-inflammatory macrophage migration inhibitory factor (MIF) in PAH patients. MIF promoter polymorphisms (-173C, -794CATT5-8) have been associated with disease susceptibility or phenotype in sev-
eral inflammatory syndromes. We hypothesized that MIF promoter polymorphisms may influence PAH development or severity.

Methods: Genomic DNA was isolated from 117 European-American PAH pa-
tients, including idiopathic (PAH; N=30) and systemic sclerosis-associated PAH (SSc-PAH; N = 82), healthy European-American controls (N=264), and SSc pa-
tients without PAH (N=343). Allele and genotype frequencies for the MIF -173C
single nucleotide polymorphism and the -794CATT5-8 variable nucleotide tandem repeat were compared between PAH patients and controls, and were compared with initial hemodynamic indices and survival in PAH patients.

Results: We found no significant difference in the frequencies of either MIF pro-
mitter polymorphism between controls and PAH patients. SSc-PAH patients with the MIF -173C polymorphism had higher cardiac output (P=0.04), cardiac index (P=0.003), and stroke volume index (P=0.01) at diagnosis. Neither polymorphism predicted survival in PAH patients.

Conclusion: The MIF -173C polymorphism may improve initial hemodynamic

ics in SSc-PAH. However, MIF promoter polymorphisms do not predict PAH susceptibility or survival. These results suggest that MIF may function as a disease-modifying gene in SSc-PAH.

P3172

Dexamethasone induces anti-remodelling effects in rat pulmonary arterial smooth muscle cells

Laura Price1, Frederic Perros2, Dongmin Shao1, Jie Zhu1, David Montani2, Peter Dorfman4, Marc Humbert1, Ian Adcock5, John Wort1. 1Department of Pulmonary Hypertension, Royal Brompton Hospital, London, United Kingdom; 2Service de Pneumologie et Réanimation Respiratoire, Centre National de Référence de l’Hypertension Pulmonaire Sèvère, Hôpital Antoine Béclère, Hôpitaux Universitaires Paris-Sud; 3Department of Histology, Royal Brompton Hospital, London, United Kingdom; 4Section on Experimental Medicine and Toxicology, Imperial College London, Hammershmith Hospital, London, United Kingdom; 5Cell & Molecular Biology Airways Disease Section, National Heart and Lung Institute, Faculty of Medicine, Imperial College London, London, United Kingdom

Introduction: Dexamethasone (dex) reverses PAH and pulmonary vascular remod-
eling in established rat monocrotaline (MCT)-induced PAH, we tested contributing mechanisms in pulmonary arterial smooth muscle cells (PASMC). Nuclear local-
ization of the p65 subunit of NF-kappaB was used as a marker of inflammation in MCT-exposed rats.

Methods: PASMC from control and MCT 6-week old male Wistar rats were treated with increasing dex concentrations. Proliferation (3H-thymidine) and apop-
tosis (Hoechst nuclear staining; DNA fragmentation ELISA) assays were performed.

Results: Dex reduced proliferation of PASMC at all concentrations with a maximal effect seen at 10-7M (3H-thymidine counts/minute 84997±6802 to 1993±3135, p<0.0001). Dex increased serum starvation-induced PASMC apoptosis as deter-
mined by Hoechst staining and DNA fragmentation in a time- and concentration-
dependent manner, reaching a plateau at 72hrs with 10-7M dex (0.40±0.17 to 1.29±0.54, p<0.001). In rat lung, caspase immunostaining was increased in the PASMC layer in dex-treated MCT rats vs. MCT-alone controls (0.40±0.4% vs. 58.3±1.00%, p<0.0001). Finally, nuclear p65 was reduced in PASMC and endothelial cells in MCT-treated rats at all doses studied.

Conclusion: Dexamethasone reduces proliferation and augments apoptosis in rat

PASMC in vitro, and reduces activation of NF-kB within vascular cells. These results, at least in part, may explain the reversal of PAH by dex seen in the rat MCT-PAH model.

P3173

Exogenous BMPR2 modulates TGF-β signalling in human small airway epithelium and smooth muscle cells

Feng Feng, Paul N. Reynolds. Thoracic Medicine, Royal Adelaide Hospital, Adelaide, SA, Australia

Introduction: Idiopathic Pulmonary Arterial Hypertension (IPAH) is a fatal dis-
ease characterized by reduced BMPR2 and increased TGF-β expression. 

Aims and objectives: To investigate the effects of upregulation of BMPR2 on TGF-β signalling in human small airway epithelial cells (hSAEC) and pulmonary artery smooth muscle cells (hPASMC)

Methods: The BMPR2 gene was delivered to both hSAEC and hPASMC using a plasmid construct or Adenovirus vector, then TGF-β signalling events assessed.

Results: In hSAEC, TGF-β upregulated P3-8MAPK phosphorylation and vimentin but downregulated pancytokeratin, consistent with epithelial to mesenchymal trans-
ition (EMT). In preliminary studies, prior transduction to upregulate BMPR2, ameliorated the TGF-β-induced increase in vimentin. In hPASMC, TGF-β did not affect P3-8MAPK, but led to a substantial increase in phosphorylated ERK 42/44 and Smad2, and reduced phosphorylation of Smad3/5/8. These effects were largely prevented by BMPR2 transduction.

Conclusions: To date, these findings suggest that BMPR2 gene delivery reduces TGF-β-induced epithelial to mesenchymal transition and TGF-β signalling in smooth muscle cells.

Increased right ventricular cardiomyocyte stiffness in patients with pulmonary arterial hypertension

Zhibao Rain1, M. Louis Handoko1, Nico Westerhof2, Crix dos Remedios3, Marc Humbert1, Peter Dorfman4, Christophe Guignabert4, Anton Vonk-Noordegraaf1, Jolanda van der Velden1, Frances S. de Man4,1Pulmonology, VU University Medical Center, Amsterdam, Netherlands; 2Physiology, VU University Medical Center, Amsterdam, Netherlands; 3Anatomy, The University of Sydney, Australia; 4INSERM U999, Paris-Sud University, Paris, France

Introduction: This study aims to determine whether changes in right ventricular
(RV) cardiomyocyte contractile apparatus are involved in RV failure secondary to pulmonary arterial hypertension (PAH).

**Methods:** Maximal force and passive stiffness were determined in membrane-permeabilized RV cardiomyocytes isolated from RV tissue obtained after heart-lung transplantation of PAH-patients and non-failing donors. Maximal force was measured at maximal Ca2+-activation, while cardiomyocyte passive stiffness in relaxing solution (low Ca2+ concentration).

- The role of β-Adrenergic receptor signaling on cardiomyocyte passive stiffness was mimicked by determining passive stiffness after PKA incubation.

**Results:**

- No significant differences were found in cardiomyocyte maximal force in PAH patients and controls.
- Passive stiffness was significantly increased at all sarcomere lengths in PAH patients compared to donors.
- PKA incubation partially restored RV cardiomyocyte passive tension in PAH patients to donor values.

**Conclusions:** Our study demonstrates increased RV cardiomyocytes passive stiffness in PAH patients, partially restored by PKA incubation. This finding suggests that reduced β-adrenergic receptor signaling plays an important role in the development of RV diastolic stiffness in PAH patients.

P3177

**The role of bromodomain-containing protein 4 in the constitutive activation of nuclear factor-kappa B in endothelial cells from patients with pulmonary arterial hypertension**

Natalis Gumbarenko1, Christophe Guignabert1, Ly Tu1, Frederic Perros1, Ian Adcock1, Marc Humbert1, Stephen Wrot1. INSERM U999, Centre Chirurgical Marie Lannelongue, Université Paris-Sud 11, Le Plessis-Robinson, France; 1Department of Critical Care, National Heart and Lung Institute, Imperial College, London, United Kingdom

**Background:** Pulmonary arterial hypertension (PAH) is characterized by a progressive increase in pulmonary vascular resistance leading to right heart failure and death. Pulmonary endothelial cells (P-ECs) are well known as producers of cytokines and chemokines essential in the recruitment of inflammatory cells to the lungs, and a constitutive activation of the nuclear factor-kappa B (NF-κB) signaling pathway in P-ECs has been recently described in PAH. RelA lysine-310 acetylation of NF-κB generates a specific docking sites for bromodomain-containing protein 4 (Brd4). We hypothesise that Brd4 through an NF-κB-dependent mechanism contributes to the hypoproliferative and proinflammatory phenotype in P-ECs in patients with PAH.

**Aim:** The aim of the study was to evaluate the in vitro effect of Brd4 inhibition using the selective inhibitor JQ1 on proliferation and apoptosis in P-ECs.

**Methods and results:** The effect of JQ1 on P-ECs proliferation was established by assessing the incorporation of BrdU. We found a strong anti-proliferative effect of JQ1 in P-ECs (Fig. 1A). We also demonstrated that JQ1 induces caspase-3 activity in P-ECs resulting in increased apoptosis (Fig. 1B).

**Conclusion:** Selective Brd4 inhibitors, such as JQ1, may represent novel therapeutic agents for the treatment of PAH. Further work is necessary to explore this hypothesis.

P3176

**Upstream mediators of p53 in cigarette smoke induced endothelial apoptosis**

Bo Kim, Leonid Serebreni, Lan Wang, Paul Hassoun, Rachel Damico. Medicine, Johns Hopkins University, Baltimore, MD, United States

**Background:** Pulmonary endothelial cell (EC) apoptosis is an early determinant of lung destruction in emphysema. We set out to characterize the upstream molecular mediators responsible for p53 dependent cigarette smoke (CS) induced EC apoptosis and rationalize them as potential therapeutic targets. p38 mitogen activated protein kinase (MAPK) has been shown to be activated in alveolar walls in patients with COPD. We have observed that XOR activation is necessary for CS-induced EC apoptosis. XOR activation by mechanical stress or hypoxia is through p38 MAPK dependent pathways. We hypothesize that p38 MAPK activation and its upregulation of XOR activity are necessary upstream events in p53 dependent CS-induced EC apoptosis.

**Methods:** Pulmonary microvascular endothelial cells (PMVEC) were exposed to cigarette smoke extract (CSE) for 4 and 24 hours. Molecular and pharmacologic approaches were used to manipulate p38 MAPK, XOR, and p53 expression. End-points included Western blotting and quantification of EC apoptosis as well as XOR enzymatic activity using the pterin fluorimetric assay (Beckman et al., 1989). Results: Exposure to CSE increases p38 MAPK activity, XOR activity, and p53 expression in our PMVEC. When EC were pretreated with inhibitors for p38 MAPK, XOR, or p53, they were protected from CSE-induced apoptosis. Inhibition of p38 MAPK blocked CSE-induced XOR activation. Suppression of the mitochondrial function of p53 with pifithrin-μ blocks CS-induced apoptosis. Conclusions: CS exposure induces increased apoptosis in PMVEC that is dependent on p33 expression and XOR activation. Inhibition of p38 MAPK prevents upregulation of XOR activation and p53 expression, protecting cells from CS-induced apoptosis.

**Methods and results:** The combined therapy of HGF and G-CSF for pulmonary hypertension in rats

Yinghua Guo1, Longxiang Su1, Yinghui Li2, Natalis Gumbarenko1, Longxiang Su1, Yinghui Li2, Natalis Gumbarenko1, Longxiang Su1, Yinghui Li2. 1INSERM U999, Centre Chirurgical Marie Lannelongue, Université Paris-Sud 11, Le Plessis-Robinson, France; 2State Key Laboratory of Space Medicine Fundamentals and Application, Chinese Astronaut Research and Training Center, Beijing, China

**Introduction:** Despite advances in therapy of PAH, the treatment and prognosis remain poor.

**Objectives:** This study was to investigate whether expression of HGF through the transplantation of genetically modified MSCs combined with G-CSF could offer therapeutic benefit.

**Methods:** Three weeks after monocrotaline, SD rats were randomly divided into PAH (n=10), MSCs (transplantation of 5×10^6 MSCs transfected with an empty adenovirus vector, n=10), HGF (transplantation of 5×10^6 MSCs transfected with Ad-HGF, n=10), G-CSF group (100 μg/kg daily for 5 days, n=10) and HGF+G-CSF group (transplantation of 5×10^6 MSCs transfected with Ad-HGF and G-CSF, 100 μg/kg daily for 5 days, n=10). Three weeks later, hemodynamic, histomorphological, endothelial and angiogenesis function were detected, involving serum levels of TGF-β, ET-1 and protein level of VCAM-1 and MMP-9.

**Results:** Compared with HGF, G-CSF and PAH group, HGF and G-CSF group have significantly less right ventricular hypertrophy, PASP and mPAP (p<0.05). Histologically, vascular smooth muscle cell proliferation and extra cellular matrix were also significantly decreased (p<0.05). The vascular density of...
HGF+G-CSF group is higher than control group ($P < 0.05$). The TGF-β and ET-1 concentration in the plasma of pulmonary hypertension rats showed markedly decreased in HGF group and HGF+G-CSF group ($P < 0.05$). Furthermore, HGF induced gene and protein expression of VCA-M1 and HGF treatment together with G-CSF synergistically stimulated MMP-9 expression.

**Conclusion:** Transplanted HGF-MSCs combined with G-CSF could offer synergistic therapeutic benefits for the treatment of pulmonary hypertension. This study illustrates mechanisms underlying the synergistic effect of G-CSF and HGF combination.

**P3179**
A critical role for p130cas in the progression of pulmonary hypertension in humans and rodents

Ly Tu1,2, Frances de Man1,2,4, Barbara Gieren1,2,3, Marie-camille Chaumais1,2, Florence Lecerf1,2,3, Charlene Franco1,2,3, Frederic Peres1,2, Peter Dorfmüller1,2, Elie Fadel1,2, David Montani1,2,3, Marc Humbert1,2,3, Eddahbi Saadak1,2, Christophe Guignabert1,2,3, Centre Chirurgical Marie Lannelongue, INSERM UMR 999, Le Plessis-Robinson, France; 2Faculté de Médecine, Univ Paris-Sud, Orsay, France; 3Service de Pneumologie, AP-HP, Clamart, France; 4Institute for Cardiovascular Research (ICuR-VU), VU University Medical Center, Amsterdam, Netherlands

Pulmonary arterial hypertension (PAH) is a progressive and fatal disease characterized by pulmonary arterial muscularization due to excessive pulmonary vascular cell proliferation and migration, a phenotype dependent upon growth factors and activation of receptor tyrosine kinases (RTKs). p130cas is an adaptor protein involved in several cellular signaling pathways that control cell migration, proliferation and survival. We hypothesized that in experimental and idiopathic PAH p130cas signaling is over-activated, thereby facilitating the intracellular transmission of signal induced by fibroblast growth factor (FGF), epidermal growth factor (EGF), and platelet derived growth factor (PDGF). In ipAH patients, levels of p130cas protein are higher in the serum, in walls of distal pulmonary arteries, in cultured smooth muscle (PA-SMCs) and pulmonary endothelial cells (P-ECs) than controls. These abnormalities in the p130cas signaling were also found to be in evidence for convergence and amplification of the growth-stimulating effect of EGF, FGF2 and PDGF signaling pathways via p130cas signaling pathway. Finally, we found that daily treatment with each of the EGF-R inhibitor gefitinib, the FGF-R inhibitor dovitinib and the PDGF-R inhibitor imatinib started 2 weeks after a subcutaneous monocrotaline injection substantially attenuate the abnormal increase in p130cas and ERK1/2 activation and regress established PH. Our findings demonstrate that p130cas signaling plays a critical role in ipAH by modulating pulmonary vascular cell migration, proliferation and by acting as an amplifier of RTKs downstream signals.

**P3180**
Surgery for obstructive sleep apnea: Sleep endoscopy determinants of outcome

Ioannis Koutrasarelis1,2, Madeline Ravesløt1, Emmanouil Vagiakis1, Spyros Zakynthinos2, Nico de Vries3,4, Centre of Sleep Disorders, Medical School of Athens University, Athens, Greece; 3Department of Otorlaryngology, Head and Neck Surgery, Sint Lucas Andreas Ziekenhuis, Amsterdam, Netherlands

Although drug-induced sleep endoscopy (DISE) is often employed in order to determine the site of obstruction in patients with obstructive sleep apnea (OSA) who will undergo upper airway surgery, it remains unknown whether its findings are associated with surgical outcome. This study tested the hypothesis that DISE variables can predict the outcome of upper airway surgery. Forty-nine OSA patients (41 men; mean apnea-hypopnea index (AHI) 30.9±18.5 events/h) underwent firstly DISE, secondly upper airway surgery, and thirdly follow-up polysomnography to assess surgical outcome. Twenty-three patients (47%) were responders and twenty-nine non-responders (53%). Non-responders had a higher occurrence of complete or partial circumferential collapse at velum, and of complete antero-posterior collapse at tongue base or epiglottis, in comparison with responders. Multivariate logistic regression analysis revealed that, among baseline clinical characteristics and DISE findings, the presence of complete circumferential collapse at velum, and of complete antero-posterior collapse at tongue base were the only independent predictors of upper airway surgery failure. Patterns of collapse on DISE associated with failure. A. complete circumferential collapse at velum; B. complete antero-posterior collapse at tongue base; C. complete antero-posterior collapse at epiglottis. In conclusion, DISE findings are predictors of upper airway surgery outcome in OSA.

Conclusions: It can be concluded that in a healthy population, the BMI has no influence on the position dependent collapsibility of the airway. This means that collapse of the UA in healthy subjects is mostly defined by the natural collapsibility of the subject’s airway.

**P3181**
BMI is not the driving factor in position dependent upper airway collapsibility in healthy subjects

Cedric Van Holsbeke1, Wim Vos1, Samir Vinchurkar1, Jan De Backer1,4, Oswald Peters2, Nassif Nadjmi3, Wiltfried De Backer2, Respiratory, Paediatrics, CHU UCL, Brussels, Belgium; 2Pediatric Respiratory Medicine, University Hospital Antwerp, Edegem, Belgium; 3Maxillofacial Surgery, A.Z. Monico, Antwerpen, Belgium

**Introduction:** In obstructive sleep apnea (OSA) patients, the minimal cross-sectional area (CSA) of their upper airway (UA) correlates well with the severity of their pathology. However, since there is a correlation between body mass index (BMI) and severity of OSA in a population of OSA patients, it is not known if the minimal CSA is defined by the natural collapsibility of the UA or by the mass of the surrounding tissue. The objective of this study is to evaluate the influence of BMI on the position dependent changes in UA geometry assessed by CT imaging.

**Materials and methods:** A total of 20 normal subjects who had BMI $<$ 25, 6 had a BMI between 25 and 30 and 7 had a BMI $>$ 30 were included. 15 valid CBCT scans could be analyzed as the rotating gantry of the CBCT touched the shoulders of some subjects with a BMI $>$ 30, causing motion artifacts. The supine UA CT scans were performed using the GE VCT LightSpeed scanner and the upright CBCT scans were performed using the ISi-CAT scanner.

**Results:** BMI was not a predictor for difference between the minimal CSA in a supine and upright posture (R=0.05, p=0.86) as seen in the figure.

**Conclusions:** BMI is not the driving factor in position dependent upper airway collapsibility in healthy subjects.
and can be an important screening tool as well as an important part of pre-test physical examination. However, its role in predicting severity of OSA remains doubtful and needs further study.

**P3184**

**Validation of respiratory inductive plethysmography in people with obesity hypoventilation syndrome**

Carly Hollier 1,2, Alison Harmer 1, Lyndal Maxwell 1, Collette Menadue 1, Amanda Piper 1, Grant Wilson 1, Respiratory and Sleep Medicine, Royal Prince Alfred Hospital, Sydney, NSW, Australia; 1Faculty of Health Sciences, University of Sydney, NSW, Australia; 2Faculty of Health Sciences, Australian Catholic University, Sydney, NSW, Australia; 3Faculty of Health, University of Canberra, Australian Capital Territory, Australia

The excessive chest and abdominal adiposity present in obesity hypoventilation syndrome (OHS) may reduce the accuracy of respiratory inductive plethysmography (RIP). The aim of the study was to validate RIP measures of ventilation in OHS against a clinical standard (spirometry). Measures of tidal volume (VT), minute ventilation (VE) and respiratory rate (RR) were obtained simultaneously from RIP (LifeShirt™) and a spirometer during two 40-minute air/supplemental O2 breathing tests. 16 paired samples were obtained per subject. Using the Bland Altman method, bias was expressed as spirometer-RIP mean difference (MD), and as a percentage. Differences between groups were assessed with independent samples t-tests. 162 viable paired samples were obtained from 13 subjects with OHS and 107 paired samples were obtained from 13 age- and gender-matched controls. Error of RIP measures was larger in subjects with OHS: VT: MD=3mL (1%), LOA=-216 to 222mL (±36%) compared with controls, MD=5mL (1%), LOA=-160 to 169mL (±20%); VE: MD=0.2L/min (2%), LOA=-4.1 to 4.4L/min (±36%) in subjects with OHS compared with MD=0.1L/min (1%), LOA=1.4 to 1.5L/min (±20%) for controls; and RR: MD=0.2br/min (2%), LOA=5 to 5br/min (±27%) in subjects with OHS compared with MD=0.1br/min (1%), LOA=1 to 1br/min (±12%) for controls. Between group differences were only statistically significant for RR (p<0.05). VT %error correlated strongly with body mass index (t=b=0.53, p<0.01) and waist circumference (t=b=0.61, p<0.01). In conclusion, the accuracy of RIP is reduced in people with OHS, limiting its capacity for detecting small changes in ventilation.

**P3185**

**Validation of raised serum bicarbonate for diagnosis of obesity hypoventilation syndrome**

Vladimir Macavei 1, Kristen Spurling, Himender Makker. Sleep and Ventilation Unit, Department of Respiratory Medicine, North Middlesex University Hospital, London, United Kingdom

**Introduction:** The need for early detection of Obesity Hypoventilation Syndrome (OHS) is clear because delay in the diagnosis and treatment is associated with significant morbidity and mortality.

**Objective:** To validate previously reported raised serum bicarbonate of 27 mmol/l for the diagnosis of OHS in obese patients attending sleep clinic.

**Methods:** A retrospective analysis of prospectively collected sleep clinic data on consecutive obese patients referred to sleep clinic from January 2009 to January 2011 in the North Middlesex University Hospital was performed. Subjects with suspected sleep disorders were evaluated according to our clinic protocol and capillary blood gases were measured in obese subjects (BMI=30 kg/m²).

**Results:** 525 consecutive patients (mean age 51±14.127, 65.71% males, mean BMI 34.59±8.1) were evaluated. A total of 344 (65.52%) were obese (mean age 52.29±12.4, 63.66% males) of which 128 (37.2%) were morbidly obese (BMI>40 kg/m²), 275 (50.5%) were morbidly obese patients were found to have OSAHS (AHI>20, %O2<90) and 272 (51.52%) were morbidly obese patients with OHS. AHI<15 was found in 162 subjects and AHI>20 was found in 163 subjects. Error was expressed as limits of agreement (LOA) and as a percentage. Differences between groups were assessed with independent samples t-tests. 162 viable paired samples were obtained from 13 subjects with OHS and 107 paired samples were obtained from 13 age- and gender-matched controls. Error of RIP measures was larger in subjects with OHS: VT: MD=3mL (1%), LOA=-216 to 222mL (±36%) compared with controls, MD=5mL (1%), LOA=-160 to 169mL (±20%); VE: MD=0.2L/min (2%), LOA=-4.1 to 4.4L/min (±36%) in subjects with OHS compared with MD=0.1L/min (1%), LOA=1.4 to 1.5L/min (±20%) for controls; and RR: MD=0.2br/min (2%), LOA=5 to 5br/min (±27%) in subjects with OHS compared with MD=0.1br/min (1%), LOA=1 to 1br/min (±12%) for controls. Between group differences were only statistically significant for RR (p<0.05). VT %error correlated strongly with body mass index (t=b=0.53, p<0.01) and waist circumference (t=b=0.61, p<0.01). In conclusion, the accuracy of RIP is reduced in people with OHS, limiting its capacity for detecting small changes in ventilation.

**P3186**

**Effects of supplemental O2 on PCO2 and ventilation in people with obesity hypoventilation syndrome**

Carly Hollier 1,2, Alison Harmer 1, Lyndal Maxwell 1, Collette Menadue 1, Gunnar Unger 1, Grant Wilson 1, Respiratory and Sleep Medicine, Royal Prince Alfred Hospital, Sydney, NSW, Australia; 1Faculty of Health Sciences, University of Sydney, NSW, Australia; 2Faculty of Health, University of Canberra, Australian Capital Territory, Australia

Breathing 100% O2 increases PCO2 in some people with obesity hypoventilation syndrome (OHS). It is not known how lower concentrations of O2 affect people

**569s**
with OHS. This study investigated the effect of clinically relevant O2 concentrations on PCO2, pH and minute ventilation (Ve) in stable OHS patients pre and post treatment with positive airway pressure (PAP), and in controls. In a double-blind randomised crossover study, 14 subjects with OHS and 14 age- and gender-matched controls breathed inspired O2 fractions (FiO2) of 0.28 and 0.5, each for 20min, separated by a 45min washout. The OHS group were retested after 3 months of nocturnal PAP. Arterialised-venous PCO2, and pH, and Ve were measured every 5min. Data were analysed with repeated measures ANOVA. In OHS pre-PAP, small rises in PCO2 of 2.0±1.7mmHg, 3.7±3.2mmHg (both p<0.01) occurred after 20min of breathing FiO2 0.28 and 0.5, respectively, with no significant difference between concentrations. pH fell accordingly, with FiO2 0.5 inducing mild acidemia (7.34±0.030, p<0.01). Ve fell below the room air baseline for both FiO2 0.28 (5±11%, p<0.01) and FiO2 0.5 (7±20%, p<0.01). The controls' responses differed significantly from the OHS group (p<0.01). PCO2 and pH did not change significantly with either FiO2 and mild hyperventilation occurred (Ve +1.3±1.9%, FiO2 0.28, +12±1.7%, FiO2 0.5). In OHS, O2-induced PCO2 rises tended to be smaller after PAP (1.2±2.3mmHg, FiO2 0.28, and 0.9±1.7mmHg, FiO2 0.5). Commonly used concentrations of O2 caused hyperventilation, small PCO2 rises and mild acidemia in stable OHS. When providing supplemental O2 for people with stable OHS, close monitoring and targeting of O2 saturations is recommended.

P3187 Multiscale entropy analysis of RR time series obtained from polysomnographic recordings in wide age spectrum group
J.J.A. Van der Grinten1, C.P. M. Van Der Grinten2, G.J. De Vries1. 1Dept of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 2Dept of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Costs and complication of polysomnography lead to attempts to develop cheaper and simpler methods. The analysis of heart rate's dynamics is biased by several physiological factors. The aim of this study was to check influence of age on multiscale entropy (MSE) of RR time series.

64 patients undergoing routine diagnostic in sleep lab were recruited (36 male, 28 female, age 1.5-63 yrs mean: 25.2±20 yrs, RDI: 0.4-9 1/h mean:1.5 1/h). The full night PSG (ASSM 2007) were performed. The R-R intervals were detected in recorded ECG signal (250Hz), and the multiscale entropy (Goldberg’s MSE) was calculated (m=2, r=0.15, scale = 1–20).

We found high correlation between entropy in SE(1) and age (Fig. 1) in adults, however in the children group (age<15) there was no such relation.

After removing subjects younger than 15yrs the correlation increase (R=0.58, p<0.001). Using MSE we found significant differences between the lowest and highest quartiles (Fig. 2)

We conclude that entropy is biased by age in adults and the lack of such relation in young group needs further investigations.

P3188 Effect of nasal CPAP therapy on functional respiratory parameters and cardiopulmonary exercise test in obstructive sleep apnea syndrome
Ozge Oral Tapan1, Can Sevcan2, Oya Ili3, Ibrahim Orman4, Muammer Kayatekin5, Yucel Demiral5. 1Dept of Chest Diseases, Karaman State Hospital, Karaman, Turkey; 2Dept of Chest Diseases, Dokuz Eylul University, Izmir, Turkey; 3Dept of Chest Diseases, Dokuz Eylul University, Izmir, Turkey; 4Neurology, Dokuz Eylul University, Izmir, Turkey; 5Pathology, Dokuz Eylul University, Izmir, Turkey; 6Public Health, Dokuz Eylul University, Izmir, Turkey

Aim: Nasal CPAP treatment is an effective treatment modality for patients with OAS. It can improve physical and mental functions by reducing daytime hyper-somnolence, arousal index and sleep fragmented. The purpose of this study was to evaluate whether pulmonary functions, exercise limitation confirmed with CPET and quality of life can be improved after eight weeks of nCPAP treatment.

Method: We evaluated our case group with physical examination, SF-36 health survey, body composition analysis before and after nCPAP treatment for 8 weeks. Spirometric flow rates, PImax, PEmax, lung volumes and exercise capacities with CPET were measured.

Results: 31 of 40 patients (4 female, 27 male) completed the study. The mean age was 53.4±1.46, 51.6±1.6 of cases had comorbidities and the smoking history rate was 54.8. All of them had exercise limitation before treatment. After treatment there were increases in PImax-PEmax (p<0.05), VO2 peak (p<0.001), Load max (p<0.001), maximal heart rates (p<0.001), all SF-36 scores except pain (p<0.05) and a decrease in systolic blood pressure (p<0.005). We didn’t see any changes in body compositions, spirometric flow rates except FEV1 and lung volumes.

Conclusion: OSAS may lead to exercise limitation. nCPAP treatment is effective in reducing exercise limitation, can help to control blood pressure and improves respiratory muscle strength. nCPAP can also improve the quality of life scores in OSA patients without any comorbidities or with comorbidities under control. Our findings may suggest that these results are the improvements of patients’ cardiac function, daytime somnolence and fitness.

P3189 End expiratory lung volume as a predictor of obstructive sleep apnea severity
A.J.M. Lebon1, C.P.M. van der Grinten2, G.J. De Vries3. 1Dept of Respiratory Medicine, Orhis Medical Centre, Sittard, Netherlands; 2Dept of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Background: One of the contributing factors to upper airway collapses in obstructive sleep apnea (OSA) is reduced end expiratory lung volume (EELV) (Kapur, V.H. et al. Respiratory Care 2010;55). There is evidence for correlation of apnea hypopnea index (AHI) with EELV in supine position during sleep (Owens, R. W. App Physiol 2010;108:445-51). In respiratory function testing however, EELV is routinely measured in sitting position and during wake (EELVaw).

Aims and objectives: To establish the relationship between EELVaw and OSA. We hypothesized that EELVaw may affect the severity of OSA.

Methods: In an observational study the relationship between EELVaw and OSA in 59 adult patients of Orhis Medical Centre, Sittard (The Netherlands) was assessed using a regression analysis. EELVaw was evaluated by helium dilution technique, and severity of OSA by apnea hypopnea index (AHI) based on polysomnography measurements. In addition EELVaw was compared to other predictors of OSA; Epworth sleepiness score (ESS), Mallampati score, body mass index (BMI), and neck- and abdominal circumference, by means of a multiple regression analysis.

Results: EELVaw was a predictor of AHI, R=0.392 (p<0.003). Multiple regression analysis demonstrated that abdominal circumference explained 15.5% of variance of AHI, and together with EELVaw, 23.4% of the variance of AHI was explained. Other predictors were not significant.

Conclusions: EELVaw contributes to the severity of OSA and might therefore be useful to differentiate between high and low risk patients for OSA in screening and diagnostics settings. Abdominal circumference also appeared to predict severity of OSA and had even more impact on AHI compared to EELVaw.

P3190 Inflammatory processes and effects of continuous positive airway pressure (CPAP) in overlap syndrome
Serkan Nural, Erzin Gunay, Bilal Halici, Mehmet Unlu. Department of Chest Diseases, Afyon Kocatepe University, School of Medicine, Afyonkarahisar, Turkey

Aim: We aimed to compare serum levels of the inflammatory mediators of C-Reactive Protein (CRP), Tumor Necrosis Factor-α (TNF-α) and Asymmetric-Dimethyl-Arginine (ADMA) in Chronic Obstructive Pulmonary Disease (COPD), Obstructive Sleep Apnea Syndrome (OSAS) and their coexistence called Overlap Syndrome (OVS). Also, we planned to investigate the changes of these mediators with the treatment of continuous positive airway pressure (CPAP) in OSAS and OVS patients.

Methods: CRP, TNF-α, ADMA levels were analyzed by ELISA method with the blood samples taken from patients with COPD (N=25), OVS (N=25) and moderate-severe stage OSAS (N=25) in the morning after polysomnography application and second blood samples taken from OSAS and OVS patients who underwent regular CPAP treatment throughout 3-6 weeks.

Results: In comparison of three groups prior to CPAP treatment, ADMA levels in OSAS group were significantly lower than in COPD group (p=0.009), but
OSA is often associated with obesity and metabolic syndrome. The aim of this study was to assess prevalence of hyperuricaemia in OSA patients and relations between elevated plasma uric acid (UA) and OSA severity, obesity and cardiovascular diseases. We studied 1144 OSA pts: AHI = 39.7±21.7, BMI = 34.2±6.4 kg/m², mean SAO₂ = 90.8±5.7%, T90 = 26.6±28.9%, Epworth score = 11.3±3.5. Points. Hyperuricaemia [males: UA > 7 mg/dl (2005-2007) and > 8.5 mg/dl (since 2008), females: UA > 5.7 mg/dl (2005-2007) and > 6.2 mg/dl (since 2008)] was found in 354 pts (30.9% (different laboratory methods)). Comparison of subjects with hyperuricaemia and normouricaemia is shown in table.

Logistic regression analysis revealed that arterial hypertension, obesity (BMI > 30 vs < 30 kg/m²), and T90 > 30% were independent predictors of hyperuricaemia (OR=1.76; 95%CI – 1.23-2.51; p=0.002, OR=2.47; 95%CI – 1.67-3.65; p<0.001 and OR=1.79; 95%CI – 1.34-2.40; p<0.001, respectively) after adjusting for NT-proBNP, diabetes, heart failure, coronary artery disease, COPD and stroke.

Conclusions: Hyperuricaemia was frequent in OSA patients. Main predictors of hyperuricaemia were obesity, overnight desaturation time - T90> 30% and arterial hypertension.

P3193
Cardiovascular diseases are responsible for increased plasma NT-proBNP level in obstructive sleep apnoea (OSA) patients
Robert Pływaczewski1, Łucza Jonczak1, Przemysław Bielen1, Łukasz Janczak1, Monika Targowska1, Anna Czyzak-Gradowska2, Dorota Gorecka2, Paweł Śliwiński1.1 Department of Diagnosis and Treatment of Respiratory Failure, National TB & Lung Diseases Research Institute, Warsaw, Poland; 2nd Department of Respiratory Medicine, National TB & Lung Diseases Research Institute, Warsaw, Poland

Increased plasma NT-proBNP concentration in OSA subjects was associated with severe obstructive sleep apnoea syndrome (OSAS) and OSAS severity, obesity, overnight desaturation time - T90>30% and arterial hypertension. Moreover, increased NT-proBNP was found in OSA patients with hyperuricaemia and normouricaemia.

Logistic regression analysis revealed that heart failure (OR=4.4; 95%CI – 4.09-4.74; p<0.0001), atrial fibrillation (OR=4.22; 95%CI – 3.89-4.58; p<0.0001), coronary artery disease (OR=2.29; 95%CI – 2.16-2.43; p<0.0001), arterial hypertension (OR=1.87; 95%CI – 1.75-2.0; p<0.0001) and COPD (OR=3.77; 95%CI – 1.27-4.77; p=0.0001) were independent predictors of increased NT-proBNP after adjusting for BMI, diabetes, hyperuricaemia and stroke.

Conclusions: Increased plasma NT-proBNP concentration in OSA subjects was mainly related to cardiovascular diseases.
Conclusions: We found a dose-response relationship between the severity of sleep apnea during the night in women and the levels of BNP in the morning.

P3195
The relationship between uric acid levels and mean plateau volume and metabolic syndrome in males with obstructive sleep apnea syndrome
Ahmet Akkaya, Onder Ozturk, Uluğ Bük Khayri, Mustafa Saygin

Aim: The aim of our study was to investigate the post-treatment changes in the level of UA and the relationship between serum uric acid (UA) levels and mean plateau volume (MPV) and metabolic syndrome in males with obstructive sleep apnea syndrome (OSAS).

Material and methods: Seventy nine men who had performed a single night polysomnography (PSG) (mean AHI=42.59±2.79 events/hour), were included to the study. Demographics characteristics, serum uric acid levels, MPV and PSG results were recorded. We divided patients in two groups according to centiles of UA levels: 1st with hyperuricaemia - UA > 6.86 mg/dL and 2nd with normouricaemia - UA < 6.86 mg/dL.

Results: There was a statistically positive correlation between UA (0.03±0.13 mg/dL) and AHI (p=0.037), BMI (p=0.013), waist circumference (p.<0.002), desaturation % (p=0.047). Subjects with hyperuricaemia had higher AHI, BMI, (p.<0.05), waist circumference (p.<0.01), neck circumference, oxygen saturation index (ODI). UA desaturation % and triglyceride. The duration of REM decreased and Stage 1 and 3 increased. The UA and MPV were found higher in patients with MS and OSAS and UA levels decreased after CPAP treatments. However, OHI and AHI were included to the model to estimate AHI at stresse regression analysis (R square 58%, p.<0.001).

Conclusion: This study showed that obesity was the determinant of hyperuricaemia and high levels of UA was found with MS and OSAS. The levels were decreased after CPAP therapy. An also, it is thought that high levels UA and MPV are associated with cardiovascular complications in OSAS.

P3196
Adaptive servo ventilation in the treatment of central sleep apnea related to ischemic stroke
Anne-Kathrin Brill, Regula Rosit, Matthias Guggert, Sebastian Robert Ott

Respiratory and Sleep Medicine, University Hospital (Inselspital) and University of Bern, Switzerland

Background: Adaptive Servo Ventilation (ASV) is a well-established treatment of central sleep apnea (CSA) related to chronic heart failure (CHF). So far, only few studies evaluated effectiveness and complications of ASV in patients with CSA of other etiologies. Therefore, we analyzed ASV in CSA following ischemic stroke.

Methods: Retrospective analysis of ASV treatment in stroke patients with CSA between 2005 and 2011. Patients with acute stroke (<1 month) or diagnosis of CHF were excluded. Demographic, clinical (including Epworth sleepiness scale; ESS), polygraphic/polysomnographic, ventilator setting and compliance data were collected.

Results: Fifteen out of 123 patients treated with ASV suffered from CSA or complex sleep apnea related to ischemic stroke (median time from stroke 11 month). 13/15 patients were pretreated with positive pressure ventilation without clinical success (CPAP 11/15; BiPAP 2/15). Indication for ASV was complex sleep apnea in 6 patients, CSA/Cheyne-Stokes-Breathing in 5 patients, and mixed sleep apnea in 4 patients. At follow up after 66.3±42.0 days, mean daily use of ASV was 5.4±2.4 h per night. ASV significantly improved AHI (46.7±24.3 to 8.5±12.0 h, p=0.001). ESS was reduced from 8.7±5.7 to 5.6±2.5 (p=0.08).

Conclusion: Our data clearly suggests that ASV is a well-tolerated and clinically effective treatment in patients suffering from CSA related to ischemic stroke. Prospective randomized trials are warranted to establish ASV in the treatment of stroke related central sleep apnea.

P3197
Relationship between NT-proBNP level, echocardiographic parameters and cardiovascular diseases in patients with obstructive sleep apnea (OSA)
Anna Czyzak-Gradkowska, Anna-Kathrin Brill

Respiratory and Sleep Medicine, University Hospital (Inselspital) and University of Bern, Switzerland

Brain natriuretic peptide (BNP) is a hormone secreted by the ventricles in response to heart overload. The aim of this study was to assess prevalence of elevated NT-proBNP (inactive form of BNP) level in OSA patients and its relations to echocardiographic parameters and OSA-associated cardiovascular complications.

We studied 87 OSA pts, mean AHI was 42.3±24.1 age - 57.5±10.6 yrs, mean plasma NT-proBNP level was 198.5±357.3 pg/ml. Elevated NT-proBNP concentration was found in 34 pts with OSA. Comparison of OSA pts with normal and elevated NT-proBNP level is shown in a table below.

Elevated NT-proBNP level was found in 39.8% OSA subjects. Logistic regression analysis revealed that elevated NT-proBNP level (>125pg/ml) did not correlate with studied echocardiographic parameters in OSA pts (p>0.05). NT-proBNP level negatively correlated with AHI (r=-0.25, p=0.02). Elevated NT-proBNP concentration indicated at increased risk of coronary artery disease (OR = 12.94, 95%CI = 2.4-68.5, p<0.01).

Conclusions: Increased plasma concentration of NT-proBNP was not related to echocardiographic parameters, but it was associated with occurrence of CAD in OSA subjects.

355. “Predicting the future”: the impact of reference values on a range of respiratory parameters

P3198
All-age multi-ethnic reference values for spirometry: The Global lung function initiative (GLI)
Janet Stocks, Sanja Stanjevic, Tim Cole, Xavier Baur, Graham Hall, Bruce Calver, Philip Quanjer

Centers for Respiratory Unit, UCL, Institute of Child Health, London, United Kingdom; #Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, Canada; 2MRC Centre of Epidemiology for Child Health, UCL, Institute of Child Health, London, United Kingdom; 3Universitätsklinikum Hamburg-Eppendorf, Hamburg - Pneumologie; 4Arthromedizin and Maritime Medizin, Hamburg, Germany; 5Telethon Institute for Child Health Research, University of Western Australia, Perth, WA, Australia; 6Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, United States; 7Department of Pulmonary Diseases and Department of Pediatries, Erasmus Medical Centre, Erasmus University, Rotterdam, Netherlands

Background: The GLI (an ERS Task Force) was established to develop the first global reference equations for spirometry. These are the result of unprecedented international cooperation and are endorsed by six international respiratory societies, including the ERS.

Methods: Data from 74,187 healthy non-smokers aged 3-95 years were used to derive reference equations using modern statistical methods, including development of age dependent lower limits of normal.

Results: All-age reference equations are now available for Caucasians, African Americans, South East Asians (south of the Huaihe River and Qinling Mountains), and South East Asians (north of the Huaihe River and Qinling Mountains). For individuals not represented by these four groups a composite equation is provided. Since the observed ethnic differences were proportional to Caucasians, for groups not represented, samples of healthy subjects, composed of at least 300 individuals, studied according to international standards (Quanjer et al ERJ 2011, 37; 658-664) and with height and age measured accurately to one decimal place.

Conclusion: The GLI 2012 reference equations are a major step forward and provide a robust reference standard to streamline interpretation of spirometry across all-ages worldwide. Widespread use of the GLI equations will, however, depend on timely implementation by manufacturers of spirometric devices.

P3199
A comparative study of FVC, FEV1, and TLC in non-smoking Saudi students at Eastern Province, Saudi Arabia with Caucasian reference values
Noor AL-Khathlan, Stephanie Enright, Mohammed Amr El-Noueama

Child Health, London, United Kingdom; 2Child Health Evaluative Sciences, The Hospital for Sick Children, Toronto, Canada

Introduction: It is well-known that pulmonary function testing (PFT) values vary with height, age, gender, and ethnicity. The influence of ethnic variation on PFT values from the Caucasian population. We aimed to compare Saudi measured values, including the ERS.

Methods: Data from 74,187 healthy non-smokers aged 3-95 years were used to derive reference equations using modern statistical methods, including development of age dependent lower limits of normal.

Results: All-age reference equations are now available for Caucasians, African Americans, South East Asians (south of the Huaihe River and Qinling Mountains), and South East Asians (north of the Huaihe River and Qinling Mountains). For individuals not represented by these four groups a composite equation is provided. Since the observed ethnic differences were proportional to Caucasians, for groups not represented, samples of healthy subjects, composed of at least 300 individuals, studied according to international standards (Quanjer et al ERJ 2011, 37; 658-664) and with height and age measured accurately to one decimal place (Quanjer et al ERJ 2012, PM:22183491), can be used to validate the GLI and/or create an appropriate adjustment factor (www.lungfunction.org).

Conclusion: The GLI 2012 reference equations are a major step forward and provide a robust reference standard to streamline interpretation of spirometry across all-ages worldwide. Widespread use of the GLI equations will, however, depend on timely implementation by manufacturers of spirometric devices.
for forced vital capacity (FVC), forced expiratory volume in one second (FEV1), and total lung capacity (TLC), with Caucasian RV.

Methods: Healthy non-smoker university students were recruited to perform spirometry and plethysmography. Measurements were obtained according to ATS/ERS recommendations, standardized for height and age and compared with Caucasian RV.

Results: We studied 128 subjects, 16 of which were excluded for technical reasons. Significant difference (p<0.01) was found between the measured values in Saudis (52 males and 60 females) and Caucasian RV. The means for the measured values of FVC, FEV1 and TLC for Saudis were found to be lower than the means of RV for Caucasians by about 10%, 5% and 8% respectively for males and 16%, 12% and 5% respectively for females.

Discussion: Matching the reference and patient populations when selecting RV for PFT is significant. The observed differences we found between Saudis' PF and Caucasian RV can be deemed of great importance and maybe explained in terms of environmental and life-style factors. However, larger study is required to confirm these findings.

Background: Spirometry is the most common method to evaluate pulmonary function. The European Respiratory Society recommends the development of new reference equations, in order to upgrade and improve the existing ones.

Aim: Develop reference equations to calculate reference values adjusted to a healthy population of college students.

Methods: A total of 49 healthy female individuals with ages ranging 17 to 25 years old were enrolled in the present study. A standardized respiratory and allergy symptoms questionnaire was applied and spirometry was performed in the selected individuals. FEV1, FVC and FEV1/FVC were used as dependent variables in simple and multivariate linear regression models.

Results: Height is the variable that best explains variation of FEV1 (r² = 0.36; p < 0.001) and FVC (r² = 0.44; p < 0.001), while weight is the variable that best explains FEV1/FVC (r² = 0.15; p = 0.006). Knudson’s equations were the most different from this model, while Quanjer’s were the closest.

Conclusions: There are no spirometry alterations in patients with morbid obesity with no history of cardiovascular, skeletal, neuromuscular or respiratory diseases. There are no difference between sexes.

Spirometry measurements in the morbid obesity
Khalid Abu Shamg 1, Maria Hernandez 1, Amaia Iridoy 1, Susana Clemos 1, 1Pneumología; 2Spain Pneumology, 3Internal Medicine, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain

Background: The obesity is a particular case of thoracic respiratory function restriction. Obstructive Apnea Syndrome and hypoventilation have been described in relationship to the morbid obesity (MO).

Objective: To evaluate the alterations presented in spirometric measurements concerning the healthy subject with morbid obesity.

Methods: Spirometry and flow-volume curve were performed in 44 patients suffering of MO studied in our Department. Of 44 cases, 8 were male (18.2%) with a mean age of 37.4±8.8 years and 36 women (81.8%) with a mean age of 39.9±11.1 years.

Conclusions: There are no spirometry alterations in patients with morbid obesity with no history of cardiovascular, skeletal, neuromuscular or respiratory diseases. There are no difference between sexes.

P3202
Comparison of different predicted and lower limit of normal (LLN) values in ventilation disorders detection
Marina Kamegev 1, Artem Tsitkovich 1, Alina Bylkova 1, Vasily Tretfovsky 1, 1Lung Function Laboratory, Institute of Pulmonology Pavlov's State Medical University, St. Petersburg, Russian Federation; 2Information Technologies in Education, Institute for Informatics and Automation of RAS, St. Petersburg, Russian Federation; 3Department of Physics, Mathematics and Informatics, Pavlov's State Medical University, St. Petersburg, Russian Federation; 4Department of Hospital Therapy, Pavlov's State Medical University, St. Petersburg, Russian Federation

Methods: To estimate the agreement of Russian equations (Klement), ECCS and NhanesIII spirometry evaluating systems in determining the types of ventilation abnormalities by predicted and LLN (5th percentile) values.

Materials and methods: The study enrolled 7,779 Caucasians examined in pulmonary clinics of St.Petersburg's Pavlov's State Medical University in 2005-2011: 3,584 males (mean age 47.40±0.25, mean height 175.44±0.18) and 4,195 females (mean age 49.66±0.20, mean height 162.29±0.10). The cases that can not be classified as norm, obstruction or restriction, were accumulated in the “mixed” group.

Conclusion: The best agreement was obtained by ECCS and Klement systems both in predicted values and LLN. NhanesIII significantly differs from both Klement and ECCS in LLN for all groups. In predicted values these three systems agreed in obstruction but still generally disagree in norm and restriction.

P3203
The effect of body composition on pulmonary function
Jung Eun Park 1, Jin Hong Chung 2, Kyeong Cheol Shin 1, Kwan Ho Lee 1, 1Internal Medicine, Yeungnam University College of Medicine, Daejeon, Korea; 2Internal Medicine, Yeungnam University College of Medicine, Daejeon, Korea

Background: The pulmonary function test (PFT) is the most basic test methods to diagnose lung disease. The purpose of this study was to research correlation of the body mass index (BMI), the fat percentage of the body mass (Fat%), the muscle mass, the fat-free mass (FFM) and the fat-free mass index (FFMI), waist-hip ratio (WHR) on the forced expiratory volume curve.

Methods: Between March and April 2009, a total of 291 subjects were enrolled. 152 men and 139 female (mean age: 46.3±9.92) were measured the FVC, FEV1, FEF25-75, from the forced expiratory volume curve by the spirometry and the body composition Calopero, with the bioelectrical impedance method. From the correlation and multiple linear regression between body composition and pulmonary function were used executed.

Result: BMI and Fat% had no correlation with FVC, FEV1, in male, but FMFI is positively correlation. In contrast, BMI and Fat% had correlation with FVC, FEV1, in female, but FMFI had no correlation. Both male and female, FVC and FEV1, had not significant correlation with WHR (male FVC r=0.237, FEV1, r=0.36; p-value <0.05) (female FVC r=0.175, FEV1, r=0.213; p-value <0.05).

In a multiple linear regression of considering body composition at total sex group, FVC was explained FMM, BMI, FMFI in order (R²=0.579, 0.657, 0.663), FEV1 was explained only Fat% (R²=0.011). FH25-75 was explained mean muscle mass. FMFI (R²=0.126, 0.138, 0.148).

Conclusion: The BMI, Fat%, muscle mass, FMFI, WHR have significant correlation with pulmonary function but (coefficient of determination) were not high enough for explaining lung function.

P3206
Impact of a pulmonary laboratory quality control oversight on continual improvement
Carl Mottram, Susan Blonsunique, Karin Kjek, Jeremy Road. Pulmonary Function Quality Control Program, Diagnostic Accreditation Program, Vancouver, BC, Canada

Introduction: The purpose of this study was to evaluate the impact of a quality control (QC) oversight program on compliance with QC, biological coefficient of variation (CV) targets, and test performance improvements.

Methods: The Diagnostic Accreditation Program (DAP) of British Columbia is responsible for accrediting 27 pulmonary function (PF) laboratories representing 45 testing systems throughout the Canadian province. In 2008 DAP elevated the required elements of their quality assurance program to be more consistent with the current ATS-ERS recommendations for QC testing. This included increasing the frequency of the biological testing and adding a diffusing capacity mechanical QCM model. DAP also changed the data review model to include assessment by an external consultant with a feedback report process to the sites. We compared the data through 2011 to assess the impact of the feedback process. Data were categorized into major and minor subsets for compliance, BioQC targets, and test performance based on an assessment of overall impact of the deficiency on lab performance (e.g. BioQC DLCO CV target < 5%, a CV >5-10 categorized as major; CV >10% a major deficiency).

Results:

<table>
<thead>
<tr>

Discussion: There was a significant improvement in all three areas of the monitoring program with a total improvement of 61% (p<0.05). Using a formal external oversight process which includes written feedback appears to improve the overall outcome of this regulated quality assurance program.

P3207
Validation of spirometer calibration syringes
Blenning Madison, Lung Function Laboratory, Allergy and Lung Clinic Helsingør, Helsingør, Capital Region, Denmark

The calibration syringe is probably the most important instrument in pulmonary function laboratories, yet no validation results have been published.

Methods: We weighed a 3 L calibration syringe before and after emptying it of water and determined the corresponding volume of gas by using a modified rolling seal spirometer.

Results: The volume of a spirometer calibration syringe could be verified with an accuracy of ±15 ml. All syringes larger than one litre had volumes within the label claimed volume ±0.5%.

Conclusion: Spirometer calibration syringes have a stable stroke volumes. The maximal interval between syringe validations should perhaps be extended beyond the 1-year period required by current standards. Use of two syringes would allow one syringe exceeding the maximal permissible error to be detected earlier.
The comparison study on the effects of high versus low flux membrane on pulmonary function tests in hemodialysis patients

Ali Moemen, Hamid Reza Ronaghi, Glaheh Kiani, Massoule Amari. Internal Medicine Department, Shahrekord University of Medical Sciences, Shahrekord, Chaharmahal va Bakhtiyari, Islamic Republic of Iran.; 2School of Medicine, University of Medical Sciences, Shahrekord, Chaharmahal va Bakhtiyari, Islamic Republic of Iran.

Background: Several studies have been carried out to evaluate the effects of dialysis on pulmonary function tests (PFT). Dialysis procedure may reduce volumes and capacities of the lung or cause hypoxia; however, based on our knowledge, there was no previous study on evaluation of effects of membrane type (high flux vs. low flux) on PFT in these patients. The aim of this study was the evaluation of this relationship.

Materials and methods: In a cross-sectional study, 43 hemodialysis patients without pulmonary disease were enrolled. In these patients dialysis was conducted by low and high flux membranes and before and after of procedure, spirometry were done and the results were evaluated by t-test and chi square.

Results: Mean age of the patients was 56.34 years. Twenty three women (53.5%) and 20 men (46.5%) were enrolled. Patients' body weight after dialysis were decreased significantly compared to before dialysis. Type of membrane (high flux vs. low flux) had not significant effect in PFT results of the patients (P>0.05).

Conclusion: Since high flux membranes are more expensive than low flux membranes and there was no significant difference in the results of spirometry of patients, it could not be offered of high flux membrane for this purpose.

P3210

Pulmonary volumetric analyses based on three-dimensional computed tomography (3D-CT) potentiated the application in the daily clinical practice.

Hiroshi Muto1, Sayaki Hiraoka1, Kako Mota1, Musamichi Koyanagi1, Kenichi Yokoyama1, Yoshinosuke Fukuchi1, Toshiaki Nitatori1, Hajime Goto1, Sayuki Hiraoka1, Keiko Mota1, Masamichi Koyanagi1.

Background: Three-dimensional computed tomography (3D-CT) potentiates the application in the daily clinical practice.

Methods: Forty four patients (30 COPD, 12 lung cancer, 2 miscellaneous) were enrolled in this study. Lung volumes (LV), as well as the low attenuation volume (LAV), were measured based on 3D-CT both at end inspiratory volume (EIV) and end expiratory volume (EEV) and compared with the physiological data of ordinary pulmonary function tests.

Results & discussion: Lung volumes determined using reconstituted 3D-CT images at end inspiratory volume (EIV), those at end expiratory volume (EEV), and their difference (EIV – EEV), were significantly associated with TLC (p<0.0001), RV (p<0.0001), VC (p=0.0028), respectively. Furthermore, the percentage of the LAV to LV at EIV (LAV/LV%) was associated with the changes in the various results of pulmonary function tests, including FEV1, %FVC, RV/LV, VC. Both FEV1 and %FEV1 were associated with LAIExp and LVEp, in participants whose LAV were larger than 10mL. These results suggested that 3D-CT, taken at both EIV and EEV, provides the data not only on lung volumes in the static state, but also dynamic information. Furthermore, there is a significant association between the FEV1 and the difference between the normal attenuation volumes (NAV) of the 3D-CT at EIV and those at EEV (p<0.001). This suggested that not only LAV but also NAV contributed to the airflow limitation, represented by FEV1 reduction.

Conclusion: 3D-CT reveals not only the physiological properties, but also provides some insights into the mechanism of respiration.

P3211

Estimation of chest-wall mechanics by laser self mixing interferometer

Ilaria Milesi1, Emanuela Zanni2, Peter Kostic3, Michele Norgia3, Chiara Venereoni1, Antonio Dell’Olmo3,2, Peter Frykholm1, Raffaelle Dellacà1, Tatyana Molostova, Zaurbek Aisanov.

Background: Several studies demonstrated that the chest wall (CW) may be split into at least two compartments (rib cage and abdomen) characterized by spatial distribution inhomogeneities in CW mechanics. Up to now, it has been assessed by means of complex technique such as Optoelectronic Plethysmography (OEP). We have developed a CW scanning system (CWSW) based on self-mixing laser interferometers that allows measuring relative displacement contactless with high spatial resolution (<1 μm) in an economical and easy to use way.

Methods: Five healthy subjects, in supine position, were analyzed while submitted to a sinusoidal pressure forcing at the mouth with components at 5, 11 and 19 Hz.

Results: Displacement of several points on their CW has been measured with the CWSW and phase shift among these points and the pressure stimulus was estimated by spectral analysis.

Conclusion: The impedance averaged maps in the figure below show high spatial inhomogeneities, in particular one may appreciate that at 5 Hz it is possible to identify the region of the rib cage, where the pressure stimulus moves fast, and the abdomen where the pressure wave is slowed down by the high inertive component.

P3212

Specificity and sensitivity of the methacholine challenge test for the diagnosis of asthma in athletes

Alexander Chemkov, Tatyana Pashkova, Malika Mustaphina, Svetlana Chikina, Tatiana Molostova, Zaurbek Aisanov. Functional Diagnostic, Research Pulmonology Institute, Moscow, Russian Federation

The report of recurrent symptoms of bronchial obstruction as chest tightness, wheeze and cough provoked by exercise is a prerequisite for the diagnosis of asthma or exercise-induced bronchospasm (EIB) in athletes. The report of symptoms should be verified by the demonstration of reversibility of airflow obstruction, EIB or other methods of diagnosing either indirect or direct bronchial hyperreactivity (BHR). The purpose of this study was to examine specificity and sensitivity of the methacholine challenge test (MCT) for the diagnosis of asthma in athletes.

Twenty seven athletes (16 M/11 F, mean age 22.0±4.3 yrs) with respiratory
symptoms were studied. Lung function with assessment of reversibility to salbutamol (n=27) and challenge tests with methacholine (n=25) were performed. The specificity and sensitivity of the MCT were evaluated.

**Subjects and methods:** Patients with respiratory symptoms raising suspicion of asthma and patients with partially controlled asthma underwent methacholine challenge (MC) using ATS Guidelines (1999). The test was considered negative for a PC20 >16 mg/mL and borderline for 8-16 mg/mL. Bronchial hyper-reactivity was considered severe for PC20 <0.125 mg/mL.

Pre-test probability of bronchial hyper-reactivity was recorded by the pulmonologist using visual analog scale (VAS) based on history, clinical findings and previous spirometry results; the scores ranged from 0 (no hyper-reactivity) to 10 (doubtful hyper-reactivity).

**Results:** 50 patients were evaluated. VAS scores and PC20 values differed significantly in the two groups:
- In the 26 patients with known asthma VAS scores were 5.1-10 (mean 7.6). MC showed moderate or severe bronchial hyper-reactivity in all subjects, with PC20 0.03-2 mg/mL (mean 0.56).
- In the 24 patients with suspicion of asthma VAS scores were 0.9-9 (mean 4.8). MC was negative in 13, borderline in 2 patients and showed bronchial hyper-reactivity in 9 (severe in 1, moderate in 5, mild in 3 patients; mean PC20 5.3).

A strong correlation was seen between VAS pre-test scores and PC20 values in the suspicion of asthma group (r=0.832, p<0.000) and a weak correlation in the known asthma group (r=0.389, p=0.049).

**Conclusions:** Pre-test clinical probability of bronchial hyper-reactivity recorded by the pulmonologist on visual analog scale correlated well with the PC20 values at methacholine challenge in patients with suspicion of asthma. However using mMRC to determine symptoms & GOLD stage for risk produced a significantly different distribution (A=20.3%; B=24.7%; C=5.0% and D=50.0%: p<0.001).

Data using mMRC score & exacerbation frequency was similar to that using GOLD stage and different to that using CAT with exacerbation frequency (p<0.0001).

**Conclusions:** Using either mMRC or CAT scores to determine symptoms results in a significant difference in the proportion of patients being categorised into the risk categories which will affect risk assessment and hence therapeutic choice. Longitudinal follow up and monitoring will enable the best method and threshold to be determined for patient management.
Conclusions: Both definitions, had longer time to sleep onset, lower sleep quality, more awake nighttime symptoms were more breathless (BDI domains, focal scores p < 0.0001 for all, both definitions). A significantly higher percentage of patients with nighttime symptoms reported sleep disturbance on SGRQ vs those without (p<0.0001 both definitions). Patients with nighttime symptoms were more breathless (BDI domains, focal scores p<0.002, both definitions), had longer time to sleep onset, lower sleep quality, more awakenings, difficulty falling back to sleep, less total sleep, and were less rested in the AM6778. Both definitions were those with some symptoms.

Conclusions: COPD nighttime symptoms are associated with impaired health status, breathlessness, and poor sleep. Clinicians should consider COPD nighttime symptoms when prescribing treatment.

P3219
Nighttime symptoms and reduced quality of life among COPD patients
Michelle McBean1,2, Cynthia Cates1, Careen Stavros1, Tourkodimitris1, Esther Garcia1,2, Juliana Sethyan1,2, 1Health Economics & Outcomes Research, Forest Research Institute, Jersey City, United States; 2Clinical Development, Forest Research Institute, Jersey City, United States.

Aims: To assess the rate of decline of FEV1 over time in patients with GOLD stage 3-4 COPD and compare the rate of decline in non-smokers and smokers.

Methods: The primary outcome was the rate of decline of FEV1/year in current smokers versus non-smokers; secondary outcomes included the rate of decline in FEV1 at different stages of airflow obstruction. In a retrospective case series, we included patients with a primary diagnosis of COPD, GOLD stage 3–4 under regular review with 3 years spirometry data performed in the respiratory clinic using standard methods. The sample was divided into non-smokers, persistent smokers, and intermittent quitters.

Results: Data was available for 95 patients range 3-23 years. The rate of decline in smokers was significantly higher than non-smokers. The mean (SD) decline in FEV1 (ml/yr) was faster in earlier stages in GOLD2 53.2 (16.7); GOLD3 32.0 (29.7) and GOLD4 5.9 (7.2). In the overall sample the line of best fit of FEV1 over time was exponential. The rates of decline (mean (SD)) in non-smokers GOLD3 was 33.9 (35.3) and GOLD4 17.3 (51.3) and for smokers GOLD3 = 42.7 (34.5) and GOLD4 = 25.3 (NA).

Conclusion: Even in late stages the decline in FEV1 is faster in smokers than intermittent quitters who declined faster than non-smokers. Unlike the Fletcher Peto diagram we found that the decline in FEV1 was faster in earlier than later stages. The benefits of quitting diminish as the disease progresses. To minimise lung damage it is essential identify people in early stages and for them to stop smoking immediately.

P2319
Comparison of quality of life scores with modified Medical Research Council (mMRC) dyspnoea scale using data from the European health-related quality of life study
Paul Jones1,2, Lukasz Adamek3, Gilbert Nadeau3, Norbert Banki3, 1Clinical Science, St. George’s University, London, United Kingdom; 2Respiratory Centre of Excellence, GlaxoSmithKline, Uxbridge, United Kingdom; 3Biostatistics and Epidemiology, GlaxoSmithKline, Munich, Germany.

The 2011 Global Initiative for chronic obstructive lung disease (GOLD) guidelines recommend a combined assessment for measuring the impact of COPD which considers current symptoms and future exacerbation risk. Two symptom cut-points are proposed using the COPD Assessment Test (CAT) score ≥ 10 and modified Medical Research Council (mMRC) dyspnoea score ≥ 2. There are currently no published data comparing CAT scores by different mMRC grades.

This analysis examined health status scores for CAT, St George’s Respiratory Questionnaire (SGRQ) and short form health survey (SF-12) Physical Component (PC) split by mMRC grade in a primary care population using data from the Health-Related Quality of Life in European COPD Study.

Data from 1817 patients (mean [SD] FEV1, 1.06 [0.6]; age 64.9 [9.6] years; males 72%) were used. The CAT, SGRQ and SF-12 PC scores are tabulated.

The mMRC showed a clear relationship with scores from the comprehensive generic and disease-specific measures. mMRC Grade 1 was associated with very significant levels of health status impairment. Even the patients with mMRC Grade 0 had modestly elevated CAT and SGRQ scores, which means that mMRC Grade 0 does not mean the absence of symptoms.

P3220
The effect of reducing breath holding time to assess diffusion capacity
Elisa Magro, Barry Kenedy, Sophie Crinion, Orla Cotter, David Curran, Terry O’Connor. Department of Respiratory Medicine, Mercy University Hospital, Cork, Ireland.

The single breath method to measure diffusion capacity requires a subject to inspire a gas mixture followed by a 10–2 second breath hold. However, dyspnoea may preclude measurement in patients with advanced pulmonary disease. We sought to determine if breath hold time reduction had a significant effect on measured DLCO values.

Forced spirometry and CO-diffusion by the single breath method were performed in duplicate with breath-holding for 10–2 seconds, 8.1±2 seconds and 6±2 seconds in 30 controls (FEV1, 107±2.04% predicted), 30 severe COPD patients (FEV1, 37.2±6.92% predicted), and 30 patients with interstitial lung disease (ILD) (FEV1, 69.5±17.61% predicted). There was no significant difference between DLCO(SB) and DLCO(VA) measured at 10, 8 and 6 seconds in the control (p=0.4431) and ILD groups (p=0.5915). However, there was a significant difference between DLCO(SB) (p=0.0003) and DLCO(VA) (p=0.0183) measured at 10, 8 and 6 seconds in the COPD group.

In the presence of severe airway obstruction the DLCO decreases with breath hold time reduction. However, in healthy controls and patients with ILD, there was no significant change in the DLCO when breath hold time is reduced from 10 to 6 seconds. This could allow for a reduction in breath hold time when measuring the DLCO in patients with advanced ILD who are unable to breathe hold for 10 seconds.

P3221
Reference values for respiratory system resistance in adults
Donata Buryga1,2, Marion Heil-Neumann1,2, Matthias Wüst1,2, Loenzo Ziegler-Hettbrock1,2, 1Eva Study Center, Helmholtz Zentrum München, Gauting, Germany; 2Institute for Lung Biology and Disease, Helmholtz Zentrum München, Neuherberg, Germany.

The degree of airway disease is usually determined in spirometry using mane-
vers that require quite some effort, i.e. FEV1 and FVC. Bodyplethysmography can assess airway obstruction during tidal breathing by determination of airway resistance. Reference values for resistance are, however, scarce. Within the embaphema versus airway disease (Eva) study we therefore have determined airway resistance in a population of 261 apparently healthy Caucasian subjects aged 45 to 75 with 163 males and 98 females. These were ex-smokers for more than a year or never smokers (27%) with no evidence of acute or chronic lung disease. We determined total resistance (Rt), inspiratory resistance (Ri), expiratory resistance (Rex) and specific resistance (Sr). Rex for the entire group was 0.22±0.11 kPaxsec/L (95 Percentile = 0.45) for males it was 0.20±0.12 kPaxsec/L and for females it was 0.26±0.12 kPaxsec/L. Rin for the entire group was 0.16±0.07 kPaxsec/L (95 Percentile = 0.29) for males it was 0.15±0.07 kPaxsec/L and for females it was 0.18±0.08 kPaxsec/L. Rin for the entire group was 0.19±0.09 kPaxsec/L (95 Percentile = 0.34).

The resistance values for the females as compared to males were significantly higher for all 4 types of parameters (p<0.001 each). As expected resistance parameters Rin and Rex showed a strong inverse correlation with FEV1 (mls). There was no impact of age or packyears. The data obtained can form the basis for the evaluation of airway resistance in obstructive lung diseases like COPD.

Supported by EU FP7 project #200506.

P3222
The longitudinal determinants of decline in COPD and asthma-COPD overlap in an Australian population
Vanessa McDonald1,2, Juanjuan Fu1, Jodie Simpson1, Peter Gibson1,2,3
1Priority Research Centre for Asthma and Respiratory, the Faculty of Health, The University of Newcastle, NSW, Australia; 2Department of Respiratory and Sleep Medicine, John Hunter Hospital, Newcastle, NSW, Australia; 3Woolcock Institute of Medical Research, The University of Sydney, Glebe, NSW, Australia

Longitudinal examination of the characteristics of COPD and asthma-COPD overlap will improve our understanding of these conditions and help identify the role of systemic inflammation (SI). We hypothesised that overlap and SI are associated with the greatest decline in FEV1, and health status.

Aim: To determine the association between the decline of FEV1, and other clinical outcomes over time.

Methods: A prospective cohort study with 4 year follow up. Participants with COPD and asthma-COPD overlap, underwent an assessment of spirometry, health status, and biomarkers of CRP and sputum cell counts at baseline and 4 years. Results: 84 (84%) of the original cohort were contactable, 41(41%) were re-assessed, and there were 15 deaths. The mean (SD) age at follow up was 72.2 (6.8) years. COPD and overlap diagnosis was 57.5% and 42.5% respectively. The mean difference in 2 years between the SI and MDW was 0.39 (0.77). 6MWD decreased by 42 (44.4) meters, Rin was a 2.2 (11.4) unit decrement in SGRQ. Changes did not differ by diagnosis. Those with SI (CRP >3 mg/L) at baseline had the greatest decline in SGRQ (diff 5.7 (2.4) versus -2.2 (2.5); p=0.03), but there was no difference in FEV1 decline. Mean (SD) baseline FEV1% pred (41.12.3) V 59.5 (18.0); p=0.0007, 6MWD (319 (100) V 440 (97); p=0.0001) and SGRQ (55 (16) V 42 (17); p=0.0009) was worse in the group that died compared to survivors.

Conclusions: Overlap asthma-COPD is not associated with increased functional decline. SI is associated with declining health status, suggesting a need to target treatment to low grade SI. Overall there was only slight health status and functional decline over 4 years, however the 15% that died had the greatest baseline impairment.

P3223
Association between COPD and other co-morbid conditions: Results from a 1-day, point-prevalence study in 2,04,912 patients from 860 cities and towns in India
Sapna Madas1, Komalkirti Apri1, Monica Barne1, Sonali Harangule1, Jadeep Gogilay1, Sushmeeta Chhrowala2, Nidar Mahajan2, Salvi Sundeen1
1Respiratory Research, Chest Research Foundation, Pune, Maharashtra, India; 2Respiratory, Cipla Ltd, Mumbai, Maharashtra, India

COPD is known to be associated with various systemic manifestations. We aimed to study the association between COPD and cardiovascular disease, diabetes, and anaemia in a cohort of patients from 22 states and 5 union territories in India.

Methodology: 13,225 general practitioners (GPs) and general physicians (Gen Ps) from 860 cities and towns were randomly selected and invited to participate in this 1-day point-prevalence, cross-sectional study. On 1st February 2011 all participating doctors captured details of age, gender, presenting symptoms and diagnosis of all patients who visited them. Clean data was transferred into the EPA INFO software and associations between COPD and other co-morbid conditions were analyzed using chi-square test.

Results: 24,000 doctors commented and provided clean data of 2,04,912 patients (M: 54.1%; F: 45.9%) who visited their clinic/hospital. Of these 6118 (3.0%) patients had COPD. Presence of doctor-diagnosed COPD was strongly associated with presence of chronic heart disease (CHD) (OR: 2.66 (2.3, 3.0; p<0.0001), Hypertension (HT) (OR:2.19 (2.0, 2.4; p<0.0001), Congestive Heart Failure (CHF) (OR:4.55 (3.5, 5.3; p<0.0001), Diabetes (OR: 1.71 (1.6, 1.9; p<0.0001)), Stroke (OR:2.17 (1.6, 2.9; p<0.0001), Arthritis (OR:1.34 (1.2, 1.6; p<0.0001) and Anaemia (OR:1.27 (1.1, 1.4; p<0.0001)). These associations remained even after adjustment for confounding factors.

Conclusion: COPD is strongly associated with the presence of CHD, HT, CHF, Diabetes, Arthritis and Anaemia in an Indian population.
using atomic force microscopy. Both, CAT questionnaire and ADO index were also assessed. Ten smokers with normal lung function were used as controls.

Results: On admission, E in COPD patients (956±422 Pa) is increased compared to controls (439±216 Pa) (p<0.05). Compared to admission, the 14 patients who completed the study improved lung function (FEV1 and PaO2), CAT score (from 23±6 to 13±6), C-RP values and number of leukocytes at convalescence; however, there were no changes in the 11 patients who recovered, no differences were observed between admission and recurrence (907±376 vs 881±359 Pa). A significant association between ADO index and E at admission in COPD patients (r=0.25) (Rho 0.60, p<0.05) was observed. These findings suggest that the rheological properties of neutrophils may be driven by a different underlying inflammatory response.

Supported by SEPAR - 2010, CIBERES Almirall and Esteve.

P3227 Phenotyping of patients with COPD from exhaled air by ion mobility spectrometry
Angelika Kronseder1, Marietta Truger1,2, Stefan Peters1, Stefan Karrasch1, A. Rembert Koczulla1, Dennis Nowak1, Rudolf A. Jörres1, Ana Raquel Gabriel da Silva1. 1Institute and Outpatient Clinic for Occupational, Social and Environmental Medicine, LMU, Munich, Germany; 2Department of Respiratory Medicine Campus Innenstadt, LMU, Munich, Germany; 3Department of Internal Medicine, Section of Pulmonary Diseases, University of Marburg, Germany; 4Esgo Superior de Saúde de Universidade de Aveiro, Universidade de Aveiro - Av. Edficio III Campus Universitário de Santiago, Santiago, Aveiro, Portugal

Background: COPD is a heterogeneous disease including several comorbidities. Different phenotypes have been proposed, among them patients with frequent exacerabations. We investigated whether an electronic nose is sensitive in the detection of such characteristics.

Methods: Thirty stable COPD patients and 26 control subjects breathed at rest into a special 6.5L tube via a valve. Analysis for VOCS was done online by ion mobility spectrometry (IMS, Siemens). It turned out that data could be condensed into 23 volatile compounds and 939 reading points (the retention time yielding a matrix of 23x693 signals. For each matrix element values were compared between groups or within COPD patients by Mann-Whitney-U-test at p<0.005. Columns with numbers of significant rows were considered as different. This handling of multiple testing of correlated data was based on bootstrap results indicating <2 differences occurring by chance at p=0.005.

Results: Ten columns differed between COPD patients and controls, 2 between COPD III versus II, and 2 between patients with (n=14) and without at least one exacerbation during the last year, while the distribution of COPD stages (FEV1) was similar in the latter patients. In single columns the number of significant rows much exceeded the threshold of 10. The analysis of comorbidities also suggested differences in IMS signals.

Conclusion: Breath profiles from a highly sensitive electronic nose correlated with COPD disease severity and characteristics. This might help in the non-invasive differentiation between COPD phenotypes.

P3238 Sputum VEGF level increases with treatment of COPD acute exacerbation
Zsófia Lőráz, András Bikov, Gabriella Gálfi, György Lesonczy, Illdók Horváth. Dept. Pulmonology, Szentendrei University, Budapest, Hungary

Introduction: The role of vascular endothelial growth factor (VEGF) in COPD pathogenesis has been studied widely; however the change in blood and airway VEGF levels during the treatment of an acute exacerbation has not been investigated. In this study we aimed to evaluate the changes in plasma and sputum VEGF levels during COPD exacerbation.

Methods: 14 subjects (64±10 years) with established COPD participated in the study. Spontaneous sputa and EDTA-plasma samples were collected for VEGF measurement at admission to hospital due to an acute exacerbation of COPD (Anthonisen type I-II) and also at discharge from hospital. During hospitalization (8±1.1 days) patients were treated with systemic corticosteroids (n=12) and/or with antibiotics (n=7). VEGF concentration was measured by ELISA. Data are shown as mean±SD and analyzed with parametric tests.

Results: Sputum VEGF levels positively correlated with FEV1 percent predicted (r=0.61, p=0.02) and FEV1/FVC (r=0.55, p=0.04) at baseline, whereas age, dyspnea, presence of bacteria in sputum, presence of emphysema, diffusing capacity and blood eosinophils higher than 2% were the most important linked if there was a statistically significant correlation between the two variables being explored. Dyspnea, presence of bacteria in sputum by polymorphonuclear reaction, leukocytosis, active smoking, pulmonary hypertension on echocardiography, PaCO2, inspiratory capacity to total lung capacity (ICTLC) and fibrinogen were the most important and interconnected nodes of the exacerbome on admission whereas age, dyspnea, presence of bacteria in sputum, presence of emphysema, diffusing capacity and blood eosinophils higher than 2% were the most important associated factors.

Conclusion: The present study supports the necessity of an novel approach to help understanding the heterogeneity of severe COPD exacerbation.

Supported by FSI 051463 and an unrestricted research grant from GSK.

P3320 Association of gastro-esophageal reflux disease symptoms with COPD severity and acute exacerbations of COPD
Konstantinos Bartziokas1, Andriana Papaioannou2, Stamatoula Tsikrika2, Fotini Karakontaki2, Zoi Nouvaki1, Alexip Papadopoulos1, Evangelion Kastanaki2, Napoleon Bargestas2, Stylianos Pappas4, Iakarimeni Hanouiti2, Konstantinos Kostakis2, 1Respiratory Medicine Department, Anna Maria Fleming General Hospital, Athens, Greece; 23rd Respiratory Medicine Department, Sismanoglion General Hospital, Athens, Greece; 32nd Respiratory Medicine Department, University of Athens Medical School, Attikon Hospital, Athens, Greece

Background: Gastroesophageal reflux disease (GERD) is common in COPD patients but there is little prospective data on the impact of GERD on COPD exacerbations.

Objectives: To evaluate the association of GERD and GERD-related therapy with disease severity and exacerbation frequency in COPD patients.

Methods: 1087 COPD patients and 392 controls were included. GERD symptoms were evaluated with GERD-Q questionnaire and treatment with proton pump inhibitors (PPIs) was recorded. All patients were contacted monthly and acute exacerbations of COPD (AECOPD) and hospitalizations for COPD exacerbations were recorded.

Results: The presence of significant GERD symptoms was more common in COPD patients compared to controls (25.4 vs. 9.0%, p<0.001) and was associated with more severe disease. Frequency of AECOPD and hospitalizations in 1 year was associated with GERD score (r=0.703, p<0.001 and r=0.723, p<0.001, respectively). COPD patients with GERD symptoms experienced more AECOPD and hospitalizations compared to patients without GERD symptoms (4.18±0.79 vs. 3.59±0.79, p=0.001). COPD patients receiving PPIs experienced less AECOPD and hospitalizations than COPD patients who did not receive PPIs, both in the presence of GERD symptoms (1.0±0.69 vs. 4.27±1.60 AECOPD, p<0.001 and 0.90±0.56 vs. 2.69±1.81 hospitalizations, FEV1=16 Pa, p<0.003) and in the absence of GERD symptoms (0.88±0.79 vs. 1.25±1.22 AECOPD, p<0.001, and 0.28±0.47 vs. 0.52±0.75 hospitalizations, p<0.01).

Conclusions: GERD symptoms are significantly associated with COPD exacerbations and treatment with PPIs is related to less exacerbations and hospitalizations.

Different factors may play a role in the pathogenesis of COPD exacerbations (ECOPD). The Exacerbations of COPD in Spain (ECOS) is a multi-center longitudinal study aimed to improve our understanding of the pathobiology and heterogeneity of ECOPD. We aimed to explore the weight and interaction of the different domains that are involved in the heterogeneity of the disease by building a network that link and relate all of them (exacerbome). In the ECOS study we included 99 patients in whom we obtained a battery of tests during hospitalization because of ECOPD, when clinically stable and after discharge. A selection of variables from the demographic, symptoms, lung function, biology, microbiology and imaging domains were analyzed and used to construct the exacerbome, where each node correspond to each of these variables, node size is proportional to the percentage of abnormal values of that particular variable and nodes were linked if there was a statistically significant correlation between the two variables being explored. Dyspnea, presence of bacteria in sputum by polymearce chain reaction, leukocytosis, active smoking, pulmonary hypertension on echocardiography, PaCO2, inspiratory capacity to total lung capacity (ICTLC) and fibrinogen were the most important and interconnected nodes of the exacerbome on admission whereas age, dyspnea, presence of bacteria in sputum, presence of emphysema, diffusing capacity and blood eosinophils higher than 2% were the most important associated factors.
Antibiotic use for hospitalized chronic obstructive pulmonary disease exacerbations: A propensity adjusted analysis

Isabelle Rault1, Florence Le Meunier 1, Coraline Hybiak 1, Houcine Bentayeb 1, Peter Wouters 2, Marie Bontenry 3, Eimeldin, London, United Kingdom; 4Respiratory Medicine, University of Dundee, United Kingdom; 5Respiratory Medicine, Doncaster Royal Infirmary, Doncaster, United Kingdom; 6Respiratory Medicine, Royal Infirmary of Edinburgh, United Kingdom; 7Respiratory Medicine, Ninewells Hospital, Dundee, United Kingdom; 8Respiratory Medicine, Perth Royal Infirmary, Perth, United Kingdom; 9Respiratory Medicine, St. John’s Hospital, Livingston, United Kingdom

Background: Antibiotics are frequently used in the treatment of chronic obstructive pulmonary disease (COPD) exacerbations. However, international guidelines suggest their use should be restricted to specific sub-groups based on the American Thoracic Society Criteria. The aim of this study was to assess the impact of antibiotic therapy on outcome in COPD.

Methods: We conducted a multi-centre prospective observational study assessing patients hospitalized with COPD exacerbation. Multivariable logistic regression was used to compare outcomes in patients treated with and without antibiotic therapy, including adjustment using a propensity score and adjustment for recognised predictors of 30-day mortality. The outcome of interest was 30-day mortality and length of hospital stay.

Results: Of 1031 patients included in the study, Median age was 74 years (interquartile range 63.75–81.78) and 48.7% were female. Mean FEV1 was 46% (standard deviation 19%). 30-day mortality was 5.4%. 818 patients (79.3%) received antibiotic therapy on admission (28.3% combined therapy, 76.6% monotherapy). Antibiotic prescribing based on American Thoracic Society criteria was Type 1: 84% patients received antibiotics. Type 2: 78.6% and Type 3: 70.3%. After adjustment for propensity to receive antibiotic therapy and recognised predictors of mortality, there was no association between antibiotic use and 30-day mortality (OR 0.96 (0.37-2.48), p=0.9) or length of hospital stay (p=0.8).

Conclusion: Antibiotic treatment is frequently used in hospitalised acute exacerbations of COPD. This study did not find any evidence of benefit in terms of mortality or length of hospital stay.

363. EBUS-TBNA: a never ending story

Nagoya Medical Center, Nagoya, Japan; 2Department of Kyoto University Health Service, Kyoto, Japan

Introduction: Although ROSE during EBUS-TBNA can reduce the puncture number and diagnostic accuracy in patients with suspected lung cancer.

Methods: We conducted a multi-centre prospective observational study assessing patients hospitalized with COPD exacerbation. Multivariable logistic regression was used to compare outcomes in patients treated with and without antibiotic therapy, including adjustment using a propensity score and adjustment for recognised predictors of 30-day mortality. The outcome of interest was 30-day mortality and length of hospital stay.

Results: Of 1031 patients included in the study, Median age was 74 years (interquartile range 63.75–81.78) and 48.7% were female. Mean FEV1 was 46% (standard deviation 19%). 30-day mortality was 5.4%. 818 patients (79.3%) received antibiotic therapy on admission (28.3% combined therapy, 76.6% monotherapy). Antibiotic prescribing based on American Thoracic Society criteria was Type 1: 84% patients received antibiotics. Type 2: 78.6% and Type 3: 70.3%. After adjustment for propensity to receive antibiotic therapy and recognised predictors of mortality, there was no association between antibiotic use and 30-day mortality (OR 0.96 (0.37-2.48), p=0.9) or length of hospital stay (p=0.8).

Conclusion: Antibiotic treatment is frequently used in hospitalised acute exacerbations of COPD. This study did not find any evidence of benefit in terms of mortality or length of hospital stay.

3254 Rapid on-site cytologic evaluation during endobronchial ultrasound-guided transbronchial needle aspiration for diagnosing lung cancer: A randomized study

Goncalo Travassos1,2, Maria Capela 1,3, Santia Ugarte 1,2,3, Gloria Nunes 1, Manuela Correia 1, Catarina Martins 1, Sara S. Dias 1, Paula A. Vildeira 1, Maria João Marques Gomes 1, CEDOC, Faculdade de Ciências Médicas, UNL, Lisbon, Portugal; 2Interventional Pulmonology Unit, Hospital Puñal de Valencia, Lisbon, Portugal; 3Interventional Pulmonology Unit, Hospital Beatriz, Loures, Portugal; 4Departamento Universitário de Saúde Pública, Faculdade de Ciências Médicas, UNL, Lisbon, Portugal

Background: We realize a study about patients who get an EBUS-TBNA in 2011. On each of them, our nurses were asked to evaluate the efficacy of the EBUS aspiration through the macroscopic aspect of the sample. The nurses’ responses (RON) were: needle-aspiration negative or needle-aspiration positive. Nurses’ on site evaluations were compared with the final diagnosis obtained by the cytologist (ROC). Our nurses have an experience of EBUS-TBNA since 3 years in routine.

Results: 98 patients (72 men and 26 women) were included in this study. We realize 536 needle aspirations. The most often punctured areas were 7 (66/156, 42%) and 4R (34/156, 21.8%). Lung cancer was diagnosed in 52 of the 98 patients (53%) with most often adenocarcinoma (32/52).

Conclusion: On site evaluation by a non pathologist may optimize efficiency of EBUS-TBNA and is cost-effectiveness.

3256 Role of molecular and cellular techniques applied to EBUS-TBNA of mediastinal lymph nodes for lung cancer staging

Antonio Bagulho,1,2,3, Gloria Nunes 1, Manuela Correia 1, Catarina Martins 1, Sara S. Dias 1, Paula A. Vildeira 1, Maria João Marques Gomes 1, FAC, Faculdade de Ciências Médicas, UNL, Lisbon, Portugal; 2Interventional Pulmonology Unit, Hospital Puñal de Valencia, Lisbon, Portugal; 3Interventional Pulmonology Unit, Hospital Beatriz, Loures, Portugal; 4Departamento Universitário de Saúde Pública, Faculdade de Ciências Médicas, UNL, Lisbon, Portugal

Introduction: Accurate NSCLC staging is of major importance since it dictates the choice of treatment and prognosis. EBUS-TBNA is a minimally invasive method to sample mediastinal lymph nodes. The most important identification of cancer biomarkers is important to improve EBUS-TBNA staging.

Aim: Assess the feasibility and role of EBUS-TBNA combined to the identification of tumour-associated antigens and tumour-associated immune responses to diagnose lymph node metastases and pathological characteristics in lymph node aspirates.

Methods: In a prospective study, EBUS-TBNA samples from 57 patients with confirmed or suspected lung cancer were analysed by cytopathology, flow cytometry (FACS) and reverse-transcriptase polymerase chain reaction (RT-PCR).

Results: All samples were adequately processed by the 3 different techniques. Among the 47 samples diagnosed with tumour cell by cytopathology, 70% showed the presence of cytokeratin-19 (CK-19) cells by FACS and 83% of the SCLC were CK-19 negative. CK-19 phenotype and gene expression were significantly correlated (r = 0.901) and cells with this phenotype also expressed CEA, sialyl Lewis X and CD44+ in 22.2%, 25.0% and 18.7% of cases. The expression of the EPCAM gene was significantly higher in the cytopathologically diagnosed cases (p = 0.03). The analysis of immune cells profile in the aspirates of these patients revealed a decrease in total leukocytes (p = 0.023) and a decrease in monocytes (p = 0.039).

Conclusions: The combination of molecular and cellular biology techniques with EBUS-TBNA might be a feasible option to improve NSCLC staging and offer an individualized diagnostic and therapeutic approach to lung cancer patients.

3257 Endobronchial ultrasound guided biopsy followed by real-time PCR is an applicable method to analyse SHOX2 methylation level in mediastinal lymph nodes of lung cancer patients

Katrin Bähner, Lucas Freitag, Claudia Iwascu, Dirk Theegarten, Jeremias Wohlschläger, Roze Imsak, Kaid Darwiche. NRW, Ruhrlandklinik Essen, Germany

Previous studies have shown that SHOX2 DNA methylation can potentially serve as a tumour marker in lung cancer patients. DNA methylation of SHOX2 could have been assessed in serum and bronchial aspirates. This study aimed to find out, if there is an opportunity to analyse SHOX2 DNA methylation level in lymph node tissue obtained by endobronchial ultrasound guided biopsy in context of diagnosis and lymph node staging.

Tissue from mediastinal lymph nodes was taken from ten patients with proven lung
In five cases the tissue was obtained by transbronchial forceps biopsy, in other five by transbronchial needle aspiration (TBNA). Samples were treated with lysis buffer, excluding the unmethylated 5hmC DNA from amplification. A real-time PCR duplex assay was then used to quantify the amount of total DNA, as well as methylated DNA. DNA was successfully extracted and analysed by real-time PCR. Valid measurements of SHOX2 DNA methylation level could be achieved in all samples, as well.

These outcomes allow comparing SHOX2 DNA methylation level in patients suspected to have lung cancer in further studies. DNA methylation level of SHOX2 by real-time PCR is an applicable procedure to analyse SHOX2 DNA methylation level in mediastinal lymph nodes of lung cancer patients.

3258

Endobronchial ultrasound-guided fine needle aspiration in the same procedure

Salvador de la Torre Carazo 1, Ricardo García-Luján 1, Rodrigo Alonso Morafejo 1, Anatomía Gómez López 1, Beatriz Astas Acores 1, Nuria Alberola 2, Eduardo de Miguel Poch 1, 1Pneumonology, Hospital 12 de Octubre, Madrid, Spain; 2Pathology, Hospital 12 de Octubre, Madrid, Spain

Introduction: Current papers show usefulness of a combined endobronchial and endoscopic ultrasound-guided fine needle aspiration (EBUS-FNA and EUS-FNA) of mediastinic adenopathies (1,2).

Aim: To analyse the initial results of EBUS-FNA of mediastinic adenopathies in a tertiary hospitals bronchoscopic unit.

Methods: Descriptive, prospective study of all the ecobronchoscopic procedures done May 2011-January 2012. EBUS-FNA was performed when no endobronchial accessibility of SHOX2 or its aspiration considered non representative by rapid onsite evaluation. Mediastinoscopy was performed when no diagnosis was yielded with the endobronchoscope.

Results: 54 patients underwent a bronchoscopic procedure in that period. In 9 cases EBUS-FNA was performed (16.7%). Region 7 in 4 cases and 4L in 5 cases were sampled. In every case we started with an EBUS exploration: 5 of them were non representative with EBUS-FNA and in 4 cases no accessible adenopathies were found with EBUS.

EUS-FNA yielded the following diagnosis: 3 non Hodgkin lymphomas, 2 lymphoid hypereplasia with atrophic lymph nodes (with posterior mediastinoscopic biopsies in which no evidence of malignancy was proven), 1 epithoroid lung cancer, 1 colorectal carcinoima’s metastasis, 1 sarcoidosis and 1 secondary amyloidosis. Every EUS-FNA was representative and no technique complications were described.

Conclusion: Every case in which EBUS-FNA was performed, was diagnostic, no false negatives were observed. This suggests that EUS-FNA done in the same procedure is beneficial in those procedures in which EBUS-FNA does not yield a conclusive diagnosis.

1Herth FJ et al. Chest. 2010;138:790-4

3259

Endobronchial ultrasound-guided sampling can be used for successful molecular sampling in routine clinical practice

Lianne Castle 1, Lianne Castle 1, Antolina Gómez López 1, Beatriz Astas Acores 1, Nuria Alberola 2, Eduardo de Miguel Poch 1, 1Pneumonology, Hospital 12 de Octubre, Madrid, Spain; 2Pathology, Hospital 12 de Octubre, Madrid, Spain

Introduction: The combination of EUS- and EBUS-FNA is a reasonable and safe technique for mediastinal restaging in NSCLC patients, and after our data, in patients with negative results of the continued endoscopic technique, a surgical restaging of the mediastinum might not be mandatory.

3261

Combined endosonographic staging followed by cervical mediastinoscopy in the real world, do we still need it?

Frik (H.E.M.) van der Heijden 1, Ad F.T.M. Verhegen 2, Olga J.C. Schunuuriers 3, 1Pulmonary Diseases, Radboud University Medical Center, Nijmegen, Netherlands; 2Cardiothoracic Surgery, Radboud University Medical Center, Nijmegen, Netherlands

Introduction: The combination of EUS- and EBUS-FNA is an accurate preoperative staging method in NSCLC, challenging the status of cervical mediastinoscopy (CM) as the gold standard. In a recent RCT combined endoscopic staging (CES) had greater sensitivity compared to CM. After negative CES, a CM had to be performed in 11 patients to find one positive result (Annema JAMA 2010). Defranchi [JAMA 2010] found 4 patients (9.5%) with positive lymph nodes that were not found in the cervical staging. Defranchi had greater sensitivity compared to CM. After negative CES, a CM had to be performed in 11 patients to find one positive result [Annema JAMA 2010]. Defranchi [JAMA 2010] found 4 patients (9.5%) with positive lymph nodes that were not found in the cervical staging. After our data, in patients with negative results of the continued endoscopic technique, a surgical restaging of the mediastinum might not be mandatory.

1, Stanislaw Orzechowski1, Jerzy Soja 2, Juliusz Pankowski4 , 3, 4L – 27, 7 – 61, 8 – 4). CUS-NA revealed metastatic lymph node involvement in 7/63 patients. A total of 21 patients were found N2 positive after negative CM, of which 14 were N2+ nodes in the right paratracheal stations 2R and 4R, only accesible for EBUS. A diagnostic sensitivity, specificity, accuracy, PPV and NPV of the restaging CUS-NA was 62% (95% CI – 60–90), 95% (95% CI – 85–97), 80%, 91% (95% CI – 80–100) and 74% (95% CI – 71–91), respectively. No complications of CUS-NA were observed.

Conclusions: CUS-NA is a reasonable and safe technique for mediastinal restaging in NSCLC patients, and after our data, in patients with negative results of the continued endoscopic technique, a surgical restaging of the mediastinum might not be mandatory.
364. Treatment of lung cancer

3262 Bevacizumab (Avastin®) aerosol therapy (AT) inhibits primary and metastatic tumor growth in a murine model with human non-small cell lung cancer (NSCLC).

Yehuda Schwarz 1, Alex Starr 1, Alexandra Lunitinsky 1, Lilah Israeli 1, Ofer Merimsky 2, Departments of Pulmonary Medicine, 2Departments of Oncology, Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Rationale: Avastin is used by systemic delivery only in lung cancer treatment, although the potential AT administration exists. AT of Avastin may increase drug concentration in the tumor and so augment the drug efficacy.

Objectives: To evaluate the effect of Avastin AT using mouse models of human (H1299) NSCLC.

Methods: An animal model of advanced disseminated NSCLC by orthotopically inoculated of cultivated human NSCLC cells into animal-lung was developed in our lab. AT was performed 5 times a week from day 5 to day 21 after inoculation using a jet nebulizer and a cage specially constructed for the inhalations. The dosages used were 0.05 mg/kg and 0.005 mg/kg of Avastin. The effect of nebulization on Avastin was assessed in terms of in vitro inhibition of tumor cell growth (XTT assay). In vitro growth of H1299 cells was mildly inhibited by AT Avastin (10%-20%).

Results: 40% reduction of lung/tumor weight and 50% inhibition of regional metastases was seen with Avastin AT. It was well tolerated by the animals without any gross pathological or histological changes in the heart, kidney, liver or spleen. Histological examination of the lungs showed congestion and hemorrhage in the 0.05 mg/kg treated animal, but only minimal findings were seen in the 0.005 mg/kg treated group. Hematological and blood biochemical examination were normal in the treated mice.

Conclusions: We demonstrated efficacy of Avastin aerosol treatment in animal model of NSCLC with minimal side effects. The study opens a new therapeutic approach by aerosolizing Avastin to treat patients with advanced disseminated lung cancer.

3263 Definitive radiation therapy for elderly patients with stage III NSCLC not candidates for combined chemoradiotherapy

Keith Sirlincha 1, Grace Mhango 1, Ethan Halm 2, Marcelo Benomi 1, Jian Winiwsky 1, 1Department of Medicine, Mount Sinai School of Medicine, New York, NY, United States; 2Department of Medicine, University of Texas Southwestern, Dallas, TX, United States

Purpose: Combined chemoradiation is the treatment of choice for locally advanced (stage IIIA-IIIIB) non-small cell lung cancer. However, elderly patients are frequently unable to tolerate this treatment; the benefit of radiation therapy (RT) alone for the management these patients is not well studied. Using population-based cancer data, we evaluated if use of RT alone is associated with improved survival of unresected stage III elderly NSCLC patients.

Methods: Using the SEER registry linked to Medicare we identified 13,522 patients 65+ years of age with unresected stage IIIA-B NSCLC diagnosed between 1992-2009. We excluded cases receiving chemotherapy as well as patients who could not be candidates for RT because they died within 4 weeks of cancer diagnosis. We determined propensity scores for patients receiving RT alone vs. no therapy based on their pre-treatment characteristics. Survival of patients treated with and without RT was compared using Cox regression adjusting for propensity scores. The odds for toxicity requiring hospitalization among patients treated with RT were also estimated, adjusting for propensity scores.

Results: Overall, 7,703 (57%) patients received RT. RT alone was associated with improved overall survival (HR: 0.76; 95% CI 1.00-0.80) and in analyses adjusting for propensity scores. RT treated patients had an increased adjusted risk of hospitalization for pneumonitis (OR: 136; 95% CI 1.18-928) and esophagitis (OR: 8; 95% CI 1.4-17).

Conclusions: These data suggest that definitive RT alone is associated with improved survival in elderly patients with unresected stage III NSCLC. RT was also associated with risk of severe toxicity.

3264 Histology as a potential clinical predictor of outcome in advanced non-small cell lung cancer (NSCLC) treated with vinorelbine and mitomycin (VM) chemotherapy combination

Thomas Wilhelm 1, Thierry Berghmans 2, Cornelia Kropf 1, Jean-Jacques Lafitte 3, Kathrin M. Stolzer 1, Marianne Paesmans 4, Stefan Ruediger 1, Arnaud Scherpereel 4, Joama Blanta 1, Wolfgang Rottbauer 1, Jean-Paul Sculier 4, Christian Schumann 1, 1Department of Internal Medicine II, University of Ulm Medical Center, Ulm, Germany; 2Department of Intensive Care Unit and Thoracic Oncology, Université libre de Bruxelles, Brussels, Belgium; 3Department of Pulmonology, CHU de Lille, Lille, France; 4Data Center, Institut Jules Bordet, Université libre de Bruxelles, Brussels, Belgium

Introduction: Histology has emerged as an important clinical predictive factor in patients with advanced NSCLC treated with chemotherapy.

Aims: To analyze combined patient level data from 2 phase II trials on efficacy and safety of VM in advanced or metastatic NSCLC, in order to determine histology and other patient and disease characteristics including gender, smoking history and TTF-1 immunohistochemistry (IHC) might be potential clinical predictors of outcome.

Methods: Response rates, undiagnosed survival times and Cox covariate adjusted hazard ratio estimates (HR) were calculated for each subgroup in each individual trial and in the pooled data set.

Results: A total of 175 patients were included in this retrospective analysis. Adjusted HRs for both overall survival (OS) and progression free survival (PFS) consistently favored non-adenocarcinoma (non-AC) histology subgroups, achieving statistical significance for OS in the pooled data (p=0.175; HR 0.677; 95% CI 0.488-0.938; p=0.019) and within one of those two trials (n=65; HR 0.561; 95% CI 0.318-0.988; p=0.045). TTF-1 negative IHC was associated with non-significant favorable OS compared to TTF1 positive subgroup in the cox-adjusted analysis (n=33; HR 1.233; 95% CI 0.55-2.730; p=0.608) and showed a significantly higher response rate (25% vs. 0%; p=0.040). Gender and smoking history were not strongly related to outcome.

Conclusions: These results suggest that non-AC histology and TTF-1 negative IHC may be considered as potential predictors of favorable clinical outcome in the treatment with VM. This approach warrants further investigation in a phase III study.

3265 A mRNA signature predicts outcome of patients (pts) with advanced non small cell lung cancer (NSCLC) treated with cisplatin (C) and vinorelbine (V): A ELCWP prospective study

Thierry Berghmans 1, Luc Willems 2, Marianne Paesmans 3, Lieveke Ameye 4, Jean-Jacques Lafitte 5, Anne-Pascale Meert 1, Arnaud Scherpereel 4, Alexis Cortois 1, Céline Mascagni 6, Ingrid Cottin 6, Tiffany Demae 1, Nathalie Loeller 1, Jean-Paul Sculier 4, 1Intensive Care Unit and Thoracic Oncology, Institut Jules Bordet, Brussels, Belgium; 2Molecular and Cellular Biology Laboratory, Gembous Agro-Bio-Tech, Gentilieu, Belgium; 3Data Centre, Institut Jules Bordet, Brussels, Belgium; 4Pneumology, CHU Lille, Lille, France; 5Oncology, Institut Jules Bordet, Brussels, Belgium

Background: C-based doublets are standard 1st line treatment for advanced NSCLC, without good predictor for response and survival, and important toxicity. Our aim is to identify a predictive mRNA signature for response to 1st line C (60 mg/m2 D1) + V (25 mg/m2, D1+8), by comparing mRNA expression between responders (R) and non responders (NR). Results: From 180 pts screened (04/2009 to 11/2011), 34 were assessable; 14 partial responses were observed. Fifty (fold change (FC) > 2) and 19 (FC > 3) mRNA were significantly differentially expressed between R and NR. After a stepwise variable selection, a two-mRNA signature predicted response with 93% sensitivity, 100% specificity, 100% PPV, 95% NPV. By restricting to the 19 mRNA with a FC > 3, a two mRNA signature predicted response with 100% sensitivity, 100% NPV, 70% specificity, 70% PPV. The two models have the same diagnostic performance (p=0.58). A 2 mRNA signature specifically predicting overall survival was designed using mRNA with a FC > 3. It distinguished pts with poor and good survival (HR for death 22.2, p < 0.0001).

Conclusion: mRNA signatures predict response and are prognostic for survival in pts with NSCLC treated with CV in 1st line. The validation of these results in an independent cohort, taking in consideration conventional prognostic factors, is ongoing.

3266 Combination of erlotinib and bevacizumab in non small cell lung cancer patients

Efimia Boutsikou, Theodoros Kontakiots, Pavlos Zarogoulidis, Paraskavi Patakia, Konstantinos Zarogoulidis. Pulmonary Department of Aristotel University of Thessaloniki, G. Papanikolaou Hospital, Thessaloniki, Greece

Bevacizumab and Erlotinib have recently been demonstrated to prolong overall survival in patients with non squamous NSCLC. We present the results of a 4 arm trial we designed to evaluate the efficacy and toxicity of the combination of docetaxel, carboplatin, bevacizumab(b) and erlotinib(e) in the first-line treatment of patients with NSCLC. 229, stage IIIb+IV, non squamous NSCLC patients were treated with 2 cycles of carboplatin (AUC5.5)+ docetaxel (100 mg/m2) (CT). After completion of two treatment cycles, pts were evaluated for response and divided into 4 groups: 61/229 continued with 4 more cycles of CT(control group), 52/229 received CT plus E 150mg daily, 56/229 received CT plus B 7.5mg/kg and 60/229 were treated with the combination of CT, E and B until disease progression. The primary endpoint was overall survival(OS).

In the 4 years follow up of the study, there was no statistical difference in survival and time to progression among four groups. After division of pts according to their response in responders and non responders after 2 cycles of chemotherapy, non-
responders who received additional therapy with bevacizumab or combination therapy had a survival benefit (65/4d (349-970) and 681/351-1921 respectively), which is statistically significant compared with the continuation of treatment with cytotoxic chemotherapy (p<0.001). The combination therapy had a comparable safety profile with that of B and E taken individually. Administration of BE±E in combination with first-line chemotherapy, followed by bevacizumab and erlotinib monotherapy as maintenance, has shown promising results in pts with NSCLC, with reduced toxicity as compared with chemotherapy alone, but did not translate into a longer OS.

3267
 TTФ-1 for prediction of response to chemotherapy in patients with locally advanced or metastatic small cell lung cancer (SCLC)

Daniel Miβch1, Jens Kollmeier1, Torsten Blum1, Sergio Griff2, Christian Boch1, Timo Weiss3, Catharina Crolow3, Wolfram Grüning3, Thomas Maiinger3, Torsten Bauer1,2

1Department of Pneumology, HELIOS Klinikum Emil von Behring, Pulmonary Diseases Clinic Hechershon, Berlin, Germany; 2Department of Pathology, HELIOS Klinikum Emil von Behring, Pulmonary Diseases Clinic Hechershon, Berlin, Germany; 3Department of Pneumology, HELIOS Klinikum Schwerin, Germany

Background: The thyroid transcription factor-1 (TTФ-1) plays a crucial role in differentiating primary lung from other cancers, especially in adenocarcinoma (AC). Furthermore, data indicate a possible association between TTФ-1-status and overall survival (OS) in AC patients. So far, no impact on OS was described in SCLC patients. Besides OS, it is unknown if the TTФ-1-status influences chemosensitivity of SCLC and might therefore predict response to chemotherapy.

Aim: To compare the response to chemotherapy in a population of patients with SCLC stage III/IV according to their TTФ-1-expression.

Methods: We analyzed 294 patients (f = 110; m = 184) with SCLC stage III/IV (according to UICC-6, stage III, n = 32; IIIB, n = 87; IV, n = 175) diagnosed in our institution between 01/05 and 12/08. Median age was 65 (±10) years. TTФ-1-expression was preoperatively determined. Response to treatment was evaluated using the Response Evaluation Criteria in Solid Tumors (RECIST Version 1.0). The overall response rate (ORR) and the disease control rate (DCR) were calculated and compared between the group of TTФ-1-positive and TTФ-1-negative SCLC.

Results: The information on TTФ-1 and response to treatment was available in 178 (77%) cases. 150 (84%) had TTФ-1-positive and 28 (16%) TTФ-1-negative SCLC. Analyzing the ORR, we observed a better response to treatment for patients with TTФ-1-expression (DCR 90%) as compared to those with TTФ-1-negative SCLC (DCR 71%; p = 0.013). Regarding the ORR, there was no statistically significant difference between both groups (TTФ-1-pos. 75% vs. TTФ-1-neg. 71%; p = 0.642).

Conclusion: TTФ-1-expression may be associated with better response to chemotherapy in SCLC.

3268
 Primary lung cancer treated using radiofrequency ablation – One year outcome data

Fausil Kamal1, Julie Beeson1, Sunny Kaul2, Sarah Stirling2, Simon Mattison2, Juliette Tennant3, Pusha Norman4, Paras Dalal1

1Respiratory Medicine, Royal Brompton & Harefield Hospitals NHS Foundation Trust, London, United Kingdom; 2Critical Care, Royal Brompton & Harefield Hospitals NHS Foundation Trust, London, United Kingdom; 3Radiology, Royal Brompton & Harefield Hospitals NHS Foundation Trust, London, United Kingdom; 4Medical School, imperial College, London, United Kingdom

Background: Percutaneous image guided radiofrequency ablation (RFA) is increasingly used as an alternative treatment option for patients with inoperable primary non small cell lung cancer (NSCLC) but there are little published outcome data. We report safety & efficacy of RFA in patients with NSCLC (stages I-IV) at 1 year.

Methods: Thirty-eight patients underwent 50 RFA procedures. Thirty-eight patients underwent 50 RFA procedures. Local progression & survival were evaluated prospectively at 3, 6, 9 & 12 months.

Results: Complications, local progression & survival were evaluated prospectively at 3, 6, 9 & 12 months. Statistical analysis was performed using log rank test & Cox regression analysis to determine hazard ratios with 95% confidence intervals (CI). Kaplan-Meier survival curves were plotted to show any differences in the survival pattern using Stata 10.1 (Statacorp, Texas USA).

Results: There were no cases of procedure related mortality. Complications included pneumothorax (61%) of which 10 patients (43%) had an iatrogenically created pneumothorax as part of the procedure, pleural effusion (5%) & respiratory failure (3%).

At 1 year, new (suspected) nodules observed in 21% (n=8), 88% of patients with tumours <3cm were progression free compared to 76.9% of tumours >3cm (p=0.36).

Mean time to progression for all cases 11.4 months (CI 10.7-12.1).

Overall & cancer specific 1 year survival were 86.8% & 92.1% respectively.

Conclusion: RFA is a safe, effective & well-tolerated treatment option in patients with inoperable primary lung cancer (stages I-IV).

IMPRS (IMP) was a 24-wk, randomised, double-blind study comparing imatinib vs. PBO in 202 symptomatic pts with severe PAH despite ≥2 PAH-therapies with PVR >300 dyn s cm⁻5. A 3-yr open-label extension is ongoing. In the extension, IMP imatinib pts continued on maintenance dose (200 or 400mg once daily [QD]) while IMP PBO pts received imatinib 200mg QD, increasing to 400mg QD if tolerated. Data lock for the present analysis was 11 Nov 2011. 144/150 pts entered the extension (66 IMP imatinib, 78 IMP PBO). Median overall exposure in the extension was 276 days. At extension entry, mean±SD 6MWD had increased from IMP baseline by 43±55 vs. 5±63m for IMP imatinib vs. IMP PBO pts. In IMP imatinib pts, improvements in 6MWd were maintained after 48 wks of imatinib (24 wks in IMP + 24 wks in extension: 45±64m increase from IMP baseline [n=54]). In IMP PBO pts, 6MWd increased 16±4tm from IMP baseline after 48 wks imatinib in extension (n=20). There were 6 deaths in the extension, all in IMP PBO pts. AEs in the extension included nausea (36.8%), peripheral oedema (27.8%), peripheral oedema (22.2%), vomiting (22.2%), and nasopharyngitis (20.8%). SAEs in ≥3% of patients included RV failure (7.0%), dyspnoea (4.2%), worsening PAH (4.2%), syncope (4.2%), subdural haematoma (SDH, 4.2%) and device-related infection (3.5%). Unexpectedly, SDH occurred in 8 pts (2 in IMP, 6 in ext), all in patients on imatinib and anticoagulation. 5 pts with SDH recovered, 1 died of SDH and 2 died of unrelated causes. Efficacy and safety assessments continue every 6 months to provide additional data regarding benefits and risks of imatinib in advanced PAH. Imatinib is currently not approved for treatment of PAH.

The anti-proliferative effects of apelin on pulmonary adventitial fibroblasts
Lauren Brasch1, Colin Church 1, Roger Wadsworth2, Andrew Peacock 1, David Welsh 2, Scottish Pulmonary Vascular Unit, Western Infirmary, Glasgow, United Kingdom; 2Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, United Kingdom

Background: Pulmonary arterial hypertension (PAH) involves remodelling of the pulmonary artery resulting in right heart failure. Apelin is an endogenous peptide with physiological actions in the cardiovascular system. Pre-clinical models indicate that apelin deficiency may mediate or contribute to the pathogenesis of PAH which involves pulmonary artery fibroblasts (PAF).

Objectives: To determine if Apelin had an effect on the proliferation and migration of rat PAF.

Methods: PAF were isolated from Sprague Dawley rats. The PAF were incubated in normoxic and hypoxic conditions (35mMgHg for 24h) and proliferation in response to Apelin was assessed. The presence of the Apelin receptor (API) was detected by Western Blotting. PAF were also cultured to 100% confluency and the cell monolayer was scratched and cell migration was determined after incubation with apelin.

Results: API receptor was detected in PAF cells. Hypoxia alone increased the proliferation of PAF and this effect was abrogated with the addition of 200nM Apelin.

Conclusions: Apelin can reduce the increased proliferation of PAF to hypoxia and reduce the migratory capacity of these cells. Apelin may have anti-remodelling properties that require further investigation.

3273
Cicletanine in pulmonary arterial hypertension (PAH): Results from a phase 2 randomized placebo-controlled trial
Aaron Waxman1, Ronald Oudiz2, Shelley Shapiro3, Mardi Gomberg-Maitland4, Anne Keogh1, David Badesch5, Hunter Gillies6, Gennyne Walker9.
1Department of Medicine, Pulmonary and Critical Care, Brigham and Women’s Hospital, Boston, MA, United States; 2Division of Cardiology, West Los Angeles VA HealthCare Center, Los Angeles, CA, United States; 3Division of Medicine, Pulmonary Hypertension Center, University of Colorado, Denver, CO, United States; 4Department of Medicine, Mayo Clinic, Rochester, MN, United States; 5Division of Cardiology, Harbor-UCLA Medical Center, Torrance, CA, United States; 6Department of Cardiology, West Los Angeles VA HealthCare Center, Los Angeles, CA, United States; 7Department of Medicine, Pulmonary Hypertension Center, University of Colorado, Denver, CO, United States; 8Department of Medicine, Intermountain Medical Center and The University of Utah, Murray, UT, United States; 9Cardiovascular Clinical Research, Gilead Sciences, Inc., Foster City, CA, United States

Cicletanine (CIC) is an anthrapyrazine with vasorelaxant and diuretic properties. Potential efficacy was observed with compassionate use of CIC in worsening PAH. A controlled study investigating the safety and efficacy of CIC for PAH was performed.

162 subjects were randomized to 12 weeks of placebo (n=61) or CIC at doses of 150 mg qd (n=39), 150 mg bid (n=40) or 300 mg qd (n=42). Subjects could be on stable doses of an endothelin receptor antagonist, phosphodiesterase type 5 inhibitor, parenteral prostanoxol, or any 2-drug combination. The primary analysis was comparison of change in 6-minute walk distance (6MWMD) following 12 weeks of treatment with daily doses of CIC 300 mg (150 mg bid+300 mg qd; n=80) to placebo. Secondary analyses included dyspnea, WHO functional class, NT-proBNP, and a subset analysis of pulmonary hemodynamics (n=50).

The adverse events reported more frequently with CIC were nausea, hypokalemia, and fatigue, consistent with known properties of diuretics. Although CIC was generally well-tolerated, no improvements in exercise tolerance, symptoms or hemodynamics were observed in patients with PAH after 12 weeks of CIC treatment.

**Pulmonary hypertension due to alveolar hypoventilation: Functional impact and improvement of haemodynamics and exercise capacity under non-invasive positive pressure ventilation**

Matthias Held, Johanna Walthelm, Stefan Barun, Christine Roth, Berthold Jany.

**Department of Internal Medicine, Mission Medical Hospital, Würzburg, Bavaria, Germany**

**Background:** For pulmonary hypertension (PH) due to lung diseases guidelines recommend treatment of the underlying disease. Due to preserved cardiac index (CI) in alveolar hypoventilation the functional impact of elevated pulmonary artery pressure (PAP) is not clear. The impact of non-invasive positive pressure ventilation (NIPPV) on exercise capacity of patients with PH due to alveolar hypoventilation is unclear.

**Objective:** To characterize the functional impact of PH due to alveolar hypoventilation and the haemodynamic and functional consequences of NIPPV.

**Methods:** Analysis of hemodynamics and functional capacity of 18 patients with daytime PH due to alveolar hypoventilation. The analysis included the data from baseline after a complete diagnostic work-up and after 3 months of NIPPV.

**Results:** Compared with a mean PAP of 49±12 mmHg, a CI (3.2±1.66), a 6-minute walking distance (6-MWD) of 303±13 m and severely elevated nt-pro-BNP levels, mPAP correlated negatively with maximal workload (R=−0.7166, p=0.029) and six-minute-walking distance (R=−0.621, p=0.010). Under NIPPV, we found a significant reduction of mPAP (17.75 mmHg, p=0.005), NT-pro-BNP serum levels (−2110 pg/ml, p=0.0014), improvement of the 6-MWD (+33 m and +131 m, p=0.0082) and maximal workload (+18 W, p=0.028). CI did not change significantly. Changes of workload and mPAP correlated negatively (R=−0.7545, p=0.0305).

**Conclusions:** Despite preserved CI elevated mPAP has a functional impact for patients with PH due to alveolar hypoventilation. NIPPV leads to a significant reduction of PH and improvement of exercise capacity.

**Improved right ventricular function after substantial afterload reduction in patients with pulmonary arterial hypertension**

Mairi Hyytinen-Veeredonk1, Tim Marcus2, Harm-Jan Bogaard1, Nico Westerhof3, Anton Voon-Noordegraaf1.

**1Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2Physics and Medical Technology, VU University Medical Center, Amsterdam, Netherlands; 3Physiology, VU University Medical Center, Amsterdam, Netherlands**

**Introduction:** In pulmonary arterial hypertension (PAH), increased load leads to right ventricular (RV) dysfunction. We showed that despite a modest reduction in pulmonary vascular resistance (PVR) after treatment, RV function can decrease resulting in poor prognosis1.

**Aims:** To characterize the functional impact of PH due to alveolar hypoventilation and the haemodynamic and functional consequences of NIPPV.

**Methods:** Analysis of hemodynamics and functional capacity of 18 patients with daytime PH due to alveolar hypoventilation. The analysis included the data from baseline after a complete diagnostic work-up and after 3 months of NIPPV.

**Results:** Compared with a mean PAP of 49±12 mmHg, a CI (3.2±1.66), a 6-minute walking distance (6-MWD) of 303±13 m and severely elevated nt-pro-BNP levels, mPAP correlated negatively with maximal workload (R=−0.7166, p=0.029) and six-minute-walking distance (R=−0.621, p=0.010). Under NIPPV, we found a significant reduction of mPAP (17.75 mmHg, p=0.005), NT-pro-BNP serum levels (−2110 pg/ml, p=0.0014), improvement of the 6-MWD (+33 m and +131 m, p=0.0082) and maximal workload (+18 W, p=0.028). CI did not change significantly. Changes of workload and mPAP correlated negatively (R=−0.7545, p=0.0305).

**Conclusions:** Despite preserved CI elevated mPAP has a functional impact for patients with PH due to alveolar hypoventilation. NIPPV leads to a significant reduction of PH and improvement of exercise capacity.

**Inhaled corticosteroids and bone mineral density in children: A prospective 12-year follow-up study after early-life wheezing**

Vera Sideleit1, Mari Hyytinen-Veeredonk1, Lina Kröger1, Henni Kröger3, Kalle Koivula1, Matti Korpipää4, Didi Paukkuri5, Helke Koskimäki6, Tiia Marinu2, Harm-Jan Bogaard1.

**1Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2Physics and Medical Technology, VU University Medical Center, Amsterdam, Netherlands; 3Pulmonary Diseases, University of Eastern Finland and The National Graduate School of Clinical Investigation, Kuopio, Finland; 4Department of Paediatrics, Kuopio University Hospital, Kuopio, Finland; 5Department of Surgery, Kuopio University Hospital, Kuopio, Finland; 6Paediatric Research Centre, Tampere University and University Hospital, Tampere, Finland**

**Background:** Inhaled corticosteroids (ICS) are the drugs of choice for asthma. Corticosteroids can have many detrimental effects on bone mineralization and growth, despite of inhaled administration.

**Aims and objectives:** To evaluate the association between the long-term use of ICS in childhood and bone mineral density (BMD) in teenagers.

**Methods:** Ninety-one children hospitalized for wheezing at age <24 months were respectively followed until 12.2 (median) years of age. ICS use was collected by interviewing the parents, supplemented by data from patient records. Cumulative doses, the duration of ICS use and systemic steroid doses were calculated. At the last check-up, BMD (BMDareal, g/cm²) was measured by dual energy X-ray absorptiometry (DXA) in 89 children, and apparent volumetric BMDs (bMDvel, g/cm³) were measured for the lumbar spine and femoral neck. Height, weight and pubertal stage were recorded.

**Results:** The regular use of ICS at age <6 years was associated with a lower BMDareal of the lumbar spine (mean 0.76, 95%CI 0.71-0.81 vs. 0.88, 94.80-0.92; p=0.006). A lower BMDareal and bMDvel of the femoral neck were associated with higher cumulative doses of ICS at 0-12.2 (median) years of age. Pearson’s correlation coefficients were r (r2) = 0.320 (0.10) for BMDareal and r (r2) = 0.291 (0.08) for bMDvel. Age, sex and pubertal stage were significantly associated with both BMDareal and bMDvel, but did not confound the results.

**Conclusions:** The use of ICS during childhood may be related to a decrease in BMD at early teenage, though the clinical manifestations of reduced BMD usually occur later in adulthood.

---

**3278**

**Inhaled corticosteroids and risk of oropharyngeal colonization by streptococcus pneumoniae in children with asthma**

Lingjie Zhang1, Silvio Prietsch2, Ana Paula Mendes1, Andrea Grott2, Greichel Rocha2, Lilian Carrion2, Pedro Silva3, Maternal and Child Health, Faculty of Medicine, Federal University of Rio Grande, RS, Brazil; 2Laboratory of Microbiology, Faculty of Medicine, Federal University of Rio Grande, RS, Brazil

**Introduction:** Recent epidemiological studies have raised concerns about possible link between use of inhaled corticosteroids (ICS) and risk of pneumonia in patients with chronic obstructive pulmonary disease. This cross-sectional study aimed to investigate association between ICS and oropharyngeal colonization by Streptococcus pneumoniae (S. pneumoniae) among children (up to 18 years old) with asthma.

**Methods:** Two age-matched groups of patients were consecutively recruited: 1) Exposed group: children who had persistent asthma and were being treated with daily ICS for at least 30 days; 2) Non-exposed group: children who had asthma and were not being treated with ICS. Oropharyngeal specimens were measured before and after 4 weeks of treatment with oropharyngeal colonization by Streptococcus pneumoniae (S. pneumoniae) among children (up to 18 years old) with asthma.

**Results:** A total of 192 patients (96 in each group) were included in the study. In
the exposed group, the mean daily dose of ICS was 400 mcg of beclomethasone or equivalent and the mean duration of treatment was 8.6 months. The prevalence of oropharyngeal colonization by S. pneumoniae was higher among children exposed to regular use of ICS than among those exposed to reduced or frequent use of ICS. Parents of children with the lowest and highest adherence rates were identified. One group of (highly educated) parents deliberately did not use ICS according to doctor’s advice, but adjusted the ICS dose based on their perception of asthma control in their children, leading to regular use of ICS, but at a dose lower than prescribed. The other group of parents (most with lower educational levels) were faced with barriers impeding regular ICS use. These barriers included chaotic family life and parenting problems. A common and consistent finding was the low adherence rate in children 8-12 yrs of age, who were given full responsibility for taking their ICS without parental support or supervision. Conclusion: Assessment of ICS use in children with asthma prevents intentions of non-adherence, family driven barriers remain an important cause of non-adherence. The excessive responsibility put on school-aged children to organize their own ICS medication taking is a common and possibly modifiable barrier.

3281 Pulmonary immunoglobulin E levels and the response to anti-immunoglobulin E antibody therapy in paediatric severe therapy resistant asthma

Iman Al Darraji,1,2 Alios Spokes1,2, Cara Bossley1,3, Timothy Oates1,4 1Princess Amalia Children’s Clinic, Isala Klinieken, Zwolle, Netherlands; 2unit population of children with asthma Barriers to adherence to inhaled corticosteroids in a high adherent population of children with asthma

Ted Klek1, Susanne Lubbner1, Ad Kaptein1, Eric Duiverman1, Paul Brand1.

TUESDAY, SEPTEMBER 4TH 2012

Background: Most acute wheezing episodes in preschool children are associated with viral respiratory tract infections, most commonly rhinovirus. Rhinovirus, like RSV, decreases extra-cellular ATP leading to airway surface liquid dehydration. This, along with sub-mucosal edema, mucus plaques and inflammation cause failure of mucus clearance (MC). Such preschool children do not respond well to available treatments, including oral steroids. This calls for pro-MC and pro-hydration treatment like hypertonic saline.

Methods: Randomized, controlled, double-blind study. Forty one children (mean age 31.9±11.7 months, range 1-6 years) were divided into two groups: (a) 20 children (median age 5.9 yrs, range 4-13 yrs) who were asked to use saline (0.9%) and (b) 21 children (median age 4.9 yrs, range 1-6 yrs) who were asked to use hypertonic saline (3%). Both groups were given a continuous nebulized saline (0.9%) or hypertonic saline (3%) mist in the early morning. Both groups received the same inhaled treatments. The primary outcome measured was length of stay (LOS) and secondary outcomes were admission rate (AR) and clinical severity score (CS). Results: LOS was significantly shorter in the HS than in the NS group: median (range) 2 (0-6) days, versus 3 (0-5) days (P=0.027). AR was significantly lower in the HS than the NS group: 62.2% versus 92%. CS improved significantly in both groups but did not reach significance between them.

Conclusion: HS inhalations significantly shortens LOS and lowers AR in preschool children presenting with acute wheezing episode to the ED.
cell recruitment, and protected from allergen-induced tissue inflammation and goblet cell metaplasia. Protection against asthma was achieved following delivery of modified mRNA either before or after the onset of allergen challenge, demonstrating its potential as both a preventative and a therapeutic. Mechanistically, Foscpx3 upregulation was critical in downregulating IL-23 and IL-17 production, and recombiant IL-23 or IL-17 expression during challenge abolished protection conferred by Foscpx3 mRNA. Taken together, our results provide evidence that chemically modified Foscpx3 mRNA protects against allergic asthma in vivo, which may pave the way for considering modified mRNA as a safe therapeutic tool for the treatment of asthma, allergy and beyond.

367. Cardiovascular disease and sleep-disordered breathing

3285 Prediction of cardiovascular risk from nocturnal pulse wave signal using the autonomic state indicator technology

Dirk Sommerneyer1,2, Ding Zou1, Derek Eder1, Jan Hedner1, Joachim Ficker3, Winfried Randerath4, Thomas Penzel1, Bernd Sandner5, Ludger Grote1, 1Department of Pulmonary Medicine, Salzherske University Hospital, Gothenburg, Sweden; 2Institute for Monitoring, Diagnosis and Assistance, SHRI University Heidelberg, Heidelberg, Germany; 3Department of Pulmonary Medicine, Medical University Nord, Nürnberg; 4Department of Pulmonary Medicine, Bethanien Hospital, Solingen, Germany; 5Department of Cardiology, University Hospital Charité, Berlin, Germany; 6Department of Pulmonary Medicine, Bethesda Hospital, Wuppertal, Germany

Introduction: Analysis of continuous physiological signals measured by pulse oximetry during sleep may provide a novel method to assess cardiovascular (CV) risk. The sleep period appears to be a particularly useful window for assessment.

Methods: Subjects (n=520, 346 males, age 55.0±13.4 y, BMI 29.9±6.1 kg/m²) were referred to five sleep centers in Germany and Sweden. CV risk factors were assessed and subjects were classified by the ESC/ESH risk matrix into five separate risk classes. The autonomic state indicator (ASI) algorithm extracted patterns of the peripheral pulse wave and SpO2 signal by amplitude and time/ frequency analysis from the overnight digital photoplethysmographic recording and computed a CV risk score (range 0.1–1.5) corresponding high levels of heart rate variability. Nine defined parameters (irregular pulse, RCDc, pulse rate variability, pulse wave variability, pulse propagation time, oxygen desaturations, duration of periodic symmetric desaturations and baseline SpO2) were used to determine the final score.

Results: In the validation group (n=390), the developed algorithm detected high CV risk in ESC/ESH scores 4 and 5 patients with a sensitivity of 74.5% and specificity of 76.4%. The area under the ROC curve was 0.80. The ASI CV risk score was elevated in patients with an already established CV endpoint (MI ±0.34, p<0.001). Successful TAVI had a significant impact on CSA, but not on OSAS; p<0.001. TAVI results (AI ≥ 2) presented with no change in OSAS (T 10.5±7.8% to 12.5±6.5%, p=0.5) and an increase in central respiratory events (26.3±13.2% to 29.2±18.4%, p=0.036). Conclusion: There is a high prevalence of OSAS and CSA in pts in TAVI candidates. Successful TAVI had no significant impact on OSAS, but improved CSA significantly. TAVI resulting in moderate to severe AI is accompanied by a deterioration of CSA. Presence of CSA after TAVI may indicate prognostically relevant haemodynamic alterations in AI and/or heart failure.

3286 Mortality in heart failure patients with nocturnal Cheyne-Stokes respiration receiving adaptive servoventilation (ASV) therapy

Olaf Oldenburg1, 1, Thomas Bitter1, Birtgi Wellmann1, Natalie Prb2, Berna Kothcher1, Zisis Dimitrakis1, Birgit Krause2, Thomas Fischbach1, Dieter Horstkotte1, 1Department of Cardiology, Heart and Diabetes Center North Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen, Germany; 2Circus Research Unit, Heart and Diabetes Center North Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen, Germany

Sleep-disordered breathing (SDB) with Cheyne-Stokes respiration (CSR) is of major prognostic impact in heart failure (HF) patients. Adaptive Servoventilation (ASV) therapy was recently introduced to specifically treat CSR in these patients. First results on mortality (time of death, left-ventricular assist device (LVAD) device implantation and heart transplantation (HTX)) of a prospective registry are presented.

A total of 186 HF patients (NYHA II ≤ LEF ≤ 45%, treated according to present HF guidelines, with nocturnal CSR) were referred to five sleep centers in Germany and Sweden. Mean age at inclusion (168 male, 91%) was 67.6±13.1 y, BMI 28.5±4.1 kg/m², NYHA functional class 2.6±0.6, NT-proBNP levels 2722±3.420 pg/ml, left ventricular ejection fraction 31±8% and peak VO2 during cardiopulmonary exercise testing 14.4±4.7 ml/kg/min. AHI before ASV initiation was 38.8±14.8, apnoea-index 22.2±15.2. After 20.7±6.1 months a total of 35 patients (18.8%) reached an endpoint: 28 (15.1%) died, 6 (3.2%) received HTX and one (0.5%) LVAD implantation. Within the follow-up period, ASV therapy was discontinued by 26 patients (14.0%) and 15 patients (8.1%) met indication for cardiac resynchronization therapy (CRT).

Mortality in HF patients with nocturnal CSR and ASV treatment remains high. If there is any reduction in mortality and/ or hospitalization is currently be investigated by 2 randomized controlled trials, first results are not expected before 2014. With 14% discontinuation, ASV therapy seems to be well tolerated and accepted.

3287 Sleep-disordered breathing in patients undergoing transfemoral aortic valve implantation for severe aortic stenosis

Zisis Dimitrakis1, Marcus Wiemer1, Werner Scholz1, Lothar Faber1, Thomas Bitter1, 1, Messerrated2, Kevin Bullen1, Christian Pints1, Dieter Horstkotte1, Olaf Oldenburg1, 1Department of Cardiology, Heart and Diabetes Center North Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen, Germany; 2Department of Gastroenterology, University Hospital, Heraklion, Greece

Purpose: We examined the prevalence of sleep-disordered breathing (SDB) in patients (pts) with severe aortic valve stenosis before and after transfemoral aortic valve implantation (TAVI).

Methods: 79 pts (50% males, average age 83.0±6.3 years) had cardiorrespiratory polygraphy (PG) screening before TAVI. 62 of them (48.4% males, mean age 82.5±6.9 years) underwent a second PG screening 21.0±4.7 days after TAVI.

Results: 49 (62.0%) pts had OSAS, 25 (31.6%) and only 5 (6.3%) presented without significant SDB (apnoea-hypopnoea-index, AHI <5.0). Of 62 pts evaluated before and after valve implantation 36 (58.1%) had OSAS, 21 (33.8%) presented with CSA and no SDB was detected in 5 pts (8.0%). SDB was more severe in CSA compared to OSAS (AHI 34.5±18.3 vs 18.0±12.6, p<0.001). Successful TAVI had a significant impact on CSA, but not on OSAS; pts with optimal TAVI results (aortic valve regurgitation, AI ≤ grade 1) demonstrated a significant reduction of central respiratory events (39.6±19.6% to 23.1±16.0%, p<0.05), while no changes were detected regarding OSAS (18.8±13.0% to 20.2±15.3%,p=0.40). Pts with prismatic CSA-TAVI results (AI ≥ 2) presented with no change in OSAS (10.5±7.8% to 12.5±6.5%, p=0.5) and an increase in central respiratory events (26.3±13.2% to 29.2±18.4%, p<0.036).

Conclusions: There is a high prevalence of OSAS and CSA in pts in TAVI candidates. Successful TAVI had no significant impact on OSAS, but improved CSA significantly. TAVI resulting in moderate to severe AI is accompanied by a deterioration of CSA. Presence of CSA after TAVI may indicate prognostically relevant haemodynamic alterations in AI and/or heart failure.

3288 PAI-uPA system in patients with obstructive sleep apnea syndrome (OSAS) in CPAP treatment

Elena Angelici1, Alessia Steffanina1, Caterina Antonaglia1, Giovanni Alessandrini1, Michela Mordenti1, Paolo Palange1, Rita Canipari1, 1Malattie Infettive e Sanità Pubblica, Policlinico Umberto I La Sapienza, Rome, Italy; 2Urologia, Policlinico Umberto I La Sapienza, Rome, Italy

Background: Prothrombotic state in OSAS play a role for cardiovascular risk. Plasminogen activator inhibitor (PAI) is one of the primary regulators of the fibrinolytic system. We evaluated plasma levels of PAI and PAI/uPA and their correlation with Apnea-Hypopnea Index (AHI), Oxygen Desaturation Index (ODI) and percentage of time with SpO2<90% (T<90%) before and after 1 month with CPAP.

Methods: Thirty-nine patients (age 57±1.54; BMI 34.5±1.07) with OSAS (AHI 28.4±3.16; ODI 35.7±3.4; T<90% 23.1±3.3) 20 smokers (S) and 19 no smokers (NS), and 16 age matched healthy control subjects were studied. Before and after 1 month with CPAP, uPA and PAI were measured in serum by ELISA.

Results: At baseline, PAI levels were higher in OSAS compared to controls (95.36±3.99 and 83.96±6.06 ng/ml, respectively). PAI levels were similar in S and NS subjects and were inversely related to AHI, BMI, ODI and T<90% in OSAS. PAI was higher in S compared to NS subjects; moreover, it was slightly higher in the controls compared to the OSAS (S 0.23±0.03, NS 0.22±0.02; S 0.206±0.01, NS 0.182±0.02 ng/ml, respectively). In OSAS uPA levels were inversely related to AHI, BMI, ODI and T<90%; uPA/PAI ratio was higher in controls compared to OSAS. PAI levels after CPAP slightly decreased, while uPA levels slightly increased. We observed an increase in uPA/PAI ratio from 1.90±0.04 and 2.56±0.55 to 2.14±0.32 and 3.14±0.79, in S and NS patients respectively.

Conclusions: Our preliminary data are compatible with an impairment of fibrinolytic activity in OSAS. The increase of uPA/PAI ratio after CPAP suggests a role of the PA system in the reduction of cardiovascular risk through the decrease of the prothrombotic state.
3289
Treatment of central and obstructive sleep apnea in stable heart failure patients with auto-ventilator reduction severe sleep fragmentation – A randomized controlled trial
Michael Arzt1, Friederike Series2, Keir Lewis1, Amit Benjamin1, Pierre Escourrou3, Ruth Lugart1, Christoph Binner1, Michael Pfeifer1,2,4
1Department of Clinical Medicine II, Division of Respiratory Medicine, University Hospital, Regensburg, Germany; 2Centre de Recherche, IUCPQ, Université Laval, Quebec, Canada; 3Department of Respiratory Medicine, Prince Philip Hospital and Swansea College of Medicine, Wales, United Kingdom, 4Centre Medicine du Sommeil, Hopital Antoine Béclère, Clamart, France; 5Center for Pneumonology, Donauaustlauf Hospital, Donauaustauf, Germany

Background: It is of debate, whether treatment of central sleep apnea (SA) reduces sleep fragmentation. Therefore, we tested, whether auto-ventilator reduction (ASV, BiPAP-ASV, Philips Respironics) reduces sleep fragmentation in heart failure (HF) patients with severe central or obstructive SA.

Methods: 42 patients with HF (age 66±9y, LVEF <40%) and SDB (apnea-hypopnea index, AHI 48±19/h, 51% central SA) were randomized to either ASV (n=21) or optimal medical treatment alone (control, n=21). Polysomnography (PSG) and 5 days of actigraphy with centralized scoring by blinded raters were obtained at baseline and 12 weeks.

Results: In the ASV-group AHI and central AHI were significantly suppressed compared to the control-group (-41±12/h, ±p<0.001 and -24±14/h, ±p<0.001, respectively). The arousal index (AIr), sleep stage 1 (S1), PSG and the fragmentation index (actigraphy) were significantly reduced (-14.7±2.1/h versus 2.6±13.3/h, ±p=0.032 and 36±47 versus -6±41 min, ±p=0.005 and -11±4.6±10 versus -2.9±4.9 h, ±p=0.002, respectively) and sleep efficiency (SE) and daytime activity duration (actigraphy) significantly increased in the ASV-group compared to controls (5.2±1.0 vs. 1.0±1.0 h, ±p=0.01 and 21±4.5 vs. 24±4.1 min, ±p=0.009, respectively). Effects of ASV on AHI, S1, SE and daytime activity duration were similar in HF patients with obstructive and central SA (p>0.05 for all comparisons).

Conclusions: ASV-treatment significantly improves sleep fragmentation similarly in HF-patients with either central or obstructive SA. These effects were associated with a modest increase of daytime activity duration.

3290
Tea sound intensity relates to daytime high blood pressure in non-apneic snorers
Hiroshi Nakanod1, Kenji Hirayama1, Yumiko Sadamitsu1, Shizue Shin1, Tomoko Iwatag1, 2Sleep Disorders Center, Fukuoka National Hospital, Fukuoka City, Japan; 3Palmonology, Fukuoka National Hospital, Fukuoka City, Japan

Background: The relationship between snoring and cardiovascular diseases had been assumed to be due to existing sleep-disordered breathing (SDB). Recently, we have reported that snoring sound intensity as assessed by ambient sound (TS-Leq) was 1.74 in the non-apneic normal-weight patients. It may suggest a pathologic role of non-apneic snoring.

Conclusions: The increased heart rate and the higher prevalence of dysmhrhythmias at altitude are consistent with increased sympathetic tone associated with hypoxemia. AC reduces bradyarrhythmias at altitude, possibly by improving sleep disordered breathing. Grant: Swiss National Science Foundation; Lung League of Zurich; Clinical Trials Center, University Hospital of Zurich, Switzerland.

3292
Impact of CPAP treatment on the changes of maxki+ k channel beta subunit-1 expression in patients affected by sleep apnea-hypopnea syndrome (SAHS)
Candela Caballero1, Angeles Sanchez Armengol2, 3, Mª. Jesús Domínguez-Suárez1, María Abal1, Carmen Carmona1, Pablo Stiefel1, Francisco Capote1, 4Unidad Médico-Quirofáctica Enfermedades Respiratorias, Virgen del Rocio Hospital, Sevilla, Spain; 2Unidad de Hipertensión, Virgen del Rocio Hospital, Sevilla, Spain

Regulatory function on the vasodilatation of the maxki+ k channel beta subunit has been described in mouse model. CPAP treatment was shown to be related with an increase of the beta subunit expression.

Objective: To determine the relations between oxymetric and endothelial situation and subunit beta1 expression in the moment of recruitment and after 3 month of CPAP in SAHS patients.

Methods: The study population consisted of 43 OSA patients living at 600m altitude. We included patients with severe central or obstructive SA. CPAP was titrated to control AHI <5/h, at altitude on placebo, heart rate was higher and dysrhythmias were more prevalent than at 490m. AC reduced bradyarrhythmias, apnea/hypopneas and improved oxygen saturation (table).

Dysrhythmias, oxygen saturation and breathing disturbances

490m Altitude, placebo 490m Altitude, AC
Heart rate, bpm 67 (60; 76) 75 (68; 83)* 73 (67; 81)*
Blood pressure events, 1/d 0.0 (0.1) 3 (0.178) 0.0 (0.179)
Ventricular extrasystoles, 1/d 24 (18, 30) 31 (4; 428) 26 (24; 29)*
Asthma and/or urticarial events, 1/d 0.0 (0.1) 0 (0.1) 0 (0.2)
Nocturnal oxygen saturation, % 93 (92; 94) 87 (86; 89)* 89 (87; 91)*
Apnea-hypopnea index, 1/h 51 (42, 73) 70 (56, 89) 54 (46; 63)*

Conclusions: The increased heart rate and the higher prevalence of dysrhythmias at altitude are consistent with increased sympathetic tone associated with hypoxemia. AC reduces bradyarrhythmias at altitude, possibly by improving sleep disordered breathing.

3293
Ventilatory response to hypercarbia in newborns of smoking and substance abusing mothers
Samal Ali1, Ravindra Bhal1, Kim Wolff2, Simon Hannam1, Gerrard Rafferty1, Anne Greenough1, 1Division of Asthma, Allergy and Lung Biology, King’s College London, United Kingdom; 2Addiction Sciences, King’s College London, United Kingdom

Infants of smoking and substance abusing mothers have an increased risk of sudden infant death. A possible explanation for the association is that such infants have neurodevelopmental abnormalities which adversely affect the control of ventilation.

366. New developments in paediatric respiratory physiology

3294
Acetazolamide improves cardiac dysrhythmias in patients with obstructive sleep apnea at altitude. A randomized controlled trial
Tosyal D. Latshang1, Yvonne Nussbaumer-Ochsner1, Barbara Kaufmann1, Silvia Ulrich-Sosomin1, Malcom Kohler1, Robert Thuennebre2, Ivan Fauchère3, Anika S. Sagemann4, Frank Scherf5, First Drits1, Burkhard Bloch1, 1Sleep Disorder Center and Pulmonary Division, University Hospital, Zurich, Switzerland; 2Sleep Disorder Center and Pulmonary Division, Kantonsspital St.Gallen, St.Gallen, Switzerland; 3University Hospital of Basel, Switzerland; 4Clinic for Cardiology, Cardiovascular Center, University Hospital, Zurich, Switzerland

Background: Untreated lowlanders with obstructive sleep apnea syndrome (OSA) benefit from acetazolamide (AC) during an altitude stay in terms of improved nocturnal oxygenation, breathing disturbances and sleep quality (Nussbaumer-Ochsner, Chest 2012). The current study evaluates whether AC reduces the increased rate of cardiac dysrhythmias at altitude.

Methods: 43 OSA patients living at ≤600m discontinued CPAP 3 days before baseline examination at 490m and during 2 altitude sojourns at 1860-2500m for 3 days each, one on AC 2x250mg/d, the other on placebo, according to a randomized cross-over design. Holter ECG and polysomnography were performed at 490m and at altitude.

Results: At altitude on placebo, heart rate was higher and dysrhythmias were more prevalent than at 490m. AC reduced bradyarrhythmias, apnea/hypopneas and improved oxygen saturation (table).

Dysrhythmias, oxygen saturation and breathing disturbances

490m Altitude, placebo 490m Altitude, AC
Heart rate, bpm 67 (60; 76) 75 (68; 83)* 73 (67; 81)*
Blood pressure events, 1/d 0.0 (0.14) 3 (0.178) 0.0 (0.179)
Ventricular extrasystoles, 1/d 24 (18, 30) 31 (4; 428) 26 (24; 29)*
Asthma and/or urticarial events, 1/d 0.0 (0.1) 0 (0.1) 0 (0.2)
Nocturnal oxygen saturation, % 93 (92; 94) 87 (86; 89)* 89 (87; 91)*
Apnea-hypopnea index, 1/h 51 (42, 73) 70 (56, 89) 54 (46; 63)*

Conclusions: The increased heart rate and the higher prevalence of dysrhythmias at altitude are consistent with increased sympathetic tone associated with hypoxemia. AC reduces bradyarrhythmias at altitude, possibly by improving sleep disordered breathing.

Grants: Swiss National Science Foundation; Lung League of Zurich; Clinical Trials Center, University Hospital of Zurich, Switzerland.
Aims: To test the hypothesis that infants of substance abusing mothers (SA) and of smoking mothers (SM) compared to infants of non substance abusing, non-smoking mothers (controls) would have a poorer ventilatory response to hypercapnia.

Methods: Infants were assessed before maternit/neonatal unit discharge. Respiratory flow (and tidal volume) was measured using a plethysmograph inserted into a face mask placed over the infant’s mouth and nose. The ventilatory responses to three levels of inspired carbon dioxide (baseline = 0%, 2% and 4% CO2) were assessed.

Results: 8 SA, 15 SM and 15 control infants were assessed. The birth weight of the SM group was higher than the SA group (p=0.01). At baseline SA infants had a higher respiratory rate (p=0.03) and minute volume (p=0.049) compared to controls and SM infants (Table). Both the SA and SM infants had a lower respiratory response to 2% CO2 (p=0.02) and 4% (p=0.004) CO2.

Conclusion: These results are consistent with infants of smoking and substance abusing mothers having a damped ventilatory response to hypercapnia.

3294 The acute effect of surgical repair of mitral valve insufficiency on airway and respiratory mechanics and pulmonary hemodynamics in children Iliona Malaspinas, Lionel Chok, Maurice Begaht, Wald Halbre, Ferenc Petek.

Introduction: Increased pulmonary blood flow and pressure were shown to be responsible for the lung function impairment in children with congenital heart diseases. We investigated the acute effect of surgical repair of the mitral valve insufficiency (MVI) leading to postcapillary pulmonary hypertension is reflected in the mechanical properties of the respiratory system, and whether surgical repair of MVI improves respiratory mechanics in children.

Methods: Airway resistance (Raw), respiratory tissue damping (G) and elastance (E) were measured using the multiple breath inert gas washout (MBW) technique in 25 children with MVI under general anaesthesia before and immediately after surgical repair of the MVI. Concomitantly, pulmonary arterial pressure (PAP) was directly measured in the pulmonary artery before aortic cannulation and chest closure.

Results: Surgical repair of MVI led to a significant decrease in the mean PAP for a decrease (from 33.0 ± 5.2 to 22.0 ± 4.8 mmHg, p=0.004). These postoperative pulmonary haemodynamics changes were associated with significant decreases in Raw (5.5 ± 1.1 to 4.4 ± 1.1 cmH2O/l, p=0.008) with no significant effects on G (11.5 ± 5.2 to 10.1 ± 3.1 cmH2O/l, p=0.07) and H (60.2 ± 9.5, 65.2 ± 13.7 cmH2O/l, p=0.2). Postoperative changes in Raw and PAP exhibited no significant correlation.

Conclusion: These results demonstrate an immediate improvement of airway function after surgical repair of MVI in children. Further experiments are needed to clarify the direct effect of the postoperative decrease in postcapillary pulmonary hypertension and vascular engorgement in this beneficial change. The acute effect of surgical repair of mitral valve insufficiency on airway and respiratory tissue mechanics and pulmonary hemodynamics in children.

Regional pulmonary function testing by electrical impedance tomography in healthy children and children with asthma Barbara Vogt, Gunnar Elke, Philipp von Bismarck, Tobais Ankermann, Norbert Weiler, Ian Frenich.

Introduction: Electrical impedance tomography (EIT) is able to assess regional dynamic lung volume changes and to determine spatial distribution of lung function in the chest cross-section. The aim of our study was to examine the regional lung function in healthy children and children with asthma before and after exercise.

Materials and methods: 10 healthy children (11±3 yr, mean±SD) and 10 children with asthma (12±3 yr) were examined by EIT during conventional pulmonary function testing at baseline and after stairs running for 5 min. EIT data were acquired at 33 scans/s (GE-MF CareFusion, Höchberg, Germany). Regional forced vital capacity (FVC), forced expired volume in 0.5 s (FEV0.5) and tidal volume (VT) were determined in 912 EIT image pixels before and 3 min after exercise. Spatial heterogeneity of ventilation was characterized by the coefficient of variation (CV) calculated from all pixel values of FVC, FEV0.5 and VT.

Statistical analysis: A Mann-Whitney test was used to compare the non-parametric data between healthy children and children with asthma. Children with asthma were divided into three groups: non-atopic children, atopic children and children with severe atopy.

Results: Significant exercise-dependent differences in CVFVC were found in both patient groups whereas CVFEV0.5 and CVVT were not affected by exercise. CVFVC was significantly different between the healthy children and children with asthma after but not before exercise. CVFVC and CVVT were not significantly different between the groups both at baseline and after exercise.

Conclusion: EIT detected regional lung function differences between healthy children and children with asthma during forced full expiration. Future analysis should aim at characterization of peripheral airways by novel EIT-derived measures of regional lung function.

3297 Ventilation inhomogeneity in children with cystic fibrosis and primary ciliary dyskinesia Bettina Greil, Frederik Bachwald, Astrid Mader, Per Gustafsson, Kim N. Nielsen.

Introduction: The diagnostic value of the FOT depends on breathing. Inspira- tion usually provides better breathing. The information may be important to improve the diagnostic of asthma based on bronchial reversibility.

Methods: A cross sectional study was performed in 24 children with PCD and 25 with CF, matched by age and FEV1. N2 MBW in triplets (Exhalyzer D, EcoMedics AG) and spirometry were performed within one occasion in clinically stable patients. Lung Clearance Index (LCI), an index of global VI, and specific indices of VI arising in the conductive (Scond) and the acinar (Sacin) airway zones were measured. The aim at characterization of peripheral airways by novel EIT-derived measures of ventilation inhomogeneity to children with CF and PCD.

Results: There was no significant difference in LCI, Scond and Sacin (z-scores) between the two patient groups, although LCI, z-scores tended to be higher in PCD (Table 1).

Conclusion: In contrast to our expectations severity of peripheral airway involve- ment is similar in children with CF and PCD.

Ways to shorten the lung clearance index measurement II – How long to wash?
Florian Singer, Sophie Yannine, Chiara Abbas, Markus Roos, Philipp Latzin.
Division of Pulmonology, Department of Paediatrics, Inselspital, University Hospital, Bern, Switzerland

Background: Inert gas multiple-breath washout (MBW) derived lung clearance index (LCI) is a sensitive lung function parameter in subjects with mild cystic fibrosis (CF) lung disease, but rarely measured in clinical routine due to lack of available equipment and lengthy protocols. Using an available nitrogen (N2) MBW setup (Exhalzyler D, Eco Medics, Switzerland), we assessed shortened N2MBW protocols for LCI.

Methods: Thirty-three school-aged children with CF and 21 controls performed triplicate N2MBW measurements. LCI was calculated as cumulative expired volume over functional residual capacity determined during N2MBW at 9% (1/11th) and 2.5% (1/40th, the current standard) end-tidal N2 concentration.

Results: LCI differed significantly between healthy and CF children at both concentrations. The 9%-LCI was modestly associated with final 2.5%-LCI (R2 = 0.7) but took less time and was of similar diagnostic value. Comparing 9%- and 2.5%-LCI, mean (SD) test duration was 1.0 (0.9) and 2.2 (1.0) min; mean (95%CI) area under the receiver operating characteristic curve was 0.9 (0.8-0.9) and 0.8 (0.8-0.9), and upper limits of normal LCI (4.5 and 8.4) correctly classified 72% and 74% of children, respectively. Mean (SD) coefficient of variation was 5.7 (3.9)% for 9%-LCI and 5.7 (3.2)% for 2.5%-LCI.

Conclusion: LCI determined at 9% end-tidal N2 concentration during N2MBW is (3.9)% for 9%-LCI and 5.7 (3.2)% for 2.5%-LCI.

appropriate pediatric lung function reference equations for ethnic minorities are lacking. We investigated the extent to which differences in body proportions as indicated by the sitting/standing height ratio (Sit/Stand Ht) explain ethnic differences in FEV1.

Methods: As part of the SLIC study (commenced 2011), standard anthropometry including sitting height and spirometry were assessed in multi-ethnic London school children. FEV1 was expressed in Z scores to adjust for sex, age and height (Stanojevic2009). Statistical analysis was by univariable and multivariable regression.

Results: 379 healthy children (age: 5-10y, 43% boys; 31% White, 44% Black, 11% Asian –0.5 (–0.7; –0.2) –0.3 (–0.6; –0.1), other –0.5 (–0.7; –0.2) –0.3 (–0.6; –0.1).

Conclusion: This study shows that Sit/Stand Ht accounts for some of the differences amongst ethnicities in FEV1, and provides further evidence that sitting height should be an essential part of standard anthropometry. Further work to explore the extent to which differences in body shape, size and composition contribute to ethnic differences in lung function is in progress.
after virtual resection, these data did correlate well with the observed postoperative data ($R^2=0.88<0.01$, $R^2=0.55<p<0.01$; $R^2=0.45,p<0.01$).

**Conclusion:** RFI does provide insights in the influence of LRS on the postoperative airway volumes, resistances and internal flow redistribution and can be used to predict postoperative lung mechanics.

### 3.302

**Intraoperative marking of a small pulmonary nodule with the multi-axis angiography system.**

Masahiko Minokura,1 Yusuke Okamoto1, Tohru Sakurai2, Yuji Takeda2, Shigeki Morita3.1 General Thoracic Surgery, Saga Prefectural Hospital, Saga, Japan; 2Thoracic and Cardiovascular Surgery, Saga University, Saga, Japan

**Introduction:** Often cases are difficult to identify the localization of small pulmonary nodule during operation. preoperative CT guided marking have been described. However, there were some problems including iat embolism, pneumothorax or detection ratio. Now, we used Artis zeego (Siemens co ltd, Germany) which drew up a CT-like image during operation to determine the localization of the pulmonary nodules. This is the first report of intraoperative marking using the Artis zeego.

**Material:** Artis zeego is the first multi-axis angiography system based on robotic technology that can be positioned the way a physician wants. It can be controlled with far greater ease and precision than conventional C-arm system.

**Methods:** The patient was fixed lateral position under general anesthesia, and was sterilize and draped on the operation table. After marking to the pleura where was predicted the nearest portion from the nodule with a clip under the VATS view, Artis zeego was entered and provide a CT-like image. After Artis zeego was disconnected from the patient, the excision region was determined by the image.

**Results:** Four patients, five small pulmonary nodules were performed this procedure. All regions were successfully detected by the image and removed completely. Since this system did not provide to detect pulmonary regions, there were some problems including narrowing of the bed for lateral position, the little device, the elbow or equipments were easy to strike on the machine when rotation.

**Conclusions:** This procedure could be an extremely useful and safety method for intraoperative marking a small pulmonary nodule. We also need to resolve some problems of this procedure such as the devices.

### 3.303

**The concept of prevention of postoperative respiratory complications in lung surgery.**

**Objectives:** Disciform atelectases can be a predictor of a severe postoperative respiratory complications. The aim of the study was to elaborate a set of measures aimed at prevention of these complications in patients subjected to operations on the lungs.

**Materials and methods:** We compared two comparable (in terms of surgery, comorbidities, age) groups of patients underwent lung resection. Two modes of ventilation were used during the operation. In group I (n = 313) ventilation regimen was CMV, standard techniques were used to create expiratory training with PEEP 2. In group II (n = 310) high frequency jet ventilation (HFJV) was carried out (VT = 2 ml; k g-1; f = 100 min-1; I: E = 1:2). In the postoperative period in group I traditional ventilation was conducted. In group II non-invasive mechanical ventilation (Noninvasive HFJV) was used in Continuous Positive Airway Pressure mode (VT = 2 ml; k g-1; f = 300 min-1; I: E = 1:1), inspiratory training was applied. Chest radiograph was undertaken next day after surgery.

**Results:** In Group II, compared with the group I reduction in the incidence of disciform atelectases was noted in first two days after surgery by 3.4 times.

**Conclusion:** On the base of the results obtained we formulated the concept of prevention postoperative respiratory complications after lung resections, which is as follows: 1.Intraoperative - conducting HFJV mode VPN, 2. On the first day after surgery, x-ray control to detect the beginning of the disciform atelectases 3. Holding in the immediate postoperative period of non-invasive mechanical ventilation in mode CPAP/PEEP 4. In the delayed postoperative period breathing exercise to improve the expanding of the lungs.

### 3.304

**Exercise test as preoperative predictor before pulmonary resection surgery.**

Bret Daniel,1 Numa Roa,3 Elena Lopez4 Santa Maria, Maria Alice 1, Juan B Galder1.1 Pulmonary Dpt, Cruces Hospital, Barakaldo, Bizkaia, Spain; 2Pulmonary Dpt, Cruces Hospital Cibers, Barakaldo, Bizkaia, Spain

**Exercise test (V02) before pulmonary resection surgery was incorporated into the new guidelines (A.Brunell Eur Respir J 2009; 34: 17-41) in the case that the patient presents a FEV 1 and/or TICO < 80% predicted, assuming that the exercise test reproduce the situation of cardio-respiratory overload that occurs during the surgical intervention.

**Material and methods:** Prospective descriptive study, three months, which included 48 patients evaluated for possible lung resection due to lung neoplasms who presented values less than 80% in the FEV 1 or TICO and performed a maximum exercise test to complete the preoperative assessment.

**Results:** Mean age (65±8 years); 41 M, 7F. According to the retrieved V02 patients were divided in 3 groups and comparing the values of the FEV 1 and TICO in each group Table 1.

25 patients presented a DLCO and FEV1% < 80%, of them 4 presented a V02 between 10-15, 14 between 15-20 and 7 > 20. Correlations between FEV1 VS V02(0.478,P < 0.001) and V02 VS TICO(0.287, P <0.065).

28/48 patients were operated and in the postoperative follow up (1 month) there was no death and 8 (28.5%) of them had postoperative complications (2 empyema, 2 hemothorax, 1 fistula, 2 pneumonia, 1 respiratory failure). These patients presented the following functional parameters FEV1 (166±74), DLCO 51±8, 17.4 ml/kg/min V02.

**Conclusions:** Patients with mechanical and/or decreased gas exchange (< 80%), present a lower (V02 max.) The use of the algorithm that includes as initial step exercise test predicts a good postoperative surgery.

**Six minute walk test (6MWT) in patients with diagnosis of lung cancer – Clinical value in physiological evaluation candidates for surgical treatment.**

Monika Franczuk, Piotr Radzinski, Jerzy Ursichniewicz, Marek Kraw, Renata Langfort, Stefan Wesołowski, Tadeusz Orłowski. Lung Function Dept, Thoracic Surgery Dept, Rehabiliation Dept., Dept. of Pathology, National Research TB and Lung Diseases Institute, Warsaw, Poland

The lung function testing (LFT) and assessment of exercise capacity in patients with lung cancer are important tools for qualification for the surgery and estimation the risk. However the commonly used 6MWT is not recommended by the current guideline as a reliable method of evaluation (Brunelli 2009).

The aim of the study was to analyze the differences in LFT and 6MWT between patients with and without complications after lung resection. The analysis included 127 operated pts (mean age 63±13 yrs, 80 M, 47 F), with histopathologically confirmed NSCLC. Patients with a history of previous lung resection, chemotherapy or radiotherapy were not included into the study. The comparison of LF and 6MWT was performed and the differences between pts without (86 pts) and with (41 pts) postoperative complications (e.g. arhythmias, PAL, hemorrhage) were noted. FEV1 2.4 vs. 2.1L, p=0.01 (91.3 vs. 73.5%, p=0.001), FEV1/FVC 69.2 vs. 60.3% (p=0.001), ppoFEV1 1.9 vs. 1.6L, p=0.01 (71.9 vs. 51.3%, p<0.001), 6MWT distance 430 vs. 415m (ns), SaO2 start 96.9 vs. 95.5% (p=0.001), SaO2 min 95vs. 92.2% (p<0.001). In univariate analysis ppoFEV1 p>0.05, 6MWT distance and minimal value of SaO2 during the test were significant prognostic variables.

**Conclusions:** Patients with postoperative complications had lower lung function indices (FEV1, ppoFEV1) and lower minimal saturation during 6MWT than those with uneventful postoperative course. Those findings suggest that 6MWT, highly reliable in estimating exercise tolerance in COPD patients, ILD and IAHP, can be valuable also in assessment of lung cancer patients, candidates for surgical treatment.

### 3.306

**Effect of pre-operative short-term rehabilitation on peak V02 in patients with NSCLC.**

Petra-Oliver Bridewell1, Jean-Marie Tschopp2, Chetna Bhata3, Isabelle Frisen4, Frederic Triponze5, Jean-Marie Schundy5, John Robert6, Thierry Rochal7, Marc Licker7.1 Pulmonary Care Division, University Hospitals, Geneva, Switzerland; 2Pulmonary Care Division, Resea santé Vaillie, SouthMontana, Switzerland; 3Anesthesiology Division, University Hospitals, Geneva, Switzerland; 4Thoracic Surgery Division, University Hospitals, Geneva, Switzerland; 5Physiotherapy Division, University Hospitals, Geneva, Switzerland

Preoperative fitness is best assessed with cardio-pulmonary exercise testing (CPET) in patients with non-small cell lung cancer (NSCLC). Peak Oxygen consumption (V02 peak) is predictive of short-term complications after thoracic surgery. Feasibility and effect of short-term (2 to 3 weeks) rehabilitation on fitness and short-term outcomes are unknown.

We planned a pragmatic, randomized controlled trial (RCT) comparing short-term rehabilitation (R) with usual care (UC) in patients with operable NSCLC.

**Method:** This ongoing study enrolls patients after baseline CPET from 2 centres in

Structured light plethysmography for the non-contact estimation of chest and abdominal motion changes after thoracic surgery: pilot experience
Iris Levai1, Simon Baker2, Willem de Boer2, Richard Iles3, Aman Coonar2.
1PneumaCare Ltd, St. John's Innovation Centre, Cambridge, Cambridgeshire, United Kingdom; 2Department of Respiratory Paediatrics, Addenbrookes Hospital, Cambridge, United Kingdom; 3Department of Thoracic Surgery, Papworth Hospital, Papworth Everard, Cambridgeshire, United Kingdom

Introduction: Structured Light Plethysmography (SLP) is a non-contact method of studying chest and abdominal motion which can relate to tidal and spirometric volumes. This can also be studied with a 3D-viewer.

Methods: We obtained serial data from 10 patients who underwent thoracic surgery. They were scanned pre and postoperatively with a PneumaScan-P2™ device (PneumaCare, Cambridge, UK). A checkerboard grid of light was projected onto the patient's chest area. Two digital cameras, recorded the grid movement during breathing. Data was presented as a respiratory volume trace over time and as Konno-Mead plots for left v. right hemithorax and chest v. abdomen movement. A post-operative patient is shown in figure 1.

Results: In some patients following thoracic surgery we demonstrate reduced chest wall motion on the operated side. We find improvements in chest wall movement over the recovery period. In one patient no significant difference in pre and post op scans can be found. This patient had virtually no pain post-op and returned to work 5 days after his limited thoracotomy and lung resection.

Conclusions: SLP can objectively measure chest wall movement in thoracic surgery patients. There may be a role for it in monitoring post-operative recovery and we are exploring this further.

370. Lung, heart, muscles and brain: the pathway of oxygen during exercise in health and COPD

370B
Lung structure and function in a rat model of emphysema: A longitudinal study
Marja Saabu1, József Tola1, Balázs Maá1, Harikrishnan Parameswaran2, Erzsébet Bartolák-Suki3, Béla Suki4, Zoltán Hantos5. 1University of Szeged, Department of Medical Physics and Informatics, Szeged, Hungary; 2Boston University, Biomedical Engineering Department, Boston, MA, United States

Our aim was to evaluate the long term structure-function relations in a rat model of emphysema. Rats were treated with porcine pancreatic elastase to produce PPE, n=21 or saline (controls, C, n=19) intratracheally. Before the treatment (day 0) and 3, 10, 21 and 105 days thereafter, respiratory impedance was measured with forced oscillation technique and tissue elastance (H) was calculated. At 3, 21 and 105 day the lungs were fixed, sections were obtained and stained with hematoxylin and eosin, modified Movat’s, Masson’s and Alcian blue method to visualize elastin, collagen and proteoglycans. Randomly selected regions were photographed. The images were automatically segmented and the equivalent diameter of alveolar airspaces (D), mean elastin (Me), mean collagen content (Mc) and mean proteoglycan ratio (Mp) were measured. H decreased through the time-course in the treated animals (p<0.001). D was different between the control and the treated groups at 21 (p=0.027) and 105 days (p=0.004). Me increased in the treated groups (21 d, 105 d; p<0.001), Mc decreased in the treated groups (3 d, 21 d; p<0.001) and Mp was different between the 2 groups (21 d p<0.001, 105 d p<0.016). Multiple linear regression revealed significant correlations between H, D and Me/Mp (r2=0.47, p<0.001; r2=0.712, p<0.001; r2=0.547, p=0.042). We conclude that the progression of emphysema in the PPE model occurs by gradual septal wall failures leading to enlarged airspaces, which in turn decreases the tissue elastance of the lung. This irreversible process results in strong functional and microstructural relations with the components of the extracellular matrix.

3709
Cerebral cortex blood flow, oxygen delivery and oxygenation during normoxic and hypoxic exercise in healthy humans
Zafiris Louvaris1,2, Ioannis Vogiatzis1,2, Helmut Habazettl1, Vasileios Andrianopoulos1,2, Harrieth Wagner3, George Zakynthinos1, Charis Roussos4, Peter Wagner5. 1Department of Critical Care Medicine and Pulmonary Services, Evangelismos Hospital, "M. Simou, and G.P. Livanos Laboratories", National and Kapodistrian University, Athens, Greece; 2Department of Physical Education and Sport Sciences, National and Kapodistrian University, Athens, Greece; 3Institute of Physiology, Charité Campus Benjamin Franklin, Berlin, Germany; 4Institute of Anesthesiology, German Heart Institute, Berlin, Germany; 5Department of Medicine, University of California San Diego, La Jolla, CA, United States

Background: During maximal hypoxic exercise a reduction in cerebral oxygen delivery may constitute a signal to terminate exercise.

Aim: To investigate whether the rate of increase in cerebral cortical oxygen delivery is limited in hypoxia compared to normoxic exercise.

Methods: We assessed frontal cerebral cortex blood flow using near infrared spectroscopy and the light-absorbing tracer indocyanine green dye, as well as frontal cortex oxygen saturation (StO2%) in 11 cyclists during incremental exercise to the limit of tolerance (WRmax) in normoxia and acute hypoxia (FiO2=0.12).

Results: In normoxia, cerebral cortex blood flow and oxygen delivery increased (p<0.05) from baseline to sub-maximal exercise reaching peak values at near-maximal exercise (80% WRmax: 287±9, 81±23% and 75±22% increase relative to baseline, respectively), both leveling off thereafter up to WRmax (328±10%). Cerebral cortex StO2% did not change from baseline (66±3%) throughout graded exercise. During hypoxic exercise, cerebral cortex blood flow increased from baseline to sub-maximal exercise peaking at 80% WRmax (213±6%, 60±15% relative increase) before declining towards baseline at WRmax (289±5%). Despite this, cerebral cortex oxygen delivery remained unchanged from baseline throughout graded exercise, being at WRmax lower than at comparable loads (287±9%) in normoxia (by 58±13%). Cerebral cortex StO2% fell from baseline (58±6%) on moderate exercise in parallel with arterial oxygen saturation, but then remained unchanged to exhaustion (47±4%).

Conclusion: Cerebral cortex oxygen delivery is limited in hypoxia compared to normoxia, thus potentially compromising maximal exercise capacity in hypoxia.
3310 Cerebral cortex oxygen delivery and exercise limitation in patients with COPD
Joannas Vorgiatzi1,2, Zafeiris Louvaris3,4, Helmut Habscheid1,4, Vassileios Andrianopoulos1, Harrieth Wagner2, George Zakynthinos1, Charis Roussos1, Peter Wagner3, 1Department of Critical Care Medicine and Pulmonary Services, Evangelismos Hospital, "M. Simou, and G.P. Livanos Laboratories", National and Kapodistrian University, Athens, Greece; 2Department of Physical Education and Sport Sciences, National and Kapodistrian University, Athens, Greece; 3Institute of Physiology, Charité Campus Benjamin Franklin, Berlin, Germany; 4Institute of Anesthesiology, German Heart Institute, Berlin, Germany; 4Department of Medicine, University of California San Diego, La Jolla, CA, United States

Background: During hypoxic exercise in healthy humans, limited frontal cerebral cortex oxygen delivery may signal the brain to cease exercise.

Aim: Whether in patients with COPD exercising-induced arterial O2 desaturation, frontal cerebral cortex oxygen delivery is reduced, remains unknown.

Methods: By near infrared spectroscopy, we measured both frontal cerebral cortex blood flow (CBF) using indocyanine green dye, and cerebrovascular O2 saturation (%SO2) in 12 COPD patients during constant-load exercise at 75% of peak capacity. Subjects exercised breathing air, 100% O2 or normoxic heliox, the latter two in balanced orders.

Results: Time to exhaustion breathing air was less than for oxygen or heliox (394±3 vs. 670±3 and 637±46 sec, respectively). In each condition, CBF increased from rest to exhaustion. At exhaustion, CBF was higher breathing air and heliox than oxygen (50.4±2.3 and 31.4±3.5 vs. 26.6±3.2 ml min-1 ·100g-1, respectively), compensating lower arterial O2 content (CaO2) in air and heliox, and leading to similar frontal cerebral cortex oxygen delivery (air: 5.3±0.4 O2; 5.5±0.6 and heliox: 5.6±1.0 O2 min-1 ·100g-1 respectively). In contrast, end-exercise %SO2 was greater breathing oxygen compared to air or heliox (67±4 vs. 57±3 and 53±3%, respectively), reflecting CaO2 rather than frontal cerebral cortex oxygen delivery.

Conclusion: Prolonged time to exhaustion is explained by oxygen and heliox despite similar cerebral cortex oxygen delivery as in air, lower %StO2 with heliox than oxygen, yet similar endurance time, and similar %SO2 on air and heliox despite greater endurance with heliox, do not support the hypothesis that cortical oxygen delivery is important in limiting exercise capacity in COPD.

3311 Tissue oxygenation profiles during prolonged exercise in hypoxia
Samuel Verges1, Thomas Rupp1, Marc Jubera2,3, Bernard Wuyama4, Guillaume Sarramon5, Stephane Perrier6, 7MPH Laboratory, IRREM, Joseph Fourier University, Toulouse, France; 2LPE Laboratory, Lyon University, St Etienne, France; 3MIP Laboratory, Nantes University, Nantes, France; 4M2H Laboratory, Montpellier University, Montpellier, France

Introduction: Tissue oxygenation is altered during hypoxia (H) at rest and during exercise(1). It remains however debated whether these perturbations are similar between tissues as well as between cerebral areas implicated in motor output. The purpose of our study was to assess the effect of hypoxic exposure on quadriceps, prefrontal (PFC) and motor cortices oxygenation during prolonged submaximal cycling in H.

Methods: A 4-h wash-in period, either in normoxia or H, 12 subjects performed a 80-min cycling exercise at 45% of their maximal aerobic power (N4F0=21%, H4F0=11%). A third condition (H4F0=9%) consisted in a 80-min resting period in which the arterial saturation (SpO2) reached during H4F0 was matched by adjusting FiO2, Oxy(HbO2)- deoxy(Hb) and total[THb]-haemoglobin changes were measured on each site by near-infrared spectroscopy.

Results: H4F0 and N4F0 resulted in similar SpO2 reduction (~20%). Quadriceps exercise-induced [HbO2] reductions were associated with increased and unchanged [THb] in N4F0 and H4F0 respectively, while [THb] dropped significantly in H4F0. PFC showed a large [THb] increase at exercise with a four-fold [HbO2] increase in N4F0 compared to H4F0. Motor cortex showed similar [HbO2] changes than PFC in H4F0 but not at exercise. Indeed, motor cortex [THb] was stable in H4F0 and N4F0 while [HbO2] decreased and [HHb] increased in N4F0, these latter changes being significantly accentuated in H4F0.

Discussion: This study quantifies for the first time the respective effects of prolonged cycling exercise and SpO2 drop on muscle and cerebral oxygenation responses in H and demonstrates important specificities between tissues and cortical sites.

3312 Exercise testing confirms the role of impaired central circulatory function and elevated right ventricle stroke work index in patients undergoing lung transplantation
Marijke Ververs1,2, Hilary Armstrong1, Tomoko Kato1, Matthew Bacchetta1, Christian Schulte1, 1Rehabilitation and Regenerative Medicine, Columbia University, New York, NY; United States; 2Division of Cardiology, Department of Medicine, Columbia University, New York, NY; United States; 3Surgery, Columbia University, New York, NY; United States

Introduction: Right ventricular (RV) workload assessed by RV Stroke Work Index (RWSWI) is a negative predictor of outcome in acute respiratory failure. Cardiopulmonary exercise testing (CPET) may have a role in detecting central circulatory impairment (CCI) in patients before lung transplantation (LTx) at risk for impaired RV function.

Aims and objectives: To demonstrate correlation of ventilatory inefficiency (VI) on CPET for detection of CCI in patients before LTx with RWSWI.

Methods: 172 patients undergoing evaluation for LTx who had CCI and right heart catheterization were included. RWSWI (stroke volume index*mean pulmonary arterial pressure = mean right atrial pressure*0.0136) was calculated from invasive hemodynamic data. Pearson’s correlation, significance 0.05, was assessed between RWSWI and CPET parameters.

Results: RWSWI correlates highly with VI and inversely with hemodynamics on CPET, but not with peak capacity or workload.

p<0.05; VE: Minute Ventilation; SBP: systolic blood pressure; DBP: diastolic blood pressure; PetCO2: Pressure of end tidal CO2; VCO2: Rate of carbon dioxide produced; VO2: volume of oxygen consumed.

Conclusions: High right ventricular workload correlates with ventilatory inefficiency and impaired hemodynamics on CPET. Thus, exercise parameters may predict right ventricular work and LTx outcomes.

3313 Additive effects of non-invasive ventilation to hyperoxia on pre-frontal cerebral oxygenation during exercise in patients with COPD
Miguel Rodrigues, Mayron Oliveira, Tírira Trepoew, Aline Souza, J. Alberto Neder. Neder. Pulmonary Function and Clinical Exercise Physiology Unit (SEFICE), Respiratory Division, Department of Medicine, Federal University of São Paulo – Paulista School of Medicine (UNIFESP-EPM), São Paulo, SP, Brazil

Rationale: Changes (Δ) in cerebral oxygenation (COx) during exercise are modulated by the dynamic coupling between O2 delivery (cerebral blood flow and arterial O2 content) and O2 utilization. Non-invasive positive pressure ventilation (NIV) adds benefit to HiOx in increasing pre-frontal cerebral oxyhemia. Non-invasive ventilation (NIV) improved muscle and cerebral COx at sub-maximal levels of exercise compared to HiOx (p<0.05). Iso-work rate Qr was larger with HiOx-alone on COx during ramp-incremental exercise in patients with moderate-to-severe COPD.

Methods: Thirty non-hypocapnic males (FEV1=48±15.1% predicted) were randomly assigned to receive each intervention on different days. ΔCOx was determined by near infrared spectroscopy (fold-changes in HbO2), oxyhemoglobin saturation by pulse oximetry (SpO2), and cardiac output (Qt) by impedance cardiography.

Results: As expected, SpO2 remained near 100% throughout the tests (p<0.05). Area under ΔCOx on HiOx was significantly correlated with ΔQt (r=0.82). Peak exercise cardiac output did not differ between interventions (74±20 W vs. 78±19 W; p<0.05). NIV-HiOx was associated with larger increases in ΔCOx at sub-maximal levels of exercise compared to HiOx (p<0.05). Iso-work rate Qr was larger with NIV-HiOx than HiOx (2.6±1.0 vs. 1.6±0.6 fold-changes, p<0.05) and related to improved stroke volume (p<0.05).

Conclusions: NIV adds benefit to HiOx in increasing pre-frontal cerebral oxygenation in patients with COPD, an effect associated with enhanced central haemodynamic responses to exercise.

3314 Central hemodynamics, pleural pressure and normoxic helioxduring exercise in patients with chronic obstructive pulmonary disease
Bart Boerstra1, Harm-Jan Bogaard1, Herman Greepenhoff1, Nico Westerhof1,2, Amsterdam Vnt. Noordzegrad1, 3Pulmonary Diseuses, VU University Medical Center, Amsterdam, Netherlands; 2Physiology, Institute for Cardiovascular Research, VU University Medical Center, Amsterdam, Netherlands

Background: Altered pulmonary mechanics, due to airway obstruction, are thought to hamper cardiac function during exercise in patients with COPD. If so, improving airflow would lead to an enhanced cardiac function.

Methods: Pleural pressure, dynamic hyperinflation and central hemodynamics, by right heart catheterisation, were simultaneously measured in patients with moderate to very severe COPD at rest and during exercise; both in ambient air and while breathing a normoxic helium-oxygen mixture (heliox).

Results: Seventeen patients were included (FEV1; 53±17%, FEV1/FVC: 42±10%).

TUESDAY, SEPTEMBER 4TH 2012
Breathing heliox lowered expired pleural pressure at rest (3.8±2.6 to 1.8±2.3 mmHg) and during exercise (8.2±3.6 to 6.1±3.3 mmHg), both p<0.05. During exercise we did not find any improvements in stroke volume or cardiac output. At rest we found improvements in cardiac output (6.1±4.1 to 6.6±4.1 L/min/m²), stroke volume (80±22 to 87±19 ml/m²) and mixed venous oxygen saturation (66±6 to 69±6%, all p<0.05). Dynamic hyperinflation did not improve with heliox.

Conclusion: Heliox breathing did not affect cardiac function during exercise. This implies that altered pulmonary mechanics do not substantially affect cardiac function during exercise in COPD.

P3315 Evaluation of mechanisms determining endothelial function in patients with COPD
Christian F. Clarenbach1, Anne C. Stoevhas1, Arnoldus J. R. van Gestel2, Gianna Campanella1, Valentina A. Rosi1, Noriane Siev1, Olivier Senn2, Robert Thurhner3, Erich W. Russi1, Malcolm Kohler1. 1Pulmonary Division, University Hospital, Zurich, Switzerland; 2Institute of General Practice and Health Services Research, University of Zurich, Switzerland; 3Pulmonary Division, Cantonal Hospital of Munsterlingen, Switzerland

Background: COPD is associated with increased cardiovascular mortality. Factors contributing to vascular damage in patients with COPD are mostly unknown. However, it has been suggested that airflow limitation, systemic inflammation, oxidative stress, sympathetic activation, hypoxia and impaired physical activity may lead to endothelial dysfunction and undergo this association.

Objective: To determine the impact of airflow obstruction, systemic inflammation, oxidative stress, sympathetic activation, hypoxia and physical activity on endothelial function in COPD.

Methods: In patients with stable COPD (GOLD stage I–IV) assessments of endothelial function by flow-mediated dilatation (FMD), conventional cardiovascular risk factors (PCoA-score), airflow obstruction (FEV1), systemic inflammation (CRP), oxidative stress (malondialdehyde), sympathetic activation (baroreflex sensitivity), hypoxia (blood gases) and physical activity (steps per day) were performed. Associations between endothelial function and these potential underlying mechanisms were assessed in univariate and multivariate analysis.

Results: 106 patients (35% GOLD stage III, 25% III, 40% IV) were included. In univariate analysis FMD correlated with FEV1 (ρ=0.53, p<0.001), baroreflex sensitivity (ρ=0.25, p=0.01), and steps per day (p=0.07, p=0.01) but not with CRP, malondialdehyde, hypoxia or PCoA-score. In multivariate analysis all proposed mechanisms only FMD and steps per day were independently associated with FMD.

Conclusions: Endothelial function in COPD seems to be primarily determined by the severity of airflow obstruction and the level of physical activity.

P3316 Poor treatment outcomes of XDR-TB patients in resource-limited settings
Giovanni Seti1, Elize Pietersen2, Rosella Centis3, Malika Davids2, Andrea Piana1, Devan Vaghela2, Kai Kliiman4, Lia D’Ambrosio3, J.K. Samaria1, Satyadeo Chaubey2, 1Epidemiology and Medical Statistics Unit, Department of Biomedical Sciences, University of Cape Town, South Africa; 2Department of Chest Diseases, J. N. Medical College, Sawangi-Wardha, Maharashtra, India; 2Dept. of Chest Diseases, Banaras Hindu University, Varanasi, UP, India; 2Dept. of Chest Diseases, J. N. Medical College, Sawangi-Wardha, Maharashtra, India

Background: According to the last report of the World Health Organization 69, countries have diagnosed at least one case of extensively drug-resistant tuberculosis (XDR-TB). Treatment success rates for XDR-TB have been highly variable. To determine the impact of airflow obstruction, systemic inflammation, oxidative stress, sympathetic activation, hypoxia and physical activity on endothelial function in COPD.

Objective: To compare XDR-TB-related treatment outcomes (i.e. culture conversion and mortality) in MHI vs. LI countries

Methods: A comparative retrospective evaluation of a European (Italy and Estonia) vs. South African datasets, which included only culture-confirmed XDR-TB cases, was performed. Covariates, potentially associated to negative or positive treatment outcomes, were partially explored.

Results: A total of 235 XDR-TB patients were enrolled [61 from Europe (70.5%, males) and 174 (51.2% males) from South Africa]. Their mean (standard deviation) age was 47.0 (12.2) and 35.2 (11.2) years, respectively (P<0.001). HIV co-infection was significantly more frequent in the South-African cohort (82/174, 47.1%, vs. 25/58, 3.5%; P<0.001). A higher proportion of deaths was recorded among South African XDR-TB cases (61/174, 35.1%, vs. 14/61, 23.0%; P=0.08). By contrast, the proportion of culture converters during anti-TB treatment was significantly higher in the European group (28/57, 49.1%, vs. 33/174, 19.0%; P<0.001). HIV co-infection was significantly associated with death, but not culture conversion, in the combined cohort (aOR: 2.37; P=0.008).

Conclusion: Unfavorable outcomes, although common in both settings, are more frequent in a resource-poor setting. These data can inform prevention and treatment strategies for XDR-TB in different settings.

P3318 The incidence of multi drug resistant tuberculosis among patients receiving standardized treatment regime for suspected MDR-TB
Sahlin Augusto Le1, Joven Gongon1, Lawrence Raymond1,2, Vivian Lofranco1,2, Vincent Balanag1. 1Pulmonary Medicine, Lung Center of the Philippines, Quezon City, Philippines; 2Public Health Domiciliary Unit, Lung Center of the Philippines, Quezon City, Philippines

The LCP-PMDT started the implementation of Standardized treatment regime for all smear positive Drug Resistant tuberculosis suspects. The appropriateness of these regimes need to be evaluated. This is a Descriptive prospective cohort study, the objective is to determine the Incidence of MDR-TB among patients receiving Standardized Treatment regime for suspected MDR-TB. 256 patients received standardized treatment regime,180 patients have available culture and DST results, 76 patients still have pending culture and DST results. Of the 180 patients with available culture and DST results, 113 were confirmed MDR-TB. 55 of 72 (76.3%) patients belonging to the others Non-DOTS multiple treatment group were confirmed MDR-TB compared to 7 (30.3%) patients with Non-DOTS with single treatment. 17 of 18(94%) patients who belonged to category I failure group were confirmed MDR-TB. 5 of 11 (45.5%) patients under Category I RAD, 8 (33.3%) of 24 patients under category I relapse were confirmed MDR-TB. 11 of 20 (55%) patients under category II relapse and 10 (90.1%) of 11 patients under category II failure were confirmed MDR-TB.

Conclusion: MDR-TB occurs more frequently among the standardized regimen II group (category I failure, category II failure, and other Non-DOTS with multiple treatment).

Recommendations: Initiation of standardized regimen for MDR-TB for patients with Category I failure, Category II failure, category II relapse and those with Non-DOTS with multiple treatment while awaiting the results of the DST. Category II treatment regimen, should be used in category I RAD and category I Relapse pending culture and DST results.

P3318 Non-pharmacological factors for the emergence of drug resistance in patients of pulmonary tuberculosis: An Indian overview
J.K. Samaria1, Satyadeo Chaubey2, 1Dept. of Chest Diseases, Insect of Medical Sciences, Banaras Hindu University, Varanasi, U.P, India; 2Dept. of Chest Diseases, J. N. Medical College, Sawangi-Wardha, Maharashtra, India

Objective: To evaluate the impact of non-pharmacological factors on the emergence of drug resistant tuberculosis in eastern Uttar Pradesh.

Material and methods: 150 diagnosed cases of drug resistance pulmonary tuberculosis via culture and sensitivity were evaluated of their socio-economic background with special reference to their literacy, annual income, housing, reason of discontinuation of treatment, migration status etc. Data was collected and analysed statistically.

Observation: Prevalence of drug resistance was more in large families(76%), with lower housing area per person(62%), with at least one migration history(75.3%), having at least one member previously sputum positive(65.3%) and lower annual income(66%). Also was more in illiterate(58%). The reason of discontinuation were adverse effect(18%), resolution of basic symptoms/early asymptomatics(40%), advised by unqualified doctors(12%), social stigmat(8%), and non affordable private treatment(15.3%).

Conclusion: Role of socioeconomic factors can’t be denied in emergence of drug resistance. Patient centered approach especially proper counselling may help in this regard.
P3319
The efficacy of a rifabutin-containing regimen for rifabutin-susceptible multi-drug-resistant tuberculosis
Kyung-Wook Joo, Wonju Jin, Iwhoon Ly, Young Ju Jung, Sang-Do Lee, Woo Sung Kim, Dong Soon Kim, Tae Sun Shim. Division of Pulmonary and Critical Care Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea

Objective: We investigated the efficacy of rifabutin (RBU)-containing regimen for the treatment of RBU-resistant multidrug-resistant tuberculosis (MDR-TB).

Methods: From 256 patients diagnosed with MDR-TB at Asan Medical Center in South Korea between January 2006 and December 2010, 39 patients (15.2%) were susceptible to RBU. Of these 39 patients, nine patients who were appropriately treated with a RBU-containing regimen were included. Twenty-seven MDR-TB patients who were resistant to RBU, were selected as a control group, and the outcomes of both groups were retrospectively compared.

Results: In the nine patients with RBU-susceptible MDR-TB, their mean age was 43.7 years and the proportion of extensively drug-resistant TB (XDR-TB) was 44.4% (4/9). Baseline characteristics and the drug resistance pattern (except RBU) did not differ between the two groups. Treatment success (cure in six (66.7%) and treatment completion in three (33.3%)) on the other hand, the treatment success rate was 48.1% (13/27) and treatment failed in 14 (51.9%) of the 27 patients in the control group (p = 0.012).

Conclusions: RBU seems to be useful in the treatment of MDR-TB in patients who are susceptible to RBU.

P3320
Treatment outcomes of MDR-TB cases registered in Bucharest sector 4 during 2006-2010
Mirela Tigau, Ileana Dediu, Emilius Bejan, TB and other Chronic Diseases, "Marius Nasta" Institute of Pneumology, Bucharest, Romania

Introduction: Although the TB incidence rate declined significantly in Romania in the last decade, from 142.2/100,000 in 2002 to 90.2/100,000 in 2010, the MDR-TB remains at a rate of attendance (2.9% in new and 10.9% in retreated cases).

Objective: To analyze the treatment outcomes of MDR-TB cases registered in the TB Dispensary of Bucharest Sector 4, in order to optimize the TB control in its territory.

Material and methods: We conducted an observational retrospective study of 78 MDR-TB cases registered in Sector 4 between December 2004-December 2008.

Data have been collected from the TB register of the dispensary, TB information system, treatment records and epidemiological surveys.

Results: Out of 78 MDR-TB patients, 35 have been included in the DOTS Plus project financed by the Global Fund (GLC group) and 43 have been treated from NTP resources (NTP group). Chronic patients represented 11.5% in GLC group and 30.9% in NTP group. Overall success rate was 3 times higher in the GLC group (82.8%) than in the NTP group (25.3%).

Conclusions: For tuberculosis control it is important to include patients in DOTS Plus project because this group shows higher success rates at the end of the treatment (82.8% vs 25.3%).

P3321
Treatment outcome of multi drug resistant tuberculosis patients in modified DOTS-PLUS: A new strategy
Rajendra Prasad 1, Abhijeet Singh 2, Rahul Srivastava 2, Ramawadh Singh Kushwaha 3, Rajiv Garg 3, Sanjeev Kumar Verma 3, Girdhar Belur, Medical University, Tomsk, Tomsk area, Russian Federation; 2Department of Tuberculosis and Pulmonology, "Marius Nasta" Institute of Pneumology, Bucharest, Romania, 3Tuberculosis of Lungs, Tomsk Regional Clinical Tuberculosis Hospital, Tomsk, Tomsk area, Russian Federation

Background: MDR-TB remains a worldwide problem which is difficult to treat and has greater risk of relapse. Multi Drug Resistant tuberculosis (MDR-TB) is an increasing worldwide problem which is difficult to treat and has greater risk of relapse.

Objective: To analyze long term treatment outcome with second line drugs in patients with MDR-TB.

Methods: A prospective cohort study analyzing 98 consecutive patients with MDR-TB attending the Dept of Pulmonary Medicine, CSMMU, between June 2000 to Feb 2010 with follow-up till February 2012. All the patients were given modified DOTS Plus Protocol of Revised National Tuberculosis Control Programme (RNTCP). Treatment included monthly follow up, adherence check up, radiological and bacteriological assessment (spumum smear advised monthly till conversion then quarterly; culture for MBT at 0,6,12,18,24 months); intense health education and monitoring of adverse effects. Patients outcome considered as cure when atleast 2 of the last 3 cultures were negative and as failure when the same were positive.

Results: All the patients had resistance to at least Isoniazid and Rifampicin with mean no. of 3.02 drugs and were sereogative for HIV. Default rate and expiry rate at the completion of 24 months of treatment were observed to be 7(7.1%) and 10(10.2%) respectively. Mean smear and culture conversion time were 3.4±3.2 months (1-11) and 4.6±2.5 months (4-12) respectively. Spumum smear and culture conversion rate were 75(8102.5%) and 71(817.5%) respectively with only 10(10.2%) patients remained culture positive. Significant side effects were experienced in only 17.4% patients.

Conclusions: Modified DOTS-PLUS strategy can be model for treatment of MDR-TB in private sector.

P3322
Failure in treatments of patients according DOTS-PLUS program
Medico-social predictors
Tina Fellegy 1, 2. 1Department of Tuberculosis and Pulmonology, Siberian State Medical University, Tomsk, Tomsk area, Russian Federation; 2Department Tuberculosis of Lange, Tomsk Regional Clinical Tuberculosis Hospital, Tomsk, Tomsk area, Russian Federation

The problem of treatment patients who suffering from multi drug resistance tuberculosis of lungs (MDR-TB) is one of the symptoms of phthisiology now. Efficiency of treatment of this group patients according the program DOTS-PLUS fluctuates in a range 61%-77%, and failure in treatment is registered in 3%-14% of cases in different countries. The purpose of our research is revealing predictors of failure in treatment of the patients suffering MDR TB.

200 MDR TB patients who were treated under program DOTS-PLUS in the Tomsk region (from 2000 to 2008) have been included in case-control study. Patients with failure in treatment (n=100) were in the main group, and patients (n=100) who were cured were in the comparison group.

The age of patients varied from 16 till 75 years. The deficiency of body weight (BMI < 15.99 and less) has brought to the formation failures in treatment (OR 11.0). Revealing cavernous tuberculosis at the initial stage increased risk of failure more than in 5 times (OR 5.69). The complications increasing risk of failure in treatment were respiratory insufficiency (OR 3.25), anemia (OR 13.78) and hemoptysis (OR 3.80). For therapy failure following accompanying diseases had prognostic value: pathology of urinary system (OR 6.62), chronic not obstructive bronchitis (OR 2.43), pathology of gastrointestinal tract (OR 2.32) and pathology of the heart (OR 3.52).

Thus development of MDR TB and efficiency of its treatment depends from both social, and medical factors which are necessary to consider at the initial stage of treatment and to apply measures for their minimization.

P3323
Success of the patient-oriented approach to MDR-TB treatment in Tomsk Oblast, Russia, 2000-2009
Sergey Mishavin 1, Petr Golubchikov 2, Alexandre Barnashov 3, Vera Bayerlen 1, Alexandre Golubchikov 2, Dmitriy Ranganath 1, Natalya Zemlyanaya 2, Petr Golubchikov 1, Olga Sirokina 1, Vera Golubchikova 1, Evgeniy Ansimov 1, 1TB Dispensery, Tomsk Oblast TB Service, Tomsk, Russian Federation; 2Tobacco Oblast Department, Red Cross of Tomsk Oblast, Tomsk, Russian Federation; 3NGO, Partners in Health, Boston, MA, United States

MDR-TB reservoir decreased from 29.3% (2003) to 10.4% (2009). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.

In 2000-2009, 1141 MDR TB patients were treated in Tomsk Oblast (civilian sector). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.

In 2000-2009, 1141 MDR TB patients were treated in Tomsk Oblast (civilian sector). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.

In 2000-2009, 1141 MDR TB patients were treated in Tomsk Oblast (civilian sector). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.

In 2000-2009, 1141 MDR TB patients were treated in Tomsk Oblast (civilian sector). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.

In 2000-2009, 1141 MDR TB patients were treated in Tomsk Oblast (civilian sector). MDR-TB treatment effectiveness: 63.1% - cured, 12.6% - failed, 8.3% - died, 13.78 - treatment failed.
Methods: A descriptive analyses of 93 consecutive patients with MDR-TB attending the Department of Pulmonary Medicine, CSMMU, between June 1998 to February 2008 with follow-up till December 2010. All patients were admitted for average duration of 70 days and received a regimen chosen from Kanamycin, PAS, Ethionamide, Cycloserine, Fluoroquinolone, Isoniazid, Ethambutol and Pyrazinamide. Patients outcome was considered as cured when all sputum examination were negative and as failure when the same were positive. Results: All the patients had resistance to at least Isoniazid and Rifampicin with mean no. of 3.38 drugs. Average duration of pretreatment chemotherapy was 34.5 (10-62) months. Of 93 patients enrolled, 75 completed the treatment as planned, 5 patients died during treatment, and 13 patients abandoned it or lost to follow up. Considering the best scenario cure rate was 93.33% (70/75) and in worst scenario cure rate was 75.27% (70/92). Out of 75 cured, 68 came for follow-up for mean duration of 53.3 (10-98) months. Relapse rate was 9.33% (7/75). Significant side effects were experienced in 13 (13.98%) patients. Conclusions: In MDR-TB patients, regimen consisting of Ethionamide, PAS, Fluoroquinolone and Cycloserine with injection Kanamycin in initial 4.6 months appears to be safe and effective. MDR-TB can be cured successfully with appropriate combination chemotherapy for an adequate duration requiring a strategic approach. P3325 Peculiarities and results of treatment in XDR pulmonary tuberculosis (PTB) Sergey Skornyakov, Jeyg Motus, Elena Kildyusheva. Research Department, Urals Research Institute for Phthisiopulmonology, Ekaterinburg, Russian Federation Conclusions: First-line drugs were administered, adverse effects of drugs were identified, side effects were experienced in 13 (13.98%) patients. Objective: To evaluate the effectiveness and safety of the individual-tailored regimens of MDR-TB treatment based, in common case, on K/Cap, Ofl/Lev, Pt, STZ/Smx, KMx/SMx. Those patients were divided for at least 2 years. Later-generation fluoroquinolones - Lfx or Mfx. When resistance to Kmo we used Cm. Of oral bacteriostatic 2nd –line Pto, Cx, PAS. Of drug group 5 - AmClx/Clr. Ctr. Artificial pneumoperitoneum was applied in 26 patients, surgery was performed in 16. Results: Cure was achieved in 37 (63.7%) patients including those subjected to collapse therapy and/or surgery. Late results were followed in 50 cases. Culture remains negative in 32 (64%) of patients including 22 of 26 after collapse therapy and 14 of 16 after surgery. That was confirmed by multiple spum culture examination in terms of more than a year. Conclusion: The development of XDR PTB resulted from close household contact, sputum culture examination in terms of more than a year. P3326 Evaluation of characteristics and treatment results of patients treated as multidrug resistant tuberculosis (MDR-TB) Necati Yilmaz1, H. Arap2, Tulin Kuyucu3, Ates Baran1, Mualla Partal1, O. Kaya Koksalan, I. Aksay1, A. Kose1. 1Chest Disease, H.M. Sutcu, 2Chest Disease, H.M. Sutcu, 3Medical TB Epidemiology Laboratory, Institute for Medical Experimental Research (DETA), Istanbul University, Istanbul, Turkey. The development of XDR PTB resulted from close household contact, sputum culture examination in terms of more than a year. Conclusion: The development of XDR PTB resulted from close household contact, sputum culture examination in terms of more than a year. P3327 Use of linezolid in complex MDR-TB cases Yi-Wen Huang1, Hui-Chen Tsai1, Chin-Nien Chang2, Wen-Ta Yang2.1Pulmonary and Critical Care Unit, 2Surgery Department, Changhua Hospital, Taichung County, Taiwan; 1Tuberculosis Department, Taichung Hospital, Taichung, Taiwan. Introduction: The control of tuberculosis is facing challenges with the development of drug resistance as more drugs are used. Complex MDR-TB has recently emerged as a global public health issue. In Taiwan, there are around 600 new MDR-TB cases with 1.0% new TB cases, 6.2% treatment cases and 10.0% XDR-TB. Treating MDR-TB has become much more difficult, a new treatment regimen is mandatory. Aim: To evaluate the effectiveness and safety of the individual-tailored regimens (ITR) for new and re-treatment TB patients, based on total both express and liquid and solid media DST and accessibility to TB drugs of the all lines (the present Moscow TB Control Center setting). Background: MDR-TB treatment based, in common case, on K/Cap, O/Lev, Pt, Cs, PAS and, depend on the drug-resistance pattern (DRP), E and/or Z. But the adequate chemotherapy regimen (min 3-4 drugs) is often impossible due to the DRP and/or drugs intolerance. Aim: To make treatment outcome analysis and to determine the factors associated with unfavourable treatment results in cases with MDR-TB. Conclusions: This study shows high mortality rate in MDR-TB cases during two years after treatment initiation. XDR-TB is the strongest predictor of poor treatment outcomes. Previous TB treatment, weight loss and positive smears for acid-fast bacilli at the start of treatment are the other important factors associated with unfavourable treatment results. P33328 Treatment outcome and factors associated with unfavourable treatment results in cases with multidrug-resistant tuberculosis in Bulgaria for the period 2009-2010 Vladimir Milanov1, Mariya Zambirova1, Tonka Vareva1, Elizabeta Bachiyiska2, Antoniya Koletova1. 1National Tuberculosis Reference Laboratory (NTRL-B), National Center of Infectious and Parasitic Diseases (NCIPS), Sofia, Bulgaria; 2Manager, Specialized Hospital for Active Treatment of Lung Diseases, Gabrovo, Bulgaria. A retrospective study of all patients with MDR-TB in Bulgaria who started treatment for the period September 2009-March 2010 was performed. Aim: To make treatment outcome analysis and to determine the factors associated with unfavourable treatment results in cases with MDR-TB. Materials and methods: Medical records, recording and reporting forms for the MDR-TB cases included in treatment and TB registries of the NTRL-B were examined. Results: A total of 50 MDR-TB patients with mean age 45.8 years started treatment during the period. The male to female ratio was 2.3:1. Nineteen patients (38%) were new, and the other 31 cases were previously treated: 12 relapses (24%), after failure – 8 (16%), after default – 10 (20%). The median duration of recorded disease before treatment was 3.1 years (range, 0-13). None of all the patients tested for HIV had a positive result. Eight cases were found with XDR-TB during the treatment: 4 in 2010, and 4 – in 2011. Treatment was given for 18-24 months, including at least 12 months after culture conversion. Twenty four months after beginning of treatment, 24 patients (48%) were cured, 19 patients (38%) died, and one patient (2%) interrupted treatment. The cases with XDR-TB had higher mortality rate than the other MDR-TB cases (75% vs. 30.9%). Conclusion: This study shows high mortality rate in MDR-TB cases during two years after treatment initiation. XDR-TB is the strongest predictor of poor treatment outcomes. Previous TB treatment, weight loss and positive smears for acid-fast bacilli at the start of treatment are the other important factors associated with unfavourable treatment results. P3329 The individual-tailored treatment regimens for multidrug-resistant tuberculosis Tatiana Ivazhanskaya, Sergey Borisov, Natalia Litvinova, Yulia Garmash. Clinical Department, Moscow Research and Clinical Center for TB Control, Moscow, Russian Federation Background: MDR-TB treatment based, in common case, on K/Cap, Off/Lev, Pt, Cs, PAS and, depend on the drug-resistance pattern (DRP), E and/or Z. But the adequate chemotherapy regimen (min 3-4 drugs) is often impossible due to the DRP and/or drugs intolerance. Aim: To evaluate the effectiveness and safety of the individual-tailored regimens (ITR) for new and re-treatment TB patients, based on total both express and liquid and solid media DST and accessibility to TB drugs of the all lines (the present Moscow TB Control Center setting).
Methods: The prospective unblinded non-randomized one-centered study includes 66 pulmonary TB patients, 18-71 y.o., 40 male and 26 female. MDR-TB in 38 pts (14 new and 24 re-treatment), XDR-TB in 28 (4 and 24). The ITR included in all cases first/second-line TB drugs (accordingly DRP and drug tolerance) and linezolid (Lz), in 42 pts moxifloxacin (Mox) was used and azithromycin (Az)/clarithromycin (Cl), meropenem (Mrn)/imipenem + cilastatin must be added.

Results: The sputum smear conversion for MDR-TB pts - 97,4% (37/38, 36 - at the end of the 8th week) and for XDR-TB - 82,1% (23/28, 20 - at the end of the 16th week). The severe side-effects, attributed to Lz, were obtained in 5 pts (7,6%): peroneal neuropathy (3 pts, Lz excluded in 1), obstinate vomiting (1 pt, Lz excluded) and anemia (2 pts, Lz continued). The severe tachycardia, attributed to Az, were obtained in 1 pts (Az excluded).

Conclusion: The regimens, based on second-line TB-drugs (include Mox) and drugs from the WHO’s “fifth group” are well-tolerated and high effective in MDR- and XDR-TB, but require the timely drug susceptibility testing and the full set of the expensive drugs.

P3330

Study of isoniazid-resistant tuberculosis including outcomes in a high prevalence area in London

Guruprasad Bhat1, Geoffrey Packle2, 1Thoracic Medicine, Royal Free Hospital, London, United Kingdom; 2Respiratory Medicine, Newham General Hospital, London, United Kingdom

Background: Isoniazid resistance is the most common form of mono drug resistance in tuberculosis (TB). There has been an outbreak of isoniazid-resistant TB in North London. An outbreak committee has made recommendations.

Aim: To study isoniazid resistant TB patients attending Newham community chest clinic.

Methods: The notes of 31 isoniazid-resistant TB patients treated between 2004 to 2009 were studied. The reference laboratory gave confirmation of resistance.

Results: The age range was 17 to 73 (median 32). Male: female - 2.1:1. 72(3%) patients had the North London outbreak strain. Of the 31 patients (2065%) had pulmonary involvement, 11(35%) had extensive disease and 8(26%) were sputum smear positive. The extra-pulmonary presentations were lymphadenopathy, abscesses and miliary TB in 13(5%) patients. 10(3%) cases had risk factors for resistance - HIV, previous TB, alcohol, drug abuse and being in prison. 14(45%) patients had risk factors for non-adherence were given directly observed therapy. 17(55%) had treatment supervised weekly by community pharmacists. Patients received a 12month regime containing rifampicin, pyrazinamide and ethambutol, or a 9-month regime that also included moxifloxacin. 7(23%) patients had drug adverse effects. 30(97%) patients completed treatment successfully.

Conclusion: The majority of our patients were not associated with the outbreak. Treatment completion rates were satisfactory, and exceeded the target (90%) set by the TB outbreak control committee. There was no difference in treatment completion rates between the two regimes.

P3331

Drug resistance trends and patterns of mycobacterium tuberculosis isolates from pulmonary tuberculosis patients at a tertiary care hospital in Turkey

Etra Fıtran Yazar1, Birsan Pınar Yıldız1, Gülsah Guillouglu1, Sedat Altina1, Veyvel Yılmaz1, Derya Hırınç Cengen1, 1Pulmonology, Yedekale Chest Disease and Surgery Training and Research Hospital, Istanbul, Turkey; 2Clinical Microbiology and Infectious Disease, Yedekale Chest Disease and Surgery Training and Research Hospital, Istanbul, Turkey

Objective: To determine the proportions and patterns of resistance to commonly used tuberculosis (TB) drugs (isoniazid (INH), rifampicin (R), ethambutol (E) and streptomycin (S)) among pulmonary TB patients and assess potential risk factors for drug resistance.

Methodology: Strains were collected from 1584 sputum smear negative or positive pulmonary TB patients with culture positive in tertiary care hospital of Turkey. Specimens were cultured in liquid and solid media, and drug susceptibility tests were performed for first-line drugs including isoniazid, rifampicin, streptomycin, ethambutol and pyrazinamide.

Results: Drug susceptibility testing (DST) has been obtained from all samples 442 (27.9%) of 1584 isolates were resistant to at least one of five antibiotics tested. 380 (18.9%) isolates were resistant to isoniazid; 168 (10.6%) to streptomycin; 137 (8.6%) to ethambutol; 220 (13.9%) to rifampicin. 146 isolates (9.2%) were multidrug resistant. Results also showed 49% of patients were below the age of 40 years.

Conclusion: Regardless of previous treatment history, the high resistance observed in isoniazid, which is a first-line drug. Treating culture-positive TB patients based on DOTS together with strengthened control programs should therefore be considered in the management of TB patients.

P3332

How big is the problem with MDR-TB cases in Macedonia? A retrospective analysis of cases registered in the National MDR-TB Register in Macedonia from 2001 till 2011

Biljana Iljevska Poposka1, 1Thoracic Medicine, Royal Free Hospital, Skopje, Macedonia, The Former Yugoslav Republic of

Background: Multi-drug resistance tuberculosis (MDR-TB) is one of the most challenging problems in the National Strategy for control tuberculosis in Macedonia. The aim of this study was to present all patients with MDR-TB who were registered in the National MDR-TB Register in Macedonia from 2001 till 2011.

Material: 32 patients who were treated with individualized therapeutic regimes were enrolled in the study. Patients follow-up ended when an outcome was recorded or, in December 2011 for those still on treatment.

Results: 29 patients were with bacteriological confirmation, and 3 cases were suspected for MDR-TB. MDR-TB cases participate with 0,5-4,6% in the total resistant strain obtained from positive culture during the last six year. 30 patients (93,75%) had acquired resistance and only 2 patients (6,25%) had primary MDR resistance. Time to culture conversion was two months or less in the most of patients. The results of treatment outcome are: 9 patients were cured (28,12%), 13 patients (40,62%) died, 5 patients interrupted the treatment (15,62%) and 5 patients (15,62%) are still on treatment. No one patient had XDR-TB initially, but only one cases emerged XDR-TB during the treatment.

Conclusion: To improve management and treatment results of MDR-TB patients in Macedonia, we need more efforts in providing necessary medications, clinical conditions and treatment under direct control.

P3333

Comparison of moxifloxacin and ofloxacin in treatment of multidrug resistant pulmonary tuberculosis

Huseyin Arpaj1, Murat Yalcinso1, Emin Nilgun Ordu1, Tulin Kuyucu1, Sevinç Bilgen1, Isik Akyay1, Muallia Partal1, O. Kaya Koksal2, 1, Chest Disease, H.M. Stavros Church Chest Disease and Chest Surgery Training and Research Hospital, Istanbul, Turkey; 2Molecular TB Epidemiology Laboratory, Institute for Medical Experimental Research (DETAIE), Istanbul University, Istanbul, Turkey

Multidrug resistant tuberculosis (MDR-TB) is defined as pulmonary tuberculosis caused by isoniazid and rifampicin resistant. Fluoroquinolones must be involved in standard treatment regimen of MDR-TB. Effect of old and the new generation fluoroquinolones are compared on sputum conversion to treat MDR-TB. 63 MDR-TB patients included. Patients were divided into two groups according to usage of ofloxacin and moxifloxacin. 26 patients used moxifloxacin and 37 patients used ofloxacin. Mean age was 32.7±12.3 in moxifloxacin group and was 38.1±1.4 in ofloxacin group. Gender distribution(F/M) in moxifloxacin and ofloxacin group was 2/24, 14/23, respectively. All patients were HIV negative. Sputum conversion, culture conversion and treatment period were compared between two groups.

Table 1. Comparison of sputum conversion, culture conversion and treatment time with use of Moxifloxacin and Ofloxacin

</tbody>
</table>

Maun-Whitney U test 95% confidence interval.

There was no significant difference in sputum conversion and culture conversion and treatment time between two group (p>0.05).

Conclusion: In spite of the declared information that moxifloxacin is more efficient than ofloxacin in treatment of MDR-TB; in this study there was no significant difference in sputum conversion, culture conversion and treatment time. Although patient number is not a lot, this result can make us think that economic reasons are important when selecting the quinolone group for the treatment.

372. Paediatric bronchology

P3334

HRCT features do not predict the clinical course in children with protracted bacterial bronchitis

Konstantinos Dogrus1, Ethimia Alexopoulou1, Aggeliki Nicopoulou1, Michael Anthracopoulos1, Vasillis Grammeniatis1, Marios Papadopoulos1, Konstantinos Priftis1, 11th Department of Paediatrics, Attikon Hospital, Athens, Greece; 2Second Department of Radiology, Medical School, University of Athens, Attikon Hospital, Athens, Greece; 3Respiratory Unit, Department of Pediatrics, University Hospital, Rio - Patras, Greece

Background/Aim: Chronic wet cough suggests endobronchial infection. We
aimed to investigate the relation between the initial radiological findings and clinical course as well as the evolution of radiological findings in patients whose clinical findings persisted despite treatment.

Methods: We retrospectively reviewed 90 patients aged 0.6 to 16.4 years, with chronic endobronchial infection. In 25 (27.8%) patients follow-up HRCT scan was performed (1st group), 6-38 months apart (median 13 mo) based on clinical grounds, mainly on the durability of symptoms despite long courses of antibiotic treatment and physiotherapy; the remaining 65 (72.2%) had a remitting course and a second scan was not considered necessary (2nd group). Severity of involvement was assessed with Bhalla score and presence of bronchiectasis, per se.

Results: Radiological findings on the first HRCT did not differ between the 2 groups (Bhalla scores: 2.7±0.3 and 2.6±0.3, p=0.80; presence of bronchiectasis: 10 and 27; p=0.9 in the 1 and 2nd group, respectively). In 1st group 10 children had bronchiectasis in the 1st HRCT scan compared with 14 in the 2nd scan (p=0.10). Bhalla scores did not differ between the 1st and the 2nd CT scan (mean values:±sd: 2.7±0.2 and 2.9±0.4, respectively, p=0.60). There was no difference in bronchoscopic bronchoalveolar lavage findings.

Conclusion: Radiological findings do not suffice to predict the clinical course of protracted bacterial bronchitis. Although the literature suggests that radiological findings in such cases are reversible, this is not the rule. Apart from the intensity of treatment, there are probably other - yet unidentified- factors that determine the final outcome of the disease.

P3335 Bronchoscopic findings in children with primary ciliary dyskinesia: Most but not all bacterial bronchitis

Helen Burscest, Folke Brinkmann, Nicolaus Schwerk, Gesine Hansen.
Pediatric Pneumology, Medical University of Hannover, Germany

Chronic bacterial infections of the lower respiratory tract (LRTI) are a relevant problem in patients with primary ciliary dyskinesia (PCD) and therefore a continuous antibiotic treatment regime is often used. However, it remains unclear if all of these children indeed have relevant chronic LRTI and thus profit from antibiotics. Data on bronchoalveolar lavage fluid (BALF) with cytological and microbiological analysis in PCD patients are still lacking.

In a retrospective study BALF findings of 19 children with PCD were analyzed and the clinical course of patients treated with antibiotics has been investigated. Median age of the patients at the time of bronchoscopy was 10 year (range 4-17 years). Sputum inversion was seen in 10 patients. The main symptoms leading to bronchoscopy were chronic cough, recurrent bronchitis or pneumonia. Lung function was performed in 17 patients before bronchoscopy. FEV1 ranged between 62-114% (median 80%). In the BALF of 12 patients significant bacterial counts (>10^5 CFU/l) have been detected. The most frequent isolated species was Haemophilus influenzae (n=10) and Streptococcus pneumoniae (n=3) were the most frequent isolated species. In all of the cases a BALF-cytology was performed a granulocytic inflammation was detected. In further analysis these findings correlated with a worse lung function before bronchoscopy (FEV1 <80%) and a significant improvement of lung function under antibiotic therapy.

Bronchoscopy is a safe diagnostic method in children with PCD to distinguish between patients with LRTI from these without infections. This has an extensive clinical relevance because we could show that patients with a proven infection profit from an antibiotic therapy.

Conclusions: FB is valuable in the assessment of patients with extrathoracic tracheomalacia since HCTs cannot be recommended as a safe approach (radiation of the thyroid). However, CT scans provide a more accurate estimation of extrathoracic tracheomalacia as it is not influenced by the effects of general anestheis.

P3337 Bronchoscopic findings and interventions in patients with long-term tracheostomy

Andreas Pfleger, Ernst Eber. Department of Paediatrics and Adolescence Medicine, Medical University of Graz, Austria

Aims: To describe airway abnormalities identified by flexible bronchoscopy (FB) in patients with long-term tracheostomy (LTT) and interventions as a consequence of FB findings.

Methods: Records of patients with LTT followed from Jan 08 to Dec 11 were reviewed. FBs were performed as routine surveillance FBs, additional scheduled FBs, or because of disease or tracheostomy related complications. Resulting interventions (ventilator -, cannula -, or medication changes, and surgical interventions) and extra caregiver trainings were recorded.

Results: In 52 patients (20 f, 32 m) 210 FBs were performed. 30 patients had LTT for long-term ventilation, 22 as a bypass for upper airway obstruction. Median age was 4.5 yrs (0.1-32.7). In 97 instances FBs were performed transanula, in 93 via the cannula, and in 20 via both routes. In 13 instances (6%) complications led to FBs; in 23 (11%) additional scheduled FBs, and in 174 (83%) surveillance FBs were performed. The mean frequency of FBs was 1.1/patient and year (0.25-2.7). The most common findings were airway malacia in 38%, clinically relevant granulation tissue in the suprastomal region in 8%, at the end of the cannula in 7%, and in other regions in 13%. Cannula changes were performed in 21%, ventilator changes in 4%, and surgical interventions in 3%. 12% of the caregivers received extra training on correct suction techniques.

Conclusions: In this series of patients with LTT we found a high incidence of airway abnormalities. As FB findings resulted in interventions in a quarter of our patients we recommend that FB should be performed at least once a year. Patients with significant airway pathology, however, may benefit from more frequent endoscopic evaluations.

P3338 Nasal nitric oxide measurement using continuous aspiration by hand-held device discriminates patients with primary ciliary dyskinesia from healthy subjects

Silvia Monfell1, Kjell Alving2, Sara De Stefano1, Laída Lisa Di Micco1, Angela Di Giorgio1, Francesca Santamaria1,1 Department of Paediatrics, Federico II University, Naples, Italy; 1 Department of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden

Background: Low nasal nitric oxide (nNO) has been reported in subjects with primary ciliary dyskinesia (PCD) and healthy subjects. No study compared nNO measured using continuous nasal aspiration in PCD and healthy subjects by a hand-held device.

Aim: To find out whether nNO measured by a hand-held analyser using the continuous aspiration method discriminates PCD from healthy subjects.

Methods: Twenty-three PCD patients (median age, 15.8 yrs; range, 4.6-32.8) and 23 healthy controls (age, 15.7 yrs; range, 4.3-32.1) measured nNO with a hand-held electrochemical device (NIOX MINO®, Aerocrine AB) during oral breathing through a mouthpiece.

Results: Median (range) nNO values were 12 (5-62) and 506 (215-777) ppb in PCD and controls, respectively (p<0.001). Sensitivity and specificity at different cut-off points for nNO are reported in the Table.

Conclusions: Measurement of nNO by the hand-held device using the continuous aspiration method has an excellent sensitivity and specificity in distinguishing PCD from healthy subjects. Its wider use might result in an increased number of detected individuals suspected to have PCD.

---

**Cut-off points (ppb)** | **Sensitivity (%)** | **Specificity (%)**
---|---|---
36 | 78 | 100
44 | 83 | 100
51 | 87 | 100
58 | 91 | 100
138 | 100 | 100

Conclusion: Measurement of nNO by the hand-held device using the continuous aspiration method has an excellent sensitivity and specificity in distinguishing PCD from healthy subjects. Its wider use might result in an increased number of detected individuals suspected to have PCD.
The effect of air pollution can play a role in the development and/or the exacerbations of chronic lower airway diseases (CLADs) in children.

The aim of this study is to investigate the association between the major component of inhalable particulate matter (PM10), black carbon, contained in lower airway macrophages (AMs) of children with CLADs and variables that may affect individual exposure.

We studied 24 children undergoing FOB for CLADs. For each child the area of the black material (BM) in AMs, sampled by bronchoalveolar lavage, was determined by analysis of digitized light microscopic images of random AMs; median carbon content of AMs was obtained calculating the area (μm²) of BM.

Children had a median age of 6 years (range 2.9-16.6); they were affected by current lower airway infection in 12 cases (PCD in 2), by asthma in 7, by chronic cough in 3 and by laryngospasm in 2 cases. There was a correlation between the median area of BM and air PM10 levels during the week before FOB (ρ<0.001).

No significant correlation was found between FEVI measured in 14 children. No significant difference in black area size in AMs was detected comparing children based on sex, underlying disease or household. Preschool-children had a larger median black area in AMs than school-children, even if the difference was not significant (0.071 μm² vs 0.35 μm², p=0.35).

In conclusion the median area of BM in AMs is correlated to air pollution exposure in children affected by CLADs, but it seems not to correlate to underlying diseases, age, sex and FEVI. A larger study group is necessary to better define the correlation of PM10 and CLADs in children.

Identification of KCNRG, a bronchial autoantigen, in a children with IPEX syndrome

Véronique Houdouin1, Didier Chevenne2, Cecile Raverdy3, Souhir Zaoui2, Bénédicte Neven1, Nadja Tubiana1, Mohammad Alimohammadi1, Jean Claude Carrel1, 1Department of Pediatric Pulmonology, Hôpital Robert Debré, Paris, France; 2Laboratoire de Recherches Immunologiques et Hormonologiques, Hôpital Robert Debré, Paris, France; 3Department of Pediatric Endocrinology, Hôpital Robert Debré, Paris, France; 4Department of Pediatric Immunology and Rheumatology, Hôpital Necker-Enfants Malades, Paris, France; 5Department of Medical Sciences, University Hospital, Uppsala, Sweden

IPEX syndrome is a rare disorder of immune regulation caused by mutations in the FOXP3 gene, which is required for the suppressive function of naturally arising CD4+ CD25+ regulatory T cells. It is associated with the presence of common autoantibodies associated with autoimmune disorders.

We report an infant, who manifested at first week after birth a type 1 diabetes mellitus and eczema. IPEX syndrome was confirmed by proved V408M mutation in the FOXP3 gene. At one month old he developed wheezing, cough, respiratory distress without infection. Despite treatment with salbutamol and budesonide nebulized, he was still symptomatic. High-resolution tomography scan showed hyperinflation, trapping, and ground-glass opacities. Analysis of bronchoalveolar lavage showed 1 350 000 cells/ml, with 65% alveolar macrophages without infection. Autoantibodies to KCNRG were present in serum at one month and still persist at nine months. Treatment with mycophenolate mofetil was started because of combination of severe diarrhea, persistent respiratory symptoms with an optic neuromulbeulized corticotherapy. One month after the beginning of immunosuppressive therapy the corticotherapy was reduced.

KCNRG, a potassium channel regulating protein expressed in bronchial epithelial cells. The presence of this antibody was first described in the polyendocrine syndrome type 1. The presence of this antibody in another autoimmune syndrome confirms the fact that KCNRG is a major bronchial autoantigen.

The recognition of pulmonary autoimmune phenomenon is important because the airways bronchiolitis in this case respond well to immunosuppression.
P3344 Pulmonary alveolar proteinosis due to a novel mutation in CSF2RA

Pulmonary alveolar proteinosis (PAP) is a rare disease characterized by pulmonary accumulation of surfactant protein. Congenital forms can result from mutations in granulocyte macrophage-colony stimulating factor (GM-CSF) receptor genes, leading to impaired differentiation of alveolar macrophages. We present the case of a 3-yr-old girl born to consanguineous parents presenting with progressive dyspnoea, cough and failure to thrive. Her arterial oxygen saturation was 80% while breathing ambient air and dropped to 50% during agitation. Chest radiographs showed bilateral opacities, and high-resolution computed tomography (CT) revealed interlobular densification with typical “crazy paving” pattern. Due to a milky, opaque appearance of bronchiolalveolar lavage fluid (BALF) and a strongly PAS-positive staining in histology, the diagnosis of PAP was suspected. After whole lung lavage (WLL), significant clinical improvement occurred. Oxygen saturation increased to >90% and follow-up chest radiographs showed partial clearing. Currently, the patient is undergoing WLL every 4-6 weeks. After 10 months of treatment, she has gained 9 kg of weight, visits kindergarten, and has a good quality of life. The patient’s serum- and BALF- GM-CSF concentrations were significantly elevated. Functional analyses of neutrophils and monocytes showed significantly reduced GM-CSF responsiveness. Sequencing revealed a novel mutation in exon 2 of the GM-CSF receptor alpha chain gene (CSF2RA). Regarding long-term treatment, she has gained 9 kg of weight, visits kindergarten, and has a good quality of life.

P3345 An unusual development in a girl with recurrent croup – Case report

Diana Reppucci, Jaerg Hammer, Daniel Trachsel. Pulmonology and Intensive Care, University Children’s Hospital, Basel, Switzerland.

Background: Recurrent croup is common in childhood. Rare congenital and acquired pathologies may mimic viral croup.

Case: A girl with previously suspected laryngomalacia was admitted with a first episode of croup at 8 months of age, only partially responding to inhaled adrenalin. Laryngoscopically, the dorsal tracheal mucosa bulged into the subglottic area causing a 50% narrowing of the airway, and a CT showed a soft tissue mass, but not suggestive of a hemangioma that was not suggestive of a hemangioma. In view of the inconspicuous appearance, the rapid recovery from the croup, the young age, and the location it was decided not to biopsy the lesion. After an uneventful observational period with decreasing symptoms the girl presented again at 4 years of age with a typical OSAS. With respect to the personal history, a bronchoscopy was made that confirmed significant adenotonsillar hypertrophy, but also revealed marked growth of the subglottic mass. A transtracheal biopsy was performed, and a plexiform neurofibroma was found. Due to the infiltrative growth of the neurofibroma, extensive surgery including partial tracheal resection became necessary. Eventually, the diagnosis of neurofibromatosis (NF) type 1 was made.

Conclusion: Neurofibromata in NF1 may occur in the laryngeal area, presenting early in infancy mimicking common croup.

P3346 Type IV laryngotracheoesophageal cleft: A case of success

Manuel Ferreira-Magalhães1, Inês Azevedo1, Susana Passaer2, Jorge Spratley1, Jorge Correia-Pinto3, Venceslau Hespanhol1, Jose Mateu4. 1Pediastric Department, Centro Hospitalar S. João, Porto, Portugal; 2Pneumology Department, Centro Hospitalar S. João, Porto, Portugal; 3Otorhinolaryngology Department, Centro Hospitalar S. João, Porto, Portugal; 4Pulmonology Department, Centro Hospitalar S. João, Porto, Portugal; 5Pulmonology Department, Centro Hospitalar S. João, Porto, Portugal; 6Pulmonology Department, Hospital Virgen del Rocío, Seville, Spain.

Introduction: Laryngotracheoesophageal clefts (LITEC) are extremely rare congenital anomalies. Mortality and morbidity is high due to difficulty in assure newborn stability, surgical approach and associated comorbidities.

Clinical case: A 12 days male newborn, without relevant prenatal history, was admitted in NICU with feeding problems and suspected tracheoesophageal fistula. Pulmonary parenchma was preserved. After initiation of ventilatory support he developed severe acute respiratory distress. Diagnosis of a type IV LITEC, extended to carina, was made by emergent rigid laryngoscopy with immediate selective intubation of right bronchus. Multidisciplinary surgical correction was performed 48 hours after, with international expertise collaboration. Tracheoesophageal separation was made by median sternotomy, requiring cardiopulmonary bypass. Few days after surgery the newborn underwent gastrotomy, fundoplication and tracheostomy because of severe tracheomalacia causing difficulties in ensure noninvasive ventilation. At 3 months a small bleeding granuloma near carina was coagulated with YAG laser. Consecutive endoscopic evaluations showed a partial LITEC dehiscence. Successful transversal surgical correction and definitive tracheostomy decannulation was made at 10 months. By 20 months he had a normal growth and development, with little hoarseness, sporadic cough and almost full oral feeding.

Conclusion: Type IV LITEC is the rarest and severest form of laryngeal clefts. This was an atypical presentation without any severe respiratory distress in the first hours of life and any prenatal or pulmonary findings. These aspects and the prompt expertise intervention assured an excellent outcome without major comorbidities.

P3347 Whole lung lavage with PAP in a 12 year old female using ET tube under GA

Menoukhanum Thekkinkattil1, Menon A.R. Narendra2. 1Pulmonology, Sri Ramakrishna Hospital, Combatorame, Tambaladin, India; 2Cardiac Anaesthesia, Sri Ramakrishna Hospital, Combatorame, India.

Alveolar proteinosis is a rare disease in children as the rare cause of severe respiratory failure. In 2002 report at least 410 cases were reported world-wide. The estimated annual incidence is 0.36 and the prevalence 3.76 cases/million population. In neonates the mortality is 100% Lung transplantation improves survival. In adults, PAP is mainly seen in males at the age of 40-55. In female children alveolar proteinosis is rare. PAP is characterized by intra-alveolar accumulation of proteinaceous material. It is not associated with inflammation and lung architecture is preserved. Case study: A 12 year old girl was admitted with breathlessness, cough, with two weeks duration. She was referred from a private hospital in Salem with X-ray and CT features of PAP. alpha. She was taken up for medical traumatology. CT scan repeated showed features of alveolar proteinosis. After stabilizing her with intubation and antibiotics she was taken up for whole lung lavage on the right side. Since the double lumen catheter of 26 size could not permit insertion of bronchoscope, through 6.5 ET tube under general anesthesia Right lung was lavaged with about 1700 ml of normal saline. The catheter tolerated the procedure well. She was kept in the ventilator for one day and exubated. The saturation went up to 90%. The left lung was washed after one week. The saturation and clinical signs and symptoms improved. She is again admitted on 22/12/2011 for the next lavage session. The treatment for alveolar proteinosis is whole lung lavage in adults. We report the case in a young girl (rarely reported)treated with whole lung lavage using ET tube (rarely tried).

P3348 Endoscopic laser-assisted management of pediatric airway lesions: A single institution experience

Juan L. Antón-Pacheco, Carmen Luna, Gloria García-Hernández, Francisco Gómez-Acebo, Miguel Á. Villafañe. Pediatric Airway Unit & Division of Pediatric Surgery, Hospital Universitario 12 de Octubre, Madrid, Spain.

Background: Laser endoscopic surgery is increasingly being used in the treatment of pediatric airway disorders. It is a safe and effective technique when used by experienced surgeons.

Aims: We evaluated the outcomes of laser therapy in a selected group of patients with congenital and acquired airway lesions.

Methods: The medical charts of patients who were treated for airway disorders with diode laser between January 2008 and December 2011 at a tertiary care children’s hospital were reviewed. All the procedures were performed endoscopically using rigid or flexible instruments. Data included relevant history and physical examination, diagnostic work-up, number of laser procedures, complications, and outcomes.

Results: 37 patients who had laser surgery were identified.13 girls and 24 boys with a mean age of 20 months (range, 3 days-12 years). 47 laser surgeries were performed, representing 1.2 procedures per patient. Indications for laser therapy were: Laryngomalacia 11 cases (29%), granulation tissue 8 (21%), vocal cord paralysis 7 (19%), laryngeal stenosis 5 (13%), vascular-lymphatic malformation 3 (8%), subglottic cyst 1 (2.7%), congenital tracheal stenosis 1, and papillomatoasis 1 case. In 7 patients (19%), other concomitant endoscopic procedures were performed. Two complications were identified: Postlaser bleeding and aspiration in one patient, and subcutaneous emphysema and pneumothorax in another patient. In 89% of patients, partial or complete clinical improvement occurred after laser therapy.

Conclusions: Endoscopic laser surgery is a safe and effective technique when treating airway disorders in children. It is a good alternative to open surgery in selected patients either used alone or in combination with other endoscopic procedures.

P3349 Endobronchial blockers: A tool in the interventional flexible bronchoscopy in children

Bojta Osuna, Jose Antonio Pela, Jose Antonio Gil, Joan Figuerola. Pediatrics, Son Espases University Hospital, Palma Mallorca, Balearic Island, Spain.

Introduction: Techniques for selective lung ventilation usually involves the use of large devices or tools not designed for the airway. Placement in children is difficult and a variety of complications have been reported.

Objectives: To evaluate the efficacy and safety in selective ventilation and selective lobar blockade of a recently developed tool, the Arndt endobronchial blocker.

Methods: A prospective study was performed analyzing all children who underwent a bronchial blockade between 2008 and 2011. We use the 5 Fr Arndt blocker
and a pediatric fiberoptic bronchoscope (2.8mm). The following variables were recorded: age, indication, location, duration and number of insertion attempts, other techniques performed, complications, and effectiveness assessed by the surgeon or pediatric intensivist.

**Results:** Blocker placement was successful in 17 of 18 patients. Median (range) age was 37 (14-78) months. 9 cases = 2 years old. The main indications were thoracic surgery, pulmonary bleeding and persistent bronchopulmonary fistula. Number of attempts needed was 1 to 4 (median 1). Average time for positioning the blocker was 7.5 minutes. In 3 procedures, we injected saline (Tissucol) through the 2Fr central lumen of the blocker. The most frequent complication encountered was dislodgement toward main bronchi or trachea in 5 cases, related to turning the patient into a lateral position. They were managed deflating the cuff and placing the blocker again. Average satisfaction after the procedure (assessed from 1 to 5) was 4.7.

**Conclusion:** Arndt endobronchial blockers are useful. Our initial experience has shown that placement with a fiberoptic bronchoscope is easy, acceptably rapid and effective.

**P3350**
The use of transbronchial biopsies in pediatric lung diseases in a tertiary care hospital in Bogota, Colombia
Patricia Pumarega, Fernando Polo, Jorge Carillo, Alvaro Morales. Pediatrics. Hospital Universitario San Ignacio, Bogota, Colombia Pathology, Hospital Universitario San José, Bogota, Colombia Epidemiology, Hospital Universitario San Ignacio, Bogota, Colombia

A total of 12 Transbronchial Biopsies (TBB) were performed in pediatric patients during the last year at the Hospital Universitario San Ignacio, using an adult small bronchoscope (5.5 mm outer diameter Olympus).

**Results:** In 9 patients adequate lung tissue for histological diagnosis was obtained. In two patients with HIV infection, respiratory symptoms and chest x-ray abnormalities, pathogens were identified and successfully treated positive ZN (13 y.o. female) and P. Jiroveci (12 y.o. female). Several patients presented with dyspnea and mosaic patterns in the chest x-ray: in three cases the information was useful, and all of them improved after treatment. 12 y.o. male in whom lung metastasis were found (successful chemotherapy initiated), 14 y.o. male in whom capillaritis was found (improvement after treatment). In an 8 y.o. male insufficient sample was reported. In patients with malignancies, useful information was provided: in patients with lymphomas and lung infiltrates CMV was identified and treated (10 y.o. male) and P. Jiroveci was found in two patients with leukemia. The only complications were a small pneumothorax that did not require intervention and hypotension in a septic HIV patient that was sent to Intensive Care for management.

**Conclusion:** The Transbronchial biopsy is an effective and safe procedure to obtain lung tissue for histologic diagnosis in a variety of conditions such as tumors, infections or pulmonary infiltrates and that can be considered as first–line diagnostic procedure in pediatric patients.

A pilot study for benign central airway stenosis: Local injection of triamcinolone acetonide through an endobronchial blocker
Yu Chen, Shiyue Li. Respiratory Medicine, The First Affiliated Hospital of Guangzhou Medical College, Guangzhou, China

**Objectives:** To evaluate the efficacy and security of local injection of Triamcinolone acetonide (TA) for benign central airway stenosis (BAS).

**Methods:** Forty intractable BAS patients were selected and averagely divided into treatment group and control group. Local injection of TA was used to cover entire stenosis lesions. Interventional procedures were combined to manage complicated airway stenosis. After a 6 months follow-up, compared two groups with airway diameter, stricture rate, dyspnea score, and clinical stabilizations before and after the treatment.

**Results:** No statistically significant differences in the two groups. A 6 months follow-up, 16 patients remain stable after treatment, besides 4 patients appear restenosis in treatment group, compare with Control group 20 cases restenosis. Restenosis interphase time and clinical stabilization time was markedly increased. No local injections related complications was recorded.

**Conclusion:** Local injections of TA therapy combined with traditional interventional techniques for BAS has good curative effect. It shows advantages in long-term efficacy, few side-effects, and good safety.

Role of single port medical pleuroscopy using optical biopsy forces in diagnosing malignant pleural effusion
Debabountain Bhattacharyya, M.S. Barthwal1, C.D.S Katoch1, Anand Arora2.
1Respiratory Medicine, Military Hospital (CardioThoracic Centre), Pune, Maharashtra, India, 2Pathology, Military Hospital (CardioThoracic Centre), Pune, Maharashtra, India

**Introduction:** Medical pleuroscopy is useful in early confirmation of malignant pleural effusion. Optical biopsy forces help in getting adequate number and amount of specimen from a single port giving a small incision.

**Aims and objectives:** To assess the efficacy and safety of single port medical pleuroscopy using optical biopsy forces in diagnosing malignant pleural effusion.

**Methods:** This is a retrospective study of all patients who had been histopathologically proved to have malignant pleural effusion by single port diagnostic medical pleuroscopy using optical biopsy forces between January 2009 and January 2012 in a tertiary care hospital in India.

**Results:** 39 patients (25 males and 14 females) underwent medical pleuroscopy during the period of study with a possible diagnosis of malignant pleural effusion. Mean age of patients was 4 years (ranging 70-82). 37 patients (94.9%) were confirmed to have malignancy by medical pleuroscopic biopsy. Adenocarcinoma was the commonest malignancy – 15 (40.5%), followed by squamous cell carcinoma – 11 (29.7%), small cell carcinoma – 5 (13.5%), poorly differentiated carcinoma – 3 (8.1%), malignant mesothelioma – 2 (5.4%), and non-Hodgkin’s lymphoma (2.7%). Reports were inconclusive in two patients. VATS biopsy subsequently confirmed them to be adenocarcinoma and mesothelioma respectively. Complications encountered during the perioperative period included: superficial wound infection in one (2.5%), and air leaks more than 7 days in two (5.1%) cases.

**Conclusions:** Single port medical pleuroscopy using optical biopsy forces has a high diagnostic rate in malignant pleural effusion. The procedure is also safe.

Medical thoracoscopy performed using FOB & single rigid port under conscious sedation
Vijay Kumar Channammehthy, Aparna Mazumreddy, Anamika, Abhijeet Ingle, Amitha Reddyreddy. Department of Pulmonary, Critical Care & Sleep Medicine, Yashoda Super Speciality Hospitals, Hyderabad, AP, India

**Background & Objectives:** Pleural effusion can remain undiagnosed following thoracentesis in a significant number of cases. We evaluated our own technique for performing thoracoscopic under conscious sedation using a 7mm rigid port and a flexible fiber optic bronchoscope for the diagnosis of patients with unilateral pleural effusion. We evaluated cost of care by comparing the same procedure with rigid thoracoscopy.

**Methods:** Twenty four patients with unilateral pleural effusion who underwent thoracoscopy under conscious sedation using a 7mm rigid port and a flexible fiber optic bronchoscope during April 2011 to Feb 2012 were retrospectively studied. Two patients who underwent rigid thoracoscopy for evaluation of undiagnosed effusion were taken to consideration for cost analysis.

**Results:** Thoracoscopy done under conscious sedation using FOB and a 7mm port is a safe procedure to perform in the diagnosis of pleural effusion in all cases. The visualization of the pleura and lung using this instrumentation was adequate for to acquire an impression. A forces biopsy of the pleura could therefore be easily and effectively performed. Cost analysis does reflect 30% decrease in cost to patient.

**Conclusion:** This technique is considered to have clinical utility as a diagnostic tool for evaluation of pleural effusion. This method is safe and effective. As procedure was performed with FOB, it is user friendly for a pulmonologist and inexpensive to the patient.

Usefulness of semiflexible thoracoscopy under local anesthesia for patients with unknown pleural effusion

Yuichi Yamada, Yuji Hamada, Ken Yamada, Hirotaka Nishikiori, Koji Kuronuma, Mitsuo Otsuka, Hiroki Takahashi. Third Department of Internal Medicine, Sapporo Medical University School of Medicine, Sapporo, Japan

Background: Pleural effusion may arise from a wide range of diseases. However, it is difficult to make a diagnosis by thoracocentesis or needle biopsy. Recently, semiflexible thoracoscopy has been performed under local anesthesia for diagnosis or treatment of pleural diseases.

Objectives: To determine the benefit and safety of the thoracoscopy for the diagnosis of unknown pleural effusion or the treatment of pleural diseases.

Methods: Between April 2001 and June 2011, we performed the thoracoscopy in 39 patients (31 men and 8 women) who could not be diagnosed by cytotologic and bacteriologic examinations of pleural fluid by thoracocentesis. We used a semiflexible thoracoscope (LFT 240, Olympus Medical Systems Co., Tokyo, Japan) for the observations of pleural cavity, and obtained pleural biopsies from abnormal areas of parietal pleura.

Results: We underwent semiflexible thoracoscopy in 29 patients for diagnosis of pleural diseases and 22 cases were provided the pathological diagnosis (6 pleuritis carcinomatosa, 2 malignant mesothelioma, 1 synovial sarcoma, 7 effuyma, 3 tuberculosis pleural effusion, 2 rheumatoid arthritis and 1 sarcoidosis). In addition, semiflexible thoracoscopy was performed for the treatment in 10 cases with acute or chronic empyema for the purpose of detachment of fibrin, destruction and removal of the septum.

Conclusions: Semiflexible thoracoscopy under local anesthesia can be safely performed by pulmonary physicians. It is considered an easy and useful examination for the diagnosis of pleural diseases.

Use and comparison of a fiber optic bronchoscope as an alternative to a purpose built thoracoscope

Chatura Wiratanshe, Duminda Yasaratne, Prasanna Wijerathene, Dushantha Madedega. Respiratory Medicine, Teaching Hospital, Kandy, Central Province, Sri Lanka

Background: Mechanical failure of (fiber optic thoroscope) FOT at our unit, which was an established investigation in pleural disease led to a search for an alternative.

Objective: To demonstrate the use of a fiber optic bronchoscope (FOB) for local anesthesia thoracoscopy and to compare it with a purpose build thoracoscope.

Methodology: The new procedure was similar to standard local anesthetic thoracoscopy with the difference being an 8mm internal diameter endotracheal tube used as the trochar through which FOB was inserted. 22 patients with undiagnosed unilateral plural effusion underwent the procedure from July to November 2011. Their results were compared to those obtained using purpose built FOT in 22 consecutive patients from January 2011.

Results: Modified FOB thoracoscopy was successful in 77% of patients while purpose built FOT was successful in 86%. All failures were attributed to lungs not collapsing due to adhesions. Time taken to empty fluid from the pleural cavity and total procedure times were longer with FOB. The biopsy size using FOB was significantly smaller. Histological diagnostic yield was matched in both groups. Histological evidence of TB was obtained 22%(5) in FOB group and 27%(6) in the FOT group. A universal complication in both groups was post procedure pain which was relieved with use of simple analgesics. Other procedure related complications were not encountered in both groups.

Conclusion: A modified procedure with FOB can be used safely with a reasonable success rate to investigate pleural disease by experienced operators although there are limitations.

Talc pleurodesis in malignant pleural effusions: A 5-year experience

Joana Filipe Cruz1, Daniela Alves1, Cecilia Pacheco1, Manuel Vaz2, Lourdes Iglesias1, Adriana Magalhães1. 1Pneumology, Hospital de Braga, Braga, Portugal; 2Pneumology, Hospital de Sao Joao, Porto, Portugal

Introduction: Talc pleurodesis is an excellent therapeutic option in patients with malignant pleural effusions (MPE), however the best method to perform it remains a matter of debate.

Objectives: To compare two different methods of talc instillation in terms of clinical efficacy and safety in patients with MPE.

Methods: Retrospective study of patients with MPE submitted to talc pleurodesis between 2006 and 2010. Two different techniques were compared: thoracoscopic talc poudrage (TP) and talc slurry through the chest tube (TS).

Results: A total of 93 patients were evaluated (47 TP group, 46 TS group). Clinical demographics and primary malignancies were similar in both groups. The overall complication rate was 54.8%, without significant difference between the two groups. Most frequent complications were thoracic pain (32,3%), fever (24,7%), subcutaneous emphysema (7,5%) and prolonged drainage (5,4%). No serious complication or death was registered. The average length of hospital stay was 8 days in the TP group vs 19,7 days in the TS group (p=0,001). The average chest drain and suction duration was 5,6 days in the TP group vs 19,7 days in the TS group (p=0,001). Among patients alive at 30 days, efficacy in local control of MPE was 82,5% in the TP group (33/40) vs 72,1% in the TS group (31/43) (p=0,259). There was no difference in mortality between the two groups (p=0,336).

Conclusion: Talc pleurodesis was a safe and effective palliative treatment for patients with MPEs. Patients who underwent thoracoscopic talc poudrage had a significant shorter length of hospital stay and chest drainage duration. There was no difference regarding complications, efficacy and mortality.

Performing biopsies during semirigid thoracoscopy is often a difficult and time-consuming task due to the low mechanical power when using dedicated flexible forceps. Biopsies by cryoprobe could overcome these limitations. The purpose of this study was to compare the feasibility, size and quality of the specimens obtained by cryobiopsy with specimens obtained by flexible forceps.

Fifteen patients with pleural effusion of unknown origin that underwent semirigid thoracoscopy were included. Biopsies were obtained using a flexible autoclavable cryoprobe 20416-032 (ERBE, Germany) 2,4 mm in diameter or flexible FB-55CD-1 Olympus forceps.

The change of complication rate in chemical pleurodesis after replacement of
talc preparation from small to large particle size – A longitudinal cohort study
Hoi Nam Tse1, Ka Yan Wai1, King Ying Wong2, Kwok Sang Yee2, Lai
Yun Ng2
1Medical Department, Kwong Wah Hospital, Hong Kong, Hong Kong; 2Department of TB and Chest Unit, Wong Tai Sin Hospital, Hong Kong, Hong Kong
Background: Talc particle size is an important determining factor for complication
in talc pleurodesis.
Aims: To investigate any change in complication rate for talc pleurodesis after
replacement of talc preparation from small to large particle size.
Methods: It is a longitudinal cohort study conducted in Kwong Wah Hospital,
Hong Kong. Talc preparation was changed from small (mean diameter <10μm) to
large particle size (Steritalc®; mean size: 31.3μm) since 1st Jan,10. Patients who
received new talc preparation (1st Jan 10 to 31st Dec,11) were compared to those
received old talc preparation (1st Jan07 to 31st Dec09). The safety profile and
efficacy of pleurodesis were compared between the 2 groups.
Results: 141 patients were recruited. Since the change of talc preparation from
small to large particle size, ARDS was totally eliminated. Post-pleurodesis fever
was significantly reduced from 30.7 to 9.4%, resulting in a significant drop in
antibiotic use.
Table 1. Complications rate in chemical pleurodesis since the change of talc preparation from
small to large particle size.

<table>
<thead>
<tr>
<th></th>
<th>Small particle size</th>
<th>Large particle size</th>

Moreover, the efficacy of chemical pleurodesis was not jeopardized.

Conclusions: There was a significant reduction in complication rates in chemical
pleurodesis after replacement of the talc preparation from small to large particle size.

P3360
Chest drain safety checklist
Burhan Khan, Hamid Amrty Raud. Department of Respiratory Medicine, Darent Valley Hospital, Dartford, Kent, United Kingdom
Background: Intercostal chest drains are amongst the most invasive procedure a
medic will undertake; not infrequently by a junior trainee. Adverse events un-
fortunately are well reported with chest drains, the UK’s National Patient Safety
Agency (NPSA) reported1, little is known about the learning curve attributed to the procedure.
Aim: To devise a chest drain proforma to improve patient safety and prevent
adverse and never events.
Methodology: We used an iterative model building upon the WHO surgical safety
checklist. Results: We devised and piloted a “Chest drain safety check list” utilising a
2-person stepwise approach.

Conclusion: This checklist represents a process that should lead to a systematic
and safe approach to inserting chest drains.

P3361
The need for including pleural procedure sessions in respiratory physicians’
job planning in the United Kingdom
Rahul Makherje1, Shiv Shukla2, Vikas Punnumiya1, Milan Bhattacharya2, Richard Steyn3
1Department of Respiratory Medicine & Physiology, Heart of
England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 2Department of Thoracic Surgery, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 3Department of Respiratory Medicine, Milton Keynes NHS Foundation Trust, Milton Keynes, United Kingdom
Background: In 2008, the UK National Patient Safety Agency (NPSA) issued an
alert for risks associated with insertion of intercostal chest drains (ICD) and high-
lighted issues related to insertion by non-specialists and by inadequately trained or
supervised junior doctors.
Methods: In an acute hospital (catchment population about 280000), an education
campaign targeted at emergency medicine on-call doctors was started in August
2008 questioning the need for out-of-hours insertion of ICD. Three physician-led
elective sessions/week were introduced in November 2008; trainees were directly
supervised by experienced physicians (consultants); all unavoidable out-of-hours
ICD procedures were reviewed by respiratory consultants.
Results: Fifty-two patients underwent ICD insertion in 5 months: 18 (34.62%)
for pneumothorax; 34 (65.38%) for effusions. Of the 34 with pleural effusions, 31
(91.17%) had radiological imaging pre-procedure. The 3 (8.82%) who had ICDs
without prior radiological imaging were due to suspected empyema thoracis in
the emergency department. Only 2 ICDs (3.84%) - both for pneumothoraces -
were complicated by infection of the pleural space. No other major complications
occurred in the remaining 50 patients. Initial ICD was displaced in 8 patients
needing further ICD insertions (15.38%), confirming a significant improvement
with respect to the local average.
Conclusion: The successful pilot of consultant-led ICD-insertion sessions led to
reduced length of stay, improved outcomes and improved trainee feedback - hence
our policy recommendation to include pleural procedure sessions in physician job
plans which is currently not undertaken uniformly in the UK.

P3362
Medical thoracoscopy: Learning curve of a new service
Arun Khanna, Sanjay Adlakha, George Mabeza, Irfan Wahedna, Robert Berg,
Chris White. Respiratory Medicine, Derby Hospital NHS Trust, Derby, Derbyshire, United Kingdom
Introduction: Many hospitals have, or plan to establish, a Medical Thoracoscopy
(MT) service. Whilst high diagnostic yields and low adverse event rates are widely
reported1, little is known about the learning curve attributed to the procedure.
Aims: To examine the diagnostic rate per annum (‘hit rate’) and learning curve of a
Medical Thoracoscopy service in a large District General Hospital.
Methods: We retrospectively analysed data from our first 100 consecutive MT’s
since November 2008. Procedures were carried out by three Consultants with
experience of Medical Thoracoscopy, one Consultant learning the technique and
trainees under close supervision. ‘Hit-rate’ per year was calculated and trend
analysed to determine the learning curve.
Results: ‘Hit-rate’ was 65% in year 1, 79% in year 2 and 89% in year 3,
demonstrating a steep learning curve for this skill. Histologically confirmed diag-
nosis included mesothelioma (n=34), metastatic lung cancer (n=20; predominantly
non-small cell lung cancer), other metastatic malignancy (n=16;predominantly
Ca Breast), pleural Tuberculosis (n=4), chronic inflammation (n=13) and fibrous
pleural plaque (n=1).Five MT’s were performed for palliative purposes, one had
to be abandoned and six failed to achieve a diagnostic yield. No major procedure
related adverse events were noted during the study period.
Conclusions: This data provides insight into the diagnostic learning curve of a new MT service. Improved patient selection and enhanced operator skills should produce a diagnosis rate of over 90% in year 4. The study also re-confirms the safety and high diagnostic yield of this procedure, even outside the settings of mesothelioma.

P3363
Significance and long-term outcome of nonspecific pleuritis after medical thoracoscopy

Xanthi Tsatsaki, Maria Chorti, Niki Marouinis, Maria Kokoletaki, Constantine Mantzaroussis, Vasilis Filadaktis, 1 Second Department of Chest Medicine, Sismanoglou General Hospital, Athens, Greece; 2Department of Pathology, Sismanoglou General Hospital, Athens, Greece; 3Department of Cytology, Sismanoglou General Hospital, Athens, Greece; 4Department of Anesthesiology, Sismanoglou General Hospital, Athens, Greece

Introduction: A specific diagnosis of an exudative pleural effusion (EPE) often poses a clinical challenge for the pulmonary physician. Although medical thoracoscopy (MTH) remains the gold standard technique in the work up of patients with EPE, a definite histological diagnosis will not be established in a significant number of the cases and will therefore be characterized as non-specific pleuritis (NSP).

Objective: To study the outcome of patients with NSP in a group of patients with long term follow up.

Method: A retrospective analysis was performed on 110 patients who underwent thoracoscopy for EPE, over a 7 year period, at our Institution. In 47 (42.7%) cases, that were histologically diagnosed as NSP, long-term follow up was available (a minimum of 24 months). MTH was performed by a respiratory physician, experienced in the procedure, under local anesthesia and IVIM sedation.

Results: A definite histological diagnosis was established in 63 patients. In the remaining 47 (42.7%), 35 men and 12 women with mean age of 64.5 years, the diagnosis of NSP was rendered. Four of the latter (8.5%) were subsequently diagnosed with malignancy after an interval of 3-5 months (2 mesotheliomas, 2 adenocarcinoma). A probable cause was established on clinical grounds in 13 (27.6%) cases. Finally, in 30 (63.8%) patients, the underlying etiology for NSP was not discovered and was therefore, described as “idiopathic pleuritis”.

Conclusions: In our series 3.6% proved to be false negative, after a mean follow up of 4 months. Furthermore, in 27.3% of our undiagnosed EPE cases, a definite diagnosis could not be determined and was characterized as “idiopathic pleuritis”.

P3364
Eosinophilic pleural effusions – Is everything clear?

Jan Plemiski, Pranilek Dvorak, Zuzana Taligova, Renata Sabova, Stanislava Sabova. 2nd Pneumology, Specialized Hospital of St.Zoerardus, Nitra, Slovakia (Slovak Republic)

Introduction: Eosinophilic pleural effusion (EPE) for long time was considered a result of benign concomitant diseases with a good prognosis. Blood or air in the pleural fluid (PF) could cause EPE in most cases. In some EPE the etiology is unknown. Epidemiology is varied from 5-12%. We analysed our patients (pts) with PF and we focused on the group with EPE.

Aim: To share our own experience with diagnosis, differential diagnosis and prognosis of EPE.

Methods: We analysed 390 pts with a definitely confirmed diagnosis of pleural effusion. The diagnosis was confirmed biochemically, cytological analyses of PF, histologically by blind pleural biopsy or by medical thoracoscopy. Cell count was made routinely. Light’s rule was used for the diagnosis of transudates and exudates. EPE was defined when 10% or more eosinophilic leucocytes appeared on a differentials cell count.

Results: 3 M and 19 F, median age 71 years (51-85 yrs) had EPE (3.33%). From them 3 had lung carcinoma, 1 breast carcinoma, 2 pneumonia, 2 heart failure, 1 pnuemothorax, 1 traumatic PL, 1 pancreatitis as diseases causing EPE and only 1/3 had idiopathic EPE (7.6%), or 0.25% from 390 pts. Median of eosinophils in PE was 25% (from 10% to 88%). Ten of the PE were exudates and 3 transudates.

Conclusions: In our cohort of pts with EPE 30.8% had carcinoma and only 1 was idiopathic. Median age is high. Prognosis is better in 2/3 pts and it was interesting that 3 pts had transudates. Also of interest was the lower incidence of EPE in our cohort in comparison to literature sources. EPEs present the inhomogeneous group of pleural diseases with unclear prognosis.

P3365
Occurrence of malignancy after an initial diagnosis of post-thoracoscopy fibroinflammatory pleuritis

Ben Sutton, Rakesh Panchal, Sanjay Agraval, Jonathan Bennett. Institute of Lung Health, Glenfield Hospital - University Hospitals of Leicester, Leicester, United Kingdom

Introduction: Fibroinflammatory (FI) is a common thoracoscopy diagnosis and implies a benign aetiology, however, the number of cases that subsequently result in malignancy is not fully known.

Objectives: To evaluate what proportion of patients with FP following thoracoscopy develop malignancy.

Methods: Retrospective analysis was conducted of all thoracoscopies performed for unexplained exudative pleural effusions between 2005-2009. In cases with an initial histological diagnosis of FP, review of radiology and history for at least 24 months post thoracoscopy was undertaken.

Results: Of 177 thoracoscopies, 90 (49%) were malignant and 87(51%) were non-malignant. FP was the diagnosis in 68 (38%) of cases, with 55(81%) male and a mean age of 72.5 (±10.4) yrs.

In 10 (15%) FP cases the subsequent diagnosis confirmed malignancy, with 5 (7.5%) of mesothelioma. Four had further immediate positive investigation (false negatives), six developed overt malignancy at a later stage. Of the 68 patients 35 (51%) had died, 27(39%) with no evidence of malignancy, with a mean survival of 502 days.

Mean survival of those with malignancy was 534 days p 0.75. Patients who died with a benign process were significantly older, 74 yrs vs. 70.5yrs p=0.043 (±11.4).

Conclusions: The majority of FP cases follow a benign course but need 2 years follow-up, as a proportion develop malignancy after a significant interval. Benign exudative pleural effusion is a poor prognostic marker in the elderly despite the absence of subsequent malignancy.

P3366
Role of Abram’s pleural biopsy in determining the cause of empyema thoracis

Shabana Ghazali, Ashok Kumar, Nusrat Idrees, Nadeem Irizi, Maria Malik. Chest Medicine, Jahang Post Graduate Medical Centre, Karachi, Sindh, Pakistan

Introduction: Empyema thoracis remains a major problem in developing countries. Clinical outcomes in tuberculous empyema are generally believed to be worse than in non-tuberculous. So with the help of Abram pleural biopsy early detection of the cause of empyema and its treatment could be possible.

Objectives: To evaluate the role of Abram’s pleural biopsy in determining the cause of empyema thoracis.

Methods: A prospective study of patient’s data was undertaken at the Pulmonology department at the largest public tertiary care centre in Karachi, Pakistan. Pleural biopsies for histopathology were obtained using Abram’s pleural biopsy needle from 46 patients admitted with empyema thoracis between August 2010 and August 2011; along with pus for Gram staining, routine culture, AFB smear and AFB culture, and the results of these variables were compared for diagnostic efficiency.

Results: A comparison of the diagnostic tools used showed positive Gram staining in 28 out of 46 (60.9%) cases. Bacterial cultures were positive in 24 (52.1%) of the cases, with the 10 (21.7%) positive for Streptococcus pneumonia, 8 (17.4%) positive for Pseudomonas aeruginosa, 6 (13%) positive for Staphylococcus aureus; and 15 (32.6%) with AFB growth. AFB smear positivity in culture was 4 (8.6%).

Whereas histopathology revealed 28 (60.9%) cases as having acute on chronic pyogenic inflammation, 12 (26.1%) with chronic non-specific inflammation, and 6 (13%) with acute on chronic granulomatous inflammation.

Conclusions: In comparison to other diagnostic techniques, there is no benefit of performing Abram’s pleural biopsy in determining the cause of empyema thoracis. Pus culture has a better yield in specifying the cause in most cases.

P3367
Risk of intrapleural hemorrhage following thoracocentesis

Marie-Ève Bureau, Yves Lacasse, Simon Martel. Département de Pneumologie, Institut universitaire de Cardiologie et de Pneumologie de Quebec, Quebec, QC, Canada

Background: Diagnostic or therapeutic thoracocentesis is usually a simple and safe procedure. The extent to which coagulation abnormalities induced by antithrombotic therapy (ATT) increase the risk of intrapleural hemorrhage following thoracocentesis is unknown.

Objective: To examine the risk of intrapleural hemorrhage following diagnostic or therapeutic thoracocentesis in patients with or without ATT.

Methods: We conducted a retrospective cohort study of all the diagnostic or therapeutic thoracocentheses performed in our institution over a three-year period (2007-2009). We considered only the procedures performed without ultrasonic guidance. Antiplatelets and anticoagulant therapy at the time of the procedure were recorded. Coagulation parameters (international normalized ratio, partial thromboplastin time, platelet count) and hemoglobin level were also noted. We defined intrapleural hemorrhage as either a recurrent pleural effusion with a fall in hemoglobin >20 grams/liter, or a hemothorax necessitating pleural drainage.

Results: A total of 695 patients underwent 953 thoracocentheses; data were available from 940 of them. 738 procedures (78.5%) were performed on patients on either antiplatelets or anticoagulant therapy. Overall, 7 intrapleural hemorrhages were noted (overall incidence rate: 0.7%), all in patients with antithrombotic therapy (ATT). 7/38 vs. no ATT: 0.02; Fisher’s exact test: p = 0.22).

Conclusion: The incidence of intrapleural hemorrhage following thoracocenthe- sis was low. Although the event rates in patients with or without ATT were not statistically different, all intrapleural hemorrhages occurred in patients with antithrombotic therapy.
The aim of our study was to analyze lung function throughout infancy and adolescence in cohorts of CF patients diagnosed after neonatal screening. We retrospectively evaluated the spirometry of patients born in the years 1992–1994 who had been visited at least three times yearly and compared the decline in FEV1 and FEF 25-75 (both % predicted) in pre-adolescence (pre ado; age range 8–12 years) and during adolescence (age range 13–17 years). The mean decrease in FEV1% was -0.35 (SD ± 1.19) in the pre ado period and -1.41 (SD ±1.17) during adolescence with no significant difference in decline between the two periods, (p=0.45, paired t test). However, the mean variation in FEF 25-75 was 7.9% (SD ± 3.2) in pre ado and -6.7 (SD ±2.6) during adolescence (p=0.009).

Our data show that lung function decreases during adolescence in CF patients as reflected by a loss in FEV 25-75 which is consistent with an anatomical dam-age initially located in smaller peripheral airways. Although FEV1 is universally adopted as a surrogate outcome it seems to be poorly sensitive in evaluating lung disease progression in CF during adolescence.

P3371
Comparative study of three quality of life instruments in adolescent and adults with cystic fibrosis
Monica Cobrian1, Javier Ferrero2, Emilio Ansegotgi1, Amparo Sole1. 1 Lung Transplant and Cystic Fibrosis Unit, Hospital Universitario y Politécnico La Fe, Valencia, Spain; 2Personality, Evaluation and Psychological treatments, University of Valencia, School of Psychology, Valencia, Spain

Multiple patient reported outcomes have been used in order to measure quality of life in Cystic Fibrosis in Spain, but it is important to find a consensus on which is the most reliable and valid quality of life instrument.

Objective: To compare three quality of life questionnaires widely used among CF patients in order to prove which of them is more valid and reliable when measuring quality of life and disease severity.

Methods: Two disease-specific questionnaires: Cystic Fibrosis Questionnaire-Revised (CFQ-R), and St. George Respiratory Questionnaire (SGQR), and a generic instrument: the Short-form-36 health survey (SF-36), were simultaneously adopted as a surrogate outcome it seems to be poorly sensitive in evaluating lung disease progression in CF during adolescence.

Strong correlations (≥0.70) were found between several of the scales in the three questionnaires: physical functioning, role limitation, energy and vitality, and mental health. The CFQ-R allows a better differentiation of the varying levels of disease severity, plus it has disease-specific scales.

Discussion: An instruments’ validity and applicability should be considered when choosing a questionnaire to measure HRQoL in CF patients. The CFQ-R proved to be the most suitable, although some of its subscales could be reviewed.

P3372
Comparison of the Cystic Fibrosis Questionnaire with the St George’s Respiratory Questionnaire in adult patients with cystic fibrosis
Markus Hofeg, Astrid Hirt, Thomas Kurowski, Annette Boehrer. Division of Pulmonary Medicine, University Hospital, Zurich, Switzerland

Background: The Cystic Fibrosis Questionnaire (CFQ-R) is widely used in out- come studies. Nevertheless, correlation with pulmonary function test (PFT) is weak, namely in mild to moderate impairment.

Aim: To prospectively evaluate the accuracy of the CFQ-R with PFT (FEV1, obstructive ventilation defined as ratio FEV1 to vital capacity (FEV1/FVC), and hyperinflation defined as ratio residual volume to total lung capacity (RV/TLC)) and to compare it with the St George’s Respiratory Questionnaire (SGQR).

Methods: Clinical data including PFT were collected. CFQ-R and SGQR were obtained. Spearman correlation was performed.

Results: 32 patients (13 females) with a mean age of 29±11y, body mass index (BMI) of 22.3±3.4kg/m², FEV1 of 67±29%, FEV1/FVC of 0.67±0.14 and RV/TLC of 0.46±0.15 are evaluated. Results of CFQ-R were: physical well-being 74±25, vitality 79±19, eating 93±20, treatment burden 75±19, health perception 72±24, social role 72±18, body image 73±24, role 73±24 weight 77±32, respiration 68±19 and digestion 79±23. Total score of SGQR was 23±17, with following subdomains: symptom 44±25, activity 25±23, impact 15±14. PFT was strongly correlated (p<0.0001) with SGQR activity (FEV1, rh=0.67) and total score (r=0.68), moderately correlated (p<0.005) with CFQ-R physical (0.63) and SGQR symptom score (r=0.59) and weakly correlated (p<0.01) with CFQ-R treatment burden (0.54), health perception (0.57) and role (0.55).

Conclusions: In adult CF patients CFQ-R is only moderately correlated with pulmonary function. In contrast, the SGQR, initial developed for patients with chronic obstructive pulmonary diseases showed a better correlation with PFT.
P3374

The use of high frequency chest wall oscillation during an acute infective pulmonary exacerbation of cystic fibrosis

Ann Banks1, Georgia Davies2, Penny Agent3, Leyla Osman3

Background: Cystic fibrosis (CF) patients hospitalised for an acute infective pulmonary exacerbation require increased airway clearance. Specialist physiotherapists may be a limited resource. We investigated the use of high frequency chest wall oscillation (HFCWO), in addition to usual airway clearance techniques (ACTs).

Objective: The aim was to assess the utility of HFCWO (The Vest, Airway Clearance System, Hill-Rom) as a self administered therapy compared to European ACTs in facilitating recovery from an acute infective pulmonary exacerbation in people with CF when used in addition to supervised physiotherapy.

Method: A non-blinded randomised, controlled design was used. Patients who met inclusion criteria were randomised to control or HFCWO groups. All patients received four daily sessions, two supervised by a specialist CF physiotherapist and two carried out independently. The control group carried out their usual ACTs, the study group used HFCWO with pauses to buflf and cough. The primary outcome measurement was change in FEV1.

Results: n=36 (64% male). Data was analysed using the Wilcoxon Rank Sum test.

<table>
<thead>
<tr>

<td>10 (–30, 50)</td>
</tr>
</tbody>
</table>

Conclusion: Change in FEV1 was not significantly different between groups, however a significant improvement in FVC was demonstrated. HFCWO should be further explored as an adjunct to treatment of infective pulmonary exacerbations of CF.

P3375

Long inhalation time is associated with short treatment time when using the I-neb AAD system in target inhalation mode

Tim Spencer1, Alex Black1, Nicholas Smith2, Kurt Nikandar3, Tony Dyche1

1 Respironics Respiratory Drug Delivery (UK) Ltd, Chichester, West Sussex, United Kingdom; 2 PFS Consultants Ltd, Portsmouth, Hampshire, United Kingdom; 3 Philips Respironics, Respironics New Jersey, Inc., Parsippany, NJ, United States

The I-neb Adaptive Aerosol Delivery (AAD) System is designed to emit aerosol only during the inspiratory phase of breathing and can be operated in tidal breathing mode (TBM), in which the user breathes in a normal manner during treatment, or target inhalation mode (TIM), in which the user is guided to longer inhalations via feedback from the I-neb AAD system. The I-neb AAD system is equipped with a patient logging system (PLS) to facilitate the analysis of patient breathing by recording data on treatment time and mean inhalation time per breath per treatment.

Forty nine patients with cystic fibrosis were enrolled in a 13 week handling study; PLS data was analyzed for 43 of these patients. Each patient’s mean treatment (nebulization) time and inhalation time per breath were calculated for treatments taken in TBM or TIM in order to determine the relationship of these variables.

The median of patient mean treatment times for TBM and TIM were 291 and 146 s, respectively. The median of patient mean inhalation times were 2.6 and 6.9 s, respectively. Patients with longer inhalation times generally had shorter treatment times and patients using TIM had shorter treatment times than those using TBM. It might therefore be of benefit for patients using TBM to switch to using TIM.

P3376

Inferior efficacy and safety of tobramycin 300mg/4ml nebulizer solution in patients with cystic fibrosis and chronic Pseudomonas aeruginosa infection

Henryk Mazurek1, Raphael Chiron2, Guido Varoli3, Deborra Santoro4, Helen Cicirello5, Yuri Antipkin6

1 Adult CF Centre, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom; 2 Imperial College, NHLL, London, United Kingdom; 3 Physiotherapy Department, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom

Introduction: Inhaled tobramycin is considered standard of care for the management of chronic Pseudomonas aeruginosa (Pa) infection in patients (pts) with cystic fibrosis (CF).

Objectives: To compare the long-term efficacy and safety of tobramycin 300mg/4ml nebulizer solution (TNS4: Bramitob ®, Chiesi Farmaceutici S.p.A.) administered over 56 weeks (seven 28-day on/off cycles) was assessed in CF pts chronically infected with Pa.

Methods: A total of 324 CF pts aged ≥ 6 years with baseline 1-second forced expiratory volume (%FVC) ≥ 40% were randomized in an initial 8-week, open-label trial (Core) to receive TNS4 or tobramycin 300mg/5mL (TNS5, Tobi®, Novartis) using PARI Turbo Boy N compressor and PARI LC Plus nebulizer. 209 pts (of which 100 received TNS4 in the Core) continued for an additional 14-week, single-arm extension phase with TNS4 only (Ext). FEV1% predicted and Pa bacterial load in sputum were measured during 14 study visits. Safety was assessed through monitoring of adverse events and audiometry.

Results: Non-inferiority in terms of FEV1% predicted between TNS4 and TNS5 was demonstrated in the Core (mean changes from baseline 7.1% and 7.6%, respectively). After 56-week treatment with TNS4, the mean change from baseline in FEV1% predicted was 5.7% [95% CI: 2.8;8.6]. Reduction in log10CFU/g Pa bacterial load was -1.13 [95% CI: -1.58;-0.68]. No remarkable safety findings were detected.

Conclusions: TNS4 demonstrated a sustained and significant improvement in lung function over a 56-week period and a reduction in Pa density in sputum. TNS4 was safe and well tolerated. Supported by Chiesi Farmaceutici S.p.A.

Pharmacokinetics of tobramycin nebulizer solution (300mg/4ml) administered by Pari e-Flow rapid vs Pari LC plus nebulizer in patients with cystic fibrosis and Pseudomonas aeruginosa infection

Mirko Gogoni1, Gianluigi Poli1, Helen Cicirello2, Debora Santoro2, Daniela Acerbi3, Josef Ruzicka4

1 Clinical Corporate Development, Chiesi Farmaceutici, Inc, Rockville, MD, United States; 2 Corporate Clinical Development, Chiesi Farmaceutici S.p.A., Rockville, United States; 3 Institute of Pediatrics, Obstetrics and Gynecology, UAMS, KY, USA

Introduction: New generation nebulizers are increasingly used to reduce the time required for inhalation, potentially improving patient compliance.

Objectives: To compare the pharmacokinetic (PK) profile of tobramycin nebulizer solution (TNS) 300mg/4ml (Bramitob®) administered with the Pari e-Flow rapid versus the Pari LC plus nebulizer.

Methods: Randomized, crossover trial, enrolling 27 cystic fibrosis (CF) patients with chronic Pseudomonas aeruginosa infection. Patients received two twice-daily, 28-day treatment periods with TNS 300mg/4ml, delivered by either nebulizer, sep-
arated by a 4-week wash-out. Blood and sputum samples were collected on days 1 and 28 over the first 12 and 8 hours, respectively. Primary endpoints were plasma tobramycin maximum concentration (Cmax) and area under the curve (AUC(0-28)) on day 28.

Results: 27 patients were randomized and 25 completed the study. Patients were 18-47 (mean 25.5) years old. On Day 28, the geometric mean ratios (e-Flow rapid vs LC plus) 5.7 (90% CI 0.80-2.33), respectively. Nebulization time was significantly shorter for the e-Flow rapid as compared to the LC plus: 5.7±2.0 versus 12.1±2.2 min (mean ± SD on day 28).

Conclusion: Plasma and sputum PK data support comparable pulmonary delivery of TNS 300 mg/ml, in CF patients using different nebulizers with a shorter nebulization time for the Pari e-Flow device.

Temporal changes in the prevalence of respiratory pathogens in children and adolescents with cystic fibrosis (CF)

Prajad Nagarajan1, Jyotsna Vaswani2, Julian Forton1, Iolo Doull1, 1Pediatrie Respiratory Medicine & Cystic Fibrosis, Children's Hospital for Wales, Cardiff, Wales, United Kingdom; 2Pediatrie, Royal Gwent Hospital, Newport, Newport, United Kingdom

Introduction: Changes in the prevalence of respiratory pathogens in CF may reflect improved therapeutic strategies and clinical practice within a CF centre.

Aims: We hypothesized that active microbiological surveillance and a low threshold for low dose nebulised antibiotics might reduce the prevalence of respiratory pathogens in patients with CF.

Methods: Retrospective review of data of patients under full care at a paediatric CF centre in Cardiff between 1998(n=88) and 2011(n=70). We calculated the number of isolates for common pathogens from 1998 onward (expressed as a percentage for each year); mean number of respiratory cultures taken for each patient per year; and the rate of chronic P aeruginosa (Lee 2003) from 2002 onward. Changes in prevalence over time were assessed by linear regression.

Results: Non-significant increase in mean (SD) number of respiratory cultures from 5.3(3.22) to 7.4(2.89) per patient/year. The prevalence of P aeruginosa in fe-no long term nebulised antibiotic therapy decreased significantly from 43.8% in 1998 to 14% in 2011(n= 40, p=0.001), while chronic P aeruginosa infection decreased from 19% in 2002 to 2.9% in 2011(n= 9.9, n=0.001). We also observed significant decreases in the prevalence of A fumigatus (n= 9.9, n=0.001), A influenzae (n=0.58, p=0.03) and B cepacia (n=0.78, n=0.001), and a non-significant reduction in the prevalence of S Aureus with non-significant increases in the prevalence of S maltophilia or MRSA.

Conclusion: Active microbiological surveillance and a low threshold for long term nebulised antibiotics was associated with significant reductions in both the prevalence of P aeruginosa infection and the rate of chronic P aeruginosa infection.

P3379

Long-term linezolid in cystic fibrosis patients chronically colonized with Staphylococcus aureus (SA)

Amparo Sole1, Monica Cebrian1, Emilio Ansótegui1, Emilio Monte2, Eduard Saltman1, Jose Luis Perez2, 1Lung Transplant and Cystic Fibrosis Unit, Hospital Universitario y Politecnico La Fe, Valencia, Spain; 2Pharmacy, Hospital Universitario y Politecnico La Fe, Valencia, Spain; 3Microbiology, Hospital Universitario y Politecnico La Fe, Valencia, Spain

Treatment of chronic colonization with methicillin-resistant Staphylococcus aureus (MRSA) and non-MR in cystic fibrosis (CF) patients shows a wide variability among CF units. While some caregivers prescribe continuous treatment with inhaled/oral antibiotics, others only treat infectious exacerbations.

Methods: 52 CF patients were included. Mean age was 25.1 years. All patients were chronically colonized by SA (56.9%) and showed a poor clinical progress and respiratory function after receiving several conventional antibiotic cycles to treat infectious exacerbation.

Every patient was prescribed continuous treatment with oral Linezolid: 600mg/12h for 15-21 days every 45 days, for a minimum of 1 year. Serial spirometry, sputum analysis and blood analysis were determined to rule out toxicity derived from a chronic treatment with Linezolid. Health related quality of life was measured every three months with the Cystic Fibrosis Questionnaire-Revised (CFQ-R) to detect any change.

Results: An infection in the pulmonary function drop in FEV1 and FVC was observed, with a recovery and slowing down of this drop after treatment. After a treatment period of at least one-year, no resistances against Linezolid nor serious adverse events were observed. Patient reported outcomes showed improvement in functionality and in clinical symptoms, with a significant decrease of cough and expectoration during the treatment.

Conclusion: Treatment with Linezolid cycles is effective and safe in those patients colonized by SA who present both a clinical and functional torpid progress with conventional treatments. Linezolid allows the stabilization of the symptoms and lung function.

Limitations: Prevalence could have been underestimated as spontaneous breathing was not observed in some children due to anesthetic factors. As technique used was visual estimation there is a potential for observer bias.

Conclusions: A high prevalence of tracheobronchomacia was found in young children with CF. There is a need for further studies to understand the significance of tracheomalacia in CF.

P3382

Oral health and some risk factors in children with cystic fibrosis

Seda Meng1, Yasemin Gokdemir2, Sertac Peker2, Bulent Karadag2, Benil Kargul1. 1Pediatric Dentistry, Marmara University Dental School, Istanbul, Turkey; 2Pediatric Pulmonary Disease, Marmara University Faculty of Medicine, Istanbul, Turkey

Cystic fibrosis (CF) is one of the most common genetic diseases worldwide. Previous studies in patients with CF have reported variable dental caries prevalence and physicochemical properties of saliva. The aim of this study was to investigate prevalence of dental caries and the relation with treatment, salivary flow rate, buffering capacity in children with CF compared with healthy peers.

A cross-sectional observational survey was undertaken in children attending out-patient clinic. Study population included 30 children with CF (mean age 10.2±4.8 years).

The prevalence of ABPA in CF is variable (6-15%). Currently, the role of rAsp f 1 in ABPA diagnosis and treatment monitoring is unknown.

Patients: Serial determinations of serum specific IgE against recombinant AF antigens were analysed yearly during 5 years in 157 adult CF patients. 19 patients fulfilled serologic criteria for ABPA, but only 9 suffered from respiratory symptoms, lung infiltrates or lung function deterioration.

Results: 9 of 157 CF patients (3 women), prevalence 6%, mean age 22 (16-33) years; BMI mean 21 (20-22). In 8/9 Delta F508 mutation was found. At time of diagnosis, 4 patients showed AF colonization, 8 had Pseudomonas aeruginosa (PA). In all patients, total IgE was higher than 500 U/ml, and AF specific IgE was positive. Titrations for rAsp f 1 varied, with highest titrations for rAsp f 1 and rAsp f 2. Two cases with the most torpid progress showed high titers for rAsp f 3. Lung function’s distribution (FEV1) was similar in all cases.

All patients were treated with systemic corticosteroids (3 weeks and gradually reducing the dose after 3-6 months), and itramozone/voriconazole. There were two relapses after two years, which started with respiratory symptoms.

Conclusion: In CF patients, compatible symptoms as wheezing dyspnea and functional-radiological deterioration suggest ABPA diagnosis. During treatment, only total and specific AF IgE titers, as well as lung function, served for monitoring. In our daily practice, specific AF component IgE titration does not provide prognostic nor prognostic advantages, and neither does conventional sputum culture.
years), compared with a control group of 30 healthy children (mean age 9.9±1.4 years). Mean saliva pH was 7.25±0.45 for CF children and 7.45±0.34 for control (p=0.57). Mean salivary flow rate of the CF children was 1.30±0.7ml/min and 1.54±0.9ml/min for the control group (p=0.09). And the mean buffering capacity was 8.47±2.7 for CF children and 8.20±1.58 for control (p=0.64). Among the group of children with CF, 23% of children being carrying free. DMFT (Decayed Missing Filled Teeth) was 0.64±0.45 in children and 7.3±2.7 in control children (p=0.001). Of all CF children, 60% CF brush their teeth once a day. Most of CF children (26±6%) start to brush teeth after 2 years of age. Although CF is a serious systemic chronic disease of childhood, buffering capacity of saliva seems to be higher than control group. Related to this characteristic of saliva, DMFT score of CF children were found to be lower than healthy group.

Background: In Belgium in 2011, 35% of the 15-29 years age group were regular smokers. No information was available about epidemiology of smoking by CF patients in our country. Objectives: a) primary aim: to identify active (AS) and passive (PS) smokers in the Belgian CF patients b) secondary aim: to investigate physical, psychological and behavioural dependence of AS CF patients.

Methods: AS and PS were identified by means of a urinary cotinine dosage. Patients with positive results were asked to meet with a tohacologist, in order to evaluate their expired CO2, their physical, psychological and behavioral dependence to nicotine, and their HAD score.

Results: (Interim analysis) 29 out 706 patients (4.5%, 78.8% of target) had positive urinary cotinine (> 100 mcg/ml), 17 positive patients met the tabacologist (12 AS, 5 PS). Among AS (mean age 28±1.0, 84±58), mean urinary cotinine level was 0.86±0.23 mcg/ml, maximum CO exp 0.8 ±0.33 pmol/min, and CO2 7.1 ±2.7 (p=0.025). Fagreström score was 4.5±1.3 (1-9). 84% had a previous quit attempt. 41% AS smoked cannabis. Anxiety was associated with urinary cotinine level (R=0.825, p=0.009). All AS wished to receive specific help for smoking cessation at their CF reference center.

Conclusions: Active smoking is less prevalent among CF patients in Belgium than in healthy adolescents and young adults. CF AS had developed a moderate physical dependence to nicotine; their urinary cotinine was associated with their anxiety level. Smoking cessation help should be available at CF reference centers.

Comparison of nanoduct versus macroduct sweat test for the diagnosis of cystic fibrosis in the newborn screening programme in Switzerland

James Barben1, Cornia S. Ruegg2, Sabina Gallant1, Claudia E. Kuehlm2.

Background: Newborn screening (NBS) for cystic fibrosis (CF) is based on immuno-reactive trypsinogen (IRT) and 7 CFTR mutations, was introduced in Switzerland during pregnancy 2011. In the pilot phase, we compared the performance of two sweat test methods for diagnosing CF in the NBS.

Methods: All children with a positive screening result were referred to a CF center for confirmatory (diagnostic) testing with: a) the Nanoduct sweat test (conductivity); and b) the Macroduct test (chloride). If sweat test results were positive, borderline or inconclusive, an extensive DNA analysis was performed.

Results: Within one year, 84 children were screened positive. In 30 children the diagnosis of CF could be confirmed, 53 had normal investigations, and 1 child was not yet fully investigated. All details of the investigations were available for 76 children. The children were seen in a CF center at a median age of 24 days. The Macroduct was attempted in 64 children, the Nanoduct in 71 children. A reliable test result was available in 66% (42/64) for the Macroduct and 79% (57/61) for the Nanoduct. In 37 children both sweat tests could be performed; in 19 only the Nanoduct and in 5 only the Macroduct was feasible. In 8 children none of the two sweat tests could be performed, and confirmation or exclusion of CF was based on extensive DNA analysis alone.

Conclusions: In this pilot study, the Nanoduct sweat test showed a better feasibility for use in newborns compared to the Macroduct test, mainly because it needs a lower sweat volume. Analysis of a larger dataset will allow to compare sensitivity and specificity of the two tests for the final CF diagnosis.

Conclusion: Race and ethnicity are significant factors for FeNO values in healthy individuals. Hay fever seems to play an important role in the mean difference between race/ethnicity categories. An objective measurement of atopy is probably needed to clarify this relationship.

Volatile organic compounds exposure and respiratory function in preschoolers from mothers participated in a randomized clinical trial during pregnancy

Attilio Barraza-Villarreal1, Consuelo Escamilla-Nuñez1, Leticia Hernandez-Cadema1, Efrain Navarro-Olivos1, Jose Luis Taxcal-Sangrador2, Claire Shackleton3, Peter A. Sly4, Usha Ramakrishnan5, Isabelle Romeo6, Andrei Malinovschi3,4, Christer Janson3,4, Kjell Alving1,2,3,4, 1Allergology, Instituto CUF, Matosinhos, Portugal; 2Health Information and Decision Sciences, Faculty of Medicine, Porto, Portugal; 3Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; 4Department of Medical Sciences, Clinical Physiology, Uppsala University, Uppsala, Sweden; 5Allergology, Hospital S. João EPE, Porto, Portugal; 6Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden

Background: Race and ethnicity are factors known to affect the prevalence of respiratory symptoms. Different racial/ethnic groups may have different levels of exposure to volatile organic compounds, which may affect respiratory function.

Methods: We measured FeNO in 162 children (mean age 6-79 years) from 76 multi-racial families. Race and ethnicity was coded as Mexican American (20%), Other Hispanic (11%), Non-Hispanic White (43%), Non-Hispanic Black (20%) and Other Race- Inc. Multi-Racial (5%). Adjustments were made using multiple-linear regression models.

Results: Non-Hispanic Whites have the lowest FeNO values (mean 15.8 ppb, 95%CI 14.5, 16.1) and Other Race - Including Multi-Racial the highest (20.0 ppb (18.6; 21.4)). Race and ethnicity significantly affect FeNO values even after adjusting for age, gender, BMI and reported hay fever in non-asthmatic subjects (B=0.30, p=0.01), but not in individuals with self-reported asthma (B=0.09, p=0.83). However, the mean difference between race/ethnicity categories was reduced after excluding subjects with hay fever.

Conclusion: Race and ethnicity are significant factors for FeNO values in healthy individuals. Hay fever seems to play an important role in the mean difference between race/ethnicity categories. An objective measurement of atopy is probably needed to clarify this relationship.

Environmental exposure and other risk factors for airway diseases

Self-reported race and ethnicity affect FeNO values in healthy individuals

Tazio Jacinga1,2, Andrei Malinovschi3,4, Christer Janson3,4, João Fonseca1,2,5, Kjell Alving1,2,3,4, 1Allergology, Instituto CUF, Matosinhos, Portugal; 2Health Information and Decision Sciences, Faculty of Medicine, Porto, Portugal; 3Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; 4Department of Medical Sciences, Clinical Physiology, Uppsala University, Uppsala, Sweden; 5Allergology, Hospital S. João EPE, Porto, Portugal

Methods: We analyzed the valid FeNO measurements (NIOX MINO) recorded in the National Health and Nutrition Examination Survey 2007-10 (n=13,275; age 6-79 years). Race/ethnicity is coded as Mexican American (20%), Other Hispanic (11%), Non-Hispanic White (43%), Non-Hispanic Black (20%) and Other Race - Inc. Multi-Racial (5%). Adjustments were made using multiple-linear regression models.

Results: Non-Hispanic Whites have the lowest FeNO values (mean 15.8 ppb, 95%CI 14.5, 16.1) and Other Race - Including Multi-Racial the highest (20.0 ppb (18.6; 21.4)). Race and ethnicity significantly affect FeNO values even after adjusting for age, gender, BMI and reported hay fever in non-asthmatic subjects (B=0.30, p=0.01), but not in individuals with self-reported asthma (B=0.09, p=0.83). However, the mean difference between race/ethnicity categories was reduced after excluding subjects with hay fever.

Conclusion: Race and ethnicity are significant factors for FeNO values in healthy individuals. Hay fever seems to play an important role in the mean difference between race/ethnicity categories. An objective measurement of atopy is probably needed to clarify this relationship.
Conclusions: Exposure to volatile organic compounds air concentrations in the general environment decrease the respiratory function in Mexican Preschoolers.

P3387
Effects of short-term exposure to air pollution on the levels of exhaled nitric oxide among adults – Results from the ADONIX study in Gothenburg, Sweden
Lar Mosd 1, Santosh Dahgam 2, Kristina Wess 3, Fredrik Nyberg 4, Anna-Carin Olin 2, Public Health and Clinical Medicine, Occupational and Environmental Medicine, Umeå, Sweden; 3Uppsala Academy at University of Gothenburg, Occupational and Environmental Medicine, Gothenburg, Sweden; 4AstraZeneca R&D, AstraZeneca R&D, Mölndal, Sweden

The fraction of exhaled nitric acid (FENO) is a marker of airway inflammation, used clinically to diagnose and monitor asthma. FENO can be measured at different exhalation flows to monitor different parts of the airways. Air pollution is known to cause adverse health effects, and inflammation has been suggested as a main pathway. In this study we examined whether short-term exposure to ozone (O3), nitric oxides (NOx) or particulate matter less than 10 μm (PM10) are related to increased levels of FENO.

From 2001 through 2008, 5841 randomly selected adults aged 25-75 years in Gothenburg, Sweden, were clinically investigated. FENO measurement at three different flow-rates, and in this study we included FENO measured at the highest (200mls) and lowest (50mls) flows. Air pollution data were collected from an urban and background station, and we studied the effects of the 3, 24 and 120 hour averages preceding the clinical examination. Log-linear regression was applied to estimate the associations of air pollution on FENO.

One inter-quartile range (IQR) increase of NOx, NO2, and SO2 in the average FENO270, and NO2, SO2, and O3 in the average FENO50 was associated with a 5.1% (95% CI 1.7-8.5) increase in FENO270 and 3.6% (95% CI -0.4-3.4) increase in FENO50. For NO2, a small effect was seen for the 24- and 120-hour averages in FENO270, while no clear effect was seen for PM10. The effect of ozone on FENO50 and FENO270 was significantly lower among asthmatic subjects; however the effect on asthmatics could not be separated from null.

In summary, short-term exposure to O3 gives rise to a small increase in FENO270 and FENO50, measures of inflammation in the distal and proximal airways.

P3388
Estimated short-term effects of air pollutants on daily respiratory emergency department visits in three Swedish cities
Katarina Melsen, Bertil Forsberg, Department of Public Health and Clinical Medicine, Occupational and Environmental Medicine, Umeå University, Umeå, Sweden

Large number of epidemiological studies has found associations between daily changes in ambient particulate air pollution and different kinds of health outcomes. Our aim was to estimate the short-term effects of different air pollutants on daily emergency department visits for respiratory diagnoses in three largest cities in Sweden to find the effects in different environments. Data on daily number of visits from 2001 through 2008 in Stockholm, Gothenburg and Malmö were collected from the national Patient Register and data on daily air pollution concentrations (PM10 and Ozone) on days when available, and data from the local environmental agencies. In addition to visits for all respiratory causes focus was on visits for asthma (ICD10: 345-346) and on associations between air pollution and daily visits in different age classes. Data was analysed using additive Poisson regression models to examine the association between daily visits and the average levels of air pollutants on the day of visit and the day before the visit (lag 0). For each city a statistical model was constructed for each health outcome and also for each age class. For example, a Stockholm model adjusted for the time trend, temperature, relative humidity, birch pollen levels, day of week and public holidays gives an increase of 2% (95% CI 0.5 to 3.6) in daily visits for asthma for all ages per 10 μg/m³ increase in PM10. The estimated effect for children is 2.5% (95% CI 0.7 to 4.4%) and for elderly 4.9% (95% CI 1.1 to 8.8%), respectively. In this study we have found associations between relatively low daily levels of air pollutants and emergency department visits for respiratory diagnoses.

P3389
Impact of close-proximity and background air pollution on lung function of elementary schoolchildren in Guadeloupe (French West Indies)
Biree Kamarati 1,2, Céline Robert 1, Virginie Rondelau 3, Marie-Alice Mounouchy 3, Lucie Cordeanu 4, Édith Dole-Georgin 5, Jean-Claude Gouranton 6, Gérard Marcq 1, David Laureau 1, Chantal Rahérison 1,4, Santé Travail Environnement, Unité: Bordeaux Segalen/ISPED/INSERM 897, Bordeaux, France; 2Biology, Universite Segalen/ISPED/INSERM 897, Bordeaux, France; 3Association Asthme Guadeloupe, Basse-Terre, France; 4Service de Pneumologie, CHU Bordeaux, Bordeaux, France

Background: Air pollution is often associated with respiratory diseases. High levels of asthma prevalence and severity of respiratory symptoms were found in West Indies, but little is known about the impact of air pollution in these regions. This study aimed at describing air pollution impact on lung function of schoolchildren in Guadeloupe.

Methods: Data from 27 randomly chosen elementary Guadeloupian schools including 1,463 children (8-13 years old) were obtained using a standardized protocol adapted from the second phase of the International Study of Asthma and Allergy Childhood (ISAAC). Two dependent variables were the expiratory flow before run (PEF) and variation of peak expiratory flow after run (ΔPEF) were investigated using several linear mixed models to measure effects of i) medium-term close-proximity pollution (indoor and outdoor) of O3 and NO2 and ii) short and medium term background pollution of O3, NO2, SO2 and PM10. The heterogeneity between schools was assessed by random intercept.

Results: Of 1,463 children, 223 (16%) were found with asthma. The values of PF and PEF were in average 272 L/min (range: 130-460) and -1% (range: -56%-97%) respectively. A 1 μg/m³ increase in outdoor medium-term close-proximity O3 pollution level was significantly associated with a PF decrease (β=-0.32, 95% CI -0.61-0.03). Effect of medium-term background O3 pollution on PF was higher in asthmatic children than non-asthmatic children. No association was identified with the other air pollutants.

Conclusion: Our results suggest that O3 has an acute effect on child lung function in Guadeloupe even with values levels inferior to WHO guidelines.

P3390
Air pollution in Reykjavik and dispensation of drugs for angina pectoris
Runhildur Guðný Gíslamóardóttir, Helga Zonga, Önni Olafsson, Vilhjálmur Rafnsson, Centre of Public Health Sciences, School of Health Sciences, University of Iceland, Reykjavik, Iceland

Introduction: Ambient air pollution is associated with increase in morbidity from heart diseases. Air pollution concentrations in the Reykjavik area are known to exceed official European health limits several times every year.

Objectives: To evaluate the association between ambient air concentrations of O3, NOx, PM10 and H2S in Iceland’s capital area Reykjavik and the dispensation of drugs for angina pectoris.

Methods: Data on the daily dispensing of drugs for angina pectoris were obtained from The Icelandic Medicine Registry. Data on hourly concentrations of NOx, NO2, PM10, and H2S were obtained from The City of Reykjavik, and The Environment Agency of Iceland. A case-crossover design was used and the study period was January 1st 2005 to December 31st 2009.

Results: Exposure to air pollution was associated with the dispensing of drugs for cardiovascular disease (C01DA). For every μg/m³ increase of NOx concentrations the dispensing of glycerol trinitrates (sub-group C01DA02) increased by 11.6% (at lag 0) and 7.1% (at lag 1). Similarly, an increase by 10 μg/m³ of O3 concentration was associated with 9.0% (at lag 0) and 7.2% (at lag 1) increase in glycerol trinitrate dispensations.

Conclusion: The findings indicate that increased air pollution levels are associated with increased dispensation of glycerol trinitrate. We caution that this is the first study to examine the association between ambient air pollution and dispensation of drugs for angina pectoris, hence further evidence is needed for definite conclusions of this association. Drug dispensing may potentially be a sensitive indicator of health when estimating the effects of air pollution.

P3391
Occupational air pollutants – More hazardous for respiratory health than smoking? Results from the obstructive lung disease in northern Sweden studies
Ulf Heilund 1,2, Linnea Hedman 1, Bo Lundback 1, Eva Rönnmark 1,2, The OLN Studies, Norrbotten County Council, Umeå, Sweden; 2Occupational and Environmental Medicine, Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 3Krafting Research Centre, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Background: Both smoking and occupational air pollutants (OAP) are risk factors for impaired respiratory health. Comparisons of their effects and how they interact are scarce.

Aim: To compare the effects of ever smoking and ever OAP on non-malignant respiratory disorders and to assess their interactions.

Material and methods: In a population-based incidence study of asthmatic and bronchitic disorders in northern Sweden, 5896 subjects answered a postal questionnaire in 1996 and in 2006 (79% of the responders in 1996). Cumulative incidences were calculated. Risk factors were analysed in multiple logistic regressions adjusted for possible confounders and the results are presented as odds ratios (OR). Ever/never smoking (S) and ever/never OAP were used as a combined variable with four categories or as dichotomous variables, respectively.

Result: Cumulative incidences for 10 years were for S0/OAP: 3.2-7.4, S1/OAP: 3.3–9.5, S0/OAP: 3.8–11.0, and for S1/OAP: 7.1–15.0. Using a combined variable with S0/OAP as the reference odds ratios were for S1/OAP: 0.99–1.8 with some significant results, S0/OAP: 1.0-2.2, with more significant results, and S1/OAP: 1.4–3.4 with all results significant. Interactions between smoking and OAP were mostly multiplicative for both asthmatic and bronchitic populations. Population attributable risks based on dichotomous variables were for smoking about 15%, for OAP about 20%, and for smoking and/or OAP about 25%.

Conclusion: OAP were at least as strong a risk factor as smoking for impaired respiratory health. Both smoking and OAP ought to be considered as possible confounders.

Urban living is a risk factor for allergic sensitization among adults in northern Sweden

Kajsa Warner1, Sigrid Sundberg1, Anne Lindberg1,2, Bo Lundbaek3,4, Eva Romnack1,2, 1The OLIN Studies, Norrbotten County Council, Luleå, Sweden; 2Department of Pulmonary Medicine and Allergology, Soderbryck Hospital, Luleå, Sweden; 3Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 4Department of Internal Medicine/Krefting Research Center, Sahlgrenska Academy, Gothenburg, Sweden

Aim: To assess prevalence and risk factors for allergic sensitization based on skin prick test (SPT) and specific IgE in adults.

Methods: In 2009 a random sample of 737 adults in ages 20-69 years was invited for examinations including SPT and blood sampling for specific IgE. SPT with ten common airborne allergens were performed in 463 subjects aged 20-60 years. A wheal ≥3 mm was considered as a positive reaction. Blood samples for specific IgE were collected in 692 subjects, and specific IgE was analyzed for the same allergens as tested in the SPT. An elevated level of specific IgE was defined as ≥0.35 IU/ml.

Results: In general, the prevalence of allergic sensitization based on SPT and specific IgE, respectively, yielded similar results. The prevalence of any positive SPT was 39% versus 35% for any elevated IgE. p=0.23. The prevalence of sensitization to cat and dog was significantly lower based on IgE compared to SPT, while sensitization to other allergens showed almost identical figures irrespectively of method used. The risk factor analyses based on SPT and IgE, respectively, yielded similar results. The prevalence decreased significantly by increasing age. A family history of rhinitis (OR 3.1; 95% CI 2.0-4.8 for any positive SPT, OR 2.7; 95% CI 1.8-4.0) and urban living (OR 1.7; 95% CI 1.1-2.7 for any positive SPT and OR 1.5; 95% CI 1.0-2.3) were significant risk factors for allergic sensitization. 

Conclusions: A similar sensitization pattern was observed when assessing the prevalence of allergic sensitization by SPT and specific IgE, respectively. Young age, a family history of allergic rhinitis and urban living were significant risk factors for allergic sensitization among adults.

Normal antioxidative enzyme activities in several genes are associated with less bronchial hyperresponsiveness (BHR) among young Danes

Vivi Schlunssen1, Tine Halsen Malling2, Torben Sigsgaard1, Charlotte Brach-Andersen3, Gerr Thomassen4, David Sherson5, Lars Skakhaage6, Jesper Barlum7, Øyvind Omland1, 1Department of Public Health, Section for Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; 2Department of Occupational Medicine, Aalborg Hospital, Part of Aarhus University Hospital, Aarhus, Denmark; 3Department of Clinical Genetics, Odense University Hospital, Odense, Denmark; 4Department of Occupational Medicine, Hospital of Southwest Denmark, Esbjerg, Denmark; 5Department of Occupational Medicine, Odense University Hospital, Odense, Denmark

Background and aim: BHR might be associated to the oxidative defense. We hypothesize that genotypes coding for normal antioxidative enzyme activity (AEAs) influence the occurrence of BHR.

Methods: In a cross sectional study 7,271 subjects aged 20-44 year (73% response rate) were recruited using an asthma screening questionnaire. All subjects with asthma (n = 460) and a 20% random sample (n = 728) were clinically investigated, including a bronchial provocation test, skin prick test (SPT) with 13 Aeroallergens, and a blood sample. A bronchial provocation test was available for 956 subjects, and BHR was defined as at least 20% drop in baseline FEV1. Variants in the following genes were genotyped: Glutathione peroxidase, GPX1 (Pro198Leu, rs1050450), manganese superoxide dismutase, SOD2 (Ala16Val, rs4880) and 3 glutathione S-transferases; GSTP1 (Ile105Val, rs1695), GSTT1 (gene copy nr) and GSTM1 (gene copy nr).

Results: The frequency of BHR was 12.8% in the random sample and 42.6% in the asthma sample. Log. reg. models showed a neg. association between being BHR and having at least 4 genotypes coding for normal AEA compared to no normal genotype, OR 0.24 (0.06-0.94) adj. for smoking, FEV1, sex, atopy, height2 and SPT-size of HDM. The result were similar after further adjustments for BMI, age, a family history of rhinitis and urban living were significant risk factors for allergic sensitization. 

Conclusions: A similar sensitization pattern was observed when assessing the prevalence of allergic sensitization by SPT and specific IgE, respectively. Young age, a family history of allergic rhinitis and urban living were significant risk factors for allergic sensitization among adults.

Oxidative stress in obese and nonobese patients with and without asthma

Lecia Hernandez-Cashin1, Fernando Holguin2, Albino Barraza-Villarreal2, 1Comprehensive Asthma Nurse1, Efrian Navarro-Olivos1, L.A. Brown3, L. Burwell3, Isabelle Romieu4, 1Environmental Health Department, National Institute of Public Health, Cuernavaca, MOR, Mexico; 2University of Pittsburgh, Pittsburgh, Pennsylvania, United States; 3London School of Public Health, Emory University, Atlanta, GA, United States; 4Head of Nutrition and Metabolic Section, International Agency of Research Cancer, Lyon, France

Rationale: Oxidative stress plays a role in the pathogenesis of many chronic inflammatory lung diseases.

Alternatively, increasing BMI may lead to an increase in airborne oxidative stress and obesity increases the risk for developing new onset asthma in adults and children. Exhaled breath condensate (EBC) collection is a noninvasive method to investigate pulmonary oxidative stress biomarkers.

Methods: We measured exhaled nitrites and nitrites, 8-isoprostane, pH and oxidized (GSSG) glutathione, to assess alveolar oxidative stress in obese patients (52 asthmatics and 135 non-asthmatics) and 118 nonobese (52 asthmatics and 135 non-asthmatics). EBC was collected over 10 min using a refrigerated denser according to European Respiratory Society/ American Thoracic Society recommendations.

Results: We found an increase in the concentrations of GSSG and 8-isoprostanes in both groups of obese patients (both asthmatic and non-asthmatics) compared with nonobese patient (asthmatic and non asthmatic) (p < 0.001) and a slight decrease in the pH of EBC in obese patients with asthma compared with the rest (p < 0.05). In relation to nitrites and nitrites were statistically lower in obese patients with asthma and without asthma than the total non-obese patients.

Conclusions: Our results suggest that obesity leads to an increase proinflammatory mechanisms that could be associated with increased systemic inflammation and oxidative stress and may affect the status or condition of asthma.

Bone mineral density is associated with the risk of non-small cell lung cancer, the HUNT study

Peter Hatlen1, Arnulf Langhammer2, Bjørn Henning Grønberg3, Sven M. Carlsen4, Siri Forsne5, Tore Aamand6, 1Circulation and Medical Imaging, Faculty of Medicine, NTNU, Trondheim, Norway; 2Public Health and General Practice, Faculty of Medicine, NTNU, Trondheim, Norway; 3Cancer Research and Molecular Medicine, Faculty of Medicine, NTNU, Trondheim, Norway; 4Public Health and General Practice, Faculty of Medicine, NTNU, Trondheim, Norway

Background: The overall survival in lung cancer is poor. The highest survival has been observed for cancers diagnosed in early stages, so early identification of patients at risk is important. Estrogen receptors have been found in non-small cell lung cancer. This may indicate that estrogen promote carcinogenesis. Estrogen level is associated with bone mineral density (BMD). Hence, BMD might be used as surrogate measure of long term estrogen exposure.

Aim: To investigate whether low BMD is associated with lower risk for lung cancer.

Method: We analyzed data from a cohort study, the Nord-Trøndelag Health Study (HUNT-study) linked to the Norwegian Cancer Registry. 18156 subjects under-
went bone densitometry of the forearm. The results were reported as z-scores and categorized into tertiles. All analyses were stratified by sex. Body mass index (BMI), lung function and smoking were tested as confounders in logistic regression models. BMI and lung function changed the odds ratios less than 10% and were not included in the final model.

**Results:** 72% of the 18156 participants were females. In the low z-score group we found more ever smokers (P < 0.01), but no difference in age and sex distribution between the three z-score groups. In all 194 cases with non-small cell lung cancer were identified. Among these 56% were females, 87% were ever smokers and the mean age was 72±11 years.

In men, low compared to high z-score was associated with a higher risk of lung cancer, OR 3.3 (95% CI: 1.85-5.99) and adjusted for smoking OR 2.93 (95% CI: 1.62-5.32) were found. In women no association with BMI was seen.

**Conclusion:** Low bone mineral density is associated with a higher risk of lung cancer, in men, but not in women.

**Individual decline of FEV1 show diversity in COPD**  
Jukka Koskelo1, Aleksi Kallio1, Henna Kupiainen1, Ari Lindqvist1, Maritta Kilpelainen1, Janne Pitkäniemi1, Vuokko Kinnula1, Tarja Laatinen1.  
1Department of Medicine, University of Helsinki, Finland; 2Research Environment Services, CSC - IT Center for Science Ltd. CSC - IT Center for Science Ltd.; 3Espoo, Finland; 4Department of Pulmonary Medicine and Clinical Immunology, University of Turku, Finland; 5Department of Public Health, University of Helsinki, Finland

Our objective is to develop methods to gain better understanding of individual development of lung functions in COPD sub-phenotypes. The patients (N=600) have been recruited from two Finnish University Hospitals. Their medical records have been carefully evaluated including spirometry results. A mixed-effects model was used to obtain predictors for the individual development of FEV1. To manage the within-patient variation of consecutive measures, simulation methods were used to determine which patients were presenting significant differences using logistic regression analysis. Our preliminary results suggest that COPD patients show diversity in their risk of future FEV1 decline. Development of robust screening protocols at early stages of COPD might be of value in revealing the rapid decliners.

**P3398**  
**Age of menarche and risk of asthma: Systematic review and meta-analysis**  
Sofie Lieberoth1, Vibeke Bakker2, Simon Francis Thomsen*.  
1Respiratory Medicine, Copenhagen, Denmark; 2Department of General Practice, Gentofte Hospital, Gentofte Hospital, Copenhagen, Denmark

**Aim:** To conduct a systematic review and meta-analysis of the relationship between the age at menarche and risk of asthma.

**Methods:** A prespecified literature search strategy was used to identify all articles directly addressing the relationship between asthma and age at menarche. We were interested in studies with asthma defined as self-reported asthma, diagnosed asthma or asthma symptoms and in studies defining early menarche as menarche before the age of 12 years of age or younger. Further, we were interested in controlled trials, prospective and retrospective cohort studies, case-control studies and cross-sectional studies with or without modelling.

**Results:** Our searches identified 34 articles of which 8 matched the inclusion criteria (two cross-sectional studies, three case-control studies, two retrospective studies, and one prospective study) with a total of 18124 patients. All articles were consistent in their results, showing a clear positive relationship between asthma and age at menarche. Estimates from the selected studies showed that the risk of asthma was increased between 1.13 and 2.34 times in girls with early menarche.

**Conclusions:** Early age at menarche is associated with increased risk of asthma. Hormonal, immunological, genetic, and environmental factors may act in a developmental context to explain this relationship.

**HRT, lung function, respiratory symptoms and menopausal status**  
Francisco Gomez Reig1, Ferenc Macsali1, Cecile Svanes1, Shyamali Dharmage1, Tula Drava1, Enno Ottinen2, Ann Johannesson3, Christer Janson3, ford Sunyer1, Eva Lindberg4, Joachim Heinrich5, Thorarin Gislason6, Deborah Jarvis1, Benedicte Leynart5.  
1Gynecology and Obstetrics, Haukeland University Hospital, Bergen, Norway; 2Gynecology and Obstetrics, Haukeland University Hospital, Bergen, Norway; 3Department of Occupational Medicine Haukeland University Hospital, Bergen, Norway; 4Centre for Molecular, Environmental, Genetic & Analytic Epidemiology, Melbourne University, Melbourne, Australia; 5Dep. Epidemiology and Public Health, Swiss Tropical and Public Health Institute, Basel, Switzerland; 6Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; 7Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; 8Department of Public Health, University of Turku, Finland; 9Department of Public Health, University of Helsinki, Finland

Menopausal women using HRT had higher FEV1 (adj diff 70 ml 95%CI=64 to 136) but no increase in respiratory symptoms (OR=1.00 (0.68 to 1.48) compared to menopausal women not using HRT. Menopausal women using HRT had indicated more asthma symptoms (OR=1.65 (0.86 to 3.18)) and indicated lower FVC (adj diff -103 ml 95%CI=4 to 136) but no increase in respiratory symptoms (OR=1.00 (0.68 to 1.48)).

**Conclusion:** The association between HRT and respiratory health was modified by menopausal status. In this population of women in the perimenopause, HRT appeared to be beneficial for respiratory health among menopausal women, but possibly led to adverse respiratory outcomes among those still menstruating. The conflicting evidence in the field might be due to lack of account for menopausal status when investigating effects of HRT.

**Age at onset and persistence of eczema and the subsequent risk of asthma and allergic rhinitis**  
Bianca Angelica1, John Su2, Caroline Lodge3,5, David Hill3, Cliff Hosking3, Erbas Bircan4, Catherine Bennett1,9, Lyle Gurrin3, Christine Axelrad3, Michael Abramson4, Katie Allen2,3, Shyamali Dharmage1,5, Adrian Lowe1,3,6,7,8,9.  
1School of Public Health, University of Melbourne, Carlton, VIC, Australia; 2Pediatrics, Royal Children’s Hospital, Parkville, Australia; 3Respiratory Diseases, Murdoch Children’s Research Institute, Parkville, Australia; 4Department of Puediatriciatric, John Hunter Children’s Hospital, Newcastle, Australia; 5School of Public Health, La Trobe University, Melbourne, Australia; 6Deakin Population Health, Deakin University, Melbourne, Australia; 7Department of Epidemiology & Preventive Medicine, Monash University, Melbourne, Australia

**Background:** Few studies have simultaneously addressed the importance of age at onset and persistence of eczema for the subsequent development of asthma and allergic rhinitis in children.

**Objective:** To examine age at onset of eczema and persistence as predictors for childhood asthma and allergic rhinitis at ages 6, 7 and 12 years.

**Methods:** A prospective birth cohort was recruited comprising 620 infants with a family history of allergic diseases. Telephone interviews were conducted 18 times in the first two years of life, annually from age 3 to 7, and at 12 years to document any episodes of eczema. Current asthma and allergic rhinitis were assessed at ages 6, 7 and 12.

**Results:** Very early-onset (<6 months) persistent eczema was related to current asthma (adjusted OR=6.9, 95%CI 2.4-14.7) and allergic rhinitis (aOR=6.5, 95%CI 1.9-10.9) at age 12 years. Adjustment for anti-allergen sensitisation in infancy dramatically reduced these associations. There was no evidence that early-onset remitting eczema (only present < 2 years) or late-onset eczema (onset > 2 years) were associated with current asthma and allergic rhinitis. These results were consistent with the 6-7 year findings.

**Conclusion:** Eczema which commences very early in life and persists into toddler years is strongly associated with childhood asthma and allergic rhinitis, and is possibly mediated by anti-allergen sensitization. However remitting and late intervention, the risk of diseases associated with early-onset eczema might be reduced.
376. Cellular signalling mechanisms in the airways

P3401 Effect of body mass index on lung function in children
Fabio Cribellaro1, Andrea Bruno1, Giuseppina Cuttica1, Stefania La Grutta1, Marco Meli1, Salvatore Bucchiari1, Giuniana Ferrante1, Silvia Ruggieri1, Giovanna Viegli1.

Background: Asthma and obesity are important health issues in industrialized countries and obesity is a risk factor for asthma. Our study aimed at investigating the effect of body mass index (BMI) on lung function in a large sample of healthy children enrolled in two cross-sectional surveys performed on random samples of children, aged 10-17 years, living in the city of Palermo, Southern Italy. At school, all the subjects completed self-administered questionnaires regarding past and current respiratory symptoms and personal information, and performed spirometry. On a total of 3,200 children, 807 reporting wheeze ever, nocturnal cough, or exercise-induced cough were excluded from the analysis. 2,393 subjects (49% M) were evaluated.

Methods: Height-adjusted lung function measures were plotted against BMI Z-score for each gender and age class, and slope values were computed by linear regression analysis. Height-adjusted FVC and FEV1 were positively correlated to BMI Z-score in both males and females. Slope values (L/BMI Z-score unit) were 0.057 in males and 0.114 in females for FVC and 0.022 and 0.072 for FEV1, respectively, being significantly steeper among females in each age class. FEV1/FVC ratio was inversely correlated to BMI Z-score with similar slope values for male and female. FEF25-75/FVC ratio was negatively correlated to BMI Z-score: the slope values were steeper among females in each age group. In conclusion, despite both FVC and FEV1, are positively correlated to BMI, their disproportionate increase as BMI increases could cause a reduction of relative airway size as measured by the FEF25-75/FVC at higher BMI values. This could, at least in part, contribute to the reported association between overweight-obesity and asthma.

P3402 Effect of TGF-β on FoxO activity in airway smooth muscle cells
Charalampos Michaeloudes1, Josie Baker, Pankaj K. Bhavsar, Jian Fang Chun.

Airway Diseases Section, National Heart and Lung Institute, Imperial College, London, United Kingdom.

Background: TGF-β is a mediator of abnormal airway smooth muscle (ASM) function in asthma and COPD. TGF-β triggers ASM cell (ASMC) hyperplasia and increases intracellular oxidants whilst reducing antioxidant enzyme expression. The O subfamily of forkhead box transcription factors (FoxO1, -3 and -4) activate CREB and CREM signaling, the MUC5AC expression in airway goblet cells was examined. Finally, the expression of FOXG1 in airway goblet cells was examined. Next, after transfection with pEFBOS-NIC (upregulating Notch signaling) or treated with γ-secretase inhibitor (downregulating Notch signaling), the MUC5AC expression in airway goblet cells was examined. Finally, the transcriptional regulatory mechanisms were analyzed.

Results: Notch signaling negatively regulates the expression of MUC5AC in airway goblet cells
Hai Feng Ou Yang, Respiratory Medicine, Xijing Hospital, Xian, Shanxi, China

Introduction and background: Goblet cell metabolism and airway mucus hypersecretion contributed to the pathogenesis of asthma and COPD. Evidence has shown that Notch signaling modulates the development of lung epithelial and the differentiation of intestinal goblet cells. Whether Notch signaling can regulate the expression of MUC5AC, a major component of airway mucus, is still unknown.

Aim and objective: To investigate whether Notch signaling can regulate MUC5AC expression in airway goblet cells.

Methods: Expression of Notch receptors and downstream molecules in airway goblet cells was examined. After transfection with pEFBOS-NIC (upregulating Notch signaling) or treated with γ-secretase inhibitor (downregulating Notch signaling), the MUC5AC expression in airway goblet cells was examined. Finally, the transcriptional regulatory mechanisms were analyzed.

25-hydroxide-vitamin D induces TSLP expression in human bronchial epithelial cells via the VDUP1 pathway
Haijun Zhao, Dan Zhang, Cheng Hao Peng, Yang Xia, Shaoli Cai, Respiratory Unit, Nanfang Hospital, Guangzhou, China

Background: Airway epithelial cells (AEC) express 1α-hydroxylase and are able to convert 25-hydroxy-vitamin D (25(OH)D) to an active form that plays a role in mucosal immunity. Thymic stromal lymphopoietin (TSLP), a cytokine mainly produced by AECs during allergic asthma reactions, plays a critical role in the activation of Th2 inflammatory responses. Therefore, we hypothesized that 25(OH)D would enhance the expression of TSLP in airway epithelia (16HBE cell line) and that vitamin D3 upregulated protein 1 (VDUP1) could be involved in this process.

Methods: 16HBE cells were cultured with 25(OH)D, and TSLP and VDUP1 mRNA and protein expression were then determined by means of quantitative PCR, ELISA, and Western blot analysis, as appropriate. The role of VDUP1 on TSLP expression was assessed in untreated and 25(OH)D-treated 16HBE cells where VDUP1 levels were manipulated via overexpression or siRNA-mediated silencing. The effect of 10 μM triaracozole, a chemical inhibitor of 1α-hydroxylase, on the expression of TSLP was also determined.

Results: 25(OH)D significantly induced TSLP and VDUP1 mRNA expression in 16HBE cells. Silencing of VDUP1 dramatically inhibited 25(OH)D-mediated induction of TSLP, and overexpression of VDUP1 upregulated baseline TSLP expression and 25(OH)D-induced TSLP expression in 16HBE cells.

Conclusion: These data demonstrated that vitamin D increased TSLP expression in 16HBE cells via upregulation of VDUP1.

P3407
Acetylcholine leads to STAT-1 mediated oxidative/nitrosative stress in human bronchial epithelial cells
Missella Prodi1, Gianluca Daniela Albano1, Angela Marina Mentallano1, Caterina Di Santo1, Rosalia Gagliardou1, Giulia Anzalone1, Loredana Riccobono1, Anna Bonanno1, Michael Paul Pieper2, Mark Gjomarkaj1, IBIM, CNR, Palermo, Italy; 2Boehringer Ingelheim, Pharma, Biberach, Germany

The induction of nitric oxide synthase (iNOS) expression via the signal transducer and activator of transcription 1 (STAT-1) is involved in the mechanism of ox-idative/nitrosative stress in bronchial epithelial cells during airway inflammation of COPD and to evaluate the effect of the anti-inflammatory treatment. Therefore, we investigated whether ACh generates oxidative/nitrosative stress in bronchial epithelial cells via STAT-1 pathway activation in human bronchial epithelial cells (16HBE). We aimed to investigate whether ACh generates oxidative/nitrosative stress during airway epithelial cells and nitrotyrosine in the supernatants were evaluated by flowcytometry in 16HBE cells. Acetycholine leads to STAT-1 mediated oxidative/nitrosative stress in human bronchial epithelial cells.

P3408
TLR2 and TLR4 induced tolerance in alveolar macrophages: differential effect on TNFα and IL-8 release
Sophie Reynolds1, Jieyan Hua2, James Jack3, Robin Meloy2, Damien van der Broek2, Vanessa Calvert2, 1IBIM, CNR, Palermo, Italy; 2Boehringer Ingelheim, Pharma, Biberach, Germany

TLR2 and TLR4 signaling potentiates airway secretion from the swine submucosal gland via NO/cGMP/cGK pathway
Koji Murakami1, Tsutomu Tamada1, Masayuki Nara2, Koji Murakami1, Masahito Ebina1, 1Department of Respiratory Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; 2Department of Comprehensive Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan

Rationale: Airway secretion plays an important role in the airway defense as a part of innate immunity. A major fraction of the airway fluids appears to be derived from submucosal gland in response to ACh. Toll-like receptor 4 (TLR4) recognizes gram-negative bacteria and activates the innate immune systems. However, the biological role of TLR4 in the airway secretion is not well understood.

Methods: Freshly isolated swine tracheal submucosal gland cells were investigated their secretory activities as ion currents by applying a patch-clamp technique. LPS was used as a potent TLR4 ligand. The expression of TLR4 was estimated by both the immunofluorescent staining and R-PCR. The involvement of NO/cGMP/cGK-dependent protein kinase (cGK) pathway was investigated by applying both the NO synthase and GKI inhibitors. The synthesis of endogenous NO was estimated by an intracellular NO indicator, DAF-DA.

Results: LPS significantly potentiated the ACh-evoked ion currents. This potentiating effect was completely abolished by the pretreatment of anti-TLR4 antibody or the TLR4 antagonist. The immunofluorescent staining and RT-PCR revealed the abundant expression of TLR4 on tracheal submucosal glands. Two different inhibitors of each NOs and cGK completely abolished the LPS-induced potentiating effect, respectively. LPS further increased the ACh-induced synthesis of NO.

Conclusions: Our studies revealed that TLR4 signaling could potentiates the electrolyte and water secretions from tracheal submucosal glands via the activation of NO/cGMP/cGK pathway. These findings suggest that TLR4 takes part in the airway mucosal innate immune systems as one of important pathogen-specific secretagogue.
IL-33 is released rapidly and in large quantities following ALT exposure and a distinct IL33 expression and release from airway epithelium. In vivo IL-33KO BAL was confirmed the IL-33-ST2 axis was confirmed in ST2 and IL-33 KO mice which showed no detectable IL-33 in BAL followed by rapid clearance (below detection limit of 2pg within 4-5 hrs). Key downstream effects were an increase in IL-5 and 24 hours BAL IL-5 was significantly increased (both 10ng/ml) and the cytokine production was examined with proteome profiler antibody arrays (R&D) that detect the production of 40 cytokines simultaneously. Results: Basal and induced production of IL-1- alpha was similar in cells grown on collagen-1 and fibronectin but IL-1-beta could not be detected in cells grown on collagen-4. Low levels of G-SCF were detected in cells on collagen-1 fibronectin stimulated with cytokines, but when cell were grown on collagen-4 the levels were statistically higher. There were no difference in basal and induced production of GRO-alpha and IL-8 on cells grown on collagen-1 or fibronectin. The basal level of IL-8 was dramatically reduced on collagen-4 compared to collagen-1 and fibronectin. However cytokines triggered similar levels of IL-6 production regardless of matrix substrate. Conclusions: In this study we show that the extracellular matrix actively contributes to modify cell phenotypes. Cells grown on collagen-4 that represents a "homeostatic matrix" produced a different repertoire of inflammatory mediators than cells grown on "remodeled matrix proteins" collagen-1 and fibronectin.

**Inhibition of A. fumigatus growth by human respiratory cells**

Viviane Bailey, Jean-Paul Laget, Michel Chignard. Innate Host defense and Inflammation - Inserm U874, Institut Pasteur, Paris, France Aspergillus, Institut Pasteur, Paris, France Innate Host defense and Inflammation - Inserm U874, Institut Pasteur, Paris, France

The innate immune response to fungi mainly involves macrophages and neutrophils. By contrast, the possible participation of respiratory epithelial cells has been poorly studied. In this study we observed that RENCROS display the property of inhibiting mycelium development of Aspergillus fumigatus (A.f) and that this activity is linked to PI3 kinase activation. Bronchial cells (BEAS-2B cell line) were incubated with A.f and the growth of the fungus was estimated by optical microscopy observation and measurement of galactomannan concentrations in the extracellular media. The role of PI3 kinase pathway was evidenced by the use of the specific inhibitor LY294002 (30 μM). Spore internalization in RENCROS was followed by epifluorescence. FITC-labeled spores (green) when outside of cells were further labelled with an anti-FITC antibody labeled with a red fluorochrome (Alexafluor 568). In the presence of REC, most of the spores do not germinate as opposed to spores incubated in the absence of cells. The growth quantification by galactomannan concentration measurements display a 4.5 lower concentration in the presence of cells. The anti-aspergillus activity is inhibited when cells are incubated with LY294002, indicating the involvement of the PI3 kinase pathway. Of note, inhibitors of p38 MAP kinase and ERK1/2 are inactive. We evidenced that the activity is directed against the spores and not against the hyphae but is not linked to the spore internalization.

In conclusion, as macrophages and neutrophils, REC play a role in the anti-aspergillus activity. They are able to prevent the mycelium development and as such potentially prevent its dissemination.

**Acknowledgements: Work supported in part by a grant from Vaincre la Mucoviscidose.**

**Characterisation of endogenous IL-33 using a model of Alternaria-induced pulmonary inflammation**

Suzanne Cohen, Jayesh Majithiya, Nicola Davis, Ian Scott, Laura Robinson, Arthur Lewis, Andrew Prior, Marlon Rebello, Dominic Corkill, Matthew Sheean, Richard May, R&RD, MedImmune, Cambridge, United Kingdom; R&D, MedImmune, Gaithersburg, United States

**Background:** IL-33 is a potential mediator of chronic inflammatory diseases including asthma. However, endogenous forms of IL-33 are poorly understood. Here we have used a model of Alternaria alternata (ALT) challenge to investigate in vivo mechanisms of IL-33 processing and release.

**Methods:** Cytokines were quantified in bronchoalveolar lavage (BAL) from BALB/C mice by MSD assay. Mast cells were differentiated from bone marrow over 5 weeks and stimulated with BAL or recombinant IL-33 for 24 hours. Results: Intranasal challenge with 50μg ALT to anaesthetised BALB/C mice caused a spike (∼2000 pg at 15-30min) of IL-33 in BAL followed by rapid clearance (below detection limit of 2pg within 4-5 hrs). Key downstream effects were an increase in 5 and 24 hours BAL IL-5 (∼400pg and ∼600pg, respectively) and eosinophilia at 24 hours. Conclusions: These findings suggest that IL-33 expressed in AT I cells, is involved in the transport of the airway epithelium.

**Results:** IL-33 conc. in post-lung transplant BAL trended towards an increase following diagnosis of BOS but did not reach statistical significance. However, elevated levels of IL-33 were associated with positive microbial culture (mean 178.107pg/ml±4.289pg/ml vs 71.31pg/ml±0.007). IL-33 was strongly expressed in airway epithelia with a predominant nuclear location IL-33 was not detected in response to epithelial cell damage. Conclusions: IL-33 is strongly expressed in the airway epithelium of chronic respiratory conditions but does not appear to be released as an alarmin in response to airway epithelial cell damage. Elevated IL-33 associated with infection in the post transplant population may contribute towards allograft dysfunction but further work is required to evaluate the cellular mechanistic pathways.
Activation of both transcription factors STAT5 and IRF-1 is insensitive to corticosteroid insensitivity in severe asthma. The long-acting β2-agonist, salmeterol (SA; 8) were obtained from endobronchial biopsies, cultured at passage 4-5. ASMC of the healthy (9), non-severe (NSA; 8) and severe asthmatics (SA; 8) were cultured at passage 4-5.

**Aims and objectives:**

- Compare protein/mRNA, phosphorylation, and nuclear expression in SA, NSA, and healthy (9).
- Compare with non-overweight subjects, obese subjects with asthma were less responsive to treatment. The aim of this study was to investigate the relationship between BMI and response to treatment in a group of patients that were referred for asthma control.

**Background:**

Increases in body mass index (BMI) are reported to influence asthma response to treatment. The aim of this study was to investigate the relationship between BMI and response to treatment in a group of patients that were referred for asthma control.

**Patients and methods:**

- Effectiveness measurements in this analysis included percentage of changes in forced volume in 1 second (FEV1), forced volume capacity (FVC), FEV1/FVC, and FEF25-75%.
- A total of 293 subjects with asthma of both genders and above 18 years of age were divided into the following BMI categories: 107 (36.5%) non-obese (BMI <25), 186 (63.5%) overweight and obese (BMI ≥25). Percentage of change was defined as change in variable between baseline and end-of-treatment.

**Results:**

- Analyses of non-overweight vs. overweight/obese asthmatics demonstrated non-significant differences in baseline FEV1 (1.62 ± 0.56 L vs. 1.63 ± 0.55 L, p = 0.89); FVC (2.58 ± 0.73 L vs. 2.47 ± 0.82 L, p=0.25); and FEF25-75% (1.04 ± 0.55 m/sec vs. 1.05 ± 0.50 m/sec, p=0.47) respectively.
- Compared with non-overweight subjects, obese subjects with asthma were less responsive to treatment than non obese asthmatic subjects. Percentage changes of FEV1, FVC, FEV1/FVC, and FEV1/FVC in non-obese versus obese patients were: 79.57 ±6.14% vs. 62.1 ± 6.14%, p<0.005; 47.7 ± 11.7% vs. 39.9 ± 28.3%, p=0.036; 151.98 ± 127.8% vs. 123 ±91.12%, p=0.041; 20.54 ± 15.63% vs. 15.63 ± 11.32%, p=0.005 respectively.

**Conclusion:**

Cigarette smoke extract treatments increased mTORC1 activity in U937 cells, and ramipril partially reversed corticosteroid insensitivity caused by cigarette smoke exposure.
Conclusion: Percentage changes of spirometric values to treatment in overweight/obese asthmatic patient were lesser in compared with non-overweight subjects.

P3421
Perceptions and factors affecting poor adherence to inhaled steroids among bronchial asthma patients in Kuwait
Radhakrishna Panicker, Nermina Arifhodzic, Mona Al-Ahmed, Shahrarai Huda. Allergy, Rashid Allergy Centre, Kuwait, Kuwait Statistics and Research, Kuwait University, Kuwait, Kuwait

Background: Poor adherence to regular inhaled steroids is a cause of poor asthma control.

Aim: To assess adherence to treatment, factors of poor adherence, perception on inhaled steroids among asthmatics in Kuwait

Design: Observational study

Subjects: 150 asthmatics (95 m,55) 15-60 years, were recruited and followed up for 12 consecutive months from January 2009 to December and asked to fill in a questionnaire of adherence, beliefs about asthma,treatment and reasons for non adherence.

Results: First 3 months, 66 (44%) were adherent to twice daily dosage, but at 12 months only 25%. More males were adherent at 3 months (63.6% vs. 36.4% p<0.05) and at 12 months (81.6% vs 18.4% P<0.05).Employed as compared to unemployed (p<0.05), educated to secondary school and above, as compared to the less educated (p<0.05) were more adherent at 3 and 12 months. At 12 months, younger asthmatics were more adherent than expatriates (p<0.05).

Logistic regression analysis of the beliefs for non adherence showed 52% did not consider asthma as a serious disease. 82% stopped medicine because of fear of side effects, 75% were influenced by the wrong advice by relatives or friends, that long term steroids are dangerous (p<0.05). 80 (51.6%) believed tablets are less dangerous than inhalers.

Conclusion: Adherence to inhaled steroids was poor. Factors were, females, fear of side effects, fear of side effects from inhalers and relatives with wrong information on steroids and poor understanding about asthma.

Since the employed and educated patients showed good adherence, asthma education is important in asthma management. In non-adherence, the clinician should find methods to overcome the barriers of non adherence.

P3422
Community-acquired pneumonia in pediatric patients: New diagnostic priorities
Zoya Nestarenko1, Olena Ivanina2. 1Department of Pediatrics, SI “Lugansk State Medical University”, Lugansk, Ukraine; 2Polyclinic Department, Lugansk Municipal Children’s Hospital #2, Lugansk, Ukraine

Background: High incidence of childhood community-acquired pneumonia (CAP), changes in CAP manifestations, reduced significance of classical diagnostic criteria, leading to inadequate treatment, work against lowering risk of complications and mortality.

Aim: To study the features of actual clinical course of pediatric CAP.

Methods: 64 patients aged 1-18 years, with clinically and radiographically diagnosed CAP with detection of serum antibodies against intracellular pathogens, were followed up for 12 months. Patients were divided into two age groups: aged 1-4 (group A, n = 24) and 5-18 (group B, n= 40). All patients had numerous phenotypic signs of hematogenous infectious diseases.

Results: All patients had indistinct clinical manifestations. Recurrent course of CAP was in 54(84.4%) patients. CAP caused by Chlamydia pneumonia (Cp) was more frequent in group A – in 23 patients (95.9% of the group), by Mycoplasma pneumonia (Mp) – in group B, in 37 patients (92.5% of the group).

Asthma was diagnosed in 20(45.5%) patients mainly of group B, with recurrent CAP in 34.5% of asthmatic patients, 62.1% of them had pulmonary hypertension (PH), 6.7% - CT signs of bullous emphysema (BE).

Conclusion: 1. Close relationship between HCTD and CAP is revealed. 2. Cp-CAP was more frequent in pediatric patients up to 4 years old. Mp-CAP - in children 5 years and older. 3. Recurrent CAP was the cause of asthma exacerbation in one-third of patients with asthma and CAP. 4. Asthma in children with CAP and HCTD was more severe with development of PH, BE.

P3423
Strategy and implementation documents were published to improve outcomes in COPD and asthma in England
Sue Hill, Joanna Clarke, Kevin Holton, Robert Winter, Anne Moger, Matt Kearney. Respiratory Programme, Department of Health, London, United Kingdom

Rationale: Despite three million people estimated to have COPD in the UK, only 900,000 currently have a diagnosis. Variation in care and outcomes is significant. Action was required to move from a reactionary service, treating those with moderate to severe disease, to prevention, earlier diagnosis and pro-active management.

Methods: A systematic evidence review was undertaken with the engagement of a range of healthcare professionals from primary and secondary care. Following wide consultation, consensus was reached on six high-level objectives to improve outcomes for patients which would require a collaborative approach involving public health, health and social care services.

Results: An Outcomes Strategy for COPD and Asthma was published in July 2011. This was accompanied by an implementation document specifically for the health service, which set out in more detail the actions to help meet the objectives. A baseline dataset of indicators for measuring and monitoring outcomes for improvements in the respiratory care have been established and benchmarking data produced to assess variation in models of service provision across England. This dataset is responsive to change at all levels of the provider system from local through to national and helps to identify areas and particular aspects of care for local action.

Conclusion: Through the Outcomes Strategy for COPD and Asthma, the NHS implementation document that accompanies it, and the regional clinical leadership, care and outcomes for COPD are improving through a shift in the burden of the disease to prevention, diagnosis and proactive management.

P3424
The directions of mild asthma evolution
Olena Yuliano1, Vitaly Kupav2, Dmitriy Nagatin3, Alexander Zhebskoy4. 1Pulmonology, Samara Regional Clinical Hospital, Samara, Russian Federation; 2General Practice, Samara State Medical University, Samara, Russian Federation; 3Allergology and Immunology, Samara Regional Clinical Hospital, Samara, Russian Federation; 4Allergology and Immunology, Samara State Medical University, Samara, Russian Federation

Mild asthma is the heterogenic cohort with low level of adherence and asthma control, so investigators curiously study it.

The aim was to study the results of evolution of the disease in mild asthma cohort among patients with available data for the period of 3 years.

We studied the history of 141 patients with a 3 year history of mild persistent asthma. Three groups were formed: 1st group – had actual controlled asthma (141), 2nd - had partially controlled asthma (n=74), 3rd - uncontrolled asthma (n=24).

E-data base collected the data of all the patients and includes information concerning educational level, passing educational asthma programs, lung function, Ig E level, treatment regimens, asthma control, measured by ACQ and ACT, cooperation index, life quality level and etc.

We observed in the 1st group – higher level of lung function and life quality level. Patients of this group more often took part in asthma educational programs, had higher cooperation index (p<0.05). Besides this 1st group didn’t get any therapy for 3 last months and 6.9% passed successfully allergen-specific immunotherapy. We have revealed difference in educational status and life quality level in other two groups. Patients of the 2nd group had significantly higher KCS, 269 (6.13±3.9 mg per day vs 108.9±4.19±5 mg per day in the 2nd group), Ig E level, low cooperation index, more rarely have made planned visits to their physician (p<0.05). Obvious difference in asthma control assessed by ACT between 2nd and 3rd groups was found.

Conclusion: The results of evolution of the disease finally demonstrate several interventions that could influence predictably on it: taking part in asthma educational programs, pass allergen-specific immunotherapy, making planned visits to the physician.

P3425
Current smoking and low HRQoL as strong predictive factors for acute care among elderly asthma patients
Paula Kaukil1, Henna Karjonen2, Ari Lindqvist2, Tari Haalstael1, Tarja Laitinen3. 1Dept of Allergy, Skin and Allergy Hospital, Helsinki, Finland; 2Research Unit of Pulmonary Diseases and Division of Pulmonology, Helsinki University Central Hospital, Helsinki, Finland; 3Dept of Pulmonary Diseases and Clinical Allergology, Turku University Hospital, Turku, Finland

Objective: To examine risk factors for emergency visits among elderly asthma patients in a well-organized asthma care setting.

Methods: The study population was a random sample of 344 patients visiting the Pulmonary Clinic of Helsinki University Hospitals (HUCH) with a diagnosis of asthma (A54.4-46) during the years 1995-2006. 95% asthma patients had at least one emergency visit and formed the active group. 227 patients without emergency visits formed the control group. Uni- and multivariate logistic regression was used to analyze the significance of several demographic and clinical variables for the need of emergency treatment.

Results: The study population was on average 56 (SD 13) years old and 72% of the patients were women. Follow-up among cases covered 799 patient-years and on average 0.4 emergency visits per patient-year was identified. Asthma, lower and upper respiratory infections were described as the discharge diagnosis in 45%, 17% and 6% of the visits, respectively. The cases were older, had suffered longer from asthma, had lower lung functions, and were more often ex- or current-smokers. In the multivariate analysis current smoking and low HRQoL (health related quality of life) remained independent risk factors for emergency room care (OR 3.9; CI 1.7-8.8 and OR 1.9, CI 1.2-3.0, respectively).

Conclusions: Current smoking is a risk factor for the need of emergency care. Also those with self-estimated poor HRQoL are in a risk for emergency treatment. In this study population, enrolled in the special care setting, the promotion of smoking cessation might play an important role in prevention of acute hospital care among elderly asthma patients.

P3428  Which device for which patient? Criteria for selecting inhaler devices

Saeed Badaloo, Omar Al Rawas. Medicine, Sultan Qaboos University Hospital, Al Khoud, Oman; Medicine, Sultan Qaboos University, Alkhood, Oman

Inhalation is the preferred route of delivery for anti-asthma medications. Asthma management guidelines recommend inhalation choice, but they don’t provide specific guidance regarding devices selection.

Unless all asthmatic patients are able to use their inhaler devices correctly, poor inhalation techniques will continue to be one of the major obstacle of asthma management. Prescribing a suitable device for the patient will guarantee better inhaler technique and improves medication delivery to the airways and as a result will improve level of asthma control.

The ideal inhaler device is the device that is easy to be used by the patient and enable the desired medication to reach the airways. The selection of the device should be made after assessing patients abilities to ensure that they are able to understand the instructions and to perform the necessary steps correctly. However, in reality inhaler devices are often prescribed according to patient age, level of education, cost of the device, pharmaceutical companies recommendations or previous experience.

To guide our prescribers in selecting the best devices for their patients, we developed inhaler devices selection criteria according to patient’s cognitive, physical and inhalation abilities.

The aim of this presentation is to present the criteria assessment steps and inhaler devices choices.

P3427  Methacholine challenge response in controlled asthma and correlations with other disease characteristics

Inna Stoicescu1, Ileana Stoicescu1, Diana Ionita1, Daniela Dospinoiu1, Felicia Cojocaru1, Camelia Nita1, Alina Croitoru1, Madalina Burecu1, Carmen Stroescu2.

Clinical Pneumology, M. Nasta Institute of Pneumology, Bucharest, Romania; 2Respiratory Physiopathology, M. Nasta Institute of Pneumology, Bucharest, Romania; 3Exploratory Pneumology, Arensia Clinical Research, Bucharest, Romania

Aim: To assess methacholine challenge response in patients with controlled asthma and its correlations with other asthma characteristics.

Subjects and methods: Patients with controlled asthma performed methacholine challenge test (MCT) using ATS Guidelines (1999). Bronchial hyper-reactivity was considered severe for PC20 0.125 mg/mL and moderate for 0.125-2 mg/mL.

Spirometry, exhaled nitric oxide (NIOX) and blood eosinophils measurements were performed the same day prior to MC. A bronchodilator test was performed the next day and dFEV1 was calculated (difference and % from the baseline FEV1 value).

The allergic rhinitis history was noted. Correlations between parameters were calculated.

Results: Twenty-two patients were evaluated: mean age 47, 7 males.

The mean PC20 was 0.558 mg/mL (range 0.003-2). Nine patients had severe and 13 moderate hyper-reactivity.

Mean baseline dFEV1 was 84%, mean NIOX 35 ppb (range 5-108), mean dFEV1 0.46 L (0.04-1.35) and 23% (3-63), blood eosinophils 234/mmc (30-840) and 3% (0-6.9-4). Ten of the patients had allergic rhinitis.

The PC20 values correlated with dFEV1 post-bronchodilator value (r=0.429, p=0.046), but with no other parameters studied. The severity of hyper-reactivity was only associated with the dFEV1 values (p=0.017).

The bronchial response was similar regardless the presence of allergic rhinitis. The performed statistical evaluations show a statistically significant control.

Conclusions: Moderate/severe bronchial hyper-reactivity was seen in our patients with asthma considered controlled when using GINA 2011 criteria. NIOX values, eosinophil blood counts and bronchodilator response showed high variability. None of the studied characteristics correlated with the methacholine response, except for the bronchodilator response.

P3428  Exhaled nitric oxide correlations in patients with controlled and partially controlled asthma

Ileana Stoicescu1, Diana Ionita1, Daniela Dospinoiu1, Camelia Nita1, Felicia Cojocaru1, Alina Croitoru1, Madalina Burecu1, Carmen Stroescu2.

Clinical Pneumology, M. Nasta Institute of Pneumology, Bucharest, Romania; 2Respiratory Physiopathology, M. Nasta Institute of Pneumology, Bucharest, Romania; 3Exploratory Pneumology, Arensia Clinical Research, Bucharest, Romania

Aim: To assess NIOX values correlations with other disease characteristics in patients with controlled and partially controlled asthma.

Subjects and methods: Patients with controlled and partially controlled asthma performed exhaled nitric oxide (NIOX), spirometry, bronchodilator test and blood eosinophils measurements. The allergic rhinitis history was noted. Correlations between NIOX values and the other parameters were calculated.

Results: 42 asthma patients were evaluated: mean age 43, 14 males; 24 had controlled and 18 partially controlled asthma.

NIOX values varied between 5 and 151 ppb (mean 41) in the whole group of 42 patients.

All the tested parameters differ between the two groups. Significant differences were only seen in baseline FEV1 value (75% from predicted in the partially controlled, 85% in the controlled, p= 0.035) and blood eosinophils values (371/mmcc, 4.5% in the partially controlled, p=0.012; 155/mmcc and 2.3% in the controlled asthma patients, p=0.023).

In the whole group of 42 patients NIOX values correlated with blood eosinophils (r=-0.492, p=0.001), not with FEV1 values or the dFEV1 increase after the bronchodilator administration (p=0.05). The correlations were similar when the two groups were analyzed separately. NIOX values correlations with blood eosinophils values were r=0.577, p=0.012 in the partially controlled, and r=0.412, p=0.040 in the controlled group.

No correlations were seen related to the presence of allergic rhinitis.

Conclusions: Exhaled nitric oxide values showed high variability and only correlated with blood eosinophils values in our group of patients, regardless of asthma control.
The relationship between the serum YKL–40 level and severity of asthma
Serap Duru, Gulbahar Yuce, Atil Kelesoglu, Melike Erdem, Erdem Ağa, Murat Keşgören, Fatma Kara, Sadık Arıç, Chest Diseases, Diskapi Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey; Chest Diseases, Etilk Eğitim ve Araştırma Hastanesi, Ankara, Turkey; Diskapi Yıldırım Beyazıt Education and Research Hospital, Emergency Clinic, Ankara, Turkey; Department of Biochemistry, Ankara Pediatrics Hematology and Oncology Hospital, Ankara, Turkey

Aim: The aim of this study was examined a relationship between the serum YKL–40 (chitinase-3-like-1) level and severity of asthma. Methods: In the study, 90 female non-smoker and without additional disease patients (ages 20–66) in a stable and exacerbation period for asthma were grouped as Group I: Stable mild persistent asthma (n: 30), Group II: Stable moderate and severe persistent asthma (n:30), Group III: Exacerbation period (n:30). The differences of the serum YKL–40 level among all the groups were examined with ELISA. Also, in the patient groups with asthma, the serum YKL–40 level was compared with age, age of asthma, body mass index (BMI), forced expiratory volume in first second (FEV1), peak expiratory flow (PEF), total IgE results. One-way analysis of variance was used to examine differences between groups.

Pearson’s correlation coefficient was used for correlation between variables.

Results: The serum YKL–40 levels during asthma exacerbation period were found the highest average (36.36±10.49 ng/ml) while the serum YKL–40 levels were found the lowest average (13.20±5.60 ng/ml) in stable mild persistent asthma have (p<0.05). There was a negative correlation the serum YKL–40 levels and FEV1, PEF, exacerbation period (p<0.05). There was no correlation between the serum YKL–40 levels and other variables in three groups.

Conclusion: Increased the serum YKL–40 may be a marker used to evaluate the level of asthma severity.

P3432 Heritable connective tissue disorders as factor modifying asthma symptoms in pediatric patients
Zina Nesterenko1, Olena Ivanova2
1Department of Pediatrics, SI “Lugansk State Medical University”, Lugansk, Ukraine; 2Polytech Department, Lugansk Municipal Children’s Hospital 2, Lugansk, Ukraine

Background: High prevalence of heritable connective tissue disorders (HCTD) among children changes clinical manifestations of common childhood diseases, leading to diagnostic and therapeutic errors.

Aim: To study clinical features of asthma (A) in children with HCTD.

Methods: In 2005–2007, 186 patients with moderate allergic asthma (GINA Guidelines 2009) were followed up for two years. 33.4±1.6% patients had mild persistent A, 57.49±5% − moderate persistent A and 10.08% − severe persistent A. 55.68±3% patients clinically, serologically and immunologically diagnosed. All children had phenotypic manifestations of HCTD.

Results: CAP caused by Mycoplasma pneumonia was in 80% of asthmatic patients with CAP. By Cytomegalovirus – in 36.3%, by Chlamydophila pneumonia - in 29.1%. 47.3% of patients with A and CAP had recurrent episodes of CAP that caused A exacerbation. Pulmonary hypertension (PH) was in 28.8% of patients with A and in 32.7% of patients with CAP and A. 33.3% of the latter had severe persistent asthma. The EIT evidence of pulmonary fibrosis (PF) and emphysema bullae (EB). Patients with A exacerbation due to CAP received antibiotic treatment (macrolides) (ABT) besides controller therapy, and this provided the achievement of A control.

Conclusions: 1. A exacerbation in 80% of asthmatic patients was due to CAP caused by Mycoplasma pneumonia. 2. Recurrent episodes of CAP were in 47.3% of asthmatic patients with HCTD. 3. 28.8% of patients with A and HCTD, and 37.2% of patients with A, HCTD and CAP had evidence of PH, with PF and EB in 33.3% of the latter. 4. Basic therapy of asthmatic patients with CAP included ABT to achieve A control.

P3433 Relationship of body mass index and current asthma status among adult asthmatics presenting in the outpatient department
Shane Boissy1, Joel Santigal2, Adele Espaldon1
1Medicine-Pulmonary Medicine, Philippine General Hospital, Manila, Philippines; 2Medicine-Pulmonary Medicine, Philippine General Hospital, Manila, Philippines

Purpose: To determine whether a relationship between body mass index (BMI) and current asthma status among adult asthmatics seen in the outpatient departments of the Philippine General Hospital Asthma Comprehensive Care Unit, have better asthma control, decrease asthma severity, higher FEV1, and good response to bronchodilator.

Methods: All adult patients who fulfilled the inclusion criteria seen in the outpatient department (OPD) of the Philippine General Hospital from November 2010 to December 2011 referred by consultants, fellows in training and residents will be gathered and ask to complete a questionnaire after informed consent was obtained. If subject has no pulmonary function test, a free pulmonary function test will be done.

Results: BMI status was significantly associated with outcome measures. Majority of the obese patients have uncontrolled asthma. Results showed that, patients, regardless of their body mass index, who were enrolled at the Philippine General Hospital Asthma Comprehensive Care Unit, have better asthma control, decrease asthma severity, higher FEV1, and good response to bronchodilator. Obese asthmatics have more severe asthma, poorer asthma control, with more frequent attacks, more frequent use of relievers, and are overall less responsive to bronchodilators. Those asthmatics with proper education of their disease have better levels of control.

Clinical Implications: Proper weight management improves asthma control; prevent asthma attacks and better response to bronchodilators. Thus prevent hospitalization. Enrollment to asthma education program enhanced asthma management.

P3434 The role of the tracheal phonography in chronic obstructive lung disease and asthma diagnosis
Yuri Kulakov, Tatiana Khairzamanova, Mikhail Kinakin, Chair of Hospital Therapy, Vlandovostok State Medical University, Vladiwostok, Primorsky Region, Russian Federation

Obstructive lung diseases are the most common chronic diseases of bronchopulmonary system. According to epidemiological markers were identified more than 11 million people with chronic obstructive lung disease (COPD) in Russian Federation, and most common cause of population disability. In recent years, have been increasing the rates of asthma. The purpose of this study is to determine the role of tracheal phonography of forced expiration in the obstructive lung diseases diagnosis. This acoustical method is based on registration of forced expiratory noises which recording from laryngho-tracheal area. There were examined 59 patients with obstructive lung diseases at the age 46-58 years. It was diagnosed that 24 patients had bronchial asthma and 35 one had COPD. We compared spirometry grades and duration of the noise detected by tracheal phonography of forced expiration. All patients had lengthening of the acoustic value of 1.5-5 times the calculated norm. According to the correlation analysis between the acoustic value and FVC (r = 0.64, p<0.05), FEV1 (r = 0.46, p<0.05) and PEFR (r = 0.11, p<0.05). The result of our research is allowing us to recommend the acoustic method for chronic obstructive lung disease and asthma diagnosis.

P3435 Study of motivation in patients with bronchial asthma
Ludmila V. Borodina1, Anastasiya S. Vodolazskaya2, Viktor P. Kolosov3
1Laboratory of Pernigilation of Non-specific Lung Diseases, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation; 2Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation

The disease leads to revaluation of personal values and motivation, that is why the patients are usually motivated to escape failures and are afraid of risk. The motivation of patients with bronchial asthma (BA) has not been studied enough.

Aim: To study motivation of BA patients.

Methods: 168 patients (78% of whom were women) with BA of different severity. The mean age was 47±11.9 years; the mean duration of the disease was 6.0±7.7 years. The test “Motivation to success” by T. Ehlers, method of diagnosis of the ability to risk by Schubert, Marlowe-Crowne Social Desirability Scale were used.

Results: The patients were divided into three groups. The 1st group included 37 patients with mild BA, the 2nd – 95 patients with moderate BA, and the 3rd group – 36 patients with severe BA. The patients of all groups had a motivation to success predominantly of medium and high level (the mean values are 3.14±0.66, 2.9±0.83, 3.05±1.24 points, respectively, at the maximum of 4 points). The patients of the 1st and 2nd groups were equally careful (low degree of readiness to risk: 2.4±0.63 and 2.36±1.03 points, respectively). By this criterion they significantly differed from the patients of the 3rd group who had medium values of the test (3.05±1.24, p<0.05). The level of approval motivation were low in the majority of the examined patients (in 78% of respondents it was within the range from 1.2±0.41 to 1.2±0.45 points).

Conclusion: BA patients have quite a high motivation to success achievement and a desire to get the result not depending on the disease severity. The low approval motivation appears due to the orientation to the personal opinion. The motivation have to be taken into account for effective doctor-patient communication.

P3436 Use of leukotriene modifiers promotes to decrease bronchial hyperreactivity in bronchial asthma patients

Background: Clinical studies proved, that leukotriene modifiers have mild and vari- able broncholytic effect, decrease symptoms, improve lung function and decrease asthma exacerbations.

6188
Objectives: This study aimed to investigate the influence of leukotriene modifiers (antagonists of Cys-LR1—montelukast) on bronchial hyperreactivity in steroid-naïve bronchial asthma patients.

Methods: A total of 58 patients (52 adults and 6 children) were included in the open-label study. Asthmatic patients were divided into three different age groups: 4-11 years (n=60), 12-64 years (n=62) and ≥ 65 years (n=52). COPD patients consisted of all ages groups (n=53).

Results: Clinically not controlled asthma with respect to Eosinophilic Lung Disease (EOL) questionnaire was present in 25% of patients. Moreover, the number of exacerbations in the previous year was reported by 37% of patients. Amongst COPD patients, 24% reported exacerbations of asthma.

Conclusion: The use of leukotriene modifiers (montelukast) in combination with inhaled steroids is an effective treatment for asthma and COPD patients with leukotriene receptor hypersensitivity.

P3437
ObSErVational study for thE monItoring of not controlled Asthma (SERENA)
Andrea Rossis1, Antonio Corrado2, on behalf of SERENA/AIPO Study Group.
1Pulmonary Unit, University and General Hospital, Verona, Italy; 2Respiratory Intensive Care Unit and Thoracic Pathophysiology Laboratory, University and General Hospital Careggi, Firenze, Italy.

Background: International guidelines recommend control of asthma as a major goal of therapy. Patients with "well-controlled" asthma present no exacerbations. However, it is well known that implementation of guidelines in real clinical practice may be difficult. Objective: To assess the level of asthma control in real clinical practice in patients treated with inhaled steroids and/or bronchodilators following the GINA guidelines. Methods: This 6 months observational study was promoted by AIPO and was carried out in 16 Pulmonary Units. Consecutive patients with asthma, treated after GINA guidelines, attending the outpatients of each center were enrolled (2010). Data on exacerbations and treatments were collected by means of a web based Case Report Form, and control of asthma was assessed with the Asthma Control Test (ACT) questionnaire.

Results: The number and characteristics of the patients enrolled are reported in Table 1.

Table 1. Patients characteristics
N of patients Gender (MF) Age BMI Smokers Ex smokers Non smokers
584 200388 53 (19-88) 27 (16-341) 28% 72%

91% of patients were treated with LABA+ICS, while 9% with ICS and SABA. 60% of patients reported 1 exacerbation, 16% 1 Emergency Visit and 44% 1 non programmed visit in the year preceding the study. The data on control of asthma in the age groups is reported in Table 2.

Table 2. Control of asthma (ACT score)

P3439
Clinical pattern of COPD in South India—A global public health problem
V.P. Gopinathan, A. Suparya. Dept of Pulmonary Medicine, JMMC,Tiruchir, Trichur, Kerala, India.

Chronic Obstructive Pulmonary Disease (COPD), among all noncommunicable diseases and chronic respiratory diseases, continues to be on the increase, mostly attributed to limited doctor/patient health education globally. Associated comorbidities are not often evaluated concurrently that a sizeable number of patients die of alternate disorders. Spirometry being the gold standard for diagnosis is forgotten that these patients are treated for few days as “Bronchitis”. The purpose of this communication is to highlight the clinical pattern of this disease as guidelines for the medical profession.

A total of 235 patients in the age group (35-77) were evaluated in the year 2011. The diagnosis was established by history, exposure to tobacco, atmospheric and/or industrial pollutants, clinical and laboratory examination and not the least, spirometry. EKG, imaging studies and eco were done as relevant.

The clinical observations include:
1. Majority were males and smokers.
2. 8 patients (4%) were not tobacco smokers.
3. Non tobacco smokers and those with comorbidities were symptomatic early.
4. Patients with echo based pulmonary arterial hypertension/cor pulmonale died early.
5. Majority of patients were elderly-60-70 years.
6. Common comorbidities were cardiovascular and musculoskeletal and related features.
7. Few of the patients initially presented with cardiac symptoms, diverting the attention of the primary disease, often forgotten.
8. Associated tuberculosis and diabetes mellitus were not uncommon.

Comments: There is still need for improved patient/doctor health education. All patients with smoking history for 5 or more years should be evaluated early before developing complications.

379. COPD: epidemiology and varia

P3440
Peak inspiratory flow rates through placebo dry powder inhaler device in various asthma and COPD patients
Raju Ds1, Kaja Judge1, Pratim Samarth1, Liisa Raitikainen1, Timo Vanto1.
1Lung Clinic, Turku University Hospital, Turku, Estonia; 2Children’s Clinic, Allergy Centre, Turku University Hospital, Turku, Estonia; 3Lung Clinic, Lasnamäe Medicum, Tallinno, Estonia; 4Children’s Clinic, Turku University Hospital Turku, Finland; 5Lung Clinic, Jorvi Hospital, Espoo, Finland.

Dry powder inhalers (DPIs) are inspiratory flow driven. We sought to characterise inspiratory flow parameters of placebo dry powder inhaler devices in asthma patients of various age groups and in patients with chronic obstructive pulmonary disease (COPD) in an open, randomised, multicentre study (SALIF). Preliminary data of the Easyhaler® test device will be presented.

The primary variable was the peak inspiratory flow (PIF) rate through the inhaler. Three inspiratory flow curves were recorded and the best of them was analysed. To ensure consistent dose delivery of the drug peak inspiratory flow rates for this device should be ≥ 28 L/min or higher.

A total of 227 subjects with documented diagnosis of asthma and/or COPD of various severities were included in the open-label study. Asthmatic patients were divided into three different age groups: 4-11 years (n=60), 12-64 years (n=62) and ≥ 65 years (n=52). COPD patients consisted of all ages groups (n=53).

Descriptive statistics of PIF values in different subgroups

Course features of COPD in women and men
Mykola Ostrovskyy, Oleksandr Varunkiv, Iryna Savelikhina, Mariana Kulychny-Misnok, Internal Medicine #3, Ivano-Frankivs'k National Medical University, Ivano-Frankivs’k, Ukraine

**Background:** COPD is a leading among the present problems in Pulmonology. Epidemiological data indicate a greater prevalence of this nosology among men.

Prevalence of COPD in the world among men is 9.3%, and among women - 7.3%.

Given that COPD - a disease mainly of the second half of life, it should be noted that at this period women are characterized by a extinguishing of steroidogenesis function. This factor may be one of those that aggravating the course COPD in women.

**Aim:** To study the severity of breathlessness on a MMRC scale in women and men with newly diagnosed 2nd stage of COPD.

**Materials and methods:** The main inclusion criteria were: 1) age of patients ≥ 40 years; 2) Experience smoking ≥ 10 pack-years; 3) FEV1 ≤ 80% predicted; 4) FEV1/FVC ≤ 0.65; 5) Smoking ≥ 10 pack-years. All participants were treated at pulmonology department of Ivano-Frankivsk regional center of phthisiologhy and pulmonology. The average age of women was (58.5±2.8) years and men - (54.7±3.1) years.

**Results:** The level of FEV1 on average was 61.6±2.4% in women, and - 58.4±3.9% (p>0.05) in men. Index of breathlessness on a MMRC scale in women was 3.6±0.4, and 2.9±0.4 - in men. Thus, exploring the clinical course of 2nd stage of COPD among women and men aged 50 to 60 years, we can say that, despite the identical clinical manifestations of disease, there is a greater severity of breathlessness on a MMRC scale in women as in men.

**Conclusion:** The clinical course of COPD in women compared with men characterized with more severe shortness of breath on a MMRC scale with less ventilation violations, according to spirometry.

**P3441**

Is high level of IgE an additional problem in smoking patients with severe and very severe chronic obstructive pulmonary disease (COPD)?
Natalia Sleczhko, Yuriy Mostovoy, Andrii Sidorenko, Chair of Prophylaxis of Internal Diseases, Vinnytsia National Medical University n.a. M.I. Pirogov, Vinnytsia, Vinnytsia region, Ukraine

Smoking is one of the greatest risks factors of COPD and it increases the risk of allergic sensibilisation.

The aim of the study was to estimate the level of IgE and its possible connection with COPD severity and sensibilisation to allergens in smoking patients with severe and very severe COPD and great length of smoking.

**Methods:** The 30 patients with very severe COPD were enrolled. It was estimated smoking history (body mass index (BMI), spirometric parameters (forced vital capacity (FVC), forced expired volume in 1 second (FEV1)) and level of total IgE.

**Results:** The skin prick test with local significant allergens (home dust, pollen of ambrosia, birch, fur of cat) was performed to patients with increased level of IgE.

**Conclusion:** The smoking patients with severe COPD has allergic constitution with increased IgE level and sensibilisation to different allergens. There is no strict correlative connection between the length of smoking and level of the IgE.

**P3442**

Quality of COPD diagnosis in Ukraine: A phone survey
Ivan Voshnyevsky, Olga Khitrenko, Triana Kugler. Internal Medicine and General Practice - Family Medicine Department, Donetsk National Medical University, Donetsk, Ukraine

**Background:** Quality of COPD diagnosis remains poor in post-Soviet countries. There is limited information about beliefs and patterns of care of COPD in Ukrainian general practitioners (GP).

**Aim:** To explore the knowledge, beliefs and working stereotypes about diagnosis of COPD in Ukrainian GPs.

**Methods:** We performed a telephone survey of 85 GPs in Donetsk region, Ukraine. As criteria for selected GP diagnosis we answered on these questions:

1) "How many of COPD patients in your practice are both > 40 years old and smokers > 10 pack-years?" (correct was considered 80% and more); 2) "How many of COPD patients in your practice needed spirometry (SM) to confirm the diagnosis?" (correct was considered 100%); 3) "And how many of them actually asked for medical help to allergist. There is no significant connection between level of IgE and spirometric parameters. Allergic sensibilisation to home dust and the 3 patients had sensibilisation to fur of cat.

**Results:** The 24 patients had increased level of IgE (329,5 ± 88,9%) with increased level of IgE (> 8000) were present just in 20% (17 of 85) GPs.

**Conclusions:** Quality of COPD diagnosis is in very poor. 20% GPs demonstrate adequate knowledge and practice in correct COPD diagnosis.
Despite the significant differences in previously recognized and unrecognized COPD, there was no difference between the two in LOS (1.8±2.3 v. 1.9±2.3; p=0.09). LOS adjusted for procedure (actual/expected LOS) was also not significantly different (p=0.43 and 0.99±1.14 for recognized and unrecognized COPD, respectively; p=0.45).

Conclusion: The prevalence of unrecognized COPD among surgical patients is quite high and it appears to affect perioperative morbidity similarly to previously recognized COPD. The data suggests that spirometric testing of an at risk population for COPD may have value in preoperative assessment.

P3445
Clinical and functional characteristics of Italian and Spanish patients with alpha 1-antitrypsin deficiency
Barbara Piras1, Ilaria Ferrarotti1, Beatriz Lara1, Maria Teresa Martinéz2, Ana Bustamante3, Pietro Pirina3, Maurizio Luissent3, Marc Miravitlles1,4,1
1Institute of Respiratory Disease, University of Sassari, Italy; 2Centro per la Diagnosi dei Deficit Ereditari di Alfati-antitripsina, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Italy; 3Pneumology, Spanish Registry of Alpha-1-antitrypsin Deficiency, Spain, Spain; 4Instituion d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, Ciber de Enfermedades Respiratorias (CIBERES), Barcelona, Spain

Alpha-1 antitrypsin deficiency (AATD) is a rare genetic condition associated with pulmonary disease, for which national and international registries play a crucial role.

Methods: With the aim of providing a clinically better characterisation of AATD patients, we conducted an observational cross sectional study on adult patients affected by severe AATD enrolled in the Spanish and Italian national registries.

Results: We assessed 745 subjects, 416 enrolled in the Spanish and 329 in the Italian Registries with a mean age of 49.9 years (SD=13.8). The 57.2% of subjects were male and the 64.9% smokers or former smokers. The majority were index cases (81.2%), mostly with PI*ZZ genotype (73.4%), the mean diagnostic delay was 9 years (SD=12.1). Compared with PI*ZZ (n=547), PI*SZ (n=124) subjects had an older age at diagnosis and better preserved lung function despite a higher mean smoking consumption. Characteristics of PI*ZZ patients with chronic obstructive pulmonary disease (COPD) (n=412) were compared according to GOLD severity stages. Mean age was similar in GOLD I, III and IV, but subjects in GOLD II were older. In GOLD I women and non-index cases were prevailing. The rate of never smokers significantly decreased when severity of COPD increased. Augmentation therapy was administered to 19% of GOLD I, 48% of GOLD II, 59% of GOLD III and 51% of GOLD IV patients.

Conclusions: Early diagnosis of AATD is still an unmet need. PI*ZZ patients in both smoking and non-smoking groups had more severe respiratory disease than PI*SZ, despite less smoking consumption. Augmentation therapy is provided to similar proportions of patients with all degrees of severity of airflow obstruction from GOLD I to IV.

P3446
Bacterial airway colonization is not associated with increased procalcitonin in stable COPD
Dania Stelzl1, Renaud Louis2, Joachim Aerts1, Tobias Welte4, Alicia Lacomara1, Wim Boersma6, Kostantinos Kostikas3, Francesco Blass5, Branislava Milenkovic9, Cristina Prat5, Jan Rakic1, Lucas Boeck1, Barbara Piras1, Andrea Pratelli5, Gernot Rohde10, Antoni Torres11, Pietro Pirina1, Maurizio Luisetti2, Marc Miravitlles3,4
1Clinic of Pulmonary Medicine, University Hospital, Aachen, Germany; 2Department of Pulmonary Medicine, Oslo University Hospital, Oslo, Norway; 3Department of Respiratory Physiology, Glittreklinikken, Hakadal, Norway; 4Institute for Pulmonary Diseases, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 5Pneumology, Hospital Clinic, Barcelona, Spain; 6Pneumology, IRCCS Policlinico, Milan, Italy; 7Department of Respiratory Medicine, Belgrade, Serbia; 8Pneumology, Instituto de Investigaciones Biomedicas August Pi i Sunyer (IDIBAPS), Hospital Clinic, Ciber de Enfermedades Respiratorias (CIBERES), Barcelona, Spain; 9Pneumology, IRCCS Policlinico San Matteo, University of Pavia, Italy; 10Pneumology, University Hospital, Maastricht, Netherlands; 11Pneumology, Hospital Clinic, Barcelona, Spain; 12Clinical Diagnosis, Thermo Scientific Biomarkers, Hennigsdorf, Germany

Background: Bacterial colonization of the airways hampers the utility of sputum microbiology at exacerbation of COPD. We hypothesize that, in contrast to exacerbation, circulating procalcitonin remains low in chronic bacterial airway colonization in stable COPD.

Results: Despite the significant differences in previous colonization in patients with positive sputum cultures were similar (median 95% CI 0.080 [0.069-0.094] vs. 0.076 [0.064-0.091] vs. 0.080 [0.066-0.100]; p=0.312).

Conclusion: In contrast to acute exacerbation of COPD, procalcitonin values remain low in chronic bacterial airway colonization in stable COPD.

P3447
Air travel and COPD: A new algorithm for pre-flight evaluation
Anne Edvardsson1, Ana Akera1, Carl Christian Christensen2, Ole Hennung Skjønberg3,4
1Department of Respiratory Physiology, Glittreklinikken, Hakadal, Norway; 2Department of Pulmonary Medicine, Oslo University Hospital, Oslo, Norway

The reduced pressure in the aircraft cabin may cause significant hypoxaemia and respiratory distress in patients with COPD. Simple and reliable methods for predicting need for supplemental oxygen during air travel have been requested.

Objective: To construct a pre-flight evaluation algorithm for COPD patients.

Methods: In this prospective, cross-sectional study of 100 COPD patients, sea level pulse oximetry at rest (SpO2_slt) and exercise desaturation (SpO2_o2max) were used to evaluate whether the patient a) is fit to fly without further assessment, b) needs further evaluation with hypoxia-altitude simulation test (HAST) or c) should receive in-flight supplemental oxygen without further evaluation. HAST was used as reference method.

Results: An algorithm was constructed using a combination of SpO2_slt and SpO2_o2max. Categories for SpO2_slt > 95%, 92-95%, and <92%, the cut-off value for SpO2_o2max was calculated to 84%. Arterial oxygen pressure <6.6 kPa was the criterion for recommending supplemental oxygen. When validated on a separate group of 50 COPD patients, this algorithm had a sensitivity of 100% and a specificity of 80%.

Patients with SpO2_slt > 95% combined with SpO2_o2max ≥ 84% may travel by air without further assessment. Supplemental oxygen is recommended if SpO2_slt 92-95% combined with SpO2_o2max < 84%, or if SpO2_slt < 92%. Otherwise, HAST should be performed.

Conclusions: The algorithm is a simple tool for pre-flight evaluation of COPD patients.

P3448
Indications of small airways disease in healthy smokers
Hid de Jonge1,2, Laurent Reulens1,3, Nick ten Hacken1,3, Dirkje Postma1,2
1Maarten van den Berge1,2,3, Dept of Pulmonary Diseases, University of Groningen, University Medical Center Groningen, University of Groningen, University Medical Center Groningen, Netherlands; 2GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands

It has been well established that small airways disease is a risk factor for COPD development. Cigarette smoking is the main risk factor for COPD development. We investigated whether smokers, without COPD and an FEV1 > 80%pred, have indications of small airways involvement.

Healthy smokers and non-smokers (asymptomatic, FEV1 > 80%pred, FEF25-75 > 70%) were included. We performed spirometry, body plethysmography, and impulse oscillometry (IOS) in all subjects. Smokers were compared to non-smokers using Student’s t or Mann Whitney U test.

56 non-smokers (28 < 40 years and 28 > 40 years old) and 54 smokers (26 < 40 years and 28 > 40 years old) were included. Large airways parameters were comparable between smokers and non-smokers. In contrast, small airways parameters differed between smokers and non-smokers. Smokers had a lower FEF25-75 and R5-20, AX and Rf than non-smokers. No differences in RV or RV/TLC were found between smokers and non-smokers.

Data are median (interquartile range) and differences tested with Mann-Whitney U test, unless stated otherwise. * median (IQR), differences tested with Student’s t-test.

We demonstrate changes in small airways parameters in smokers with normal lung function. These changes are already present in smokers ≤40 years old. Whether this small airways disease in young smokers is a first step in COPD development, remains to be elucidated in further studies.

P3449
Usefulness of COPD assessment test (CAT™) for the management of COPD according to GOLD 2011
Takashi Motegi1,2, Takeo Ishii1,2, Kumiko Hattori1,2, Yuji Kurumoki1,2, Ryoko Futamata1,2, Koichi Yamada1,2, Akiko Gemma1,2, Koziro Kida1,2
1Respiratory Care Clinic, Nippon Medical School, Tokyo, Japan; 2Division of Pulmonary Medicine, Infectious Diseases, and Oncology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background: The GOLD report (2011) proposes a new strategy for the management of stable COPD—the use of the CAT score. Is a CAT score >10 a useful borderline value for disease severity in a Japanese cohort?

Purpose: To determine the association between the CAT score of patients, and prior exacerbation frequency and usage of medical resources.

Method: A total of 180 patients recruited from a secondary COPD clinic. The CAT score was examines under stable conditions at least four weeks after any exacerbations. We investigated the association between the CAT score and various clinical parameters, including pulmonary function tests, 6-minute walking distance (6MWD), the St George’s Respiratory Questionnaire (SGRQ), the Hospital Anxiety and Depression score (HAD), a multidimensional assessment system (BODE index), exacerbation rate of the previous year, and the use of resources such as unscheduled visits and long-term oxygen therapy (LTOT).

Results: The mean age was 71.9, and %FEV1 was 59.3%. The CAT score was significantly associated with following parameters: %FEV1 (r= -0.42, p < 0.001), 6MWD (r= -0.26, p < 0.001), total SGRQ score (r= 0.74, p < 0.001), HAD-depression (r= 0.40, p < 0.001), HAD-anxiety (r= 0.32, p < 0.001), and BODE index (r= 0.46, p < 0.001). The patients with CAT score ≥10 was significantly associated with prescribed LTOT (p<0.001), frequent unscheduled visit (p<0.019), and frequent exacerbation of previous 1-year (p=0.006), but the subjects with CAT score ≥20 was not associated with exacerbation frequency.

Conclusions: We concluded that a CAT score ≥10 can be considered a reasonable borderline value for exacerbation frequency and usage of medical resources in a Japanese cohort.

P3450
COPD assessment test (CAT) in the evaluation of COPD
Virginia Almadina, Jesus Sanchez, Ana Gomez-Bastero, Agustin Valido, Maria Pavon, Alonso Montemayor. Pneumology, Hospital Universitario Virgen de la Macarena, Sevilla, Spain

Objective: To evaluate the correlation of CAT with other specific questionnaires and with clinical/functional parameters.

Methods: A prospective study analyzing DOSE, BODE and BODE index, GOLD stage, quality of life questionnaires (SGRQ, CRQ, and CAT), and number of exacerbations-year (no. ex-years), dividing patients into non-exacerbator (<2 exacerbations in the last year) and exacerbator (≥2) were done.

Results: No differences in general variables were found. Analyzing the correlation between CAT and CRC/SGRQ we found a significant correlation (r=0.70; CAT/CRC r= -0.66, p<0.001). The relationship of the questionnaires vs clinical/functional outcome is reflected in the table, where rates are moderate correlation with CAT, although improved with respect to SGRQ and CRQ, except in GOLD stages.

*p<0.05

No significant differences between stages of severity or prognosis and scores on CAT, except for GOLD stages, were found.

Figure 1. Relationship between CAT and clinical-prognostic parameters.

Conclusions: 1. Correlation of CAT with other quality of life questionnaires is moderate. 2. SGRQ and CRQ appreciate better clinical and prognostic variables. While CAT is more easily applied in daily practice, does not discriminate between different situations or serious prognosis, except in extreme stages of GOLD.

P3451
Relationship between COPD assessment test (CAT) and declines of lung function in COPD patients
Hyun June Kwak, Ji-Yong Moon, Tae Hyung Kim, Sang-Heon Kim, Jung Won Sohn, Dong Ho Shin, Sung Soo Park, Ho Joo Yoon. Internal Medicine, Department of Respiriology, Hanyang University College of Medicine, Seoul, Korea

Background: COPD assessment test (CAT) is a recently developed questionnaires used for assessing and monitoring chronic obstructive pulmonary disease (COPD). However, the relationship with CAT score and the other clinical parameters of COPD are not well determined yet. In this study, we aimed to investigate if CAT score is associated with the measures of clinical courses such as annual decline of lung function and acute exacerbation of COPD.

Methods: We enrolled the patients with COPD, who were followed for more than two years. CAT and St. George Respiratory Questionnaire (SGRQ) were performed and information of clinical parameters of COPD was collected in a retrospective manner.

Results: A total of 77 patients with COPD were recruited. CAT score showed a fair correlation with SGRQ score (r=0.42, P<0.001) and FEV1 (r=0.231, P=0.02). Higher CAT score was significantly associated with more rapid decline of FEV1 over 2 years (P=0.02) and acute exacerbation of COPD (P≤0.002).

Conclusions: CAT score showed good relationship with various clinical parameters of COPD, including FEV1, acute exacerbation and deterioration of lung function. These findings suggest that CAT reflects various features of COPD and could be used more widely in assessing and monitoring of COPD.
P3452 Evaluation of the quality of life with COPD assessment test
Alexandra Corlante1, Viktoria Simi1, Victor Bottoni1, Donna Ranu2,3
1Internal Medicine, State Medical and Pharmaceutical University “Nicolaic Testemianu”, Chisinau, Republic of Moldova; 2Respiratory Medicine, Institute of Phthisiopneumology “Chiril Dragusin”, Chisinau, Republic of Moldova

Background: COPD Assessment Test (CAT) is a short, simple questionnaire for assessing and monitoring chronic obstructive pulmonary disease (COPD) patients.

Methods: 60 consecutive COPD patients were enrolled into the study. We analyzed age, gender, anthropometric, pack years, spirometric data (FEV1, FVC, FEV1/FVC, BODE index (BMI, FEV1, MRC, 6 MWD)). Health-related quality of life was assessed by the CAT and the St. George Respiratory Questionnaire (SGRQ).

Results: COPD patients were studied, mean age was 60.2±7.5 years, mean FEV1, % was 34.6±11.3%. Patients across all stages GOLD/ATS/ERS classification had similar age and pack/year (p>0.01). Pearson correlation coefficient analysis demonstrates in COPD patients a significant positive correlation between the CAT and the total score of the SGRQ (r=0.59, p<0.01). Also correlations between CAT and MRC score negatively with 6 MWD (r=-0.52, p<0.01). The forward stepwise regression analysis shows that the age, dyspnoea and oxygen saturation are important predictors of HRQL in COPD patients which explains 58% of the CAT score.

Conclusion: COPD Assessment Test is a useful instrument to assess disease impact in COPD patients and sensitive to changes in patients with COPD independent risk factors for worsening of HRQL.

P3453 COPD care and management at nurse-led COPD-clinics in Swedish primary health care: A literature review
Eva Overland Eriksson, Eva Abeg Lennman, Aninka Nyberg, Dalarna University, School of Health and Social Studies, Falun, Sweden

Aim: The aim was to describe evidence-based knowledge regarding care and management of patients at nurse-led COPD-clinics in Swedish primary health care.

Methods: A literature review included ten studies, three qualitative, six quantitative and one both qualitative and quantitative. The search was carried out in PubMed/MEDLINE and CINAHL between year 1999 and 2012 with the search-words: COPD, nurse-led clinics, patient education, primary healthcare, quality of life, self-management, smoking cessation and Sweden. Two reviewers rated independently and extracted data from the articles.

Results: At nurse-led COPD-clinics in Swedish primary health care, nurses ran structured investigations including measurements according to medical guidelines, and gave information about self-management and smoking cessation. The COPD-clinics allotted sufficient time according to the guidelines: when the nurse had been trained in COPD care, more patients were diagnosed with COPD and fewer exacerbations were noted among COPD-patients. The structured programs for smoking cessation and self-management were used, an increased number of patients stopped smoking and patients’ quality of life was improved. COPD nurses showed shortcomings in self-management and smoking cessation concerning individualized care, the involvement of patients in shared understanding and responsibility and motivational dialogue. The prevalence of CB was 64% (622/974). Between groups (CB vs no CB), no significant difference was observed for age, sex, smoking habit and baseline FEV1. Patients with CB had higher HFEV1% predicted, 38.0±3.6 (p<0.001) and more prevalent current smoking, 42.4% vs. 31.2% (p<0.0001). Baseline SGRQ total and symptom scores were similar between CB and emphysema patients, 49.5 vs. 48.7 (p=0.46) and 56.1 vs. 53.7 (p=0.06) respectively, but SGRQ activity and impacts scores were higher in CB subjects, 64.2 vs. 67.2 (p=0.01) and 39.0 vs. 36.2 (p=0.02) respectively. In adjusted analyses, CB was not associated with more frequent exacerbations, 1.12, p=0.26. Cough and sputum scores are outlined in Table 1.

Table 1. Cough and Sputum Scores

<table>
<thead>
<tr>
<th>Cough</th>
<th>Sputum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean cough score</td>
<td>1.20</td>
</tr>
<tr>
<td>Cough score ≥ 2</td>
<td>193 (22.8%)</td>
</tr>
<tr>
<td>Sputum score ≥ 2</td>
<td>160 (18.9%)</td>
</tr>
</tbody>
</table>

Conclusion: Physicians distinguished between subjects with CB who despite better FEV1, had worse SGRQ activity and impacts scores than emphysema subjects. However, subjects with physician identified CB actually differed on baseline cough but not sputum scores.

P3455 Predictors of mortality in a well-characterised group of patients with COPD
Saher B. Shaker1, Udo-Michael Goehring2,3, Fernando Martinez1
1Medical, Nycomed Belgium, Brussels, Brabant, Belgium; 2Pneumology, Centre Hospitalier Universitaire du Saart-Tilman, Liège, Belgium; 3Medical, Nycomed France, Antony, France

Objective: To identify clinical, physiological and radiological predictors of mortality in a well-characterised group of patients with COPD.

Method & material: Patients who participated in 3 clinical trials were included in this study. In these trials, patients were evaluated with clinical data, lung function tests and quantitative computed tomography (relatve area of emphysema < 910 HU [RA-910]). The date and cause of mortality were reported during 10 years, and the data of those who were still living by February 1st 2012 were censored at this time point. Data were analysed using Cox proportional hazard regression model first in a univariate model then in a stepwise multiple regression model.

Results: Data from 208 patients with moderate to severe COPD were available. A total of 104 patients died. The median survival time was 10.4 years (95% CI 9.4–∞). Age, packy years, FEV1, DLCO and RA-910 were significant predictors of mortality in a univariate model. In a multivariate model with a stepwise selection, age (p=0.005), packy years (p=0.02) and RA-910 (p=0.017) emerged as the significant predictors of mortality, whereas FEV1 (p=0.05) and DLCO (p=0.14) did not reach statistical significance.

Conclusion: In this population of smokers with moderate to severe COPD, age, packy years and the degree of emphysema on CT as RA-910 were the most important predictors of mortality.

P3456 Epidemiology of the “chronic bronchitis” phenotype of COPD-patients in Belgium and Luxembourg
Jean Louis Corhay1, Walter Vincker2, Marc Schlesser3, Pascale Bossuy3
1Pulmonary & Critical Care Medicine, University of Michigan, Ann Arbor, MI, USA; 2Internal Medicine, State Medical and Pharmaceutical University “Nicolae Testemianu”, Chisinau, Republic of Moldova; 3Respiratory Medicine, Institute of Phthisiopneumology “Chiril Dragusin”, Chisinau, Republic of Moldova

Background: Chronic bronchitis is a phenotype that has been associated with increased mortality, frequent exacerbations and disease progression. Aims and objectives: To investigate the prevalence of CB in a large cohort of COPD patients and identify features associated with CB.

Methods: Cross-sectional analysis of a multicenter cohort of COPD patients from Belgium and Luxembourg. The cohort comprised 974 patients (67.8±9.6 years; 72% males, FEV1 52.5±15.8% predicted). Results: The prevalence of CB was 64% (622/974). Between groups (CB vs no CB), no significant difference was observed for age, sex, smoking habit and prevalence of most comorbidities. However prevalence of cachexia and skeletal muscle wasting were higher in CB. The number of pack years was higher, and both FEV1% predicted and body mass index were lower in CB. The proportion of patients with CB increased with GOLD stage and was higher in emphysema phenotype and patients exposed to occupational risk factors. Patients with CB had increased numbers of mild (0.7±0.9 vs 0.3±0.9; p=0.002), moderate (1.1±1.4 vs 0.5±0.9; p<0.0001) and severe (0.3±0.8 vs 0.2±0.6; p=0.0185) exacerbations per patient per year. Frequent (moderate to severe) exacerbations (two or more per patient per year) occurred more frequently in patients with CB (62.7% vs 14.2% of patients; p<0.0001).

Conclusions: Prevalence of CB is high in COPD and increases with disease severity. CB is associated with occupational risk factors, occurrence of mild, moderate and severe exacerbations, frequent moderate or severe COPD exacerbations, and systemic co-morbidities such as cachexia and skeletal muscle wasting.

An old disease from a new perspective – GOLD 2011 recommendations for COPD

Rena T. Rubinsztajn, Tailuex Przybylowski, Marta Maskey-Wareczowska, Krszysztof Karwat, Ryszarda Chazan. Department of Medicine, Pneumonology and Allergology, Warsaw Medical University, Warsaw, Poland

The GOLD 2011 recommendations for chronic obstructive pulmonary disease (COPD) introduce a new classification system to optimize treatment in individual patients. Except for FEV1, this classification incorporates dyspnea severity or the CAT score and the number of exacerbations.

The aim of our study was to compare the GOLD 2010 and 2011 COPD classification.

The study group consisted of 128 patients. Based on the post-bronchodilator FEV1 only, as recommended in the GOLD 2010 report, there were 21 patients in stage I, 53 patients in stage II, 35 in stage III and 19 in IV, respectively. In all patients, the number of exacerbations per year was noted and dyspnea was assessed with the modified MRC scale. The patients were subsequently graded to group A,B,C, D as proposed in the combined COPD assessment in GOLD 2011.

<table>
<thead>
<tr>
<th>Patients characteristic</th>
<th>n</th>
<th>nMRC 0–1/2</th>
<th>Number of exacerbation 0–1/2</th>
</tr>
</thead>
<tbody>
<tr>
<td>GOLD I</td>
<td>21</td>
<td>12/9</td>

<td>8/27</td>
<td>14/21</td>
</tr>
<tr>
<td>GOLD IV</td>
<td>19</td>
<td>0/19</td>
<td>9/10</td>
</tr>
</tbody>
</table>

We had problems with grading of 37 (28.9%) patients according to the GOLD 2011 criteria; there were 14 patients in GOLD stage I/II with ≥ 2 exacerbations per year and 23 patients in GOLD stage III/IV with < 2 exacerbations per year.

**Patients classification with the GOLD 2011 staging system**

</tr>
</tbody>
</table>

We conclude that despite the fact that the new GOLD 2011 combined assessment is aimed at optimizing therapy, in clinical practice, there may be problems with patient classification. This especially concerns patients with mild/moderate airflow limitation and frequent exacerbations and those with severe airway obstruction without frequent exacerbations.

**P3458**

Quantification of elastin fibre remodelling in COPD using probe-based confocal laser endomicroscopy (pCLE)

Michael Bennett, John Fleming, Tom Havelock, Joy Connay. Peter Howarth, Southampton Centre for Biomedical Research, University Hospital Southampton NHS Foundation Trust, Southampton, Hampshire, United Kingdom; 1Faculty of Health Sciences, University of Southampton, Hampshire, United Kingdom; 2Faculty of Medicine, University of Southampton, Hampshire, United Kingdom

COPD causes disruption of alveolar elastin and probable disruption of the elastin in the airway wall. pCLE can be used during bronchoscopy to image the elastin structure. A method for the automatic assessment of the directional distribution of the elastin fibres is presented. The structural disorder caused by the remodelling process can then be objectively quantified. Figure 1 shows examples of the analysis output, with detected elastin fibres in green, showing greater disorder in the case of mild COPD.

Effect of fluticasone propionate/salmeterol on exercise endurance in moderate-severe COPD

Wenlan Yang, Jinning Liu, Beilan Gao, Kebin Chong. 1Department of Pulmonary Function Test, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Department of Respiratory Medicine, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Objective: To investigate the effect of Fluticasone Propionate/Salmeterol on exercise endurance and pulmonary function in patients with moderate-severe COPD.

Methods: 53 patients with moderate-severe COPD were randomly divided to two groups. Treatment group inhaled dry powder SFC(salmeterol 50ug, fluticasone Propionate 250ugs) twice daily for 24 weeks. Control group got symptomatic treatment for 24 weeks. Predose and postdose pulmonary and cycle cardiopulmonary exercise test evaluations were compared.

Results: There were no difference in predose pulmonary and CPET between two groups. In treatment group, With SFC treatment for 24 weeks, FVC, FEV1, IC were significant increased, ITGV, RV and TLV were significant increased(p<0.05); Peak WR increased, but had no statistically difference. Peak VO2, peak VO2/kg, peak VCO2, peak O2 pulse, peak VE were significant increased(p<0.05); VD/VT and lowest VE/VCO2 were decreased from (p<0.05); postdose improvement in IC was significantly correlated with the increase in Peak VO2. Peak VO2/kg, Peak VE, VD/VT and Lowest VE/VCO2 but not with FEV1. Predose and postdose pulmonary and CPET were no changes in control group.

Conclusion: Exercise tolerance in patients with moderate-severe COPD were distinguished impaired. After long term SFC treatment, lung hyperinflation at rest and exercise were decreased, exercise endurance were increased when compared with symptomatic treatment. CPET is useful in COPD patients as it allows objective measurement of the exercise tolerance and evaluation of the response to therapeutic intervention.

**P3460**

Roflumilast significantly decreased inflammatory biomarkers in induced sputum in current smokers patients with severe chronic obstructive pulmonary disease

Alireza Sadraie, 1Gabriel Mamalovad, 2Adlyatif Abdullayev3. 1Internal Medicine, Azerbaijan Medical University, Baku, Azerbaijan; 2Internal Medicine, Azerbaijan Medical University, Baku, Azerbaijan; 3Pulmonology, Central Hospital of Oil Workers, Baku, Azerbaijan

The aim our study was identify the impact of ROFLUMILAST to inflammatory biomarkers in induced sputum in current smokers patients with severe COPD.

All patients were divided in two groups: 124 patients have received BUDES-ONIDE/FORMOTEROL 640/18 mcg/day and ROFLUMILAST 500 mcg/day; 224 patients have received only BUD/FORM. 640/18 mcg/day. All patients were current smokers and observed during 6 months. In patients with severe COPD whom applied ROFLUMILAST together with BUD/FORM, the level of inflammatory biomarkers in induced sputum significantly decreased after 6 months therapy.
patients group with ROFLUMILAST therapy the number of neutrophils decreased importantly(39.1 + 9.8 vs 20.4+6.7%, p<0.001).This decreasing at the same time was accompanied with reducing the level of pro-inflammatory cytokins in induced sputum. IL-6 was decreased up to 15.7+4.2 pg/ml vs 29.6 + 6.9 pg/ml before treatment, p<0.001).The anti-inflammatory influence of ROFLUMILAST was accompanied with improving of lung function(_FEV1 increased up to 48.7+6.4 % vs 39.1% before treatment, p<0.05).Our study showed that, the added ROFLUMILAST to the therapy with BUD/FORM. significantly decreased the level of inflammatory biomarkers in current smokers with severe COPD.Summarized the followings we can conclude that,ROFLUMILAST as additional drug to the therapy with BUD/FORM. through reducing the severity of chronic inflammation may improve the lung function of the current smokers patients with severe COPD.

P3463 Long term oxygen therapy (LTOT) prescription in chronic obstructive pulmonary disease (COPD) patients in Wigan (northwest England) Sharada Gunar, Ayun Zubair, Andrew Cross, Imam Arze, Abdul Ashish. Department of Respiratory Medicine, Royal Albert Edward Infirmary, Wigan, United Kingdom

Background: LTOT has been shown to provide a survival benefit in severe COPD. In UK, since 2006, following a Royal college directive LTOT prescriptions were to be issued only by hospital specialists managing such patients after formal assessments (BTS working group report, January 2006). The directive aimed to standardise LTOT assessments, issue and follow up to hospital based practitioners and specialist services.

We audited the oxygen prescriptions for adult patients in Wigan between 2006-2011 to study concordance of Royal college directives with our oxygen prescriptions.

Methods: We analysed the oxygen prescription data provided by our suppliers (our products) for the patient details and prescriber source.

Results: There were 313 patients in whom oxygen was prescribed for COPD as the indication. The breakdown of prescriber source is as below:

<table>
<thead>
<tr>
<th>Health professionals prescribing LTOT in Wigan between 2006-11</th>
<th>N=313 (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hospital COPD nurses</td>
<td>192 (62)</td>
</tr>
<tr>
<td>General Practitioners</td>
<td>71 (22.6)</td>
</tr>
<tr>
<td>Hospital doctors</td>
<td>31 (10)</td>
</tr>
<tr>
<td>Other hospitals</td>
<td>9 (2.9)</td>
</tr>
<tr>
<td>Community respiratory nurses</td>
<td>8 (2.5)</td>
</tr>
</tbody>
</table>

Conclusions: There are still a substantial proportion of oxygen prescriptions issued at a community level by the general practitioners and community based nurses for patients with COPD. We are unsure regarding the assessments undertaken for the adequacy of such prescriptions. This could potentially lead to harm and is likely to lead to increased cost for the healthcare services. At the current times of austerity and duplication of services should be avoided to ensure the patients and NHS gets the maximal benefit from LTOT provision.

P3464 The occurrence of pneumonia in COPD patients treated with salmeterol / formoterol ADRS were reported in 181 patients. Most frequently reported ADRs were clinical bacterial pneumonia 4.9%, dysphonia 3.2%, bronchitis 1.2% and pneumonia (other) 0.8%. In 1,358 patients who were treated with SFC250 for any duration, diagnosis of pneumonia was reported as an adverse event in 8.4% of patients in the prior year, and 8.4% after starting SFC250. For the 922 patients were treated with SFC250 for 1 year, the diagnosis of pneumonia was made in 8.7% and 7.3% of patients in the year prior to and after starting SFC250, respectively. Pneumonia was more frequent in patients who had a hospitalization, lower BMI, longer duration of COPD, ex-smoker, severe COPD and patients with complication. The trend was the same in the year prior to and post SFC250.

Conclusions: In clinical practice setting, the frequency of pneumonia was comparable before and after starting SFC250.

P3465 Influence of tiotropium bromide and formoterol on bronchial hyperresponsiveness in COPD

Up to 60% of COPD patients can present bronchial hyperresponsiveness (BHR) which may be a pathophysiological feature of COPD rather than a surrogate marker of airway obstruction.

Aim: To evaluate an effect of single dose tiotropium bromide (TB) and formoterol on BHR in COPD patients.

Methods: 30 COPD II outpatients with BHR of mean age of 59 yrs were studied. The BHR level was analyzed initially and post-dose in 60 minutes after 18 mg TB (1-st group, n=11) and 12 mg formoterol (2-d group, n=19). BHR was assessed in methacholine challenge.

Results: A high level of BHR (provocative dose - PD_{20}=<0.04 mg) was at 40% of
COPD patients, medium (PD20 0.04-0.22 mg) at 43% and low (PD20 0.23 -0.47 mg) at 17% of the surveyed initially. Pre-bronchodilator PD20 in average were comparable in both groups: 0.10 mg for the 1-st and 0.12 mg for the 2-nd group (p=0.67). BHR levels after bronchodilators were significantly less in both groups. Thus, PD20 mean values increased in 2.4 times after formoterol (p<0.0007) and in 3.6 times after TB (p=0.0005). The number of negative tests (PD20 ≥ 0.47 mg, BHR < 15%) in the 1-st group was more than in the 2-nd: 54.5% of patients after TB and 21.1% after formoterol (p=0.06).

Conclusion: Long-acting bronchodilators – TB and formoterol after single administrations reduce BHR level in COPD patients. TB promotes more bronchoprotective effect than formoterol in COPD.

P3466
Influence of tiotropium bromide (TB) and carbocysteine (C) on mucociliary clearance (MCC) in patients with COPD
Tetyana Pertsueva, Oleyna Lykholyt, Oleyna Gurzhz, Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Aim: To compare the influence of TB alone and in combination with C on MCC. M&C: 27 smoking pts with severe COPD in stable condition were divided in 2 grs: gr.1=14, gr.2=13. All pts received TB 18 µg/d for 1 month. Gr.2 also received C 45 ml/d. Spirometry; biochemical parameters of sputum (medium weight molecules (MWM), trypsin, α1-proteinase inhibitor (α1-PI)) were researched for MCC evaluation.

Results: Dynamic of indices for gr. 1 in table 1, for gr. 2 in table 2.

Conclusions: 1. TB demonstrated positive influence on MCC: broncholytic effect reduces damage influence of bronchial contents’ accumulation on cilia; activation of local trypsinolytic activity of sputum reduces of sputum viscosity; selective influence on M3-cholinoreceptors leads to bronchial secretion’s limitation and to anti-inflammatory effect, as a result – to decrease of MWM level, which leads to decrease of sputum viscosity. 2. Benefit of C addition to TB appeared only in greater increase of trypsinolytic activity of sputum reduces of sputum viscosity; selective anti-inflammatory effect, as a result – to decrease of MWM level, which leads to decrease of damage influence of bronchial contents’ accumulation on cilia; activation of local trypsinolytic activity of sputum reduces of sputum viscosity; selective influence on M3-cholinoreceptors leads to bronchial secretion’s limitation and to anti-inflammatory effect, as a result – to decrease of MWM level, which leads to decrease of sputum viscosity.

P3467
Microbiological screening infectious exacerbation of chronic obstructive pulmonary disease

Biological materials (sputum, swabs or swabs from the nose), obtained from 162 patients with AE of COPD. Microbiological examination of the material was carried out in accordance with the rules of GLP. Laboratory diagnosis of viral infection carried by rapid diagnosis (by enzyme immunoassay (ELISA), fluorescent antibody (IFA) and immunochromatographic assay.

The majority (84.1±3.3%) of patients with AE of COPD was caused by bacterial, and (31.8±1.4%) - viral pathogens, of which (9,8±4.1%) cases - only the bacterial pathogens in the (15.3±3.3%) - only viruses and (14.3±3.1%) - a combination. The greatest significance of bacterial pathogens were H. influenzae in 49.1% of cases, S. pneumoniae - in 22.6%, K. pneumoniae - in 9.4%. M catarrhalis - in 13.2%, E. coli - in 6.6%, S. aureus - 7.6%. Among the viral agents most frequently detected adenoviruses - in 31.6% of cases, influenza A and B - in 34.2%, para influenza - 26.3% and RS virus - at 7.9%

In patients with AE of COPD viral pathogens found: the influenza viruses A and B - Feb 7 (17,5±6,1%), Apr 5 (12,5±3,3%); Apr 37,5±4,2%; parainfluenza - May 3 (7,5±4,2%), Oct 7 (17,5±6,1%); adenoviruses - Feb 6 (15, 0±5,7%), Apr 1 (2,5±2,5%), Oct 5 (12,5±5,3%); RS virus - May 3 (7,5±4,2) %, which generally coincided with the seasonality of the disease to viral respiratory infections, caused by these pathogens.

The frequency of detection of viral pathogens of AE COPD also depended on the duration of the examination of patients from early relapse. In the first three days of exacerbation frequency detection of viral pathogens was (77,5±6,0%) ± 7.01; 4 - 7 day aggravation - (22,5±6,6)%; 8 days later and none of the patients viral pathogen was not detected.
Effects of endurance training on pulmonary and systemic levels of interleukin-8 in patients with stable COPD

Ernest Sala, Catalina Balaguer, Felin Renom, Àngel Ríos, Raquel Extremera, Alícia Bimmel, Bernal Togores, Amanda Iglesias, Josep Lluís Valera, Àlvar Aguait, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Joan March, Banyoles, Spain Servei de Pneumologia, FISAB, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, CIBER de Enfermedades Respiratorias, Palma de Mallorca, Spain Servei de Pneumologia, CIBER de Enfermedades Respiratorias, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Joan March, Banyoles, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Joan March, Banyoles, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Hospital Joan March, Banyoles, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain Servei de Pneumologia, Servei de Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain

Background: Patients with Chronic Obstructive Pulmonary Disease (COPD) may show increased levels of interleukin (IL)-8 (CXCL8). Respiratory physiotherapy may reduce IL-8 induced sputum, but no information is available about the potential effects of endurance training on systemic or pulmonary levels of IL-8.  

Objective: To investigate the effects of endurance training on pulmonary and systemic levels of IL-8 in patients with stable COPD.  

Methods: Levels of IL-8 were quantified in plasma and induced sputum (ELISA) in a group of patients with moderate to severe stable COPD (study group [S]: n=64; 61±4 [mean±SD] years, FEV1: 49.5±14.2% pred. post-bd.) before and after an 8 weeks controlled endurance training program, and in a control group (C): n=5, 61±4 years, FEV1: 45.4±6.6% pred. post-bd., who did not perform such a program.  

Results: After 8 weeks, levels of IL-8 in plasma (from 4.2±4.3 to 3.9±4.4 pg/mL; C: from 4.4±4.2 to 6.5±6.2 pg/mL) and sputum (from 2217.1±1555.5 to 4153.2±3024.5 pg/mL; C: from 3012.8±1593.03 to 2599.9±1200.12 pg/mL) remained unchanged in either group, despite that S showed, respectively, an increase of peak oxygen consumption (from 1.1±0.3 to 1.2±0.3 L/min, p=0.04) and a decrease of lactate acid levels at peak exercise (from 5.5±1.0 to 4.2±0.7 mmol/L, p<0.05).  

Conclusions: In patients with stable COPD, a controlled endurance training program does not modify the pulmonary and/or systemic levels of IL-8. Hence, the beneficial effects of physical training cannot be attributed to the reduction of systemic pro-inflammatory cytokines.

Antielastin antibodies in chronic obstructive pulmonary disease

Belén Nuñez,1, 2 M. Rosa Julià,1 Jaume Sauleda,1, 2 Antonio Clemente,1 Judith García Aymérez,1, 3 Jose María Anto1, 2, 3 Álvar Aguait1, 3 PAC-COPD Study Group. 1Pneumologia, Hospital Son Espases, Palma de Mallorca, Spain, 2PAC, CIBER-Enfermedades Respiratorias, Banyoles, Illes Balears, Spain, 3Imunologia, Hospital Son Espases, Palma de Mallorca, Illes Balears, Spain.  

Aim: To optimize an anti-inflammatory therapy in COPD patients.  

Materials and methods: 24 pts in stable phase (age - 63±5.9 yrs), divided into two subgroups according to the stage of COPD. Measurements included clinical status, spirometry, serum levels of MMP-2 and MMP-9 by immune-fluorescent method (in conventional units).  

Results: Level of MMP-2 in all COPD pts was lower than in control (Table 1), besides it correlated with FEV1 (r=0.47, p<0.02). Level of MMP-9 in COPD pts in the whole was significantly higher than in control but regardless of FEV1 there were selected two phenotypes of COPD: 1st – with normal level of MMP-9, 2nd – with high one (Table 2).

Conclusion: 1) low level of MMP-2 in all COPD pts reflects delay of tissues regeneration and intensification of inflammation because of degradation of monocytic chemotaxic protein-3 even starting with II; 2) high level of MMP-9
in some COPD pts reflects degradation of collagen, remodulation of tissues and intensification of inflammation; 3) MMP-9 may be used as a marker of COPD phenotypes and thus – to optimize an anti-inflammatory therapy.

P3475
Adenovirus IgG avidity – A marker of outcome in COPD-exacerbations
Lucas Bock 1, Mesut Gency 1, Michael Tammi 1, Mirjan Christ-Canin 1, Beat Mueller 1, Michael Roth 1, Daiana Stolz 1, 1Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital, Basel, Switzerland; 2Endocrinology, University Hospital, Basel, Switzerland; 3Internal Medicine, Kantor Hospital, Aarau, Switzerland

Background: Adenovirus causes respiratory infections in healthy and chronically ill adult individuals. Virus replication, cell lysis and inflammation provoke pulmonary damage. Little is known about adenovirus infection, reinfection and reactivation in acute exacerbations of COPD (AECOPD).

Objectives: To evaluate effects of adenovirus infection during and after AECOPD.

Methods: 208 patients with severe AECOPD were tested for anti-adenovirus antibodies at exacerbation and after two weeks. Outcome parameters were measured for two years.

Results: Studied patients were predominantly male (54.8%), had an age of 70.9±8.9 years, a FEV1 of 41.2±17.2% predicted and smoked 45.2±27.9 pack years. At the time of exacerbation 39 patients (18.6%) had anti-adenovirus IgM and low-avidity IgG, indicating a present adenovirus infection. At exacerbation, patients with acute adenovirus infection were younger (p=0.031) and presented a lower hospitalization rate in the previous year (p=0.037). In contrast, they reported a poorer health-related quality of life at admission (p=0.003) and persistently impaired functional status 14 days after exacerbation (p=0.044). Patients with initial low-avidity adenovirus IgG who failed to convert to high-avidity adenovirus IgG within two weeks (n=13, 7%) had more recurrent AECOPDs within six months (1.23 vs. 0.63; p=0.032) and a shorter time to re-hospitalisation for AECOPD or death (p=0.018).

Conclusion: Adenovirus related severe AECOPD cases potentially have a more severe clinical course. In addition, patients who remain at low-avidity adenovirus IgG are at higher risk for subsequent AECOPDs and hospitalisation or death.

P3476
Impact of morning symptoms experienced by COPD patients on exacerbation risk, rescue inhaler usage and normal daily activities
Mark Small, Sarah Brownfield, Ryan Pollard, Steve Fermer. Respiratory, Adelphi Real World, Macclesfield, United Kingdom

Background: Patients consider the impact of COPD on morning activities to be substantial. Evidence of the association of morning symptoms and the impact on the entire day with poor breathing control contributes to the understanding of their importance for managing COPD patients.

Objectives: To quantify the impact of morning symptoms experienced by patients receiving inhaled corticosteroid plus long-acting f2agonist (ICS/LABA) by association with exacerbation frequency, rescue usage and impact on daily activities.

Methods: Data were drawn from a real world study of consulting COPD patients in the USA and Europe in 2011. Results were tested for significance (p<0.05) using Mann-Whitney and negative binomial regressions. Confounders included age, gender, BMI, comorbidities, severity, smoking status and adherence.

Results: Of the 3790 patients in the study, 593 were receiving ICS/LABA-only (+/- rescue). Of the 177 patients reported to experience morning symptoms, cough (65.5%) and excess sputum (53.1%) were the most common. Compared with patients without morning symptoms, these patients were associated with higher mean exacerbation frequency in the last 12 months (1.04 vs. 0.63; p<0.001), rescue usage per day (0.58 vs. 0.46 p=0.025) and daytime impact on a 7-point Likert scale where 7 represents a constant impact (3.61 vs 3.00 p=0.018).

Conclusion: Morning symptoms were associated with significantly more impaired breathing control for patients treated with ICS/LABA-only therapy. The association implies morning symptoms are an important indicator when assessing the impact of COPD and their presence suggests that further therapeutic intervention may be necessary.

P3477
Effect of melatonin on sleep quality of chronic obstructive pulmonary disease
Mark Small, Sarah Broomfield, Ryan Pollard, Steve Fermer. Respiratory, Adelphi Metro Centre for Respiratory Diseases, Macclesfield, United Kingdom

Introduction: Melatonin increases the sleep quality in certain COPD patients but its effectiveness is not yet clear.

Studies have shown that melatonin increases the sleep quality in certain COPD patients with poor sleep quality. The subjects received oral 3 mg melatonin (N = 27) or placebo (N = 27) in one dose 1 hours before sleep for a period of 30 days. The sleep quality was measured by Pittsburg Sleep Quality Index (PSQI) and daytime sleepiness was measured by Epworth Sleepiness Scale. Lung function and oxygenation was measured by spirometry and pulse oximeter.

Methods: Finally 48 patients completed the protocol and entered the final phase. Melatonin significantly resulted in improved global PSQI scores, especially sleep quality (P = 0.001), sleep latency (P = 0.001), sleep duration (P = 0.024) and sleep efficiency (P = 0.003). There was no significant difference in daytime sleepiness, lung function and oxygenation.

It was removed by rigid bronchoscopy. None of the cases had any risk factor for aspiration such as older age and altered mental status.

Unrecognized FB aspiration can result in obstructive pneumonitis, atelectasis, lung abscess, empyema, bronchectasis, hemoptysis, and pleural effusion. For that reason, patient with chronic cough, recurrent or unresolved lung infections even if no history of aspiration might be detected for FB aspiration.

P3480

Scar Grafting: An Infection Per 26 cases

Natalie Zehb, Hanane Benjelloun, Abdelaziz Bukhatar, Najiba Yassine, Abdelkrim Bakhousi. Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca

Inhalation of foreign bodies is rare in adults. Inhalation of scarpin is a phenomenon more frequent in the female population in Morocco. The aim of our study was to describe the characteristics of this particular foreign body and illustrate the circumstances and consequences of its inhalation. Twenty-six young patients all veiled, were hospitalized in the service of Respiratory Diseases University Hospital Ibn Rushd of Casablanca between January 2005 and July 2011 for inhaled scar pin. The mean age was 16 years. Inhalation was accidental in all cases, whereas patients initiated to wear the veil. The penetration syndrome was found in all cases. Clinical examination was normal in all patients. The chest X-ray showed the foreign body as a linear opacity, located right in 18 cases and left in eight cases. Flexible bronchoscopy was able to extract the pin in 21 cases. The pin was released spontaneously in three cases and two patients were operated on. The scar pin is a foreign body especially more common in women who wear the Islamic veil. Flexible bronchoscopy is an essential means of therapy, but the best preventive treatment is avoiding to put in the mouth sharp objects.

P3483

Chest drain fixation: How can we prevent drains from falling out? Lessons from an audit

Ali Al Ameri, Lucy Hcken, Steven Thomas. Respiratory, Calderdale Royal Hospital, Halifax, West Yorkshire, United Kingdom

Introduction and objectives: Chest drain displacement/falling out is the most common complication of small bore drains inserted by the Seldinger technique. This often necessitates repeat drain insertion, with resulting morbidity, delay in further procedures such as pleurodesis, and prolongs hospital stay. Varying techniques of securing chest drains have been described but limited data is available on which method is optimal. We compared two commonly used techniques which are currently in practice at our district general hospital: sutures, and sutureless dressing.

Materials and methods: A retrospective case note audit was performed of patients requiring chest drain insertion over a 12-month period in 2010. Seventy one small bore chest drains were evaluated according to the rate of displacement of those secured by sutures versus those with dressing alone. A prospective re-audit was then performed in 2011 over a period of 8 months, following recommendations to change practice to fixation with sutures. Fifty-four drains were evaluated, with sutures as the method of fixation in the majority.

Results: In the 2010 audit, the majority of drains were secured with dressing alone (47 v 24). Accidental displacement was observed in 37 of the total 71 drains (52%). Of those with dressing fixation only, 75% were displaced, compared to 4% of drains which were sutured in place. Twenty one patients required repeat drain insertion. During the 2011 re-audit, sutures were used in 48 out of 54 (89%). Only 6 drains were accidentally displaced (11%).

Conclusion: The results of this audit suggest that securing a chest drain with a suture, as compared to dressing alone, is more effective in preventing accidental displacement.

P3484

Surgical lung biopsy – Gold standard for diagnosis of idiopathic interstitial pulmonary fibrosis?

Olena Semendyayeva1, Nadiya Monogarova1, Vladimir Gavrysh2, Evgeniya Merenkova1, Sergey Leshenko1. 1Chair of Internal Medicine named after O.Y. Gavrysh, Donetsk National Medical University named after M. Gorky, Donetsk, 2Department of Interventional Lung Diseases, National Institute of Tuberculosis and Pulmonology named after F.G. Yanovskyy, Kiev, Ukraine

The current classification of idiopathic interstitial pulmonary fibrosis (IPF) is based on the account of the specificities of the clinical picture, radiological and pathological features. This raises the question of how much the necessity of verification of the diagnosis of IPF data pathologic study biopsy or autopsy lung material. To answer this question, we asked three highly-skilled pathologist with considerable experience in pulmonology, to conduct an independent analysis of the same histological lung tissue of patients with various forms of IPF. For the analysis of slides, presented 73 patients with IPF. Material for histological study was obtained during open and videotorakoskopich lung biopsy and at autopsy.According to clinical studies and results of computed tomography high-resolution was found clinical diagnosis of idiopathic fibrosing alveolitis (IFA) for the pathomorphological study,
non-specific interstitial pneumonia (NSIP), lymphoid interstitial pneumonia (LIP), cryptogenic organizing pneumonia (COP) and respiratory bronchiolitis associated with interstitial lung disease (RB-ILD). Match the clinical diagnosis with the conclusions of three experts were only in 15 cases (20.5%), two experts in 33 (47.9%) and one - in 15 cases (20.5%). In most cases, differences in interpretation of histological data did not go beyond the group of IIP. Differentiated forms of IIP are very difficult. At the same time, identification of each form of IIP is not an end in itself, it is essential if accurate diagnosis determines the treatment tactics. In our opinion, surgical biopsy of the lungs is necessary in the differential diagnosis of IIP with other interstitial lung diseases.

P3485
Non-traumatic chylothorax – A retrospective analysis
Hang Siang Wong
1, Inês Neves 1, Fernando Coelho 1, Maria Teles 2, Anaabela Marinho 1
1 Pneumology, São João Hospital, Porto, Portugal; 2 Clinical Pathology, São João Hospital, Porto, Portugal

Introduction: Chylothorax (CL) is the presence of lymph in the pleural space. Diagnosis is based on lipoprotein profile of the pleural fluid (PF). The etiology is variable.

Aims: To characterize presentation and causes of non-traumatic CL.

Methods: Retrospective analysis of adults with CL (triglycerides ≥ 110 mg/dl) hospitalized in a central hospital between Jan/04 and Jun/11. A review, after computer supported search of hospital files of patients diagnosed with CL was made. Clinical, laboratory and image presentation, as well as treatment and outcome were analyzed.

Results: We identified 27 (43.5%) patients (pts) with non-traumatic CL; 19 (70.4%) were women. The median age was 62 years (33 – 96 years old). Dyspnea was present in 22 (81.5%), cough in 7 (25.9%) and chest pain in 6 (22.2%). Effusion was unilateral in 22 (81.5%), with milky appearance in 16 (59.3%); exudate in 7 (25.9%), chylous in 1 (3.7%). Mean ± sd of the triglycerides was 477 ± 443 mg/dL. Etiologies: Lymphoma in 14 (51.8%), metastatic cancer in 4 (14.3%), pulmonary tuberculosis in 2 (7.4%), liver cirrhosis in 2 (7.4%), lymphangioleiomyomatosis in 2 (7.4%), inconclusive in 3 (11.1%). Chest drain was needed in 11 (40.7%) pts, pleurodesis in 5 (11.1%). Infectious complications were seen in 13 (48.1%). Effusions solved in 16 (59.3%), persisted in 6 (22.2%), 5 pts were lost to follow up.

Conclusion: Our findings mirror those in the literature - CL may have no classic milky appearance, can be transudate, infectious complications are common and the most frequent cause was lymphoma.

P3486
Utility of closed pleural biopsy in a teaching hospital in Singapore
Hsiang Seng Wong, Respiratory Medicine, Changi General Hospital, Singapore, Singapore

Introduction: The yield of closed pleural biopsy is quoted in most studies to be around 90% for pleural TB and 70% for malignancy.

Objective: To determine the yield of closed pleural biopsy in our institution and the possible factors affecting the yield.

Methods: This was a retrospective study. All pleural biopsies done from 1/6/10 till 31/7/11 were included. Inclusion criteria were subjects with lymphocytic exudate pleural effusion who underwent closed pleural biopsy. All closed pleural biopsies were done under ultrasound guidance either by a respiratory trainee or an interventional radiologist.

Results: A total of 50 subjects underwent closed pleural biopsy. The positive yield of closed pleural biopsy in the cohort was 33/50 (66%). Out of the 33 positive yield, 17 (51.5%) were pleural TB, 6 (18.2%) were malignancy and 10 (30.3%) were other. The positive yield of pleural TB was 17/26 (65.4%), malignancy 6/13 (46.2%) and others 10/11 (90.9%). 32/50 (64%) pleural biopsies were done by respiratory trainees and 18/50 (36%) by interventional radiologists. The positive yield of pleural biopsies done by respiratory trainees was 18/32 (56.3%) and by interventional radiologists 15/18 (83.3%). No difference in the yield of closed pleural biopsy across the ages from 22 to 94 years old (p=0.85), male versus female (p=0.76), race (p=0.26), respiratory trainees versus interventional radiologist (p=0.067), TB versus malignancy (p=0.312).

Conclusion: The yield of closed pleural biopsy was lower compared to most studies in other centers. Age, gender, race, operator experience, TB versus malignancy did not show any significant difference in the yield.

P3487
Comparison of serum & pleural levels of NT-ProBNP in patients with acute dyspnea and pleural fluid referred to emergency department
Ali Taghazoli, Amir Ghaffarzad, Hamid Reza Mortezabaghi, Majid Noroumisey, Mahboub Pourghaemi. Tuberculosis and Lung Diseases Research Center, Tabriz; University of Medical Sciences(TUMS), Tabriz, Islamic Republic of Iran Emergency Department, Tabriz University of Medical Sciences(TUMS), Tabriz, Islamic Republic of Iran

Background: Etiologic diagnosis of Pleural effusion is very important. Light criteria are sensitive for identifying exudates, but they misclassify 15% to 25% of transudates as exudates. N-terminal B-type natriuretic peptide is a cardiac neurohormone specifically secreted from the ventricles in response to volume expansion and pressure overload. This study compares serum and pleural levels of NT-ProBNP in patients with acute dyspnea and pleural fluid for diagnosis of heart failure.

Methods & materials: In an analytic-descriptive cross-sectional study, 43 patients with acute dyspnea and pleural fluid in two groups (15 patients with CHF and 28 patients with other pathology) were analyzed. NT-ProBNP measurement were performed by electrochemiluminescence immunosay method on admission. According to other biochemical analysis (albumin, total protein, cholesterol, triglyceride, amylase, LDH) were performed and gradient and ratio of this markers were accounted.

Results: The Mean±SD serum NT-proBNP levels in CHF and nonCHF patients were 15423±3351 pg/ml and 4751±1616 pg/ml, respectively, and plural NT-ProBNP levels in CHF and nonCHF patients were 14823±3249 pg/ml and 3569±1231 pg/ml, respectively.

Conclusion: NT-proBNP is a sensitive marker for the diagnosis of pleural effusions from heart failure.

P3488
Conservative pneumothorax management: How big is too big?
Greg Haag1, Kathryn Ogden1, Michael Schenker2, Peter Mooney2, Oliver Jensen1, Duncan Scott1. 1 Medicine, Launceston General Hospital, Launceston, TAS, Australia; 2 Launceston Clinical School, University of Tasmania, Launceston, TAS, Australia

Guidelines on primary spontaneous pneumothorax (PSP) management differ but commonly recommend intervention especially for larger PSPs. Evidence for recommending intervention over conservative management, even for large PSPs, appears scarce. We believe intervention is rarely required, that complications can and do ensue, and that conservative management of PSP has good outcomes without the risks associated with guideline-mandated intervention. Conservative management of large PSPs is outside current guidelines, despite a long international and local history of large PSPs being successfully managed in this way. We report to examine the evidence base for compelling reasons to change our current conservative practice. We are conducting a Cochrane Review of management of PSP; this is ongoing. We have performed a retrospective review of PSP patients admitted to our hospital and mostly managed conservatively, with good outcomes, no complications, and no increase in hospitalisation or readmission.

P3499
The influence of the patients’ participation in trials on the adherence to treatment in future
Andrii Sadorey, Yuriy Mostovoy, Nataliia Sleptchenko. Chair of Propedeutics of Internal Medicine, Vinnytsia National Medical University n.a. M.I. Petrov, Vinnytsia, Vinnytsia region, Ukraine

The aim of the study was to estimate the influence of participation in trials on the adherence of the patients to the treatment of chronic obstructive pulmonary disease (COPD) and concomitant arterial hypertension (AH) after the trial finishing. 43 patients (average age 51.5±6.5 years) with severe and very severe COPD and concomitant moderate AH were enrolled. On the each visit patients received information about the necessity of the regular taking of the basis therapy of the main and concomitant disease. The duration of the trial visits were 160±32 minutes instead of 21±5 minutes in case of routine ambulatory visits. Patients filled diaries concerning their knowledge about COPD and AH, taking of the basis therapy of both diseases. The statistical program SPSS 16.0 used for working with the data of study. It was revealed that before the trial only 22 (51%) of the patients had basis therapy due to COPD and only 18 (42%) of them took antihypertensive therapy regularly. In the 6 months after the trial completing these data were 38 (88%) and 37 (86%) respectively. Patients answered that their knowledge about COPD and AH grows at 75±9%. The patients had 1,1±0.2 COPD exacerbations during the 6 months before the trial and during the next 6 months after the trial completing they had 0.7±0.1 COPD exacerbations (p=0.041). Perhaps, the improvement of the patients’ adherence to the treatment of COPD and AH connected with better cooperation between the patient and investigator than it was in routine clinical practice.

Conclusion: The participation in trial due to COPD improves the adherence of the patients to the treatment of COPD an AH connected with better cooperation between the patient and investigator but it is not effective in many cases, regardless of size. We continue to study PSP cases prospectively.
Patients with dyspnea is necessary for evaluating progression of the disease and MRC dyspnea scale and 6mw test. Since the assessment of level of function of P3491 Findings of our study showed that there are good correlation between subjects P3492 lung cancer, necrotizing pneumonia carried higher mortality. Active tuberculosis Surgery (n=48) 10 20.8 Levels of management vs mortality in hemoptysis Fariba Ghorbani, Shadi Shafaghi Shadi Shafaghi, Katayoun Najafizadeh. Lung transplantaion Research Center, National Research Institute of TB and Lung Disease, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran Background: Since the description of dyspnea varies from patients to patient and also varies in various cultures, the aim of this study was evaluation of Persian version of MRC dyspnea scale and comparison of it with results of an objective test, 6 minute walking test (6mw).

Methods: In this cross-sectional study, 150 consecutive patients with chief complaint of dyspnea who referred to the physiotherapy department of Dr Masih Daneshvari hospital, Tehran, Iran for performing 6mw were selected. The severity of dyspnea was assested by MRC dyspnea scale. Results: 51% were male and the mean age of patients was 47 yr. 87.5% (n=287) had pulmonary diseases, 39 (26%) had cardiac diseases and 24 (16%) had dyspnea with unknown origin. The mean of disease duration was 8 yr and 23 (15%) used oxygen at home. Overall, 14% of patients were in level 1 MRC, 41% in level 2, 20% in level 3, 21% in level 4 and 4% in level 5. The mean (SD) of distance, decrease in oxygen saturation and increase in Borg dyspnea scale were 474±117 m, 8±8% and 2.2±, respectively. Levels of MRC dyspnea scale were negatively correlated with distance (r=0.500, P<0.001) and positively correlate with decrease in oxygen saturation (r=0.209, P<0.010) and increase in Borg dyspnea (r=0.387, P<0.001).

Conclusion: Findings of our study showed that there is good correlation between MRC dyspnea scale and 6mw test. Since the assessment of level of function of patients with dyspnea is necessary for evaluating progression of the disease and 6mw test needs skilled personnel and appropriate place, MRC dyspnea scale could be a good alternative.

P3491 Hemoptysis: Causes, interventions and outcomes – Indian single centre experience Deepak Talwar, Jitshu Chudraw, R.C. Jain, Sandeepan Kumar. Pulmonary and Critical Care Medicine, Metro Center for Respiratory Diseases, Noida, UP, India Introduction: Hemoptysis, requires multidisciplinary management & is lacking in tuberculosis hospitals. We evaluated profile of patients admitted with hemoptysis in tertiary respiratory care center. Methods: Retrospective analysis of 377 patients admitted with hemoptysis in Metro Centre for Respiratory Diseases between 2006-2011 done and results analyzed. All patients had active medical management and those suitable for surgery underwent elective or otherwise bronchial artery embolization (BAE) or bronchoscopic interventions (BI done).

Results: Mean age of patients was 49.5±16.52 years with 76.59% (n=287) being male. Mortality in male patients was significantly (59.6%Vs 40.4%; p<0.001). MN risk was also associated with a significantly longer length of stay (OR 1.054, p<0.001). A tumorous disease markedly increased MN risk (OR 2.33, p<0.001), while it was highly reduced in sleep-related breathing disorders (OR 0.04, p<0.001). MN risk was also associated with a significantly longer length of stay (10.2±6.9 5 vs. 5.4±6.0 days).

Conclusion: The application of a validated screening tool significantly contributes to detected patients at risk for malnutrition. Especially patients older than 65 as well as those with specific diseases need increased attention regarding MN risk. An early intervention could help to reduce length of stay.

P3494 Non-CF bronchiectasis: Correlation between body mass composition, lung function, inflammatory syndrome, gender and quality of life Adina Turcanu, Iulian Mihai, Roxana Aricescu, Traian Mihaescu, Pneumology, Clinic of Pulmonary Diseases, Iasi, Romania Background: The impact of bronchiectasis on health care’s costs and quality of life is important due to prolonged and repeated periods of hospitalization. Aim: Assess the situation of hospitalized patients diagnosed with non-CF bronchiectasis by studying the relationship between body mass composition, lung function and gender.to study how these parameters correlate with the inflammatory profile associated with acute recurrent respiratory infections.

Methods: 30 consecutive patients (15 male, 15 women) enrolled in 2011, evaluated through HRCT, bioimpedance, spirometry, inflammatory profile and Saint George Questionnaire.

Results: We observed that 70% of the patients (12 male and 9 women) had high percent of fat, the percentage of water was low at 60% of the patients (5 males, 6 females; also, the lean percentage was low at 28 patients (equal for both sex). Regarding the pulmonary function and the inflammatory syndrome we observed that 90% (27 patients) had abnormal values for CRP and ESR, and all patients had obstructive dysfunction syndrome (FEV1 between 34-45% from predicted values). 80% of the answers from Saint George Questionnaire indicated that the quality of life was medium to poor. We correlate this to low percent of lean and water, the presence of inflammatory syndrome and obstructive respiratory syndrome.

Conclusions: Body mass composition in patients with non-CF bronchiectasis is correlated with gender. Patients probably due to chronic lung disease and recurrent infections associated with the inflammatory syndrome. Obstructive lung condition
syndrome is present at almost all the patients and with the rest of parameters can be correlated with the decrease of the quality of life.

**P3495**

**Effects of inhaled saline and oxygen on noninvasive markers of airway and lung function**

**Myriam Ehret**, Stefan Karrasch, Angelika Kronseider, Stefan Peters, Dennis Nowak, Rudolf A. Jirres, Uta Ochmann. Institute and Outpatient Clinic for Occupational, Social and Environmental Medicine, Ludwig-Maximilians-University, Munich, Germany

**Introduction:** Inhalation challenges have been shown to induce pulmonary effects, e.g. an increase in 8-isoprostanate levels in exhaled breath condensate (EBC) by hyperoxic air. The current study examined the sensitivity of noninvasive measures such as bronchial (FeNO) and alveolar (NOalv) nitric oxide, diffusing capacity for nitric oxide (DLNO) and carbon monoxide (DLCO), and hydrogen peroxide (H2O2) in EBC to detect alterations induced by oxidative or osmotic inhalative stress.

**Methods:** 20 healthy nonsmoking subjects aged 19-50y inhaled nebulised 3% hypertonic saline solution (HSS) over 20 min and 100% O2 at a flow of 50ml/min over 30 min on two days. Before and after inhalation spirometry, multifold exhaled NO, DLCO and DLNO were measured and EBC was collected and analysed for H2O2 using an optimised procedure with inhalation filter.

**Results:** HSS inhalation induced a median decrease in FEV1 of 3% (P<0.001) and in DLNO of 1.5% (P=0.05); no changes occurred for DLCO, alveolar volume, FeNO and H2O2. Results for NOalv were ambiguous in both inhalation groups. Hyperoxic air did not cause significant changes in any other parameter.

**Conclusion:** These results suggest that HSS inhalation not only causes slight airway obstruction but also induces alterations of fluid balance in the lung periphery that can be detected via DLNO but not DLCO. DLNO could thus be of clinical value in the diagnosis of mild pulmonary edema, e.g. related to cardiac dysfunction.

**Cytokine response in the lungs, pleural fluid and serum in children after thoracic surgery using one-lung ventilation**

**Davide Donnare, Oleksandr Katlov, Oleksandr Mazulov, Kateryna Dmytriieva. Anaesthesiology and Intensive Care, Vinntsa National Medical University, Vinnitsa, Ukraine**

Thoracic surgery mandates usually a one-lung ventilation (OLV) strategy with the collapse of the operated lung and ventilation of the non-operated lung. These procedures trigger a substantial inflammatory response. The aim of this study was to analyze the cytokine reaction in both lungs, pleural space and blood in patients undergoing lung resection with OLV.

**Methods:** Broncho-alveolar lavage (BAL) fluid of both the collapsed, operated and the ventilated, non-operated lung, respectively, pleural space drainage fluid and blood was collected and the concentrations of interleukin (IL)-6, IL-1RA were determined with enzyme-linked immunosorbent assays in 24 patients.

**Results:** Substantial inter-individual differences in the BAL fluid between patients in cytokine levels occurred. In the pleural fluid and blood these inter-individual differences were less pronounced. Both sides of the lung were affected and showed a significant increase in IL-6 (14.2±2.2 and 1.5±0.7 pg/ml, mean ± se) and IL-1RA (23.3±2.1 and 8.2±2.6 pg/ml, mean ± se) concentrations over time in the children with one-lung ventilation (OLV) and non one-lung ventilation (p<0.001). Except for IL-6, which increased more in the collapsed, operated lung, no difference between the collapsed, operated and the ventilated, non-operated lung occurred. In the blood, IL-6 and IL-1RA increased early, already at the end of surgery.

**Conclusion:** The inflammatory response of cytokines affects both the collapsed, operated and the ventilated, non-operated lungs. The difference in extent of response underlines the complexity of the inflammatory processes during OLV in contrast to the cytokines.

**P3497**

**Treatment effect of inhaled prolonged bronchodilator therapy (IPBT) combined with inhaled glucocorticosteroids (IGCS) on respiratory symptoms and external respiratory function in MDTR pulmonary TB patients with broncho- obstructive syndrome (BOS)**

**Galina Kuklina**, Vladimir Romanov 1, Department of Granulomatous Lung Disease, Central TB Research Institute, Moscow, Russian Federation; 2Department of Granulomatous Lung Disease, Central TB Research Institute, Moscow, Russian Federation

**Aim:** To study treatment effect of IPBT combined with IGCS on respiratory symptoms and external respiratory function in MDTR pulmonary TB patients with BOS.

**Methods:** We studied treatment effect of IPBT combined with IGCS on respiratory symptoms of 44 MDTR pulmonary TB patients with BOS: fibrotico-cavernous tuberculosis 16 patients, disseminated tuberculosis 8 patients, casesous pneumonia 6 patients, infiltrative pulmonary tuberculosis with cavities 14 patients. All patients were treated by standard TB chemotherapy on the base of WHO recommendations.

All patients were treated by one dose of 50/500 mcg of combined IGCS (including prolonged beta2-agonist-salmeterol and fluticasone propionate) twice a day during one month. Then this drug was not used during 5 months. Treatment effect was evaluated, first, at the beginning of the treatment and then at the end of treatment by this drug and, last, in 6 months, at the end of study. Respiratory symptoms were evaluated by 5-mark grading system and cumulative index (CI). FEV1 was shown in percents out of standard indications.

**Results:** We found that the use of combined bronchodilators CI decreased per 24.3% and dyspnea decreased per 37.5% during one month. And during the next 5 months CI decreased only per 10.3% and dyspnea per 13.3%. FEV1 increased from 63.3% to 85.4% during one month of inhaled broncholytic combined with IGCS use.

**Conclusion:** IPBT combined with IGCS significantly prompts dyspnea decrease and respiratory symptoms expression and, at the same time, it prompts FEV1 increase.

**381. The good clinical practice: useful case report**

**P3498**

**Transbronchial lung biopsy, our results in 1197 patients**

**Ludek Sieblick1, Sarka Letfnerova2, Pavla Zachova2, Radislav Matej2, Marinna Vasakova1. 1Department of Respiratory Medicine, First Medical School of Charles University and Thomayer Hospital, Prague, Czech Republic; 2Department of Pathology and Molecular Medicine, Thomayer Hospital, Prague, Czech Republic**

**Background:** Transbronchial lung biopsy (TBLB) is routinely performed by pulmonologist to diagnose focal and diffuse lung diseases. Compared with open lung biopsy, TBLB has lower morbidity and mortality. The authors summarize the results of 1197 patients who underwent TBLB.

**Objective:** To evaluate the diagnostic yield of TBLB performed without any guidance during the procedure in various pulmonary affections.

**Methods:** Retrospective analysis of 1197 patients who underwent TBLB within the years 2008 to 2011. Patients were selected in groups according to a disease: focal lesion, suspected sarcoidosis, intestinal lung disease (ILD) other than sarcoidosis, pneumonia and bronchial asthma. No method of guidance during the bronchoscopy was used. The site for TBLB was chosen by a physician after revision of chest CT or chest radiograph. Results fulfilling the requested morphologic criteria of specific disease and leading to the final clinical diagnosis were judged to be true positive.

**Results:** The overall diagnostic yield of TBLB was 26.6%. Highest sensitivity was observed in sarcoidosis - 60.2%. In the subgroup of 302 patients with lung cancer, TBLB confirmed the disease in 142 (47.0%) cases. In the ILD excluding sarcoidosis group sensitivity, specificity, positive-predictive and negative-predictive value was: 12.4%; 92.9%; 91.4% and 14.8%, respectively. In 18 persons (1.5%) pneumothorax developed, major bleeding was observed in 7 patients (0.6%). There was no mortality.

**Conclusion:** We recommend TBLB for diagnosing focal pulmonary lesions and morphologic confirmation of sarcoidosis. For its safety TBLB is a convenient method even in other diseases mainly because numerous patients can avoid surgical lung biopsy.

**P3499**

**Intrapulmonary lipoma in children: A case report and literature review**

**Chunmei Zhig, Ling Cao. The Capital Institute of Pediatrics, Beijing, China**

**Objective:** To help early diagnosis of lipoma in children by reporting a rare case of intrapulmonary lipoma in a child.

**Case presentation:** A 13-month-old boy was hospitalized because of cough and fever. Physical examination revealed rales and wheezing over his lungs. Chest
Radiograph showed patchy infiltrate and consolidation near his left hilar. Chest CT scan showed patchy infiltration and round-shape, hypodense homogenious lesions located in the lower lobe of right lung without any calcification. After 19 days of antibiotics treatment, his clinical symptoms and signs disappeared, he underwent chest CT scan (Figure 1) again after treatment, and the result showed the patchy infiltration dissolved, however, the lesions in the lower lobe of right lung remained without any change. He was discharged. One month and one year later he was examined by chest MRI. The lesions were diagnosed as intrapulmonary lipoma by T2 weighted MRI images (Figure 2) with fat suppression.

Conclusions: Intrapulmonary lipoma can also be identified in children. Chest CT scan and MRI are very important for making correct diagnosis.

P3500
Munchausen syndrome by proxy presenting as unexplained hemoptysis: A report of two cases
Salewska Tłoga Yaw1, Guzin Cinel2, Ugur Ozcelik2, Ebru Yakcin2, Deniz Dogru2, Nural Kapetan1. 1Department of Pediatrics, Pediatric Asthma and Allergy Unit, Hacettepe University, Ankara, Turkey; 2Department of Pediatrics, Pediatric Chest Diseases Unit, Hacettepe University, Ankara, Turkey

Hemoptysis is a serious symptom in early childhood and further investigation may be required in some cases. Munchhausen syndrome by Proxy (MSP) must be kept in mind particularly when suspicious behaviors of the supervisors are observed. Case 1: A thirteen-month-old boy was admitted with recurrent hemoptysis. He was hospitalized because of persisting symptoms for four months, however no reason was found and he was subsequently discharged. Detailed history revealed that hemoptysis had occurred only in times when he was alone with his mother. Despite comprehensive diagnostic evaluation including laryngoscopy, Computerized Tomography, bronchoscopy and endoscopy, no definitive etiology was diagnosed. During his hospitalization, the mother reported new bleedings of the child and blood stained clothes were noticed. Examination of security footage revealed that the mother was sneakingly obtaining the blood samples of another patient and deceiving medical staff. Case 2: An-eight-month old girl was admitted with a history of having vomited blood for two months. Reluctance of her mother was noticed by the physician during history taking. Upper endoscopic investigation revealed linear hemorrhagic lesions at pharynx and tonsils. No definitive etiology was diagnosed despite comprehensive investigations. During hospitalization, the doctor witnessed that her mother was injuring the child with her finger and making her bleed. She was warned about security footage of the room and her complaints resolved spontaneously.

Munchhausen syndrome by proxy is an unusual and difficult to identify cause of child abuse. It must be taken into consideration particularly in conditions with secondary gain of family members.

P3501
Thoracic splenosis – Case series and review of the literature
Nissim Artish1, Ariel Rockach1, Nauma Bogot2, Irith Hadas-Halperen2, Gabriel Izbički1. 1Pulmonology, Shaare-Zedek Medical Center, Jerusalem, Israel; 2Pediatric Chest Diseases Unit, Hacettepe University, Ankara, Turkey

Introduction: Splenosis is a rare finding of ectopic splenic tissue found within the thoracic cavity, abdomen or peritoneal cavity. In thoracic splenosis the splenic tissue most often grows in the form of a nodule and the auto-transplantation is usually caused by a previous penetrating or blunt trauma to the thoracic-abdominal region, resulting in splenic rupture.

Cases: We present three cases of thoracic splenosis. All the patients were Caucasian males aged 40-63 presenting with pleural masses that mimicked malignancy, who were eventually diagnosed as thoracic splenosis. All of them had a history of traumatic event to their upper abdomen which occurred 13-40 years ago resulting in splenectomy.

Methods: We made a Medline search in order to find all the cases of thoracic splenosis. We reviewed the cases in order to specify this rare condition.

Results: We found 39 case reports of patients diagnosed with thoracic splenosis. In the majority of the cases the patients are asymptomatic and are incidentally diagnosed with left hemithorax pulmonary lesions found via chest radiography or thoracic computed tomography. The average period of diagnosing thoracic splenosis from the time of trauma is roughly 21 years and ranges from 6 to 46 years. The diagnosis is challenging and the patients usually undergo extensive workup including surgical biopsy

Conclusion: We conclude that splenosis is a rare entity but one should think about this possibility in a patient with a left thoracic mass and a history of abdominal trauma, splenic rupture and splenectomy.

Conclusion: In asymptomatic or mildly symptomatic adult patient with lung sequestration, conservative follow up instead of surgery is a legitimate option.

P3503
Acquired tracheoesophageal fistula – A rare cause of chronic episodic cough
Anishesh Gupta1, Saurabh Kansal2, A.P. Kansal1, Bidhi Chand1. 1Chest and Tuberculosis, Govt. Medical College, Patiala, Punjab, India; 2ENT, Dayanand Medical College, Ludhiana, Punjab, India

Introduction: Acquired tracheoesophageal fistula (TOF) is a rare entity and occurs as a result of trauma, malignancy, granulomatous infection, any previous surgery of trachea and esophaogus. Symptoms include uncontrolled coughing after swallowing. The majority of acquired fistulas occur at cervico-thoracic junction.

Case report: We report a case of 55 yr female who presented to us with cough and regurgitation particularly after intake of liquids since two mths. There was no history of tuberculosis or malignancy. Patient was on antihypertensive agent for four mths but not on ACE inhibitors. On routine investigations TLC and ESR were raised but chest xray was normal. Sputum was negative for AFB. Patient was managed on lines of Gastro Esophageal Refux Disease with no improvement. CECT chest showed consolidative changes. Nothing significant found in upper GI endoscopy. Barium swallow revealed the losing of contrast into trachea and in bronchi, showing the presence of tiny fistula at C3-C4 vertebral level. Due to higher position of fistula, patient was advised to undergo surgery.

Discussion: An acquired TOF bypasses the laryngeal protection and leads to repeated aspiration. We are reporting a rare case of acquired TOF possibly of infective etiology which is a rare occurrence at such a age. It was also the cause of chronic episodic cough in this patient which was not relieved with various treatments. Malignant and traumatic causes have now superseded infection. Barium swallow will demonstrate the defect in 70% of lesions. The management of acquired TOF involves minimizing further aspiration to prevent pulmonary infections. Definitive management involves stenting or surgical repair with treatment of underlying cause.

Conclusion: Pulmonary sequestration in asymptomatic adults; a plea for conservative observation
Artemios Dimitriou, Yehudit Rozenman, Issahar Ben Dov. Pulmonary Department, Sheba Medical Center, Tel Aviv, Israel Radiology Department, Sheba Medical Center, Tel Aviv; Israel Pulmonary Department, Sheba Medical Center, Tel Aviv, Israel

Background: Pulmonary sequestration (PS) is a rare congenital anomaly. Due to recurrent infections, the treatment in children is surgical removal of the sequestrated lung and this recommendation expands to adulthood.

Objective: To test if asymptomatic or mildly symptomatic adults with PS could be offered conservative follow up instead of surgery.

Methods: We conducted a case series analysis of all patients above 20 yrs old, with sequestration seen in our institute from 2000-2012. Diagnosis, symptoms, patient characteristics, natural course and treatment were reviewed.

Results: During a median follow up of 7 yrs, no major infection occurred and the lesion size remained unchanged in 4/5 patients while mild infection that resolved with oral antibiotics was noted in 1/5.
In this case, we report a newly categorized mediastinal cyst called Mullerian cyst, which was reported for the first time by Hattori et al in 2005. A 51-year-old female patient was admitted to our hospital with the complaint of dysphagia. T2-weighted chest magnetic resonance imaging (MRI) showed a cystic lesion attached to the vertebral column in the posterior mediastinum.

The patient underwent right thoracotomy. The cyst was tightly attached to esophagus and corpus of the 5th thoracic vertebra. The intact cyst was freed from posterior mediastinum.

It was lined by a ciliated tubal-type epithelium and had a thin wall composed of smooth muscle. The epithelium showed estrogen and progesterone receptor expressions immunohistochemically. Mullerian cysts arise from remnants of the Mullerian duct and can be located anywhere along the path of Mullerian duct regression. Pelvis is the most common localization and their occurrence in the mediastinum is extremely rare. However, mediastinal Mullerian cyst is newly known entity, it should be kept in mind for the differential diagnosis of posterior mediastinal cysts.

P3505
First presentation of a case of pulmonary alveolar microlithiasis with spontaneous pneumothorax
Naseh Saghi1, Shilan Mohammadi2. 1Internal Medicine, Kurdistan University of Medical Sciences, Sanandaj, Kurdistan, Islamic Republic of Iran; 2Pediatric Medicine, Kurdistan University of Medical Sciences, Sanandaj, Kurdistan, Islamic Republic of Iran

Pulmonary Alveolar Microlithiasis (PAM) is a rare disease of unknown etiology. It is characterized by the presence of small calculi within the alveolar space. Clinical features vary and some patients may be asymptomatic for a long time with subsequent occurrence of dyspnea, dry cough, chest pain, and ultimately, respiratory failure. Recurrent spontaneous pneumothorax is a late complication of the disease. Herein we report a case of alveolar microlithiasis in a 42-year-old male whose first presentation was the symptoms of pneumothorax. He was admitted with sudden onset dyspnea and right sided pleuritic chest pain. After treatment of pneumothorax with insertion of chest tube, pulmonary function revealed normal indices. The chest radiograph demonstrated diffuse confluence of dense micronodular infiltrate. High-resolution CT scan revealed diffuse ground glass attenuation and calcifica-

tions along the interlobular septa and subpleural regions. A transbronchial lung biopsy confirmed the diagnosis of PAM.

P3506
Benign metastatic leiomyoma of uterus with lung damage
Ivetta Dvorakovaskaya, Dali Dzadzua, Irina Platonova. Laboratory of Pathomorphology, Research Institute of Pulmonology, St. Petersburg, Russian Federation

Benign metastasizing leiomyoma of uterus is difficult to diagnose due to frequent location in the lungs. The characteristic manifestation is polygonal cells. The most common localization is pelvis. However, their occurrence in the lungs is extremely rare. We report a case of pulmonary metastasis of uterine leiomyoma in a 46-year-old woman with no previous history of gynecologic disease. The patient was admitted with sudden onset dyspnea and right sided pleuretic chest pain. After treatment of pneumothorax with insertion of chest tube, pulmonary function revealed normal indices. The chest radiograph demonstrated diffuse confluence of dense micronodular infiltrate. High-resolution CT scan revealed diffuse ground glass attenuation and calcifica-

tions along the interlobular septa and subpleural regions. A transbronchial lung biopsy confirmed the diagnosis of PAM.

Hyper eosinophilic syndrome (HES) is characterized by blood eosinophilic count 1500 or more for 6 months & eosinophil infiltrations of multiple organs like skin, heart, bone marrow, lungs. We report a unique case, rare in a female case report: 20 years old female had progressive dyspnea since 1 year. One report with her showed peripheral eosinophilia of 27% Respiratory system revealed signs of left pleural effusion with fluid eosinophilia. Eosinophilic pneumonia was diagnosed. Blood eosinophil count was 2750 cells. PTECG was normal. The thorax revealed RA thrombus & RV infarctions and cardiac MRI showed typical endomyocardial fibrosis in RV.

Echo showed RA thrombus & apical fibrosis. Hypereosinophilic syndrome (HES) is characterized by blood eosinophilic count 1500 or more for 6 months & eosinophil infiltrations of multiple organs like heart, bone marrow, skin. HES is a rare syndrome, rare in a female case report: 20 years old female had progressive dyspnea since 1year. One report with her showed peripheral eosinophilia of 27% Respiratory system revealed signs of left pleural effusion with fluid eosinophilia. Eosinophilic pneumonia was diagnosed. Blood eosinophil count was 2750 cells. PTECG was normal. The thorax revealed RA thrombus & RV infarctions and cardiac MRI showed typical endomyocardial fibrosis in RV.
A rare cause of hemoptysis: Munchausen syndrome

The authors report a case of a 65-year-old male patient, suffering of hypertension and permanent atrial fibrillation (treated with warfarin), with no previous history of pulmonary pathology, who presented with fever, wheezing, cough and hemopurulent sputum 4 days before. The chest radiograph showed middle lobe (ML) and lower right lobe (LLR) consolidation leading to the diagnosis of community acquired pneumonia as compared to normal subjects. The aim of our study was to assess pulmonary functions and the cardiopulmonary response to exercise in acromegalic patients. Ten patients who were followed by endocrinology department outpatient clinic were enrolled to study. Disease activity was evaluated by growth hormone (GH) and elevation of its peripheral mediator insulin-like growth factor-1. Acromegaly is known to significantly increase mortality rate. Cardiovascular diseases are the most common causes of death in acromegalic patients. Moreover acromegalic patients with cardiac hypertrophy have a decreased cardiopulmonary reserve compared to normal subjects. The main clinical symptoms were dyspnea in 20 pts (95.2%), cough in 19 pts (90.9%), fever in 17 pts (80.9%), pain in 5 pts (23.8%). AEP or CEP was the result of CD in 3 pts (teoplasmosis), in 1 pt. with sarcoidosis, rhinitis and in 2 with allergic bronchopulmonary aspergillosis. In 17 pts CD was identified. A statistical significance was found between the age of pts with AEP (56±12.2) and CEP (67±12.9) (p<0.05). There were no statistically significant differences between patients with AEP (614±279.3) and CEP (709±311.3) and in the groups of AEP (860.7±976.7) and CEP (579±429.3). 11 pts have been continually treated with corticosteroids, 8 pts temporarily. The longest treated patient has been receiving corticosteroid for more than 13 yrs.

Conclusions: EP is a very interesting disease. Treatment with antibiotics is unsuccessful, but corticosteroid treatment leads to a dramatic improvement. Dividing EP into AEP and CEP is not so clear cut.

Drug excipients allergy

P3512
Vipukumar Shah, Allergy & Asthma, Allergy Clinic, Surat, Gujarat, India

Introduction: Because of its rarity, drug excipients allergy is often unsuspected by the doctors. Some times the active drug is blamed and discontinued unnecessarily when the real culprit is drug excipients. This was suspected when patients reported exacerbation of urticaria with anti histaminic which are actually used for treating urticaria. After suspecting drug excipient as the cause of allergy.

Material: To know actual cause it was decided to do patch testing with common drug excipients. The common excipient selected were Yellow Tartrazine, Titanium Dioxide, Sunset Yellow, Brilliant Blue, Quinoline Yellow, Talcum, and Ponceau 4R.

Method: Patch testing material were prepared by using the basic material and suitable vehicle. 24 patients were selected for patch testing. Patch was put on patients back after 48 hrs reading were taken to confirm the skin sensitivities. Results: Out of 24 patients 15 patients were positive for Yellow Tarrtazine only, 3 patients showed positive to Titanium Dioxide. 2 patients were positive to Quinoline Yellow and Talcum. 2 were positive with Brilliant blue. 3 patients were positive Yellow Tarrtazine, Sunsets Yellow and Talcum.

Conclusion: Drug excipients play an important role in causation is required to be standardised for patch testing. This type of patients should be treated in view of such investigations and preferably treated with drug without excipients.

Rosai-Dorfman disease: Presentation of a clinical case

Rubin Guruds1, Elisa Barrera2, Elias Abbad1, Karla Cabada. 1Department of Neumology and Thoracic Surgery, Specialty Medical Center, Juarez City, CHIH, Mexico. 2Institute of Biomedical Sciences, Autonomous University, Juarez City, CHIH, Mexico

Introduction: Rosai-Dorfman disease (RDD) is a rare histiocytic proliferative process, infrequent and idiopathic benign with painless cervical or systemic lymphadenopathy, fever, leukocytosis, polyclonal hypergammaglobulinemia and accelerated erythrocyte sedimentation. In a low percentage, there are extranodal manifestations. The historical diagnosis consists of filling of sinusoids in ganglia with linfocytes, plasmatic cells and histocytes positive for S100, CD68, glia with linfocytes and histiocytes positive for S100, CD68, edema of face, neck and arms. The erythrocyte sedimentation was accelerated (90 mm/hr). Chest x-rays showed mediastinum widening and tumor in the pulmonary right hilum. The computed tomography showed right hilum hypervascular of 7 cm. The bronchoscopy with biopsy showed right bronchi infiltrate with tumoral edema of face, neck and arms. The erythrocyte sedimentation was accelerated (90 mm/hr). Chest x-rays showed mediastinum widening and tumor in the pulmonary right hilum. The computed tomography showed right hilum hypervascular of 7 cm. The bronchoscopy with biopsy showed right bronchi infiltrate with tumoral
aspect. The histopathological findings revealed histiocytic proliferation and others with eosinophilic cytoplasmic features and lymphoid cells. Emperipoliseis and plasmatic cells where identified, with Russell bodies. With the diagnosis 120 mg a day of interferon-alpha was initiated, continuing with 40 mg daily over 6 months with favorable response reducing the size of the lesion. **Discussion:** In this case, the manifestation of the disease was dyspnoea produced by the bronchial obstruction and compaction of the superior vena cava due to the hilar infiltrative histiocytic mass, so our initial probable diagnosis was a bronchogenic cancer. This extranodal manifestation is infrequent, but it is to be taken into account as part of the pulmonary and mediastinal pathology.

**P3514**
Three tumors in a young woman with Cushing's syndrome

Lizza Hendek1, Remy Mostard1, Eric van Haren1, Linda van de Winkel2, Patrick van Battum5, Wendie Schreurs3, 1Pulmonary Medicine, Atrium Medical Centre, Heerlen, Netherlands; 2Internal Medicine, Atrium Medical Centre, Heerlen, Netherlands; 3Nuclear Medicine, Atrium Medical Centre, Heerlen, Netherlands; 4Department of Ophthalmology, Uludag University Faculty of Medicine, Bursa, Turkey; 5Department of Pulmonary Diseases, Uludag University Faculty of Medicine, Bursa, Turkey.

**Case:** A 38-year old female with no relevant medical history was referred to internal medicine with clinical features compatible with Cushing’s syndrome. Laboratory results suggested ectopic adrenocorticotropic hormone (ACTH) production. The pituitary gland had a normal aspect on magnetic resonance imaging but computed tomography of the chest showed a smooth, oval mass in the posterior mediastinum and a nodule in the left upper lobe. Diffferential diagnosis consisted of carcinoid, small cell lung cancer or neuroendocrine tumor. Bronchoscopy showed no endobronchial lesions but both lesions could not be reached with fluoroscopic guidance. On 18F-deoxyglucoson positron emission tomography (18FDG-PET) increasing 18FDG uptake was seen in the mediastinal mass and in the right gluteal region, but not in the left upper lobe. Somatostatin scintigraphy showed uptake in the left upper lobe, but not in the other masses. Histological biopsy of the gluteal mass showed a desmoid type fibromatosis. Wedge resection with peroperative frozen section resulted in a benign tumor and a type 1a (TAa) was found. For treatment and staging resection of the left upper lobe with mediastinal lymph node sampling and resection of the mediastinal mass followed in the same session. The resections were complete but one lymph node (N2) was positive for carcinoid metastases. The mediastinal mass appeared to be a schwannoma.

**Conclusion:** Cushing’s syndrome caused by ectopic ACTH in a TAaN2M0 typical carcinoid. Furthermore, the two PET-positive lesions appeared to be a schwannoma and a desmoid type fibromatosis. This case stresses the importance to link presenting condition with imaging features and to obtain histological confirmation.

**P3515**
The treatment of a non-Lagrenhans-cell histiocytosis, Erdheim-Chester disease: A case report

Dane Edger1, Asi Gerek Dilekteşi1, Ahmet Ursavas1, Duygu Kopruoglu1, Saduman Balaban Adim1, Cokhan Gokalp1, Ugur Yavas1, Ercument Ege1.
1Department of Pulmonary Diseases, Uludag University Faculty of Medicine, Bursa, Turkey; 2Department of Pathology, Uludag University Faculty of Medicine, Bursa, Turkey; 3Department of Radiology, Uludag University Faculty of Medicine, Bursa, Turkey; 4Department of Ophthalmology, Uludag University Faculty of Medicine, Bursa, Turkey.

Erdheim-Chester disease (ECD) is a rare, non-Langerhans histiocytosis with multi-system involvement. Pulmonary involvement is uncommon. We present a 46-year-old woman who presented with chronic cough, dyspnea and yellowish plaques in the peripheral area. She was previously diagnosed as diabetes insipidus. Chest radiographs showed bilateral diffuse interstitial infiltrates. Symmetric sclerotic bone lesions, dural nevve thickening were defined on imaging studies. Histopathologic examination of the skin lesions revealed infiltration of CD-68 positive foamy histiocytes. She was diagnosed as ECD with pulmonary, pituitary, skeletal, orbita, central nervous system and skin involvement. Following first-line treatment with corticosteroids her syptoms worsened. Treatment with interferon-alpha was started. She had an marked improvement in symptoms, radiologic findings and skin involvement under this treatment.

**Conclusion:** ECD should be considered in the differential diagnosis of interstitial lung diseases. As there is no standard treatment for this disorder, interferon-alpha can be effective in the treatment of Erdheim-Chester disease.

**P3516**
High grade laryngeal stenosis caused by an extramedullar metastasis of plasmacytoma

Joern Brune. Pulmonology, Lung Centre Hener, Hener, Germany

We report the case of a 69-year-old woman who was presented to our department with rapidly progressive hoarseness, stridor and dyspnea for week. The patient had a history of multiple myeloma for 3 years and resected breast cancer for 1 year. On fiberoptic bronchoscopy a high grade (>80%) right sided laryngeal submu- cosal mass, affecting both supra- and infraglottic parts of the larynx, was found for the reason she has symptoms. We performed a surgical tracheostomy considering it the only viable option of airway managament. An MRI scan of the neck revealed a right sided cervical mass of 7x3cm, as well as an enlarged lymph node in the right supravaculariauricular region (I1). Biopsy was performed both of the lymphnode (core needle biopsy) and the laryngeal mass (EBUS-TBNA). The histological and immunohistochemical findings were consistent with metastasis of the known multiple myeloma. Extramedullar metastasis of multiple myeloma is a rare complication of the disease occurring. Laryngeal stenosis due plasmacytoma has been described in pediatric patients, but never in adult patients before.

**P3517**
Urinary incontinence in adult bronchiectasis patients: Common but treatable

Jonathan Miller1, Hilary Tedd1, Jackie Rees2, Anthony DeSozya1.
1Bronchiectasis Service, Newcastle NHS Foundation Trust, Newcastle, United Kingdom; 2Continence Service, Newcastle NHS Foundation Trust, Newcastle, United Kingdom.

**Background:** Patients suffering from urinary incontinence (UI) often avoid seeking medical attention, due to embarrassment, consequently remaining untreated. UI negatively impacts of quality of life, psychological health and relationships.

In patients with non-CF bronchiectasis, it may also reduce adherence to chest physiotherapy. UK Physiotherapy Guidelines (2009) suggests screening for UI in patients with non-CF bronchiectasis.

**Methods:** Screening at new specialist bronchiectasis clinic for symptoms of UI, with referral onto Continence specialist services.

**Results:** Of the initial 116 patient referred to the bronchiectasis service, 76 were female. 55% of female patients had UI (UI-Br). 87.5% of UI-Br patients reported symptoms for over 5 years, with 40% of patients describing symptoms of over 10 years duration. 37% reported UI as having a terrible impact on quality of life. Patients were assessed by a Continence Nurse Consultant. A personalised UI management plan was formulated, including education on pelvic floor strengthening, urge suppression and voiding techniques. Other treatments used included bladder retraining (40%) and toilet resheduling (40%). Over 60% of patients have been discharged by the Continence Service, following symptom improvement.

**Conclusions:** In asking about UI, in line with UK guidelines, we identified symptomatic patients and referred them onto an appropriate specialist service. We identified a high prevalence of UI in female patients with non-CF bronchiectasis. Patients suffered symptoms for a prolonged period with a significant impact on quality of life. Through appropriate specialist input, these distressing symptoms have been improved in the majority of our patient group.

**P3518**
Hypogammaglobulinemia, reduced B cell count and recurrent sino pulmonary infections: Good’s syndrome

Murat Türk, Nurdan Köktürk, Numan Ekim. Pulmonary Medicine, Gazi University School of Medicine, Ankara, Turkey

A 62-year-old woman with a history of thyroidectomy for capsule-invasion-free, type AB thymoma, presented with cough, dyspnea and fever. She had frequent respiratory tract infections for 9 months. Her initial physical examination was normal. Abnormal laboratory studies on admission were anemia, leukocytosis, proteinemia, elevated erythrocyte sedimentation rate, C-reactive protein and procalcitonin levels. On chest tomography, multiple mediastinal and hilar lymph nodes, bilateral traction bronchiectasis and miliary nodules were seen. E-Coli was isolated in bronchoalveolar lavage. TBNB and TBB were negative for probable thymoma metastasis.

For the probability of Good’s Syndrome, serum immunoglobulin levels were measured and found normal for lgA, low for lgG and high for lgM. Flow cytometry demonstrated 8% of CD19+, 12% of CD56+, 14% of CD57+, 30% of CD4+, 37% of CD8+ cells in total lymphocytes; consistent with B-cell immunodeficiency. With the diagnosis of Good’s Syndrome, intravenous immunoglobulin treatment was started. During her follow-up, she was hospitalized twice for respiratory tract infections. Now she is on ciprofloxacin profilaxis.

Good’s syndrome is a rare cause of combined B or T cell deficiency. Its main characteristic are hypogammaglobulinemia, reduced or absent B cells, reduced serum levels of IgG, IgA and IgM. Recurrent sino pulmonary infections caused by encapsulated microorganisms. Management of syndrome includes surgical resection of thymoma, treatment of infections and immunoglobulin replacement therapy. Good Syndrome is a rare but treatable condition and it should be considered in patients with the diagnosis of thymoma and frequent respiratory tract infections.
P3519
Expiratory muscle activity and nasal expiratory pressure during reverse sniff
Toshitaka Ichikawa1,2, Masanori Yokoba1,3, Naoshito Ishii1, Akira Takakura1,3, Atsuhiko Matsunaga1, Masahiko Kimura1, Tadasu Abe3, Noriyuki Masuda3,4, Paul Easton5, Masato Katagiri1,3,11,12, Graduate School of Medical Sciences, Kitasato University, Sagamihara, Kanagawa, Japan; 2Rehabilitation Medicine, Tokai University Oiso Hospital, Oiso, Kanagawa, Japan; 3School of Allied Health Sciences, Kitasato University, Sagamihara, Kanagawa, Japan; 4School of Medicine, Kitasato University, Sagamihara, Kanagawa, Japan; 5School of Clinical Medicine, University of Calgary, AB, Canada

The evaluation of expiratory muscle strength is of clinical importance in patients with neuromuscular respiratory disease. Maximal expiratory pressure (MEP) has achieved wide acceptance as a simple non-invasive measurement of expiratory muscle strength. However, MEP measurement is difficult for neuromuscular disease patients. In this study, we measured expiratory muscle activity during reverse sniff, a maneuver akin to “blowing your nose”, and we analyzed the relationship between expiratory muscle activity and reverse sniff nasal expiratory pressure (RSNEP).

In 5 healthy subjects, mean age 21.2 yrs, weight 69.2 kg, height 176.6 cm, we inserted fine wire electrodes into transversus abdominis muscle (TA) using high-resolution ultrasound. RSNEP was measured through a catheter that occluded one nostril, while the contralateral nostril remained open. Subjects performed short, sharp, maximum and variable intensity of reverse sniff, beginning from FRC, while standing. TA EMG activity was expressed as percent of maximum EMG (%EMGmax) throughout respiratory and non-respiratory maneuvers. Mean MEP was 80.8±36.0 cmH2O. Mean maximum RSNEP was 34.9±18.7 cmH2O, and mean TA EMG activity at maximum RSNEP was 73.9±23.6%EMGmax. TA EMG activity increased with stepwise increments in RSNEP. In every subject, the linear relationship between RSNEP and TA EMG activity was significant (r = 0.56, p<0.05).

We conclude that RSNEP corresponds to the activity of the expiratory muscle transversus abdominis, and that this simple maneuver may be useful for assessment of expiratory muscle strength.

This study was approved by Kitasato university human ethics committee. This work was supported by MEXT of Japan KAKENHI (2350061).

P3520
Inspiratory muscle training (IMT) as an adjunct to pulmonary rehabilitation (PR) in patients with severe COPD
Dragan Stojanovic, Oliver Goh1, Benjamin Krämer, Sebastian Fuchs, Vroni Huber, Michael Wittmann, Konrad Schultz. Fachbereich Pneumologie, Klinik Bad Reichenhall, Zentrum für Rehabilitation, Pneumologie und Fachbereich Pneumologie, Klinik Bad Reichenhall, Germany

Background: Up to now there is insufficient evidence for IMT as an adjunct to PR in patients with COPD.

Method: From November 2011 until January 2012 in our clinic 198 COPD patients underwent a 3-week inpatient PR, including 90 with COPD III-IV. Of these patients the control group (CG, n=38) received standard PR, consisting among other things of physical training, education, breathing therapy and psychosocial support. The intervention group (IG, n=52) underwent an additional IMT with at home training. Subjects performed short, sharp, maximum and variable intensity of reverse sniff, beginning from FRC, while standing. TA EMG activity was expressed as percent of maximum EMG (%EMGmax) throughout respiratory and non-respiratory maneuvers. Mean MEP was 80.8±36.0 cmH2O. Mean maximum RSNEP was 34.9±18.7 cmH2O, and mean TA EMG activity at maximum RSNEP was 73.9±23.6%EMGmax. TA EMG activity increased with stepwise increments in RSNEP. In every subject, the linear relationship between RSNEP and TA EMG activity was significant (r = 0.56, p<0.05).

We conclude that RSNEP corresponds to the activity of the expiratory muscle transversus abdominis, and that this simple maneuver may be useful for assessment of expiratory muscle strength.

This study was approved by Kitasato university human ethics committee. This work was supported by MEXT of Japan KAKENHI (2350061).

P3521
Predictive factors of survival in amyotrophic lateral sclerosis patients with respiratory dysfunction
Ints Neves1, Hans Dabo1, Inês Belchior 1, Anabela Marinho1, Tiago Pinto2, Miguel Gonçalves1,2, João Carlos Winck1,2. 1 Pneumology, Department, Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Portugal

Background: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder that causes severe respiratory dysfunction which is the major cause of death. Early management of respiratory symptoms may improve outcomes and survival.

Aim: Describe survival of patients with ALS and respiratory dysfunction and identify predictive factors of survival.

Methods: Retrospective analysis of patients with ALS evaluated in an outpatient setting. Ventilatory support data was screened. Kaplan-Meier survival analysis was performed and predictive factors were evaluated by Cox multivariate regression.

Results: 60 patients (25 females) with a median age of 64.5 years (range 34-80) were analyzed. At presentation, 33 patients (55%) had initial slow bulbar-onset and 27 (45%) rapid bulbar-onset. Non-invasive ventilation (NIV) was initiated in 52 patients (86.7%), with a mean vital capacity of 1699±678 L and 22±40.8 months after diagnosis. Mean duration of NIV was 19.6±23.7 months. Mechanical assisted cough was used in 23 patients (38.3%). Gastrostomy was performed in 21 patients (17 rapidly bulbar) and tracheostomy in 10 (9 rapidly bulbar) after a mean time of 13.6±17.0 months under NIV. The 5-year survival was 48%. The median overall survival and survival after respiratory muscle aids initiation was significantly higher in slowly bulbar patients compared with rapidly bulbar (p=0.03 and p<0.01, respectively). In multivariate analysis, predictive factors of survival were younger age, slow bulbar-onset, and early NIV initiation.

Conclusion: Survival may be prolonged in patients with ALS and respiratory dys- function with early NIV initiation. Age and bulbar onset have significant negative impact on survival.

P3522
Short-form Sun-style Tai Chi as an exercise training modality in people with COPD: A randomised controlled trial
Hana Dayi Wu1, Ming Leng1, Zoe McKenough2, Matthew Peters3, Jennifer Alison2, 1Department of Physiotherapy, Condon Repatriation General Hospital, Concord, NSW Australia; 2Discipline of Physiotherapy, Faculty of Health Sciences, University of Sydney, Lidcombe, NSW, Australia; 3Department of Thoracic Medicine, Concord Repatriation General Hospital, Concord, NSW, Australia

The aims of the study were, in people with COPD to: determine the effect of short-form Sun-style Tai Chi (sSCT) compared to usual medical care on exercise capacity, balance and quality of life (Part A) and investigate the exercise intensity of sSCT (Part B).

Method: Part A was a single blinded, randomised controlled trial with concealed, random allocation of participants to either the Tai Chi Group (TCG) or Control Group (CG) (usual medical care only) after confirmation of eligibility. Participants in the TCG training for one hour, twice weekly for 12 weeks at a moderate dyspnoea or exertion level (score = 3 in a 10 point scale). Part B was a repeated measures design where participants who had completed training in TCG performed incremental shuttle walk test and sSCT while wearing a portable metabolic system. Exercise intensity of sSCT was determined by the percent of oxygen consumption (VO2) reserve.

Results: Of 42 participants (mean (SD) age 73 (8) years, FEV1% 59 (16)% predicted), 38 completed Part A of the study (19 in each group) and 15 completed Part B. Compared to control, S SCT significantly increased incremental shuttle walk distance (mean difference, 95% CI 55 metres, 31 to 80) and endurance shuttle walk time (384 seconds, 186 to 510); reduced medial-lateral body sway in semi-tandem stand (-12.4 mm, -21 to -3); and increased total score on the chronic respiratory disease questionnaire (11 points, 4 to 18). The exercise intensity of S SCT in COPD was 53 (18)% of VO2 reserve.

Conclusion: Short-form Sun-style Tai Chi was an effective training modality in people with COPD and the exercise intensity was moderate which met the recommendation for training in COPD.
Twenty-three participants completed the survey, mean (SD) age 74 (8) years.

**Methods:** The Cochrane Airways Group Specialised Register of trials and the PEDro database were searched to identify randomised controlled trials comparing breathing retraining to no breathing retraining or another intervention in COPD.

**Primary outcomes** were dyspnoea, exercise capacity and quality of life; secondary outcomes were QoL.

**Results:** 16 studies involving 1104 participants with mean FEV1 30.5% predicted were included. Few studies reported allocation concealment, assessor blinding or intention to treat analysis. Two studies showed improvement in 6-minute walk distance after 3 months of yoga involving pranayama timed breathing techniques (mean difference 45m, 95% CI 29.6-61m), with similar improvements in single studies of pursed lip breathing (mean 50m) and diaphragmatic breathing (mean 35m).

Effects on dyspnoea and quality of life were inconsistent. Two studies reported that addition of ventilation feedback (VFB) to exercise training did not improve dyspnoea, exercise tolerance or quality of life more than exercise training alone. One study showed that VFB alone was less effective than exercise training for improving exercise capacity. No adverse effects were reported.

**Conclusion:** Breathing retraining in COPD is safe and improves exercise capacity when compared to no intervention; however there are no consistent effects on dyspnoea or quality of life. Breathing retraining may not have additional benefits beyond that offered by exercise training for people with COPD.

Tai Chi, like it or not? The COPD experience

Becky Wu, Max Leung1, Zoe McKeeough1, Matthew Peters1, Jennifer Allison1,2

1Phytherapy, Concord Repatriation General Hospital, Concord, NSW, Australia; 2Discipline of Physiotherapy, University of Sydney, NSW, Australia; 3Department of Thoracic Medicine, Concord Repatriation General Hospital, Concord, NSW, Australia.

**Aim:** To determine the experience of people with COPD to Tai Chi. Methods: Participants, who finished 12 week short-form Sun-style Tai Chi (SSTC) training program, completed a survey of eight questions. Each question was answered by putting a stroke on a 10 cm Visual Analogue Scale with anchors at either end, ranging from the negative of the question on the left to the positive of the question on the right. The number of supervised training sessions attended and the number of days unsupervised home training practised was reported.

**Results:** Twenty-three participants completed the survey, mean (SD) age 74 (8) years, mean FEV1% predicted 59 (17%). Participants attended 21 (2) supervised training sessions out of a possible 24 sessions and performed 4 (1) days per week of unsupervised home training. The Table below indicates the results of four survey questions.

<table>
<thead>
<tr>
<th>Tai Chi survey questions (score out of 10 cm)</th>
<th>Mean (SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>How enjoyable was your Tai Chi exercise program</td>
<td>8.9 (1)</td>
</tr>
<tr>
<td>How helpful was the Tai Chi program at improving</td>
<td></td>
</tr>
<tr>
<td>a) Physical fitness</td>
<td>7.9 (2)</td>
</tr>
<tr>
<td>b) Balance</td>
<td>7.9 (1)</td>
</tr>
<tr>
<td>c) Shortness of breath</td>
<td>7.0 (2)</td>
</tr>
<tr>
<td>How hard were the following parts of the Tai Chi program</td>
<td></td>
</tr>
<tr>
<td>a) Remembering the movements</td>
<td>5.3 (3)</td>
</tr>
<tr>
<td>b) Balancing during Tai Chi movements</td>
<td>6.5 (2)</td>
</tr>
<tr>
<td>c) Coordinating your breathing and the Tai Chi movements</td>
<td>7.0 (2)</td>
</tr>
<tr>
<td>Would you continue Tai Chi training as your regular exercise regimen</td>
<td>8.4 (2)</td>
</tr>
</tbody>
</table>

**Conclusion:** Participants reported that SSTC was a highly enjoyable exercise which they perceived improved their physical fitness, balance and shortness of breath. Compliance with supervised and unsupervised training was high. Importantly, participants indicated that they would continue Tai Chi as their regular exercise regimen.

Effects of Tai Chi Qigong exercise training on asthma control

Sunae Wu, Kiatnok, Potnajae Kornnongpong, Pompong Learsanartrakul

Division of Pumonary and Critical Care Medicine, Department of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

**Background:** Though exercise training increased exercise capacity in asthma, its effect on asthma control has not been well described. This study aims at exploring the impact of Tai Chi Qigong(TCQ) exercise training on asthma control.

**Methods:** This prospective, case-control study recruited adult asthmatics with pre-bronchodilator FEV1 of ≤75% predicted. In addition to the self-monitored peak-expiratory flow rate (PEFR) and Asthma Control Questionnaire (ACQ), patients in TCQ and control groups were assessed at 0, 4 and 10 weeks. These included 6-minute walking distance(6MWD), pre and post-6MWD spiroometrics and dyspnea indices(Borg), transitional dyspnea indices(TDI), Saint George Respiratory Questionnaires(SGRQ) and maximum inspiratory pressure(MPI). TCQ exercise trainings were provided to the TCQ group during week 4-10.

**Results:** There were 29 and 8 patients in TCQ and control groups respectively. After TCQ training, the TCQ group demonstrated significant improvements in PEFR and Asthma Control Questionnaire(ACQ), patients in TCQ and control groups were assessed at 0, 4 and 10 weeks. These included 6-minute walking distance(6MWD), pre and post-6MWD spiroometrics and dyspnea indices(Borg), transitional dyspnea indices(TDI), Saint George Respiratory Questionnaires(SGRQ) and maximum inspiratory pressure(MPI). TCQ exercise trainings were provided to the TCQ group during week 4-10.

**Conclusions:** TCQ exercise training improved asthma control. This finding and the associated improvements in exercise capacity, muscle strength and dyspnea signalled that TCQ training could be considered an effective, adjunctive asthma-therapy.
tended to reach greater improvements in ACT (especially in items 2, 3 and 4, i.e. shortness of breath, asthma symptoms at night, rescue inhaler) and NQ than the CG, but these trends weren’t significant between groups.

Conclusion: BT could be a promising adjunct to PR.

P3528
Speech and language therapy effectiveness in vocal cord dysfunction management
Nicola Parryter, Sarah Manney, Adol Mansur, Severa & Brittle Asthma Unit, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom

Introduction: Vocal cord dysfunction (VCD) “paradoxical vocal cord adduction” is misdiagnosed as asthma, resulting in over medication and increased hospital admissions. There is anecdotal evidence of the benefits of Speech Therapy (SLT) in management of VCD. This study explored the impact of SLT on symptom control and hospital admission prevention.

Method: One hundred consecutively referred patients (mf ratio=1:5, mean age 45yrs, range = 16-77) underwent detailed assessment at a tertiary VCD clinic with nasendoscopy confirmed VCD. No 81/100 (81%) had physician-diagnosed asthma, 45/81 (56%) required oral steroids. Patients received four sessions of SLT. Treatment effectiveness was assessed pre/post therapy, using in-house self-rated, VCD symptoms score (range 0-25). N=21/100 (21%) patients reported hospital admission with dyspnoea in the year prior to assessment. Data were analysed to determine number of hospital admissions one year pre/post SLT intervention.

Results: Differences pre/post therapy were assessed using Wilcoxon Signed Ranks Test. Significant reduction in patient reported symptoms was noted post SLT pre vs. post therapy; mean (SD) = 17.88 (3.10), 8.16 (4.13) respectively, p<0.0001. Reduction in hospital admissions was noted in the year post SLT intervention; pre vs. post therapy mean (SD) = 10.7 (8.8), range = 2.3-15, 1.2 (2.2), range = 0-6, p<0.0001. Conclusion: SLT significantly improves symptom control and reduces hospital admissions in VCD. The availability of effective therapy prompts the need to increase awareness of vocal cord dysfunction.

P3529
The long-term effect of ambulatory oxygen (AO) in normoxaemic COPD patients who participate in pulmonary rehabilitation (PR) and desaturate during exercise. A randomised study
Thomas Ringbaek, Geri Martinez, Peter Lange. Respiratory Medicine, Hvidovre Hospital, Copenhagen, Denmark

Introduction: The long-term benefits of AO in combination with PR in COPD patients experiencing exertional desaturation have not been studied.

Patients and methods: Normoxaemic COPD who participated in PR and desaturate >4% and below 90% during endurance shuttle walk test (ESWT) were randomised to control (n=23) or AO 2 L/min. from a portable oxygen concentrator (n=22) to be used during physical activity.

PR consisted of supervised training 20 wks + unsupervised daily training at home and then 13 wks without supervised training.

Results: Only 45 of 165 eligible patients wanted to participate. Mean FEV1=32% and MRC=4.5 (3.5).

Supplemental oxygen improved satO2 during ESWT by 2.3% (p<.001). In the study period of 33 wks, 10 and 6 patients withdraw from the AO group and control group, respectively. Patients spent in average 7.9 hours/week on oxygen.

Conclusion: AO greatly reduces hypoxaemia in COPD patients undergoing PR and can be used as a supplementary therapy during physical activity.

P3530
Preliminary results of noninvasive ventilation during a pulmonary rehabilitation program in patients with COPD
Koa M.H. Ida1,2, Lieve De Backer2,3, Denise Daems2, Erwin Boelen2, Glenn Leemans1,2,3, Dirk Vissers1,3, Wilfried De Backer2,3,1 Department of Health Sciences, Aarts University College Antwerp, Merksem, Antwerp. 2Respiratory Medicine, University Hospital Antwerp, Edegem, Antwerp. 3Faculty of Medicine and Health Sciences, University Antwerp, Wilrijk, Antwerp, Belgium

Introduction: Exercise training at higher intensities seems to result in a better training effect. However, in some patients with COPD this intensity is limited due to decreased ventilatory pump capacity. Noninvasive ventilation (NIV) relieves the work of breathing, so higher intensities are reached and could result in a better exercise tolerance.

Objective: Analysis of the effects of Bi-pap during an exercise training program in COPD on lung function and maximal exercise capacity.

Methods: 8 patients were randomized in a NIV (n=5) or control group (n=3). Patients trained with or without NIV for a period of 6 weeks. Lungfunction and exercise tests were started before and after 6 weeks. NIV was set on IE pressure of 4/1 and 2 leakage valves were added for patients comfort.

Results: Ventilation at maximal tolerated load (VE max) changed significantly in the experimental group and did not reach significance in the control group compare to baseline (p>0.043). In the same test setting there was no significant drop in heart rate.

Conclusions: Noninvasive ventilation during exercise training may change ventilation at maximal tolerated load and heart rate after 6 weeks. This allows patients to train at a higher level and achieve better training results because of a better ventilatory adaption during exercise.

P3531
Benefits of a new device for inspiratory muscle training in COPD
Voicu Tudorache1, Cristian Oancea1, Nicolina Bertici1, Ovidia Fita-Mladinescu1, Monica Marc1, Claudiu Avram2, Alexandru Somesan1, Pneumology, University of Medicine and Pharmacy, Timisoara, Timis, Romania; 2Physical Education and Sport Faculty, West University, Timisoara, Timis, Romania

In chronic obstructive pulmonary disease (COPD), inspiratory muscle weakness may occur as a result of the combined effects of increased work of breathing, malnutrition, hypercapnia/hypoxemia and others. The benefit of inspiratory muscle training (IMT) depends on patients phenotype but also on the type exercise methods.

The aim of the study was the evaluation of medium (3 months) and short-term (at the end of a pulmonary rehabilitation program, PRP) effects of IMT using the TrainAir® electronic system.

47 patients with COPD (GOLD stage III, IV) without previously PRP were divided in 2 groups. Both groups followed one month a comprehensive PRP, but the group of patients that initially presented lower values of the respiratory maximum pressures IMT was added. Patients’ assessment consisted of: spirometry, maximum inspiratory and expiratory pressures (MIP, MEP), 6-minute walk test (6MWT), body composition, MRC scale, and COPD Assessment Test (CAT).

Our results demonstrated in both groups the increase of exercise capacity on short and medium term (p<0.025) measured by the distance expressed in meters walked to 6MWT as compared to the initial value (500±173 and 488±146 vs. 457±51 for the IMT group, 492±99, and 479±87 vs. 452±105 for the control group). IMT significantly reduced the difference between groups for MIP (kPa) (from 2.9±1.0 to 2.3±0.75, p=0.002), and the effect had been maintained over the medium term (p=0.016). Also, CAT score reduces more significantly on medium term in the presence of IMT (from 21.27±4.13 to 16.91±2.21 vs. from 22.5±2.19 to 19.50±1.85 in control group, p<0.001).

In conclusion, in COPD patients, in addition to the improvement of MIP, IMT was beneficial for patients’ symptomatology.

P3532
The impact of PEEP, CPAP and BiPAP in post-exercise recovery from dyspnea in COPD patients
Anush Mahadevan, Laurent Brouqueyre, Chuck Cain, Alan Cropp. Home Respiratory Care, Philips Respironics, Monroeville, PA, United States Pulmonary Rehabilitation, Pulmonary Rehabilitation Associates, Boardman, OH, United States

Dyspnea is the chief complaint of COPD patients limiting their ability to perform activities of daily living reducing quality of life. To relieve dyspnea, patients may try short acting bronchodilators, pursed lip breathing or physically stop activity.In this study we evaluated different types of positive airway pressure (PAP) therapies to help COPD patients recover from dyspnea following activity.

639s
The aim of this study was to determine if PAP therapies would reduce the patient’s recovery time from a Borg of 7 to their baseline Borg following a standardized exercise regimen. 10 COPD patients classified as Gold Stage 2, 3 or 4 with an FEV1 less than 55% were evaluated. These patients were subjected to a baseline test where they recovered without any device to the baseline Borg. During 2 successive visits, during the recovery phase, patients were asked to try 6 different types of PAP therapy. This included 2 levels of PEEP, CPAP or BiPAP therapy. Borg scores were measured every minute during exercise & every 30 seconds during recovery phase. Time to recover was measured with other physiological parameters. Results indicate that all forms of PAP therapy tested aided the patients to recover faster. Among the 3 tested therapies, BiPAP provided the shortest recovery time improving the time to recover to baseline by 40±9%. CPAP was 2nd best at 27±16.6%. PEEP provided 26±1.3% improvement. These findings indicate that PAP therapy helps COPD patients recover from shortness of breath following activity. The impact of these therapies on other physiological endpoints (Heart Rate, Respiratory Rate & SpO2) are being analyzed. These are being further tested to confirm the findings.

P3533 Efficacy of Nordic walking in rehabilitation of patients with COPD: 
Preliminary data
Maria Altini1, Giuseppina Fumurato1, Silvano Dragonieri1,2, 
Mauro D’Alessandro1, Vincenzo Digilio1, Mauro Carone3. 
1Pulmonology, Fondazione S. Maugeri, Cassano Muro, Italy; 2Pulmonology, University of Bar, Italy 
Background: Nordic walking is a well-known activity which combines sport and physical training and is widespread in Scandinavia as summer training for Nordic ski athletes and it is extremely simple to perform. However, there are very few studies which evaluated the use of Nordic walking in the field of physical rehabilitation. The aim of the study is to assess the efficacy of Nordic walking in patients with COPD. 
Methods: We enrolled 11 patients with COPD (mean age 64.2±1.3) in a stable phase of their disease and randomized them into two groups. The study group was composed by 5 patients who performed a daily 30 minutes session of Nordic walking for 5 days a week for a total period of 3 weeks. The control group was composed by 6 patients who were treated with traditional rehabilitation (selective training of arms and legs) for the same period as study group. Both the groups performed educational intervention and exercises for respiratory coordination. The two groups of patients performed spirometry, blood gas analysis, 6 minutes walking test, MRC, BDI/TDI, EuroQol, and Saint George test before and after the rehabilitation period. 
Results: Patients in the study group had a significant improvement in terms of post training 6 minutes walking test, MRC, EuroQol, and Saint George (p < 0.05) whereas patients in the control group had only an improvement in MRC (p < 0.05).
Conclusions: This preliminary study shows the efficacy of nordic walking in reducing dyspnea, improving physical performance and quality of life in a small group of patients with COPD. If confirmed in larger studies nordic walking could become part of the training schedules for COPD rehabilitation.

P3534 Effectiveness of pulmonary rehabilitation including occupational therapy (OT) on the prognosis of patients with COPD 
Ryoji Koyama, Keisuke Miki, Seigo Kitada, Kenji Yoshimura, 
Yoyukata Tateshi, Mari Mikis, Masahide Mori. Respiratory Medicine, NHO Toneyama National Hospital, Toyonaka-city, Osaka, Japan 

Aim: We reported that the appropriate pulmonary rehabilitation including OT according the pathophysiology of patient with COPD improved his or her prognosis in the historical control study. In this prospective observational study, we investigated the effectiveness of our pulmonary rehabilitation program on the survival prognosis of COPD patients with long-term oxygen therapy (LTOT).

Method: The subjects were 72 patients with COPD (male: female, 65:7, 69±6.8 years old, FEV1 0.7±0.20 L, 96 predicted 36±14.0%, FVC/FVC 38±10, who underwent LTOT between 1995 and 2005. All patients were on medication and underwent CPET before pulmonary rehabilitation program. We decided the safe range using the data of CPET, and it was represented by each patient's SpO2 and underwent PLB using a portable sleep recorder (PSR: SAS2100 by NIHON KOHDEN).

Results: Forty-six patients died during the follow-up period. Causes of death were the respiratory failure in 20 cases (43.5%), malignant diseases in 10 cases (21.7%) and other diseases in 16 cases (34.8%). The overall 50% survival time was 9.0 years. The 50% survival time in patients with less than 30% of FEV1 predicted, 11ml/kg/min of peak oxygen uptake were 8.7 years and 8.1 years after PLT, respectively.

Conclusion: The appropriate pulmonary rehabilitation including OT according to the pathophysiology of each individual patient with COPD decreased the number of death caused by respiratory failure and greatly improved the prognosis of patients with very severe COPD as compared to the previous studies.

P3535 Respiratory muscles trainings as physical rehabilitation in patients with chronic obstructive pulmonary disease and myoccardial infarction 
Grigory Aruryunov, Anna Rylova, Elena Kolesnikova, Natalia Rylova. Therapy, The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation 

Background: Patients with MI and concomitant COPD often can’t take part in physical trainings as a part of cardiac rehabilitation.

Purpose: To study the effect of respiratory muscles trainings (RMT) in patients with acute MI and COPD.

Methods: 87 patients were randomized to either an exercise training group (EG) or to a control group (CG). Patients were on their 5-7 day of MI. The EG participated in a RMT with gradual increase of inspire and expire resistance. RMT were held with the use of Threshold IMT and PEP devices. RMT were started at the hospital on the 5-7th day after MI and were continued for 1 year at home by patients themselves.

Results: In 1 year the distance of 6 minute walk test increased significantly in EG (285±8.7 m vs 275±3.4±9.28, p < 0.01). VO2peak also increased significantly in EG (68.4±1.55 vs 46.6±1.16 ml/kg/min, p < 0.01). RMT helped to stabilize mean pulmonary pressure (MPP) (35.4±4,7 mm Hg in TG vs 40.7±6.9 mm Hg in CG, p < 0.05). There was a statistically significant increase in the maximal inspiratory mouth pressure in most of patients (0.6 kPa ± 0.8 vs 4 kPa ± 1.1, p = 0.01). Health related quality of life (HRQL) increased in both groups, but in EG patients it grew significantly higher according to SQRQ and SF-36. In a year there were no lethal outcome in both groups. EG patients had significantly less hospitalizations because of HF progression (7.8% in EG vs 14.6% in CG) and pneumonias (2.1% vs 15.3%).

Conclusion: RMT in patients with MI and COPD can be started at their acute period. It improves physical capacity, stabilized MPP, increase HRQL and decrease number of hospitalizations during first year after MI.

P3536 Comparison of the effects of the diaphragmatic breathing exercise in rehabilitation to COPD subjects with normal and high body mass index 
Zoran Stojanovska1, Jorda Blanka1. 1Dpt. for Primary Health Care, MORE, Skopje, Macedonia, The Former Yugoslav Republic of; 2Dpt for Functional Diagnosis, Institute for Occupational Health, Skopje, Macedonia, The Former Yugoslav Republic of 

Background: COPD rehabilitation is a coordinated program of exercise, disease management training, and counselling that can help COPD patients to stay more comfortable and improve to carry out patient’s day-to-day activities. COPD is an heterogeneous disease with a mixture of clinical and functional phenotypes, hence individualization of action strategies, such as pulmonary rehabilitation is very important.

Aim: To compare the effects of diaphragmatic breathing exercise technique in improving quality of life in COPDs with normal and increased BMI.
week for 8 to 56 days. We evaluated the breathing pattern by PSR, respiratory rate (RR), 6-minute distance (6MD), and oxygen saturation (SpO2) before and after these programs.

Case A: Vital Capacity (VC) 0.94L (%VC 44.8%), Forced Expiratory Volume in one second (FEV1) 0.52L (%FEV1 37.4%).
Case B: VC 2.34L (%VC 80.1%), FEV1 0.65L (%FEV1 37.4%).
Case C: VC 1.73L (%VC 61.0%), FEV1 0.57L (%FEV1 34.3%).
Case D: VC 2.17L (%VC 75.9%), FEV1 0.58L (%FEV1 35.6%).
Case E: VC 1.37L (%VC 61.6%), FEV1 0.96L (%FEV1 73.2%).

Results: The average height of waveforms of the breathing pattern increased about 3 times. 6MD in 2 cases and SpO2 in 3 cases increased in this study; however, the 3 other cases of 6MD and 2 other cases of SpO2 remained unchanged. Additionally, RR decreased in 4 cases. Since the start of the program, changes in the breathing pattern from mouth to nose breathing were observed.

Conclusions: This study revealed that BAT and PLB resulted in a decrease of RR and a change in the breathing pattern; furthermore, after this program, changes from mouth to nose breathing were observed.

P3538
Consumed by breathlessness – A critical interpretative synthesis
Samantha Harrison1,2, Lindsay App1, Mick Steiner1, Sally Singh3,4
Norelle Robertson5,6,7, NHR CLAHRC-LNR, Pulmonary Rehabilitation Research Group, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; 5School of Psychology, University of Leicester, United Kingdom; 6Health and Life Sciences, Coventry University, Coventry, United Kingdom

Background: COPD is characterised by acute exacerbations (AE) often prompting hospital admission. The application of The Common Sense Model suggests that scrutinising the reported experiences of AE and constructing understanding of appraisals of AE may suggest ways to target interventions.

Methods: A systematic review was conducted. The terms: exacerbate* OR hospital* AND Chronic obstructive* OR emphysema OR bronchitis AND interview* were used to search electronic databases. Inclusion criteria included: primary research published in English of the patient’s experience of an AE, COPD, using qualitative methodologies. 8 full text papers were included.

Data were extracted by 3 researchers and constructs elicited by 3researchers via Reciprocal Translational Analysis.

Conclusions: Patients are fearful of their symptoms, this prompts constant vigilance and increased passivity. Targeted interventions that acknowledge intense fear and shape appraisals and acceptance may reduce distress and improve focus of self-management messages.

P3539
Effect on prevention of readmissions of a home-based education and exercise program implemented early after a severe exacerbation of COPD
Roque Coll-Fernández1, Natalia Martínez2, Maribel Aranzá3, Héctor Prados1
Xavier Pomares1, Amalia Moreno1, Montserrat Teixidó2, Francisco Epelde1, Fernando Cabaleiro1, Edurad Monso2, Physical Medicine and Rehabilitation, Corporación Sanitária Parc Taulí, Sabadell, Spain; 2Rehabilitation, Corporación Sanitária Parc Taulí, Sabadell, Spain; 3Primary Care, Institut Català de la Salut, Barcelona, Spain; 4Emergency, Corporación Sanitária Parc Taulí, Sabadell, Spain

Introduction: Exacerbations and hospitalizations in patients with chronic obstructive pulmonary disease COPD) represent a major health burden and the impact of early education and rehabilitation programs on readmission after an exacerbation are open to debate.

Objectives: To assess the effect of a two-month, home program (HP) based on education and exercise, implemented just after a severe exacerbation of COPD, on future hospital admissions and number of outpatients visits.

Methods: Following a case-control design, COPD patients who had just undergone treatment of an acute exacerbation were enrolled on to a multidisciplinary intervention HP that included education sessions and exercise training from the second day after discharge (1 group), for a period of 8 weeks, and were compared with a non-intervention group which received usual care (UC group). Primary outcome was the rate of severe exacerbations and secondary outcome outpatients visits during a 6-month follow-up period.

Results: 10 patients underwent the program and 12 patients were included in the control group (1 group mean [SD] age 72[7] years, 45[17%] predicted, m) 7 patients were readmitted to hospital with an exacerbation in the UC group (58%) and 1 in the 1 group (10%) (p<0.05). The difference in the number of outpatients visits in both groups was not statistically significant (1 group [IQR 0.2]; UC group [IQR 0.1]).

Conclusions: A post-exacerbation multidisciplinary HP in COPD may reduce re-exacerbation events that require admission over a 6-month period, without a significant increase in the number of outpatients visits.

P3540
Effectiveness of an additional tobacco-dehabitation-coaching (TDC) through nursing staff during inpatient pulmonary rehabilitation (PR)
Birgit Schwaighofer, Angela Burgschwaiger, Renata Stochelska, Zuzana Jurdikova, Konrad Schultz, Fachbereich Pneumologie. Klinik Bad Reichenhall, Germany

Background: Tobacco dehabitation (TD) is an essential component of PR. The nursing staff could be able to make an important contribution to TD. We studied the effectiveness of additional coaching from the nursing staff to an already existing comprehensive TD programme (TDP).

Methods: From February until July 2011 717 patients were admitted (3-week inpatient PRs) of which 26% were smokers. The classification of “smoker” was made in data consolidation served by patients, the physician’s estimation and biomonitoring (COHb). Intervention group (TDC + coaching through nursing staff = TDC): All smokers within the observed ward were invited to short supportive conversations by the nursing staff (in the first week twice a day, in the following weeks twice a week). In the observed time span 336 patients (95 of which smokers) were assigned to the ward with the associated pilot study. 63 smokers participated in the offered TDC voluntarily (78% male, 53.9 ± 8.1 y). 61 patients regularly used NRT. The control group consisted of 381 consecutive patients from a different ward, observed within the same time span, of which 90 were smokers (59% male, 52.9 ± 9 y). These patients took part in the same TDP, but without TDC.

Results:

Discussion: Those smokers who took part in the TDC refrained from smoking significantly more often than those who did not obtain this support.

P3541
Retrospective survival of COPD patients according to disease stage and pulmonary rehabilitation program
Audhild Hjalmarsen1, Torodd Brenn1, Marijke Jongma Risberg1, Kathrine Meisler Antonsson1, Elisabeth Kristiansen Benum1, Institute of Clinical Medicine, Department of Pulmonary Medicine, University of Tromso, Norway; 2Institute of Community Medicine, University of Tromso, Norway; 3Department of Physiotherapy, University Hospital of North Norway, Tromso, Norway; 4Pediatric Department, Central Hospital of Nordland, Bodø, Norway; 5Department of Medicine, General Hospital of Helgeland, Sandnessjøen, Norway

The aim of this study was to examine the retrospective survival of patients with chronic obstructive pulmonary disease (COPD) according to type of pulmonary rehabilitation (PR) program and Global Initiative for Obstructive Lung Disease (GOLD) stage.

Retrospectively, 193 patients (mf 92/101, mean age 69.2 ± 8.6 SD) receiving PR were studied with lifetable analyses. FEV1 % pred was significantly different in the in-patient (n = 72), out-patient (n = 72), and maintenance group (n = 49) [mean 54.5 ± 21.8 SD, 52.2 ± 17.7, and 42.9 ± 15.0, respectively (p < 0.001)]. The evaluated impact of variables on survival in the three groups was significant for age, FEV1, and the use of long-term oxygen therapy (LTOT) (p < 0.001, HR 1.06, p < 0.01, HR 0.98, and p < 0.005, HR 2.18, respectively). Mean survival was eight years in GOLD stage 4 (n = 22), six in stage 3 (n = 79), and >10 in stage 1 (n = 18) and 2 (n = 74). The impact of the evaluated variables on survival in the GOLD stages was significant for age, LTOT and stage 3 (p < 0.005, HR 1.05, p < 0.01, HR 2.33, and p < 0.02, HR 4.24, respectively). For the in-patient, out-patient and maintenance group days of PR were mean 30.3 ± 20.4 SD, 18.9 ± 10.4 and 30.6 ± 20.3, respectively (p < 0.001), stays in hospital 0.35 ± 0.85, 0.86 ± 1.46, and 1.17 ± 1.60, respectively (p < 0.003), and days in hospital 2.90 ± 8.89, 4.78 ± 8.26, and 9.04 ± 15.69, respectively (p < 0.010).

In conclusion, patients with GOLD stage 4 lived significantly longer than stage 3. Older age, decreased pulmonary function and LTOT predicted poorer survival in all PR groups. In addition to older age and LTOT, stage 3 predicted significantly poorer survival.
P3542 Pulmonary rehabilitation affects lung hyperinflation and cardiovascular response in exercise in COPD
Davide Elia1, Patagota Tzuni2, Sara Rampini1, Marina Aiello1, Francesco Andriani1, Maria Rosaria Gioi1, Emilio Marangoli1, Enrico Maria Clini1, Alfredo Gheta1, Carlo Neuro-Pulmonary Dpt, Respiratory Diseases, University Hospital, Parma, Italy; 2Department of Oncology, Haematology, Respiratory Diseases, University of Modena-Reggio Emilia, Ospedale Villa Pineta (Pavullo, MO), Modena, Italy

Background: Pulmonary rehabilitation (PR) including exercise training has been reported useful for idiopathic pulmonary fibrosis (IPF) patients. The aim of this study was to compare the characteristics of five exercise measurements in evaluating the efficacy of PR in IPF patients.

Methods: Twenty-three COPD patients (9F; age 70 yrs ± 8; BMI 28 kg/m² ± 5) with moderate to severe airflow obstruction (FEV₁/FVC range: 65-36%) admitted to a 6-week PR course performed a pre-to-post evaluation of lung function test and symptom-limited cardiopulmonary exercise test (CPET). Inspiratory capacity (IC) manoeuvres, VO₂ dyspnoea (D) and leg fatigue (F) were assessed during the CPET. Cardiac response was also assessed by means of oxygen pulse (VO₂/H), product of systolic blood pressure and heart rate normalized for the maximum workload (DP/W), and heart rate recovery at the 1st min (HRR).

Results: Workload (W) and Maximum oxygen uptake (VO₂max) increased from 61.2 W ± 23.7 to 74.5 W ± 33.4, p= 0.002, and from 23.7 to 74.5 W ± 33.4, p= 0.002, respectively) following PR. The IC for a given W significantly changed from 0.03 L/W ± 0.01 to 0.02 L/W ± 0.01 (p=0.01). VO₂/H increased from 4.1 L/min/bpm ± 2.7 to 9.8 L/min/bpm ± 2.7 (p=0.006). DPW decreased from 352.2 ± 103.3 to 288.7 ± 113.2 (p=0.002), and HRR changed from 8.6 bpm ± 6.7 to 13.3 bpm ± 8.8 (p=0.007) at peak of exercise. Moreover, D (from 1.3 ± 0.5 to 1.3 ± 0.6, p=0.005) and F (from 1.3 ± 0.6 to 0.98 ± 0.56, p=0.005) reduced at peak/W.

Conclusions: Our study shows that training effect during rehabilitation course in COPD is associated with significant reduction of lung hyperinflation and improved cardiovascular response to exercise.

P3543 Endurance time is the most sensitive exercise measurement for evaluating pulmonary rehabilitation efficacy in patients with idiopathic pulmonary fibrosis
Shinichi Arizono1,2, Hironori Taniguchi1, Yasuhiko Kondo1, Tomoki Kimura2

Kensuke Kataoka3, Tomoya Ogawa1, Fumiko Watanabe1, Jun Hirasa1, Kazuyuki Tabira3, Jun Hirose1, Fumiko Watanabe1, Jun Hirasa1, Kazuyuki Tabira3

Objective: Pulmonary rehabilitation (PR) has been reported effective for improving exercise capacity and HRQoL in patients with idiopathic pulmonary fibrosis (IPF). It is unknown which exercise measurements are more suitable for evaluating PR efficacy in IPF patients. The purpose of the present study was to compare the characteristics of five exercise measurements in evaluating the efficacy of PR in IPF patients.

Methods: We performed a case-control study in which 53 IPF patients were divided into the PR group and the control group (C group). The PR group underwent a 6-week PR course performed a pre-to-post evaluation of lung function test and symptom-limited cardiopulmonary exercise test (CPET). Inspiratory capacity (IC) manoeuvres, VO₂ dyspnoea (D) and leg fatigue (F) were assessed during the CPET. Cardiac response was also assessed by means of oxygen pulse (VO₂/H), product of systolic blood pressure and heart rate normalized for the maximum workload (DP/W), and heart rate recovery at the 1st min (HRR).

Results: Workload (W) and Maximum oxygen uptake (VO₂max) increased from 61.2 W ± 23.7 to 74.5 W ± 33.4, p= 0.002, and from 23.7 to 74.5 W ± 33.4, p= 0.002, respectively) following PR. The IC for a given W significantly changed from 0.03 L/W ± 0.01 to 0.02 L/W ± 0.01 (p=0.01). VO₂/H increased from 4.1 L/min/bpm ± 2.7 to 9.8 L/min/bpm ± 2.7 (p=0.006). DPW decreased from 352.2 ± 103.3 to 288.7 ± 113.2 (p=0.002), and HRR changed from 8.6 bpm ± 6.7 to 13.3 bpm ± 8.8 (p=0.007) at peak of exercise. Moreover, D (from 1.3 ± 0.5 to 1.3 ± 0.6, p=0.005) and F (from 1.3 ± 0.6 to 0.98 ± 0.56, p=0.005) reduced at peak/W.

Conclusions: Our study shows that training effect during rehabilitation course in COPD is associated with significant reduction of lung hyperinflation and improved cardiovascular response to exercise.

P3546 Early versus late pulmonary rehabilitation on anxiety and depression in chronic obstructive pulmonary disease patients with acute exacerbations
Liv Karin Vesteng1, Anne Edvardsen, Karianne Spetaas Henriksen, Siri Skumlien.

Objective: To study the effect of a cost and home based PR program & to compare the improvement in outcome in non PR group.

Results: The mean 6MWD showed an average increase of 75.72 meters in the study group, while an average decrease of 2.1 meters in control group. Mean value of study group was higher for 6-MWD results and difference between the two groups was statistically significant (p<0.05). AQ-20 showed a mean decrease of 6.12 in study group and 1.5 in control group which is also statistically significant (p<0.05).

Conclusion: A simple outpatient-based PR can improve health status, quality of life and exercise capacity in patients with COPD.

Clinical implications: This can be promoted on a wide scale & can benefit a lot of COPD patients in resource poor setting.

P3547 Role of low cost pulmonary rehabilitation programme in COPD in rural area of India
Shiv Sagar Gupta, Kartik Sood. Pulmonary Medicine, Era’s Lucknow Medical College, Lucknow, UP, India

Background: Chronic obstructive pulmonary disease (COPD) is the 4th leading cause of death in the world (WHO 2000). COPD patients appear to benefit from Pulmonary Rehabilitation (PR) & maintenance of physical activity, improving their health status, decreased dyspnoea & fatigue (Berry MI et al, AJRCCM 1999; 160:1248-53). PR is done with exercise equipment, supporting staff & follow up. In resource poor areas this is not possible. We evaluated the effect of home based PR programme in COPD patients in rural areas of India.

Methods: COPD patients in stable state who were ready to follow up for 12 weeks at 2 weeks interval were included, 40 patients who completed the PR formed the study group while 20 patients who were not included in PR formed control group. The Airways questionnaire-20 score (AQ-20) and the 6 minutes walk distance (6-MWD) were analysed in both groups, who continued on a similar drug management.

Objective: To study the effect of a low cost and home based PR program & to compare the improvement in outcome in non PR group.

Results: The mean 6MWD showed an average increase of 75.72 meters in the study group, while an average decrease of 2.1 meters in control group. Mean value of study group was higher for 6-MWD results and difference between the two groups was statistically significant (p<0.05). AQ-20 showed a mean decrease of 6.12 in study group and 1.5 in control group which is also statistically significant (p<0.05).

Conclusion: A simple outpatient-based PR can improve health status, quality of life and exercise capacity in patients with COPD.

Clinical implications: This can be promoted on a wide scale & can benefit a lot of COPD patients in resource poor setting.
P3547 Pulmonary rehabilitation in patients referred for lung transplantation
Dariusz Jastrzebski, Matej Ochman1, Jacek Worski2, Slawomir Zeglen2, Jerzy Korolec1, Dyrk Langsides and Tuberculosis, Medical Academy of Silesia, Zabrze, Silesia, Poland; 1Dyrt of Transplantology, Silesian Centre for Heart Diseases, Zabrze, Silesia, Poland

The purpose of this study is to prospectively examine efficiency of Nordic Walking, a low cost, accessible and proven beneficial form of physical exercise as form of pulmonary rehabilitation in patients referred for lung transplantation.

Material and methods: 22 patients, referred for LT in Dyrt of Lung Diseases and Tuberculosis were invited to take part in the study. The PR program, which conducted for 18 weeks, was based on Nordic Walking exercise training. Lung function tests (FVC, FEV1), mobility (6 minute walking test (6 MWT)), rating of dyspnea (Borgs scale, MRC and Baseline Dyspnea Index) and quality of life (SF-36 and SGRQ) were performed before and after the complete exercise program.

Results: No adverse events were observed after completed the PR program in patients referred for LT. After 18 weeks of PR with Nordic Walking programme we observed significant (p<0.05) increase of mean results of 6 MWT (310.2 vs. 372.1). Also results of lung function test showed improvement (FVC, FEV1) but without statistical significances. No statistical significant differences were observed in perception of dyspnea (MRC, OGD, Borgs scale) before and after completed the study. SGRQ showed significant (>4 pts) improvement in activity score. General health quality of life questionnaire (SF-36) showed improvement in domains: Physical Functioning, Role-Physical, Bodily pain, General Health and Social Functioning but only in Role-Physical domain the improvement was statistically significant (p<0.05).

Conclusion: Pulmonary rehabilitation with Nordic Walking programme is safe, cost-effective and easy to use in end stage lung disease patients referred for LT resulting improvement in mobility and quality of life.

P3548 Home-based pulmonary rehabilitation program following a severe exacerbation of COPD
Roger Goyache1, 2, Josune Ormaza1,2, Montserrat Bae1, Francisco Epe1a, Natalia Martinez1,2, Silvia Pozo1,2, Carmen Caballero1, Eduard Mon1,2, 1Physical Medicine and Rehabilitation, Corporació Sanitària Parc Taulí, Sabadell, Spain; 2Primary Care, Institut Cataluà de la Salut, Barcelona, Spain; 4Emergency, Corporació Sanitària Parc Taulí, Sabadell, Spain

Introduction: Pulmonary rehabilitation (PR) is an effective intervention for patients with chronic obstructive pulmonary disease (COPD) and is recommended by clinical guidelines. Timing of referral for rehabilitation, immediately after exacerbations of COPD, to later on while the patient is in a stable state, however, is open to debate.

Objectives: To evaluate the effects of a two-month, home-based PR program on dyspnea, exercise capacity, muscle strength and activities of daily living in COPD patients after a severe exacerbation.

Methods: COPD patients who had just undergone inhospital treatment for a severe exacerbation were enrolled on to a multidisciplinary home PR program within 48-72 hours of discharge. The program consisted of twice-weekly sessions for a period of 8 weeks. Lung function, oxygen saturation, exercise capacity (six-minute walk distance test), quadriceps strength, sedentary index and London Scale Scoring were recorded at hospital discharge and after 2 months. Body weight and muscle mass measurements were compared to determine the change in the measured variables after the program (paired t test).

Results: 10 patients underwent the program (mean [SD] age 71.90 [7.1] years, baseline FEV1 42.71[11] % predicted). Significant improvements were attained after the program in exercise capacity (pre 280m and postprogram 354m p<0.05), oxygen saturation (pre 91.4%, and postprogram 94.4% p<0.001) and London Scale Scoring (pre 22.1 and postprogram 14.9 p<0.001). No statistically significant improvements in lung function, BODE index and quadriceps strength were observed.

Conclusions: Post-exacerbation PR improve exercise capacity tolerance in COPD patients with a significant impact on activities of daily living.

P3549 Dry sodium chloride aerosol in rehabilitation of patients with COPD
Danilo C. Berton1,2, Irena Pomikowska3, Robert Szalkowski3, Jacek Chojnowski Chojnowski2,1, Clinical Research Rehabilitation Pulmonary Center, Hospital 122 of Federal Medical Biological Agency, St. Petersburg, Russian Federation; 2Climic of Pulmohogy and Physical Medicine, Medical University in Bydgoszcz, Cecochineck, Poland

Aim of the study: The main objective was to estimate the efficacy of inhaled dry sodium chloride aerosol (DSCA) in rehabilitation therapy (RT) of patients with COPD.

Objects and methods: It was double blind placebo study. 72 patients (pts) with moderate and mild stage of COPD were recruited. They were randomized in 2 groups - interventional group (IG) (21 m, 18 f, 60.3±10.8 yrs) and control group (CG) (22 m, 11 f, 58.5±8.9 yrs). All patients received RT. daily procedures of chest massage, light radiation, physical exercises. Pts of IG were treated with the DSCA (45 min twice a day for 14 days). DSCA containing particles with size of 1-5 μm and level of mass concentration in the room of 10-15 mg/m3 was produced by ultrasonic generator GBA-01.17 (Haimone, Lithuania). CG received placebo inhalations (inhalations with room air) instead of DSCA. Clinical, functional parameters and measures of health-related quality of life (HRQL) by SF-16 and LCQ (10 items) were estimated before and after the complete RT procedures and in 3 months.

Results: Improvements of clinical symptom scores were observed in the both groups after the course of RT (p<0.05), but in 3 months positive effect was noticed only in IG (before-13.5±4.4; after-9.1±4.3; in 3 months-9.6±4.3; p<0.05). Measures of LCQ were changed significantly after RT only in pts of IG, received DSCA (3.5±2.5 and 5.2±4.6; p<0.05). Positive changes of physical functioning measures (SF-16) were observed in IG and CG groups after RT, but they have been kept till 3 month only in IG.

Conclusions: Application of inhalations of DSCA on the background of the RT in pts with COPD renders to positive effect.

P3550 Pulmonary rehabilitation and the association of anaemia with clinical and functional parameters in patients with COPD who referred to a pulmonary rehabilitation programme
Dicle Kayaşar, Pınar Egrnin, Fazıl Utkan, Salih Battal, İpek Candemir, Nilgün Mendi, Filiz Tasdemir, Fatma Sengül, Nurcan Iğesel, Pervin Demir. Atatürk Chest Disease and Chest Surgery Training Hospital, Pulmonary Rehabilitation and Home Care Center, Ankara, Turkey

Polycytemia is commonly associated with COPD but recent reports suggest that anaemia is also prevalent. Aim: The aim of this study was to determine the prevalence of anaemia in patients with COPD who referred to PR programme and to explore the clinical and functional associations between anaemia.

Materials and methods: 398 COPD patients who referred to Atatürk Chest Disease and Chest Surgery Training Hospital PR Center between January 2008 and December 2011 were evaluated retrospectively and 176 patients were included. Patients were classified as anaemic,polycthyemic or normal. Dose was assessed with the MRC and EQ-5D dyspnea, quality of life assessed with SGRQ. Exercise capacity was measured using the ISWT, ESWT, body composition was assessed with BMI, FM% and depency were assessed with the HADS. Results: Anaemia was present in 14 (3.5%) patients and polycythaemia in 24 (6.1%) patients with COPD. Exercise tolerance and health-related quality of life (HRQL) by SF-16 and LCQ (10 items) were calculated. No statistically significant differences were observed in any the domains: Physical Functioning, Role-Physical, Bodily pain, General Health and Social Functioning but only in Role-Physical domain the improvement was statistically significant (p<0.05).

Conclusion: Anaemia is associated with poor clinical and functional outcomes in patients with COPD who referred to PR programme and provide support for the evaluation and monitoring of anaemia in these patients.

P3551 Outcomes of pulmonary rehabilitation according maintenance treatment in real life COPD patients
Daniele C. Berton1,2, Cassia C. da Costa1,3, Ana Luiza Zulikowski1,2, Maria Lucia Machado1,2, Danilo C. Berton1,2, Paolo L.Z. Teixeira2,3, 1Medicine, Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil; 2Health Science Institute, Fervole University, Novo Hamburgo, Brazil; 3Medicine, Health Science Federal University of Porto Alegre, Brazil

Pulmonary rehabilitation (PR) improves health status as well as exercise tolerance in symptomatic patients with chronic obstructive pulmonary disease (COPD).

Maintenance bronchodilator (BD) therapy is recommended to improve symptoms and could enhance ability to train and augment benefits of PR.

We aimed to evaluate if the modality of inhaled medication therapy could improve exercise tolerance and health-related quality of life (HRQL) in real life patients with COPD who were referred to PR.

We compared HRQL (Saint George Respiratory Questionnaire; SGRQ) and six minute walk distance (6MWD) after PR according to maintenance treatment: no long-acting bronchodilators (N); long-acting β2-agonist or anticholinergic BD (LABD); combined treatment with long-acting β2-agonist plus inhaled corticosteroid (double therapy; DT); or DT plus long-acting anticholinergic BD (triple therapy; TT). All groups used short acting bronchodilators as needed.

One hundred forty five COPD patients (64% males) who attended PR and classified according their treatment. Twenty nine received no maintenance therapy; TT). All groups used short acting bronchodilators as needed.

No difference was found related to baseline spirometric, 6MWD and SGRQ values. The whole sample presented significant improvements in total and specific domains of SGRQ (p<0.05) as well as 6MWD (53.1±65.7; p<0.01) with no difference among treatment groups.

In conclusion, in a real life cohort of COPD patients the specific maintenance therapy did not interfere in clinical PR outcomes.
**P3552**

**Influence of pulmonary rehabilitation in patients with COPD in respiratory hospital admissions (Rha) and emergency department visits (EDv)***

Marcos Garcia1, Macarena Arroyo Varela1, Antonio Oreñado Galindo1, Adolfo Domenech del Río1, María Jesús Prunera Pardell1, Ana María Godoy Ramírez2, José Luis De la Cruz Ríos1, Belen González Sánchez1, Marta Estrambadors Marín1,2, Panneumology, Hospital Carlos Haya, Málaga, Spain; 2Rehabilitation, Hospital Carlos Haya, Málaga, Spain

**Introduction:** Pulmonary Rehabilitation (PR) provides significant clinical benefits to patients with severe and very severe COPD

**Objectives:** To verify the effect of PR on COPD patients in our Hospital, not only in terms of Lung Function Tests but also in Rha and EDv.

**Methods:** 148 patients were studied, 106 started PR from January 2009 to October 2010 and 42 did not.

We compared EDv and Rha of patients for one year before and after receiving PR and also with the patients who did not participate. Changes in FEV1 and in 6MWT (6-minute walk test) were also studied.

**Results:**

<table>

*Statistically significant.

Both EDv and Rha show a decrease, being statistically significant in the case of EDv. Also FEV1 and 6MWT show a statistically significant improvement.

**Conclusions:** PR is an effective intervention in treating COPD patients, as it shows significant clinical improvements by increasing capacity to perform physical exercise and by lowering EDv and Rha rates.

**P3553**

**Six months and one year follow up of COPD patients who had oral nutritional supplement therapy as a part of pulmonary rehabilitation program**

Ipek Candemir, Pınar Ergin, Dicle Kayzam, Ergri Simsek, Salihia Batdal, Nilgün Mendil, Fatma Sengül. Chest Diseases, Ankara Atatürk Chest Diseases and Surgery Training and Research Hospital, Rehabilitation Center, Ankara, Turkey

We evaluated long term efficacy of oral nutritional supplement (ONS) which was indicated according to body composition abnormalities in patients with COPD. 41 patients who were given ONS were enrolled. Pulmonary function tests, quality of life, exercise capacity, dyspnea sensation, and body composition data were recorded before and after PR program, at 3, 6 month and in 20 patients 1 year follow-up visit.

Table1 summarizes parameters of patients that were grouped according to ONS duration. In all groups ONS lead to sustained improvements of exercise capacity, dyspnea, symptom management, and body composition at 3 and 6 month. Quality of life was protected in group 1, in other groups it was over baseline values despite loss at 6 month. Both exercise capacity and quality of life decreased at the end of the first year, exercise capacity was lower than baseline. Improvements in symptom control, dyspnea, body composition were protected in one year follow up.

**P3554**

**Intensity of training and physiologic and clinical changes after pulmonary rehabilitation programme in patients chronic obstructive pulmonary disease***

Barbara Vaggagni, Francesco Costa, Laura Malagrinò, Laura Parazzaga, Sandra Antonelli, Giovanna Decusatis, Claudia De Simone, Sabrina Santenieri, Pierluigi Paggiaro. Cardiothoracic and Vascular Department, University, Pisa, Italy

The aim of the study was to evaluate the efficacy of a pulmonary rehabilitation programme (PRP) in relation to the intensity of exercise training achieved during PRP in patients with Chronic Obstructive Pulmonary Disease (COPD). We performed a retrospective analysis on 92 COPD patients (FEV1% 54) who participated in a PRP between 2007 and 2009. All subjects did an outpatient training exercise programme lasted 2 months. The training sessions were 20 and each session consisted in 30 min of cycleergometer exercise associated with 30 min of upper limb exercise. Before and after the PRP the following measurements were done: Changes in 6MWT and cardiopulmonary exercise test (CPET), upper and lower limb endurance (UELLLE), MRC, MMIP and MEP, quality of life by SGRQ. Patients were divided into two groups based on the achievement (Group 1) or not (Group 2) of high intensity training, meaning the intensity of 75% of Wmax reached in CPET pre PRP, sustained for as long as 25 - 30 minutes for 8 final sessions of the PRP.

After PR changes from baseline were significant for all measurements in Group 1, but not in Group 2. Therefore, reaching and maintaining high intensity of exercise training is associated with better results obtained by PRP in COPD patients.

**Two-years of a community maintenance follow-up program in patients with COPD***

Eugenio Zambon1, Pilar Cebollero2, María Hernández2, Esteban Gorostiaga4, Javier Ibanes2, Javier Hueto2, José Cascante2, Milagros Antón1,3. Health Science Department, Public University of Navarre, Tudela, Spain; 2Respiratory B Department, Complejo Hospitalario de Navarra, Pamplona, Spain; 3Respiratory A Department, Complejo Hospitalario de Navarra, Pamplona, Spain; 4Studies, Research and Sport Medicine Center, Navarre Institute for Sport and Physical Activity, Pamplona, Spain

**Introduction:** Benefits of short-term outpatient rehabilitation programs (RP) have been showed in patients with COPD that decline gradually over one year after discharge. Moreover, the capacity of maintenance follow-up programs to preserve the benefits of pulmonary rehabilitation programs is controversial. Therefore, the objective of this study was to examine the efficacy of a two year, supervised, community maintenance follow-up program to maintain the benefits of an initial 12-week outpatient RP.

**Methods:** Eight patients (moderate to severe) COPD men (GOLD), dyspnea 2-3 (MMRC) were included. All patients performed a two years, supervised, community maintenance program (CMP) (twice a week) following a 12-week outpatient rehabilitation program (twice a week). Maximal dynamic resistance (IRM) of the upper limb (chest press and dorsal) and lower limb (leg press and leg extension), and peak power output at 70% of IRM in leg press were measured. Analysis of variance with repeated measures was used for statistical analysis.

**Results:** Initial data from the RP were used as a baseline for all outcomes. IRM in leg press increased (P <0.001) by 20% in RP and 22% in CMP from baseline. IRM in chest press increased (P <0.001) by 32% in RP and 45% in CMP. IRM in knee extension and dorsal increased (P <0.001) by 36 and 55% in RP and 38 and 35% in CMP, respectively. Power output of the lower limb at 70% of IRM increased by 33% in RP and 30% in CMP (from 55±1.08 to 73±4.12 to 72±25.8 W, P <0.05) from baseline.

**Conclusions:** A low volume, supervised, CMP is able to maintain and improve the benefits of a short-term RP in COPD patients. Supported by Ministries of education of Spain and Health Department of Navarre.
Attendance vs prescription: Exercise attendance rates for people with COPD: Systematic review

Marie Williams1, Lucy Lewis1, Zoe McKeough1, Anne Holland1, Annemarie Lee2, Renae McNamara2, Anna Phillips3, Louise Wiles4, Leona Knappman5, Sally Watts5, Maree Milross5, Tania Ellinas6,7, School of Health Sciences, University of South Australia, Adelaide, SA, Australia; 2Clinical and Rehabilitation Sciences, The University of Sydney, NSW, Australia; 3Department of Physiotherapy, Alfred Health, Melbourne, VIC, Australia; 4Department of Physiotherapy, La Trobe University, Melbourne, VIC, Australia; 5Department of Physiotherapy, The University of Melbourne, Victoria, Australia; 6Department of Physiotherapy, The University of Sydney, NSW, Australia; 7Faculty of Health Sciences, The University of Melbourne, Victoria, Australia; 8Department of Respiratory Medicine, Repatriation General Hospital, Adelaide, SA, Australia; 9School of Medicine, Flinders University, Adelaide, SA, Australia

The duration, frequency, mode and intensity of exercise programs for people with COPD are recommended by international consensus statements. The question for this review was: How consistently are a priori criteria and attendance rates reported for people with COPD participating in exercise programs? A systematic search of CINAHL, Embase, and CENTRAL (Cochrane), was undertaken in October 2011. Studies were eligible for inclusion if published in English, included people with COPD, assessed the effects of rehabilitation as the primary intervention (+/- adjunctive strategies) and included at least 2 weeks exercise training (+/- education). There were no limits placed on intervention site (hospital, community, home) or publication date. Data extraction processes were confirmed prospectively for consistency (>80% agreement), with pairs of reviewers extracting data independently and disagreements resolved by consensus. The search returned 752 citations (497 citations excluded from title and abstract) with 255 full text articles retrieved for review. Of the 174 articles reviewed to date, a further 21 citations have been excluded. Of the 153 studies, 100% report the at training sessions (n = 83) and less than a third of these report a priori criteria for attendance (n = 23, 28%). These preliminary analyses suggest that reporting of attendance rates in COPD exercise trials is low, which makes it difficult to calculate dose-response relationships between exercise participation and improvements in health outcomes.

P3556

The effectiveness of a home-based pulmonary rehabilitation program (PRP) in people with COPD

Anna Scholtes1, Sarah Dennis2, Christy Bruce1, Kim Nguyen1, Serena Hong1, Matthew Jennings1, Physiotherapy Department, Liverpool Hospital, Liverpool, NSW, Australia; 2UNSW Research Centre for Primary Health Care and Equity, University of NSW, Sydney, NSW, Australia

Background: PRP has been shown to be one of the most effective interventions for COPD. However several barriers have limited participation. To overcome some of these barriers a Home-Based PRP was offered to people who were unable to attend the Hospital-Based PRP.

Aim: To assess the effectiveness of a Home-Based PRP in improving exercise capacity and quality of life in people with COPD unable to attend the Hospital-Based PRP.

Methods: A retrospective review of patients recruited to a Home-Based PRP at Liverpool Hospital between January 2009 and November 2010. 6MWT and SGRO were used. Data analysed by SPSS using the Paired T Test.

Results: 67 patients were recruited with an average age of 72 years of these 33% completed the PRP and post PRP assessment, and 30% completed the 12-month post PRP follow up. At post-PRP 6MWT improved by 36.7m P=0.001 and SGQRI improved by 9.5% P=0.003. At 12-months (compared to baseline) post-PRP 6MWT was -12.6m P=0.5 and SGQRI improved by 3.5% P=0.4. Difference in outcomes between males and females were also noted as outlined in the table.

Conclusions: A Home-Based PRP can be a suitable alternative for patients who are unable to attend a Hospital-Based PRP. However, a CTR with appropriate sample size would be required.

P3558

Referral to pulmonary rehabilitation amongst patients admitted to hospital with COPD

Kylie Johnston1, Mary Young2, Karen Grimmer-Somers2, KAL Antic3, Peter Frith4, School of Health Sciences, University of South Australia, Adelaide, SA, Australia; 2Department of Respiratory Medicine, Repatriation General Hospital, Adelaide, SA, Australia; 3International Centre for Allied Health Evidence, University of South Australia, Adelaide, SA, Australia; 4Department of Thoracic Medicine, Royal Adelaide Hospital, Adelaide, SA, Australia; 5Respiratory, Allergy & Sleep Services, Repatriation General Hospital, Adelaide, SA, Australia

Background: Pulmonary rehabilitation (PR) is recommended in the management of patients with COPD. However, little information is available about the incidence of referral to PR amongst COPD patients.

Aim: This study prospectively examined consecutive patients admitted to hospital with a primary diagnosis of COPD, to determine the incidence and characteristics of patients referred (versus not) to PR.

Method: Demographic, disease and admission characteristics were collected using prospective and retrospective medical record review, and patient interview at the end of hospital admission. Information about referral to and attendance at a PR program in the past, and referral to PR from the current admission, were obtained from patient interview and confirmed in medical records.

Results: From 190 patients, 64 were recruited to interview (77 excluded due to insufficient English language, cognition, or missed; 43 were repeat admissions and 6 declined). Included patients were aged 72(12) years (mean(SD)), with FEV1%predicted=44(19)%; 61% had a respiratory physician involved in their ongoing care. Of the 64 patients interviewed, 39 (61%) had been referred at some point since diagnosis to PR, but only 15 (24%) had attended. During the current admission, 20% (n=13) had been referred to PR. In 12 cases (19%), PR had been discussed but no referral made, and in 39 cases (61%) PR had not been discussed.

Conclusion: A proportion of COPD patients admitted to hospital had not been referred either in the past, or at the time of the index admission, to PR. Further analysis of this data to determine characteristics associated with referral (or not) will help direct strategies to implement PR in more people with COPD.

The evaluation of pulmonary involvement pattern in high resolution computerized tomography of patients with rheumatoid arthritis in Iran from 2010-2011

Kazem Navari, Reza Farokhsersht, Mohamadreza Masoodi, Shahram Zare, Najmen Ziaee. Internal Medicine Department, Hormozgan Medical University of Sciences, Bandar Abbas, Islamic Republic of Iran Internal Medicine Department, Hormozgan Medical University of Sciences, Bandar Abbas, Islamic Republic of Iran Internal Medicine Department, Hormozgan Medical University of Sciences, Bandar Abbas, Islamic Republic of Iran Internal Medicine Department, Hormozgan Medical University of Sciences, Bandar Abbas, Islamic Republic of Iran

RA is a chronic systemic disease Pulmonary involvement is the most frequent manifestation of rheumatoid arthritis. The goal of this study was to assess pulmonary involvement pattern in patients with RA by HRCT Scan in Bandar-abbas.

Methods: In this prospective study fifty patients with RA referred to rheumatology clinic in Bandar Abbas were evaluated. Data were obtained included: age, sex, duration of disease, methotrexate usage, smoking, pulmonary chronic disease, clinical symptoms of pulmonary involvement and patient self assessment. After clinical and laboratory investigations, HRCT were performed.

Results: Mean age of 49.3 years. Three patients with respiratory symptoms and 47 patients without pulmonary complaint. The most frequent pulmonary involvement in HRCT findings sub pleural fibrosis (26%) and followed by air trapping and mosaic pattern (20%), pleural thickening (14%), honey combing (10%), pulmonary nodules (8%), oblong bronchial thickening (8%), ground glass pattern (8%). Bronchectasis (8%), Alveolar (2%) and reticular pattern (2%). There was no statistically significant relationship between lung involvement pattern and, rheumatoid factor positivity. Anti CCP and methotrexate usage but correlation between HRCT findings and age, duration of the disease, disease activity (DAS 28) and respiratory symptoms was significant (P<0.05).

Conclusion: The results of our study indicate HRCT was useful for evaluation of pulmonary involvement in patients with RA although these patients had no respiratory symptoms. Larger and prospective studies are needed to assess of lung involvement pattern in HRCT in asymptomatic RA patients.
Computerized tomography findings of pulmonary nocardiosis at diagnosis
Fattey Soma Onoue1, Afa Yildirim2, Orhan Yildiz3, Dayeu Pencin1, Emme Dogany4, Nuri Turaz1, Imai Kocyigit1, Emine Doganay1, Yumiko Ando, Asami Ono, Tomoko Nakayama, Haruka Sato, Ayaka Kira, Koichi Honda, Hiromu Mori. Radiology, Oita University Faculty of Medicine, Yufu, Oita, Japan

Background: Nocardiosis is a rare chronic respiratory infection with varied clinical presentations. The aim of the present study was to analyze the radiographic features of pulmonary nocardiosis at diagnosis.

Methods: Ten consecutive patients with pulmonary nocardiosis were evaluated. The findings on chest CT scans and the CT manifestations of the disease were retrospectively reviewed.

Results: Three radiologists (H.I. and M.I.), who were board-certified by Japan Radiological Society, diagnosed and standardized the radiographic features present in the 10 patients. The findings of high-resolution CT (HRCT) imaging in patients with pulmonary nocardiosis were as follows: ground-glass opacity (GGO) (100% of cases), consolidation (60% of cases) and nodules (50% of cases). Among these, 8 patients (80% of cases) showed bilateral findings. The nodules were predominantly unilateral in 2 patients (20% of cases). The nodules were predominantly unilateral in 2 patients (20% of cases). The nodules were predominantly bilateral in 2 patients (20% of cases). The nodules were predominantly unilateral in 2 patients (20% of cases). The nodules were predominantly bilateral in 2 patients (20% of cases). The nodules were predominantly bilateral in 2 patients (20% of cases).

Conclusion: Pulmonary nocardiosis tends to cause bilateral GGO and consolidation at diagnosis. At least 80% of cases showed bilateral findings. These findings may be useful for the diagnosis of pulmonary nocardiosis.
Background: The study of the normal ageing process is becoming more important as life expectancy increases. To our knowledge, no studies reporting chest HRCT findings in asymptomatic, non-smoking elderly subjects with both normal echocardiogram and PFTs were conducted. **Objectives:** To describe chest HRCT findings in a population of asymptomatic, non-smoking elderly subjects with normal echocardiogram and PFTs. **Methods:** After institutional approval, patients over 65 years old recruited from the Geriatrics outpatient clinic were studied and compared with normal volunteers under 50 years old. Written consent was obtained. Participants were submitted to a questionnaire, echocardiography and PFTs for assessing absence of disease, and afterwards submitted to chest HRCT. Scans were interpreted and findings were scored, including pulmonary nodules, cysts, parenchymal bands, interlobular septal thickening, reticular opacities and bronchiectasis. Non-parametric tests were used for the statistical analysis, with P < 0.05 representing statistical significance. **Results:** The HRCT findings of 53 asymptomatic subjects over 65 years old (mean age 74.6 y) were compared with those of 24 volunteers under 50 years old (mean age 35.7 y). The prevalence of abnormal scans was higher in the elderly (84.9% vs 12.5%, P < 0.001). Comparing both groups, significantly more elderly subjects had scans with parenchymal bands (35 vs 3; P < 0.001), interlobular septal thickening (12 vs 0; P = 0.014) and lung nodules (10 vs 0; P = 0.026). **Conclusion:** Parenchymal bands, interlobular septal thickening and lung nodules are present in asymptomatic elderly subjects and may represent normal ageing of the lungs.

P3566 Thoracic manifestation of myeloperoxidase-antineutrophil cytoplasmic antibody (MPO-ANCA)-related disease: CT findings in 149 patients

Yumiko Ando 1, Fumito Okada 2, Koichi Honda 2, Asami Ono 2, Tomoko Nakayama 2, Shunru Matsumoto 2, Hiromu Mori 2. 1Radiology, Niigata National Hospital, Niigata, Japan; 2Radiology, Otou University, Otou, Japan

**Objective:** The purpose of this study was to assess pulmonary CT findings in patients with myeloperoxidase-antineutrophil cytoplasmic antibody (MPO-ANCA)-related disease. **Materials and methods:** The pulmonary CT scans of 149 patients with elevated MPO-ANCA levels (77 with microscopic polyangiitis, 8 with Churg-Strauss syndrome, 12 rapidly progressive glomerulonephritis and 42 with unclassified disease) were retrospectively assessed with regard to parenchymal and mediastinal abnormalities. **Results:** The CT findings consisted of ground-glass attenuation in 110 Patients (74%), consolidation in 67 patients (45%), traction bronchiectasis in 46 patients (31%), and honeycomb in 46 patients (31%). Consolidation, thickening of bronchovascular bundle, interlobular septal thickening, and pleural effusion were more frequently observed in patients with classified disease than in those without an unclassified disease. Honeycombing was more frequently observed in patients with unclassified disease than in those with classified disease. **Conclusions:** The CT findings in patients with MPO-ANCA consisted mainly of ground-glass attenuation, consolidation, and traction bronchiectasis. Consolidation, thickening of bronchovascular bundle, interlobular septal thickening, and pleural effusion were more frequently observed in patients with classified disease than in those with unclassified disease. In contrast, honeycombing was more frequently observed in patients with unclassified disease than in those with classified disease.

P3567 Sarcoidosis; the great mimicker: A CT study

Sheida Rostamzadeh 1, Shahram Kalkouei 1, Shirin Dianati 1. 1Radiology, Mash Daneshvari Hospital, Shahid Beheshti University of Medical Science, Tehran, Islamic Republic of Iran

**Purpose:** Assessing manifestations of sarcoidosis in chest CT to make clinicians and radiologists consider this disease in daily practice. **Material and methods:** CT and HRCT scans of 59 patients with biopsy-proven sarcoidosis were reviewed. **Results:** Many of the classical findings including bilateral hilar and paratracheal adenopathy and other forms of parenchymal involvement like bronchovascular bundle thickening, nodularity, fibrobronchiectatic and fibrocavitary changes affecting upper and middle zones as well as pleural thickening were noted as previously mentioned by many authors. But what highlights our study is the interesting uncovering of 30.5% unilateral and bilateral asymmetric parenchymal involvement, also scattered parenchymal metastasis-like nodules (20.3%), Patchy ground glass opacities mimicking BOOP (33.9%), the galazy nodular pattern (11.9%) and enlargement of main pulmonary artery (23.7%).

Parenchymal manifestations are shown in Fig. 1. In addition to the usual widely known mediastinal lymphadenopathy stations, we found a considerable amount of hilar involvement (55%), paraseptal ophthalmic (22%), and 6.8% intraaparenchymal lymph nodes and the least common pulmonary ligament lymph nodes (1.7%).

**Conclusion:** Sarcoidosis can present with unusual findings in uncommon sites so whenever looking at a pulmonary CT we should ask: “Am I dealing with sarcoidosis?”

P3568 MDCT differences between cardiac edema, viral pneumonia and ARDS

Aleksandar Ivkovic 1, Tamara Milosavljevic 2, Zoran Radiotinovac 1. 1Center of Radiology, KC Nis, Serbia; 2Radiology, ZC Vranje, Serbia

**Purpose:** Acute respiratory distress syndrome (ARDS) is a type of severe, acute lung dysfunction affecting all or most of both lungs that occurs as a result of illness or injury. The main radiological problem is to see differences with cardiac edema or viral pneumonia. Main purpose is to show possibilities of MDCT in detection of important differences. **Methods:** We examined 356 patients with ARDS, 656 with viral pneumonia and 456 with cardiac edema. Patients were examined by 16/64 MDCT using virtual bronchoscopy, perfusion and pulmonary angiography. There were 194 male and 162 female patients from 13 to 82 years with ARDS, 303 male and 353 female with viral pneumonia, 9 to 54 years; 201 male and 255 female, 54 to 76 years old. **Results:** ARDS was caused by injury in 204 cases and with acute illness in 148 cases. 6 cases were without known cause, probably drug abuse. Patients were with hypoxia, PF ratio was less than 200 and all had bilateral x-ray changes. The usual diagnostic approach is to perform standard x-ray of the lung but in cases of myeloperoxidase-antineutrophil cytoplasmic antibody (MPO-ANCA)-related disease the main problem is to see differences with ARDS and from pneumonia; also if patients have cardiac problems in history it is not necessary that they do not have ARDS. There are 2 major radiological differences: first is quality of alveolar fluid and second is condition of alveolar wall. Also important differences are in condition of airways and blood vessels.Different diagnosis was made in 18.9% of patients. **Conclusion:** Fast diagnoses for patients in critical care units are vital to patient life. MDCT with virtual bronchoscopy, perfusion and pulmonary angiography can give us fast answer and prediction. MDCT can be performed in patients with mechanical ventilation.

Endoscopic narrow-band imaging-quantitative assessment of airway vascularity of sarcoidosis

Koumei Yanase1, Yasushi Ohno1, Fumihiko Kamiya1, Junki Endo1, Fumita Ito1, Norihiko Funagachi1, Hiroshi Ishara2, Shinya Minatoguchi1, 1Second Department of Internal Medicine, Gifu University School of Medicine, Gifu, Japan; 2Pharmacology, Gifu University School of Medicine, Gifu, Japan

Introduction or background: Various changes of subepithelial vessels of the bronchial mucosa occur in some respiratory diseases. NBI is a new technology that improves the image contrast of the surface structure by adjusting the spectrum feature regarding the wavelength dependency of the light penetration depth into the tissue and the hemoglobin absorption. We have observed in sarcoidosis patients of subepithelial vessels using a narrow-band imaging of bronchofiberscope.

Aims and objectives: It was our aim to investigate the ability of narrow-band imaging in combination with computerized image analysis to quantitatively assess airway vascularity in sarcoidosis patients.

Methods: In consecutive sarcoidosis patients, the routine procedures, optical analysis of the main carina and the upper lobe carina were performed. From every site five representative pictures were chosen.

Results: A total of 16 sarcoidosis patients were analyzed. Increased numbers of vessels were found and these vessels were also observed in areas of cartilage. Angiogenesis or mucosal thickening was observed.

Conclusion: High magnification view with NBI revealed a clear fine subepithelial microvessel network that could be seen hardly with the ordinary filter. This com-

Relation between vascular patterns visualized by narrow band imaging (NBI) videobronchoscopy and histological type of lung cancer

Bosan Zoric, Branislav Perin, Goran Stojaovic, Vladimir Stojic, Vladimir Carapic, Senka Milutinov, Tatjana Sarcev, Milan Antonic. Clinic for Pulmonary Oncology, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica, Vojvodina, Serbia

Introduction: Narrow Band Imaging (NBI) videobronchoscopy is a new technique for visualization of bronchial mucosa. It has shown to be efficient in lung cancer detection. The primary aim of this study was to evaluate relation between vascular patterns visualized by NBI as described by Shibuya and histology of lung cancer.

Patients and methods: The study included 65 patients with suspected lung cancer scheduled for bronchoscopy. After identification of endoscopically visible tumor NBI was used to determine predominant type of pathological vascular pattern (dotted, tortuous, abrupt-ending blood vessels – Shibuya descriptors). Pearson’s chi-square test was used to test statistical significance between vascular pattern and histological type of cancer.

Results: Lung cancer was confirmed in all patients.63.1% was diagnosed with squamous cell lung cancer (SCLC);24.6% had adenocarcinoma;9.2% had small cell (SCLC) and 3.1% large cell lung cancer(LC). Dotted blood vessels were significantly(p<0.000) associated with adenocarcinoma, identified in 68.4% adeno-

nocarcinoma and 31.6%SCLC. Tortuous blood vessels were identified in 72% SCC,8% adenocarcinoma,12%SCLC and 8% of LC. Tortuous blood vessels were significantly(p<0.000) associated with SCLC. Abrupt ending vessels were identified in 81% SCC, 14.3% SCLC and 4.8% adenocarcinoma, this type of blood vessels was also significantly associated(p<0.000) with SCC.

Conclusions: Dotted visual pattern of blood vessels identified during NBI video-

bronchoscopy is highly suggesting adenocarcinoma histology of lung cancer, while tortuous and abrupt ending blood vessels significantly suggest squamous cell histology of lung cancer.

P3575

Safety profile, efficacy and patient comfort with propofol sedation in outpatient fiberoptic bronchoscopy

Puneet Khanna, Vikas Maurya, Vipin Kauts, Rajesh Punde. Department of Critical Care and Respiratory Medicine, BL Kapur Memorial Hospital, New Delhi, Delhi, India

Introduction: Procedural sedation is suggested in outpatient bronchoscopy to
improve tolerance & patient satisfaction. Propofol, a short acting intravenous hypnotic, offers advantages over benzodiazepines/opiates.

Objectives: We analyzed the feasibility, efficacy & safety profile of propofol administered by a trained nurse for outpatient bronchoscopy.

Methods: A total of 276 flexible bronoscopies performed between 2009 & 2011 using propofol sedation only without premedication were retrospectively reviewed. Patient demographics, indications, type of procedure, procedure time, medication doses, comfort level on 10cm verbal analogue scale (VAS, 0-10) & adverse events were analyzed from procedure records.

Results: Of the 276, two-thirds (182, 66%) of patients were male with an average age of 56 years (range 18–92). An average weight of 73 kg. Indications included diagnostic BAL (127, 46%), TBLB (68, 25%), TBNA (41, 15%) & EBB (22, 8%). Average procedure time was 36 minutes (range 12–145). Average propofol dose was 1.86 mg.kg−1 (range 0.12–2.23 mg) while 37 received combined sedation (mean 2.74mg). No sedation related complications were reported. Increased duration of FB and age of 56 years (range 18–92) were attributed to hypoxia & bronchospasm. There were no procedure-related deaths. A majority (196, 71%) of patients reported VAS of 4-6 with good amnesia, while 56 (20%) had VAS > 6 & 24 (8.6%) had VAS < 3.

Conclusions: Propofol is an easy to administer, safe, & effective procedural sedative for outpatient bronoscopies providing acceptable comfort.

P3576 Lidocaine administration to the laryngopharynx for inducing anesthesia before bronchoscopy: A comparative study of Jackson’s spray method and ultrasonic nebulization

Kensaku Takahashi1, Emiko Yamakawa1, Kouki Tsuj1, Yukiko Kaneko3, Yoko Hamakawa3, Kaori Okubo2, Toshie Chiyomori2, Filomila Zikopoulos2, Taeko Kameyama3, Kazuki Shim1, Yoko Hamakawa3, Shohei Kane1, Susumu Noguchi1, Akari Moriyama1, Yojiro Yutaka1, Hiromichi Katakura1, Naoki Sakai1, Akira Yamanaka1, 1, 2, 3

Objectives: To compare the degrees of pain experienced by patients and additional intraoperative amounts of lidocaine required when lidocaine is administered using Jackson’s spray and an ultrasonic nebulizer.

Methods: Patients who were given laryngopharyngeal anesthesia before bronchoscopy were divided into 2 groups of 20 patients each: group A, which was given 4% lidocaine 5 mL by using Jackson’s spray, and group B, which was given 2% lidocaine 10 mL by using an ultrasonic nebulizer. The degrees of pain in group A were significantly higher than those in group B (A: 3.5 ± 1.2 vs. B: 2.2 ± 0.9, p = 0.03). An analysis based on patient age and smoking history showed that the rate of lidocaine use in group A was significantly high in elderly persons (less than 70 years of age) and smokers (p = 0.05).

Conclusions: Laryngopharyngeal anesthesia before bronchoscopy, the Jackson spray requires a large amount of lidocaine at the time of bronchoscopic examination for bronchoscopic time, compared with the ultrasonic nebulizer.
were used in ≥50%, and floroscopy systems were used in 99.8%. Biopsies were performed after discontinuation of therapy in patients receiving antipatecl clot drugs and anticoagulants in 96.7% and 97.4% of the facilities, respectively. Atropine was administrated for premedication in 67.5% of the facilities, a decrease from previous surveys. Intravenous sedation was given in 36.1% of the facilities. In 21.9% of these, the procedure was conducted in the outpatient clinic for ≤70% of patients. A bronchoscope was orally inserted in ≥70% of patients in 95.7% of the facilities. Intravenous access was maintained during the examination in 92.5% of the facilities, oxygen saturation was monitored during examinations in 99.0%, oxygen was administered in 97.6%, and resuscitation equipment was available in 96.6% of the facilities. Bronchoscopes were disinfected using an automatic washing machine, but glutaraldehyde was used in 42.2%.

**Conclusions:** Japanese-specific characteristics in bronchoscopic practice were identified. Whether procedures used in Japan meet international guidelines with respect to safety should be monitored continuously. In addition, a Japanese evidence-based consensus is needed.

P3580

The ratio of HBsAg, anti-HCV and anti-HIV positivity in patients indicated for fiberoptic bronchoscopy before the procedure

Seyfettin Günsel, Mehmet Aydogan, Omer Deniz, Alper Gundogan, Gurkan Metin, Ergun Topkapan, Hayati Bilgic

Introduction: Performing fiberoptic bronchoscopy has many risks for the bronchoscopy personnel. May be the most important risk is the transmission of tuberculosis bacilli from the patient to the bronchoscopy personnel. In addition, transmission of blood-borne viruses such as hepatitis B, HCV and HIV might be the other important risk for the bronchoscopy personnel particularly for the bronchoscopist. Splash of bronchial secretions to conjunctiva might be considered as the main route of transmission. Non-inact skin exposure might be the second route.

Aim: The aim this study was to investigate the ratio of the patients having positive results for blood-borne viruses undergoing bronchoscopy before the procedure.

Methods: We retrospectively screened the medical files/records of the patients undergoing bronchoscopy procedure between May 2011 and January 2012.

Results: There were 183 patients with a bronchoscopy indication. Mean age was 55±17 years. 123 patients had HBsAg, anti-HCV and anti-HIV test results. HBsAg was positive in five patients (4%). Anti-HCV and anti-HIV test results of all the patients were negative.

Discussion: In our country, different results for HBsAg positivity, between 2%-10%, were reported in different studies. Our results are similar the results of these studies. A ratio of 4% HBsAg positivity should not be seen as a small ratio. Absence of anti-HCV and anti-HIV positivity might be attributed to the small number of study group.

Conclusion: This study suggests that bronchoscopy personnel are under the risk of hepatitis B transmission. Large studies are needed to indicate the transmission risk of blood-borne viruses for the bronchoscopy personnel.

Verucous carcinoma of the tracheobronchial tree – An underdiagnosed entity?

Claas Steppen, Joseph Alhana, Juergen Schubbert, Jens Kruppmann

Herren: We retrospectively screened the medical files/records of the patients undergoing bronchoscopy procedure between May 2011 and January 2012.

Results: There were 183 patients with a bronchoscopy indication. Mean age was 55±17 years. 123 patients had HBsAg, anti-HCV and anti-HIV test results. HBsAg was positive in five patients (4%). Anti-HCV and anti-HIV test results of all the patients were negative.

Discussion: In our country, different results for HBsAg positivity, between 2%-10%, were reported in different studies. Our results are similar the results of these studies. A ratio of 4% HBsAg positivity should not be seen as a small ratio. Absence of anti-HCV and anti-HIV positivity might be attributed to the small number of study group.

Conclusion: This study suggests that bronchoscopy personnel are under the risk of hepatitis B transmission. Large studies are needed to indicate the transmission risk of blood-borne viruses for the bronchoscopy personnel.

Hemangiopericytoma – An extremely rare bronchial tumour, a difficult diagnosis

Roxandra Ulmeanu, Ramona Nedelev, Dalia Manolache, Radu Matache, Dan Ioan Ulmeanu, Andrada Florian, Radu Stoica, Oana Deleanu, Doina Boiculescu, Florin Mihaiulan. Bronchology, INP Marius Nasta, Bucharest, Romania

Pneumology, INP Marius Nasta, Bucharest, Romania Surgery, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania Anesthesia and Intensive Care, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania Pulmonology, INP Marius Nasta, Bucharest, Romania

Background: Hemangiopericytoma is a rare mesenchymal tumour originating from the capillary pericytes (about 1% of vascular tumors). Its primary localization in the lung is extremely rare.

Case presentation: A 52-year-old man, smoker (60PY), is diagnosed two months ago by bronchoscopy and chest CT scan with the main left bronchus tumour with subsequent negative biopsies. He was admitted to our hospital for re-examination and clarification and endoscopic diagnosis. "Encéfaloidal" endoscopic tumour that stenoses left bronchi from the beginning by 65%, but without bronchial wall infiltration around the tumor.

1. We performed rigid bronchoscopy and "Jet" ventilation with snare electroresection of tumour in three stages. Histopathological examination of a biopsy specimens - non-small carcinoma. Follow bronchoscopy intervention, persist only distal total obstruction of left main bronchus.

2. Radical left pneumonectomy with mediastinal lymphadenectomy and intrapericardial atriocephalic anastomosis. Postoperative chemotherapy that combined carboplatin and taxol were performed.

Conclusion: Hemangiopericytoma is a rare vascular slow-growing tumor with high local recurrence and poor prognosis because the recurrence of disease. Preoperative diagnosis is difficult. Surgical radical excision is the treatment of choice, although the criteria for determining the area of resection have not been established.

P3583

Pulmonary-alveolar microtheliosis (PAM) as a rare differential diagnosis of diffuse lung diseases diagnosed by transbronchial cryobiopsy

Henrik Wurz1, Sérgio Griff2, Michael Knappik1, Nicolas Schönfel1, Torsten T. Bauer1, Thomas Mairinger3, Wolfram Grünitz1, 1Department of Pneumology, Med. II, Klinikum Bautzen, Bautzen, Germany; 2Institute of Pathology, HELIOS-Klinikum Emil v. Behring, Berlin, Germany; 3Department of Pneumology, HELIOS Kliniken Schwerin, Mecklenburg-Vorpommern, Germany

Introduction: PAM is a rare pulmonary disease of unknown origin. Microscopically, it is characterized by diffuse alveolar calcification. Chest x-ray usually presents a "sandstorm" image. Diffuse lung diseases are typically diagnosed by computed tomographic imaging; histological validation is won by surgical lung biopsy. Current studies show a more important role of transbronchial cryobiopsy for histological diagnosis.

Case report: A 26-year-old male presented with dyspnea. The radiographic images (chest x-ray, computed tomography) showed interstitial pulmonal changes without radiological guidance; the cryoprobe was cooled for five seconds and then retracted after bronchoscopy intervention, persist only distal total obstruction of left main bronchus. The specimen were rared between two experienced lung pathologists.

Results: Histologically the cryobiopsy showed only few hints for PAM, whereas in the cryobiopsy a pulmonary-alveolar microtheliosis could be proven due to big amount of alveolar tissue with concentric calcification. In respect to untypical radiographic signs this was determining.

Conclusion: There is a huge variety of diffuse lung diseases. The diagnosis of PAM was surprising because the radiographic images showed an untypical morphology. The histological diagnosis of PAM was proven by transbronchial cryobiopsy. This shows the potential impact of transbronchial cryobiopsy in different entities of interstitial lung disease.

P3584

Management of video capsule bronchial aspiration

Matthieu Buscot, Stéphane Martinez, Hélène Filipi1, Xavier Beubet1, 1Pulmonology, University Hospital, Nice, France; 2Gastroenterology, University Hospital, Nice, France

A 74-year-old patient with of occult gastrointestinal bleeding was referred for a small bowel exploration using video capsule endoscopy. Medical history revealed...
left hemiparesis and swallowing disorders as sequel of stroke. A video capsule endoscopy was scheduled after the advice of the ENT specialist. Within minutes after the capsule ingestion, the patient developed a typical choking episode. Real-time visualization of the video-endoscopic “bronchial tree” images by the gastroenterologist quickly assisted by the pulmonologist enabled locating the capsule at the level of the main carina/left main bronchus. Immediate bronchoscopy under general anaesthesia allowed the pulmonologist to gently catch the video capsule and to readily place it within the gastro-intestinal tract (stomach). Small bowel exploration could then be performed “as scheduled” and revealed duodenal and jejunal angioomas as the source of the bleeding. Pictures as well as short video sequences of the choking episode and of the gastro-intestinal placement of the capsule with the bronchoscope are presented. Based on this experience and on the literature (about 9 reported cases of tracheobronchial video capsule aspiration) two recommendation can be made:

1. Caution should be taken in patients with swallowing disorders
2. Immediate tracking by of the capsule initial path is recommended

The present case also shows that a combined approach (gastroenterologist + pulmonologist) permits to replace the video capsule in the right way during the same procedure.

A case of primary tracheal B cell lymphoma leading to obstruction of central airway

Seda Tural Onel1, Levent Dalar1, Sinem Nedime Sokucu1, Ahmet Levent Karasu1, Ramazan Celik1, Aysegul Akbas1, Nurdan Simsek1, Sedat Altin1, 2 Pulmonology, Yoldashe Teaching and Research Hospital, Istanbul, Turkey; 2 Pulmonology, Adiyaman State Hospital, Adiyaman, Turkey

Primary malignant tumors of the trachea are rare, and they follow up such as asthma, chronic obstructive pulmonary disease incorrect diagnoses. Tracheal tumors are rare and the incidence less than 0.01% and the majority of squamous cell carcinoma. Very few cases of primary lymphoma of the trachea have been reported so far. 72 years old male patient admitted to our clinic with complaints of shortness of breath, bronchoscopy showed a mass obstructing the tracheal lumen of the almost complete. Dioxide laser and coring was performed for emergency debulking.

There was no another focus of the patient's systematic screening whose pathological result is B-cell lymphoma. Reported due to a rare tracheal tumor.

**P3586**

Foreign body aspiration by a 31 years old female patient, mimics diaphragmatic hernia

Styliani Sarantoulaki, Maria Mouzouraki, Emmanouil Ntaoukakis. Pulmonary Unit, General Hospital of Chania, Crete, Greece

Introduction: We present a case of food aspiration by a 31 years old female patient, masquerading as diaphragmatic hernia. Aims and objectives: Our aim is to show that food aspiration is a life threatening condition and it can easily escape detection.

Methods: A 31 years old female presented at the emergency department with shortness of breath. Her past history was unremarkable. The chest X-ray demonstrated total collapse of the left lung and herniation of the stomach and large intestine into the left pleural cavity. Chest CT- scan demonstrated the presence of stomach and large bowel in the left chest suggesting a postero-lateral diaphragmatic hernia. The patient was subjected to an postero-lateral thoracotomy. To our surprise there was only local evagination of the left hemidiaphragm. Atelectasis of the left lung persisted despite ventilation with high pressures. The patient subjected in intraoperative flexible bronchoscopy and there was presented a large quantity of mucus surrounding a soft mass adhered at the wall of the bronchus. Rigid bronchoscopy was performed the following day and a piece of meat was extracted. Results: Atelectasis soon dissipated and the patient had normal breath again, after the extraction of the food mass. Conclusion: Foreign body aspiration is unusual in adults, except those who are debilitated or have neuropsychiatric disorders. The doctors must be suspicious about this condition even in young healthy patients and bronchoscopy must be used as diagnosing and therapeutic step before the patient subject a thoracotomy.

**P3587**

Endoscopic resection of airway benign tumors by argon plasma coagulation

George Daher, Samir Chalita. Pulmonary Section, Hotel Dieu Hospital, Beirut, Lebanon

Benign airway tumors with central airway obstruction require immediate intervention for symptoms relief. Argon Plasma Coagulation (APC) is a cheap tool readily available in hospitals. Four patients presented for obstructing tracheal or bronchial tumor (2008 to 2011). Initial investigations included fiberoptic bronchoscopy and CT imaging of the chest. Argon plasma was set to 35 Watt and delivered in non-contact fashion through a large fiber during rigid bronchoscopy. Initially tumor coagulation was done followed by mechanical resection and finally APC was applied to tumor base. Patients were discharged next day and followed clinically by CT imaging and bronchoscopy. All patients were reevaluated one year after ablation to eliminate recurrence.

Case1: 24 years old female presented for uncontrolled asthma. Endoscopic resection with APC revealed tracheal schwanna.

Case2: 35 years old female, 6 month pregnant, intubated for respiratory failure due to obstructive tracheal tumor. Endoscopic resection yielded low-grade muco-epidermoid carcinoma of the trachea.

Case3: 60 years old male, smoker, with concomitant sarcomatous carcinoma of the kidney presents for dyspnea, persistent cough and obstructive lesion of the right main bronchus. Ablation by rigid bronchoscopy and APC unraveled bronchial hamartoma.

Case4: 57 years old male, smoker, presents for persistent cough. Rigid bronchoscopy and APC resection of right bronchial obstruction uncovered a hamartoma.

APC is an effective and efficient tool to use during resection of benign bronchial tumors, it’s safe to use in pregnant patient and provides immediate airway relief. Swannamara, hamartoma and low-grade muco-epidermoid tumors can be treated with this modality.

**P3588**

An unusual approach to manage a bronchopleural fistula following carinal pneumonectomy

Samir Naik, Brendan Madden, Robin Kanagasby. Cardiothoracic Medicine, St. Georges Hospital, London, United Kingdom

A 52-year-old lady was referred with a T4N0M0 lung adenocarcinoma in the right main bronchus with protrusion into the trachea. She was an exsmoker with COPD and hypothyroidism.

She had a right carinal pneumonectomy with anastomosis of left main bronchus on to the trachea. Post discharge she was readmitted with dyspnoea three weeks later. Her post pneumonectomy space was abnormally enlarged which was managed successfully with intercostal tube drainage.

Six weeks later she represented with dyspnoea and sepsis which did not respond to antibiotics. She had a right thoracotomy and bronchoscopy which showed two bronchopleural fistulas (BPF) at the anastomotic site. Unfortunately the BPF persisted. Surgery was not considered appropriate. She then had a rigid bronchoscopy and a 4cm X 16 mm covered stent deployment to cover the defects. A day later she still had an air leak. Chest X-ray four days later showed that the stent had migrated upwards. She had replacement of the stent with a larger 4cm X 18 mm device. Following day, the air leak stopped completely. Her follow up chest x-ray three months later has been stable with no recurrence of BPF.

This case illustrates the management difficulties of BPF complicating high bronchial to tracheal anastomosis with differing airway diameters. Placement of large stent could have jeopardised the integrity of the airway anastomosis. The first stent migrated because it was preferentially sized with respect to the bronchial diameter. When a larger stent was inserted adequate closure ensued without airway anastomotic dehiscence.

Although surgical treatment of BPF is gold standard carefully selected patients may benefit from endobronchial closure.

Models must be able to bleed – The real interventional bleeding simulator a new training model for interventional bronchoscopy procedures as a sufficient substitute for training on live animals

Marin Hackl1, Armin Salzmann2, Michael Lueff2, Klaus Lemke2, Herbert Jannig3, 1 Center of Pneumology, TILAK-LKH Natters, Natters, Austria; 2 PROdesign, ArtiCHEST, Heiligkreuzsteinach, Heidelberg, Germany

Introduction: Until now bleeding could be only trained on live pigs. Background: The current available models are not able to demonstrate acute bronchial bleedings.

Methods: We developed a new Simulation model for interventional bronchoscopy including a real-life-simulation of bleeding in bronchial tree. The model contains 2 transparent covers,a full expanded pig lung, an intubation head and an artificial diaphragm. We inserted “endobronchial tumors” and simulated different realistic bleeding situations with artificial blood.

Results: At an interventional training course organized by the Austrian Society for Pneumology (2010/2011) the simulator different simulated bleedings. The feedback given by all the 32 trainees showed a convincing

P3590 Does pseudo-ROSE enhance the diagnostic utility for conventional TBNA? Andrew Modford, Anikumar Pillai. North Bristol Lang Centre, Southmead Hospital, Bristol, United Kingdom

Background: Conventional transbronchial needle aspiration (TBNA) is a useful mediastinal diagnostic and staging technique. It is more accessible and cheaper than endobronchial ultrasound. Some centres use ROSE (rapid on-site evaluation for cytology with a cytotechnologist) to improve results but limited by cost and resources. There are less published studies on pseudo-ROSE (a cytotechnician assesses sample adequacy alone).

Hypothesis: Pseudo-ROSE improves diagnostic utility of TBNA.

Methods: 22 consecutive patients underwent pseudo-ROSE-TBNA for investigation of suspected lung cancer (with N2 or N3 disease on CT) in a UK teaching hospital by previously described methods. Diagnostic utility to detect mediastinal metastases was calculated via contingency table analysis (GraphPad Prism 5).

Results: Pseudo-ROSE-TBNA resulted in 13 true positive cases (59% of cohort) of malignancy (5 small cell, 8 non-small cell) with 7 true negative cases and 2 presumed false negative cases (10mm nodes in stations 10R and 3 on CT but not confirmed). 87% sensitivity, (compared to 78% in a UK non-ROSE study) 78% negative predictive value, 68% cancer prevalence and 91% accuracy. Pseudo-ROSE-TBNA detected granulomatous disease due to sarcoidosis in 3 of the 7 true negative cases.

Conclusion: Pseudo-ROSE improves the diagnostic utility of conventional TBNA for lymph node metastases in high prevalence cohorts with malignancy. In the absence of endobronchial ultrasound or conventional ROSE, pseudo-ROSE should be used as an effective and inexpensive adjunct to conventional TBNA.

P3591 Transbronchial node aspiration for intrathoracic lymphadenopathy Hooman Deorgi Yankov1, Arda Kiani1, Mehdi Bakhtian1, Negar Shekhi1, 2Thoracic Disease Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran. 3Chronic Respiratory Diseases Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran. 4Tobacco Prevention and Control Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Background and objectives: Lymph node evaluation has been important for many years both regarding diagnosis and staging. This study was aimed at evaluating the diagnostic yield of transbronchial needle aspiration biopsy (TBNA) in patients with intrathoracic lymphadenopathy.

Methods: Our understudy population included all patients suffering from undiagnosed intrathoracic lymphadenopathy (LAP) with no accompanying pulmonary lesions on chest CT scan who had referred to bronchoscopy unit of Masih Daneshvari Hospital. After determining the anatomical location of LAP patients underwent fiberoptic bronchoscopy (FOB) and TBNA using 19-gauge eXelson aspiration needle. Four samples were taken from each patient from the same LAP location.

Results: In this study 39 patients were evaluated. The most common anatomical location of LAP was the paratracheal area seen in 14 patients (35.2%). Next was subcarinal area and also hilar area with 12 cases (38.5%) for each of them. Five patients (15.6%) had LAP in other anatomical locations. Evaluation of the aspirates obtained by TBNA showed that the sample was adequate and diagnostic in 21 patients (55.26%); adequate but non-diagnostic in 9 patients (23.68%) and inadequate in 8 cases (21.06%). Definite diagnosis was made in 22 patients among which the most common differential diagnosis was atypical and malignant lesions in 11 cases (55%) followed by sarcoidosis in 8 (36.36%), tuberculosis (TB) in 2 (9.09%) and other diagnoses in 1 (4.55%) case.

Conclusion: Based on our study results, TBNA was diagnostic in more than half the cases. Various studies have reported a wide range of results in this respect but all of them including ours emphasize on the acceptable diagnostic yield of this technique.

P3592 Minimally invasive diagnostic techniques for mediastinal lesions Rossen Petkov1, Yordanka Yamakova2, Emilka Petkova1, Danail Petkov1, Deceg Yankov1. 1Thoracic Surgery Department, University Hospital of Pulmonary Diseases, Sofia, Bulgaria. 2Clinic of Anesthesia and Intensive Care, University Hospital of Pulmonary Diseases, Sofia, Bulgaria. 3Endocrinology Clinic, USBL of Endocrinology, Sofia, Bulgaria

Aim: The aim of the study is to evaluate the diagnostic value and the complication rate of various minimally invasive diagnostic techniques by patients with mediastinal lesions (ML).

Materials and methods: In a prospective study (from 2001 to 2009) we observed 421 patients (pts) (227 males and 194 females, age x ± SD: 45.7±16.7 yrs.) with ML (x ± SD: 56 mm ± SD: 20mm). By 275 pts US guided true-cut needle biopsy (US-TCNB) were performed. By 18 pts we did CT guided TBNA. VATS (n=124), mediastinoscopy (n=18), anterior mediastinotomy (n=16) and thoracotomy (n=29) were performed by 187 pts: 17 pts with uninformative TCNB results (14 US-TCNB and 3 CT-TCNB), 37 with benign lesions proved by TCNB and 133 pts with ML inaccessible for image guided TCNB.

Results: US-TCNB gave an adequate material to the morphological diagnosis in 261 (94.9%) of patients with ML, sensitivity (Se) 96% and NPV 80%. The complication rate was 0.8%. CT-TCNB yielded positive diagnosis in 88.9% of cases, Se 88% and NPV 33%. The complication rate was 22%. VATS gave a morphological diagnosis in 121 pts (97.6%), Se 97% and NPV 84%. The complication rate of VATS was 9.7%. The accuracy of the mediastinoscopy was 87.5%, Se 86% and NPV 50%. The accuracy of the anterior mediastinotomy was 88.9%, Se 87.5% and NPV 50%. The complication rate of these procedures was 5%

Conclusion: US – TCNB appears to be effective and a safe method in patients with US accessible ML. According to our results US- or CT-guided TCNB should be the first step in tissue diagnosis of mediastinal masses. Mediastinal lesions that are inaccessible by these methods can be diagnosed by mediastinoscopy, anterior mediastinotomy and VATS.

P3593 Interobserver analysis of assumed optimal positions for transbronchial needle aspiration Kariel Roth1, Tomas Eagan2, Jon Hardie1. 1Department of Internal Medicine, Helse Møre og Romsdal, Ålesund Hospital, Ålesund, Norway. 2Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway

Background: Various guidelines have described the optimal positions for transbronchial sampling from lymph node stations. The variability in expert opinion for these positions is unknown.

Objective: To describe the interobserver variability in the assumed optimal position for transbronchial needle aspiration (TBNA) from lymph node station 4, 7, 10 and 11.

Methods: Four physicians with large experience in TBNA were shown six bronchoscopic pictures and asked to describe the optimal positions for TBNA. The physicians marked an area for the assumed best position for different lymph node stations. A mean diameter was calculated for each area. The mean diameter represented the intraobserver spread for each expert in the lymph node station. The distance to the average X and Y-coordinate defined the interobserver variation.

Results: The mean diameter that represented the average spread was 1.14 cm (95% confidence interval: 0.91-1.38 cm). Lymph node station 11 had an average intraobserver diameter below the 95% confidence interval. The average intraobserver diameter in lymph node station 4R and 10L were above the 95% confidence interval.

The median interobserver distance was 0.64 cm (interquartiles range 0.17-1.04 cm). Lymph node station 7L had a mean interobserver distance smaller than the 25% quintile, lymph node station 10R and 10L had an interobserver distance larger than the 75% quintile.

Conclusions: The interobserver spread was large in station 4R and 10L, the interobserver variation was large in 10R and 10L compared to the other lymph node stations that were evaluated.
P3594
The diagnostic yield and safety of fine needle aspiration of intrathoracic hydatid cysts: A three year retrospective study
Ohanian B. Ozal1,2, Corneel F.N. Koelegerm1, Ragael Braun1,2, Elvis M. Iruzen1, Floran von Groot-Bidlingmaier1, Colleen A. Wright3, Mercia Louw1, Pavel T. Schubert1, Chris T. Bolliger1, 1Medicine, University of Stellenbosch, Cape Town, South Africa; 2Anatomical Pathology, University of Stellenbosch, Cape Town, South Africa

Background: Hydatid disease remains a clinically relevant entity in much of the developing world. A presumptive diagnosis may be confirmed by cytological analysis of liquid obtained by percutaneous aspiration of the cyst. There is, however, a paucity of data on the safety and diagnostic yield of this approach.

Objectives: To assess ultrasound (US)-assisted transthoracic fine needle aspiration (TTFA) of suspected thoracic hydatid cysts with regards to safety and diagnostic yield.

Methods: We retrospectively included 11 cases (35±9±9.1 years, 7 females) who underwent US-assisted TTFA over a three-year period and who were eventually confirmed to have histological proof (surgical resection) of hydatid cyst. Cytological review, and the diagnostic yield of US-assisted TTFA was compared with serology (using histology as the gold standard).

Results: Cytology was diagnostic in 5±1±1 of cases (45.5%), compared to serology that was diagnostic in 6±8±1 cases (75%, p = 0.352). Cytology was diagnostic in one case with negative serology. A serious complication (empyema) was observed in one case.

Conclusions: US-assisted FNA of thoracic hydatid cysts has a modest diagnostic yield. US-assisted FNA should be reserved for cases with indistinct imaging and/or a negative serology, given the risk of complications.

P3595
EBUS-TBNA for diagnosis of granulomatous mediastinal lymphadenopathy
Sia Yang1, Min Y. Koh1, Tham-Hun Ong1, Ghee-Chee Phua1, Devanand Anantham1, Department of Respiratory and Critical Care Medicine, Singapore General Hospital, Singapore, Singapore

Methods: Retrospective review of all patients who underwent EBUS-TBNA for suspected granulomatous mediastinal lymphadenopathy at Singapore General Hospital between 2008 and 2011.

Results: Over 3 years 33/371 patients underwent EBUS-TBNA for suspected granulomatous mediastinal lymphadenopathy – 18 for tuberculosis(TB) and non-tuberculous mycobacterial (NTM) lymphadenitis, 15 for sarcoidosis. Mean age 47±18 years, 54.5% male. Total of 49 lymph node stations were sampled, with stations 7 the most frequent (43%). Median size of lymph node was 17mm (8-30), median number of passes per lymph node 2 (1-5), and core biopsy obtained in 45/92±1. Median follow-up was 9 months (0.5-26).

Conclusions: EBUS-TBNA can be useful in the diagnosis of suspected granulomatous mediastinal lymphadenopathy. A presumptive diagnosis may be confirmed by cytological analysis or microbiology culture. A negative result does not exclude the diagnosis of granulomatous lymphadenitis and further workup is required.

P3596
EBUS-TBNA in a tertiary care center: Real life experience and quality assessment
Philippe Neveug1, Michel Gagnon, Thomas Vandenmootele, Department of Pulmonology, Centre Hospitalier de l’Université de Montréal, Montréal, QC, Canada

Introduction: Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) has become the standard minimally invasive modality for sampling mediastinal lymph nodes. In this study, we evaluate our performance with the technique and propose a methodology that can be used in other centers.

Method: We included all EBUS-TBNA procedures performed in 2011 in our service. We proceeded to a thorough analysis of each case from a pragmatic perspective to evaluate the regional node sampling yield and our ability to conlude the investigation by achieving diagnosis and staging, avoiding unnecessary surgery and allowing direction for management.

Results: EBUS-TBNA was performed in 53 consecutive patients. The indication was suspicion of malignant disease in 46 patients (87%) and benign in 7 patients (13%). In total, 117 nodes were sampled. The overall sensitivity ranged from 76 to 91% and the negative predictive value ranged from 78 to 92%. The median size of nodes was discovered, histological precision was obtained in 68%. EBUS-TBNA was clinically sufficient in 43 of the 53 patients (diagnostic yield = 81%) and prevented 18 out of 27 patients (67%) from undergoing surgery. No major complications were reported.

Conclusion: The attained sensitivity and negative predictive value are similar to what has been published. Thorough analysis of patient cases is key in improving performance with this technique, and we encourage all centers to analyze their practice periodically in order to maintain quality standards. Finally, in our establishment, EBUS-TBNA offers clinicians an additional step to simplify healthcare and probably reduce the economic burden of such investigations.

P3597
Transesophageal ultrasound-guided fine needle aspiration (EUS-guided FNA) as first diagnostic step of intrapulmonary lesions
Miguel Romagnoli1, Lucia Crociani1, Carlo Guriol1, Gian Luca Casoni1, Alessandra Dubini2, Sara Tomassetti1, Christian Guroli1, Claudia Ravaglia1, Venerino Pololeti1, 1Thoracic Diseases, Palumnoiu Unit, Firel, Italy; 2Pathology, Pathology, Forli, Italy

Background: Bronchoscopy fails to establish a diagnosis in up to 30% of patients with centrally located lung cancer. EUS-guided FNA has been used for the diagnosis of suspected lung cancer near or adjacent to the esophagus in patients who had undergone a non-diagnostic bronchoscopy. Aim: To prospectively assess the feasibility and yield of EUS-FNA as first diagnostic step in the diagnosis of intrapulmonary tumours located near or adjacent to the esophagus.

Study design: Patients with a CT-scan of the chest revealing an intrapulmonary nodule located near or adjacent to the esophagus were enrolled. They underwent EUS-FNA (Olympus, GF UCT 160) under deep sedation.

Results: Forty-three patients were included, and EUS-FNA diagnosed lung cancer in 33 cases (12 NSCLC, 2 SCLC) (yield=100%). No complications occurred. The typing of NSCLC was allowed by cytological specimens in 9 cases (65%), by cell blocks in 3 cases (21%), whereas NSCLC could not be subtyped in 2 cases (14%).

Conclusions: EUS-guided FNA might represent the first diagnostic step in patients with intrapulmonary tumours located near or adjacent to the esophagus.

P3598
Virtual bronchoscopic navigation combined with endobronchial ultrasound for diagnosing small peripheral pulmonary lesions
Masafumi Misawa, Haruki Kobayashi, Kei Nakashima, Nobuhiko Asai, Naoko Katsurada, Hideki Makino, Norihiro Kaneko, Masahiro Aoshima, Pulmonary Department, Kameda Medical Center, Kamogawa city, Japan

Background: Flexible fiberoptic bronchoscope may be a valuable procedure to evaluate pulmonary nodules. However, a diagnostic yield has been reported as low as 34% for peripheral lesions less than 5 cm in size.

Objectives: This case series study evaluated the value of the virtual bronchoscopic navigation (VBN) combined with endobronchial ultrasound (EBUS) for diagnosing peripheral pulmonary lesions.

Methods: Enrolled subjects were patients with pulmonary lesions which were deemed too small and peripheral for a conventional bronchoscopy sampling, who were referred to Kameda Medical Center for diagnostic bronchoscopy between September 2010 and February 2012. VBN was utilized to produce a pathway into the target lesion. Once the fiberoptic bronchoscope was advanced as far as possible in this pathway, a guide sheath with EBUS probe was then advanced to the target lesion under fluoroscopic guidance. After fluoroscopy guidance of the lesion by EBUS, the probe was removed leaving the guide sheath in place. Samplings were then performed through the guide sheath under fluoroscopic guidance.

Results: Study subjects included 58 patients with 62 lesions, mean age 68 years.

The mean lesion size was 20 mm in diameter. Bronchi seen on VB image were highly consistent with the actual structure. The sensitivity for diagnosing malignancy was 43% and negative predictive value was 61%. Overall accuracy for diagnosis of all lesions was 69%.

Conclusion: VBN combined with EBUS is useful method for collecting samples from small peripheral pulmonary lesions and may help increase the diagnostic yield of trawbronchial samplings in diagnosing small peripheral pulmonary lesions.

P3599
Efficacy of transbronchial biopsies in diagnostics of smear-negative pulmonary TB
Ilya Sivokozov, Olga Lovacheva. Endoscopy, CTRI RAMS, Moscow, Russian Federation

Background: Around half of all cases of tuberculosis are smear-negative. In order to achieve the final diagnosis and to find a susceptibility profile of mycobacteria, bronchoscopy is used. Aim: To investigate the effectiveness of bronchoscopy in the diagnosis of smear-negative TB

Materials and methods: We analyzed 99 cases of smear-negative, therapy-naive patients with pulmonary TB without cavity according to chest CT. All of them undergo a bronchoscopy with bronchial swabs with/without brush-biopsy of targeted bronchi. We analyzed further dataset: results of cytological examination of brush-biopsy (acid-fast bacilli detection, components of specific granuloma,

Adil Zamani
Pulmonary Medicine, Memam Medical Faculty, Konya University, Konya, Turkey

Background: Significant bleeding may occur following forceps biopsy or brushing of necrotic or hypervascular tumors in the airways. In some cases, such methods as endobronchial instillation of iced saline lavage and epinephrine may fail to control the bleeding.

Objective: To describe and assess the efficacy of a new bronchoscopic technique using intratumoral injection of tranexam acid (IIT) for control bleeding during biopsy procedure.

Methods: IIT was performed in those patients who had endoscopically visible tumor lesions with continued active bleeding following the first attempt of bronchoscopic sampling (forceps biopsy or endobronchial needle aspiration). Tranexam acid (TEA) in dose of 250-500 mg was injected through a 22-gauge Wang cytology needle (MW-122) into the lesion. After 2-3 minutes of waiting, multiple forceps biopsy specimens were obtained from the lesion.

Results: Between Oct 2009 and Jan 2012, 14 male patients (mean age, 61 yrs; range, 41-80 yrs) underwent bronchoscopy IIT. Two patients with drug-eluting stents were on continuous dual antiplatelet therapy (aspirin plus clopidogrel). Multiple (3 to10; mean, 5.7) and deep biopsy specimens were obtained from the lesions without producing active bleeding. The following histopathologic diagnoses were made: squamous cell carcinoma (n=9), non-small cell lung cancer (n=3), and small cell carcinoma (n=2). There were no side effects observed with TEA.

Conclusion: Bronchoscopic IIT is a useful and safe technique for controlling significant bleeding due to forceps biopsy procedure, and might be suggested as a prebiopsy injection for endobronchial necrotic or hypervascular tumors.

P3601 Comparison of conventional forceps biopsy and cryobiopsy in endobronchial lesions
HasseReza Jabbadarami1, Ramin Sami1, Arda Kiani2

Background and objectives: Forceps biopsy has long been the standard method of extracting samples from endobronchial lesions, however diagnostic yield of the specimen obtained by this method<72% is not very desirable due to small size and artifact. Therefore, in order to increase the diagnostic yield in endobronchial lesions as well as diminish the complications we evaluated a new technique called cryobiopsy using flexible cryoprobes to obtain frozen samples.

Methods: All patients with endobronchial lesion except for vascular lesions referred to Intervention ward of Masih Daneshvari Hospital were included in this study. For each patient, 6 specimens were obtained by conventional forceps, and 2 were extracted through cryobiopsy, one of them 3 seconds after freezing (CB3), and the other one 5 seconds after freezing (CB5) during the bleeding procedure, and diagnostic yield of the samples were evaluated closely.

Results: Of all 30 patients, diagnosis was achieved for 27 patients (90%). Diagnostic rate of forceps biopsies was 67.8%, while this rate was 86% and 78% for CB3 and CB5 respectively. Although there was no significant difference between these three rates, total diagnostic yield of both CB3 and CB5 together was significantly higher than conventional biopsy (P-value=0.016). Severe bleeding requiring APC to be controlled occurred in 2 cases during CB5, while no major hemoptysis happened during forceps biopsy.

Conclusion: According to our results, obtaining at least two samples from endobronchial lesions by cryobiopsy technique can lead to a higher rate of diagnosis compared with 6 samples by forceps biopsy. However, duration of freezing 3 or 5 seconds does not have a significant impact on the quality of specimen.

P3602 Additional benefit of cryotechnique in transbronchial biopsy for histological diagnosis in interstitial lung disease (ILD)
Henrik Wurps1,2, Sergio Grif2, Henrik Behring2, Tomsten Blum3, Nicolas Schöndfeld1, Thomas Mairinger2, Torsten T. Baeza1, Wolfram Gemma3,1
1Klinik für Pneumologie, Lungenklinik Heckeshorn, HELIOS-Klinikum Emil v. Behring, Berlin, Germany; 2Department of Pathology, HELIOS-Klinikum Emil v. Behring, Berlin, Germany; 3Pneumologische Klinik, HELIOS Kliniken Schwerin, Mecklenburg-Vorpommern, Germany

Background: Due to the small specimen size of transbronchial forceps biopsy, the histodiagnostic quality of the specimen is often difficult. In comparison transbronchial cryobiopsies were shown to be bigger and to contain more often and larger amount of alveolar tissue.

Methods: Since 2009, all histological results of patients suspicious of ILD (clinical signs, pulmonary function, CT-scan-criteria) who underwent bronchoscopy with transbronchial forceps- and cryobiopsy were analysed concerning the impact of the additional use of cryotechnique.

Results: We evaluated 34 cases of patients (age 60.0±13.2 years) who underwent forceps- and cryobiopsy. For 10 patients (29.4%) neither forceps- nor cryobiopsy assured a histological diagnosis. In 11 cases (32.4%) both methods assured a diagnosis. In 12 cases (35.3%) a histological classification was found only in the cryobiopsy, in 1 case (2.9%) only in the forceps biopsy.

Conclusion: By additional use of the cryprobe in transbronchial biopsy, in this prospective case series up to today we were able to increase the amount of ensured histodiagnostic diagnoses in ILD from 12/34 = 35.3% without cryobiopsy to 23/34 = 67.6% with cryobiopsy. This shows the high potential of cryotechnique as a tool in transbronchial biopsy in the diagnostic of ILD.

P3603 In vivo probe-based confocal laser endomicroscopy in chronic diffuse parenchymal lung disease
Mathieu Salam1,2, Stéphane Domoinique1, Francis Rousse1, Anne Genevieve3, Vincent Jouenueux4, Gérard ZALCMAN5, Luc Thibeville1,2, Clinique Pneumologique, Rouen University Hospital, Rouen, France; 2Quant.I.F - LITIS KA 4108, Rouen University Hospital, Rouen, France; 3Department of Pathology, Rouen University Hospital, Rouen, France; 4Department of Radiology, Rouen University Hospital, Rouen, France; 5Department of Pneumology, Amiens University Hospital, Amiens, France; 6Department of Pneumology, Cuen University Hospital, Cuen, France

Diagnosis of diffuse parenchymal lung diseases (DPLD) is challenging and requires a multidisciplinary approach. Probe-based confocal laser endomicroscopy (pCLE) enables microimaging of the distal lung in vivo.

Objective: To describe pCLE features in DPLD patients.

Methods: pCLE was performed in 52 patients (mean age 67.6 years) who underwent forceps biopsy and/ or cryobiopsy. Furthermore, 21 healthy volunteers (HV) were investigated by pCLE. Results were compared between HV and each of the pathologic groups, blinded to the diagnosis (Fisher’s exact test and Bonferroni correction). The association between the pCLE and CT-scan features was assessed using multivariate analysis.

Results: 9 of the 17 pCLE descriptors were significantly more frequent in DPLD patients than in HV (131 areas) by the 20-Chromosome of bronchial cells, convoluted alveolar elastic fibers, alveolar nodules; in idiopathic pulmonary fibrosis (n=8, 36 areas) by interalveolar septal fibers and a rigid acinar elastic network; hypersensitivity pneunonitis (n=6, 34 areas) by bronchial and alveolar cells; non-specific interstitial pneumonia (n=6, 38 areas) by fluorescent bronchial cells, septal fibers and a rigid network; asbestosis (n=10, 72 areas) by alveolar mouths <200 μm, alveolar fibers >20 μm, septal fibers, and a rigid and dense acinar elastic network; systemic sclerosis (n=8, 38 areas) by fluorescent alveolar cells, septal fibers and a rigid network. HRCT honeycombing was associated to pCLE large alveolar mouths and a disorganized elastic network; both interlobar septa thickening and cysts were associated to the presence of septal fibers using pCLE.

Conclusion: pCLE could be added to the multidisciplinary discussion for the etiological diagnosis of DPLD.

P3604 Retrospective study of transbronchial cryobiopsy (TCB) data in a case series of 20 patients with interstitial lung disease
Sebastian Böing1, Lars Hagmeyer2, Sven Stieglitz2, Christina Priegnitz2, Winfried Randerseth1. Institute for Pneumology, University Witten/Herdecke, Solingen, Germany

Introduction: So far surgical lung biopsies are the state-of-the-art technique to ensure histological data in patients with interstitial lung disease. We analyzed whether histological specimens obtained by TCB could contribute to establishing the definite diagnosis and whether the procedure is a safe one.

Methods: A series of 20 patients showing interstitial patterns in high-resolution computer tomography underwent the procedure of TCB. In all patients, 2-3 biopsies were performed and 13.2 years) who underwent forceps- and cryobiopsy.

Results: In 16/20 (80%) the pathological findings correlated well with the other suspected diagnosis according to clinical, serological, radiological and bronchoalveolar lavage fluid evaluation findings. In 4/20 (20%) patients the diagnosis
remained doubtful after TCB so that these patients were subsequently forwarded to video-assisted thoracoscopic biopsy. In 3/4 (75%) of these cases the surgical approach and the TCB specimen showed the same histological pattern, therefore leading to a definite diagnosis. Regarding the study of the studied procedures in 4/20 (20%) patients an iatrogenic pneumothorax occurred after TCB, endobronchial bleeding was severe in 1/20 (5%) cases and moderate in 11/20 (55%) cases. Bleeding in all patients could be stopped by endoluminal application of adrenaline.

Conclusions: TCB seems to be a suitable minimal-invasive tool in the diagnostic work-up of IFL-patients with a moderate peri-procedural risk.

P3607
Diagnostic approach of lung malignancies through CT-guided percutaneous needle cytology and biopsy
C. Ribeiro 1, G. Ladeira 1, G. Ladeira 2, Ana Oliveira 1, Manuela Vazanelle 1, Tiago Pereira 1, Barbara Parente 1, 2 Pulmonology Department, Centro Hospitalar de Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 2 Radiology Department, Centro Hospitalar de Vila Nova de Gaia, Vila Nova de Gaia, Portugal

Background: The use of CT-guided percutaneous needle procedures is well established in the diagnostic approach of suspected lung malignancy.

Aim: To evaluate the efficacy and the complication rate of these procedures.

Methods: A retrospective study of patients submitted to thoracoscopic needle cytology/core biopsy for suspected lung malignancy in a 2 year period.

Results: We assessed 129 episodes concerning 117 patients (213 punctures), 76% male, mean age 65.4 years. Most common localizations were RUL 35.7% and RIL 22.5%. 55% had other lesions.

Cytology was performed in all patients; core needle biopsy was needed in 23.3%. 107 patients have a definite diagnosis (malignancy in 83.2%) of which 63.6% were done as an extemporaneous exam. The most frequent diagnosis was lung adenocarcinoma (36.4%) and NSCLC (12.1%).

We assessed 15 episodes of pneumothorax (7% of punctures), 3 needle aspiration and 1 tube drainage, 3 small hemorrhagic episodes and 1 hemoptysis. The distance to the chest wall significantly affected the presence of pneumothorax (3.8 vs 17.6mm; p<0.01).

Nodules that were diagnosed as cancer were statistically bigger than non malignant lesions (51.7 vs 33.8 mm) (p=0.01). Big nodules had a higher need of core needle biopsy in order to obtain a diagnosis (p=0.01).

The presence of caviation or ground glass opacification did not interfere with diagnostic accuracy.

Conclusions: CT-guided percutaneous lung punctures are important tools in the diagnostic approach of lung malignancies with a low rate of complications. The possibility of having a pathologist to provide an extemporaneous exam speeds the diagnosis and reduces the need for further invasive diagnosis and iatrogenic damage.

P3608
Role of bronchial artery embolisation in chronic recurrent haemoptysis
Jayashri Bhattacharjya 1, Kamal Pathak 2, M. S. Bhatia 1, CDS Katech 3

Introduction: Bronchial artery embolisation (BAE) involves selective bronchial artery angiography, followed by embolisation of identified abnormal vessels. It is well used in massive haemoptysis. But there are only a few literatures on its use in chronic recurrent haemoptysis.

Aims and objectives: To assess the efficacy and safety of BAE in the management of chronic recurrent haemoptysis.

Methods: This is a retrospective study of all patients with chronic recurrent haemoptysis who underwent BAE between January 2007 and January 2012 in a tertiary care hospital. The decision to offer BAE and its timing was jointly made after assessment by respiratory physician and interventional radiologist.

Results: 63 patients, (39 males and 24 females), underwent BAE for chronic recurrent haemoptysis during the period of study. Mean age of patients was 32.5 years (range: 18-81 years). Maximum number of patients recruited in this study had active pulmonary tuberculosis (29 cases – 46.0%). Amongst them, five patients had MDR, and one case had XDR-TB. 18 (28.5%) patients had bronchiectasis. Malignancy was the cause of haemoptysis in 7 (11.1%) cases. Mycetoma was present in 5 (7.9%) cases. One patient (1.5%) had lung abscess. BAE was successful in 58 (92.1%) cases. Bleeding stopped in 3 more patients following repeat procedure within a period of 48 hours. There was no major complication. Three patients had a short period of self limiting febrile illness. Three other patients developed local haematoma which improved following compression of the local part.

Conclusions: BAE is an effective means of controlling chronic recurrent haemoptysis. It is also a safe procedure.

P3609
Bronchial artery embolization in chronic recurrent haemoptysis: A multicenter study in 218 cases
Maria Dimasi 1, Katerina Dimakou 2, Sofia Tasli 1, Maria Salomidou 1, Melita Nikolopoulou 1, Demostenis Antoniou 1, Andreas Ananasitosopoulos 1, Ilias Igloussis 1, Maria Pomoni 1, Katerina Malagari 3, 1 11th Pulmonary Department, "Sotiria" Athens Chest Hospital; Athens, Greece; 2 11th Pulmonary Department, "Sotiria" Athens Chest Hospital, Athens, Greece; 3 Radiology, University of Athens, Greece

Aim: To evaluate the sort and long term results in control of massive and chronic recurrent hemoptysis in 218 patients with special microspheres (embospheres).

Material and methods: Fifty six patients with massive and 162 with chronic recurrent hemoptysis were included. Microspheres were used to achieve distal embolization with precisely calibrated microspheres of hydrogel core and polyezene
cover, sized 300-400μm in more than 500μm if antenguted shunting were seen. The mechanical properties of these spherical particles prevent aggregation and clogging allowing more optimal embolization and accurate choice of the diameters of vessels to be occluded.

REULTS: The most common cause of hemoptysis was bronchectasis in 126 (58%) of patients, of whom 27 (12.4%) had cystic fibrosis, followed by lung cancer in 27 (12.4%), tuberculosis cavities in 14 (6.4%), mycetomas in 3 (1.6%), fibrotic tumor in 2 (1.6%), bullae cyst in 5 (2.3%), Takayasu arteritis in 1 (0.5%), arteriovenous malformation in 1 (0.5%) and cryptocogenic in 19 (8.7%) cases. Non bronchial collaterals were embolized in 36 (16.6%). Successful control of the hemoptysis was seen in 89% after the 1st session and in 94% after the 2nd. Mean follow up period was 3.7 years. In cystic fibrosis bronchecsis the overall recurrence was 36%, with a mean time to recur 26.2 months, whereas without cystic fibrosis recurrence was 11%, in amean time of 3.3 years.Major hemoptysis free rate was 92.2%, 83.3% and 69.6% at 1, 3 and 5 years respectively. Fever was seen in 3.6% and transient chest pain in 12.4% of cases.

Conclusion: The management of massive and chronic recurrent hemoptysis is safe and successful using precisely calibrated embospheres.

### 387. Diffuse parenchymal lung disease I

**P3610** From basic lesions to a pathological staging of pulmonary fibrosis

Irina Stoia Djeska

1Pneumology, University of Medicine and Pharmacy, Timisoara, Timis, Romania; 2Histopathology, University of Medicine and Pharmacy, Timisoara, Timis, Romania; 3Thoracic Surgeons, University of Medicine and Pharmacy, Timisoara, Timis, Romania

**Introduction:** Pulmonary fibrosis is characterized by some morphological basic lesions which are associate to different degrees at the time of diagnosis. Based on this issue, a pathological staging of pulmonary fibrosis could be helpful to predict the evolution and the response to therapy.

**Material and methods:** We have quantified the severity of lesions on 20 patients with lung fibrosis namely: the aspect of the pulmonary parenchyma, the presence and density of the inflammatory infiltration, the density and distribution of the collagen fibres and variable evolution and four cases (20%) of degree II (4-6) were more likely to remain stable. Collagen fibres were not organized in fascicles.

**Results:** Four cases (20%) of degree IV (10-12) had a poor survival. There were found major changes of the parenchyma, extended nodular fibrosis and inflammatory infiltration as a marker for progressive evolution. Twelve cases (60%) of degree III (7-9) showed collagen fibres in homogenous fascicles and variable evolution and four cases (20%) of degree II (4-6) were more likely to remain stable. Collagen fibres were not organized in fascicles.

**Conclusion:** Histological score could represent a useful tool in the evaluation of pulmonary fibrosis and reflects its heterogeneity. Our results suggest that the actual scoring system of pulmonary fibrosis can be improved, to give more precise information about clinical outcome.

**P3611** Th1/Th2/Th17-related cytokines in the bronchoalveolar lavage fluid of patients with sarcoidosis in relation to smoking

Tomasz Urbankowski

1Histopathology, University of Medicine and Pharmacy, Timisoara, Timis, Romania; 2Thoracic Surgeons, University of Medicine and Pharmacy, Timisoara, Timis, Romania

**Introduction:** Sarcoidosis (SA) is a multiorgan granulomatous disease. The inflammatory process in involved organs is characterized by Th1/Th2 imbalance and participation of Th17 cells, what was recently documented. SA is more prevalent among non-smokers than in smokers, however the impact of cigarette smoking on inflammation in SA remains unclear.

**Methods:** The aim of the study was to evaluate the Th1/Th2/Th17-related cytokine concentrations in bronchoalveolar lavage fluid (BALF) of patients with pulmonary SA in relation to smoking status. 61 SA patients were investigated (26 ever (S) and 35 never-smokers (NS)). The concentrations of IL-17A, INFγ, TNFα, IL-10, IL-6, IL-4 and IL-2 were measured by flow cytometry using Cytometric Bead Array method. The concentrations of TNFα, IL-10, IL-4 and IL-2 were below minimum of detection in most cases. There was significant correlation of INFγ concentration with number of macrophages and between IL-6 concentration with number of neutrophils (R=0.6, P<0.05, r=0.3, P<0.05, respectively).

**Results:** We found higher concentration of INFγ and lower of IL-6 in S than in NS (1.28 ± 1.6 vs 2.38, respectively, different very significant). The mean concentration of IL-17A was 6.1 pg/mL and did not differ between S and NS. There was significant correlation of IL-17A with IL-6 concentration (R=0.9, P<0.05) in the whole group and in S group. The concentration of IL-6 correlated negatively with the results of pulmonary function tests.

**Conclusion:** Our observation shows a slightly different profile of cytokine concentration in the BAL of smoking patients with SA. The lack of significance may be related to the short smoking history of patients.

**P3612** Validation of a novel prognostic tool for idiopathic pulmonary fibrosis

Merven E.M. Wilkie

1Dept. of Gene Therapy, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz; 2Laboratory of Molecular Diagnostics and Immunology, Institute of Tuberculosis and Lung Diseases, Warsaw; 3Dept. of Lung Diseases and Tuberculosis, Collegium Medum, Nicolaus Copernicus University, Bydgoszcz, Poland

**Introduction:** Idiopathic pulmonary fibrosis is a progressive disease with a median survival of 2-3 years. There is no universally accepted tool for identifying individuals with a poorer prognosis. du Bois et al proposed a 4 point scoring system to predict 1 year mortality. This tool requires external validation.

**Methods:** Data was collected on 94 consecutive patients with IPF. The du Bois score was calculated based on age, respiratory hospitalisation, baseline forced vital capacity (FVC) and 6 month change in FVC. The predictive value of the score was assessed using the area under the receiver operator characteristic curve (AUC). Patients were followed up for at least 3 years or until death.

**Results:** Median age was 69 years (interquartile range 64-76). 74.7% were male. 1 year mortality was 10.6%. The 1 year mortality was 0% for those scoring 0-14 points, 11.5% for those with 15-21 points, 23% for those scoring 22-29 and 21% for those scoring >30 points.

Prediction for 1 year mortality, the AUC was 0.76 (95% CI 0.67-0.85,p=0.004) indicating moderate predictive value. For prediction of 3 year mortality, AUC was 0.72 (0.64-0.78,p=0.0005).

**Conclusions:** This study validates a novel risk score for prediction of outcome in patients with idiopathic pulmonary fibrosis.

**P3613** Expression of interleukin-27 (IL-27) in human lower airways.

Pathophysiological implications in pulmonary sarcoidosis (PS)

Piotr Kopinski1, Tomasz Wendska1, Joanna ChorzewSKA-Wynikno1, Grzegorz Przybylski1, Ewelina Polgesek1, Andrzej Dyczek2, 1Dept. of Gene Therapy, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz; 2Laboratory of Molecular Diagnostics and Immunology, Institute of Tuberculosis and Lung Diseases, Warsaw; 3Dept. of Lung Diseases and Tuberculosis, Collegium Medum, Nicolaus Copernicus University, Bydgoszcz, Poland

**Background:** Interleukin-27 was recently discovered as a cytokine secreted by antigen presenting cells, participating in T cell priming and supporting Th1 type immune polarization. IL27 expression has not been examined yet in lower airways. **Aims:** Identification of IL27 sources in human lower airways. Preliminary assessment of IL27 expression in bronchoalveolar lavage (BAL) in interstitial lung diseases (ILD) patients.

**Materials and methods:** Two IL27 expression in BALF of patients with systemic sarcoidosis (SA) and controls were detected by indirect phenotyping and flow cytometry in BALF cells from patients with PS (incl. steroid treated subjects), idiopathic pulmonary fibrosis (IPF) and controls, as well as in Human Lung Fibroblasts (HLF) and pneumocyte type II (A549) cell lines. IL27 extracellular secretion was tested by ELISA (cat. no E90385Ha, Diaclone) in supernatants of BALF and cell cultures.

**Results:** BAL detectable IL27 levels were shown by ELISA in 6 (median 9ng/ml) of 13 PS untreated patients. IL27 was not found in BAL supernatants of steroid-treated PS, IPF and controls. HLF and A549 and alveolar macrophages were positive for intracellular IL27. Surprisingly, IL27+ BAL lymphocytes were found in all tested groups (PS: 8.1±6.2%; IPF: 37±13.4%; controls: 46±15.8%, median±SEM, insignificant).
Conclusions: In physiological conditions, IL27 is produced in lower airways by lung fibroblasts, epithelial and BAL immune cells, including lymphocytes. Its increased expression in PS suggests IL27 to play a role in I LD pathophysiology, probably as Th1 activity marker.

P3614
Pulmonary graft-versus-host disease (GVHD) post- stem cell transplant (SCT) for haematological malignancies: Good response to treatment if diagnosed early
Bharathirajase Jeyaraman1, F. Begum2, K. Raj1, H. Milburn1. 1Department of Respiratory Medicine, Guys Hospital, Guy’s & St Thomas’ NHS Trust, London, United Kingdom; 2Medicine, Kings College, London, United Kingdom

Introduction: Grafl-Versus-Host Disease (GVHD) of the skin and gut are relatively common following allogeneic transplant for haematological malignancies but GVHD affecting the lung can be subtle. In this study, we evaluated patients who developed lung GVHD post stem cell transplant (SCT) to determine early warning signs and response to treatment.

Method: Patients undergoing SCT for haematological malignancies were monitored with serial pulmonary function (PFT). Symptoms of increased breathlessness (SOB) or fall in PFT prompted investigation with high resolution CT scan (HRCT).

Results: 11 patients developed lung GVHD following allogeneic SCT for lymphoma (n=7) or leukemia (n=4). 6 had adjuvant chemotherapy, and 7 total body irradiation. 10 had exertional SOB. 3 developed pulmonary GVHD within 1 year of SCT.

PFT changes are shown.

All patients had mosaicism with gas trapping on HRCT at diagnosis, and were commenced on steroids, with 6 having other immunosuppressants.

Conclusion: Exertional SOB and changes in PFT are important early indicators of developing GVHD which can be confirmed on HRCT. Treatment with immunosuppressants results in successful resolution in the majority, particularly in those who were diagnosed early in the course of this complication.

P3615
Response to physical exercise in sarcoidosis
Katarzyna Hildebrand

Department of Medicine, Pneumonology and Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland

The aim of this study was to analyze the response to exercise in untreated patients with pulmonary sarcoidosis. We recruited 39 patients (15 females) at mean age 39±4.9 years to undergo lung function testing (spirometry, bodyplethysmography, CO diffusing capacity) and symptom limited cardiopulmonary exercise test on a treadmill. Histological confirmation of sarcoidosis was obtained in 64% of patients; on the basis of radiologic findings 37% of patients were diagnosed with stage I, 51% with stage II and 11% with stages III and IV. Muscle fatigue was the main reason for exercise termination (82% of patients), followed by ECG abnormalities, blood pressure increase or vertigo and dyspnea reported by 10% and 5% of patients, respectively. Decreased exercise tolerance (defined as V′O2peak < 82% of predicted) was diagnosed in 15 (38%). V′O2peak in patients with decreased exercise tolerance was significantly lower than in patients with normal response to exercise (32.6±7.8 vs 27.2±6.6 ml O2/kg/min; p<0.05). Patients with impaired response also had a lower PaO2 at peak exercise (87±18.5 vs 100±18.6 mmHg; p=0.05) and widened alveolar-capillary oxygen gradient (17.5±10.1 vs 7.9±8.1 mmHg; p=0.05). Some significant correlations between V′O2max and FEV1% pred. (r=0.40; p<0.05), FVC % pred. (r=0.43; p=0.008), RV/TLC (r=0.41; p<0.01) were also noted.

Conclusions: Impaired exercise tolerance can affect up to 40% of patients with sarcoidosis. Lower PaO2 and widened alveolar-capillary oxygen gradient suggest an important role of gas exchange abnormalities in the pathogenesis of impaired response to exercise.

P3616
Isolated lymphocytic bronchiolitis with B cell clonality: Diagnosis in 3 cases using immunoglobulin gene rearrangement analysis
Irina Lalin1, Vincent Couton1, Françoise Thévolet-Bejou1, Françoise Berger3, Chalètra Khousa1, Baakar El Zoubi2, Gilles Salles2, Jean-François Cordier1.
1Respiratory Medicine - Reference Center for orphan Pulmonary Disease, Louis Pradel University City Hospital, Lyon, France; 2Hematology, CH Lyon Sud, Lyon, France; 3Pathology, CH Lyon Sud, Lyon, France

Background: Lymphocytic bronchiolitis is characterised by diffuse infiltration of the bronchiolar walls by lymphocytes, which may organise into germinal centres (follicular bronchiolitis). B cell clonality demonstration may result in a diagnosis of low- grade B-cell lymphoma.

Patients and methods: Patient #1: 59-yr old female, non-smoker, presented with chronic cough, dyspnea, sicca syndrome, negative anti-SSA/SSB antibodies, severe airflow obstruction, ground glass opacities at HRCT, and 51% of lymphocytes at BAL. Patient #2: 54-yr old female, non-smoker, presented with chronic cough, restrictive lung disease, diffuse micronodules at HRCT, 90% lymphocytes at BAL, monoclonal IgG lambda of 4.2 g/l. Patient #3: 66-yr old female, non-smoker, with history of rheumatoid arthritis and Sjögren syndrome, anti-SSA and -SSB antibodies, presented with hemoptysis, Bence-Jones protein, airflow obstruction, 2 lung amyloid nodules and multiple cystic lung disease.

Results: Lung biopsy with immunohistochemistry demonstrated lymphocytic bronchiolitis in all three cases with a majority of CD 20 positive B –cell. PCR-based DNA testing for immunoglobulin gene rearrangement analysis of lung biopsy demonstrated B-cell clonality in all three cases (VK-JK, FR1-JH), and low-grade MALT lymphoma was eventually diagnosed.

Conclusions: Lymphocytic bronchiolitis may correspond to low-grade MALT lymphoma which may be demonstrated by gene rearrangements rearrangement analysis.

P3617
The relationship between leptin and proinflammatory cytokines with bone mineral density in patients with sarcoidosis (pts)
Elibetra Puscumia1, Michal Bednarek1, Anna Gielins-Geremek1, Anna Kowalczyk1, Joanna Chorrostowska-Wynimko1, Paulina Jagus2, Ada Rozy1, Jack Grudyn1, Dariusz Chmielewski1, Dorota Gorecka1. 12nd Department of Respiratory Medicine, National Institute of Tuberculosis and Lung Diseases, Warszawa, Poland; 23rd Department of Lung Diseases, National Institute of Tuberculosis and Lung Diseases, Warszawa, Poland

Aim: The aim of the study was to investigate whether there is a relationship between leptin or cytokines and BMD in pts.

Methods: 85 pts, none was treated with steroids, 46M and 39F, age 41+9 years to undergo lung function testing (spirometry, bodyplethysmography, CO diffusing capacity) and symptom limited cardiopulmonary exercise test on a treadmill. Histological confirmation of sarcoidosis was obtained in 64% of patients; on the basis of radiologic findings 37% of patients were diagnosed with stage I, 51% with stage II and 11% with stages III and IV. Muscle fatigue was the main reason for exercise termination (82% of patients), followed by ECG abnormalities, blood pressure increase or vertigo and dyspnea reported by 10% and 5% of patients, respectively. Decreased exercise tolerance (defined as V′O2peak < 82% of predicted) was diagnosed in 15 (38%). V′O2peak in patients with decreased exercise tolerance was significantly lower than in patients with normal response to exercise (32.6±7.8 vs 27.2±6.6 ml O2/kg/min; p<0.05). Patients with impaired response also had a lower PaO2 at peak exercise (87±18.5 vs 100±18.6 mmHg; p=0.05) and widened alveolar-capillary oxygen gradient (17.5±10.1 vs 7.9±8.1 mmHg; p=0.05). Some significant correlations between V′O2max and FEV1% pred. (r=0.40; p<0.05), FVC % pred. (r=0.43; p=0.008), RV/TLC (r=0.41; p<0.01) were also noted.

Conclusions: Impaired exercise tolerance can affect up to 40% of patients with sarcoidosis. Lower PaO2 and widened alveolar-capillary oxygen gradient suggest an important role of gas exchange abnormalities in the pathogenesis of impaired response to exercise.

Multi nodular parenchymal pulmonary amyloidosis in primary Sjogren’s syndrome: A case report
Ewa Sama Ovynak1, Ozlem Canno2, Fatih Kurnaz2, Mustafa Cakal1.
1Department of Chest Diseases, Erciyes University Medical School, Kayseri, Turkey; 2Department of Pathology, Erciyes University Medical School, Kayseri, Turkey

Lymphocytic bronchiolitis may correspond to low-grade MALT lymphoma which may be demonstrated by gene rearrangements rearrangement analysis.

Results: Pts with low BMI had decreased lumbar spine BMD(T–score<-1). The differences were statistically significant for group with normal BMI(18.5-BMI<25), compared to overweight(25-BMI<30), p=0.045 and to obese (BMI>30), p=0.0005. There were no such results for femoral neck BMD. The highest values of leptin were found in pts with obesity. The differences between pts with normal BMI compared to those with obesity was statistically significant (p=0.026). There was a weak correlation between leptin and BMI, R=0.2, leptin and IL-1, R=0.27, leptin and phosphate in urine, collected over 24h, R=0.31. No correlation was found between leptin and TNF-a or IL6.

Conclusions: In our group BMD was related to BMI but not to leptin levels nor other cytokines. Obesity, through its mechanical loading effect have a protective influence on bone tissue metabolism. Leptin, cytokines have a role in bone growth, development and loss. Further research is required to ascertain the importance of adipokines or cytokines for BMD.

Amiolyodosis is a rare cause of pulmonary infiltrates in primary Sjögren’s syn-
be moderate restriction, and BAL fluid was negative for acid-fast bacilli (AFB), fungi. Bronchoscopic with transbronchial lung biopsy revealed hyaline eosinophilic material associated with a giant cell granulomatous reaction, a patchy lymphocytic infiltrate. The Congo red stain was positive in this hyaline material and showed apple green birefringence on polarising microscopy. Electrophoresis of serum proteins revealed a monoclonal IgG. In the bone marrow (BM) plasma cells were increased to 10-15%. PSA (AL) associated with SS was diagnosed. Amyloid deposits were found not only in the lung but also in skin and BM biopsy specimens. Staining for amyloidosis should be performed in patient with SS and pulmonary infiltration.

P3619
Sarcoidosis is a frequent benign cause of lymphadenopathy in neoplastic patients
Claudia Ravaglia, Carlo Gurioli, GianLuca Casoni, Riccarda Romagnoli, Sara Tomssetti, Christian Gurioli, Poletti Venerino.
Pulmonology Unit, Department of Thoracic Diseases, Pierantoni-Morgagni Hospital, Forlì, FC, Italy

Background: Clinical and radiographic aspects of sarcoidosis and malignancy might mimic one another, making the distinction between the two difficult in some cases. Cancer and sarcoidosis have been associated in some case series from the literature but this association remains controversial. Objectives: A descriptive retrospective study to evaluate the incidence of sarcoidosis in patients followed-up for previous cancer and referred for hilar/mediastinal lymphadenopathies, with no pulmonary lesions.

Methods: We conducted a retrospective chart review of all patients who were referred to our pulmonology department in the period between January 2007 and December 2011 with a new onset hilar/mediastinal lymphadenopathies during follow-up for previous neoplasms.

Results: Forty-eight patients (31 males, 17 females) of mean age 63 years (range 20-81) underwent EBUS/EUS trans-bronchial needle aspiration (TBNA). Patients were referred to our pulmonology department between January 2007 and December 2011 with a new onset hilar/mediastinal lymphadenopathies during follow-up for previous neoplasms.

Results: Forty-eight patients (31 males, 17 females) of mean age 63 years (range 20-81) underwent EBUS/EUS trans-bronchial needle aspiration (TBNA). Patients were referred to our pulmonology department between January 2007 and December 2011 with a new onset hilar/mediastinal lymphadenopathies during follow-up for previous neoplasms.

Conclusions: Our study suggests that sarcoidosis should be considered in the differential diagnosis of patients with a history of malignancy who develop hilar/mediastinal lymphadenopathies; a tissue diagnosis should be obtained before instituting therapy for presumed cancer recurrence.

P3620
Clinical study of pulmonary hypertension complicating pulmonary Langerhans cell histiocytosis
Weilig Han1, Leping Deng1, Zuluan Jin2, Chen Wang3, 1Department of Respiratory and Critical Medicine Care, Beijing Chaoyang Hospital, Beijing, China; 2Department of Pathology Medicine, Beijing Chaoyang Hospital, Beijing, China; 3Beijing Hospital, Health Ministry, Beijing, China

Objective: To study the clinical features of pulmonary hypertension (PH) complicating pulmonary Langerhans’ cell histiocytosis (PLCH).

Methods: Medical records of 11 PLCH patients were reviewed from June 2006 to June 2011.

Results: 4 of the 11 PLCH patients presented PH with more severe clinical presentations. The major symptoms were laboring dyspnea and diminished exercise capacity (NYHA functional class III/IV), which were complicated with the sigh of right heart failure. The cystic change and pulmonary artery/main artery >1 were predominated on chest high-resolution computed tomography. Right heart enlargement was also found. As to pulmonary function presentation, the patients displayed severe carbon monoxide diffusing capacity impairment and significant hypoxemia. The pulmonary artery systolic pressure were highly increased. Besides the clinical symptoms, the laboratory features presented, involvement of both arteries and veins was also observed. Oxygen and symptomatic therapy were essential in the part of clinical treatment. 3 of the 4 PLCH-PH received corticosteroids or immunosuppressive agents, but the effect was not ideal. Only one case of PLCH-PH have a stable condition.

Conclusion: Pulmonary hypertension is a common complication of PLCH and seems to predict a poor prognosis. It is necessary to derive an early diagnosis and prevention.

P3621
BAL findings in idiopathic NSIP and IPF
Mirella Romagnoli, Claudia Ravaglia, Sara Tomatsetti, Christian Gurioli, Carlo Gurioli, GianLuca Casoni, Poletti Venerino.
Phlebitis Thoracic Diseases, Pulmonology Unit, Forlì, Italy

The role of bronchoalveolar lavage (BAL) in differentiating idiopathic NSIP (i-NSIP) and idiopathic pulmonary fibrosis (i-IPF) is still controversial. Some authors described that BAL lymphocytosis is more likely suggestive of NSIP rather than IPF. Others stated that BAL neutrophilia is more suggestive of IPF, whereas other authors reported that BAL findings are not discriminating between NSIP and IPF.

BAL findings were retrospectively assessed in 57 patients, 26 with a histologically proven diagnosis of iNSIP (surgical lung biopsy n=19, criobiopsies n=7), and 31 with a diagnosis of IPF. BAL was obtained before lung biopsy, or at the first patient evaluation for some of the IPF patients. All patients underwent bronchoscopy during stable clinical conditions, and BAL excluded malignancy and/or infections before BAL. Total and differential cell counts did not differ between iNSIP and IPF.

Seventeen of the 26 iNSIP patients (65.3%) and 20 of the 31 patients with IPF (64.5%) displayed severe carbon monoxide diffusing capacity impairment and significant hypoxemia. The pulmonary artery systolic pressure were highly increased. Besides these classical symptoms, the laboratory features presented, involvement of both arteries and veins was also observed. Oxygen and symptomatic therapy were essential in the part of clinical treatment. 3 of the 4 PLCH-PH received corticosteroids or immunosuppressive agents, but the effect was not ideal. Only one case of PLCH-PH have a stable condition.

Conclusion: Pulmonary hypertension is a common complication of PLCH and seems to predict a poor prognosis. It is necessary to derive an early diagnosis and prevention.

P3622
BAL markers of alveolar/capillary abnormality in IPF
Emanuele Pastorelli, Alessia Comandini, Paola Rogliani, Assunta Porretta, Francesco Cavallini, Cesare Salini.
Respiratory Medicine, University of “Tor Vergata”, Rome, Italy

Several lines of evidence suggest that alveolar-capillary abnormalities, including increased alveolar sepal capacity and pulmonary vento-occlusive disease, are characterizing feature of IPF and may play a role in its progression. This study assess altered capillary permeability, abnormal intra-alveolar coagulation and alveolar hemorrhage as markers of alveolar/capillary abnormality.

Methods: Bronchoalveolar lavage (BAL) samples from 62 subjects (53 IPF patients and 14 healthy volunteers) were evaluated for s-alveolar macrophagin (s-AM) and f-alveolar macrophagin. All patients were studied by EBUS/EUS by linear approach.

Results: 26-12.6 BAL total and differential cell counts did not differ between iNSIP and IPF. The median (range) lymphocytes% was 11.5 (2-75) in iNSIP, and 7 (1-48) in IPF; the median (range) neutrophils% was 10.5 (0-59) in iNSIP and 20 (1-83) in IPF. In the iNSIP group (age 56±12 years) patients were significantly younger than in IPF (age 70±6; p<0.001), with a predominance of females (iNSIP n=17, IPF n=22) and 15 patients in the IPF group (48%) died during follow up. BAL findings were based of survival of changes in lung function.

Conclusion: BAL findings are not helpful to discriminate the diagnosis between iNSIP and IPF patients. However, these data suggest that there might be different clinical-biological phenotypes in both iNSIP and IPF patients.

P3623
Survival after surgical lung biopsy in patients with a histological pattern of non specific and usual interstitial pneumonia
1Department of Pulmonology, Center of Interventional Lung Diseases, St. Antonius Hospital, Nieuwegein, Netherlands; 2Department of Pathology, St. Antonius Hospital, Nieuwegein, Netherlands; 3Department of Radiology, St. Antonius Hospital, Nieuwegein, Netherlands; 4Division of Heart and Lungs, University Medical Center, Utrecht, Netherlands

Background: Surgical lung biopsy involves a mortality risk, but is warranted to differentiate between fibrosing interstitial pneumonias with varying prognosis and response to therapy.

Objective: We evaluated 1 and 3-month mortality rate and post-operative course in patients with histopathological confirmed Usual Interstitial Pneumonia (UIP) and Non-Specific Interstitial Pneumonia (NSIP) after surgical biopsy.

Methods: Data and lung function were retrospectively collected from 1993 until 2008 from 57 patients that underwent surgical biopsy in our center that resulted in a histological pattern of UIP or NSIP. We analyzed 1 and 3-month mortality rate, post-operative hospital stay, drain removal, prolonged air leak and infectious complications.

Results: 1-month mortality rate was 5.1% (2/39) for UIP versus 0% (0/18) for NSIP. 3-month mortality rate was 10.2% (4/39) for UIP versus 0% for NSIP. No significant differences were observed in outcome measures. Notably, the NSIP...
group had a worse pre-operative lung function than the UIP group. Mean forced expiratory volume in 1 second (FEV1) was 71% percent of predicted in NSIP versus 82% in UIP (p < 0.005) and NSIP had a lower mean diffusing capacity of the lung for carbon monoxide (DLCO) of 41% versus 51% in UIP patients (p < 0.002).

**Conclusion:** After lung biopsy 3-month mortality in fibrosing interstitial pneumonias is relatively high (7%) and the majority (68%) of biopsies resulted in a UIP pattern. Four patients died within 3 months after biopsy all with a UIP pattern corresponding with a diagnosis of Idiopathic Pulmonary Fibrosis. This is remarkable because they had a significantly better pre-operative lung function.

### P3624

A newly developed sling incorporating a shock absorber to minimize the motion effect on SpO2 during the 6-minutes-walk test

**Katsi Miyamoto, Yuya Tanaka, Toshiaki Kurimoto. Department of Rehabilitation, Faculty of Health Sciences, Hokkaido University, Sapporo, Japan**

Recently, the degree of desaturation during 6-minute walk test (6MWT) is considered to have prognostic value in patients with idiopathic pulmonary fibrosis. In this study, we demonstrate a negative effect of motion on SpO2 during the walking and present a newly developed device that minimizes the negative effect during the test.

**Subjects and methods:** Ten healthy volunteers (26±11 yrs) performed 6MWT in 4 different manners: 1) usual walking, 2) usual walking while trying to minimize the effect of motion on the finger on which the oximeter-probe was placed, 3) usual walking using a newly developed sling with a shock absorber (75%) wrapped around the finger and the probe, and 4) walking on a treadmill at the same speed as the usual 6MWT while the finger and the probe were in a resting position without movement. SpO2 was measured continuously using a Pulsox 300i (Konica-Minolta)

**Results:** During the usual walking with/without the moving finger, there was severe desaturation of more than 4% from the baseline. However, when walking with the new device or on the treadmill there was only a small change in the SpO2 which was within the accuracy of the oximeter.

**Motion effects on SpO2**

<table>

**Conclusions:** SpO2 monitoring during 6MWT does not provide reliable data on desaturation. However, using the new device, more reliable data on desaturation are available.

### P3625

Effects of lymphadenopathy on pulmonary function tests in sarcoidosis

**Onur Aran1**, **Ebis Yılmaz Çevik2**, **Yener Aydın2**, **Mehmet Meral1**, **Yusuf Bilgen1**, **Fatih Alper5**, **Ali Metin Görgün1**, **Metin Akgan1**, **Chest Department, Atatürk University, Erzurum, Turkey; 2Thoracic Surgery, Atatürk University, Erzurum, Turkey; 3Internal Medicine, Atatürk University, Erzurum, Turkey; 4Radiology, Atatürk University, Erzurum, Turkey**

**Background and objectives:** The pulmonary function test (PFT) is an important examination in the follow-up of sarcoidosis. We aimed to investigate the effect of the presence of lymphadenopathy (LAP) alone or after controlling parenchymal involvement in PFT.

**Materials and methods:** A total of 63 sarcoidosis patients were enrolled retrospectively in the study. Respiratory functions were evaluated via PFT. Radiological evaluations of the patients were done with chest x-ray and high-resolution computed tomography (HRCT). Bronchoscopy investigations were performed on all patients. Possible factors that affect PFT were evaluated.

**Results:** There is statistically significant correlation between the bronchoscopic findings and PFT parameters (p < 0.01). Forced vital capacity (FVC) was affected more in the presence of LAP in bronchi neophants, it was more or less the same for forced expiratory volume in the first second (FEV1). Considering grade of HRCT findings, there is a statistically significant relation between FVC, FEV1, and the presence of hilar LAP, intrahilar LAP and lobar LAP (p=0.001). There is a statistically significant correlation with the presence of micronodules in HRCT and all parameters of PFT. There is a statistically significant negative correlation between the radiological stage of sarcoidosis and FVC, FEV1.

**Conclusion:** We revealed that besides parenchymal involvement of the disease, special localization of lymph node involvement also has an important effect on the PFT parameters of sarcoidosis patients.

### P3626

Airway-centered interstitial fibrosis – Two case reports

**Vitor Meda, Maria Sousa, Jessica Jones, Ana Campos, Simões Torres. Pneumology, Hospital São Teotonio, Viseu, Portugal**

Airway-centered interstitial fibrosis (ACIF) is a rare interstitial lung disease (ILD) of unknown cause characterized by chronic cough and progressive dyspnea and history of inhaled exposure. There is progressive peribronchial infiltration of interstitial inflammation and fibrosis with bronchiolar metaplasia. The majority of patients are non-responsive to corticotherapy and prognosis is poor. We describe two female patients, 65 and 66 years, presenting with chronic dry cough and progressive dyspnea. They were non-smokers, farmers and with a history of inhaled exposure to birds. Pulmonary function tests showed a moderate obstructive pattern in one case and moderately decreased CO diffusion in both patients. Chest radiographs revealed diffuse reticulonodular infiltrates. Chest computed tomography (CT) showed reticular fibrosis and ground glass infiltrates in one case and a UIP pattern in the other. Bronchoalveolar lavage showed an increase in lymphocytes and neutrophils in one case. The diagnosis was made by surgical biopsy revealing peribronchovascular lesions and lymphoplasmocytary infiltrate compatible with ACIF. Treatment with oral steroids for 12 months in both patients. In one case the disease progressed with worsening symptoms, pulmonary function tests and CT imaging even after combined immunosuppression with Azathioprine. In the other case the patient’s symptoms and CT imaging improved. These cases had similar clinical, radiological and pathological features as most of the few cases reported in literature. Both were non-smokers but had been exposed to birds. However, disease progression varied considerably as one patient improved but the other worsened even after combined immunosuppression.
P3629
The markers of inflammatory process activity and fibrinogenesis activity in patients with idiopathic pulmonary fibrosis
O.V. Karas'ova, E.S. Khmel, E.N. Kovalenko, V.V. Rodionova. Hospital therapy and Prophylaxis, Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine

Purpose: To define the inflammatory markers and severity of idiopathic pulmonary fibrosis (IPF).

Methods: There were examined 29 patients with IPF (men - 21, women - 8) in the age of 35 - 57 years. Duration of disease was from 2-3 months till 2-3 years. Control group included 10 practically healthy persons (donors).

Methods: Common clinical methods, X-ray examination, definition of hemostasis parameters. The hardphase method of immune analysis was used for measuring level of plasma fibronectin (PFN) and lavage fibronectin (LFN). Patients had been examined during the period of disease aggravation.

Results: Patients with IPF had increased level of PFN and decreased activated blood recalcification time (ABRT) (p < 0.05). The level of PFN was 319,211 ± 0,5482 and r=0,4969; p =0,05). Severity of patients condition correlated with increased level of PFN.

Conclusions: Revealed inflammatory markers and changes in hemostasis system testify about activation of fibrinogenesis and forming of chronic disseminated intravascular coagulation.

P3630
Hypersensitivity pneumonitis by feather duvet: A series of Vall d’Hebron Hospital
Ferran Morell, Ana Villar, Susana Gomez-Olles, Maria Jesus Cruz, Maria Dolores Untoria, Xavier Muñoz. Respiratory, Hospital Vall de Hebron, Barcelona, Spain

Introduction: Exposure to avian proteins is a frequent cause of Hypersensitivity Pneumonitis (HP). We describe a series of HP secondary to exposure to feather duvet.

Material and methods: In the outpatient clinic of interstitial lung disease during the years 2004-2011, 28 patients were diagnosed with HP with definite causality from exposure to feathers contained in the feather duvet. Diagnosis criteria: diagnosis of HP, contact with feather duvet coincident with the onset of symptoms; IgG + and/or positive bronchal challenge test (BCT). In neither case had history of exposure to any agent known as a producer of HP.

Results: 15 male; mean age 59 years. Presentation was acute in 5, subacute in 4 and chronic in 19 cases. Anosultation was normal in 10 patients, revealed crackles in 17 and wheezing in 1. PEC mean was 67.57%. DLCO 52.60%. IgG + in front of avian antigens in 11/24, and in front of fungi in 16/24. A culture of feather duvet was positive for fungi in 6 cases. The BCT was positive in 8/11 in front of avian antigens and 47% against fungi. Pathological study was performed in 16/28 patients, showing a characteristic pattern of subacute HP in 6/16, consistent with HP in 8/16 and UIP pattern in 2/16. Surgical lung biopsy (BPQ) was performed during the study in 7 cases and revised from the samples of another center in 7. During the follow up lung transplantation, was performed in 4 patients (2 of them already had previous BPQ).

Conclusions: Our study confirms that exposure to a minimum but persistent agent may be sufficient for disease development. Diagnosis at an advanced stage of chronic HP is common. Project funded by FIS PI101577 (ISCIII) and SEPAP 2010.

P3632
Macrolides inhibit cytokine production by alveolar macrophages in bronchiolitis obliterans organizing pneumonia
Miurul Cai1,2, Francesco Bonomo1, Hsiu-Jung Dai1,2, Rafael Sarria1, Joseun Guzman1, Ulrich Costabel1. 1Department of Pneumology and Allergology, Ruhrlandklinik, University Hospital, Essen, Germany; 2Beijing Institute of Respiratory Medicine, Beijing Chao-ang Hospital, Capital Medical University, Beijing, China; 3Department of Neurosciences, Faculty of Medicine and Dentistry, Baskue Country University, Bilhau, Spain; 4General and Experimental Pathology, Ruhr University, Bochum, Germany

Background and objective: Bronchiolitis obliterans organizing pneumonia (BOOP) is a distinct clinicopathological entity histologically characterized by intra-alveolar granulation tissue and absence of extensive fibrosic lesions. Effective macrolide treatment of BOOP has been reported anecdotally. This study aimed to investigate whether alveolar macrophages (AMs) produce aberrant proinflammatory cytokines and chemokines which may be pivotal in the disease pathogenesis. Macrolides inhibit this cytokine production, CAM more efficiently than AZM.

Methods: AMs collected from bronchialalveolar lavage (BAL) from 6 BOOP patients and 8 non-ILD controls were cultured for 24 hours in the presence or absence of CAM, AZM, lipopolysaccharide (LPS), or dexamethasone (DEX). Tumor necrosis factor alpha (TNF-α), soluble TNF receptor 1 (sTNFR1), sTNFR2, interleukin 1beta (IL-1β), IL-6, IL-8, IL-10, interferon gamma inducible protein 10 (IP-10) and CC chemokine ligand 18 (CCL18) were measured in the culture supernatant by ELISA.

Results: The spontaneous and LPS-stimulated production of all investigated cytokines by AMs was significantly increased in BOOP compared to controls. CAM and AZM induced a dose-dependent suppression of spontaneous TNF-α, sTNFR2, IL-6, IL-8 and CCL18 production (p < 0.05). CAM also inhibited the IL-1β, IL-6 production. CAM and AZM significantly and dose-dependently attenuated the LPS-stimulated production of sTNFR1, sTNFR2, IL-8 and CCL18 (p < 0.05). CAM also inhibited the LPS-stimulated TNF-α, IL-1β, IL-6 and IL-10 production.

Conclusions: AMs from BOOP patients produce abundant proinflammatory cytokines which may be pivotal in the disease pathogenesis. Macrolides inhibit this cytokine production, CAM more efficiently than AZM.

Conclusions: Although IPF was more frequent in the CPFE group than in the IP group, the occurrence of acute exacerbations after surgery was not different between the two groups.

P3633

A case of lymphoid interstitial pneumonia associated with common variable immunodeficiency

Martin Schreder1,2, Fabrizio Mezzasalma 1, Pasquale Di Martin Schreder

Case report: In October 2009, a 51 year old woman presented with a 12-months history of recurrent pyrexia and was subsequently diagnosed with CVID. CT scans showed bilateral pulmonary consolidations, while bronchoscopy revealed acute inflammation of the bronchial mucus and purulent secretion. The patient received antibiotic treatment and immunoglobulin replacement. She remained asymptomatic until January 2012, when she was readmitted with increasing dyspnea and fatigue for 2 weeks prior to admission. CT scans showed progressive opacities mainly in the lower zones. Despite immediate treatment with broad-spectrum antibiotics, the patient developed acute respiratory failure requiring invasive mandatory ventilation and, ultimately, extracorporeal membrane oxygenation. Open lung biopsy was performed 5 days after admission. Histologic workup showed diffuse interstitial infiltration of T lymphocytes, plasma cells and histiocytes, consistent with a diagnosis of LIP. Treatment with prednisone (1mg/kg) resulted in rapid clinical and radiological improvement. The patient was discharged 4 weeks after admission. At present, she remains clinically stable at a steroid dose of 0.25mg/kg.

Discussion: The finding of bilateral ground-glass infiltrates in a patient with CVID should raise suspicion of LIP. Open lung biopsy is required to establish the diagnosis.

Conclusions: The finding of nontuberculous granulomas alone is not sufficient for the final clinical diagnosis of tuberculosis. Due to high incidence of tuberculosis in our country there is a tendency to overdiagnose tuberculosis.

P3634

Disease progression according to IPF phenotype

David McAllister1, Pauline Macfarlane2, Gareth Stewart6, Andrew Robson2, Donatella Castria1, Rosa Metella Reim1, Fiztrizio Mezzalazza1, Pasquale Di Sipio1, Elena Bargaghi1, Rita Filippi1, Carlo Perle2, Paola Rottoli1, 1Department of Clinical Medicine and Immunological Science, Respiratory Disease and Lung Transplantation Section, Siena, Italy, 2Department of Cardiology, Haemodynamic Unit, Siena, Italy

Introduction: The aim of our study is(1) to evaluate the prevalence of Pulmonary Hypertension (PH) in Idiopathic pulmonary fibrosis (IPF) patients; (2) to determine the accuracy of PAP measurements with Doppler echocardiography (DE) versus Right Heart Catheterization (RHC); (3) to analyze survival in pts with or without PH; (4) to determine any correlation between functional data and haemodynamic parameters. We analyzed 54 IPF pts referred to our Centre who underwent RHC. PH was defined when PAPm ≥25 mmHg. PH was diagnosed in 30/54 pts (55%, PAPm=30±5 mmHg, PAPS=48±10, PW=11±3, RVP=3±1.2). There was a significant correlation between PAPm values at DE and RHC (r=0.0001), but Bland-Altman analysis illustrated mean difference: -5.1±4.4. The large limits of agreement (-17 +27) showed that DE should not be used to replace RHC. No difference in survival was found between PH group(1) and no PH group(2). Pts were divided according PH onset (<12 months) from IPF diagnosis: group A, or >12 m: group B) and we observed a significant difference in survival between group A and B (p=0.0042, 35m versus 56). The correlation between PH group and other pts groups (2B+, 3B, 0.0005, 35 versus 52.11% of group A needed oxygen-therapy after a median time of 8m since IPF diagnosis, while 32.76% of all other pts (group 2B+ after 16m<0.002). We observed a significant correlation between Six Min Walking test distance (WTD) performed in room air and PAPm at RHC(p=0.039).

Our data confirms that PH has an high prevalence in IPF and RHC is the gold standard for PH diagnosis. An early onset of PH is related to a worst prognosis and to a precarious oxygen-therapy request. A decrease of WTD could help clinicians to suspect PH in IPF pts.

P3637

Obstructive findings in sarcoidosis, diagnosis and therapies modalities

Jelica Videnovic-Ivanov, Snezana Filipovic, Violeta Vacunic, Vlada Zugic, Pulmonology, Clinic for Lung Diseases and Tuberculosis, Belgrade, Yugoslavia

Introduction: Symptoms of respiratory disturbances are common during the interstitial lung disease after surgery. Although IPF was more frequent in the CPFE group than in the IP group, the occurrence of acute exacerbations after surgery was not different between the two groups.

Introduction: Lymphoid interstitial pneumonia (LIP) represents a rare disease that typically occurs in association with autoimmune diseases and dysproteinemia. We report a case of LIP in a patient with common variable immunodeficiency (CVID).

Case report: In October 2009, a 51 year old woman presented with a 12-months history of recurrent pyrexia and was subsequently diagnosed with CVID. CT scans showed bilateral pulmonary consolidations, while bronchoscopy revealed acute inflammation of the bronchial mucus and purulent secretion. The patient received antibiotic treatment and immunoglobulin replacement. She remained asymptomatic until January 2012, when she was readmitted with increasing dyspnea and fatigue for 2 weeks prior to admission. CT scans showed progressive opacities mainly in the lower zones. Despite immediate treatment with broad-spectrum antibiotics, the patient developed acute respiratory failure requiring invasive mandatory ventilation and, ultimately, extracorporeal membrane oxygenation. Open lung biopsy was performed 5 days after admission. Histologic workup showed diffuse interstitial infiltration of T lymphocytes, plasma cells and histiocytes, consistent with a diagnosis of LIP. Treatment with prednisone (1mg/kg) resulted in rapid clinical and radiological improvement. The patient was discharged 4 weeks after admission. At present, she remains clinically stable at a steroid dose of 0.25mg/kg.

Discussion: The finding of bilateral ground-glass infiltrates in a patient with CVID should raise suspicion of LIP. Open lung biopsy is required to establish the diagnosis.

Conclusions: The finding of nontuberculous granulomas alone is not sufficient for the final clinical diagnosis of tuberculosis. Due to high incidence of tuberculosis in our country there is a tendency to overdiagnose tuberculosis.

P3635

Sarcoidosis and tuberculosis: A rare combination?

Diana Calara1, Oxana Manteu1, Victor Bontan1, Internal Medicine, State Medical and Pharmaceutical University "Nicolae Testemitanu", Chisinau, Republic of Moldova

Tuberculosis and sarcoidosis are chronic granulomatous diseases that are similar in many aspects, although different. They occur concomitantly very rarely. TB is an infectious disease caused by M. tuberculosis morphologically defined by granulomas with caceous necrosis. Sarcoidosis is a systemic disease of unknown etiology, and is characterized by noncaseous granulomas.

Conclusions: Patients with both definite and probable IPF have poor prognoses, but survival was worse in definite IPF. The IPF index may be of clinical value in definite and probable IPF.

P3636

Precocious detection of pulmonary hypertension in idiopathic pulmonary fibrosis

Donataella Castria1, Rosa Metella Reim1, Fiztrizio Mezzalazza1, Pasquale Di Sipio1, Elena Bargaghi1, Rita Filippi1, Carlo Perle2, Paola Rottoli1. 1Department of Clinical Medicine and Immunological Science, Respiratory Disease and Lung Transplantation Section, Siena, Italy; 2Dept. of Cardiology, Haemodynamic Unit, Siena, Italy

The aim of our study is(1) to evaluate the prevalence of Pulmonary Hypertension (PH) in Idiopathic pulmonary fibrosis (IPF) patients (pts);(2)to determine the accuracy of PAP measurements with Doppler echocardiography (DE) versus Right Heart Catheterization (RHC);(3) to analyze survival in pts with or without PH;(4)to determine any correlation between functional data and haemodynamic parameters.

We analyzed 54 IPF pts referred to our Centre who underwent RHC. PH was defined when PAPm ≥25 mmHg. PH was diagnosed in 30/54 pts (55%, PAPm=30±5 mmHg, PAPS=48±10, PW=11±3, RVP=3±1.2). There was a significant correlation between PAPm values at DE and RHC (r=0.0001), but Bland-Altman analysis illustrated mean difference: -5.1±4.4. The large limits of agreement (-17 +27) showed that DE should not be used to replace RHC. No difference in survival was found between PH group(1) and no PH group(2). Pts were divided according PH onset (<12 months) from IPF diagnosis: group A, or >12 m: group B) and we observed a significant difference in survival between group A and B (p=0.0042, 35m versus 56). The correlation between PH group and other pts groups (2B+, 3B, 0.0005, 35 versus 52.11% of group A needed oxygen-therapy after a median time of 8m since IPF diagnosis, while 32.76% of all other pts (group 2B+ after 16m<0.002). We observed a significant correlation between Six Min Walking test distance (WTD) performed in room air and PAPm at RHC(p=0.039).

Our data confirms that PH has an high prevalence in IPF and RHC is the gold standard for PH diagnosis. An early onset of PH is related to a worst prognosis and to a precarious oxygen-therapy request. A decrease of WTD could help clinicians to suspect PH in IPF pts.
course of sarcoidosis. The aim of analysis is to notice obstructive findings in sarcoidosis.

Method: The analyses is retrospective in all incoming patients to the Clinic for lung diseases and tuberculosis CC of Serbia in Belgrade.

Results: 127 (8.7%) patients with dry cough and occasionally dyspnea was the imparient of lung function. The main findings were: FEV1/FVC 63.1% in 57.44.8% patients; in 27.21.1% patients – FEV1/FVC were 55.7%, in 3.2.3% patients FEV1/FVC were 68.7%. Gender distribution were as followed: 264 (66.2%) Female-Male 135 (33.8%); average ages were 43.32 years. Extrathoracis sarcoidosis involvement were find out in 3 (2.3%) patients (skin, lymph nodes). Lung and nonpulmonary sarcoidosis is notify in 27 pts and in 97 pts lung were the only sarcoi
dosis manifestation. Radiographic stage of lung involvement: I:87 (68.5%), II:31 (24.4%), III:7 (5.5%), IV:1 (0.78%). Acute onset of sarcoidosis is predom
inantly with average level of ACE: 75.3 U/L. After obtaining the diagnosis of sarcoidosis, inhaled corticosteroids were administered, 160 mcg-daily through 3 months with controls which means: ACE and UCA/24h levels, lung function, chest X ray. Regression of symptoms such as dry cough were obtained in 55% for patients after the period of 2 months; 45% patients were excluded due to persistent of symptoms seeking prednisone.

Conclusion: Inhaled corticosteroid have the role in sarcoidosis treatment resolving symptoms such as cough, improvement of FEV1, but the main therapy in most of the patients is still orally administered prednisone.

P3638 Natural history of idiopathic pulmonary fibrosis: Are slowly progressive and rapidly progressive really steady conditions?

Elisabetta Balestero, Emanuela Rossi, Ariel Fiorianini, Claudia Rinaldo, Francesca Lunardi, Monica Loy, Federico Rea, Manuel Cosio, Marina Saetta, Fiorella Calabrese. Department of Cardiologie, Thoracic and Vascular Sciences, University of Padova Medical School, Padova, Italy

Idiopathic pulmonary fibrosis (IPF) is a devastating lung disease with heterogeneous

clinical course. Some patients experience an accelerated disease progression (rapid progressors) while other remain relatively stable over time (slow progressors).

The aim was to investigate the different course of the disease in relation to survival. The study population included 55 IPF patients (age at diagnosis 53±1) categorized in rapid progressors and slow progressors by two distinct criteria: pre-diagnosis criteria (symptoms onset and IPF diagnosis) or post-diagnosis criteria (decline in FVC% over 12 months). When stratified by pre-diagnosis criteria 18% were rapid progressors while 66% were slow ones. When stratified according to post-diagnosis criteria 67% were rapid progressors and 33% were slow ones. The patients were divided as 70% and 25% for rapid and rapid progressors respectively indicating that up to 30% of patients did not maintain the same label. Stratification by pre-diagnosis criteria was not related to survival. Conversely, stratification by post-diagnosis criteria had a prognostic significance; indeed, rapid progressors had decreased survival as compared to slow ones (28.1±49.8mo, p=0.02). Of interest, rapid progressors according to post-diagnosis criteria, often display an unstable decline alternating periods of functional stability to a rapid deterioration.

In conclusion our data suggest the need to be cautious in labelling IPF patients to a fixed phenotype from the beginning of symptoms till death. It is possible that IPF patients show a variable and unpredictable clinical course rather than a steady condition.

P3639 The clinical relevance of autoimmunity in idiopathic pulmonary fibrosis

Sara Tomassetti, Christian Giurioli, Claudia Ravaglia, Sara Piccisci, Gian Luca Casoni, Micaela Romagnoli, Carlo Giurioli, Venerino Poletti. Pulmonary, GB Morgagni Hospital, Forli, Italy

The aim of this study was to evaluate the clinical significance of autoimmunity in IPF:

This is a retrospective controlled study comparing clinical characteristics and outcome of IPF patients with (n=73) and without (n=87) positive autoimmunity. Seventy-three cases with positive autoimmunity included: 46 (63%) ANA (anti nuclear antibody), 20 (27%) RF (rheumatoid factor), 2 (3%) anti CCP (anti cyclic- citrullinated), 3 (4%) ENA (antibodies to extractable nuclear antigens), 2 (3%) ANCA (anti-neutrophil cytoplasmatic antibody). No differences were found between patients with positive and negative autoimmunity in terms of age, gender, smoking history, prevalence of familial IPF, high resolution computed tomography features.

*p<0.05, **p<0.001.

During follow up two patients developed an autoimmune disease (one rheumatoid arthritis and one scleroderma).

Survival between IPF patients with and without positive autoimmunity did not differ 77.4 months (95% CI 56.1-97.8).

Conclusion: A small minority (2.7%) of IPF patients with positive autoimmunity test at diagnosis developed an autoimmune disease during follow-up. The presence of positive autoimmunity testing do not influence neither IPF clinical presentation nor survival.

P3640 Sarcoidosis and autoimmune thyroid disease

Claudia Ravaglia, Carlo Giurioli, GianLuca Casoni, Micaela Romagnoli, Sara Tomassetti, Christian Giurioli, Venerino Poletti. Pulmonology, Department of Thoracic Diseases, Morgagni Hospital, Forli, FC, Italy

Background: Association between Sarcoidosis and other autoimmune diseases has been previously described and a common pathogenesis has been hypothesized.

Objectives: A descriptive retrospective study has been conducted to evaluate the incidence of thyroid diseases in patients with pulmonary sarcoidosis.

Methods: We conducted a retrospective chart review of all patients diagnosed with sarcoidosis between 2004 and 2011 at the Morgagni Hospital, Forli; those who were also diagnosed as having an autoimmune thyroid disease were selected. Results: 39 out of 246 (15.9%) patients with sarcoidosis were identified as having autoimmune thyroid disease, 9 male and 30 female. Sarcoidosis presented as Löffgren’s syndrome in 6 patients patients (15.4%). 3 patients developed Graves’ disease (7.7%), 12 patients developed Hashimoto’s thyroiditis with hypothyroidism (30.8%) and 24 patients had thyroid nodules with normal thyroid function (61.5%).

Conclusions: Our study suggests that sarcoidosis may be associated with autoimmune thyroid diseases at some time of its evolution, either as hyperthyroidism or hypothyroidism. We are now following up sarcoidosis patients with no thyroid disease to see if any thyroid disease can develop after the diagnosis or during the period of activity of sarcoidosis.

P3641 Assessment of disease severity using imaging scores in pulmonary sarcoidosis

Vicent Botnamu, Diana Calarga, Oxana Munteanu. Internal Medicine, State Medical and Pharmaceutical University “Nicolae Testemitanu”, Chisinau, Republic of Moldova

The value of imagistic methods in diagnosing and assessing the inflammatory activity in sarcoidosis is well known. The aim was to assess the association between imagistic findings (radiographic score, and HRCT score by Oberstein et al.[SarcoidosisVasc Diffuse Lung Dis 1997,14:65–72]) and disease severity defined by functional disturbances in sarcoidosis.

We have evaluated the clinical records of 70 patients with biopsy proven or highly suggestive of sarcoidosis, cases registered in a 3rd level medical institution, during year 2011, who underwent chest X-ray, HRCT, and pulmonary function tests. The HRCT images were scored by two readers. Spearman’s rank correlation coefficients were calculated to estimate the association between imagistic scores and respiratory function disturbances.

We found a relationship between both radiological staging and HRCT abnormalities with functional parameters. All HRCT subscores, except lymph node enlargement, correlated with FEV1, FVC, MMEF25-75, and DLCO (p<0.001).

Compared with radiological stages, HRCT findings appeared to be more sensitive in tracing abnormal gas exchange, with no significant difference in other functional parameters.
Aline Domingos Pinto Ruppert, Vera Capelozzi, Edwin Roger Parra

Background: Speckle tracking has emerged as valuable tool for comprehensive assessment of regional myocardial function, providing angle-independent measurements of ventricular strain. Aim of this study was to evaluate left ventricular (LV) function in patients with newly diagnosed sarcoidosis, utilizing the novel method of 2D speckle tracking.

Methods: Forty one patients with sarcoidosis and unremarkable medical history were included. Image acquisition was performed in a conventional 2D Doppler and TDI measurements, speckle tracking echocardiography was applied and LV global longitudinal strain was derived from the obtained images. LV base and apex rotation angles were assessed from which LV twist was derived.

Results: The mean age of patients (17 men) was 41.65 years old. Compared with controls, patients had similar conventional 2D and Doppler measurements. TDI revealed increased E/E' in the patient group vs control group (8.72±1.65 vs 4.6±1.32, p<0.05). Strain analysis demonstrated reduced global longitudinal strain values in the patient vs control group (18.86±1.79% vs 21.88±2.18% p<0.05). Furthermore, LV twist was increased in the patient group as compared to the boiundaries (12.52±2.6% vs 10.21±1.80, p<0.05).

Conclusions: Speckle tracking echocardiography revealed impaired strain and rotational indices, implying elevated filling pressures of the left ventricle. This may represent a sign of myocardial involvement in patients with sarcoidosis. Therefore deformation imaging could be valuable adjunct for screening.

P3643

Overexpression of angiotensin II type 1 receptor (AGTR1) and lymphatic vasculature rarefaction is present in scleroderma with pulmonary involvement

Aline Domingos Pinto Ruppert, Vera Capelozzi, Edwin Roger Parra, Faculdade de Medicina da Universidade de São Paulo, Brazil

Background: The aim of this study was to evaluate the activity of angiotensin II type 1 and 2 receptors and lymphatic vessels in lungs of patients with systemic sclerosis comparing to normal lung tissue (NLT).

Methods: Lung specimens were obtained from 23 female patients with scleroderma. NLT were obtained from 10 individuals who died suddenly of non-pulmonary causes. Immunohistochemistry and histomorphometry were used to evaluate the expression of AGTR-1 and AGTR-2 pulmonary expression. We also studied the lymphatic (D2-40) expression and the percent of area occupied by lymphatic vessels in lungs specimens. Pulmonary fibrosis was obtained from high-resolution computed tomography (HRCT) score.

Results: We observed higher amount of AGTR-1 and AGTR-2 expression in the pulmonary parenchyma of patients with scleroderma when compared with NLT (p<0.01). The density of lymphatic vessels was markedly reduced in pulmonary parenchyma of patients with scleroderma compared with NLT (p<0.001). Similar situation was observed when we compared the area occupied by these lymphatics in lungs specimens. Pulmonary fibrosis was obtained from high-resolution computed tomography (HRCT) score.

Conclusions: Our data showed that the AGTR-1 and AGTR-2 expression in the pulmonary parenchyma of patients with scleroderma was higher when compared with NLT (p<0.01). The density of lymphatic vessels was markedly reduced in pulmonary parenchyma of patients with scleroderma compared with NLT (p<0.001). Similar situation was observed when we compared the area occupied by these lymphatics in lungs specimens. Pulmonary fibrosis was obtained from high-resolution computed tomography (HRCT) score.

P3644

The relationship between the shuttle walk test, lung function and BMI in patients with sarcoidosis

Rebecca Freeth, Colin Leonard, Jayne Holme, Annette Duck. North West Lung Centre, University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom

Introduction: Monitoring patients with sarcoidosis is important and challenging.

The incremental shuttle walk test is used in outpatient settings and we assessed its correlation with lung function, BMI and age.

Methods: A retrospective study of data from 63 patients with sarcoidosis who had a shuttle walk test with their lung function tests. Spearman’s correlation coefficient (rs) was used to assess the relationship between the shuttle walk test (distance walked, oxygen saturations) and Borg score (before and after exercise), with lung function (FEV1, FVC% predicted), age and BMI. A stepwise multiple linear regression model of distance walked was developed.

Results: Correlation is seen between the shuttle walk and lung function (table 1). The distance walked also correlated with age (rs=-.372, p=0.003) and BMI (rs=-.303, p=0.016). There was correlation between the Borg score post exercise and the BMI (r=-.253, p=0.046). The multiple regression model of distance walked identified BMI (rs=3.195, p=0.002) and FEV1 (rs=0.061, p=0.003) as significant independent variables.

P3645

Interstitial lung disease associated with autoimmune thyroiditis (ILD-AT)

Osama Stefanian, Marina Koval, Evgeniy Shmelev, George Kaltsakas, Anastasios Kallianos, Ouranis Anagnostopoulou, George Tzelepis, Konstantina Aggeli, Universidade de São Paulo, Brazil

Background: Interstitial lung disease (ILD) associated with autoimmune thyroiditis (AIT) is considered an orphan syndrome mainly seen in women. The level of thyroid peroxidase in serum initially elevated in all of patients returned to normal after treatment. The results of treatment were as much better as shorter was the disease duration.

Objective: To show some peculiarities of an orphan syndrome which is often misdiagnosed.

Methods: Patients and 8 methods, which were related to ILD-AT were revealed among about 5000 patients with various interstitial lung diseases during 25 years.

Results: ILD-AT was diagnosed in 7 female patients (age 49-60 years) and 1 male (age 23 yrs). In 5 cases the onset of pulmonary and thyroid disease was simultaneous in 3 autoimmune thyroiditis (AT) appeared several years earlier than ILD. The average duration of disease was 8.6 yrs to the moment of ILD-AT was diagnosed (range 1-27 yrs). In all patients ILD-AT presented with constant dry cough, dyspnea and crackles in lungs. NSIP pattern was seen on HRCT scans of all patients. Spirometry found out restriction in 6 of 8 cases (FVC 52-20%) while FEV1/FVC ratio was not decreased and bronchodilator test was negative. DLCO was lowered to 52.6-25.2% as well as PaO2 arterial blood level (69-49 mm Hg) in all patients. Long term treatment with low dose corticosteroids (during 2-27 yrs) prevented disease progression. The level of thyroid peroxidase in serum initially elevated in all of patients returned to normal after treatment. The results of treatment were as much better as shorter was the disease duration.

Conclusions: Appearance of constant dry cough and dyspnea should be the reason for chest HRCT, spirometry and DLCO measurement in patients with AT. Patients with interstitial lung disease of unknown origin should be tested for AT. In spite of rather favorable course ILD-AT should be diagnosed in time and treated long to avoid diffuse pulmonary fibrosis formation.

P3646

6-minute walk test predicts pulmonary artery pressure in patients with collagen vascular disease associated interstitial pneumonia

Kota Takahashi, Hiroaki Asakura, Hiroyuki Taniguchi, Yasuhiro Kondoh, Tomoki Kimura, University of California, Los Angeles, CA, USA

Objective: It has been reported clinical importance of pulmonary hypertension (PH) in collagen vascular disease (CVD), however the role of PH in interstitial pneumonia related CVD (CVD-IP) has been scarcely evaluated. We sought to determine the prediction factor of mean pulmonary artery pressure (MPAP) in patients with CVD-IP.

Methods: Patients with CVD-IP underwent right heart catheterization (RHC) within 3 months of initial evaluation at our institution. Patients with left ventricular dys-function, incomplete follow-up, and patients with respiratory failure were excluded.

Results: We studied 44 patients (19, male mean age 59.8±11.0 years). They were 13 with RA, 13 with SSC, 9 with PM/DM, and 9 with others. PaO2 at rest was 83.1±6.9 mmHg, MPAP was 17.2±5.5 5mmHg (12.2±3.8mmHg, 13.2±9.5%), cardiac index (CI) was 3.6±0.8 L/min/m², pulmonary vascular resistance index (PVR) was 223±102 Wood units/m², 5 Minute ventilation (VC) was 78.4±21.0%, percentage of carbon oxide of minuscule capacity (9DLCO) was 50.9±16.7%, and 6-min walk distance (MDW) was 502±142 m, and minimum SpO2 at 6-min walk test (SpO2md) was 85.6±5.9%, respectively. The median observation period was 3.8 months (range 4-11 months) for patients with CVD-IP.

Conclusions: In the univariate model, MPAP was significantly correlated with 9DLCO (r=0.377, P=0.013), and SpO2md (r=0.552, P<0.001). In the multivariate model, MPAP was significantly correlated with 9DLCO (r=0.360, P=0.014) and SpO2md (r=0.595, P<0.001).
P3647
Sarcoidosis – Diagnostics, prognosis and therapy in everyday pneumological practice. A retrospective analysis
Marina Donzelli1, Ilona Biková, Jana Škrivcová. Department of Pulmonary Medicine, University Hospital, Brno, Czech Republic

Background: Currently, prognostic factors, or therapy in sarcoidosis are frequently discussed, however, up-to-date data concerning the incidence and the management of sarcoidosis in everyday pneumological practice are still missing. Therefore, we decided to analyze the characteristic of comprehensive cohort of sarcoidosis patients.

Methods: We retrospectively analyzed all 169 patients, whom the diagnosis of sarcoidosis was set at our pulmonary department in years 2005-2010. After excluding 19 patients that had other diseases and 9 because of non-Caucasian origin, 141 patients were added for further analysis. Male sex outnumbered females 55%-45%. Median age was 44 years, however 20% of patients were younger than 20 years. The median age of sarcoidosis patients was 48 years (20-79). Females:males ratio was 1:5.1. Non smoker:smoker ratio was 2:2.1. Familial occurrence was observed in 4 patients. At diagnosis, stage 0 was present in 3.5% patients, stage I in 34% patients, stage II in 49.5% patients, stage III in 11% patients, and stage IV in 2% patients. In 76 patients there was extrapulmonary sarcoidosis. The coincidence of sarcoidosis with other autoimmune diseases was observed in 10 patients (6 patients had systemic lupus erythematosus). Spontaneous remission was seen in 36% patients, 57% of stage I, 29% of stage II, and 11% of stage III. 64% received corticosteroids. 16% of patients developed chronic sarcoidosis. In sarcoidosis patients with spontaneous resolution, no relapse of disease was observed. On the other hand, 10% of treated patients relapsed. Median time to sarcoidosis relapse was 6 months. There was no difference in age between good and poor risk groups of patients. Observed lethality was 1.2% (2 patients).

Conclusion: Male gender, X-ray stage I or II, lymphocytic alveolitis in bronchoalveolar fluid, spontaneous regression, and active disease duration up to 2 years appear to be good prognostic factors.

P3648
BALF cells expression phenotypes and cytokine levels in BALF supernatant in fibrosing interstitial lung diseases
Martina Vášáková1, Eliška Stránka2, Petra Mandaková3, Martina Sterčová1, Jaromír Kušař7,8. 1Department of Respiratory Medicine, Charles University and Thomayer Hospital, Prague, Czech Republic; 2Department of Pathology and Molecular Medicine, 2nd Medical Faculty, Charles University and University Hospital Motol, Prague, Czech Republic; 3Department of Pathology and Molecular Medicine, Thomayer Hospital, Prague, Czech Republic; 4Faculty of Information Technology, Czech Technical University, Prague, Czech Republic

Aims: Fibrosing interstitial lung diseases (fILDs), namely idiopathic pulmonary fibrosis (IPF) and fibrotic nonspecific interstitial pneumonia (NSIP), are processes with unknown etiology and grim prognosis. We hypothesize that expression profile of BALF cells and cytokine concentrations in fILDs depend on Th2 cytokine milieu and enhance fibroproliferative healing.

Methods: 10 patients with fILDs and 9 controls (C) were included into the study. BALF samples were used for FACs to detect spontaneous and stimulated proliferation of TNF alpha, percentage of lymphocytes expressing IL-2, IFN-gamma and TNF-alpha, and percentage of epithelial cells expressing proteinase-activated receptors (PAR 1,2,3). IFN-gamma, IL-1 beta, IL-2, IL-5, IL-6, IL-8, IL-10, IL-12p70 and TNF beta values were evaluated by means of bead-based analysis. Concentrations of CD124, PAR-2, TGF-beta 1 and TNF-alpha in BALF were detected by ELISA as well.

Results: We observed significantly higher concentrations of IL4R and TGF-beta 1 in BALF in fILDs versus C. The expression of PAR-2 on EP was higher in fILDs compared to C as well.

Conclusion: Our results supported a hypothesis about the role of Th2 type immune response in pathogenesis of fibrotic ILDs. The higher concentrations of IL-4R might be a sign of IL-4 influence, and the increased expression of TGF-beta and PAR-2 gives evidence for ongoing epithelial- mesenchymal transition and fibrogenesis in fILDs.

P3649
Pulmonary eosinophilic syndromes characterization. The role of peripheral eosinophilia
Hélène Nogueira 1,2, Patricia Mota 1, Natalia Melo 1, Marília Beltrão 3. 1,2,5, University of Minho, Braga, Portugal; 3Faculdade de Medicina, Universidade do Minho, Braga, Portugal

Introduction: Pulmonary eosinophilic syndromes (ES) are a heterogeneous, rare and not fully characterized group of diseases. The eosinophils accumulate in the airways and the alveoli. The main causes are asthma, parasitic diseases, inflammatory bowel disease, and infections. The most common esophageal cause is eosinophilic esophagitis. These disorders can be associated with idiopathic pulmonary fibrosis, bronchiectasis, and sarcoidosis.

Objectives: Evaluation of ES patient's clinical features and its evolution.

Methods: 47 patients with >20% BAL eosinophils or compatible histological features were included and its clinical files retrospectively analyzed.

Results: 10 patients that had sarcoidosis and 9 because of lacking information, 19 patients were enrolled: 8 presented Chronic Eosinophilic Pneumonia (CEP), 6 Churg-Strauss Syndrome (CSS), 3 Acute Eosinophilic Pneumonia and 2 Allergic Bronchopulmonary Aspergillosis (ABPA). Mean age at symptoms onset 37±14.6 and at diagnosis 43±14.3 years. The majority was female (68.4%) and nonsmokers (76.5%). Peripheral eosinophilia was observed in 78.9% patients (1.7±3.1 32x10^9/L), mean eosinophils in BAL was 51±29.16%. airflow obstruction was observed in 55.6% patients, 22.2% had restrictive pattern, 16.7% mixed pattern and 5.6% normal values, without significant differences among entities. Concerning CEP, CSS and ABPA cases after treatment, 83.3% presented obstructive pattern, 16.7% normal values and a significant increase of FEV1 (p=0.038) and RV (p=0.019) were observed. The RV was associated with mild peripheral eosinophilia or persistent eosinophilia (p=0.045). Mild peripheral eosinophilia at diagnosis was associated to its persistence after treatment (p=0.023).

Conclusion: In this series, mild peripheral eosinophilia was associated with its persistency and respiratory hyperinflation after treatment, suggesting that the degree of peripheral eosinophilia is associated to a distinct clinical evolution.

The decrease of surfactant protein D in bronchoalveolar lavage fluid in patients with idiopathic pulmonary fibrosis and nonspecific interstitial pneumonia
Hiroaki Nishibashi, Hirofumi Chiba, Mitsuao Otsuka, Koji Kurokuma, Hiroki Takahashi. Third Department of Internal Medicine, Sapporo Medical University School of Medicine, Sapporo, Hokkaido, Japan

Background: Surfactant protein (SP)-A and SP-D are useful biomarkers for the diagnosis and evaluation of activity of interstitial lung diseases. SP-A and SP-D, which are lung specific proteins, belong to a subgroup of the C-type lectin su-

Results: In IFP and NSIP patients, SP-D levels in BALF were significantly lower than those from healthy controls (p=0.006 and p=0.003) and sarcoidosis patients (p=0.02 and p=0.01). SP-A levels in BALF were no significant difference among these patients and controls. The significant positive correlation of SP-D levels between serum and BALF was found in IFP patients (p=0.529, p=0.008). In NSIP patients, the correlation of SP-D levels between them was not significant. No correlation of SP-A levels between serum and BALF was observed in any patients groups.

Conclusion: In IFP patients, SP-D levels in BALF were lower than those in healthy controls and had significant positive correlation with those in serum.

P3651
Characteristics of inspiratory and expiratory reactance in interstitial lung disease
Hiromi Iwamoto, Noboru Hattori, Yoshinori Harata, Ayu Sugiyama, Izumi Nakamura, Misako Nakagawa, Shintaro Miyamoto, Yojiro Onami, Nobuhisa Ishikawa, Kazunari Fujita, Hiroshi Murai, Nobuki Kohn. Molecular and Internal Medicine, Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan

Forced oscillometry is a noninvasive method to measure respiratory impedance and widely used in obstructive lung diseases, but has not been well studied in restrictive lung diseases. This study was conducted to investigate the characteristics of measurements obtained by impulse oscillation system (IOS) in patients with interstitial lung disease (ILD).

IOS and spirometry were performed in 64 ILD patients, 54 asthma patients, 49 chronic obstructive pulmonary disease (COPD) patients, and 29 controls. Respiratory resistance and reactance were assessed as measurements averaged over several tidal breaths (whole-breath analysis) and as measurements separately averaged during inspiration and expiration (inspiratory-expiratory analysis). Whole-breath analysis failed to distinguish between ILD and obstructive lung diseases. Inspiratory-expiratory analysis demonstrated no difference between inspiratory and expiratory reactance at 5 Hz (X5) in controls and asthmatic patients. Expiratory X5 was more negative than inspiratory X5 in COPD patients. In contrast, expiratory X5 was found to be less negative than inspiratory X5 in ILD patients. Furthermore, within-breath change in X5 was inversely correlated with vital capacity and diffusing capacity of carbon monoxide in ILD patients. These results suggest that increased magnitude of X5 during inspiration compared with that during expiration is a characteristic feature of IOS measurements in ILD patients.
The efficacy of pirfenidone in scleroderma related interstitial lung disease
Yukiko Miura1, Yoshia Tsuonuda, Toru Tanaka, Hiroyuki Takoi1, Yohi Yatagai, Shiuh Lyon Lin, Yoshia Yatagai, Akimasa Sekine1, Kenji Hayashi2, Taketumi Saito1, Chiharu Iinuma1, 1Department of Respiratory Medicine, National Hospital Organization Ishikawa Memorial Hospital, 2Department of Pulmonary Medicine, National Hospital Organization Ishikawa Memorial Hospital, Tokyo, Japan

Introduction: Major cause of death in Systemic Sclerosis (SSc) is interstitial lung disease, and cyclophosphamide is an only agent which significantly demonstrated a beneficial effect on lung function in patients with scleroderma-related interstitial lung disease (SSc-ILD), however the effect was quite modest, and it is necessary to identify a reasonable alternative.

Objectives: TGF-beta1 plays a critical role in the pathophysiology of pulmonary fibrosis. Pirfenidone exerts its antifibrotic effect through regulation of TGF-beta1 which is one of the important inducers of fibrogenesis in SSc. We suggest pirfenidone may be a possible option for SSc-ILD.

Methods: We administered pirfenidone to 3 patients with SSc-ILD and evaluated pulmonary function.

Results: Case 1 is a 62-year-old female. Vital capacity (VC) improved by pirfenidone. The change rate was +27.3% (+0.51L) for 5 months. Case 2 is a 75-year-old female. VC improved remarkably, at the change rate of +44.4% (+0.21L) for 25 months. Case 3 is a 66-year-old female. VC improved at the rate of +8.0% (+0.17L) for 26 months.

Conclusion: All of 3 patients with SSc-ILD demonstrated the favorable efficacy of VC by pirfenidone without severe adverse events. The previous studies documented that deteriorating lung function was associated with increased mortality in SSc-ILD. Therefore, it is necessary to identify and treat early stages of patients with SSc-ILD for the prevention of pulmonary function impairment. Pirfenidone exerts its antifibrotic effect through regulation of TGF-beta1, which is one of the important inducers of fibrogenesis in SSc. We suggest pirfenidone may be a possible option for SSc-ILD.

Effect of pirfenidone on chronic interstitial pneumonia
Hiroyuki Takoi1, Yukiko Miura1, Yoshia Tsuonuda, Yoshia Yatagai, Shiuh Lyon Lin, Yohi Yatagai, Akimasa Sekine1, Kenji Hayashi2, Taketumi Saito1

Introduction: Several reports reveal the favorable effect of pirfenidone on early stage of idiopathic pulmonary fibrosis (IPF), but impacts on non-specific interstitial pneumonia (NSIP) and interstitial pneumonia (IP) associated with collagen-vascular diseases (IP-CVD) are not clear.

Objectives: To examine the effect of pirfenidone on chronic IP including IPF, NSIP and NSIP-CVD.

Methods: Thirty-two patients were enrolled in the study evaluating the safety and efficacy of pirfenidone in IPF. NSIP, and IP-CVD. Clinical diagnosis are IPF14, NSIP14, IP associated with scleroderma3, and rheumatoid arthritis1. Based on IPF/CVD at rest and SPO2 after 6 minutes walk test (6MWT), disease severity of those patients were classified into four groups [Table 1]. We retrospectively analyzed subjective symptom in British Medical Research Council scale, pulmonary function, KL-6, SP-D and CT findings before and during pirfenidone administration.

Table 1. Disease severity of patients

<table>
<thead>
<tr>
<th>PaO2 at rest (mmHg)</th>
<th>SPO2 after 6MWT</th>
</tr>
</thead>
<tbody>
<tr>
<td>I: 81-94</td>
<td>60-69</td>
</tr>
<tr>
<td>II: 70-79</td>
<td>When &lt;90%, to III</td>

<td>III: 60-69</td>
<td>When &lt;90%, to IV</td>
</tr>
<tr>
<td>IV: 60-69</td>
<td>unmeasurable to perform 6MWT</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Results: Correlations was observed between subjective symptom and VC, but was not between subjective symptom and KL-6, SP-D, CT findings. After administration of pirfenidone, VC improved above 5% in 22%, 50%, 25%, 45% of patients (severity grade I, II, III, IV, respectively). Subjective symptoms highly improved in patients with scleroderma (improvement rate: 63% in scleroderma vs. 14%, 14%, 0% in IPF, NSIP, RA, respectively).

Conclusions: Pirfenidone might have the favorable efficacy independent of disease severity, without severe adverse events, in chronic IP, especially in associated with scleroderma.

P3654 Telephone consultations for follow-up of interstitial lung disease: Patient satisfaction survey
Rina Adhikary, Leanne Cheyne, Paul Beirne. Department of Respiratory Medicine, Leeds Teaching Hospitals NHS Trust, St. John’s University Hospital, Leeds, United Kingdom

Introduction: The long-term follow-up required by Interstitial Lung Disease (ILD) patients imposes a significant burden on healthcare resources. Telephone consultations have been piloted as an alternative to some face-to-face consultations in a teaching hospital based ILD service. Patients whose next consult is anticipated to be uncomplicated (eg stable patients having interval lung function tests) are offered a phone consult with the ILD consultant.

Aims and objectives: To assess whether ILD patients are as satisfied with a telephone consultation as with a face-to-face consult.

Methods: A postal survey was sent to 95 consecutive ILD patients who had a phone consult over a 12-month period. Patients used a 5-point score to report if, in comparison to a face-to-face consult, the phone consult was as punctual, convenient, reassuring, and afforded the same opportunity to ask questions, and facilitated the same understanding of information.

Results: 52 patients (55%) posted responses (see Table 1). 67% agreed phone consultations were as punctual. 78% agreed they were as convenient. 77% felt as reassured and as able to ask questions. 88% understood the information given just as easily. 80% were willing to have another phone consult.

Discussion: The majority of ILD patients selected for a telephone consultation were at least as satisfied as with a face-to-face telephone. Telephone consultations are acceptable to the majority of ILD patients for at least some of their follow-up.

P3655 NSIP: A diagnosis? Thomas Nivière1, Pierre-Alain Gevenois1, Benjamin Bondue1, Paul De Vuyst2,1 Hematology, Institut Jules Bordet, Brussels, Belgium, 2Radiology, Erasme, Brussels, Belgium

Introduction: Nonspecific interstitial pneumonia (NSIP) is the most discussed entity in the group of idiopathic interstitial pneumonias. Recognized in 2002 by the American Thoracic Society and the European Respiratory Society as a provisional diagnosis, NSIP may be idiopathic or associated with a number of clinical settings.

Objective: The objective of this study was to determine the proportion of strictly idiopathic NSIP among a cohort of patients whose initial lung CT scan considered NSIP as a possible diagnosis.

Method: 73 adult patients with an initial CT pattern of NSIP were selected in our database of adult patients with ILD (1998-2011) and were enrolled in a monocentric retrospective study. Anamnestic, clinical, functional, biological and pathological data were reviewed for each patient as well as the evolution of disease.

Results: In only 21 patients (71.2%) an alternative diagnosis could be made, most frequently an underlying connective tissue disease (n= 22, 30.1%) and idiopathic pulmonary fibrosis (n=12, 16.4%).

The other diagnoses include hypersensitivity pneumonitis (n=7, 9.6%), drug-induced lung disease (n= 5, 6.8%), sarcoidosis (n=1, 1.4%), a sequel of ARDS (n=1, 1.4%), LIP (n=1, 1.4%) and a RBILD (n=1, 1.4%).

Conclusion: This study demonstrates that idiopathic NSIP is a rare condition among patients presenting a radiological NSIP pattern. Therefore an integrated multidisciplinary approach is recommended in order to diagnose alternative/associated diseases needing for most of them a specific treatment.

P3656 6-minute walk test (6MWT) in patients with idiopathic pulmonary fibrosis (IPF): Confirmation of the minimal clinically important difference (MCID) Steven Nathan1, Carlo Albera2, Roland du Bous1, 1Williamson Bradford4, Ulrich Costabel1, Talmadge King1,2, Paul Noble1, Steven Sahn1, Dominique Valeyre1, 1Advanced Lung Disease and Transplant Program, Inova Fairfax Hospital, Falls Church, VA, United States; 2Clinical and Biological Sciences, University of Turin, Italy; 3Department of Medicine, Imperial College, London, United Kingdom; 4Clinical Research, InterMune, Inc., Brisbane, CA, United States; 5Pneumology/Allergy, Ruhrahlandklinik, Essen, Germany; 6Department of Medicine, University of California San Francisco, CA, United States; 7Department of Medicine, Duke University School of Medicine, Durham, NC, United States; 8Department of Medicine, Medical University of South Carolina, Charleston, SC, United States; 9Department of Medicine, Assistance Publique-Hôpitaux, Paris, France

Introduction: The 6MWT is a practical measure of exercise tolerance in patients with IPF. MCID estimates for 6MWT distance (6MWED) in patients with IPF have ranged between 10–58 in [1-3]; we sought to confirm these estimates in an independent cohort of patients with IPF.

Methods: All patients randomized to placebo in the CAPACITY studies were
The efficacy of transbronchial biopsies without fluoroscopy control in patients with IPF.

Conclusions: Analysis of 6MDW data from a large cohort of IPF patients yielded an MCID estimate of 22–37 m. This finding is consistent with previous estimates which, taken together, provide a meaningful benchmark for assessing 6MDW in patients with IPF.

P3657
The efficacy of transbronchial biopsies without fluoroscopy control in diagnostics of extrinsic allergic alveolitis
Iya Sirokzov, Olga Lovacheva, Eugene Shmelev. Granulomatosis Disease/Endoscopy, CHP RMDS, Moscow, Russian Federation

Background: Extrinsic allergic alveolitis (EAA) is usually established based on results of CT exam, immunology, and transbronchial lung biopsy (TBLB) during flexible bronchoscopy (FSB). As a rule, TBLB should be performed under fluoroscopy control, but it is not always possible, and in such situation efficacy of TBLB is controversial.

Aims: To investigate the effectiveness of TBLB and bronchoalveolar lavage (BAL) during FBS in patients with newly diagnosed EAA.

Materials: 66 patients with EAA were enrolled into the study, all of them underwent CT of the chest with subsequent FBS with TBLB and BAL. We analysed the diagnostic efficacy of TBLB upon histology and cytology, and diagnostic changes in BAL. Additionally, mean and median number of tissue samples, samples quality, frequency of pneumothorax and severe bleeding were analyzed.

Results: There were 37 females in the group, mean age for both sexes - 48.3 years, varied from 19 to 73 years. Mean disease duration from first symptoms/chest abnormalities was 87.1 weeks. Mean tissue samples number was 2.23, varied from 1 to 5, median 2. There were no complications. Lung tissue was observed in 42/66 cases (64.5%). Upon histology, granulomas and tissue infiltration were seen in 30 out of 66 patients (45.4%), additionally due to cytology granulomas were found in 4 cases, thus total efficacy of TBLB was 34/66 (51.5%). Among the rest 32 patients, diagnostically significant changes in BAL were found in 16 patients, so the total efficacy of TBLB plus BAL reached 50/66 (75.7%).

Conclusion: Bronchoscopy with TBLB and BAL even without fluoroscopy control is effective and safe way to establish the diagnosis of allergic alveolitis.

P3658
KL-6 compared to LDH as a prognostic factor in Caucasian patients with idiopathic pulmonary fibrosis
Shibatani Osakami1, Francesco Bonella2, Yasuo Hotsumasa1, Nobuhisa Ishikawa3, Noboru Hattori1, Nobuyuki Hirohashi1, Koichi Tanigawa1, Shinichiro Ohshimo2, Nobuoki Kohno3, Josune Guzman4, Ulrich Costabel2.

1Department of Respiratory Medicine, St. Mary’s Hospital, Imperial College NHS Trust, London, United Kingdom; 2Department of Medicine, Imperial College London, London, United Kingdom; 3Microbiology, St. Mary’s Hospital, Imperial College NHS Trust, London, United Kingdom; 4Cytopathology, St. Mary’s Hospital, Imperial College NHS Trust, London, United Kingdom; 5Infectious Diseases, Imperial College London, London, United Kingdom

Background: Idiopathic pulmonary fibrosis (IPF) is a fatal lung disease with a poor prognosis. Little is known about sensitive prognostic markers for IPF. Aims: The aim of our study was to investigate the significance of KL-6 compared to LDH as a prognostic marker in Caucasian patients with IPF.

Methods: We prospectively collected 79 Caucasian patients with IPF. Serum samples were obtained at enrollment. Serum levels of KL-6 and lactate dehydrogenase (LDH) were measured by ELISA and the correlation between baseline serum levels of the markers and the survival was evaluated.

Results: Median follow-up period was 372 (1-7088) days. Sixteen (20%) patients died during follow-up. There was no significant difference in the baseline serum KL-6 levels between patients who survived and not survived. Receiver operating characteristic (ROC) curve analysis for predicting non-survival showed larger area under the curve for KL-6 than LDH (0.617 and 0.553, respectively). When the cut-off levels of 1300 U/mL for KL-6 and 280 IU/L for LDH were set, sensitivity, specificity and accuracy for predicting non-survival were 81%, 60% and 66% for KL-6 and 56%, 51% and 52% for LDH. In Kaplan-Meier analysis, patients with baseline serum KL-6 level ≥1300 U/mL showed shorter survival compared with patients with baseline serum KL-6 level <1300 U/mL (p=0.02). LDH showed no statistical impact on the prognosis (p=0.20). In multivariate analysis, baseline serum KL-6 level ≥1300 U/mL was an independent predictive factor for poor prognosis (hazard ratio=4.46, p=0.030).

Conclusions: Baseline serum KL-6 level ≥1300 U/mL is an independent predictive factor for poor prognosis in Caucasian patients with IPF.
herpes I and II viruses (HVI and HVII). We also correlated sex, age, AIDS and immunosuppression therapy.

Results: We detected by immunohistochemistry the epithelial alveolar infection of MV and CMV in 30.8% and 15.4% in DAD pattern, respectively. Endothelial CMV infection was observed in 25% of CLF pattern. When we divided the age in two groups 1 patients with ≤ of 43 years old and ≥ of 72 years old, the first group had more infection of MV, CMV than the second group. The Spearman’s correlation showed a positive correlation between epithelial and endothelial CMV infection and AIDS (r=0.472, p=0.003).

Conclusion: The epithelial and endothelial viral infections observed in these diseases reinforce the possible viral participation in the pulmonary fibrosis disease. These findings are particularly relevant given the increased interest in the epithelial injury and repair as it relates to the pathogenesis of many diffuse lung diseases.

P3661
Pirfenidone, proton pump inhibitor, N acetyl cysteine (PINPOINT) therapy for IPF: Tolerance and safety profile among Indian patients

Preksha Deshmukh1, H.S. Sandeep2, Paraj Chaudhari3

Santhakumar Subramaniam1, David Miedinger2, Joerg Leuppi2, Arvind Kate3.

1Pulmonology, Lung Care & Sleep Centre, Vashi, Navi Mumbai, Maharashtra, India; 2Pulmonology, Institute of Pulmonology, Medical Research & Development, Mumbai, Maharashtra, India

Rationale: To our knowledge there are no data of PirfenDine, P3Oon pump Inhibitor. N-acetyl cysteine (PINPOINT) therapy in IPF. We retrospectively examined the safety & tolerability of PINPOINT in IPF-UIP.

Methods: 40 consecutive patients with IPF-UIP administered PINPOINT, Pirfenidone 200 mg three times day & titrated to 400 mg three times day over 2 to 4 weeks, a proton pump inhibitor & N-acetyl cysteine 1800 mg/day. Baseline liver function tests were performed. Lung function & 6MWT were possible in 25 patients. Patients were followed at 2 weeks, then monthly/quarterly. Predisuasion was adhered to follow up based on clinical assessment. Four newly diagnosed patients were given only PINPOINT.

Results: Baseline mean spO2 at rest was 95% & mean FVC 1.30 litres (55% predicted). Baseline liver function were normal in all patients. Mean lowest spO2 on 6 minute walk test was 90%. There was no significant increase in liver enzymes at follow up. 17 patients had pulmonary hypertension on 2D Echo. Mean duration of follow up was 241 days. In 25 patients, Pirfenidone could be increased to 1200 mg/day. Dose could not be increased to 1200 mg/day in 11 patients due to gastrointestinal side effects (nausea/vomiting 10 patients, loose motions - one patient). Pirfenidone was stopped in five patients because of skin itching & rash (4 patients 600mg/day, 1 patient 1200 mg/day). 5 patients continued to take Pirfenidone despite skin itching (no skin discoloration) after counseling about side effects & took symptomatic treatment. 5 patients expired during this period. Conclusion: PINPOINT therapy appears to be well tolerated in patients in IPF-UIP.

P3662
Frequency and impact of interstitial lung disease on clinical state and mortality in systemic sclerosis

Walia Chebli1, Sophia Ayed1, Nadia Boudawara1, Leila Boussifara2, Sylvia Malhoub3, Mohamed Habib Sfar1, Jadel Knaani2.

1Internal Medicine, Taher Sjar Hospital, Mahdia, Tunisia; 2Pneumology, Taher Sjar Hospital, Mahdia, Tunisia; 3Internal Medicine, Fatouma Bourjibah Hospital, Monastir, Tunisia

Background: Interstitial lung disease (ILD) is a frequent complication and a leading cause of morbidity and mortality in Systemic Sclerosis (SSc).

The aim of our study was to determine the frequency of ILD in a cohort of Tunisian SSc and to assess the influence of this association on clinical, biological features and outcome of SSc.

Methods: A retrospective study included 30 consecutive patients with SSc who fulfilled the American Rheumatism Association’s criteria. Patients were divided into four descriptive disease subsets: lcSSc, dcSSc, SSc sine scleroderma and other organ involvement.

A retrospective study based on the follow up (FU) of ILD patients who developed CTD during at least 3 years follow up period. Patients: A cohort of 120 ILO patients attending a specialist clinic with an increased ILD pattern. Patients were divided into four descriptive disease subsets: lcSSc, dcSSc, SSc sine scleroderma and overlap syndrome.

Results: The ILD cases without clinical history of CTD and with UIP-like or NSIP pattern on the background of histology specimens, must be followed for long time period.

It is of important value such patients to be checked initially and in follow up by HRCT, clinical and laboratory tests.

In these subgroups of patients the prognosis is better than UIP/IPF patients.

P3663
Pirfenidone in idiopathic pulmonary fibrosis (IPF): Early single centre Irish experience

Peter Barry, Lorna Murphy, Majella Tuohy, Eoin Judge, Jim Egan. Department of Respiratory Medicine, Mater Misericordiae University Hospital, Dublin, Ireland

Introduction: Pirfenidone is an orally bio-available synthetic molecule, which has recently been approved for the treatment of mild to moderate IPF in Europe. It regulates the activity of TGF-β and TNF-α in vitro. Open label pirfenidone prescription commenced in June 2011 in the Republic of Ireland. We report the early experience of a single centre with pirfenidone.

Methods: We conducted a retrospective review of medical records of those patients who were prescribed pirfenidone. We analysed baseline demographics, symptoms and pulmonary function. Comparisons between groups were conducted using paired t-testing.

Results: 26 patients (20 male) received the medication. 22 patients remain on the medication. 1 patient died due to IPF exacerbation and 3 others discontinuing the medication secondary to side effects. 15 (58%) of patients have reached target dose of medication. 7 subjects continue to take pirfenidone at a reduced dose. 14 participants reported side effects potentially related to pirfenidone. The most commonly reported side effect was fatigue followed by gastro-intestinal disturbance and photo-sensitivity. An increase (< 2 fold) in transaminases was noted in 1 patient. Patients who experienced side effects or required dose reduction were on average older but this did not reach statistical significance. Amongst subjects who had repeated pulmonary function testing (n=14), there was no significant decline in TLC or FVC between baseline and follow up.

Conclusions: Pirfenidone is a novel agent for the treatment of limited IPF. The side effect profile in an Irish population appears consistent with recent published data. Further follow up is required to establish efficacy in an Irish population.

P3664
Lung fibrosis and ILD in patients with systemic sclerosis: an Irish experience

Sylvia Mahjoub3, Mohamed Habib Sfar1, Jalel Knani2.

1H. S. Sandeep1, Parag Chaudhari 1, 2Pathology Department, Athens Chest Hospital ‘Sotiria’, Athens, Greece; 3Radiology Department, Athens Chest Hospital ‘Sotiria’, Athens, Greece; 4Radiology, Athens University, Athens, Greece

Aim: A retrospective study based on the follow up (FU) of IPD patients who developed CTD during at least 3 years follow up period.

Methods: A cohort of 120 ILO patients attending a specialist clinic with an increased ILD pattern and HRCT findings. A number of 12 cases who were undertaken surgery biopsy (OLB/VAAT) were selected for the study.

Results: The above 12 patients developed during the follow up period CTD, six cases have f-NSIP on the background and 6 have UIP-like pattern.

Conclusions: The ILD cases without clinical history of CTD and with UIP-like or NSIP pattern on the background of histology specimens, must be followed for long time period.

It is of important value such patients to be checked initially and in follow up by HRCT, clinical and laboratory tests.

In these subgroups of patients the prognosis is better than UIP/IPF patients.

P3665
Pulmonary functions in systemic sclerosis

Abdalla Khoury1, Piras Abou-Trebeh1, Saeid Hammoud2.

1Internal Medicine, Aleppo University Hospital, Aleppo, Syrian Arab Republic; 2Rheumatology, Aleppo Faculty of Medicine, Aleppo, Syrian Arab Republic

Background: Pulmonary involvement is the leading cause of systemic sclerosis (SSc)-related deaths.

Objective: To determine the prevalence of pulmonary involvement in systemic sclerosis and its distributions on the disease subsets, and to study its relation with other organ involvement.

Methods: We analyzed 43 SSc patients, a careful history and clinical examination was performed to each patient. All the patients were submitted to chest radiographs and high-resolution CT (HRCT) and underwent pulmonary function testing and echocardiography and electrocardiography and six minutes walk test. Patients were grouped into four descriptive disease subsets: lcSSc, dcSSc, SSc sine scleroderma and overlap syndrome.

Results: Of the 43 patients, (53.5%) of patients had lcSSc and (27.9%) dcSSc. Overlap syndrome was diagnosed in (11.6%) of patients, SSc sine scleroderma was present in (7%) of patients, (93%) were female and the mean age of 41.6±11.51, (55.8%) of the patients had pulmonary symptoms or signs, dyspnea was the most prevalent symptom (37.2%). Pulmonary fibrosis was most prevalent involvement (41.9%), and it was more common in dcSSc (41.6%) compared with lcSSc (30.4%). Pulmonary hypertension was second in prevalence (PASP> 35 mmHg) 20.9% and it was more common in lcSSc (21.7%) compared with dcSSc (8.3%). (62.8%) of the patients had restrictive pulmonary function test. (65.1%) of the patients had normal six minutes walk test.

Discussion: Our results will be discussed with well known international studies.

Tuesday, September 4th 2012
Introduction: University Hospitals Coventry and Warwickshire is a large acute teaching NHS trust which serves a population of over 1 million. There has been an ILD MDT since 2006. In July 2010 a consultant with an interest in ILD was appointed. The MDT constitutes a thoracic surgeon, pathologist and radiologist with expressed interest in ILD.

Aim: To describe the spectrum of ILD presenting in secondary care.

Method: It is departmental policy to discuss all incident cases of ILD in the MDT. Diagnoses were made according to BTS guidelines, and by consensus. Numbers were compared by χ², and ages by Mann-Whitney U-test.

Results: From September 2010 to July 2011, 89 suspected cases were discussed in the ILD MDT, 10 of whom proved not to have significant ILD. The diagnoses of the remaining 79 are given in table below.

<table>
<thead>
<tr>

P3667
A retrospective cohort study of interstitial lung diseases in Denmark

Charlotte Hyldegaard, Elisabeth Bendstrup, Ole Hilberg. Department of Respiratory Diseases, Aarhus University Hospital, Aarhus C, Denmark

Introduction: Interstitial lung diseases are a heterogeneous group of diseases with varying degrees of inflammation and fibrosis. Epidemiological data based on the current diagnostic criteria are sparcible.

Objectives: The aim of this study was to characterize the distribution of ILD subtypes in a cohort of Danish patients referred to a tertiary referral hospital.

Methods: We included 431 patients diagnosed with interstitial lung disease (sarcoidosis excluded) and first visit at our department between April 1, 2003 and April 1, 2009. All diagnoses were re-evaluated according to current diagnostic criteria including the 2011 ATS/ERS IPF-guidelines. Details on diagnostics, lung function, comorbidity and treatment were recorded at baseline and throughout the follow-up period.

Results: A total of 186 patients were diagnosed with idiopathic interstitial lung diseases. In this group IPF (n=121) was the most common diagnosis (108 definite and 13 probable IPF) followed by NSIP (n=30), and DIP (n=20). Other large groups comprised 11% of cases and have a median age of 50 years (Quitters) while 8 either continued to smoke or were inconsistent in their cessation attempts (Smokers). Baseline lung function at diagnosis was compared to current values of FEV1, FVC, TLCO and KCO between Quitters and Smokers.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Smokers (n=8)</th>
<th>Quitters (n=4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FEV1</td>
<td>–63%</td>
<td>–84%</td>

<tr>
<td>FVC</td>
<td>–89%</td>
<td>–89%</td>
</tr>
<tr>
<td>TLCO</td>
<td>–58%</td>
<td>–58%</td>
</tr>
<tr>
<td>KCO</td>
<td>–31%</td>
<td>–31%</td>
</tr>
</tbody>
</table>

There was a significant difference in median rate of decline of TLCO (p=0.036) and KCO (p=0.014) between Quitters and Smokers, with a trend towards a difference for FEV1 (p=0.141) and FVC (p=0.285).

This case series confirms previous findings supporting the importance of smoking cessation which can have a positive impact on lung function. Continued smoking however can result in continued decline at a rate faster than that reported in healthy normals and patients with COPD.

Spontaneous pneumomediastinum & subcutaneous emphysema in idiopathic pulmonary fibrosis (IPF) with bronchial wall leak

Chetan Pai1, Ram Chopra, Vaibhav Pandharik, Anand Yannawar, Jaymala Gaikwad, Manisha Bhosle, Sharad Patil. Pulmonar Medicine, Ruby Hall Clinic, Pune, Maharashtra, India

Spontaneous pneumomediastinum & subcutaneous emphysema in IPF is due to alveolar rupture but air leak due to bronchial rupture is rare. We present unique case of bronchial leak seen on bronchoscopy in a patient of IPF. Non traumatic subcutaneous & mediastinal emphysema due to bronchial rupture in IPF is rare & is being reported for the first time. Case report-55 years male admitted with severe progressive dyspnoea & dry cough of 1 month. Massive subcutaneous emphysema was seen on chest, neck & arms. CT thorax showed pneumomediastinum & IPF in lower lobes.

Put on steroids & 100% O2 but no relief. Bronchoscopy showed air bubbles oozing from irregular opening near superior segment of left lower lobe.

Glue was applied to seal bronchial wall leak & to our amaze subcutaneous emphysema started regressing with clinical improvement. Repeat CT scan showed decrease in mediastinal air. Discussion-Bloomberg considered the cause of non traumatic subcutaneous & mediastinal emphysema to be due to weakness of the air or bronchial wall. Air escapes via bronchovascular channels to mediastinum & subcutaneous tissues, described as Maclin effect.

P3670 Coagulation factor IX deficiency does not afford protection from pulmonary fibrosis in the experimental murine bleomycin model
Kerem Erkmen1, Lin Cong2, Bruno Crestani3, Olivier Christophe4, Arnold Spek5, 6INSERM U700, Faculté de Médecine Xavier Bichat, Paris, France; 2Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands; 3Pulmonology, Hospital Bichat, Paris, France; 6INSERM U770, Hopital le Kremlin Bicêtre, Le Kremlin-Bicêtre, France

Introduction: Animal and human studies strongly suggest the importance of the coagulation cascade in acute and chronic lung injury. Indeed, beyond their role in hemostasis, coagulation factors can signal via their cellular receptors, the protease-activated receptors. We hypothesized that the absence of coagulation FactorFIX, which is essential for the activation of the coagulation cascade would reduce fibrosis development and progression.

Methods: We used the murine model of bleomycin-induced pulmonary fibrosis in wild-type (WT, n=14) and FIX deficient mice (n=13). After 14 days, we assessed markers of tissue fibrosis, inflammatory cell influx in the bronchoalveolar lavage fluid (BALF), and cytokines levels in the BALF, blood and lung homogenate of the animals.

Results: Mortality during the experiment was higher in the FIX deficient mice compared to wildtypes (23% versus 7%). The remaining FIX deficient mice (n=10) developed pulmonary fibrosis to a degree similar to WT (n=13). There was no significant difference in the Ashcroft score between WT and FIX deficient mice (4.0±1.4 versus 4.2±0.4), in the alpha-actin alpha (0.94±0.09 versus 0.70±0.07) and in the inflammatory cell number. In contrast, we observed in the placebo of the FIX deficient mice significant elevations in levels of cytokines IL-12, TNFs, IFNγ, MCP-1 and IL-6.

Conclusion: Mice with a congenital deficiency of FIX are not protected against bleomycin-induced pulmonary fibrosis. These data strongly argue against an important role of the blood coagulation cascade in the progression of pulmonary fibrosis, and raise important concerns about the use of anticoagulant therapy in patients.

P3671 Aggravation of bleomycin-induced pulmonary fibrosis in senescence-accelerated mouse
Baobei Lou, Qian Ye, Huaping Dai, Kewe Huang, Chen Wang. Department of Respiratory Medicine, Beijing Chao-Yang Hospital, Beijing Institute of Respiratory Medicine, Beijing, China

Objective: Idiopathic pulmonary fibrosis (IPF) is predominantly a lung fibrotic disease of older adults, and the process underlying aging might significantly influence the development of pulmonary fibrosis. Bleomycin-induced lung injury was investigated in murine models of accelerated senescence (SAMP8) and of normal aging (SAMR1). The levels of TH1/TH2 related cytokine were also measured.

Methods: Bleomycin or PBS was injected into the tracheal lumen of 12-month-old SAMP8, 4 and 12-month-old SAMR1 mice. Seven, 14 and 28 days after the injection, the mice were killed and the lungs were harvested for pathological examination, hydroxyproline assay and protein detect. Lung TGF-β1 expression was determined by western blot, and the levels of IL-4 and IFN-γ were detected by ELISA.

Results: The aggravated bleomycin induced lung injury was observed in 12-month-old SAMP8 compared with 4 and 12-month-old SAMR1. Twenty eight days after injection of bleomycin, Aschoff score was significant higher in 12-month-old SAMP8 than in 4 and 12-month-old SAMR1 (P<0.05, respectively). Seven days, 14 days and 28 days after bleomycin injection, lung TGF-β1 expression was increased in 12-month-old SAMP8 and SAMR1 compared with 4-month-old SAMR1. Similarly, the level of IL-4 and the IL-4/IFN-γ ratio of the lungs tended to be higher in 12-month-old SAMP8 and SAMR1 than in 4-month-old SAMR1, but the differences were not statistically significant.

Conclusion: Bleomycin-induced pulmonary fibrosis in SAM was aggravated by aging. The old SAM with bleomycin-induced pulmonary fibrosis might be inclined to Th2-biased immune responses. (This work was funded by Natural National Science Foundation of China Grants 81070046).

P3672 Lung function progression in Langerhans cell histiocytosis
Sophie Krivinskas1, Philip Ind1, Anthony Chu2, 3Respiratory Medicine, Imperial College Healthcare Trust, Hammersmith Hospital, London, United Kingdom; 4Dermatology, Imperial College Healthcare Trust, Hammersmith Hospital, London, United Kingdom

It is a rare, multisystem dendritic cell disorder commonly involving the lungs. The natural history is variable with little lung function outcome data. Our database of 92 patients referred to AC for treatment, 51 patients were male; mean age at diagnosis was 31 (range 1-77) years (y). 1702 patients, 10 male, mean age 31 y, had primary lung disease (PLCH). 14/75 had systemic LCH with lung involvement (SLCH). All PLCH had smoked with mean 13 pack-yr; 9/17 continued smoking after diagnosis. Initial lung function (n=115) showed mean %predicted FEV1, 76 (34-113)%; VC 81 (53-114)%; TLC 67 (19-108)%. 2 patients had obstructive, 3 restrictive, and 3 mixed lung disease. 9/14 SLCH patients were male, mean age 25y, 10 had smoked; mean 12 pack-y, 7 continued smoking after diagnosis. Initial lung function (n=9) showed mean %predicted FEV1, 83 (72-105)%; VC 89 (72-104)%; TLC 76 (49-106)%. Method: 14 (range 8 to 14 months) patients were followed after injection of bleomycin, 70 (30-103)%predicted, VC was 84 (51-109)%; TLC was 63 (17-105)%. Mean change in FEV1; -7.1±3 to 12%+, in VC was 1 (1.9 to +14%+), in TLC was -10 (-49 to +29)%, in 11/17 patients received treatment. To date 3 have died, 10 are in remission and 4 have active disease.

In SLLCH (n=6) at mean follow up of 6 (2-22) y mean FEV1 was 83 (66-101)%predicted, VC was 92 (79-103)%; TLC was 93 (82-94)%. Mean change in FEV1, was -3 to -9 to +55%, in VC was -1 (14 to +92%) and in TLC was 14 (+2 to +45%). 12/14 patients received treatment. To date 1 has died, 8 are in remission and 5 have active disease.

LCH is rare but is in this relatively small, selected series lung function is worse and declines more in patients who present with primary lung involvement than those with lung involvement in systemic LCH.

P3673 Correlation between spirometry, six minute walk test and HRCT characteristics of patients with interstitial lung diseases in a tertiary care center in Sri Lanka
Asoma Siribaddana1, 2M.T. Muthunayake3, D.B. Dassanayake1, K.P. Gunaratne1, S.R. Lalin Gunaratne1, 1Respiratory Unit, Teaching Hospital, Kandy, Sri Lanka; 2Department of Radiology, Teaching Hospital, Kandy, Sri Lanka

Objectives: To find out the correlation between spirometry, six minute walk test and HRCT characteristics of patients with ILDs.

Methods: Study was done in chest unit, general Hospital, Kandy (GHK) from January 1, 2011 to December 31, 2011. Ethical clearance was granted by Ethical Committee of GHK. Patients with suspected ILDs on chest radiography and showed restrictive lung defect on spirometry underwent HRCT scan of the chest. Pathological findings of HRCT (parenchymal nodules, fibrosis, ground glass and mosaic perfusion) were graded a score using the scoring system described by Zara et al. (Ann. Med. 2005, 12, 31-34). Six minute walking test was performed. Correlations were analyzed using Pearsons and Spearmans correlation coefficient.

Results: Twenty one patients [5 (23.8%) males, 16 (76.2%) females] with ILD were studied. There was a significant positive correlation between resting satura-tion and forced vital capacity (FVC) (r = 0.52, p = 0.02), resting saturation and forced expiratory volume in 1 second (FEV1) (r = 0.549, p = 0.012), six minute walk distance and FVC (r = 0.505, p = 0.023). There were no correlations between HRCT scores with spirometry, and six minute walk test parameters.

Conclusion: Although there was a correlation between spirometry and six minute walk test, pathological distribution described by HRCT showed no correlation with spirometry or six minute walk test in patients with ILD.

P3674 Uncommonly common? Common variable immunoglobulin deficiency 'masquerading' as sarcoidosis
Rana Alkur1, David Miller1, Anne-Marie Shanks1, Richard Herriot2, 1Chest Clinic C. Aberdeen Royal Infirmary, Aberdeen, Scotland, United Kingdom; 2Immunology Department, Aberdeen Royal Infirmary, Aberdeen, Scotland, United Kingdom

Introduction: Multisystem granulomatous inflammation can be a presenting fea-ture or a complication of common variable immune deficiency (CVID). A propor-tion of patients diagnosed with 'sarcoidosis' may actually have underlying CVID, recognition of which may be associated with considerable diagnostic delay.

Method: 2 cases are presented to illustrate this along the results of an audit.

Case 1: LC presented aged 28 with chronic cough and deranged LFTs. HRCT showed multiple pulmonary nodules and generalised lymphadenopa-thy. Granulomas were seen on liver biopsy. A diagnosis of sarcoidosis was made 4 years later after several chest infections, severe panhypogammaglobulinemia was demonstrated and a revised diagnosis of CVID made.

Case 2: DG presented aged 29 with cough, breathlessness and generalised lymphadenopathy. Granulomas were seen on liver biopsy. A diagnosis of sarcoidosis was made after lymph node aspirate demonstrated granulomata.13 years later, investigations after a protracted pneumonia revealed panhypogammaglobulinemia.

Standard immunoglobulin replacement therapy at a dose of 40mg/kg/month was started in both cases after the diagnosis of CVID. An audit of our cohort of 148 patients with diagnosed sarcoidosis found that 47% had not had serum immunoglobulins checked during diagnostic work-up.

Conclusion: Chest physicians often omit to check immunoglobulins when assess-ing patients with suspected sarcoidosis. This may not be surprising given the lack
of advice on measurement of immunoglobulins in current Intersitial Lung Disease guidelines. While CVID is uncommon, awareness, early diagnosis and effective treatment can reduce morbidity, mortality and complications and improve quality of life.

P3675 Electrocardiographic characteristics in patients with sarcoidosis
Elias Gialafos, Vasileios Kouranos, Alfonso Jurado Roman, Maria Gallego, Juan Jiménez, Anastasios Kallimanis, Ourania Anagnostopoulou, John Aragis, Aggeliki Rapti, George Tzelpis. 1: 1st Cardiology Unit, University of Athens, Greece; 2: 5th Pulmonary Clinic, General Hospital of Chest Diseases “Sotiria”, Athens, Greece; 3: Cardiology Clinic, Heart Hospital UCL, London, United Kingdom; 4: 2nd Pulmonary Clinic, General Hospital of Chest Diseases “Sotiria”, Athens, Greece; 5: Department of Therapeutics, University of Athens, Greece

Background: Several studies have emphasized the importance of early identification of cardiac sarcoidosis. Aim of our study is the evaluation of electrocardiographic (ECG) characteristics in a cohort of sarcoidosis patients indicating myocardial involvement.

Methods: Consecutive patients with biopsy proven sarcoidosis (n=315) were examined from October 2002 through October 2011. Exclusion criteria were presence of pacemaker and/or implantable cardioverter defibrillator. Heart rate (HR), PQ, QRS, QT and QT corrected intervals, PQRS and T wave axis were collected. Also, complete and incomplete right (RBBB) and left (LBBB) bundle branch block, right (RVH) and left (LVH) ventricular hypertrophy, repolarization and intraventricular abnormalities were noted.

Results: Only 59 out of 315 patients had a normal ECG. Mean HR was 75±13.5 beats/min, QT=417.5±21.2 ms while axis of P, QRS and T wave were: 42.6±19.8°, 20.79±34.0° and 34.7±25.9°, respectively. Six patients were found at atrial fibrillation while the rest were at sinus rhythm. PQ interval ±17.56 msec. RBBB was detected in 55 (11 complete and 44 incomplete) and LBBB in 9 patients (8 complete and 1 incomplete). Sixty patients were found with ventricular hypertrophy (56 LVH/4 RVH). At least one lead repolarisation abnormality was found in 177 patients including inferior lead abnormalities at 28, anterior lead abnormalities at 23 and lateral leads abnormalities at 23 patients.

Conclusion: Although ECG is a widely available tool used in the diagnosis of cardiac sarcoidosis various abnormalities were described implying necessity of extensive investigation in order to detect cardiac involvement.

P3676 Survival predictors in a cohort of patients with idiopathic pulmonary fibrosis
Mauricio Salinas, Matias Florenzano, Gabriel Cavada, Alvaro Underaga.
1: Facultad de Medicina, Universidad de Chile, Santiago, Region Metropolitana, Chile

Idiopathic Pulmonary Fibrosis (IPF) is a bad prognosis disease with heterogeneous progression. Only few studies, including relative small sample size, have searched for bad prognosis factors. The aim of this study was to analyze survival predictors in a retrospective cohort.

The study was conducted at the National Thorax Institute in Santiago, Chile. Registrers of patients in the period between 1991 and 2008 with clinical, radiological and surgical biopsy concordant with IPF were analyzed. We performed survival analysis with mixed models and proportional Weibull hazard models. A total of 142 patients were analyzed. The average age was 58 years and 41.5% were males.

The mean survival was 80 months. In univariate analysis were predictors of mortality: diffusing capacity of the lung for carbon monoxide (DLCO) less of forty percent and desaturation during six minute walk test (6MW) at baseline. The rate of decline of forced vital capacity (FVC) was mortality predictor. The rate of decline of FVC is a strong mortality predictor in this study and allows distinguishing bad prognosis groups.

P3677 Pathological findings in histiocytosis X with pulmonary hypertension
Javier Villuela, Jose Cifrian, Beatriz Abascal, Alejandro Daly, Carlos Amado, Sonia Fernandez-Rozas, David Ibure, Felipe Zurzano, Roberto Mols, Javier Gomez-Román. 1: Pulmonary Medicine, Hospital Marques Valdecilla, Santander, Spain; 2: Pathology Department, Hospital Marques Valdecilla, Santander, Spain; 3: Thoracic Surgery, Hospital Marques Valdecilla, Santander, Spain

Objective: To evaluate the hemodynamic characteristics, pulmonary function and pathological findings in patients with Langerhans cell histiocytosis (LCH) and Pulmonary Hypertension (PH) not explained otherwise.

Methods: A retrospective study was conducted in patients with Langerhans cell histiocytosis. Echocardiogram, lung biopsies, lung function tests and hemodynamic recordings were reviewed.

Results: Twenty patients were studied, with a mean age of 41±10 years. 8 patients (40%) had severe PH. The mean delay between the diagnosis of LCH and PH was 2.1 years. Six minute walk distance was 409±101 m. Systolic PAP: 62±15 mmHg. FVC was 62±15% of predicted, FEV1 45±21% and DLCO 41±9. All patients were on long-term oxygen therapy. After a median follow-up of 9.1 years, 1 patient is clinically stable, 1 patient had died of cardiac arrest while waiting for lung transplant, and 6 patients had undergone lung transplantation with 83% survival at 1 and 3 years. Histopathological lesions studied in explanted lungs suggested a veno-occlusive origin for this kind of complication, with capillary congestion, interstitial granulomatosis-like changes and fibrosis of septa, something that has been rarely described in LCH.

Otherwise, it is interesting to remark the presence of three cases of malignant neoplasias in the global serie. This association has been described as isolated cases in literature review. Two patients suffered from malignant lymphoma and one female patient had an uterine cervix carcinoma.

Conclusions: Pulmonary Hypertension could have a veno-occlusive origin in LCH. A relationship between malignant neoplasias and LCH may be possible.

P3678 A combinational approach to optimize biomarkers efficacy in identifying patients with sarcoidosis and monitoring respiratory functional worsening
Gregorino Paone, Gian Luca Di Tanna, Sandro Batella, Francesco Belli, Salvatore D’Antonio, Mario Giuseppe Alma, Giovanni Schmidt, Giovanni Puglisi, Annarita Vestri. 1: Department of Cardiovascular, Respiratory, Nephrologic and Geriatric Sciences, University “La Sapienza”, Rome, Italy; 2: Department of Public Health and Infectious Diseases, University “La Sapienza”, Rome, Italy; 3: Department of Respiratory Diseases, S. Camillo-Forlanini Hospital, Rome, Italy;

Background: Sarcoidosis is a multisystemic granulomatous disease of unknown aetiology which affects lungs and lymphatic system its diagnosis is established by histologic evidence of non-caseating granuloma and the clinical course is unpredictable.

Aims: We aimed to investigate whether a panel of biomarkers combined together may help identify sarcoidosis and predict its functional worsening.

Methods: We analyzed 30 subjects with sarcoidosis and 34 with IPF. Participants underwent PFTs, radiologic investigations, and fiberoptic bronchoscopy. We examined BALF cellular profiles and BALF and serum concentrations of ECP, MPO, tryptase, procollagenIII, IL-6, and TNFα.

Results: The linear predictor score based on the combination of BALF lymphocytes, CD4, C4D, and ECP, correctly allocated 29 patients with sarcoidosis (97% of correct classification; 95% CI, 84.4%-99.8%) and 28 with IPF (82% correct classification; 95% CI, 68.8%-92.2%). The AUC was 0.93.

We also analyzed PFTs of participants with sarcoidosis during a 2-years follow-up period. At revaluation 76% of participants had stable disease, and 24% experienced a worsening of the respiratory function. The combination of BALF neutrophil percentage, ECP, and tryptase, yielded a 100% correct classification of patients (95% CI, 90.6%-100%); the AUC was 1. None of the markers analyzed as a single variable reached a similar allocation rate and a dissatisfying discrimination was obtained using markers from peripheral blood.

Conclusion: This combinational method could be a valuable approach to optimize biomarkers performance in the effort to identify sarcoidosis and to predict its clinical course.
Peripheral blood and in BAL were performed in 10 subjects. Of bronchial obstruction which made the BAL impossible. T-SPOT.TB tests in suspected for sarcoidosis were included in this study. 1 was withdrew because radiographs were abnormal in 22% patients. Most common radiological finding was obstructive defects in 12% and mixed defect in 6%. FEF25-75% was abnormal on HRCT thorax were interstitial lung disease suggestive findings (31%) and with abnormal Spirometry in 51% and abnormal HRCT in 59.30% patients. Chest diagnosis between sarcoidosis and tuberculosis? – Pilot study

Material and method:

11 subjects (4 female, 7 male; mean aged 45.8 ± 15.1 years) were evaluated in a prospective fashion. All patients underwent clinical interview, chest radiography, high resolution computerized tomography and lung function tests (spirometry, lung volumes by plethysmography and carbon monoxide diffusion DLCO).

Results:

Clinical characterization: 69.4% female, age 54.9 ± 13.6. Smoking status: 64% non-smokers. Disease duration was 9.2 ± 6.1 years. Disease activity was the most prevalent (91.7%), followed by lymph nodes and cutaneous involvement. Number of extra pulmonary organ involvement was 1.6 ± 1.1 organ per patient. Near 62% of patients had interrupted working activity, 15.5% had to change job due to sarcoidosis morbidity. Up to 26% of patients had used immuno-presssure drugs for sarcoidosis, and 81.6% had taken corticosteroids. Three patients (4.1%) used oxygen therapy. Scadding stage: 28.2 ± 25% stage 1; 16.9% stage 2; 23.9% stage 3; 15.5% stage 3 and 15.5% stage 4. Lung function data: FVC 85.9 ± 16.5%, VEF1 82.7 ± 15.1%, VEF25-75% 96.8 ± 15.6%, TLC 89.7 ± 14.9%, RV 103.1 ± 26.1%. DLCO 76.7 ± 17.7%. Tomographic findings: parenchymal involvement in 64.5% of patients. Large (> 1.5 cm) lymph nodes in 13.9%. Conclusion: Our sample of patients prospectively evaluated is quite similar to other series of outpatients described.

Prevalence of pulmonary involvement in rheumatoid arthritis patients in Indian population

Krisna Bihari Gupta, Dhikai Tyagi, Harpreet Singh, Sarita Magu. Respiratory Medicine, Pt. B.D. Sharma Post Graduate Institute of Health Sciences, Rohtak, Haryana, India Respiratory Medicine, Pt. B.D. Sharma Post Graduate Institute of Health Sciences, Rohtak, Haryana, India Radiology, Pt. B.D. Sharma Post Graduate Institute of Health Sciences, Rohtak, Haryana, India

Rheumatoid arthritis (RA) is the most common chronic connective tissue disorder that significantly affects the lungs. The aim was to evaluate the pulmonary involvement in RA patients and its correlation with duration of RA. A total of 100 diagnosed cases of RA, divided into two groups of 50 patients each on the basis of duration of RA i.e. < 5 years and > 5 years were evaluated. All the patients were assessed for clinical characteristics. High resolution computed tomography (HRCT) thorax and Spirometry findings. Disease severity was assessed by DAS28 score. Respiratory symptoms were present in 41% patients. Pulmonary involvement (either abnormal HRCT thorax/Spirometry or both) was found in 67% patients with abnormal Spirometry in 51% and abnormal HRCT in 59.30% patients. Chest radiograms were abnormal in 22% patients. Most common radiological finding on HRCT thorax was interstitial lung disease suggestive findings (31%) and bronchiectasis (29.41%). On Spirometric, restrictive defect was found in 33% obstructive defects in 12% and mixed defect in 6%. FEF25-75% was abnormal in 18.8% patients. Risk factors for the presence of pulmonary involvement were increasing age and presence of rheumatoid factor. No association was found with gender, duration of disease, severity of disease. A high prevalence of pulmonary involvement was found in RA independent of duration of illness. HRCT appeared to be more sensitive tool.

Results: All 10 patients were AFB and MTB DNA negative in BAL. T-SPTOP.TB test was positive in peripheral blood in 2/10 and in BAL in 1/10. The culture of BAL was positive for MTB only in the case who had positive T-SPTOP.TB test both in BAL and in peripheral blood.

Conclusion: Positive T-SPTOP.TB performed in BAL could be helpful in differential diagnosis between sarcoidosis and tuberculosis. Further studies are needed.
Patients with idiopathic pulmonary fibrosis (IPF) have limited exercise capacity due to dyspnea, abnormal lung mechanics, pulmonary hypertension and other mechanisms. We tested the hypothesis that 24 sessions of exercise in the form of a rehabilitation program would improve six-minute walk test (6-MWT) distance, peak exercise oxygen uptake (VO2 peak) and dyspnea (Borg dyspnea index) after exercise in patients with typical IPF. We investigated possible underlying mechanisms including hypoxemia, oxidant stress and pulmonary hypertension. Subjects with IPF defined by clinical criteria were randomly assigned to a 3-month pulmonary rehabilitation program or to a control group that did not participate in rehabilitation. Before and after the 3-month rehabilitation or observation, subjects underwent 6-MWT and exercise gas exchange studies (cycle ergometry). Blood samples were obtained for 15-F2t-isoprostanes, lactate and NT-proBNP measurements immediately before and after cycle ergometry. Rehabilitation did not cause a significant increase in 6-MWT distance or a decrease in dyspnea. Subjects who completed pulmonary rehabilitation maintained VO2 peak at baseline over three months. The control group had a significant decrease in VO2 peak over the same 3 months. Plasma lactate increased significantly after ~50-watt cycle ergometry exercise testing at 0- and 3-month evaluations in both groups; this was associated with significant decreases in arterial oxygen saturation. Pulmonary rehabilitation maintained peak oxygen uptake, but did not improve exercise capacity of patients with moderately severe IPF. Low-level exercise was associated with significant hypoxemia and systemic oxidant stress.

391. Distinguishing phenotypes and dealing with comorbidities in primary care

P3687
Diagnostic delay of pulmonary embolism in primary and secondary care: A retrospective study

Robert Jackson1, Carol Ramos1, Diana Cardenas1,2, Constanza Sol3

1Pulmonary Diseases, Isala Klinieken, Zwolle, Netherlands; 2General Practice, Isala Klinieken, Zwolle, the Netherlands. 261 patients were included for analysis.

391 patients diagnosed with pulmonary embolism between 2008 and 2009 in the community and is associated with worse clinical outcomes. It is also a stronger predictor of mortality. Multivariate logistic regression analyses showing number and length of hospital admissions depending on Charlson index and degree of dyspnoea. Presence of diabetes as comorbidity independent predictor of longer hospital admission.

P3688
Effects of aerobic and strength training on symptoms and exercise capacity of IPF patients

Robert Jackson1, Carol Ramos1, Diana Cardenas1,2, Constanza Sol3

1Pulmonary Diseases, Isala Klinieken, Zwolle, Netherlands; 2General Practice, Isala Klinieken, Zwolle, the Netherlands. 261 patients were included for analysis.

Patients with IPF defined by clinical criteria were randomly assigned to a 3-month pulmonary rehabilitation program or to a control group that did not participate in rehabilitation. Before and after the 3-month rehabilitation or observation, subjects underwent 6-MWT and exercise gas exchange studies (cycle ergometry). Blood samples were obtained for 15-F2t-isoprostanes, lactate and NT-proBNP measurements immediately before and after cycle ergometry. Rehabilitation did not cause a significant increase in 6-MWT distance or a decrease in dyspnea. Subjects who completed pulmonary rehabilitation maintained VO2 peak at baseline over three months. The control group had a significant decrease in VO2 peak over the same 3 months. Plasma lactate increased significantly after ~50-watt cycle ergometry exercise testing at 0- and 3-month evaluations in both groups; this was associated with significant decreases in arterial oxygen saturation. Pulmonary rehabilitation maintained peak oxygen uptake, but did not improve exercise capacity of patients with moderately severe IPF. Low-level exercise was associated with significant hypoxemia and systemic oxidant stress.

P3689
The impact of anemia on patients with chronic obstructive pulmonary disease in the community

Carolina Grischi, Jode Smith, Karen Moore, Noel Okelly. Department of Community Health Services, Leicestershire Partnership NHS Trust, Leicester, United Kingdom

Background: Anemia of chronic disease (ACD) has been shown to be linked with multi-faceted clinical consequences in patients with chronic obstructive pulmonary disease (COPD) enrolled in clinical trials. The predictive value of ACD has not been evaluated in stable COPD patients in the community.

Methods and results: We evaluated 488 patients (9.4%) with stable COPD under the care of a regional nurse-led community respiratory team between June 2008 - November 2010. 86% of patients were on inhaled beta agonists; 43% on long acting anti-muscarinics, 54% on inhaled steroids and 8% on oral steroids. Mean age of the patients was 73.9±6.1 years, 43% were females and mean MRC grade was 2.2±0.7. ACD was defined as hemoglobin (Hb) between 9.1-9.2 g/dL. Mean Hb levels were 14.1±0.7; 13.9±0.3; 14.0±0.6 and 13.7±0.2 g/dL at 0, 6, 12 and 24 months. To rule out iron deficiency we sample ferritin. Mean serum ferritin levels in the entire study population were 242±159 g/L at the start and 227±19.8 g/L at the end. The prevalence of ACD was 13.9±1.2 (95% CI) and 14.5±1.3% respectively at the start and end of the study period. 2-year survival was 93% in the entire population; 81% in the anemic group (p<0.001). Risk-adjusted hazard ratio for 24 month mortality was 1.43 (1.19-1.90) for the anemic patients.

Conclusions: High prevalence of comorbidity, particularly cardiovascular disease being the main cause of death. Level of frailty depending on comorbidities of COPD geriatric hospitalized patients related to their prognosis. Implementation of aggressive strategies to prevent or treat comorbidities necessary for a better care of patients, together with the correct management of the respiratory disease.

P3690
Sleep does not affect health status in a primary care COPD population

Corina de Jong, Janwillem Kocks, Thys van der Molen. General Practitioners Medicine, University Medical Center Groningen, Netherlands

Introduction: Knowledge on the relation between sleep quality and health status in mild COPD patients is very limited.

Aims and objectives: The aim of the current study was to evaluate the effect of sleep on health status as measured by the Clinical COPD Questionnaire (CCQ) in a primary care COPD population.

Method: 38 COPD patients were enrolled in the study, which was part of a larger study evaluating health status based treatment versus standard GOLD guideline based treatment. The participants completed the CCQ (symptoms, mental, functional and total scale) and the Pittsburgh Sleep Quality Index (PSQI; duration, disturbances, latency, daytime dysfunction, efficiency, quality, medication need and total score).

Results: Mean participant age was 66 years; mean number of packyears 41; 72% male; GOLD I 36%, GOLD II 56%, GOLD III 8%. In the univariate analyses relations were found between the CCQ total scale and FEVI ( spearman -0.416, p<0.009), CCQ total and daytime dysfunction ( spearman 0.404, p<0.012) and CCQ total and GOLD stage ( spearman 0.369, p=0.023). No relations were found with group allocation, age, social economic status, medication, BMI or packyears. Multivariate analyses confirmed health status to be related to FEVI and daytime dysfunction. The relation with GOLD stage was not confirmed.
Conclusion: Health status by means of CCQ is related to FEV1 and daytime dysfunction. None of the other sleep quality scales showed to have an influence on health status. The current study gives an insight into the possible relation between health status and sleep in a primary care COPD population and shows that the PSQI is a relevant instrument, however the n of 38 is too low for definitive conclusions.

Methods: During 2006-2011 years we studied 128 children with chronic cough and persistent wheezing. Median age was 8.5 months. Clinical history showed that 52 had concomitant symptoms of suspected FA: atopic dermatitis 31 (24.5%), diarrhea 8 (6.2%), rhinitis 6 (4.6%), urticaria 9 (7%), combination of two or more symptoms 15 (11.7%). 47 had concomitant symptoms of suspected GER (persistent regurgitation and vomiting). 29 had only respiratory problems. Regurgitation was found in 63.9% of patients. 58% had at least one laboratory parameter outside laboratory limits: positive skin prick 31, eosinophilia in nasal or sputum secrets 12, increased circulating EGF 16, specific EGF 10.

Conclusion: Patients younger than 24 months with GER and respiratory symptoms should be evaluated for food allergy. There is connection between GER and FA (specially cow milk allergy). Atopy and positive tests can help to separate GER patients for need of elimination diets.

P3602 Daily activities and quality of life in COPD patients: Psychological determinants

Saska Wędzal, Jan-Willem Lammers, Roger Decates, Ad Kaptein, Marekz Schumanms, Respiratory Diseases, University Medical Center, Utrecht, Netherlands; 2Rehabilitation, Nursing Science & Sports, University Medical Center, Utrecht, Netherlands

Background: Psychological variables play an important role in COPD patients’ management of their illness and daily life. To develop self-management interventions to improve Quality of Life (QoL) in COPD patients, more detailed studies are needed.

Objective: To study the influence of illness perceptions, proactive coping competencies and depressive symptoms on daily activities and QoL in COPD patients.

Methods: In a 24% sectional study in primary care, 90 COPD patients (GOLDI-3) completed the following questionnaires: Brief Illness Perception Questionnaire, Utrecht Proactive Coping Competence scale, Center for Epidemiologic Studies Depression Questionnaire (CES-D), General Health Questionnaire (GHQ-12). The influence of illness perceptions, proactive coping competencies and depressive symptoms on daily activities and QoL were assessed with multiple linear regression analysis.

Results: COPD patients had worse QoL on most of the daily activities and QoL domains. Higher scores on illness perception questionnaire were related to worse QoL (β = -0.24, p < 0.01). Proactive coping competencies had a significant positive influence on QoL (β = 0.27, p < 0.01). However, higher depressive symptoms were related to worse daily activities and QoL (β = -0.23, p < 0.01).

Conclusion: COPD patients have worse QoL with worse illness perceptions, lower proactive coping competencies and higher depressive symptoms. In this study, illness perceptions were a stronger predictor for worse QoL than depressive symptoms. Further research is needed to evaluate the impact of psychological determinants on daily activities and QoL in COPD patients.

P3604 Diagnosing asthma and COPD in primary care patients in Serbia: A multicenter study

Marija Vukoja, Predrag Rebić, Zorica Lazić, Marija Mitic Milickić, Bransilava Mileņković, Biljana Zvezdin, Ivan Cekerevac, Mirjana Jovančević Drenčeva, Sanja Heonča, Ivan Kapotić, Lung Function Centre, The Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia; 2Hospital for Pulmonology, Clinical Centre of Serbia, Belgrade, Serbia; 3Centre for Pulmonary Diseases, Internal Clinic, Clinical Centre, Kragujevac, Serbia; 4Asthma Department, The Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia

Background: Asthma and chronic obstructive pulmonary disease (COPD) are often unrecognized and undertreated.

Aim: The aim of this study was to describe the frequency of COPD and asthma in patients with respiratory symptoms and/or smoking history in primary care settings in Serbia, and to examine the agreement between general practitioners (GPs) and pulmonologists on the diagnosis of COPD and asthma.

Methods: In this multicentric, prospective, observational study GPs from practices in 3 different centers in Serbia identified eligible patients from October 2009-Jan 2010. The study included all adult patients with respiratory symptoms and/or smoking history based on structured interview. The patients were referred to a pulmonologist and underwent a diagnostic work-up, including spirometry.

Results: There were 2074 patients, 38.4% men, mean age 54±15.5 years. Patients were mostly current (40.3%) or ex-smokers (27.4%). The common symptoms included shortness of breath (84.9%), cough (79.1%) and wheezing (63.8%). The COPD diagnosis was confirmed by pulmonologists in 455 (21.9%) and asthma in 435 (21.9%) patients. COPD was newly diagnosed in 226 (10.9%) and asthma in 269 (13.0%) of the cases. There was a moderate agreement between general practitioners (GPs) and pulmonologists on the diagnosis of COPD and asthma.

Conclusion: A significant number of patients seen in GPs office were diagnosed with COPD or asthma and half of them represent new cases. A substantial proportion of patients referred to pulmonologist by primary care physicians have been misdiagnosed.
CL, 3.20-8.35), the presence of emphyma in the X-ray - OR, 3.11 (95% CI, 2.37-4.06). Age 57 years and over - increases 5.25 times (95% CI, 3.90-7.70). The likelihood of lower BMD in the 2nd stages is 2.28 (95% CI, 1.36-3.50) and in the 3rd stage is greatly increased - OR, 10.91 (95% CI, 6.98-17.05). The hypoxia (SO2%) significantly increases the risk of secondary reduction of BMD - OR 15, (95% CI 10.05-22.38).

Conclusion: Factors that increase the likelihood of reducing the BMD are the frequency and type of exacerbations, age, duration and severity of disease, the presence of occupational factors, emphyma and hypoxia.

P3696

Distribution of dyspnea etiologies among patients with either acute or chronic breathlessness and normal cardiorespiratory function

Stylianos Michalelis1, George Babolekos2, Efthychia Koutrelissi1, Alexandros Alexopoulou1, George Jonas1, Konstantinos Paraskevopoulos1, Sofia Karagianni1, Ist Dept. of Thoracic Medicine, Stavrosios Georgios General Hospital, Athens, Attiki, Greece; 2Faculty of Health Professions, Technological University, Athens, Attiki, Greece

We aimed at investigating the distribution of dyspnea etiology in patients with normal cardiorespiratory function (NCF). We studied 57 pts. (33 male & 24 female) aged 58.4±4.7 yrs. who presented at the Outpatients’ Department during the past 12 months, complaining of breathlessness with no other respiratory symptoms. Patients complainable of either acute breathlessness (AB group- starting within the past 48 hrs.) or chronic (CB-group-more than 48 hrs. duration). All had a chest X-ray along with spirometry, arterial blood gases and heart ultrasound, having been rated as normal. Those in whose diagnosis was not mainly established, underwent further testing including hormonal profile, lung perfusion scan, computerized chest tomography & angioigraphy and respiratory muscle testing. In AB group (31 pts. 15 male & 19 female) aged 46.4±4.7 yrs. the final diagnosis was: 18 pts. (58%) acute psychogenic hyperventilation syndrome (HS), 11 (36%) anemia due to silent gastrointestinal bleeding (GB) and 2 (6%) hypothyroidism (HT). In CB group (26 pts:18 male & 8 female) aged 61 ±36.8 yrs. the final diagnosis was: 6 pts. (23%) HS, 7 (27%) GB, 3 (12%) obesity-deconditioning (OD, 3 (12%) anemia of the abdomen in males was similar to that in females, the ratio of visceral adipose tissue to total adipose tissue was statistically different. In males, total abdominal adipose tissue and visceral adipose tissue were inversely associated with the value of FEV1% predicted (FVC) and FEV1/FVC ratio. In females, total abdominal adipose tissue and visceral adipose tissue, but not subcutaneous adipose tissue, were inversely associated with absolute FVC and FEV1 values. In conclusion, abdominal visceral obesity is inversely associated with lung function.

P3697

Health state and the quality of life in patients with chronic obstructive pulmonary disease (COPD) in Poland: A study using the EuroQol-5D SD questionnaire

Piotr Boroń1, Wojciech Lubinski2, 1Lung Function Lab, National TB & Lung Disease Research Institute, Warsaw, Poland; 2Headquarter, The Military Institute of Medicine, Warsaw, Poland

Introduction: Chronic obstructive pulmonary disease (COPD) is a severe disease that leads to respiratory disability and a considerably reduced comfort of living that affects all the aspects of patient activity.

Objectives: The aim of our study was to assess the quality of life (QoL) in patients with diagnosed COPD using, as the research tool, EuroQol-5D, a health-related QoL questionnaire.

Patients and methods: The data were obtained using designed questionnaire by conducting a cross-sectional survey in a large (N=9310) group of patients with COPD.

Results: Mild and moderate COPD patients (GOLD stage 1 and 2) constituted the majority of the study population (16% and 54%, respectively). A perceptible COPD-related low health state was shown for each stage of the disease, including patients with mild to moderate COPD. Significant differences were observed between the groups of patients stratified by spirometry results in perceived health state assessed with the questionnaire and on a visual analogue scale (VAS). Using linear regression models the association between the health status measured using VAS scale and comorbidities (especially heart failure), and severe (or very severe) COPD status was found (p<0.001). Patients with the history of exacerbations had significantly lowered health status assessed by VAS scale (p<0.001).

Conclusions: EQ-SD along with VAS seems to be a useful tool to characterise health state of patients with COPD. It is noteworthy that also in the milder stages of the disease there are limitations in various life aspects that are important to the patients.

P3698

Association of CAT scores with exacerbations and comorbidity in COPD patients in a randomized primary care setting

Ioanna Tsaligia1, Dimitra Sifaki-Pistolia, Anna Dakanali, Nikolaos Sialakas, Nikolaos Tzanakis. Thoracic Medicine, Faculty of Medicine, University of Crete, Heraklion, Greece

Introduction: Health status measurement with CAT has been proposed for COPD management in the updated GOLD guidelines. We aimed to investigate CAT score correlation with AECOPD and comorbidity in a Greek cohort of COPD patients

Methods: Data were selected from 544 COPD patients from Greece through a prospective cross-sectional study, attending primary health care units. Demographic data, previous treatment, lung function testing, exacerbations and co-morbidity were recorded. Chi-square test, bivariate Pearson r correlation and binary logistic regressors were applied on data regarding the CAT score, FEV1 (95 pred.), FVC, FVC% and certain clinical parameters of the disease.

Results: CAT scores classification percentages showed: 38% mild CAT score, moderate impact level 46%, severe score 15% and very severe score 1.9%. 56% of the patients with exacerbated disease had medium CAT score while the 19.6% of them had a high impact score (p<0.001). A positive correlation was found between CAT scores and risk for exacerbation Odds (95%CI): 1.2 (1.0-3.0), p<0.001 for the group with moderate impact CAT score, 1.9 (1.4-3.1), p<0.001 for high impact and 2.1, (1.3-2.9), p<0.001 for very high impact. Patients with comorbidity presented a higher risk of developing high and very high impact of CAT score: Odds(95%CI): Stroke 2.4 (1.7-4.2), p<0.001, heart failure 1.5, (1.19-1.7), p<0.001, peripheral vascular disease 1.3 (1.0-1.8), p<0.001, ischemic heart disease 1.8, (1.3-3.0), p<0.001, osteoporosis 1.5(1.2-1.8), p<0.03 and depressive symptoms 1.3 (1.1-1.8), p<0.04.

Conclusions: The co-existence of other diseases with COPD increases the probability of presenting a worse health status.

P3699

Effects of abdominal visceral obesity measured by bioelectric impedance analysis on lung function

Seung Ho Cheo, Seung Joo Kang, Seong Yeon Kwon. Internal Medicine, Seoul National University Hospital Healthcare System Gunpoam Center, Seoul, Korea

While many studies suggest the impact of obesity on lung function, studies of abdominal visceral obesity on lung function provide inconclusive informations. The aim of this study was to investigate the association of abdominal visceral fat measured by bioelectrical impedance analysis and changes in lung function. We included never-smokers between the ages of 18 and 80yr, who had undergone spirometry and abdominal adipose tissue analysis with bioelectrical impedance analysis during March 1, 2009 to December 31, 2010 as part of the health examination. Among a total of 67,368 participants, 54.3% were male. The mean body mass index and waist circumference among males and females were 24.8 kg/m² and 23.1 kg/m² and 83.7 cm, respectively. Although total adipose tissue of the abdomen in males was similar to that in females, the ratio of visceral adipose tissue to total adipose tissue was statistically different. In males, total abdominal adipose tissue and visceral adipose tissue were inversely associated with the value of FVC and FEV1. In females, total abdominal adipose tissue and visceral adipose tissue, but not subcutaneous adipose tissue, were inversely associated with absolute FVC and FEV1 values. In conclusion, abdominal visceral obesity is inversely associated with lung function.

Pilot study of reliability of PQH-9 questionnaire for evaluation of depression in hospitalized asthmatic patients

Saied FallahFarsi, Ali Cheraghvandi, Mitra Safa, Firoozeh Talischi. Nursing Research and Pulmonary Health Center, Mash Daneshvari Hospital, Tehran, Islamic Republic of Iran

In chronic pulmonary disease patients, consideration of physical signs of illness such as difficulty breathing, etc. as well as psychiatric conditions which occur due to lack of adaptability with disease are important. In this study it was tried to evaluate a short and comprehensive questionnaire for screening for psychiatric disease and the PQH-9 for depression and GAD-7 for anxiety were evaluated. This was a cross-sectional study with completion of questionnaire by one inter-viewer. All asthma patients hospitalized at Mash Daneshvari Hospital during the summer of 2011 who were able to respond to questionnaire and agreed to participate were included in the study. Demographic information was also collected. Data was entered into the computer and analyzed via SPSS 12 software. In total 20 patients participated for the pilot study with mean age of 58±18 years and 70% were female. Fifty six percent were illiterate and average years of illness were 9±5 years. Depression and anxiety was found more in women compared to men which a larger study for significance evaluation is needed. The Cronbach alpha values for PQH-9 were 0.645 and for GAD-7 0.837. The shortness of the questionnaires makes them practical. A larger study is in progress by researchers for determining validity and reliability of the two questionnaires and comparison with the GHQ-12.

The role of inflammatory markers in obstructive pulmonary disease

Eliana Laranje, Nada Bogdancovic. Pulmonology, University Hospital Center Zemun, Belgrade, Serbia; Pulmonology, University Hospital Center Zemun, Belgrade, Serbia

Background: Asthma and chronic obstructive pulmonary disease (COPD) are characterised by airway and systemic inflammation, but little is known about
P3702
Neutrophils and the increased risk of cardiovascular events in severe COPD
Kenji Yuzuri1, Naoko Kamada2, Yoshimura Fujibe1, Masayuki Kashima1, Kenichi Asakura1, Minko Sato1, Tazuko Sato1, Kenji Kikuchi4.

Methods: Five male outpatients with COPD (83±4 age, forced expiratory volume in 1 second (FEV1) 39±17%, predicted), all ex-smokers and undergoing long-term oxygen therapy, were included. Measurements were obtained monthly for the ratio of circulating neutrophil cell count to peripheral white blood cell count (neutrophil %), FEV1, forced vital capacity (FVC), hANP, and baPWV from July 1, 2011, to December 15, 2011.

Results: Neutrophil% (67.4±11.1%) was significantly correlated with BaPWV (2465.8±652.7cm/s) (r=0.48, p<0.05) and hANP (27.6±8.7 pg/ml) (r=0.47, p<0.05). However, BaPWV was not correlated with FEV1 or FVC.

Conclusions: This report suggests that neutrophils might be involved in the increased risk of cardiovascular events in sever COPD.

P3703
Status of upper airways in exacerbation of COPD
Evgeny Gillianov1, Vera Nemirova1, Tatjana Tlika1, Valentina Kudryavtseva2, Elena Samoilenko2, Sergey Klimentov1, Boris Lepeiko3, Yulia Lepeiko3.

3 Chair of Otolaryngology, Vladivostok State Medical University, Vladivostok, Primorsky Region, Russian Federation; 2Chair of Therapy, Vladivostok State Medical University, Vladivostok, Primorsky Region, Russian Federation; 1Department of Pulmonology and Otolaryngology, Vladivostok City Hospital No. 1, Vladivostok, Primorsky Region, Russian Federation

Introduction: Inflammatory cells and mediators that may lead to destructive changes in airways, pulmonary vasculature, and lung parenchyma may be associated with an increased risk of cardiovascular events in patients with chronic obstructive pulmonary disease (COPD).

Methods: We tested the hypothesis that neutrophils in venous blood have a relationship with serum human atrial natriuretic peptide (hANP) and brachial-ankle pulse wave velocity (baPWV) in COPD.

Results: Mean neutrophil% was 67.4±11.1% and hANP was 27.6±8.7 pg/ml.

Conclusion: Neutrophil% and hANP were correlated with baPWV in exacerbation of COPD.

P3704
RIB FRACTURE CAUSED BY COUGHING IN A YOUNG PATIENT
Sakulh Vilaip1, Kusman Kavavich1.

1 Department of Pulmonary Medicine, Ekshein Military Hospital, Ekshein, Turkey; 2 Department of Thoracic Surgeons, Galhane Military Medical Academy, Ankara, Turkey

Introduction: A cough is a voluntary or involuntary explosive expiration that protects the lungs against aspiration and promotes the movement of secretions and other airway constituents upward toward the mouth. Rib fracture which is usually caused by coughing usually occurred due to underlying pathologic factors such as osteoporosis, renal failure, metastatic tumors. We presented a young patient with rib fracture caused by coughing.

Case report: A 53-year-old man had visited the hospital with the complaint of immediate onset and localized left-sided chest pain which was occurred due to coughing induced by upper airway infection. The history of patient was not significant and he had no injury to his chest. The crepitation and tenderness were determined on his physical examination. The thorax computed tomography was revealed a rib fracture on the left tenth rib. When we evaluate him for an endocrinopathy, we did not find any abnormality. We decided that his rib fracture was occurred due to coughing.

Conclusion: A rib fracture should be considered in mind in a patient who admitted with immediate onset and localized chest pain.

Artiology and outcome of dyspnoea in emergency department patients
Stavros Vogiatzis1, Klio Elefteriou2, Vasilios Tsouasis1, Anna Gavrilidou3, Marianne Kakhou4. Dpt of Pulmonology, Papageorgiou General Hospital, Thessaloniki, Greece

Introduction: Dyspnoea is a common and complex diagnostic problem in ED patients.

Aim: To record initial diagnoses and outcome in ED cases of dyspnoea in a general hospital.

Material: Adults whose presenting complaint was dyspnoea during 3 consecutive summer on calls. Methods: On site recording of relevant data. SPSS 18 was used for statistical analysis.

Results: 54/2.9% patients presented to A&E complaining of dyspnoea out of a total attendance of 1861 persons. 33 were male (61.1%) and the mean age was 66.1 years. At triage severity was characterized as: 1(11.1%), 2(28.9%), 3(33.3%), 4(16.7%), 5(50%). BORG scale of dyspnoea was: 1(5.6%), 2(5.6%), 3(4.8%), 4(31.5%), 5(11.1%), 6(5.6%), 7(11.1%), 8(7.7%), 9(9.1%), 10(9.3%). Onset of dyspnoea was acute in 7 patients (13%), subacute in 38 patients (70.4%) and in 9 (16.7%) patients there was acute deterioration of chronic dyspnoea.

Initial diagnoses were: COPD(20.4%), asthma(5.6%), cancer(9.3%), pleuritis(7.4%), haemoptysis(7.4%), pulmonary embolism(1.9%), febrile infection(22.2%), SAOS(1.9%), heart failure(14.9%), coronary artery disease(3.7%), hypertension(1.9%), neuropsychiatric disease(1.9%) and miscellaneous(1.9%).

Patients were treated at short stay units (3.7%), special departments (48.1%), ITU(1.9%), specialist centres(1.9%) and at home(44.4%). The mean duration of hospitalization was 7±2 days.

 Concordance between admission and discharge diagnoses was 70.7%. Additional medical problems were identified in 25.9% of the patients that presented with dyspnoea.

Conclusion: Dyspnoea in ED patients is a complex medical problem that requires meticulous clinical attention.

Induction of inflammation, oxidative stress and autophagy in human alveolar type I epithelial cells following exposure to silver nanoparticles
Martina Zambianchi, Andrew Thorley, Teresa Tetley. Lung Cell Biology, National Heart and Lung Institute, London, United Kingdom

The use of silver nanoparticles (AgNP) in health products is increasing due to their antimicrobial activity. However, their impact on health is poorly understood. It is known that the particle reactivity increases as size decreases, thus AgNPs may induce inflammatory responses that their bulk sized counterparts do not. It is known that 50% of inhaled nano-sized (<100nm) particles preferentially deposit in the peripheral lung. Thus, inhalation of AgNPs might have adverse effects on the alveolar epithelium. We hypothesise that AgNPs induce an oxidative stress-dependent proinflammatory response in the human alveolar epithelium and activate autophagy.

Human alveolar type I epithelial cells (TT1) were exposed to 80nm AgNPs for up to 24h. IL-6 and IL-8 release was measured by ELISA and reactive oxygen species (ROS) production measured by dihydroethidium staining. n-acetylcysteine (NAC) was used to evaluate the role of ROS in mediator release. The plasmid assay was used to assess free radical-induced DNA damage and the autophagy markers LC3II/LC3I measured by immunoblotting.

AgNPs induced significant oxidative stress within 4h and IL-6 and IL-8 by 24h. NAC pre-treatment inhibited Ag50 (g/ml=0.31; Ag50 g/ml=0.073) and induced a significant increase in the LC3II/LC3I ratio (P<0.01; Ag 50% vs. n), suggesting that AgNPs activate autophagy.

Our study shows that AgNPs induce oxidative stress-dependent inflammation, DNA damage and a unique finding of autophagy responses in TT1 cells suggesting that AgNPs may have adverse effects on the lung.

P3708
Defective macrophage phagocytosis in COPD is associated with reduced STAT1 phosphorylation
Rebecca Holloway1, Peter Fenwick1, Iain Kilty1, Peter Barnes1, Louise Donnelly1, National Heart and Lung Institute, Imperial College, London, United Kingdom; 2Inflammation and Remodelling Research Unit, Pfizer Inc., Cambridge, MA, United States

Macrophages are professional phagocytes that maintain sterility and remove in- vading pathogens. Chronic obstructive pulmonary disease (COPD) is associated with increased lung macrophages but the lower airways are colonised with bacteria such as Haemophilus influenzae and Streptococcus pneumoniae. This is associated with a decreased phagocytic response of COPD macrophages to these bacteria. IFNγ stimulation is increased in COPD airways and is associated with decreased phagocytosis. IFNγ stimulation activates the JAK/STAT pathway via phosphorylation of STAT1 to initiate signal transduction. We hypothesise that reduced phagocytosis in COPD is linked to STAT1 phosphorylation and JAK/STAT activation. Monocyte derived macrophages (MDM) from non-smoker, smoker and COPD donors and COPD lung tissue macrophages (n=4-3) were challenged with fluorescently labelled inert beads or heat killed bacteria (H. influenzae or S. pneumoniae). IFNγ stimulation (10ng/ml, 10min) was used as a positive control. STAT1 phosphorylation was assessed by Western blotting.

STAT1 was phosphorylated in response to inert beads in both non-smoker and smoker MDM but not in those from COPD donors. In addition, none of the phagocytic prey initiated STAT1 phosphorylation in COPD lung tissue macrophages. However, IFNγ stimulation caused phosphorylation of STAT1 in all three donor groups.

To conclude, COPD MDM and lung tissue macrophages are capable of STAT1 phosphorylation although not in response to phagophagic prey. This is in contrast to non-smoker and smoker cells that show JAK/STAT activation in response to inert beads. Further investigation of this signalling pathway in phagocytosis may lead to increased knowledge of COPD pathogenesis.
of severe asthma and COPD. We have examined TNFα-induced resistance to GC-dependent transcription by steroidal and non-steroidal GR agonists in the absence and presence of a LABA, formoterol.

Methods: GC-dependent transcription was modeled by a simple 2 x GR-luciferase reporter in human bronchial epithelial BEAS-2B cells treated with TNFs (10 ng/ml) for 1 h prior to addition of GR ligands, and harvested after 6 h for luciferase assay. Results: TNFα reduced by 43-54% the ability to drive 2x-GR-dependent transcription by dexamethasone, budesonide, fluticasone propionate or fluticasone furoate. The GC’s des-ciclesonide, GW70808X, RU24858 and the non-steroidal GR agonist, GS5027, all showed reduced maximal responses (Emax) with intrinsic activities 0.5-0.77 relative to dexamethasone. In each case, TNFα reduced Emax by a further 39-55%. Conversely, formoterol enhanced GR-dependent transcription by each ligand and rescued the resistance induced by TNFα; these effects were proportional to the Emax of each drug. Statistically significant reversal of TNFα-induced resistance was observed with the c-jun N-terminal kinase inhibitor, JNKs, and PS-1415, an IkB kinase 2 (IKK2) inhibitor.

Conclusions: TNFα induces GC resistance to steroidal GR ligands that are both full and partial agonists, as well as to a non-steroidal GR agonist. This effect is rescued by the addition of formoterol. It is possible that inhibition of inflammatory signalling may also reduce GC resistance.

P3712
The effects of human lung mast cell products on the synthetic functions of lung fibroblasts
Hatem Alkhouri1, Michael Wai-Shing1, David Krimmer2, Brian Oliver1,
Carol Armour1, J. Margaret Hughes1, 1Faculty of Pharmacy, University of Sydney, NSW, Australia; 2Woolcock Institute of Medical Research, University of Sydney, NSW, Australia

Activated mast cell numbers are generally increased in the bronchial wall and alveolar parenchyma of people with asthma. Mast cells release a wide variety of cytokines and mediators that may modulate the activities of structural cells such as fibroblasts and contribute to airway remodelling in asthma.

Objective: To examine the effects of human lung mast cell (HLMC) products on the synthetic functions of airway and parenchymal fibroblasts.

Methods: HLMCs were co-cultured with lung fibroblasts and their supernatants (SN) collected after 2 and 24h. The SN were added to serum-deprived airway and parenchymal fibroblasts for up to 48h. Fibroblast and mast cell cytokine release and extracellular matrix (ECM) deposition were measured using ELISAs.

Results: Both 2 and 24h HLMC SN significantly increased the synthetic functions of parenchymal and airway fibroblasts in a concentration-related manner. Release of CXCL8 was increased up to 3.9 and 3.1-fold from parenchymal fibroblasts by 2 and 24h SN respectively and 2.4-fold from airway fibroblasts in a concentration-dependent manner. Interestingly, although fibroblast deposition was unchanged, both the 2 and 24h SN significantly increased collagen IV deposition by airway, but not parenchymal fibroblasts up to 1.5-fold, whereas only the 24h SN increased tenasin-C deposition [1.8-fold] by the airway cells.

Conclusions: HLMC products increase lung fibroblast cytokine release and differentially regulate airway and parenchymal fibroblast ECM deposition. Thus HLMC may promote further inflammation and airway remodelling in asthma.

P3713
TNFα stimulates the expression different chemokines including CXCL10, CCL5 and ICAM-1 in developing air smooth muscle (ASM) cells:
Modulation by fluticasone and TNFα receptors
Hitesh Pandya1, Abubacarr Gasama1, Latifa Chachi1, Helen Pearson1, Y.S. Prakash2, Erol Guillard1, Yasmin Ameer2, 1Immunity, Inflammation and Infection, Institute for Lung Health, University of Leicester, England, United Kingdom; 2Department of Anaesthesiology, Mayo Clinic, Rochester, MN, United States

Corticosteroids are only partially effective in treating children with Chronic Lung Disease (CLD) or chronic asthma. Low to moderate doses of steroids are generally effective in limiting symptoms, but higher doses are lead to serious side effects with little extra effect on symptom control. In this study, we used fetal ASM cells from human airways to determine their responsiveness to inflammatory chemokines associated with CLD. Fetal ASM cells exposed to TNFα secrete different chemokines including CXCL10, CCL5 and CXCL8. Pre-treating cells with fluticasone (0.001–100nM) led to a dose-dependent suppression of all chemokines although the magnitude of inhibition was greater on CCL5 (over 95%) when compared to CXCL10 or CXCL8 (less than 60%) at 100 nM fluticasone. Using rFcR α, we also found that expression of cytokine genes was only partially repressed by fluticasone (100nM). Neutralizing antibodies against TNFα receptors revealed that engagement of both TNFR1 and TNFR2 mediates TNFα-induced chemokines expression. Our data suggest that generation of pro-inflammatory chemokines by fetal lung cells is only partially responsive to corticosteroid therapy. The mechanisms underlying this resistance are unclear.

p38 inhibitors suppress release of inflammatory cytokines and may have a therapeutically role in COPD.

P3715
Effect of beclomethasone dipropionate, formoterol and their combination on TNF-α-induced ICAM-1 and IL-8 expression in human bronchial epithelial cells
Silvana Cianchetti1, Cristina Cardini1, Gabriele Niccoli2, Alessandro Celi1, Pierluigi Paggiaro1.
1Cardiothoracic and Vascular Department, University of Pisa, Italy; 2Medical Affairs Department, Chiesi Farmaceutici S.p.A., Parma, Italy

Background: The adhesion molecule and chemokine expression in the airways has been implicated in inflammatory lung diseases.

Aim: To investigate the effect of beclomethasone dipropionate (BDP) and formoterol (F) alone and in combination (BDP/F) on TNF-α-induced ICAM-1 expression and IL-8 release in human bronchial epithelial cell line Calu-1.

Methods: Calu-1 cells were treated (30') with BDP (10^-11–10^-5M) or F (6/100nM) to investigate the effect of beclomethasone dipropionate (BDP) and formoterol (F) alone and in combination (BDP/F) on TNF-α-induced ICAM-1 expression and IL-8 release in human bronchial epithelial cell line Calu-1.

Results: Both 2 and 24h SN respectively also increased IL-6 and TNFα release of inflammatory cytokines from macrophage-lineage cells. Peripheral blood mononuclear cells (PBMC) and monocyte-derived macrophages (MDM) were isolated from non-smokers (NS), smokers (S) and COPD patients.

Conclusions: BDP and F in combination provided greater inhibition of ICAM-1 and IL-8 expression as compared to each drug. These observations may imply
that BDPPS exerts anti-inflammatory effects in airways by modulating adhesion molecule and chemokine expression in bronchial epithelial cells.

P3716 Anti-inflammatory and cytoprotective actions of the endogenous docosahexaenoic acid (DHA) electrophilic derivative 17-oxo-DHA
Chiara Cipollina1,2, Stefania Gerbino1, Serena Di Vincenzo1, Rosalia Curto1, Mark Gjomarkaj3, Bruce A. Freeman3, Francisco J. Schopfer3, Elisabetta Pace1,1
1Institute of Biomedicine and Molecular Immunology, National Research Council, Palermo, Italy; 2Department of Pediatrics, Semmelweis University, Budapest, Hungary; 3Research Laboratory of Biomedicine and Molecular Immunology, National Research Council, Palermo, Italy; 4Department of Pharmacology & Chemical Biology, University of Pittsburgh - School of Medicine, Pittsburgh, PA, United States

Inflammation of the airways is a hallmark of chronic obstructive pulmonary disease (COPD), one of the leading mortality cause worldwide. Bronchial epithelial cells and resident macrophages represent the first barrier in the lung against pathogens and external insults such as cigarette smoke, which is a major risk factor for COPD. Although the activation of the innate inflammatory response is required for defense purposes, uncontrolled activation, typical of COPD, leads to chronic inflammation causing tissue damage and enhanced risk of infection. Currently there is no therapy able to revert disease progression in COPD and therefore the search for new drugs is highly active. Omega-3 derived electrophilic fatty acids have been recently discovered as endogenous anti-inflammatory molecules produced by activated macrophages by the action of cylooxygenase-2.

In the present work, the anti-inflammatory and cytoprotective actions of the electrophilic DHA-derivative 17-oxo-DHA were evaluated in lipopolysaccharide-activated macrophages and in bronchial epithelial cells. We report that 17-oxo-DHA suppresses LPS-induced TNFalpha production in macrophages and increases intracellular glutathione and the expression of heme-oxygenase 1 in both cell types, thus providing protection against oxidative stress caused by cigarette smoke and inflammatory actions.

Although the molecular mechanisms are still under investigation, overall the present results support a role for the electrophile, omega-3 derived 17-oxo-DHA in limiting inflammatory reactions and modulating the antioxidant response, thus reducing cellular damage and promoting the resolution of inflammation.

P3717 Comparative anti-oxidative effects of carbocysteine and fumaric acid propionate in cigarette smoke stimulated airway epithelial cells
Elena Benucci1, 2, Maria Ferraro1, Serena Di Vincenzo1, Rossella Balsamo1, Angella Bruno1, Luca Lipari1, Mark Gjomarkaj3

Cigarette smoke extracts (CSE) induce oxidative stress, an important feature in chronic obstructive pulmonary disease (COPD). Oxidative stress contributes to the poor clinical efficacy of corticosteroids. Carbocysteine, an anti-oxidant and mucolytic agent, is effective in reducing the severity and the rate of exacerbations in COPD patients. The effects of carbocysteine on CSE induced oxidative stress in nasal and in bronchial epithelial cells as well as the comparison of these anti-oxidant effects of carbocysteine with those of fumaric acid propionate are largely unknown.

The present study was aimed to assess the effect of carbocysteine (10-5 M) in cell survival and intracellular reactive oxygen species (ROS) production in CSE stimulated bronchial (16-HBE) and in CSE stimulated nasal (RPMI 2650) epithelial cells. We compared these effects with those of fumaric acid propionate (10-5 M). Carboceysteine or fumaric acid propionate did not induce cell necrosis (propidium positive cells) or cell apoptosis (Annexin V positive/propidium negative cells) in 16 HBE and in RPMI 2650 at the tested concentrations. CSE increased intracellular ROS production in 16HBE and in RPMI 2650. Fumaric acid propionate was not able to significantly reduce intracellular ROS production in both 16HBE and in RPMI 2650. Carbocysteine was able to significantly reduce intracellular ROS production and was more effective than fumaric acid propionate in reducing these CSE mediated effects in both cell lines. In conclusion, the present study provides compelling evidences that carbocysteine may be considered a promising strategy in diseases associated to corticosteroid resistance.

P3718 Effect of hypoxia and cigarette smoke on hypoxia-inducible factor 1α (HIF-1α) and heat shock protein 72 (HSP72) system of alveolar epithelial cells
Silvia Ferrari1, 2, Maria Ferraro1, Serena Di Vincenzo1, Rossella Balsamo1, Angella Bruno1, Luca Lipari1

Size-dependent particle uptake and trafficking by antigen presenting cells in different anatomical respiratory tract compartments
Fabian Blank1, Deborah Strickland2, Philip Stumbles2,3,4, Patrick Holt2, Christophe von Gunten1,2, Respiratory Medicine, Berne University Hospital, Berne, Switzerland. 1Cell Biology, Netherton Institute for Child Health Research, Perth, WA, Australia. 2School of Veterinary and Biomedical Sciences, Faculty of Health Sciences, Murdoch University, Perth, WA, Australia; 3Centre for Child Health Research, University of Western Australia, Perth, WA, Australia

Effects of biomedical particles on lung antigen presenting cells (APC) such as dendritic cells (DC) and alveolar macrophages (AM) remain poorly understood to date. BALB/c mice intra-nasally received different sized (20nm, 50nm, 100nm, 200nm, 1000nm) fluorescent polystyrene particles. Two and 24h after instillation, FACS and confocal microscopy were performed to assess uptake of particles+DC 24h after exposure were higher for 20nm particles compared to 1000nm particles (12.0±2.3% vs. 1.22±0.3%; p=0.0283). At 24h, in lungs parenchyma DC, preferential uptake of 20nm (43.2±4.5% ±0.0011) and 50nm particles (36.2±4.8% ±0.0011) occurred compared to 1000nm particles (7.90±0.9%). These changes mirrored LDLN, where DC preferentially trafficked 20nm (17.8±2.1% ±0.0038) and 50nm particles (20.4±1.2% ±0.0011) compared to 1000nm particles (3.47±0.89%). AM ingested all sizes with a preference for smaller particles (20nm: 88.0±1.8%; p=0.0011; 50nm: 8.6±0.5±7.9±1.2%; p=0.0038; 100nm: 69.2±2.1%; p=0.0041; 200nm: 61.5±2.1% ±0.0136; 1000nm: 53.7±2.1% 24h after exposure. Following uptake, DC upregulated expression of CD40 and CD86 independently of particle size. Confocal microscopy confirmed uptake and size distribution in AM and DC in situ. Particle size is a key factor determining uptake and trafficking from the lung to LDLN. This has important consequences on downstream immunological effects of both ambient inhaled particles and novel carriers for pulmonary delivery of drugs or vaccines.

Airway region-specific effects of carbon black nanoparticles (CBNP)
Sandra Schlick, Heinz Fechenbauer. Experimental Pneumology, Research Center, Borstel, Germany

CBNP are present in industrially produced soot used for reinforcement of elastomers (e.g. in tyres) but also for paints, toner and batteries. CBNP may have lung cytotoxic and pro-inflammatory effects. In this study, the commercially available CBNP Printex 90 (P90) and the quartz DQ12 were shown to possess cytotoxic and pro-inflammatory properties in mice and human epithelial cell lines. In contrast to previous findings in mice and epithelial cell lines our study could not show pro-inflammatory effects of P90 or DQ12 on microdissected airways. In contrast to previous findings in mice and epithelial cell lines our study could not show pro-inflammatory effects of P90 or DQ12 on microdissected airways. A slight increase in cytotoxicity was indicated with increasing P90 concentrations. Although our results do not show significant cytotoxic or pro-inflammatory effects of P90 and DQ12 on proximal and distal airways, this does not exclude that oxidative stress, apoptosis or proliferation of airway cells are affected by P90 or DQ12. In the future, chemically modified CBNP will be analysed to reveal the impact of functional surface groups on the particle’s toxicological properties. Supported by the BMBF-joint project Carbon Black (03X0893A).

Targeting miRNA-based medicines to cystic fibrosis airway epithelial cells using nanotechnology
Paul Henderson1, Jun Xue1,2, Iris Cunningham1,2,3, Noel G. McElvaney1, Sally Ann Cryan1,2, Catherine M. Greene1, 1Department Medicine, 2School of Pharmacy, Royal College of Surgeons in Ireland, Dublin, Ireland

Cystic Fibrosis (CF) is characterised by chronic pulmonary inflammation. microRNAs (miRs) are regulatory RNAs which inhibit gene expression. miR-126, a regulator of TOM1, is decreased in CF bronchial brushings; TOM1 is reciprocally increased. Polymeric nanoparticles of Polyethyleneimine (PEI) and Chitosan-TPP can be used to deliver nucleic acids into bronchial epithelial cells. Here a proof-of-concept study was performed testing their efficacy at delivery of premiR-126 into non-CF and CF bronchial epithelial cell lines. PremiR-126-nanoparticles were prepared and characterized using a Zetasizer and used to transfect CFBE410- and 6HBE14o- cell lines. RNA extraction and cDNA synthesis, CDNA was prepared and miR-126 and TOM1 expression was assessed using qRT-PCR. Toxicity was measured by high content analysis (HCA). Over-expression of miR-126 resulted in down-regulation of TOM1 in both cell types. The effects of polymeric, cationic nanoparticles was shown to efficiently deliver premiR-126 into cells in order to achieve this knockdown. PremiR-126 encapsulated in PEI at a nanoparticle/premiR (N/P) ratio of 1:1 resulted in knockdown of TOM1 in CFBE410+ cells, with a reduction of ~47% in TOM1 expression in comparison to a scrambled negative control complexed with commercial transfection reagent (p<0.05). HCA showed no significant difference in cell counts between untreated cells and cells treated with PEI- and chitosan-TPEmiR-126 nanoparticles suggesting they are relatively non-toxic. miRs are potential novel targets for respiratory gene therapy and could be targeted to CF bronchial epithelial cells in the future using PEI nanoparticles. Funding: SFI and HRB PD/2007/11.

Effect of anti-IgE therapy on microRNAs in the lungs of mice with allergen-driven airway remodeling
William Henderson1, Jun Xue1, Federico Farin2, Richard Beyer3, Theo Bammeter1, 1Medicine, University of Washington, Seattle, WA, United States; 2Environmental Health, University of Washington, Seattle, WA, United States

Rationale: Current therapies have had limited effect on structural or airway changes in patients with asthma. We recently found that anti-IgE therapy significantly increased asthma airway hyperreactivity and subepithelial fibrosis in a mouse asthma model (Henderson et al., AIRCCM 183: A4066, 2011). MicroRNA (miRn) or miRs, small non-coding RNAs, are key regulators of gene expression that may serve as novel biomarkers and therapeutic targets in disease states.

Study Aim: Determine the effect of anti-IgE therapy on miRNA expression in a mouse asthma model with airway remodeling.

Methods: Mice periodically given OVA (days 14-163) were treated with 100 μg monoclonal rat IgE anti-IgE (R35-92, Pharmingen) (OVA/anti-IgE group), rat IgG1 isotype control antibody (OVA/IgG1 group), or saline (OVA/Saline group) days 73-75, and then once weekly until day 163 when lung miRNA was isolated. miRNA transcriptional profiling was carried out using Affymetrix miR 2.0 arrays with data analysis by Bioconductor limma package. MRnRNas whose expression was changed >1.5-fold (p<0.05) were considered differentially expressed.

Results: 21 miRNAs were significantly changed in the OVA/Saline group vs saline-treated controls including upregulation of proinflammatory miR-21 and miR-155. MRnRNAs 467e, 511, and 744 were downregulated and the antiinflammatory miR-16* upregulated in the OVA/anti-IgE group vs the OVA/IgG1 group. Conclusion: The ameliorating effect of anti-IgE treatment on established airway remodeling in this asthma model is likely mediated by its differential effects on gene expression in the lung. Our data direct attention to key miRNAs that may serve as biomarkers for this remodeling process.

microRNA profiling of murine alveolar epithelial type II cells
Stefan Debush, Katharina Singer, Rabea Imker, Oliver Eickelberg, Melanie Koengshoff, Susanne Krauss-Etschmann. Comprehensive Pneumology Center, Klinikum der Universitaet Muenchen, Helmholtz Zentrum Muenchen, Germany

Rationale: Alveolar epithelial type II cells (ATII) have key roles in innate immune response, surfactant production and as precursors for ATI cells (Mason RJ, Respiratology, 2006). To obtain insight in gene regulatory networks specific for ATI we established a method for negative isolation of ATI cells and investigated their microRNA (miR) profiles.

Methods: Single cell suspensions were prepared from whole lungs of female C57BL6 mice (6-12w) using dispase and mechanical dissociation. ATI were obtained by sorting (BD FACs Aria II) CD45-CD31-alkfluorescence-high cells (sATII). Sorted cells were characterized by flow cytometry, immunocytochemistry (ICC) and RT-qPCR. MR profiles were determined using TaqMan® Arrays Cards (ABI). MR profiles of sATII were compared to cells obtained by panning (pATII) according to a standard method (Koenigshoff M et al., JCI, 2009) using negative selection in antibody-coated (CD45, CD16/32) petri dishes.

Results: Up to 99% of sATII cells were CD45-CD31-CD74+. sATII expressed higher mRNA levels for SPC while miRNAs for CD31, CD45, ZO-1 and α-SMA were expressed at lower levels compared to pATII. mRNA levels for CD74, AQPS and SP-A were similar in both populations. ICC confirmed proFiC expression on sATII. MR profiling revealed 11 miRs expressed at equal abundance (~1.5x) in sATII and pATII. 128 miRs were up (+1.5x) and 64 miRs were downregulated (~1.5x) in sATII compared to pATII. In addition, 3 miRs were only detectable in sATII while 14 miRs were unique to pATII.

The lung in a dish - A new tool to study interactions of inhaled (nano)materials with lung cells

Corinne Jud1, Silvia Angeloni2, Loretta Müller2, Martha Liley2, Alke Petri-Fink2, Barbara Rothen-Rutishauser2

1Adolphe Merkle Institute, University of Fribourg, Marly, Switzerland; 2Centre Suisse d’Electronique et de Microtechnique, CSEM SA, Neuchâtel, Switzerland;

The human lung is exposed to a huge number of nanosized materials with each breath. To study the interaction of those materials with the lung, biomimetic cell culture models are needed. The human air-blood tissue barrier consisting of epithelial cells, the basal lamina and endothelial cells is less than 1 μm thick. Conventional cell culture inserts have a thickness of ~10μm which has been a major drawback to establish realistic models. Therefore, a novel ultrathin porous membrane with a thinness of 500nm was developed to refine an established human air-blood tissue barrier model consisting of epithelial cells (A549), monocyte-derived macrophages and dendritic cells by replacing the conventional inserts with the novel membranes but also complement it with endothelial cells (EA.hy926). Epithelial cells seeded on the upper side of the membrane and endothelial cells on the lower side grow to confluence and form a tight bilayer. Immune fluorescence stainings revealed the typical characteristics of epithelial/endothelial cells and specific markers (von Willebrand factor and PECAM) were exclusively detected in the endothelial cell layer. Experiments with all four cell types have been performed and showed that all cell types can be cultured together as a quadruple model on the new ultrathin membrane. Once fully established and characterized, this new system will offer an advanced 3D cell culture model of the human airway barrier and an excellent tool to study the effects of inhalable substances (e.g. nanomaterials) with a realistic lung model. This will significantly reduce the number of animals used to perform inhalation risk assessments and will offer a controlled system for different studies.

Pulmonary haptoglobin (pHp) is a scavenger system preventing arterial leukages

M. Abdullah1, E. Velliner1, P. Zabel2, N. Riezik3, C. Vock3, T. Goldmann1

1Clin. d. Exp. Pathology, Research Center, Borstel, Germany; 2Clinical Medicine, Research Center, Borstel, Germany; 3Microbial Interface Biology, Research Center, Borstel, Germany; 4Experimental Pneumology, Research Center, Borstel, Germany

Haptoglobin is a long known molecule. The recently discovered pHp variant is a scavenger system which can be a local first line immunoregulatory molecule which could play a crucial role coming into focus in the course of immunoregulatory events in the human lung. Here we describe the fast release of pHp upon different stimuli using a human tissue enriched cell culture system. Furthermore, the pHp in the supernatants of human tissue cultures after stimulation periods as short as 1h is detectable. A hypothesis has been that the pHp release is occurring in the supernatants immediately after stimulation. As nasal NO is increasingly used for screening of PCD, further work assessing the upper airway’s role in the low levels of nasal NO seen is warranted. Data collection continues.

Epithelial ciliary beating analysis in chronic airway diseases

Mustapha Kamel Khellouffi1, José Gerald1, Marius Socol1, Jules Dupire1

1Adhesion and Inflammation, UMR CNRS 7135 INSERM U1067, Marseille, France; 2Clinique des Bronches, Allergie et Sommeil, APHM Aix-Marseille University, Marseille, France

Human bronchial epithelial cells (HBEC) activation and increased mucus production are constant features of epithelium in chronic airway diseases. However, the mechanisms and involvement of mucociliary component are poorly understood in these diseases. We used an in vitro model of bronchial epithelial cell culture in air-liquid interface obtained from bronchial biopsies of asthmatic patients (mild and severe) or COPD patients. We questioned the regulation of mucociliary couple in this system using an original approach combining biology and physics. Methods: HBEC were obtained after processing biopsy were expanded on tissue culture-treated plastic and then, were plated on uncoated nuclepore membranes in air-liquid interface for 21 days to obtain a mucociliary phenotype. For each epithelium re-differentiated in vitro, we first measured thickness and cilia beating frequency (CBF). We used fast videomicroscopy (37°C). The effect of mucus presence on cilia beating was assessed by measuring frequency before and after addition of PBS. Results: Preliminary results are presented in table 1 and are expressed as median (min-max). Conclusion: At present we did not find any major change in the velocity of cilia beating according to the airway diseases in our air-liquid interface system. The contribution of mucus should be better investigated.

Air liquid interface culture can alter ciliary beat pattern in epithelium from primary ciliary dyskinesia patients

Claire Jackson1,2, Janice Coles1,2, Patricia Goggan1, Amanda Harris1, Jane Lucas1,2

1Primary Ciliary Dyskinesia Diagnostic Service, University Hospital Southampton Foundation Trust, Southampton, Hampshire, United Kingdom; 2Primary Ciliary Dyskinesia Research Group, Faculty of Medicine, Clinical and Experimental Sciences, Southampton NHR Respiratory Biomedical Research Unit, Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Introduction: Primary Ciliary Dyskinesia (PCD) is a rare inherited heterogeneous disorder of cilia, impairing mucociliary clearance. PCD is diagnosed by low nasal nitric oxide concentration, abnormal airway ciliary function with corresponding ultrastructural defects, excepting atypical cases. PCD may be differentiated from secondary dyskinesia by assessing differentiated ciliated epithelium at air liquid interface (ALI). Aim: To evaluate ciliary beat pattern (CBP) on PCD airway epithelium before and after ALI culture. Methods: Ciliary function of nasal brushing epithelium from 9 PCD patients with ultrastructure defects confirmed by TEM, was analysed (n=10 cell clusters) at 37°C by high-speed video microscopy (100x objective). Confluent basal ep-
In vitro culture of human airway epithelial cells in asthma

Wing Van Heela Wanga, Lucy B. Woodmana, Robert A. Hirsta, Edith Gomezb, Andrew J. Wardla, Christopher O’Callaghana, Christopher E. Brightlingb, c

a Institute for Lung Health, Glenfield Hospital, Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom; bInstitute for Lung Health, KKCSR, Leicester Royal Infirmary, Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom

Introduction: The airway epithelium is considered important in the pathogenesis of several respiratory conditions including asthma. While studies of airway epithelial cell (AEC) cultures obtained from adults and children have provided valuable insight into the role of these cells in airway disease, little is known about how neonatal AEC phenotype impacts on respiratory disease in later life. We describe a novel method for culturing nasal AEC within days of birth.

Methods: Nasal swabs from healthy, unsedated infants within 72 hours of birth by gently brushing both nostrils with an interdental brush. Brushes were agitated in specialised AEC growth media and primary cell monolayers grown to confluence before sub-culture. IL-8 concentrations were measured in supernatants of transient passage AEC monolayers at rest and after exposure to IL-1β & TNF-α (both at 10ng/ml).

Results: Sampling was acceptable to parents and there were no adverse effects. Primary cultures were successfully established in 74/82% of 90 neonates sampled. Epithelial lineage of the cells was confirmed by morphological analysis and positive immunostaining for cytokeratin 19 and negative staining for potentially contaminating cell types. Constitutive IL-8 secretion was observed and was not affected by cytokine treatment.

Conclusion: We describe a safe, minimal invasive and reproducible method of culturing AEC from neonates suitable for functional cell analysis and amenable to large population based studies. This novel technique offers a unique opportunity to study "naive" AEC not yet exposed to the confounding effects of environmental pollutants and pathogens and may prove useful in elucidating the early origins of respiratory disease.

P3733

CSE exposure abrogates regulatory effects of the bronchial epithelium on B cell survival and IgA production in a coculture system. A pivotal role of TACI

Maha Zehra Latpepa, Bruno Dettyb, Marylene Leccoa, Yves Sibilla, a,b,c

a Charles Pilette, bInstitut de Recherche Expérimentale et Clinique, Pulmonologie, ORL, Dermatologie, Université Catholique de Louvain (UCL), Brussels, Belgium; cService de Pneumologie, Cliniques Universitaires de Mont-Godinne, Yvoir, Belgium; dService de Pneumologie & Centre de l’allergie, Cliniques UCL, Saint-Luc, Brussels, Belgium

Background: Chronic obstructive pulmonary disease (COPD) is associated with chronic airway inflammation and structural remodelling, in particular of the epithelium, which is impaired in its capacity to transport immunoglobulin (Ig) A. Although COPD is mostly related to cigarette smoking, only a minority of smokers develops this disease and factors of cigarette exposure susceptibility remain not clear. Even though peribronchial lymphoid follicles have been described in severe COPD, it remains unknown whether B-cell conditioning is altered in this disease, especially after CSE (Cigarette Smoke Extract) exposure.

Objectives: In this study, we report on CSE exposure data using a coculture model of B cells with human primary bronchial epithelium (re)differentiated in vitro in air-liquid interface.

Methods: IgA synthesis was studied following CSE exposure in CD19+ B cells (purified by immunomagnetic sorting from healthy blood donors) after co-culture for 13 days with a bronchial epithelium from severe COPD patients. B cells were also assessed by flow cytometry for cell activation and survival.

Results: In four independent experiments, we observed that IgA production and cell survival were upregulated in B cells cocultured with the bronchial epithelium, as compared to B cells cultured alone. CSE exposure of the epithelium abrogated these effects, and this was associated with the suppression of TACI induction upon co-culture.

Conclusion: These data suggest that a crosstalk exists between B cells and the epithelium with respect to COPD, which could be mediated at least in part through regulation of TACI.

P3734

A novel method for harvesting and culturing airway epithelial cells from neonates

P3736

Goblet cell metaplasia, induced mainly by TH-2 cytokines like IL-13 and IL-4, is a common feature of several respiratory diseases such as asthma, COPD, and Cystic fibrosis. Recent clinic trials demonstrated that blocking IL-13 signaling seems to be an effective therapeutic strategy. In order to develop more efficient drugs, a reliable and reproducible in vitro cell model would be invaluable. Epithelium has developed a high quality in vitro cell model of the human airway epithelium (MucilAir) which can be maintained at a functional and homeostatic state for a year, allowing long term tests of drug candidates. In order to create an in vitro
cell model of the airway goblet cell metaplasia, Muc1Air was treated with IL-13 at different concentrations, ranging from 0.3 to 30 ng/ml. Using in situ Alcian Blue staining, as well as histological analysis, we demonstrated that Muc1Air showed an increased goblet cell density after 14 days of IL-13 treatment, in a dose dependent manner. Furthermore, ELISA analysis revealed a concomitant increase of Eotaxin and Peristin released in the culture media as a function of IL-13 concentration. Despite some subtle morphological differences of the goblet cells between donors, the results from several different batches of Muc1Air are very similar and therefore reproducible. Taken together, Muc1Air is a relevant and reliable model for studying Goblet cell metaplasia, and for assessing the efficacy of drug candidates.

P3736
Do characteristic airway epithelial change precede the development of lung fibrosis? Ectopic epithelial marker protein expression in bleomycin induced fibrosis replicates that seen in bronchiolized epithelium in IPF fibrosis? Ectopic expression of the gel forming mucin, MUC5B was recently described as a specific marker for the bronchiolized epithelium seen in IPF and IPF-like conditions. We have shown that it is co-expressed in this region with LPLUNC1 but not with other airway submucosal gland proteins, including Zinc-alpha2-glycoprotein and Proline-rich protein 4. To shed light on a temporal association of expression of these markers, we have developed a mouse model of airway remodeling events. This mouse model is induced by the pro-fibrotic agent bleomycin (Bleo). MUC5B and LPLUNC1 were co-expressed in a population of goblet cells in the airways of mice within 3-7 days of Bleo exposure, prior to the onset of a fibrotic process. Continued expression is seen during the development of fibrosis between 14-21 days post treatment. In contrast, in mice treated with PBS neither protein was seen (due to mouse airways being essentially free of goblet cells). Staining was absent from the fibrotic regions and the lung parenchyma, as is the case in IPF. Our data show that the ectopic expression seen in human IPF is mirrored by that seen in the Bleo mouse model. Furthermore it suggests that these epithelial remodeling events precede the development of lung fibrosis and these can be studied in mice.

P3737
A unique session of aerobic exercise does not decrease pulmonary inflammation in a murine model of asthma
Ronald0 Aparecido da Silva1, Francine Maria Almeida1, Clarice Rosa Oliveí2, Beatrix Manguerra Sarayva1, Milton A. Martins1, Celso Ricardo Fernandes Carvalho1. 1Physiopathology Experimental, School of Medicine of University of Sao Paulo, SP, Brazil; 2Clinical Medicine Sao Paulo, School of Medicine of University of Sao Paulo, SP, Brazil; 3Physical Therapy, School of Medicine of University of Sao Paulo, SP, Brazil
Recent studies have shown that long term exercise training reduces airway inflammation. However, there is a lack of evidence of the effects of a single session of exercise. Objective: To evaluate the effects of a single session of aerobic exercise in the airway inflammation. Moreover, there is a lack of evidence on the effects of a single session of exercise. Methods: Thirty two mice were divided in Groups (n=8): Control (CT), Aerobic Training (AT), OVA, and OVA+AT. Groups OVA were sensitized by intraperitoneal injections of OVA/500µg/mice in the days 0, 14 and 28 followed by 30 min of 1% OVA inhalation (days 21th, 23th, 25th and 28th). CT and AT groups received saline. Exercise (AT groups) was performed in the day 28th for 60 min at 50% intensity of maximal capacity. Bronchoalveolar fluid (BALF), lung tissue and blood were collected in the day 29th. It was evaluated: total and different cells in BALF, IgE and IgG1 titers, peribronchial eosinophils, and airway remodeling (smooth muscle, collagen and elastic fibers, and mucus expression). Eotaxin, RANTES, VEGF, ICAM, VCAM, IL-1ra, NF-kb and Foxp3 in the airways were also evaluated. Statistical significance was evaluated by two way ANOVA followed by Bonferroni or Newman-Keuls. Results: OVA increased IgE; and IgG1 levels, total and eosinophil cell counting, and all remodeling features (smooth muscle, collagen and elastic fibers, and mucus expression) (p<0.05). In addition, OVA increased the expression of oestotxin, RANTES, VEGF, ICAM, VCAM, NF-kb and Foxp3 (p<0.05). On contrary, a single bout of aerobic training did not changed any of these effects (p>0.05). Conclusion: A single exercise session seems do not have any anti-inflammatory effect in a murine asthma model.

P3738
Aerobic training inhibits leukocytes production of oxidants, pro-inflammatory and pro-fibrotic factors reducing asthmatic phenotype
Rodolfo Paula Vieira1, Ronaldo Aparecido Silva2, Ana Paula Ligeiro Oliveira2, Milton Arruda Martins3, Celso Ricardo Fernandes Carvalho2. 1Post-graduation Program in Biophotonics Applied to Health Sciences, Nove de Julho University, Sao Paulo, SP, Brazil; 2Physiopathology Experimental (LIM 14), University of Sao Paulo, SP, Brazil; 3Clinical Medicine (LIM 20), University of Sao Paulo, SP, Brazil
Aerobic training results in beneficial effects to asthmatic patients and also in animal models of asthma. However, the studies have not evaluated yet the effects of aerobic training on the peribronchial leukocytes activation. This study evaluated the effects of 4 weeks of low intensity aerobic training on the expression of inflammatory and fibrotic mediators by peribronchial leukocytes. 32 BALB/c mice divided in 4 experimental groups: Control, Exercise, OVA and OVA+Exercise were sensitized on days 0, 14, 28 and 42 and challenged with aerosolized OVA 1% for 3x/week, beginning on 21st day for 4 weeks. Low intensity aerobic treadmill training started on day 22nd for 4 weeks. 72 hours after last OVA challenge mice were assessed to lung inflammation, levels of IL-5 and IL-10 in BAL fluid by ELISA and for quantitative analysis of peribronchial leukocytes activation. The results showed that aerobic training in sensitized animals resulted in significant decrease of total cells and eosinophils in BAL fluid, decreased level of IL-5 and increased level of IL-10 in BAL fluid (p<0.01), decreased expression of IL-4, IL-5, IL-13 (p<0.001), CCL5, CCL10 (p<0.001), ICAM-1 and VCAM-1 (p<0.05), GP91phox and 3-nitrotyrosine (p<0.001), NF-kb and TNFα (p<0.001), while increased the expression of IL-10 (p<0.001). Concerning the airway remodeling, aerobic training in sensitized animals resulted in decreased expression of TGF-beta, IGF-1, VEGF and EGF (p<0.001). We conclude that aerobic training in sensitized animals results in a direct effect on peribronchial leukocytes reducing the expression of important factors related with the airway inflammation and remodeling.

P3739
Involvement of oxidative and nitrosative stress in the development of proteolytic pulmonary emphysema
Mánuila Langete1,2, Cristiane Costa1, Tatiana Victon1, Renata Nesi1, Alan Lopes1, Jackson Alves2, Vanessa Martins3, Angela Resende3, Vincent Lagente4, Luís Porto2, Samuel Valenca1. 1Instituto de Ciências Biomédicas, Universidade Federal do Rio de Janeiro, RJ, Brazil; 2Pós-graduação em Biologia Humana e Experimental, Universidade do Estado do Rio de Janeiro, RJ, Brazil; 3Pós-graduação em Biocências, Universidade do Estado do Rio de Janeiro, RJ, Brazil; 4INSERM U 991 - Faculté de Pharmacie, Université de Rennes 1, Bretagne, France; 5Departamento de Patologia, Universidade de São Paulo, SP, Brazil
Our aim was to investigate the participation of oxidative stress in elastase-induced pulmonary emphysema. C57BL/6 mice were submitted to pancreatic porcine elastase (PPE) instillation (0.05U or 0.5U) per mouse (i.t.) to induce pulmonary emphysema. A separated group of mice were treated with amonoguanidine 1% (AMG). Lungs were collected on days 7, 14 and 21 after PPE instillation. Control group was sham-injected. We performed BAL, biochemical analyses of oxidative stress, and lung stereology and morphometry. Emphysema was histologically characterized at 23 days after 0.5 U of PPE, presenting increased alveolar linear intercept and volume density of airspaces in comparison with the control group. TNF-α was elevated at 7 and 14 days after PPE 0.5 U, concomitant with reduction of IL-10 levels at IL-10 levels at the same time-points. Myeloperoxidase was elevated in all groups treated with 0.5 U of PPE. A contribution of oxidative stress at early stage of emphysema was observed with increased levels of nitrite, malondialdehyde and superoxide dismutase activity at 7 days after PPE 0.5 U. Glutathione peroxidase activity was increased in all groups treated with 0.5 U of PPE. With iNOS inhibition by AMG 1%, emphysema was attenuated. Furthermore, the proteolytic stimulus by PPE enhanced expression of iNOS and nitrotyrosine, PPE stimulus also induced eNOS expression, but AMG reduced it. Our results suggest a pathway of oxidative and nitrosative stress by nitric oxide production via iNOS expression in pulmonary emphysema.

P3740
The serotoninergic receptor subtype 5-HT1RB contributes to the pathogenesis of allergic airway inflammation
Tobias Mölling, Amgerret Hüttel, Melanie Grimm, Marco Izdol. Pneumology, University Medical Center Freiburg, Germany
In addition to its well described role in the nervous and cardiovascular system, 5-HT1B, also known as serotonin-1B receptor (5-HT1B), has also shown to influence immune responses and the immune-regulatory properties. Furthermore, elevated levels of free serotonin have been detected in the serum of symptomatic asthmatics. However, the exact serotoninergic receptor subtype involved have not been elucidated, yet. In this study we questioned whether the subtype 5-HT1RB is involved in the pathogenesis of experimental asthma. Expression of 5-HT1RB receptors in lung tissue was analyzed by immunohistochemistry. Allergic airway inflammation was studied in the classical OVA-alum model and in a model of house dust mite (HDM) induced airway inflammation. The experimental induction of allergic airway inflammation led to an increased...
5-HTR1B expression in the lungs of animals sensitized to OVA and challenged with OVA-aerosols. 5-HTR1B expression was even higher in animals with chronic OVA-aerosol challenge as depicted by reduced bronchoalveolar lavage eosinophils and lymphocytes, by reduced perivascular and peribronchial inflammation, as well as by reduced production of Th2 cytokines by re-stimulated mediastinal lymph node cells. The intratracheal application of NAS 181 had also protective effects in HDM-induced asthma. Here we provide evidence that 5-HTR1B receptors modulate asthmatic airway inflammation. Therefore, 5-HTR1B receptors might be promising targets for the development of new anti-asthmatic drugs.

P3741
The antimicrobial peptide CRAMP protects against emphysema

Christian Herr1, Sadek AlAlwani2 , Rebecca Eschmann2, Christoph Bedwender1, Robert Bals1,1, Internal Medicine, Universitätsklinikum, Homburg, Germany; 2Internal Medicine, Alzey-Kappel, Germany

Rationale: COPD is one of the most prevalent causes of death worldwide and is associated with an ongoing destruction of pulmonary structures that finally lead to the development of emphysema. Antimicrobial peptides (AMP) are a part of the innate immune system. The AMP CRAMP is expressed in the murine homologue of the human calcium dependent antimicrobial peptide (nCAP-18/LL-37). It plays an important role in angiogenesis, cancer and chemotaxis. This work will show that CRAMP is important in lung function in an elastase-induced model of lung destruction.

Methods: Lung destruction was initiated by two times intratracheal administration of elastase. Ten days after the last administration lung function was measured. Cytokines in BAL were measured by ELISA. The lungs were resected and fixed for stereological analysis. Lung tissue was also used for immunohistological staining and RNA-extraction.

Results: Elastase treated CRAMP-ko animals had significantly higher neutrophil influx, more IL1ß and TNF-α in their BAL as the controls. 30 days after the first elastase treatment CRAMP-ko had a higher mean linear intercept and a significantly decreased pulmonary system resistance and elastance. MMP-9 expression and activity was increased and the concentration of VEGF was decreased in the elastase treated CRAMP-ko as compared to the elastase treated wildtype mice.

Conclusion: This work shows that the antimicrobial peptide CRAMP has a protective function in a model of elastase induced lung destruction. CRAMP-ko animals showed more inflammation, a higher degree of lung destruction as well as a higher expression and activity of MMP-9. The concentration of VEGF was significantly lower in the elastase treated ko animals.

P3742
Importance of the receptor for advanced glycation end products in the respiratory mechanics

Samira Al-Robyn, Andreas Simm, Rolf-Eckardt Silber, Angelika Bierhaus, Babett Barthling, Department of Cardiothoracic Surgery, University Hospital, Halle (Saale), Germany; Department of Cardiothoracic Surgery, University Hospital, Halle (Saale), Germany Department of Medicine I and Clinical Chemistry, University of Heidelberg, Germany; Department of Cardiothoracic Surgery, University Hospital, Halle (Saale), Germany

Background: There is an increasing clinical interest in studying the receptor for advanced glycation end products (RAGE) and its soluble forms in pulmonary diseases. Interestingly, RAGE and its soluble forms are preferentially expressed in alveoli thereby challenging the pathophysiological role of RAGE. As we have already shown the importance of RAGE as an adhesion molecule in alveolar cells, this study aimed to investigate the age-dependent physiological significance of RAGE in respiratory mechanics.

Methods: Lungs of young (1-6 month), adult (6-9) and old (>24) RAGE knockout (ko) and wild-type mice were analyzed ex vivo using the perfused isolated lung system with negative-pressure ventilation at weight-matched constant tidal volume. Elastin expression was assessed by gene array and histochemistry. Results: Dynamic lung compliance increased gradually with the age in RAGE ko as well as in wild-type mice. Independent of age, the lungs of RAGE ko mice showed higher compliance than that of the wild-type. In this context, old wild-type and young-adult RAGE ko mice had similar lung dynamic compliance. According to the effect of RAGE deficiency on lung compliance, we determined a reduced collagen mRNA and protein expression in the lung tissue of RAGE ko mice. However, lack of RAGE had no significant effect on airway resistance and epithelial layer permeability.

Conclusion: Our study suggests the physiological importance of RAGE and its function in mediating an appropriate lung compliance in which its/their impact on the elastin expression might play a critical role.

P3743
Long-term exposure to tobacco smoke on alveolar macrophages phenotype with regard to genetic and age predisposition

Stefania Lyamina, Timothee Vedemen, Igor Malyshev. Laboratory of Cell Biotechnologies, Moscow State University of Medicine and Dentistry, Moscow, Russian Federation

Core role of tobacco smoke as a risk factor in chronic obstructive pulmonary disease (COPD) is proved, but COPD develops not in every smoker. Since long-term tobacco smoke is a functional phenotype of alveolar macrophages (AM) with regard to genetically determined macrophages phenotype while aging.

Methods: Experimental COPD reCOPD was simulated in vivo in two genetic mouse strains:C57/Bl6 (n=40)-predominant M1 phenotype, and Balb/c (n=40)-M2 phenotype. ECOPD groups included 30 mice, control-10 mice. Tobacco smoking lasted for 6 months-2 cigarettes i.d. COPD was verified histologically. AM functional phenotype was assessed by nitric oxide production (NO) spectrophotometrically.

Results: COPD was confirmed histologically in both eCOPD groups, changes were more expressed in C57/Bl6. There was no significant difference in basal NO production (nBO) in eCOPD groups, but induced NO production (nSO) significantly decreased during 6 months and was much lower in C57/Bl6 than in Balb/c: 3.80±0.21 vs 5.53±0.29 mM (p<0.05). There were no differences in initial nBO in both controls; nSO significantly decreased in both controls during 6 months. Aging decreased INO in both controls - from 26.40±3.2 to 6.60±0.45 mM in C57/Bl6, and from 19.21±1.20 mM to 7.57±0.72 mM in Balb/c, changes were more expressed in C57/Bl6.

Conclusions: We elicited genetic predisposition to COPD risk factor - tobacco smoke, associated with M1 macrophages phenotype and age-related transformation of AM phenotype toward anti-inflammatory M2, increasing with long-term inhalation of tobacco smoke and more expressed in M1 phenotype.

P3744
Cell therapy with adipose tissue-derived stem/stromal cells for elastase-induced pulmonary emphysema in rats

Naoko Funada1, Misako Takahashi1,2, Otsuki Miyazawa1, 1Division of Respiratory and Infectious Diseases, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan; 2Institute of Medical Science, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan

Background: Studies demonstrating lung repair by stem cells or growth factors have been reported in animal emphysema. We focused on adipose tissue-derived stromal/stem cells (ASC) for regenerative medicine, since it has a high potential to secrete multiple angiogenic factors and differentiate various kinds of cells. Aim: To demonstrate the therapeutic impact of ASC transplantation and to elucidate mechanisms of the effects in rat emphysema models.

Methods: ASC were isolated from rat subcutaneous adipose tissue. Emphysema was induced by intratracheal instillation of porcine pancreatic elastase (PPE). One week after PPE, cell transplantation was performed intravenously. One and 2 weeks after transplantation, we assessed pulmonary function and histopathological changes and measurement of chemokine levels in lung tissue.

Results: ASC transplantation restored pulmonary function to near normal levels and enlargement of the alveolar airspaces was also inhibited. Immunohistochemical analysis revealed some transplanted ASC were localized at damaged alveolar spaces. Vascular endothelial growth factor (VEGF) was significantly reduced by PPE. After ASC transplantation, VEGF level was not reduced. Hepatocyte growth factor (HGF) and cytokine-induced neutrophil chemoattractant-1 (CINC-1) levels were significantly higher than PPE.

Conclusions: Transplantation of ASC for emphysema rats improved pulmonary function and inhibit enlargement of the airspaces. Secretion of HGF, VEGF, and CINC-1 by surviving ASC after transplantation may have contributed to lung repair. Cell therapy with ASC may be a new therapeutic strategy to improve pulmonary function and inhibit alveolar destruction.

P3745
Differential effects of atorvastatin, pravastatin, rosuvastatin and simvastatin on lungs from mice exposed to cigarette smoke

Samuel Valença1, Thiago Ferreira1, Alan Lopes2, Denise Cardoso2, Karla Pires2, Larissa Silva-Neto1, Manuella Lanzetti1, Jackson Alves2, Eduardo Trajano1, Renata Nesa1, Marina Barroso1, Romulo Pinto1, Claudia Benjamin1, Luís Porto1, 1Instituto de Ciências Biomédicas, Universidade Federal do Rio de Janeiro, RJ, Brazil; 2Programa de Pós-graduação em Biologia Humana e Experimental, Universidade do Estado do Rio de Janeiro, RJ, Brazil; 3Instituto de Nutrição Josué de Castro, Universidade Federal do Rio de Janeiro, RJ, Brazil

Short-term cigarette smoke (CS) exposure leads to acute lung inflammation through its influence on oxidants/antioxidants imbalance, but lately studies have shown anti-inflammatory and antioxidant effects. Therefore, we aimed analyzing the effects of four different statins on the lungs of mice exposed CS. Male C57Bl/6 mice were divided into six groups (n=8 mice/group). Mice exposed to the smoke from 12 cigarettes/day/5 days (CS group); exposed to smoke from 12 cigarettes per day for 5 days.
days plus aortovasctam (10 mg/kg/day; CS+A group), or pravastatin (5 mg/kg/day; CS+P group), or rosuvastatin (5 mg/kg/day; CS+R group) or simvastatin (20 mg/kg/day; CS+S group), control group was sham-smoked. One day after the last CS exposure, mice were sacrificed, the bronchoalveolar lavage fluid (BAL) was performed and the lungs were removed for histological analysis and homogenized for biochemical analyses. Oxidant levels were reduced in CS+S (p < 0.05); DPHP levels were increased in CS+A, CS+R and CS+S (p < 0.05); nitrite levels were reduced in CS+P, CS+R and CS+S (p < 0.05). MCP-1 levels were reduced in CS+R and CS+S (p < 0.01); hydroperoxide levels were reduced in CS+R, CS+S and CS+P (p < 0.001); catalase activity was reduced in CS+A, CS+P (p < 0.01) CS+R and CS+S (p < 0.05) when all compared with CS group. These results suggest that simvastatin is the best treatment for acute lung injury induced by CS due to reduction of inflammatory and oxidant markers.

P3746 Pulmonary function, oxidative stress and inflammatory markers in LPS-induced acute lung injury: Differential effects of aortovasctam, pravastatin and rosuvastatin

Samuel Valenca1, Manuella Lanzetti2, Adriana Melo2, Larissa Silva-Neto2, D. Richardson5, Robert Vooswinckel1,2.

1Department of Pulmonary, Critical Care, Neurology and Anesthesiology, University of São Paulo, São Paulo, Brazil; 2Faculty of Medical Sciences, Federal University of São Paulo, São Paulo, Brazil; 3Department of Thoracic Surgery, University of São Paulo, São Paulo, Brazil; 4Pulmonary Medicine, Kyorin University, School of Medicine, Mitaka, Japan; 5Laboratory of Pathological Physiology, King’s College London, London, United Kingdom

The present study was designed to determine what statin could attenuate acute lung injury (ALI) induced by lipopolysaccharide (LPS) in C57BL/6 mice. Young male mice (n = 23) were divided into 5 groups (n = 6 each): injected with LPS 1p. (10 mg/kg), LPS plus aortovasctam (10 mg/kg/day; LPS+A group) or pravastatin (5 mg/kg/day; LPS+P group) or simvastatin (20 mg/kg/day; LPS+S group). Control group received saline (p.). In a separated group of mice (n = 5) the sum of pulmonary arterial and venous systolic pressures (DeltP) and static elastance (E(st)) were measured. One day later (24 h), the animals were sacrificed, BAL performed and lungs were removed for histopathological analysis and homogenized for biochemical analyses. The amount of leukocytes was lower in LPS+P (p < 0.01) and LPS+S (p < 0.05). Cytokine levels of MCP-1 was lower in LPS+P (p < 0.01) while IL-6 was lower in LPS+P (p < 0.01) and LPS+S (p < 0.05). Redox markers (superoxide dismutase and catalase) were lower in LPS+A (p < 0.01). Lipid peroxidation (malondialdehyde and hydroperoxides) were lower in all treated groups (p < 0.05). Myeloperoxidase was lower in LPS+P (p < 0.01). DeltaPtot and E(st) was significantly higher in the LPS group than in the other groups. Our results suggest that aortovasctam, but not simvastatin, exhibits anti-inflammatory and antioxidant actions in LPS-induced ALI.

394. Fibrogenesis between epithelial injury and fibroblast proliferation

Fei Li1,2, 3Department of Respiratory and Critical Medicine Care, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China; 2Faculty of Respiratory Medicine, Capital Medical University, Beijing, China; 3Laboratory of Respiratory and Pulmonary Circulation, Beijing Institute of Respiratory Medicine, Beijing, China

Alveolar fibroblasts are key cells to the process of alveolar septation as PDGFRα knock-out prevented alveolar myofibroblast differentiation and completely blocked secondary septation formation. Lipofibroblasts have been proposed to be essential for septation, peak in number during septation and regress significantly thereafter. Whether PDGFRα expressing precursors are deriving both lineages of fibroblasts is unsolved.

For identification of active PDGFRα expression, PDGFRα-GFP knock-in mice were used. Immunofluorescence staining revealed a co-expression of PDGFRα-GFP and uSMA in the bronchial compartment as well as in the alveolar space. The expression of ADRB co-localizes with the precursor marker in a subset of cells. The same pattern of expression could be observed in the constitutive PDGFRαCre and the conditional PDGFRαCreER mice. PDGFRα-GFP mice showed that PDGFRα-expressing precursor cells are differentiating into myo- as well as lipofibroblasts. The constitutive PDGFRαCre and conditional PDGFRαCreER mice revealed restriction of PDGFRα signalling to bronchial smooth muscle cells and alveolar fibroblasts in the lung. Lineage tracing with conditional PDGFRαCreER mice could confirm that postnatal PDGFRαCreER cells derive lipofibroblasts and myofibroblasts.

P3748 Nr2f is closely related to enhance bleomycin induced airway inflammatory responses caused by diesel exhaust particles in mice

Ying-Ji Li1, Tkako Shimizu1, Yusuke Inagaki1, Ken Takeda2, Arata Azuma1, Hajime Takizawa4, Yamamoto Masayuki1, Tomoyuki Kawada1, Shojo Kudoh2, 4Hygiene and Public Health, Nippon Medical School, Tokyo, Japan; 3Pulmonary Medicine, Kyorin University, School of Medicine, Mitaka, Japan; 2Biochemistry, Tokoha University Graduate School of Medicine, Sendai, Japan; 4Fukuyoshi Hospital, Anti-Tuberculosis Association, Kyojoe, Japan

Diesel exhaust particles (DEP) induced oxidative stress play an important role in proinflammatory reaction on airway. Nr2f is involved in the transcriptional regulation of many antioxidant genes. In the present study, we investigated the effect of DEP on an experimental model of bleomycin (BLM)-induced airway inflammatory responses in both Nr2f+/+ and Nr2f−/− mice. BLM was administered IV to Both Nr2f+/+ and Nr2f−/− C57BL/6d mice at a dosage of 80 μg/kg body weight on day zero. Mice were exposed to 1mg/m3 DEP for 8 hrs/day and 5 days/week. We designed two experimental groups as follows: group 1, BLM alone, clean air; group 2, BLM plus pre-4wks-DEP exposure. Cell populations in BALF were examined at 10 days after BLM injection. We also examined cytokines and chemokines.

In the DEP exposed group, the percentage changes from BLM alone group in the total number of cells and macrophages remarkably increased in the both Nr2f+/+ and Nr2f−/− mice. BLM was administered IV to Both Nr2f+/+ and Nr2f−/− C57BL/6d mice at a dosage of 80 μg/kg body weight on day zero. Mice were exposed to 1mg/m3 DEP for 8 hrs/day and 5 days/week. We designed two experimental groups as follows: group 1, BLM alone, clean air; group 2, BLM plus pre-4wks-DEP exposure. Cell populations in BALF were examined at 10 days after BLM injection. We also examined cytokines and chemokines.

These findings suggest that DEP might be an important factor on the BLM induced lung injury, and Nr2f might be an important genetic factor in the determination of susceptibility to BLM induced lung injury caused by DEP via regulating the macrophages defense mechanisms in mice.

P3749 Inhibiting CXCR4/CXCL12 axis attenuates lung fibrosis both in vitro and in vivo

Fei Li1,2, Haiping Dai1,2,3, Jing Geng1,2,3, Xuelong Xu1,2, 1Department of Respiratory and Critical Medicine Care, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China; 2Faculty of Respiratory Medicine, Capital Medical University, Beijing, China; 3Laboratory of Respiratory and Pulmonary Circulation, Beijing Institute of Respiratory Medicine, Beijing, China

Background: Lung fibrosis is characterized by fibroblast proliferation and collagen deposition. CXC chemokine receptor 4 (CXCR4), which binds the stromal cell-derived factor 1 (SDF-1/CXCL12), has been shown a critical role in cell proliferation. Here, we aim to examine the exact modulatory effects of CXCR4/CXCL12 on the fibroblast proliferation and lung fibrosis.

Methods: In vitro, primary human lung fibroblasts (HLF) was isolated from patients with idiopathic pulmonary fibrosis and primary spontaneous pneumothorax for thoracoscopy with stapling of any air leak. CXCR4 protein level was assessed by indirect immunoblotting. MTT was used for the proliferation assay of bleomycin stimulated normal HLF in the presence or absence of AMD3100, an antagonist of CXCR4. In vivo, C57BL/6 mice were injected intraperitoneally with saline or AMD3100 (200μg) 1 day before intratracheal instillation of bleomycin (5mg/kg). Survival rate, lung fibrosis and pulmonary function will be assessed.

Results: The basal level of CXCR4 expression was higher on fibrotic HLF. Bleomycin could promote the proliferation of normal HLF, which could be significantly attenuated by AMD3100 pretreatment. AMD3100 administration significantly increased the survival rate of mice on day 2i compared with bleomycin treatment alone. According to the histology, pulmonary fibrosis was attenuated by AMD3100 pretreatment in later stage of bleomycin injury. However, no significant differences in total lung capacity and airway resistance were observed between these groups.

Conclusion: Collectively, our data suggest that AMD3100 could significantly attenuate lung fibrosis both in vitro and in vivo through inhibiting CXCR4/CXCL12 axis.
Shigehisa Yanagi
alveolar epithelial cells and suppressing lung inflammation

Nobuhiro Matsumoto, Masamitsu Nakazato.
Division of Neurology, Respirology, Endocrinology and Metabolism, Department of Internal Medicine, University of Miyazaki, Japan

Acute lung injury (ALI) is a critical illness syndrome consisting of acute respiratory failure with bilateral pulmonary inflammatory response that is refractory to current therapies. ALI is characterized by injury of the alveolar capillary barrier, neutrophil accumulation, and induction of pro-inflammatory cytokines followed by devastating lung fibrosis. Ghrelin, an acylated peptide produced in the stomach, increases food intake and growth hormone secretion, suppresses inflammation, and promotes cell survival. We investigated the pharmacological potential of ghrelin in the treatment of ALI by using a bleomycin-induced ALI model in mice. Ghrelin or saline was given to mice daily starting 1 day after bleomycin administration. Ghrelin-treated mice showed a definitively higher survival rate than saline-treated ones. They also had smaller reductions in body weight and food intake.

The amelioration of neutrophil alveolar infiltration, pulmonary vascular permeability, induction of pro-inflammatory cytokines, and subsequent lung fibrosis were notable in ghrelin-treated mice. Additionally, ghrelin administration reduced the injury-induced apoptosis of alveolar epithelial cells. Our results indicate that ghrelin administration exerts a protective effect against ALI by protecting the alveolar epithelial cells and regulating lung inflammation, and highlight ghrelin as a promising therapeutic agent for the management of this intractable disease.

P3751
A longitudinal characterization of lymphangiogenesis in bleomycin-induced pulmonary fibrosis mouse model
Masahito Yamashita 1, Miyuki Nisato 1, Hitoshi Kobayashi1, Yuji Shibata2, Takashi Soma2, Kohri Miyoshi2, 1Respiratory, Allergy and Rheumatology, Iwate Medical University, Morioka, Iwate, Japan; 2Pathology, Iwate Medical University, Morioka, Iwate, Japan.

Background: The roles of lymphangiogenesis in the pathogenesis of pulmonary fibrosis has been studied; however, it has not been associated with this condition in human.

Objective: To clarify longitudinal characteristics of lymphangiogenesis in bleomycin-induced pulmonary fibrosis mouse model.

Animal and methods: Pulmonary fibrosis was induced in C57BL/6 female mice by intratracheal injection of 3.0 U/kg of bleomycin. Three mice were sacrificed in each group at days 0, 7, 14, 21, 28, and 35 days after. Formalin fixed and paraffin embedded lung tissues were used for immunohistochemical and morphometric analyses. Antibodies specific for Vegfr-3, Cd31 and type 1 collagen were used to detect lymphatics, blood vessels and collagen, respectively.

Results: The dilatation of the existing lymphatics around bronchus and large blood vessels was observed on Day 7, and numerous lymphocytes were organized around them. The lymphatics were newly formed in fibrotic lesions on Day 14, although capillaries were barely detected in the lesions. In Masson Trichrom staining, connective tissue was most prominent on Day 21, and loose after that. The area densities of interstitium and hydroxyproline concentration in lung homogenates were maximally increased on Day 21. The existing and the newly formed lymphatic densities were significantly increased on Day 21, respectively (p < 0.05).

Conclusion: In the early stage, the existing lymphatics may play a role in the organization of lymphoid structure, which possibly facilitate the fibrogenesis. In the later stage, the newly formed lymphatics may be associated with the tissue resolution.

P3752
Bioavailability of vascular endothelial growth factor (VEGF)? A role in pulmonary fibrosis?
Shaney Barratt1, Caroline Jarrett 1, Gavin Welsh1, David Bates2, Ann Millar1.
1 Lung Research Group, University of Bristol, United Kingdom; 2Microvascular Research Laboratories, University of Bristol, United Kingdom

Vascular endothelial growth factor (VEGF) is both a growth factor and permeability factor, involved in tissue repair and as such, has been proposed to have a role in the pathogenesis of pulmonary fibrosis. VEGF is generated as multiple isoforms of two families, VEGFxxxb and VEGFxxx, and mediates its effects through specific receptors, VEGFR-1 and VEGFR-2 co-receptors, neuropilin-1 and neuropilin-2. We hypothesised that these receptors, co-receptors and isoforms would be differentially expressed in normal versus fibrotic fibroblasts. Normal fibroblasts (NF) and fibrotic fibroblasts (FF) (from patients with proven UIP) were extracted from lung samples using the explant method. Expression of VEGFR-1, 2, and NRPI-1, NRPI-2, and VEGF isoforms was established at the protein level using western blotting whilst receptor expression was confirmed with immunofluorescence staining of cells in culture.

Both NF and FF expressed VEGFR1 and 2. NRPI-1 and 2 and VEGFxxx,xxxb isoforms did not significantly differ in VEGFR-2 and NRPI-1 expression between NF and FF fibrast. However, both fibrast expression of VEGFR-1 and NRPI-2 were significantly reduced in NF versus FF (p<0.05, non-paired t-test).

VEGF receptors, co-receptors and isoforms are expressed differentially in NF and FF. This suggests a potential role for changes in VEGF bioactivity in the development of pulmonary fibrosis.

Bleomycin (BLM)-induced pulmonary fibrosis (PF) in rats

Objective: To investigate the pharmacological potential of RKT in the treatment of ALI by using a bleomycin-induced ALI model in mice. Ghrelin, an acylated and orexigenic peptide, produces predominantly in the stomach. We previous studies have reported that RKT increases plasma level of ghrelin, an antidiabetic and anti-inflammatory peptide.

RKT administration was investigated the pharmacological potential of RKT in the treatment of ALI by using a bleomycin (BLM)-induced lung fibrosis, and highlight the potential role for changes in VEGF bioactivity in the development of pulmonary fibrosis.

Acute lung injury (ALI) is a critical illness syndrome consisting of acute respiratory failure with bilateral pulmonary infiltrates that is refractory to current therapies. ALI is characterized by injuries of the alveolar epithelial barrier, infiltrations of neutrophils into lung parenchyma, and induction of pro-inflammatory cytokines followed by devastating lung fibrosis.

Rikkunshito (RKT), a traditional Japanese medicine, consists of several kinds of flavonoids which have been shown to have anti-inflammatory effects. In addition, previous studies have reported that RKT increases plasma level of ghrelin, an acylated and orexycoric peptide, produced predominantly in the stomach. We investigated the pharmacological potential of RKT in the treatment of ALI by using a bleomycin (BLM)-induced lung injury model in mice.

RKT or distilled water was given to mice orally and daily starting from the day of BLM administration. RKT-treated mice showed a definitively higher survival rate than distilled water-treated ones. They also had smaller reductions in body weight and food intake compared to the controls. Additionally, RKT-treated mice showed reduction of pulmonary epithelial permeability, neutrophil alveolar infiltration, and subsequent lung fibrosis.

RKT administration resulted in increase in plasma levels of ghrelin in BLM-treated mice. However, RKT administration also exerted protective effects against BLM-induced ALI response on ghrelin-deficient mice in addition to ghrelin-competent mice. Our results indicate that RKT administration exerts a protective effects on BLM-induced lung injury in mice, independently of the effects of ghrelin, and highlight RKT as a promising therapeutic strategy for the control of the ALI.

Leukotriene (LTC4) aggravate bleomycin-induced pulmonary fibrosis in mice
Masamitsu Tatewaki, Hirokuni Hirata, Masafumi Arima, Takeshi Fukuda, Pulmonary Medicine and Clinical Immunology, Dokkyo University School of Medicine, Tochigi, Japan Developmental Genetics, Chiba University Graduate School of Medicine, Tochigi, Japan

Background: Synthesis of cysteinyl leukotrienes (cys-LTs) is thought to cause inflammatory disorders such as bronchial asthma and allergic rhinitis. Recent reports have suggested that LTC4 is an important regulator of pulmonary fibrosis. This study examined the effect of LTC4 in LTC4 synthesize-overexpressed transgenic (Tg) mice with bleomycin-induced pulmonary fibrosis. We also focused on the function of lung-derived fibroblasts in the Tg mice.

Methods: To administration of bleomycin, pranlukast hydrate, a cyst-LT1 receptor antagonist, was intratracheally instilled. Concentrations of IL-4, -13, and TGF-β1 mRNA was measured by real time PCR. Results: The levels of IL-4, -13, and TGF-β1, and pulmonary fibrosis were greater in Tg than in WT mice. The reduction of LTC4 function in Tg mice could be decreased both these cytokines and pulmonary fibrosis. Furthermore, continuous LTC4 secretion from fibroblasts was higher in Tg than in WT mice, while reduction of LTC4, by pranlukast in fibroblasts from Tg, but not in those from WT mice, decreased cell viability and expression of TGF-β1 mRNA.

Conclusion: These findings first suggest that overexpression of LTC4 by pranlukast in fibroblasts from Tg, but not in those from WT mice, to mimic epithelial-mesenchymal interactions in the human lung.

Distal airway epithelial cells differentiate into ATII-like cells as suggested by morphological changes as well as increased expression of differentiation markers AQP3, SP-A, SP-C in the 3D model. Wnt11 was identified in the model and in human lung explant cultures as one of the main regulators of ATII differentiation. Added Wnt11 increased the expression of ATII markers, while silencing of Wnt11 resulted in elevated levels of EMT markers N-cadherin and S100A. We conclude that the 3D lung model is applicable for studying epithelial-mesenchymal interactions in the lung. Our finding may mark Wnt11 as a potential therapeutic target in lung regenerative therapy.

LSC 2012 Abstract – Imaging Wnt/beta-catenin signalling in an ex vivo tissue culture model of lung repair
Franziska Uhl, Melanie Königshoff, HMGU, Comprehensive Pneumology Center, Munich, Germany

Emphysema is a pathophysiological hallmark of COPD and characterized by airspace enlargement and impaired alveolar repair processes. Recently, Wnt/beta-catenin signalling has been linked to epithmesenchymal changes in human disease and animal models thereof. Here, we aim to further decipher the underlying mechanisms and image structural changes involved in lung repair processes. We applied an ex vivo tissue culture model from wildtype (C57Bl/6) and Wnt reporter mice (Bat-/-TopGal) subjected to elastase treatment or PBS. Tissue slices (300 μm) generated using a vibratome were viable in culture for up to 7 days ex vivo (WST-1: d1: 21 ±6 vs. d7 41 ±67%). Structural integrity of control (C) and epithmesenchymal (E) lung slices was determined by qPCR and immunofluorescence microscopy. Functional Stipc was decreased in E lung slices compared with control and further decreased over time shown by ELISA (d1: 135±19 ng/ml C vs. 82±17 ng/ml E). Wnt signalling activation by Lef1 led to an increase in Stipc expression accompanied by increased β-galactosidase staining in alveolar regions and upregulated target gene expression, such as Axin2, Dkk2 or Lef1. Epithmesenchymal tissue slices closely reflect COPD-like changes in vivo. Lung slices are viable up to 7 days ex vivo allowing determination of structural changes and cell fate in the diseased lung upon signal pathway modification.

P3759
Proliferation of alveolar type II pneumocytes is stimulated by Jagged-1 in vivo
Rainer Zembach, Susanna Desole, Caroline Linhart, Kathrin Watzinger, Christian M. Kähler. Department of Internal Medicine I - Pneumology, Medical University Innsbruck, Austria

Notch is an ancient cell-signaling system that regulates the specification of cell fate. Recently, Notch was found to confer antigen presenting cell function on mast cells and induce histamine release in human basophils and regulate migration and survival of eosinophils. In acute lung injury, alveolar type II cells activate macrophages, secrete soluble mediators, migrate and spread in response to the injury. Additionally, Notch stimulates myofibroblast differentiation and migration of cultured RLE-6T7 cells. However, until now, nothing is known on the role of Notch activation regarding proliferation of rat alveolar type II cells. Rat alveolar type II cells (RLE 6T7) were obtained from the American Type Culture Collection (ATCC no. CRL-2300; Manassas, VA, USA) and were cultured in DMEM/Ham’s F12 containing 10% fetal calf serum and L-glutamine. Cell proliferation was measured by direct cell count and the fluorometric proliferation assay EZ4U basing on tetrazolium salt reduction. Cells were incubated with the test substances in medium containing 0.5% fetal calf serum for 24h at 37°C and 5% CO2. Jagged-1 significantly stimulated proliferation of alveolar epithelial cells within a wide concentration range [5μg/ml to 100μg/ml]. The maximum effect was observed at 100ng/ml. To show specificity of the observed effect, rat alveolar type II cells were preincubated (45 min) and co-incubated with the specific gamma secretase inhibitor DAPT [107 M] which completely abolished the effect of Jagged-1 (10μg/ml).

Hence, we report for the first time that the Jagged-1/Notch signalling pathway is affecting rat alveolar type II cell proliferation in vitro.

P3760
Wnt11 inhibits epithelial-mesenchymal transition induced by TGFb1 in human type II alveolar epithelial cells
Demokos Barthe1, 2, Vijay D’Souza1, Judith E. Pongracz2, David R. Thickett1.

Methods: Wnt11 inhibits epithelial-mesenchymal transition induced by TGFb1 in human type II alveolar epithelial cells.

Increased activity of TGFβ1 plays a crucial role in the pathogenesis of idiopathic
pulmonary fibrosis (IPF). Alveolar type II cells (ATII) undergo EMT expressing mesenchymal markers when exposed to a high concentration of TGFβ1 in both in vitro and in vivo models. Mesenchymal signals might contribute to the differentiation and regeneration of pulmonary epithelium. Wnt11 is a secreted glycoprotein known to be expressed in the mesenchyme of the embryonic lung. We constructed a 3-dimensional (3D) human tissue model of primary human pulmonary cells to mimic epithelial-mesenchymal interactions in the lung. Our results indicate that human lung fibroblasts are a source of Wnt11 in the lung tissue model. ATII cells isolated from human lung samples were treated with recombinant TGFβ1 and/or Wnt11. Expression levels of the EMT markers Vimentin, alpha smooth muscle actin (αSMA) and SLUG were determined by qPCR and immunofluorescence. We found that Wnt11 inhibits EMT induced by TGFβ1 in ATII monolayers and in 2D and 3D ATII/fibroblast co-cultures. Wnt11 treatment resulted in decreased expression of EMT markers compared to TGFβ1 treated cell cultures.

**Conclusion:** Our data suggest that mitochondrial metabolism plays an important role in the phenotypic activation of lung fibroblasts in both TGFβ1 stimulated cells in vitro and bleomycin-induced fibrosis in vivo.

---

**Figure 1.** Human ATII cells subjected to TGFβ1 and Wnt11 treatment.

We propose that the pulmonary mesenchyme might contribute to the homeostasis of epithelial cells by secreting Wnt11. This finding that effects of TGFβ1 can be antagonized by Wnt11 may mark it as a potential therapeutic target in the fibrotic diseases of lung.

**P3761 Epithelial Pten controls acute lung injury and fibrosis by regulating intercellular junctional integrity and EMT.**

Shibuehisa Yamagi, Kahori Miyoshi, Hiromu Tsuouchi, Nobuhiro Matsumoto, Masamitsu Nakazato. Division of Neurology, Respiratory, Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, University of Miyazaki, Japan

Injury to alveolar epithelial cells (AECs) and its repair process are integral to the pathogenesis of acute lung injury (ALI) and idiopathic pulmonary fibrosis (IPF). Disruption of AECs integrity and its reconstitution are crucial for ALI progression. In addition, myofibroblasts, key effector cells in IPF, partially originate from AECs through epithelial-mesenchymal transition (EMT). However, the regulation mechanisms of AECs integrity remains unclear. We explored the role of epithelial Pten in lung injury by generating a postnatally and lung epithelium-specifically Pten-null (SOPten) mouse strain. Sixty percent of SOPten mice died of hypoxia, whereas all control mice survived after bleomycin insult. SOPten mice demonstrated aggravation of ALI and lung fibrosis with enhanced disruptions of intercellular junctional complexes of AECs and degradation of basement membranes. Epithelial-derived myofibroblasts were increased in epithelium-specific Pten-deficient mice. Lung sections of bleomycin-treated SOPten mice showed increased pAkt, pS6K, Snail and MMP expression. Reduced claudin-4, E-cadherin, and laminin-beta1 expressions. Systemic Akt inactivation definitively saved SOPten mice through amelioration of bleomycin-treated SOPten mice showed increased pAkt, pS6K, Snail and MMP expression. Reduced claudin-4, E-cadherin, and laminin-beta1 expressions. Systemic Akt inactivation definitively saved SOPten mice through amelioration of bleomycin-treated SOPten mice showed increased pAkt, pS6K, Snail and MMP expression. Reduced claudin-4, E-cadherin, and laminin-beta1 expressions. Systemic Akt inactivation definitively saved SOPten mice through amelioration of bleomycin-treated SOPten mice showed increased pAkt, pS6K, Snail and MMP expression. Reduced claudin-4, E-cadherin, and laminin-beta1 expressions.

**Methods & results:** Using an epithelial mesenchymal transition (EMT) model, immunoblotting demonstrated up-regulation of E-cadherin and suppression of Fibronectin expression by TLD extract, thereby reversal of EMT in the treated A549 cells. Additional experiments displayed that TLD can inhibit hyper-expression of p-ERK 1/2, p-Akt, p-STAT3, NF-κB, and α-SMA in lung fibroblasts of nonspecific interstitial pneumonitis (NSIP) and HMGB1-stimulated up-regulation in those of normal or NSIP, concomitant with reduced levels of inflammatory cytokines. Alzet osmotic minipumps application of TLD extract to Bleomycin/BLM-challenged mice significantly decreased acute inflammation and pulmonary fibrosis. Mucosal application of TLD extract to native mouse trachea by Ussing chamber recordings suggested activation of Cyt secretion by increasing cAMP. These effects were mimicked by a mix of isolated components.

**Conclusion:** We suggest that the extract from TLD may provide a novel and effective treatment for interstitial lung fibrosis through multi-ingredient synergistic regulation of cAMP signaling.

---

**P3764 Chemokine profiles of A549 human alveolar epithelial cells that underwent epithelial-mesenchymal transition by TGF-β and/or TNF-α.**

Hiromi Hara1, Yasushiro Yamashita1, Akira Saito1, Taisuke Jo1, Yu Mikami1, Hajime Takizawa2, Takahide Nagase1, Tadashi Kohyama1, 1Department of Respiratory Medicine, University of Tokyo, Japan; 2Department of Respiratory Medicine, Kyouin University School of Medicine, Tokyo, Japan

Epithelial-mesenchymal transition (EMT) is supposed to be implicated in the pathogenesis of lung fibrosis through enhanced TGF-β1 signaling. TNF-α has also been implicated in tissue fibrosis. Recently, TGF-β1 induced EMT is augmented by TNF-α, suggesting that enhanced EMT by TNF-α may be important in the pathological processed of lung diseases. However, the mechanism of enhanced EMT by TNF-α has not been fully elucidated. Therefore, we evaluated the cytokine/chemokine profiles of the cells that underwent EMT by TGF-β1 and/or TNF-α.

**Methods:** A549 cells were incubated for 48 hours with 5 ng/ml of TGF-β1, 10 ng/ml of TNF-α, or TGF-β1 and TNF-α to undergo EMT. After 48 hours incubation, growth medium was changed to serum-free medium, and the supernatants were collected at 48 hours. Cytokine/chemokine array was performed using Ray Bio human cytokine array V. Relative values were quantitated by densitometry, and normalized to that obtained in non-treated sample.

**Results:** TNF-α induced production of inflammatory chemokines, such as RANTES and MCP-1. TGF-β1 induced production of inflammatory chemokines, including GM-CSF, GRO, GRO-A, MCP-2, and MCP-3. Simultaneous stimulation with TNF-α and TGF-β1 reduced production of GM-CSF, GRO, GRO-A, IL-6, MCP-1, RANTES, and these effects were enhanced on the production of GRO, GRO-A, IL-8, and MCP-1.

**Conclusion:** The cells treated with TGF-β1 or TNF-α have different chemokine profile, and the effect on chemokines production was enhanced by the combination with TGF-β1 and TNF-α. This study might contribute to understanding mechanism of EMT enhanced by TNF-α and pathogenesis of lung fibrosis.
CONCLUSION: This study showed that PF is able to decrease pulmonary fibrosis (11.13 to 15.67) and PQ+antioxidant (11 95%CI 7.77 to 14.23) groups. The not decrease the lung fibrosis (p=0.413). Life expectancy decreased in PQ+NS (11 of ALI

The role of pre-receptor glucocorticoid metabolism in regulating the severity of ALI

The role of pre-receptor glucocorticoid metabolism in regulating the severity of ALI

P3764

Hyperoxia increased lung resistance and decreased compliance, total lung capacity and forced expiratory flow. After recovery, resistance, compliance and total lung capacity had normalized whereas forced flows remained low. Sphingolipids, including ceramides, were significantly increased after hyperoxia. Ceramides were still increased after 2 weeks of recovery, but normalized to control values after 4 weeks. Addition of D-sphingosine during the first 5 days of recovery reduced ceramide levels at 2 weeks and partially reversed the hyperoxia-induced increase in alveolar size and arrest in alveolarization at 4 weeks, although no further improvement in lung function parameters was observed.

Aim: To characterize lung function and BAL sphingolipid profile of newborn mice during hyperoxia exposure and recovery in room air, and to examine the effect of D-sphingosine supplementation during recovery.

Methods: Newborn mice were exposed to 80% O2 for 4 weeks and allowed to recover in room air for another 4 weeks. Lung function measurements, histological and morphometrical analysis of lung tissue was performed and BAL fluid was collected during hyperoxia and after recovery with and without D-sphingosine supplementation. Sphingolipids in BAL were quantified by tandem mass spectrometry.

Results: Hyperoxia increased lung resistance and decreased compliance, total lung capacity and forced expiratory flow. After recovery, resistance, compliance and total lung capacity had normalized whereas forced flows remained low.

Molecular pathogenesis of Idiopathic Pulmonary Fibrosis (IPF) remains unclear. We recently demonstrated a key role for the PI3K pathway in both proliferation and differentiation into myofibroblasts of lung fibroblasts treated with TGF-β. In this study we assessed the expression of Class I PI3K p110 isoforms in IPF lung tissue and fibroblast cell lines. Moreover, we investigated the in vitro effects of the selective inhibition of p110 isoforms on IPF fibroblast proliferation and fibrogenic activity.

To evaluate expression levels of PI3K p110 isoforms, IHC as well as Western blot and Flow Cytometry analysis were performed on normal and IPF tissue sections. No significant differences between normal and IPF tissue/cells were observed for the expression of PI3K p110 α, β and δ isoforms whereas p110γ resulted overexpressed in both IPF lung homogenates and ex-vivo fibroblast cell lines. The IHC results show a strong immunoreactivity for p110γ in myofibroblasts of IPF lungs. Moreover, in pathologic bronchiolar structures of IPF lungs, basal cells exhibited a pronounced nuclear expression of p110γ which was hardly detectable in normal lung tissues. Furthermore, as a consequence of both p110γ pharmacological inhibition and gene silencing, a significant inhibition of proliferation rate and α-SMA expression were observed in IPF fibroblasts whereas no effects were found on normal cells.

Our data indicates that PI3K p110 γ isoform can be a novel pharmacological target.
Inhibition of the sonic hedgehog pathway at the primary cilium prevents the effect of TGF-beta 1 on alveolar epithelial cells.

Elika Farrokhi Moshaj1, Arnaud Mailleux1, Valérie Besnard1, STEPHANE BRAYER1, MONIQUE DEBOUX1, 2, Bruno Crestani1, 1., 1 INTERIM U700, UFR de Médecine Xavier Bichat, Paris, France; 2 Laboratoire de Biochimie, Hôpital Bichat, Paris, France; Service de Pneumologie, Hôpital Bichat, Paris, France.

Introduction: The mesenchymal differentiation of alveolar epithelial cells induced by Transforming Growth Factor beta-1 (TGF-beta1), also called Epithelial Mesenchymal Transition (EMT), may contribute to Locidpathic Pulmonary Fibris (IPF). The Sonic Hedgehog (SHH) pathway is involved in epithelial cells-fibroblasts interaction during fetal lung development and lung fibrogenesis in adult lung. Previously, our laboratory has demonstrated that the SHH pathway is necessary to the action of TGF-beta 1 in human pulmonary fibroblasts (Cigna et al. in revision).

Aims: We hypothesized that the SHH pathway could play a role in mesenchymal differentiation of alveolar epithelial cells induced by TGF-beta 1.

Methods: We assessed the effect of TGF-beta 1 (1-5 ng/ml) for 48h in serum-free medium. The expression of E-cadherin, N-cadherin, and fibronectin was evaluated by real-time PCR, Western blotting and immunocytochemistry. The migratory capacity of A549 is also measured in these conditions.

Results: Inhibition of the pathway via SMOGLI abolishes the effect of TGF-beta 1 on the migration of epithelial cells but does not influence the effect of TGF-beta 1 on cell differentiation. By contrast, the inhibition of the HH pathway in the primary cilium with HPI-4 prevents and reverses the effect of TGF-beta 1 on epithelial cell differentiation.

Conclusions: Our results indicate that the primary cilium controls the effect of TGF-beta 1 on A549 cells in vitro.

Protective effect of mesenchymal stem cells (MSC) on hypoxia-induced epithelial-mesenchymal transition of alveolar epithelial cells (AEC)

Yurdagul Uzunhan1, Nadia Randrianarison1, Dominique Macheaux1, Nicolas Dard1, Jerome Larghero2, Carole Planis1, 1 EFA 2635, UFR SMH, Université Paris 13, PRES Sorbonne Paris Cité, Bobigny, France, Metropolitan; 2 Centre de Thérapie Cellulaire, Hôpital Saint Louis, Paris, France, Metropolitan.

Background: Epithelial-to-mesenchymal transition (EMT) of AEC induced by TGF-β1 or hypoxia (HX) may contribute to pulmonary fibrosis. In animal models of lung fibrosis, administrated fibroblastic MSC reduced fibrosis and mortality by an unknown mechanism. We hypothesized that MSC may favor alveolar wound healing by preventing hypoxia-induced EMT. We tested in vitro the paracrine effect of MSC on the phenotypic changes of AEC induced by HX.

Methods: Rat AEC cultured on Transwell filters were exposed to HX (3 or 1.5% O2) for up to 12 days in the presence/absence of human MSC on the bottom of well. Epithelial electrical resistance (TER) as well as epithelial markers (E-cadherin, ZO-1, TFP-1) and mesenchymal markers (smooth muscle α-actine, vimentin) were assessed by ohm-meter, immunofluorescence and Western blot at days d1, d2, d7, d12.

Results: Exposure of AEC to HX resulted in a dose- and time-dependent decrease of TER and of epithelial marker expression, together with an increase in mesenchymal marker expression. These effects were reproduced by treatment with cobalt chloride and were partially prevented by anti-oxidant drugs (Euk134 or α-tocopherol). By contrast, with 100 μM vitamin E and C, hypoxia with 100 μM vitamin C, hypoxia with 100 μM vitamin C and hypoxia with a combination of vitamins E and C (10-7, 10-6 M respectively) TER measurement, immunofluorescence staining of ZO-1 and RT-PCR to detect IL8, IL6, TNF-α and ZO-1 expression were used.

Results: The reductions of the TER in hypoxic groups (hypoxia and hypoxia with antioxidants) were associated with the reduction in the ZO-1 thickness and downregulation of ZO-1 expression compared with the control. In contrast, the expression of IL-8, IL-6 and TNF-α was upregulated in the hypoxic groups compared with the control.

Conclusions: Hypoxia-induced barrier permeability dysfunction represented by the decrease in TER and the reduction of ZO-1 levels is associated with an increased expression of pro-inflammatory cytokines IL-8, IL-6 and TNF-α. The antioxidant vitamins E and C had only a slight protective effect against hypoxia damage.
originating at the initiation of oxidation amino acid rests of protein at the exacer-
beration (0.05±0.01U/mg) and remission stage (0.03±0.00U/mg) than in control
subjects (0.01±0.00U/mg) (p<0.05). COPD patients had a decreased amount of
carbohydrate derivatives at the stage of elongation of the process. This may be due to
the considerable protein destruction. We have shown low level of reduced thiol at
the exhaustion of antioxidant system. The data received correlate with disruption
of pulmonary function and oxygen saturation in COPD patients.

Purpose of the study: The evaluation of the IV-type collagen level dynamics in
BALF of patients with 3rd stage COPD during the treatment with Roflumilast.

Materials and methods: The contents of the IV-type collagen in BALF was evalu-
ated in 39 patients with III stage COPD in a random stage using enzyme-linked
immunosorbent assay before and after 3 months of treatment with the inhibitor of
phosphodiesterase 4 – Roflumilast, 500 mg per day, inside, together with the basic
local 3rd stage COPD treatment (GOLD, 2010).

Results of the study: The contents of the IV-type collagen in BALF before the
treatment in patients with 3rd stage COPD was (69±3±12) ng/ml, which is in 7.4 times higher than in almost healthy people, whose contents consisted of (9±0.5±54) ng/ml. After the second examination in 90 days, the
above-mentioned indicator in patients fell down by 2.45 times and was equal
(28±2±2.3) ng/ml.

Conclusions: The depression of IV-type collagen levels demonstrate the ability to
slow down pneumosclerosis progression in patients with III COPD who are treated
with Roflumilast.

The depression of IV-type collagen levels demonstrate the ability to
slow down pneumosclerosis progression in patients with III COPD who are treated
with Roflumilast.

The effect of intravenous immunoglobulin on oxygen-dependent metabolism
of blood cells in patients with community acquired pneumonia

Usman Farkhudinov, Albert Mirchadaurov, Rafagat Farkhudinov. Department of Internal Diseases, City Hospital 21, Ufa, Russian Federation Department of Internal Diseases, Bashkortostan State Medical University, Ufa, Russian Federation

Active oxygen forms (AOF) determine the microbicidal activity of phagocytes.

Their low generation may be one of the reasons of latent inflammatory process.

The aim was to study the effect of i.v. immunoglobulin immunovenin (IMV) on the
production of AOF in in-vitro experiments and in patients with community-
acquired pneumonia (CAP).

Methods: The method of chemiluminescence (CLL) registration was used to study
the effect of various doses of IMV (0.005 mg/ml, 0.03 mg/ml, 0.05 mg/ml) on the
production of AOF in the blood of healthy subjects. In the clinical part of the
research AOF generation was studied in 35 patients with CAP. 17 patients with
CAP received standard therapy. In 18 patients IMV was added to the treatment

Results: In in-vitro experiments IMV dose of 0.05 mg/ml increased CLL inten-
sity of blood by 18.4±0.3% (p<0.05) the doses of 0.01 mg/ml and 0.05 mg/ml
increased CLL intensity by 48.6±2.1% (p<0.05) and 64.5±3.4% (p<0.05)
respectively. In comparison with normal findings CLL intensity of blood in pa-
tients with CAP has been found to be reduced by 1.5 times. The use of IMV in patients has increased production of AOF in blood and resulted in positive
dynamics of clinical findings. In the case of standard therapy low CLL intensity of
blood maintained, the inflammatory process often had a prolonged course.

Conclusion: IMV may be used in the treatment of patients with CAP owing to
its influence on AOF. It allows to increase AOF production by phagocytes and
decrease the incidence of latent inflammatory processes.

Converse airway effects of nicotine in vitro and in vivo

Yuan Xu, Lars-Olaf Cardell. Division of Ear, Nose and Throat Diseases, CLINTEC, Karolinska Institutet, Stockholm, Sweden

Cigarette smoke, which contains high concentrations of nicotine and endotoxin
(LPS), plays a pivotal role in the development of asthmatic airway inflammation
and hyperreactivity (AHR). But the mechanisms behind this are poorly known.
The present study examines the effects of nicotine and LPS on murine airways
both in vitro and in vivo.

In the in vitro model, murine tracheal segments were cultured in presence of
nicotine (10 μM) and/or LPS (10 μg/ml) for 4 days. Smooth muscle contractility
was assessed with myograph and inflammatory mediator expressions measured
with real-time PCR. In the in-vivo model, mice were exposed to nicotine (24
mg/kg/day) via osmotic pumps for 28 days followed by intranasal (i.n.) LPS
(1 mg/ml) instillation during the last 3 days. Airway resistance was measured
using FlexiVent® after i.v. methacholine challenge and inflammatory cells in
the bronchoalveolar lavage fluid were counted. In vitro, nicotine increased contractions to Bradykinin (BK) and des-Arg9-BK. Carb cholactons only increased after combined nicotine and LPS exposure.

Moreover, nicotine specifically up-regulated Toll-like receptor 2 and 4 as well as
inflammatory mediators COX-2 and MCP-1 in vivo, micro- and macrophages,
but i.n. LPS caused both AHR and acute pulmonary neutrophilic inflammation.

28-days of in-vivo nicotine exposure suppressed the LPS-induced AHR both in
central and peripheral airways and prevented pulmonary neutrophil infiltration.

It is interesting to note that the local smooth muscle effect of nicotine differs
markedly from the in-vivo effect which involves a much more complex system
of inflammatory cells and mediators. This is important to acknowledge when
evaluating the toxic effect of nicotine.
P3780 Effect of stress on free radical indices in bronchial asthma

Elena Zaprudnova1, Svetlana Soodaeva2, Igor Klimanov2

Effect of stress on free radical indices in bronchial asthma

We investigated the influence of stress on the levels of some free radical indices in exhaled breath condensate (EBC) at people with asthma (BA) compared with healthy people.

The control group (n=57) included healthy, young people aged 20 - 23 years. The second group (n=62) included young people who suffer from BA (remission) aged 20-23 years.

The levels nitrate/nitrite, metabolites NO, and malondialdehyde (MDA) were determined at rest and under stress in both healthy and in people with BA. Stress state of subjects formed on the background of the educational process, as exam stress is one of the first places among the causes of mental stress in students.

The study found that people suffering from BA, there is increased production of NO in the lungs, which is reflected in increased levels of NO metabolites in EBC by 1.3 times compared with control. Patients with BA most sensitive to stress conditions in comparison with healthy young people, resulting in a higher level (1.3 times) in their production of NO metabolites during stress (5.8±0.03 mM in patients with BA during stress and 4.5±0.05 mM in healthy under stress, p <0.05). In patients with BA as an increase in basal level of MDA in a 1.6 times (p <0.05) in EBC in comparison with control. Under conditions of stress has been increased increase of lipid peroxidation, as evidenced by increased concentrations of MDA in EBC of 1.5 times in normal and 1.7 times in patients with BA. Thus, the most active enhancement of free radical processes in the lungs leads to the conclusion that patients with BA most sensitive to the stress associated with the educational process.

P3781 Regulation of VEGF receptors and co-factors by hypoxia and hyperoxia

Thomas Biyeh, Shaney Barratt, Caroline Jarrett, Gavin Welsh, Ann Millar. Lung Research Group, University of Bristol, United Kingdom

VEGF exerts its biological effect through specific receptors, VEGFR-1 and VEGFR-2 and co-receptors, neuropilin-1 and neuropilin-2, leading to a complex regulatory system. The presence of hypoxia in lung disease and its treatment by high flow oxygen have been proposed to contribute to lung injury. We hypothesised that hypoxia and hyperoxia may lead to changes receptor and co-receptor expression and hence regulation of VEGF bioactivity.

A549 (ATCC) as a model for lung epithelial cells and Human pulmonary microvascular endothelial cells (HMVEC-li) were obtained and cultured in 24 hours in a PROXO chamber in normoxic (N), hyperoxic 90% O2 (H), hypoxic conditions were represented by culture in the presence of Cobalt chloride (CoCl2). The cells were then lysed for protein or RNA extraction. Expression of VEGFR1, 2 and NRP-1, NRP-2 was established at both mRNA and protein level by q-PCR, immunofluorescence and Western blotting.

These findings evidence the beneficial role of NO and VIP pathways in preventing the lung inflammatory response to hypoxia and indicating their protective potentials against the subsequent development of airway hyperresponsiveness.

Grant support: OTKA K81179. The first author is a laureate of the long-term ERS fellowship.

P3784 Protective effects of erythropoietin and N-acetyl cysteine on methotrexate-induced lung injury in rats

Hasan Kahraman1, Mahmut Tokur2, Ergul Kurutas3, Selim Bozkurt4, Vedat Bakan5, Harun Cirakli6, Nurhan Koksal1

Objective: To evaluate the effects of P3784(Erythropoietin) on the expression of plasmaglobulin activator inhibitor (PAI-1) in lipopolysaccharide(LPS) induced acute lung injury(ALI).

Methods and results: ALI was induced in P3784(-/-) and C57BL/6J mice 4hrs or 24hrs after intratracheal instillation of LPS(5mg/kg), characterized by inflammation in morphology, higher wet/dry ratio, elevated protein concentration and increased neutrophils in bronchial alveolar lavage fluid(BALF), which were more significantly in P3784(-/-) mice. After LPS administration, PAI-1 mRNA expressions were markedly increased in a time-dependent manner and the PAI-1 concentration in BALF were markedly increased by 4hrs and decreased nearly to baseline at 24hrs in P3784(-/-) mice compared to C57BL/6J mice. Autoaphagy was significantly enhanced with higher expression of LC3B in P3784(-/-) mice compared to C57BL/6J mice. Primary cultured macrophages were stimulated by LPS (100ng/ml) for 4hrs. The level of reactive oxygen species(ROS) in macrophages from P3784(-/-) mice was significantly higher than that from C57BL/6J mice. The release of PAI-1 was significantly increased in macrophages from P3784(-/-) mice compared to wildtype mice after LPS instillation. PAI-1 release was partially suppressed by extracellular signal-regulated kinase(ERK) and p38 mitogen-activated protein kinase inhibitor(MAPK) but not by c-Jun N-terminal kinase inhibitors.

Conclusions: In LPS-induced ALI, P3784(-/-) mice increased PAI-1 expressions of partially dependent on enhanced autophagy in lungs and p38 MAPK and ERK in macrophages. Thus, P3784 predicts against fibronolytic activity under inflammation by regulating autophagy.

P3783 Prevention of hyperoxia-induced lung injury: Counterbalancing the deleterious effects of endothelin-1 in rat lungs

Deagie Crescek1, Yves Donat1, Xavier Belin1, Jean-Claude Pache1, Ferenc Petek2, Waldit Habre3, 1Department of Anaesthesiology, Pharmacology and Intensive Care, University of Geneva, Switzerland; 2Department of Pediatrics, Medical School, University of Geneva, Switzerland; 3Department of Clinical Pathology, University of Geneva, Switzerland; 4Department of Medical Physics and Informatics, University of Szeged, Hungary; 5Pediatric Anesthesia Unit, Geneva Children’s Hospital, University Hospitals, Geneva, Switzerland

Rationale: Endothelin (ET-1) plays a major role in the hyperoxia-induced pulmonary hypertension leading to lung damage. We determined the role of the ratio of oxygen NO/ET-1 pathway in the lung function decline changes following hyperoxia exposure in rats.

Methods: Airway resistance (Raw);respiratory tissue damping (G) and elastance (H) were obtained by forced oscillations at baseline conditions and following incremental doses of iv methacholine (MCH) in 4 groups of 28-day-old rats. Animals were exposed for 3 days to: room air (Group C, n=6), hyperoxia (> 95% O2, Group HC, n=5); hyperoxia with concomitant administration of vasoactive intestinal peptide (VIP 150 μg/kg/day iv, Group HV, n=4) or oral sildenafil citrate (20 mg/day, Group HS, n=4).

Results: Hyperoxia led to significant increases in G (38.66%, 62.63%, 38.41% in groups HC, HV, HS respectively, p<0.05) and in H (59.91%, 67.3%, 70.85%, p<0.05) in all groups, while Raw did not change. Airway hyperresponsiveness to MCh was observed in rats of Group HC, which was prevented by treatments with VIP or sildenafil.

Conclusions: These findings evidence the beneficial role of NO and VIP pathways in preventing the lung inflammatory response to hyperoxia and indicating their protective potentials against the subsequent development of airway hyperresponsiveness.

TUESDAY, SEPTEMBER 4TH 2012
(MTX), EPO group was administered, SC of 5 mg/kg MTX and 2000 IU/kg EPO, and NAC group was given 5 mg/kg MTX and 200 mg/kg NAC once daily for 4 consecutive days. At the fifth day, the right lungs were extracted. Oxidative damage was evaluated by measuring the malondialdehyde (MDA) level and superoxide dismutase (SOD) and catalase (CAT) activities. Histological damage was evaluated by inflammation and congestion scores.

Results: In MTX group MDA levels were significantly higher, CAT and SOD activities were significantly lower than those in the Sham, EPO and NAC groups (P < 0.05). In EPO group MDA levels, CAT, and SOD activities were higher, but not significant higher than in group NAC. In group MTX both scores were significantly higher than in group sham (P < 0.05). The congestion score of group MTX was significantly higher than those in group EPO and NAC (P < 0.05). When the group EPO was compared to the group NAC, the difference was not significant (P > 0.05).

Conclusion: EPO and NAC have significant preventive effects on methotrexate-induced lung damage in rats.

396. Various issues in clinical physiology

P3785 Acute effects of volume-oriented incentive spirometry on chest wall kinematics in patients chronic stroke Ellis Linn, Gardêna Ferreira, Tânia Campos, Rodrigo Melo, Elis Emanuelle, Renato Targino, Figueiredo, Physiotherapy, Physical Therapy, Federal University of Rio Grande do Norte, Natal, RN, Brazil

To study the acute effects of incentive spirometry (IS) volume-oriented on chest wall kinematics in chronic stroke patients and healthy subjects. Volume of chest wall (CW), abdominal (ab), abdominal rib cage (RC) and pulmonary rib cage (RCp) compartment were assessed in 20 chronic stroke patients (experimental group,EG) age 56.9±7.3 years old, FVC%:81.5±10.9% and FEV1/FVC:80.5±9.7 and 20 age-matched healthy subjects (control group,CG), age 56.5±3.0 years old, FVC%:95.6±8.8% (p=0.0026) and FEV1/FVC:80.5±8.4 by bidimensional Plethysmography. Protocol comprise 3 moments: quite breathing (QB), volume-oriented IS (3 series/10 repetitions) and recovery quite breathing (rQB). The tidal volumes of chest wall in EG was lower compared to the CG, in QB (0.05±0.01L), IS (1.8±2.3 L) and rQB (0.4±0.5 L) (< p<0.001). The tidal volume increase in chest wall 75% in EG and 73.3% CG during IS. Different pattern of breathing were found in tidal volume in EG compared to CG on ab compartment: QB(54.1% vs 43.7%), IS(43.3% vs 40.9%) and rQB(48.9% vs 46.2%); RCp compartment, QB(30.7% vs 37.9%), IS(37.7% vs 39.9%) and rQB(32.9% vs 37.3%). Right and left hemithorax volume were different in EG, in QB (2.1±0.6 ml) and rQB (0.4±0.5 ml) independent of stroke side impairment. Increase in chest wall 75% in EG and 73.3% CG during IS. Different pattern of breathings were found in tidal volume in EG compared to CG on ab compartment: QB(54.1% vs 43.7%), IS(43.3% vs 40.9%) and rQB(48.9% vs 46.2%)

Method: Twenty one subjects aged from 18 to 30 years were examined. After being examined at the low altitude (Bishkek, 700 m above sea level) all subject were transported to 3200 m. At the HA patients were repeatedly examined in the 7th, 14th and 21st days of the surgery. Group Bishkek HA-7 HA-14 HA-21 Descent Normoresponders 43,7±1,7 40,4±1,1 41,0±1,6 41,6±1,9 46,5±1,7 Hyperresponders 45,8±2,1 38,6±1,5 42,4±2,5 44,1±2,8 48,4±3,0

Conclusion: At Bishkek the 1st group had the higher max VO2 value, but after the ascent at HA the max VO2 significantly decreased at that group (from 45.8 to 38.8 ml/kg/hr, p < 0.01), while the 2nd group demonstrated the nonsignificant max VO2 reduction. Later these differences disappeared. Obtained data can denote the presence of the interrelation between sPAP response to HA hypoxia and decrease of the physical capacity at HA. This supposition may be tested on a largersample of volunteers.

P3787 Slowly adapting stretch receptors upregulate mixed cough responses in the rabbit Chayra Abdou, Sissi On, Brune Demoulin, Odile Ruckebusch, Anne-Laure Leblanc, Noëlle Bertin, François Marchal, Silvia Varechova, EA 3450 Laboratoire de Physiologie, Faculté de Médecine, Vandoeuvre les Nancy, France

Rationale: Inhibition of slowly adapting stretch receptors (SIRS) inhibits the cough reflex (CR), but it is not clear whether SIRS stimulation facilitates CR and/or expiration reflex (ER). The issue is relevant to the long term understanding of chronic cough because those mechanisms that regulate cough are poorly understood.

The aim of the study was to determine whether SIRS stimulation by continuous positive airway pressure (CPAP) alters CR and/or ER in the rabbit.

Method: 5 rabbits were anesthetized and tracheostomized. The trachea was exposed to punctuate mechanical stimuli at control and with 4.5 cmH2O CPAP. 24 stimulations were aimed in each condition in each animal. CR and ER were identified from airflow and volume signals, diaphragmatic and abdominal muscle electrical activity. The reflexes were defined as a forced expiratory effort preceded (CR) or not (ER) by an augmented inspiration. Mixed responses were differentiated from the pattern of the first breath as ER/CR.

Results: 241 stimulations, evenly distributed in inspiration and expiration, were obtained at control (n = 121) and on CPAP (n = 120). The overall incidence of positive responses significantly increased from 66% at control to 85% on CPAP (p = 0.0005). Incidence of ER, CR or ER/CR was not significantly altered. In control, the mixed ER/CR response significantly increased from 14% at control to 38% on CPAP (p = 0.0005).

Conclusions: SIRS stimulation up regulates airway defensive reflexes, namely ER/CR. Thus SIRS appear to sensitize preferentially those ER-facilitated coughs. It is speculated that a proper identification of airway defensive responses in patients may be relevant to a better understanding of chronic cough.

P3788 The effects of inspiratory muscle fatigue on swallowing physiology in healthy young adults: Preliminary results Joanna Malizia, Carol E. Garber, Georgia Malandraki, John H. Saxman, Biobehavioral Sciences, TC, Columbia University, New York, NY, United States

Introduction: Fatigue of the respiratory muscles has been associated with swallowing disorders in many respiratory and neurological diseases, however, the mechanism with which fatigue affects the swallowing function remains unclear.

Aims: The aim of the present pilot study was to examine the effects of respiratory muscle fatigue on swallowing physiology in healthy adults.

Methods: Participants included 10 healthy young adults randomly assigned in two groups: an expiratory and an inspiratory muscle group. Respiratory and electrophysiological measurements were obtained during the following tasks: three abdominal water swallows, b100nl continuous water swallows and cold swallow test (cracker), at three time points: at baseline, immediately post exercise-induced fatigue, and finally, after a 15-min rest period. A loaded breathing device was used to induce fatigue. Surface electromyography was employed to capture muscle activity of the submental and the infrahyoid muscles during swallowing.

Results: Electromyographical findings showed that, for the submental muscle, the integral was found to be significantly higher during the immediate post-fatigue condition compared to both the baseline and post-rest conditions (p < 0.05) in all tasks for both the inspiratory and expiratory groups.

Conclusion: These preliminary results suggest that fatigue of the expiratory muscles has an effect on selective electrophysiological measures of swallowing. The greater impact of the submental muscles during swallowing compared to the infrahyoids could be a compensatory strategy, given the fatigue of the lower respiratory muscles.

P3789 Orthodeoxia in hypoxaemic morbid obesity reverts one year after bariatric surgery Eva Rivero1, Ebyham Arismendi2, Ana Tejedor1, Yolanda Terriola,1, Concepcion Gustillo,2, Felip Burgos1,2, Salvador Delgado1,2, Jaime Balsa1,1, Robert Rodriguez-Roizm1,2, Anaesthesiology, Hospital Clinic, Barcelona, Spain;2 Respiratory Diagnostic Center, Hospital Clinic, Barcelona, Spain;1Gastrointestinal Surgery, Hospital Clinic, Barcelona, Spain

Introduction: In morbid obesity (MO), pulmonary gas exchange (GE) abnormalities are influenced by postural changes that are known to improve after bariatric surgery (BS).

Objective: To unravel the determinants of GE in MO at upright (U) and supine...
P3790

Time-dependence of lung recovery after a 4-week exposure to traffic and sugar cane burning air pollutants
Walter Zin1, Flavíaazzolino-Rocha1, Vinicius Oliveira1, Dayse Moreira1, Barbara Barcellos1, Manuela Lanzetti2, Samuel Valença3, Paulo Saldivia3, Debora Vilela1,3, Chagno Filho Pathologies, Federal University of Rio de Janeiro, RJ, Brazil; 2Department of Histology and Embryology, Rio de Janeiro State University, Rio de Janeiro, RJ, Brazil; 3Institute of Biomedical Sciences, Federal University of Rio de Janeiro, RJ, Brazil; 4Department of Pathology, University of Sao Paulo, SP, Brazil

Exposure to particulate matter from urban air pollution (UP) or biomass burning (BP) has been associated with lung impairment. We investigated the time-dependency of lung functional recovery in BALB/c mice exposed to UP or BP particles. During 4 weeks they received 3 nose-only instillations of 15 μL of distilled water (C) or UP or BP (15 μg/μL of saline). Mice were weighed weekly. 1 (C1, UP1, BP1), 2 (C2, UP2, BP2), 7 (C7, UP7, BP7) or 14 (C14, UP14, BP14) days after the last instillation, pulmonary mechanics, FRC and histology were measured; catalase and superoxide dismutase activities were evaluated in lung homogenates. Body mass gain was similar among the groups. Pulmonary elastance and its viscoelastic component (cmH2O/mL), resistive and viscoelastic pressures (cmH2O) were higher in UP1 (31 ± 1.6, 14 ± 0.8, 1.5 ± 0.1), respectively) and BP1 (30 ± 0.4, 16 ± 0.8, 1.4 ± 0.1) than in C1 (23 ± 4.3 ± 0.1, 0.6 ± 0.4, 0.8 ± 0.1, respectively). These parameters returned to control values at day 2, except for resistive pressure that normalized at 7 days. Alveolar colage (S) was larger in UP1 (21 ± 8.5) and BP1 (23.2 ± 1.9) than in C1 (17 ± 3.0) and returned to baseline at 7 days, while bronchocostriction index and alveolar and bronchial lesion scores increased in UP1 (2.3 ± 0.3, 3 ± 0.3) and 3.2 ± 0.4, respectively) and BP1 (2.3 ± 0.3, 2.8 ± 0.3 and 2.3 ± 0.4, respectively) in relation to C1 (1.5 ± 0.2, 1.0 ± 0.3 and 0.8 ± 0.4, respectively) and normalized in 2 days. No differences were found in FRC and oxidative stress. Thus, a 4-week exposure to UP and BP induced lung impairment that resolved 7 days after the last exposure. Supported by FAPERJ, CNPq, MCT.

P3791

Exposure to hypercapnia and muscle function
M. Sansarizkaya1,2,3, S. Pascual1,2, F. Sánchez-Corredera4,5, M. Domínguez Álvarez1,6, C. Casadevall1,7, E. Bascur1,7, S. Grau1,7,2,3 Respiratory Department (ERS Short-fellowship grant), Siberian State Medical University, Tomsk, Russian Federation; 2Servei Pneumologia, CEXS, Hospital del Mar – IMM. UPF. CIBERES (ISCiii), Barcelona, Catalonia, Spain

Hypercapnia has been proposed as one of the systemic factors participating in muscle dysfunction occurring in COPOD. Aim: To assess the effects of acute and chronic exposure to hypercapnia on peripheral and respiratory muscle function.

Methods: Two subgroups of 8 Wistar rats each were submitted to either a hypercapnic gas mixture (FICO2 0.5) or room air, 2 h for 15 days. Maximal inspiratory pressure (MIP), lower limb dymanometry (LDD), breathing pattern, work of breathing, Po1 and arterial blood gases were determined at the beginning and at the end of each exposure.

Results: Acute exposure to hypercapnia (1st single bout) did not involve changes in muscle function. However, chronic exposure to hypercapnic bouts resulted in a lower weight gain, and a decrease in both MIP (% ref) and LDD (% ref) in hypercapnic animals when compared with control (C) group. Interestingly, acute exposure to hypercapnia in the last (15th) day also involved a decrease in both MIP and LLD. Acute hypercapnia resulted in increases in respiratory rate (RR) but minute ventilation (VE) and P0.1 remained constant. Chronic exposure to hypercapnic bouts did not change breathing pattern nor ventilatory drive.

Conclusions: Although a single acute exposure to hypercapnia did not induce changes in muscle function, repeated exposures resulted in both a loss in muscle strength and an increase in susceptibility to a further impairment with new hypercapnic bouts. The similar behavior of respiratory and limb muscle strength, both normalized by rat anthropometry, indicates that the loss of force is the result of hypercapnicia and not a consequence of either the increase in ventilatory work or the decrease in weight gain. Supported by ERS short fellowship, SEPAR and J.Grau Grants.

P3792

Disturbance of airway patency is accompanied by a decrease of exhaled breath temperature in asthmatics
Julia M. Perelman1,2, Antonio G. Prete1,3,4, Nelson J. Acosta5, Nelly M. Smirnova. Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation

Introduction: Allergy in asthmatics is accompanied with the increase of exhaled breath temperature. The correlation of this parameter with airway patency is known to be about.

Aim: To study the correlation between bronchi patency and exhaled breath temperature in patients with bronchial asthma.

Methods: The exhaled breath temperature (T*°C) during quiet breathing using a device “X-halo” (Delmedica Investments Pte Ltd), lung function (FEV1, FVE1,FVC) and the level of hydrogen peroxide (H2O2) in exhaled breath condensate (EBC) were studied in 82 patients with bronchial asthma (the mean age 35.0±1.1 years).

Results: The patients were divided into two groups according to the presence of airway patency impairment or its absence (FEV1, 80.8±2.69 and 108.3±2.09%; p<0.001, FEV1/FVC 68.3±1.37 and 77.8±1.23%; p<0.001, respectively). In the group of patients with airway patency impairment there were a significant decrease of exhaled breath temperature (34.0±0.14°C) and the increase of H2O2 level (1.18±0.08mmole/ml) in EBC in comparison with the group of patients with out lung function changes (34.5±0.14°C; p<0.05; 0.89±0.08 mmole/ml; p<0.05, respectively). There was found the correlation between the exhaled breath temperature and FEV1 (r=0.02; p<0.05) and the bronchodilation response to β2-agonist SABR FEV1 (r=0.41; p<0.01), as well as between the level of H2O2 in EBC and FEV1 (r=0.64; p<0.01).

Conclusion: The decrease of exhaled breath temperature in asthmatics is associated with the disturbance of bronchi patency and reversibility of bronchial obstruction.

P3793

Central alterations during prolonged exercise in normoxia and hypoxia
Samuel Verges1, Marc Jubeau2,3, Thomas Rupp1, Stéphane Perrey1, Bernard Wanty1, Patrick Levy1, Guillaume Miller1,2, 3HP2 Laboratory, INSERM, Joseph Fourier University, Grenoble, France; 2LPE Laboratory, Lyon University, Saint-Etienne, France; 3M2H Laboratory, Montpellier University, Montpellier, France; 4MIP Laboratory, Nantes University, Nantes, France

Introduction: Prolonged cycling exercise in normoxia (N) induces fatigue due to both peripheral and central alterations. Interestingly, it has been reported that cerebral perturbations are greater during short-duration isolated exercise in hypoxia (H) compared to N. The purpose of this study was to test the hypothesis that central alterations are accentuated in H compared to N during prolonged whole-body exercise.

Methods: Ten subjects performed two sessions consisting of 3 80-min cycling bouts at 45% of their relative maximal aerobic power in N and H (FIO2 < 12%). Before exercise and after each bout, transcranial magnetic stimulation was used to assess cortico spinal excitability (motor evoked potential; MEP) and intracortical inhibition (cortical silent period; CSP) of knee extensors. Femoral nerve electrical stimulation was used to measure muscle characteristics. Voluntary activation was added for all but two of the three conditions.

Results: A significant but similar torque reduction was observed at the end of the exercise in N and H. With the exception of CSP, a significant time effect was observed for all parameters. CSP was longer and the reduction of twitch peak torque was lower in H than in N. No other significant differences were observed between N and H.

Discussion: Fatigue level was found to be similar between N and H when exercise is performed at the same relative intensity. Even if the brain is importantly affected by hypoxia2 as shown by the greater intracortical inhibition, this does not appear to further affect central motor drive.

P3794

Regional lung ventilation distribution among individuals with chronic heart failure after an inspiratory muscle training program: A randomized controlled trial

Objectives: To evaluate regional lung ventilation distribution in patients suffering (S) while breathing ambient air, in random order, before and one year after BS.

Methods: 15 (14 females; 51±SE72 yrs; BMI, 47±2 kg/m2) hypoxemic -H (PaO2, 73±5 mmHg) and normoxic N- (PaO2, 80±4 mmHg), matched for age, sex and BMI were studied before and after BS. GE measurements, including ventilation-perfusion (V/AQ) distributions were performed.

Results: Before BS, H patients at U exhibited moderate V/AQ imbalance (low V/AQ of distal areas compared to S). In addition, PaO2 at U was improved by (±9.15±0.2 mmHg), (p<0.03, each). Moreover, H patients at U improved PaO2 by (±6.7±0.6 mmHg) compared to S and V/AQ imbalance postural differences between Pre and Post BS also improved (p<0.02).

Conclusions: Hypoxemic morbid obesity is associated with orthoadoxia. This novel finding may be related to a gravitational heterogeneous redistribution of pulmonary blood flow and a chronic systemic inflammatory. Sarcopenia ingenion reverts completely this phenomenon.

Supported by FIS (PI00831108), Esteve and CIBERES.

P3795 Does SpO2 correlate with SaO2 in stable COPD patients? 
Eidgeep Kumar Yadavilli1, Vinay Shankar Sreerag Lakshman, Paul Stockton, Simon Twste, Sanjeev Araval. Respiratory Medicine, St. Helen's and Knowsley Teaching Hospitals NHS Trust, Prescot, Merseyside, United Kingdom

Background: Pulse oximetry is commonly used to measure oxygen saturations (SpO2) in assessment of patients with stable COPD. This is considered to be equivalent to oxygen saturations measured on a blood gas analyser (SaO2). The ATS, ERS and GOLD guidelines for COPD define suitability for long term oxygen therapy with PaO2 less than 7.3kPa or SaO2 of less than 88%.

Aim: To establish if SpO2 correlates to SaO2 in stable COPD patients.

Methods: Retrospective study of patients with stable COPD attending oxygen clinics in an acute teaching hospital.

Results: N=73, Male 29%, Mean Age70 (range 53 - 93), Mean FEV1 0.89 L, current smokers 29%, 26% on oxygen, mean MRC grade 4, mean BORG score at rest 2 and mean h��cotat (HCT) 0.41. On’t paired testing in all patients, no statistically significant difference was noted between SpO2 and SaO2 (p value: 0.972), the mean SpO2-SaO2 is -0.012% (95% CI of -0.71 to 0.69).

However, in current smokers subgroup (N=21) high variation between these values was noted, with the mean SpO2-SaO2 1.067%. There was a tendency for SpO2 to be lower than SaO2 (95% CI of -1.03 to 3.17).

Conclusions: As the difference between SpO2 and SaO2 is high in current smokers, SpO2 reading using pulse oximetry might not be reliable. Further studies with larger sample size are needed to evaluate this further.

P3796 Breathing patterns in mountaineers climbing to extreme altitude (7546m)
Tsoval D. Latshang1, Ainara Garde2, Alexander J. Turk1, Thomas Hess3, Jane Tuke1, Caroline L. Baker1, E. Bloch1.
1Sleep Disorders Center and Pulmonary Division, University Hospital, Zurich, Switzerland; 2Institute of Biodynamics of Catalunya and CIBER de Bioengineering, Biomaterials and Nanomedicine, Universitat Politècnica de Catalunya, Barcelona, Spain; 3Pulmonary Division, Dept. of Internal Medicine, Cantonal Hospital, Winterthur, Switzerland; 4Department of Ophthalmology, University Hospital, Zurich, Switzerland; 5Institute of Laboratory Medicine, Cantonal Hospital, Aarau, Switzerland; 6Medical Intensive Care Unit, Dept. of Internal Medicine, University Hospital, Zurich, Switzerland; 7Department of Surgery, Cantonal Hospital, Aarau, Switzerland; 8Department of Intensive Care Medicine, University Hospital, Berne, Switzerland; 9Sleep Disorder Center and Pulmonary Division, Cantonal Hospital, St. Gallen, Switzerland

Background: We investigated breathing patterns and oxygenation in mountaineers climbing to extreme altitude (7546m) and correlate it with functional capacity and quality of life. The present study also analyzed the changes in arterial and predicted MIP, higher MLFHzq score and greater distance walked in the 6MWT, as well as a reduction in the BORG scale after the 6 MWT in relation to the control. For the OEP, IMT group members exhibited higher values for total chest wall volume (Vcw), abdominal rib cage volume (Vrc,a) and abdominal volume (Vab) when compared to the control.

Conclusions: For patients with COPD, IMT proved efficient in improving muscle strength, functional capacity and quality of life. The present study also analyzed the changes in arterial and predicted MIP, higher MLFHzq score and greater distance walked in the 6MWT, as well as a reduction in the BORG scale after the 6 MWT in relation to the control. For the OEP, IMT group members exhibited higher values for total chest wall volume (Vcw), abdominal rib cage volume (Vrc,a) and abdominal volume (Vab) when compared to the control.

TUESDAY, SEPTEMBER 4TH 2012
thus causing the water level in the smaller section to alternately rise and fall, simulating diaphragmatic movement. FRC, tidal volume (Vt) and respiratory rate (RR) were adjusted by altering the volume of water within the phantom lung and the ventilator settings. We performed MBW on the phantoms lung at a variety of values of FRC, Vt and RR. Each experiment was performed in triplicate. Measured FRC was then compared to the true FRC in each case.

**Results:** Measured FRC was within 5% of true FRC in all but one experiment. The intraoperator correlation coefficient for the triplicate measurements was 0.999, suggesting that the MBW technique is highly repeatable.

**Conclusion:** We conclude that MBW performed using an Innocor gas analyser is highly repeatable and accurate. Simple one-compartment lung phantoms appear to be a promising method for the validation of MBW systems.

**Methods:** This cross-sectional study was conducted in 2011 at the University Hospital of Basel, Switzerland. Patients with COPD stages I to IV were investigated. Functional exercise capacity was measured by the six-minute walk test according to the guidelines of the American Thoracic Society. Spirometry was performed according to current guidelines. Health status was assessed by the CAT. A forced entry multiple regression analysis was calculated. The regression included 6MWD, forced expiratory volume in one second in % of predicted (FEV1%,predicted) and Body-Mass-Index (BMI). The dependent variable was the CAT-score.

**Results:** Complete data were available for 73 individuals (age 67 ± 9.8 years, 58.9% males). FEV1%predicted 69.7 ± 22.7%, 6MWD 434.7 ± 99.1 m, CAT-score 12.5 ± 6.8, BMI 25.7 ± 5.5. Age and 6MWD significantly contributed to the model (β = -0.49 respectively p = 0.46, p < 0.01). BMI and FEV1%predicted did not significantly influence the CAT-score (β = 0.14 respectively p = 0.8).

**Conclusion:** The association of the 6MWD and the CAT-score indicates that higher physical fitness level is related to improved health status and thus decreased impact of COPD on an individual's life.

**P3801**

**Respiratory disability and reproducibility of arterial stiffness by pulse wave velocity (PWV) in stable COPD patients**

Isabelle Vividou 1,2, Clémence Minet 1,2, Renaud Tamisier 2, François Arthub 1, Jean-Christian Borel 1,2, Jean-Philippe Baguet 3, Patrick Lévy 1,2, Jean-Louis Pépin 1,2, 1INSERM U 542, HPP Laboratory (Hypoxia: Pathophysiology), Joseph Fourier University, Grenoble, France; 2Lcomotion Rehabilitation and Physiology Department, Grenoble University Hospital, Grenoble, France; 3Department of Cardiology, Grenoble University Hospital, Grenoble, France

**Background:** Pulse wave velocity, a validated method for assessment of arterial stiffness, is widely used in studies evaluating cardiovascular risk and/or efficacy of new bronchodilators for improving arterial stiffness in COPD patients. However, PWV reproducibility studies are lacking in this population.

**Methods:** 38 stable COPD patients (79% men, 63 ± 10 years, FEV1 = 53 ± 17% of predicted values) were included. Using the Complior™ device, the carotido-femoral PWV was measured at baseline (d0), after 2 weeks (d15) and 6 weeks (d42). Pearson coefficient and Spearman coefficients and Kendall's Coefficient of Correlation (ICC) allowed comparing PWV at d0 vs. d15 (short-term reproducibility) and d42 (middle-term reproducibility). The relationship between PWV and inflammatory status (CRP, TNF and ILE) were also investigated.

**Results:** Mean PWV values were 11.10 ± 9.11, 11.05 ± 12.17 and 11.24 ± 2.52 m/s at d0, d15 and d42, respectively. For short-term reproducibility (d0 vs. d15), Spearman coefficient was r = 0.78, p = 0.001 and ICC = 0.790 (range 0.632-0.885). For middle-term reproducibility (d0 vs. d42), Pearson coefficient of correlation was r = 0.76, p = 0.001 and ICC = 0.749 (range 0.567 - 0.861). There was no significant link between PWV and inflammatory markers neither for baseline values nor for between-sessions differences, suggesting that minor changes in inflammatory status did not influence the reproducibility of PWV.

**Conclusion:** Using the Complior™ method, PWV measurements had good reproducibility in stable COPD patients. Such assessment of arterial stiffness can be properly used as objective outcome for randomized trials.

**P3802**

Early oxygen desaturation is related to acute mountain sickness (AMS) development during acute high altitude (HA) exposure

Guia Mandolesi 1, Luca Pomadori 1, Giovanni Avançini 1, Eva Bernardi 1, Manuela Bartesaghi 2, Annalisa Cogo 1, 1Biomedical Sports Studies Center, University of Ferrara, Italy; 2Department of Experimental Medicine, University of Milano Bosco, Milano, Italy

Early oxygen desaturation during HA exposure (both in the field and during HA simulated test) has been reported to be significantly related to AMS development. Aim: Monitor oxygen saturation (SpO2) and AMS during the ascent from Alagna (1200m) to Capanna Regina Margherita (4559m) with an overnight stay in Gnifetti Hut (3647m).

**Methods:** 66 subjects (55M, 18-67 yrs), intending to climb M. Rosa, were recruited at the cable care station in Alagna, equipped with a 24-h data memory pulse oximeter (Pulsion-35s, Minolta) and asked to fill the Lake Louise questionnaire for AMS diagnosis. 25 subjects (37.8%) showed a LL score ≥ 3 (AMS+ group), 41 were in AMS-group.

**Results:** SpO2% in AMS+ and AMS- was similar in Alagna (94.6 ± 1.9 vs 95.1 ± 2.2) but was lower in AMS+ during HA exposure: at 3257m, after 30-40 min. of cable ascents 95.5 ± 1.3 vs 97.7 ± 3.5, *p* < 0.001, and in Gnifetti Hut at rest (94.6 ± 1.2 vs 98.6 ± 2.4, *p* < 0.001) and during the night (76.9 ± 4.6 vs 79.3 ± 5.7, *p* < 0.001). AMS+ spent more time with lower SpO2%: time (%) at rest in Gnifetti Hut with SpO2% < 80 (15.8 ± 13.8 vs 7.2 ± 7.7, **), and during the night with SpO2 80-95%, and < 70 (33.2 ± 32.9 vs 15 ± 18.5, **; 11.8 ± 19.3 vs 2.7 ± 6.2, *. *). Only 34 subjects (26m) climbed to Capanna Regina Margherita (14AMS+); AMS+ maintained SpO2% < (73.4 ± 5.1 vs 76.8 ± 8.3, *. * and > time (hours) spent with SpO2% < 80 and > 75 (3.5 ± 1.2 vs 2.7 ± 0.9, *; 2.5 ± 1.4 vs 1 ± 0.8, *; ) *p < 0.05, ** *p < 0.01.

**Conclusions:** Lower SpO2% in AMS+ occurs very early at the beginning of HA exposure after 30-40 min. of ascent. Subjects which subsequently develop AMS always spend more time with SpO2% significantly lower than healthy subjects (AMS-).
The estimation of respiratory muscles (RM) status by echodensitometry in men with chronic obstructive pulmonary disease (COPD)

Alexandre Lemieschewski1, Mikhail Nedzved1,2, Alexander Pochtcheev1,2, Alexander Makarevich1, Sviatlana Limusheuskaya1,2, General Surgery, Belarusian State Medical University, Minsk, Belarus; 2Human Pathology, Belarusian State Medical University, Minsk, Belarus. 1Department of Internal Medicine No. 1, Belarusian State Medical University, Minsk, Belarus

Aim: Investigate the RM status.

Material and methods: We obtained the indices: homogeneity (H), structural density (SD), echogenicity (E) and dispersion (D) of the internal oblique abdominal muscle (intOAM) by ultrasonic scanner. We carried out histological research of intOAM. Research was made in 20 COPD pts: 1st group (10 – 1st stage); 2nd group (10 – 2nd stage). Control - 12 healthy subjects.

Results: There have been areas of myolysis, cell proliferation of periurium, “megroth” of fatty tissue between myobrills (MF). There is interstitial sclerosis, sections “contractions” of MF. Among the relatively preserved MF was found deep dystrophic one with protein granules of different sizes in the appearance of the sarcoplasm. The H in pts of the 1st and 2nd groups was 20.8 and 19.3 respectively (p < 0.05). The E also was different in pts of the 1st and 2nd groups (3.7 and 4.8). The D was increased in the 2nd group 18.6 vs. the 1st group 17.5. The SD had the tendency to decrease. Increasing of COPD severity was associated with significant enhancing of “contractions” (p=0.72), destruction of MF (p=0.69) and proliferation of fibroblasts (r=0.52). We detected the presence of negative correlations between H, SD and sclerosis (r=0.39 and r=0.51 respectively). Meanwhile the E was higher in these pts and correlated directly (r=0.48; p<0.05). The D was increased in the presence of fragmentation of MF (p=0.52). The E correlated in the 2nd group with fat mass (r=0.62). This may indicate the accumulation of intramuscular fat in the second stage.

Conclusion: The proposed echodensitometric parameters reflect the degenerative processes occurring in the RM.

Positive effect of CPAP therapy in OSA patients on A-FABP, CRP and triacylglycerol levels and diastolic blood pressure

Mila Davydenko, David Stekal, Vitezslav Kolek, Jana Zapletalova, Milan Sova. Department of Respiratory Medicine, Faculty of Medicine and Dentistry, Palacky University Olomouc, Czech Republic

Aim: The influence of CPAP therapy on A-FABP, CRP and triacylglycerol (TAG) levels and diastolic blood pressure (DBP)

Subjects and methods: Eighty-one patients (70 males, a mean age of 53.9 ± 24.8 years) diagnosed with OSA and indicated for CPAP treatment. Anthropometric, DBP and blood serum levels of A-FABP, CRP and TAG were measured before and after 3 months of CPAP treatment

Results: There were significant differences in A-FABP, CRP, TAG levels and DBP between the 1st and 2nd groups. A-FABP levels reached a mean value of 39.7 ± 27.7 (p<0.001) in the 1st group and 21.7 ± 14.2 ng/mL (p<0.001) in the 2nd group. CRP levels were 5.3 ± 9.2 (p<0.05) in the 1st group and 2.1 ± 1.3 ng/mL (p<0.05) in the 2nd group. TAG levels were 1.7 ± 0.8 (p<0.001) in the 1st group and 1.5 ± 0.7 mmol/L (p<0.001) in the 2nd group. DBP was 77.3 ± 5.3 mmHg (p<0.001) in the 1st group and 70.7 ± 4.3 mmHg (p<0.001) in the 2nd group.

Conclusion: A-FABP, CRP and TAG levels significantly decreased after CPAP therapy. DBP decreased significantly after CPAP therapy.

P3805
Evaluation of renal function in a cohort of patients affected by obstructive sleep apnea

Paolo Pozzi1, Sara Marelli1, Giovanni Tripepi2, Carmine Zoccali1, Luigi Ferini Strambi1, 2Sleep Medicine Center, San Raffaele Turro Scientific Institute, Milan, Italy; 1Clinical Epidemiology of Renal Diseases and Hypertension, CNR-BIBM, Reggio Calabria, Italy

Introduction: Obstructive sleep apnea (OSA) has been linked to chronic kidney disease (CKD). We investigated the renal function (GFR) of a cohort of non-CKD patients admitted to our Sleep Medicine Unit for suspected OSA.

Materials and methods: 374 subjects underwent a cardiorespiratory polysomnography (PSG) and a blood collection for GFR. Oronasal airflow, respiratory efforts and oxyhaemoglobin saturation were recorded. PSG was scored according to AASM rules. GFR was calculated trough the MDRD equation. Descriptive statistics, analysis of variance (ANOVA), linear regressions were performed. A p value < 0.05 was considered significant.

Results: Patients were 53 ± 12 years old, with a mean BMI > 30. Estimated GFR was 95.1 ± 19 mL/min/1.73 m². The population was suffering from severe OSA (AHI=45.8 ± 19.7; min spO2=72 ± 10.9%; T90 <90% 24 ± 26.6%). No differences were seen in baseline GFR according to AHI and ODI. A significant difference in GFR according to T90% (p=0.005) and min spO2 (p=0.017) was observed. These results were attributable to higher levels of GFR in more hypoxemics. GFR showed no correlation with AHI, ODI or T90%, but it was related to min spO2. These results were confirmed in univariate linear regressions, but not in multivariate regression analyses. However, when mild to moderate OSA cases were excluded, spO2 turned out to be the first independent predictor of GFR.

Conclusion: In severe OSA cases, GFR seems to be inversely related to the severity of oxygen desaturation, but not to the common OSA’s indexes. These findings may be due to nephropulmonary compensatory mechanisms against chronic hypoxia that need to be studied in a longitudinal way.

P3806
Treatment of central sleep apnea in patients with heart failure: A retrospective observational study

Gergi de Vries1,2, Petra Meijer1, Tristanne Bilijham1, Huib Kerstjens1,2, Peter Wijkstra1,2, 1Department of Pulmonary Medicine, University of Groningen, University Medical Center Groningen, Netherlands; 2GRIAC Research institute, University of Groningen, University Medical Center Groningen, Netherlands

Introduction: In patients with heart failure (HF) and central sleep apnea syndrome (CSAS) different therapeutic options, such as continuous positive airway pressure (CPAP), bi-level PAP (BiPAP) and adaptive servoventilation (ASV) are available. All are potentially effective in improving heart function and in reducing apnoe-hypopnea index (AHI), while ASV is generally considered to be most effective.

Aim: To assess how HF-patients with CSAS (AHI > 15) respond to the different treatments in terms of AHI.

Methods: CPAP was given first, and when ineffective or when patients still experienced SAS related complaints, followed by BiPAP and/or ASV. Efficacy was assessed by a sleep study under treatment. Treatment was considered effective when AHI reduced <15% or reduced at least 50% from the baseline AHI to a value <20/hour.

Results: 14 males (70 y) were assessed.

Figure 1. Overview of the efficacy of the treatments.

Conclusions: Although ASV seems to prove to be most effective in HF-patients with CSAS, CPAP and BiPAP together are still effective in 57% of the patients.
Obstructive sleep apnea in patients with typical atrial flutter: Clinical, prognostic and therapeutic implications

Niria Gara, Vicent Bazan, Ermengou Valles, Miguel Feliu, Carles Sanjuán, Miguel Caínzos, Regola Benito, Joaquim Gea, Jordi Bruguera, Julio Martí, Núria Grau, Department of Cardiology, Hospital del Mar. Parc de Salut Mar, Barcelona, Spain.

Background: The clinical yield of successful cavo-tricuspid isthmus (CTI) radiofrequency ablation for the treatment of atrial flutter (AF) is limited by a high incidence of atrial fibrillation (AFib) in the long term. The association of obstructive sleep apnea (OSA) could favor an incomplete arrhythmia control in this setting. We assessed the impact of continuous positive airway pressure (CPAP) therapy in reducing the occurrence of AFib after CTI ablation.

Methods: A cohort of consecutive patients undergoing successful CTI ablation for typical AF was screened for OSA and followed-up during 12 months. Upon diagnosis of severe OSA, CPAP therapy was initiated. Relationship of the following variables with the occurrence of AFib during follow-up was investigated: CPAP therapy initiation, hypertension, body mass index, underlying structural heart disease, left atrial diameter and previous AFib documentation prior to CTI ablation.

Results: We included 56 patients (age 66±11 years, 12 female), 27 of whom (48%) were diagnosed from severe OSA. Twenty-one patients (38%) had AFib during follow-up. Freedom from AFib prior to ablation was associated with a lower incidence of AFib after this procedure (from 67% to 34% of cases; p=0.019). Additionally, CPAP therapy initiation in those patients never being diagnosed from AFib resulted in a reduction of AFib episodes during follow-up (from 46% to 6% of cases; p=0.025).

Conclusions: Severe OSA is a prevalent condition in patients with typical AF, and its treatment by means of CPAP therapy results in a lower incidence of new-onset AFib after CTI ablation.

Obstructive sleep apnea syndrome (OSAS) is a frequent disease associated with increased risk of cardiovascular disorders. The aim of this study was the evaluation of changes in osteoprotegerin serum levels and in body composition parameters in patients with sleep apnea syndrome.

We examined 47 patients with OSAS (mean age 55.42±7.91, mean AHI 32.76±19.98) and 29 persons from control group (mean age 49.48±13.68). All subjects underwent bioelectrical impedance analysis with a single-frequency bioimpedance analyzer (Model BIA 101 Akem) and polysomnography Grass Aura Lite. The osteoprotegerin serum level was measured using a ELISA kit: Human Osteoprotegerin (R&D Systems).

We didn’t show either differences in osteoprotegerin serum levels between OSAS patients and control group (4,496 vs 4,631 pmol/l, p=0.680) nor correlations between osteoprotegerin and AHI (p=0.484, R=0.08). Moreover we didn’t find changes in osteoprotegerin levels in OSAS patients with diabetes (p=0.251, with hypertension (0.911) or ischemic heart disease (0.876).

We observed higher BMI in OSAS patients (p=0.009), but from all body composition parameters we revealed only lower phase angle in OSAS patients (5.65, vs 5.87, p=0.047). We evaluated the relationships between osteoprotegerin and body composition parameters and we found only tendency, that osteoprotegerin level correlated negative with muscle mass percentage (MMF) (p=0.069, R=0.299) and positive with fat mass percentage (FM). CRP was significant higher in OSAS than in control group (6.59 vs 3.85, p=0.006) R=0.198, p=0.08), but we didn’t find correlations between osteoprotegerin and CRP (p=0.929, R=0.010).

Our study didn’t show changes in osteoprotegerin in OSAS patients.
defined using a full polysomnography study. The glucose metabolism was investi-
gated by oral glucose tolerant test. Blood glucose and IRI were determined on the 0, 60th, 120th, 180th min. 18 patients were with newly diagnosed IGT. 12 patients had NBG. Resistin (RayBio) and FFAs (Wako) were determined in both groups. IRI was 25.29 μIU/ml in IGT patients. In patients with NBG, IRI was 21.3 mlU/l. BMI did not differ significantly between patients with IGT and NBG. BMI was 40.42 ± 11.5 and 41.21 ± 10.9 in those with NBG. AHI (60.8%) was higher in patients with NBG compared to those with IGT – 50.6. Patients with NBG had also higher plasma levels of FFAs – 0.360/mmol/l compared to patients with IGT – 0.210/mmol/l. Only resistin was higher - AHI ≥ 30. IGT patients compared to NBG – 3.98 ng/ml. IRI in IGT patients was 25.29 μIU/ml and correlated best to the levels of resistin (p<0.05).

The commonly used clinical parameters – BMI, AHI, FFAs were higher in patients with OSA and NBG. They are not reliable clinical markers for the early detection of impaired blood glucose metabolism in OSA patients. Only resistin correlated to the levels of IRI and could be applied as a predictor and early detection marker of impaired blood glucose metabolism in OSA patients.

P3812

The need of higher CPAP pressure in a population with obstructive sleep apnea (OSA) and refractory hypertension (RHT) versus controlled hypertension-a retrospective study

Oana Claudia Helgian1, Andra-Elena Malaru2, Stefan Mihaiucă3, Ruxandra Umeana2, Florin-Dumitru Mihalut1. 1Institute of Pneumology “Marius Nasta”, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2Pneumology, University Hospital “Gheorghe Asachi” Iasi, Iasi, Romania; 3Institute of Pneumology “Marius Nasta”, Bucharest, Romania; 4Clinical Hospital of Infectious Diseases and Pneumology “Victor Babes” Timisoara, Timisoara, Romania; 5Institute of Pneumology “Marius Nasta”, Faculty of Medicine and Pharmacy, Oradea University, Bucharest, Romania

Rationale: RHT is common in obese patients, refractoriness among them is frequently caused by OSA. A previous study held in our clinic showed that patients with RHT had higher CPAP failure rate.

Methods: After exclusion criteria (central/mixed SAS, obesity-hyperventilation/orlap syndrome, obstructive/restrictive respiratory dysfunction, CPAP failure) applied to 214 SAS patients with HT, we studied 34 patients with controlled HT and RHT/demographics, anthropometrics, symptoms, comorbidities, sleep study’s: Chi test,TTest, Pearson. The 2 groups were similar in terms of smoking habit and antihypertensive treatment.

Results: Controlled HT-27 patients (79.4%); 14 men (77.8%), 8 women (20.6%); RHT-7 patients (20.6%); 4 men (57.1%), 3 women (42.9%). RHT patients were younger: 49.6 ± 8.8 vs 58.4 ± 12.1 years, p<0.04, morbid obesity: 45.5% vs 7.4% (p<0.01), higher Epworth score: (12.6 ± 5.1 vs 6.4 ± 2.4, p<0.005) and more comorbidities (ischemic heart disease: 33.3% vs 7.6%, p<0.02, dyslipidemia: 83.3% vs 28.6% (p<0.02). Also RHT patients needed higher pressure to correct respiratory events (1.7 ± 1.2 vs 9.8 ± 1.7 cm H2O), even if they had mild OSA in a higher range(57.1% vs 22.2%, p<0.05). There was no linear dependence between BMI and CPAP pressure variables, after CPAP/AHI, minimum Sao2 and BP values (Pearson, p<0.5).

Conclusions: After CPAP failure exclusion, patients with OSA and RHT still need higher CPAP pressure. Rich does not correlate with obesity. RHT patients will cost more the health system due to their cardiovascular comorbidities, young age and sleepiness. Further studies have to elucidate the need of higher CPAP pressures in RHT patients.

Left ventricular function assessment in patients with obstructive sleep apnea syndrome

Ramazan Rizak1, Rabah Elwash3, Mahmood Ahmed2, Rehbar Yasen2. Chest Diseases, Faculty of Medicine, Menaouya University, Shebin Elkom, Menaouya, Egypt Chest Diseases, Faculty of Medicine, Menoufia University, Shebin Elkom, Menaouya, Egypt; Egypt Cardiology, Faculty of Medicine, Menoufia University, Shebin Elkom, Menaouya, Egypt

Background: There are conflicting data on the effect of obstructive sleep apnea syndrome (OSAS) on the cardiac structure and function in human subjects.

Aims: To assess the left ventricular functions in patients with OSAS.

Patients and methods: Forty patients with OSAS, diagnosed by full polysomnography, underwent ECG and echocardiography using conventional mode and doppler tissue imaging to assess the function of the left ventricle.

Results: 11 patients had mild OSAS, 11 patients had moderate OSAS and 18 patients had severe OSAS. The three groups were matched in age, gender, BMI and incidence of hypertension. Severe OSAS had significantly higher AHI, lowest oxygen saturation, average oxygen saturation, and desaturation time % of total sleep time (<90%). Pulmonary hypertension and left ventricular diastolic dysfunction were significantly higher in moderate and severe OSAS groups. No difference between groups was found in LV systolic function. Diastolic dysfunction parameters were better correlated with AHI and lowest oxygen saturation during sleep.

Conclusion: Assessment of left ventricular function is mandatory in OSAS patients even if they have no cardiac symptoms. Severer obstructive sleep apnea syndrome may result in left ventricular diastolic dysfunction. Doppler tissue imaging is a better echocardiographic tool for assessment of left ventricular diastolic dysfunction. Severity of left ventricular diastolic dysfunction is correlated with AHI and lowest O2 saturation during sleep.

P3814

Serum aminotransferase levels in patients with severe obstructive sleep apnea

Nadia Adimi1, Froogh Soltani2, Nazanin Kipaour3, Zohreh Mohammad Taheri4, 1Respiratory and Sleep Medicine, National Research Institute of Lung and Tuberculosis, Tehran, Islamic Republic of Iran; 2Pulmonary and Sleep Medicine, National Research Institute of Lung and Tuberculosis, Tehran, Islamic Republic of Iran; 3Pulmonary and Sleep Medicine, National Research Institute of Lung and Tuberculosis, Tehran, Islamic Republic of Iran

Background: Obstructive sleep apnea (OSA) is one of the most common sleep disorders with a plethora of complications. Currently the impact of hypoxia due to OSA on liver function is targeted growing attention. This study evaluated the association between serum aminotransferase levels as accepted predictive factor for liver injury and factors connected with OSA severity (apnea hypopnea index (AHI), lowest oxygen saturation level, oxygen desaturation index (DI), percent of time below 90% saturation (T<90%)).

Materials and methods: 66 patients with BMI ≥ 30, who their OSA was confirmed by PSG, were divided equally into two groups based on AHI. 33 patients in control group with 5 ≤ AHI < 15, and 33 patients in case group with AHI ≥ 30 event/hours were enrolled. We compared serum level of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) with OSA severity factors in each group.

Result: Mean DI was (56.5 ± 26.9) (14.0 ± 10.4) in case and control group respectively (P-value <0.001). T<90% was (33.1%) and (14.2%) in case and control group respectively (P-value <0.001). A significant different in mean DI level and T<90% were observed in case and control group, respectively mean levels of AST (21.3 ± 8.6), (21.5 ± 9.39) and ALT (24.2 ± 14.07), (19.8 ± 9.74) were not significantly different (P-value =0.935) (P-value = 0.142). Pearson correlation showed there is a weak relation between mean DI<90%, AST (0.069) and ALT (P=0.837).

Conclusions: This study showed there is no significant correlation between serum aminotransferase levels and OSA severity.
Methods: We compared age and body mass index (BMI) matched non-to-moderate and severe OSA in the 239 male subjects hospitalized for examination of OSA. We analyzed the relationships between fat areas by computed tomography, comorbidity, polysomnographic data, arterial and venous blood data. Results: Of the 239, 52, 67 and 94 had mild, moderate and severe OSA. We compared all the 94 severe OSA with 85 of the 143 non-to-moderate OSA matched with age and BMI. While waist circumference was the same, severe OSA had a significantly larger VFA. Between the 2 groups, arterial oxygen partial pressure (PaO2), HbA1c and fibrinogen differed significantly. Multivariate modeling of these determinants revealed that both VFA and AHI independently determined PaO2 (contribution rate ($R^2$)=6.5% and 6.7%) and fibrinogen ($R^2$=7.5% and 4.4%), while HbA1c associated independently with AHI ($R^2$=3.7%), not VFA. Conclusions: Severe OSA had a significantly larger VFA, lower PaO2, higher HbA1c and fibrinogen than non-to-moderate OSA. Larger VFA in severe OSA suspect that VFA increase would be a key factor related to body composition in OSA becoming severe. PaO2, HbA1c and fibrinogen were independently predicted by VFA and AHI. Thus, control of OSA would decrease VFA, and in turn, a decrease in VFA and OSA might improve HbA1c and fibrinogen.

P3817
The inflammation and insulin resistance in obstructive sleep apnea
Emel Bulen,1 Mehmet Ekici,1 Uczer Kisa,1 Aysanur Ekici1,1, Department of Pulmonary Medicine, University of Kirkkale, Faculty of Medicine, Kirkkale, Turkey. 2Department of Biochemistry and Clinical Biochemistry, University of Kirkkale, Faculty of Medicine, Kirkkale, Turkey.

Objectives: The association between obstructive sleep apnea (OSA) and insulin resistance (IR) remains controversial. Sleep apnea and obesity may increase IR and inflammation by different mechanisms. This study investigated the relationship between sleep apnea and obesity with IR, and pro-inflammatory state.

Methods: A total of 133 consecutive subjects who were referred for polysomnography. 112 were documented to have OSA defined as apnea-hypopnea index (AHI) >5 and 21 control subjects with normal sleep. Inclusion criteria: male, at least 18 years old and able to cooperate. Exclusion criteria: other sleep disorders, OSA with or without comorbidities, other chronic diseases, pregnancy, and BMI >30 kg/m2. Controls were selected based on their BMI. AHI was calculated by the Actigraphy AH16 device. IR was measured using the homeostasis model assessment IR (HOMA-IR).

Results: IR was higher in the obese patient with OSA than in the non-obese patients with OSA as independent of each other in all subjects according to multivariable linear regression analysis. AHI and BMI were the determinants of IR in the moderate and severe OSA groups. BMI divided into the following two groups based on the body mass index (BMI) as BMI $\leq 30$ and BMI $>30$.

Conclusion: In the non-obese group, BMI was the only determinant of IR. However, AHI and BMI were the determinants of IR in the obese patients with OSA. However, AHI and BMI were the determinants of IR in the non-obese group. The inflammation and insulin resistance in OSA are independent of each other in all subjects according to multivariable linear regression analyses. AHI and BMI were significantly higher in the obese patients with sleep apnea than in the control group. However, AHI and BMI were also the determinants of IR in the non-obese group.

P3818
Glucose metabolism abnormalities in obstructive sleep apnoea (OSA) patients
Monika Targowska, Robert Pływaczewski, Laura Jonczak1, Przemysław Bielen1, Dorota Górecka2, Paweł Sliwinski1,1 Department of Diagnosis and Treatment of Respiratory Failure, National TB & Lung Diseases Research Institute, Warsaw, Poland; 2Department of Respiratory Medicine, National TB & Lung Diseases Research Institute, Warsaw, Poland.

Objectives: Obstructive sleep apnea is associated with disturbances in glucose metabolism and increased risk of type 2 diabetes. The aim of this study was to assess relations between OSA and diabetes. We studied 1164 OSA pts (876 males and 298 females), mean age $\pm$ 56.4 $\pm$ 10.4 years, AHI $\leq 5$ were selected upon polysomnography. Control group has been accepted as A Group. In addition, patients with OSA were divided into the following two groups based on the body mass index (BMI) as non-obese (B group) (BMI $<30$) and obese (G group) (BMI $\geq 30$).

Methods: All of inflammatory cytokines (CRP, hs CRP, TNF-α) were significantly higher in the obese patients with sleep apnea than in the control group. All of inflammatory cytokines showed significant associations with BMI while did not AHI, AI, ESS.

Results: Of the 239, 52, 67 and 94 had mild, moderate and severe OSA. We compared the 239 male subjects hospitalized for examination of OSA. We analyzed the relationships between fat areas by computed tomography, comorbidity, polysomnographic data, arterial and venous blood data. Results: Of the 239, 52, 67 and 94 had mild, moderate and severe OSA. We compared all the 94 severe OSA with 85 of the 143 non-to-moderate OSA matched with age and BMI. While waist circumference was the same, severe OSA had a significantly larger VFA. Between the 2 groups, arterial oxygen partial pressure (PaO2), HbA1c and fibrinogen differed significantly. Multivariate modeling of these determinants revealed that both VFA and AHI independently determined PaO2 (contribution rate ($R^2$) = 6.5% and 6.7%) and fibrinogen ($R^2$ = 7.5% and 4.4%), while HbA1c associated independently with AHI ($R^2$ = 3.7%), not VFA. Conclusions: Severe OSA had a significantly larger VFA, lower PaO2, higher HbA1c and fibrinogen than non-to-moderate OSA. Left and right ventricular function in obstructive sleep apnea patients
Bouchra Lamia, Mehmet Ekici1, Ucler Kisa, Aydanur Ekici1,1 Department of Diagnosis and Treatment of Respiratory Failure, National TB & Lung Diseases Research Institute, Warsaw, Poland; 2Department of Respiratory Medicine, National TB & Lung Diseases Research Institute, Warsaw, Poland.

Objectives: Obstructive sleep apnea is associated with right ventricular dysfunction including preload and afterload abnormalities. Right ventricular contractility remains difficult to assess due to the complex RV geometry. Echocardiographic speckle tracking strain analysis of CPAP therapy effects may offer new insights into understanding of regional contractility.

Methods: We assessed the hypothesis that RV dysynchrony exists in OSA patients and can be reversed by CPAP therapy.

Results: Logistic regression analysis revealed significant correlation between diabetes and cardiovascular diseases and obesity (BMI $>30$ vs $\leq 30$ kg/m²).

Conclusion: Diabetes was frequent ($>20\%$ of subjects) in moderate and severe OSA patients. Cardiovascular diseases and obesity were the independent predictors of diabetes in this group.

P3821
left and right ventricular function in obstructive sleep apnea patients
Bouchra Lamia, Stéphanie Gelinotte, Florence Portier, Luis-Carlos Molano, Catherine Tardif, Antoine Cuvelier, Jean-François Muir. Respiratory and Critical Care Department-EA 3830, Rouen University Hospital, Rouen, France.

Objective: Obstructive sleep apnea is associated with right ventricular dysfunction including preload and afterload abnormalities. Right ventricular contractility remains difficult to assess due to the complex RV geometry. Echocardiographic speckle tracking strain analysis provides a better understanding of regional contractility. We tested the hypothesis that RV dysynchrony exists in OSA patients and can be reversed by CPAP therapy.

Methods: Prospective study including patients with a confirmed OSA diagnosis.

Conclusion: Diabetes was frequent ($>20\%$ of subjects) in moderate and severe OSA patients. Cardiovascular diseases and obesity were the independent predictors of diabetes in this group.
Echocardiographic (TTE) measurements were obtained at baseline and after one month of CPAP therapy. We measured usual TTE parameters: left ventricular ejection fraction (LVEF), transmural pulsed Doppler including E and A waves velocity and Doppler tissue imaging. The speckle tracking analysis was used to generate 6 segmental RV strain curves. Time to peak strain was determined with dysynchrony defined as the difference between earliest and latest segments. Global strain was calculated.

Results: 36 patients (M: 69% mean (SD) age 56(11) yrs, body mass index 35.1(7.38) kg/m2, respiratory disturbance index 46(18.8)) were included. At baseline 56% had high blood pressure, 22% had a chronic heart disease, with a normal LVEF: 61.8%. Speckle tracking strain analysis showed RV dysfunction with a decreased RV global strain: 13.8(5.8) % and RV dysynchrony: 174 (89) ms. After one month of CPAP, RV function was significantly improved and dysynchrony was reversed: 125 (82) ms (p=0.03).

Conclusion: We observed RV dysynchrony at baseline in OSA patients. RV dysynchrony was improved after one month of CPAP therapy.

3P823

Relationship between sleep apnea syndrome, plasma myeloperoxidase levels and cardiovascular risk

Cystatin C (Cys C) is a protease inhibitor synthesized in all nucleated cells. Lately it has been proposed as an indicator of early dysfunction in glomerular filtration rate. NT-proBNP is a hormone secreted by ventricles in response to heart overload. The aim of this study was to assess Cys C plasma level in patients with OSA and its relationships with OSA-associated cardiovascular diseases. Cys C and NT-proBNP were also compared as predictors of cardiac abnormalities.

We studied 238 consecutive patients with OSA: mean age=56.87±9.97yrs, BMI=33.5±5.84.kg/m², mean AHI=38.97±21.71, mean ODI=44.85±27.85. Elevated level of cystatin C (under 50yrs: CysC<0.92mg/L, over 50yrs: CysC<1.10mg/L) was found in 40% of cases. Comparison of pns with normal and elevated level of Cys C is shown in a table below.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Elevated Cys C&lt;sub&gt;≤&lt;/sub&gt; 0.92mg/L</th>

Logistic regression analysis (LRA) revealed that CAD (OR=5.2; 95%CI=1.31-19.48, p=0.005) and HF (OR=5.2, 95%CI=1.9-19.9, p=0.001) were associated with increased CysC level. Association of increased NT-proBNP level with cardiac disorders in OSA pts was also confirmed (for CAD OR=2.5, 95%CI=1.1-5.3, p=0.01, for HF OR=4.9, 95%CI=1.6-14.9, p=0.004).

Conclusions: Increased Cys C level is strongly associated with cardiac diseases in pts with OSA. Cys C seems to be a better indicator of HF than NT-proBNP in OSA pts.

398. Clinical predictors of OSA, adherence to CPAP and psychology

3P824 Plasma levels of TNF-alpha in obstructive sleep apnea syndrome (OSA) before and after surgical intervention

Eman Reyad<sup>1</sup>, Nancy Abdelay<sup>1</sup>, Mahmoud El Prince<sup>1</sup>, Alaa Farid<sup>2</sup>, Mohamed El-serogy<sup>3</sup>.<sup>1</sup>Chest, Suez Canal University, Ismailia, Egypt; <sup>2</sup>ENT, Suez Canal University, Ismailia, Egypt; <sup>3</sup>Chest, Cairo University, Cairo, Egypt

Background: Prior studies have shown that biomarkers of inflammation, including TNF-alpha, are raised in patients with sleep apnea. TNF-alpha is one of the important risk factors for atherosclerosis, stroke and Cardiovascular disease in OSA patients.

Aim of the study: To determine whether TNF-a blood levels is elevated in OSA syndrome and whether they are reversible after surgical intervention.

Methods: Among the patients who had visited the ENT clinic for evaluation of sleep problems, 70 subjects were selected. Polysomnography (PSG) and morning venous blood serum for levels of TNF-a were performed in all the subjects and 35 patients were diagnosed as having OSA. All patients with OSA had surgical intervention according to individual cases. Laser assisted uvulopalatoplasty (LAUP), extended LAUP (LAUP and laser assisted tonsillar ablation), or laser assisted uvulopalatoplasty were done using a CO2 laser. Sleep apnea monitoring, clinical evaluation and TNF-a level were then compared before and 3 months after intervention.

Results: We compared thirty five patients with OSA(21 males and 14 females), mean age(46.6±12.4), with 35 control subjects(11males and 24 females),mean age (34.2±9.6).The mean (SD) plasma levels of TNF-alpha was significantly higher in patients with OSA than in control group (5.77±4.046 vs. 2.24±1.59g/L (p<0.039)) respectively, and TNF-alpha level significantly decreased (to 3.22±3.4g/L (P = 0.001)) after treatment Also TNF-alpha levels showed a statistical correlation with the AHI before treatment, and with neck circumference after treatment.
Conclusion: Our results suggest that TNF may be a prognostic factor for comparing patients with OSAS before and after treatment.

P3825
Prescription, subjective and objective compliances in patients with obstructive sleep apnea syndrome using positive airway pressure
Banu Sarac, Benan Caglayan, Nesrin Kizil, Efil Turan Parmakzis, Gulsen Sarac, Ali Fidan, Sevda Sener Comert, Gulten Akin Gunler. Chest Diseases, Dr. Lutfi Kirdar Kartal Teaching and Research Hospital, Istanbul, Turkey
Gold treatment for obstructive sleep apnea syndrome(OSAS) is continuous positive airway pressure(CPAP). We aimed to assess prospectively prescription,subjective and objective compliances in OSAS patients recommended PAP treatment.factors effecting compliance,648 patients (69.6% men,30.4% women/recommended to use PAP in January 2005-June 2011,were included. Patients using PAP were questioned for adverse effects and assessed with ESS/Epworth Sleepiness Scale/at follow-ups.Prescription,objective and subjective compliances were assessed.Relationship between compliance and demographic data,PSQI(polysonomography) findings,ESS scores,adverse effects were analyzed.The mean age was 51.29±4.97 and mean BMI(body mass index) was 33.52±6.56.In the first night PSG mean AHI(apnea-hypopnea index) was 54.16±26.41 and Al/apneare index)was 31.46±26.95 24h/38.3%cases attended follow-ups,246 (37.9%) were followed by phone visits and 154(23.8%) couldn’t be reached.Patients using PAP for at least 4 hours per night for at least 70% of the days monitored were regarded as compliant and who didn’t meet this criteria were considered as noncompliant. In the population 63.9%obtained PAP machine/prescription). In 248 cases attending follow-ups,subjective compliance was 85.1%-objective compliance was 64.5%.Higher ODI(oxygen desaturation index) and lower SpO2(oxygen saturation) at the first night PSG were found to positively affect prescription (p<0.05).Improvement in ESS score and satisfactory sleep were significantly correlated with objective compliance(p<0.05).Chest discomfort,difficulty falling asleep and sleep disturbances were significantly higher in noncompliant group (p<0.05).

P3826
Association between obstructive sleep apnea (OSA) and depression and the effect of continuous positive airway pressure (CPAP) treatment
Amer M. El-Sherbini1, Adel Salah Bedran2, Ashraf El Mitwalli3 1Psychiatry, Elminia University Hospital, Faculty of Medicine, Elminia, Egypt; 2Chest, Faculty of Medicine, Tanta University, Tanta, Gharbia, Egypt; 3Neurology, Mansoura School of Medicine, University of Mansoura, Mansoura, Dakhalia, Egypt
Background: Obstructive sleep apnea (OSA) is a relatively common disorder which has a negative impact on the psychological well-being of affected individuals.
Objective: To assess the association between OSA and depression as well as the effect of treatment with continuous positive airway pressure (CPAP).
Methods: A total of 37 newly diagnosed individuals with OSA underwent an overnight polysomnography and were assessed using the Epworth Sleepiness Scale (ESS), the Hamilton Depression Rating Scale (HDSRS), and the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition. Patients were assessed before and after 2 months of CPAP use.
Results: Of the 37 patients included in the study, 21 (56.7%) had clinically relevant depression as indicated by a score 10 on the HDSRS and eleven patients (29.7%) met the diagnostic criteria for a major depressive episode using the Structured Clinical Interview. Scores on the HDSRS were correlated with the Apnea Hypoaxia Index, ESS scores, and oxygen saturation. Patients showed a significant reduction in depressive symptoms and improvement in ESS scores after CPAP treatment.
Conclusion: Patients with OSA should be screened carefully for depressive disorders. CPAP should be tried first before starting other treatment modalities for depression.

P3827
The psychological burden of OSAS patients is not correlated with apnea-hypopnoea index
Dionios Bratsis1, Athanasios Tseleios1, Anna Christodoulou1, Silvia Dumiru1, Sotiris Glyfopoulos2, Emmanouelas Kosmas3, Nikolaos Tzanakis4, Michael Koutsilieris5 1Psychiatric Department, “Sotiria” General Hospital of Chest Diseases, Athens, Greece; 2Sleep Laboratory, 3rd Pulmonary Department, “Sotiria” General Hospital of Chest Diseases, Athens, Greece; 3Pulmonary Department, “Metropolitan” General Hospital, Athens, Greece; 4Department of Social Medicine, Laboratory of Epidemiology, University of Crete Medical School, Hersonissos, Crete, Greece; 5Department of Experimental Physiology, University of Athens Medical School, Athens, Greece
Introduction: Obstructive sleep apnea syndrome (OSAS) is characterized by repeated episodes of upper airway obstruction during sleep, which leads to the presence of excessive daytime sleepiness. Regarding the psychological comorbidity in patients diagnosed with OSAS, previous studies focused mainly on depressive and, secondarily, to anxiety symptoms.
Aims and objectives: To record the prevalence of the occurrence of depressive symptoms and of alexithymic characteristics in a sample of OSAS patients and to investigate their relation to respiratory parameter (Apnea - Hypopnoea Index, AHI) of polysomnography.
Methods: The study was conducted in a certified sleep laboratory. 35 randomly selected patients were examined for anxiety, depression and alexithymia using the Spielberger Trait Anxiety Inventory (STAI), the Beck Depression Inventory (BDI) and the Toronto Alexithymia Scale (TAS-20), respectively.
Results: A high prevalence of anxiety (41.4%) and depressive symptoms (55.2%) and of alexithymic characteristics (41.4%) was observed in OSAS patients. Although the control group showed a higher prevalence of anxiety (66.7%) and depression (83.3%) symptoms, there were no differences between the two groups (t-test p>0.05). With regard to severity, no differences were observed between subgroups (mild, moderate and severe OSAS, ANOVA p>0.05). Women showed higher scores in BDI and STAI compared to men (t-test p<0.05). Finally, no correlation was observed between psychometric scores and AHI (Pearson correlation p>0.05).
Conclusions: This study supports the presence of a high degree of psychological burden in patients diagnosed with OSAS, regardless of the severity, as determined by the AHI.

P3828
Continuous positive airway pressure in patients with obstructive sleep apnea: Independent predictors of adherence
Gerhard Weirich1, Andrea Gram2, Holger Woehlke2 1Pneumology, Ruhrlandklinik, West German Lung Center, University Hospital Essen, Germany; 2Science Center, ResMed, Marienheind, Germany
Background: Although continuous positive airway pressure (CPAP) is an effective treatment for obstructive sleep apnea (OSA), long-term adherence is challenging. Therefore, the identification of adherent patients is necessary to determine independent adherence predictors.
Methods: In a retrospective data analysis we studied 4263 German patients (age = 54.4±11.2 years; 82.4% male) treated with the CPAP device S8i (ResMed, Sydney, Australia). We analysed AHI, mean airway pressure, mean leakage, hours of use per night and efficiency (days of use/total days). Data of the last 156.7±3.53 months of treatment (range 30-180 days) were collected. Logistic regression was used for determining independent predictors of CPAP adherence.
Results: Mean therapy duration was 3.5±±3.6 years. Independent predictors for poor CPAP adherence (<3/month) were female gender, leakage and therapy duration. Odds ratio (OR) for female gender was 1.63, OR for leakage increment per 0.1% was 1.13, and OR for therapy duration increment from (starting from 15 years) per 1 year was 1.15. Furthermore, age, therapy duration, mask pressure and leakage were independent predictors for excellent CPAP adherence (>7/month): OR for 5-year increment of age was 1.06, OR for therapy duration increment per 1 year was 1.10, OR for mask pressure increment per 1 cmH2O was 1.08, and OR for leakage increment per 0.1% was 0.86.
Conclusion: Independent predictors for poor CPAP adherence (<3/month) were female gender, short-term therapy and higher leakage, whereas independent predictors for excellent adherence (>7/month) were higher age, long-term therapy, increased mask pressure and lower leakage.

P3829
The relationship between obstructive sleep apnea syndrome and two common urological disorders
Soner Coban1, Ege Gulec Balbay2, Kamil Cam1, Ali Kaykci1, Oner Balbay1 1Urology, Duzce University, Duzce, Turkey; 2Chest Diseases, Duzce Ataturk State Hospital, Duzce, Turkey
Erectile dysfunction (ED) and Lower Urinary Tract Symptoms (LUTS) associated with benign prostate hyperplasia (BPH) usually occur in older men. The aim was to investigate the relationship between Obstructive Sleep Apnea Syndrome (OSAS) and two urological common disorders.
Between January 2007 and April 2010, the men over the age of 50 admitted to the outpatient department of pulmonary diseases with suspected OSAS were selected. All patients had polysomnography analysis. A total of 29 patients having moderate and severe OSAS with apnea-hypopnea index (AHI)=15-30 (11 patients) and AHI>30 (18 patients), respectively were included in the first group.21 patients with AHI<5 constituted the control group. Voiding symptoms were evaluated by using International Prostate Symptom Score (IPSS) and uroflowmetry. ED was investigated by administering International Index of Erectile Function (IIEF). Both groups were comparable with regard to age, PSA, prostate volume, and prostate size by digital rectal examination, IPSS values and uroflowmetry results. On the other hand, nocturia and IIEF results were remarkably different between two groups. The average number of nocturia was 1.47, and the mean score of IIEF was 15.48 in patients with OSAS. Those were 0.88 and 19.90 in the control group, respectively (p<0.05).
In this study, IPSS and uroflowmetry values showed no difference between patients with and without OSAS. On the other hand, nocturia and IIEF results were both remarkably different in OSAS patients. As a result, OSAS was shown to be associated with nocturia and ED. Therefore, the patients with complaint of either nocturia or ED should be investigated for OSAS.
P3831 Sleep behavior and disturbance in high school students: a cross-sectional study in Jeddah, Saudi Arabia

Rosh Meraldi1, Siraj Walli2, Douaa El Derwi2, Ayman Krayem2, Rawan Nassif1

Methods: A cross sectional study was carried out from January to May 2011 on a random sample of high school students. Participants completed a questionnaire which included the Pittsburgh Sleep Quality Index (PSQI), Perceived Stress Scale (PSS) and Epworth Sleepiness Scale (ESS).

Results: 947 students were recruited, of whom 55.6% were female with a mean age (±SD) of 15.6±1.17 years. Marked delay of mean sleep week (04:58) and rise (12:04) time was identified. The total hours of sleep on school nights was 6.97±2.72, with an average estimated sleep latency of 25 minutes. Ten percent of students reported using medications within the last month to help them fall asleep. Disturbed sleep (PSQI score >5) was found in 56% of the study participants. Excessive daytime sleepiness (EDS) defined as ESS score of >10 was found in around one third (33%) of students. Fifty-five percent were identified as psychologically distressed based on PSQI. No significant difference was identified in PSQI global score between stressful and not stressed groups (p=0.590), or between different GPAs (p=0.129).

Conclusions: A high frequency of EDS was found among OA pts (38%), which was underdiagnosed and undertreated. These pts had more severe OSA than patients with NIgER; their nasal symptoms severity was associated with higher AHI. The evaluation of IgEAR in OA pts may contribute to improve these patients’ clinical approach.

P3834 Infections complications associated with the use of CPAP in patients with sleep apnea-hypopnea syndrome

Trinidad Silviente Zamora1, Pedro Méndez Martínez2, Carlos Máximo Verde1, H.G.U. Morales Meseguer, Murcia, Spain, 1Neurología, Hospital General Universitario Reina Sofía, Murcia, Spain, 2Servicio de Apoyo a la Investigación, Universidad de Murcia, Murcia, Spain

Introduction: CPAP systems can be contaminated by microbes, increasing the risk of respiratory infections. Humidifiers can add a higher risk. Our study evaluates among respiratory tract colonization and respiratory diseases related to CPAP with or without humidifier.

Objectives: A prospective study was designed. 100 CPAP-users were randomized: Group A (CPAP without humidifier): 50 patients (43 men, 7 women) between 41 and 98 years (average, 62). Patients were instructed of respiratory infection symptoms. Swabs were taken from pharyngeal exudates in all patient, and from masks and tubes in Group B.

Methods: 16 Pharyngeal exudates cultures were positive in Group A and 5 in Group B (32% versus 5%; RR 6.59, 95% CI: 1.37-32.66). Streptococcus pyogenes group A: 6 in Group A and 1 in Group B; Streptococcus beta-hemolytic group C: 3 in Group A, 2 in Group B; Staphylococcus aureus: 1 in Group A; Strepoytococcus group C: 2 in Group B. Respiratory infection symptoms: 3 patients in Group A, 5 in Group B (6% versus 10%). Swabs from masks and tubes in Group B: 31 microbial flora, 2 multiple fungal flora, 3 Turboponas candida, 1 Aeromona hidrophila, 1 Rodotoru raburi, 1 Serratia marensiens and 1 Pseudomonas aeruginosa.

Conclusion: Upper respiratory airways colonisation has been lower in the humidifier group, even though CPAP systems contamination has been common. Respiratory infection symptoms were low in both groups. Humidifiers have not significantly increased infections.

P3833 Snoring at sitting position is a good predictor of sleep apnea in Chinese patients

En-Ting Chang1, Chest, Buddhist Tzu Chi General Hospital, Hualien, Taiwan

Background: Snoring is a common symptom among adults population, and it is the most common complaint in patient with obstructive sleep apnea(OSA) syndrome. Patients who have snoring in sitting position during nap or sleep should have narrower upper airway. The aim of this study was to evaluate if the snoring in sitting position is a predictor of OSA patients.

Method: We prospective enrolled 51 male and 23 female patients. All the participants received questionnaires as well as a standard polysomnography thereafter.

Results: Patients who have self-reported snoring of sitting position (with tilt position for over 45°, 55%+ group) have higher body mass index as well as higher circumference of neck and waist, higher level of Epworth sleepiness scale.
During polysomnographic study, SS group have more percentage of S1 and less percentage of S2 sleep. Besides, SS group have more severity of apnea-hypopnea index (AHI), as well as higher AHI during REM or non-REM sleep. More oxygen desaturation index and arousal index were also noted. The sensitive and specificity of the SS group for OSA defined as AHI ≥5 were 0.77 and 0.52, with positive predictive value and negative predictive value were 0.8 and 0.48. The likelihood ratio value was 1.3. In the other hands, the sensitive and specificity of the SS group for moderate to severe OSA (defined as AHI ≥15) were 0.78 and 0.42.

Conclusion: In the present study, the symptoms of self-reported snoring of sitting position can be a useful predictor of Chinese OSA patients.

P3835
5-years APAP adherence in OSA patients
Matilda van Zeller1, Marta Drummond1,2, Ana Cristina Santos1, João Almeida1, João Carlos Winck1,2.
1Department of Pulmonology, Centro Hospitalar de São João, Porto, Portugal. 2Faculty of Medicine, University of Porto, Portugal.

Introduction: Although continuous positive airway pressure (CPAP) is effective in the treatment of obstructive sleep apnoea (OSA), inadequate adherence remains a major cause of treatment failure.

Objective: To determine long term adherence to auto-adjusting-CPAP (APAP) and its influencing factors. To evaluate initial compliance and its relation to long-term adherence.

Methods: 83 male patients with moderate to severe OSA were enrolled. After beginning, APAP patients' compliance (% of usage and hours per night) was recorded during medical appointments, after 12 days, 6 months and then annually for at least 5 years.

Results: Patients mean age was 53.8±10.8 years, mean apnoea-hypopnoea index of 25.2±0.1/h and mean Epworth sleepiness scale of 12.4±1.5. Mean follow-up time was of 65.0±1.2 months, 63 patients (75.9%) are still using APAP (73.4±7.7 months) having a mean percentage of use of 92.6±2.8 for 06:55:01±3:55 per day. Twenty patients (24.1%) abandoned treatment after 25.4±17.5 months, on average.

Conclusions: Patients who abandoned treatment during the follow-up period had lower initial compliance. Percentage of use at 12 days and 6th month was 81.7±23 and 65.8±28.5 for non-adherent patients and 96.6±7.4 and 94.3±4.9 for adherents (p<0.01 and p=0.001), mean hours per night were 04:1±1:55 and 04:07±1:57 vs. 06:18±0:28 and 08:14±0:12 (p<0.001 and p<0.001), respectively.

Non-adherent patients were younger (p=0.01). No other differences including employment state, marital status or disease severity and symptoms were found between the groups.

Conclusions: Patients who maintain long-term treatment have very good compliance. Non-adherent patients have significantly lower initial compliance than long-term adherents.

P3836
Obstructive sleep apnea among diabetics in southeastern Nigeria
Victor Umoh, Effiong Akpan, John Ekiti, Eiete Peters, Obeten Ekpo, Mfon Ekwere.
Internal Medicine, University of Uyo, Akwa Ibom State, Nigeria

Background: Diabetic patients are prone to obstructive sleep apnea (OSAS). OSAS has also been shown to be associated with increased cardiovascular morbidity and mortality. There is a paucity of data on this condition among diabetics in Nigeria. This study was carried out to determine the risk of OSAS among diabetics in Nigeria.

Methods: Diabetics attending the medical outpatient clinic of a tertiary hospital in South Eastern Nigeria were recruited into this survey. A modified version of the Berlin Questionnaire was used to determine the risk for OSAS and also obtain demographic data. Anthropometric and spirometric measurements were also obtained from all subjects. The survey was conducted over a 4 months.

Results: 114 diabetics were randomly recruited for this survey, 54 (47.4%) female and 60 (52.6%) males. 66 (57.9%) of the subjects were hypertensive. The average age of the subjects was 55.5 years and the average duration of diabetes was 7.6 years. 63(55.3%) of the subjects were found to have a high risk for OSAS, there was no gender difference in the risk for OSAS. A high risk for OSAS was associated with increased BMI, increased neck size, hypertension, alcohol use and reduced PEF. The factors that significantly predicted a high risk for OSAS were a history of hypertension (OR 55), alcohol use (OR 9), increasing BMI (OR 2) and poor BP control (OR 2).

Conclusion: OSAS is often not diagnosed among patients with diabetes and the strong association between a previous history of hypertension and OSAS may be the reason for the increased risk of cardiovascular death among diabetics.

P3837
Compliance for NIMV treatment in moderate and severe OSAS patients
Hatice Kathy Oczeitlik, Ersan Atahan, Muhammed Emin Akkoyunlu, Mehmet Bayram, Fatmanur Karakose, Murat Sezer, Levent Kart.
Pulmonology, Bismiamed Yalik University Medical Faculty, Istanbul, Turkey

Aim: In the non-invasive mechanic ventilation (NIMV) using in the treatment of obstructive sleep apnea syndrome (OSAS), compliance problem is a frequently seen difficulty. Aim in this study is to analyze the compliance of the OSAS patients to the NIMV treatment, and to search for the factors affecting the compliance.

Method: The patients given NIMV treatment in the sleep laboratory of the university hospital due to moderate or severe OSAS between 1 January 2011 and 31 December 2011 were included to our study. Polysomnographic findings of the patients were recorded. A questionnaire about compliance to the NIMV that had been set by our clinic applied to the patients by the phone calls.

Results: 75.4% of the included patients were male. The mean age was 49.5±12.3. Mean BMI, Epworth and REM sleep index of the Patients were 32.5±5.9, 10.6±4.6 and 43.2±2.3. Complication related to the NIMV device use was seen in 37 (27%) of the patients. The most frequently seen complications were dryness of mouth, discomfort due to mask, dryness of throat, irritation of the eyes, nasal congestion, bloating, claustrophobia and headache. Sixteen (11.9%) patients was not using the NIMV device due to device discordance. Six of these patients have severe, and 10 of these patients have moderate OSAS.

Conclusion: Compliance to the NIMV in the OSAS treatment is still an important problem. Patients treated with NIMV should be kept under close observation and should be informed about the risks of the disease if not used the device.

P3838
Evaluation of continuous positive airway pressure compliance in a group of obstructive sleep apnea patients
Nasr Alfaraj, Hany Shaarawy, Chest Disease Department, Zagazig University, Zagazig, Egypt

Currently, the treatment of choice for OSA is nasal CPAP but the documented efficacy of CPAP may be poor because of decreased compliance.

Objective: Objective is to evaluate the CPAP compliance in a group of OSA patients in the state of Kuwait.

Methods: 60 patients proved to have OSA by polysomnography, (ESS) and (FOSS) were done for all patients then follow up for 3 months were done and then patients reassessed again.

Results: Only 45 patients (75%) were compliant on CPAP with a mean runtime of 5.2±0.46 hour/night, CPAP significantly improved the AHI from 44.8±10.85 to 7.5±3.93 (p<0.05), ESS from 17.88±3.2 to 3.47±1.14 and total FOSQ from 83.78±1.67 to 160.9±1.40 (p<0.01), on using correlation study there was significant correlation between the CPAP runtime and the baseline Body Mass Index (BMI), AHI, ESS but on using stepwise regression analysis the only 2 variables showed significant correlation were the BMI and ESS.

Conclusion: In this group of patients the rate of CPAP compliance was considered good (75%) and the only factors that can predict short term CPAP compliance were the BMI and ESS.

P3839
S100B protein: A useful marker in obstructive sleep apnea syndrome
Sergio Dorr, Ibrahim Hikmet Firat, Nojyen Çolak, Zeynep Gogus, Tuncay Delibashli, Nadid Arslan.
Chest Disease, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey Chest Disease, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey Endocrinology, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey Microbiology, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey Endocrinology, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey Chest Disease, Diskapi Yildirim Beyazit Research and Education Hospital, Ankara, Turkey

Aim: Up to now, there have been a few studies performed on serum S100B protein level in patients with obstructive sleep apnea syndrome (OSAS). We aimed to underline the importance of the serum S100B protein as biochemical marker of cerebral damage in patients with OSAS.

Method: Forty-three newly diagnosed OSAS patients [apnea-hypopnea index (AHI): 37.5 (11.3-137), female/male: 18/25] and 25 subjects with AHI value of below 5 [AHI: 4.4 (0.7-4.8), female/male: 9/17] were included in the study. In both groups serum S100B protein level were tested in serum samples taken after polysomnography. Differences in serum S100B protein levels between the OSAS patient group and control group were examined. In addition, association of S100B protein serum level with age, body mass index, AHI, mean apnea time, lowest SpO2 value, percentage time spent at SpO2<90% was analyzed in OSAS patient group. In the control and OSAS patient groups difference between the values was evaluated by parametric independent two samples t test while the relation between the variables and serum S100B protein level in OSAS patient group was evaluated by using Spearman correlation test.

Results: Serum S100B protein level was found to be 133.7 (20.97-230.70) pg/mL in OSAS patient group and 16.1 (10.1-22.9) pg/mL in control group (p=0.000). Serum S100B protein level was not found to be correlated with other variables (p>0.05).

Conclusion: Serum S100B protein level increases in patients with OSAS. This suggests that serum S100B protein may be a useful biochemical marker in determining cerebral damage in patients with OSAS.
Methods: We retrospectively evaluated 134 consecutive patients with moderate-severe OSAS, average age 57±0.10, admitted in a rehabilitation institute for CPAP adaptation, between 2003 and 2009. According to the different provisions of the local health organization before and after 2006, we divided patients in two groups on the basis of the mean length of hospitalization (20 days in Group 1, 7 days in Group 2). CPAP use, numbers of dropout, numbers of patients with discomfort, and numbers of unscheduled visits were assessed at 1 year.
Results: Comparisons are summarized in the table. Data are presented as mean±SD.

<table>
<thead>
<tr>
<th></th>
<th>Group 1 (n=66)</th>
<th>Group 2 (n=60)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPAP use h/night</td>
<td>4.7±2.7 h</td>
<td>4.5±2.8 h</td>
</tr>
<tr>
<td>Dropout (%)</td>
<td>9 (14%)</td>
<td>7 (12%)</td>
</tr>
<tr>
<td>Visits</td>
<td>21 (32%)</td>
<td>23 (38%)</td>
</tr>
</tbody>
</table>

Conclusions: We observed the same adherence to CPAP in terms of mean daily use in the two groups, at one year. However, to obtain the same adherence, the patients adapted in few days had more frequently discomfort, that required a greater number of unscheduled visits.

P3843 Obstructive sleep disorders in children with allergic rhinitis

Mirjana Turkalj, Davor Plavec, Daria Kucic, Romana Gjergja-juraski. Dpt of Sleep Medicine, Children’s Hospital Srebrnjak, Zagreb, Croatia

Background: Allergic rhinitis (AR) is the most prevalent chronic disease in children, associated with impairments in quality of life, sleep disorders, emotional problems, and impairment in activities. AR can induce medical complications, learning problems and sleep-related complaints, such as obstructive sleep apnea syndrome (OSAS). OSAS is characterized by repeated events of partial or complete upper airway obstruction during sleep. The aim of this study was to estimate the prevalence of obstructive sleep apnea in children with seasonal and perennial allergic rhinitis together with predictive factors.

Methods: We studied children (age 5-17 yrs, N=47) with allergic rhinitis that underwent sleep study using complete polysomnography (PSG) according to standardized protocol. All patients underwent detailed medical and family history, physical examination including ENT examination, and an array of diagnostic tests (skin-prick test, total and specific IgE, cytology of the nasal mucosa, complete and differential blood counts) and Children’s Sleep Habits Questionnaire.

Results: Results from our study showed that almost half (46%) of the examined children with allergic rhinitis suffer from obstructive sleep apnea (88% had obstructive hypopnea). Obstructive sleep apnea was significantly associated with: perennial allergies (p=0.018) and nasal congestion (p=0.026), showing a significantly higher apnea/hypopnea index (AHI) in the group with perennial allergy (p<0.025).

Conclusion: Results of this study indicate that significant number of children with allergic rhinitis may develop obstructive sleep apnea. Perennial AR is an independent risk factor for OSAS in children probably because nasal congestion is the most prevalent symptom of it.

399. Sleep apnoea: clinical topics

P3844 Socioeconomic factors affecting the acceptance of continuous positive airway pressure in sleep apnoea syndrome patients

Vasileios Michaildis, Dimitra Siopi, Nikolaos Moisiadis, Eleni Perantoni, Andreas Kosmas, Evaggelia Serafi, Venetia Tsara. Sleep Unit, GH G Papanikolaou, Thessaloniki, Greece

Background: CPAP therapy is often associated with suboptimal adherence rates and the assessment of patients’ motivations and barriers is important for the treatment. The aim of this study was to investigate factors which may affect the acceptance of CPAP among patients with SAS.

Methods: We studied 150 consecutive patients with SAS (age 5-80 years, 68% male) who were referred to the Sleep Unit in Thessaloniki, Greece. Patients were divided into two groups: those who had been diagnosed with SAS and prescribed CPAP during the last 2 years did not come to the follow-up visit despite the instructions. We contacted them via telephone and asked about their perception of treatment effectiveness and the adherence to CPAP therapy. Results: From 109 patients, 62 (56.8%) (age 49.2±11.3 years, 93.5% male) were found and answered the questions. Twenty two patients (35.5%) did not purchase the CPAP device (group 1) mainly (50%) due to economic restriction, 12 patients (19.4%) abandoned CPAP therapy after time (group 2) mainly (50%) due to subjective perception of treatment ineffectiveness and 28 patients (45.1%) continue CPAP therapy but ignored the follow-up procedure (group 3). No significant correlations were observed between anthropometric characteristics, severity of SAS, socioeconomic and employment issues and the decision about the CPAP treatment.
in each group, but group 1 had lower education level than the two others (basic level 36.4% vs 16.6%, p < 0.05). No significant differences were noted between the 3 groups with respect to method of CPAP titration, age, BMI, AHI but the ESS was higher in the craniofacial patients and snoring or noisy breathing were favored for an initial PSG to rule out SDB.

Methods: Specific diagnoses and symptoms were: Crouzon’s (n=7), Apert (n=5), Saethre-Chotzen (n=1), Goldenhar (n=1), idiopathic craniosynostosis (n=2), achondroplasia (n=8) and Pierre-Robin (n=2). Their mean age was 5.1 years, none was overweight or obese. Of these patients, 19/26 (73%) had evidence of SDB and 7 (27%) had primary snoring. In patients with SDB, the mean apnea-hypopnea index (AHI) was 10.3 (median = 5.7, range 2.5-65.0). Abnormally increased CO2 was observed in 12/26 (46%). Laboratory results (mean, median, range) were: wide range CRP (7.2, 1.0, 0.1-33.5), total cholesterol (135, 125, 112-180), HDL (40, 37, 23-59), LDL (75, 67, 52-115), tryptophane – normal, fasting glucose and insulin – normal.

Conclusion: The results confirm a high prevalence SDB in children with craniofacial anomalies with a higher rate of cardiovascular lesion. Underlying chronic inflammation also exists in these patients. Metabolic changes were not found.
Objective: This prevalence of excessive daytime sleepiness (EDS) and the association of EDS with respiratory symptoms and large variety of health variables was investigated in two well characterized random samples from the general population.

Methods: Adults aged >40 and living in Reykjavik, Iceland (n=939) and Uppsala, Sweden (n=996), were invited (www.boldstudy.org). Response rates 81, 15% and 62, 2%. In addition, the participants were asked to answer The Epworth Sleepiness Scale (ESS). Short Form-12 and standardised questions about sleep and health, diabetes and hypertension.

Results: In Reykjavik mean (± SD) ESS was 6.0±3.9, compared to 6.1±3.9 in Uppsala. The prevalence of EDS, defined as ESS scores >10, were 18.5% in Uppsala and 18.4% in Reykjavik. EDS was more common among men than women and was more prevalent in age groups >60 years (p<0.001) but not related to body mass index (BMI) or smoking status. Those reporting habitual snoring and apneas scored higher on ESS (p<0.001) and so did also those with respiratory symptoms; wheeze and breathlessness (p<0.05), cough (p<0.001), asthma (p<0.01) and nasal allergy (p<0.02). There were no difference in EDS depending on insomnia, diabetes or hypertension. Mental health scores on SF-12 were significantly lower among those with EDS (p<0.05). There was no difference regarding physical health scores.

Conclusion: Excessive daytime sleepiness is a common complaint in the general population both in Iceland and Sweden. It’s more common among men than women among those who more and have apneas. It is also related to respiratory symptoms, allergy and decreased mental quality of live.
P3855
Gastroesophageal reflux in patients with obstructive sleep apnea syndrome; Value of isolated treatment with pantoprazole
Aliaz Mohmed Hussein, Mohannad Kobasy, Mohannad-Elhater Ibrahim
Chest, Assiut University Hospitals, Assiut, Egypt Internal Medicine, Assiut University Hospitals, Assiut, Egypt Gastroenterology and Hepatology, Assiut University Hospitals, Assiut, Egypt

Objective: To test the value of treatment of gastroesophageal reflux disease (GERD) in improving the obstructive sleep apnea syndrome (OSAS).

Patients and methods: The study included 63 patients diagnosed with OSAS after complete history taking, Ewpoth sleepiness score (ESS), physical examination, and full night polysomnography. Of them 29 patients were diagnosed with concomitant GERD by standardized Reflux Disease Questionnaire (RDQ), upper endoscopy, and 24-hour pH monitoring and receiving Pantoprazole 40 mg once daily for 2 months. The patients were reevaluated by polysomnography, ESS, quality of life SF36 v2 questionnaire.

Results: The twenty- nine patients with OSAS and GERD had significantly higher body mass index (BMI), waist circumference, and reported non significant increase in sleep and daytime symptoms of OSAS. After 2 months treatment with Pantoprazole, there was significant decrease in apnea hypopnea index (AHI), snoring events, arousal index, and ESS. Meanwhile, there was a significant improvement in sleep efficiency, minimum O2 saturation, desaturation index and quality of life parameters (SF 36 v2).

Conclusions: GERD and OSAS are common co morbid conditions. Adequate treatment of GERD with Pantoprazole, 40 mg/day for 2 months was effective in improving many subjective and objective findings of OSAS. In patients with OSAS and history suggestive of GERD, upper endoscopy, pH monitoring and treatment with proton pump inhibitors (PPIs) may be an important adjunct in controlling OSAS symptoms.

P3856
Potential Impact of the economic crisis: Experience of a sleep clinic in northern Greece
Ahmadis Petrou, Nicolaou Charovuzis, Katalina Fekete Passa, Assimina Papalda, Afroditi Boutou, Georgia Pitsiou, Vasilios Bagalas, Ioannis Stanopoulos, Paraskevi Argyropoulou, Respiratory Failure Unit, G. Papamikhalou Hospital, Aristotle University, Thessaloniki, Greece

Greece has entered a long period of economic crisis with adverse effects on various aspects of daily life. From 2009, poor countries with International Monetary Fund loans displace aid from public health and report negative effects on community health. A transversal study was to evaluate the impact of the economic crisis on the population visiting a sleep clinic of a tertiary hospital between years 2008 and 2011.

Methods: Comparison of the number of patients, anthropometric data, symptoms and treatment acceptance between 2008 (beginning of crisis) to 2011 (great impact of crisis on salaries, psychology).

Results: The number of patients that visited the sleep clinic was significantly reduced in 2011 (n=127) compared with 2008 (n=463) and 2009 (n=445). The age, BMI and ESS did not differ between the years (mean 52.23 ±13.7 years, 33.67±4kg/m2, and 14.11±5.4 respectively). The main symptom of the patients was daytime sleepiness and the symptoms that were worse in 2011 compared with 2008 were headache (32.4% vs. 49.6%, p<0.001) and nightmares (44% vs. 75.9%, p<0.001). In 2008, 320 (69.1%) patients required treatment for Obstructive Sleep Apnea Syndrome with CPAP and 261(81.5%) of them received CPAP. In 2011, 111 (87.4%) required treatment, but only 68% received CPAP.

Conclusions: By the observation of the population visiting a Sleep Clinic, the economic crisis can be reflected in the number of patients, their symptoms and their perspective in treatment options.

P3857
The frequency of REM related OSA among patients with mild OSA and the relation between apnea and daytime sleepiness among these patients
Hajee Khatib Ozergil, Mohannad Emir Akkoysunlu, Fınar Bostanlı, Mehmet Bayram, Fatmiracar Karakoç, Murat Sezer, Levent Kart. Pulmonology, Bismiadem Vakif University Medical Faculty, Istanbul, Turkey

Aim: The question if REM related OSA is a specific clinical entity or if it is an early sign of severe sleep disordered breathing as there is high occurrence of REM OSA in mild and moderate cases, recently have attracted the investigators. In this study, we aimed to see the frequency of REM related OSA among patients with mild OSA; and also to evaluate relation between apnea and daytime sleepiness among REM related OSA patients.

Methods: 134 patients with mild OSA (RDI<5-15) among 1267 patients with PSG examination at sleep laboratory of Bismiadem University Hospital between August 2010 and February 2012 were retrospectively evaluated. Patients having REM apnea/Non REM apnea >2 and Non REM apnea <15 are considered as REM related OSA.

Results: 80 of 134 (5.95) patients with mild OSA were considered as REM related OSA. When REM related OSA and Non-REM OSA are compared for age, gender, daytime sleepiness, BMI, neck surround and additional diseases; mean age with REM related OSA group was found only significantly lower. Number of apnea in REM was over 15 at 87.3% of REM related OSA group and over 30 at 39.3% of them. There was no relation between apnea number at REM and daytime sleepiness system (p=0.81).

Conclusion: We may consider the result of lower mean age in REM related OSA group as a supporting result for early sign of severe sleep disordered breathing. We consider to follow up this group of patients to answer the question about subject.
Sixty OSA patients were recruited either into an intervention (n=30) or control group (n=30). Assessments occurred at week 0, week 13 and week 26. The intervention involved supervised exercise sessions, dietary advice and behaviour change counselling between weeks 0 and 13. Changes in body habitus and walking capacity (ISWD) between week 0, 13 and 26 were assessed using a mixed-design factorial ANOVA and 95% confidence intervals (CIs) of the net change in groups over time. At 13 weeks, the intervention group improved body mass (-1.7kg; P=0.001) and body fat percentage (-1.1%; P=0.001) relative to the control group, although CIs between groups over time indicate changes were not clinically important. Changes in resting heart rate (-6 [ -9, -2]) beats min^{-1}; P=0.002) and ISWD (+95 [52, 130] mm; P<0.001) were possibly beneficial. At follow-up, changes in resting heart rate were likely trivial (-3 [ -8, -1]); beats min^{-1}; P=0.250) although ISWD was probably beneficial (+110 [71, 149] m; P<0.001).

These data suggest that a change towards exercise behaviour has occurred. Interventions have potential as part of the holistic management of obese OSA patients compliant with CPAP.

Usefulness of SD-101 for screening of sleep apnea syndrome

Nobuko Hazuki1, Kazuyuki Kobayashi1, Yumiko Ishikawa1, Akane Morimoto2, Yoshitomo Nishimura3, Division of Respiratory Medicine, Dept of Internal Medicine, Kobe University Hospital, Kobe, Japan; Department of Clinical Laboratory, Dept of Medical Technology, Kobe University Hospital, Kobe, Japan

Objectives: The SD-101 is a sheet-like device for screening of sleep apnea syndrome (SAS). It examines sleep disordered breathing by sensing the alterations of body loading corresponding to respiratory movement. Polysomnography (PSG) is the essential monitor for the diagnosis of SAS. However, PSG is not suitable for screening device for all people suspected of SAS. A simple and easy device is needed for screening of many SAS patients. For evaluation of the usefulness of SD-101 in more detail, the accuracies of SD-101 was examined about detection of hypopnea and apnea.

Subjects and methods: Forty four hospitalized patients were enrolled (aged 61.0±13.8, 37 males, Body mass index (BMI) 26.0±4.9kg/m²). They were examined by both PSG and SD-101. They were classified into two group, hypopnea group (Group H, 17 patients) and apnea group (Group A, 27 patients). Group H had hypopnea index accounted for more than 50% of Apnea Hypopnea Index (AHI). Group A had apnea index accounted for more than 50% and equal of AHI.

We evaluated correlation between AHI of PSG with respiratory disturbance index (RDI) of SD-101 in each group.

Result: RDI of SD-101 had very close correlation with AHI of PSG (r 0.886 p<0.001). The sensitivity and specificity of the examination using SD-101 were 80% and 100%, respectively. RDI of SD-101 in Group H had lower correlation with AHI of PSG than RDI of SD-101 in Group A. Group H (r 0.548 p<0.05), Group A (r 0.886 p<0.001). The sensitivity of Group H (66.6%) was lower than that of Group A (88.0%).

Conclusion: RDI of SD-101 has very close correlation with AHI of PSG, however SD-101 may not detect hypopnea exactly in hypopnea predominant patients.

P3864

Effect of CPAP treatment on blood pressure levels in resistant hypertension.

A multicenter randomized study from the Spanish sleep network (NCT00616265)

Miguel Angel Martinez-Garcia1, Francesco Capote2, Francisco Campos-Rodriguez 3, Patricia Llobreter4, Maria Josefa Diaz de Atauri5, Maria Somozas6, Fernando Masa7, Monica Gonzalez8, Lirios Sicristan9, Ferran Barbé10, Joaquin Duran-Cantolla11, Jose Maria Montserrat12, on behalf of Spanish Sleep Network. 1Pneumology Unit, Villajoiosa Hospital, Alicante, Spain; 2Pneumology Service, Virgen del Rocio University Hospital, Seville, Spain; 3Pneumology Service, València University Hospital, Valencia, Spain; 4Pneumology Service, Servicio de Urgencias de Xarxa, Barcelona, Spain; 5Pneumology Service, Vall Hebrón University Hospital, Barcelona, Spain; 6Pneumology Service, La Fe University Hospital, Valencia, Spain; 7Pneumology Service, Hospital Clinic, Barcelona, Spain; 8Pneumology Service, Raval University Hospital, Barcelona, Spain; 9Pneumology Service, Sant Pau Hospital, Barcelona, Spain; 10Pneumology Service, Geriatric Tarragona, Tarragona, Spain; 11Pneumology Service, Fundació Sant Pau, Barcelona, Spain; 12Pneumology Service, Herrera de Pineda University Hospital, Barcelona, Spain

Background: Only very few small studies have analyzed the role of CPAP treatment on blood pressure (BP) levels in patients with resistant hypertension (RH).

Objective: To evaluate the effect of CPAP treatment on BP levels in patients with RH
Conclusions: Sleep apnea severity was associated with increased cancer mortality. [1.08 to 6.06], p=0.032. When stratified by gender and age (cut-off 65 years), only al-220mor SBP (-7.5 mmHg; p < 0.001). There is a positive correlation between the increase used of CPAP in hours/and the decrease in BP levels (n=0.25; p=0.014). 28% of patients in CPAP group vs 17.5% in control group normalized their BP levels; p=0.045). More patients in CPAP group significantly recovered their dipper pattern, compared with control group (p=0.088).

Conclusions: CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.

Conclusions: Sleep apnea syndrome and cancer mortality. Longitudinal multicenter study in 5,467 patients from the Spanish cohort Association between sleep apnoea and cancer mortality. Longitudinal P3865 CPAP treatment significantly decrease SBP and DBP levels and allowed the recovering of normal dipper pattern in patients with RH and sleep apnea. The magnitude of these effects correlate with the number of hours CPAP use.
Obstructive sleep apnea (OSA) is a sleep disorder characterized by recurrent episodes of upper airway obstruction and interruption of airflow. It is well known that it is associated with severe OSAS. However, the analysis of different parts of the night and of the evolution within sleep stages in OSA patients has not yet been investigated.

Objectives: Evaluate and compare HRV in 3 stages of each sleep stage in overnight polysomnographies in OSA and matched healthy controls. We studied overnight polysomnographies of 6 untreated OSA patients (mean age 50±14 yr, apnea-hypopnea index [AHI] = 9.4±6 events per hour) and 6 matched healthy controls. Time and time-domain analysis of R-R intervals (RRi) was performed for the minimum of the central 5-minute sample of stage II, III and REM sleep that was free of stage shifts, artifacts, arousals and apneas. Subsequently, we analyzed the evolution of these stages between OSA and controls.

Results: Comparing the 3 parts of each stage, we did not observe any difference intragroup (P>0.05). In addition, we only observed significant difference of RMSSD index between OSA and controls (P<0.0001) in the first REM stage. In contrast, when compared the average of 3 central 5-minute samples, we observed significant differences of mean RRi, RR tri index, TINN (ms), SD1 and SD2 between OSA and controls (P<0.05) in all stages.

Conclusions: The preliminary results show that despite of any change in the HRV evolution through 3 intervals of each stage, the number of samples analyzed during the night may influence the results of HRV in overnight polysomnography. Financial support: FAPESP

P3871 Diabetes mellitus and obstructive sleep apnea syndrome in primary care Gustavo Cimbra dos Reis1, Vânia Sacramento1, Vitor Fonseca1, Carlos Alves1, Inês Ferro1, Marta Guedes2, Patricia Quintas1, Rita Marques3, José Cabrita4, António Pinto Saravia5, Serviço de Pneumologia, CHIBM, EPE, Barreiro, Portugal; 2LINDE, LINDE, Lisbon, Portugal; 3UF, Quinta da Lomba, Barreiro, Portugal

Introduction: Obstructive Sleep Apnea Syndrome (OSAS) is a risk factor for insulin resistance and type 2 Diabetes Mellitus and its prevalence is higher on these. An adequate screening instrument for primary care units would be valuable.

Objectives: To evaluate Epworth Scale (ES) and Berlin Questionnaire (BQ), as screening tools of OSAS in a diabetic population of a primary care unit.

Methods: This response could be a protective mechanism against tissue hypoxia caused by repeated episodes of hypoxemia.

Results: Of the 24 patients studied, 18 were diagnosed from OSA (AHI>10) with a mean AHI of 26.2±9.7. Of these, 16 were highly symptomatic (ESSAPS, p<0.05). Of the 24 patients studied, 18 were diagnosed from OSA (AHI>10) with a mean AHI of 26.2±9.7. Of these, 16 were highly symptomatic (ESSAPS, p<0.05). Of the 24 patients studied, 18 were diagnosed from OSA (AHI>10) with a mean AHI of 26.2±9.7. Of these, 16 were highly symptomatic (ESSAPS, p<0.05). Cardiovascular regulation effects of CPAP therapy in obstructive sleep apnea patients with and without hypertension during daytime
Thomas Frentz1, Christoph Schoebel1, Carmen Garcia1, Martin Gloß1, Niels Wessel1, Ingo Fietze1, Sleep Medicine Center, Charité Universitätsmedizin Berlin, Berlin, Germany; 2Cardiovascular Physics, Department for Physics, Humboldt Universität Berlin, Berlin, Germany

Obstructive sleep apnea can cause changes in cardiovascular regulation during the night and during daytime. Altered regulation may not be visible in absolute values of heart rate and blood pressure but in a changed coupling between the heart beat and the respiration. In a controlled randomized study we investigated effects of CPAP therapy on daytime cardiovascular regulation.

Twenty-eight patients with OSA in total, thereof 18 with arterial hypertension and 10 with normal blood pressure, were studied at baseline and at a follow up date with three months of CPAP. The age and sex matched healthy control subjects were investigated using the same protocol. All subjects underwent cardiopulmonary coupling analysis. In addition we recorded 20 minutes quiet breathing at rest and a bicylce ergometry with ECG and blood pressure (Portapres). Cardiorespiratory coupling was investigated using symbolic coupling, new developed technique which can reveal causality between signals.

The stress test showed a significant reduction of the diastolic blood pressure at a work load of 50W and 100W (p<0.05 and p<0.01, respectively) and a decrease of the heart rate recovery time after the stress test (p<0.05).

The results indicate a reduction of vascular resistance and sympathetic activity during daytime. The coupling analysis of the resting periods by means of symbolic coupling analysis showed an effect of the CPAP therapy on the baroreflex reaction in hypertensive patients where influences of the systolic blood pressure on the heart rate changed from pathological patterns to adaptive mechanisms of the normotensive patients (p<0.05).

P3876
Increased risk of obstructive sleep apnea in patients with non-alcoholic fatty liver disease
Sarah Woschitz1, Julia Newton1, Chris Day2, John Gibson3, Sophie West1
1Department of Respiratory and Sleep Medicine, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; 2Institute for Ageing and Health, University of Newcastle, Newcastle upon Tyne, United Kingdom

Background: Increasing prevalence of Obstructive Sleep Apnoea (OSA) and Non-alcoholic Fatty Liver Disease (NAFLD) are linked through the epidemic of obesity and are both associated with increased cardiovascular risk. Studies have shown higher prevalence of NAFLD in OSA patients, but the impact of NAFLD on OSA remains to be determined.

Aims: To determine whether those with NAFLD had different clinical or biochemical characteristics to the rest of the cohort.

Methods: We conducted a retrospective database and case note review of patients with known NAFLD. The database was reviewed for detailed liver investigations and notes examined for any clinical referral for sleep investigations and outcome.

Results: Liver database and case notes of 385 patients with biopsy proven NAFLD were examined. Forty-seven patients were referred to sleep services on clinical grounds (12%). 38 were found to have OSA, 10% of the whole cohort but 86% of those referred. Analysis of variance showed no difference between groups (those with NAFLD, those without NAFLD and those with no previous sleep investigations) in: baseline liver function, diabetes, body mass index, liver biopsy scores or any characteristics to the rest of the cohort.

Conclusions: In a well-defined population of biopsy-proven NAFLD patients, OSA is common and mostly undiagnosed. There are no differences in the clinical characteristics of those referred for sleep studies and those not, other than ESS.

Aims and objectives: To evaluate the indices of quality of life after PE depending on sex and age and to determine their dynamics under the influence of warfarin.

Methods: Assessment of indices of quality of life was done in 80 patients who had survived PE during their hospital stay and out-patient treatment using the questionnaire MOS SF-36.

Results: Patients of both sexes taking warfarin after PE showed better indices of physical status (PS), psychic status (Pc), general status (GS) during out-patient treatment than during their hospital stay. Females had lower indices of quality of life than males both on the in-patient and out-patient stages of treatment.

Conclusions: Patients aged 45-60 years and over 60 taking warfarin after PE demonstrated significantly higher indices of PS, Pc and GS than those who did not take warfarin.

P3878
Thrombophilias in 60 Bulgarian patients with “idiopathic” venous thromboembolism
Natalia Stoeva1, Milena Staneva2, 1Pulmonary Department, Tokuda Hospital, Sofia, Bulgaria; 2Department of Vascular Surgery and angiology, Tokuda Hospital, Sofia, Bulgaria

In the last two decades, many inherited and acquired thrombophilias predisposing venous thromboembolism (VTE) have been known. The aim of this real life study is to analyze the frequencies of some thrombophilias in patients with acute VTE, in whom no underlying diseases or triggering-VTE factors are present ("idiopathic" VTE). 60 ethnic Bulgarians (34 men and 26 women, mean age 34.47) with VTE (39 with deep vein thrombosis (DVT) only, 12 with pulmonary PE (PE) only and 9 with both) were examined for: Leiden mutation (FVL), prothrombin factor II mutation (G20210A), plasminogen activator inhibitor-1 mutation (PAI-1), C677T and A1298C of methylenetetrahydrofolate reductase (MTHFR) mutations; deficiency of protein C (PC), deficiency of protein S (PS), deficiency of antithrombin III (AT III) and antiphospholipid antibodies syndrome (APL).

In 48 (80%) of patients (79.48% in DVT, 80.95% in PE patients) were found in total 79 abnormalities. VFTL heterogenous mutation was found in 15 (25% of all patients) and homogenous in 2 (3.3%) patients. FVL presents 21.51% of all abnormalities. PAI-1 was on the 17th place with 11% abnormalities. 11 (18.3%) were homogenous and 6 (10%) were heterogeneous in combination with other abnormalities. 6 (10%) had G20210A mutation and 14 (23%) deficiency of AT III. We also found deficiency of Pr.S in 6, Pr.C in 3; mutations C677T in 4, A1298T in 7 patients. APL was found in 5 patients.

We conclude that most of the patients with "idiopathic" VTE have one or more thrombophilias. In addition to the known role of FVL, as a thrombophilic factor, the PAI-1 mutation presents a prominent frequency in our group.

P3879
The treatment of sub massive pulmonary embolism: Thrombolytic or heparin?
Gulker Okumuş1, Mehmet Ertas1, Zuleyha Bingöl1, Eser Kiyon1, Ahmet Kaya Bilgel2, Halim Issiever1, Örhan Arseven1, 1Pulmonary Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey, 2Cardiology Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey; 3Public Health Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey

Introduction: Thrombolytic therapy (TT) decreases mortality and morbidity in the patients with massive pulmonary embolism (PE) when compared to heparin therapy. However the use of TT in patients with sub-massive PE remains controversial.

The aim of these studies is to compare the efficiency of heparin and TT for sub-massive PE.

Material and method: Patients with sub-massive PE who were treated during the last five years were included in this study. Patients who have significant hypoxemia or expansive thrombosis or proximal DVT were given TT and the others were given heparin. These groups were compared for demographics, risk factors and echocardiography findings (72nd hour, 6th and 12th month).

Results: Totally 39 patients (20 female, 19 male) were included. The mean age was 57years, the mean duration of follow up was 3.5 years. There was no difference for age, gender, risk factors between TT (n=20) and heparin (n=19) groups. Mean pulmonary arterial pressure (PAP) was 49mmHg in heparin group and 56mmHg in TT group. PAP at 72nd hour was significantly lower in TT group than the heparin group (p<0.001). PAP at 6th and 12th months were still lower in TT group than heparin group but it was not statistically significant. There was no mortality or major bleeding due to the TT or heparin.

Conclusion: As a result of our study TT decreases PAP significantly at 72nd hour in the patients with sub-massive PE so that TT could be the first choice therapy for these patients.
Dear colleagues: D-dimer is not always necessary – Reduce the cost of your hospital!

PE treatment strategies.
patients with a low sPESI but it no adds prognostic information. Risk stratification
In conclusion, cardiac troponin testing may not be required for the minority of
outcome in the study.
cTnT
point(s) had a higher sensitivity, and a higher negative predictive value than the
patients with sPESI
≥
76 patients (62.8%) to the high-risk category (18 (14.9%) advers events within 30 days diagnosis of PE. The sPESI classified
cause or nonfatal recurrent venous thromboembolism or nonfatal major bleeding.
Discussion: The cost of D-dimer for 1 patient in Albania is $12.6, for 150 patients is $1800.6. Is evident: in 12% of cases D-dimer was negative in patients with confirmed PE. In the other group, the clinical data and high score clinical probability are sufficient as an indication for the angio-CT. So, further laboratory examinations, including D-dimer may be avoided, especially in developing countries, where the cost of these tests is high for the hospitals. D-dimer is necessary in low and medium clinical probability cases.
Conclusion: In patients with high risk factors and a clear anamnesis of PE, D-dimer is not necessary. Avoiding it may reduce the hospital expenses.

P3881
Prognostic role of cardiac troponins and simplified pulmonary embolism severity index in patients with normotensive pulmonary embolism
Sazan Oguz1, Yasin Abugay1, Asim Orem2, Funda Oztuna1, Yilmaz Bulbul1, Husseyin Yaman2, Terefi Ozlu1. 1Department of Pulmonary, Karadeniz; Technical University Faculty of Medicine, Trabzon, Turkey; 2Department of Biochemistry, Karadeniz; Technical University Faculty of Medicine, Trabzon, Turkey

The new, high-sensitivity troponin T (hsTnT) assay may improve risk stratification of nonemergency patients with acute pulmonary embolism (PE). Simplified Pulmonary Embolism Severity Index (sPESI) has shown prognostic accuracy. We aimed to investigate whether risk stratification by cardiac troponin testing improves the prediction of clinical outcomes in patients with a sPESI. The primary endpoint of the study was adverse 30-day outcome, defined as death from any cause or nonfatal recurrent venous thromboembolism or nonfatal major bleeding. A total of 18 (14.9%) adverse events were observed within 30 days following the diagnosis of PE. The sPESI classified 76 patients (62.8%) into the high-risk category (≥ 1 point). Of patients with low sPESI, hsTnT >0.014 pg/mL was positive in 14/53 (26.6%) patients. hsTnT and D-dimer cTnT <0.014 had occurred non-fatal hemorrhage in a patient. The adverse event rate rose from 0% in patients with sPESI ≥ 1 or positive hsTnT, and further to 14% in those with hsTnT ≥0.014 pg/mL + sPESI ≥1. The adverse event rate rose from 1.6% in patients with sPESI ≥ 1 or positive cTnT and further to 12.4% in those with cTnT ≥0.014 pg/mL + sPESI ≥1. The adverse event rate rose from 0.6% in patients with hsTnT ≥0.014 pg/mL and sPESI ≥1. The adverse event rate rose from 1.6% in patients with sPESI ≥ 1 or positive hsTnT, and further to 14.2% in those with cTnT ≥0.014 pg/mL + sPESI ≥1. Of the 121 study patients, the hsTnT≥0.014 pg/mL + sPESI ≥1 points) had a higher sensitivity, and a higher negative predictive value than the cTnT≥0.014 pg/mL + sPESI ≥1 point(s) combinatorial model for predicting 30-day adverse outcome in the study.
In conclusion, cardiac troponin testing may not be required for the minority of patients with a low sPESI but it adds prognostic information. Risk stratification with the combination of sPESI and cardiac troponin may also serve for aggressive PE treatment strategies.

P3882
Wells clinical prediction rule and pulmonary embolism rule out criteria (PERC) in preventing over investigation of pulmonary embolism in emergency departments
Miagre Aydogdu1, Nazli Topbası Sinanoglu1, Nurettin Ozgur Dogan1, Ipek Kivlicik Oguzaln1, Ahmet Demircan2, Fikret Bildik1, Numan Ekim1.
1Pulmonary Diseases, Gaziantep University Medical Faculty, Ankara, Turkey; 2Emergency Department, Gaziantep University Medical Faculty, Ankara, Turkey.

Background: On the worse outcomes of missed diagnosis of pulmonary embolism (PE), unnecessary diagnostic tests are usually ordered to most of the patients with dyspnea or pleural chest pain.
Aims: To identify rates and causes of overinvestigation for PE in our emergency department (ED) and to search whether it was possible to reduce this overinvestigation by using Wells score and Pulmonary Embolism Rule Out Criteria (PERC) in daily practice.
Methods: A retrospective observational cohort study performed in an ED of a tertiary care university hospital. 108 patients, who had diagnostic tests with the suspicion of PE, were included in the study.
Results: Among the whole study group, 53 (49%) were diagnosed as PE (+) and overdiagnosis was present in 55 (51%) patients i.e., PE (-). The sensitivity of high Wells score was 43%, specificity 78%, positive predictive value 66% and negative predictive value 59% for PE diagnosis. PERC criteria found to be negative (when all of the 8 criteria were fulfilled) in only 5 (15%) patients. The sensitivity of the test was 98%, specificity 7%, positive predictive value 5/50, negative predictive value 98.0. When individual parameters of PERC were evaluated solely for the exclusion of PE, “no leg swelling” and “no leg swelling” were found significantly negatively correlated with the diagnosis of PE (p<0.01, r=-0.325 and p<0.013, r=-0.214 respectively)
Conclusion: Over investigation of PE in EDs still remains as an important problem. In order to prevent this, the clinical prediction rules must be developed further or may be used in combination.

P3883
Predictors of poor outcome in chronic thromboembolic pulmonary hypertension
Congyou Liu1, Zhenguo Zhai1, Yuanhua Yang1, Tuguang Kuang1, Wannna Xie1, Chen Wang2, 1Respiratory and Critical-care Medicine, Beijing Institute of Respiratory,Medicine, Beijing, China; 2Respiratory and Critical-care Medicine, Beijing Hospital, Beijing, China.

Background: Clinical and plasma biomarkers are essential to predict the outcome of pulmonary arterial hypertension (PAH). These markers might also be useful to evaluate the outcome of chronic thromboembolic pulmonary hypertension (CTEPH).
Objective: Assess the cumulative mortality and identify predictors of the patients with CTEPH.
Methods: 108 patients with CTEPH who registered in Beijing chaoqyang hospital between January 2006 and October 2011 were analyzed. The primary endpoint is death, and the second endpoint is worsening WHO functional class.
Results: During the follow-up period (4-58 months), 11 patients died (10.2%), meanwhile WHO functional class of 4 patients was worsened (3.7%). The 1-, 3-year survival rates were respectively 95.1% and 82.1%. BMI (HR 0.708; 95% CI 0.677 to 0.941; P=0.007), leukocyte(HR 1.346; 95% CI 1.145 to 1.582;P<0.001), ESR(HR 1.043; 95% CI 1.010 to 1.077;P=0.011), cardiac output(CO) (HR 0.484; 95% CI 0.243 to 0.962;P=0.039), pulmonary vascular resistance (PVR) (HR 1.002; 95% CI 1.001 to 1.003;P=0.001) were independent predictors for poor prognosis of CTEPH patients. Meanwhile 54 patients with PAH were enrolled, and the 1-, 3-year survival rates of PAH patients were 78.8% and 59.4% respectively.

P3884
Daytime measurements underestimate nocturnal oxygen desaturations in pulmonary arterial and chronic thromboembolic pulmonary hypertension
Florian Hildenbrand, Konrad E. Bloch, Rudolf Speich, Silvia Ulrich, Heart-Vessel Thorax, University Hospital, Zurich, Switzerland.

Background: Nocturnal hypoxemia is important in precapillary pulmonary hypertension (pPH) as it worsens pulmonary hemodynamics. Whether daytime oxygen saturation (SpO2) predicts nocturnal hypoxemia in pPH patients has not been conclusively studied. Therefore, we investigated the prevalence of nocturnal hypoxemia in ambulatory pPH patients in comparison to daytime SpO2 and disease severity.
Methods: Consecutive patients diagnosed with pPH classified as either pulmonary arterial (PAH) or chronic thromboembolic pPH (CTEPH) had daytime resting and exercice SpO2 (at the end of 6-minute walk), thereafter they underwent
overnight pulse oximetry at home. Functional class, pro-BNP and tricuspid pressure gradient were assessed.

Results: 63 patients (mean age±SD 66±15.43 females) with PAH (414 and CTEPH (194). The resting SpO2, exercise SpO2 and mean nocturnal SpO2 were 94±3, 87±9 and 89±6.4%. 49 patients (77%) spent >10% of the night with SpO2 <90% (sustainers), 33 (52%) spent >50% of the night with SpO2 <90% (sustainers desaturators). The positive predictive values of a daytime SpO2 <91% to predict nocturnal desaturation or sustained desaturation were 75.3% and 47%. Nocturnal SpO2 was negatively correlated with the tricuspid pressure gradient, but not with functional class, 4MW and pro-BNP.

Conclusion: Nocturnal hypoxemia is very common in PAH and CTEPH despite often normal daytime SP02 and reflects disease severity. Nocturnal pulse oximetry should be considered in routine evaluation of PAH patients and research be directed to the treatment of nocturnal desaturation in PH.

P3885
The PESI, the simplified PESI and the shock index for identification of high-risk and low-risk patients with acute pulmonary embolism

Burcu Koyden 1, Fuun Alatai 2, Selma Meritanc 2 (Chest Disease, Osmangazi University, Medical Faculty, Eskisehir, Turkey); 1Public Health, Osmangazi University, Medical Faculty, Eskisehir, Turkey

We compared the test characteristics of the pulmonary embolism severity index (PESI), the simplified pulmonary embolism severity index (sPESI) and shock index (SI) for predicting 30-day outcomes in a prospective study of 132 patients with objectively confirmed pulmonary embolism (PE). The primary outcome of the study was 30-day mortality.

Overall, 13 (9.8%) out of 132 patients died during the first month. The SI classified fewer low-risk patients (41, 31.1%) out of 132 patients, compared to sPESI (45, 34.1%) and compared to PESI (57, 43.2%). High-risk patients based on the SI had a higher mortality than those based on the sPESI and PESI (31.7%, versus 22.2% and 20.6%). Low-risk patients based on the SI had a lower mortality than those based on sPESI and PESI (0% versus 3.4% and 4%).

The SI quantified the prognosis of patients with PE better than sPESI and PESI.

P3886
Analysis of the association between protein C gene single nucleotide polymorphism and pulmonary thromboembolism in Chinese population

Yuje Zhang 1, Yafang Miao 1, Kebing Cheng 2, Xiaoyue Tan 1, Jinming Liu 1 (1Department of Pulmonary Function Test, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Department of Respiratory Medicine, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China)

Background: We investigated the role of protein C (PC) polymorphism in patients with PTE in order to find out the correlation between its polymorphism and the susceptibility of the Chinese population to develop PTE.

Methods: Sixty three consecutive patients with PTE were enrolled as the investigated group and eighty six healthy people as the control group. CT at the position of 2405 and A/G at the position of 2418 in the PC gene promoter region were detected through polymerase chain reaction-restriction fragment length polymorphism analysis.

Results: (1) The results suggested that the genotype frequencies of the two SNPs when combined together were not significantly different between two group (P>0.05). However, the allele frequency of the C2405T SNP was significantly different between the case and control group. The frequency of T allele in the PTE group was higher. (2) These results suggested that there were six different kinds of genotype distribution (TA - TA, TA - CA, TA - CG, TG - CG, CA - CG, CA - CA) and three different kinds of haplotype (TA, CG, CA).

Conclusions: These results suggest that the two polymorphisms present in the control region of PC gene are associated with an increased susceptibility to PTE in the Chinese population.

P3887
Venous thromboembolism in lung cancer with clinical analysis of 89 cases

Ren Zhu 1, Jinming Liu 1 (1Department of Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Department of Respiratory Medicine, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China)

Objective: The aim of this study was to investigate the associated clinical factors and to provide evidences for prevention and therapies of VTE in lung cancer patients.

Methods: We retrospectively reviewed the clinical data of 2,053 lung cancer patients with definite diagnosis by cytology or pathology between July 2008 and June 2010 at Shanghai Pulmonary Hospital. In 2,053 lung cancer patients, 89 were confirmed with VTE. The incidence rate of VTE in adenocarcinoma patients and non-adenocarcinoma patients was 5.65% and 3.02%. The incidence rate of VTE in Stages I-IIIa lung cancer patients was significantly decrease (1.48%) in comparison to that in stage IIb-IV patients (5.74%). Significant difference of incidence rate of VTE was showed in the patients with or without comorbidities (2.70% and 6.73%; P<0.01). The incidence rate of VTE in pretherapy lung cancer patients with normal value of platelet count, D-dimer, IL-1 and TNF was 3.72% (0.31%, 2.44%, 3.27%, respectively, whereas, the rate in pretherapy lung cancer patients with high value was 6.26% (5.91%, 10.26%, 7% respectively) (P<0.05). There were no relations between other clinical factors and the incidence of VTE. Logistic analysis showed adenocarcinoma, comorbidities, high value of D-dimer, IL-1, TNF in blood were the related important factors with increased VTE incidence.

Conclusions: Adenocarcinoma is the most common pathological type in lung cancer patients with VTE. The high risk factors of VTE include comorbidities and increase of D-dimer, IL-1 and TNF in blood. Close attention should be paid to those lung cancer patients with high risk factors of VTE.

P3888
Pulmonary perfusion scan follow-up in patients with acute pulmonary embolism

Liliana Villan 1, Roberta Pancani 1, Elena Marianti 1, Ferruccio Aquilini 1, Carlo Marin 1, Alessandro Cell 1, Antonio Palla 1, Cardio-Toracico, Pneumologia Ospedaliera, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy; 2Pneumologia, Fondazione Regionale Toscana Gabriele Monasterio, Pisa, Italy; 3Cardio-Toracico, Pneumologia Universitaria, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy

Introduction: The role of pulmonary perfusion scan in the follow-up of pulmonary embolism (PE) is not clearly known

Aim: To assess the evolution of pulmonary perfusion after a symptomatic acute PE without high-risk and the role of persisting perfusion defects in assessing the risk of recurrent PE.

Methods: A retrospective analysis (April 2005-May 2010) of patients with symptomatic acute PE for whom a pulmonary perfusion scan follow-up of at least 6 months was available. All scans were read independently by 2 readers whose agreement was calculated by kappa test. Recurrent PE was diagnosed on the basis of the presence of segmental perfusion defects not present at the previous control.

Result: The analysis refers to 252 patients, aged 69±15 years (mean ± SD).

The kappa index ranged from 0.84 to 0.98 for the different times. The number of unperfused segments decreased from 5.8±2.8 (baseline) to 2.1±2.0 (6 months, p<0.0001) to 1.7±1.8 (12 months, ns; ANOVA).

After a month from the diagnosis there were 16 recurrences; the number of unperfused segments at the last scan available prior to recurrence did not differ significantly from the number measured at the standard 6 months control in patients without recurrent PE.

Conclusion: After 6 months from acute PE there is a significant reduction in the number of unperfused segments which does not change significantly afterwards. The persistence of perfusion defects is not predictive for the development of later recurrent PE.

P3889
(Contributing factors to) the diagnostic yield of CT pulmonary angiography: A retrospective study

Minko Alex Lejauna 1, Stefan Waler 1, Steven M. Ull 1, Marijnn F. Boomsma 1, Jan Willem K. van den Berg 1, 1Department of Pulmonary Diseases, Isala Klinieken, Zwolle; 2Department of Radiology, Isala Klinieken, Zwolle, Netherlands

Introduction: Pulmonary embolism (PE) is a potentially life-threatening disease which requires quick and reliable diagnosis to start timely treatment. Clinical probability of pulmonary embolism is assessed by using a combination of Wells-score and D-dimer level. In most cases of PE, CT of pulmonary arteries (CTPA) provides a reliable diagnosis. In the Isala klinieken approximately 1000 CTPAs are performed annually, but its diagnostic yield and factors associated with improving it are unknown. In literature diagnostic yield varies from 73.1%.

Aims: To determine diagnostic yield of CTPA in our centre and factors associated with it. Differences between specialities as well as adherence to protocol were investigated.

Methods: All patients receiving a first CTPA for pulmonary embolism in 2010 were included. Data about relevant clinical information and requesting specialty were retrospectively obtained. Differences in diagnostic yield were tested using a Chi-square test. Independent predictors were identified with multivariate logistic regression.

713s
Results: PE on CTPA was found in 224 of the 974 patients (23%). Between specialties, diagnostic yield varied from 19.5-23.9% (p=0.20). Independent predictors of diagnostic yield were: age, sex, D-dimer, chest pain, cough, dyspnea, cardiac history, COPD, atelectasis/consolidation, intrapulmonary mass and/or interstitial pulmonary disease on CT. Wells-scores were poorly documented (n=127, 13.1%). Poor adherence to protocol was also shown by a high amount of unnecessary D-dimer values with a high Wells-score (55 of 58; 58.6%).

Conclusions: The diagnostic yield of CTPA in this study was relatively high. Better adherence to protocol might improve it further.

P3890
Should there be an age adjusted D-dimer cut-off value in diagnosing thromboembolic disease? A retrospective analysis
David Walder, Robert Richards. Respiratory Medicine, Princess Royal University Hospital, Bromley, Kent, United Kingdom

Previous studies using the enzyme-linked immunosorbent assay (ELISA) D-dimer in pulmonary embolism have suggested that the D-dimer cut-off should be adjusted for age. (Douma et al. BMJ 2010; 340 c1475) Using a retrospective analysis from our DVT clinic we compared latex agglutination assay D-dimer values for patients without DVT in 10 year age brackets (1696 patients). There was a significant D-dimer level rise (compared to under 50 years) with advancing age.

We analysed the data from positive DVTs to look for an age adjusted D-dimer cut-off. (212 patients)

By generating receiver operating characteristics (ROC) curves we calculated 95% sensitivity D-dimer cut-off limits for the various age brackets. A clear relationship between age and D-dimer cut-off could not be shown.

Our data again showed that D-dimer level rises with advancing age. However, with our assay an age adjusted D-dimer cut-off could not be deduced without reducing sensitivity.

P3891
Prognostic value of red cell distribution width in patients with pulmonary embolism
Seyma Ozu1, Yasir Albul1, Selda Gunaydin1, Asim Oren2, Tevki Ozlu3
1Department of Chest, Karadeniz Technical University Faculty of Medicine, Turkey; 2Department of Biochemistry, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkey; 3Department of Cardiology, Medical University of Vienna, Austria

Elevated red blood cell distribution width (RDW) has been associated with adverse outcomes of heart failure and pulmonary hypertension. We speculated that a higher RDW would be independently associated with poor clinical outcomes in pulmonary embolism (PE) patients.

A total of 702 consecutive patients with acute PE were evaluated. We collected each patient’s base-line characteristics including RDW. The primary end-point was all-cause in hospital mortality. Receiver operating characteristic (ROC) analysis was performed to determine the optimal RDW cut-off levels with regard to prognosis. We used logistic regression to assess the association between factors for the time of presentation and inhospital mortality after adjusting for patient (age, clinical and laboratory variables) factors.

There was a graded increase in mortality rate with each RDW quartiles: 5.8% in quartile I (<15.6), 9.7% in quartile II (15.7-19.4), 13.1% in quartile III (19.5-22.2) and 20% in quartile IV (>22.3) (p for trends <0.001). Patients who died had higher baseline RDW values (16.1% (11.7-28.3)) vs 14.5% (10.7-32.3) p<0.001. The optimal cutoff value of RDW for predicting inhospital mortality was >15% and the negative predictive value was 93% for mortality. In multivariate regression analysis, RDW remained associated with an increased odds of death. RDW levels may provide a potential marker to predict outcome in PE patients.

P3892
Angiogenesis in chronic thromboembolic pulmonary hypertension (CTEPH)
Sherin Puthenkalam1, Adelheid Panzenbecker1, Uwe Schubert2, Johannes Jakowitch1, Klaus T. Preissner1, Robert Vossneckel1, Walter Klepetko1, Irene M. Lang1,1, 1Department of Internal Medicine II, Division of Cardiology, Medical University of Vienna, Austria; 2Medical School, Institute for Biochemistry, Justus Liebig University, Giessen, Germany; 3Department of Lung Development and Remodeling, Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany; 4Department of Surgery, Division of Cardiothoracic Surgery, Medical University of Vienna, Austria

Background: Chronic thromboembolic pulmonary hypertension (CTEPH) is characterized by organized thrombi in the pulmonary arteries leading to right heart failure and death. In a murine venous thrombosis model we were able to demonstrate that endothelial cell-specific deletion of vascular endothelial growth factor receptor 2 (VEGF-R2)/fetal liver kinase-1 leads to misguided thrombus resolution. Following the hypothesis that CTEPH is based on inadequate thrombus resolution, we studied the role of angiogenesis in CTEPH.

Methods: Fibrotic CTEPH thrombi, their red fresh portions, and unthrombosed pulmonary arteries were collected from patients undergoing pulmonary endarterectomy. Real Time PCR, immunohistochemistry, in vitro 3D angiogenesis and proliferation assays were performed.

Results: Biochemical analyses revealed that angiogenic molecules such as angiopoietin-2, VEGF, basic fibroblast growth factor and markers for endothelial cells (ECs) such as VEGF-R2, von Willebrand factor and VE cadherin were decreased in CTEPH thrombi compared with pulmonary arteries and fresh pulmonary clots. However, homogenized CTEPH thrombi promoted angiogenesis in an in vitro 3D angiogenesis assay and stimulated the proliferation of human umbilical vein ECs.

Conclusion: Angiogenic molecules are downregulated in fibrotic CTEPH thrombi compared with parent pulmonary arteries and fresh clots. However CTEPH thrombi appear to promote angiogenesis using ECs from healthy donors. Downregulation of genes involved in angiogenesis and lack of functional ECs in CTEPH thrombi may drive thrombus persistence, while the angiostimulatory effect of devascularized thrombi may attract bronchial artery collateralization in the direction of the thrombus.

P3893
Demographics, clinical characteristics, health resource utilization and cost of patients with CTEPH: Retrospective results from six European countries
Berd Schieweckt1, David Pittrow1, Dario Vizzai1, Joanna Pepe-Zaba2, Marius Hoepel3, Anja Gabriëls4, Jenny Berg1, Mirko Sikirica6,1 Life Sciences, Onpatight, Munich, Germany; 2Institute for Clinical Pharmacology, Technical University, Dresden, Germany; 3Polyclinic Umberto I, Universita La Sapienza, Rome, Italy; 4Pulmonary Vascular Diseases Unit, Papworth Hospital NHS Trust, Cambridge, United Kingdom; 5Clinic for Pulmonology, Hannover Medical School, Hanover, Germany; 6GHEOR, Bayer Pharma AG, Wuppertal, Germany; 7GHEOR, Bayer Pharma AG, Berlin, Germany

Objective: To describe demographics, treatment patterns, health resource utilization and related costs of patients with chronic thromboembolic pulmonary hypertension (CTEPH) in 6 European countries.

Methods: We reviewed medical charts from patients diagnosed with CTEPH and treated with medications for pulmonary arterial hypertension (PAH): Endothelin
receptor antagonists (ERA), PDE-5-inhibitors (PDE5i) or prostacyclin analogues (PA). Demographic and clinical characteristics, medications, and health resource utilization were retrospectively abstracted from patients’ medical records at specialized PH treatment centers from 6 European countries. Resource utilization was valued using country-specific unit costs; descriptive statistical analyses were performed.

Results: Twenty-one hospitals documented 119 CTEPH patients over 25.4 months time. Patients were inoperable (83.2%) or persistent after surgery (16.0%) with mean age 67.5 ± 12.1 years, 61% female, 6-minute walking distance 297 ± 119 meters, and NYHA class III/IV in 27/59/14%. At baseline, 59.7% patients received ERA, 34.4% PDE5i, and 5.8% PA. CTEPH patients experienced 1.8 ± 2.2 hospitalizations per year accounting for 14.8 ± 26.1 days in hospital. Annual cost of PAH-specific medication was the predominant economic factor averaging $36,768 ± 22,630 per year. Hospitalization costs ($4,490 ± $7,923) and concomitant medications ($2,510 ± $2,503) were lower. Other health care resource items accounted for marginal additional costs.

Conclusion: These data provide clinical characteristics and cost estimates for CTEPH patients receiving off-label therapy with medications that have been approved for PAH.

P3894
Clinical characteristics and outcomes of patients with clinically unsuspected pulmonary embolism versus patients with clinically suspected pulmonary embolism
Michael Shlitzer1,2, Yoshias Aitie1, Mirtami Segal-Trapley1,2, Arie Laor1,2, Moshe Vardi1,2, 3, Haim Bitterman2,3.
1Pulmonology Institute, Carmel Medical Center, Haifa, Israel; 2Internal Medicine Department, Carmel Medical Center, Haifa, Israel; 3the Ruth and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel

Background: The routine use of multidetector computed tomography (MDCT) has led to increased detection of unsuspected pulmonary embolism (UPE). Our aim was to compare the characteristics and prognosis of patients with UPE to patients with suspected PE (SPE).

Methods: We retrospectively reviewed the charts of patients diagnosed with PE in a community-based university hospital between the years 2002-2007. UPE was defined as PE detected on CT scans performed for indications other than PE. We compared patients with UPE to patients with SPE for differences in clinical features, ECG, imaging, and echocardiographic findings. We assessed the long-term outcomes of patients.

Results: Of 500 patients with PE, 408 had SPE and 92 had UPE. Patients with UPE were similar to patients with SPE regarding age and sex distribution. Malignancy was more common in UPE patients (27% vs. 13%, p = 0.00029). The mortality hazard ratio after adjustment for age, sex and malignancy was 1.546 (95% CI, 1.139-2.099, p = 0.0052).

Conclusions: We suggest that UPE is more prevalent in patients with a malignancy and is associated with higher mortality despite a less severe clinical presentation. UPE may be a marker of poor prognosis.

P3896
Diffusing capacity for carbon monoxide and mortality in patients with chronic thromboembolic pulmonary hypertension
Rika Sugii, Nobuhito Tanabe, Fumiaki Kato, Hajime Kusai, Takao Takeuchi, Takashi Ushibara, Ayumi Sekine, Rintaro Nishimura, Takayuki Jugo, Yoshihiko Sugiyama, Ayako Shigematsu, Seichiro Sakao, Yasunori Kasahara, Koichiro Tatsumi. Respirpology, Chiba University, Chiba, Japan

Background: Diffusing capacity for carbon monoxide (DLCO) reflects the ability of gas exchange across the alveolar-capillary interface and is also used as a marker of pulmonary vascular disease. Recently, Chandra et al. reported that DLCO predicts mortality in patients with pulmonary arterial hypertension. However, there is little data about DLCO in chronic thromboembolic pulmonary artery hypertension (CTEPH).

Objectives: The aim of this study is to reveal the correlation between DLCO and other clinical markers and to evaluate DLCO as a predictor of mortality in CTEPH patients.

Methods and results: We performed observational retrospective study of 202 consecutive patients with CTEPH (female 69.8%, age 54.6±12.8 yrs., 99-medial, 103-surgical) who underwent both pulmonary function test including DLCO and right heart catheterization from 1986 to 2011 in Chiba University Hospital. %DLCO showed correlation with age, NYHA, Hugh-Jones classification, oxygen delivery, PaO2, %VC, %FEV1 and 6-minute walk distance. However, no correlation was shown between %DLCO and mean pulmonary artery pressure, pulmonary vascular resistance, PaO2 and AaDO2. Among surgically treated patients, there is no difference about operative mortality between normal %DLCO (>70%) group and decreased %DLCO group (<70%) (11.7% vs. 13.3%, p=0.8166). Among the medically treated patients, decreased %DLCO group showed significantly poor survival than normal %DLCO group (5-year survival 69.1% vs. 86.0% p=0.0263).

Conclusion: Decreased DLCO was associated with impaired quality of life, pulmonary function, oxygen delivery in CTEPH, and predicted the mortality in medically treated patients.

P3897
Mir-17 modulates smooth muscle cell markers, apoptosis and BMPR-II levels in human pulmonary artery smooth muscle cells
Gurukumar Kollonoged Ramanathan, Prasanna Tamaparu, Asliya Younis, Samuel Jalali, Sara Garcia, Richard F. Lockey, Narasaiha Kolliputi. Division of Allergy and Immunology, Joy McCann Culverhouse Airway Disease Center Department of Internal Medicine, Morssani College of Medicine, University of South Florida, Tampa, FL, United States

Pulmonary Arterial Hypertension (PAH) is a progressively devastating disease characterized by excessive proliferation of the Pulmonary Arterial Smooth Muscle Cells (PASMC’s). Recently micro RNA (miR) has been shown to play an important role in the pathogenesis of PAH. We describe in the present study the effects of over expression of miR17/92 as a cluster or miR17 alone on human pulmonary artery smooth muscle cells (HPASMC). HPASMC were commercially obtained and were transfected with miR17/92 or miR17 encoding plasmid or control vector by electroporation. Proliferation and apoptosis resistant state of PASMC transfected with miR was assessed by MTS and caspase3/7 Glo assays respectively. RNA and protein levels of important target genes in PAH were measured using Real-time RT-PCR and western blots. HPASMC transfected with miR17/92 or miR17 show decreased cell numbers and showed an increased apoptosis as assessed by

402. Pulmonary circulation: basic mechanisms, animal models and experimental treatments
increased caspase activity. Real-time RT-PCR analysis reveals that proliferation markers such as PCNA and Cyclin D1 are not significantly altered. SMC marker calponin and bone morphogenetic protein receptor β2 levels were down regulated in both MCT and/or H2R1792-miR17 transfected cells. Voltage gated potassium channel (Kv1.5) was up regulated in PASMCs treated with miR17/22 cluster but not miR17 alone indicating that different miRs in the 17/22 cluster differentially may regulate key molecules in the development of PAH.

P3989

**Vasopressin is involved in endothelin receptor antagonist-induced fluid retention in rat. Differential effect of selective ETA and dual ETA/ETB receptor antagonists**

**Marek Vereščagin**, Daniel Strasser, Enrico Vezzali, Anna Stalder, Marc Iglarz, Patrick Hess, Martine Clozel. Drug Discovery, Actelion Pharmaceuticals Ltd., Allschwil, Switzerland

Endothelin receptor antagonists (ERAs) are associated with varying degrees of fluid retention. As endothelin B (ETB) receptors have been involved in naturessis and diuresis, we hypothesized that ETA-selective ERAs cause a significant risk of fluid overload in patients.

Aim of the present study was to understand the contribution of each ET receptor subtype in the mechanism of fluid retention in rats. Changes in fluid balance were assessed after administration of the prototypic ETA-selective sunitan and the dual ETA/ETB receptor antagonist bosantan, by measuring haematocrit (Hct), haemoglobin (Hb), plasma volume (PV), body fluid content and renal excretion function.

Acutely, sunitan caused marked dose-dependent decreases in Hct and Hb, whereas bosantan had a lesser effect. Chronic studies confirmed this difference and showed that sunitan increased PV (+50%) and elevated total body fluid content (+15%) compared with vehicle, while bosantan had a small non-significant effect (+16% for PV and +8% for total body water content). In addition, sunitan, but not bosantan, reduced water excretion and increased plasma vasopressin (AVP) concentration (3-fold increase) compared with vehicle-treated rats. In Brattleboro rats lacking AVP and in Wistar rats treated with either the AVP V2 receptor antagonist tolvaptan, or the ETB-selective antagonist BQ-788, hemodilution induced by sunitan was markedly reduced.

These results demonstrate that ERAs, particularly ETA-selective antagonists cause fluid retention by activating the AVP system via secondary stimulation by endothelin of the unthitiated ETB receptors.

P3999

**A potential new therapy for pulmonary hypertension with the use of compound 21, an angiotensin type 2 receptor (AT2R) agonist**

Erin Bruce, Vinyaak Shenoy, Anandharajan Rathnasabapathy, U. Moushakine, T. Thompson, Colin Summers, Mohan K. Rairada, Michael J. Katovich, I. Pharmacodynamics, University of Florida, Gainesville, FL, United States; 2Physiology and Functional Genomics, University of Florida, Gainesville, FL, United States; 3Center for Cardiovascular Research, Charité - Universitätsmedizin Berlin, Berlin, Germany

Pulmonary hypertension (PH) is a debilitating, chronic lung disease that often leads to right-heart failure and death. Currently available therapies are ineffective in significantly improving the quality of life and reducing mortality rates, thereby necessitating the discovery of novel therapeutic interventions. The renin-angiotensin system (RAS) has been associated with the pathophysiology of PH via increased activity of the deleterious ACE/ANGII/AT1R axis. It has been suggested that AT2R are upregulated in response to cardiovascular injury, and subsequent stimulation of this receptor may oppose the deleterious actions of the RAS axis. However, the role of AT2R in PH has yet to be investigated. We propose that non-peptide AT2R agonist, Compound-21 (C21), will attenuate the progression of monocrotaline (MCT)-induced PH in 8-week-old Sprague Dawley rats.

Four weeks post a subcutaneous injection of MCT (50mg/kg), the rats displayed marked elevation in right ventricular systolic pressure (RVSP, Control: 30 ±10.78; MCT: 82.2±4.5mmHg; p<0.05; n=8-10), with subsequent development of right ventricular hypertrophy (RVH, Control: 0.25±0.05; MCT: 0.61±0.04; p<0.05; n=8-10). C21 treatment (0.3mg/kg/day i.p.) began 2 weeks post MCT-challenge resulted in significant attenuation of RVSP and RVH increases (RVSP: MCT+C21: 64.2±6.2mmHg; RVH: MCT+C21: 0.48±0.04; p<0.05; n=14). Furthermore, C21 significantly attenuated PH-induced right heart dysfunction, in terms of elevated right ventricular end-diastolic pressure and +dP/dt. Our results suggest that AT2R represents a novel therapeutic target in the management of PH, and C21 may serve as a lead beneficial compound.

**A dose-response study of nilotinib and imatinib in experimental pulmonary hypertension**

Marc-Camille Chauvais, Frederic Perros, Mathieu Molinard, Stephane Bouchet, Peter Dorfmüller, Christophe Guignabert, Sylvie Cohen-Kaminsky, Marc Humbert, David Montani, 1INSERM UMR 994 Hypertension Arterielle Pulmonaire, Physiopathologie et Innovations Therapeutiques, Université Paris-Sud, Le Plessis Robinson, France; 2INSERM U657, département de Pharmacologie, Université de Bordeaux, France

**Introduction:** Platelet derived growth factor (PDGF) and c-kit are involved in the pathophysiology of pulmonary hypertension (PH). Tyrosine kinase inhibitors (TKI) targeting PDGF receptors and c-kit such as imatinib (Im) and nilotinib (Nil) are currently tested in PH.

**Aims and objectives:** To test the efficacy of Nil and Im in experimental PH.

**Methods:** Sprague-Dawley rats were analyzed, corresponding to controls (Cont), MCT alone, MCT treated with Im at 50 or 100 mg/kg (MCT+Im50-MCT+Im100), MCT and treated with Nil at 40, 80 or 120 mg/kg (MCT+Nil40-MCT+Nil80-MCT+Nil120). TKI were administered from day 21 to 35 after MCT. Serum kinetics concentrations (SKC) of TKI were performed at day 28. At day 35 hemodynamic parameters, right cardiac hypertrophy and pulmonary vascular remodelling were studied.

**Results:** SKC showed that Nil50,Nil40 and Nil80 corresponded to human drug concentrations. A dose-response improvement in hemodynamic parameters and medial wall thickness was observed with Im and Nil.

**Conclusion:** Dose-dependent improvements of experimental PH are observed with Nil and Im.

P3901

**Genistein rescues pulmonary hypertension and attenuates abnormal vasoconstriction in rats lungs**

Sachiko Kuriva, Yasuhiro Morio, Tetsutaro Nagaska, Kuniaki Seyama, Kazuhisa Takahashi. Respiratory Medicine, Juntendo University School of Medicine, Tokyo, Japan

**Background:** Recent studies suggest that the deregulation of endothelial nitric oxide synthase (eNOS) is accountable for in the development of pulmonary hypertension (PH). Genistein, a phytoestrogen derived from soybean, has been reported to improve endothelial function.

**Objective:** We hypothesized that chronic treatment with genistein would prevent and reverse of hypoxic PH (HX) by improvement of eNOS function.

**Method:** Daily treatment with either genistein (0.2mg/kg) or vehicle was started. After 3-wk hypoxic exposure, rats were treated with the dual ETA/ETB receptor antagonist bosentan, by measuring haematocrit (Hct), plasma volume (PV), body fluid content and renal excretory parameters and diuresis, it was paradoxical to observe that ETA-selective ERAs cause a significant risk of fluid overload in patients.

**Results:** Genistein treatment prevented the progression of PH to right ventricular failure and restored vascular remodeling in HX. And also, genistein rescued pre-existing PH. These effects were mediated by improvement of eNOS function and restoring the interaction of eNOS and eNOS-related proteins. Furthermore, exogenously administration of genistein rapidly attenuated abnormal vasoconstriction in HX by improvement of eNOS function.

**Conclusion:** These results indicated that genistein not only had protective and reversal effects against the development of hypoxic PH, but also attenuated abnormal vasoconstriction of PH. The underlying mechanism might be related to the improvement of eNOS function.

P3902

**Modified exhaled nitric oxide measurement in monocrotaline-exposed rats to monitor pulmonary hypertension**

Magdalena Sophie Strobl, Catharina Schreiber, Stefan Hubmer, Helga Bergmeister, Irene M. Lang, Diana Bondonner. Department of Internal Medicine II, Division of Cardiology, Medical University Vienna, Austria

**Background and aims:** Rats exposed to monocrotaline (MCT) are broadly used as animal model for pulmonary arterial hypertension (PAH). In analogy to human disease, right heart catheter (RHC) is the established gold standard for pulmonary pressure monitoring. Although exhaled nitric oxide (ENO) levels have been shown to correlate with pulmonary pressures in humans with pulmonary hypertension, no link between ENO and pulmonary pressures could be established in rats. The
aim of the present study was to test whether a technical modification of the NO measurement process could help generate reliable ENO values that correlate with pulmonary pressures as assessed by simultaneous RPP.

Methods: 23 male Sprague-Dawley rats were studied 28 days after MCT-exposure and unilateral pneumonectomy. Hemodynamic parameters were monitored by an implantable telemetry system (DSI Datascience, St. Paul, MN U.S.A.). ENO was measured by means of chemiluminescence (CLD 66, Eco Physics, Durmrten, Switzerland) in single, conscious, spontaneously breathing rats. ENO values measured by a standard accumulation method (ENO standard) and those obtained after process modification (ENO modified) were correlated with mean pulmonary arterial pressures (mPAP).

Results: After process modification, measuring errors were diminished and potential influencing factors eliminated. There was a clear correlation between ENO modified and mPAP (r=0.007, R=–0.49), while no correlation was observed between ENO standard and mPAP (p=0.236, R=–0.212).

Conclusion: Modified non-invasive ENO measurement may be used to monitor PAC in monocrotaline-exposed rats.

P3903
Bone morphogenetic protein signaling in experimental nitrofen-induced congenital diaphragmatic hernia

Martine Makanga, Celine Dewachter, Aline Vuckovic, Benoit Rendelet, Robert Naeye, Laurence Denadigue
Physiopathology Laboratory, Universite Libre de Bruxelles, Brussels, Belgium

Congenital diaphragmatic hernia (CDH) is a life-threatening cause of lung hypoplasia and persistent pulmonary hypertension of the newborn. As bone morphogenetic proteins (BMP) have been shown to play crucial roles in fetal lung and heart development, we explored the potential implication of this signaling pathway in an experimental model of CDH. Pregnant Sprague-Dawley rats were exposed to either 100 mg nitrofen or olive oil on embryonic day 9.5. On embryonic days 17 and 21, fetuses were delivered by caesarian section, sacrificed, checked for CDH and their lung and heart tissue were harvested for pathological evaluation.

Lung and heart weight-to-body weight ratios decreased by 28% and 35% (P<0.05) on embryonic day 17 and by 12% and 8% (P<0.05) on embryonic day 21. Nitrofen administration resulted in airway septa thickening, together with lower radial alveolar count. The pulmonary expressions of the BMP receptor (BMPR) type 2, BMP4 and BMP7 decreased, while the expression of BMPR1A did not change and the expression of gremlin, a BMP antagonist, increased on embryonic day 17. The pulmonary expression of DNA binding protein 1 (Id1) decreased, together with decreased pro-angiogenic factor Gli1 expression on embryonic day 21. The myocardial expressions of BMP2, BMPR1A, BMP7 and SERCA-2A were decreased, while the expressions of gremlin and noggin increased on embryonic day 17. On embryonic day 21, the myocardial expressions of Id1 and SERCA-2A decreased, while gremlin expression increased.

These results suggest that BMP signaling is downregulated in the lungs and the heart at early and late stages of nitrofen-induced CDH.

P3904
TSC/mTOR pathway promotes hypoxia-induced pulmonary hypertension in mice

Wang Wang,1 Jin Li,1, Huan Guo,1 Ai-qing Ma,2 Kai-feng Xu,1 Jun Wang,1,2
1Physiology, Capital Medical University, Beijing, China; 2Respiratory Medicine, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; Beijing Key Lab of Respiratory and Pulmonary Circulation Disorders, Beijing Institute of Respiratory Medicine, Beijing Chao-Yang Hospital, Capital Medical University, Beijing, China

Background: Chronic hypoxia is a key trigger of pulmonary vascular remodeling in pulmonary hypertension (PH). The mammalian target of rapamycin (mTOR) is involved in cell proliferation, which is negatively regulated by Tuberous sclerosis complex 1 (TSC1) in mice (Tek-cre(+)/TSC1fx/+) (provided by prof. Kai-feng Xu) were used. The mice were exposed to either hypoxia (10% O2) or normoxia (21% O2), then the right ventricular systolic pressure (RVSP) and index of right ventricular hypertrophy (RVHI) were measured. Histological examination was used to estimate the distal vascular remodeling. Western blot was used to detect the change of protein expression in vivo.

Results: Those two genotypic mice under normoxia showed no differences. After hypoxia, RVSP and RVHI of those two genotypic mice was gradually increased, but Tek-cre (+)/TSC1fx/+ mice were higher after 3 weeks (RVSP: 22.79±0.31 vs. 19.95±0.97mmHg, P<0.05; 0.32±0.01 vs. 0.25±0.02, P<0.05). The small pulmonary arteries of both Tek-cre (+)/TSC1fx/+ and Tek-cre (-)/TSC1fx/+ showed progressive medial thickening under hypoxia, but the former was more obvious. The expression of phosphorylation of S6 (biomarker of mTOR) gradually increased in progressive medial thickening under hypoxia, but the former was more obvious. The expression of phosphorylation of S6 (biomarker of mTOR) gradually increased in progressive medial thickening under hypoxia, but the former was more obvious.

Conclusion: This novel compound is able to achieve a more complete blockade of ET receptors and provides evidence for superior efficacy potential.

P3905
Feasibility of eccentric exercise training (ECCs) in monocrotaline (MT) rats: Effects on survival, echocardiographic and hemodynamic parameters

Rina Enache1,2, Stephanie Doutreleau1,2, Fabrice Faveart1, Paola Di Marco1,2, Cristina Pista1, Bernhard Gery1,2, Anne Charloux1,2, 1Service de Physiologie et Explorations Fonctionnelles, Hopitaux Universitaires de Strasbourg, France; 2EA 1072, Faculté de Medicine, Université de Strasbourg, Strasbourg, France

ECCs may be of interest in patients with pulmonary hypertension (PH) because cardiac solicitation is much lower during ECC than during concentric exercise, performed at the same mechanical power.

Aims: We assessed the feasibility, hemodynamic and survival effects of ECCs in MT rats with PH.

Methods: ECCs on treadmill was initiated 2 weeks after MT injection (40mg/kg) (30 minutes at 50% of maximal speed, slope: -15°, 5 days/week for 4 weeks). Trained rats (MTsec, n=13, control ECC (Lccle), n=7) were compared with sedentary rats (M特斯ed, n=13, CSSed, n=7). Before and after 2 and 4 weeks training, maximal speed measurement and echocardiography were performed. At 4w, right ventricular (RV) catheterisation was performed.

Results: The RV systolic pressure was 40±2 mmHg in MT, and 22±1mmHg in CL rats (p<0.001). Exercise was generally well tolerated. In the MTcc and M特斯ed groups, 3 and 2 rats developed right heart failure and died. Maximal speed significantly increased in trained rats at 4w (p<0.01) (figure). Echocardiographic parameters were not significantly different in MTsed and MTcc (cardiac output (CO), tricuspid annular plane systolic excursion (TAPSE), pulmonary artery flow acceleration time (PAAT)) (figure). RV systolic pressure was not different in MTcc (36±24mmHg) and in M特斯ed (42±3mmHg).

Conclusion: In this PH model, ECCs was well tolerated and not detrimental to the hemodynamic condition and survival. Whether ECCs could be an adjuvant therapy in PH deserve to be further investigated.

P3906
Superior in vivo efficacy of macitentan: Comparison to other endothelin receptor antagonists

Marc Illyzar, Markus Rey, Patrick Hess, Katalin Kaiser, Martine Clozel, Drug Discovery, Actelion Pharmaceuticals Ltd., Allschwil, Switzerland

Endothelin (ET) receptor antagonists used for the treatment of pulmonary arterial hypertension present different pharmacological profiles depending on their selectivity and affinity for ET receptors. Macitentan (MACI) is a new dual ETA/ETB tissue targeting receptor antagonist designed to achieve a more complete ET receptor blockade. To investigate this property, we designed a study in which rats were given MACI on top of maximally effective doses of either ambriole (AMBRI, ETA selective) or bosentan (BOS, dual ETA/ETB).

First, we measured the effects of single doses of the compounds on mean arterial blood pressure (MAP) in conscious Dahl salt-sensitive rats equipped with telemetry, and constructed dose-response curves. Maximal effective doses were 30 mg/kg for MACI and AMBRI and 100 mg/kg for BOS.

Next, we tested the potential for an additive effect of MACI on top of the now defined maximal effective doses of AMBRI and BOS. MACI 30 mg/kg further decreased MAP by 17 mmHg when given on top of AMBRI 30 mg/kg (p<0.05 vs vehicle). In contrast, addition of AMBRI 30 mg/kg on top of MACI 30 mg/kg had no additional effect (5 mmHg vs vehicle, p=0.47), confirming use of the maximal effective dose of AMBRI. Conversely, AMBRI 30 mg/kg given on top of MACI 30 mg/kg failed to induce any additional MAP decrease.

In a similar experiment, MACI on top of maximal effective dose of BOS elicited a further MAP decrease of 21 mmHg (p<0.02 vs vehicle), whereas addition of BOS had no additional effect. The add-on effect of macitentan on top of ambriole or bosentan confirms that this novel compound is able to achieve a more complete blockade of ET receptors and provides evidence for superior efficacy potential.
Resveratrol attenuates hypoxic pulmonary vascular remodeling in simulated high altitude-exposed rats: potential role of HIF-1α/NOX4/ROS inhibition
Tao Wang1,2, Ling-Li Guo1,3, Guang-Ming He1,2, Peng Luo1,2, Fu-Qiang Wen1,2
1Division of Pulmonary Diseases, State Key Laboratory of Biotherapy, Sichuan University, Chengdu, Sichuan, China; 2Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Objectives: Chronic high altitude hypoxia induces pulmonary vascular remodeling with marked hypertrophy and luminal narrowing leading to the development PAH. Pulmonary oxidative stress has been implicated in hypoxic PAH. This study aimed to investigate the effects of resveratrol, an anti-oxidant polyphenol, on hypoxic pulmonary vascular remodeling in rats.

Methods: Rats were exposed to simulated high altitude of 6000 m in a hypobaric chamber for 8 h/day, for up to 28 days. Resveratrol (10 mg/kg, ip) was daily administered 0.5 h before hypoxia exposure. Rat primary pulmonary arterial smooth muscle cells (PASMCs) were incubated under hypoxia (2% O2) in the presence of 10, 25, or 50 μM resveratrol. Pathophysiological changes and signal transduction were examined using histochimistry, fluorescence probing, Western blotting and RT-PCR.

Results: Resveratrol administration significantly reduced hypoxia-induced elevation in mPAP (23.6±2.4 mmHg vs. 30.3±1.9 mmHg; P<0.05) and medial wall thickness of pulmonary arteries (16.5±4.1% vs. 22.7±2.4%; P<0.05) in rats. Resveratrol also decreased pulmonary MDA and H2O2 levels as indicators of oxidative stress in hypoxic PAH rats. In vitro studies show that resveratrol dose-dependently inhibited hypoxia-induced rat PASMC proliferation and cellular ROS accumulation. Moreover, resveratrol reduced hypoxia-increased Hif-1α and NOX4 (a ROS contributor) expression both in vitro and in vivo.

Conclusions: Resveratrol attenuates hypoxic pulmonary vascular remodeling in rats exposed to high altitude exposure through its inhibition on Hif-1α/NOX4/ROS-generated oxidative stress under hypoxia.

Applying pharmacogenomics to pulmonary arterial hypertension (PAH): A target-based approach to therapy
Sanj Jaiswal1,2, Nayyer Hamidi1,2
1Medicine, SUNY at Stony Brook, Stony Brook, NY, United States; 2Medicine Service, Northport VA Medical Center, Northport, NY, United States

Introduction & aims: Pharmacogenomics, the study of how genetic variations influence the response to drugs, has the desirable objective of tailor-making drugs for each individual genetic makeup. The successful application of this concept in oncology provided the rationale for this study. Like most diseases in oncology, PAH is a heterogeneous disease. We aimed at identifying possible genetic variations in PAH patients. In this study, we used a target-based approach in order to perform a preliminary proof-of-concept study.

Methods: We examined 2 experimental models of PH: mice with deletion of the Vasooactive Intestinal Peptide gene (VIP-/-), and rats injected with monocrotaline (MCT), 2 models with comparable, though not identical, phenotypic features. We analyzed their particular gene alterations, with special reference to genes related to vascular remodeling and inflammation, and compared phenotypic and genotypic responses in each model to treatment with VIP.

Results: VIP+/- mice showed overexpression of genes promoting vascular proliferative and inflammation, with underexpression of anti-proliferative genes. VIP fully corrected all PH features and matching gene expression alterations. MCT rats, however, showed complex gene expression alterations: As in VIP-/- mice, those promoting vascular remodeling and inflammation, and others tending to modulate the PH. Further, VIP treatment failed to correct many of the phenotypic abnormalities, and only partially corrected the phenotype.

Conclusions: This preliminary proof-of-concept study demonstrates the importance of genomic information in determining the therapeutic response to a given drug. Full validation of the role of pharmacogenomics in PAH must await comparable studies in patients with different forms of the disease.

Resveratrol is a polyphenol that plays a major role in vascular biology, and is known to regulate the phenotype and activity of various vascular cell populations. Because most fibrotic diseases, such as Idiopathic Pulmonary Fibrosis (IPF), are associated with vascular remodeling and since endothelial progenitor cells may be involved in this process, we investigated the impact of TGF-β1 modulation of endothelial progenitor cell angiogenic properties.

Patients/methods: TGF-β1 plasma levels were determined in 64 patients with IFP and compared to controls. The effect of TGF-β1 on angiogenesis was studied in vivo in a Matrigel plug model and in vitro on Endothelial Colony Forming Cells (ECFCs). We studied the effects of inhibiting the expression of the three main receptors of TGF-β1 in ECFCs using siRNA.

Results: Total TGF-β1 plasma levels were significantly increased in patients with IFP compared to controls (P < 0.0001). TGF-β1 had proangiogenic effects in vivo by increasing hemoglobin content and blood vessels formation in Matrigel-plugs implanted in C57/B6 mice and in vitro by enhancing ECFC viability and migration. The effects were abolished by silencing the three main receptors of TGF-β1 in ECFCs.
P3912

Unique receptor dissociation kinetics of the novel endothelin receptor antagonist macitentan
John Gottfried, Celia Mueller Grandjean, Thomas Sasse, Beat Steiner, Pauline Steiner, Marc Iglarz, Katalin Kauser, Martine Clozel, Oliver Neyler. Drug Discovery, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland

Association and dissociation rates of G protein-coupled receptor antagonists can influence their in vivo pharmacological activity, such as duration of action, activity in situ, and receptor cross sensitivities and ultimately clinical efficacy.

Using signaling assays in human pulmonary arterial smooth muscle cells (PASMDC), we investigated the endothelin (ET) receptor inhibition kinetics of macitentan, a novel ET receptor antagonist currently in phase 3 clinical trials in pulmonary arterial hypertension, and compared them with the kinetics of bosentan and ambrisentan.

Calcium flux assays showed that macitentan, but not ambrisentan or bosentan, increased in potency (10-fold) upon prolongation of antagonist pre-incubation time from 10 min to 120 min, indicating slow apparent association of macitentan with ET receptors. Macitentan furthermore displayed a slow receptor dissociation rate so that inhibition of ET1-induced calcium influx and lung fibroblasts for more than 60 min after macitentan wash-out. Conversely, bosentan and ambrisentan did not maintain receptor blockade after washout and displayed a ~15-fold shorter receptor occupancy half-life than macitentan. The slow dissociation kinetics represented macitentan's an efficient antagonist of ET1-induced IP3 synthesis and ET1-induced sustained calcium flux across the whole range of ET1 concentrations tested. In contrast, bosentan and ambrisentan did not display antagonism against high ET1 concentrations in these assays.

In pulmonary arterial smooth muscle cells, macitentan is a slow-offset competitive antagonist and, unlike bosentan and ambrisentan, capable of efficient receptor blockade in functional assays irrespective of the ET1-concentration.

Pulmonary gene expression of tenasin-C and fibronectin in chronic obstructive pulmonary disease (COPD)
Marina Manco-Enriqueke,1 Susanna Estany 1, Marta Lopez 2, Maria Molina Molina 1, Inesco Escobar 1, Rosa M. Penas 1, Victor Peinado 1, Joan A. Barbera 1, Jordi Dorca 1, Salad Santos 1. 1Respiratory Medicine. Pulmonary Research Group-IDBBELL, Hospital Universitari de Bellvitge, Hospitalat de Llobregat, Barcelona, Spain; 2Pathology Department, Hospital Universitari de Bellvitge, Hospitalat de Llobregat, Barcelona, Spain; 3Respiratory Medicine. IDIBAPS, Hospital Clinic de Barcelona, Barcelona, Spain

Background: COPD is characterized by pulmonary vascular remodeling and is associated with high prevalence of cardiovascular events regardless of other risk factors. Tenasin-C (TNC) and fibronectin (EDA-FN) are extracellular matrix proteins involved in the structural and functional organization of the lung. Our previous studies showed that TNC and EDA-FN are upregulated in lung fibroblasts from patients with COPD.

Objectives: To assess the expression of TNC and EDA-FN in lung tissue of COPD patients compared to smokers without COPD.

Methods: Expression of TNC and EDA-FN was assessed in tissue samples of 20 patients, 10 with COPD and 10 without COPD. In addition, expression of TNC was assessed in cell cultures of lung fibroblasts. The expression of TNC and EDA-FN was determined by quantitative real-time PCR and Western Blotting.

Results: The expression of TNC and EDA-FN was significantly higher in COPD patients compared to smokers without COPD. The expression of TNC and EDA-FN was also significantly higher in lung fibroblasts from patients with COPD compared to smokers without COPD.

Conclusion: Our findings suggest that TNC and EDA-FN play a role in the pathogenesis of COPD, and that their expression may be a potential biomarker for the diagnosis of COPD.

P3914

Effects of a soluble guanylate cyclase stimulator, BAY 41-8543, upon right ventricular function in experimental pulmonary embolism
John Watts, Michael Gellar, Mary-Beth Fulkeron, Jeffrey Kline. Emergency Medicine, Carolinas Medical Center, Charlotte, NC, United States

Background: Pulmonary embolism (PE) increases pulmonary vascular resistance (PVR) and may cause right ventricular (RV) dysfunction, leading to poor clinical outcome.

Methods: We studied the effect of soluble guanylate cyclase stimulator (BAY 41-8543) on RV function in experimental PE. PE was induced by injecting 2.6 million/100 gm body wt, 5 hrs or moderate PE (2.0 million/100 gm body wt, 5 hrs). PVR was measured before and after APhT. According to RHC data mean SPAP was 76.8±11.5 mmHg, pulmonary vascular resistance: 539±250 dynes/sec/cm5 and a10 healthy controls were included. Plasma levels of TNC were measured by enzyme-linked immunosorbent assay (ELISA).

Results: BAY 41-8543 significantly improved all three indices of RV function: (Control 10.6±0.4 mmHg/mil/min). Moderate PE caused a significant decrease in RV peak systolic pressure (PSP) (39±11 mmHg vs. 19±3.3 PE, -dP/dt [1192±433 mmHg/sec vs. 444±64] and -dP/dt [576±60 mmHg/sec vs. 278±80]). BAY 41-8543 significantly improved all three indices of RV function (PSP 35±3, -dP/dt 1128±100, -dP/dt -568±87). Severe PE caused significant RV dysfunction (PSP 256±2, -dP/dt 369±29) and BAY 41-8543 protected RV function (PSP 34±2, -dP/dt -535±4).

Conclusions: BAY 41-8543 protects RV function in experimental PE. RV dysfunction is a poor prognostic marker in PE patients. Further studies are necessary to determine if BAY 41-8543 can improve RV function in clinical PE patients.

P3915

Fluorescence activated cell sorting for simultaneous assessment of nine surface markers of circulating endothelial progenitor cells in pulmonary hypertension
Wanda Fier 1,2, Gabor Kovaci 1,2, Leigh Marsh 3, Maria Tschermier 1,2, Andrea Olschewski 1,2, Horst Olschewski 1,2. 1Pulmonology, Medical University of Graz, Austria; 2Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria

Background: The role of circulating endothelial progenitor cells (EPCs) in pulmonary hypertension (PH) is unknown. In this pilot study we established a nine-colour staining assay for the Fluorescent Activated Cell Sorting (FACS) to characterize the circulating EPCs in PH patients as compared to healthy controls.

Methods: Peripheral and central venous blood was taken from PH patients from the left innominate vein. The patients were classified as PH patients with idiopathic PH (iPH), CTEPH, or PH due to connective tissue disease. FACS analysis was performed on 20 PH patients and 20 healthy controls.

Results: N=10 PH patients (n=1 iPH, n=3 chronic thromboembolic, n=3 left heart disease, n=3 idiopathic) and mean pulmonary artery pressure: 42±14 mmHg, pulmonary vascular resistance: 539±250 dynes/sec/cm5 and a10 healthy controls were included. Plasma levels of TNC were measured by enzyme-linked immunosorbent assay (ELISA).

Conclusion: These preliminary results suggest that multi-colour FACS is suitable for EPC quantification and characterization. Further studies are necessary to define distinct circulating EPCs as markers of PH.

P3916

Assessment of tissue velocity imaging of both ventricles in vasoreactive patients
Ekaterina Koval, M. Saidova, N. Danilov, O. Arkhipova, T. Martyynyk, I. Chazova. Cardiology, Russian Cardiology Research and Production Complex, Moscow, Russian Federation

The purpose: To estimate dynamics of right and left ventricular systolic and diastolic function by estimation Sa, of the lateral tricuspid and mitral valve annulus during acute pharmacological testing (APIT) with inhaled nitric oxide (iNO) in patients with idiopathic pulmonary arterial hypertension (iPAH).

Materials and methods: In the study we included 11 pts (11 females) with iPAH aged 31-51 (mean 39,8±7,4 years). All pts were performed right heart catheterization (RHC) with APIT and noninvasive vasodilator testing with iNO (20ppm for 10 min) before two hours to RHC. The estimation of SPAP was performed initially at rest and then at 10 min of nitric oxide Inhalation. All pts were responders. Echo included routine parameters and TVI was used for the estimation of systolic and diastolic function of RV/LV before and after APIT.

Results: In pts with iPAH (functional class II-III, WHO) the mean value of tricuspid regurgitation (TR) gradient was 64.8±11.5mmHg. In all pts included in the study the degree of TR was at least III. Taking into account right atrial pressure levels mean SPAP was 75±11.6mmHg by Transthoracic Doppler Echocardiography (TDEcho.) before APIT. Mean SPAP was 47.5±6.2mmHg, by echo APIT. According to RHC data mean SPAP was 76,8±16,6mmHg before test and 46,6±7,9mmHg after iNO. We found no significant dynamic of routine echo parameters. To 10’ of iNO there was significant improvement Sa. Eo of RV during APIT with iNO. There was improvement Sa, Eo of LV but not significant.

403. Pulmonary circulation: clinical end-points and clinical physiology
Conclusion: TDEcho may be used for an accurate assessment of vasodilator response as compared to RHC data. During APht with INO only Sa, Eo of RV may be used for detecting vasoreactive patients.

P3917

Subtle assessment of quality of life in PH patients on inhaled iloprost treatment

Vera Reuber, Henning Teich, Frank Reichenberger, Robert Woswinckel, Friederike Seeger, Werner Seeger, Ardekshah Ghofrani. University of Giessen Lung Center, University Hospital, Giessen, Germany

Background: Pulmonary hypertension (PH) is a disease characterized by vasoconstriction, remodeling of the small pulmonary vessels, and a lack of endogenous prostacyclin. Prostacyclin and its analogues are potent vasodilators and widely used in PH treatment. Information on the quality of life of PH patients is limited.

Methods: 24 patients who suffer from different forms of PH and receive inhaled iloprost, either as first line or as add-on therapy, are followed. Patients received questionnaires concerning multiple aspects of their quality of life. NYHA function, Borg dyspnea score (BDS) and heart rate increase during the test (6MWD), results of the right-heart catheterization, and biomarker levels were recorded at the moment of baseline and follow-up (Nov. 2007 - Feb. 2009).

Results: 76% of patients described an improved state of health compared with the situation before start of inhalation. Furthermore significant correlations between qualities of life and other important measures of PH could be shown. Improvements of NYHA-class, 6MWD, laboratory values (uric acid, BNP) and also of hemodynamic measurements (i.e. mPAP, PVR, CO, CI) during inhalative therapy with iloprost were detected. 6MWD improved significantly from 314.2±128.8 m to 354.4±131.0 m (p<0.001). 11 patients (23%) could improve their NYHA-class, 32 (66.6%) stayed unchanged and 5 (10.4%) deteriorated. These differences between baseline and follow up are significant (p<0.001).

Conclusion: Quality of life is an important measure for PH patients. Improvement in quality of life correlated very well with other important measures of PH.

P3918

The clinical relevance of heart rate increase in the interpretation of six-minute walk test in pulmonary hypertension

Gabor Kogya1,2, Christina Stöck1, Alexander Avian2, Xhiljisme Kajiku1, Vasilis Franchini1,2, Tiarcher1,2, Horst Olchewski1,2. 1Pulmonology, Medical University of Graz, Austria; 2PL-D, Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria; 3Medical Informatics, Statistics and Documentation, Medical University of Graz, Austria

Background: Six-minute walk test (6MWT) is an important prognostic marker in pulmonary hypertension (PH). We hypothesized that clinical improvement might not only be characterized by an increased walk distance but also by changes in Borg dyspnea score (BDS) and heart rate.

Patients and methods: Patients with PH and subjects without PH but with an abnormal exercise-induced pulmonary arterial pressure (PAP) increase were included. Each patient performed a 6MWT with "normal", "less than normal" and "more than normal" effort.

Results: 23 patients with PH (n=11 pulmonary arterial hypertension, n=10 chronic thromboembolic PH, n=2 other; mean PAP: 40±12mmHg) and 6 subjects with abnormal exercise-induced PAP increase (resting mean PAP: 16±5mmHg) participated. 6MWT were 482±89, 447±60 and 402±82m in the walks with "more than normal", "normal" and "less than normal" effort respectively. The respective BDS and heart rate increase was 3.2±1.5, 2.0±1.2 and 0.7±0.9, and 38±16, 31±14 and 23±14 min1 (3.0±1.4, 2.0±1.3 and 0.8±0.9, and 40±16 vs 34±13 vs 23±15 min1 in PH patients). The difference in walk distance between "less than normal" and "more than normal" tests was 342±84 m (p<0.001). The respective BDS and heart rate increase was 3.2±1.5, 2.0±1.2 and 0.7±0.9, and 38±16, 31±14 and 23±14 min1 (3.0±1.4, 2.0±1.3 and 0.8±0.9, and 40±16 vs 34±13 vs 23±15 min1 in PH patients). The difference in walk distance between "less than normal" and "more than normal" tests was 342±84 m (p<0.001). "Less than normal" BDS and heart rate increase was associated with the difference in heart rate increase during the test (p=0.001, r=0.61 in all subjects; p=0.001, r=0.76 in PH patients). On average, an 80m increase in 6MWT was associated with an additional 15 mm Hg heart rate increase. Between the BDS and 6MWT there was no significant correlation.

Conclusion: Based on our pilot study, heart rate may be suitable to assess the effort level of subjects and may be incorporated to refine 6MWT in the follow-up of PH patients.

P3919

Wrist actigraphy predicts outcome in patients with pulmonary hypertension

Silke Ulich1, Manuel Fischer2, Rudolf Speich2, Konrad E. Bloch3. 1HeartVox, Thorax, Respiratory Clinic, University Hospital, Zurich, Switzerland; 2Internal Medicine, City Hospital Waid, Zurich, Switzerland; 3HeartVox, Thorax, Respiratory Clinic, University Hospital, Zurich, Switzerland

Rationale: Pulmonary hypertension (PH) impair quality of life, exercise and survival. Simple measures to monitor the disease are needed. We tested whether actigraphy by a wrist-worn device in the patients home reflects disease severity in PH patients.

Methods: We studied 23 outpatients with precapillary PH (15 females) in WHO functional classes II-IV. Evaluations comprised clinical examination and actigraphy during 2 weeks while patients pursued their usual life at home. Actigraphies were correlated with clinical data and mean pulmonary arterial pressure (mPAP). Death, lung transplantations and pulmonary endarterectomy were recorded during 4 years.

Results: Actigraphies revealed a mean±SD day-time with activity of 14.5±7.1±14 hours, activity counts were 146±125±4. Very severely impaired patients (mPAP 501±79±59 mHz) rested more time immobile during nights (8.2±5±1±18h) and were less active during days (544±44±counts/mm) compared to modestly impaired patients (mPAP 33±7±7±mmHg; night-time immobile 6:58±0:39h; day-time activity 229±1±48±counts/mm, P<0.05 all instances). Of 19 patients followed for 4 years, 5 died, 1 underwent lung transplantation. Kaplan-Meier analysis revealed a shorter survival without lung transplantation in patients being active for less than 15h per day compared to patients with more than 15h of activity per day (log-rank 131.0 m (p<0.001). 11 patients (23%) could improve their NYHA-class, 32 (66.6%) stayed unchanged and 5 (10.4%) deteriorated. These differences between baseline and follow-up are significant (p<0.001).

Conclusion: A long nocturnal rest and reduced day-time activity recorded by actigraphy are associated with severe hemodynamic impairment and reduced survival in patients with PH. Therefore, wrist actigraphy performed during everyday life in the patient’s home holds promise as a simple tool for assessment of disease severity and prognosis in patients with PH.

P3920

Central venous-to-arterial carbon dioxide difference (CO2 GAP) in patients with arterial pulmonary hypertension: A pilot study

Marcelo Rocha, Fabricio Costa, José Ernőto Façanha Barreto. Pulmonology, Hospital de Messejana, Fortaleza, CE, Brazil Pulmonology, Hospital de Messejana, Fortaleza, CE, Brazil Interventionalist Cardiology, Hospital de Messejana, Fortaleza, CE, Brazil

Pulmonary arterial hypertension (PAH) is characterized by increased pulmonary vascular resistance that can lead to right failure and death. Right ventricular (RV) function is a major determinant of functional capacity and prognosis in PAH, with a reduced survival in patients with decreased cardiac index. Several studies have already shown that venous-to-arterial CO2 difference (CO2 GAP = PaCO2 minus PACO2) is inversely correlated to cardiac index (CI) in septic and non-septic circulatory failure.

Objectives: To analyze the value of the CO2 GAP in PAH patients and its relationship with the cardiac index.

Methods: The right heart catheterization was performed using the Seldinger technique with a 2Fr sheath inserted via the basilica vein. Cardiac output was measured using the thermodilution technique.

Results: We analyzed 26 patients with PAH (80% women and 20% men). 86% were classified as WHO group 1 (34% had idiopathic PAH) and 7% were WHO group 4 (chronic thromboembolic pulmonary hypertension). Most patients were in NYHA functional class II (50%) and the mean 6-min walk distance was 451 meters. At the time of enrollment, 78% were treated with pulmonary vasodilators (39% sildenafil alone and 39% sildenafil + bosentan). CI, CO2 GAP and central venous oxygen saturation (ScvO2) were compared by Pearson correlation. We found a negative correlation between CI and CO2 GAP (R square 0.15 and p: 0.04) and a positive correlation between CI and venous oxygen saturation (R square 0.81 and p: 0.0002).

Conclusion: In PAH patients, the CO2 GAP may be a useful tool to analyze right ventricular function. Future research should analyze its value in the prognosis of PAH patients.

P3921

Psychometric validation of the living with pulmonary hypertension questionnaire in pulmonary arterial hypertension patients

Nicola Bonner1, Linda Abete2, Juliette Neumenter3, Mirko Sikic3. 1PRO, Addiphil Values, Bollington, Cheshire, United Kingdom; 2Statistics, Mapi Consultancy, Lyon, France; 3GHEOR General Medicine, Bayer Healthcare, Berlin, Germany

Background: The Living with Pulmonary Hypertension questionnaire (LPH) was adapted from the Minnesota Living with Heart Failure Questionnaire for use in patients with pulmonary arterial hypertension (PAH). Objectives: To confirm the structure, assess the psychometric properties and provide guidance for the interpretation of the LPH. Methods: LPH was given at baseline and last visit (week 12) to patients with PAH as part of a double blind, Phase III, clinical trial; this data was used to perform the LPH validation analyses: description of items, scores and quality of completion, construct validity, reliability, clinical validity and responsiveness. Analyses to provide an estimation of the Minimal Important Difference (MID) for the LPH scores were performed.

Results: The LPH Emotional and Physical scores met the criteria for convergent and discriminant validity; for the total score all but two items met the test for item convergent validity. Internal consistency reliability of the LPH scores was demonstrated by Cronbach’s alpha values of >0.70 for all LPH scores. The LPH Physical and Total scores discriminated between World Health Organisation (WHO) Functional classes and 6 Minute walking tests, indicating clinical validity and were also responsive to change in clinical severity, as measured by change in WHO functional class and Borg CR 10 Scale. Further investigation is required to confirm the responsiveness of the Emotional score. Estimation of MID using distribution-based methods indicated a change of 3 points for the sub-scales and 7 for the total score to be clinically meaningful.

Conclusion: The LPH is a valid and reliable instrument.
hypertension – The most relevant differences between survivors and non-survivors in three-years observation study

Introduction: The impact of modern treatments of pulmonary arterial hypertension (PAH) on pulmonary vascular pathology remains unknown. The last series reporting the pathology of severe pulmonary hypertension date back two decades, well before usage of current therapies (e.g. sildenafil).

Methods: Analysis of pulmonary vascular remodelling and inflammation in 62 PAH and 28 control explanted lungs systematically sampled, with matched clinical pathological data. The tissue was obtained by the Pulmonary Hypertension Breakthrough Initiative.

Results: Total wall, intima, and media fractional thicknesses of pulmonary arteries were increased in the PAH group versus the controls, and correlated with pulmonary hemodynamics. Despite a high variability of morphological measurements within a given PAH lung and among all PAH lungs, pathological subphenotypes were detected in cohorts of PAH lungs. This included a subset of lungs lacking intima or media remodeling, which had similar numbers of profiles of plexiform lesions, as seen in lungs with more pronounced remodeling. Perivascular inflammation was present in a high number of PAH lungs and correlated with mean pulmonary arterial pressure (mPAP) as well as intima and total wall thickness. The number of profiles of plexiform lesions was significantly lower in lungs of patients who were never treated with prostacyclin or its analogues.

Conclusions: Our results indicate that multiple features of pulmonary vascular remodeling exist in patients treated with modern PAH regimens. Perivascular inflammation may have an important role in the processes of vascular remodeling, all of which may ultimately lead to increased pulmonary artery pressure.

P3923 The proANP increase during exercise may predict the PAP increase in connective tissue disease patients at risk of PAH

Maria Tscherner1,2, Gabor Kovacs1,2, Friedrich Fruhwald1, Robert Maier1,2, Dr. Barbara Obereiter-Pietsch1, Alexander Arsan1, Vasile Foris1, Man, Harm Jan Bogaard.1

The proANP increase during exercise may predict the PAP increase in connective tissue disease patients at risk of PAH.

Patients and methods: We investigated plasma levels of proANP and NTproBNP stage of pulmonary vascular disease and may be clinically relevant.

Conclusions: Three-year survivors comparing to non-survivors had significantly higher DICO% pred. and less disturbances of gas distribution expressed as TLC-VA. Nevertheless only DICO% pred. was an independent prognostic variable.

P3925 Acquistion of echo-Doppler parameters of pulmonary hypertension in COPD

Andrew Goudie, Pipa Hopkinson, William Anderson, Brian Lipworth, Allan Struthers. Centre for Cardiovascular and Lung Biology Research, University of Dundee, United Kingdom

Background: Pulmonary hypertension in COPD is of key prognostic significance. Doppler echo in the presence of TR can estimate RVSP/PAP. Acquisition rates and TR jet quality are reduced in COPD and hyperinflation. TR jet quality influences pressure estimation accuracy. An alternative assessment for PH is the time to peak pulmonary flow velocity, pulmonary acceleration time(ACT). An ACT <105 ms suggests PH. We examined the availability/quality of TR jet vs. pulmonary flow waves (FW) in COPD.

Methods: COPD patients were invited for echo and PFTs. Availability/quality of TR jet and FWs were assessed. RVSP was calculated from the max. TR velocity. RVSP=10 mmHg. ACT was a 3 measurement avg. using pulse wave Doppler placed in the right ventricular outflow tract.

Results: A total of 63 patients were screened, 63% male. Mean age 67.8 years (SD 11.5), FEV1 (%pred.) 64.7 vs 48.4 (p=0.01), FEV1/VC – 0.77 vs 0.69 (p=0.03), VC (%pred.) 84.7 vs 62.7 (p<0.05), TLC-VA (ml) – 660 vs 1470 (p=0.001), TLC-V/A. 58.5 vs 82.0 (p=0.01). TR was detected in 43 patients(68%) where TR jet was sufficient for RVSP measurement in 28(44% of total cohort). TR jet quality was poor, fair, good and excellent in 17,10,12, and 4 subjects respectively. Mean RVSP 43 mmHg, 95% CI[39-47]. ACT was measurable in 61 patients(97%) with good or excellent quality FWs in 58 (95%). Mean ACT 113 ms, 95% CI[108-118]; mean mAP 25 mmHg, 95% CI[23-28]. Subcostal vs. parasternal acquisition of ACT resulted in superior availability and quality in 80% of patients.

Conclusion: Contrasting RVSP, ACT is available in almost all COPD patients. TR jet quality is commonly poor whereas that of FWs is frequently excellent due to the ease of subcostal acquisition. These findings suggest that in addition to RVSP, ACT should be measured routinely when assessing COPD patients for PH.

P3926 Telemetric right ventricular pressure measurements and serial echocardiography in experimental pulmonary arterial hypertension

Michał Alexander de Rafał, Ingrid Schali, Antoni Vonk-Noordegraaf, Frances de Man, Harm Jan Bogaard. Department of Pulmonary Medicine, VU University Medical Center, Amsterdam, Netherlands

This study characterized hemodynamic changes in the Sugen-Hypoxia (SuHx) model by telemetric acquisition and echocardiography. The SuHx rat model is based on the combined exposure to the VILEG-receptor inhibitor SU5416 and hypoxia and is used in Pulmonary Arterial Hypertension (PAH) research due its histological features resembling the plexogenic pulmonary vascular remodeling seen in human PAH.

SU5416 (25 mg/kg s.c.) was administered and animals were housed at 10% oxygen for 4 weeks, followed by re-exposure to normoxic conditions. Telemetric right ventricular pressure acquisition was continuous from surgery onwards. Serial echocardiography was performed weekly under anesthetic conditions. Speckle tracking and speckle strain correlations were calculated between echocardiographic parameters and telemetric RVSP.

Telemetric RVSP increased immediately after administration of SU5416 and exposure to hypoxia. In the consecutive re-exposure to normoxic conditions, a considerable interindividual variability was observed. Echocardiographic parameters were similar to those in the first exposure to hypoxia. The correlation between echocardiographic parameters and telemetric RVSP was higher in the second exposure to hypoxia. The model might be useful for the study of PAH and the evaluation of new treatment strategies.
differences were less pronounced. RVEDD, but not PAAAT/c and TAPSE was significantly correlated to RVSP.

Telemetry and echocardiography both show a progressive response in the hypoxic period. Individual variability among animals resulted in different RVSP responses upon re-exposure to normoxic conditions. RVEDD correlated significantly with RVSP, whereas TAPSE and PAAAT/c seemed not suitable as surrogate markers for RVSP.

P3927 Correlation of computed tomography measurement of small pulmonary vessels with hemodynamic factors in pulmonary arterial hypertension

Yusuke Masegusa, Toshikazu Sugita, Naoko Kawata, Nobuhito Tanabe, Koshiro Tatsuni. Respiratory, Graduation School of Medicine, Chiba University, Chiba, Japan

Background: Previous studies have shown that the percentage of total cross-sectional area of small pulmonary vessels (CSA) for the lung area assessed on computed tomography (CT) is significantly correlated to pulmonary arterial hypertension (PAH).

Purpose: We aimed to study correlation of the percentage of CSA less than 5 mm² (%CSA<5) with hemodynamic factors in patients with pulmonary arterial hypertension (PAH).

Materials and methods: 14 subjects (5 male, 53±12 yrs) with PAH underwent noncontrast CT scan and right heart catheterization (RHC). Three CT slices were selected from noncontrast CT images. The upper cranial slice was taken approximately 1 cm above the upper margin of the aortic arch, the middle slice was taken approximately 1 cm below the baria, and the lower cranial slice was taken approximately 3 cm below the right inferior pulmonary vein. We measured CSA less than 5 mm² and lung area from each images, and calculated the percentage of total CSA for the lung area (%CSA<5). The correlation of %CSA<5 and hemodynamic data obtained by RHC were evaluated.

Results: %CSA<5 was 11.2±6.26%. mean pulmonary arterial pressure (mPAP), systolic pulmonary arterial pressure (sPAP), and pulmonary vascular resistance (PVR) were 41.0±15 mmHg, 65.27 mmHg and 53.6±332 dyn cm⁻², respectively. The correlation coefficient of %CSA<5 with sPAP, mPAP and PVR were -0.60 (P=0.02), -0.59 (P=0.03) and -0.60 (P=0.02), respectively.

Conclusions: %CSA<5 measured on CT images significantly correlate with sPAP, mPAP and PVR in subject with PAH.

P3928 Does lung function predict response to therapy in PAH associated with connective tissue disease?

Christopher Valerio1, Benjamin Schreiber1, Clive Handler1, Christopher Denton2, John Coghlin1. 1Pulmonary Hypertension, Royal Free Hospital, London, United Kingdom; 2Pulmonary Medicine, Royal Free Hospital & UCL Medical School, London, United Kingdom

Introduction: PAH specific therapies have been trialed in several lung diseases without success. It has also been shown that a low FVC is associated with a poor prognosis in CTD-PAH.

Methods: From the Royal Free Hospital pulmonary hypertension associated with connective tissue disease database we identified patients with lung function tests within 6 months of right heart catheterisation performed to confirm pulmonary hypertension. Patients who had repeat haemodynamic studies within a year of diagnosis on first line therapy (bosentan) were included.

Results: There were no significant haemodynamic differences between groups at baseline (ANOVA). Follow up catheter studies demonstrated a good haemodynamic response with improvements in mean PA pressure (FVC < 45%) and pulmonary vascular resistance (FVC > 70%).

P3930 Histopathology of idiopathic pulmonary arterial hypertension in patients with low or normal diffusion capacity

Eugene Nossekk1, Pia Trpp1, Harm jan Bogaard1, Anco Boonstra1, Anton Vonk-Noordegraaf1, Katrien Grunberg1. 1Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands; 2Pathology, VU University Medical Center, Amsterdam, Netherlands

Introduction: In patients with Idiopathic Pulmonary Arterial Hypertension (IPAH) a wide range of diffusion capacity for carbon monoxide (DLCO) values can be observed. Low DLCO in IPAH is associated with worse prognosis when compared to normal DLCO.

Hypothesis: Histopathological pattern(s) of pulmonary vasculopathy in IPAH differ between patients with low and normal DLCO.

Methods: We retrospectively analyzed the histopathological (combinations of) patterns of vasculopathy in IPAH patients with low and normal DLCO. Low DLCO was defined as lowest tertile of the bimodal distribution of DLCO-value in a series of 170 IPAH patients* (<45% pred.). DLCO in the upper 2 tertiles (>45% pred.) was defined as normal DLCO.

Results: Out of 170 IPAH patients, complete data sets were obtained in 20 patients: low DLCO N=10; normal DLCO N=10. Results are shown in table 1 (study is ongoing).

Conclusion: A PVOD*/PCH-like pattern is more common in IPAH with low DLCO, while plexogenic arteriopathy prevails in IPAH with normal DLCO.

Reference: [1] Trpp et al. abstract this meeting.
Conclusions:
Iron deficiency is more prevalent in SSc-PAH than in SSc patients (ID vs SSc-PAH without ID, p<0.001) while circulating iron, ferritin and transferrin were higher than in SSc (p<0.001), hepcidin in both groups.

Methods:
One year changes in cardiopulmonary exercise test variables and six minute walking distance (6MWD) were related to survival using Univariate Cox regression and Kaplan-Meier analysis in 40 PAH patients (mean age 44±2 yrs).

Results:
After a mean follow up time of 81 (±5) months, two patients were scheduled for lung transplantation and 10 had died. Survival analysis showed that from all exercise variables only one-year changes in maximal oxygen uptake (VO2), VO2/heart rate (O2pulse) and 6MWD were significant predictors of survival. Kaplan-Meier analysis (with ideal cut-off points estimated by receiver operating analysis) showed that patients with > 5% increase in VO2 or O2pulse had a significantly better cumulative survival (78±12% and 78±10%, respectively) compared to patients with < 5% increase in VO2 or O2pulse (cumulative survival 40±13% and 27±20%, respectively). Patients with < 6% decrease in 6MWD had a significantly better cumulative survival (84±7%) compared to patients with > 6% decrease in 6MWD (cumulative survival 25±15%).

Conclusion:
Changes in VO2, O2pulse and 6MWD from baseline to one year of follow up predict survival in PAH. Consequently, these variables could be considered to guide treatment in PAH patients.

Iron deficiency in patients with systemic sclerosis-associated pulmonary arterial hypertension

Gerrit Ruiters1,2, Alexandre Voskuyl1, Irene Lanzer1, Frances de Man1,2, Pieter Postma3, John Wharton4, Nico Westerhof, Willem van der Laarse5, Luke Howard1, Martin Wilkins1, Anton Vonk-Noordegraaf1, 1Pulmonology, Institute for Cardiovascular Research, VU University Medical Center, Amsterdam, Netherlands; 2Physiology, Institute for Cardiovascular Research, VU University Medical Center, Amsterdam, Netherlands; 3Rheumatology, VU University Medical Center, Amsterdam, Netherlands; 4Pharmacology and Therapeutics, Experimental Medicine, Hammersmith Hospital, Imperial College London; 5Pulmonary Hypertension Service, Hammersmith Hospital, Imperial College London, United Kingdom

Background:
Systemic sclerosis-associated pulmonary arterial hypertension (SSc-PAH) has a poor clinical outcome compared to other types of PAH. Recent data has shown that iron deficiency (ID) is associated with poor survival in idiopathic PAH. Inflammatory cytokines and increased hepcidin levels play a role. We hypothesise that a high prevalence of ID in SSc-PAH is linked to poor clinical outcome.

Methods:
Measures of iron status were performed retrospectively in serum from SSc-PAH patients (n=49) and systemic sclerotic patients without PAH (SSc, n=131). Six minute walking distance (6MWD) was also compared between the groups.

Results:
Circulating soluble transferrin receptor (sTfR) levels in SSc-PAH patients were higher than in SSc (p<0.001) while circulating iron, ferritin and transferrin saturation were reduced. The prevalence of ID, defined by sTfR >28.1 nmol/L, was 47% in SSc-PAH compared to 20% in SSc (p<0.001). Although hepcidin levels were lower in SSc-PAH than in SSc patients (p<0.001), hepcidin in both groups were high compared to reference values. There was no significant correlation with interleukin-6 (IL-6) levels (p=0.82), since IL-6 was higher in SSc-PAH compared to SSc patients (p<0.01). 6MWD was lower in SSc-PAH compared to SSc patients (p<0.001) and was even more reduced in case of ID (SSc-PAH with ID vs SSc-PAH without ID, p<0.05).

Conclusions:
Iron deficiency is more prevalent in SSc-PAH than in SSc patients and is associated with lower exercise capacity. The role of hepcidin in this process remains to be elucidated.
404. Epidemiology of asthma

P3936 Asthma and asthma-like symptoms in Greece. The Greece asthma national prevalence survey Eleftherios Zervas1, Stelios Loukides2, Konstantinos Kositskas2, Petros Bakkaoun3, Efthimis Tziratzakis1, Mina Gagua4, on behalf of Asthma Working Group of Hellenic Thoracic Society. 17th Respiratory Medicine Dept and Asthma Center, Athens Chest Hospital, Athens, Greece; 22nd Respiratory Medicine Dept, University of Athens Medical School, Attikon Hospital, Athens, Greece; 3Respiratory Medicine Dept, University of Athens Medical School, Athens Chest Hospital, Athens, Greece; 4Respiratory Medicine Dept, University of Crete Medical School, University Hospital, Heraklion, Greece

Background: Asthma is a major health problem world-wide. Prevalence surveys of asthma provide valid information and help design national programs of health care services. Recent were data missing from Greece.

Objectives: To study the prevalence of asthma and associated symptoms in the adult population of Greece.

Methods: A nation-wide, cross-sectional, community-based survey of asthma and asthma-like symptoms was conducted, using a pre-tested structured questionnaire based on the ECRHS Questionnaire for adults. A stratified random sampling method was used to select 2,191 participants, aged > 18 years old. Data was collected with face-to-face interviews.

Results: The self-reported current prevalence of physician-diagnosed asthma and asthma-like symptoms were as follows: physician-diagnosed asthma 9%, asthma attack 2.3%, use of asthma medication 3.7%, awakening from shortness of breath 22.3%, awakening from cough 24.1%, wheezing 19% and nasal allergies 23.3%. The incidence of asthma was calculated as 16 new cases per thousand people. Smoking prevalence was high both in the general population and in asthmatics (39.2% and 36.4%, respectively). Asthma prevalence was higher in Athens (10.9%), while there was no difference between rural and urban areas (8.5% and 7.8%, respectively).

Conclusions: The prevalence of asthma and associated symptoms in Greece is high, presenting a substantial increase from the last survey conducted 20 years ago. The results of this survey highlight the increasing social burden and impact of asthma in Greece and may aid policy makers and healthcare providers to plan effective health strategies for the proper diagnosis and management of this disease.

P3937 Assessment of the prevalence of bronchial asthma among the population in Yaroslavl from 1999 to 2010 and analysis of financial resources for the free-drugs from the funds of municipal budget in 2000-2010 Shamil Palvurtin1, Ilya Zilber2, Alexander Petrochenko1. 1Department of Clinical Pharmacology, Yaroslavl State Medical Academy, Yaroslavl, Russian Federation; 2Department of Pulmonology, Clinical Hospital n.a. N.V.Solovyev, Yaroslavl, Russian Federation

Objective: To evaluate the prevalence of bronchial asthma (BA) in Yaroslavl from 1999 to 2010 and analysis of financial resources for the free-drugs from the funds of municipal budget in 2000-2010.

Methods: A prospective cohort study; the data of the healthcare department.

Results: In 1999, patients with BA in Yaroslavl was 4053 man. In 2010 number of spirometry, unification of approaches to diagnosing of BA and education for doctors. Recent were data missing from Yaroslavl.

Implementation of standards and increased diagnostic capacity of healthcare made it possible to reveal a large number of patients with BA in the late 90-ies and in the beginning of 2000-ies. Due to great social significance of BA there was a steady tendency to increase the expenses on of free-drugs during the ten-year period.

P3938 Prevalence of asthma and asthma symptoms in a nationally-representative sample of adults in England Matt Kearney1, Jenny Mindell2, Rachel Craig3, Julia Hall4, Joanne Clarke1, Bronwen Thompson1, Anne Moger1, Kevin Holton1, Robert Winter4, Sue Hill1. 1Department of Health, Medical Directorate, London, United Kingdom; 2Department of Epidemiology & Public Health, University College London, United Kingdom; 3NatCen Social Research, NatCen Social Research, London, United Kingdom; 4Cambridge University Health Partners, Addenbrooke’s Hospital, Cambridge, United Kingdom

Introduction: Asthma imposes a major burden on the NHS and individuals, with high numbers of emergency department attendance, hospital admission and days lost from work. Although the goal of asthma treatment is for patients to be symptom-free and able to lead a normal active life, evidence suggests that there is a wide variation in quality of care and outcomes.

Aims: To estimate the prevalence of asthma and level of symptom control in the population of England.

Methods: The annual Health Survey of England is a cross-sectional study of a random, nationally representative sample of 8,000 adults. It includes detailed interviews and objective measures by nurses. The 2010 survey examined lung health awareness, earlier diagnosis and proactive disease management.

Results: The prevalence of lifetime doctor-diagnosed asthma was 16% in men and 17% in women: of these 30% of men and 39% of women had experienced an asthma attack in the last year. 9% of men and 10% of women had current asthma (i.e. symptoms or medication in the last 12 months): in the last week around half of these reported daytime symptoms, a quarter symptoms that interfered with usual activities, and a quarter difficulties with sleep. Over half those with current asthma used beta-agonist inhalers every day, suggesting inadequate management and poor symptom control.

Conclusion: This large population survey confirms that current symptomatic asthma is common and that many people with asthma have poor disease control with frequent symptoms that interfere with normal life. To tackle this, a national Outcomes Strategy for COPD and Asthma in England has been launched to promote lung health awareness, earlier diagnosis and proactive disease management.
Subjects with both the diagnoses of asthma and COPD represent a relevant clinical population with more severe and frequent exacerbations.

P3940
The prevalence of asthma symptoms in middle aged Australian adults
Michael Armstrong1, Michael Valente1, Minh Thi Hong Le1, Su Wei Khung1, Erik P. Rönmark2, Anders Bjerg3, Anders Bjerg4, Lucio Casali2, Maria Grazia Panico1, Pietro Pirritano1, Maria Grazia Panico5, Pietro Pirritano6, Caterina Bucca7, Giuseppe Verlato1, Marcella Ferrari1, Roberto de Marco1, Eva Rommark2, Kjell Toren3, Bo Lundback4, Jayanthi Natarajan9, Giselle Björkman6, Michael Valente3, Ming Zhe Liu1, Michael Valente1, Min Tho Hong Le1, Su Wei Khung1, Geza Benke1, Shi Yamali Dharmage1, Bruce Thompson1, 1School of Public Health & Preventive Medicine, Monash University, Melbourne, VIC, Australia; 2Centre of Molecular Environmental & Genetic Analysis, University of Melbourne, Parkville, VIC, Australia; 3Allergy, Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, VIC, Australia

Introduction: ISAAC and the European Community Respiratory Health Survey (ECRHS) have shown that the prevalence of asthma in children and young adults is higher in Australia than many other Western countries.

Aim: To describe changes in respiratory symptom prevalence in adults as they age.

Methods: We followed up a cohort of young adults from South Eastern Melbourne initially recruited for ECRHS in 1992. A validated postal questionnaire was sent to 726 surviving participants. After 1 month, non-respondents were sent a second survey. The survey is still on going.

Results: Of the first 166 questionnaires received to date, 73 (44%) were from males and the mean (SD) age was 55 (5.7) years. The prevalences (95%CI) of respiratory symptoms and diseases are:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Prevalence (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheezing in the last 12 months</td>
<td>25.5</td>

</tbody>
</table>

Conclusions: The prevalences of respiratory symptoms and asthma are broadly consistent with previous surveys of this age group. The prevalence of symptoms and diseases is significantly higher in females than in males. The prevalence of asthma increases with age. The results of this study are similar to those of the International Study of Asthma and Allergies in Childhood (ISAAC) and the European Community Respiratory Health Survey (ECRHS). The results of this study are similar to those of the International Study of Asthma and Allergies in Childhood (ISAAC) and the European Community Respiratory Health Survey (ECRHS).

Funding: NHMRC of Australia.

P3941
Association between upper airway diseases and bronchial asthma
Leonardo Antonio1, Pierpaolo Marchetti1, Massimiliano Bugiani1, Lucio Casali1, Maria Grazia Panico1, Pietro Pirritano1, Virginia Ferrerio1, Caterina Bucca2, Giuseppe Verlato1, Marcella Ferrari1, Roberto de Marco1, Eva Rommark2, Kjell Toren3, Bo Lundback4, Jayanthi Natarajan9, Giselle Björkman6, Michael Valente3, Ming Zhe Liu1, Michael Valente1, Min Tho Hong Le1, Su Wei Khung1, Geza Benke1, Shi Yamali Dharmage1, Bruce Thompson1, 1School of Public Health & Preventive Medicine, Monash University, Melbourne, VIC, Australia; 2Centre of Molecular Environmental & Genetic Analysis, University of Melbourne, Parkville, VIC, Australia; 3Allergy, Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, VIC, Australia

Background: In contrast to studies of asthma and rhinitis, few studies among adults investigating the associations between asthma, rhinitis and eczema have been published. The objective of the study was to investigate these associations including the impact of chronic rhinosinusitis.

Methods: A large-scale postal questionnaire on asthma, rhinitis, respiratory symptoms and eczema, as well as possible risk factors was mailed to 30000 randomly selected subjects aged 16-75 years in Sweden. Current disease was defined as report disease in combination with current symptoms or medicine use.

Results: The prevalence of current asthma, current rhinitis and current eczema was 8.0, 20.7 and 11.5%, respectively. The prevalence of those having either current asthma, rhinitis or eczema was 31.3%. Either current asthma or rhinitis was reported by 24.5%, current asthma or eczema by 17.8%, and current eczema or rhinitis by 28.3%. All three conditions was reported by 1.7%. The overlap was greatest for current asthma and rhinitis, 4.4%, while it was 3.9% for current rhinitis and eczema and 1.7% for current asthma and eczema. Family histories of either asthma and/or allergy were the dominating risk factors for all three conditions. Generally all clinical and morbidity variables, including lung function, methacholine reactivity and positive skin prick tests, were most affected among those having all three conditions, particularly if they also had chronic rhinosinusitis.

Conclusion: About one third of the adult population of West Sweden have either current asthma, rhinitis or eczema, while only 1% had all three conditions. Thus, there is a considerable need for more severe and frequent exacerbations.

P3942
Greater risk of wheeze in young female compared to male smokers – Results from the Swedish GAZLEN survey
Anders Bjerg1, Linda Ekerljung1, Jonas Eriksson1, Inga Sif Olafsdottir2, Roelinde Middelbeeld1, Karl Franklin3, Berit Forsberg3, Kjell Larsson3, Jan Lovatell1, Kjell Toren3, Sven-Erik Dahlen4, Bo Lundback5, Christer Janson6, 1Dept of Internal Medicine, Krefting Research Centre, University of Gothenburg, Göteborg, Sweden; 2Occupational and Environmental Medicine, Sahlgrenska School of Public Health, University of Gothenburg, Göteborg, Sweden; 3Centre for Allergy Research and Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 4Dept of Respiratory Medicine and Allergy, University of Umeå, Sweden; 5Environmental and Occupational Medicine, Dept of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 6Lang and Allergy Research, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 7Medical Sciences: Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden

Smoking has greater negative impacts on lung function and COPD risk in females. However, sex-related differences in smoking burden, body composition and exposure confound this association. We studied wheeze in relation to smoking and sex in a large well-characterised population.

In 2008 the GAZLEN questionnaire was mailed to 45000 Swedish adults (16-75 yrs), and 66% participated. Respiratory symptoms, smoking and other exposures were analysed by multivariate regression. Asthmatic wheeze: wheeze with breathlessness and without a cold.

Females reported more wheeze and asthma wheeze, 17.3% vs. 15.8% and 7.1% vs. 6.1%, all p<0.01. 39% of both sexes were ever-smokers, and more females were current smokers, 14.5% vs. 13.3%, p<0.01. Males had higher mean age, BMI and pack-years, all p<0.01. Twice as many males were exposed to gas, dust, fumes, and fewer had university education. Females had more traffic exposure and employment in healthcare and cleaning. Adjusted for all these factors, female current smokers aged 16-52 yrs had higher risk of wheeze and asthmatic wheeze, OR 1.28 vs. males (interaction p<0.04) and OR 1.52 (p<0.02). Each pack-year increased the risk of wheeze more in women, OR 1.01 (p<0.01). The interactions were independent of weight, height and age at smoking initiation, and less consistent in subjects aged >52 yrs.

The large, population-based study of female compared to male smokers had higher risk of wheeze after adjustment for important confounders. This increased susceptibility was greater in pre-menopausal ages, and was not explained by differences in body composition or smoking habits. This points toward biological, possibly hormonal, underlying mechanisms.
P3944 The association between metabolic factors and asthma in adolescents of southern Taiwan
Tsu-Nai Wang1, Tsu-Yu Yuan1, Li-Yu Wang2. 1 Department of Public Health, College of Health Science, Kaohsiung Medical University, Kaohsiung, Taiwan; 2 Department of Mackay Medical College, Mackay Medical College, New Taipei City, Taiwan

Background: The prevalence of asthma has increased distinctly over the last two decades. Amongst metabolic syndrome has also been observed. Few studies have discussed the relation between metabolic factors and asthma.

Objective: This study aimed to assess whether there is an association with asthma and metabolic factors.

Methods: The cross-sectional study randomly sampled 5783 subjects ≤ 18 years old from elementary, junior and senior high schools in southern Taiwan. There were 5754 eligible subjects in the ultimate analysis because they completed a questionnaire, anthropometric measurements and blood samples collection. Furthermore, we conducted a meta-analysis including 13 studies according to criteria to review the association with asthma, BMI, and total cholesterol (TC). We also found a significant association between asthma and abdominal fat (aOR=4.4, p=0.009) and high concentrations of cholesterol (aOR=1.9, p<0.001).

Conclusion: We did not measure high density cholesterol [HDLC] and low density cholesterol [LDLC]. Therefore, we cannot determine the relationship between disease and cholesterol was resulted from HDL or LDL. Asthma patients are more obese, have higher concentrations of cholesterol and more metabolic factors.

P3945 Incidence of asthma and wheeze among teenagers is associated with environmental risk factors
Linnea Hedman1, Martin Andersson1,2, Anders Bjerg1, Sigrid Sundberg1, Eva Ronmark1. 1The OLIN Studies, Norrbotten County Council, Luleå, Sweden; 2 Public Health and Clinical Medicine, Occupational and Environmental Health, Umeå University, Umeå, Sweden

Aim: To study the incidence of asthma and wheeze among teenagers in relation to environmental risk factors, including smoking.

Method: In a longitudinal study about asthma and allergic diseases within the Obstructive Lung Disease In Northern Sweden (OLIN) studies, a cohort of school children (n=3,430) was followed annually from age 7-8yrs by completion of an extended ISAAC questionnaire. Skin prick tests (SPT) were performed at age 12yrs. In the endpoint survey (age 18yrs) 2,861 (83% of original responders) participated. Risk factor analyses for the cumulative incidence of asthma and wheeze from age 12 to 18yrs were performed (mean follow-up time 6.5y).

Results: The cumulative incidence of physician-diagnosed asthma was 7.6%, current asthma 6.6%, and current wheeze 22.4%. Interestingly, increasing number of siblings was inversely related to the incidence of physician-diagnosed asthma, current asthma and current wheeze in multivariate analyses (OR 0.8-0.9). Current smoking was related to the incidence of asthma (OR 1.6) and current wheeze (OR 2.8). Ex-smoking (OR 2.5), living close to a road with heavy traffic (OR 1.3) and house dampness (OR 1.3), respectively, was significantly associated with the incidence of current wheeze. As expected, female sex, positive SPT, and parental history of asthma were also significant risk factors.

Conclusion: Beside the risk factors sex, positive SPT, and heredity of asthma, several environmental risk factors were found, including smoking, traffic exposure, and house dampness. Thus, the incidence of asthma and wheeze among teenagers could partly be reduced by smoking prevention and improvement of their living environment.

P3946 A longitudinal study of airway symptoms among local residents after a Norwegian air polluting oil tank explosion
Jens Tore Granslo1, Bjørn Eli Hollund1, Lygre Stein1, Magne Bråtveit2, Bente Elisabeth Meen1. 1The OLIN Studies, Northseth County Council, Luleå, Sweden; 2 Department of Public Health and Primary Health Care, University of Bergen, Norway

Background: In 2005 oil tanks containing mixtures of sulphuric hydrocarbons exploded and caught fire in a Norwegian industrial harbour. This study assesses airway symptoms in the nearby population approximately 1.5 and 3.5 years after the explosion.

Methods: The population was examined twice, 1.5 and 3.5 years after the explosion, including persons above 17 years. Persons living ≤5 km from the accident site were examined. The questionnaire comprised 200 persons living ≥20 km away. 317 persons answered a questionnaire including four questions with symptoms related to upper airways and eight related to lower airways.

Results: In the follow-up period “Cough with phlegm” among exposed males was significantly reduced from 43% to 28% (McNemar test p=0.015). In the control group 28% and 24% had cough with phlegm at these time points. Adjusted odds ratios between exposed and controls in the first and second examination were 2.1 (95% confidence interval 1.0, 4.5) and 1.7 (0.7, 2.9), respectively. “Daily cough” among exposed males were 46% and 35% in the first and second examination (McNemar test p=0.057), and 31% and 28% in the control group. Adjusted odds ratios were 2.7 (1.3, 5.8) and 1.5 (0.5, 3.6) when comparing exposed and controls in the first and second examination. There were no changes in prevalence of airway symptoms among females between 1.5 and 3.5 years after the accident.

Conclusion: The prevalence of some symptoms from the lower airways was reduced among exposed males in the follow up period after an oil tank explosion.

P3947 Weather variables and emergency hospital visits for adult asthma exacerbations in Malta
Eleanor Geraldo, Caroline Gouder, Josef Micallef, Richard Pulliccino. Department of Respiratory Medicine, Mater Dei Hospital, Birirkarja, Malta

Background: Asthma exacerbation requiring hospital treatment has been shown to exhibit seasonality in several studies

Objective: To analyse the relationship between weather conditions and hospital visits with asthma in Malta.

Methods: All Adults treated for asthma exacerbation in our accident & emergency department (ED) in 2010 were included retrospectively. Information on demographic variables was collected. Daily weather data including: temperature, barometric pressure, maximum % relative humidity, mean wind speed and precipitation; was obtained from the Meteorological office at Malta International Airport.

Results: 328 adults received treatment for asthma exacerbation at the ED in 2010; 53% required admission. 70.4% were females. A high incidence of ED visits was observed during November, December and January, with the lowest incidence recorded in June and July. A significant association was found between age and number of ED visits (p<0.005); with the most common being the 20-40 age group.

Conclusions: ED visits for asthma in Malta exhibit seasonality. These are associated with high mean wind speeds and high precipitation 1 and 2 days before presentation. These findings have important implications for developing an effective preventive strategy with increased vigilance during periods of increased risk.

P3948 Worrying smoking habits in young Swedish women
Goran Wennergren1, Linda Ekerljung2, Bernt Alm1, Jan Lottvall1. 1 Department of Paediatrics and Refferting Research Centre, University of Gothenburg, Sweden; 2 Krefting Research Centre, University of Gothenburg, Sweden

Background: Following 10 years of decreased smoking among young people in Sweden, we now have indications of a drastically increased smoking prevalence. The aim was to provide up-to-date information on the prevalence of smoking and smoke-associated respiratory symptoms in young adults in Sweden, with special focus on possible gender differences.

Methods: A large-scale, detailed postal questionnaire focusing on asthma and respiratory symptoms, as well as possible risk factors (the West Sweden Asthma study). The questionnaire was mailed to 30000 randomly selected subjects aged 16-75 years in Gothenburg and the surrounding region in western Sweden, response rate 62%. The analyses are based on responses from 2702 subjects aged 16-25 years (1154 men, 1548 women).

Results: Significantly more young women than men were active smokers (23.5% vs 15.9%; p<0.001). In addition, women started smoking earlier and smoked more cigarettes per day. Longstanding cough, sputum production, recurrent wheeze, any wheeze last year, dyspnoea, wheezing with breathlessness or without cold, waking with tight chest, nasal obstruction and rhinorrhoea were significantly more common in smokers compared with non-smokers.

Conclusion: The smokers to a great extent had smoking parents, while subjects with non-smoking parents in 75% were non-smokers. In the multivariate analysis, smoking increased the risk of symptoms, such as recurrent wheeze, OR 2.0 (95% CI 1.4-3.0) and sputum production, OR 2.4 (1.9-3.1).

P3949 Worrying smoking habits in young Swedish women
Goran Wennergren1, Linda Ekerljung2, Bernt Alm1, Jan Lottvall1.

Background: Following 10 years of decreased smoking among young people in Sweden, we now have indications of a drastically increased smoking prevalence. The aim was to provide up-to-date information on the prevalence of smoking and smoke-associated respiratory symptoms in young adults in Sweden, with special focus on possible gender differences.

P3949
Social determinants of asthma: Results from UK household longitudinal study
Ivy Sharia. European Centre for Environment and Human Health, Peninsula College of Medicine and Dentistry, Torquay, Cornwall, United Kingdom The William A. & Barbara R. Owens Institute for Behavioral Research, University of Georgia, GA, United States

Background: Asthma is a prevalent respiratory disease, but its social determinants are not well investigated in detail.

Aims: It is aimed to explore social determinants of asthma in recent years.

Methods: Data were extracted from UK Household Longitudinal Study (2009-2010). Demographics, family background, migration history, and self-rated health were taken as aspects of social determinants. Deprivation at the regional level was included as well. Asthma was defined according to physician diagnosis by self-reporting. Regression models were performed and 95% confidence intervals were calculated.

Results: Associations among family background, migration history, self-rated health, and asthma were observed (p < 0.001). Higher asthma episodes were also found in the deprived areas (p < 0.001). These are consistent with demonstration of a positive association between lower SES and risk of wheezing in children and adolescents, both in high- and low/middle-income countries from previous studies. These are also related to other medical chronic problems such as high blood pressure and heart disease.

Conclusions: The association between social inequality and asthma prevalence is critised not being fully understood until the 21st century and called on for further investigation. This study has tried to answer this with a large national representative sample with complete household conditions. Some shared contributing factors will absolutely need further care to be eliminated across common non-communicable diseases when then next step is to communicate with policy makers to generate proper strategies on preventing asthma from childhood to adulthood with a lifetime approach.

P3950
Difficult to control asthma in the EGEA2 study
Sébastien Candelise, Christiane Piri, Christophe Pison1,2, Frédéric Gomord1, Jocelyne Jun1, Nicole Le Moual1,2, Raphaelle Varraso1,2, Jean Bouquet1,2, Francine Kauffmann1,2, Valérie Siroux,1 1Team of Environmental Epidemiology Applied to Reproduction and Respiratory Health. National Institute of Health and Medical Research, U823, Albert Bonniot Institute, Joseph Fourier University, La Tronche, France; 2Pediatry, Grenoble University Hospital, La Tronche, France; 3Team of Respiratory and Environmental Epidemiology, Centre for Research in Epidemiology and Population Health (CESP), National Institute of Health and Medical Research, U1018, La Tronche, France; 4Team of Fundamental and Applied Bioenergetics, National Institute of Health and Medical Research, U1055, La Tronche, France; 5Pneumology, Grenoble University Hospital, La Tronche, France; 6Pneumology, Lyon University Hospital, Lyon, France; 7Pneumology, Trousseau Hospital, Paris, France; 8IFR69, Paris-Sud University, Villejuif, France; 9Pneumology, Montpellier University Hospital, Montpellier, France

Introduction: Many French asthmatics still have uncontrolled asthma which may result from inadequate or lack of compliance to treatment, or difficult to control asthma. The aim of this study was to compare phenotypic characteristics of the difficult asthma patients and well controlled patients.

Methods: The study was conducted in 406 asthmatics recruited in the EGEA study (Epidemiological study on the Genetics and Environment of Asthma) and was performed as a cross-sectional study in 2010. Demographics, family background, migration history, and self-rated health were collected. Regression models were performed and 95% confidence intervals were calculated.

Results: Among the 227 (56%) uncontrolled asthmatics (120 partly-controlled), 71 (31%) had a high level of treatment. Compared to uncontrolled asthmatics with low treatment, those with high treatment did not differ by sex and smoking, but were 10 years older (p < 0.001), had more often adult-onset asthma (46.5% vs 28.2%, p < 0.001), had lower FEV1/Spredicted (75.4±21.3 vs 87.7±19.3, p < 0.001) and reported more often regular medical visits in the last 12 months (72.9% vs 21.8%, p < 0.001), among whom 80.4% vs 64.7% with a respiratory specialist, p(0.03).

Conclusion: In the EGEA study, a majority of asthmatics was uncontrolled despite adequate treatment in one third of the subjects. In this cross-sectional analysis, uncontrolled asthmatics with high treatment had significantly lower FEV1 compared to those with low treatment. Further longitudinal analyses will be conducted to assess the long term effect of asthma treatment.

P3951
Prevalence of severe asthma in the hospital of Montes Claros - MG
Rodrigue Caldeira, Maíra Rodrigues, Medicine and Pneumology, Fanorte, Montes Claros, MG, Brazil Medicine, Fanorte, Montes Claros, MG, Brazil

Introduction: Asthma attacks can be triggered by respiratory infections, environmental pollutants, sudden temperature changes, among other factors, being directly related to an increased likelihood of hospitalization. Every year occurs 370,000 hospitalizations for asthma in Brazil and this is the fourth leading cause of hospitalization in the public health system.

Aims: To investigate the prevalence of severe asthma in hospitalized patients in the University Hospital in the city of Montes Claros - MG.

Methods: Descriptive and retrospective study. We have analyzed 111 medical records of patients admitted in the University Hospital from January 2008 to June 2011, due to the exacerbation of asthma. Through the use of a form, information have been collected from the medical records of 50 patients with severe asthma.

Results: The prevalence of severe asthma was 45%. Of the 50 patients with severe asthma, the average was 15 years, 60% were females, 52% had other hospitalizations due to asthma. 82% of the cases had asthma diagnosed before the admission. Of these, 44% of subjects were doing regular treatment and 31% used inhaled corticosteroids associated with bronchodilator. Regarding the hospitalization, the average of admission time was 4.6 days. Related to the climate was observed that most of the patients were admitted in the fall (40%) or in the winter (26%).

Conclusions: The study showed high prevalence of severe asthma and that there is an increase in primary care patients because of the frequency of asthma exacerbations hospitalizations. Moreover, few patients do regular treatment, which causes low life quality, absenteeism from school and work and risk of death.

P3952
Characteristics of the uncontrolled asthmatic patients on GINA step 4 treatment in Korea
Kwang Ha Yu1, Ki Suk Jung2, Yong Il Hwang3, Yong Bum Park4, San Yoon Lee1, Seung Hun Jung1, Joo Hee Kim1, Dong Gyu Kim1, Yang Deok Lee1, 1Internal Medicine, Konkuk University Hospital, Seoul, Korea; 2Internal Medicine, Hallym University Medical Center, Puang Chon, Korea; 3Internal Medicine, Hallym University Medical Center, Seoul, Korea; 4Internal Medicine, Korea University Hospital, Seoul, Korea

Although the majority of asthma patients can obtain the targeted level of control, some patients will not do so even with the best therapy. The aim of this study was to explore the clinical characteristics of the bronchial asthma patients who do not achieve the well-controlled status despite the step 4 treatment of the GINA guideline in Korea.

This study was a part of the clinical phenotype of asthma investigation in Korea which was performed using structure questionnaire during February 2011 - June 2011. Of the overall study subjects, we enrolled 112 patients from 5 teaching hospitals in Korea who were on GINA step 4 treatment at least 1 year. We defined the difficult-to-treat asthma as uncontrolled asthma status or at least 1 unscheduled visit during the prior year related to the treatment of the difficult asthma. We compared the demographic, clinical, and laboratory data between difficult-to-treat asthma patients and well controlled patients.

The difficult-to-asthma patients had lower the ratio of FEV1/FVC than well controlled asthma patients (66.8% vs 69.0%, p=0.008). The proportion of patients with experiencing the symptom aggravation in work/place was higher in difficult-to-treat group than well controlled group (33.3% vs 14.5%, p=0.03). However, the age, FEV1, smoking status and body-mass index were not different between the groups. The presence of co-morbidities such as COPD, reflux esophagitis and cardiovascular was not also different. In conclusion, a total 24.1% of asthma patients are not in well controlled status despite GINA step 4 treatment. Occupational history should be considered in these patients an addition to the known risk factors.

P3953
The number of asthma attacks reported by subjects with physician-diagnosed asthma in Italy has increased from 1998-2000 to 2007-2010. Preliminary results
Lucia Carzolletti1, Leonardo Antonicelli1, Lucio Casali1, Isa Cervieri1, Massimiliano Bugani2, Maria Grazia Panico2, Pietro Pirna2, Giuseppe Verlato1, Roberto de Marco1, 1Department of Public Health and Community Medicine, University of Verona, Italy, 2Department of Allergy, Immunology and Respiratory Diseases, University Hospital “Ospedali Riuniti” Ancona, Italy, 3Department of Internal Medicine - Unit of Respiratory Diseases, University of Perugia, Italy, 4Respiratory Diseases Division, Foundation IRCCS “San Matteo” Hospital, University of Pavia, Italy, 5Department of Respiratory Medicine, University of Turin, Italy, 6Unit of Epidemiology, ASL-52 Salerno, Salerno, Italy, 7Institute of Respiratory Diseases, University of Sassari, Italy

In Italy, the prevalence of current asthma increased during the last 10 years, but few information are available on the temporal change of asthma severity in the same period.

The present study is aimed at quantifying the temporal change in the number of asthma attacks as a proxy of asthma severity in the last 10 years in the Italian adult population with diagnosed current asthma.

The same screening questionnaire was administered to random samples of 20-44 year-old subjects from the general population in 4 Italian centres (Pavia, Sassari, Turin and Verona) in 1998-2000 (in the frame of the Italian Study on Asthma in Young Adults, ISAYA; response rate 76%) and in 2007-2010 (in the frame of the Gene Environment Interaction in Respiratory Diseases, GEIRD, study; response rate 53%). The number of asthma attacks was modelled by means of a negative binomial model, adjusting for centre, sex, age, drug use and design confounders.
Asthma in the Young Adults (ISAYA)

Asthma remission and longitudinal changes in control in the Italian Study on physician adherence to the prescribing guidelines. It needs to be clarified whether this increase in the mean number of asthma attacks in GEIRD with respect to ISAYA subjects with diagnosed current asthma had a 62% higher mean number of attacks (s.d. 10.1) in ISAYA and 4.4 (s.d. 13.2) in GEIRD. The adjusted relative change (95%CI:3.6;4.7%). The mean number of asthma attacks in the last year was 3.1 asthma attack in the last year increased from 2.8% (95%CI:2.5;3.2%) to 4.1% (95%CI:3.4;4.8) in 5 years.

Methods:
Aims and objectives: To evaluate and compare a comprehensive set of existing and novel regression-based estimators of parameters from the two-compartment model of exhaled nitric oxide. Since CaNO estimation is a key result of multiple flow FeNO estimates were highly correlated. We used simulated multiple flow datasets to assess the statistical properties of the estimators and multiple flow datasets from 1507 schoolchildren from the National Institute for Cancer Research (IST), Genova, Italy; 2Dept of Epidemiology, University of Verona, Italy; 3Dept of Public Health and Community Medicine, University of Verona, Italy; 405. Methodology in epidemiologic research

P3954
Asthma remission and longitudinal changes in control in the Italian Study on Asthma in the Young Adults (ISAYA)

Amelia Greens1, Luca Cazzolleti2, Angela Corsico1, Federica Albicini1, Erica Gmi1, Vanessa Rontoni1, Eti Maria Giulia Di Vincenzo1, Roberto de Marco2, Isa Cerveri1. 1Respiratory Diseases Department, Foundation IRCCS “San Matteo” Hospital, University of Pavia, Italy; 2Unit of Epidemiology & Medical Statistics Department of Public Health and Community Medicine, University of Verona, Italy

There is little information on asthma remission and longitudinal changes in control in the last decade. In the frame of the ISAYA, a random sample of 354 asthmatics identified between 1998 and 2000 in 6 Italian centres (Pavia, Torino, Verona, Pisa, Sassari, Sassuolo) was followed-up 10 years apart (response rate 60%). At follow-up, asthma was considered in remission if a subject did not report any asthma-like symptom or drug use in the last year. A modified version of the GINA classification of asthma control, based on the frequency of diurnal and nocturnal symptoms, daily life activity limitations, and rescue medication use, was used. One of the 210 subjects who participated in the follow-up, asthma had remitted in 61 (29%) subjects and was still present in 149 (71%). The likelihood of remission for subjects reporting asthma-like symptoms, attacks and asthma drug use at baseline was 70% for the same IDA in subjects who did not report them, as evaluated by means of a logistic model. Among non remitted subjects, 41 (28%) had controlled, 60 (41%) partially controlled and 46 (31%) uncontrolled asthma at baseline. Among 138 subjects with information at follow-up, 38 (28%) had controlled, 69 (50%) partially controlled and 31 (22%) uncontrolled asthma. At a multicomponent logistic model, women were more likely to have partially or uncontrolled asthma than men; increasing age, chronic cough and phlegm and total or partial lack of control at baseline increased the risk of uncontrolled asthma at follow-up. More than 1 out of 4 subjects with asthma recover from their illness; however, less than 30% of the remaining subjects had controlled asthma a decade after.

P3955
Seasonality of primary care utilization for asthma, COPD and pneumonia in Karachi (Pakistan)

Zeeshan Raza, Aiman Ghani, Aisha Ahmad, Fatima Ahmad, Nadeem Rizvi. Undergraduate Medical Student of fourth year, Dow Medical College, Karachi, Sindh, Pakistan

Background: The increase in the health care burden from respiratory diseases is noticeable in the developing countries and its seasonal variation has epidemiological significance. Aims and objectives: This study aimed to assess the seasonality of primary care utilization for acute exacerbations of respiratory diseases with respect to the age and gender of the patients and to examine the mortality rates of the patients hospitalized.

Methods: We conducted a retrospective study to assess the seasonal patterns in hospital admissions due to acute exacerbations of respiratory diseases (asthma, COPD and pneumonia) in Jinnah Postgraduate Medical Centre, Liaquat National Hospital, and Aga Khan University Hospital, Karachi for a two year period from January 1, 2009 to December 31, 2010. Data were collected from Hospital Records Department through patients discharge files of those who had a primary physician diagnosed for asthma; COPD or pneumonia. Climatic data for average rainfall and humidity were obtained from Pakistan Meteorological Department and was analyzed with respect to the seasonal distribution of the diseases.

Results: There were total 3,205 patients analyzed, from them 53.77% had asthma, 26.35% had COPD and 19.87% had pneumonia. Highest number of hospital admissions for COPD, pneumonia and asthma were observed from mid of Dec to Feb (Winter), with a peak occurring in the month of March (early Spring), whereas significantly less cases occurred in May(Summer) and November (Autumn).

Conclusion: The results demonstrated a clear seasonal pattern indicating the highest number of patients admitted in the month of winter and a peak occurring in the spring season for asthma, COPD and pneumonia.

P3956
Estimating parameters in the two-compartment model of exhaled nitric oxide

Sandra Eckel1, William Linn1,2, Kiros Berhanu3, Muhammad Salam1, Edward Rappaport1, Yue Zhang1, Frank Gilliland1. 1Preventive Medicine, University of Southern California, Los Angeles, CA; 2Environmental Health, Los Amigos Research & Education Institute, Downey, CA, United States

Introduction: The fractional concentration of exhaled nitric oxide (FeNO) is a biomarker of airway inflammation. FeNO decreases with increasing flow, which has led to the development of mathematical models whose parameters quantify proximal and distal sources. FeNO measured at the conventional 50 ml/s flow rate is primarily from proximal sources, so the parameters may provide additional insight. Parameters are estimated from FeNO data measured at multiple flow rates, but there is no standard estimation method.

Aims and objectives: To provide recent screening data from the German central laboratory for AATD in Marburg, Germany.

To provide recent screening data from the German central laboratory for AATD in Marburg, Germany.

Methods: From dried blood spot (DBS) samples we performed AAT measurements (for internal use only) and genotyping for S and Z alleles. When either of both tests was suggestive for AATD we went on to perform phenotyping by IEF. When phenotyping resulted in bands suggestive for rare deficiency alleles we conducted complete sequencing of the AAT gene.

Results: In the period from August 2003 to February 2012 more than 50,000 test kits had been requested of which 13,010 kits have been returned. Of these, 75 were not evaluable, and 185 samples had already been submitted before. Our results are based on 12,750 analyzed samples.

In descending order of frequency, we have diagnosed the following phenotypes: PMM (8577, 67.27%), PMZ (2383, 18.69%), PI (846, 6.69%), PIZ (441, 3.50%), PIZ (192, 1.51%), PSS (38, 0.29%). 140 samples were submitted to gene sequencing. Here we found 75 rare (R) genotypes (PZSR 59; PMR 10; PSR 2; PIR 2).

Conclusion: Almost a third (32.73%) of the submitted samples was found to represent at least a carrier status, and over 8% carried a genotype that is associated with a severe AATD. We conclude that screening is useful to detect AATD and should be expanded in Germany.

P3958
Normality ranges of urine oxidative stress markers (8-OHdG and isoprostane) in Italian people free from respiratory diseases – Preliminary results

M. Elisabetta Zanolin1, Aiman Ghani, Aisha Ahmad, Fatima Ahmad, Nadeem Rizvi. 1Respiratory Diseases Department, Foundation IRCCS “San Matteo” Hospital, University of Pavia, Italy; 2Unit of Epidemiology & Medical Statistics Department of Public Health and Community Medicine, University of Verona, Italy

Background: The study of oxidative stress (OxS) is becoming increasingly im-
portant in respiratory disease research. To our knowledge, the reference ranges of urinary 8-hyroxy-deoxy-guanosine (8-OhD) and 8-isoprostane (isoprostane), a DNA and a lipid oxidation product respectively, have not yet been determined in subjects without respiratory diseases.

Aim: To assess the reference range of 8-OHd and markers in Italian people aged 20-64 free from respiratory diseases (controls).

Methods: 8-OhD and isoprostane were measured in spot-urine samples collected in the frame of Gene-Environment Interactions in Respiratory Diseases (GEIRD) study, a nested multi-case control survey. The biomarkers levels were corrected on creatinine concentration. Only controls (n=227) were considered for this aim of the work. The possible effects of potential determinants on 8-OHd-biomarkers were studied before determining the normality range in selected subgroups of controls. Multiple linear regression was fitted to data using the logarithm of 8-OHd or isoprostane as dependent variables and sex, age, season, smoke, body mass index, as covariates. The appropriate percentiles were calculated.

Results: Both 8OHd and isoprostane concentrations were significantly higher in smokers than in non smokers (p<0.05 and 0.047 respectively), while the other covariates did not influence 8-OHd. The 95% 8-OHd normality range in non smokers varied from 0.26 to 25.94 ng/ml. The 95% isoprostane reference interval was 0.03 - 5.42 ng/ml in non smokers.

Conclusion: Provisional 95% normality range for urinary 8-OHd and isoprostane were determined in subjects free from respiratory diseases.

P3959 Levels of cat, grass and mite specific IgE and symptoms on specific exposure

Marco Oliveri1, Joachim Heinrich2, Dan Norback3, Simona Villani4, Josep M. Antó5, Giuseppe Verlato6, 1 Unit of Occupational Medicine, University Hospital, Verona, Italy; 2 Unit of Epidemiology & Medical Statistics, Dept. of Public Health & Community Medicine, University of Neuberg, Germany; 3Department of Medical Science & Environmental Medicine, Upsala University, Sweden; 4Department of Public Health, Neuroscience, Experimental and Legal Medicine, University of Parma, Italy; 5Centre for Research in Environmental Epidemiology, CREAL, Barcelona, Spain

Objective: To investigate the association between specific IgE levels to different allergens and symptoms on specific exposure.

Methods: In the frame of the European Community Respiratory Health Survey II specific IgE to cat, Timothy grass and house dust mite were assessed in 8409 subjects. Participants were asked whether they presented cough, wheeze, chest tightness, breath shortness, runny or stuffy nose, itchy or watering eyes on exposure to: cats, trees, grass, flowers, or pollen; a dusty part of the house, or near pillows or duvets.

Results: A clear dose-effect relationship was found between IgE levels to cat, grass and mite, respectively, and symptoms on exposure to animals, pollen and dust (Table 1). The relation between mite sensitization and symptoms on dust exposure was less steep. A similar pattern was observed when evaluating the number of symptoms on exposure: the Spearman’s ρ was, respectively, 0.45, 0.45 and 0.19 when considering the relation between sensitization to cat, grass and mite and number of symptoms on specific exposures.

Table 1. Percent prevalence of symptoms on exposure to animals, pollen and dust, respectively, as a function of IgE levels to cat, Timothy grass and house dust mite

Conclusion: Both the prevalence and the number of allergic symptoms on specific exposure increase with increasing specific IgE levels.

P3960 Candidate gene association study of chronic obstructive pulmonary disorder using a targeted high throughput sequencing approach

Joakim Klar1, 1 Unit of Thoracic Surgery, Tokyo Women’s Medical University, Chiba Medical Center, Chiba, Japan; 2Dept. of Thoracic Surgery, Tokyo Women’s Medical University, Yachiyo Medical Center, Chiba, Japan; 3Dept. of Lung Cancer Screening, Chiba Foundation for Health Promotion and Disease Prevention, Chiba, Japan; 4Dept. of Health and Welfare, Government of Chiba City, Chiba, Japan; 5Dept. of Disease Prevention, Chiba City Medical Association, Chiba, Japan; 6Dept. of Medical Oncology, Graduate School of Medicine, Chiba University; 7Dept. of Pulmonary Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan

Aims: Assessment of objective and subjective impairment of the upper airways in chronic obstructive pulmonary disease (COPD).

Background: Pathologic correlates of the upper airways have been rarely evaluated in chronic obstructive pulmonary disease (COPD).

Methods: Chronic obstructive pulmonary disease (COPD), a progressive and disabling disease, is characterized by airflow limitation accompanied by symptoms including breathlessness, chronic cough, and sputum production. It is the third leading cause of death worldwide, and it is responsible for a significant burden of disease, including hospitalizations, emergency department visits, and workdays lost. The prevalence of COPD is estimated to be 15% of the adult population, and the prevalence is expected to increase as a result of the aging population and increased smoking rates. The pathogenesis of COPD is complex and involves both genetic and environmental factors. Genetic studies in humans and in animal models suggest that developmental genes are important determinants of adult lung function that may ultimately contribute to COPD.

Results: Patients carrying mutations in FGF10 show a significant decrease in lung function parameters consistent with COPD. Based on these results, we are currently investigating in total 200 kb enriched sequence, including 22 genes implicated in lung development and 71 genes or regions previously associated to COPD.

Conclusion: These findings support the idea that genetic variants affecting lung developmental genes are important determinants of adult lung function that may ultimately contribute to COPD.

P3961 Efficacy of COPD detection by using a community-based annual screening program for lung cancer

Yasu Sekine1, Kimimori Suzuki2, Kazuko Kubota3, Hiroshi Ikegami4, Tadahiko Fujisawa5, 1Dept. of Thoracic Surgery, Tokyo Women’s Medical University, Chiba Medical Center, Chiba, Japan; 2Dept. of Lung Cancer Screening, Chiba Foundation for Health Promotion and Disease Prevention, Chiba, Japan; 3Dept. of Health and Welfare, Government of Chiba City, Chiba, Japan; 4Dept. of Disease Prevention, Chiba City Medical Association, Chiba, Japan; 5Dept. of Medical Oncology, Graduate School of Medicine, Chiba University, Chiba, Japan

Aims: Assessment of the effectiveness of COPD detection by using a community-based annual screening program for lung cancer.

Background: In Japan, community-based lung cancer screening by chest X-ray has been established. Japanese residents who are 40 years old or higher can freely receive chest X-ray every year. We utilized this screening system in Chiba City in order to detect COPD. From April 2010 to March 2011, 83,924 participants received regular lung cancer screening by chest X-ray at the first examination centers, which was approximately 30% of objective residents. We set the criteria of suspicious of COPD indicating 60 years or older, positive smoking history and having any chronic respiratory symptoms. 1,170 (1.3%) were recognized as suspicious of COPD and 351 of them (36.2%) received further examination including pulmonary function test (PFT) and/or chest computed tomography (CT) as the second close examination at 39 second examination centers.

Results: 138 participants (25.0%) were reported as COPD from the second examination centers and 42.2% of them were necessary for COPD treatment. Only eight participants (5.8%) were already diagnosed COPD before screening. PFT and/or chest computed tomography (CT) could be collected from 173 participants, and 43 (24.9%) were diagnosed as COPD (FEV1 less than 70%). Emphysema grades according to Goddard classification on CT revealed that 21.1% was radiological emphysema. One patient with normal chest X-ray was detected lung cancer by CT and could receive curative surgery.

Conclusion: COPD screening by using a community-based lung cancer screening program may be effective for detection of COPD. These patients can be treated COPD as early as possible.

P3962 Computed tomography of the paranasal sinuses in chronic obstructive pulmonary disease

Euzer Helen Stensel1, Caroline Newerla2, Selina Durr1, Claudia Gerhards1, Sabina Mair1, Christoph Stoppich1, Antje Welge-Lüssen3, Stefanie Zogg2, Yasuo Sekine1, Joachim Heinrich2, Dan Norback3, Simona Villani4, Josep M. Antó5, Giuseppe Verlato6, 1Dept. of Pulmonary Medicine, University Hospital, Basel, Switzerland; 2Radiology, University Hospital, Basel, Switzerland; 3Otorhinology, University Hospital, Basel, Switzerland

Aims: To investigate candidate genes, with emphasis on genes important for lung development, for genetic variants predisposing to the development of chronic obstructive pulmonary disease (COPD) using targeted enrichment in a cohort of COPD patients.

Methods: Twelve patients with heterozygous loss of function mutations in a lung developmental gene, the fibroblast growth factor 10 (FGF10), was investigated for pulmonary function and COPD was classified according to the ATS/EURS 2005 standard. To identify novel variants associated with COPD, we are currently conducting a candidate gene association approach using targeted enrichment (Haloplex; Halo Genomics) and a high throughput sequencing (Illumina) using patients and controls retrieved from the Swedish Obstructive Lung Disease in Norrbotten (OLIN) sample set. This strategy allows for the detection of all genetic variants in the enriched sequence, without the limitations when investigating known variants using SNP arrays.

Results: Patients carrying mutations in FGF10 show a significant decrease in lung function parameters consistent with COPD. Based on these results, we are currently investigating in total 200 kb enriched sequence, including 22 genes implicated in lung development and 71 genes or regions previously associated to COPD.

Conclusion: These findings support the idea that genetic variants affecting lung developmental genes are important determinants of adult lung function that may ultimately contribute to COPD.
We found a positive correlation between the CT score and the SNOT-PNS (r = 0.22, p < 0.05). The endoscopic score correlated positively with the SNOT-PNS (r = 0.29, p < 0.05) as well as with the SNOT-20 (r = 0.42, p < 0.01). Subjects in higher risk groups presented higher scores in endoscopy (p < 0.05), SNOT-PNS (p < 0.05) and SNOT-20 (p < 0.01).

Conclusion: Pathologic correlates of the upper airways were found in more than half of the patients with COPD.

P3963 Waist circumference and lung function among adolescents: The Pelotas 1993 birth cohort

Fernando C. Wehrmeister1, Jerovnya Martinez-Mesa1, Pedro C. Hallal1, Helen Gonçalves1, Cora Araújo1, Maria C.F. Assunção1, Ricardo B. Noal1, Rogelio Perez-Padilla2, Ana Maria B. Menezes1. 1Post-Graduate Program in Epidemiology, Federal University of Pelotas, Brazil; 2National Institute of Respiratory Diseases, National Institute of Respiratory Diseases, Mexico City, Mexico

Background: BMI is frequently used to evaluate obesity, but it is unable to assess fat distribution. Much attention has been given to abdominal fat measured by waist circumference (WC). Abdominal fat is a known risk factor for chronic diseases, but the impact of lung function among adolescents remains uncertain.

Objective: To evaluate the association between WC and lung function parameters among adolescents.

Methods: The original cohort comprised 5,249 hospital born children during the calendar year of 1993 in Pelotas, Brazil. In 2008-9, when participants were 15 years old, all cohort members were evaluated. WC was measured by trained interviewers and lung function tests were performed to obtain FVC and FEV1. Multiple linear regression models were performed and all analyses were stratified by sex.

Results: 1,969 boys and 2,032 girls had data for spirometry and for WC. In the crude analyses we found a positive relationship between WC and FVC (liters) for both boys and girls. After adjusting for height, BMI, physical activity and wheezing in the past year, we found an inverse relationship between WC and FEV1 (β = -0.015 [95%CI -0.023; -0.008]), and FVC (β = -0.010 [95%CI -0.018; -0.001]) only for boys. For girls, the association was not significant. When we analyzed the predicted values, there was a significant association with WC, (%FEV1, β = 0.413 [95%CI -0.619; -0.206]; %FVC β = -0.242 [95%CI -0.464; -0.205]) only for boys.

Conclusions: Increases in WC were associated with worse lung function parameters in Brazilian boys aged 15 years old. Improvement of lung health in adolescent can prevent lung diseases in adult life.

P3964 Lung function and respiratory symptoms as predictors of mortality: The HUNT study

Linda Leivseth1, Tom Ivar Lund Nilsen2, Xiao-Mei Mai1, Roar Johnsen1, Arnulf Langhammer1, 1Department of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim, Norway; 2Department of Human Movement Science, Norwegian University of Science and Technology, Trondheim, Norway; 3Department of Public Health and General Practice, HUNT Research Centre, Norwegian University of Science and Technology, Levanger, Norway

Background: Impaired lung function is associated with increased mortality. However, whether respiratory symptoms, independent of lung function, are associated with all-cause or cardiovascular (CV) mortality is not clear.

Objective: To prospectively study associations of lung function and respiratory symptoms with all-cause or CV mortality is not clear. How- ever, whether respiratory symptoms, independent of lung function, are associated with all-cause or CV mortality is not clear. Therefore, we conducted a cross-sectional study to investigate this relationship.

Methods: The study included 5319 women and 4972 men who participated in the Lung study of the Norwegian HUNT study in 1995-97. Cox regression was used to calculate adjusted hazard ratios (HRs) for all-cause and CV death associated with pre-bronchodilator percent of predicted FEV1 (ppFEV1), grades of COPD, and respiratory symptoms (chronic bronchitis, wheeze, and dyspnoea).

Results: Lung function was inversely associated with all-cause mortality. A 10% reduction in ppFEV1, gave a HR of 1.17 (95% confidence interval [CI] 1.09-1.25) in women and 1.23 (95% CI 1.16-1.30) in men. Compared to ppFEV1 < 70%, ppFEV1 < 50% was associated with a HR of 6.85 (95% CI 4.46-10.52) in women and 3.88 (95% CI 2.60-5.79) in men. Results for COPD grades corresponded to those found for ppFEV1. Levels of the respiratory symptoms, only dyspnoea remained associated with all-cause mortality after adjusting for lung function (HR 1.68 [95% CI 1.11-2.53] in women and 1.63 [95% CI 1.11-2.11] in men), and within levels of lung function. Overall, associations between lung function and CV mortality were weaker, and no clear relation was found for respiratory symptoms.

Conclusions: Our results suggest that pre-bronchodilator lung function is a strong predictor of all-cause mortality, and that dyspnoea is associated with all-cause mortality independent of lung function.

P3965 The effect of menopause on the lung function among Korean women; the fourth Korean National Health and Nutrition Examination Survey (KHANES IV)

Won Jai Jung1, Young Sam Kim1, Jin Ye Jung1, Kyung Su Jung1, Eun Young Kim1, Se Kyu Kim1, Joon Chang1. 1Division of Pulmonology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Sex hormones appear to play an important role in women’s lung health. But the literature on menopause and lung health is scarce, especially lung function. Some studies showed improvement or no change in forced expiratory volume in the first second (FEV1), forced volume capacity (FVC) in association with hormone therapy. And a few studies showed that postmenopausal women had significantly lower FEV1 and FVC, especially among lean women. This study examined whether menopausal status was related to the lung function.

Design & methods: Data were obtained from the 4th Korean National Health and Nutrition Examination Survey of 2007-9. A total of 1382 Women aged 44 to 61 years not receiving hormone replacement (712 premenopausal women and 670 postmenopausal women) were included in this analysis. Women who were current pregnancy, lactation, amenorrhea induced by hysterectomy were excluded. In our study, a postmenopausal woman was defined as a woman whose current age was 1 year after her age of menopause.Age, height, BMI, smoking status were adjusted by multiple linear regression analysis.

Results: Postmenopausal status is not significantly associated with lower FVC (-33mL, p-value = 0.353), but associated with lower FEV1 (-77mL, p-value = 0.032).

Conclusion: Postmenopausal status can be related with lower lung function in this study.

P3966 Effect of hospitalization on exercise capacity in patients with chronic obstructive pulmonary disease (COPD)

Maria Antonia Rupon1, Elena Gismondo-Santos1, Jaume Ferrer1, Judith Garcia-Aymerich2. 1Department of Pulmonology, University Hospital Vall d’Hebron, Barcelona, Spain; 2CREAL Centre for Research in Environmental Epidemiology (CREAL). Barcelona, Spain

Introduction: Exercise capacity has become an important measure to assess COPD functional status, response to medical interventions and prognosis. However, the determinants of exercise capacity change over time in COPD patients are poorly known.

Aim: To estimate the effect of hospital admissions on exercise capacity decline in COPD patients.

Measurements: 226 patients with moderate-to-severe COPD from our original PAC-COPD Study had their exercise capacity measured when clinically stable using the six minute walking distance (6MWD) both at baseline and 1.7 years after. Sociodemographic variables, lifestyle, co-morbidities, and clinical and functional status were also assessed. Hospital admissions (timelines and causes) during the follow-up were gathered from centralized government datasets. Linear regression was used to model changes in exercise capacity.

Results: At baseline, patients were mostly male (92%), aged mean (SD) 67(8) years, postbronchodilator FEV1 54(17)% and 6MWD 448(83) m. During the follow-up period, patients decreased their exercise capacity (mean -20m/y). More- over, 87 (39%) had at least one hospitalization (more than a half due to COPD). After adjusting for dyspnea, lung hyperinflation (RV/TLC), and baseline 6MWD, COPD admissions rate increased the 6MWD decline: -15m/y and -30m/y in ≤1 admission/year and > 1 admission/year, respectively, compared to patients with no admissions (p<0.001). Remaining variables were not related to the 6MWD decline, after adjusting for hospital admission.

Conclusions: These findings show that hospital admissions due to COPD exacerbation have a great impact on exercise capacity deterioration in moderate-to-severe COPD patients.

P3967 Chronic obstructive pulmonary disease surveillance: Potential usefulness of the Texas behavioral risk factor survey surveillance system

David Colbaugh1, Bradford Jackson2, Karon Singh7, Sejong Bae3. 1Internal Medicine, University of Texas HSC-Tyler, TX, United States; 2Biostatistics, University of North Texas HSC, Fort Worth, TX, United States

Background: Public health surveillance of COPD has traditionally focused on risk factors and measures of disease occurrence, but these measures are insufficient to monitor effectiveness of disease control strategies.

Objectives: The purpose of this analysis was to evaluate the potential usefulness of a population-based telephone surveillance system for monitoring patient-reported outcomes among patients with COPD.

Methods: The Behavioral Risk Factor Surveillance System (BRFSS) is a state- based system of telephone surveys. In 2009, the Texas BRFSS included a question about physician-diagnosed COPD and self-rated health status. We conducted a cross-sectional analysis of self-reported COPD, fair/poor health status, and the in- fluence of lifestyle factors, health care access and co-morbidity conditions. Adjusted prevalence ratios (PR) were calculated using multivariate logistic regression.
Results: Adults with COPD reported significantly worse health status compared to adults without COPD (fair/poor: 49.1% vs. 13.7%, p < 0.001). In multivariate analyses lifestyle and health care access factors significantly (p < 0.05) associated with fair/poor health status included: current smoker (PR=2.9), former smoker (PR=2.0), physical inactivity (PR=3.0), having a personal doctor (PR=4.8), inability to see a doctor due to costs (PR=3.6), and pneumonia shot (PR=6.1). Co-variables considered significantly (p < 0.05) associated with fair/poor health status were: obesity (PR=3.5), asthma (PR=1.7), cardiovascular disease (PR=3.2), and cancer (PR=1.7).

Conclusion: These results suggest that the BRFFS may be useful at the population level for surveillance of COPD.

P3968 Newly developed simple QoL questionnaire in early detection of COPD in a population of smokers at risk for COPD development
Biserka Radićević1, Vlasta Jurić1, Ante Pejčić2, Luka Kačka3, Nino Kharevich3, Ivan Gudelj1, Rosandica Rosandic-Pašević1, Karla Tuđa1, Zdenka Mestrović1, Davorka Martinkovic1, Dave Plesac2. 1Psychology, Institute for Medical Research a Occupational Health, Zagreb, Croatia; 2University Centre for Research a Occupational Health, Zagreb, Croatia; 3Department for Internal Medicine, County Hospital, Dubrovnik, Croatia

Objective: Assessing the role of the newly developed QoL questionnaire (MARKOQ) in early detection of COPD in a population at risk for COPD.

Methods: The MARKOQ is a self-administered questionnaire with 18 questions. Subjects were smokers with ≥20 pack-years, both gender, 40-65 yrs of age, with no diagnosis of COPD. They were referred to a pulmologist (history, physical, lung function) for diagnosis of COPD and the staging. MARKOQ was administered twice at primary care clinic and 2-4 weeks later at a pulmonology clinic.

Results: Sample included 219 consecutive subjects (48.5% males), mean (SD) age 52.6 (6.9) yrs with 38.0 (17.4) pack-years. 25.3% were diagnosed as COPD (stage I, 18.1%, stage II 6.7%, stage III 0.6%). Spearman correlations showed very good internal consistency of MARKOQ (Cronbach’s alpha=0.89) and test-retest reliability (r=0.84). The correlation with CAT scores was r=0.54. MARKOQ significantly discriminated (F=20.2, p=0.003) patients with GOLD stage II or higher (mean=19.9, SD=8.7) from those in stage I (mean=12.9, SD=10.1) and “healthy” smokers (mean=12.9, SD=8.4) (CAT scores were not discriminative). Correlations of MARKOQ scores were only significant for FEV1 (r=0.22, p=0.003).

Conclusion: The MARKOQ developed for an early detection of COPD may be able to detect early changes in QoL complementary to lung function impairment. The exact validity of the MARKOQ will be known after the reevaluation based on the cohort follow-up.

Supported by an unrestricted grant by GlaxoSmithKline (GSK) E-Tracking number CTR114338.

P3969 External multicentric validation of a COPD detection questionnaire
Miguel Berenguer1, Gabriel García1, Ramon Alchagor1, Hector Altieri1, Oscar Cabedoloto1, Juan Figueroa Casas1, Luis Larrategui1, Luis Nannini1, Pedro Grabate1, Gustavo Zabert1, Daniel Paskansky1, Sebastian Fuclé2. 1Sociedad Espanola de bronquial obstructiva crónica (SEGOB), Buenos Aires, Argentina; 2Departamento Medico Novartis, Laboratorio Novartis, Buenos Aires, Argentina

Introduction: Chronic obstructive pulmonary disease (COPD) is a preventable disease. The development of a simple questionnaire can help to improve the diagnosis.

Objective: External validation of the questionnaire to detect COPD in Argentina.

Material and Methods: We performed a questionnaire in subjects with over 40 years old and history of smoking ≥ 10 or more pack/year. Demographic data and pre and post bronchodilator spirometry were performed. Subjects with previous diagnosis of COPD or asthma were excluded.

Results: 468 subjects were evaluated. 100 (21.1%) had spirometric diagnosis of COPD. In univariate analysis patients with COPD had higher median age (58 years vs 54 years, p < 0.001), pack years (PR=50) versus 30 (p < 0.001), lower BMI (26 vs 28, P = 0.02), higher incidence of males (68.8% vs 43.9%, P < 0.001), cough for 3 months (55.2% vs 33.8%, P=0.001), chronic cough (47.9% vs 28.8%, P < 0.001), phlegm for 3 months (50% vs 37.2, P=0.02), chronic phlegm (40.6% vs 26.1%, P = 0.005), dyspnea (62.5% vs 51.9%, P = 0.06), wheezing (55.2% vs 47%, P = 0.15), wheezing without infection (38.5% vs 33.9%, P = 0.39), stave at home (10.4% vs 7.5%, P = 0.35) and risk profession (18.9% vs 18.5%, P = 0.78). The presence of at least 3 of these variables had a sensitivity of 95% and a specificity of 25.29%, positive predictive value (PPV) of 22.62% and negative predictive value (NPV) of 95.65%. The presence of at least 6 variables had a sensitivity of 90% and a specificity of 70.97%, a PPV of 50% and a NPV of 95.65%

Conclusion: This simple questionnaire for demographic and clinical data can be useful for detection of COPD.

P3970 Childhood asthma control test: Validation of the Arabic Tunisian dialect version in 51 patients
Hanadi Ouali1, Makram Zied1, Anissa Berraiss1, Boutheina Ben Safia1, Jamel Ammar2, Amira Sellami1, Samir Ennigrou1, Agnès Hamzaoui1. 1IB Department of Pediatric and Respiratory Disease, Abderrahmen Mami Hospital, Ariana, Tunis, Tunisia; 2Epidemiology, Medicine University, Tunis, Tunisia

Children Asthma Control Test or c-ACT was translated in different languages. We propose to validate the Arabic Tunisian version by checking if it’s understood by patients and their parents and the conformity with the control criteria of international recommendations. Cross-sectional study was conducted in 51 asthmatic children, aged from 4 to 11 years, followed for at least 6 months. c-ACT was administrated before consultation. The level of asthma control was compared to that estimated by the expert based on GINA criteria with an evaluation period of 4 weeks. Understanding of this Arabic version has been confirmed with the parents and their patients. This version showed a satisfactory internal consistency with Cronbach’s alpha equal to 0.853. The area under the ROC curve equal to 0.993 is highly significant (p < 0.001). The c-ACT showed a significant discriminative ability of patients with different level of control of their asthma (p < 0.001). The study of the performance of c-ACT 19 point threshold, to identify children uncontrolled, found a sensitivity of 73.7% and negative predictive value of 86.5%. Considering the 20 point threshold, sensitivity and negative predictive value reached respectively 94.7% and 96.9%. There is a highly significant correlation (p < 0.0001) between the level of control patients detected by the c-ACT and that estimated by the specialist with a kappa coefficient equal to 0.778. Most children have understood the Arabic version of the c-ACT. This study demonstrated a good correlation between the result of c-ACT in dialectal Arabic and clinical evaluation. The usefulness of this version will be evaluated after its release.

P3971 Shortness of breath associated with chronic conditions among those with and without asthma or COPD
Joshua Lawson, Shelley Kyrkych, Rhonda Bryce, Punam Pathwa, Chandima Karunanayake, Louise Hagel, Donna Rennie, James Dosman. Canadian Centre for Health and Safety in Agriculture, University of Saskatchewan, Saskatoon, Canada

Background: Some chronic conditions may result from similar underlying mechanisms or may exacerbate lung disease suggesting the investigation of disease inter-relationships. We sought to determine if SOB was more common among adults with chronic conditions and to examine this association among those with asthma and COPD.

Methods: In 2010 we conducted a cross-sectional mail survey of rural households as part of the Saskatchewan Rural Health Study. One adult per home provided information about each adult living in the home. There were 8261 adults from 4624 households (42% participation) included. We examined the associations between reported diagnosed chronic conditions (diabetes, cardiovascular disease, and sleep apnea) and SOB after adjusting for potential confounders and stratifying by history of doctor-diagnosed asthma or COPD. High SOB was defined by a score of ≥ 3 on the MRC breathlessness scale.

Results: The respondents’ mean age was 56 years (SD=16 years) with 51% of the population being female. Approximately 14% had a MRC score ≥ 3. After adjustment, there was increased risk of high MRC score associated with the presence of diabetes (odds ratio (OR)=1.68, 95% confidence interval (CI)=1.32-2.14), cardiovascular disease (OR=2.18, 95%CI=1.80-2.65), and sleep apnea (OR=2.19, 95%CI=1.60-3.00). The associations with SOB were weaker among those with asthma or COPD with the exception of that for sleep apnea, which was stronger.

Conclusions: Some conditions were associated with high SOB among those with and without a history of lung disease. These relationships may result from common pathways, possibly inflammatory, and may precede more serious chronic lung disease.

P3972 Detection of quality of life with COPD assessment test in chronic obstructive pulmonary disease and effect of dyspnea on disease-specific quality of life in these patients
Qasirnan Okutan, Dilaver Tas, Ersin Derimier, Zafer Kartaloglu. Pulmonary Diseases, Gatahane Military Medical Academy, Istanbul, Turkey

Background: The measurements for level of dyspnea such as Medical Research Council (MRC) dyspnea scale or modified Borg dyspnea scale were used common in the trials. COPD assessment test (CAT) is a recently introduced to use to disease-specific quality of life and follow-up of the patients with COPD.

Objective: We aimed that assessed effect of the dyspnea in disease-specific quality of life detected by CAT score in the patients with COPD.

Methods: In this study, 90 stable patients with COPD as defined by the GOLD criteria were included. The level of dyspnea was assessed with two different scales, MRC dyspnea scale and modified Borg dyspnea scale, and disease-specific quality of life assessed with the CAT score.

Results: Patients’ mean ± SD age was 68.5±10.9 (range 41 – 97) years. A significant relationship was established among CAT score, MRC dyspnea scale, modified Borg dyspnea scale, the GOLD stage of the patients with COPD. There

Tuesday, September 4th 2012

731s
was a positive correlation between dyspnea scales and the GOLD stage of the patients (p<0.001), and also positive correlation between CAT score and dyspnea scales (p<0.001). The CAT score and dyspnea scales had a significant correlation with hospitalization and emergency room applications (p<0.05).

**Conclusion:** It is suggested that dyspnea is an important symptom that impacts the quality of life in patients with COPD. The CAT is simple, fast and an easy intelligible measurement for the disease-specific quality of life and it is correlated with levels of dyspnea of the patients with COPD.

### P3973 Validation of quality of life questionnaire St George’s for patients with respiratory diseases in Colombia, Latin America

**Authors:** Ana Carolina Vargas1, Vector Calvo2, Antioquia, Hospital San Vicente de Paúl, Medellín, Antioquia, Colombia; 2 Antioquia, Instituto de Alta Tecnología Médica, Medellín, Antioquia, Colombia

**Background:** The SGRQ a self-administered questionnaire specific for pulmonary diseases, validated in different cultures and countries. The objective of this study was to adapt one specific scale of quality of life in patients with acute and chronic pulmonary diseases in Colombia, Latin America.

**Materials and methods:** The Spanish version of the SGRQ was applied to 277 patients with COPD and asthma; the different components and overall scores of SGRQ were described; the forced expiratory volume in one second (FEV1), % predicted FEV1, 6-minute walk test (6MWT) and SF36 were used in the assessment battery.

**Results:** The SGRQ showed Chronbach’s alpha coefficient internal consistence was 0.94 for the overall total scale, 0.89 for symptoms, 0.93 for activity and 0.89 for impact. Correlations of coefficient inter-reliability were 0.82 and intra-reliability 0.065 for the overall scores. The contents validity of the three factor structure was established; in construct validity met a slight difference between acute and chronic patients in activity with statistically and clinically significant (p<0.05). On evaluation of the concurrent validity of the SGRQ and the score of physical function (α=0.67), vitality (α=0.51) and social function (α=0.46) of SF68, good correlations were found. The responsiveness showed statistical differences (p<0.05) with the scores being less in the second measurement (better quality of life).

**Conclusions:** SGRQ version for acute and chronic patients in Colombia is psychologically equivalent to the original version, reliable, valid and could be used in our country and Spanish speaking countries with similar ethnic, cultural and social conditions.

### P3974 How accurate are assessments of exacerbations through patient self-reports? A systematic review

**Authors:** Anna Frei1,2, Lara Siebeling1, Callista Wolters1,2, Patrick Maggengrumm1,3,4, Marco Zoller2, Gerben ter Riet3, Milo Puhan1,5

**Methods:** To evaluate the accuracy of different methods to ascertain exacerbations in longitudinal studies and to estimate the effect of misclassification in randomised trials.

**Aims and objectives:** To evaluate the accuracy of different methods to ascertain COPD exacerbations in longitudinal studies and to estimate the effect of misclassification in randomised trials.

**Methods:** We used event-based definition of exacerbations that required newly prescribed systemic corticosteroids and/or antibiotics. Methods to ascertain exacerbations in 411 primary care COPD patients from ICE COLD ERCI cohort over 3 years included (1) 6-months follow-ups and (2) review of patient charts by an experienced physician. These 2 methods were compared against reference standard of adjudication committee (AC) where 3-4 experienced physicians independently adjudicated exacerbations following AC meeting where consensus on final classifications was reached. We calculated sensitivity and specificity and estimated the effects of long-acting bronchodilators vs. placebo on exacerbations by correcting for misclassification.

**Results:** 59.6% of 411 patients had at least 1 exacerbation during the 3 years according to the AC. Patient self-reports had a sensitivity and specificity of 84% and 75%, adjudication by single physicians between 88-96% and 87-96%. The pooled relative risk reduction from meta-analysis changed from 11% (95% CI 1-20%) to 35% (4-56%) when corrected for misclassification.

**Conclusions:** Conventional methods to assess exacerbations without central adjudication are likely to underestimate treatment effects substantially. Use of central or expert adjudication could reduce sample size requirements by up to 5-fold.

### P3976 Surveillance of antibiotic resistance in Streptococcus pneumoniae from 2000 to 2011 and serogroup distribution in Tunisia

**Authors:** Emma Mehiri, Asma Ghariani, Sabrina Bouchenna, Leila Slim-Saidi

**Methods:** Multicenter study performed in public hospitals of Tunisia. Surveillance of antibiotic resistance in Streptococcus pneumoniae is a major problem and has reached very high levels in certain countries. In this study, we report the level of resistance of Streptococcus pneumoniae over a 12-year period and the serogroup’s distribution in Tunisia. From January 2000 to december 2011, 1953 strains were collected, in Aberraham Mami Hospital of pneumology, Tunis, Ariana, Tunisia.

**Results:** The rate of penicillin G non susceptible pneumococci (PNSS) was 40.4% including 8.2% of high resistance level. The strains showed reduced susceptibility to amoxicillin and cefotaxim in 17.4% and 12.7% of cases respectively. An increase of resistance is showed from 2000 to 2011 to B-lactamin. In addition, high levels of resistance to other antibiotics were noted. Thus 60.7%, 40.9% and 14.2% of strains were resistant to erythromycin, tetracycline and chloramphenicol respectively. The most common serogroups were 16, 9, 14, 23 and 23 and were associated to penicillin G non susceptible pneumococci. Serogroup 1 was also found in severe pneumococcal infection.

**Conclusion:** In conclusion, the high rate of PNSS and the multidrug resistance of S.pneumoniae show the need of rational use of antibiotics.

### P3977 Clinical, spirometric and radiological characteristics of Brazilian rheumatoid arthritis patients

**Authors:** Alexandre Melo Kawassaki1,2, Suzana Pinheiro Pimenta1,2, Fernando Kay1,2, Marianne Kael Veronessa Kawassaki1, Jeda Maria Magalhaes Laurindo1, Carlos Roberto Ribeiro Carvalho1, Ronaldo Adib Kairalla1 1Pulmonary Division, Heart Institute (InCor), University of Sao Paulo Medical School, Sao Paulo, SP, Brazil; 2Pulmonary, Hospital 9 de Julho, Sao Paulo, SP, Brazil; 3Radiology, University of Sao Paulo Medical School, Sao Paulo, SP, Brazil; 4Intensive Care Unit, Hospital Estadual Vila Alpina (HEVA), Sao Paulo, SP, Brazil; 5Rheumatology, University of Sao Paulo Medical School, Sao Paulo, SP, Brazil

**Results:** Rheumatoid Arthritis (RA) is a common inflammatory disease, and pulmonary in-
volvement is usual. An algorithm has been proposed for evaluation and management of RA patients with suspected interstitial lung disease, based on chest radiograph, physical examination and symptoms (Kim, E.J. et al. Chest 2009;136:1397-1405).

**Objective:** To describe clinical, spirometric and radiological characteristics of Brazilian RA patients using low-cost evaluation.

**Methods:** Patients with RA, irrespective of having pulmonary involvement, were evaluated, and data regarding pulse oximetry, spirometric measures and digital chest radiograph were obtained.

**Results:** 248 RA patients were analyzed. 85% were female, mean age was 56±10 years, median disease onset time was 16 years (IQR 7.75-24). The most common exposure was mold (22%). 50% had no smoking history, 17% were current smokers and 33% were former smokers. Pulse oximetry was normal (above 94%) in 87%. MRC dyspnea index 1 or 2 were observed in 50% and 32%, respectively. Most commonly used drugs were Methotrexate (92%), Prednisone (80%) and Chloroquine (78%). Spirometry was classified as normal (70%), obstructive (11%), restrictive (11%), mixed (5%) and unspecified (7%) patterns. At the moment, data for chest radiograph is available for 71 patients (29%), parenchymal abnormalities were observed in 56%, mainly linear (38%) and reticular opacities (18%).

**Conclusion:** This is the first study in Brazilian RA patients to analyze digital chest, pulsoximeters and to evaluate lung function. Spirometric alterations are common in RA patients. Abnormalities in digital chest radiographs were more frequent than previously described in conventional radiographs.

**P3978**

**Risk factors that determine time to first RSV hospitalization in CARESS:**

**The Canadian registry of palivizumab 2005-2011**

**Ian Mitchell1, Bosco Paes2, Krista Lantcoon1, Abby Li3. 1Paediatrics, University of Calgary, AB, Canada; 2Paediatrics, McMaster University, Hamilton, ON, Canada; 3Sunnybrook Hospital, University of Toronto, ON, Canada

**Objective:** Evaluate risk factors that determine time to first RSV hospitalization in children at high-risk of RSV infection who received prophylaxis.

**Design:** Method: Prospective, observational, registry of infants who received ≥ 1 dose of palivizumab during the 2005-2011 RSV seasons across 30 sites. Neonatal and demographic data were collected from the parent/caregiver at enrollment. Data related to respiratory infection events were collected monthly.

**Results:** 10,452 infants were enrolled; average age 5.5±6.0 months. Infants were typically male (56-4%), Caucasian (71%), average gestational age (GA) 32 ± 5.6 completed weeks. 700C (67%) infants received palivizumab for prematurity (35 weeks GA) only, 836 (8%) had chronic lung disease, 1048 (10%) had congenital heart disease and 1562 (15%) had underlying medical disorders (e.g. CNS disorders, airway anomalies and cystic fibrosis). Hospitalization rates for respiratory- and RSV-related hospitalization were 14% and 1%, respectively. Risk factors for RSV hospitalization included: having siblings (HR=2.16, df=1, p=0.001), more than 5 people in household (HR=2.02, df=1, p<0.0005) and smoking exposure (HR=1.80, df=1, p<0.0005). Time to first hospitalization increased with the number of risk factors from 1 (HR=3.42) to 3 risk factors (HR=10.40).

**Conclusions:** Time to first RSV hospitalization after the first palivizumab dose are similar to those reported in the literature, with a natural history of RSV. The effect of multiple risk factors pose a cumulative increased risk for RSV hospitalization, similar to the Canadian and European risk scoring models for 33-35 weeks’ GA infants.

**P3979**

**Genetic epidemiology of hereditary hemorrhagic telangiectasia associated with pulmonary arteriovenous malformation**

**Takanobu Shioya1, with pulmonary arteriovenous malformation**

**1Department of Physical Therapy, Akita University Graduate School of Health Sciences, Akita, Japan; 2Department of Physical Therapy, Hongo University of Health Sciences, Kobe, Japan; 3Department of Pulmonary Medicine, Akita University Graduate School of Medicine, Akita, Japan; 4Department of Radiology, Akita University Graduate School of Medicine, Akita, Japan; 5Department of Public Health, Kyoto University School of Medicine, Kyoto, Japan

**Background:** Hereditary hemorrhagic telangiectasia (HHT) is an autosomal dominant disorder characterized by aberrant vascular development such as pulmonary arteriovenous malformation (PAMV). We report here a genetic epidemiologic study in PAMV associated with HHT in Japan.

**Method and subjects:** A total of 137 pedigree members were traced of which 81 were alive and 42 were affected by HHT in a county, A population 1.1 million located in northern Japan.

**Results:** Linkage analysis in two large families complicated with PA VM revealed a linkage to the HHT1 locus (encoding endoglin; ENG). Three novel mutations were identified by PCR-RFLP method in peripheral blood DNA samples. Genotypes were distributed in a Hardy-Weinberg equilibrium.

**Conclusion:** These data demonstrate that the NAT2 fast or slow acetylators genotype did not associated with the risk of developing lung cancer in North Indian population when compared with controls.

**P3980**

**Nat2 gene polymorphism in lung cancer: A study from north India**

**Sandeep Bhattacharya1, Rajnikant Shukla1, Surja Kant2, Balraj Mittal3.**

**1Physiology, CSM Medical University, U.P.; 2Erishite KGMCI, Lucknow, U.P.; 3Pulmonary Medicine, CSM Medical University, U.P.; 4Erishite KGMCI, Lucknow, U.P.; India**

**Genetics, Sanjivi Gandhi Post Graduate Institute of Medical Sciences, Lucknow, U.P, India**

**Purpose:** This study was conducted to examine: 1) whether the NAT2 genotypes are risk factors for Lung cancer, 2) to study possible association of tobacco smoking with NAT2 genotype of these patients.

**Materials and methods:** This case control study was undertaken over a period of 19 months and included 100 Lung cancer patients and 145 controls. The NAT2 genotypes were identified by PCR-RFLP method in peripheral blood DNA samples. Genotypes frequencies and the association of the genotypes among patients and controls group were assessed by x2 test and Binary Logistic regression.

**Results:** The NAT2 fast acetylator genotype frequency of slow or fast acetylator genotypes was not significant in lung cancer patients alone (OR = 1.18, 95% CI: 0.69 - 2.03, p value = 0.583) in non-smoker (OR = 1.06, 95% CI: 0.43 - 2.64, p value = 0.899) and smoker (OR = 1.32, 95% CI: 0.59 - 2.93, p value = 0.494) vs. immunocompetent adults in Spain.

**Conclusion:** These data demonstrate that the NAT2 fast or slow acetylators genotype did not associated with the risk of developing lung cancer in North Indian population when compared with controls.

**P3981**

**Serotypes distribution and clinical features of IPD in immunocompromised vs. immunocompetent adults in Spain**

**Antoni Torres1, Marta Rodríguez Créixems2, Inmaculada Grau3, Luis Molinos4, Olga Rajm5, Pedro Linareis6, Jose Luis De La Creu7, Avianzia Fenolho8, Josefa Liliana4, Isabel Cifuentes10, 1Pulmonology, Hospital Clinic i Provincial, Barcelona, Spain; 2Microbiology, Hospital Universitario Gregorio Marañón, Madrid, Spain; 3Infectology, Hospital Universitario de Bellvitge, Barcelona, Spain; 4Pulmonology, Hospital Central de Asturias, Oviedo, Spain; 5Pulmonology, Hospital Universitario de La Princesa, Madrid, Spain; 6Infectology, Complejo Hospitalario Universitario, A Coruña, Spain; 7Pulmonology, Hospital Regional Universitario Carlos Haya, Málaga, Spain; 8Centro Nacional de Microbiología, Instituto Carlos III, Madrid, Spain; 9Microbiology, Hospital Universitario de Bellvitge, Barcelona, Spain; 10Medical, Piferi España, Madrid, Spain

**Background:** Immunocompromise is a main risk factor for Invasive Pneumococcal Disease (IPD).

**Objectives:** To analyse clinical presentations, comorbidities, and outcome of IPD by immunological status and serotypes (Ss) distribution to determine PCV13 coverage.

**Methods:** Prospective surveillance of culture-confirmed IPDs in adults (≥18 years) performed in 7 Spanish hospitals (August 2010-June 2011). Immunocompromise included presence of immunosuppression, HIV infection/AIDS, other immunodeficiencies, cancer or chronic renal disease.

**Summary and conclusion:** The population prevalence of HIBT in the county was estimated to be 1:8,000-1:5,000, roughly comparable with those reported in European and U.S. populations, which is contradictory to the traditional view that HIBT is rare among Asians. We recommend that families with HHT be screened for gene mutations in order that high-risk individuals complicated with PAVM receive early diagnosis and treatment initiation that will substantially alter their clinical course and prognosis.
Results: 191 cases were included (age 62.2±17.8 years, 58.1% males). Table 1 shows by immunological status, patient characteristics and vaccines coverage. Conclusions: Previous pneumonia is significantly more frequent among immuno-compromised patients. PCV13 coverage depends on immunological status, with the highest coverage for immunocompetent patients (64.4%). Facing limitations of the 23-valent polysaccharide (25% of immunocompromised patients had been vaccinated), receiving conjugate vaccines could be a better strategy for both immunocompetent and immunocompromised patients.

P3982 Prescription of antitussives in asthma: A cross-sectional study in primary care in France and in Italy

E. Van Ganser1, Eric Van Ganser2, Gilles Devouassoux3, Jean Mike Tiusut1, Regis Souza1, Carlos Roberto Ribeiro Carvalho1, Ronaldo Adib Kairalla1. 1Pulmonary Division, Heart Institute (InCor), University of Sao Paulo Medical School, Sao Paulo, SP, Brazil; 2Echocardiography Division, Heart Institute (InCor), University of Sao Paulo Medical School, Sao Paulo, SP, Brazil

Background: Pulmonary hypertension (PH) has negative impact in sarcoidosis prognosis. Prevalence of pulmonary hypertension (PH) among patients with sarcoidosis has not been investigated by screening studies confirmed by hemodynamic evaluation.

Objectives: (1) to determine the prevalence of PH among outpatients with sarcoidosis in a tertiary center and (2) compare the presence of systolic pulmonary artery pressure estimated by echocardiogram (SPAP) ≥ 40 mmHg to the diagnostic gold standard for PH (mean pulmonary artery pressure mPAP ≥ 25 mmHg) measured by pulmonary artery catheterization, in patients with tricuspid reflux velocity (TRV) ≥ 2.5 m/s.

Methods: Seventy-two consecutive patients of 163, from our outpatient sarcoidosis clinic (ATS/ERS criteria), underwent echocardiographic evaluation to assess TRV and to estimate SPAP. Patients with TRV ≥ 2.5 m/s (possible PH) underwent pulmonary artery catheterization. Lung function testing and high-resolution CT (HRCT) also were performed in all patients in Italy.

Results: Nineteen patients had TRV ≥ 2.5 m/s; 18 underwent hemodynamic evaluation (one patient died before the procedure). PH (mPAP ≥ 25 mmHg) was diagnosed in 4 patients and its prevalence was 5.6% (95% CI 0.2-10.8%). Five patients (6.9%), had SPAP ≥ 40 mmHg, estimated by echocardiography, but only two of them had PH (mPAP ≥ 25 mmHg); on the other hand, two patients with SPAP < 40 mmHg, estimated by echocardiography, had PH in hemodynamic study.

Conclusion: PH prevalence in outpatients with sarcoidosis was 5.6%. SPAP > 40 mmHg estimated by echocardiogram was not accurate to diagnose PH (3 false positive and 2 false negative).

P3985 Study of pulmonary embolism prevalence depending on age and sex by autopsy data

Natalia Tsvimboluk, Yuriy Mostovoy, Natalia Slepchenko. Chair of the Propeadectics of Internal Medicine, Vinitsa National Medical University n.a. M.I. Pirogov, Vinitsa, Vinitsa region, Ukraine

Background: Pulmonary embolism (PE) is the third most frequent cause of death after ischemic heart disease and stroke. Problems concerning statistic data as for PE and the dynamics of its prevalence are insufficient in Ukraine.

Aims and objectives: To study the dynamics of PE prevalence depending on age and sex, to determine factors leading to fatal outcome between 1993 and 2002 and to study the causes of fatal PE development.

Methods: To determine the dynamics of prevalence and causes of fatal PE development we undertook a retrospective analysis of 2260 case reports of patients who died during 1993-2002 years.

Results: The results of 2260 autopsies done during the period of 1993-2002 showed that PE in the structure of pathologic diagnosis occurred in 121 cases (5.3%). Deep vein thrombosis of lower extremities (23.1%) and ischemic heart disease (19.0%) were the major etiological factors causing the development of fatal symptoms of PE in patients during the last decade.

Conclusions: Individuals suffering from deep vein thrombosis, ischemic heart disease with atrial fibrillation and those undergoing operations for oncologic diseases are at great risk of PE development. If sudden dyspnea, chest pain and decrease of blood pressure appear in the patients of risk group additional methods of examination should be used to exclude PE.

P3986 Role of eczema as a risk factor for allergic rhinitis in adolescents

Konstantinos Paraskeva1, Eleftherios Vassilakos2, 1Pediatrics, Private Medical Health Care, Kastoria, Greece; 2Otorhinolaryngology, University of Ioannina, Greece

Introduction: Allergic rhinitis (AR) is one of the most important chronic diseases affecting adolescents. AR often occurs together with eczema.

Aim: To investigate prevalence of eczema and/or positive family history of eczema in adolescents with AR and without AR.

Material and methods: A cross-sectional study conducted on a convenient sam-
ple of 300 adolescents with AR (180 boys and 120 girls), aged 14-17, and equal number of adolescents without AR matched by sex and age selected from three different provinces in Greece. Retrospective analysis of AR and eczema was based on anamnesis and data from medical archives.

**Results:** Eczema is presented in 34% of adolescents with AR (35% of the boys and 33% of the girls). The prevalence of eczema was significantly higher in adolescents with AR compared to adolescents without AR (34% vs 6%, p<0.01). Positive family history of eczema had 31% of adolescents with AR (33% of the boys and 29% of the girls) and its prevalence was significantly higher compared to adolescents without AR (31% vs 5%, p<0.05).

**Conclusion:** Results confirm the role of eczema (personal or family history) as a risk factor for AR in adolescents.

P3987 Effect of hospital volume on patient outcomes in pleural infection

Jia-yi Chen-Lin1, Chun-Li Li1,2, Chang Yi Li1,2, 1Intensive Care Medicine, Chi Mei Medical Center, Tainan, Taiwan; 2Medical Research, Chi Mei Medical Center, Tainan, Taiwan; 3Public Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan

**Background:** We aimed to investigate the hospital view outcome relationship (HVOR) in patients with pleural infection, which is important because outcomes may be improved by volume-based selective referral if an inverse HVOR is present. **Methods:** We analyzed 24,876 patients with pleural infection in 2,188 hospital-years from Taiwan’s National Health Insurance Research Database between 1997-2008. Primary outcome was hospital mortality. Secondary outcomes were hospital length of stay and charges. Hospital volume was measured both as a categorical and a continuous variable (per one case increase per hospital-year); and the effect of volume was assessed using multivariate logistic regression models with generalized estimating equations accounting for hospital clustering effect. Adjusted covariates included patient and hospital characteristics (model 1), pleural surgery (model 2) and length of hospital stay (model 3).

**Results:** HVOR was significant only when volume was measured as a categorical variable. Patients treated in the highest volume quartile (≥14 cases per hospital-year) had a 23% lower risk of hospital mortality than those in the lowest volume quartile (1 case per hospital-year) after adjusting for patient and hospital characteristics (model 1: adjusted OR 0.73, 95% CI 0.55-0.96). However, after adjusting for treatment covariates (model 2 and 3), the volume effect on hospital mortality disappeared. Hospital volume only explained a small proportion of variation in hospital mortality (1.2 log likelihood/df=0.26%).

**Conclusions:** In patients with pleural infection, the effect of hospital volume on patient outcomes is small, depends on volume measures and can be explained by differences in treatment across hospitals.

P3988 Ethnic peculiarities of chlamydiosis in bronchial asthma

Svetlana Smirnova, Alevtina Sharaviri. Siberian Branch under the Russian Academy of Medical Sciences, "Scientific Research Institute for Medical Problems of the North", Krasnoyarsk, Russia

**Aim:** To study ethnic peculiarities of chlamydiosis prevalence in bronchial asthma (BA) patients of Krasnoyarsk and Kyzyl.

**Materials and methods:** We have examined 239 subjects (from 17 to 78 years): the Europoids (n=159), the Mongoloids (n=80). Among them: BA (n=187), control (n=52). We have determined Chlamydia pneumoniae and Chlamydia psittaci (C pneumoniae et psittaci), Chlamydia trachomatis (C trachomatis) by direct immune fluorescence technique (DIF) for smears of oropharynx, their antibodies from blood serum by DIF – 3.9%, IgM – 3.1%, IgG – 25.6%; in the Mongoloids – 19.0%, 3.4%, 1.7%, respectively. In control groups C pneumoniae et psittaci had by DIF – 14.5%, IEA IgM – 3.9%, IgG – 41.9%; in the Mongoloids – 25.9%, 4.7%, 3.4%, respectively.

**Results:** The frequency of C pneumoniae et psittaci in the Europoids by DIF – 3.9%, IgA – 3.1%, IgM – 25.6%; in the Mongoloids – 19.0%, 3.4%, 1.7%, correspondingly. In control groups C trachomatis in the Europoids by DIF – 19.0%, IEA IgA – 0.0%, IgM – 0.0%, IgG – 6.7%; in the Mongoloids – 13.6%, 0.0%, 9.1%, 40.9%, correspondingly.

**Conclusion:** Were found ethnic peculiarities: in the Mongoloids more frequent than in the Europoids – IgG to C pneumoniae in BA; IgM to C pneumoniae, IgM to Chlamydia in control groups.

P3989 Clinical characteristics and outcomes of community acquired pneumonia (CAP) in adults ≥18 years of age in a well defined area of Badalona, Spain

Antoni Sicras-Mainar1, Isabel Cifuentes2, Cristina Méndez3, Ruth NAVARRO,1, 1Dirección de Planificación y Desarrollo Organizativo, Badalona Servei Assistencial SA, Badalona, Barcelona, Spain; 2Medical, Pijfer Esparta, Madrid, Spain; 3Medical, Pijfer Esparta, Madrid, Spain; 4Documentación Médica, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain

**Background:** It is known that CAP often requires hospital admission. However, the prevalence between hospitalizations and outpatient visits for CAP is not well established. **Objective:** To analyse differences between adults with CAP treated as inpatients or outpatients in a well-defined health care area. **Methods:** Retrospective review of medical records of patients ≥18 years old diagnosed with CAP from January 1st 2008 to December 31st 2009 belonging to Badalona (population ≥18 years: 90,015) and attended by 6 primary care centres and 2 hospitals. **Results:** 581 patients were included in the study (incidence rate: 6.0000 adults). 58% were diagnosed at hospital settings. Hospitalised patients (41.5%) were older (mean age: 66.6 years vs. outpatients: 51 years; p<0.001) and had more comorbidities. Inpatient admission was associated with liver disease (OR=5.9), stroke (OR=3.6), dementia (OR=3.5), COPD (OR=2.9), diabetes mellitus (OR=1.9) and age (ORs=1.1; p<0.002). Among cases with microbiological tests done (61.9%; 100% of inpatients vs. 35% of outpatients), 48.3% had negative result (52.7% in inpatients vs. 39.5% in outpatients). Strepococcus pneumoniae was the most prevalent pathogens (34.5% were older, 7.7% in inpatients vs. 46.3% in outpatients). For inpatients, readmission rate was 19.1% and mortality rate 2.5%. Length of hospital stay was 4.4 days. **Conclusions:** Despite current therapeutic measures, CAP continues to be a major health issue with almost 1 out of 2 CAP patients requiring hospitalization. The increase in the future of elderly people and thus of comorbidities stress the need to implement better strategies for CAP prevention.

P3990 Hospitalizations from pandemic influenza (pH1N1) infections among patients with asthma in Spain

Javier de Miguel Diez1, Liliana Morán Caicedo1, Pilar Carrasco Garrido2, Valentin Hernandez Barrera2, Jorge Chancafe Morgan2, Angel Gil de Miguel2, Rodrigo Jimenez Garcia2,1 Pneumology, Hospital General Universitario Gregorio Maranon, Madrid, Spain; 2Preventive Medicine, Universidad Rey Juan Carlos, Alcorcon, Madrid, Spain

**Objectives:** We describe and analyze the clinical characteristics and outcomes for all persons suffering asthma who were hospitalized with laboratory confirmed pH1N1 infection in Spain in 2009.

**Methods:** This is an observational retrospective study using hospitalization data collected by the Spanish National Hospital Discharge Database. We selected all hospital admissions with diagnosis ICD-9-CM code 488.1 (pH1N1). Discharges were grouped according, according to the presence or not of asthma.

**Results:** The total number of persons hospitalized with pH1N1 was 11,499. Of those, 8,988 suffered asthma. The most common underlying medical condition among asthmatic subjects was obesity (10.97%). The IHM was much lower among asthmatic patients than among those without this disease (0.85% vs. 2.76%, p<0.05). Also, the mean LOS and the mean costs per patient were lower for asthmatic patients (5.38 days and 2,566 €), when compared to hospitalized patients without asthma (7.08 days and 3,186 €). Multivariate analysis, suffering asthma was a factor independently associated with a higher probability of surviving during the hospitalization with pH1N1, (OR=0.42, 95% CI 0.11-0.71). For asthma sufferers, those that died during the hospitalization with influenza pH1N1 were significantly older, suffered more concomitant chronic diseases and had a longer LOS and higher costs.

**Conclusions:** Among individuals hospitalized in 2009 with pH1N1 infection in Spain the prevalence of asthma was 8.98%. The most common underlying medical condition among asthma subjects was obesity. Suffering asthma was independently associated with lower risk of dying during the hospitalization with pH1N1.
The incidence of allergic diseases and respiratory infections in 5-6 years old children

Maia Khkerheetidze1, Nani Kavlashvili1, Sounaya Ben Saad1,2, Amel Chetour1,2, Soffie Takaki1,2, Rodia Mahonouchi1, Fatima Tettar1,2, Braham Driza1, Ali Ben Kheder1,2,3,4, Maia Kherkheulidze1,2,3,4

P3994

The incidence of allergic diseases and respiratory infections in 5-6 years old children

Maia Khkerheetidze1, Nani Kavlashvili1, Eka Kandelaki1, Maia Chkhaidze2, Tsitino Parulava2,3,4, Pediatrics, State Medical University, Tbilisi, Georgia; 2Pediatrics, Children’s New Hospital, Tbilisi, Georgia

Aim: To assess incidence of allergic disorders and respiratory infections in 5-6 years old children of Georgia.

Methods: The cross sectional study using specially developed parent questionnaire was conducted in Georgia. At all 1500 parent of 5-6 years children were interviewed. 1499 questionnaires were analyzed by SPSS program.

Results: From 1499 children 32% were 5 years old and 68% 6 years old. The 54% live in urban, 35% in rural area and 11% in high mountains. The study revealed that 23% of children have respiratory viral infections 7-8 times per year, 19.9 – 3.5 times, 53.4% – 1.2 times and 24.2% became ill very rarely. The study show statistically significant difference between the viral infection frequency in rural and urban area (Pearson Chi-Square = 33.895 df = 6 Asymp. Sig. (2-sided) = 0.000). There was not significant difference in morbidity according to family income, size and education. Morbidity is statistically significantly higher in boys and in children attending kindergarten and primary school in comparison with non-organized children (Pearson Chi-Square 14.985 Asymp. Sig. (2-sided) = 0.002). The frequency of chronic diseases reported by parents is 4.1%, from those 47% are allergic disorders (asthma, rhinitis, atopic dermatitis). The most parents associate the asthma exacerbation with viral infections. The 42% of children with asthma and rhinitis were vaccinated with seasonal influenza vaccine. Exacerbation of allergy was significantly less in vaccinated children.

Conclusion: Incidence of allergic disorders among children is raising. Viral infections are risk factors for asthma exacerbation. Vaccination against seasonal influenza should be encouraged.

P3995

PreventTB: Attitudes of decision makers and care providers towards tuberculosis prevention in Germany

Christian Gusfeld, Christoph Lange. Medizinische Klinik - Forschungszentrum Borstel/Arbeitsgruppe Infektiologie, Zentrum für Medizin und Biowissenschaften, Borstel, Schleswig-Holstein, Germany

Background: Prevention of tuberculosis with chemotherapy is highly effective, if targeted at high risk populations. However, acceptance of preventive chemotherapy is very variable in Europe.

Methods: We developed and validated a standardized questionnaire to evaluate the attitudes related to tuberculosis prevention of decision makers and caretakers of patients in Germany.

Results: At a first stage we sent 500 questionnaires to health care professionals and received 130 answered forms back. During the second stage 3000 study inviations were sent for an online survey via e-mail. Among the 540 online survey participants were 250 pulmonologists, 189 health officers, 26 general practitioners and 45 other medical professions.

Out of all online participants 48.8% (n=249) would use QuantiFeron Gold in tuberculin-skin-test (n=126), 23.3% T-SpotTB® (n=119) and 3.2% (n=16) other testing devices in the future. In a first stage we sent 500 questionnaires to health care professionals and received 130 answered forms back. During the second stage 3000 study invitations were sent for an online survey via e-mail. Among the 510 online survey participants were 250 pulmonologists, 189 health officers, 26 general practitioners and 45 other medical professions.

In the last decade, ambient particles have decreased from 150µg/m³ to 40µg/m³ in Sao Paulo city (SP) because of public policies to control fuel emissions. Traffic professional are more exposed to air pollution. We tested if ambient air from SP is still deleterious to traffic professionals. Non or ex-smokers (≤1 year) car drivers (N=46) and traffic controllers (N=23) were evaluated 4 times. We checked clinical symptoms and blood inflammatory markers (HDL/LDL, total cholesterol, triglycerides, blood cell counting, clot tests, ultra sensitive c reactive protein- us CRP and erythrocyte sedimentation rate-ESR) on the day after workshift. Pollutants were collected during 24h exposure by individual samplers for fine particles (reflectance) and NO2/NOx (colorimetry). Clinical and blood data were tested against pollutants by linear regression model for repeated measures through generalized estimated equation (GEE). Alpha was 5%. PM2.5 was 40.33±20.83µg/m³ and NO2 197±43.47µg/m³.

407. COPD beyond tobacco
mation, hypercapnoleucytosis and lymphocytes and monocytes increment in traffic professional.

Troller fuel exhaust and respiratory impairments; cross sectional study in Indian fishermen
Subhajit Maitra1, Santi Gopal Maity1, Prasun Haldar1, Asis Pandit2
Subhasish Sahu1, *Department of Physiology, University of Kalyani, West Bengal, India; 1Department of Physiology, Krishnagar Government College, Krishnagar, WB, India

Introduction: The fishermen of India are exposed regularly to the fuel exhausts of the trollers. No study has been reported on the respiratory health of the fishermen.

Aim: The study aimed to see whether there is a relationship between troller fuel exhaust and respiratory impairments among the fishermen in India.

Methods: A total of 259 male fishermen participated in the study among which 152 were regularly exposed to troller fuel exhaust (mean age 58±9.8 years) and 107 were never exposed to that (mean age 53±10.3 years). Evaluation of the examined subjects was done using the EIRS questionnaire for the assessment of respiratory symptoms and lung function test. Data were analysed using odds ratio with 95% confidence interval and independent ‘t’ test adjusting for age, smoking status, parental asthma and second hand smoke exposure at home or work.

Results: Fishermen exposed to troller fuel exhaust had higher prevalence of respiratory symptoms for chronic phlegm (OR = 3.4, 95% CI = 1.2-8.3), morning cough with sputum (OR = 2.3, 95% CI = 1.1-4.6), prolonged cough (OR = 2.5, 95% CI = 1.4-6.2), whistling in chest (OR = 2.8, 95% CI = 1.4-7.3) and breathing trouble (OR = 2.6, 95% CI = 1.2-6.2) compared to the those exposed to troller fuel exhaust. Spirometric parameters showed that the mean values of FVC, FEV1, FEV1/FVC, FEV25/75%, FEV50%, FEV75% and FEV25-75% were lower in the subjects exposed to fuel exhausts but statistically significant (p<0.01) was observed for FEV25%, FEV50%, FEV75% and FEV25-75%.

Conclusion: The study suggests that occupational exposure to troller fuel exhaust is associated with higher respiratory symptoms and lung function impairment among fishermen of India.

P3998
To study the effect of chronic inhalation of street dust on pulmonary function in street cleaners
Zubair Ahmed1, Shadab Mohammad2, Bharendra K. Agrawal2
Aslam Mohammad1, 1TB and Resp. Diseases, J. N. Medical College, AMU, Aligarh, UP, India; 2Department of Physiology, J. N. Medical College, AMU, Aligarh, UP, India

Purpose: Street cleaners who sweep streets manually are exposed to different types of substances which have deleterious effect on pulmonary functions. We conducted this study to find out this study to know the status of pulmonary functions in these occupationally exposed persons.

Methods: One hundred ten street cleaners, 30 non-smokers and 30 smokers, who were cleaning the streets for more than 5 years were included in this study. Sixty controls, 30 smokers and 30 non-smokers, were also included for comparison. Their lung functions FVC, FEV1, PEFR and FEV25-75 were assessed by spirometry. Statistical analysis of data was done according to unpaired ‘t’ test using SPSS version 16.0 software.

Results: The mean FVC, FEV1, PEFR and FEV25-75 were 85.87±15.16%, 63.82±14.79%, 65.65±16.22% and 53.31±20.29% respectively in nonsmoker cleaners, while in smoker cleaners these were 85.0±15.96%, 59.96±17.35%, 60.90±14.91% and 51.78±19.31% respectively. FVC was not found to be affected in these persons while other parameters were significantly decreased as compared to those in controls. In controls these were 88.66±12.92%, 88.50±18.80%, 90.16±14.30% and 84.00±18.20% respectively in nonsmokers and 84.25±11.2%, 78.42±16.80%, 60.62±18.22% and 62.36±16.50% respectively in smokers.

Conclusion: Obstructive pattern was observed in both smoker and non-smoker cleaners. Smoker cleaners had significantly higher obstruction than smoker controls. Thus street dust was found to act synergistically with smoking and further aggravated obstruction in airways so these persons should take proper preventive measures.

Clinical implications: Street dust acts synergistically with smoking and further aggravates obstruction in airways so these persons should take proper preventive measures.

P3999
COPD among non-smokers
Dabravka Pelicaric, Bojana Butorac Petanjek, Sanja Grle Popovic, Tajana Jalušic, Bojana Butorac Petanjek, Sanja Grle Popovic, Tajana Jalušic Gluncic, Mile Bogdan Gluncic

Aim: COPD among non-smokers from chronic obstructive pulmonary disease [COPD] and at investigating into its etiology.

Subjects & methods: The study comprised a total of 250 subjects, diagnosed with COPD in line with 2010 Global Initiative for chronic Obstructive Lung Disease [GOLD] criteria. The subjects were first divided into 3 GOLD criteria-based subgroups [GOLD I, GOLD II & GOLD III/V] and later on into the smoking and non-smoking arm. The non-smoking arm was also subdivided based on possible COPD risk factors. All study subjects underwent lung function and bronchodilator response testing.

Results: Age differences between the two study arms were proven statistically insignificant. Age differences between GOLD I and GOLD II subgroups proved statistically significant [p=0.0405]. The disease severity registered across younger smokers equaled to that of far older non-smokers.

As for COPD risk factors, occupational exposure and earlier pulmonary TB were far more common in men, while passive smoking and the exposure to bio-fuel combustion releases were more common in women. Frequent respiratory infections experienced during childhood and adolescence were also more common in women. Out of 66 non-smokers, 40 had only one, 17 two and the remaining 9 none of the COPD risk factors, but this failed to affect the disease severity.

Conclusion: The results of this study prove that tobacco smoke and its constituents are not the only culprits for COPD onset. The disease can also be developed by non-smokers due to a number of risk factors elaborated herein.

P4000
Respiratory symptoms and lung function parameters in workers exposed to wood smoke and cooking oil fumes in Nigeria
Olanisum O. Adewole1, Olufemi Desalu2, K. K. Kenneth3, Tayo Adewole4, Greg Enhor1, Medicine, OAUTHC, Ille Ife, Nigeria; 2, Medicine, University of Ilorin, Nigeria; 3, Medicine, Federal Medical Center, Kano, Kebbi, Nigeria; 4, Family Medicine, OAUTHC, Ille Ife, Nigeria

Introduction: Exposures to wood smoke and oil fumes occurs in both home and industrial setting and is associated with occurrence of both respiratory and non respiratory diseases.

Mai suya is a common job in most northern Nigeria. Our aim is to study the prevalence and respiratory function parameters among this group.

Method: This is a community, and case controlled study involving mai suya and workers who are not exposed to wood smoke and oil fumes in an occupational setting.

Results: Both groups underwent an interviewer administered questionnaire followed by on spot spirometric test. Chi square was used to test association between respiratory symptoms and the job categories. Odd ratios were determined for the risk of respiratory symptoms and exposure to wood and oil fumes.

Conclusion: The mean FEV1, FEV1 (predicted), FVC, PEFR and FEV25-75% were significantly lower among the test group compared with the control group among all respondents.

Conclusion: Workers exposed to wood smoke and oil fumes have increased risk of respiratory and altered pulmonary functions.

P4001
Gene polymorphism could be a useful prognostic tool in patients with work-related chronic bronchitis
Serhoi Laskons1, Sivakov Alexander2, Rybina Tatiana3, Elena Amelchenko3, Natalya Savelieva1, Oksana Omelyanyenko2, Treshkova Tatiana3, 1Department of Clinical Laboratory Diagnostics, Allergy and Immunology, Grodzno State Medical University, Grodno, Belarus; 2Department of Acupuncture, Belarussian Medical Academy of Postgraduate Education, Minsk, Belarus; 3Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus; 4Department of Pulmonology, 10th Minsk City Clinic, Minsk, Belarus; 51st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus

Objective: Study aimed to assess gene polymorphism for the prognosis of the work-related chronic bronchitis.

Methods: 63 patients with work-related chronic bronchitis were enrolled to the study. Control group included 20 healthy comparable male volunteers without occupational hazards. Study participants were genotyped on tumor necrosis factor-a (TNF- a) gene - G308A and G238A, IL-8 gene (A=252T2), proteintyrosine-kinasephosphatase 22 (PTP 22) gene(R620W), microsomal epoxidhydrolase gene (T337C and A416G). Spirometry, CAT questionnaire data were analyzed.

Results: TNF- a gene polymorphism revealed that heterozygous type was most frequent. IL-8 gene heterozygotes A=252T2 carriers revealed higher IL-6 values vs the homozygote AA and TT (Kruskal-Wallis test: H=5,34, p=0,07). Respiratory failure was the rare complication in proteintyrosinephosphatase 22 gene(R620W) heterozygotes (Chi-Square=6,12, p<0.05). TritTpr carriers had higher pulse rate vs theArgArg carriers(Kruskal-Wallis test: H=9,23, p<0,01). Heterozygotes had higher CAT points and lower minute volume of respiration vs theArgArg carriers (Chi-Square = 10,28, p<0,005). PTP 22 heterozygotes revealed first work-related chronic bronchitis manifestation in younger age than those with theArgArg type (Chi-Square=3,96, p<0,05).
P4002 Indoor pollution and poor ventilation inside the houses synergize to cause airflow limitation in non smokers high altitude dwellers

Luca Pomarè1, Manuela Bassi1, Rosana Maria Brunò2, Enrico Dou3, Giuseppe Misericocchi4, Lorenzo Pratà5, Ramesh Sharma5, Kamal Tapa2, Amatissia Cingi2,1, Biomedical Sport Studies Center, University of Ferrara, Italy; 2Department of Internal Medicine, University of Pisa, Italy; 3Institute of Clinical Physiology, CNR-IFIC, Pisa, Italy; 4Travel and Mountain Medicine Centre, Nepal International Clinic, Kathmandu, Nepal; 5Department of Experimental Medicine, Laboratory of Clinical Physiology and Sport Medicine, University of Milano-Bicocca, Milano, Italy

Indoor air pollution from biomass smoke fuel is linked to respiratory diseases. We performed spirometry in 3 villages of a nepalese valley where neither traffic nor industries are present, people use biomass fuels for heating and cooking, often without a chimney, and have a very low smoke habit (4%) so that only the effect of indoor pollution can be investigated. We measured the ventilation inside the houses (Ventilation Index [VI] = window surface/kitchen cubic meters) and the environmental (not reported) and exhaled carbon monoxide as a surrogate marker of indoor pollution. A total of 364 subjects performed an acceptable and reproducible spirometry. We calculated the % of subjects with non reversible bronchial obstruction (GOLD) and the % of subjects with FEF25-75 <70% of predicted. Note that in the last ten years indoor ventilation has been improved in the buildings of Pengboche, the village most frequented by trekkers.

Results

| Village-altitude, m | Subjects | Age (mean±SD) | FEV1/FVC | FEF25-75 | Exhaled CO | VI | P

In cells 4, 5, the % of subjects with spirometric characteristics (i.e. FEV1/FVC <0.75) is reported.

Exhaled CO and VI are negatively correlated (p <0.002). We conclude that subjects living in poorly ventilated houses and only exposed to indoor pollution have a high incidence of COPD and of abnormalities of FEV1/FVC which could be interpreted as an early marker of bronchial obstruction (Pellengiaro R et al, 2005).

P4003 Investigation of lung involvement with DLCO in women exposed to biomass smoke

Ahmet Arisoy1,2, Jovanka Vukeliçaric3,1, Bulent Orzay1,2, Selamı Ekin1,3, Hande Akcay1,2, Emine Yıldız1,2, Gülseren Kelebek1,2, Gönül Topçu1,2, Enes Işıklı1,2,1, Biomedical Sport Studies Center, University of Ferrara, Italy; 2Department of Internal Medicine, University of Pisa, Italy; 3Institute of Clinical Physiology, CNR-IFIC, Pisa, Italy

Objective: The reason why the female gender has a significantly higher risk factor to respiratory illnesses compared to males is not known, although some researchers speculate that sex hormones may interfere in the proneness to these diseases. The physiologic hormonal fluctuation during the menstrual cycle is known to induce changes in nasal epithelium and lung inflammation. The aim of this study is to analyze how the hormonal cycling of female mice is affected by near-ambient levels of pollution. Particulate matter (PM) was concentrated by an ambient particulate matter concentrator (APC). 14 Male (M) Balb/C mice were divided into two groups: without exposure to PM (M/A/control group) and exposed to PM. 28 Female Balb/C mice were divided into four groups, according to the estrous cycle. Only female mice from proestrus (PE) and estrus (E) were enrolled. Those from PE were divided into two subgroups: with and without exposure to PM (PE/PM and PE/A). Mice from E were also divided into two subgroups: with and without exposure to PM (E/PM and E/A). Neutral and acidic mucus content was quantified in epithelium through morphometry. Inflammatory cells were analyzed by bronchoalveolar lavage (BAL). APM exposure in MPM increased both neutrophils in BAL (p<0.001) and neutral mucus content (p<0.016) from nasal epithelium, when compared to PE/PM. No statistical difference was observed to E/PM. In the M/A group, it was observed an increase in both total BAL (p=0.042) and macrophages (p=0.003) when compared to PE/PE. At high altitudes these levels of PM exposure promoted a higher neutrophil recruitment in male than in female mice in proestrus.

P4005 Tumor necrosis factor-α (TNF-α) gene polymorphism in work-related chronic bronchitis patients

Sergio Laklak1,2, Sivakov Alexander3, Rybina Tatyanà1, Elena Amelchenko1, Natalya Sviatchëv1, Oksana Omelyanenko1, Treshkova Tatyanà1,2, Department of Clinical Laboratory Diagnostics, Allergology and Immunology, Grodno State Medical University, Grodno, Belarus; 3Department of Acupuncture, Belarussian Medical Academy of Post-Graduate Education, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus; 4Department of Pulmonology, 10th Minsk City Clinic, Minsk, Belarus; 51st Department of Internal Diseases, Belarussian State Medical University, Minsk, Belarus

Objective: Cytokine gene polymorphism could contribute to different susceptibility of occupational dust exposure and work-related chronic bronchitis development and management.

Methods: 87 work-related bronchitis patients were enrolled in the study. Spirometry, pulse oximetry data, autonomic regulation, questionnaire SDNA were obtained on exacerbation and after treatment. Patients were genotyped on TNF-α gene G(-308)A and G(-238)A transitions.

Results: TNF-α gene polymorphism revealed that heterozygous type was most frequent. Homozygous GG- G(-308)A and G(-238)A were determined in 5.7% and 1.1% of patients respectively. GG 308 carriers had a higher bronchial obstruction (FEV1/FVC) in heterozygotes .70 kg vs 85 kg, p<0.04). Homozygotes revealed better pulmonary tests results after the treatment FEV1/FVC increase (1.00 vs -0.69, respectively, p<0.04), respiratory volume (0.18 vs 0.02 L/min,0.05), minute volume of respiration (6.20 vs 0.55, L=0.01) GG 238 homoygotes demonstrated lower vital capacity vs those in the heterozygous (63 vs 71.5% of the predicted, respectively, p<0.02) GG 238 had higher oxygen saturation at rest (p<0.02), at the breathing holding (p<0.01) and at the hyperventilation (p<0.005). Homozygotes had lower points increase in CAT test than those in heterozygotes after the treatment (-5 vs -1, p<0.04) better. Patients results (1.20 vs 0.35 points, p=0.04).

Conclusion: TNF-α gene polymorphism is reliable for the prognosis of the work-related chronic bronchitis. GG 308 and GG 238 carriers with work-related chronic bronchitis revealed better pulmonary tests results and better improvement after the treatment vs the heterozygotes with the comparable length of service.

P4006 Cytokines and immunoglobulins for the prognosis of the work-related chronic bronchitis

Sergio Laklak1,2, Sivakov Alexander3, Rybina Tatyanà1, Elena Amelchenko1, Natalya Sviatchëv1, Oksana Omelyanenko1,2, Department of Clinical Laboratory Diagnostics, Allergology and Immunology, Grodno State Medical University, Grodno, Belarus; 3Department of Acupuncture, Belarussian Medical Academy of Post-Graduate Education, Minsk, Belarus; 2Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus; 4Department of Pulmonology, 10th Minsk City Clinic, Minsk, Belarus; 51st Department of Internal Diseases, Belarussian State Medical University, Minsk, Belarus

Objective: Study aimed to assess cytokines and immunoglobulins for the prognosis of the work-related chronic bronchitis due to the occupational dust exposure.

Methods: 63 patients with work-related chronic bronchitis were enrolled to the study. Control group included 20 healthy comparable male volunteers without occupational hazards. Serum IL-6, IL-10, TNF-α, IgG, IgA, total IgM were measured. Spirometry and respiratory pressure measurements were analyzed. Results: TNF-α levels correlated with the body mass (r=0.39, p<0.05), age (r=-0.37, p<0.05) and spirometry data - minute volume of respiration (r=0.51, p<0.01) and respiratory volume (r=0.44, p<0.03). IL-10 levels were associated with the body mass (r=0.45, p<0.02) and total protein level (r=0.50, p<0.02). IL-6, Ig A and Ig M levels revealed statistically significant correlation with the WEC counts (r=0.07, p<0.01), eosinophils (r=0.39, p<0.03), total eosinophils (r=0.51, p<0.05). Ig A, E,G values correlated with the minute volume of respiration (r=0.42, p<0.05).

Effects of differences in exposure conditions on pulmonary functions

Tsvoshi Nishimakagawa, Hideaki Senjyu, Masaharu Asai, Takako Tanaka.

Medical Science, Graduate School of Biomedical Sciences, Nago University, Nago, Japan

Introduction: Air pollution due to industrial waste and tobacco smoke has a serious detrimental influence on pulmonary functions. However, few reports have been published regarding the effects of differences in exposure conditions on the pulmonary functions.

Aims and objectives: The objective of this study was to examine how the differences in exposure conditions affect the pulmonary functions.

Methods: The subjects consisted of 869 people presented with functional decline as a result of working or living in an area with air pollution, and 434 people participated in an epidemiological investigation in an area without air pollution. Reviews of pulmonary function tests were conducted by employing the medical examination data. Pulmonary functions were compared in smokers versus non-smokers in the area with pollution vs. non-smokers with pollution and were also compared to smokers in the non-polluted area (smokers without) and non-smokers in the non-polluted area (non-smokers without).

Results: In terms of the %VC, the values were 90.9%, 95.5%, 98.2%, and 97.4% in the smokers with pollution, non-smokers with pollution, smokers without and non-smokers without, respectively. For the FEV1%, the value for smokers with pollution was 65.2%, non-smokers with pollution was 70.1%, smokers without was 70.8%, and non-smokers without was 79.2%. The smokers with pollution had a lower FEV1% than the other groups (p<0.001).

Conclusions: Air pollution and tobacco smoke exposure are associated with reduced VC and FEV1%. In particular, exposure to both factors had a stronger effect on the FEV1 than did exposure to one factor. Therefore, active smoking cessation instruction is necessary for subject in the polluted area.

P4007

The effects of atorvastatin in mustard gas exposed patients with chronic obstructive pulmonary disease: A randomized controlled trial

Hassan Ghobadi1, Shahzad M. Lari2, Farhad Pourzar12.

1All���meh University of Medical Sciences, Arak; 2International Medicine (Pulmonary Division), Arak University of Medical Sciences, Arak; 3International Medicine (Pulmonary Division), Mashhad University of Medical Sciences, Mashhad; 4Community Medicine, Arak University of Medical Sciences, Arak; 5International Medicine (Pulmonary Division), Baqiyatallah University of Medical Sciences, Tehran, Islamic Republic of Iran

Background: Statins have anti-inflammatory effects in patients with chronic obstructive pulmonary disease. This study designed to evaluate the effects of atorvastatin on serum highly sensitive C-reactive protein (hs-CRP) and pulmonary function in sulfur mustard (SM) exposed patients with chronic obstructive pulmonary disease.

Methods: In a double blind clinical trial, 50 patients with chronic obstructive pulmonary disease due to sulfur mustard and high hs-CRP, randomly entered in this study. 45 patients completed the study (n=22, placebo and n=23, atorvastatin). Serum hs-CRP, pulseoximetry, spirometry and six-minute walk distance test (6MWDT) were measured. COPD assessment test (CAT) and St George's respiratory questionnaire (SGRQ) were completed by patients at the beginning of trial and after 9 weeks of prescription of 40 mg/day atorvastatin or placebo. At 4th week, pulseoximetry, spirometry and 6MWDT were measured.

Results: At 4th week, there was no improvement in the atorvastatin group compared to the placebo group in SP02, FEV1, and 6MWDT (p=0.79, p=0.12, p=0.12 respectively). At 9th week, there was no improvement in atorvastatin in serum hs-CRP, SP02, FEV1 and 6MWDT compared to the placebo (p=0.35, p=0.28, p=0.94, p=0.43 respectively) but there was an improvement in atorvastatin in quality of life with (CAT score, P<0.01 and SGRQ total score, P=0.004).

Conclusions: Atorvastatin does not alter serum hs-CRP and lung functions but may improve quality of life in SM-injured patients with chronic obstructive pulmonary disease.

Key Word: Sulfur mustard, Atorvastatin, hs-CRP. Chronic obstructive pulmonary disease.

Presence of hypertension (HT), ischemic heart diseases (IHD) and a family history of hypertension are independently associated with reduced peak expiratory flow (PEF) and lower Forced Vital Capacity (FVC) in Saudi population

Kamal Ali Alkuma1, Monica Barne1, Bill Brashier1, Sagna Madi1, Jaideep Gogtay1, Basant Pachisia2, Sundeep Salvi1.

1Research, Chest Research Foundation, Pune, Maharashtra, India; 2Research, CIPLA LTD., Mumbai, Maharashtra, India

Background: Reduced lung function has been shown to be an independent predictor of cardiovascular mortality in patients of hypertension and IHD in earlier studies.

We aimed to study the association between HT, IHD and PEF values amongst road transport workers from Andhra Pradesh, India.

Methods: 7,154 bus drivers, conductors, garage workers and office-based workers of the Andhra Pradesh State Road Transport Corporation (APSRTC) were randomly selected from 24 bus depots and administered a health questionnaire, underwater blood pressure monitoring, spirometry, and PEF values with the EU scale peak flow meter (Breathmeter®). CIPLA Ltd., India). Current, past and family histories of cardiovascular and respiratory ailments were captured. Associations between PEF values and HT and IHD were studied using the chi square test and the values expressed as odds ratios.

Results: Presence of HT, IHD and a family history of HT were independently associated with low PEF values, defined as less than 80% predicted PEF value [OR 1.3, 95% CI 1.1 – 1.5, p=0.008; OR 1.9, 95% CI 1.2 – 2.0, p=0.004; OR 1.2, 95% CI 1.0 – 1.4, p=0.039 respectively]. No difference in odds ratios were observed between different occupations.

Conclusions: PEF values of at least 80% predicted are strongly associated with presence of HT, family history of HT and presence of IHD. Reduced peak flow values should stimulate the need for performing a cardiovascular assessment.

P4011

Study of daytime sleepiness among tunnel workers on rotating schedule

KiraKiri Karkoulias1, Dimitoshen Liykoras1, Dimitrios Patrouchas1, Maria Sarganiou1, Fotios Sampsonas1, Evantia Faliaika1, Athanasios Tsakalis1, Konstantinos Spirooulos1.1Pulmonary Medicine, University Hospital, Patras, Greece; 2Computer Engineering and Informatics, University of Patras, Greece

Introduction: Working on shifts, and especially, on a night shift, influences the endogenous sleep regulation system leading to diminished sleep time and increased somnolence. This may be dangerous in some cases, especially in large scale constructions, such as tunnels.

Aims and objectives: The aim of our study was to examine whether sleep duration and daytime sleepiness differed between day and night shifts among tunnel workers.

Methods: In this study 42 male workers (during the last semester) in a tunnel construction were recruited and examined at workplace. They underwent spirometric control and they were asked to complete a questionnaire referring to demographic factors, status of health and the Epworth Sleepiness Scale.

Results: The workers present a mean age of 42 years old and a mean Body Mass Index (BMI) of 27.2 kg/m². 69% of them were active smokers, while 31% have never tried smoking. Interestingly, 93% of the tunnel workers were consuming two coffees per day at least, while the remaining 7% were not drinking coffee at all. Almost one third of them reported alcohol consumption on a daily basis. Severe cardiologic, respiratory or endocrine disease was not reported among the participants and neither were depression and anxiety disorders. Our results showed that almost all the workers had gathered a score less than 10 in the Epworth
Sleeping Time Scale (a score of 10 or more is considered sleep), except for two subjects in which statistical analysis did not reveal any statistically significant correlation between somnolence and the work schedule (p>0.88).

Conclusions: The rotating shift in a dark and demanding environment, as in the tunnel construction, does not play a significant role in daytime sleepiness.

P4012
Basic spirometric parameters of coke plant workers over the years
Emilija Kolarczyk, Wiesława Szot, Joanna Zajac, Department of Hygiene and Dietetics, Jagiellonian University Medical College, Kraków, Poland

The aim of this study was to examine respiratory system efficiency in workers employed as coke plant battery staff in Steel Mill in Kraków over the years.

Methods: The spirometric examinations were performed at 3 different times: 1st in 1974 -65 workers (age: 32.7±4.8 years, period of occupational exposure: 8.8±4.6 years), 2nd in 1990 - the same 65 workers (they worked all the time in the same workshop: 48.8±5.1 years; 24.6±4.7 years). 3rd in 2012 - 49 workers (age: 46.27±8.9, period of occupational exposure - 22.4±7.91). In 1974-1990 the levels of industrial pollution at workplace were similar. The concentration of SO2 was 15.4±6.6 mg/m3 and exceeded TLV, NOx -2.6±1.5 mg/m3, total dust-7.5-29.1 mg/m3 and free silicon dioxide-1.5-11.5%, geometric dimension of dust granule-3.9-4.5 um. In 2012 due to changes in both ownership of coke plants and increase in workers security, measured values were: SO2 -8.9±4.4 mg/m3, NOx -2.1±1.1 mg/m3, total dust-0.3-3.0 mg/m3 and free silicon dioxide -2.0-3.6%.

Results: The medians of basic parameters measured at 1st, 2nd and 3rd examination were as follows:

<table>
<thead>
<tr>
<th></th>
<th>VC</th>
<th>FEV1</th>
<th>FEV1/VC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1st</td>
<td>5.22</td>
<td>4.91</td>
<td>79%</td>
</tr>
<tr>
<td>2nd</td>
<td>4.46</td>
<td>3.37</td>
<td>79%</td>
</tr>
<tr>
<td>3rd</td>
<td>4.89</td>
<td>3.81</td>
<td>79%</td>
</tr>
</tbody>
</table>

Conclusions: After 16 years of occupational exposure to gaseous and dust pollutants (1st & 2nd) significant decline of basic respiratory parameters was noted but they were still in the normal range. After transformations in Poland the coke plant was modernized and environmental conditions significantly improved therefore it was agree with expectation that the new generation of workers also had the high efficiency of respiratory system.

P4014
Spriometric findings in asbestos-exposed subjects with pleural plaques missed by chest radiography but detected by HRCT
Erikson Bagat1, Mario Terra-Filho2, Lara Maris Nápolis1, José Alberto Neder3, Gustavo de Souza Portes Meireles4, Reynaldo Tavares Rodrigues5, Luiz Eduardo Nery1, 1Occupational Health Department, Universidade Estadual de Campinas, SP, Brazil; 2Pneumology, Universidade de Sao Paulo, SP, Brazil; 3Pulmonary Division, Universidade Federal de Sao Paulo, SP, Brazil; 4Department of Radiology, FLEURY SA, Sao Paulo, SP, Brazil

Introduction: High-resolution computed tomography (HRCT) is recognizable more sensitive than chest X-ray (CXR) in detecting small-to-moderately large pleural plaques (PP) in asbestos-exposed subjects.

Objectives: We reasoned that if the PP missed on CXR is associated with decreased lung function, this would lend support to a wider use of HRCT in these subjects.

Methods: HRCT and spirometry were obtained in 1075 miners and millers who have been exposed to progressively lower airborne concentrations of asbestos over time (Groups I to III) and were free of PP or asbestosis on CXR.

Results: We found that 100/1075 (9.3%) of the subjects had PP only on HRCT (44/40 (48.8%) in Group I, 44/537 (8.2%) in Group II and 12/448 (2.7%) in Group III. As shown in the Table, subjects with PP on HRCT but not CXR had consistently lower spirometric values than those defined as normal by both methods (p<0.05). Similar results were obtained after adjusting for smoking status.

Conclusions: We conclude that the lack of sensitivity of CXR in detecting PP in asbestos-exposed subjects is a matter of concern, as subjects with these abnormalities only on HRCT had decreased lung function values. This seems of special relevance among more exposed subjects.
P4016
Exposure characteristics of patients with different pathological types of malignant mesothelioma
Bill Munk, Peter Franklin, Patrick Abouage-Sarfo, Alison Reid, Nola Olsen, Latha Samuel, Geoffrey Berry, Nicholas de Klerk, Charles Guaidhuier, Perth, WA; Australia School of Population Health, University of Western Australia, Perth, WA, Australia; Western Australian Institute for Medical Research, University of Western Australia, Perth, WA, Australia; School of Public Health, University of Sydney, Australia; Centre for Child Health Research, University of Western Australia, Perth, WA, Australia

Background: Malignant mesothelioma (MM) of the pleura and peritoneum has 3 main pathological sub-types: epithelioid, sarcomatoid and biphasic with different clinical behaviour and prognosis but all related to asbestos exposure.

Aim: To identify any distinguishing characteristics of patients with different subtypes of MM that may relate to their differing clinical manifestations.

Methods: All cases of MM that have been recorded in Western Australia since the first case in 1962 until 2010 were reviewed for the demographic characteristics, histological type, and asbestos exposure history.

Results: There have been 1867 (1612 male) confirmed cases of MM between 1960 and June 2011. Of those there are 23 sarcomatoid, 744 epithelioid and 367 biphasic subtypes with 519 cases not specified. Analyses were confined to cases with defined pathological sub-types. Results from univariable analyses are presented in Table 1. In a multinomial regression, age at diagnosis, exposure route and topography were significantly associated with subtype.

Characteristics of MM subtypes

Mean (SD)

Conclusion: Compared to other subtypes sarcomatoid MM appears in older subjects and is less common with environmental exposure to asbestos. It is also less common in the peritoneum than pleura.

P4017
End of domestic asbestos exposure epidemic in Metsovo; N.W. Greece
Carmen Miro,2 Thomas Vadoulou3,3 George Dascalopoulos3,3 Konstantinos Tsampoulos1,1 Stavros Constantopoulos1,1 Yotanala Dalavanga4,4 Department of Pneumonology, University of Ioannina, Medical School, Ioannina, Greece; 2Department of Hygiene and Epidemiology, University of Ioannina, Medical School, Ioannina, Greece; 3Department of Radiology, University of Ioannina, Medical School, Ioannina, Greece; 4Department of Anatomy-Pathology Embryology, University of Ioannina, Medical School, Ioannina, Greece

Introduction: Metsovo has been exposed to tremolite asbestos from a white-wash used by all until 1940. This exposure has resulted in frequent pleural calcifications (PCs) and a mesothelioma epidemic, fading due to abandonment of lito.

We have reported that most older Metsovites have PCs in chest CT and asbestos bodies (ABs) in BAL. These parameters are used now in younger Metsovites to evaluate if those not exposed are free from signs of exposure.

Materials & methods: 22 Metsovites age 30-49 had chest CTs and 8 of them BAL. Age was chosen because it takes 30 yrs for PCs to appear and because they were born between 1960-80 when lito use had declined considerably giving us unique opportunities to correlate clinical and pathological findings.

Results: Only 3/22 had used lito (35,47,48 yo). All 8 BAL studies were negative, in contrast to the exposed control group, where 6/7 (85.7%) BAL studies showed ABs. Only one chest CT was positive for PCs (49yo: lito until 13yo). From the 86 chest CTs, 5 belonged in the 30-39 and 9 in 40-49 yo group. None of the 30-39yo group had PCs and none had used lito. There was one CT positive in the 40-49yo group (11%). He had used lito in childhood as was the case with 2/6 others of this group in which lito history was obtained.

Conclusion: There is no evidence of asbestos exposure in younger Metsovites who have not used lito. The domestic use of this tremolite-whitewash has been the only source of asbestos in Metsovo. Its abandonment has resulted in the end of this epidemic.

P4018
Asbestos-related disease: Clinico-pathological correlation
Jill Murray1, Numbizawo Ndlovu2, Jen WeitenNaudé,3 1Pathology, National Institute for Occupational Health (National Health Laboratory Service) and University of the Witwatersrand, Johannesburg, South Africa; 2Asbestos Relief Trust, University of Cape Town, South Africa

Introduction: The accurate diagnosis of asbestos-related diseases is important. For compensation asbestos is definately diagnosed without the aid of pathology while the diagnoses of lung cancer and mesothelioma require surgical lung biopsies. South African law makes provision for the autopsy examination of the cardiorespiratory organs of deceased miners for compensation purposes. This provides unique opportunities to correlate clinical and pathological findings.

Methods: Deceased cases assessed in-life for compensation using chest radiographs by the Asbestos Relief Trust and who had an autopsy at the National Institute for Occupational Health from May 2010 to May 2011 were studied. The in-life and autopsy diagnoses of asbestosis and its severity, mesothelioma and lung cancer were compared. Sensitivities, specificities and related values were calculated.

Results: 94 cases were studied. ARDs were diagnosed at autopsy in 78 (83%) of the cases: 47 (50%) had asbestosis, 20 (21%) mesothelioma and 15 (16%) lung cancer. Sensitivity, specificity and accuracy rates for the clinical diagnoses were 47%, 83% and 65% for asbestosis; 65%, 96% and 89% for mesothelioma and 49%, 100% and 90% for lung cancer respectively.

Discussion: Cases with slight asbestosis were more likely to be missed clinically (69%) than marked disease (42%). Many malignancies were undiagnosed in life. These findings underline the difficulty of diagnosing ARDs and the importance of autopsies in detecting disease missed in-life.

P4019
Relationship between endogenous NO and blood gas parameters in former asbestos workers
Lubov Barbinova, Alexandra Preisser, Xavier Baur. Department of Clinical Occupational Medicine, Institute for Occupational Medicine and Maritime Medicine, University Medical Center Hamburg Eppendorf, Hamburg, Germany

Introduction: Background: Nitric oxide is a major endogenous regulator of the vascular tone. Inhaled nitric oxide gas has been used for treatment of pulmonary arterial pressure and hypoxaemia (especially in persistent pulmonary hypertension of the newborn).

It is not known whether there is a relationship between endogenous bronchial NO concentration and blood gas parameters.

Patients and methods: 48 former asbestos workers (all non-smokers) were examined within the framework of a surveillance program. Lung function tests, blood gas analyses, diffusion capacity for CO (DL,CO), and multiple FeNO measurements were obtained within the framework of a surveillance program. None of the patients exhibited high FeNO values (FeNO=16.9 ppb).

Results: Only 3/22 had used lito (35,47,48 yo). All 8 BAL studies were negative, in contrast to the exposed control group, where 6/7 (85.7%) BAL studies showed ABs. Only one chest CT was positive for PCs (49yo: lito until 13yo). From the 86 chest CTs, 5 belonged in the 30-39 and 9 in 40-49 yo group. None of the 30-39yo group had PCs and none had used lito. There was one CT positive in the 40-49yo group (11%). He had used lito in childhood as was the case with 2/6 others of this group in which lito history was obtained.

Conclusion: There is no evidence of asbestos exposure in younger Metsovites who have not used lito. The domestic use of this tremolite-whitewash has been the only source of asbestos in Metsovo. Its abandonment has resulted in the end of this epidemic.

Discussion and conclusions: The decreased values of DL,CO reflect the pulmonary fibrosis in asbestos exposed subjects. This is associated with reduced FeNO. The positive correlation between Cao2 and DL,CO may be due to its vasodilatative effects.

P4020
The evaluation of the relationship between malignant mesothelioma and environmental asbestos exposure in Sivas
Serifie Iliek1, Husseyin Yalcin2, Kursat Epozturk 1, Omer Tamer Dogan1, Zeyn Seyilkil1, Ibrahim Akkurt1. 1Department of Chest Diseases, Cumhuriyet University, Faculty of Medicine, Sivas, Turkey; 2Department of Geological Engineering, Cumhuriyet University, Sivas, Turkey

Objectives: Sivas province is located in the Central Anatolia where asbestos exposure is common. We aimed to study the relationship between environmental asbestos exposure and epidemiologic features of patients with MM.

Methods: In total, 219 patients with MM who were diagnosed in our hospital between 1993 and 2010 were retrospectively analyzed in terms of demographical and clinical features. Rock, soil and house plaster samples were taken from the habitats of those patients and were evaluated with optical microscopy and X-ray diffraction methods.

Results: The patients aged between 18 and 85 years (male/female=1:4.4). Most of the patients (86%) confirmed an asbestos exposure. The most frequent symptoms were chest pain (60%) and dyspnea (50%) and the duration of the symp-
Conclusions: MM is primarily related to environmental chrysotile exposure in Sivas. However, single or combined roles and/or interactions of other fibrous and non-fibrous minerals in the etiology of MM are not yet fully understood and remain to be investigated.

P4021
Prevalence of obstructive and restrictive functional patterns in a population of environmental asbestos exposed
Siyami Dereoglu1, Paolo Trovati2, Pierluigi Carratu1, Onofrio Resta1, Marina Mussi1, 2Pulmonology, University of Bari, Italy; 3Public Health, University of Bari, Italy; 4Occupational Medicine, University of Bari, Italy
Background: Tremolite is one of the six recognized types of asbestos. This material is toxic and inhaling the fibers can lead to asbestosis, lung cancer and both pleural and peritoneal mesothelioma. Resident population in the area of Lagonegro (Basilicata, Italy) has been shown to be exposed to environmental tremolite pollution, deriving from superficial rocks and asbestos caves. A branch of the ongoing health surveillance program for residents is evaluating the prevalence of obstructive or restrictive pulmonary functional patterns.

Methods: A total number of 1353 individuals were included into this study. The study group was composed by 695 residents in the tremolite-exposed area of Lagonegro (age 49.3±16.68, current smokers 122, ex-smokers 134). The control group was composed by 658 individuals living in areas not tremolite-exposed (age 54.13±17.75, current smokers 121, ex-smokers 174). All the participants to the study performed a lung function test.

Results: Prevalence of obstructive disease was 0.58% in the exposed group and 0.236 (95% CI 0.079-0.708) in the non-exposed group (p=0.539). Prevalence of obstructive disease was 0.58% in the exposed group and 0.236 (95% CI 0.079-0.708) in the non-exposed group (p=0.539). Prevalence of obstructive disease was 0.58% in the exposed group and 0.236 (95% CI 0.079-0.708) in the non-exposed group (p=0.539). Prevalence of obstructive disease was 0.58% in the exposed group and 0.236 (95% CI 0.079-0.708) in the non-exposed group (p=0.539).

Conclusions: According to our data, tremolite exposure has apparently no influence on the prevalence of functional respiratory deficit. It is necessary to follow the exposed group in time by repeated measurements.

P4022
The prevalence of silicosis in dental prosthetic technicians working in Kahramanmaras City
Hasan Kahraman1, Muge Cinkara1, Nurhan Koksal2, Fuat Ozkan2, Hasan Ekerbicer1, 2Chert Disease, Kahramanmaras Sutcuimam University, Faculty of Medicine, Kahramanmaras, Turkey; 3Radiology, Kahramanmaras Sutcuimam University, Faculty of Medicine, Kahramanmaras, Turkey; 4Public Health, Kahramanmaras Sutcuimam University, Faculty of Medicine, Kahramanmaras, Turkey
Objective: The aim of our study is to determine, the presence and the frequency of occupational silicosis in dental prosthesis technicians in Kahramanmaras.

Materials and methods: The questionnaire was administered to participants prepared by the Turkish Thoracic Society for occupational and environmental lung diseases, physical examination was performed, PFT were measured, and HRCT was taken. The resulting images were evaluated independently by three readers. When at least two report as pathologic, cases were accepted as silicosis.

Results: Technicians involving the study were 82, 80 of them were male (97.5%). The mean age was 30.9±6.8, the mean pack-year of smoking was 12.4±13.8, the mean working period was 15.8±8.7 years. In 7 abnormal respiratory examination findings were detected. During working, 24 (29.3%) continuously, 21 (25.6%) never, 37 (45.1%) occasionally used the mask. No statistically significant difference was found between the mask usage and HRCT findings of silicosis (p>0.05) and between the symptoms in workplace and the duration of working period (p>0.05). PFT of employees were evaluated as normal. In evaluation of HRCT, 51 (62.2%) had normal and 19 (23.2%) had radiology compatible with silicosis. The localizations of the radiological involvement were determined; only upper lobes in 12 (63.2%), only the lower lobes in 1 (5.3%), upper and middle lobes in 3 (15.8%), upper and lower lobes in 2 (10.5%) and together with the upper, middle and lower lobes in 1 (5.3%) person.

Conclusions: This study showed that dental prostheses technicians have high risk for catching silicosis.

P4023
Silicosis caused by sandblasting in teflon coated pan manufacturing
Nurhan Koksal, Hasan Kahraman, Nurhan Atilla. Pulmonary Diseases, Faculty of Medicine, Kahramanmaras Sutcuimam University, Kahramanmaras, Turkey

Silicosis is an occupational disease of the lungs caused by inhalation of crystalline silica and is marked by fibrotic pulmonary reaction. Sandblasting has been commonly used during abrading of jeans, glass, and metal. We presented 17 silicosis cases occurring in teflon coated pan manufacturing. Symptoms questionnaire, pulmonary function tests, carbon monoxide diffusion test, and thorax HRCT were done. All of employees are male and mean age was 28.8±5.2 (18-41). The mean duration of working period for this job was 24.8±15.4 (9-60) months.

NS=No symptom, D= Dyspnea, C=Cough, S=Sputum, CP=Chest pain, AS=Acute silicosis, ACS=Accelerated silicosis, CS=Classical silicosis, ST=Silicotuberculosis, NCS=No clinical symptoms, RF=Respiratory failure.

Clinically total 17 cases was evaluated, 7 cases as classic silicosis, 6 cases as classical silicosis, 3 cases as accelerated silicosis (ACS) and one case as silicotuberculosis (ST). Four cases of AS and one ST case were died during follow-up. Acute respiratory failure was present in one AS case and one ACS case. Clinical follow-up of other patients has been continued. In view of this report, sandblasting of teflon pan manufacturing cause silicosis. These clinical type commonly acute form and mortaly was high.

P4024
Silica-induced inflammammasome activation in lung epithelial cells
Paul Peeters1, Tim Perkins2, Niki Reyneau1, Broke Mossman3, Eemil Wouters1, 1Department of Respiratory Medicine, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University, Maastricht, Limburg, Netherlands; 2Department of Pathology, University of Vermont College of Medicine, Burlington, VT, United States

Introduction and objectives: In myeloid cells the inflammasome plays a crucial role in innate immune defenses against pathogen- and danger-associated patterns such as crystalline silica. Respirable mineral particles impinge upon the lung epithelium causing irreversible damage, sustained inflammation and silicosis. In this study we investigated lung epithelial cells as a target for silica-induced inflammasome activation.

Methods: Primary mouse tracheal epithelial cells, human bronchial epithelial cells (BEAS-2B) and primary normal human bronchial epithelial cells (NHBE) were exposed to toxic but nonlethal doses of crystalline silica over time to perform functional characterization of NLRP3, caspase-1, IL-1β, IL-18 and HMGB1. Gene expression microarray, quantitative RT-PCR, BioPlex analysis, caspase-1zymatic activity assay, western blot techniques and cytokine specific ELISA were performed.

Results: We were able to show particle uptake by lung epithelial cells, transcriptional and translational upregulation of the components of the NLRP3 inflammasome platform, as well as activation of caspase-1. This activation furthermore led to maturation of pro-IL-1β to secreted IL-1β, and a significant increase in the unconventional release of alarmins such as IL-33 and HMGB1. Small interfering
DNA experiments using sNLRP3 revealed the pivotal role of the inflammatory component in diminished release of pro-inflammatory cytokines, danger molecules and growth factors.

**Conclusion:** Our novel data indicate the presence and functional activation of the NLRP3 inflammasome by crystalline silica in human lung epithelial cells, which prolongs an inflammatory signal mediating a cadre of lung diseases.

Screening healthcare workers for Mycobacterium TB: Is QFT-G now the test of choice?

Robert Smyth, Parthiban Nadarajan, Anne Gileece, Liam Cormican. Respiratory Department, James Connolly Memorial Hospital, Dublin, Ireland

**Introduction:** Quantiferon-Gold (QFT-G) is FDA approved for the diagnosis of infection with Mycobacterium tuberculosis. CDC guidelines have supported the use of QFT-G in all cases where Tuberculin Skin Test (TST) is used, including screening of healthcare workers (HCWs). We sought to establish the benefits of QFT-G in HCW screening within our own hospital practice.

**Methods:** In June 2010, a QFT-G test was screened, by TST all newly employed HCWs. 41 patients over the period had full data for analysis. Country of origin and evidence of prior distant history of BCG vaccination on examination, were also documented. A TST of ≥10mm was considered a positive result and was followed by a QFT-G.

**Results:** 41 TST were performed, 35/41 (85.4%) had a BCG scar. TST was positive in 23/41 (56.1%). QFT-G was positive in 15/23 (65.2%). Significantly 8/23 (34.8%) TST proved to be false positives on the basis of a subsequent negative QFT-G. **Conclusion:** HCWs are identified as a cohort at risk of Mycobacterium TB infection. As a lab based assay QFT-G is not subject to biases or the errors of TST placement or reading. It also negates the need for a return visit in 48-72 hours for interpretation. 34.8% of our cohort had a false positive TST leading us to question the sensitivity of the test in this cohort. QFT-G has proved itself to approach 98% sensitivity and 89% specificity and is a suitable replacement for TST in HCW screening.

GTn heme oxygenase-1 polymorphism in beryllium-exposed dental technicians

Moshe Stark1, Yehuda Lerman2,3, Lee Newman2,6, Lisa Maier2, Elizabeth Freeman1,2,4,5, Institute of Pulmonary Diseases, National Laboratory for Public Health Research, Jerusalem, Israel; 2Occupational Health Department, Clalit Medical Services, Tel-Aviv, Israel; 3Department of Epidemiology, Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel; 4Department of Occupational and Environmental Medicine, Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel; 5Division of Occupational Health Sciences, National Jewish Medical Center, Denver, United States; 6Environmental Occupational Health Department, University of Colorado, Aurora, Denver, United States

**Background:** Dental technicians (DTs) are exposed to Beryllium (Be) and other substances capable of inducing lung disease. Heme oxygenase-1 (HO-1) play a protective antioxidant role in the lung. The guanine-thymidine (GT) n repeats in the HO-1 promoter determine HO-1 induction level. Short (GT) n repeats (n < 25) and (S genotype) is considered as protective since HO-1 is induced more rapidly than in long (GT) n repeats (n ≥ 25; L genotype).

**Aims:** To evaluate the correlation of HO-1 polymorphisms to functional and exposure parameters in DTs and the protective role of HO-1 on Be Oxide (BeO) exposed A549 epithelial cells apoptosis.

**Methods:** 65 DTs were followed-up for 2 years by questionnaires, induced sputum (IS) particles size distribution laser analysis (Dapi 2000 Donner Tech and Pulmonary Function Tests). HO-1 genotyping was done by PCR DNA sequence (ABI prism 310). A549 epithelial cell line was cultured with BeO and pretreated with Hemin and ZnPP (for stimulation and inhibition of HO-1 respectively), HO-1 gene expression was evaluated in IS and A549 cells by quantitative PCR and apoptosis by TUNEL staining.

**Results:** Association was found between GTn and HO-1 gene expression in IS (p=0.35 p=0.017), the GTn>25 group had higher HO1 expression than the GTn≤25 group (0.18±0.16 Vt 0.70±0.06 p= 0.007 respectively). Decrease in DLCO (Diffusion Lung CO) was associate with GTn>25. Hemin increases the HO-1 gene expression and decreases the apoptosis levels in A549 epithelial cells while is increased by ZnPP.

**Conclusions:** DLCO decrease is associated with L genotype. Decrease apoptosis in BeO-exposed A549 epithelial cells by hemin may indicate a protective role of HO-1.

Hypersensitivity pneumonitis related to Streptomyces mesophile and Penicillium chrysogenum: The usefulness of the Medical Indoor Environment Council (MIEC)

Angelica Tom1, Carine Metz-Favre1, Gil Wirtz2, Gabriel Reboux3, Marine Ott1, Romain Kessler1, Frédéric de Blay1,1 Pulmonology, CHU Brabois, Nancy, France; 2Chest Diseases, CHRU Strasbourg, France; 3Laboratory of Parasitology, CHU Besancon, Besancon, France

**Introduction:** Hypersensitivity pneumonitis (HP), secondary to the inhalation of organic antigens at home are rare and the diagnosis is very often difficult without home visit. Observation: We report a case of a 55 years male patient, ex-smoker, with an allergic asthma since childhood, well controlled with inhaled cortico-steroids, who developed two respiratory distresses during asthma exacerbations. HPS was suspected because of the fever (39°C), the dry cough, rapidly progressive dyspnea, chest pain and crutches. Blood gas analysis found a hypoxemia of S2 immHg, and the CT-scan showed a few ground glass images in the upper lobes. 126 respiratory function tests showed a severe obstructive syndrom and a decrease of diffusion test. Allergological investigation: The diagnosis was suspected because the symptoms were linked to domestic environment, triggered by stays in a camper. The (MIEC) visited the house and the camper and performed air and dust samples. Moldy walnuts were found in the camper. The identification of microorganisms presents on the nuts, in the air and in the dust, were used for the search for precipitins in double diffusion (DD) and electroversion (IE). Of the 14 antigens tested, serological tests were considered significant for Streptomyces mesophile (5 bands DD, 6 bands Eisand Penicillium chrysogenum (1 band DD, 4 bands E)). The patient removed the nuts from his camper. Since then, he has not experienced any exacerbation.

**Conclusion:** This is a case of domestic HSP to Streptomyces mesophile and Penicillium chrysogenum. The MIECs intervention was useful for the diagnosis and the treatment.

**P4028**

Geochemical factors and incidence of sarcoidosis in Tomsk region

Oleg Denisova1, Georgy Chernogoryuk2, Ksenia Egornova2, Mikhail Kobushkin3, Pulmonology, Tomsk Regional Hospital, Tomsk, Russian Federation; 2Hospital Therapy, Siberian Medical University, Tomsk, Russian Federation; 3Geocology and Geochemistry, Tomsk Polytechnic University, Tomsk, Russian Federation

**Methods:** Sarcoidosis incidence has been studied according over a 20-year period (528 patients without unhealthy working conditions). The incidence rate has been defined per 100000 of population in the geochemical and environmental regions. 126 measurements of 23 chemical elements (Na, Ca, Sc, Cr, Fe, Co, Zn, Br, Ag, Sb, Au, La, Th, U, Hf, Se, Hg, Sm, Eu, Yb, and Lu) were made by the neutron activation analysis in the dust-aerosol, soil and drinking water in Tomsk and Tomsk region. Sarcoidosis highest incidence was found on the territories exposed to anthropogenic factors: in Seversk 67.3 (nuclear fuel industries), Octabryksky district of Tomsk 56.8, Tomsk rural district 68.14, Strezhevoy 47.2 (fuel and oil industries). In these districts the incidence rate was significantly higher compared to the mean findings in region - 42.6 (χ2 = 7.9411.6; p < 0.05). The incidence in the mainly agricultural districts was minimal 23.5. In Seversk recurrent forms were significantly higher - 20.56 versus 0.23 in Tomsk (χ2 = 7.941; p < 0.01). The correlations have been found between: the sarcoidosis incidence and the Na content in the dust aerosols (r = 0.9; p < 0.05), Ce in the soils of industrial territories (r = 0.9; p < 0.05), Ca in drinking water (r = 0.8; p < 0.01), recurrent forms of sarcoidosis and Lu in soils of the contaminated territories (r = 0.8; p < 0.05), Cr in soils of agrarian districts (r = 0.65; p < 0.05). Thus, the correlation between the ecological state of the territories and sarcoidosis incidence is sure to exist. Uncertainty of the obtained data does not allow understanding which factor plays the role. One cannot deny the influence of trace elements which have shown the correlations: Na, Ca, Lu, Ce, Cr.

Exhaled airway and alveolar nitric acid in extrinsic allergic alveolitis

Paul Blanc1, John Balmes1, Patty Quinlan1, Irina Tobotykh2, Carlos Ibarrahen1, Anna-Carin Olin1, Kjell Torin2, Patricia Kata1, Medicine, University of California San Francisco, CA, United States; 1Division of Research, Kaiser Permanente, Oakland, CA, United States; 2Occupational and Environmental Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

**Background:** In extrinsic allergic alveolitis (EAA), alveolar nitric oxide (AlvNO) and the airway fraction of exhaled nitric oxide (FEno) have not been well studied.

**Methods:** EAA cases were derived from a referral center and an integrated health delivery organization (BHCDO); age- and gender-matched referrals were recruited from the BHCDO. Subjects were invited to participate in home visits including spirometry (EasyOne; ndd Medical Technologies, Andover, MA, USA) and FEno electrochemical quantification (NO Vario; FILT, Berlin, Germany) at 3 months (EasyOne; ndd Medical Technologies, Andover, MA, USA). Flow rates (50, 100, and 300 ml/sec) yielding the measured airway FEno and the calculated AlvNO. We tested differences by EAA status using the chi square, t-test, and Wilcoxon rank sum.

**Results:** We completed home visits in 18 EAA cases and 106 referents; 91 in each group (77% and 86%, respectively), yielded interpretable FEno and AlvNO
results. There were no statistical differences by case vs. referent status for age (60.6±13 v. 60.6±11 years), female sex (50% v. 65%), or height (167.9± vs. 167.9± cm). EAA cases compared to referents had lower forced vital capacity (FVC) (3.1±1.0 l.; v. 3.5±1.0 l.; p<0.01) and reduced FVC % predicted (81.1± v. 96.1±%: p<0.001). Airway Fluo was higher in cases than referents (22.5±14.1 ppb v. 17.4±8.4 ppb: p=0.03), as was Alveo (4.1±4.9 v. 2.7±4.9 ppb: p=0.003).

**Conclusion:** Both airway Fluo and Alvio are increased in EAA, supporting exploration of their associations with disease activity and health status.

**Clinical:** Assessing airway Fluo and Alvio in EAA may provide insights into exposure status and disease management.

Supported by NIH 1RC1ES018211.

**P4030**

**Smoking cessation clinic: One year experience**

Jose Andrés García Romero de Tejada, Cristina López Roedobos, Gonzalo Segrelles Calvo, Emma Vazquez Espinosa, Rosa Mar Gómez Punter, Julio Ancochea Bermúdez, Olga Raja Naranjo. Pulmonology, Hospital Universitario de La Princesa, Madrid, Spain

**Introduction:** Tobacco is the most important preventable cause of premature death worldwide. Only about 45% of people are able to quit smoking on any given attempt without medicines or other help. Smoking cessation clinics and others healthcare providers have been shown to improve smoking cessation rates.

**Aim:** To analyse the characteristics of the smokers in a Smoking Cessation Clinic in Madrid.

**Material and methods:** From November 2010 to October 2011, 200 consecutive smokers were included in this study. Demographic data, comorbidities, smoking history, nicotine dependence (Fagerstrom test scores), motivation to quit (Richmond test scores), treatment and success in quitting smoking were recorded. The statistical software SPSS was used for analysis of the results.

**Results:** Mean age of 51.7 years, with 56% of them being women. Body mass index was 25.35 kg/m². Mean age at smoking initiation was 17.33 years, and men were slightly younger (16.11 vs 17.3, p=0.002). Men also consumed more tobacco (pack-years index was 47.23 in men vs 34.47, p=0.001) and had higher nicotine dependence than women (p=0.019). Six-month continuous abstinence quit rate was 46.43% in women and 50.68% in men (p=0.024). Varenicline was the more effective treatment (success rate 46.9%). 70% of the smokers had tried to quit before, and just 10 patients success at their first attempt (all of them were women). 72 smokers (36%) left the program after the first visit.

**Conclusions:** 1. Men significantly started to smoke earlier, consumed more tobacco and had higher nicotine dependence than women. 2. Six-month continuous abstinence quit rate was significantly higher in women. 3. Varenicline was the more effective treatment for smoking cessation in our experience.

**P4031**

**Results in a tobacco consulting room in Albacete University Hospital in 2009**

Francisco Javier Celajes Gonzalez, Javier Cruz Ruiz, Raul Godoy Mayoral, Ana Isabel Tornero Molina, Sergio Garcia Castillo, Mariela Plenc Ziegler, Abel Martinez Garcia, Juan Paustrana Calderon, Rafaela Sanchez Simon-Taler, Juan Carlos Ceballos Romero. Pulmonology, Complejo Hospitalario Universitario de Albacete, Spain

**Introduction:** Results in a Tobacco Consulting Room in 2009.

**Material and methods:** Retrospective descriptive analysis of the results obtained from patients who attended in a Tobacco Consulting Room from 1 January to 31 December 2009 and subsequent follow-up to complete a year.

**Results:** 291 of 428 patients (51.2% male), mean age 46 years and mean cigarettes/day 27.5. Moderate-severe nicotine dependence (Fagerstrom 6.8) and high motivation (Richmond 8.11). Respiratory comorbidity: 12.1% COPD, 7.6% asthma, 11% OSAS and 0.3% HOI; Cardiac: Ischemic Cardiopathy, 4.8% and Arrhythmia, 2.1%; CVRF: 30.9% dyslipidemia, 19.9% HT and 9.3% DM. 42.6% global asthmatic, 11% OSAHS and 0.3% HOT; Cardiac: Ischemic Cardiopathy, 4.8% and Ar-

**Conclusions:** 1. Men significantly started to smoke earlier, consumed more tobacco and had higher nicotine dependence than women. 2. Six-month continuous abstinence quit rate was significantly higher in women. 3. Varenicline was the more effective treatment for smoking cessation in our experience.

**P4032**

**Smoking cessation success rate in smokers referred to Iranian clinics**

Tahal Moosavi1, Ali Abdollahi1, Mohamadraza Masjedi1.1 Research Unit, Iranian Anti-Tobacco Association, Tehran, Islamic Republic of Iran; 2 Chronic Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran

**Background:** Quitting smoking at any age can be effective in reducing smoking-related health conditions. At present, smoking cessation is considered the cornerstone of tobacco control policies. This study aimed to evaluate the success rate of smokers presented to smoking cessation clinics during 2005-2010 and to determine the effective factors in this respect.

**Methods:** In this historical cohort study, all participants attended the smoking cessation clinics, affiliated to the Iranian Anti-Tobacco Association, between 2005 and 2010 were studied. Success rate was assessed two weeks after the quitting onset.

**Results:** Totally, 772 participants including 510 men and 262 women were studied. 50.9% of participants reported a history of quitting and a significant correlation was observed between history of quitting and success rate (p=0.04). The success rate also had a significant relationship with higher educational level and presence of restrictions on smoking. In addition, the success rate was inversely correlated with increased nicotine dependence. However, no significant relationship was found between sense of pleasure, increased concentration or personality boost and success rate of smoking cessation. By the end of the second week following abstinence, 544 participants (71%) had successfully quit smoking.

**Conclusion:** History of quit attempts and higher educational level had significant correlations with success rate of smoking cessation. Presence of restrictions on smoking is also effective in this regard. However, this study showed that increased rate of nicotine dependence reduced the success rate of smoking cessation.

**Russian advisory telephone line of help for smoking cessation**

Oleg Sukhovskoyev, Petr Yablonskiy. Advisory Telephone Centre of Help for Smoking Cessation, State Research Institute of Phthisiopulmonology, Sank-Petersburg, Russian Federation

Effective assistance in stop smoking must include behavioral and medical ther-

**Aim:** To describe the prevalence and intensity of different symptoms in relation to tobacco abstinence, personal’s abilities and demand of telephone psychological and medical counseling.

**Methods:** 3840 smokers (18-78 years) who rang the Russian advisory telephone line of help for smoking cessation (ATL) were interviewed about smoking (nico-

tine dependence, smoking behavior, motivation to quit smoking, earlier cessation experience), respiratory symptoms, personal’s traits and social status.

**Results:** There were men (69,4%) and women (30,9%) among the respondents (63,9% - people 18-34 years); 31,4% had high education.43% were married. The mode of respondents had high motivation to quit smoking (71%). In 85% of cases smokers had experience in smoking cessation (including 8% were treated with nicotine dependence) and in 48% of cases had high intensity of withdrawal symptoms (4 and more scores) of withdrawal symptoms (more two symptoms). Frequency of respiratory symptoms among smokers was 39%, chronic diseases - 41%. 63% respondents are needed in consultation only; 31,4% received the consultative psychological and medical support during 1 month, 5,6% were sent to the hospital doctor to quit smoking. After 1-3 sessions ATL 28,4% of smokers stopped tobacco consumption.

**Conclusion:** Consultative telephone line helps change behavioral patterns and contributes to effective smoking cessation.

**P4034**

**Values of saccharin transit time test in smokers following a smoking cessation programme in Brazil**

Fernanda Maria Machado Rodrigues, Dionei Ramos, Alessandra Quchoeta Toledo, Rafaela Fagundes Xavier, Marceli Rocha Leite, Juliana Nicollino, Luiz Carlos Carvalho Junior, Juliana Tivaki Ino, Ercy Mara Cupido Ramos. Physiotherapy, State University of Sao Paulo, Presidente Prudente, SP, Brazil

**Introduction:** Exposure to cigarette smoke causes changes that undermine the mucociliary clearance and may be influenced by different exposure conditions. The aim of this study was to present nasal mucociliary clearance (MC) by means of the saccharin transit time (STT) test and to evaluate the effects of different exposure intensities on MC in smokers following a smoking cessation programme in Brazil.

**Methods:** 42 current smokers with normal lung function were divided into mild [under 20 packyears (PY); n=15] and heavy (from 21 PY; n=27) smokers and evaluated concerning exhaled carbon monoxide (CO) by CO analyser and MC by STT. A matched control group of 25 healthy non-smokers was assessed using
the same text. Tests were conducted between 8 and 9 AM with air temperature and relative humidity controlled. Statistical analyses were performed using Mann Whitney U test.

**Results:** Smokers showed higher eCO and STT (6.5±5.9 ppm and 12.2±18 ppm) compared to control group (21±33 ppm and 7.9±6.13 ppm) (p<0.0001 and p=0.0187), respectively. Also, STT in heavy smokers was higher than in mild smokers. Stanely et al. (1986) evaluated smokers’ STT and also found a higher STT when compared with nonsmokers, however, despite were younger smokers with lower PY these values have been higher than those found in both groups in Brazil.

**Conclusion:** Cigarette smoke impairs mucociliary clearance and, in Brazilian smokers, the damage intensity was directly related to the charge exposure. Even at worse exposure conditions, this sample showed better STT.

---

**P4035 Smoking cessation: A problem for older adults?**
Manuela Stoleru, Stefan Mihaicuta, Alexandru Copan, Neamt, Romania Pneumology, Clinic “Victor Babes”, Timisoara, Timis, Romania

**Introduction:** The prevalence of tobacco smoking is high in both men and women and touch all ages. Cigarette smoking poses substantial health risks at any age, but is particularly alarming for older smokers with all various illness.

**Objective:** To compare the efficacy of smoking cessation pharmacotherapy among older and younger smokers and to evaluate whether the age represent an obstacle to quit smoking.

**Method:** We evaluate 216 male persons interested to stop smoking in an national romanian program from 01.07.2008 to 31.12.2009. The volunteers were grouped: age < 40, 40-59 and > 60. Terms assessed were: number of cigarettes, Fagerstrom test, type of treatment, the level of CO expire. The therapies used include nicotine replacement, bupropion and varenicline for a maximum 12 weeks.

**Results:** For the group > 60 it was a highest number of packs of cigarettes per year 46.3±21.8 (95% CI 38.01 - 54.61). The nicotine dependence evaluated by the Fagerstrom test is not significantly different in the three groups (5.8±2.2, 5.2 SD for the group >60, 6.29±2.55 for the group for 40-60 and 6.17±2.01 for the last one). The results of CO expired levels sound alarming for all clusters: > 60 - CO > 13.03±4.58 SD, 40-60 age CO 13.98±5.72 SD and for the group < 40 we rest in the same coordinates: CO = 15.13±8.716 SD. Abstinence rates in the older group > 60 was 34.48% in report with group 40-59 (48%) and group > 39 (44.8%).

**Conclusion:** The treatment for smoking cessation guide to almost similar abstinence rates in older and younger smokers. Physicians have annually a lot of opportunities to sustain their older patients to improve their health status and quality of life by quitting smoking.

---

**P4036 Effectiveness of varenicline as an aid to smoking cessation in primary care: An observational study**
Stefan Andreas, Jean-Francois Chenot, Ruth Diebold, Sarah Peachey, Karl Mann. Lungenfachklinik Innhausen, Kre. Kassl, Universitätsklinikum, Göttingen, Germany Department of General Practice, Institute for Community Medicine, University Medicine, Greifswald, Germany Medical Affairs, Pfizer Pharma GmbH, Berlin, Germany Medical Affairs, Pfizer Ltd, Surrey, United Kingdom Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany

**Introduction:** The effectiveness and safety of varenicline have been well established in randomized controlled trials. In the primary care setting, in which varenicline is commonly prescribed, only limited information is available on its use in patients with smoking-related comorbidities.

**Objective:** To assess the efficacy and safety of varenicline in a large sample of patients seeking smoking cessation treatment through their general practitioners.

**Methods:** This was a 12-week, prospective, observational, non-comparative phase IV trial conducted in Germany. The primary endpoint was the 7-day point prevalence of abstinence rate at Week 11–12, evaluated by verbal report using the nicotine use inventory.

**Results:** Overall 1391 subjects were enrolled. 1177 received study medication and were evaluated for efficacy and safety. A total of 66.7% participants had at least one concurrent comorbidity, chronic obstructive pulmonary disease (35.5%), hypertention (29.6%), depression (10.4%), diabetes mellitus (8.2%), and asthma (7.9%) being the most commonly reported. In the 7-day period between Weeks 11 and 12, 837 of 1177 subjects (71.9%; 95% confidence interval: 68.5, 73.7) were abstinent. A total of 205 all-causality adverse events were reported in 130 subjects (11.0%), of which 189 (in 122 participants [10.4%]) were considered treatment-related, and 2.2% were classified as serious or severe. There were no fatal adverse events.

**Conclusion:** These real-world data indicate that even in a setting outside of the clinical trial environment and in patients with smoking-related comorbidities, varenicline is an effective smoking cessation aid with an acceptable safety profile.

---

**P4037 Efficacy of nicotineless non-pharmacologic alternative tool for smoking cessation program using varenicline**
Ya Kasamatkas, K. Yoshimoya, M. Kadaya, Respiratory Medicine, Matsushita Memorial Hospital, Osaka, Japan

**Background:** Tobacco addiction is associated with not only nicotine dependence but also mental dependence based on the habitual smoking situation (e.g. drink alcohol, after meal). The efficacy of substitute nicotineless non-pharmacologic tool (e.g. nicotineless electronic cigarettes) in these situations for smoking cessation was unclear.

**Method:** This prospective observational study aimed to investigate the efficacy of non-pharmacologic alternative tool in patients who were treated with a 12-week outpatient smoking cessation program using varenicline. We screened 180 patients who were treated with the program from March 2010 to February 2012. Tobacco addiction in this study was defined as a condition with both at least five points of the Tobacco Dependence Screener (TDS; Kawakami, et al., 1999) and at least 10 pack year. At the first medical examination, we instructed all the patients to use the nicotineless alternative tool when they urge to smoke. We assessed the success rate of smoking cessation at 12 weeks.

**Result:** Of 136 patients were eligible (35 were lost, 9 dropped). The success rate was 77.8%. Eighty patients (58.9%) used alternative tool as we instructed. The success rate of the patients who used alternative tool was significantly higher than that of the patients who didn’t use the tool (p<0.001). In multivariable logistic regression analysis, the independent predictors of smoking cessation failure were unreatable side effect (p=0.05) and disuse of alternative tool (p=0.01).

**Conclusion:** In ourpatients smoking cessation program using varenicline, non-pharmacologic alternative tool was useful for patients who urge to smoke in the habitual smoking situations.

---

**P4038 Evaluation of the correlation between pictorial health warning labels and decision to quit smoking**
Ali Abdallahs, Research Unit, Iranian Anti Tobacco Association, Tehran, Islamic Republic of Iran

**Background:** Applying health warning labels on tobacco products, as an efficient measure for reducing tobacco consumption rate, put an end on tobacco industry abuse through attractive and beautiful packaging. Iran is among the leading countries in legalizing the application of warning labels on tobacco products and has executed it since February, 2009. At present in Iran, 50% of the front and back of tobacco packages should be covered by warning labels. The present study aimed at investigating the relationship between health warning labels and smoking cessation intention in smokers.

**Methods:** This descriptive cross-sectional study was carried out in summer of 2011, two years after applying the first series of health warning labels on tobacco products in Iran. 2,020 smokers from all districts of Tehran were interviewed. Data were collected. Obtained data were analyzed by SPSS v.17.

**Results:** Among our understudy subjects, 1,273 (65.7%) consumed labeled cigarettes (66% of men and 41% of women). Regarding influence of warning labels on tobacco consumption by the smokers, 18.2% stated a decrease in their consumption rate, and 15.7% reported their intention for quitting. Also, 35.7% of these smokers believed that putting disgusting graphic labels on cigarette packaging would increase their motivation for quitting.

**Discussion:** Evidence reveals that graphic warning labels could produce a great motivation for quitting and avoid smoking initiation in non-smokers. We found that more than 58% of female smokers used non-labeled cigarettes that was twice the rate in men. It may be indicative of less motivation in women and greater impact of pictorial warning labels on them.

---

**P4039 Smoking cessation process**
Ika Perse,1 Nada Lazovic2, Branimar Gvozdenovic3, 1 Department for Tobacco Prevention and Smoking Cessation, Clinic for Pulmonary Diseases and TB, Clinical Center of Serbia, Belgrade, Serbia, 2 Department for Smoking Cessation, Health Center Cacak, Serbia, 3 PPD Serbia, Belgrade, Serbia

**Introduction:** Serbia has ratified the Law on protection from exposure to tobacco smoke. The Law regulates all working and public places to be a smoke-free.

**Objective:** Consideration of the effects of smoking cessation by gender, education, and the employment status in 2010 when the Law is ratified.

**Methods:** The analysis of data was performed by means of t-test for independent samples and analysis of variance (ANOVA).

**Results:** A total of 2,030 smokers were interested for the smoking cessation program in the Serbian counselings. Of these, 1,489 smokers attended the program, and 1,134 (75.7%) finished it. The Law motivated 187 (16.5%) smokers to participate in the cessation program. There were 34.6% (M) and 65.4% (W) (p<0.01). The majority of subjects (59.9%) had the secondary school education 59.9%. There were 64.7% employed smokers in total. Regarding the gender, women (40.4%) were more successful than men (32.7%). Women with the secondary school and those not employed (60.7%, 30.7% respectively) were significantly more successful than men (43.7%, 21.9% respectively) (p<0.01). Men with higher education and male students (54.7%, 7.8% respectively) were significantly more successful than women (40.4%, 18.2% respectively) and those not employed (43.7%, 21.9% respectively) (p<0.01)
Results: include Nicotinic substitutes, the bupropion and varenicline.

Methods and material: 

Material and methods: Prospective study with the patients attending our smoking cessation practice in the last 6 months. We analyzed different variables and Cardiovascular events.

Agustín S. Valido Morales

This evaluation was carried out 3 and 6 months after the treatment initiation which lasted up to 2 months. We carried out a descriptive analysis.

Results: From a total of 313 patients (175 varenicline; 138 bupropion). The treatment with varenicline was more frequent in men who were older, with a higher smoking history, diabetes, ischemic heart disease and higher scores in the Richmond test. We observed no significant differences regarding the cardiovascular events in both groups.

Conclusions: Both drugs have shown the same safety profile for cardiovascular events.

We observed a higher frequency regarding the blood pressure increase.

The role of gender within the “stop smoking” program

Manuela Stoica, Pulmonology, Hospital Bisericani, Alexandru Cel Bun, Neamt, Romania

Introduction: Understanding individual differences in smoking behavior and addiction to nicotine can increase knowledge in the development of therapy, influence the outcomes of treatment, and is a challenge for developers.

Objective: The purpose of our study was to evaluate the role of sex in the effectiveness of smoking cessation to the National Romanian Program.

Methods and material: It is a study of a sample of 306 smokers from 01/07/2008 to 31/12/2009 interested in stopping smoking. They were assessed on the age, sex, domicile, the level of CO expire, test Fagerstrom, the family situation, the type of tobacco and the amount for a maximum period of 12 weeks. First line treatments include Nicotinic substitutes, the bupropion and varenicline.

Results: We evaluated 216 (70.58%) male, the average age was 43.72 years SD 13.5 95% CI 41 92-45.53, smoking 30.9 mg/day compared with 41 women age 40.53 average SD 11.8 95% CI 38.06 43.01 who smoke 15.66 mg/day medium, SD Ni 11 95% CI = 14.87 - 19.64. Men also started smoking earlier and had high dependence on nicotine than women. There is not a clear difference in the Fagerstrom test: TF = 5.85 for women TF = 5.62 for men.

The costs were almost equally distributed between the two categories.

Conclusion: There are no significant differences in looking at marital status: 76.92% compared to married women with 77.77% men. In both categories, the therapeutic attitude is dominated by the Champs 65.95% men to 51.38% women. At the end of the treatment, were abstinent 40.65% men and 47.68% women.

Conclusion: Sex does not appear to be a predictive factor of cessation in treated individuals persons. Analyses of individual differences should focus on the identification of the processes that control the smoking behavior.

Correlation between the age of smoking initiation and maintaining continuous abstinence for 5 years after quitting

An Abdulahim1, Makan Sadri2, Valid Moosavi3, Mohammadreza Masjedi3, 1Research Unit, Iranian Anti Tobacco Association, Tehran, Islamic Republic of Iran; 2Truuck Disease Research Center, National Research Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran; 3Chronic Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran

Background: Several factors are involved in increasing or decreasing the success rate of quitting smoking and continuous abstinence. This study aimed at evaluating the correlation between age of smoking initiation and continuous abstinence after quitting smoking.

Materials: This study was conducted on 398 smokers who presented themselves to the smoking cessation clinic in 2005. Participants were then followed continuously for 5 years and their success or failure in continuous abstinence was recorded in 2010.

Results: Three hundred and five participants (76.6%) including 172 males and 132 females were able to successfully quit smoking at the end of the course. Evaluation and follow up on these subjects at the end of 2010 revealed that 111 cases (27.8%) including 64 men and 47 women were still maintaining their continuous abstinence after 5 years. The mean age of initiation of smoking among participants was 21.01 ± 5.28 years. This rate was 21.94 ± 5.33 in cases 5 years after their smoking cessation and 20.71 ± 5.35 in unsuccessful quitters. Analysis showed a significant correlation between age of smoking initiation and daily cigarette consumption rate (P<0.001). By one year increase in age of smoking onset chance of daily cigarette consumption rate less than 30 cigarettes decreased by 6% (OR=0.94).

Conclusion: It seems that age of smoking initiation can to a great extent predict the success or failure of smoker in quitting and holding on to their abstinence in the future. The sooner the person starts smoking, the lower the chance of successful quitting and abstinence.
Conclusion: The family socioeconomic status, smoking habits, dependence degree, treatment adherence and the occurrence of lapses were predictors of relapse.

P4044

Couples of significant others (COSO) in a joint effort to quit smoking are more successful in achieving and maintaining abstinence
Aikaterini Tsoutsa, Ioanna Nikoloutou, Theodoros Vassilakopoulos, Spyridon Zakynthinos, Pararkevi Katsanos, Pulmonary & Critical Care Dpt, Evangelismos Hospital, Athens, Greece

Motivational support is crucial in the success of the smoking cessation. Significant others are a proven source of that support. As far as we know social support has been used to achieve smoking cessation higher rates, but only as support and not as a concurrent attempt of a couple to quit smoking. We investigated whether the inclusion of couples of significant others in a joint effort to quit smoking in smoking cessation groups formed by a population based sample of participants would increase their success rate compared to the participants that receive the same treatment alone. This was a randomized population-based intervention study at the smoking cessation clinic of Evangelismos hospital. We monitored for people that are related in the initial screening stage. Couples included life partners, family members or very close friends. Smokers were in all motivational stages. All participants underwent the same intervention with motivational and behavioural components in the smoking cessation groups and received medical consultation and pharmacotherapy (Varenicline). We compared so far the smoking cessation rates of 25 “couples” and 50 randomized smokers that followed our smoking cessation programme. We found that participants that joint the COSO quit smoking in a higher rate (58%) than of smokers (38%). Within the dyad the person more motivated to quit smoking was usually the first to quit. Among couples that quit smoking, men were more successful (65%) than women (49%). We conclude that higher smoking cessation rates were obtained in COSO joining our smoking cessation program.

P4045

Education level and relapse to smoking
Michelis Davy1, Giuseppe Madonia 2, Franca Impellizzeri 2, Vincenzo Bellia1, Maria Rosaria Bonigjorno1, 1Dipartimento di Medicina Interna e Specialististica. Sezione di Pneumologia, Università di Palermo, Sicily, Italy; 2U.O.C. di Pneumologia, A.R.N.A.S. Civico Palermo, Palermo, Sicily, Italy

Background: Cigarette smoking is the most common risk factor for COPD and lung cancer. Smoking cessation programs are very important for primary prevention of lung disease, but limited data are available on their effectiveness in the long term. Aim: To investigate the factors responsible for smoking relapse over 24 months after smoking cessation.

Methods: From January 2009 to December 2009, 148 smokers (72 men and 76 women, mean age ± SD 49.9±11.8 yr) undergoing a smoking cessation program were enrolled. The protocol included motivational counselling, drug therapy (Nicotine Therapy Replacement), Fagestrom Test, exhaled CO measurement and spirometry. We assessed cigarette smoking cessation at 12 months. The smoking-cessation rates were calculated. Cessation rates were compared between smokers and persistent quitters. We analyzed the baseline, week-4, week-8, week-12, week-24 and week-28 of smoking abstinence and number of cigarettes smoked, and exhaled carbon monoxide levels were measured at each visit. Smoking reduction and abstinence rates were calculated. Adverse events and product preferences were also reviewed.

Results: Sustained 50% reduction in the number of cig/day at week-52 was shown in 16% of participants. Sustained smoking abstinence at week-52 was observed in 9.75% of participants. Participants’ perception and acceptance of the product was good.

Conclusion: The use of e-Cigarette substantially decreased cigarette consumption without causing significant side effects in smokers not intending to quit.

P4047

Physicians’ smoking habit, training and attitude toward cancer patient smoking cessation: The Istituto Nazionale dei Tumori experience
Micaela Lina 1,2, Paolo Pozzi1, Cinzia Brunelli1, Marco Alessandro Pierotti1, Roberto Botti1, 1Psychology Unit, 2Tobacco Control Unit, 3Scientific Direction, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Backgrounds and aim: Guidelines recommend all physicians to ask patients (Pts) about their smoking status and to offer cessation advice (SC). Aim of the study was to examine the smoking habit of medical doctors (MDs) at the Milan Istituto Nazionale dei Tumori (INT), to relate this to their level of training and to their attitudes in suggesting patients to quit smoking.

Materials and methods: All MDs of the INT (n=285) were mailed a web-based survey.

Results: Fourteen percent of MDs were current smokers; only 23% of all clinicians received a training proposal in SC; 6% attended a SC course, even if 43% declared their willingness to do it. 86% of them asked Pts about smoking status, but only 50% advised Pts to quit and 32% assessed their motivation to do it. Guidelines were disregarded because of lack of time, fear to increase patients’ stress or lack of skills in SC. Smoking habits didn’t influence training attendance,willingness to be trained in SC or Pts referral to Tobacco Control Unit.

Conclusion: Smoking prevalence among INT MDs was still too high for healthcare providers and a low proportion of them was ever involved in a SC training session; however, smoking status doesn’t appear to influence MDs’ choice of training rather than the eventual referral of cancer smoker Pts to the dedicated Unit. Surveys like this should encourage cancer centers to make SC as part of their core mission and to implement SC training in their institutional policies.

P4048

Differences between the recommended and real dose in a smoking cessation practice
Ana Gómez-Bastero, Virginia Almadana, Concepción Romero, Estefania Lugue, Andrés Vega, Soledad Montserrat, Teodoró Montemayor. Respiratory Medicine Unit, Hospital Universitario Virgen Macarena, Seville, Spain

Aims: To analyze the dose and time decided by the patient regarding what is recommended and its influence on the tobacco cessation rate.

Methods: We included patients who attended our practice during the last 6 months. We analyzed several variables: recommended dose (varenicline (V): 0.51 mg, 2 months; bupropion (B): 150 mgs/day, 2 months), real dose and duration of the treatment, tobacco cessation rates and causes of early abandonment of medication.

Results: n=312 patients: V (56%) and B (44%). By comparing both groups, we couldn’t find differences regarding cessation rate after 3 V (64.4%/B: 67.2%) or 6 months (V: 64.2%/B: 67.2%). We realized the patients followed the recommended dose (V: 82.3%/B: 94.2%, p<0.001). Cessation rates are shown in figure 1.

Figure 1. Patients who fulfilled the dose recommended versus patients who didn’t: N.S.: not statistically significant.

P4046

Modifications in the smoking habits of 200 regular smokers experimenting the electronic-cigarette focusing on smoking reduction and smoking abstinence
Pasquale Caponnetto, Biomedicine Clinica e Molecolare, University of Catania, Italy

Background: Cigarette smoking is a tough addiction to break. Therefore, im-proved approaches to smoking cessation are necessary. The electronic-cigarette, a battery-powered electronic nicotine delivery device resembling a cigarette, may help smokers to remain abstinent during their quit attempt or to reduce cigarette consumption. (1)

Aim and objectives: We designed a prospective study to monitor possible mod-ifications in the smoking habits of 200 regular smokers, not intending to quit, experimenting the most popular marketed e-Cigarette in Italy (‘Cigaretta’) focus-ing on smoking reduction and smoking abstinence.

Methods: Study participants were invited to attend a total of six study visits: at baseline, week-4, week-8, week-12, week-24, and week-52. At each visit, number of cigarettes smoked, and exhaled carbon monoxide levels were measured at each visit. Smoking reduction and abstinence rates were calculated. Adverse events and product preferences were also reviewed.

Results: Sustained 50% reduction in the number of cig/day at week-52 was shown in 16% of participants. Sustained smoking abstinence at week-52 was observed in 9.75% of participants. Participants’ perception and acceptance of the product was good.

Conclusion: The use of e-Cigarette substantially decreased cigarette consumption without causing significant side effects in smokers not intending to quit.

p<0.0001 by x²

Conclusion: About a fourth of the quitters at 12 months restart smoking at 24 months. The level of education seems to be an important factor in late, but not early, relapse to smoking. Both subjective and environmental effects may play a role.
Regarding the duration of treatment: V: 6.6±1.6/B: 7.9±0.7, p<0.001. Cessation rates after 6 months: V: 96% vs 51.2%/B: 95.7% vs 6.8%; p<0.001. Causes of medication abandonment are shown in table 1.

p<0.134

Conclusions: Using 2 month treatments and half the recommended dose of B, cessation rates are good >64%. Below 5 week treatments are clearly insufficient with B as well as V. Causes of early abandonment of medication were mainly due to economic and psychological reasons.

P4049 Can we really relieve the withdrawal syndrome with pharmacotherapy in smoking cessation?

Zeynep Pınar Önen, Elif Sen, Banu Eris Gulpay, Pınar Akın Kahalak, Ozmut Akkoç Yıldız, Turan Acıcan, Sevgi Saryal, Gürbüzer Karabiyikolu.

Chest Disease, Ankara University School of Medicine, Ankara, Turkey

Primary goal of the smoking cessation treatment protocols are to relieve the withdrawal symptoms. However the exact effectiveness at the high tobacco dependence patients considering the smoking cessation treatment is still an unknown problem.

Aim: To evaluate the prevalence of withdrawal symptoms during smoking cessation treatment and compare the effectiveness between the different treatment modalities in high tobacco dependence patients.

Methods: From a total number of 435 active smokers (mean age of 44±11) with high tobacco dependence rates were prospectively evaluated between 2004 and 2010. Each patient answers the same questionnaire including smoking status and medical background. Nicotine dependence and CO levels were evaluated. Smoking cessation program was administered individually according to the guidelines and all of the patients were followed at least 1 year.

Results: The continuous abstinence following therapy at the end of first year was 50.5%. Withdrawal syndrome during smoking cessation treatment developed at 89% of behavioral treatment without pharmacotherapy, 80% of nicotine replacement 88% of bupropion and 94% of varenicline in all treatment protocols (more than 50% in each group) and somnolence is the distinctive symptom for the bupropion treatment (p<0.001). Hunger was not the predominant withdrawal symptom in the varenicline treatment.

Conclusion: According to our results, even one year smoking cessation success is high in our cohort the main goal of the smoking cessation protocols is not achieved. Pharmacotherapy is not superior to pure behavioral treatment to relieve the withdrawal syndromes.

410. Tobacco and shisha exposure in children and adolescents

P4050 Acute impact of a single e-cigarette smoking on symptoms, vital signs and airway inflammatory response

Sofia Viskidi1, Stamatis Tiskirka2, Sofia-Antiopi Gemmimata1.

George Kasalas1, Anaustasios Palaimidas1, Nikolaos Kouvalis1, Christina Gratziou1, 1 1Athens University Respiratory Medicine Clinic, Sotiria Chest Diseases Hospital, Athens, Greece; 2 3rd Respiratory Medicine Clinic, General Hospital Sismanoglion, Athens, Greece

E-cigarette is a battery powered electronic nicotine delivery device. Many smokers use it, because it is marketed as a safer alternative to smoking. The aim of our study was to evaluate the acute effect including smoking a single e-cigarette for 10 minutes on symptoms, vital signs, exhaled CO, exhaled NO and airways temperature in never smokers and in smokers with and without chronic airway obstruction.

We studied 37 consecutive subjects (17 male), aged:42±1.4year (mean±SD). Nine were never smokers, 15 were smokers with normal spirometry and 13 smokers with chronic airway obstruction (7 asthmatics, 6 with COPD). All subjects answered a questionnaire about symptoms (cough, sore throat, eye irritation, dizziness and feeling of satisfaction) immediately after smoking a single e-cigarette for 10 minutes. We also measured oxygen saturation (SpO2), heart rate (HR), exhaled CO, exhaled NO and airways temperature pre and post smoking.

After smoking a single e-cigarette for 10 minutes, our group reported cough (65%), sore throat (68%), irritation in eyes (24%), difference in taste (78%), dizziness (24%) and feeling of satisfaction (51%). In addition, there was a statistically significant: a) increase in HR (from 75±10 to 92±17, p<0.001), b) increase in eCO (from 15±12 to 15±9, p=0.03), and c) a decrease in SpO2 (from 97±6±1 to 96.76±1, p=0.012) after smoking.

We conclude that after smoking a single e-cigarette for 10 minutes there was a change in symptoms, vital signs and indices of airway inflammation in a statistically significant manner. Further studies are needed to establish the immediate and long-term effects of e-cigarette smoking.

P4051 Occurrence, health impact and motivation to quit smoking among young people and effectiveness of tobacco control programs

Natalia Astalavery, 1 O. Naumova, 2 D. Kobzev, 1 I. Gamova, 1 L. Perfilova, 1

E. Udovichenko. 2 Allergy and Immunology, Saratov State Medical University, Saratov; Russian Federation; 1 Business & Management, Leeds Trinity University College, Leeds, United Kingdom

Introduction: Global Adult Tobacco Survey identified high levels of smoking in Russia and was followed by the young people smoking study in Saratov region in 2011 to improve Tobacco Control effectiveness.

Aim: The assessment of smoking, its health impacts and motivation to quit was conducted among college (FE) and university (HE) students.

Methods: Anonymous standardized Respiratory Health Assessment and COPD Differential Diagnoses Questionnaires were used in 3 groups: FE: 15-18 years (126 respondents) and HE: 19-24 years, studying medicine (120) and management (168); 54%-male, 46%-female. CO testing of breath (1ppm resolution) was used (10% respondents did not reveal their smoking). Respiratory disease risk assessment was based on respiratory symptom scores, spirometry was performed in line with ERS/ATS standards.

Results: The prevalence of smoking among students: FE:31%, medics-5.1%, managers-35.2%. With the same starting age (12.6-male and 13.9-female) in all students the respiratory problems symptoms: cough, sputum, dyspnea, etc occurred in: FE-18%, medics-27%, managers-39%, and FEV1 decreased 10.2%, 26%, and 45% correspondingly. Unlike HE students, FE does not realise health risks and will not seek a support to quit. There was a difference in major motivations to quit: female-fertility impact, appearance; male-erectile & sperm impact, sport; medics-pulmonary health, impact on intellect; managers-cost of cigarettes and waste of working time.

Conclusion: Tobacco Control among young people can be more effectively promoted through personalized messages to a particular target group, g. e. addressing specific motivations via Social Media.

P4052 Knowledge about smoking and its harm among high school students

Mariana Martins Ambroz, Liana Sousa Coelho, Suzana Erica Tanni, Lívia F.S. Baldini, Laura M.O. Caram, André Luiz Bertani, Caroline Knaut, Iilda de Godoy, Irmã de Godoy. Disciplina de Pneumologia, Faculdade de Medicina de Botucatu, Universidade Estadual Paulista, UNESP, Botucatu, SP, Brazil

Introduction: Harmful effects of tobacco for human health are widely known, nevertheless, the prevalence of smoking is still increasing among adolescents.

Objectives: To evaluate the behavior as well as the knowledge of high school students in Botucatu, São Paulo, Brazil.

Methods: This work was developed with authorization of the Board of Education of the city Botucatu, in public secondary school. The students of the high school were invited to answer a questionnaire about smoking and its harms. Descriptive analysis of the data was done.

Results: We obtained 292 (41.7%) valid questionnaires (age: 15.9±1 years, 54.8% female). About smoking habits, 33.2% tried cigarettes at least once and 64.9% were female, 5% smoke more than 15 days/month, and 89.0% reported don’t smoke. Most students (68.5%) do not have parents or relatives who smoke indoor. 91.1% know that cigarettes cause health problems and 81.8% said that nicotine is the substance responsible for addiction. Besides of that, 62.7% are not sure about the amount of toxic substances present in the cigarette. About the use of nicotine in young people, 7.9% believe that it acts more lenient, while 19.5% believe that it acts in a powerful way, making the addiction more difficult to overcome, 24.3% say the nicotine activity is the same as in adults, and 43.2% are unsure (5.1% did not answer). About the possibility of smoking, 79.5% said that they will not smoke in the next five years and 73.3% would refuse a cigarette if their best friend offered one. 51% confirmed that they received information about the harm of smoking from teachers.

Conclusion: This study noticed that, despite of all media information, young people show little knowledge about smoking and its harms.
Dijana Mayer1, Ivana Pavic Simetin1, Divo Ljubicic1

Introduction: Important changes have occurred in the prevalence and patterns of cigarette smoking by young people. Given the known consequences of smoking for morbidity and mortality and the nature of smoking habits established during adolescence, changes in smoking behaviors carry extraordinary implications for the health of these youngsters throughout their lives.

Aims and objectives: To investigate the prevalence and pattern of cigarette smoking among Croatian pupils.

Methods: The Croatian GYTS (Global Youth Tobacco Survey) was a school-based survey of pupils in 7th and 8th grade primary, and 1st grade secondary school conducted in year 2011. A two-stage cluster sample design was used to produce representative data for all of Croatia. A total of 3,551 students aged 13-15 participated in study.

Results: The overall response rate was 90.1%. Any form of tobacco is currently used by 28.6% pupils (boys = 28.6%, girls = 27.9%); 66.5% of pupils had ever smoked cigarettes (boys = 66.6%, girls = 65.9%). More than one-quarter (27.2%) currently smoke cigarettes (boys = 26.7%, girls = 27.6%). 12.0% smoke daily manufactured cigarettes (boys = 12.1%, girls = 11.2%). 14.9% currently smoke cigarettes (boys = 15.2%, girls = 14.1%). Almost one quarter of ever smokers initiated smoking before age ten (boys = 30.4%, girls = 16.3%). Of never smokers, even 22.1% are likely to initiate smoking next year.

Conclusion: The results of Croatian GYTS 2011 indicate significant tobacco use and exposure to tobacco among pupils in Croatia. There is an urgent need to prevent tobacco smoking prevalence among these individuals and reduce morbidity and mortality throughout their lives.

P4054

Influence of family’s smoking on their children in high school
Hiroshi Okiyama, Yuaki Amimoto, Youko Murakami. Pediatrics, Fukuoka National Hospital, Fukuoka City, Japan

Background: Smoking is important as one of the aggravation factors of respiratory diseases, including bronchial asthma. The smoking rate in Japan is maintaining the still high value. Although it is presumed that the start of smoking is before 20 years old, the actual condition is not necessarily clear. To grasp the actual condition of smoking in high school students is important for this age is the points to be the time for remission or adult asthma.

Aim: The aim of this study is to clarify the reality of the smoking in high school students from the viewpoint of the influence of family smoking.

Subjects and methods: In 2009, four high schools in Japan were asked to complete a questionnaire to students. Questionnaire is anonymous and, as information about individuals, was asked to fill in only in the age and gender. 1815(827 male, 988 female) were obtained from a valid answerer.

Results: 1. Who currently has asthma symptoms, history of asthma was decreased in the order of the person who has smoking mother, father, others.

2. Children had a higher prevalence of smoking and from younger age when father and mother is smoker, especially father had been smoking.

3. Children of smoking parents are more likely to initiate smoking at a younger age than non-smoking parents.

Conclusion: Parental smoking is likely to influence adoption of smoking among young children. Preventing smoking habits and at least reducing smoking habits among children makes a protective factor against tobacco use in people.

P4056

Tobacco false attributions in smokers and not smokers teenagers
Khall Abu Shams1, Maria Hernandez1, Mercedes De Carlos1, Amaia Irure2, Susana Clemens2, Amaya Villanueva2. 1Pneumology, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain; 2Psichiatric, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain; 3Internal Medicine, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain

Introduction: The tobacco is now a widespread habit among the teenagers where they begin early to smoke. The false attribution have an important role to push the adolescents to take the decision to begin early to smoke i.e. to think that they are more attractive, modern, adult and more independent.

Methods: A representative sample of teenagers of our community offering a questionnaire. The results of Croatian attributions with two answers: true or not true. The sample was of 350 students, 180 girls and 170 boys between 12-18 years. The values of the correct answers is between 0 and 10 points analyzing the results with Kruskal Wallis test.

Results: 193 students (55.14%) smoke and 157 (44.86%) not smoke. We found significant differences of false attributions between smokers and not smokers. The smokers have most of false attributions about smoke habit having less scoring in the questionnaire (HI: 6.45, gl: 1, p: 0.011).

Table 1

Conclusions: The smoke teenagers have more false attributions than not smokers.

P4057

Does parental smoking influence the adoption of this habit among their children?
Maria Malik, Umar Misbah. Chest Medicine, Jinnah Post Graduate Medical Centre, Karachi. Pakistan Research Department, Institute of Business Administration, Karachi, Pakistan

Hypothesis/Background: Parental smoking is likely to influence adoption of the habit by their children. There is a positive correlation between parents smoking and their children developing this habit.

Objective: To find out if there is a correlation between parental smoking and their children adopting this habit.

Methods: Primary and secondary researches were undertaken. Primary research comprised of a questionnaire, filled by 256 participants aged between 16 to 25 years from different private schools and colleges all over Pakistan. Interviews of 30 people were also conducted for further collection of information as a part of secondary research.

Results: Literature review supported our hypothesis. Children were 5 percent less likely to smoke if parents did not smoke; children both whose parents smoked were 2.69 times more likely to smoke than 12thgrade compared to those whose parents did not smoke. Primary research showed that indigenous data also corresponds to the hypothesis. The chi-squared test of association, Χ2 = X2 (0.05, 1, 1), shows there is association between parental smoking and children smoking.

Conclusions: The effect of parental smoking cannot be ignored, however since smoking habit is caused by a variety of factors, only a correlation can be developed. Prevention from and negative attitudes of parents are the most effective way of preventing or at least reducing smoking habits among children.
P4058
Prospective inquiry studying of tobacco smoking among high-school students in Plovdiv, Bulgaria (2004-2010)
Fili Staneva1, Rosita Vakancheva1, Zlatka Ivanova2, Stanislav Kavet2, Georgi Belev1, Nonka Mateva1, Ivan Novakov1, 1Pulmonology, University Hospital "St. George", Plovdiv, Bulgaria; 2Haelt Management and General Medicine, Medical University, Plovdiv, Bulgaria; 3Thoracic Surgery, University Hospital “St. George”, Plovdiv, Bulgaria

Introduction: Tobacco smoking is world major cause for premature death and serious health problems. The efforts should be directed towards prevention of smoking, which most often is even in childhood.

Aims: To investigate in dynamics certain aspects of smoking among adolescents.

Methods: It was organized a study in sections method, using a direct anonymous interview in Plovdiv schools. There were interviewed 800 students in 2004 and 460 in 2010. The questionnaire is from translated and adapted version by GYTS, WHO’s program form. The statistical processing of data is completed by descriptive statistics and Student’s t-test. It was used the program pack SPSS v.18.0.

Results: For the six year period, we reported a statistically significant decrease in the number of students who have tried to smoke cigarettes and of those who smoke regularly. In 2004, 84.875% of the adolescents have tried a cigarette, as well as in 2010 72.39% (t=5.12; p<0.001). At the age of 14-15 those who have started to smoke were 28.375% in 2004 and 23.04% in 2010 (t=2.11; p<0.05). The percentage of the students who smoke every day reduces from 25.375% to 19.565% (t=2.42; p<0.05). There is a statistically significant increase in the percentage of students who disagree with the smoking in common places from 57.75% to 68.48% (t=3.86; p<0.001). The ability to easily buy cigarettes from young people remains alarming- 46.625% in 2004 and 68.48% in 2010 (t=6.79; p<0.001).

Conclusions: There is a significant decrease in the number of adolescents who smoke and in the same time there is more to be done in preventing tobacco smoking by children.

P4059
Estimation of prevalence and features of smoking status in young people
Natalia Mokina, Galina Sakharkova, Nikolay Antonov. occupational Diseases and Clinical Pharmacology, Samara State Medical University, Samara, Samara Region, Russian Federation

The purpose: To study the prevalence and features of tobacco smoking in young people (students of Samara region, for revealing the most informative, sensitive and effective question from the given category.

Methods: 158 young people aged of 17-27 years (20±21,1), 66 male and 82 female were surveyed by means of BMI, PEF, FEV1, FVC, FEV1/FVC, the experience and non-smoking, smoking index.

Results: 59% men were smokers and 41% non-smokers. 15% women were smokers and 85% non-smokers. The greatest number smoking was at the age of 22 years of both sexes.

The most informative parameters by standard canonical coefficient (SCC) were: PEF (SCC=4,7), the factor of smoking (SKK=1,4), the intensity of smoking (AUROC=0,7), the age (SCC=0,7). The ROC-analysis has shown the greatest sensitivity and specificity, at a confidence interval of 95%, for: PEF (AUROC=0,9), smoking index (AUROC=0,7), smoking duration (AUROC=0,7), smoking intensity (AUROC=0,7).

Conclusions: Thus, the group of high risk was young people aged 22 years of both sexes. The most informative, sensitive and specific tests at the given category of patients were PEF, [P]ICB, smoking index, duration and intensity.

P4060
The attitude of the teachers working in Manisa City Center toward the practice of the law on prevention of hazards of tobacco products numbered 5727 and the rate of smoking cessation among teachers
Tugba Goktalay1, Yavuz Havlucu1, Saliha Altiparmak2, Gul Gerceklioglu 3, Selhan Ozbey4, Pinar Guzel4, 1Department of Biostatistics, Ege University, Izmir, Turkey; 2School of Health Services, Celal Bayar University, Manisa, Turkey; 3Vocational School of Health Services, Celal Bayar University, Manisa, Turkey; 4School of Public Health, Dokuz Eylul University, Izmir, Turkey; 5Department of Biostatistics and Medical Informatics, Celal Bayar University, Manisa, Turkey

This study is aimed to investigate the attitude of the teachers in Manisa toward the law numbered 5727 came into force on 19 July 2009 and the smoking cessation rate before and after of application of this law.

The study was conducted in 727 teachers working in primary and secondary schools in Manisa between May2011 and June2011.588 teachers(80,8%)participated to the study filled out the questionnaire.

47.8% of them had positive rate of ex-smokers and current smokers were 30% and 36.1% in male and 16.7%and 26.4% in female respectively.97.3% of nonsmokers, 94.5% of ex-smokers,100% of occasionally smokers,and 75.5%of current smokers supported the law(p<0.001). In current smokers,annual smoking cessation rates between 2001-2002,2006-2007 were between 1.1% and 3.4%.

Smoking cessation rates in 2007-2008,2008-2009, and 2009-2010 were 3.61%,6.16%, and 6.50%respectively. Between August2010 when the law came into force and June2011, It was 10,69%. With joinpoint trend analysis, there was no statistically significant change in annual smoking cessation rate between 2001-2001 and 2006-2007 years(p=0,5); but it was found statistically significant between 2007-2008 and 2010-2011 years(p=0,02).

Teachers have a positive attitude about the law. Smoking cessation rate in current smoker teachers was significantly increased after July 2007.

P4061
What do the adolescents think about smoking and ban strategies in Turkey? Bakir Umut Tugay1, Burcu Ihan1, Tubat Cakat1, Tugba Kabakci2, Hatice Koç2, Nazan Tugay3, 1Physiotherapy and Rehabilitation, Mugla University, Mugla, Turkey

Preventing youth from initiating tobacco use is a key aspect of all tobacco prevention efforts. Most smokers become tobacco dependent before age 18 years. The purpose of the present study was to investigate thoughts of high school children about smoking behaviours and antismoking policies in Turkey. 731 students volunteered (336 male, 395 female, mean age 16.20±1.15) to participate in the study from 7 different high schools. After taking written consent from their parents all the students filled the 16 item questionnaire developed by the researchers. 72.7% of the students thought that their teachers were not good models for not smoking. 10.9% believed that smoking is a sign of growing up and 45.7% the students believed that they can quit whenever they wanted if smoked. 85% of the students totally or partially agreed with the prohibition of cigarette advertising and 95.4% of the students agreed with the prohibition of smoking in public places but 42.8% of the students believed that smoking on the streets is not a stimulating behavior. 30.6% did not think that increasing the cigarette prices would not have positive effect on decreasing smoking rates. 10% and 12% of the students thought that water pipe and light cigarettes are less harmful than the normal cigarettes respectively. A clear opportunity for intervening with youth lies in the school setting, so besides the ban policies, comprehensive tobacco control and education programs including the parents should be initiated.

P4062
Prospective analysis among medical school of University of Sao Paulo: GHPPS (2008/2011)
Renato Pascoli, Stella Martins, Gustavo Prado, Ana Mortas, Elisa Lombardi, Frederico Fernandez, Mario Terra-Filho, Ubiratan Santos. Division of Pneumology, Heart Institute (InCor) School of Medicine, University of Sao Paulo, SP, Brazil

Introduction: Knowledge acquired in tobacco-related diseases and treatment are fundamental for futures physicians who will have to manage with this pandemic disease.

Objectives: To determine the prevalence of smokers, Shisha use, passive smoking; knowledge about tobacco-related diseases, smoking cessation techniques and treatment on medical students.

Methods: Cross-sectional survey randomly sample of 211 medical students from 3rd year of 2008 and 6th year of 2011. The questionnaire used was the self-administered Global Health Professional Students Survey (GHPPS) after translation and validation to Portuguese. The GHPPS was supplemented with questions about knowledge acquired.

Results: Responded 101 x 110 students 3rd/6th. Low prevalence of smokers among the male population with a fall in the 6th year (7.9 x 4.6%, p<0.001), female smoker. Current/past use of Shisha were higher in 3rd/6th (47.5% x 46.4%, p=0.522). The students have a Knowledge of Smoke Free Places in college, buildings and clinics, (45.4% x 91.8%, p<0.001). Curriculum and Training analyses about smoking showed a significant gain of knowledge on smoking cessation (9.9% x 98.1%, p<0.001); importance of educational materials to cessation (29% x 72.7%, p<0.001) and Non-nicotine treatment (46.5% x 99.1%, p<0.001). Diseases associated to smoking are well known, except tuberculosis (42.6% x 38.3%, p=0.523).

750s
Conclusions: Both non-smokers and smokers had normal lung function indices. Induced sputum increased knowledge about the curriculum, training, and smoking-related diseases.

2University of Latvia, EKMI, Riga, Latvia; 3P. Stradiņa, KUS, Riga, Latvia

Tobacco smoking: Still an important lifestyle component for adolescents and these future physicians have tools to act in the smoking pandemic.

Results: Lung function measurements, sputum induction (IS) and sputum cell anonymous questionnaires about tobacco use. The prevalence of smoking was relatively high in all age groups (21.8% for group A, 35.6% for group B). The prevalence of smoking was significantly lower in females compared to males (p = 0.05). Regression analysis showed significant dependency of FOXP3-positive T-regulatory cells from the number of macrophages of induced sputum (r² = 0.118; p = 0.030) from the number of neutrophils.

It is of great importance to be able to diagnose early inflammatory changes that can lead to COPD in airways of young cigarette smokers.

Agnese Kislina

The aim of this study was to analyze the cell spectrum of induced sputum from young cigarette smokers, with emphasis on T-regulatory cells. Methods: A self-administered questionnaire was distributed to house physicians, but also involve specific immune mechanisms with recruitment of T-reg lymphocytes. The lymphocyte response is probably adaptive.

P4064

Evaluation of cell spectrum in induced sputum of young cigarette smokers

Agnese Kislina1, Gunta Strazda2, Liga Balode3, Zane Sinikevica3, Darja Isajeva1, Sergejs Isajeva2, Normunds Jurka1, Immanuels Taivans3, Valentina Gordjusina4, Viesturs Silins3,4 University of Latvia, Latvia; Faculty of Medicine, Riga, Latvia; University of Latvia, EKMI, Riga, Latvia; P. Stradiņa, KUS, Riga, Latvia

Conclusions: Total ban doesn’t decrease initiation of tobacco use with shisha in Pakistani teenagers. Preventive campaigns are needed to inform adolescents that shisha is harmful and may be a gate for initiation of tobacco use, but, unfortunately, all budgets for this prevention has been cut down for 5 years in France.

P4067

Knowledge attitude and practice of shisha (water pipe) use in doctors

Ashok Kumar, Shaista Ghazal, Shaista Gharazi, Shamshuddin, Nusrat Idrees, Nadeem Rizvi, Chest Medicine, Jinah Postgraduate Medical Centre, Karachi, Sindh, Pakistan

Background: Tobacco use in the form of shisha has adverse effects similar to cigarette smoking.

Objectives: To assess the knowledge, attitude and practice of doctors about shisha(water pipe) use and its hazards as doctors serve as role model of society and can play a very important role in educating public.

Methodology: A self administered questionnaire was distributed to house physicians, postgraduate, medical officers and consultants in different teaching hospitals of Karachi.

Results: 343 doctors from different teaching hospitals of Karachi filled the questionnaire of which 170 were females. Approximately 29.5% doctors have used shisha some time in their life. Of total survey population 56.5% house officer, 73.9% postgraduates, 65.9% medical officers and 91.3% of consultants agreed that shisha contains tobacco (p value 0.001) and 58% house officers, 77% postgraduates 68.3% medical officers and 91.4% of consultants believed that it is harmful to health (p value < 0.001). Knowledge about hazards of passive shisha use was found to be very poor. Only 25.2% house officers, 40.5% postgraduates, 34.1% medical officers and 69.6% of consultants were confident that neonatal deaths are associated with passive shisha exposure (p value <0.001) while 51.9% house officers, 64.2% postgraduates, 53.7% medical officers and 87% of consultants believed that shisha exposure during pregnancy can lead to Sudden Infant Death Syndrome (p value 0.001). Conclusions: Our study indicates that there is lack of knowledge among doctors specially house officers regarding contents used in shisha and its hazardous effects on health. Steps should be taken for educating doctors especially juniors about different methods of tobacco use and its hazards.

Prevalence of hookah consumption in Tehran

Makan Sadegh1, Ali Abdolahim2, Mohammadreza Masjedi1,2 Tracheal Diseases Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 3 Research Unit, Iranian Anti Tobacco Association, Tehran, Islamic Republic of Iran; Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran

Background and objective: Not much information is available in the literature.
411. Tobacco comorbidity

P4070 To assess the effect of smoking on cardiovascular system

Amrapala Gupta 1, Sushila Seel 1, Rajesh Gupta 2, Jyothi Behara 1, 2. 1Physiology, Pr BD Sharma PGIMS, Rohtak, Haryana, India; 2TB & Respiratory Medicine, Pr BD Sharma PGIMS, Rohtak, Haryana, India

Background: Smoking alters autonomic functions and increases adrenergic activity that predisposes to cardiovascular morbidity and mortality. Heart rate Variability (HRV) is a measurement of autonomic activity.

Methods: Study included 60 subjects in total, of which 30 (Test group-A) were chronic smokers with history of at least 10 pack years and 30 (Group-B) non-smoker controls. The HRV was recorded in the supine posture in relaxed state. We recorded the frequency domain analysis [low frequency domain (LF), high frequency domain (HF) and LF/HF ratio] for which five minute recordings were taken and data was generated using the Polyrite D system.

Results: There was a significant (P<0.001) decrease in heart rate with decreased RR interval was recorded as compared to control group-B. Along with, there was a decline in LF and HF domains. Difference was calculated between test group and control group.

Conclusion: This result indicates that smoking results in negative cardiac autonomic modulation and smoking cessation is recommended to prevent cardiac morbidity and mortality.

P4072 Spiroergometry among smoking and non-smoking patients

Tatiana Lefeva 1, Julia Krasnova2. 1Therapy, Academy of Advanced Medical Education, Pr. Park, Russian Federation; 2Gerontology, Academy of Advanced Medical Studies, Irkutsk, Russian Federation

Aim: To evaluate parameters of spirometry at smoking and non-smoking patients.

Materials and methods: 47 patients were examined (20-were smoking (an index of smoking 15 packs/year), 27-non-smokers). The mean age of the first group dominated by men (52.6 ± 7.4 years and second, 40.0 ± 9.5) years, (P<0.05). The next parameters of a spirometry were studied. Heart rates (HR), Sistolic blood pressure, Diastolic blood pressure, VO2peak, VCO2peak, VIEpeak, O2-puls, EQCO2, PET CO2rest.

Results: Characteristics of parameters of spirometry at smoking and non-smoking patients.

Conclusion: Smoking patients had higher indicators of HR on 5 minute of rest, sistolic blood pressure of rest diastolic blood pressure upon the maximum loading and on 5 min of rest than non-smokers.
P4073 The influence of active and former smoking on the amount and quality of sleep in an obstructive sleep apnea (OSA) population versus habitual snorers Oana-Claudia Deleanu1, Diana Pocora2, Ruxandra Ulmeeana1, Stefan Mihaucuet1a, Florin-Dumitru Mihaliant1. 1Institute of Pneumology “Marius Nasta”, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2Institute of Pneumology “Marius Nasta”, Bucharest, Romania; 3Institute of Pneumology “Marius Nasta”, Faculty of Medicine and Pharmacy, Oradea University, Bucharest, Romania; 4Clinical Hospital of Infectious Diseases and Pneumology “Victor Babes”, Timisoara, Romania

**Objective:** We analyzed effects of smoking and smoking status on sleep in 2 groups (OSA and habitual snorers) comparable regarding comorbidities and dependencies.

**Results:** We analyzed 71 OSA patients (18% women, 82% men) successfully CPAP treated (other pathologies excluded: 25/35% nonsmokers, 19/27% active smokers (YP=21±5.2;7,Fagerstrom=3.5±2.1), 27(38%) exsmokers (YP=25±9.1±18.8); mean values: age=54.3±13 years, Epworth=8±2.6±5.4 total sleep time=5.6±2h, arousal index=29±2.3±7h, AHI=38±1.5±36.6h. We compared OSA active smokers with control group of 11 active smokers snorers (2 women, 9 men, age=41.1±13.7 years, Epworth=4.09±3.6), YP=23±2.2±25.4, Fagerstrom =4.6±2.3±2, total sleep time=4±7±2.8h, arousal index=15.8±11.6h). OSA smokers sleep quality is affected vs. non-smokers (more arousals, p=0.02). There was no difference in total sleep time, efficiency, sleep latency, sleep stages or OSA severity (except worse nocturnal hypoapnea in active smokers: r=-0.49,p=0.03); no differences between active smoking vs. male sex, or between OSA and nonsmokers. YP index correlates with arousal index, but doesn’t correlate with nicotine dependence.

**Conclusion:** Smoking intensity and sleep quality (arousal index/correlated, unrelated to nicotine dependence. Studies are needed to prospectively assess effects of smoking on sleep and OSA using a non-smoking control group.

P4074 Effects of smoking and smoking cessation on decline in pulmonary function Shinobu Otsuna, Mie Aoki, Toshiyuki Ogasa. First Department of Medicine, Asahikawa Medical University, Asahikawa, Hokkaido, Japan

(Background) Natural course of pulmonary function after smoking cessation is still unclear. We sought to assess influences of smoking habits to lung function in subjects with various smoking habits.

**Subjects and Methods** Total of 860 subjects were recruited from patients who attended to rural primary care clinics except for respiratory disorders. Each participant was asked to answer the following questions: age, smoking habits, medical history, and forced vital capacity (FVC) and forced expiratory volume in second (FEV1).

**Results** Both %FEVI (measured FEVI/predicted FEVI X 100) in current smokers (CS) and %FEVI in ex-smokers (ES) were lower than %FEVI in non-smokers (NS). There was no difference in %FEVI among the subgroups divided by age both in current smokers and ex-smokers. Also, there was no difference in %FEVI among the subgroups divided by duration of smoking cessation in ex-smokers. Moreover, it was confirmed that age, highest amount of cigarette smoking were significantly related to FEVI both in male CS and male ES. In male CS, the estimated decline of FEVI per age was 2.6 mL. In male ES, the estimated decline of FEVI per age was 2.5 mL, and excess of decline pack-year of smoking was 1.5 mL. In female CS, the estimated decline of FEVI per age was 1.6 mL, and excess of decline pack-year of smoking was 1.3 mL.

**Conclusion** Our data suggested that influences of smoking on FEVI were observed even in healthy ex-smokers.

P4075 Prenosological diagnosis of respiratory function abnormalities in smokers Marina Seerzbaeva, Mikhail Pogodin, Nina Aleksandrova. Laboratory of Respiratory Physiology, Pavlov Institute of Physiology, St. Petersburg, Russian Federation

Chronic tobacco poisoning leads to the gradual development of various patholog-ical processes at the cellular, tissue, organ and system levels, but their clinical manifestations may have delayed effect. Prenosological diagnosis of respiratory function disorders in smokers is very important in order to promote an effective behavioral intervention for smoking cessation. The study was performed for evaluation of simple and noninvasive diagnostic methods of respiratory disorders in smokers. Maximal inspiratory pressure (MIP), peak inspiratory flow (PIF) and dSO2 may be adequate diagnostic methods for early detection of respiratory pathology in smokers. These methods can be used in routine clinical practice.

P4076 Comorbidity in smokers – A cumulative effect of exogenous and endogenic factors? Elvira Ivancheva1, Rosita Iavicnova2, Filip Stoy1, Vanya Youzorouka2, 1Pulmonology, Medical University, Plovdiv, Bulgaria; 2Pulmonology, Medical University, Sofia, Bulgaria

This work is an analysis of our studies and literary data about a cumulative effect of tobacco smoke and another risk factors and comorbidities. There is investigated the connection between COPD and COPD and lung cancer (COPD + Ca) (NS). There was no difference in %FEV1 among the subgroups divided by age both in current smokers and former smokers and %FEV1 in ex-smokers (ES) were lower than %FEV1 in non-smokers (NS). There was no difference in %FEV1 among the subgroups divided by age both in current smokers and male sex, or between OSA and nonsmokers. YP index correlates with arousal index, but doesn’t correlate with nicotine dependence.

**Conclusion:** Smoking intensity and sleep quality (arousal index/correlated, unrelated to nicotine dependence. Studies are needed to prospectively assess effects of smoking on sleep and OSA using a non-smoking control group.

P4077 High environmental tobacco smoke and other air pollutants exposure in patients with allergic rhinitis non smokers Dragica Peselj1, Ljudmila Nagorni-Obradovic1,2, Biljana Savic1. 1Institute of Pneumology “Marius Nasta”, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania; 2Teaching Hospital of Allergology and Immunology, Clinical Centre of Serbia, Belgrade, Serbia

**Background:** Chronic exposure to cigarette smoke inhibits surface immunoglobulin-mediated responses in B cells. Immunomodulatory effects of cigarette smoke are evidence based and the effects of environmental tobacco smoke (ETS) on immune system are in focus of current research.

**Aim:** Aim of the study is to analyse tobacco smoking status in patients (Ps) with allergic rhinitis (AR) with special regard to ETS. **Methods:** In this observational questionnaire based study successive series of Ps treated for AR at two tertiary level health care facilities in Belgrade, Serbia, was enrolled from January 2010 to December 2011, and valid questionnaires were analyzed for Ps demographic and social data, and tobacco smoking status.

**Results:** Study group consisted of 182 Ps; average age: 36.2±12.50; male/female ratio: 0.75. Tobacco smoking status analysis showed: 12.6% current smokers, 15.4% former smokers, and 136/184 (72%) Ps non smokers. About two thirds of the ‘non smokers’ have been exposed to ETS while 166/182 (91.2%) Ps have been exposed to both tobacco smoke ingredients (at home and/or at working place), and to the other air pollution.

**Conclusion:** High proportion of AR Ps is exposed to tobacco smoke and/or the other environmental pollution, which might present a serious problem and challenge for further research in the field of immunomodulation.

P4078 Effectiveness of smoking cessation in patients with psychiatric disease Zeynep Pinar Östen, Elfet Sen, Bamu Eras Güllübay, Faten Alin Kabadab. 1Dipartimenti dell’Apparato Respiratorio, Chest Disease, Ankara University School of Medicine, Ankara, Turkey

**Background:** Smoking cessation treatment is considered to be less effective in patients with psychiatric diseases.

**Aim:** To evaluate the smoking cessation rate in patients with psychiatric dis-orders, compare the effectiveness between the different treatment modalities and demonstrate the discrepancies from other patients. **Methods:** From a total number of 609 active smokers; 52 with psychiatric diseas-es (most discriminant concomitant condition was depression) were prospectively evaluated between 2004 and 2010. Each patient answers the same questionnaire including smoking status and medical background. Nicotine dependence and CO of hypoxemia during any apnea than nonsmokers. Our results showed that the measurement of PIF, PEF, MIP and dSO2 may be adequate diagnostic methods for early detection of respiratory pathology in smokers. These methods can be used in routine clinical practice.
levels were evaluated. Smoking cessation program was administered individually according to the guidelines and all of the patients were followed at least 1 year.

**Results:** There was no difference between the groups in age, baseline Fagerstrom nicotine addiction score, exhaled carbon monoxide level and treatment protocols. However, total amount of smoked tobacco (27.8±12.1 pack-year) and cigarette consumption per day (21.1±10) was higher in patients with psychiatric diseases (p<0.01 for all). The cessation rates with or without psychiatric diseases were respectively 44.2% and 55.6%. Effectiveness of treatment modalities are 44.4% for nicotine replacement treatment (a total amount of 5.7% for the group without psychiatric diseases). The survey was conducted in closed, ethnically homogenic population of Kashubians.

**Conclusion:** Searching for CHRNA3, CHRNA4, CHRNA5, and CHRNB4 genes polymorphisms influencing nicotine dependence in the ethnic population of Kashubians, North Poland

Alicja Sieminska, Karolina Kita, Beata Wajda, Lucyna Gorska, Ewa Jassem.

**Depart of Allergology and Pneumonology, Medical University of Gdańsk, Poland**

Genome wide association studies showed that genes encoding nicotinic receptor CHRN subunits might be potentially involved in the pathogenesis of nicotine dependence. We aimed to investigate whether polymorphisms in the sites rs12914008, rs16969968, rs2226196, rs578776, rs7148770 of CHRN, CHRNA3, CHRNA4 and CHRNA5 subunits influence nicotine dependence. The survey was conducted in closed, ethnically homogenic population of Kashubians. The study sample consisted of 45 unrelated subjects, daily or occasional smokers. Several variables of smoking habit were recorded, and the nicotine dependence was scored with the use The Fagerstrom Test for Nicotine Dependence (FTND). Genotyping was performed in blood samples, and genotypes were correlated with the severity of nicotine dependence with the use of multivariate logistic regression analysis.

**Results:** Distribution of genotypes for all polymorphisms did not deviate from expectations predicted by the Hardy-Weinberg equilibrium. We found that A allele carriers of rs16969968 polymorphism had higher risk of heavier smoking, i.e. 10 or more cigarettes per day, than G allele carriers (OR = 1.54; 95% CI: 1.00-2.35).

In the separate analysis, performed in the group of subjects with the history of smoking shorter than 5 years, higher risk of a stronger nicotine dependence (i.e. FTND score 4 or more) in A allele carriers of rs12914008 polymorphism than in G allele carriers was found (OR = 14.96; 95% CI: 1.42-158.0).

**Conclusion:** Polymorphisms in the sites rs16969968 and rs578776 of CHRN and CHRNA3 subunits genes may influence the severity of nicotine dependence.

Akinori Ebihara, 1 Akihumi Watanabe1, Asuka Nagai2, Takayuki Nakanoto2, Tokauzawa Iwao3, Ichiro Kawaibara3. 1Pulmonary Medicine, Tokai University Hospital, Tokyo, Japan; 2General Thoracic Surgery, Tokai University Hospital Tokyo, Tokyo, Japan; 3Medicine, Erino Town Clinic, Hokkaido, Japan

**Background:** We have previously reported at the 2011 ERS Annual Congress that early exposure to tobacco smoke significantly increased the prevalence of COPD. As a follow up, we hypothesized that COPD from early exposure to smoke may cause an increase of IMT that correlates with the increase in the prevalence of smoking-related vascular comorbidities. (Methods) We identified potential subjects into three groups: G1) history of COPD and early exposure; G2) history of COPD and non-early exposure; G3) subjects without COPD and analyzed the measurements IMT. IMT were measured using the longitudinal axis of the common carotid arteries from ultrasound. We defined early exposure as when habitual smoking started before age of 20. (Results) A total of 152 subjects (72±10 years old; SD) were enrolled into the study after informed consents were obtained. G1, 2, and 3 consisted of 41 subjects (age 68.4±9 yrs), 80 subjects (71.1±11), and 31 subjects (69±10) respectively. Maximum value of IMT in G1 was 1.34±0.12mm, G2 was 1.23±0.13, and G3 was 1.12±0.16. Groups with history of COPD had higher maximum value of IMT when compared with group without COPD. Furthermore, G1 demonstrated higher value when compared with G2, suggesting early exposure to smoke as possible etiology within subjects with COPD. (Conclusion) In subjects with COPD, early exposure promoted atherosclerotic changes, which may increase the likelihood of smoking-related vascular comorbidities such as cardiovascular and cerebrovascular diseases. Further studies are needed to elucidate the precise magnitude of the increase in risk of these comorbidities associated with COPD and early exposure.

**Conclusion:** This study aimed at evaluating the correlation between not smoking at home and intention to quit.

**Methods:** This descriptive cross-sectional study was carried out in Tehran in 2011, on 2,020 smokers. Information were collected by interviewers through a standardised questionnaire such as age of smoking onset, daily rate of smoking, price of cigarettes, using labeled or non-labeled tobacco products, history of quit attempts, cessation intention, water-pipe consumption, and knowledge about anti-tobacco laws.

**Objective:** This study aimed at evaluating the correlation between not smoking at home and intention to quit.

**Methods:** This descriptive cross-sectional study was carried out in Tehran in 2011, on 2,020 smokers. Information were collected by interviewers through a standardized questionnaire such as age of smoking onset, daily rate of smoking, price of cigarettes, using labeled or non-labeled tobacco products, history of quit attempts, cessation intention, water-pipe consumption, and knowledge about anti-tobacco laws.
and not smoking at home. Family members can have a positive role in encouraging considerable role in increasing the intention of its members for smoking cessation. Tobacco smoking at home can motivate smokers to quit smoking. Family has a significant association between tobacco smoking at home and intention to quit. Chi-Square test revealed a significant association between tobacco smoking at home and intention to quit.

Discussion: As this study and some other studies have shown, restrictions on tobacco smoking at home can motivate smokers to quit smoking. Family has a considerable role in increasing the intention of its members for smoking cessation and not smoking at home. Family members can have a positive role in encouraging other members to quit smoking or sustain their abstinence.

P4084 Mapping the tobacco retailers in Edirne, Turkey
Cetin Karlikaya1, Huseyin Ince1, Nurcan Ozkan1, 2
Faculty of Medicine, Edirne, Turkey; 2Architecture and City Planning, University Edirne Technical Sciences Vocational School, Edirne, Turkey; 1Primary Health Care Training Program, University of Health Sciences, Istanbul, Turkey

Objective: Smoking rate is on the rise in Turkey. Although many marketing bans have been effectively implemented, regulations related to retail tobacco outlets have gone unnoticed and have not been effectively supervised. In this study, we aim to manifest that a lack of legal regulation related to the high retail tobacco outlet density with displays.

Methods: In the center of Edirne, marketing environment, numbers and geographical distribution of retail tobacco outlets are documented and mapped with geographical information systems.

Results: There were 569 retail tobacco points of sale in 520 stores. We calculated one tobacco retail outlet per 270 people. This retail outlet density rate is above the country average and about four times higher than in Istanbul. Products especially attracting children, such as chocolates, sweet candies and chewing gums were set up near the tobacco stands and were easy for children to see and reach. It is seen on the city map that 47% of retail tobacco outlets are within 100 m to education, health, and sport facilities.

Conclusions: We concluded that one of the reasons of the increasing prevalence of cigarette use especially among adolescents in Turkey is deregulation of the retail tobacco marketing environment during privatization process of national tobacco monopoly. Using the mapping techniques can help to control retail marketing environment.

P4085 Smoking prevalence and practice in special categories: Taxi drivers
Isaana Munteanu1, Florin Mihalain2, Daniela Ivascu2, 1Pneumology, 2Pomology, 1, Marain Natsu Clinic, Bucharest, Romania

The goal of the survey was to estimate the prevalence of tobacco consumption on taxi drivers and secondhand smoke (SHS) exposure in cars. The study is important because it is the first one made in Romania on this topic and there are a few of them reported in medical publication. There are decisions of local council on banning smoking in taxis for both driver and customer. The data were collected from a 5-10 min questionnnaire which contain demographic data, Fagerstrom Nicotine Dependence Scale and questions regarding smoking practice in the car. The questioners were directly distribute to taxi drivers from three large taxi companies from Bucharest.

Results: 100 questioners were collect for statistical analysis from 400 taxi drivers. The lot was made by 94/6men and 6/4women; average age 37.7±9.5±8.9years; driving experience averaged 6.7±4.4±5.5years; hey work in shifts: 7/1% only in day, 63/6% in night and 29/3% in alternative. The work years on night shift aver- age were 3.9±4.36. Smokers 70.7%, (average age 38.04±9.78) years Exsmokers 10.1%, Nonsmokers 19.2%. Number of cigarettes/day (0-5) 15.7%, 10/20 66.6% and > 20/515.7%. Nicotine dependence was high, 70% of smoker light their cigarette in the first 5 minutes of waking. 35% of smoke in the taxi, if the customer doesn’t express his opinion regarding smoking.

Conclusions: The prevalence of smoking is higher than the national average (30%). The study group consists of young people who work at night and have a high dependence on nicotine. There is company internal rules that bans smoking, so many taxi drivers refrain from smoking in taxis, but not when they don’t have client. Smoke free policy can support a smoking cessation program among them.

P4086 A survey to assess smoking awareness and attitudes of staff at a local hospital
Jodie Azragnadi1, Sarah Degiovanni2, Luisa Farrugia3, Neville Calleja3, 1Physiotherapy, 2Social Services, 3Pharmacy, Mater Dei Hospital, Malta; 2Department of Oncology, Sir Paul Boffa Hospital, Floriana, Malta; 3Department of Health Information and Research, Ministry of Health, the Elderly and Community Care, Gwardamanija, Malta; 1Department of Health Promotion and Disease Prevention, Ministry of Health, the Elderly and Community Care, Msida, Malta

Objectives: To determine the smoking awareness levels in hospital staff. To assess the impact of smoking cessation programme (SCP) and other smoking cessation methods on smoking habits and attitudes of hospital staff.

Methods: A cross-sectional, descriptive, quantitative study was carried out. Data were collected using a semi-structured questionnaire. Staff were recruited from all hospital departments. A total of 462 person (95.95%) mentioned a history of smoking. There were 435 (92.4%) smokers who 261 (57.7%) had moderate or high nicotine dependence. A significant correlation was detected between first substance abuse experience or daily substance abuse during the first 2 years following smoking onset (P<0.001). Those who started smoking at a younger age in our study started substance abuse significantly sooner than others or developed a daily addiction to it. Using below formula, we can anticipate how long after smoking experience one would probably experience their first substance abuse (P<0.001).

First substance abuse experience age=7.7±2.78 (first smoking experience age)

Conclusions: A significant correlation exists between smoking and future substance use. Therefore, efforts must be made to prevent tobacco consumption in the first place. For those who are already smokers, preventive and supportive measures must be undertaken to prevent substance abuse especially in the first two years following smoking initiation.

P4087 Evaluation of smoking pattern and its correlation with addiction among substance abusers
Mahbild Arayeg1, Zahrab Hessami2, Gholamreza Heydari2, 1, Mohammadreza Arayeg1, MohammadReza Masjedi2, 1Tobacco Prevention and Control Research Center (TPCRC), National Research Institute of Tuberculosis and Lung Diseases, Tehran, Iran; 2National Research Institute of Tuberculosis and Lung Diseases, National Research Institute of Tuberculosis, Tehran, Islamic Republic of Iran

Introduction: Since tobacco consumption is not illegal, people are often not considering it as an addictive substance. It has been revealed that young smokers have a stronger desire and tendency to experience high risk behaviors and have a greater risk of substance abuse.

Objective: This study aimed at evaluating the pattern of smoking and its effect on initiation of substance abuse in those presenting to the rehabilitation centers and substance abuse clinics.

Materials and methods: In this descriptive cross sectional study, 487 cases referred to the rehabilitation centers and substance abuse clinics in Tehran were evaluated with a standard questionnaire.

Results: A total of 462 person (95.95%) mentioned a history of smoking. There were 435 (92.4%) smokers who 261 (57.7%) had moderate or high nicotine dependence. A significant correlation was detected between first substance abuse experience or daily substance abuse during the first 2 years following smoking onset (P<0.001).

Conclusions: A significant correlation exists between smoking and future substance use. Therefore, efforts must be made to prevent tobacco consumption in the first place. For those who are already smokers, preventive and supportive measures must be undertaken to prevent substance abuse especially in the first two years following smoking initiation.

P4088 Short-term effects of quitting smoking in TNF-α and interleukin-10 serum and nasal lavage levels
Marceli Rocha Lopes, Dionei Ramos, Rafaela Fagundes Xavier, Juliana Tyaki Ito, Fernanda Maria Machado Rodrigues, Juliana Nicolin, Alessandra Choqueita de Toledo, Ercy Mara Cipulo Ramos. Phisiotherapy, UNESP - São Paulo State University, Presidente Prudente, SP, Brazil

Some systemic benefits of quitting smoking are known, however, the immediate effects on inflammatory biomarkers have not been well described. The purpose of this study was to evaluate inflammatory biomarkers during a smoking cessation program (SCP). Twenty two abstinent smokers (age 50-55 years; 13-36 pack/year index; FEV1% 96±82 (104-80%) were included in this study. They were recruited from hospital staff. The measurements of TNFα and interleukin-10 (IL-10) serum and nasal lavage samples were evaluated at baseline and after 7, 15, 30 and 60 days of abstinence. The measurements of TNFα and interleukin-10 (IL-10) serum and nasal lavage samples were evaluated at baseline and after 7, 15, 30 and 60 days of abstinence.

Background: Rising smoking-related morbidity and mortality would be expected to lead to increased awareness among hospital staff regarding the harmful effects of cigarettes.

Climate and objectives: The aim is to assess the smoking habits of individuals working within a hospital setting who are directly or indirectly exposed to patients with smoking-related illnesses. The survey addresses health issues and attitudes towards smoking. The timing is opportune in that Mater Dei Hospital Malta is to be declared a totally smoke-free hospital.

Methods: A questionnaire was compiled, based on various tools validated in the literature. These were distributed to all members of staff at our General Hospital, targeting more than 3600 individuals.

Results: 27.1% of male and 24.8% of female staff are active smokers. Males were significantly (p=0.001) more likely to have started smoking at a younger age than females. Almost half find difficulty in refraining from smoking in forbidden areas. Only 22.2% of smokers refrain from smoking in hospital. The highest percentage of smokers are in the youngest age group (18-25 years). 10.4% of doctors and 23.6% of nurses are active smokers. 25.7% of non-smokers had previously smoked, the greatest incentive for quitting being for health reasons. Most members of staff are aware of the adverse effects of smoking and a number have symptoms suggestive of smoking-related pathology.

Conclusions: Hospital staff mirror the general population with respect to smoking habits and comorbidities. This is unacceptable and emphasizes the need to implement harsher measures whilst educating our hospital staff so that these in turn may serve as educators to patients and hospital visitors.
abstinence (p<0.0001). There was a significant decrease in TNF-α levels on nasal lavage in abstinent smokers after 60 days of abstinence (p=0.0186). For TNF-α levels on blond plasma and IL-10 on blond plasma and nasal lavage there was no observed significant difference. The abstinence promoted decreased exC0 and COHb levels after 7 days, decreased in TNF-α levels on nasal lavage in 60 days and of abstinence.

P4089
Is motivational Q-mat test useful to predict smoking cessation?
Zohra Hessami, Hoosian Sharifi, Gholamreza Heydari, Mohammaddreza Masjedi.
Tobacco Prevention and Control Research Center, National Research Institute of Tuberculosis and Lung Diseases, Tehran, Islamic Republic of Iran

Background: Smoking is one of the major causes of cancer, heart and pulmonary diseases, one of essential steps in tobacco control is persuading the smokers to quit smoking. Encouraging smokers to the quit can be possible if the smoker has enough motivation for quit. In this study we investigated abstinence rate after 6 months according to level of motivation to quit (Q-mat score) and level of nicotine dependency (Fagerstrom score).

Material and method: This study was conducted on the volunteers of smoking cessation clinic in Tehran. They underwent tests for nicotine dependence, motivation degree assessment by FT and Q-mat test respectively. Thereafter, smokers started the cessation program consisting in behavioral therapy and pharmacotherapy. Their quit rate was by verified by telephone and through exhaled co measurement after 6 months.

Results: In this study 345 volunteers were studied from which 311 (90.1%) male. The mean age was 37.6±11.04 years. After 6 months follow up abstinence rate was 39%. The mean of Q-mat score was 15.8±5.1 (14.9-16.7 CI 95%) in participants who stopped smoking and 15.4±5.1 (14.7-16.9 CI 95%) among participants who failed smoking cessation (p=0.4). The mean of FT was 5.2±2.6 (4.7-5.6 CI 95%) in participants who stopped smoking and was 6.2±2.6 (5.7-6.4 CI 95%) among participants failed (p=0.002).

Conclusion: The results of this study indicate that volunteers may have high participants failed (p=0.002).

P4090
Usefulness of paediatric dyspnoea scores for evaluative purpose in acute wheeze
Jolita Behkof, Irene Marjie Barrels, Roelien Reimink, Paul Brand. Princess Amalia Children’s Clinic, Isola Klinieken, Zwolle, Netherlands

Clinical dyspnoea scores are the most commonly used methods to assess wheeze severity and response to bronchodilator treatment in young children. We performed a prospective observational study to assess the (external) validity of 3 frequently used dyspnoea scores: Asthma Score (AS), Clinical Asthma Score (CAS) and Pulmonary Index (PI), before and after bronchodilator treatment. We studied 46 hospitalized children (0-8 yrs) with a wheeze exacerbation. Video and audio recordings of breathing pattern and lung sounds were made before and after salbutamol inhalation. 3 paediatricians and 4 nurse practitioners independently reviewed these recordings and rated the degree of dyspnoea using the three scores. This was repeated after 4 weeks to evaluate intra-observer reliability. Inter- and intra-observer reliability were evaluated by intraclass correlation coefficient (ICC, considered adequate when >0.70), responsiveness by Guyatt’s RR (considered adequate when > 1.96). Differences in scores within and between observers were larger than those before and after treatment.

Inter- vs intraobserver reliability and responsiveness of three dyspnoea scores

<table>

We conclude that the poor within- and between-observer reliability of these three dyspnoea scores renders them invalid for use as an evaluative instrument in children 0-8 years of age with an acute wheeze exacerbation.

P4091
Clinical scores for the assessment of acute dyspnoea in wheezing children:
Systematic review
Jolita Behkof, Roelien Reimink, Paul Brand. Princess Amalia Children’s Clinic, Isola Klinieken, Zwolle, Netherlands

A reliable, valid, and easy-to-use assessment of the degree of wheeze-associated dyspnoea is important to provide individualised treatment for children with acute asthma, wheeze or bronchiolitis. We conducted a systematic review to assess validity, reliability, and utility of all available paediatric dyspnoea scores. We searched Pubmed, Cochrane library, National Guideline Clearinghouse, Embase and Cinahl for eligible studies. We included studies describing the development or use of a score, assessing two or more clinical symptoms and signs, for the assessment of severity of dyspnoea in an acute episode of asthma, wheeze or bronchiolitis in children aged 0-18 years. Study selection and data extraction was done independently by two reviewers. Validity, reliability and utility of the reviewed 32 children scores were assessed by 15 quality criteria for clinimetric studies. We retrieved 41 articles describing 32 dyspnoea scores. Thirteen scores were judged unsuitable for clinical use, because of insufficient face validity, use of items unsuitable for children, difficult scoring system or need of auscultation skills, leaving 19 possibly useful scores. The median number of quality criteria that could be assessed was 6 (range 5-10). The median number of positively rated quality criteria was 2 (range 1-5). In conclusion, none of the published dyspnoea scores has been sufficiently validated to allow for clinically meaningful use in children with acute wheeze. Proper additional validation of existing scores is warranted to allow clinicians and researchers to use the available paediatric dyspnoea score for clinical or research purposes.

P4092
Clinical predictive rules to identify preschool wheezers at risk for subsequent asthma: Can we rely on them? Could we improve their performance?
Sanneke Fouza1, Eleni Skylogianni2, Konstantinos Boile1, Konstantinos Periti2, Michael B. Andracopoulos1, Paul L Brand3. 1Pediatric Respiratory Unit, University Hospital, Patras, Greece; 2Third Pediatric Department, Atikon Hospital, Athens University Medical School, Athens, Greece; 3Princess Amalia Children’s Clinic, Isola Klinieken, Zwolle, Netherlands

Background: Various predictive rules have been developed to identify wheezy preschoolers at risk for persistent asthma. The aim of this study was to evaluate the performance of the asthma predictive index (API), modified API (mAPI), and PIAMA score, and to examine whether the presence of reversible airflow obstruction (RAO) could improve the prediction of later asthma.

Methods: This retrospective study included 32 children aged 6-8 years with recurrent wheeze who had regular follow-up for the last 4 years. Active asthma was defined as doctor-diagnosed asthma or wheeze that required long-term medication in the previous 12 months. RAO was defined as a bronchodilator response ≥80% for respiratory resistance and ≥35% for respiratory reactance determined with the forced oscillation technique (FOT).

Results: Active asthma was present in 32 children (34.8%). 21 children (22.8%) had positive API, 10 (10.9%) positive mAPI, and 55 (59.8%) had PIAMA score ≥ 20; RAO was documented in 25 children (27.2%). The stringent API had positive and negative likelihood ratio (LR+ and LR-) of 3.0 and 0.69 respectively. The mAPI had LR+ 1.6 and LR- 0.73, and the PIAMA score LR+ 1.5 and LR- 0.52. The combination of API (or mAPI) and RAO resulted in LR+ 3.8 and LR- 0.24 (LR+ 3.2 and LR- 0. 4), whereas the combination of PIAMA score and RAO resulted in LR+ 1.4 and LR- 0.39.

Conclusion: All tested indices had limited overall ability to predict –especially to rule-out– subsequent asthma in preschoolers with recurrent wheeze. Combination of asthma predictive models with FOT-determined RAO may improve the prediction of later asthma in wheezy young children.
Parents reported asthma symptoms in the past 12 months in 57 children. Asthma maintenance medication was used in the past 12 months in 38 children. The diagnostic questionnaire total score (0-100) was significantly different between children with (n=63) or without symptoms and/or asthma medication use at follow-up (54 versus 42, p=0.005). Sensitivity, specificity, positive and negative predictive values of the questionnaire were 40%, 82%, 69% and 56%, respectively.

Conclusions: These preliminary results show asthma symptoms and/or medication use at school age in half of the children with respiratory symptoms at preschool age. Further analyses of the final database are needed to draw definite conclusions with regard to the diagnostic accuracy of this newly developed diagnostic tool.

P4094
Usefulness of the asthma predictive index in clinical practice: A systematic review and clinical epidemiological analysis
Sotiris Fouzas1, Paul Brand2, Paediatric Respiratory Unit, University Hospital, Patras, Greece; 2Princess Amalia Children’s Clinic, Isala Klinieken, Zwolle, Netherlands

The Asthma Predictive Index (API) has been developed from follow-up data of the Childhood Asthma Study in Asthmatic Children (CASCACH). The API includes 5 symptom-patterns of wheeze that parents can use to identify their child’s asthma status into 7 categories. The most severe is the multiple-trigger pattern (3 or more symptoms in any 24h period). API scores range from 0-4 and were shown to be a good tool to predict disease course.

Objective: We investigated whether multiple-trigger wheezers were more likely to have abnormal pulmonary function in preschool wheezers.

Background: Multiple-trigger wheezers are commonly used among preschoolers with wheeze. However, symptom-patterns of wheeze have not been related to pulmonary function tests or markers of airway inflammation.

Methods: Twenty-six control subjects and 25 wheezers (11 episodic and 14 multiple-trigger wheezers) were tested. FEV1, FeNO and LCI did not differ significantly among episodic and multiple-trigger wheezers. The presence of current atopy was associated with higher FeNO (p=0.024) but did not influence pulmonary function and LCI significantly. Eight out of the 25 (32%) wheezers showed a significant increase in FEV1 and 15 out of the 25 (60%) wheezers showed a significant decrease in LCI, after administration of inhaled salbutamol.

Conclusions: Asthmatic children report significantly lower asthma control than their parents using the C-ACT, irrespective of the child’s age. This may indicate that parents underestimate asthmatic complaints of their children.

P4095
Pulmonary function and inflammation discriminated by symptom-pattern phenotypes in preschool wheezers
Elpis Hatzigiorou, Fotis Kirvasillis, Vasiliki Avramidou, Elektra Toulou, John Tsianakis. 3rd Paediatric Dept, Paediatric Pulmonology Unit, Aristotle University of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece

Background: The discrimination of episodic and multiple-trigger wheezing is commonly used among preschoolers with wheeze. However, symptom-patterns of wheeze have not been related to pulmonary function tests or markers of airway inflammation.

Objective: We investigated whether multiple-trigger wheezers were more likely to have abnormal FEV1, increased ventilation inhomogeneity (LCI) and increased fraction of exhaled nitric oxide (FeNO) than episodic wheezers. We also investigated whether multiple-trigger wheezers were more likely to have a positive reversibility test, than episodic wheezers.

Methods: FEV1, LCI and FeNO were measured in healthy children and those with recurrent wheeze aged 4 to 6 years.

Results: Twenty-six control subjects and 25 wheezers (11 episodic and 14 multiple-trigger wheezers) were tested. FEV1, FeNO and LCI did not differ significantly among episodic and healthy preschoolers. On average, LCI was abnormal in 18 wheezers (72%). Multiple-trigger wheezers had an average increase of 3.1% (P=0.0001) in LCI, compared with episodic wheezers. FEV1 and FeNO did not differ significantly among episodic and multiple-trigger wheezers. The presence of current atopy was associated with higher FeNO and did not influence pulmonary function and LCI significantly. Eight out of the 25 (32%) wheezers showed a significant increase in FEV1 and 15 out of the 25 (60%) wheezers showed a significant decrease in LCI, after administration of inhaled salbutamol.

Conclusions: Multiple-trigger wheeze is associated with pulmonary function abnormalities independent of atopic status. LCI is the most sensitive indicator of abnormal pulmonary function in preschool wheezers.

P4096
The childhood asthma control test: Children versus parents
Andrea Vosseel van Beijeren1, Mariëlle Pijnenburg1, Daan Caudri1, Hen Bracke1,2, Pediatric Pulmonology, Erasmus University Medical Centre - Sophia Children’s Hospital, Rotterdam, Netherlands; 2Pediatrics, Catharina Hospital, Eindhoven, Netherlands

Introduction: The Childhood Asthma Control Test (C-ACT) is a validated patient-completed questionnaire to assess asthma control in children 4-11 years, which is divided into two parts. One part is filled in by the child, the second part by the parent.

Objectives: To compare asthma control scores between children and their parents.

Methods: Asthmatic children 4-11 years and their parents visiting our outpatient asthma clinic in 2011, completed the C-ACT as part of routine patient care. Spearman correlation and Intraclass Correlation Coefficient (ICC) between C-ACT by child and parent were calculated. Both scores were expressed as percentage of the maximum and pair wise compared using the Wilcoxon Signed Ranks Test and a Bland-Altman plot.

Results: 272 children (aged 6.68 yrs, 66.8% male) and their parents participated. Correlation between C-ACT score between children and parents was moderate (r=0.72, p<0.001); the ICC was reasonable (0.77, p<0.001). Children scored median 75% (0-100) of the maximal score, whereas parents scored median 87% (0-100). On average children scored 8.5% lower than parents (p<0.001, see figure 1). The difference between children and parents was independent of the child’s age (p = ANOVA=0.804).

Conclusions: Asthmatic children report significantly lower asthma control than their parents using the C-ACT, irrespective of the child’s age. This may indicate that parents underestimate asthmatic complaints of their children.

P4097
Level of asthma control among asthmatic children in Thessaloniki area in northern Greece
Katerina Chryssoudou, Fotini Kirvasillis, Nikolaos Karantaglis, Kalliopi Kontoulis, Elpis Hatzigiorou, John Tsianakis. Paediatric Respiratory Unit, 3rd Paediatric Dept, Hippokration General Hospital, Aristotle University, Thessaloniki, Greece

Background: In spite of the use of international guidelines for the diagnosis and treatment of asthma, there is continuing evidence of poor asthma control among asthmatic children. Level of asthma control has not been previously evaluated in Greece.

Aim: To evaluate the level of asthma control among asthmatic children in the city of Thessaloniki (Northern Greece).

Method: Parents of children > 2 years old with doctor’s diagnosis of asthma interviewed by the same physician using a detailed questionnaire including asthma symptoms, limitation of activities, need for rescue medication, asthma exacerbations and emergency visits. 365 children were examined either in Asthma Clinic, or the Emergency Department from November 2010 to May 2011.

Results: Mean age of the children was 7.8 years. 93/365 (25.48%) of them achieved adequate control of asthma, as defined by GINA (Global Initiative for Asthma). 176/365 (48 22%) had partly controlled asthma, whereas uncontrolled asthma was found in the 96/365 (26.3%) of the children. 104/365 (30%) of the study population had used rescue medication for more than two days during the previous week, whereas 70/365 (19.2%) of them reported limitation of activities and 62/365 (17%) had nocturnal symptoms within the previous month.

Conclusions: One out of four of the children suffering from asthma in Thessaloniki area achieves control of the disease. An increased use of rescue medication for more than two days was reported in 1/3 children, limitation of activities and nocturnal symptoms in around 1/5 of the children.

Can response to inhaled corticosteroids in preschool children with recurrent wheezing predict asthma at age six years?

Safaa Wafy

Caregivers reported few problems due to their child’s asthma whereas

Conclusions:

(r= -0.168, p=0.35).

1Chest Department, Assiut University Hospital, Assiut, Egypt; 2Community and

wheezing predict asthma at age six years?

Can response to inhaled corticosteroids in preschool children with recurrent

Methods:

From the Asthma DEtection and Monitoring (ADEM) study, 160 recur-

rent wheezers aged 2-4 years (≥ 2 episodes, ISAAC questionnaire) received 200μg
diclohexamethone for eight weeks. Before and after treatment symptom score (in-

versely to severity), airway resistance (Rint) before and after and 300 μg Salbutamol,
Fractional exhaled Nitric Oxide (FeNO), and exhaled breath condensate markers
(pH, interleukin (IL) 1a, IL-2, IL-4, IL-5, IL-10, IL-13, IFNg, scCAM, and Eotaxin) were assessed. At the age of 6 years a final diagnose (asthma or transient wheezing) was based on symptoms, lung function, and medical use. Analysis was performed by logistic regression.

Results: At the age of 6 the study group consisted of 61 asthmatics and 99 transient wheezers. At the age of 2-4 years symptom score before (ORadjusted=0.86 95%CI=0.79-0.94, p<0.01) and after treatment (ORadjusted=0.88, 95%CI=0.81-0.96, p<0.01), and prebronchodilator Rint after treatment (ORadjusted=2.80 95%CI=1.77, 51, p=0.04) were significantly associated with asthma at the age of 6 years. However, all parameters tested did not change during treatment.

Conclusions: In recurrent wheezing children, asthma at 6 years was associ-

ated with more severe symptoms before and after ICS treatment and increased prebronchodilator airway resistance after ICS treatment at 2-4 years of age.

P4099 Asthma-related quality of life in children: Correlation with asthma control and lung function

Sandra Klaisen-Beeren1, Peter Merkus2, Anneke Lansdorfs3, Hein Brandelli4

Norbert van den Berg5, Johan de Jongste1, Anja Vaessen-Verberne6

Marielle Pijnenburg7,1, Pediatric Pulmonology, Erasmus University Medical Centre – Sophia Children’s Hospital, Rotterdam, Netherlands; 2Pediatric Pulmonology, Radboud University Medical Centre, Nijmegen, Netherlands; 3Pediatrics, Rijnstate Hospital, Arnhem, Netherlands; 4Pediatrics, Catharina Hospital, Eindhoven, Netherlands; 5Pediatrics, Flevo Hospital, Almere, Netherlands; 6Pediatrics, Amphia Hospital, Breda, Netherlands

Introduction: Children with asthma often have sleep disturbances, absence from school and limitations of physical activity that may reduce their quality of life (QOL). Therefore, asthma-related QOL is an important endpoint in childhood asthma.

Objectives: To assess QOL in children and adolescents with asthma, and to correlate QOL with asthma control, lung function and FENO.

Methods: QOL was assessed by caregivers of asthmatic children aged 4-11 yrs and by adolescents with asthma (12-18 yrs) using the Pediatric Asthma (Care-

givers) Quality of Life Questionnaire (PAQLQ). PAQLQ scores were correlated with asthma control (assessed by the (Childhood) Asthma Control Test (C-ACT) and GINA classification) and with FEV1 and FENO.

Results: 221 children (mean age 10.5 yrs, 148 male, n=76 >11 yrs) participated. Median FEV1 was 97.1% (59.139) and median FENO 18.6 ppb (4-170). Median PAQLQ score of caregivers was 6.46 (3.69-7), with median sub domain scores of 6.75 (activity) and 6.44 (emotional). Median PAQLQ score of adolescents was 6.18 (3.52-7), with sub domain scores of 6.10 (symptoms), 5.40 (activity) and 6.88 (emotional). Median PAQLQ score in children with controlled asthma (n=43) was 6.85 (5.54-7), in partly controlled asthma (n=84) 6.52 (4.23-7) and in uncontrolled asthma (n=85) 5.78 (3.52-7) (<0.05). PAQLQ scores correlated strongly with C-ACCT scores (r=0.60, p<0.05), but not with FENO (r=0.048, p=0.49) or FEVER (r=-0.186, p=0.35).

Conclusions: Caregivers reported few problems due to their child’s asthma whereas adolescents reported lower QOL, in particular on activity. Pediatric asthma QOL correlated strongly with asthma control, but not with FENO and FEV1.

P4100 Assessment of quality of life in asthmatic children. A case- control study

Safia Majeed1, Kim van den Brand1, Quirijn Jobsis1, Steven Hovig1

1Chest Department, Assisut University Hospital, Assisi, Egypt; 2Community and Public Health Department, Assisut University, Assisi, Egypt; 3Community and Public Health Department, El Achzar University, Assisi, Egypt; 4Community and Public Health Department, E-Achzar University, Assisi, Egypt

Introduction: Health-related quality of life (HRQL) has become an increasingly important issue in the management of asthma and it is now often used to evaluate the effectiveness of antiasthma drugs.

Objective: To assess impairment in QOL in asthmatic children and to determine the influencing factors.

Methods: 230 asthmatic outpatients, aged 7-18 years, from chest outpatient clinic in school health insurance, Assisi, compared with another 272 non asthmatic pa-

tients. Two questionnaires were used for each patient: asthma questionnaire and St George’s Respiratory Questionnaire (SGRQ) to assess QOL.

Results: Asthma affected boys more than girls (62.2% and 37.8%). The mean age of asthmatic children was 9.1±2.1 years. Allergic rhinitis were highly significantly associated with asthmatic patients. About 40% diagnosed as uncontrolled asthma based on their night awakening, 70% >26.5% based on their activity limitation and daytime symptoms. Severe asthma reported in 42.6%. Asthma affects quality of life of all patients. There were significant differences between the two groups as regard Symptom, Activity, Impact and Total score (all P < 0.0001) of St George’s. There was a negative correlation between asthma severity and quality-of-

life score. Allergic rhinitis, was strongly and negatively associated with the overall SGRQ score (p=0.038). Lower QOL was associated with school absence, younger (<11 yrs) and among patients with poor adherence/illiterate patient. Asthma affected all life style of the majority of patients as, physical exercise limitation, sleep disturbance, and emotional function etc.

Conclusion: Bronchial asthma in our community affected QOL of children, so reduce asthma severity and improve asthma symptoms attempts to improve their QOL.

P4101 Effect of asthma control and quality of life on the use of alternative medicine

Elia Erdem, Yasemin Gokdemir, Rehtia Erzu, Fazilet Karakoc, Bulent Karadag.

1Department of Pediatric Pulmonology, Marmara University School of Medicine, Istanbul, Turkey

Asthma is the most common chronic lower respiratory tract disease of childhood. It may affect the quality of life of the child and the parents. Nowadays, use of alternative treatment (AT) methods are increased in treatment of asthma and/or relief of symptoms. But there are limited studies showing the efficiency of AT and evaluating the association between asthma control and AT usage. We investigated the prevalence of AT usage and effect of AT usage on asthma control and quality of life in patients with asthma.

Study included 80 patients with asthma followed up in Pediatric Pulmonology Department. “Pediatric Asthma Quality of Life Questionnaire” (PAQLQ) was used to evaluate the quality of life. “Asthma Control Test” (ACT) and “Asthma Control Questionnaire” (ACQ) were used to measure asthma control.

Mean age of the patients were 9.2±4.3. 63.8% of the patients used at least one method of AT in their life before the recommended treatment. The most commonly used methods were: carbolic molasses (36.3%), herbs (26.3%), quails (25.2%), honey in black radish (15.1%), olive oil (15.0%), garlic (5%), respectively. Of whole, 59.6% of the patients got benefit from AT. Mean score of PAQLQ was 5.9±1.0. Parents with younger kids were found to use more AT methods (p=0.002). There were no association between the use of AT and time of the diagnosis of asthma, time of anti-inflammatory drugs usage, PAQLQ, ACT and ACQ (p>0.05).

In conclusion, AT is frequently used in our patients. We found that there was no effect of level of asthma control and quality of life on preferring AT.

P4102 Allergy and asthma severity

Svetlana Kamenov1, Lozana Markovic2, Aleksandar Kamenov3

1Department of Pulmonology, Health Center, Nis, Serbia; 2Department of Immunology, Clinical Center, Nis, Serbia; 3Department of Vascular Surgery, Clinical Center, Nis, Serbia

Background: Asthma, allergic rhinitis (AR) and atopic dermatitis (AD) are multifactorial illnesses determined by complex interplay between genetic and environmental factors with different phenotype expression. The majority of asth-

mas have AR and studies have shown that treatment of AR helps control asthma symptoms. The objective of this study was to evaluate if the presence of AR and/or AD interfere with asthma severity.

Methods: We evaluated 1,350 asthmatic children aged 0 – 18 years (median 9 years), attending Health Center Nis. These data were collected by standard protocol and registered in a computer data base. Asthma diagnosis and severity were established by GINA (1995) criteria. Skin prick tests (SPT) were performed with common aeroallergen extracts and tests were considered positive if wheal diameter greater than or equal 3 mm. Data were analyzed by chi square test.

Result: Asthma severity was mild in 61.8%, moderate in 28.0% and severe in 10.2%. Male to female ratio was 1.3:1. AR was present in 59% of the patients, 72% in 6.2% , and both AR and AD in 2.1%. Regardless asthma severity there was no difference in the frequency of AR and/or AD among asthmatics. SPT was positive to at least one allergen in 78% of patients. The frequency of SPT positivity was 58% in mild asthma and increased to 85% in severe asthma (p<0.001).

Conclusion: Asthma severity was not related to the presence of AR and/or AD in this group of asthmatic children, but there was a relationship in the frequency of positive skin tests according to asthma severity.

Drug deposits were analyzed using HPLC. Results are presented as coefficient of variation of the delivered doses.

The co-efficient of variation was highest for the conventional VHC for all test conditions. Use of an anti-static VHC can minimize variability (improve reproducibility) in delivered dose under in vitro test conditions.

Figure 1. Left: Facemask seal leakage (%); Top right: SAM 0; Bottom right: SAM 1.

There was a wide variation in leakage from different VHC facemasks and also between SAMs. The smallest amount of leakage for both SAMs was seen with the OptiChamber Plus Z-Stat and conventional AeroChamber Plus (Z-stat and AC Plus; Philips Respironics, Respironics New Jersey, Inc., Parsippany, NJ, United States), followed by the OptiChamber Diamond with LiteTouch facemask.

**Table 1. Coefficient of variation for delivered dose at each time delay/flow rate combination (n=10)**

P4104

**In vitro comparison of the effect of inhalation delay on the variability of the delivered dose from valved holding chambers**

Dark Von Hollen, Paul Hancock, Ross Hatley, Kurt Nikander

Philips Respironics, Respirro New Jersey, Inc., Parsippany, NJ, United States; Respirro Respiratory Drug Delivery (UK) Ltd, Chichester, West Sussex, United Kingdom

The valved holding chamber (VHC) has been designed to optimize delivery for those using pressurized metered dose inhalers (pMDIs). We tested the effects on delivered dose of increasing delay between pMDI actuation and flow through the VHC, using both anti-static and conventional VHCs.

Ten anti-static Diamond (Diamond; Philips Respironics) VHCS, anti-static AerocChamber Plus (Z-Stat and conventional AerocChamber Plus; Z-stat and AC Plus; Monaghan Medical Corp.) VHCs were washed and air dried and six HFA albuterol sulfate pMDIs (ProAir HFA, 90 μg albuterol, Teva Specialty Pharmaceuticals LLC) were primed before use. For each run the pMDI was actuated into the VHC, after a delay of 0, 5 or 10 s flow through the VHC and attached filter occurred at an extraction flow rate of 5, 15 or 30 L/min for 10 s. The pMDI was actuated 10 times for each of the 10 VHCs of each brand at each delay/flow rate combination.

P4105

**Hypothalamic-pituitary-adrenal axis suppression in children at Cape Town allergy units – Prevalence and predictive factors**

Ekheder Zeiling1, Carl J. Lombard2, Galal3, Stephen Hough4, Elvis Iruuen5, Eugenine Weinberg5,1, Paediatric Endocrine Unit, University of Stellenbosch, Cape Town, Western Cape, South Africa; 3 Paediatric Endocrine Unit, Medical Research Council, Cape Town, Western Cape, South Africa; 1 Paediatric Endocrine Unit, University of Stellenbosch, Cape Town, Western Cape, South Africa; 2 Pain Clinic, University of Stellenbosch, Cape Town, Western Cape, South Africa

**Background:** Hypothalamic-pituitary-adrenal axis suppression (HPAS) is generally thought to be rare in children treated with corticosteroids (CS), since HPAS may be partially masked by recovering HPA function.

**Objective:** To determine the prevalence & predictive factors for HPAS in children treated with CS at the allergy clinics in Cape Town.

**Methods:** 143 asthmatic children, 5-18 years old, on inhaled CS (ICS) with additional CS were recruited. Clinical features compatible with HPAS were documented: Daily and cumulative CS dose, adherence, asthma score and lung functions were recorded. A metapyrone test was performed if the 0:00 h cortisol (C) was > 8nmol/l. Spearman correlation coefficients (r) were calculated between the post-metapyrone (PMTP) ACTH, 11-deoxycorticosterone (11DOC), 11DOC+C, and each variable. A multiple linear regression model of ΔACTH & a logistic regression model for HPAS were developed.

**Results:** Prevalence: All HPAS 65.1 (56.5-72.9)%; low (PMTP 11DOC, 11DOC + cortisol) 33.3 (23.7-40.9)%; low (PMTP ACTH, 11DOC, 11DOC + cortisol) 16.3 (9.3-23.3)%; hypocortisolism 6.1 (1.8-10.5)%.

**Conclusions:** About 2/3 of asthmatic children on CS may have a degree of HPAS. In one third the asthmatics may still be suppressed while hypothalamic-pituitary function may have recovered. Predictive factors for HPAS are concomitant use of BMI, adherence to ICS and NS.

P4106

**Fatigue: A symptom of asthma in children?**

Ghislaine van der Zande1, W.B. Vreede1, H. Heneweer3, 1 Paediatric Pulmonology, DeKinderkliniek, Almere, Netherlands; 2 Master Program Physician Assistant, Hogeschool Utrecht, Netherlands

**Introduction:** In children with symptoms of fatigue asthma is frequently diag-
nosed. However fatigue is not mentioned as a symptom in definitions of asthma in children.

**Aim of the study:** Exploration of the consistency between the symptom fatigue and the diagnosis asthma in children. Consequently asthma can be diagnosed earlier and faster and the care for these patients will improve.

**Method:** A retrospective analysis of the files of 440 patients between the age of 5 and 18 years with the diagnosis Asthma de Novo between May 15th 2009 and May 15th 2011. The data of patient characteristics, pulmonary function tests and symptoms were analyzed.

**Results:** There was an uneven distribution between boys (58%) and girls. The boys had a average age of 9.9 years, the girls of 11.0 years. In both groups the various pulmonary function parameters were abnormal. 52% of the patients complained of fatigue. The distribution of symptoms in boys and girls is equally.

**Conclusion:** Fatigue is the most frequently mentioned symptom of asthma in children, after complaints during exercise, dyspnea and coughing. Fatigue is not a specific symptom. The results can therefore only be an assumption. It is recommended to involve asthma in the differential diagnosis of unexplained fatigue in children.

**Role of MgSO4 in PICU management of children with status asthmaticus**

Shahid Sheikh1, Nadeem Khan 2, Melissa Frasure 3 , Nancy Ryan-Wenger4, Karen McCoy 1, 4

1Division of Pulmonary Medicine, Department of Pediatrics, Nationwide Children Hospital and Ohio State University, Columbus, OH, United States; 2Division of Critical Care, Department of Pediatrics, Nationwide Children Hospital and Ohio State University, Columbus, OH, United States; 3Division of Respiratory Care, Nationwide Children Hospital, Columbus, OH, United States; 4Division of Nursing Research, Nationwide Children Hospital, Columbus, OH, United States.

**Background:** This retrospective study was done to understand the use of MgSO4 for treatment of children with status asthmaticus in a pediatric intensive care unit (PICU).

**Methods:** Charts of all patients ≥5 years of age admitted to the PICU with status asthmaticus, at Nationwide Children’s Hospital, Columbus, OH, between 2000-2007 were reviewed.

**Results:** Among 222 encounters, 203 received continuous albuterol, 216 received IV steroids, 113 receive Terbutaline, 17 received mechanical ventilation, and 57 status asthmaticus, at Nationwide Children’s Hospital, Columbus, OH, between May 15th 2009 and May 15th 2011. The data of patient characteristics, pulmonary function tests and symptoms were analyzed.

**Quality of life after acute bronchiolitis in infancy**

Leif B. Rolfsjord1,2, Kai-Håkon Carlsen1,2, Egil Bakkeheim1, Karl C. L. Carlsen1,2, Department of Paediatrics, Oslo University Hospital, Oslo, Norway; 2Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Norway.

**Background:** Acute bronchiolitis, parental allergic disease, atopic eczema, male gender and parental stress are risk factors for asthma development. Quality of life (QoL) may be reduced in children with allergic disease, but prospective studies on risk factors for reduced QoL in infants are lacking.

**Aim:** Are asthma risk factors, apart from acute bronchiolitis associated with QoL nine months after hospitalization for bronchiolitis? The Infant Toddler Quality of Life Questionnaire (ITQOL(TM)) was sent to parents of 405 hospitalised infants included in a randomized clinical trial testing the efficacy of racemic adrenaline, the Bronchiolitis All SE-study. The 13 domains were analyzed by multiple linear regression including age at hospitalization, gender, atopic eczema, parental asthma and parental allergic rhinitis (risk factors).

**Results:** Risk factors were similar for the 209 infants (mean age 13.2 months) who did and the 196 who did not return the questionnaire. Reduced QoL was found for atopic eczema (Table 1), parental asthma and female gender (four, two and one domain, respectively), but increased in children with parental allergic rhinitis (one domain).

Respiratory complication in children with dengue
Lucia Azevedo, Daniel Leal, Ana Menezes, Selma Sias, Miguel Aide, Gesmar Herdy. Department of Pediatrics, Federal Fluminense University, Niterói, RJ, Brazil

Dengue, emerging infectious disease, has been presenting more severe in the last years. In children this diagnosis is difficult. The morbimortality is related to the early recognition and appropriate management. The goal is to know the clinical and laboratory features of children with dengue, hospitalized in the pediatric emergency of the Antonio Pedro University Hospital. Were analyzed from 2006 to 2010 the records of 63 children, 25 (39.7%) of them with respiratory complication. All had pleural effusion: 17 (68%) for the right and 8 (32%) bilateral. The age ranged between 2 and 12 years (mean = 8.2), the most was female (66%). The symptoms were: fever, abdominal pain, vomiting and headache. All had leukopenia and 23 (92%) thrombocytopenia. Ascite was found in 19 (76.6%) and thickening of the gallbladder in 5 (20%). Hypoalbuminemia in 15 (60%) and enzyme liver abnormalities in 21 (84%). The analysis was similar to that reported in the literature differing only in sex.

P4112
Additive effect of air pollution particulate matter and cigarette smoke on pneumococcal adhesion to lower airway cells
Reetika Suri1, Nasem Mushiq1, Richard Wain2, Jonathan Grigg1. 1Centre for Paediatrics, Blizzard Institute of Cell and Molecular Sciences, London, United Kingdom; 2Centre for Immunology and Infectious Disease, Blizzard Institute of Cell and Molecular Science, London, United Kingdom

Air pollution particulate matter (PM) and cigarette smoke (CS) are associated with increased vulnerability of children to bacterial pneumonia. In epidemiological studies, PM and CS are considered independent variables. We previously reported that PM10 (PM diameter <10 μm) increases pneumococcal adhesion to lower airway cells. Here we assessed whether PM and CS additively increase the susceptibility of airway epithelial cells to pneumococcal infection. Monolayers of the alveolar epithelial cell line A549 were exposed to sub-optimal doses of PM10 or cigarette smoke extract (CSE) for 3 h. The pollutants were washed off and cells exposed to Streptococcus pneumoniae for 2 h at a multiplicity of infection (MOI) of 100. After virus washing, cells were detached and lysed. Adherent bacteria were assessed by quantitative culture. Data were compared by T tests.

Both PM10 and CSE stimulated pneumococcal adhesion. An additional increase in pneumococcal adhesion was caused by PM10 and CSE combined. No decrease in viability was observed by light microscopy. The data suggests that PM10 and CSE additively increase vulnerability of airway cells to pneumococcal infection. If confirmed in animal models, additive effects of PM10 and CSE should be considered in epidemiological studies. Individuals at risk are likely to be living in countries with high PM levels and high incidence of indoor smoking.

P4113
Neutrophil count trends in BAL samples from children being investigated for chronic cough
Vanessa Alegre1, Grace Choi2, Konstantinos Dourou3, Mark Everard1. 1Academic Unit of Child Health, Sheffield University, Sheffield, United Kingdom; 2School of Medicine, Sheffield University, Sheffield, United Kingdom; 3Respiratory Paediatrics, Sheffield Children’s NHS Foundation Trust, Sheffield, United Kingdom

Introduction: Investigating probable persistent bacterial bronchitis (PBB) with a bronchoscopy allows the identification of infectious agents and quantification of cellular responses in the paediatric population who rarely expectorate sputum under the age of 10.

Methods: Bronchoscopies in children carried out 2010-11 were identified and a retrospective case notes analysis done to identify those performed because of chronic cough or proven/probable PBB. Bronchoalveolar lavage (BAL) samples were analysed for standard bacterial culture, viral PCR and neutrophil count (%). Results: 70 bronchoscopy BALs were analysed: 18.6% positive for bacteria and viral culture (B pos/V pos); 35.7% positive for bacteria but negative for viruses (B pos/V neg); 21.4% negative for bacteria but positive for viruses (B neg/V pos); 24.3% negative for both (B neg/V neg). Analysis of the BAL neutrophil count (%) was performed with one-way ANOVA and Cuzick’s test for trend. For the reasons of analysis the 4 groups were ordered as follows: group 1: B pos/V pos; group 2: B neg/V pos; group 3: B neg/V neg; group 4: B pos/V neg. The 4 groups differ significantly (means ± SD: 45.7±30.7, 18.6±21.4, 20.4±22.9, 11.6±15.2, for groups 1, 2, 3, and 4, respectively, p<0.001). Furthermore, a significant trend was found across the 4 ordered groups (p<0.001).

Conclusion: The presence of bacteria and viruses is associated with a significantly more neutrophils and thus a greater degree of inflammation than that induced by bacteria alone and could explain why recurrent viral infections are a feature of PBB.
Conclusion: Our results suggest that sodium sulfite may potentiate the activity of RV-induced diseases by increasing the production of IL-8, RANTES, and IP-10.

P4116 Differential responses of monolayer and differentiated airway epithelial cell cultures to NTHi infection
Kirst Wilson1, Lynne Bingle2, Colin Bingle2, Mark Everard3. 1Infection and Immunity, University of Sheffield, United Kingdom; 2Clinical Dentistry, University of Sheffield, United Kingdom; 3Paediatric Respiratory Medicine, Sheffield Children’s Hospital, Sheffield, United Kingdom.

The innate defence functions of the lung require a patent airway epithelium and infections are often associated with epithelial defects and phenotype alterations. Non-typeable Haemophilus influenzae (NTHi) one of the first bacterial species to infect children, reduces innate defences, allowing further colonisation with other pathogens, including RSV. We have established NTHi infections of lung derived cell lines and primary airway cells in differentiated cultures prior to the establish-ment of secondary infections with RSV as a model for paediatric RSV infection. A549, H292 and primary airway epithelial cells were grown in monolayer cultures in transwell inserts. Differentiated cultures of tracheobronchial epithelial (TBE) cells were grown at the ALI using established methods. The apical compartments of established cultures were infected with increasing doses of GFP tagged NTHi and followed for up to 7 days. Infection and cell viability was determined using confocal microscopy and bacterial counts at each time point. A549 and H292 cells, and undifferentiated primary cells became heavily infected and by day 7 almost complete loss of cells was associated with a loss of viable bacteria. Cytokine array studies showed that these cultures mounted limited cytokine responses. The ALI TBE cell cultures had an enhanced ability to overcome the same bacterial infections and this was associated with a marked cytokine response. This data suggests that differentiated epithelial cell cultures have an enhanced ability to overcome bacterial infection compared to monolayer cultures of epithelial cells. This is likely due to the innate defensive shield secreted from these complex cultures.

P4117 Video-assisted thoracoscopic surgery (VATS) and percutaneous drain insertion (PDI) in childhood empyema
Ira De Schutter1, Elke De Wachter1, Jan Lamote2, Joyce Raymond Punzalan1, 2Department of Pediatrics, Our Lady of Lourdes Hospital, Manila, Philippines; 1Department of Pediatrics, Our Lady of Lourdes Hospital, Manila, Philippines; 3Paediatric Respiratory Medicine, Universitair Ziekenhuis Brussel (UZ Brussels), Belgium; 4Department of Thoracic Surgery, Universitair Ziekenhuis Brussel (UZ Brussels), Belgium; 5Centre for Outcomes Research and Laboratory for Experimental Surgery, Universitair Ziekenhuis Brussel (UZ Brussels), Belgium.

Introduction: Pediatric parapneumonic effusion (PPE) incidence increases.
Aims: To compare different treatment options in children with PPE.
Methods: Retrospective analysis of children with PPE, admitted from 01/01/2007-30/11/2011. PPE definition: ≥1cm fluid on US or CT, and/or an opacity on chest X-ray of ≥50% of the hemithorax. Exclusion criteria: age <6, trauma, thoracotomy.
PDI and VATS were performed on clinical indication. VATS was reserved for patients (pts) with insufficient clinical improvement.
Results: Pts were treated as follows: Group A: no PDI/VATS. Group B: PDI. Group C: VATS. Group D: PDI followed by VATS.
Results: 49 pts were treated, included 35/24/26, median age 3.3y (range 0.8-14.8y); 15, 12, 11, and 11, in group A, B, C, and D, resp. Age, sex ratio and inflammatory parameters were similar in all groups.
Total length of stay (LOS) was similar for groups B, C and D, but shorter for group A (22 vs 18d, p=.023). Oxygen need was also shorter in group A compared to groups B and C (p<0.0000002384). Effective sputum induction was noted in both groups but earlier in group A (22 vs 18d, p=0.023). Oxygen need and fever resolved earlier after intervention in group C than in group B (3 vs 8d, p=0.009 and 1 vs 6d, p=0.04, resp). Time to drain removal, LOS and duration of antibiotic treatment after intervention (3 vs 6d, p<0.001; 11 vs 18d, p=0.004, and 10 vs 18d, p=0.001) were shorter in group C than in group B. ICU stay after intervention was similar in the 3 groups.
Conclusions: VATS is a good treatment option for PDI in children with PPE. Clinical improvement was faster with VATS than with PDI, indicating that early performed VATS might shorten LOS and duration of antibiotic treatment.

P4118 Cyst hydatid patients in a pediatric pulmonology department in Turkey

Cystic hydatid patients in a pediatric pulmonology department in Turkey

P4119 Adjunct treatment of pneumonia in children 6-18 years old using a hand held sputum induction device
Mary Aimee Uson1, Anjanette De Leon1, Bobby Balet1, Leslie Mac Domagas2, Joyce Raymond Punzalan1, 1Department of Pediatrics, Our Lady of Lourdes Hospital, Manila, Philippines; 2Department of Pediatrics, Our Lady of Lourdes Hospital, Manila, Philippines.

Pneumonia is consistently a leading cause of mortality and morbidity in the Philip-pines; treatment is mainly antimicrobial. Lung Flute is a safe, hand held device that helps effective induction of sputum. The objective of this study is to assess the effectiveness of Lung Flute in sputum induction for relief of cough in children 6-18 years old admitted for Pediatric Community Acquired Pneumonia (PCAP). PCAP B and PCAP C. Children ages 6-18 years old admitted with a diagnosis of PCAP B or PCAP C were included. Patients diagnosed with PCAP A, PCAP D and hyperreactive airway were excluded. Each subject was enrolled to Lung Flute group or Control group by systematic randomization. Patients in the Lung Flute group used Lung Flute 3x a day in addition to the treatment provided by the physician. Pretested questionnaire on cough was answered by both groups. McNemar test was used. Of the 35 subjects (CI 80.0%, alpha error 0.05), there were more males than females (27:8 yrs of age). Majority admitted were diagnosed with PCAP B in Lung Flute group (73.4%) and Control group (85%). There was significant decrease in the frequency of cough on Day 2 (p value 0.048954) and significant improvement on the quality of cough on Day 2 (p value 0.002627) and Day 3 (p value 0.02961). Significant improvement on the quality of life on Day 1 and Day 2 was seen (p value 0.0008483, p value 0.002, p value 0.0000002384). Effective sputum induction was noted in both groups but earlier improvement was seen in the Lung Flute group. Lung Flute is an effective device in sputum induction and may someday be used as adjunct treatment of pneumonia.

P4120 Clinical characteristics of pediatric patients affected with human Metapneumovirus who needed hospital admittance in the western region of Guatemala
Mary Allen Uesugi1, Carmen Castilla2, Fabiola Moscoso2, Mario Mejia1. 1Department of Pediatrics, Hospital Regional de Occidente, Quetzaltenango, Guatemala; 2Central America and Panama Emergent Diseases Surveillance Program, Hospital Regional de Occidente -CDC/IDR, Guatemala, Guatemala.

Introduction: Human Metapneumovirus (hMPV) was described for the first time in 2001 by van den Hoogen et al. as a cause of bronchiolitis in children, although a world spread pattern, very little is known about its epidemiological behavior in latinamerican countries.
Aim: To review the clinical characteristics of children who needed admission to our hospital due to a respiratory infection caused by hMPV.
Methods: We included in this review all pediatric patients admitted during 2010 & 2011 suffering from a viral respiratory tract infection, and had a polymerase chain reaction positive to hMPV in a nasopharyngeal aspirate, sent to the CDC in the US, for its accurate classification.
Results: We reviewed 102 clinical files. 56 were female, mean age 16 months. Three symptoms were predominant in these patients: fever (n=89), cough (n=86) and respiratory distress (n=57). An alveolar radiological pattern on chest X-rays was seen in 57% of the cases. White blood cell counts were normal although a discrete neutrophilia was observed in most cases. C reactive protein mean value 27 mg/dl. None required mechanical ventilation. Mean time hospitalization was 7.4 days. There was no mortality reported in all cases. During the year 2011, no hMPV infection was recorded, despite an intensive epidemiological surveillance.
Conclusions: hMPV is still an important cause of respiratory infection in children. Even though, during this review the mortality rate was null. It called our attention the bi annual pattern of appearance of this virus, because we did not record any...
Acute lower respiratory tract infection and vitamin D status in children

Ayse Tana Aslan 1, Tugba Eyuboglu 1, Ouzan Gulbahar 2, Cecili Orkan 1

1 Pediatric Pulmonology, Gazi University, Ankara, Turkey; 2 Biochemistry, Gazi University, Ankara, Turkey; 3 Public Health, Gazi University, Ankara, Turkey

Childhood acute lower respiratory infection (ALRI) is one of the most common reasons for morbidity and mortality especially in developing countries. Predisposing factors include season, nutrition, suboptimal immunization, lower socioeconomic status, prematurity, underlying disease, tobacco exposure and vitamin D deficiency. Vitamin D deficiency is defined as 25(OH)D < 20 ng/ml, whereas vitamin D insufficiency is defined as 25(OH)D 21-30 ng/ml. In a study in Turkey the incidence of vitamin D deficiency in children was found 8% and insufficiency 25.5%.

In this study we aimed to describe vit D status in children with lower respiratory infection. Between November 2010 and February 2011 63 children with acute lower respiratory infection between 0.5-5 years of age and 59 age matched children without respiratory symptoms were enrolled in the study. Both study and control groups received vitamin D prophylaxis for one year and they have no predisposing factors for ALRI. Vitamin D status of children with acute lower infection (mean 34.9 ng/ml) were compared with children without ALRI (mean 37.2 ng/ml). No difference was found between the patient and the control group (p=0.38). In the patient group 17 patients diagnosed to have ALRI again after February 2011 – after one year period. In terms of ALRI recurrence, statistically significant difference was found between vitamin D status normal and insufficiency patients (p= 0.003).

In conclusion although there was no association between vitamin D status and childhood ALRI, significant association was found between vitamin D status and ALRI recurrence. Larger serial studies are needed for precise results.

Mycoplasma pneumoniae infection affects total eosinophil count, the serum level of ECP, and interleukin-5 in atopic children

Jae-Won Oh, Joo-Hwa Kim, Ha-Baik Lee. Pediatrics, Hanyang University Guri Hospital, Guri, Kyunggi-do, Republic of Korea

Background: A number of studies have outlined mechanisms by which mycoplasma infection may promote allergic lung inflammation. In addition, there is increasing evidence from human studies suggesting that mycoplasma infection contributes to asthma exacerbations, and severity with the change of cytokines. The present study evaluated the change of serum levels of eosinophil count, eosinophil cationic protein, and interleukin-5 in atopic children with Mycoplasma pneumoniae infection.

Method: We recruited 137 children including 44 atopic children with mycoplasma pneumonia (Group 1), 34 non-atopic children with mycoplasma pneumonia (Group 2), 25 children with viral pneumonia (group 3), 34 non-atopic children with viral pneumonia with mycoplasma infection (Group 4). The change of total eosinophil count, serum levels of interleukin (IL)-5, eosinophil cationic protein were measured at admission and at recovery for each group by using commercial ELISA.

Results: The serum level of IL-5 at admission was increased at recovery in group 1 (114±51.1 pg/ml at admission, 143±26.5±68.4 pg/ml at recovery). However, Buserum eosinophil cationic protein concentrations were increased at clinical recovery compared to the mean serum concentration at admission (49.5 pg/ml at admission, 37.9 pg/ml at recovery in group 1; 38.2 pg/ml at admission, 27.8 pg/ml at recovery).

Conclusion: The outcomes of the present study implied changes of eosinophil and its mediators during Mycoplasma pneumonia infection may be associated with the mechanism by which the Mycoplasma pneumoniae contribute to the development of airway hyperresponsiveness.

Is there a delay in diagnosis of post infectious obliterative bronchiolitis (PBO)?

Sonal Kansara 1, Harish Vyas 2,3, Alan Smyth 1, John Somers 1, Jayesh Bhat 1

1 Paediatric Respiratory Medicine, Nottingham University Hospitals NHS Trust, Nottingham, Nottinghamshire, United Kingdom; 2 Department of Child Health, University of Nottingham, Nottinghamshire, United Kingdom; 3 Department of Radiology, Nottingham University Hospitals NHS Trust, Nottingham, Nottinghamshire, United Kingdom

Background: PBO, or an orphan lung disease results following an antecedent severe viral or lower respiratory tract infection (LRTI), commonly due to adenovirus. The clinical symptoms of PBO are non-specific. This may result in a significant delay in diagnosis.

Methods: We retrospectively examined the medical records of children with PBO to determine the time from initial illness to diagnosis based on clinical and radiological criteria as follows:

1. History of antecedent viral LRTI
2. Evidence of airway obstruction (clinical or spirometry)
3. Radiological investigations consistent with PBO

Results: Of the nine cases identified over last 17 years, adenovirus was the main organism implicated in the initial infection in keeping with description in literature. Common referrals were for difficult or severe wheeze, exercise limitation, recurrent respiratory infections or bronchiectasis. The diagnosis was made earlier in children who had a persistent oxygen requirement or were admitted under the care of respiratory paediatricians.

Conclusions: There is a significant delay in diagnosis of PBO in our experience. Severe LRTI especially with adenovirus and a prolonged oxygen requirement at initial presentation followed by persistent respiratory symptoms should prompt further investigations Confirmation of the diagnosis leads to better understanding of the disease for the child with the opportunity to network with other children with rare diseases, could lead to potentially disease modifying treatment like Azithromycin and avoid unnecessary treatment for asthma.

Pneumatoceles that required surgery in childhood: Report of 2 cases

V. Rozalia, Dimos Gidaris, Fotios Maris, Sofia Ioannidou, Dimitra Tzavella. 1st Pediatric Department, Aristotle University, Thessaloniki, Greece

Pneumatoceles are thin-walled filled with air cystic lesions that have been recognized as a potential complication of pneumonia. Although, they are usually asymptomatic, they may enlarge and compress the adjacent lung and mediastinum. The aim of this report is to describe 2 cases of severe pneumonia complicated by pneumatoceles that required surgical intervention.

Case 1
A one year old girl presented with a 2 day history of pyrexia. Radiological investigation revealed a right sided consolidation with pleural effusion. Pleural fluid culture revealed staphylococcus aureus. Antibiotic treatment and drainage failed and a CT scan on day 21 revealed an enlarging pneumatocele on the right causing mediastinal shift. The child developed acute respiratory failure; Successful decompression of the pneumatocele was achieved after initial urgent needle aspiration. Radiologic resolution was complete 2 months post initial presentation.

Case 2
A previously healthy 8 month old boy was admitted to our institution with a tension pneumatocele following a severe necrotic pneumonia. Blood culture was positive for Pneumococcus type 3F. On auscultation there was dramatically decreased air entry on the left side. CXR and CT revealed hyperinflation,large air cyst causing mediastinal shift to the right. Conservative management was initially attempted, but when oxygen saturation decreased dramatically surgical excision (pneumonectomy) was decided. The patient is now asymptomatic 2 months post discharge.

Conclusions: Tension pneumatoceles, although rare, are a serious complication of pneumonia that may need surgical intervention when the patient is in critical condition.

414. Issues in neonatal and paediatric intensive care

Educating fellows in CanMEDS physician roles via a quality improvement-based curriculum

William Canny, Christopher Colby. Division of Neonatal Medicine, Mayo Clinic, Rochester, MN, United States

Background: Of the many CanMEDS physician roles that have been adopted by European medical educators, evidence suggests that several may be particularly challenging to teach and assess, namely: Health Advocate, Collaborator, Scholar and Manager.

Objective: Since Quality Improvement (QI) activities have been shown to provide medical residents a means by which to learn skills relevant to the above CanMEDS roles, we sought to determine whether a QI-based curriculum would afford our fellows a robust, level-appropriate and assessable learning experience.

Methods: Our fellows participated in our division-level program of continuous quality improvement. In doing so, they learned and applied QI principles as they developed an evidence-based respiratory treatment protocol (RTP) intended to reduce the incidence of chronic lung disease (CLD) among neonates born at <29 weeks gestation. To assess fellow competence in CanMEDS roles, the fellowship program directors maintained educational portfolios for each fellow, including self-reflections, competency-based evaluations and evidence of scholarship.

Results: Our fellows successfully implemented their RTP, then collected, analyzed
and reported outcomes data to division leadership. Our fellows’ RTP reduced the incidence of CLD nearly 50% within one year, results they have presented at
Board of Pediatrics.

**Conclusion:**
We developed a disease-specific instrument to measure HRQL in children with BPD aged 4 to 8 years old. The clinical impact method and item analysis were used to reduce items.

**Results:**
51 children participated in the study: 20 in item generation and 31 in item reduction. 130 items were identified. With the clinical impact method 53 items with an overall importance (OI) > 0.75 were selected. Three items with highest OI were ‘easily distracted’ (2.52), ‘having a cold for longer period of time’ (2.39) and ‘coughing’ (2.39). After item analysis, 47 items remained in the questionnaire.

**Conclusion:**
This is the first time the development of a disease-specific instrument to measure HRQL in BPD has been undertaken. The items in the developed questionnaire have clinical impact. The next step will be to determine validity of these items.

**P4129**
Development of a quality of life instrument for children with bronchopulmonary dysplasia

Lysbert Schaan 1, Bertine M.J. Flokstra-de Blok 2, Jet van der Hulst 3, Anthony J.T. Dabous 1, Elianne J.E. Vlietstra 4

**Introduction:**
Bronchopulmonary dysplasia (BPD) is a common complication of premature birth. It is associated with prolonged hospitalization, long-term pulmonary morbidity and an increased risk for adverse neurodevelopmental outcome. The impact of these complications on health-related quality of life (HRQL) is not known because there is no disease-specific instrument to measure HRQL available.

**Aim:**
To develop a disease-specific questionnaire to measure HRQL in children with BPD aged 4 to 8 years old.

**Methods:**
Participants: children aged 4 to 8 years old with BPD. The first steps in the development of a HRQL instrument are item generation and item reduction.

Sources for item generation were literature, expert opinion and parents of participants. For item reduction, parents indicated how much the items affected the HRQL of their child. The clinical impact method and item analysis were used to reduce items.

**Results:**
51 children participated in the study: 20 in item generation and 31 in item reduction. 130 items were identified. With the clinical impact method 53 items with an overall importance (OI) > 0.75 were selected. Three items with highest OI were ‘easily distracted’ (2.52), ‘having a cold for longer period of time’ (2.39) and ‘coughing’ (2.39). After item analysis, 47 items remained in the questionnaire.

**Conclusion:**
This is the first time the development of a disease-specific instrument to measure HRQL in BPD has been undertaken. The items in the developed questionnaire have clinical impact. The next step will be to determine validity of these items.
prospectively defined a hypoxic episode as three consecutive measurements (at 0, 15, and 30 minutes) of \( O_2 \) sat >92%, the upper limit of the RTP. During E1 and E2, \( O_2 \) sats 92% were detected manually by the bedside nurses. During E3, the DST analyzed clinical data and automatically notified the charge nurse of a patient’s hypoxic episode. We retrospectively compared the rate of hypoxic episodes of each epoch, using the Chi-squared test to determine statistical significance.

**Results:** Neonates treated during E3 experienced fewer hypoxic episodes than those treated during E2 (17 v. 24 episodes per 1000 \( O_2 \) sat measurements; p < 0.0001). These rates were lower than that of E1 (41 episodes per 1000 \( O_2 \) sat measurements; p < 0.0001).

**Conclusion:** Use of a DST was associated with less frequent episodes of hypoxia among premature neonates and seemed to enhance the efficacy of a respiratory treatment protocol.

**P4131**

**G-CSF administration improves chronic lung disease caused by exposure to high-concentration oxygen in neonatal mice**

*Kamal Ali, Takeshi Arimitsu, Yohei Matsuzaki, Kazushige Ikeda. Pediatrics, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan*

**Background:** Chronic lung disease (CLD) is a condition that results from the inflammation-induced destruction and developmental arrest of the lungs of premature infants. To date, there is no effective treatment for CLD. Hematopoietic stem cells have been reported to differentiate into pulmonary type II epithelial cells. It is known that G-CSF acts on hematopoietic stem cells to mobilize them in the peripheral blood. It has also been reported that G-CSF exerts anti-inflammatory effects. In this study, we investigated whether G-CSF administration could improve a mouse model of CLD caused by exposure to high-concentration oxygen.

**Methods:** Neonatal mice within 24 hours after birth were placed in 80% oxygen or room air for 21 days. From day 23, pups were administered 0.5 microgram/g of G-CSF or saline for 5 days. The lungs were removed in postnatal week 6, and lung sections were stained with HE and Masson’s trichrome and immunostained for PCNA and α-SMA for histology.

**Results:** Compared with the control groups, the oxygen-exposed groups showed a similar morphological change. The oxygen-exposed, saline administered group showed a significantly improvement in pulmonary epithysma than the oxygen-exposed, saline administered group. There were no significant differences in staining with Masson’s trichrome nor immunostaining for PCNA and α-SMA.

**Discussion:** G-CSF administration significantly improved a mouse model of CLD. It is unclear whether G-CSF-mobilized peripheral blood stem cells differentiated into pulmonary epithelial cells, whether G-CSF induced the proliferation and differentiation of type II epithelial cells, or whether G-CSF exerted anti-inflammatory effects.

**P4132**

**Gestation at delivery and outcome in CDH infants following fetoscopic tracheal occlusion**

*Kanam H6, Dionysios Grigoratos1, Victoria Cornelius2, Kypros Nicolaides3, Takeshi Arimitsu, Yohei Matsuzaki, Kazushige Ikeda.*

**Background:** Newborns with congenital diaphragmatic hernia (CDH) suffer substantial morbidity and mortality. In non-randomised studies, fetal endoscopic tracheal occlusion (FETO) was shown to reduce the duration of mechanical ventilation, use of high frequency oscillation (HFO) ventilator and survival to discharge was lower (18% versus 82%, p = 0.011). The preferred intervention for infants born with the Pierre Robin Sequence (PRS). It is the preferred intervention for infants referred to our institution for respiratory assessment.

**Aim:** To determine if timing of 1st NPA insertion affects duration of hospitalization for infants with PRS referred to RGHSC.

**Methods:** A retrospective case note review of the management of infants referred to RGHSC with PRS from Oct 2009-Oct 2011 was performed.

**Results:** 12 infants were included in this study. 7/12 infants were successfully discharged with NPA support. In 57 infants 1st NPA was inserted within 48hrs of admission and discharge occurred at a median of 15 days. In the other 2 infants, NPA was not inserted until day 6 & 10 of admission respectively. Only these 2 infants required nasaogastic feeding on discharge. Parental training commenced on average 5 days later and these infants required up to a week longer in hospital. These delays did not however, impact on the timing of eventual cleft surgery. 3/12 infants were preterm and could not be managed initially with NPA due to small size. These infants all required a period of non-invasive ventilation and also had a longer hospital stay.

**Conclusions:** Our results suggest that delayed insertion of NPA in infants with PRS may result in later establishment of oral feeding and prolonged hospitalization. NPA insertion within 48hrs of admission is suggested as optimum. Preterm infants are also considered as requiring a longer hospital stay with an alternative approach to airway management.

**P4134**

**Respiratory dead space but not neonatal lung disease is associated with lung clearance index in preterm neonates**

*Kazuhiko Hashizume1, Philip Latzin2, Jane Pillow3, Cindy Thoman2, Urs Frey2, Sven Schulze4, 5, 6, 7, 8, 9. 1Department of Neonatology, University Children’s Hospital, Basel, Switzerland; 2Division of Respiratory Medicine, Department of Paediatrics, Inselplatz, University of Bern, Switzerland; 3Centre for Neonatal Research and Education, University of Western Australia, Perth, Australia*

**Background:** Neonatal lung disease (NLD), gestational age per se (GA) and breathing pattern may influence gas mixing efficiency in neonates.

**Aim:** To assess the effect of NLD, GA and breathing pattern on the lung clearance index (LCI) in preterm and term neonates.

**Methods:** 236 preterm (GA 23-36 w) and 232 term healthy control infants from two centres (Berne and Perth) were studied at a mean (standard deviation) postmenstrual age of 43.4 ± 3.5 in quiet unsedated sleep using multiple breath washout (MBW) with 4% sulphur hexafluoride and a mainstream ultrasonic flowmeter (Spironos Exhalzner D, Ecomedics AG, Duernen, CH). Functional residual capacity (FRC) and LCI were calculated from the washout trace. Tidal volume (VT), respiratory rate (RR) and respiratory dead space (Vd) estimated from the mole mass signal were calculated during 30 s of tidal breathing prior to MBW. We used multivariable linear regression to analyse outcomes.

**Results:** Only RR (R²=0.04, p<0.001) and Vd/Vt (R²=0.16, p<0.001) were positively associated with LCI. No other factors including presence of bronchopulmonary dysplasia, days of supplemental oxygen, GA, body size and body proportions at birth and at test were significantly related to LCI. After adjusting for Vd/Vt, RR was no longer significantly associated with LCI.

**Conclusions:** Vd/Vt is associated with LCI in preterm neonates and should be considered as a relevant factor when assessing and interpreting LCI in infants. The effect size of this association is moderate.

**P4135**

**Effect of the level of volume-targeted ventilation on the spontaneous respiratory activity of infants born at term**

*Olie Chowdhury, James Perera, Silke Lee, Simon Hannam, Gerrard Rafferty, Anne Greensough.*

Division of Asthma, Allergy and Lung Biology, King’s College London, United Kingdom.

Premature-born infants frequently breathe while being mechanically ventilated. The pattern of their respiratory efforts with ventilator inflation influences outcome, in particular active expiration leading to pneumothorax.

**Aim:** To compare patient-ventilator interactions in infants born at term at different levels of volume-targeting (VT).

**Methods:** 15 infants, median gestational age 38 (range 34-41) weeks were studied at a median postnatal age of five days. The infants were studied at VT levels of 4 and 6 ml/kg, applied in random order. Five infants were on conventional ventilation (CMV) and 10 on triggered ventilation (PVT). Oesophageal, gastric and airway pressures, flow and volume were simultaneously recorded for at least five minutes at each VT level; 50 consecutive breaths were analysed at each VT level.

**Results:** In the infants studied on CMV, active expiration was more common at
a VT level of 4 ml/kg than at VT levels of 0 and 6 ml/kg (p=0.0001), whereas in infants on PTV, active expiration was significantly lower at 4 ml/kg than at VT levels of 0 and 6 ml/kg (p=0.0001) (Table). At each VT level, the occurrence of active expiration differed significantly between ventilator modes.

Data are presented as % of inflations associated with active expiration.

Conclusion: The underlying mode of ventilation significantly influences whether low compared to higher levels of volume targeting will increase active expiration.

P4136
Optimal PEEP in the first week of life in mechanically ventilated extremely preterm newborn infants: Clinical setting vs. optimal setting as registered by forced oscillation technique (FOT)
Chiara Veneroni1, Linda Wallström1, Emanuela Zannin2, Raffaele Dellacà1, Richard Sindelar2, 1Dipartimento di Bioingegneria, Politecnico di Milano University, Milano, Italy; 2Department of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden

Recently it has been shown that the use of forced oscillation technique (FOT) allows identifying an optimal open-lung PEEP minimizing mechanical stress to the lungs (Kostic P, Crit Care. 2011).

The aim of this study is to characterize the optimal mechanical PEEP settings in the first week of life in mechanically ventilated preterm newborns and to compare it to the PEEP set by current clinical approach.

Four preterm newborns (GA=23-27wks, BW=679-946g) were studied at the first, third and seventh day of life. PEEP was increased by 2cmH2O above the clinically set PEEP and then decreased by four 5-minute steps of 1cmH2O. For each step the total respiratory input reactance (Xrs) at 10Hz was measured at end-expiration by sinusoidal FOT. The optimal mechanical PEEP was defined as the PEEP at which the maximum of Xrs was reached (Dellacà’, Int Care Med, 2011).

Mean±SD values of the clinically set PEEPs and the mechanically optimal PEEPs are shown in the figure.

The higher inter-subject and day-by-day variability of the mechanically optimal PEEP suggests that FOT could help in fine tuning PEEP settings related to the lung mechanical changes over time in each patient. Future studies will be address whether setting the mechanically optimal PEEP could be beneficial from a clinical point of view.

P4137
Computerized quantification of wheezing in neonates: Relationship with conventional lung function parameters
Hendrik Fischer, Silke Wiltzki, Hans Proquitté, Charles Roehr, Gerd Schmalsch. Dept. of Neonatology, Charité University Medicine, Berlin, Germany

Objective: Computerized respiratory sound analysis has been used to evaluate wheeze in infants, but it is not known whether the acoustic detection of wheeze is associated with impaired lung function. The present study aimed to investigate the relationship between wheeze detection and conventional parameters of lung function testing (LFT).

Methods: Computerized lung sound analysis with quantification of wheezing (PulmoTrack®) was performed in 78 neonates at a median (IQR) postmenstrual age of 48 (44-59) weeks and a body weight of 4818 (3835-6140) g. In the same session, LFT was performed which included bodyplethysmography, tidal breathing measurements, SF6 multiple breath washout, measurement of respiratory mechanics by the occlusion test, forced expiratory flow (V’maxFRC) by rapid thoracobulbinal compression and capillary blood gas analysis.

Results: Wheezing >5% of the breathing cycle was detected in 41/78 (53%) infants, 18/78 (23%) had inspiratory and 29/78 (37%) expiratory wheezing. Infants with and without wheezing did not significantly differ in postmenstrual age and body weight. Inspiratory wheezing had no relationship with LFT parameters. In contrast, infants with expiratory wheezing had significant changes in their breathing pattern and respiratory mechanics with increased iTEF/TE (p=0.034), end-expiratory flow (TEF10, p=0.027), airway resistance (p=0.005) and respiratory resistance (p=0.036).

Conclusion: Computerized wheeze detection is easy to perform in unsedated infants during natural sleep and may help to identify infants at risk of obstructive airway disease.

P4138
HRVC is the commonest rhinovirus group detected in children admitted to a paediatric intensive care unit with respiratory illnesses
Desmond Cua1,2, Khoo Siew-Kim2,3, Zhang Guicheng3, Lindsay Katie4, Geoff Knight5, Anthony Keil5, Jack Goldblatt5, Ingrid Laing5, Joeleen Bizinotto5,6, Peter Le Souef7,8. Respiratory Medicine, Princess Margaret Hospital, Perth, WA, Australia; 2School of Paediatrics and Child Health, University of Western Australia, Perth, WA, Australia; 3Telethon Institute for Child Health Research, Centre for Child Health Research, University of Western Australia, Perth, WA, Australia; 5Microbiology, Princess Margaret Hospital, Perth, WA, Australia; 6Paediatric Intensive Care Medicine, Princess Margaret Hospital, Perth, WA, Australia

Introduction: Respiratory viruses account for a significant proportion of acute admissions to the paediatric intensive care unit (PICU). Acute respiratory illnesses (ARI) represent 10-15% of all admissions to PICU. Recent studies have shown that human rhinovirus (HRV) was the most frequent virus detected in severe cases of ARI admitted to a PICU. There has been no study to date examining the prevalence of HRV groups (including the newly discovered HRVC group) in children admitted to a PICU.

Aim: The aim of this study was to determine the prevalence of different HRV groups in children with respiratory illnesses admitted to a tertiary PICU.

Methods: Nasopharyngeal aspirates (NPA) and clinical information were obtained from children admitted with respiratory illnesses to PICU between March 2009 and July 2011. RNA was extracted from NPA, and reverse transcribed. From cDNA, a 2-step PCR of the HRV 5’NCR was used for HRV detection, and sequencing for typing.

Results: NPA from 229 children admitted to PICU were analysed. HRV was the commonest virus, being present in 93 (40.6%) samples examined, followed by respiratory syncytial virus (RSV) which was identified in 50 (21.8%) samples. Of the 77 NPA available for HRV typing, HRV was found to be the commonest HRV group detected, representing 42 (54.5%) of the samples identified. HRV groups was found in 32 (41.5%) and HRVB in 3 (4%) of the samples analysed.

Conclusions: This study demonstrated that HRV is the commonest virus identified in children admitted to a tertiary PICU with a respiratory illness. In addition, HRVC was the commonest HRV group detected across all respiratory illness.

P4139
Use of high flow nasal oxygen (HFNO) for bronchiolitis in a general paediatric ward: Preliminary experiences
Maggie Hutton, Gerhard Millen, Chetna Kalapulla, Tina Niran. Paediatrics, Heart of England Foundation Trust, Birmingham, United Kingdom

Background: Viral bronchiolitis is a leading cause of hospitalisation. Interventions to reduce morbidity are challenging. We evaluated HFNO in infants with acute bronchiolitis on a general paediatric ward. Previous HFNO experience has been in a PICU or HDU settings.

Aim: To assess responses to HFNO in previously well children and in those with underlying co morbidity.

Methods: Prospective study between November 2011 and February 2012. Inclusion criteria were patients needing >30% FiO2 or a RR(respiratory rate)>60/minute.

Results: Nine previously well infants, mean age 40 days (range 10-120 days) were commenced on HFNO. Mean RR and pulse rate prior to initiating HFNO was 73 and 146 respectively. Mean oxygen requirement was 37%. 5 patients had observations done before 2 hours and then between 2-4 hours. A reduction in mean RR to 54 at 2 hours and 47 at 4 hours was observed. The mean pulse rate reduced to 132 and 102. Mean oxygen requirement was higher at 2 hours (43%) but reduced at 4 hours (32%). No significant change in blood gases noted. 8 children responded well to HFNO. One patient required nasal CPAP.

Five children with underlying co morbidities and acute bronchiolitis were started on HFNO. These children were older, mean age 270 days (range 60-630). Of these 5, 3 deteriorated on HFNO and required escalating interventions.

Conclusion: In previously well infants with bronchiolitis, HFNO is safe in a general paediatric ward setting and offers clinical benefits within 2-4 hours. Children with underlying disorders may not respond as well and if no improvement is seen within 4 hours, stepping up treatment may be desirable.

The evaluation of lung function measured by impulse oscillometry method in very low birth weight born children at preschool age
Meral Ozer1, Ayse Gunfener2, Zeynep Seda Uyan1, Ayse Sevim Gokalp1, Nazan Kavas1, Gulcan Turker1, Ayse Engin Arisoy1, 1Neonatology, Kocaeli University, Kocaeli, Turkey; 2Pediatric Pulmonology, Kocaeli University, Kocaeli, Turkey.

Introduction: Chronic lung disease is one of the most important complications of prematurity and results in short and long-term morbidity. Survival of more prematurely born babies leads to an increase in the incidence of bronchopulmonary dysplasia (BPD).

Aim: To evaluate the lung function of babies who were born under birth weight of 1500 grams using impulse oscillometry in preschool age.

Methods: Eighty-six children who were 3-6 years old and followed in our neonatology clinic (born under birth weight of 1500 grams) were enrolled in the study as the patient group and 40 term-born healthy children as the control group. The demographic data of the patients, duration of mechanical ventilation and oxygen therapy and presence of BPD were recorded. After routine physical examination, lung functions of children were measured by impulse oscillometry. The data were evaluated by SPSS 16 program.

Results: Forty-nine (57%) of 86 patients were non-BPD, 20 were mild BPD, 14 were moderate BPD and 3 were severe BPD. Weight and height of premature and control groups were similar. There was a statistically significant difference between the two groups in terms of resistance (R5,R10,R20), reactance (X5,X10,X20) and resonant frequency (fres). The airway resistance was significantly higher and reactance was significantly lower in the premature group. However, there was no difference between BPD and non-BPD groups.

Conclusion: Although premature babies can catch-up their peers at 3-4 years old in terms of their body percentiles, their lungs still reflect the traces of prematurity.

P4141
Effects of salbutamol therapy on pulmonary mechanics and chronic lung disease in very low birth weight infants
Oleksandr Marazlov1, Olga Yahlon1, Konstantin Bertsum2, Evgeniy Vzhetsotn2.
1Dipartment of Anatomy and Histology, Kharkiv Medical University, Kharkiv, Ukraine; 2Neonatal Intensive Care Unit, Vinitsa Children’s Regional Hospital, Vinitsa, Ukraine.

Background: To determine the changes in pulmonary mechanics before and during salbutamol therapy and to evaluate the effect of salbutamol on the duration of mechanical ventilation in very low birth weight (VLBW) ventilator-dependent infants.

Methods: A prospective single-centre trial was conducted. Forty-three patients (birth weight 600 to 1500 g, gestational age 24 to 32 weeks) who failed to be weaned from the respirator at 7 to 14 days of age were enrolled; 23 infants received a 7-day course of salbutamol (2.5 mg 4 times per day via nebulizer) and 20 patients were in the control group. A similar mean airway pressure (MAP) and fractional inspired oxygen concentration (FiO2), respiratory system mechanics (tidal volume (VT), respiratory compliance (Cr) and respiratory resistance (Rrs)) were measured before and on days 2, 5, and 7 of the study.

Results: There was a significant increase in Crs and VT in the salbutamol group as compared with the control group (P<0.001). No major changes in Res were observed. Salbutamol therapy significantly decreased FiO2 and MAP (P<0.001) and facilitated successful weaning from mechanical ventilation. In addition to a shorter duration of mechanical ventilation (P<0.01), the occurrence of CLD (FiO2 > 0.21 at 36 weeks of corrected gestational age, chest x-ray changes and Rrs changes) was significantly decreased in the salbutamol group (P<0.01).

Conclusions: Our study indicate that salbutamol therapy in VLBW infants significantly improves lung’s mechanics and facilitates extubation in infants and reduces the duration of mechanical ventilation and decreases CLD (at 28 days and 36 weeks) in a population of VLBW infants.

P4142
In vitro assessment of elastance unloading and work of breathing during proportional assist ventilation
Oli Chowdhury, Gerrard Rafferty, Simon Hannam, Stilke Lee, Anthony Milner, Anne Greenough. Division of Asthma, Allergy and Lung Biology, King’s College London, United Kingdom

Proportional assist ventilation (PAV) is a patient-triggered mode in which the elastic and resistive work of breathing (WOB) can be unloaded. The unloading level is set with the aim of achieving an optimal balance of the WOB between the ventilator and the patient. In vitro studies, however, have shown that during PAV, there are trigger delays and the pressure wave forms of the ventilator and lung models differ which may influence the relationship between the level of unloading and the WOB of the patient and ventilator.

Aim: To assess the WOB of the ventilator and a lung model with increasing amounts of elastance unloading.

Methods: A dynamic lung model, with a compliance of 0.4ml/cmH2O, was connected to a Stephanie ventilator in PAV mode. Elastance unloading was applied in stepwise increments and pressure, flow and tidal volume were recorded. Pressure-volume loops were constructed, from which the WOB was calculated for the ventilator and the lung model.

Results: The median tidal volume of breaths analysed was 3.75 (range 3.1 to 4.4) ml. As the elastance unloading was increased, the lung model showed a greater reduction in the elastic WOB than the increase of WOB of the ventilator.

The WOB in the lung model, however, was underestimated by the distortion of the inflation pressure waveform due to the trigger delay.

Conclusion: Although elastance unloading during PAV enables transfer of the WOB from the patient to ventilator, the infant has no support during the trigger delay, thus the benefit is over-estimated.

P4143
Changes in respiratory system reactance (Xrs) during the first lung volume recruitment in preterm lambs on high frequency oscillatory ventilation (HFOV)
Emanuela Zannin, Maria Natile, David Tingay, Peter Dargaville, Maria Laura Ventura, Elisabeth Perkins, Risha Bhatia, Paolo Tagliabue, Raffaele Dellacà. Dipartimento di Bioingegneria, Politecnico di Milano University, Milano, Italy

Neonatal Unit, MBBM Foundation, Monza, MB, Italy Department of Neonatology, Royal Children’s Hospital, Melbourne, Australia Newborn and Paediatric Intensive Care Unit, Royal Hobart Hospital, Hobart, Australia Neonatal Research, Murdoch Childrens Research Institute, Melbourne, Australia

The aim of this study was to assess the dynamic changes in respiratory mechanics during the first stepwise increase of mean airway pressure (MAP) in preterm lambs receiving HFOV. Six 132d preterm lambs were commenced on HFOV at MAP of 14 cmH2O and frequency (fosc) of 10Hz. Five min after birth MAP was increased up to 30 cmH2O in 2-min steps of 4 cmH2O. At the beginning (t0) and at the end (t1) of each step fosc was reduced to measure Xrs at 5Hz. Lung volume (VL) changes were simultaneously measured by electrical impedance tomography.

VL monotonically increased during the recruitment manoeuvre (RM). In average only the 22±2% (mean±SD) of the total change occurring at each step immediately followed the change in MAP, while the remaining 78±2% occurred over the next 2 min. Xrs at first decreased, then it increased over time stabilizing to a higher value compared with the lower MAP step.

Changes in respiratory system reactance (Xrs) during the first lung volume recruitment in preterm lambs on high frequency oscillatory ventilation (HFOV)
414. Assessment of physical activity, exercise, muscle function and clinical characteristics as outcomes in physiotherapy and rehabilitation

P4144

Adequate physical activity in students with and without asthma

Enini Grammatopoulou1,2, Emmanouil Skouflos1, Afroditi Evangelodimou1, Konstantinos Bartzikas1, Nektarios Staroup.1 Physical Therapy, Technological and Educational Institution, Athens, Greece; 2Physical Education and Sports Science, National and Kapodistrian University, Athens, Greece; 1Respiratory Medicine, General Hospital of 'Amalia Fleming’, Athens, Greece

Background: Early youth is decisive for the adoption of opinions concerning the physical activity which contributes to the decrease of death risk due to chronic diseases.

Aim: To examine differences in physical activities in young students with and without asthma.

Method: 578 Physical Therapy students in Athens, Greece, aged 18-30 (± 2.07) participated in the study. Adequate physical activity was assessed according the guidelines of the American Cardiology Association and the American College of Sports Medicine (yes-no). Differences in physical activity between students with and without asthma were examined through χ².

Result: 40% of the total sample reported diagnosed asthma. Adequate physical activity was stated by 40% of students with asthma and by 55.3% of students without asthma. No significant differences were found in physical activity between the two groups (p > 0.05). Students with asthma didn’t differ in physical activity regarding gender. BMI, sleep duration, alcohol consumption, income, and health-belief (p>0.05), while they differed as for smoking (p=0.018). Students without asthma didn’t differ (p > 0.05) in physical activity with regard to BMI, sleep duration, alcohol consumption smoking, income, and their health-belief, while they revealed differences as for sex (p>0.001).

Conclusion: The results of the present study in one hand are encouraging because students with asthma were as active as those without asthma, but in the other hand they are disappointing because both groups didn’t meet American guidelines for the adequate physical activity that have shown to contribute to chronic illnesses prevention.

P4145

Cardiorespiratory fitness, pulmonary function and C-reactive protein levels in adults with diabetes

Cristina Oliveira Francisco1, Anaparida Mara Cattai1, Silvia C.G. Moura1, Sergio L.B. Lopes1, Adriano M. Del Vale1, Angelo M.O. Leal2.1Physiology, Federal University of Sao Carlos, Brazil; 2Medicine, Federal University of Sao Carlos, SP, Brazil

Background/Aim: Diabetes Mellitus (DM) is associated with impairment of cardiopulmonary fitness and pulmonary function; increasing evidences have suggested that comorbidities and systemic inflammation may be involved. The objective of this study was evaluate changes in metabolic variables, C-reactive protein (CRP) levels, cardiopulmonary fitness and pulmonary function in DM patients compared with healthy subjects.

Methods: 19 men with diabetes (49.2±2 years) and 19 healthy control subjects (51.4±7 years) were studied. All subjects performed a spiroergometry and an incremental cardiopulmonary exercise test on a cycleergometer with electromagnetic breaking (workload increases, range 13-22W/min). Cardiopulmonary data were continuously collected with a metabolic unit. Heart rate (HR) was continuously monitored.

Results: See table 1.

Conclusion: The cardiopulmonary fitness is reduced in patients with diabetes but the spirometric values are preserved, and the CRP did not differ of the control subjects.

P4146

Respiratory function, functional capacity, and physical activity in patients with scleroderma

Ahmet Vardar-Yaghi1, Melda Saglam1, Ebru Calik1, Hulya Arikan1, Deniz Inal-Ince1, Sema Savci2, Ozge Ozalp1, Ali Askogan1, Mehmet Yokasghil2. 1Department of Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 2School of Physiotherapy and Rehabilitation, Dokuz Eylul University, Ankara, Turkey; 3Department of Internal Medicine, Rheumatology Unit, Hacettepe University, Faculty of Medicine, Ankara, Turkey.

Aim: Scleroderma is a chronic multisystem disease of unknown origin, characterized by fibrosis on the connective tissue of skin and internal organs. Because of pulmonary involvement, patients’ exercise tolerance is poor and functional capacity is impaired. The purpose of this study was to compare lung function, functional capacity, and physical activity, between patients with scleroderma and healthy controls.

Materials and methods: Ten scleroderma patients (9F, 1M, 53.3±9.4 years) and ten healthy controls (9F, 2M, 54.5±12.6 years) participated in the study. Pulmonary function test was performed using spirometry. Functional capacity was evaluated using six-minute walk test (6MWT). Heart rate, oxygen saturation, dyspnea and fatigue perception using modified Borg Scale was recorded before and after the test. Subject’s physical activity level was assessed using the International Physical Activity Questionnaire (IPAQ).

Results: All scleroderma patients involved in this study had preterminal lung involvement. The FEV1, FEF25-75%, and 6MWT distance were significantly lower in patients with scleroderma (p<0.05). The %6MWT distance of the patients was 64.5±22.3%. Oxygen desaturation, dyspnea and fatigue perception at the end of 6MWT were significantly higher in patients with scleroderma as compared with the healthy controls (p<0.05). The IPAQ moderate physical activity score and IPAQ total score were significantly lower in patients with scleroderma (p<0.05).

Conclusions: Lung function, functional exercise capacity, and physical activity level are adversely affected in patients with scleroderma. Exercise training programs may be useful in scleroderma patients.

P4147

Effects of exacerbation risk on symptoms and clinical characteristics in patients with bronchiectasis

Ozge Ozalp1, Naciye Vardar-Yaghi1, Ebru Calik1, Naciye Vardar-Yaghi1, Melda Saglam1, Sema Savci1, Hulya Arikan1, Meral Bosnak-Guclu1, Lutfi Coplu1. 1Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 2School of Physical Therapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey; 3Physiotherapy and Rehabilitation, Gazi University, Faculty of Health Sciences, Ankara, Turkey; 4Chest Medicine, Hacettepe University, Faculty of Medicine, Ankara, Turkey.

Aim: Exacerbations may deteriorate symptoms and clinical features in patients with bronchiectasis. The purpose of this study was to investigate effects of exacerbation risk on muscle strength, exercise capacity, dyspnea, fatigue, and quality of life in patients with bronchiectasis.

Methods: Fifteen low risk patients (0 exacerbation per year) and 15 high risk patients (>1 exacerbation per year) participated in this study. Lung function, quadriceps muscle strength (hand held dynamometer), dyspnea (modified Medical Research Council dyspnea scale, MRC), fatigue (Fatigue Severity Scale, FSS), exercise capacity (six-minute walk test, 6MWT), and cough specific (Leicester Cough Questionnaire, LCQ) and general (Nottingham Health Profile, NHP) were determined.

Results: No significant difference was found in lung function between the groups (p>0.05). Number of females was significantly higher in high risk group as compared to low risk group (p<0.05). Quadriceps muscle strength, 6MWT distance, and LCQ physical score were significantly lower; and MRC, FSS score, and NHP energy, emotional reactions, pain, physical mobility, and total scores were significantly higher in high risk bronchiectasis patients than those of low risk patients (p<0.05).

Conclusion: High risk of having exacerbations adversely affects quadriceps strength; exercise capacity, dyspnea and fatigue perception, and cough specific and general health in patients with bronchiectasis. Number of exacerbations in the previous year may be a determinant of characteristics and function in bronchiectasis.
P4148 Comparison of functional capacity, muscle strength, body composition in patients with cystic fibrosis, non-cystic bronchiectasis and healthy controls
Meri Rostam-Gechi1, Melia Saglam1, Zeynep Ariba1, Sema Savci1, Deniz Inal-Ince2, Hulya Arikran1, Ebru Yalcin3, Ugur Oczelik2, 1Department of Physiotherapy and Rehabilitation, Gaziantep University, Faculty of Health Sciences, Ankara, Turkey; 2Department of Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 3School of Physiotherapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey; 4Department of Pediatric Pulmonology, Hacettepe University, Iscan Dogramaci Children’s Hospital, Ankara, Turkey

Aim: We aimed to compare functional capacity, respiratory and peripheral muscle strength, and body composition in patients with cystic fibrosis, non-cystic bronchiectasis and healthy controls.

Methods: 43 with bronchiectasis, 36 patients with cystic fibrosis, and 35 age-sex matched controls were included. Body composition was evaluated using bioelectrical impedance analysis. Pulmonary function test was performed. Respiratory muscle strength (MIP and MEP) was evaluated using a mouth pressure device, quadriceps muscle strength using a dynamometer, functional capacity using six-minute walk test (6MWT).

Results: The weight, height, body mass index (BMI), and fat free mass, pulmonary functions, MIP and MEP, quadriceps muscle strength, 6MWT distance, were significantly lower in patients with bronchiectasis and cystic fibrosis compared with healthy controls (p<0.05). 24 patients (56%) with bronchiectasis, 23 (64%) patients with cystic fibrosis had malnutrition. 12 (28%) bronchiectasis, 16 (44%) cystic fibrosis patients’ MIP were weaker than 95%CI (80-150 cmH2O) of the controls. 8 (19%) bronchiectasis, 8 (22%) cystic fibrosis patients’ 6MWT distance were shorter than 95%CI (576-871 m) of the controls. 9 (21%) bronchiectasis, 7 (19%) cystic fibrosis patients’ quadriceps muscles were weaker than 95%CI (160-500 N) of the controls.

Conclusion: Body composition, pulmonary function, respiratory and peripheral muscle strength and functional capacity are impaired in bronchiectasis and cystic fibrosis patients. Malnutrition may lead these impairments. Pulmonary rehabilitation programs should be adjusted to improve these outcomes.

P4149 Periperal and respiratory muscle strength in pulmonary artery hypertension
Melia Saglam1, Naciye Vardar-Yaghi1, Ebru Calik1, Hulya Arikran1, Sema Savci1, Deniz Inal-Ince2, Ozge Ozalp3, Ali Akdogan1, Mehmet Yokusoglu4, Lale Tokgoren4, 1Department of Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 2School of Physiotherapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey; 3Department of Internal Medicine, Rheumatology Unit, Hacettepe University Faculty of Medicine, Ankara, Turkey; 4Department of Cardiology, Gulhane Military Medical Academy, Ankara, Turkey; 5Department of Cardiology, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Background and aim: Pulmonary arterial hypertension (PAH) is a rare pulmonary vascular disease characterized by increased pulmonary arterial pressure. The PAH patients experience dyspnea and fatigue limiting performance in activities of daily life. The aim of this study was to compare lung function, respiratory muscle strength, and peripheral muscle strength between patients with PAH and healthy subjects.

Materials and methods: Seventeen patients with PAH (4 M, 13 F) and fifteen age-matched healthy controls (7 M, 8 F) participated in this study. Pulmonary function test was performed using spirometry. Respiratory muscle strength was measured using a mouth pressure device. Lower and upper peripheral muscle strength was measured from quadriceps femoris, shoulder abductors a hand held dynamometer, and hand grip was recorded.

Results: The mean pulmonary arterial pressure was 65.57±31.77 mmHg in PAH patients, maximal inspiratory pressure was significantly correlated with mean pulmonary arterial pressure (r=0.67, p<0.05). The mean maximal inspiratory (p=0.0001) and expiratory muscle pressures (p=0.001) of patients with PAH were significantly lower than those of healthy controls. Quadriceps muscle force (p=0.05), shoulder abduction force (p=0.001), and hand grip force (p=0.018) were significantly lower in patients with PAH as compared with healthy controls.

Conclusions: High pulmonary arterial pressure results in reduced peripheral, inspiratory and expiratory muscle strength. Effects of respiratory and peripheral muscle training in patients with PAH needs further investigation.

P4150 Comparison of exercise capacity, pulmonary functions, respiratory and peripheral muscle strength between patients with idiopathic pulmonary arterial hypertension and Eisenmenger syndrome
Benzin Deniz1, Hulya Nilgun Gurses1, Semirasim Orzilmaz1, Serhat Kemaloglu2, 1Dept. of Cardiopulmonary Rehabilitation, 2Dept. of Cardiology, Istanbul University, Institute of Cardiology, Istanbul, Turkey

This study was designed to compare exercise capacity, pulmonary functions, respiratory and peripheral muscle strength between patients with idiopathic pulmonary arterial hypertension (IPAH) and Eisenmenger syndrome. Thirty-three patients with PAH of either IPAH (mean age 45.31; 12 female and 4 male) or Eisenmenger syndrome (mean age 38.41; 10 female and 7 male) were studied. Exercise capacity was determined by using six minute walk test. Also pulmonary functions, respiratory muscle strength (maximal inspiratory (MIP) and maximal expiratory (MEP) pressure) and handgrip strength were measured. Unpaired-t, Mann-Whitney and Fisher’s exact tests have been used for the statistical analysis of the data. There were no significant differences in exercise capacity, respiratory and peripheral muscle strength between the two groups. FVC% (p=0.0025), FEV% (p=0.001) and PEF% (p=0.02) of patients with Eisenmenger syndrome were significantly lower than those of patients with IPAH. In conclusion: exercise capacity, respiratory and peripheral muscle strength were similar for patients with Eisenmenger syndrome compared to those IPAH. In addition, the present study provides evidence that pulmonary functions are reduced in patients with Eisenmenger syndrome compared with IPAH.

P4151 Associations between measurements of health related quality of life (HRQoL) and physical activity (PA) in patients with interstitial lung disease (ILD)
Veronica Barque1, Silvia Perez-Bogerd2, Mirek Hornikx1, 1Physiotherapy-Postgraduate Programme in Physiotherapy/Laboratory of Respiratory Physiotherapy, Universidade Federal do Sao Carlos - UFSCar, Sao Carlos, SP, Brazil; 2Physiotherapy-Postgraduate Programme in Respiratory Physiotherapy, Universidade Federal de Sao Carlos - UFSCar, Sao Carlos, SP, Brazil

Background: ILD is a diverse group of interstitial lung diseases characterized by an impaired alveolar diffusion capacity of oxygen. PA relates to HRQoL in these patients. The aim of this study was to investigate associations between HRQoL, and PA.

Methods: We studied 54 patients with ILD (Age: 64±11 years; FVC: 81±25%; DLCO: 45±13% of the controls was assessed by the Chronic Respiratory Disease Questionnaire (CRDQ) and the Saint Georges Respiratory Questionnaire (SGRQ). The SenseWear Armband was used to assess PA. Mean steps (STEPS) and moderate intensity activity (MOD PA) were calculated over 7 consecutive days.

Results: Baseline characteristics are presented in Table 1.

Conclusion: The SGRQ and CRDQ are measuring similar concepts but HRQoL is unrelated to PA levels in patients with ILD.

P4152 Thoracicabdominal dysynchrony and it relationship with muscle strength in patients with COPD: Preliminary results
Renata Basso1, Camila Pantoni2, Elosa Requeiro1, Audrey Borghi-Silva1, Mauricio Jamami1, Valeria Pires Di Lorenzo1, Dircia Costa1, 1Physiotherapy-Postgraduate Programme in Physiotherapy/Laboratory of Respiratory Physiotherapy, Universidade Federal de Sao Carlos - UFSCar, Sao Carlos, SP, Brazil; 2Physiotherapy-Postgraduate Programme in Respiratory Physiotherapy, Universidade Federal de Sao Carlos - UFSCar, Sao Carlos, SP, Brazil

Background: Upper limbs (UL) exercises can generate thoracoabdominal dyssynchrony (TD), which increase the dyspnea in patients with COPD. However, it is unknown the influence of posture and inspiratory muscle strength (IMS) in TD.

Aim: To verify the TD in rest and UL exercises comparing sitting and standing postures.

Methods: Fifteen patients with COPD (FEV1 47±15%; age 66±9; MIP 58±21cmH2O) performed flexion-extension exercises at the shoulder (1), above the shoulder (2) and horizontal abduction-adduction (3) in sitting and standing postures. The respiratory inductive plethysmography was performed (LifeShirt) and the Borg scale was reported. The PhRIB (Phase Relation during Inspiration),
Conclusion: These preliminary results suggest that upper limb exercises cause TD independent of the postures adopted. In addition, the results suggest that the inspiratory muscle weakness seems get worse the dysynchrony.

The Correlation between Daily Physical Activity using a Compact Accelerometer and Clinical Parameters in Patients with COPD

Masaaki Nakayama1,2, Masashi Bando1, Toshie Sekine1, Takaaki Kikuchi1, Naoko Mato1, Hideaki Yasumawa1, Kocihi Itoh1, Yukihiko Sugiyama1, 1Division of Pulmonary Medicine, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan; 2Department of Internal Medicine, Hiuchitomiya Saiseikai Hospital, Hiuchitomiya, Ibaraki, Japan.

Background: In patients with chronic obstructive pulmonary disease (COPD), inspiratory muscle weakness seems get worse the dysynchrony. The ventilatory reserve may be related to better physical fitness, and hence to a lower chance of hyperinflation.

The Maximum voluntary ventilation is a better correlate of energy expenditure during simple activities of daily living than measures of airflow obstruction or respiratory muscle strength in patients with COPD.

Vinicius Cavalhers1,2, Kylie Hill1,2, Leila Donária1, Carlos Augusto Camillo1, Fabio Pitta1, 1Laboratório de Pesquisa em Fisioterapia Pulmonar (LFIP), Department of Physiotherapy, Universidade Estadual de Londrina (UEL), Londrina, PR, Brazil; 2School of Physiotherapy and Curtin Health Innovation Research Institute, Curtin University, Perth, WA, Australia.

Background: In patients with chronic obstructive pulmonary disease (COPD), the relationship between energy expenditure (EE) and measures of lung function has attracted attention. Weak to moderate associations were demonstrated between daily EE and measures of respiratory muscle strength, maximal voluntary ventilation (MVV), inspiratory capacity (IC) and forced expiratory volume in one second (FEV1) in patients with moderate to severe disease. However, as this earlier work measured EE over a 12-hour period, it is unclear to what extent the EE elicited during individual and simple activities of daily living were associated with these measures of lung function.

Objective: To explore the extent to which energy expenditure (EE) elicited during individual and simple activities of daily living is associated with different measures of lung function in patients with COPD.

Methods: Thirty-six patients (20 males; FEV1 48 ± 23.3%; GOLD classification I – 5 patients, II – 11, III – 7, IV – 7; BMI 21.8 ± 3.2 kg/m2) using a single-axis accelerometer (LifePodder, Suzuken, Japan) for 1 month. Five EE measures were monitored: total energy expenditure (kcal/day), number of steps per day, walking distance (meters/day), and the time spent performing PA (minutes/day) at light (below 3 metabolic equivalent values [METs]) and moderate (3–6 METs) intensities.

Results: There was no difference in dyspnea in both groups. Table 1 summarizes the results.

P4154

Correlation between daily physical activity using a compact accelerometer and clinical parameters in patients with COPD

Masashi Nakayama, Hideaki Yasumawa, Kocihi Itoh, Yukihiko Sugiyama, Jichi Medical University, Shimotsuke, Tochigi, Japan; Department of Internal Medicine, Hiuchitomiya Saiseikai Hospital, Hiuchitomiya, Ibaraki, Japan.

Background: Physical activity (PA) monitoring is becoming increasingly important in patients with COPD. However, the correlation between clinical parameters in COPD and PA has not yet been well studied.

Objective: To evaluate the correlation between PA using a compact accelerometer and clinical parameters in patients with COPD.

Methods: We studied daily physical activity in 30 stable COPD patients (29 males; 72.1 ± 9.5 years of age; %FEV1 54.8 ± 23.3%; GOLD classification I – 5 patients, II – 11, III – 7, IV – 7; BMI 21.8 ± 3.2 kg/m2) using a single-axis accelerometer (LifePodder, Suzuken, Japan) for 1 month. Five PA measures were monitored: total energy expenditure (kcal/day), number of steps per day, walking distance (meters/day), and the time spent performing PA (minutes/day) at light (below 3 metabolic equivalent values [METs]) and moderate (3–6 METs) intensities.

Results: Significant differences (p < 0.05) were observed between GOLD classifications for age, BMI, MRC scale, %FEV1, six minute walk test (6MWT; distance, oxygen saturation (SpO2), heart rate, dyspnea and leg fatigue on Borg scale), and nutritional conditions (serum pre-albumin, transferrin, and retinol-binding protein [RBP]).

Conclusion: Borg scale, although not significantly different among GOLD classifications, and MRC scale were strongly correlated with PA.

What is the relationship between inspiratory capacity and different measures of exercise capacity in patients with COPD?

Leila Donária1,2, Rafael Mesquita1,2, Camila Monteiro Mazzarin1,2, Isabel Cristina Hidetz Genê1, Vanessa Suziane Protob1, Nadia Aparecida Hernandez1,2, Fábio Pitta1, 1Laboratório de Pesquisa em Fisioterapia Pulmonar, Universidade Estadual de Londrina, PR, Brazil; 2Centro de Pesquisa em Ciências da Saúde, Departamento de Fisioterapia, Universidade Norte do Paraná, Londrina, PR, Brazil.

Background: Inspiratory capacity (IC) is an indirect measure of pulmonary hyperinflation in patients with chronic obstructive pulmonary disease (COPD), and may be a limiting factor to exercise capacity in this population. However, the relationship of IC with exercise capacity still needs to be better explored.

Objective: To investigate the relationship between inspiratory capacity and different measures of exercise capacity in subjects with COPD.

Methods: Thirty patients with COPD (18 men, 66 ± 8 years, forced expiratory volume in the first second [FEV1] 40 ± 14%pred) were studied. Inspiratory capacity was assessed by post-bronchodilator spirometry, whereas exercise capacity was assessed by the following three tests: six-minute walking test (6MWT), incremental symptom-limited cycle ergometry test (ISL) and constant work rate cycle ergometry test (CWR), all tests performed according to international guidelines.

Results: In the 6MWT, IC (in liters) explained 18% (p = 0.02) of the distance walked, whereas in the ISL it explained 23% (p = 0.008) of maximum work load and 19% (p = 0.02) of heart rate reached at the end of the test. In the CWR, IC showed only a simple negative correlation with oxygen saturation at the end of the test (r = 0.48).

Conclusion: The inspiratory capacity significantly contributes, albeit modestly, to some key variables of exercise capacity tests. This indicates that a greater ventilatory reserve may be related to better physical fitness, and hence to a lower chance of hyperinflation.

P4154

Sensation of leg effort at rest is related to lower peripheral muscle strength in patients with COPD

Gleem Lemmens1,2, Kris M.H. Ider1,2, Lieve De Racker1,2, Hilde Vaerenberg2,3, Glenn Leemans1,2, Kris M.H. Ider1,2, Lieve De Racker1,2, Hilde Vaerenberg2,3, 1Faculty of Medicine and Health Sciences, University of Antwerp, Wilrijk, Antwerp, Belgium; 2Respiratory Medicine, University Hospital Antwerp, Edegem, Antwerp, Belgium; 3Department of Health Sciences, Artez University College Antwerp, Merksem, Antwerp, Belgium.

Introduction: Sensation of leg effort (SLE) is known as a limiting factor in exercise capacity during a maximal exercise test in patients with COPD. The Borg scale scores this discomfort of the peripheral muscles before and during an exercise test. A high score in a maximal exercise test is known to correlate with lower skeletal muscle strength. However some patients experience SLE already at rest before the exercise test and other do not.

Objective: To evaluate if SLE at rest before exercise also could be related to peripheral muscle strength.
Methods: Data of 26 patients in a pulmonary rehabilitation program was analyzed. The Borg scale SLE before the maximal incremental exercise test. Isometric quadriceps force was assessed by a computerized dynamometer during a voluntary maximal isometric contraction with the hip at 90° and the knee at 60° flexion. The highest value was taken.

Results: SLElis light to moderate inversely correlated with isometric quadriceps force which is expressed as the percentage of strength compared to that of a healthy individual (Pearson r=0.408; p=0.039).

Conclusions: Lower quadriceps force seems to relate to higher leg effort compared to those who do not experience any leg discomfort at all. However due to the great range in quadriceps force, it is necessary to objectively measure quadriceps force to have a good clinical impression of patient’s peripheral muscle strength.

P4157 Measurement of quadriceps strength in patients with COPD using a rig-supported handheld dynamometer  
Wei Yee James, David Jolliffe, Kamrul Islam, Beverley MacLaughlin, Christopher Griffiths, Maxine Gibbon, Jonathan Feng, Dylan Morrissey, Adrian Martineau. Centre for Primary Care and Public Health, Bart's and the London School of Medicine and Dentistry, Whitechapel, London, United Kingdom

Background: Quadriceps strength (QS) predicts prognosis in COPD. Measurement using a non portable isokinetic dynamometer (ID) is the gold standard. Handheld dynamometers (HHD) are portable, but measurements of QS obtained using a HHD may be affected by operator strength. We therefore constructed a portable rig that can be bolted to a chair to support a HHD, and evaluated its performance in measurement of QS in COPD patients.

Objectives: To determine whether use of a rig to support a HHD reduces inter-observer variability in QS measurement, and generates data which correlate with those obtained using an ID.

Methods: Two operators (A-male, BMI 25.5 kg/m²; B-female, BMI 19.3 kg/m²) measured QS using unsupported HHD (12 patients) and rig-supported HHD (15 patients); values obtained for each patient were compared between operators. QS was then measured in 30 patients using both rig-supported HHD and ID; values obtained for each patient were compared between methods.

Results: Measurements of QS obtained using unsupported HHD differed between operator A vs. B (mean QS 49.5 kg vs 35.3 kg respectively; 95% CI for difference 0.9 to 1.7); however, they were highly correlated (r=0.96; 95% CI 0.95 to 0.97, p<0.001).

Conclusions: Use of a portable rig to support a HHD in the measurement of QS in COPD patients eliminates observer effects, and generates values which correlate highly with those obtained using the gold standard methodology.

P4158 A comparison of pulmonary function, functional exercise capacity and sleep quality in patients with chronic obstructive pulmonary disease and obstructive sleep apnea syndrome  
Ebra Cakir, Nurel Bellur1, Hulya Arıkan1, Nazife Vardar Yaglı1, Sema Saviç1, Melda Sağlam1, Deniz İnal-Ince1, Hakan Çalışkan1, Meral Bosnak-Güçlu1, Sadik Arıcı2, Lutfi Cıhapaşaoğlu1, 1Department of Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey; 2School of Physiotherapy and Rehabilitation, Dokuz Eylul University, İzmir, Turkey; 3Department of Physiotherapy and Rehabilitation, Gazi University, Faculty of Health Sciences, Ankara, Turkey; 4Department of Chest Medicine and Sleep Center, Diskapi Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey; 5Department of Chest Medicine, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey

Aim: Chronic obstructive pulmonary disease (COPD) and obstructive sleep apnea syndrome (OSAS) are two diseases that are characterized by obstruction of pulmonary airways. The aim of this study was to compare pulmonary function, functional exercise capacity and sleep quality in patients with COPD and OSAS.

Materials and methods: Twenty-five COPD patients (21 M, 4 F) and 25 OSAS patients (16 M, 9 F) participated in the study. Pulmonary function were measured using a spirometer. Functional exercise capacity was evaluated using a six-minute walk test (6MWT).

Results: Par-Parameters of pulmonary function, 6MWT distance and %6MWT distance were significantly lower in patients with COPD than those of OSAS (p<0.05). In patients with COPD, Borg dyspnea and fatigue were significantly increased and oxygen saturation was significantly decreased during 6MWT compared with OSAS patients (p<0.05). The PSQI sleep duration score was significantly lower, and PSQI sleep disturbances and subjective sleep quality scores were significantly higher in patients with COPD as compared to OSAS patients (p<0.05).

Conclusion: Pulmonary function and functional exercise capacity deteriorated in patients with COPD compared to OSAS patients. Exercise dyspnea and fatigue increases and oxygen saturation decreases in patients with COPD. In comparison with COPD patients, sleep duration and subjective sleep quality are adversely affected in patients with OSAS. Differences in sleep quality and exercise rat-

P4159 Evaluation of preoperative and postoperative exercise capacity by using six-minute walk test  
Renjin Deniz1, Ali Can Hatemi2, Serdar Kucukoglu2, Zerrin Yigit3, Hulya Nligum Gurses1, 1Department of Cardiopulmonary Rehabilitation, Istanbul University, Institute of Cardio, Istanbul, Turkey; 2Department of Cardio Surgery, Istanbul University, Institute of Cardiology, Istanbul, Turkey; 3Department of Cardiology, Istanbul University, Institute of Cardiology, Istanbul, Turkey

The aim of this study was to evaluate preoperative and postoperative exercise capacity of the patients by using six-minute walk test (6MWT) in patients electively undergone coronary artery bypass surgery. Twenty-nine patients whose mean age was 68.69 enrolled to the study. 6MWT was done at two time set (before operation and at discharge from hospital). Heart rate, blood pressure and oxygen saturation levels was noted, level of dyspnea and fatigue determined by Borg scale before and after test and walking distances recorded after six minutes. Walking distance was 349 meters (66% of predicted values) before operation and 284 meters (54% of predicted values) after operation. Decrease of walking distance after operation was statistically significant (among measured and predicted levels, p<0.0001). Heart rate (p=0.0002), systolic blood pressure (p=0.0002), level of fatigue (p=0.008) was significantly increased before and after operation and also diastolic blood pressure (p=0.01) was significantly increased after operation after 6MWT. Decrease of oxygen saturation was significant both the tests before and after operations (p=0.02, p=0.01). Although heart rate, blood pressure, level of fatigue changes before and after 6MWT was not significant before and after CABG, decrease of oxygen saturation after CABG was significant (p=0.004). Conclusion of this study, CABG significantly reduces exercise capacity in the early postoperative course and although this reduce, similar increase of cardiopulmonary parameters and decrease level of oxygen saturation at the end of 6MWT emphasize that exercise induce cardiopulmonary overload in the post operative course.

P4160 Using the six-minute walk test to assess exercise capacity in people with pulmonary hypertension  
Lissa Spencer, Bill Zafiropoulos, Jennifer Alison. Physiotherapy, Royal Prince Alfred Hospital, Sydney, NSW, Australia Physiotherapy, Royal Prince Alfred Hospital, Sydney, NSW, Australia Discipline Physiotherapy, University Sydney, NSW, Australia

Introduction: The aim of the study was to determine if there was a difference in six-minute walk distance (6MWD) when two six-minute walk tests (6MWTs) were performed in people with pulmonary hypertension (PH) prior to attendance at the PH clinic.

Methods: Participants with PH performed two 6MWTs for the first time prior to attendance at the PH Clinic. The tests were performed on a 32 metre continuous track in an outpatient hospital setting using standard instructions and encouragement.

Results: 212 participants completed two 6MWTs [mean (SD) age 57 (16) years; BMI 27 (6) kg/m²]. Using the better 6MWT the mean distance was 438 (139) metres and 6MWT % predicted was 87% (24). There was a significant increase in 6MWD on the second 6MWT [mean difference (95% CI): 16 m (9 to 23); p<0.0001] with 66% of participants walking further on the second walk than the first walk. There were no adverse events during testing.

Conclusion: In people with PH, when a second 6MWT was performed the increase in walk distance was significant but small. This may indicate that one test at baseline may be adequate.

P4161 Effects of radical treatment in patients with intrathoracic cancer  
B. Salih1, C. Haenemulcke2, S. Bogerd-Perez3, M. Nguyen4, K. Vermaelen1, V.F. Surmont1, G. Van Maele2, J.P. van Meerbeeck1, E. Deroo1, 1Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 2Respiratory Medicine, AZ Sint Jan, Bruges, Brugge, Belgium; 3Respiratory Medicine, CHU Sart Tilman, Liege, Belgium; 4Respiratory Medicine, Saint Pierre, Brussels, Belgium; 5Health Informatics and Medical Statistics, Ghent University Hospital, Ghent, Belgium

Introduction: In patients (pts) with intrathoracic cancer radical treatment aims to prolong life and restore quality of life. Data on its effect on exercise capacity and muscle force are limited.

Aim: To investigate the effect of radical treatment on exercise capacity, muscle force and quality of life in pts with newly diagnosed intrathoracic cancer.

Methods: Exercise capacity, peripheral muscle force and quality of life were assessed before and after radical therapy. Data are presented as median with 95% CI.

Results (table): 117 pts (86 male, age: 64 y (77 - 87); BMI; 25 kg/m² (18 - 34); 40% COPD; 35 PY (0 - 70); 105 NSCLC, 6 SLC and 6 mesothelioma were enrolled: 50% underwent surgery as sole therapy, 12% surgery + chemotherapy, 24% chemotherapy + radiotherapy, 10% surgery + chemotherapy + radiotherapy
and 4% radiotherapy only. 24 pts dropped out and 18 are still under treatment. The maximal exercise capacity and 6MW distance decreased significantly after treatment (from 100 Watt (48 - 184) to 82 Watt (38 – 147) and from 515 m (388 - 632) to 482 m (328 – 617)), respectively. Fatigue and pain increased significantly after treatment: FACT-F from 9 pnts (3 - 30) to 13 pnts (3 - 33) and VAS pain from 1 pnts (0 - 9) to 2 pnts (0 - 8).

Conclusion: Radical therapy for intractable cancer significantly decreases exercise capacity, muscle force, and increases pain and fatigue. Mature data on all pts will be available at the meeting.

P4162
Oxygen uptake is slower than heart rate on kinematics in recent myocardial infarction patients
Markus Karsten 1, Laura Neves 1, Thomas Beltramé 1, Audrey Børgli-Silva 1, Piersiope Agostino 2, Aparecida Cattá 2.
1 Physiotherapy, Federal University of Sao Carlos, SP, Brazil; 2 Departimento di Scienza Cardiovascolari, Università degli Studi di Milano, Italy

Background: The heart rate (HR) and oxygen uptake (VO₂) on-kinetics analysis provides information about the individual response to aerobic exercise, which may be reduced after recent myocardial infarction (MI), mainly due to impairment in the oxygen transport system.

Design: To determine whether the HR and VO₂ onset dynamics were affected by recent MI, we evaluated the VO₂ and HR on-kinetics in three groups of subjects with preserved ventricular (VF) and pulmonary function (PF).

Methods: Eight men (49±8 years) with a recent MI (RMI), eleven men (52±7 years) with a late MI (LMI) and ten apparently healthy men (48±8 years) (CG) underwent to PF assessment, ramp cardiopulmonary exercise test (CPX) and two constant workload exercise tests (CWETs) on treadmill at moderate and high workloads, corresponding to 75% and 125% of the gas exchange threshold identified at CPX. VO₂ was registered breath-by-breath and analyzed after smoothed by moving averages of 8 respiratory cycles. HR was recorded by digital telemetry system. A monoeponential fit was applied to analyze VO₂ and HR on-transient response to the first seconds of the CWETs. Intragroup and intergroup comparisons were performed (p<0.05).

Results: RMI group presented rVO₂ slower than tHR at moderate and high workloads. All groups presented faster tHR and VO₂ at moderate when compared to high workload.

Conclusion: Recent uncomplicated MI patients present slowing of VO₂ at aerobic exercise, which suggests impairment of oxygen delivery and extraction mechanisms.

P4163
Exercise induced dyspnea among 12-13 year old children
Heneke Johansson, Hans Hedenskog, Christer Janson, Leif Nordang, Lennart Nordvall, Katarina Norlander, Margareta Emntner.

Introduction: Many children are limited in their physical activity because of exercise induced dyspnea (EID).

Aim: The aim was to investigate the prevalence of EID, asthma and physical activity level among a population of 12-13 year old children in Uppsala, Sweden.

Method: A questionnaire was sent to 3815 parents asking them to answer the questions together with their child.

Results: The response rate was 61% (n=2312). EID during the last 12 months was reported by 14.3% (n=330) (girls 16.9 vs. boys 11.8%, p=0.001). Of all the children reporting EID, 48% reported wheezing and 30% rhinits during the last year, and 39% had ever had physician diagnosed asthma. Children with EID and asthma used bronchodilators and inhaled corticosteroids (ICS) to a larger extent than children with EID but no diagnosis of asthma (bronchodilators: 27.3 vs. 11.3%, p=0.001 and ICS: 31.2 vs. 4.4%, p=0.001). Only 12.4% of the total population (n=2312) reached the international physical activity recommendations (≥ 1 hour/day, 7 days/week on a moderate to vigorous level). 13% among children with EID and 12.3% in children without EID reached the recommendations (p=0.72).

Conclusion: Self reported exercise induced dyspnea is common in children and the majority of those children do not have an asthma diagnosis or asthma treatment. Only a minority of Swedish children have a self reported physical activity level that is in line with international recommendations.

416. Prognosis of lung cancer

P4164
Expression of macrophage migration inhibitory factor (MIF) in the serum and lung tissues in patients with non-small cell lung cancer (NSCLC)
Yifeng Luo 1, Jie Zhang 1, Haifang Luo 1, Zhihong Cai 2, Meizhi Shi1, Yubiao Guo1, 2
1 Pulmonary Department, The 1st Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China; 2 Clinical Laboratory, The 1st Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China; 3 Department of Pathology, The 1st Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China

Objective: To study the expression of MIF in the serum and lung tissues of patients with NSCLC.

Methods: Eighty-eight patients of the 1st affiliated hospital of Sun Yat-sen university with diagnosis confirmed by pathology were recruited from 2011.10 to 2012.3, including 66 patients with NSCLC (group A) and 22 patients with benign lung lesions (group B). ELISA was done to compare serum MIF level in these two groups and in 30 healthy individuals. Immunohistochemistry (IHC) was done to compare the expression of MIF between group A and B. The correlation between serum MIF level and high expression rate in lung tissues was analyzed.

Results: The serum MIF level in group A was significantly higher than healthy control (4.79 Vs 10.69/mg/mL, P<0.001), but not significantly higher than group B (14.79 Vs 13.68/mg/mL, P=0.580). Among group A, the serum MIF level in patients with advanced stage (stage III and IV) was significantly higher than those with early stage (stage I and II) (17.53 Vs 10.54/mg/mL, P<0.001). The MIF high expression rate in the lung tissues of group A was markedly higher than group B (30.3% Vs 4.5%, P<0.014). Among group A, there was significantly higher MIF expression rate in patients with advanced stage compared with those with early stage (42.1% Vs 14.3%, P=0.015). The serum MIF level had a positive correlation with MIF expression rate in the lung tissues in patients of group A (P<0.05).

Conclusions: The serum MIF level had a positive correlation with MIF expression rate in lung cancer tissues. Both of them help to predict NSCLC clinical stage and histological grade. MIF is a good histological biomarker of NSCLC.

P4165
Clinical implication of stem cell markers in N2 positive non-small cell lung cancer
Bo Young Lee 1, Mi Ae Kim1, Jae Cheo Lee1, Young Soo Park1, Hyeong Ryul Kim1, Chang-Min Choi1, 2
1 Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 2 Department of Pulmonary and Critical Care Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 3 Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 4 Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea

Introduction: Non-small cell lung cancer (NSCLC) is one of the most commonly diagnosed malignancies and the leading cause of death worldwide. Cancer stem cells (CSC) are proposed to be responsible for metastasis and chemoresistance.

Material and methods: 72 patients were diagnosed with N2 positive NSCLC. They underwent surgical resection from 2006 to 2007 in Asan Medical Center, Seoul, Korea. Immunohistochemical staining for CD133, CD44, CD24, CXCR4, Nanog, Oct4, ABCG2, E-cadherin, vimentin, and Ki-67 was performed.

Result: Most frequently expressed CSC marker in primary tumor specimens of NSCLC was CXCR4 (92.2%), followed by CD44 (29.2%), CD24 (12.5%), and ABCG2 (9.7%). However, other markers such as CD133, Nanog, and Oct4 were not expressed. E-cadherin was expressed in 86.1% of primary tumor specimens, while vimentin was expressed in 20.8%. Cell proliferative marker, Ki-67, was expressed in 16.7% of primary tumor tissues. As for specimens of lymph nodes, most frequently expressed marker was CXCR4 (93.1%), followed by CD44 (15.2%), ABCG2 (12.5%), and CD24 (10%). In 85.1% of lymph node specimens, E-cadherin was positive. Vimentin was positive in 17.9%. Among the patients showing CD44 positivity in primary tumor specimens, 70% were negative for CD44 expression in lymph nodes. Survival analysis revealed that CD44 expression is a favorable prognostic factor for overall survival (p=0.024). Multivariate analysis using Cox-regression showed that NSCLC patients with CD44 positivity have trend towards increased overall survival.

Conclusion: Various CSC markers are expressed in patients with NSCLC. Immunoreactivity for CD44 is a positive prognostic factor for survival in N2 positive NSCLC.
P4166
Association of XPD and CDA polymorphisms with clinical outcome in non-small cell lung cancer in a Chinese population
Min Zhou, Yongjie Ding, Huanyun Wan. Department of Respiratory Medicine, Ruijin Hospital, Shanghai, China Department of Respiratory Medicine, Ruijin Hospital, Shanghai, China

XPD plays a key role in the repair of DNA and platinum resistance lesions. Cytidine deaminase genes decide the velocity of catalytic activity. This study aims at investigating the relationship between the XPD, CDA genotypes and the outcome in NSCLC patients. We used RFLP to evaluate genetic polymorphism of the XPD Asp312Asp, XPD Lys75Gln, CDA Lys27Gln and CDA Ala170Thr in 93 NSCLC patients treated with cisplatin-gemcitabine regimen. 44% of patients carrying XPD 312A/Gln had progression of disease, whereas 55.6% with heterozygous XPD 312A/Gln had progression of disease as well. There were no significant correlation between XPD 312A/Gln and clinical benefit (p=0.32). 52.94% of patients with wild-type had clinical benefit (PR and SD). 56.9% of patients carrying XPD 751Lys/Gln responded to therapy. There was no difference between different genotype (p=0.517). But the difference of OS between XPD 312A/Gln and XPD 312A/Gln was very significant (20.0 months vs 12.4 months, p=0.04).

P4167
The metallopeptidase neprilysin is a hypoxia-induced prognostic factor in lung adenocarcinoma
Katharina Leithner1, Christoph Wohlkongen1, Elvira Stacher2, Jörg Lindemann3, Nicole A. Hofmann4, Birgit Eberer5, Franz Quehenberger6, Freja Maria Smolle-Jüttner7, Sijaj Philipson8, Helmut H. Pogger9, Andelko Herzenjak1, Andrea Olschewski10, Horst Olschewski11, Division of Pulmonology, Medical University of Graz, Austria; 3Institute of Pathology, Medical University of Graz, Austria; 4Division of Thoracic and Hyperbaric Surgery, Medical University of Graz, Austria; 5Stem Cell Research Unit, Medical University of Graz, Austria; 6Institute for Medical Informatics, Statistics and Documentation of Graz, Austria; 7Department of Cell Biology, Erasmus University Medical Center, Rotterdam, Netherlands; 8Experimental Anesthesiology, Medical University of Graz, Austria

Identification of hypoxia-induced pathways might lead to novel therapeutic targets in solid cancers. A comparative expression profiling study was performed in hypoxic and normoxic ex vivo cultured lung cancer fragments with preserved tumor stroma and 3D-structure. A considerable overlap was found between hypoxia-regulated genes from the ex vivo lung cancer model and published hypoxia-signatures. The stem cell marker neprilysin (membrane metallo-endopeptidase, MME, CD10), which was consistently up-regulated by hypoxia in the histological subtypes in our study, has not been reported so far to be hypoxia-induced in cancer. Neprilysin has been shown to be expressed by stroma cells, e.g. cancer-associated fibroblasts. Immunohistochemistry for neprilysin in fresh NSCLC specimens and normoxic or hypoxic fragments revealed a localization in both, stroma cells and neoplastic tumor cells. To assess a possible role of neprilysin in lung cancer progress we analyzed the association of neprilysin expression and overall survival in NSCLC patients from public microarray datasets. High expression of neprilysin was significantly associated with poor overall survival in 182 adenocarcinoma patients in a multivariate meta-analysis (p=0.00012) and in adenocarcinoma patients from two individual datasets. As a conclusion, neprilysin is a hypoxia-induced, independent adverse prognostic factor in surgically treated lung adenocarcinoma patients. The results of this study suggest an important role of stroma-derived hypoxia-induced factors for lung cancer progression.

P4168
Prognostic value of ERCC1 expression in advanced non-small cell lung cancer (NSCLC)
Jens Konigsmark1, Torsten Blum1, Daniel Minch2, Andreas Roth2, Christian Böck3, Wolfram Gruening4, Catharina Creulow5, Sergio Griff6

Background: The immunohistochemical (IHC) detection of the “excision repair cross-complementation group 1” (ERCC1) protein in resected NSCLC is prognostically relevant. Pts with ERCC1-neg. tumors appear to benefit from adjuvant cisplatin-based chemotherapy (CTX), whereas pts with ERCC1-pos. tumors do not. Aim: We compared survival of pts with non-operated NSCLC III/IV according to the four tumor subtypes in our study, has not been reported so far to be hypoxia-induced in cancer. Neprilysin has been shown to be expressed by stroma cells, e.g. cancer-associated fibroblasts. Immunohistochemistry for neprilysin in fresh NSCLC specimens and normoxic or hypoxic fragments revealed a localization in both, stroma cells and neoplastic tumor cells. To assess a possible role of neprilysin in lung cancer progress we analyzed the association of neprilysin expression and overall survival in NSCLC patients from public microarray datasets. High expression of neprilysin was significantly associated with poor overall survival in 182 adenocarcinoma patients in a multivariate meta-analysis (p=0.00012) and in adenocarcinoma patients from two individual datasets. As a conclusion, neprilysin is a hypoxia-induced, independent adverse prognostic factor in surgically treated lung adenocarcinoma patients. The results of this study suggest an important role of stroma-derived hypoxia-induced factors for lung cancer progression.

Methods: We analyzed 398 pts (m=248, f=150) newly diagnosed with NSCLC stage III/IV between 10/2009 and 12/2010. Prospectively, ERCC1 expression determined by IHC was measured and indicated as H-score. Pts where no IHC and/or H-score could be performed were excluded.

Results: 271/398 cases (68%) were suitable for IHC. 175/271 (65%) of tumors were ERCC1 pos., 96/271 (35%) ERCC1 neg. 177/271 (65%) received platinum. Survival times in days were (mean ± SEM): platinum+ERCC1+: 404±25 (n=67); platinum+ERCC1+: 346±23 (n=110); platinum-ERCC1-: 144±23 (n=29); platinum-ERCC1-: 268±33 (n=65). In Cox hazard regression analysis, the factors platinum+ (p<0.001) and ERCC1 (p=0.01) were not independent (p=0.001, interaction term).

Conclusions: Pts with palliative platinum-based Ctx for advanced NSCLC had significantly longer OS when the tumor showed no significant ERCC1 expression. In pts who did not have platinum-based Ctx, the absence of ERCC1 expression was prognostically unfavorable. This study confirms observations from adjuvant therapy also for palliative Ctx.

P4169

EGFR mutations are associated with sensitivity to tyrosine kinase inhibitors (TKI) in patients with NSCLC. Studies point to different outcome to TKI treatment according to exon mutation.

Aim: Understand how different EGFR mutations predict TKI response and affect survival.

Methods: Records review of NSCLC patients with EGFR study (2006-2011). Epidemiological, clinical and outcome information was analyzed using SPSS19.0

Results: Of 409 patients studied 53 were EGFR-positive. After exclusion of 1 drug-resistant patient (exon 20) and patients who did not use TKI or had TKI as 1st therapeutic, 22 patients were considered - 50% male, 67.5±9.8, 59.1% non-smokers.

Progression-free survival (PFS) was better in exon 19 mutations (p=0.04). Survival after TKI (STKI) was better in 18 and 19 mutated patients (no statistical difference - p=0.06).

In non-surgical stages (72.8%), exon 19 mutated patients had better global survival (GS), STKI and PFS than others (p<0.05).

Associating patients with exons 18 and 20 (described as less predictive of therapeutic outcome) GS29.1, STKI12.2 and PFS8.6 months, all higher than values found for exon21(p<0.05).

Conclusions: Exon 19 mutation conferred better prognosis to patients treated with TKI. Exons 18 and 20 (22.7%) were not associated with worse prognosis than exon 21. Although this is a small group we believe that is worth to maintain analysis of the 4 exon mutation.

TUESDAY, SEPTEMBER 4TH 2012
Prognostic value of fluorine-18 fluoroethylguanine (18-FDG) positron emission tomography imaging in patients with non-small cell lung carcinoma Ahmet Yildirim 1, Fatma Yildirim 1, Sevket Orakci 1, Umit Ozgur Akdemir 1, Can Ozturk 1, 1Department of Pulmonary Medicine, Gazi University Faculty of Medicine, Ankara, Turkey; 2Department of Pulmonary Medicine, Dr. Suat Seren Education and Research Hospital For Chest Diseases and Thoracic Surgery Hospital, Izmit, Turkey; 2Department of Nuclear Medicine, Gazi University Faculty of Medicine, Ankara, Turkey

To determine whether the amount of 18-FDG maximum standardized uptake (SU-Vax) value on the PET/CT imaging at the time of presentation has prognostic significance in patients with non-small cell lung cancer (NSCLC). Patients and methods: A retrospective review identified 142 patients with NSCLC who underwent 18-FDG PET/CT study at the time of diagnosis. Extensive clinical data, including tumor histologic cell type, stage at presentation, treatment, and SU-Vax values in the primary tumor were recorded and survival was examined. Results: Total 142 patients were included the study. 32 patients of them have stage I and II. The median SU-Vax of early stage patients is determined 13.5. Early stage patient population was subdivided into two groups according to the median value for survival. The median survival of the 17 patients with the primary tumor having an SU-Vax between 13.0 was 19.0 months. There was no statistical differences between two groups (p=0.483). The 110 patients were on advanced stage (stage III and IV). Using the median SU-Vax of 12.5, the patient population was subdivided in two groups. The median survival of the 54 patients with the primary tumor having an SU-Vax less than 9.5 was 12.0 months whereas the median survival of the 56 patients with the primary tumor having an SU-Vax of 9.5 was 11.0 months. There was no statistical differences between two groups (p=0.266).

Conclusion: 18-FDG SU-Vax uptake of the primary lesions in patients with a new diagnosis of NSCLC does not have a significant relationship with survival.

EpCAM-positive circulating cells in lung cancer patients Joanna Domagalska-Koloszy1, Tomasz Skirecki 1, Grazyna Hosier 2, 1Pneumonology, Medical University, Warsaw, Poland; 2Laboratory of Flow Cytometry, Ceneter of Postgraduate Education, Warszaw, Poland

Lung cancer is a very aggressive neoplasm characterized by high metastatic potential which is the main cause of therapeutic failures. The exact cell of origin of metastasis is not known, however several markers for them have been proposed. Recent research indicates that a rare subpopulation of the CTCs (Circulating Tumor Cells) can be detected in tumor tissue, lung tissue and peripheral blood by flow cytometry with anti-EPAM antibody and to investigate its clinical significance.

Forty-one patients diagnosed with lung cancer were enrolled into this study. Patients did not receive anticancer treatment prior to the study. The cells bearing EpCAM were detected in tumor tissue, lung tissue and peripheral blood by flow cytometry with anti-EPAM FITC antibody, analyzed in FACScantoll, BD flow cytometer. EpCAM+ cells were detected in the tumor tissue with higher proportion than in adjacent lung parenchyma and with higher proportion in adenocarcinoma (AC) than in squamous cell (SCC) type. The median proportion of circulating EpCAM+ cells was 0.0026% (260 per ml). No difference was found between SCC and NOS. The fraction of EpCAM+ cells was higher in the patients with AD and without SCC (0.0130 vs 0.0027%), was significantly lower in the blood of patients with advanced disease (IBB, IV) when compared with lower stages (I-IIIA) (0.0018 vs 0.00067%, 230 vs 504 cell per ml) and was significantly lower in patients with metastases compared to those without metastases (0.0015% vs 0.0046%, p=0.012).

Our study confirmed the presence of a rare subpopulation of the CTCs of the EpCAM-positive cells in lung cancer patients with significant differences related to histological type and stage of the disease.

Independent prognostic und predictive value of blood vessel invasion (BVI) in curatively (R0) resected stage II and IIIA non-small cell lung (NSCLC) cancer patients: Dieter Wuerflein 1, Wolfgang M. Bruckel 1, Dietmar Kraus 2, Christian Meyer 1, Manfred Wagner 1, Joachim H. Ficker 1, 1Department of Internal Medicine 3, Klinikum Nuernberg, Germany; 2Department of Thoracic Surgery, Klinikum Nuernberg, Germany; 3Klinikum Nuernberg, Inst. of Pathology, Nuernberg, Germany

Objective: A single center study was conducted to identify the prognostic and predictive role of blood vessel invasion (BVI) in surgically R0 resected stage II and IIIA non-small cell lung cancer patients.

Methods: A total of N=105 consecutive patients who had undergone complete (R0) resection for stage IIA/IIIA primary non-small cell lung cancer (NSCLC) between 01/2008 and 12/2010 at the Lung Cancer Center Nuernberg were evaluated. All pathological specimens were examined for evidence of BVI.

Results: The baseline clinical data showed no significant differences between patients with and without positive invasion (tumor/necrosis; N=64) and patients without BVI (N=49). Patients with BVI had a significantly longer tumor-free survival (13.5 vs. 11.7 months; p=0.003). 18-FDG SUVmax values in the primary tumor were recorded and survival was examined. The cumulative 2-year survival rate was 64% (95% CI of ratio 1.00 – 1.79) was significantly associated with shorter survival, while the effects of patients presented any co-morbidity at the time of diagnosis and 14.3% of them had 3 co-morbidities. Multiple Cox’s proportional hazard model was performed to evaluate the impact of co-morbidity on survival.

Results: The median survival for all patients was 9.3 months (range: 0.12 – 7.06), and the cumulative 2-year survival rate was generally poor (<1%). Multiple Cox’s proportional hazard model showed that only the patients with the major co-morbidity group of 'endocrine, nutritional and metabolic disease and immunity disorder’ was the significant risk factor to shorten the survival for non-surgical NSCLC which raises special attention for better supportive or palliative care for lung cancer patients with this type of co-morbidity.

High mRNA expressions of KLF2 improve post operative prognosis of pulmonary adenocarcinoma correlation with chemokine receptor CCR7 and genetic mutations of p53 Meiji Iinokura 1, Yuya Terashima 2, Masato Shingyoji 1, Toshihiko Iizasa 1, Hisuki Kimura 1, 1Department of Thoracic Disease, Chiba Cancer Center, Chiba City, Japan; 2Department of Molecular Preventive Medicine, The University of Tokyo, Bunkyo-ka, Tokyo, Japan

Purpose: Chemokines and chemokine receptors not only have the powerful ability to influence of tumor metastasis and tumorigenesis, but also act as anti-tumorgenic ability. Lung Kunreppel-like factor (KLF, KLF2) is a member of the family of the Krueppel-like factors (KLFs). KLF2 was initially described as a lung-specific transcription factor. KLF2 is reported to regulate some malignant cells. We examined and evaluated the effect of KLF2 on pulmonary adenocarcinoma and the relationship of their mRNA expression with CCR7, EGFR and p53 genetic mutations in pulmonary adenocarcinoma.

Results: KLF2 mRNA expression was up-regulated in these patients. The mRNA expression of KLF2 was significantly good prognosis than the groups of low expressions (p= 0.0066, HR= 2.008, 95% CI of ratio 1.215 to 3.319). The expression of KLF2 mRNA had significantly good prognosis than the groups of low expressions (p= 0.0066, HR= 2.008, 95% CI of ratio 1.215 to 3.319). The expression of KLF2 mRNA had significantly good prognosis than the groups of low expressions (p= 0.0066, HR= 2.008, 95% CI of ratio 1.215 to 3.319). The expression of KLF2 mRNA had significantly good prognosis than the groups of low expressions (p= 0.0066, HR= 2.008, 95% CI of ratio 1.215 to 3.319). The expression of KLF2 mRNA had significantly good prognosis than the groups of low expressions (p= 0.0066, HR= 2.008, 95% CI of ratio 1.215 to 3.319).
P4175 Prognostic impact of nestin expression in resected large cell neuroendocrine carcinoma of the lung
Shintaro Royce1, Yutichi Sato1, Shi Xu Jiang1, Toshihide Matsumoto2, Ken Katoh1, Satoshi Ishiga1, Masanori Yokoba1,2, Jiichiro Sasaki1, Akira Iyoda1, Masato Katajin1,2, Yukitoshi Sato1, Noriyuki Masuda1,1Department of Respiratory Medicine, Kitasato University Hospital, Sagamihara, Kanagawa, Japan; 2School of Allied Health Sciences, Kitasato University, Shinichiro Ryuge

Data of patients with LCNEC and NS CLC with neuroendocrine differentiation after surgical resection in comparison to surgical resection in NSCLC. There are no studies that have shown prognosis similar to this of patients with SCLC and worse prognosis was observed in patients with LCNEC. Nestin expression in tumor cells was immunohistochemically studied in 30 patients with resected LCNEC, and its associations with clinicopathologic parameters were evaluated. Kaplan-Meier survival analysis and Cox proportional hazards models were used to estimate the effect of nestin expression on survival. Nestin expression was observed in 8 of the 30 (26.7%) LCNECs. Clinicalpathologically, no significant association between nestin expression and age, gender, smoking habits, p-TNM stage, tumor size, or nodal status was observed. On survival analysis, nestin expression was significantly associated with a poorer prognosis in patients with LCNEC (P = 0.016). Multivariable analysis confirmed that nestin expression increased the hazard of death after adjusting for other clinicopathologic factors (HR= 3.53; 95% CI, 1.21-10.3).

The present study suggests that nestin expression is a prognostic indicator of a poorer survival probability in patients with resected LCNEC, although its prognostic significance still requires confirmation with larger patient populations. This study was approved by Kitasato university human ethics committee.

P4176 The impact of neuroendocrine differentiation in the prognosis of non-small cell lung cancer
Andriamir  Chaudhuri1, Christina Fevranoglou1, Tsipoukis Stotis1, Boutra Paraskevi1, Marios Zontanos1, Ioannis Danos2, Konstantinos Syrigos1,1Oncoology Unit, 3rd Dept of Medicine, University of Athens Medical School, Athens, Greece

Introduction: Large cell carcinomas with neuroendocrine differentiation (LCNEC) consist a distinct subcategory and represent 2-3% of lung cancers. Retrospective studies have shown prognosis similar to that of patients with SCLC and worse prognosis after surgical resection in comparison to surgical resection in NSCLC. There are data showing that perioperative chemotherapy especially platinum based combinations, improves survival.

Aim: Examine the overall survival (OS) between patients with LCNEC and NSCLC with neuroendocrine differentiation and the progression free survival (PFS) according to the stage and the therapy applied.

Method: Data of patients with LCNEC and NSCLC with neuroendocrine differentiation were collected from June 2005 to December 2010.

Results: Data from 26 patients were collected, men median age 62 years old. 15 had LCNEC and 11 NSCLC with neuroendocrine differentiation, 6 at stage I-II and 10 at stage IV. The majority were confronted with multimodal therapy (surgery, radiotherapy, chemotherapy). The median OS was 15 months for LCNEC and 15.5 months for NSCLC with neuroendocrine differentiation (95% CI). There was no difference between LCNEC and NSCLC with neuroendocrine differentiation for stages I-II (p=0.814) and IV (p=0.563) respectively. The median OS for all patients was 3.5 months and the median PFS 2.5 months (95% CI). Totally 12 patients received systematically sandostatin-LAR and 14 did not receive without difference found in OS (p=0.140).

Conclusions: Randomised trials are needed in order to prove which therapeutic intervention is the most proper and which chemotherapeutic combination is the best for lung cancer with neuroendocrine differentiation.

P4177 Long-term outcomes and prognostic factors for neuroendocrine G1 and G2 lung tumors
Julia Wallasch1, Gerhard Weinreich1, Dirk Theegarten1, Saskia Ting2, Andreas Zabel1, Georgios Stamatis1,1Department of Thoracic Surgery and Endoscopy, Ruherlandklinik, West German Lung Center, University Hospital Essen, Germany; 2Institute of Pathology and Neuropathology, University Hospital Essen, Germany; 3Institute of Pathology, BG Klinikum Bergmannsheil, Ruhr-University, Bochum, North Rhine-Westphalia, Germany

Background: Bronchial neuroendocrine G1 and G2 tumors show a favorable outcome. However, survival depends on several prognostic factors such as histological subtype, nodal involvement and other predictors.

Objectives: The presented study aimed to evaluate the long-term outcomes, survival rates and prognostic factors after resection of G1 and G2 neuroendocrine lung tumors according to the 7th edition of the TNM staging system.

Patients and methods: We conducted a retrospective review of 246 consecutive patients who underwent surgical treatment for G1 and G2 neuroendocrine tumors of the lung between 1998-2010.

Results: 246 patients (63% women) with G1 and G2 neuroendocrine lung tumors underwent thoracotomy. G1 tumors were found in 205 (83%) patients, while 41 (17%) had G2 disease. Follow-up was 65±±40.3 months. In the total study cohort with analysed 5- and 10-year survival: G1 bronchopulmonary tumor (survival 96% and 94%) was significantly different (p<0.001) from G2 bronchopulmonary tumor (survival 87% and 46%), stage I survival (94% and 85%) was significantly different (p=0.02) from stage >I (survival 86% and 59%), nodal involvement (survival 83% and 57%) was significantly different (p=0.02) in comparison to patients without nodal involvement (survival 94% and 84%), distant metastases (survival 80% and 27%) was significantly different (p=0.001) compared to patients without distant metastases (survival 94% and 84%).

Conclusions: Prognosis was influenced by histological subtype, stage of disease, occurrence of symptoms before operation, lymph node involvement and distant metastases.

P4178 The increase of circulating B7-H4-expressing CD68+ macrophage correlated with clinical stage of lung carcinoma
Jian An Hu1,2, Cheng Chen2, Yibei Zhu2, Xuegang Zhang2,1Respiratory Department, The First Affiliated Hospital of Soochow University, Suzhou, China; 2Biotechnology Research Institute, Soochow University, Suzhou, China

Purpose: To investigate the B7-H4-expressing TAM in a series of 56 cases of lung carcinoma.

Methods: Tissue samples were obtained from patients with lung cancer, who underwent lobectomy surgery. B7-H4-expressing TAM was observed by confocal microscopy. B7-H4-expressing macrophage (CD68+ cells) in peripheral blood was measured among patients with lung cancer, patients with tuberculosis and healthy donors by two-color flow cytometry. Correlation of B7-H4-expressing CD68+ macrophage with histological types, tumor size and lymph node metastasis was assessed.

Results: Lung cancer are infiltrated with Tumor-associated macrophages (CD68+ cells) that expressed B7-H4. The circulating B7-H4-expressing CD68+ cells were higher in the lung cancer group than in the tuberculosis group. The number of B7-H4-expressing CD68+ cells was positively correlated with tumor size and lymph node metastasis, and the tumor size. The proportion of B7-H4 positive CD68+ cells among CD68+ cells was also greater in late stage lung cancer than in early serious stage lung cancer. The intensity of B7-H4 staining was significantly correlated with lymph node metastasis, and the tumor size. Expression of B7-H4 was significantly higher in CD68+ cells from the late stage lung cancer (stage III-IV, n=36) as compared with the CD68+ cells from early stage lung cancer (stage I-II, n=20).

Conclusion: It is suggested that lung carcinomas increase B7-H4-expressing macrophages, which might favor tumor progression.

P4179 Prognostic value of SUVmax in patients with lung cancer who underwent surgical treatment
Daniela Alves1, João Cruz, Cecília Pacheco, Beatriz Fernandes, João Cunha. Pulmonology, Hospital de Braga, Braga, Portugal

Introduction: The metabolic activity of a tumor can be measured by the Standardized Uptake Value (SUV) of F-2-deoxy-2-fluoro-D-glucose (FDG), which may provide prognostic information.

Objective: To analyse the prognostic value of SUVmax in surgically treated patients with lung cancer.

Methods: The patients included were selected from a database of patients with lung cancer, between 2007 and 2010, who underwent surgical resection with performance of PET with quantification of SUVmax prior to surgery.

Results: 26 patients underwent surgical resection of lung lesion, with mean age 64±12.2 years, 16 (61.5%) were male. 23 underwent pre-surgical PET. The value of SUVmax was accessed in 21: 9 (42.9%) adenocarcinoma, 8 (38.1%) carcinoid tumors, 2 (9.5%) squamous cell carcinoma and 2 (9.5%) NSCLC. The mean SUVmax was 5.4±4.4. In carcinoid tumors the mean SUVmax was 3 and in NSCLC 6.9, adenocarcinoma 7.3 and squamous cell carcinoma 5.5. The pre-surgical stage was IA 6 (28.6%), IB 12 (57.1%), IIB 1 (4.8%) and III in 2 (9.5%). After surgery, staging was distributed as follows: IA 8 (38.1%), IB 7 (33.3%), IIA 1 (4.8%), IIB 1 (4.8%) and IIIA 4 (19%). Disease being occurred in 4 and upstaging in 4, with mean SUVmax of 2.2 and 3.2, respectively. With respect to surgical stage, the average SUVmax was 6.1 in stage III, 5.2 in stage II and 5.3 in stage I. Recurrence was observed in 2 (9.5%), with SUVmax of 5.6 and 1.9. The median follow-up was 23.4 months and no deaths were reported.

Conclusion: Although limited by a small sample size, higher values of SUVmax in patients with post-surgery upstaging, in adenocarcinoma and in more advanced stages was observed in this study.
Conclusions: Most of our patients had advanced disease and despite the use of TKIs in selected patients the prognosis remained poor. Common mutations were deletions in exon 19 and point mutations in exon 21.

P4181
One year survival differences of EGFR- and KRAS-mutated advanced non-small cell lung cancer (NSCLC) compared to the wildtype population
Anna Stredke1, Thomas Mairinger2, Torsten T. Bauer1, 1Department of Pneumology, HELIOS Klinikum Emil von Behring, Pulmonary Diseases Clinic Heckeshorn, Berlin, Germany; 2Department of Pathology, HELIOS Klinikum Emil von Behring, Berlin, Germany

Introduction: With investigation of the complex relationship between EGFR-related biomarkers and response to tyrosine kinase inhibitor (TKI) novel therapies for NSCLC have been established. In numerous clinical studies the effect of TKIs in patients with activating EGFR mutations is proven by a better progression free survival (PFS) while the prognostic value of KRAS mutations remain vague. The current study in our clinic retrospectively analysed the one year survival of patients with NSCLC and an activating EGFR- or KRAS-mutation.

Methods: Within 15 months until Dec 2010, all subsequent biopsies of newly diagnosed NSCLC (n=753) were tested for the ability to be analysed by Sanger- and Pyrosequencing for the presence of EGFR mutations and by LightCycler Real-time PCR for the presence of KRAS mutations. The obtained data were correlated with the centre-bound tumour registry for survival data and analysed by Kaplan-Meier estimator.

Results: In a total of 552 cases with NSCLC, EGFR mutation was present in 27/552 (4,9%, male n=10) and KRAS mutation in 85/552 cases (15,8%, male n=43). In advanced NSCLC (IIIb/IV), 16/27 patients had an EGFR mutation and 46/85 had KRAS mutation. The one year survival of advanced NSCLC and EGFR mutation was 11/16 (68,8%) vs. 5/16 (31,3%) without mutation. Stratifying according to KRAS it was 15/46 (32,6%) vs. 27/552 (4,9%, male n=10) and KRAS mutation in 85/552 cases (15,8%, male n=43). 19/154 (12,3%) patients had an activating KRAS mutation. The one year survival of advanced NSCLC and KRAS mutation was 27/552 (4,9%, male n=10) and KRAS mutation in 85/552 cases (15,8%, male n=43).

Conclusion: Comparable with previous reports, the one year survival of NSCLC with EGFR mutation is improved whereas the one year survival with KRAS mutations seems to be poorer.

P4182
Recruitment of podoplanin positive cancer-associated fibroblasts in metastatic lymph nodes predicts poor prognosis in pathological N2 stage III lung adenocarcinoma
Shinya Neri1, Kenichiro Ishii1, Keiji Aoka2, Tomoyuki Hishida3, Jung Yoshida1, Kanji Nagai4, Atsushi Ochiai1, 1Pathology, Research Center for Innovative Oncology, National Cancer Center Hospital East, Kashiwa, Japan; 2Thoracic Surgery, National Cancer Center Hospital East, Kashiwa, Japan

Background: Cancer-associated fibroblasts (CAFs) directly communicate with cancer cells and play important roles in cancer progression. Recent studies have reported that primary cancer tissue with podoplanin-expressing CAFs predicted a poorer outcome among stage I lung adenocarcinoma patients. However, whether podoplanin(+)CAFs can also be recruited into metastatic lymph nodes and influence the prognosis remains unclear.

Methods: We selected 112 patients with pathological N2 stage III lung adenocarcinoma and examined the podoplanin expression of CAFs and their prognostic impact in primary and metastatic N2 lesions.

Results: A significant positive correlation was found in podoplanin expression in CAFs between primary and metastatic lesions (P = 0.001). The differences in overall survival of patients with podoplanin-positive/negative CAFs in their primary lesion was not correlated (P = 0.927). In contrast, patients with podoplanin(+)CAFs in metastatic lymph nodes had a shorter overall survival than those without podoplanin(+)CAFs (P = 0.003). In multivariate analyses, podoplanin(+)CAFs in metastatic lymph nodes were a significantly independent risk factor for a poor outcome (P = 0.007).

Conclusions: Our study indicated podoplanin(+)CAFs in metastatic lymph nodes was a significant prognostic factor for overall survival among pathological N2 stage III adenocarcinoma patients.

P4183
Immunohistochemical expression of Bcl-2 and p53 in patients with lung cancer: Correlation with survival time
Biljana Bievka Porecka1, Szenza Smockska2, Gordana Petruvseva1, 1Biology Department, Institute for Lung Diseases and Tuberculosis, Skopje; 2Oncology Department, Clinic for Radiotherapy and Oncology, Skopje; 3Immunohistochemistry Department, Institute for Pathology, Skopje, Macedonia, The Former Yugoslav Republic of

Background and aims: Bcl-2 and mutated p53 genes are the most relevant proteins involved in apoptosis and tumor development. The aim of this study was to determine the Bcl-2, p53 and Ki-67 expression and their impacts on survival time in patients with lung cancer.

Material and methods: 127 patients with lung cancer (IC), 87 with non-small cell lung cancer (NSCLC) and 40 with small cell lung cancer (SCLC) were stained immunohistochemically on paraffin-embedded tissue, using specific monoclonal antibody for Bcl-2 and p53.

Results: The differences in apoptotic marker expression between NSCLC and SCLC were revealed: p53 expression is seen more frequently in NSCLC patients (46/87; 52,87%). Bcl-2 expression is seen in 26/40 (65,0%) SCLC patients, and only in 27/87 (31,03%) with NSCLC (p=0,000). The Kaplan-Meier survival analysis demonstrated that Bcl-2 positive SCLC patients had poor survival status (Log Rank=20,137, p=0,000). In NSCLC patients only p53 immunoreactivity was associated with shortened survival (log Rank=6,534 p=0,011). Multivariate analysis showed that over-expression of Bcl-2 and p53 were independent prognostic marker for poor survival in the patients with SCLC (HR=6,02 p=0,000), and NSCLC (HR=1,547 p=0,049), respectively.

Conclusions: The results indicated that aberrant expression of p53 and Bcl-2 have a strong effect on survival and prognosis in patients with NSCLC and SCLC and reflect their different pathogenesis.

417. Screening, diagnosis, staging and treatment strategies for lung cancer

P4184
Validation of CALIPER (Computer-aided lung informatics for pathology evaluation and rating) for the non-invasive assessment of pulmonary nodules of the adenocarcinoma spectrum
Fabjan Maldonado1, Sushrayya Raghunath2, Marie Christine Aubry1, Brian Bartholmai2, Jennifer Boland Froemming3, Mariza De Andrade4, Ronald Karwoski2, Srinivasan Rajagopalan5, Richard Robb2, Ping Yang6, Eunhee YI7, Tobias Peinkofer1, 1Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, United States; 2Department of Physiology and Biomedical Engineering, Mayo Clinic, Rochester, MN, United States; 3Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, United States; 4Department of Biostatistics, Mayo Clinic, Rochester, MN, United States; 5Department of Health Science Research, Mayo Clinic, Rochester, MN, United States; 6Department of Diagnostic Radiology, Mayo Clinic, Rochester, MN, United States

Rationale: The growing utilization of high-resolution computed tomography (HRCT) for clinical diagnosis and lung cancer screening results in identification of pulmonary nodules of unknown clinical significance. Non-invasive strategies...
for the individualized management of these lesions are required. In a pilot study we have demonstrated the consistent classification of pulmonary nodules of the adenocarcinoma spectrum using CALIPER.

Methods: Two pulmonary pathologists independently assessed histopathologic tissue invasion in 72 surgery resected pulmonary nodules (≤ 3cm) of adenocarcinoma spectrum from 88 patients. Based on consensus, all lesions were categorized as either NINN-<5mm invasive, n=60 (>5mm invasion, n=66). CALIPER mapped the individual HRCT voxels (pre-operative HRCT) within all the nodules to one of the previously identified 9 unique radiologic patterns. The nodules were categorized as INV or NINV based on the relative distribution of the patterns. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for CALIPER-based detection of tissue invasion were calculated.

Results: Sensitivity, specificity, PPV and NPV were respectively 98.5%[90.7-99.9%], 66.7%[24.1-94%], 97%[88.7-99.4%] and 80%[30-98%]. Only one case was identified as NINV by CALIPER and as INV by the pulmonary pathologists.

Conclusion: CALIPER represents a promising tool size for automated nodule detection of pulmonary nodules of the adenocarcinoma spectrum. Further prospective and retrospective validation of our data is currently ongoing.

P4185 Probability of malignancy based on automatic segmentation and software measurements of nodules in the Danish lung cancer screening trial (DLcST)
Juul Glüer1,2,3, Michael Carlsson,4,5,6 Martin Wallström,4,5,6 Kjetil Hjermstad,4,5,6 Catharina Crolow1,2,3, Asger Dirksen1,2,3, Jesper Holst Pedersen,1,2 Department of Radiology, Rigshospitalet, Copenhagen, Denmark; 5Department of Thoracic Surgery, Copenhagen University Hospital, Gentofte University Hospital, Hellerup, Denmark; 6Department of Surgery, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; 4Department of Medical Informatics and Radiology, Erasmus MC - University Medical Center, Rotterdam, Netherlands

Introduction and aim: With the widespread use of chest CT in clinical and setting screening pathways nodules are detected more frequently than ever, and the risk of malignancy needs to be determined.

Materials and methods: In DLcST, 4,104 current and former smokers, with a history of at least 20 pack years and age between 50-70 years, were randomized to either five annual multi-slice low-dose CT screenings or no screening. All participants had an annual visit to the screening clinic where lung function tests and questionnaires concerning health, lifestyle, smoking habits and psychosocial consequences of screening were performed. All scans were double-read by two experienced researchers and size were registered. Nodules between diameters of 5-15 mm were considered indeterminate, and re-scanned after three months. Participants with nodules larger than 15 mm were referred to diagnostic workup, as were those with growing nodules. Lung cancer was diagnosed by pathological evaluation.

Using volumetric software nodules were segmented automatically and for the solid and sub-solid components mass and volume were calculated as well as the largest axial diameter. All automated nodule-segmentations were visually reviewed for correctness and adjusted if needed.

Results and conclusion: We are currently analyzing the data by logistic regression with nodule size and outcome and nodule measurements, as age, sex, smoking status and history and COPD-status as explanatory variables. The results will be presented at the ERS 2012 in Vienna.

P4186 Emphysema, COPD and lung cancer screening. Update of an ongoing study
Pablo Sanchez,1 Maria Sanchez-Carpintero, Juan Berti,1 Pilar Rivero, Ana Belén Alcaide, Juan Pablo de Torres, Arantxa Campo, Jorge Zagaceta, Javier Zabalza.1 Neurología, Clinica Universidad de Navarra, Pamplona, Spain

Recently, screening with low-dose CT (LDCT) has been shown to reduce mortality from lung cancer. We reported that emphysema on a LDCT, but not COPD (FEV1/FVC <70%), is associated with an increased risk of lung cancer. We present an update of our screening study.

Data comes from a prospective cohort of an ongoing lung cancer screening study held at our center. From 2000 to 2011, current and former smokers of at least 40 years of age and at least 10 pack-years of smoking were recruited. All had annual LDCTs and most a baseline spirometry. Lung cancer incidence density and its association with risk factors were calculated with logistic regression.

From a cohort of 2697 subjects, 1925 (25% females) who had LDCTs and a history of at least 20 pack years and age between 50-70 years, were randomized to either five annual multi-slice low-dose CT screenings or no screening. All participants had an annual visit to the screening clinic where lung function tests and questionnaires concerning health, lifestyle, smoking habits and psychosocial consequences of screening were performed. All scans were double-read by two experienced researchers and size were registered. Nodules between diameters of 5-15 mm were considered indeterminate, and re-scanned after three months. Participants with nodules larger than 15 mm were referred to diagnostic workup, as were those with growing nodules. Lung cancer was diagnosed by pathological evaluation.

Using volumetric software nodules were segmented automatically and for the solid and sub-solid components mass and volume were calculated as well as the largest axial diameter. All automated nodule-segmentations were visually reviewed for correctness and adjusted if needed.

Results and conclusion: We are currently analyzing the data by logistic regression with nodule size and outcome and nodule measurements, as age, sex, smoking status and history and COPD-status as explanatory variables. The results will be presented at the ERS 2012 in Vienna.
Patients (2.6%) with ischemic stroke as leading event (n=23, 1.2%), followed by LC (SCLC 10.3%, NSCLC 89.7%). Arterial TEE were documented in 51 patients (median survival 283 days vs. 479 days).

**Introduction:** The objective of this study was to evaluate the diagnostic performance of 18F-fluorodeoxy-glucose-Positron Emission Tomography with integrated contrast enhanced Computed Tomography (FDG-PET/CT) as a routine diagnostic tool in a Rapid Outpatient Diagnostic Program (RODP) for patients referred on the basis of a chest X-ray suspicious of lung cancer.

**Methods:** A retrospective chart study was conducted of all patients referred to the two-day RODP of our tertiary care university clinic between 1999 and 2009 after an abnormal chest X-ray. We analyzed timeliness of care and the diagnostic performance of FDG-PET/CT to differentiate between malignant and benign lesions.

**Results:** In 386 patients available for analysis, 260 patients were diagnosed with non-small cell lung cancer (NSCLC), small cell lung cancer (SCLC) of both subtypes; 23 patients had another type of malignancy. 78 patients had certain benign disease, and in 45 patients the diagnosis was not pathologically confirmed but a median 24.5 months follow up confirmed a benign outcome. Sensitivity, specificity, negative predictive value, positive predictive value and accuracy of FDG-PET/CT to differentiate lung cancer from benign disease were 97.7%, 60.2%, 92.5%, 84.0% and 95.7% respectively. For lung cancer patients, median referral time was seven days, diagnostic delay was 2 days and therapeutic delay 19 days.

**Conclusion:** FDG-PET/CT in an RODP setting for suspected lung cancer has high performance in detecting cancer and facilitates timely care.

**P4192**

A proposal in small cell lung cancer staging according to TNM system

**Background:** Many pts with limited disease [LD] behave similarly to those with extensive disease [ED] from the prognostic point of view. On the other hand, a proportion of pts with ED SCLC behave similarly to those with LD. Moreover, the 7th (IASLC) TNM classification has not been evaluated with recent, large scale studies in SCLC.

**Patients and methods:** In this retrospective analysis 764 pts with proven SCLC were included managed with the same therapeutic protocols based on platinum analogues. Of these pts, 278 (36.4%) had LD, while 486 (63.6%) had ED. This classification was based on the following investigations: chest radiography, computed tomography of chest, abdomen and brain, thoracic bronchoscopy, isotope bone scan, sputum cytology and haematological and biochemical profile. We also grouped the pts according to new TNM classification (seventh edition).

**Results:** A statistically significant difference was found in survival among the LD SCLC pts with (IA + IB), (IIA + IIB + IIIA) and IIIB stage (p < 0.001). Similarly, we found a statistically significant difference in survival in ED SCLC pts with (IA + IIB + IIIB) and IV stage (p < 0.001).

**Conclusions:** A new classification of SCLC can be proposed which includes four stages based on TNM classification of NSCLC. (Stage IA+IB, (Stage IIA+IIB+IIIA), (Stage IIB) and (Stage IV)).
Results: ECOG performance status was related with both mean survival and disease-free survival time (respectively p=0.011 and p=0.044). 148 patients were grouped by using 1975 TNM and 2009 IASLC staging systems. According to survival analysis, disease-free survival was not related with stage but mean survival analysis revealed that stage 3 cases had significantly worse survival compared to stage 1 cases (p=0.005).

Conclusion: According to our results, survival was significantly worse in stage 3 patients and patients with poor performance status.

P4194 The role of pequi fruit (Caryocar brasiliense Camb) pulp oil, as a natural source of antioxidants, in experimental lung cancer
Nathália Beatriz Rijoldi Colombo1, Edwin Roger Parra1, César Koppe Grisólia2, Márcia Hage1, Denise Frediani Barbeiro1, Vera Luiza Capezolli1, Ricardo M. Reale3, Pathology, Faculdade de Medicina da Universidade de São Paulo, Brazil; 2Gene and Morphology, Universidade de Brasília, Brasília, Brazil; 3Laboratory of Experimental Atmospheric Pollution, Faculdade de Medicina da Universidade de São Paulo, Brazil; 4Clinical Emergency, Faculdade de Medicina da Universidade de São Paulo (FMUSP), Brazil

Background: Caryocar brasiliense Camb, most known as pequi, is a Brazilian fruit that has high levels of antioxidants properties. The aim of this study was to evaluate the antioxidant activity of the pequi oil.

Methods: 18 male BALB/c mice was studied: 14 animals received by gavage 0.5g/kg/day of pequi oil (Control + CBCoil = 4) during 75 days. After 15 days, 10 mice received two doses of 1.5g/kg intraperitoneal of urethane (Urethane + CBC oil = 10). The other 4 animals were only submitted to the two doses of urethane (Urethane group = 4). After 75 days, these groups were sacrificed. An antioxidant activity of pequi oil was evaluated in the lung tissues by the biochemical TBARS test (Thiobarbituric acid-reactive substances) and DNA damage by the comet test method.

Results: The lung parenchyma from the Urethane groups without oil and with oil showed necrotic formations induced by the chemical carcinogenesis in contrast with Control + CBC oil group. The image analysis of the comet assay showed a statistical significant decreased of the DNA damage cells in the Urethane + CBC oil group when compared with urethane group. TBARS test showed a significant decreased of the lipid peroxidation in the Urethane + CBC oil group, similar as values of the Control + CBC oil, when compared with Urethane group.

Conclusion: We conclude that the different natural antioxidant components found in the pequi oil are efficient to diminish the oxidative stress status and the DNA function with statistically significant improvement in emotional and global health scales, mean value for each scale was calculated pre and post ablation. The paired t test was used to assess statistical significance of the results. This revealed statistically significant improvement in emotional function (p =0.023) and the global health scales (p = 0.008).

Conclusion: This retrospective study demonstrates that patients undergoing ablation therapy for primary and secondary lung cancer describe overall improved function with statistically significant improvement in emotional and global health scales.

P4195 Is surgical resection of M1a lung adenocarcinoma with metastatic pleural nodules really a useless choice?
Jinkyeong Park1, Mi-Ae Kim2, ChangMin Choi2, HyungRyul Kim2,1Pulmonary and Critical Care Medicine, Wongsung Univ. Sanbon Hospital, Goyang, Gyeonggi, Korea; 2Pulmonary and Critical Care Medicine, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, Korea; 3Thoracic and Cardiovascular Surgery, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, Korea

Introduction: Infections are important causes of morbidity and mortality in lung cancer patients. The myelotoxicity caused by the administration of either the chemotherapeutic regimens or the radiotherapy increases the risk of potentially life-threatening infection.

Methods: This prospective study included all patients with lung cancer who referred with signs or symptoms of infection between September 2009 and October 2011. Data concerning patient’s history, disease’s diagnosis, management and therapy’s signs, symptoms and documentation were collected.

Results: Seventy one patients with lung cancer were enrolled with febrile episodes and/or microbiologically or otherwise documented infection. Forty six patients (64.8%) presented with non-small cell lung carcinoma, while 22/71 patients (31%) and 3/71 patients (4.2%) had small cell lung cancer and mesothelioma respectively. Fifteen patients (21.1%) presented with FN and totally 43/71 (60.6%) patients required hospitalization for parenteral therapy upon admission. The predominant site of the infections was the lung in 59/71 patients (83.1%). In the hospitalized setting 3 episodes of bacteremia with Staphylococcus aureus were reported and microbiologically documented infections accounted for 26.7% of the hospitalized patients. The overall mortality rate was 9.8%, while only 1 patient died in the outpatient setting despite the antibiotic therapy.

Conclusion: This study showed that the early detection and control of infection in lung cancer patients receiving therapy may improve their survival. Recognition of predisposing factors for infections and possible therapy toxicities should be evaluated carefully.

P4196 Evaluation of quality of life in patients with primary and metastatic lung cancer following radiofrequency ablation
Julia Beeson, Sunny Kaul, Winston Banya, Paras Dalal, Thoracic Radiology, Royal Brompton & Harefield NHS Foundation Trust, London, United Kingdom

Objective: Radiofrequency ablation (RFA) is an increasingly utilised treatment option for high risk patients with primary lung cancer and metastatic lung disease. We assessed quality of life in patients who were undergoing RFA for primary and secondary lung cancers at this institution in patients deemed unfit for surgical intervention.

Materials and methods: 55 patients, (42 primary lung cancer and 13 metastatic lung tumours) were entered into the study. One standard instrument was used to measure quality of life, the European Organisation for Research and Treatment of Cancer (EORTC QLQ-C30). An integrated system for assessing health-related quality of life of cancer patients. All procedures were performed by a single operator. All patients were clinically and radiologically followed-up in a standardised way, all questionnaires were collected by a single associate pre treatment and one year post ablation. Data was analysed using the Stata version 10 software.

Results: The EORTC scores were calculated for the six functional scales, the role, social, emotional, physical function, emotional functioning and global health scales, mean value for each scale was calculated pre and post ablation. There was a reported improvement in all four scales after ablation. The paired t test was used to assess statistical significance of the results. This revealed statistically significant improvement in emotional function (p =0.023) and the global health scales (p = 0.008).

Conclusion: This retrospective study demonstrates that patients undergoing ablation therapy for primary and secondary lung cancer describe overall improved function with statistically significant improvement in emotional and global health scales.
P4198 Determinants of relapse and survival in completely resected non-small cell lung cancer

Filipe Soares Pere1, Gabriel Fernandes1,2, Ana Paula Vaz1, António Morais1,2, Conceição Souto Moura2,3, Pedro Bastos2,4, Venceslau Hespanhol1,2.

1Pulmonology Department, Centro Hospitalar de São João, Pólo do Porto, Portugal; 2Division of Medicine, University of Porto, Portugal; 3Pathology Department, Centro Hospitalar de São João, Pólo do Porto, Porto, Portugal; 4Thoracic Surgery Department, Centro Hospitalar de São João, Pólo do Porto, Porto, Portugal.

Introduction: Lung resection is the treatment of choice in Non-Small Cell Lung Cancer (NSCLC). Besides TNM staging, other features have been reported as significant prognostic factors.

Aim: To analyze factors affecting relapse and survival in NSCLC after complete resection.

Methods: A retrospective study was conducted, including patients with NSCLC completely resected in the last 12 years. Clinical and histological factors were assessed and its influence on survival free of relapse and overall survival was determined.

Results: 160 patients were included, 77.5% male and 22.5% female, with a median age of 65 years. Relapse occurred in 69 patients (median survival free of relapse - 56 months). At univariate analysis, an association was found between reduced survival free of relapse and age >62 years, clinical tumor size >4cm, clinical TNM stage >IB, clinical T1, clinical N0, pathological TNM stage >IB, pathological T2, pathological N0 and vascular invasion. At multivariate analysis, tumor size >4cm (p=0.004), pathological TNM stage >IB (p=0.023) and vascular invasion (p=0.024) were associated to a reduced survival free of relapse. 64 patients died (median overall survival – 112 months). At univariate analysis, an association was found between reduced overall survival and age >62 years, clinical tumor size >4cm, clinical TNM stage >IB, clinical N0, pathological TNM stage >IB, pathological T2, pathological N0, vascular invasion and poor differentiation of tumor. At multivariate analysis, only pathological TNM stage >IB (p=0.024) remained a poorer overall survival factor.

Conclusion: Besides TNM staging, other factors are important on relapse and survival and should be considered for adjuvant therapy.

P4199 Therapeutic options for operated adenocarcinoma patients in stages I or II

Anastasios Palamidas1, Stefan Krüger1, University Clinic RWTH, Aachen, Germany

Aim: To analyze factors affecting relapse and survival in NSCLC after complete resection.

Methods: A retrospective study was conducted, including patients with NSCLC completely resected in the last 12 years. Clinical and histological factors were assessed and its influence on survival free of relapse and overall survival was determined.

Results: 160 patients were included, 77.5% male and 22.5% female, with a median age of 65 years. Relapse occurred in 69 patients (median survival free of relapse - 56 months). At univariate analysis, an association was found between reduced survival free of relapse and age >62 years, clinical tumor size >4cm, clinical TNM stage >IB, clinical T1, clinical N0, pathological TNM stage >IB, pathological T2, pathological N0 and vascular invasion. At multivariate analysis, tumor size >4cm (p=0.004), pathological TNM stage >IB (p=0.023) and vascular invasion (p=0.024) were associated to a reduced survival free of relapse. 64 patients died (median overall survival – 112 months). At univariate analysis, an association was found between reduced overall survival and age >62 years, clinical tumor size >4cm, clinical TNM stage >IB, clinical N0, pathological TNM stage >IB, pathological T2, pathological N0, vascular invasion and poor differentiation of tumor. At multivariate analysis, only pathological TNM stage >IB (p=0.024) remained a poorer overall survival factor.

Conclusion: Besides TNM staging, other factors are important on relapse and survival and should be considered for adjuvant therapy.

P4200 Effect of statin therapy in patients with lung cancer on mortality, incidence of infections and pulmonary embolism

Stefan Krüger1, Annika Vehl, Angelika Haselhuhn, Dirk Frechen. Medical Clinic I, University Clinic RWTH, Aachen, Germany.

Background: Statins (S) have antiproliferative effects. Aim of this study was to assess whether S users with lung cancer (LC) had reduced risk of mortality, infections and pulmonary embolism.

Methods: We studied the association of S use in a retrospective study in 465 pts with first diagnosis of LC. The primary variables were stage and type of LC and S use at time of LC diagnosis and thereafter. During follow-up occurrence of death, infections and pulmonary embolism were recorded.

Results: 91 pts (19.6%) had S, 371 pts not. LC stages were I-IIIA 201 pts (43.2%), IB-IV 264 pts (56.8%). Pts with S were older (67.8±10.8 vs. 64.5±9.8 yrs, p < 0.005), had higher BMI, more often diabetes, myocardial infarction and coronary heart failure. Charlson comorbidity index was not different (5.2±2.2 vs. 5.7±2.4, p = 0.08). During follow-up 43% of the pts died. In Kaplan Meier analysis stage I-IIIA pts with S had lower survival compared with pts without S (log rank test, p=0.001). However there was no significant difference in pts stage IB-IV. In pts < 65 yrs. survival was longer in pts with vs. without S (1062 (95%CI 588-3977) vs. 604 (95%CI 513-806) days, p<0.05). In pts ≥ 65 yrs. there was no difference in survival (493 (95%CI 308-776) vs. 693 (95%CI 555-917) days, p=n.s.). Incidence of severe infections and pulmonary embolism were not different in pts with and without S.

Conclusions: Long-term S therapy seems to reduce mortality in younger LC pts < 65 yrs, but not in pts ≥65 yrs. In stage I-IIIA pts S are associated with worse survival, whereas there is no difference in stage IB-IV. S do not reduce the incidence of severe infections and pulmonary embolism at follow-up.

P4201 Anaerobic exercise decreases the progression of lung cancer in experimental mice

Renato Pacelli1, Rodrigo Cal2, Carlos Santos3, Anna Morais3, Cassiano Neiva3, Antonio Cordeiro4, Kazuo Nagamine5, Patricia Curu6, Division of Pneumology, Heart Institute (InCor) School of Medicine, University of São Paulo, SP, Brazil; 7Pathology and Forensic Medicine, School of Medicine of São José do Rio Preto – FAMERP; São José do Rio Preto, SP, Brazil; 8Department of Epidemiology and Public Health, School of Medicine of São José do Rio Preto – FAMERP; São José do Rio Preto, SP, Brazil; 9Physical Activity and Health Laboratory (LAFLS), School of Medicine of São José do Rio Preto – FAMERP, Bauru, SP, Brazil; 10Laboratory of Metabolism and Physiology of Stress - mefE, Paulista State University - School of Science of Bauru – (Unesp), Bauru, SP, Brazil.

Introduction: Lung cancer is one of the most incident neoplasms in the world rep- resenting the main cause of mortality for cancer. Studies have suggested evaluate the effectiveness of the use of the physical activity in the suppression, remission and reduction of the recurrence of tumors.

Objective: To evaluate the effects of aerobic and anaerobic physical activity in the development and the progression of lung cancer.

Material and methods: Lung tumors were induced with a dose of 3mg of Ure- thane/kg, in 67 male Balb -C type mice, divided in three groups: Group 1 - 24 mice treated with Urethane and without physical activity; Group 2 - 25 mice with Urethane and subjected to aerobic swimming free exercise; Group 3 - 18 mice with Urethane, subjected to anaerobic swimming exercise with gradual loading 5 to 20% of body weight. All the animals were sacrificed after 20 weeks.

Results: The median number of lesions (nodules and hyperplasia) was 3.0 for group 1, 2.0 for group 2 and 1.5 to 3 (p = 0.052). When compared only the presence or absence of lesion, there was a decrease in the number of lesions in group 3 compared with group 1 (p = 0.03) but not in relation to group 2. There were no metastases or other changes in other organs.

Conclusions: In this study, the anaerobic physical activity but not aerobic, diminish the incidence of experimental lung tumors.

P4202 Splenectomy inhibits tumor development and metastases in murine lung cancer models

Liran Levy1, Inbal Mishalani1, Zolotarob Lida1, Rachel Bayh1, Zvi G. Fridlender1,2, 3Institute of Pulmonary Medicine, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; 4Department of Medicine, University of Pennsylvania, Philadelphia, PA, United States.

Introduction & Aims: It has been shown that inhibitors of the immune system (e.g. myeloid derived suppressor cells) reside in the spleen and inhibit the endogenous anti-tumor effects of the immune system. We hypothesized that excision of the spleen (splenectomy) can inhibit growth of relatively big tumors, and reduce metastases by modulating systemic inhibition of the immune system. Our long-term goal is to implement mechanisms elucidated in these studies into future clinical trials.

Methods: The clinical effect of splenectomy was evaluated in several murine lung cancer models. We compared immunological properties of blood and tumor after splenectomy or sham operation in tumor-bearing mice, using FACS analysis, RT-PCR and specific depletion studies.

Results: We found that splenectomy reduces tumor growth, can induce their regression, and decreases metastases. These effects disappeared in NOD/SCID mice. No significant changes in cell types were found in the blood. Splenec- tomy increased the percentage out of total tumor cells of neutrophils (2.4% vs. 4.9%, p=0.012), and macrophages (10.9% vs. 14.4%, p=0.014), which tended
to be less immunoinhibitory (non-M2/M2 macrophages ratio increased from 3.4 to 12.1, p=0.04). We further noted a tendency to increased activation of CD8+ CTL (19.2% vs. 30%, p=0.09). Tumor microenvironment was found to be more pro-inflammatory following splenectomy (e.g. upregulation of M1, TNF-α and IFN-γ). Using specific depletion of cells we evaluated the role of each cell in the effect of splenectomy.

**Conclusions:** Splenectomy inhibits the development of tumors and metastases in murine models of lung cancer, by changing the amount and characteristics of myeloid cells.

**P4203**

**Direct medical costs of lung cancer in Oran hospital**

Abdelmajid Saouab,1 Malika Metaibi1,1 Abdellatif Bennani1,1 Souad Kebabi1,1 Saada Chougrami1, Malika Guermaz1,1 Chest Clinic, Faculty of Medicine, Oran, Algeria;2Epidemiologic Department, Faculty of Medicine, Oran, Algeria

**Objective:** To analyse epidemiological profile of lung cancer and to evaluate expenses inherent in its diagnostic and therapeutic management.

**Methods:** Retrospective study of all cases of lung cancer notified during the period 2004-2008 in our chest clinic. Data concerning epidemiological characters and expenses which take into account, hospitalisation, diagnostic tests and treatment, were kept in an Epi-Info software package (Epi-info, version 6.0).

**Results:** Among 130 cases, 127 were studied. The mean age of our population was 66 years, age more than 50 years represented 80% of cases, 66.7% were male and 33.3% were female. Tobacco smoking concerned 91% of our patients. Thoracic pain represented 20.6% of cases and cough 13% of cases. Frequent localisation of lung cancer was right upper lobar 68% and tumboral extension represented 80% of cases. Histological predominant lung cancer was epidermoid carcinoma with 35% of case followed by adenocarcinoma with 15% of cases. Global cost of hospitalisation was of £157086.86 with a mean cost per patient of £1208.36.

**Conclusion:** Lung cancer management in hospital level remain problematic taken into account tobacco smoking threat and the higher expenses inherent in hospitalisation, diagnosis and treatment of the disease. The interest of a national plan against lung cancer is necessary to improve its management and to rationalize expenses.

**418. New biomarkers for lung cancer**

**P4204**

**Volatile organic compounds (VOC) in exhaled breath in patients with lung cancer, using the analytical technique thermal desorber-gas chromatography-spectrometer masses**

Javier Jareno Fernández,1 María Ángeles Muñoz Lucas,1 Belén Carrillo Aranda1, Jose Angel Maldonado Sana1, Concepcion Civera Tejada, Aníbal Aguilar Ros2, Gema Rodriguez Trigo3, Carlos Gutiérrez Ortega4, Jose Luis Alvarez Sala5, Luis Calló Sanchez5, 1Unidad Multidisciplinar de Investigación en Diagnóstico Precoz de Cáncer de Pulmón, Hospital Central del Defensor, Madrid, Spain; 2Química Física II, Facultad de Farmacia. Universidad Complutense de Madrid, Madrid, Spain; 3Farmacocinetica, Facultad de Farmacia. Universidad San Pablo CEU, Madrid, Spain; 4Neumología, Hospital Clínico San Carlos, Madrid, Spain

**Aim:** Oxidative stress is increased in lung cancer (LC) and generated volatile organic compounds (VOC). We can detect VOC in exhaled breath using the analytical technique TD/GC/MS. The determination of VOC, may be useful as a noninvasive screening in LC.

**Objective:** To determine differences in VOC present in the exhaled breath in 3 groups: LC group, COPD group and clinically healthy volunteers.

**Methods:** Case-control study with 81 patients with LC, 40 patients with COPD and 89 healthy volunteers (without respiratory disease). Informed consent accepted. Collection of exhaled breath by means BioVOC® to functional residual capacity

**Analytical technique:** TD/GC/MS (Markes-Agilent Tech.)

**Statistical analysis:** SPSS® v-15 for Windows.

**Results:** Description of the sample. Quantitative study and qualitative study of VOC

**Conclusions:** 1. Nonanoic acid is the only VOC with statistical significance between study groups: and it is independent of age and smoke custom. 2. The frequency probability to find nonanoic acid in LC group is higher than control and COPD groups 3. Nonanoic acid and beptanal could be useful to discriminate between LC + COPD patients versus LC without COPD patients.

**In our sample, nonanoic acid could be useful like a LC tumoulike marker. Supported by FIS: PI07/1116; Neumomadril 2008 and SEPAR 2010: PI-881.

**P4205**

**Retrospective study of treatment outcomes according to exon difference with EGFR mutations in non-small cell lung cancer patient in Korea**

Ho Sung Lee1, Jae Sung Choi1, Ki Hyun Seo1, Ja Ock Nu1, Yong Hoon Kim1,1 Internal Medicine, Pulmonology, Soonchunhyang Univ. Cheonan Hospital, Cheonan, Republic of Korea; 2Diagnostic Pathology, Soonchunhyang Univ. Cheonan Hospital, Cheonan, Republic of Korea; 3Radiology, Soonchunhyang Univ. Cheonan Hospital, Cheonan, Republic of Korea

**Background/Aims:** EGFR mutations in NSCLCs are most important biomarker for EGFR-TKI treatment. About 90% of EGFR mutations are clustered in exons 19 (deletion) and 21 (point mutation at codon 858) and patients with these mutations have great response to EGFR-TKIs. However, the response rates of NSCLC to EGFR-TKIs according to types of EGFR mutation in Korea are still not cleared. This study aimed to evaluate the genomic types of EGFR mutation and compare the influence of each genomic types on the response to EGFR-TKIs and clinical outcomes in patients with NSCLC.

**Methods:** We reviewed medical records from January 2007 to August 2011, and classified genotypes of EGFR mutations which were done by direct sequencing methods. Mutation status was compared with clinicopathological features. Clinical outcomes were assessed based on EGFR genotypes.

**Results:** EGFR gene mutations were identified in 43(20.2%) out of 211 NSCLC patients. EGFR mutations were significantly more frequent in females than in males (37.1% vs. 13.4%, p < 0.001), but not correlated with smoking status (22.9% vs. 18.4%, p = 0.311). There are no significant differences between exon 19 deletion and exon 21 point mutation at cordon 858 in progression-free survival (10.9 vs. 9.1 months; p = 0.554), nor in overall survival (21.8 vs. 18.2 months; p = 0.142) and disease control rate (90% vs 85.7%; p = 0.669) with EGFR-TKI treatment.

**Conclusion:** PFS and overall survival were not significantly different between exon 19 deletions and Exon 21 L858R mutations, these results are similar to those of previous studies.

**P4206**

**Clinical significance and functional roles of FoxM1 in non-small cell lung cancer**

Nuo Xu1, Deshui Jia2, Wenliang Chen1, Di Ge1, Chunxue Bai1, 1Department of Pulmonary Medicine, Fudan University, Shanghai, China; 2Shanghai Pulmonary Thoracic College, Fudan University, Shanghai, China; 3Department of Biostatistics, School of Public Health, Fudan University, Shanghai, China; 4Department of Thoracology, Zhongshan Hospital, Fudan University, Shanghai, China

**Purpose:** To test the role of FoxM1 in the metastasis of non-small cell lung cancer.

**Experimental design:** FoxM1 expression was examined in 175 NSCLC patients with or without nodal metastasis by immunohistochemistry. By lentivirus transduction, the role of FoxM1 in metastasis was also tested by in vitro methods using different NSCLC cell lines.

**Results:** In this study, the FoxM1 expression was found to be significantly associated with nodal metastasis and the cumulative 5-year survival rate. Thus, an increased expression of FoxM1 is the indicator of shortened survival and high risk of metastasis of NSCLC patients. Furthermore, we also found that increased FoxM1 expression could enhance the migratory and invasive abilities of lung cancer cells, while inhibition of FoxM1 expression could reduce the migratory and invasive properties of lung cancer cells, which are the two important parameters of metastasis biology. In addition, cells with high FoxM1 expression were presented with phenotypic changes reminiscent of EMT, which was further proved by the results of immunohotting with down-regulation of E-cadherin and ZO-1 uptake regulation of N-cadherin and Vimentin.

**Conclusion:** These results suggested that FoxM1 plays an important role in lung cancer metastasis and elevated FoxM1 expression could be used as an indicator of poor prognosis and high risk of metastasis of NSCLC patients.

Alterations of serum inflammatory biomarkers in the healthy and lung cancer patients before and post chemotherapy

Dunya Wang1, Xin Wang1, Tao Zeng2, Jie Hu1, Yuanlin Song1, Luanan Chen2, Xiangdong Wang1, Chunjue Bai1, 2Department of Pulmonary and Critical Care Medicine, Zongshen Hospital Fudan University, Shanghai, China; 3Key Laboratory of Systems Biology, NIH-Novo Nordisk Translational Research Centre for Prediabetes, Shanghai Institutes for Biological Sciences, Shanghai, China

Introduction: Only 20% of lung cancer patients could be early diagnosed with surgical treatment. Due to the high cost, it is not practical to apply CT scan and pathological biopsy for lung cancer as regular screening tools even in high-risk population. A simple but sensitive and specific assay used for lung cancer diagnosis and prognosis is warranted.

Methods: Serum samples from 55 subjects including healthy people and patients with NSCLC (30 with adenocarcinoma and 13 with squamous cell carcinoma) were collected to measure 40 inflammatory mediators by multiplexed cytokine immunosassays. All patients have completed follow up for up to two years. A series of systematical computational analysis was applied.

Results: The set of 17 cytokines (such as IL-9, CXCL10, CXCL10, etc.) prefers to recognize adenocarcinoma samples from pool of the population, while the set of 2 cytokines (MSFp and IL-29) prefers to recognize squamous cell carcinoma samples. The decision trees based on these two kinds of biomarkers can both achieve about 80% accuracy in leave-one-out cross-validation. Cytokines like CXCL5, CXCL10 and CXCL16 were also found to play important roles in cancer survival.

Conclusions: This pattern of inflammatory mediators might be useful for cancer diagnosis, prognosis and evaluation of chemotherapy effects. The results of clustering of five CEPINs supported the adopted chemotherapy is effective for NSCLC patients.

This study was supported by National Basic Research Program of China (973 Program) No. 2012CB933300.

Anti-tumorigenic effect of age-diabetes-related advanced glycation end-products in lung carcinoma

Babett Barth1, Hans-Stefan Hofmann1,2, Antonia Sohlt1, Veronika Somoz1a, Rolf Eickenhauser1, Andreas Sumit1, 2Cardiothoracic Surgery, University Hospital, Halle (Saale), Germany; 3Thoracic Surgery, Hospital Barmherzige Brueder, Regensburg, Germany; 4Research Platform for Molecular Food Science, University of Vienna, Austria

Background: Clinopathological studies indicated that lung carcinoma progression is impaired by advanced age and diabetes, which are either characterized by an excess accumulation of advanced glycation end-products (AGEs). AGEs result from the non-enzymatic reaction of sugars with proteins in the body and in foods. Therefore, our study aimed at the effect of AGEs on the non-small cell lung carcinoma (NSCLC) progression.

Methods: AGEs were quantified by detecting the AGE fluorescence in plasma samples of NSCLC patients prior to surgery. Experimentally, the tumor effect of circulating AGEs were quantified by detecting the AGE fluorescence in plasma samples from NSCLC patients of whom elevated AGEs were found to be associated with higher serum OPN levels compared to patients with low levels (25% vs. 47% 5-year-survival, P=0.011). In this regard, in vitro studies showed a lower sphereoid formation of NSCLC cells in the presence of AGE-modified plasma than non-modified plasma. 

Conclusion: The plasma AGE level has prognostic relevance for NSCLC patients, in which the tumor growth-inhibiting effect of circulating AGEs might play a critical role.

Increased levels of circulating interleukin 6, interleukin 8, C-reactive protein, and risk of lung cancer

Mariana Petrovic1; Ivan Cekerevac1; Gordana Kostic2; Violeta Iric Cupic2; Goran Davidovic2; Zorica Lazic1; Vojislav Cupurduja1; Ljiljana Novkovic1; 1Pulmonary Department, Clinical Center, Krusevac, Serbia; 2Clinical for Cardiology, Clinical Center, Krusevac, Serbia

Introduction: Previous studies that were based primarily on small numbers of patients suggested that certain circulating proinflammatory cytokines may be associated with lung cancer; however, large independent studies are lacking.

Methods: Associations between serum interleukin 6 (IL-6) and interleukin 8 (IL-8) levels and lung cancer were analyzed among 123 case patients. Associations between biomarkers and lung cancer were estimated using logistic regression models adjusted for smoking, stage, histology, age, and sex. The 10-year standardized absolute risks of lung cancer were estimated using a weighted Cox regression model.

Results: Serum IL-6 and IL-8 levels in the highest quartile were associated with lung cancer (IL-6, odds ratio [OR] = 2.89, 95% confidence interval [CI] = 1.28 to 6.23; IL-8, OR = 2.46, 95% CI = 1.02 to 4.12) and with lung cancer risk (IL-6, OR = 1.93, 95% CI = 0.87 to 2.36; IL-8, OR = 1.62, 95% CI = 1.36 to 2.48), compared with the lowest quartile. Increased IL-6 levels were only associated with lung cancer diagnosed within 2 years of blood collection, whereas increased IL-8 levels were associated with lung cancer diagnosed more than 2 years after blood collection (OR = 2.03, 95% CI = 1.05 to 2.73). The 10-year standardized absolute risks of lung cancer were highest among current smokers with high IL-8 and CRP levels (absolute risk = 7.46%, 95% CI = 4.52% to 10.25%).

Conclusions: Although increased levels of both serum IL-6 and IL-8 are associated with lung cancer, only IL-8 levels are associated with lung cancer risk several years before diagnosis.

Clinical significance of serum osteopontin levels in lung cancer

Aktorina Kazakou1, Thoeris Korersdie1, Martha Lada1, Irini Tsiotani1, Eleftherios Balaveris1, Konstantinos Gourgouliani1, Respiratory Medicine, University Hospital, Larissa, Greece

Background: Osteopontin (OPN) is a multifunctional glycoprotein associated with lung cancer (LC) via several pathways including tumour angiogenesis.

Aims and objectives: The aim of our study was to investigate possible associations between serum levels of OPN in patients with LC and clinicopathological variables, VEGF and MMP-9 levels and overall survival.

Methods: We enrolled 51 patients (mean age 66.8±8.8 years) with primary LC and 10 healthy control subjects. 43 patients were ever smokers and 8 non-smokers. 12 patients had SCLC and 39 NSCLC (18 squamous, 16 adenocarcinoma and 5 NSCLC-NOS) with stage I-II/III/IV. 19/29 patients. Serum levels of OPN, VEGF and MMP-9 were measured by ELISA.

Results: Patients with LC had statistically significantly higher serum OPN levels than controls (45.9[10.5-266.8] vs 16.6[8.29.8] ng/ml, p<0.0001). ROC analysis showed that for OPN levels >25.8 ng/ml, sensitivity for detection of LC was 88.5% and specificity was 86.7%. OPN levels were also found to be significantly lower in non-smokers (p=0.019) and in older patients (p=0.026). Moreover, patients with squamous LC had statistically significantly higher OPN levels compared to patients with adenocarcinoma. Additionally, patients with serum OPN levels lower than median value (<45.9 ng/ml) had significantly better overall survival than those with higher levels (524 days vs. 306 days, p=0.01) and a 1-year survival rate of 80% vs. 37%. Finally, OPN levels were positively associated with VEGF levels (p=0.44, p=0.001).

Conclusions: OPN levels were increased in patients with LC, and higher levels were correlated with worse survival, thus suggesting a possible diagnostic and prognostic value of OPN in patients with LC.

Investigation of survivin gene polymorphism in non-small cell lung cancer patients (NSCLC)

Engin Ayne1, Ender Coskunpinar1, Ayse Eren1, Onur Kurn1, Yasemin Musten Oltulu2, Nergiz Akkaya2, Akif Tun1, Aysum Aynaci1, Ilhan Yaylim2, Pinar Yildiz1, 1Pulmonology, Yedikule Chest Diseases and Thoracic Surgery Education and Research Hospital, Istanbul, Turkey; 2Department of Molecular Medicine, Istanbul University Institute of Experimental Medicine, Istanbul, Turkey

Introduction and aim: Survivin gene is one of the first reported inhibitors of apoptosis proteins (IAPs), which is an important family of proteins that regulate apoptosis. A common polymorphism at the survivin gene promoter (-31 GC) has been shown to influence survivin expression and the risk for cancer development.

Purpose of this study reports, relation between Turkish population who have survivin polymorphism and NSCLC also; its relevant with diseases’s development and prognosis.

Methods: 146 NSCLC cases and 98 healthy control cases who were diagnosed at Yedikule Chest Diseases and Chest Surgery, Training and Research Clinical third center were included in this study. Pulmonary function test and routine bio-chemical analysis were done for all voluntaries. PCR-RFLP technique was used for genotyping.

Results: Genotype distribution of Survivin gene’s -31GC region were detected (n=146) %77.4 GC (n=113), % 18.5 GC (n=27), %4 CC (n=6); at patient group and (n=98) % 6.1 GC (n=56), %47.5 GC (n=34), %46.4 CC (n=8); % (p=0.003), at control group: -464 TC region were detected (n=146) %40.4 TT (n=59), %48.6 TC (n=71), %11.0 CC (n=16); at patient group and (n=98) %55.1 TT (n=54), %40.8 TC (n=40), %41.1 CC (n=4) (p<0.031), at control group; -644T/C region were detected (n=146) %40.4 TT (n=59), %.48.6 CC (n=71), %11.0 CC (n=16); at patient group and (n=98) %55.1 TT (n=54), %40.8 TC (n=40), %41.1 CC (n=4) (p<0.031), at control group; -844 T/C region were detected (n=146) %40.7 TT (n=58), %45.9 TC (n=71), %11.0 CC (n=16); at patient group and (n=98) %57.1 GC (n=56), %32.7 GC (n=32), %10.2 CC (n=10) (p=0.484) at control group.

Conclusion: These results show that Survivin gene’s -31 GC polymorphism causes predisposition to lung cancer development in Turkish population.
Cox regression analyses (tumor size (P<0.01)). Higher pre-surgery serum PlGF levels were significantly associated with larger tumors (P<0.001). Within lung cancer patients compared to COPD patients and healthy controls, 0.645, 1.192 and 1.628 respectively. There was a negative correlation between stage and HO-1 activity.

Conclusions: HO-1 activity is reduced in patients with lung cancer and correlates with disease severity, suggesting its protective effect as an antioxidant enzyme. These findings may propose a role of agents stimulating HO-1 as a novel therapeutic approach in lung cancer.

P4213
Increased serum placenta growth factor level is significantly associated with progression, recurrence and poor prognosis of lung cancer
Shih-Lung Cheng, Internal Medicine, Far Eastern Memorial Hospital, Taipei, Taiwan

We recently expressed the presence of placenta growth factor (PlGF) in lung cancer specimens is correlated with the progression and prognosis. In this study, serum samples were obtained from 72 patients with lung cancer and from 30 normal control cancer specimens is correlated with the progression and prognosis. In this study, serum samples were obtained from 72 patients with lung cancer and from 30 normal control group.

Results: Serum PlGF levels were significantly higher in lung cancer patients than in normal controls (9.1±10.7 vs. 10.1±4.5, P<0.001). Serum PlGF levels dropped to near the normal control levels after surgical cancer removal. Higher pre-surgery serum PlGF levels were significantly associated with larger tumors (P<0.014). Overall response rate was 85.7% in EGFR mutation positive, 32.9% in EGFR mutation negative and 31.5% in patients with COPD and healthy nonsmokers controls.

Methods: IS was conducted according to a standard protocol. HO-1 levels were measured in IS supernatant by a bilirubin reduce-dependant reaction using bilirubin as end product.

Results: Subjects (31 with lung cancer, 29 with COPD and 30 healthy non-smokers) underwent IS and HO-1 level measurements. Mean HO-1 levels were significantly (p<0.001) lower in lung cancer patients compared to COPD patients and healthy controls.

Conclusion: Our study demonstrates that higher serum PlGF levels are associated with larger lung cancers.

P4214
Epidermal growth factor receptor mutation status in advanced non-small cell lung cancer: A single institution experience
Nemiga Yasuakine1, Marcus Zemaitis1, Vidalas Saraskas2, Asla Vitkauskienė3, Skaudris Miliauskas1, Raimundas Sakalauskas1, 1Department of Pathological Anatomy, Medical Academy, Lithuania University of Health Sciences, Kaunas; 2Department of Pulmonary Diseases, Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel; 3Laboratory of Pulmonary Diseases, Laboratory National Service for IELD, Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel; 4Sulklev Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel

Background: Lung cancer is a leading cause of morbidity and mortality worldwide, resulting in substantial economic and social burdens that are constantly increasing. There is a strong correlation between inflammation and oxidative stress and malignant transformation. Heme oxygenase-1 (HO-1) is a cytoprotective enzyme that plays a central role in the defense against oxidative stress. HO-1 has anti-inflammatory, anti-proliferative and anti-apoptotic properties and is involved in the regulation of immunological balance in a wide range of lung diseases, including lung cancer.

Conclusions: HO-1 activity is reduced in patients with lung cancer and correlated with disease severity, suggesting its protective effect as an antioxidant enzyme. These findings may propose a role of agents stimulating HO-1 as a novel therapeutic approach in lung cancer.

P4215
Role of progestrin releasing peptide (ProGRP), a serum based biomarker in early diagnosis of SCLC in cohort of high-risk patient presenting with symptoms related to lung cancer
Dawei Ying1, Yong Zhang1, Baishen Pan2, Yuanlin Song1, Chunxue Bai3, 1Department of Pulmonary and Critical Care Medicine, Zhongshan Hospital Fudan University, Shanghai, China; 2Department of Laboratory Medicine, Zhongshan Hospital Fudan University, Shanghai, China

Lung cancer has become the top killer among malignant tumors in China during past three decades. Mortality rate of lung cancer are about 23 times and 13 times higher in current male and female smokers compared to lifelong nonsmokers. An estimated 350 million people smoke in China. Early diagnosis of lung cancer and more significantly Small Cell Lung Cancer (SCLC) is a major challenge.

In the present study we analyzed serum samples of 144 high-risk patients using a serum based biomarker panel comprising of CEA, CYFRA 21-1, SCC, and ProGRP. These patients visited our service, during June 2011 to January 2012 with symptoms related to lung cancer. The average age of patients was 64.14±8.59 years. Total 92 patients were diagnosed with lung cancer (73 NSCLC, 16 SCLC, 3 unknown), 44 patients were diagnosed of non-malignant tumors while 8 patients had unknown clinical diagnosis of the lesion. The final diagnosis was based on pathology results.

Conclusion: Increased serum ProGRP in patients diagnosed with SCLC. The mean ProGRP conc. in patients with SCLC was 3731 pg/mL compared to the mean value of 33 pg/mL for patients with NSCLC and 54 pg/mL for patients with non-malignant tumors. The results showed that ProGRP can be used to identify patients that may have SCLC with a simple blood test on the same day which can lead to early diagnosis of SCLC by histological method and hopefully better prognosis. This test may also improve the differential diagnosis and selection of therapeutic approach for the patient.

This study was supported by National Basic Research Program of China (973 Program) No. 2012CB933300.

P4216
Investigation of a relationship between NF-KBIA gene polymorphism and non small cell lung cancer (NSCLC)
Farangiz Ghodrati1, Gokhan Ozkan2, Engin Ayню1, Yasemin Musteri Oltulu2, Ender Coskunpinar1, Pitay Vithya3, Ilhan Yavuz1, 1Department of Genetics and Biostatistics, Istanbul University, Istanbul, Turkey; 2Department of Molecular Medicine, Istanbul University Institute of Experimental Medicine, Istanbul, Turkey; 3Pulmonology, Third Clinic, Yedikule Chest Diseases and Thoracic Surgery Training Hospital, Istanbul, Turkey

Nuclear factor kappa b (NF-κB) is defined as a protein family. NF-κB (IkBα) is inhibitory of NF-κB transcription factor. It binds NF-κB transcription factor and blocks carrying NF-κB factor to nucleus and binding to DNA. NF-κB (IkBα) is a gene that contains six exons and locates in q413 chromosomal region. Purpose of study reports relation between Turkish people who have NF-κBIA gene polymorphism and NSCLC.

Method: 99 lung cancer cases and 99 healthy control cases who were diagnosed in our hospital included in the study. PCR-RFLP technique was used for genotyping.

Results: Genotype distribution of NF-κBIA gene’s relevant region were detected (n=99) 17.2% AA (n=17), 48.5% AG (n=48), 34.3% GG (n=34) at patient group and (n=99) 21.2% AA (n=21), 45.5% AG (n=45), 33.3% GG (n=33) at control group.

783s
Lung cancer (LC) has high morbidity and mortality rates. Today, research in biomarkers is a hot topic, and among these, the least frequently studied, are those of the metabolomics field.

Our aims are to present preliminary data using metabolomics techniques for the detection of differentiated patterns between patients with LC and non-lung cancer (NLC) patients, to obtain an effective screening method.

We obtained blood, urine, and bronchoalveolar lavage (BLA) samples from a group of patients who underwent bronchoscopy, for further analysis through mass spectrometry methods. These techniques provide us with metabolic fingerprinting, allowing the study of the metabolites involved in the process.

Identification of the resultant metabolites was performed through mass-mass fragmentation procedures. Guided by mass spectrum, the results where processed by Partial Least Squares Discriminant Analysis. We compared the results from both groups.

Initially, 7 LC patients and 7 NLC subjects' samples were included. We found differences in metabolite profiles among these groups, allowing us to differentiate between LC and NLC cases. Including the blood and urine samples, we were able to identify potential overexpressed markers, such as choline, phosphocholine, and propionylcarnitine, leaving analysis of BLA samples results pending.

In conclusion, both groups showed different metabolomics profiles in the analyzed samples, this allows for its statistical discrimination.

The preliminary data raises the possibility of further studies that will allow the development of early screening techniques.

Increased levels of plasmatic dopamine in human small cell lung cancer

Davide Scorzi, Salvatore Mariotta, Emanuela Cherubini, Pierdona Bruno, Luca Tabbi, Federica Fiorenti, Annalisa Sciamanna, Alessio Piratino, Vittorio Pietrangeli, Alberto Ricci. Dipartimento di Medicina Clinica e Molecolare, Università La Sapienza, Roma, Italy

Dopamine (DA) is a monoamine neurotransmitter with pleiotropic effects that exerts an immunomodulatory action. Inhibition of proliferation and cytotoxicity of CD4+ and CD8+ T cell. In human malignancies increased plasmatic DA levels are documented. In addiction recent reports also indicate an active production of DA by some human tumor cell lines. Small cell lung cancer (SCLC) is a very aggressive neuroendocrine human tumor able to produce several molecules with neuroendocrine effect. Actually no data are available about DA plasmatic levels in patient affected by SCLC.

Aim of this study is to assess plasmatic DA levels in SCLC patients in comparison with non-small cell lung cancer (NSCLC) and healthy subjects and to correlate this data with the plasmatic levels of neuron specific enolase (NSE).

Before treatment whole blood was collected from patients affected by lung cancer (n=50; SCLC n=15; NSCLC n=35), healthy subjects (n=10), and plasma was separated to assess its DA content by High Performance Liquid Chromatography (HPLC).

DA levels are significantly increased in patients affected by SCLC comparing with NSCLC [102.5 ± 18.3(SEM) vs 52.3 ± 5.8(SEM); p < 0.05] and with healthy subjects [102.5 ± 18.3(SEM) vs 38.9 ± 13.5(SEM); p < 0.05]. In SCLC patients these increased levels are inversely correlated with the NSE plasmatic values (r = -0.5; p < 0.05).

The data here presented show increased plasmatic DA levels in SCLC patients comparing with NSCLC and healthy subjects. Further studies are needed to assess if this increased plasmatic levels represent an active ectopic secretion of DA by SCLC and if this may exerts a possible role in the tumor growth.

Potential angiogenic biomarkers in patients with non small cell lung cancer: Possible implications

Soad Abdel Ghani, Nagla Elmelegy, Aliae Mohamed-Hussein, Randa Hanna. Biochemistry, Faculty of Medicine, Assiut, Egypt. Biochemistry, Faculty of Medicine, Assiut, Egypt. Chest Department, Assiut University Hospitals, Assiut, Egypt. Biochemistry, Faculty of Medicine, Assiut, Egypt.

To date, no single agent has gained a sufficient prognostic significance for NSCLC patients. So, there is an urgent need for new innovative biomarkers in NSCLC. The present study was designed to: 1) Evaluate the role of Nitric Oxide (NO), Sialic Acid (SA) and Glutathione S-Transferase (GST) as prognostic indicators in NSCLC. 2) Correlate the above parameters levels with the clinicopathological status of the patients.

The study included 30 patients with newly diagnosed histopathologically confirmed NSCLC, as well as 10 healthy volunteers with matched age and sex as controls. Blood samples and lung tissue biopsies were taken from all subjects on admission and after chemotherapy with and without Nimesulide (Cox-2 inhibitor).

Results: Serum and tissue levels of NO, SA and GST activities were significantly higher in NSCLC patients compared to controls. These levels decreased significantly after chemotherapy (specialy if Cox-2 inhibitors were added). The serum and tissue levels of the studied parameters decreased significantly in the responders compared to resistant cases.

In conclusion, NO, SA, besides GST correlated significantly with the clinicopathological status of NSCLC patients and are considered cheap sensitive prognostic biochemical indices.
Ki67 expression was studied by immunohistochemistry techniques. We used the Chi square test to analyze the differences in the Ki67 expression between the squamous cell carcinoma and adenocarcinoma and a bivariate analysis to study the prognostic significance of Ki67 expression according to the 5 years survival using the Wilcoxon-Gehan (W-G) test and the log rank (L-R).

Results: We included 146 patients, 91% were men with a median age of 67 yo. 99 were squamous cell carcinoma, 37 adenocarcinoma and 10 large cell carcinoma. The Ki67 expression was positive in 56% cases, negative in 42% and no valid in 2%. The Ki67 positive expression found in the different types of NSCLC is shown in Table 1 and the prognostic significance of Ki67 expression, in NSCLC and its different types, is shown in Table 2.

Conclusion: In the population studied, the Ki67 expression was higher in the squamous cell carcinoma and was associated with a bad prognosis.

P4223

Increased activity of Lyn tyrosine kinase causes multiple chronic obstructive pulmonary disease-like changes in mouse

Wei Leon Lam,1,2 Erika Duan,3 Jonathan L. McQuilter,1 Gary P. Anderson,1 Margaret L. Hibbs1.1Department of Pharmacology, University of Melbourne, Victoria, Australia; 2Department of Immunology, Alfred Medical Research and Education Precinct, Melbourne, VIC, Australia; 3Ludwig Institute for Cancer Research, Ludwig Institute for Cancer Research, Melbourne, VIC, Australia

Lyn is a member of the Src family of tyrosine kinases and it was first discovered to be an key regulator of B cell activation. There are many studies now showing that Lyn also plays a role in the progression of myelodysplastic syndromes and several types of epithelial cancer. The Lyn gain-of-function ( Lyn up/up) mutant mouse was created to investigate putative proto-oncogenic roles of Lyn. Lyn up/up mice develop chronic lung inflammation and emphysema at young age. The extent of alveolar airspace enlargement in the Lynup/up model mouse is more severe than any other gene-targeted or smoke-induced mouse model of emphysema to date. Chronic lung inflammation, characterised by increase in macrophages, neutrophils and T cells and reduced number of alveolar wall macrophages and osteopetrosis in COPD patients were also observed in Lynup/up mice. Lung tumors have also been found in some aged animals although penetrance is low. Histological assessment of lungs in the Lyn up/up mice suggest that alveolar epithelial cells are hyperplastic and there were a lack of blood vessels formation around the alveoli. There is also reduced numbers of apoptotic cells in the lung as detected by TUNEL assay. This suggests that alveolar airspace enlargement is not a result of emphysematous destruction caused by chronic inflammation but a possible attribute of perturbed signaling in endothelial and epithelial cells that needs further investigation. The complex process that leads to the occurrence of emphysema together with lung cancer is still not understood. The Lyn up/up mouse will be an excellent model to investigate the underlying co-determinant of the two seemingly opposite outcome of lung disease.

P4224

Genetic polymorphisms of k-ras gene in smoking related diseases

Radwa El-beyd, Alaa Shalaby, Olfat Shaker, Yousri Akl, Ahmed Al-halfawy, Assem Elessawy, Chest Diseases, Faculty of Medicine-Fayoum University, Fayoum, Egypt Chest Diseases, Faculty of Medicine-Cairo University, Cairo, Egypt Chest Diseases, Faculty of Medicine-Cairo University, Cairo, Egypt Chest Diseases, Faculty of Medicine-Cairo University, Cairo, Egypt Chest Diseases, Faculty of Medicine-Cairo University, Cairo, Egypt

Ras is a family of genes that have many biological functions but mainly control cell growth and development. Chemicals in cigarette smoke cause mutation in ras gene. Smoking causes lung cancer because the carcinogen bind strongly to the precise site in k-ras gene. Our aim of the study is to detect genetic polymorphism of k-ras gene in smoking related disease.

The study included 50 patients, 20 with chronic obstructive pulmonary disease (COPD), 20 with lung cancer and 10 normal subjects. All patients and normal subjects were smokers. Serum samples were evaluated. DNA was extracted and mutational analyses performed using a PCR assay. Two (10%) out of 20 COPD patients and four (20%) out of 20 lung cancer patients had mutated k-ras gene, while there was no mutation in the control group. The mutation of k-ras gene was associated with smoking history, severity of COPD and cell type of lung cancer. Mutations were observed in heavy smokers in COPD (13.3%) and lung cancer (22.2%) patients. Moderate (14.3%) and severe (12.5%) obstruction in COPD patients were associated with mutations. All k-ras mutations were observed in non small cell lung cancer (NSCLC (95%)).

In conclusion, k-ras mutation is detected in the lung cancer and COPD patients suggesting that COPD patients were in the early stages of developing cancer. For COPD patients the ras gene might be a biomarker for cancer as a screening of DNA in serum using a noninvasive technique.
Poor treatment outcomes have been reported for tuberculosis (TB) patients harbouring strains resistant to isoniazid and rifampicin (multidrug resistance or MDR-TB), fluoroquinolones and/or second-line injectable drugs. We undertook a meta-analysis for response to treatment using individual data for MDR-TB patients whose strains had additional resistance to fluoroquinolones (MDR-TB+FQ), second-line injectables (MDR-TB+Inj) or both (extensive drug resistance; XDR-TB) including demographic and clinical details, treatment regimens, and outcomes. 26 centres provided data for 424 MDR-TB+Inj, 1192 MDR-TB+Inj, 405 XDR-TB, and 4776 other MDR-TB patients susceptible to FQ and Inj. Success was lower in MDR-TB+FQ (adjusted OR=0.6 [95%CI 0.5-0.7]) and XDR-TB patients (0.4 [0.3-0.6]) than in those with MDR-TB+Inj (0.8 [0.7-0.9]) and those with MDR-TB and no additional resistance (reference). No single drug was significantly associated with treatment success in MDR-TB+FQ and XDR-TB patients. In XDR-TB patients, success was highest if at least 6 drugs were used in the intensive phase (4.9 [1.4-16.6]) and 4 in the continuation phase (6.1 [1.4-26.3]). Study results suggest that regimens of a similar duration to those recommended in MDR-TB patients but containing more drugs achieve better results in XDR-TB patients. As all data in the analysis were from observational studies, bias may be substantial and better quality evidence will be needed to guide the optimization of regimens.

### Conclusion

Algorithms are needed for identifying patients suitable for treatment of MDR-TB. DOTS PLUS ensures both correct regimens with access to all active second line drugs; fluoroquinolones and/or second-line injectable drugs present a serious challenge to TB treatment programmes. In 2006, the World Health Organization (WHO) started DOTS PLUS in 20 countries, with 1-3 cases. In countries with more than half the cases in 2006, the World Health Organization (WHO) started DOTS PLUS in 20 countries, with 1-3 cases. In countries with more than half the cases in 2006, the World Health Organization (WHO) started DOTS PLUS in 20 countries, with 1-3 cases.

### References

- **Introduction:** The MDR programme to the West Coast Winelands area consists of impatient treatment centres and an outreach programme, for treatment of patients in the community.
- **Objective:** To compare baseline demographic and culture conversion rates among patients initiating MDR-TB treatment in the community versus those initiated as inpatients.
- **Methods:** We retrospectively reviewed clinical records at the impatient Centre of patients diagnosed between 2000 – 2006 with a first episode of MDR-TB. Patients were included if started on a regimen with 3 or more second-line anti-TB drugs (SLD), came from this area and had a bacteriological confirmed diagnosis. From diagnosis to treatment initiation and from initiation to culture conversion were determined, and demographic and clinical indicators at baseline.
- **Results:** 502 patients were diagnosed with new MDR-TB, among which 324 (64.5%) started on SLD. Median age was 34, with 105 females (32%). 45/342 (45%) started in the community vs. 179 (55%) as inpatients. Inpatients and community-based were similar in baseline age and AFB result; but inpatients were more likely to be female (40% v. 23%; p<0.01), and had lower weights (47.3 kg v. 53.3 kg; p<0.01). Inpatients had a longer time to treatment initiation (76 v. 64 days; p<0.01). Of 172/545 (31%) who converted, 96 (54%) were inpatients and 76(145/52%) community-based. Days to conversion were also similar between the two groups: community 121 (Q1 61-206.5) and inpatient 105 (Q1 64.5-164).
- **Conclusion:** Algorithms are needed for identifying patients suitable for treatment of MDR-TB.

---

**DOTS PLUS versus non DOTS PLUS outcomes in MDR-TB patients**

Aim: To assess the impact of DOTS PLUS strategy on cases registered in Iasi, Romania in 2007-2010.

Method: Comparative analysis of MDR-TB characteristics, treatment regimens and outcomes.

Conclusions: Treatment outcomes in DOTS PLUS group were significantly better.

---

**Aminoglycoside ototoxicity monitoring in multidrug resistant tuberculosis:**

**How much is enough?**

Aim: To evaluate the use of frequent audiometric assessments in MDR-TB patients receiving extended-duration aminoglycosides and to describe their influence on hearing.

Conclusions: DOTS PLUS ensures both correct regimens with access to all active second line drugs and regular drug supply; it is an opportunity for proper management of MDR-TB cases.
4281 Adverse effects of moxifloxacin during tuberculosis treatment

Erik Schmok, Graham Bothamley. Respiratory Medicine, Homerton University Hospital, London, United Kingdom

Aim: Prolonged use of moxifloxacin in tuberculosis (TB) may have adverse effects, particularly prolongation of the QT interval and arrhythmias.

Methods: All TB patients treated with moxifloxacin from 2003-2011 were identified. Concurrent medication and history of drug abuse were noted. Charts noted adverse effects. ECGs were obtained on and off treatment and the longest QTc was used for the study.

Results: 93 patients treated with moxifloxacin for at least one month were identified. Adverse effects included: nausea (2), palpitations (1) and photosensitivity (1); itching, arthralgia, flushing and depression were probably due to concurrent medication. 60 patients had ECGs, mostly taken during treatment and none had a QTc >500 ms. Variability in QTc was high (standard deviation 31 ms). One male had a QTc >450 ms and 3 females >470 ms but none had arrhythmias; one patient developed right bundle branch block during treatment, but this persisted when not taking moxifloxacin. All 4 used opiates.

Code Sex Pre-treatment QTc's (ms) QTc's during treatment (ms)
8.078 M 441, 424, 444, 476 430, 472, 479
6.104 F 421, 446, 451, 456, 460, 471, 455, 476, 484, 476
9.045 F 415, 419, 460, 482 456
9.129 F 404, 409, 439, 480, 480, 490, 492

28 patients had paired ECGs on and off treatment showing a QTc interval increase of 6.4 msec (95% CI -4.2 to 17.0 msec). Five increased by 69, 51, 48, 44 and 28 patients had paired ECGs on and off treatment showing a QTc interval increase of 9.129 F 404, 409, 438, 450, 480, 373, 426, 429, 439, 480, 490, 492.

Conclusions: Moxifloxacin is well tolerated in treating TB. ECGs should be obtained at baseline and periodically, with particular attention to the QT interval.

4293 Short term glucocorticoid therapy in acute exacerbations of chronic obstructive pulmonary disease: "REDUCE", a non-inferiority multicenter trial

Tilmann Drescher1, Urvula Düring2, Christoph Hensen3, Yolanda Leibbrandt4, Sabrina Maier5, David Miedinger6, Beat Müller7, Andreas Scherr7,8, Christian Schindler9, Rolf Stockli10, Sebastian Viarte11, Christophe von Garnier10, Michael Tamm1, Jonas Rathsahuser1.

1Clinic of Internal Medicine, University Hospital, Basel, Switzerland; 2Clinic of Internal Medicine, University Hospital, Basel, Switzerland; 3Clinic for Pulmonology, University Hospital, Basel, Switzerland; 4Swiss Tropical and Public Health Institute, University of Basel, Switzerland; 5Clinic of Pneumology, University Hospital, Bern, Switzerland

Background: The optimal dose and duration of systemic glucocorticoid therapy for acute exacerbations of COPD (AECOPD) is unknown. In this trial, we aimed to demonstrate non-inferiority of 5 days vs 14 days of systemic glucocorticoids with respect to COPD exacerbation.

Methods: Patients admitted to hospital with AECOPD were randomized to receive prednisolone-equivalent daily for either 5 or 14 days in a placebo-controlled fashion. Follow-up was 180 days. The primary endpoint was time to exacerbation.

Results: Of 721 evaluated patients, 327 underwent randomization, and 304 completed the study. Mean age was 63.9±23.2 years; mean FEV1%predicted 51.5±14.3% and 60.8% were male. Exacerbations occurred in 36.8% and 38.4% of patients in the 5 day and 14 day treatment arms, respectively (p=0.81). Time to exacerbation did not differ between groups in the intention-to-treat and per-protocol analyses (hazard ratios for the short treatment arm, 0.92 (95% CI, 0.64 to 1.34; p=0.67) and 0.91 (95% CI, 0.63 to 1.32; p=0.62); respectively); nor did time to death or the combined endpoint of exacerbation and/or death, with both hazard ratios for the short treatment arm being <1 as well. With respect to the primary outcome, short treatment was not inferior to conventional treatment, since the 95%-confidence intervals did not include the predefined non-inferiority threshold of 1.515.

Conclusion: In AECOPD, 5-day treatment with systemic glucocorticoids is non-inferior to 14-day treatment with regard to re-exacerbation during 6 months of follow-up.

4292 Adverse reactions during treatment of multidrug-resistant and extensively drug-resistant tuberculosis

Susana Boavida1, Inês Sanches2, Ana Antunes3, Sérgio Campanilha2, Ana Henriques4,1 Ana Maria Correia5, AnaBela Silva3, Raquel Duarte5,7, Serviço de Doenças Infecciosas, Centro Hospitalar do Porto- Unidade Joaquin Urbano, Porto, Portugal; 2Serviço de Pneumologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 3Serviço de Pneumologia, Centro Hospitalar de Vila Nova de Gaia/Espinho, Porto, Portugal; 4Departamento de Saúde Pública, Administração Regional de Saúde do Norte, Porto, Portugal; 5Laboratório de Micobactérias e Tuberculose, Instituto Ricardo Jorge, Porto, Portugal; 6Centro de Diagnóstico Pneumológico, Centro de Diagnóstico Pneumológico, Porto, Portugal; 7Departamento de Epidemiologia Clínica, Medicina Preventiva e Saúde Pública, Faculdade de Medicina do Porto, Portugal

Introduction: Treatment of multidrug-resistant tuberculosis (MDR-TB) and extensively drug-resistant tuberculosis (XDR-TB) is often complicated by adverse reactions.

Objectives: To describe the adverse reactions, time of occurrence, attitudes and risk factors among MDR/XDR-TB patients.

Methods: Retrospective cohort of all patients with MDR/XDR-TB evaluated at the Regional Referral Center for MDR/XDR-TB in northern Portugal from July 2009 until January 2012.

Results: We analyzed 29 patients, 19 (65.5%) men, mean age 48 years. Eighteen (62.1%) had co-morbidities of which HIV infection was the most frequent (8 patients). Twenty-two patients (75.9%) had adverse reactions and 17 (77.3%) had to suspend the drug involved. Median time to occurrence of adverse reactions was 94 days (min=2, max=619). Toxicity related to the injectable drug was the most frequent - 9 (31%) with ototoxicity, and 7 (24.1%) with renal insufficiency. Hypothyroidism was present in 6 (20.7%) of the patients. Psychiatric disorders, associated to Cicloserine occurred in 6 (20.7%) patients. Multivariate analysis could not identify independent risk factors in relation to adverse reactions. The occurrence of adverse reactions was not associated with a higher risk of death or a worse outcome.

Conclusions: The occurrence of adverse reactions more often correlated with the injectable drug and occurred around the third month. We could not identify independent risk factors for adverse reactions and they did not affect the outcome.

4294 Relationship between exacerbation frequency and survival post MI in COPD patients

Jennifer Quinn1, Emily Herrett1, Adam Timms1, Harry Hemingway1, Jadwiga Wedzicha1, Liian Smeeth1. NCDE, London School of Hygiene and Tropical Medicine, London, United Kingdom; 2Cardiology, Barts and the London NHS Trust, London, United Kingdom; 3Epidemiology and Population Health, University College London, United Kingdom; 4Academic Unit of Respiratory Medicine, University College London, United Kingdom

COPD patients are at increased risk of myocardial infarction (MI).1 Particularly after an exacerbation. 2 COPD patients have shorter survival post MI compared with patients with infrequent exacerbations (IE).

All COPD patients with a first MI between 1/1/03 and 31/12/08 as recorded in the MINAP, who had no previous evidence of MI in GPRD or MINAP were included. Patients under 35, not registered with GPRD at the time of MI, or with less than 1 year of follow-up before their MI were excluded. Exacerbations were defined using pre-defined READ codes and prescription of pre-specified antibiotics and/or steroids. FEV1 had ≥ 2 exacerbations in the year preceding MI and IE <2. Data were provided by the CALIBER group at UCL. The primary outcome was death after MI. Cox proportional hazards models were used to adjust for potential confounders. 1063 patients were identified with a first STEMI or NSTEMI. 111 (10.4%) FE and 952 (89.6%) IE. The unadjusted mortality rate in MI was 285.7 deaths (95% CI 222.3-367.2) per 1000 person years and in IE 152.4 deaths (95% CI 138.1-168.1) per 1000 person years. Adjusting for confounding by smoking and gender and stratifying by age, mortality was greater in FE compared to IE; HR 1.61 (95% CI 1.23-2.11); p<0.001. Mortality was greater in patients who exacerbated in the 2 months preceding the MI; HR 3.88 (720-76 550); p<0.001.

Conclusions: FE have shorter survival after a first MI than IE. There appears to be an association between timing of exacerbations, exacerbation frequency and survival after 1st MI.

4295 The impact of airway infection on cardiovascular risk during COPD exacerbations
Anant R.C. Patel, Gavin C. Donaldson, Beverly S. Kowlessar, Alex J. Mackay, Davinder Garcia, Sibthorpe George, Jodwiga A. Wudytsch, John R. Hurst
Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom

Arterial stiffness, a validated measure of cardiovascular risk, increases from stable COPD to exacerbation (Patel et al, ERS 2011). We hypothesised this increased cardiovascular risk was mediated by airway infection.

We measured aortic pulse wave velocity (aPWV) in the stable state, at exacerbation and during recovery at 3,7,14 and 35 days thereafter. Infective exacerbations were defined by a potentially pathogenic microbe (PPM) in exacerbation sputum by culture or positive PCR for *H. influenzae, S. pneumoniae, M. catarrhalis*, or human rhinovirus.

Differences in the area under the curve (AUC) adjusted for stable aPWV level between groups were compared by unpaired t-test.

55 COPD patients (32 male, 11 current smokers) had a mean±SD FEV1 of 1.14±1.4L (46.7±18.5% predicted) and FEV1/FVC ratio 0.46±0.14. Two-thirds of them (36/55, 65%) produced a sputum sample at exacerbation. Two-thirds of these events (24/36, 67%) had an identifiable PPM. Patients with an infective exacerbation had a greater rise in arterial stiffness from stable state to exacerbation (1.4±1.7ms-1 vs 0.4±1.0ms-1, p=0.050).

Arterial stiffness was also higher during the recovery period in those with an infective exacerbation (AUC 37.4±8v 37.1±9.5ms-1days, p=0.036).

The increase in arterial stiffness during COPD exacerbations appears to be driven by airway infection and may explain the association between these infective events and increased cardiovascular risk.

4296 Evaluation of multiple admissions of COPD patients: European COPD audit
Jose Luis Lopez-Campos1, Sylvia Hartl2, Francisco Pozo-Rodriguez3, Michael Roberts4.
1Unidad Medico-Quirurgica de Enfermedades Respiratorias, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocio & CIBER de Enfermedades Respiratorias, Seville, Spain; 2Respiratory, Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom

Background: Patients with multiple admissions represent an especially at risk population with therapeutic and prognostic implications. The European COPD Audit is a clinical audit to evaluate clinical practice variability, clinical and organisational factors related to outcomes for COPD admissions across Europe (422 hospitals from 15 European countries). The current presentation aimed at evaluating multiple admission patients and their clinical features and outcomes.

Methods: The study comprised a first 8-week phase during which all consecutive cases admitted to hospital due to an exacerbation of COPD were identified and information on clinical practice and outcomes was gathered. During the 90-day follow-up second phase mortality and readmissions were sought. Multivariate odds ratios (OR) were calculated to evaluate factors associated with multiple admissions.

Results: Data on 14,456 cases are reported, of which 6,821 (47.2%) were the first admission (countries range 29.3-74.5%). Patients characteristics associated with multiple previous admissions were current smoker (OR 0.69), FEV1 value (OR 0.99), and PO2 value (OR 1.003). Health care proved to multiple admission patients was different in terms of chest x-ray not done (OR 2.03), methylxanthines use (OR 1.2), antibiotic use (OR 0.78), diuretics use (OR 1.16) and use of NIV (OR 1.11). Reports at discharge tended to have a higher use of theophylline (OR 1.23), oxygen (OR 1.8) and mechanical ventilation (OR 1.5). We also found an impact on readmission rate (OR 0.4).

Conclusions: Multiple admission patients represent a different type of COPD patient admitted to hospital, with a more severe disease requiring more resources.

4297 Emergency oxygen use and monitoring in the pre-hospital and acute hospital setting – The significance of a common problem
Jamie Johnson1, Lucy Malpas2, Fenella Johnstone3, Mike Malpas3.
1Respiratory Medicine, Worcestershire Royal Hospital, Worcester, United Kingdom; 2A + E, Worcester Royal Hospital, Worcester, United Kingdom; 3Gastroenterology, Solihull Hospital, Birmingham, United Kingdom

Introduction: Evidence shows that oxygen (O2) can cause decompensated type 2 respiratory failure (T2RF) increasing morbidity and mortality in COPD patients.

Aim: To review pre-hospital and emergency hospital use of O2 in COPD patients.

Methods: All COPD admissions in January 2011 to Worcester Royal Hospital were audited against BTS guidelines.

Results: Ambulance documentation showed no record of previous NIV or O2 alert card. There is no box to record FiO2 on the ambulance data form. O2 dose (51.6%) and mask (48.4%) recordings were suboptimal. 60% of patients were given 28% venturi masks and 13.3% non-rebreather masks. 45.8% of patients were given O2 with adequate saturations (sats). 72% of patients given O2 had sats > 92%.

In hospital, 9.5% of clerking charts contained a history of prior NIV. 2/3 of patients with adequate sats were given O2. 80% of those on O2 had sats above 92. 36.7% of patients had O2 prescribed with 45% having correct sats ranges. 15 patients had T2RF: 5 with sats > 92%. 3 patients met the criteria of NIV: all had sats > 92%.

Mean length of stay (LOS) was 6 days longer in those who had NIV. 90.5% of discharge letters did not contain an ABG result.

Conclusions: There is still a major issue with O2 use and monitoring in COPD patients. Patients are being given too much oxygen, it is not reviewed and documented accurately. This causes increased morbidity and cost, evidenced by those with hyperoxia developing T2RF and longer LOS. We recommend the ambulance data form includes an FiO2 box, O2 prescription is mandatory, documentation is improved and discharge letters include an ABG. Doctors, nurses and paramedics should all be regularly educated in O2 therapy.

4298 An audit of inpatient mortality and readmission rates in acute exacerbation of COPD – Exploring the role of comorbidity and inflammatory markers
Aisha McClintock-Tiongco, Arjun Patel, Jindruni Chakravarty, Acute Medical Unit, St. George’s Hospital, London, United Kingdom

Acute exacerbations of COPD is the cause of rising admissions and burden on resources in spite of systems to minimise inpatient stay and facilitate discharge. The system of reimbursements in the UK NHS, penalises hospitals for readmission within 30 days. Understanding the factors leading to early readmission may help to focus resources.

We audited inpatient records of 577 (female = 260) episodes in 12-months till Dec’11. Age, co-morbidities, length of stay (LOS), readmission rate, time to readmission, white cell count and C reactive protein were collected. 218 episodes with >1 admission, 47% readmissions within 30 days; and 20 inpatient deaths. Age 69 (±11) yrs men & 72 (±12) yrs women, p=0.02. The LOS was 6(±2) days men & 7 (±3) days women. 34 patients had >1 associated co-morbidity. Standard mortality was 35/1000 admissions.

Patients who died were older than (76±8 vs 70±11 yrs, p = 0.03) had higher (WCC 26.2±26 vs 12.7±9.8, p <0.01), CRP 79±100 vs 44±57 g/l, p = 0.01). A higher LOs was predicted by (WCCmax Lin reg coef B 0.118, p=0.05) and age (Spearmans r 0.19, p<0.001). Time to readmission was not predicted by any of the above parameters.

Inpatient mortality and LOS were predictably correlated with age and raised inflammatory markers. Nearly half of the patients were readmitted within 30 days, which would lead to morbidity and a loss of revenue. Yet, none of the common factors were found to predict the ‘risk of’ or ‘time to’, readmission. Therefore, future prevention of admission strategies may need to include telemedicine, monitoring at home and frequent flyrer clinic visits.

4299 Differences between men and women COPD admissions: Evidence from the European COPD audit
Christopher Michael Roberts1, Sylvia Hartl2, Francisco Pozo-Rodriguez3, Jose Luis Lopez-Campos1.
1School of Medicine and Dentistry, Barts and the London Queen Mary University of London, London, United Kingdom; 2Respiratory Care, Ludwig Boltzmann Institute of COPD and Respiratory Epidemiology, Vienna, Austria; 3Hospital 12 de Octubre, Instituto de Investigacion, Madrid, Spain; 4Unidad Medico-Quirurgica en Enfermedades Respiratorias, Instituto de Biomedicina de Sevilla, Hospital Universitario Virgen del Rocio, Seville, Spain

Introduction: Studies using administrative data from N America provide conflicting results for gender survival differences in COPD (Machado 2006, Gonzalez 2011). We used clinician collected data to look at Hospital and 90 day survival following admission with COPD exacerbation.

Method: The European audit programme collected retrospective data from clinical case notes and telephone enquiry from 15,821 patients admitted between October
Acute exacerbation of COPD is associated with three-fold elevation of cardiac troponin T. Machado Am J Respir Crit Care Med 2006;174:524. Gonzalez Thorax 2011;66:38. These data suggest women exhibit different COPD characteristics and have a higher mortality when admitted to hospital.

Determinants of exhaled NO in a population of subjects with different respiratory symptoms – Results from the Swedish GA2LEN survey

Andrei Malinovschi1, Khalid Alving2, Lennart Nordvall3, Christer Janson1.
1Department of Medical Sciences, Uppsala University, Uppsala, Sweden; 2Department of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden

The fraction of exhaled nitric oxide (FeNO) is a marker of steroid-sensitive airways inflammation and is used in asthma management. The Asthma Control Test (ACT) is one of the most used instruments to assess control in asthmatic subjects. The evidence for a relation between airways inflammation and asthma control is inconclusive so far. The aim of the present study was to assess the relation between FeNO and ACT score in treated, stable asthmatic children.

Within the frame of an industry-academy collaboration on minimally-invasive diagnostics (MIDAS), measurements of FeNO and specific IgE against aerosol allergens or food allergen mix were done in 165 asthmatic children (101 boys aged 10-18 years). Among the children, 79% (79/101) were positive against aerosol allergens and 61 (40%) tested positive against food allergens. Uncontrolled asthma (ACT score <20) was confirmed in 53 children.

FeNO levels in subjects with uncontrolled asthma (n=53) were approximately 30% higher than in subjects with controlled asthma (n=112): 19.8 ppb (15.5, 25.3) vs 15.1 ppb (13.1, 17.4), p=0.04. FeNO was a determinant of asthma control in logistic regression models both before (p=0.01) and after adjustments for gender, age, BMI, FEV1, IgE sensitisation to Aero- or food allergens (p=0.04). Furthermore, a significant relation between asthma control and FeNO could be found when using absolute values of the ACT score (p=0.016, p=0.004). In conclusion, increased FeNO in treated, stable asthmatic children relate to uncontrolled asthma. It has to be further studied if intensified anti-inflammatory therapy in these subjects would lead to improved asthma control.

Exhaled biomarkers to assess airway inflammation

Modeling of exhaled nitric oxide in relation to smoking history – A population based study

Bjorn Bakes1, Kjell Torén2, Anna-Carin Olin1.
1Allergology and Respiratory Medicine, Medicine, Gothenburg, Sweden; 2Occupational and Environmental Medicine, Medicine, Gothenburg, Sweden

Smokers produce less NO in central airways compared to nonsmokers whereas the effect of smoking on NO concentration in the peripheral alveolar regions remains unclear, particularly if axial diffusion of NO is considered. It is also unclear to what extent exhaled NO recover among ex-smokers. We have measured exhaled NO (FeNO) at three flow rates in a population sample of 3968 subjects and the aim of the present analysis has been to try and clarify effects of current and previous smoking on exhaled NO and its central and alveolar origin and to provide reference equations for exhaled NO for healthy smokers.

The essential findings are 1) FeNO of ex-smokers and nonsmokers are indistinguishable, 2) the apparent association between FeNO and time since smoking is considerably lower than the corresponding limit of normal healthy nonsmokers. 3) The association is considerably lower than the corresponding limit of normal healthy nonsmokers.

Exhaled nitric oxide levels predict uncontrolled asthma in children – Results from the MIDAS-study

Increased exhaled nitric oxide levels predict uncontrolled asthma in children

FeNO is a common method to assess airways inflammation. Determinants of FeNO have neverthless mostly been studied in the healthy general population. Therefore, we studied determinants of FeNO in a large population of subjects with respiratory symptoms that may reflect the type of patients seen in clinical practice. FeNO was measured in 1018 subjects with asthma, sinusitis, asthma and sinusitis, or symptoms suggestive of asthma but without fulfilling the asthma diagnosis criteria, aged 17-76 years (median 45 yrs).

Female gender, current smoking and having both parents smoking during childhood were related to lower FeNO while increased height, age, atopy and asthma diagnosis were related to higher FeNO, both before and after adjustments for variables given in Table.

In conclusion, constitutional factors, such as male gender, increased height and age, are related to increased FeNO in subjects with respiratory symptoms. They should be accounted for in clinical practice as their effect size is comparable to the effect of diagnosed asthma. Parental smoking during childhood was related to decreased FeNO and this warrants further studies.

Modeling of exhaled nitric oxide in relation to smoking history – A population based study

Smokers produce less NO in central airways compared to nonsmokers whereas the effect of smoking on NO concentration in the peripheral alveolar regions remains unclear, particularly if axial diffusion of NO is considered. It is also unclear to what extent exhaled NO recover among ex-smokers. We have measured exhaled NO (FeNO) at three flow rates in a population sample of 3968 subjects and the aim of the present analysis has been to try and clarify effects of current and previous smoking on exhaled NO and its central and alveolar origin and to provide reference equations for exhaled NO for healthy smokers.

The essential findings are 1) FeNO of ex-smokers and nonsmokers are indistinguishable, 2) the apparent association between FeNO and time since smoking is considerably lower than the corresponding limit of normal healthy nonsmokers. 3) The association is considerably lower than the corresponding limit of normal healthy nonsmokers.
Tanya Kralimarkova

Acute effect of inhaled corticosteroid on exhaled breath temperature in asthmatic patients

The first author is receiving an ERS Long Term Fellowship.

Conclusions: Both nNO and FENO are useful screening tests for PCD: using the composite score nNO * FENO < 7.1 ppb had a sensitivity of 92.6% and a specificity of 93.1% for a sensitivity of 92.0% from nNO measurement alone.

Figure 1. Normalized data from 5 eNoses based on different concentrations of ethanol.

Rationale: Breath analysis by electronic nose (eNose) technology represents a promising diagnostic tool in lung disease. A critical step in making this technology suitable for multi-centre trials, such as the U-BIOPRED Study, is to facilitate centralized measurements on multiple eNoses simultaneously. This can be accomplished with a (semi)-automatic measurement and control platform.

Methods: Ethanol was chosen as one of the calibration gases. Different concentrations (500 ppb-8 ppm) were generated by a permeation system. Measurements at all concentrations were done in duplicate. Total number of sensors in the platform was 81. The obtained data were processed by averaging duplicate measurements after normalisation (scale 0-1).

Results: The platform (not all individual sensors) was sensitive to ethanol at used concentrations (Fig. 1). The difference in normalized sensor deflections between duplicate measurements at 2 ppm was (mean [SD], range): 0.09 [0.1], 0.55-0.0004.

Conclusion: The eNose platform is capable of detecting ethanol at concentrations from 500 ppb to 8 ppm level with acceptable repeatability.

Implication: This method of platform calibration with standard gases is feasible and mandatory for quality control of eNose assessments in a multi-centre setting.

Do volatile organic compounds discriminate between eosinophils and neutrophils in vitro?

Florence Schleisch, 1 Jan Dallinga, 1 Monique Henken, 1 Agnes Boots, 2 Emiel Wouters, 1 Renaud Louis, 1 Frederik J. van Schooten, 2 Respiratory Medicine - ORA F 1 Lab, CHU Sart-Tilman, Liege, Belgium; 1Health Risk Analysis and Toxicology, Maastricht University, Maastricht, Netherlands; 2Respiratory Medicine, University Hospital, Maastricht, Netherlands

Inflammation associated oxidative stress leads to peroxidation of polysaturated fatty acids thereby generating volatile organic compounds (VOCs) excreted in exhaled air. The purpose of the present study is to examine whether specific VOCs are associated with eosinophilic and neutrophilic inflammation, and thus offers the possibility of noninvasive monitoring of both asthma inflammatory phenotypes.

Methods: Eosinophils and neutrophils were isolated from 27ml blood of 16 healthy non-smokers by gradient centrifugation using lymphoprep. Eosinophils were isolated from neutrophils by immunomagnetic cell separation (MACS) using anti-CD16. The average absolute number of eosinophils and neutrophils upon isolation was 3.5 x 10^6 and 19.4 x 10^6 respectively. Cells were incubated in RPMI at 37°C and activated with phorbol 12-myristate 13-acetate (100ng/ml). Headspace air was sampled at time 0', 30', 60' and 90' by introduction of ultra-pure nitrogen in closed flasks at a flow rate of 200 ml/min during 10 min. The air was pushed onto a cartridge and the total amount of trapped VOCs (volatile) was analysed by time-of-flight GC-MS.

Results: From the 2005 compounds present in the volatome, those present in at least 8% of the samples (1123 compounds) were used for further analysis. Discriminant analysis (SPSS statistics 19) showed that 5 VOCs were able to distinguish between both culturing types with 100% and 96% correct classification in original
and cross-validated set respectively. Chemical identification of the compounds is ongoing and these are potential candidates to check in asthmatic patients for their possible diagnostic value in asthma phenotyping.

442. Paediatrics and sleep apnoea/adults and upper airway stimulation

4309 Childhood obstructive sleep apnoea and elevated blood pressure: A longitudinal follow-up study
Albert Li1,2, Chen T. Au1, Crozer Ho2, Yun K. Wing2. 1Department of Paediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong; 2Department of Psychiatry, The Chinese University of Hong Kong, Shatin, Hong Kong

Background and objective: Childhood obstructive sleep apnoea (OSA) is a prevalent condition, and is associated with raised blood pressure (BP) in cross-sectional studies. This study aimed to investigate if baseline or changes in OSA severity could predict BP changes over a 4-year period.

Methods and results: Children who participated in our previous OSA prevalence study were invited to undergo repeat overnight sleep study and ambulatory 24-hr BP monitoring at 4-year follow-up. One hundred and ninety-one (62% out of 306) subjects took part in this follow-up study. Children with baseline moderate-to-severe OSA (OAI>55) had significantly higher BP at follow-up than controls. The change in OAI was positively associated with the changes in wake and sleep systolic BP. Path analysis revealed a best-fit model in which log-transformed baseline OAI and change in OAI were both independent predictors for change in sleep systolic BP, after adjusting for baseline sleep systolic BP, gender, height and body mass index z score.

Conclusions: In the first longitudinal study that examined the relationship between OSA and BP in children, we found baseline OSA severity could predict systolic BP at 4-year follow-up. One hundred and ninety-one (62% out of 306) subjects took part in this follow-up study. Children with baseline moderate-to-severe OSA (OAI>55) had significantly higher BP at follow-up than controls. The change in OAI was positively associated with the changes in wake and sleep systolic BP. Path analysis revealed a best-fit model in which log-transformed baseline OAI and change in OAI were both independent predictors for change in sleep systolic BP, after adjusting for baseline sleep systolic BP, gender, height and body mass index z score. Early diagnosis and intervention should thus be advocated in the management of childhood OSA.

4310 Adipokines in obese children and adolescents with sleep-disordered breathing
Kim Van Hoorbeeck1, Hilde Franckx2, Patrick Debrode2, Luc Van Gaal2, Kristine Desager1, Wilfried De Backer1, Stijn Verhulst1. 1Laboratory of Experimental Medicine and Pediatrics, University of Antwerp, Wilrijk, Belgium; 2Obesity Program, Ziekenhuis Oost, Gent, Belgium

Background: Sleep-disordered breathing (SDB) is prevalent in obesity. It has been linked to the metabolic syndrome. Possible mechanism is intermittent hypoxia of the fat tissue and alterations of adipokine secretion.

Aim: This study looked into the effects of intermittent hypoxia on adipokine levels before and after weight loss treatment.

Methods: Obese children and adolescents between 10-18 years were included while entering an inpatient weight loss treatment program. All patients had 2 visits: baseline and after 4-6 months of treatment. Leptin, adiponectin, TNF-alpha and IL-6 were determined at both visits and a sleep screening was performed at baseline. Mean nocturnal saturation correlated with leptin (r=0.19; P=0.02) and adiponectin (r=0.17; P=0.04). IL-6 correlated with oxygen desaturation index (r=0.20; P<0.02). TNF-alpha levels were not linked to sleep parameters. After weight loss 19% of subjects with SDB at baseline that participated in the follow-up study had residual SDB. Average weight loss was 29%. Correlation analysis did not show associations between improvements in sleep parameters and improvements in adipokines. These were mostly linked to a lowering in BMI z-score.

Conclusion: In an obese pediatric population SDB was linked to changes in the fat tissue and alterations of adipokine secretion.

4311 Prevalence of obstructive sleep apnea syndrome in obese children (NANOS study)
Maria Luz Alonso-Alvarez1, Joaquín Terán-Santos1, Cordero-Guerra José Aurelio2, Ana Isabel Navazo-Egüiza1, Estrella Ordx-Carbajo4, Monica Gonzalez-Martinez2, Maria Jose Jurado-Luque2, Odile Romero-Santo-Tomas2, Maria Rosario Carpio-Alfayate3, Jaume Corral-Petrali4, Juan Fernando Masa-Jimez1, Joaquin Duran-Cantolla1, Cristina Martinez-Null1, Antonia Barcelo-Bennassar6, 1Sleep Unit, CIBERES, Complexo Asistencial Universitario de Burgos, Burgos, Spain; 2Sleep Unit, CIBERES, Hospital Vall D’Hebron, Barcelona, Spain; 3Sleep Unit, Hospital Marques de Valdecilla, Santander, Spain; 4Sleep Unit, CIBERES, Hospital San Pedro de Alcantara, Las Palmas de Gran Canaria, Spain; 5Sleep Unit, CIBERES, Hospital Targorritania, Vitoria, Spain; 6Sleep Unit, CIBER, Hospital San Durea, Palma de Mallorca, Spain

Introduction: The most common cause of Obstructive Sleep Apnea Syndrome (OSAS) in children is the adenotonsillar hypertrophy. The prevalence of OSAS in obese children is unknown.

Methods: Aim: To determine the prevalence of OSAS in pediatric obese population.

Methods: Cross-sectional, prospective, multicenter study. The children included in the study came from general population of Spain, randomly selected, of both sexes between 3 and 14 years and body mass index (BMI) greater than or equal to percentil 95 for age and sex. Medical history, snoring and Chervin questionnaires were performed in all children included, as well as, physical examination, nasopharyngoscopy, polysomnography (PSG) with Co2 recording and blood tests.

For the assessment of the sleep stages and respiratory events, the criteria of the AASM (2007), were used. The diagnosis of OSAS was made if the apnea hypopnea index per hour of sleep (AHI) was ≥ 3.

Results: 247 children were included: 135 males (54.7%), age from 4 to 14 with an age mean of 10.82 years (SD: 2.71). The mean BMI and the mean BMI Percentile were 28.01±4.72 and 96.82±0.59 respectively. Of the 247 children studied, 122 of them (50.4%), reported the presence of snoring. The mean AHI was 5.60±9.91. 99 children were diagnosed with OSAS, so the prevalence of OSAS was 40.1% (95% CI 33.8%-46.4%). The prevalence showed no statistically significant differences based on age or sex. The correlation between AHI and BMI was directly and significantly (r = 0.150, p = 0.018).

Conclusions: The prevalence of OSAS in obese children from general population is high 40.1%. Obese in children suggests a possible risk factor for developing OSAS.

Funded: SEPAR and Mutua Madrileña.

4312 Results of a new questionnaire to assess sleep problems in childhood
Zoetia Lendvai, Krisztina Pásti, Agnes Prókai, Anna J. Szabo. Dept. of Pediatrics, Semmelweis University, Budapest, Hungary

Screening of sleep disorders in children is of high importance. In Hungary there is no standardized questionnaire for assessing sleep problems. We evaluated the results of sleep quality scales of our questionnaire and compared the data of healthy and clinical population. We analyzed the correlation between our questionnaire and validated tests and the severity of obstructive sleep apnea (OSA).

Our questionnaire is designed to estimate sleep hygiene and quality in two age groups (6-14 and 15-18 yrs.) by nighttime and daytime symptoms score. Two groups of children were analyzed: 1. healthy group (n=2020), 2. children with sleep problems (n=66). The second group filled out two validated tests, Modified Pediatric Epworth Sleepiness Scale (MP-ESS), Conner’s Rating Scales-Revised (CRS-R) and underwent polysomnography. Severity of OSAS was characterized by Apnea-Hypopnea Index (AHI) and Oxygen-Desaturation Index (ODI).

Children underwent polysomnography had significantly higher score both on nighttime and daytime symptoms scale than healthy children. Correlations were: score of nighttime symptoms scale and CRS-R score (r=0.441; p=0.001), score of daytime symptoms scale and MP-ESS score (r=0.389; p=0.001). Children in the highest quartile of nighttime symptoms scale had significantly higher AHI (mean±SD: 0.62±1.07 vs. 5.97±1.19; p=0.04) and ODI (mean±SD: 0.49±0.53 vs. 6.23±12.07; p=0.02) than children in the lowest quartile. The nighttime and daytime score index had higher sensitivity to predict OSA than other tests.

Our questionnaire can be potentially useful in evaluating sleep problems in children and give more information about sleep problems than other tests. However validation of the questionnaire is still needed.

4313 Long-term response of upper airway stimulation in obstructive sleep apnea
Wilfried De Backer1, Johan Verbraecken1, Lennart Knaack2, Arielle Olivier3, Winfried Hohenhorst1, Olivier Vanderweken1, Paul Van de Heyning1. 1Dept of Pulmonary Medicine, Antwerp University Hospital; Antwerp, Belgium; 2Zentrum für Schlafmedizin & Schlaforschung, Internist. Köln, Germany; 3Dept. of Internal Medicine, Bnai Zion Medical Center, Technion, Israel; 4Klinik für Hals-, Nasen- und Ohrenheilkunde, St. Anna-Klinik Wuppertal, Wuppertal, Germany.

Background: Previous studies identified patient selection criteria for therapy success in Upper Airway Stimulation (Inspire Medical Systems, USA) for treatment of moderate-to-severe OSA in patients intolerant to continuous positive airway pressure. The current study reported therapy response at 12-months post-implant in subjects who met selection criteria.

Methods: Among 34 implanted subjects, 18 met criteria for responder and 16 did not. AHI (Level 1 monitoring) were measured at 12 months. All patients were
monitored for device-related adverse events and patients met selection criteria for therapy response during over-night PSG.

**Results:** There were no device malfunctions or un-anticipated device-related adverse events from 6-12 months. Among patients who met selection criteria and for which data are available, the AHI reduction was maintained at 12-month. Improvement for ESS and FOSQ were also observed in these subjects from baseline to 6 months. One patient had an unusual long and thick uvula and the third one had no special features.

**Conclusion:** The current study has demonstrated that Upper Airway Stimulation to treat OSA has a sustained therapy efficacy at 12-month post-implant in a selected group of moderate-to-severe OSA subjects.

**4314 Targeted hypoglossal neurostimulation (THIN) to treat obstructive sleep apnea (OSA): A one year safety and efficacy trial**

Gimbasa Mwenga1, Philippe Rombaux2, Myriam Dury3, Benoit Lenegle1, Daniel Rodenstein1,2, Center for Sleep Medicine and Pneumology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 3ENT, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 4Plastic Surgery, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Patients with severe OSA non-compliant to CPAP need an alternative treatment. We performed a one-year safety and efficacy study of a new therapy using unilateral stimulation (THIN).

The system was implanted in 13 (12 males) out of 14 patients aged 50±10 years, with an average AHI of 20 and one patient an AHI of 22 at one year. Three patients were considered as failures: one patient had predominantly central apnea and an implanted morphine pump, one patient had an unusual long and thick uvula and the third one had no special features.

There were no serious adverse events. Three electrodes failures in two subjects led to treatment interruptions. One patient had his IPG replaced due to malfunction, and there was one twiddler phenomenon.

We performed a one-year safety and efficacy study of THIN, using unilateral stimulation.

The main efficacy outcomes were the apnea-hypopnea index (AHI), the 4% oxygen desaturation index (ODI) and the movement arousal index (MAI). Diagnostic data showed AHI 45±19, ODI 29±20 and MAI 37±13. The Total Sleep Time (TST) was 414±85 min. After one year, AHI was 2±16, ODI 15±16, and MAI 25±14, all p<0.001, with unchanged TST (406±60 min). Nine patients reached AHI < 20 and one patient an AHI of 22 at one year. Three patients were considered as failures: one patient had predominantly central apnea and an implanted morphine pump, one patient had an unusual long and thick uvula and the third one had no special features.

**Conclusion:** THIN is safe and efficient in most OSA patients.

**4315 Analysis of arousability of upper airway stimulation in obstructive sleep apnea**

Johan Verbraecken1, Joachim T Maurer2, Lennart Knaack3, Winfried Hohenhorst1, Olivier Vanderveken4, Pawel Slominski4, Stefan Uhlig5, Marisa Bonsignore5, Ludger Grote6, Jan Hedner7,8,9, Joachim T Maurer2, Lennart Knaack3, Winfried Hohenhorst1, Olivier Vanderveken4, Pawel Slominski4, Stefan Uhlig5, Marisa Bonsignore5, Ludger Grote6, Jan Hedner7,8,9

**Background:** Previous studies showed that electrical stimulation of the hypoglossal nerve (N XII) can improve obstructive sleep apnea (OSA). In this study we looked to the effect on the different arousals indices in both responders and non-responders.

**Methods:** Upper Airway Stimulation (Inspire Medical Systems, Inc) systems were implanted in moderate-to-severe OSA patients who failed, or were intolerant of CPAP. The system is intended to reduce sleep apnea by stimulating the N XII to advance the tongue-base. AHI (events/hr), Micro Arousal Index (MAI, events/hr), total number of arousals and respiratory arousals were collected using lab-based PSG in 7 patients including comparison of responders (n=4) vs. non-responders (n=3) at baseline (pre-implant) and 6-M post-implant. All arousal indices decreased statistically significantly in responders and there was no stimulation disturbance seen in the non-responder group.

**Conclusion:** Upper Airway Stimulation to treat OSA has a clear therapy efficacy at 6-M post-implant in a selected group of moderate-to-severe OSA subjects and that there is no arousal effect of the stimulation itself. It confirms the non-arousal effect of N XII stimulation as shown in our earlier pilot study (Arch Otalaryngol Head Neck Surg 2001;127:1216-23).

**4316 Regional differences in characteristics of patients referred to European sleep centers. Results from the European Sleep Apnea Database (ESADA)**

Teresa Sagarese1, Marisa Bonsignore, Ludger Grote, Jan Hedner, Walter McNicholas, Josep Montserrat, Thomas Penzel, Renata Raha, Pawel Slominski, Jan Zielinski, Dept. of Pulmonary Diseases, Turku University Hospital, Turku, Finland

The ESADA contains multiple information from patients with suspected OSA at 22 European sleep centers. We analyzed regional differences in characteristics of 551 OSA patients. Centers were grouped into the following regions: NORTH (Friede, NOR – Gothenburg, SWE – Turku, FIN), SOUTH (Barcelona, Càceres, Lleida, ESP – Milan, Palermo, ITA – Haifa, ISR), EAST (Klaipeda, LTU – Kosice, SVK – Prague, CZE – Riga, LAT – Warsaw, POL – WEST (Dublin, IRL – Edinburgh, GBR) and CENTRAL (Antwerp, Brussels, BEL – Berlin, Giessen, GER – Paris, FRA).

Mean age was 51.8 (12.6) years in the cohort and females were slightly older than males. The highest and lowest prevalence of obesity (BMI>30) was found in the WEST and NORTH regions, respectively. The sleep study technique varied between regions, with the NORTH reporting more than 99% cardiorespiratory polygraphy compared with only 34% in the EAST. Sleep apnea severity varied between regions and the proportion of male patients with severe sleep apnea (AHI>30) was 23% in the NORTH compared with >40% in all other regions. Less than 50% of all patients reported severe daytime sleepiness (ESS>10), the highest ESS was found in patients in the WEST, the lowest scores in men in NORTH and women from EAST centers. Sleep length was 7.0 (1.8) hrs in women and 6.8 (1.6) hrs in men, and was shorter in the SOUTH compared with all other regions. No systematic regional differences were detected in frequency of comorbidities.

The data shows considerable regional differences between patients referred to European sleep centers, suggesting an influence of local referral patterns and/or phenotypic traits in Europe.

**443 Novel mechanisms of acute lung injury**

**4317 On the effectiveness of steroids in acute lung injury: Experimental separation of inflammation and hypoxemia**

Lucy Kathleen Reiss, Stefan Uhlig, Institute of Pharmacology and Toxicology, Medical Faculty of RWTH Aachen University, Aachen, Germany

Acute lung injury (ALI) is defined by hypoxemia in the presence of excessive inflammation. Despite of a multitude of clinical trials the role of glucocorticoids in the treatment of ALI is under constant debate. The present study was designed to investigate the effectiveness of dexamethasone in dependence on the type and severity of lung injury and the fraction of inspired oxygen (FiO2).

C57Bl/6 mice were instilled intratracheally with 50 μL HCl at pH 1.5 or 1.8 and were then ventilated with recruitment manoeuvres (RM) and FiO2=0.3 or 1.0. Another group was ventilated without acid instillation and without RM to induce atelectasis. Dexamethasone [1mg/kg] was injected intravenously at the beginning of ventilation. Lung mechanics were followed by the forced oscillation technique. Cardiovascular parameters, oxygen saturation and body temperature were monitored. Blood gases, cytokines, neutrophil recruitment, microvascular permeability and lung histology were examined.

Dexamethasone attenuated acid-induced lung injury (neutrophil recruitment, edema formation, cytokine liberation) in all models. Hypoxemia and lung mechanics were improved in the groups instilled with acid pH 1.8 (moderate injury), but in the groups instilled with acid pH 1.5 (severe injury) or in those with atelectasis. A high FiO2=1.0 augmented acid-induced lung injury, but did not affect the effectiveness of dexamethasone.

The present study starkly were highly effective in preventing inflammation under all conditions, whereas they improved the clinical outcome in moderate, but
not in severe lung injury or in cases of derecruitment, suggesting that steroids are effective only in a subclass of patients with ALI.

Alastair Proudfoot1,2, Charlotte Summers1, Timothy Jackson1, Matthew Hind1,2, Mark Griffiths1,2, 3 Adult Intensive Care Unit, Royal Brompton Hospital, London, United Kingdom; 2Critical Care, National Heart and Lung Institute, Imperial College, London, United Kingdom; 3Respiratory Medicine, University of Cambridge, Cambridge, United Kingdom

Activation and migration of neutrophils into the lung is a central factor in both the onset and progression of acute lung injury (ALI). The assessment of neutrophil biology and trafficking in the lung is fraught with methodological pitfalls. Human ex vivo ALI models could provide a tractable platform with which to investigate neutrophil trafficking in the lung. Human lungs from brain dead donors (N=3) were cold preserved and transferred for leukocyte quantification by flow cytometry. Lung tissue was harvested for wet:dry ratio or processed to a single cell suspension for leukocyte recruitment (cells/g dry lung mass) also tended to be reduced.

Figure 1. CT image of LPS injured lung at 4 hours.

Figure 2

Further characterisation of this novel model allied with established methodology in pulmonary neutrophil trafficking will provide a powerful tool to investigate neutrophil biology in human ALI.

4319 Sphingosine kinase-1 and sphingosine-1-phosphate promote the development of acute lung injury in pneumococcal pneumonia
Bjoern Gutbier1, Stefanie M. Schönrock1, Rainer Haberberger2, Andreas C. Hocke1, Stefan Schröder1, Anja Luth1, Burkhard Kleuser1, Wilhelm G. Bertrams1, Kolja Szymanski1, Katrin Reppe1, Holger C. Müller-Redetzky1, Bernd Schmoeck1, Manfred Andratsch1, Timothy J. Mitchell1, Hartwig Schünke1, Konstantin Mayer1, Norbert Suttorp1, Martin Wittenrauth1, Capneth Study Group2, 3, Dept. of Infectious Diseases and Respiratory Medicine, Charité – Universitätsmedizin, Berlin, Germany; 1Institute of Anatomy and Histology, University of Innsbruck, Austria; 4Molecular Pneumology, Philipps University, Marburg, Germany; 5Dept. of Physiology, University of Innbruck, Austria; 6Glasgow Biomedical Research Centre, University of Glasgow, United Kingdom; 7Medical Clinic II, University of Giessen and Marburg Lung Center, Giessen, Germany; 8Capneth, Stiftung, Hannover, Germany

Pneumonia may evoke acute lung injury. Basal plasma levels of sphingosine-1-phosphate (S1P) contribute to vascular integrity. Pulmonary S1P, mainly synthesized by sphingosine kinase-1 (SphK1), regulates inflammatory mechanisms. We have therefore investigated the impact of high fat diet-induced obesity on VILI in mice. Male C57BL/6 mice were fed high fat diet for a minimum of 13 weeks, resulting in a mean body weight 30% greater than lean age-matched controls. Animals were anaesthetised and ventilated with high-stretch, standardised as plateau pressure (Pplat) 35-37cmH2O. Tidal volumes were similar between groups (mean ±SD; n=5 per group; *p<0.05 by ANOVA).

Conclusion: High fat feeding attenuates pneumonia oedema and lung dysfunction

4320 Z antitrypsin polymerization is associated with enhanced pulmonary inflammation
Sum Alam1, Zhenjun Li1, Sabina Jancauskiene2, Ravi Mahadeva1, 3Department of Medicine, University of Cambridge, United Kingdom; 3Department of Pulmonology, Hannover Medical School, Hannover, Germany

Severe antitrypsin (AT) deficiency due to polymerization of the Z variant is the commonest genetic cause of emphysema. There is variability in the development and progression of emphysema even in Z-AT homozygotes. We postulated that episodes of pulmonary inflammation could induce polymerization of AT protein thereby further reducing the anti-protease protection. 8 Transgenic mice for human Z-AT (Z-mice) and M-AT (M-mice) received 10μg of intrapulmonary LPS. BALF and lung homogenates (LH) were assessed for lung injury and inflammation. Z-mice had more pulmonary PMNs (d1, BALF 71±3x104 cells (mean(SEM)) vs. 52±4, p<0.004; d3, 6±1.5x104 vs. 4.5±0.24, p<0.001; d7, 7.1±0.51 vs. 5.7±0.29, p=0.03). Z-mice had more pulmonary PMNs-d1, BALF 71±3x104 (cells) vs. 52±4, p<0.001; BALF 490±391 ng/ml vs. 261(285-220), p<0.001. Z-mice had a higher concentration of 8-isoprostane (8-IP) and free NE in BALF compared with M-mice; 8-IP (Z vs. M), d1, 6.5±0.4 vs. 4.5±0.24, p<0.001; d3, 7±0.51 vs. 5.7±0.29, p=0.03. Z-mice had more pulmonary PMNs-d1, BALF 71±3x104 cells (mean(SEM)) vs. 52±4, p<0.004; d3, 6±1.5x104 vs. 4.5±0.24, p<0.001; BALF free NE, d1 (Z vs. M), median(IQR) 436(436-316)ng/ml vs. 213(245-113), p=0.001. ELISA and immunoblot revealed that LPS instillation in Z-AT mice led to the development of oxidized-polyamers of Z-AT, which further reduces the anti-elasticity protection and nullifies the anti-inflammatory effect of AT. This data suggests a molecular mechanism whereby infective excursions could further inactivate Z-AT and contribute to the faster decline in lung function in PZ ZZ individuals. This may explain some of the heterogeneity of the lung disease in these individuals.

4321 Obesity induced by high fat feeding attenuates ventilator-induced lung injury in mice
Joanne Pétrie1, Michael Wilson, Brijesh Patel, Kieran O’Dea, Masao Takata.
Anaesthetics, Pain Medicine and Intensive Care, Department of Surgery and Cancer, Imperial College, London, United Kingdom

Background: Retrospective analysis of Intensive Care data suggests that obesity may confer a survival advantage in Acute Lung Injury (ALI). Development of ventilator-induced lung injury (VILI) is a major determinant of ALI mortality. We have therefore investigated the impact of high fat diet-induced obesity on VILI in mice. Methods: Male C57BL/6 mice were fed high fat diet for a minimum of 13 weeks, in a mean body weight 30% greater than lean age-matched controls. Animals were anaesthetised and ventilated with high-stretch, standardised as plateau pressure (Pplat) 35-37cmH2O. 4324
Resident alveolar macrophages mediate early alveolar epithelial death signaling and dysfunction
Brijesh Patel, Michael Wilson, Masao Takata. Anesthesiology, Pain Medicine, and Intensive Care, Chelsea and Westminster Hospital, Imperial College London, United Kingdom

Acute lung injury (ALI) is characterized by alveolar epithelial dysfunction. We previously showed that early epithelial dysfunction was specifically mediated through tumor necrosis factor (TNF) p55 receptor signaling [1]. This study examined the contribution of resident alveolar macrophages (AM) to this phenomenon following acid aspiration.
C57Bl6 mice were treated intratracheally with liposomes containing either clofibrate or PBS. After 48 hours, they underwent intratracheal instillation of hydrochloric acid followed by mechanical ventilation to assess respiratory parameters. Oxygenation, respiratory elastance, alveolar TNF concentration, lung capsaicin-8 activity and alveolar fluid clearance (AFC) were measured at 90 minutes after acid instillation. Clofibrate liposomes induced an 80% depletion of AMs. AM depletion significantly improved the deterioration in respiratory elastance (cM2O/s: PBS=0.06±0.008; CLOD=0.05±0.004; p<0.05) and PaO2:FiO2 ( PBS=304±372; P=0.05), along with attenuated lung capsaicin-8 activity (arbitrary units: PBS=1476±5466; CLOD=7135±372; P<0.01), and improved AFC (%/30min: PBS=3.8±2.6; CLOD=7.1±2.4; P<0.05). Caspase-8 activity showed an inverse correlation to AFC (Pearson r=−0.766; P<0.0001) implying epithelial death receptor activation. These data suggest that during ALI induced by acid aspiration, epithelial dys- function and hypoxemia are a result of epithelial cell death receptor activation by alveolar macrophage-derived TNF. Supported by Wellcome Trust.

The influence of carboxyhemoglobin (COHb) generation on measured total lung diffusion capacity
Evgeny Babarskov1, Evgeny Stepnov2, Yury Shulagin3, Alexander Cherniak1, Zaubeck Aisanov1, Alexander Chuchalin1. Respiratory Physiology, Pulmonology Research Institute, Moscow, Russian Federation; 2 Quantum Electronics, General Physics Institute, Moscow, Russian Federation; 3 Respiratory Physiology, Institute of Biomedical Problems, Moscow, Russian Federation

Background: We found earlier that as a result of single breath diffusion capacity test for CO and NO mean relative current COHb concentration in lung capillary volume (Vc) reaches to 10% [Babarskov E. et al. ERZ 2009. v.34 suppl.5:39].

Methods: Dynamic balance equations of CO and COHb in alveolar and capillary volumes were solved by numerical method.

Results: The dependence of average relative COHb concentration on breathholding time and initial CO alveolar concentration was determined, as well as relationships between measured DLco and COHb concentration. It was demonstrated, that using of gas mixtures with usually recommended CO content (0.28%) results in COHb concentration increase to about 10%, that in turn leads to reducing of DLco about by 5% and Vc by 10%. If initial CO content in gas mixture is increased three fold (0.84%), then COHb concentration reaches to about 30%, that in turn leads to reducing of DLco about by 15% and Vc by 30%.

Conclusion: Our findings confirm possibility of experimental measurement of the difference between DLco values, which may be used for noninvasive investigating of lung hemodynamics. Particularly this allows to determine important diagnostic parameter - capillar blood flow rate across ventilated alveoli and correctly to calculate Vc.

4330
How long does it take for supine TLNO & TLCO to become stable after sitting upright?
Liam O’Reilly, Helen Ward, Martin Miller, Brendan Cooper. Lung Function and Sleep, NHS, Birmingham, United Kingdom

Introduction: We previously investigated (ERS Congress, 2011) the change in gas transfer for carbon monoxide (TLCO) from sitting to supine in healthy subjects, but were unable to find published studies showing how long subjects should be supine before a stable TLNO measurement could be made.
Method: We measured single breath TLCO & TLNO in 13 healthy subjects (5F:8M; ages 23-57 years; mean height (SD) 1.77 m (0.10)) using a Master Screen lung function system (Jaeger Ltd, Hoechberg, Germany), twice sitting at rest and then after 10, 15, 20, 25 & 30 mins respectively lying supine.

Results: Table 1 shows mean (SD) for TLCO and TLNO.

Values shown as Mean (SD) TLCO in mmol/kPa/min; TLNO in mmol/kPa/min/L; V A eff in L/mins.

Discussion: We have shown that when supine for 30 mins TLCO changes but TLNO remains stable. We confirm TLCO increases from sitting to supine but that TLNO, which reflects membrane function, remains unchanged. TLNO/TLCO demonstrates a small decrease followed by an accommodation in pulmonary capillary blood volume.

Conclusion: Supine gas transfer using TLNO + TLCO show physiological changes consistent with changes in pulmonary capillary blood volume when subjects lie supine. Measurements before 20 mins are transients and suggest care should be taken when making supine gas transfer estimations.

4331

Fraction of exhaled nitric oxide in children aged 4 to 11 years
Jana Kivastik1, Tiina Rebane2, Maire Vasar2,3. Department of Physiology, University of Tartu, Estonia; 2Children's Clinic, Tartu University Hospital, Tartu, Estonia; 3Department of Pediatrics, University of Tartu, Estonia

Introduction: Fraction of exhaled nitric oxide (FENO) is a useful marker of allergic airway inflammation and can measure the response to anti-inflammatory therapy. Availability of commercial portable FENO analyzers has made the measurement more widespread in clinical care.

Aim: To study FENO in relation to current respiratory symptoms and medication in patients of Tartu Children's Clinic and in healthy children.

Methods: We measured fraction of exhaled NO with the hand-held device (NIOX MINO; Aerocrine AB, Sweden) in 242 children aged 4-11 years. Children were classified as wheezers (wheeze during the last 12 months), coughers or healthy (groups W, C and H, resp) according to the questionnaires about respiratory and atopic problems. 79 out of 207 symptomatic children had been treated with inhaled corticosteroids (ICS) during the last month. We defined FENO values >20 ppb as abnormal, the limit suggested for children aged 12 or less by Taylor.

Results: Table 1 shows mean (SD) for TLCO and TLNO.

Correlation between gas-exchange dynamics in recovery of exercise tests and cardiovascular parameters in pulmonary hypertension
Patrick Jaka, Harri-Jan Boogaard, Anton Vanh-Neerdegraege, Dept. of Pulmonary Medicine, VUMC Medical Center, Amsterdam, Netherlands

Introduction: In pulmonary hypertension (PH), cardiac dysfunction and gas-exchange abnormalities within the lung may both delay the rate of recovery in O2-uptake ($V'O_2$) and CO2-release ($V'CO_2$) after a cardiopulmonary exercise test (CPET).

Aim: Determine the correlation between recovery rates of $V'O_2$,$V'CO_2$ after CPET with pulmonary vascular resistance (PVR) and right ventricular ejection fraction (RVEF).

Methods: In this retrospective study measurements on 12 PH-patients were used. 1-4 CPETs and heart catherisations (for PVR measurement) per patient were done. Sometimes also a cardiac MRI was performed, rendering RVEF.

Results: Changes in $V'O_2$, $V'CO_2$ strongly correlated with PVR and RVEF.

Conclusion: Diffusing capacity can predict hypoxemia during sub maximal exercise in patients with ILD.

Our data suggest that supplemental oxygen during exercise in ILD patients with a TLCO (%pred) >61% is not necessary.

4334

Diffusing capacity > 61% (predicted) predicts absence of hypoxemia during 6-Minute Walk test in patients with interstitial lung disease
H.T. de Raaf1, M. Wapenaar1, Y.M. de Feijter1, H. Groepenhoff2, M.S. Wijnen3, B. Blink van den1, H.C. Hoogsteden1, H. Stam1, 1Department of Pulmonary Diseases, Erasmus Medical Center, Rotterdam, Netherlands; 2Department of Pulmonology, VU University Medical Center, Amsterdam, Netherlands

Introduction and aim: In patients with interstitial lung disease (ILD) the 6-minute walk test (6MWT) can be used to assess the need for supplemental oxygen during physical training and in-test hypoxemia is an indicator of poor survival. We investigated if TLCO (%pred) is a predictor for hypoxemia during 6MWT.

Methods: We analysed data of 66 consecutive ILD patients who performed spirometry, TLCO-measurement and 6MWT at the same day between March 2011 and February 2012. We excluded patients with pulmonary hypertension, musculoskeletal impairment, oxygen dependence and incomplete 6MWT.

Conclusion: In PH-patients, slow recovery-rates of VO2 and VCO2 are associated with a high PVR and low RVEF.
4334 BTS recommendations for referral for hypoxic flight assessment are not appropriate in paediatrics
Patrick Jamieson, Colleen Carden. Respiratory Function Laboratory, Royal Hospital for Sick Children, Yorkhill, Glasgow, United Kingdom

Introduction: The assessment of paediatric hypoxia during commercial flight is not as well understood as the equivalent area in adults. The BTS recommends that patients with a baseline greater than 95% do not need a hypoxic flight assessment. This study examined the BTS criteria for referral for hypoxic flight assessment with respect to prevalence of hypoxia during this assessment, in a paediatric sample.

Methods: This was a retrospective audit of patients referred to a paediatric respiratory function laboratory. The test protocol used 100% nitrogen to dilute the contents of a body plethysmograph to a FiO2 of 15%, before assessing the SpO2 profile for 20 minutes. Failure of hypoxic challenge, according to BTS criteria, constituted a mean SpO2 of less than 90% when breathing FiO2 15%.

Results: 107 children (58% female) age 0.1-19.2 years (mean 7.0, SD 5.4) were tested. They were referred for a variety of conditions including muscular dystrophy, cystic fibrosis, severe asthma, long term ventilation, long term oxygen therapy and sleep breathing disorders. 83% of patients referred had a baseline SpO2 in FiO2 21% of greater than 95%. 29% of these patients were determined to be hypoxic in FiO2 15%.

Conclusions: If BTS criteria for referral were applied to this patient sample, only 6% would be detected as hypoxic in FiO2 15%. When these criteria are not used then a total of 35% of these patients are found to be hypoxic. Either the BTS criteria for detecting hypoxia are too sensitive, or the BTS indications for hypoxic flight assessments are not specific enough. This study highlights the problems associated with predicting a patient’s response to hypoxia using baseline measures.

4335 Are 6MWD and FEV1 the most clinically relevant measures? Matthews A, Rutter1, Jennifer A. Colbourne, Jonathan P. Field1, Karl P. Sylvester2. 1Tang Function Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 2Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Six minute walk tests (6MWT) are used to assess exercise tolerance and widely used to assess the response to interventions. The six minute walk distance (6MWD) is used clinically to describe the patients’ ability to tolerate exercise and is often used in comparison to FEV1. Although FEV1 and 6MWD performed concomitantly correlate, FEV1 in certain patient populations can remain stable over time while 6MWD changes over 5% (e.g. curves 7, 16). These test-curves have non-physiological flow spikes (e.g. curves 3, 17, 19), while those curves that end suddenly had small effects (e.g. curves 1, 15). The 2005 ATS/ERS guidelines on spirometry recommend validating the quality of a spirometer by simulating forced expirations with computerized syringes. It was recently shown, that these test-curves have non-physiological flow spikes of approximately 150 mL/s instead of a slow drop towards the end of the expiration(1).

Spirometers vary in their minimal detectable flow, especially turbine type spirometers. Due to the spiky flow, such difference might not be detected by the current ATS/ERS waveform tests. We used the interpolated form of the ATS curves(3) to calculate the effect on the measured FVC of the curves with varying lowest detectable flows. We evaluated flow cut-offs of 10–150 mL/s in 10 mL/s increments. Only flows that were above the cut-off were integrated for volume.

The effect on FVC was high for those ATS curves that have a low tapering end (e.g. curves 3, 17, 19), while those curves that end suddenly had small effects (e.g. curves 7, 16). The deviations in FVC become larger than the ATS/ERS repeatability criterion even with lowest detectable flows of 50–100 mL/sec. But those failures would be missed by the currently used ATS/ERS waveforms. We recommend to un-gently adapting the test curves to the interpolated version to avoid missing poor performing spirometers in the future.

446. Effectiveness of respiratory disease management in primary care

4337 Can the organisation of COPD care in primary health care centres help preventing exacerbations in COPD patients? Josefina Sundh1, Scott Montgomery2, Christer Janson3, Eva Osterlund4, Efremsson5, Bjorn Stalberg6, Karin Lisspers7. 1Department of Respiratory Medicine, Orebro University Hospital, Orebro, Sweden; 2Clinical Epidemiology and Biostatistics Unit, Orebro University Hospital, School of Health and Medical Science, Orebro University, Orebro, Sweden; 3Department of Medical Sciences, Respiratory Medicine and Allergology, Upplanda University, Uppsala, Sweden; 4School of Health and Social Studies, Dalarna University, Falun, Sweden; 5Department of Public Health and Caring Science, Family Medicine and Clinical Epidemiology, Uppsala University, Uppsala, Sweden

Introduction: COPD exacerbations are associated with lung function decline, lower quality of life and increased mortality, and can be prevented by pharmacological treatment and rehabilitation. The aim of this study was to explore if the organization of the COPD care in primary health care centres influences the risk for new exacerbations.

Methods: A clinical population of 735 COPD patients was randomly selected from 70 Swedish primary health care centres (PHCCs). Data on COPD exacerbations and following preventive measures were obtained from medical record review. Cox regression analyses were used to estimate the risk of a new exacerbation with adjustment for age and sex.

Results: During a study period of four years 458 patients had an exacerbation, and of these 278 patients (61%) had a second exacerbation during the follow-up period. Patients with a scheduled extra visit to an asthma/COPD nurse following an exacerbation had a decreased risk of a new exacerbation compared to patients with no extra follow-up besides regularly scheduled visits (adjusted hazard ratio (95% CI) 0.54 (0.32 to 0.93), p=0.026).

Conclusion: Scheduling an extra visit to an asthma/COPD nurse following a COPD exacerbation decreased the risk of reexacerbations in primary care patients. We conclude that a close cooperation between professional categories is important in the prevention of COPD exacerbations in primary care.

4338 Are disease management programs for COPD cost-effective? Melinde Boland1, Apostolos Tsiafristhas2, Annmarie Kruis2, Niels Chavannes3, Maureen Rutten-van Molken4. 1Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands; 2Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands

Background: There is insufficient evidence of cost-effectiveness of COPD disease management (COPD-DM) programs. Aim: The aim of this study is to review the impact of COPD-DM on healthcare costs and outcomes. We also investigated the impact of disease-, intervention-, and study-characteristics.

Methods: We conducted a systematic review to identify cost-effectiveness of
COPD-DM. The data, results, and characteristics of the studies were grouped and, if feasible, included in a random-effects meta-analysis.

**Results:** We included 16 papers describing 11 studies. The meta-analysis showed that DM decrease hospitalizations (RR: 0.76 [95CI: 0.63-0.93]), and let to a significant reduction of hospitalization costs ($1196 [95CI: $722 - $1670]) per patient per year (PPP). Average healthcare savings were $1914 [95CI: $1464-$2367] PPP. These savings have to be weighed against the costs of developing, implementing and managing the DM program. Our results showed great variability in study-, intervention-, and disease-characteristics. There are indications that studies with greater savings in hospital costs in studies with: severe COPD patients (GOLD stage 3+), patients with exacerbations, smokers, non-RCT design, short intervention duration, low methodological quality, 1-2 Chronic Care Model components and non-EU origin.

**Conclusion:** DM decreased the risk of hospitalization and healthcare costs (excluding program costs). Furthermore, cost-effectiveness was influenced by heterogeneity in study-, intervention-, and disease-characteristics. Although favourable results on healthcare costs and effects have been demonstrated, more studies are needed to draw conclusions on the impact of DM on total costs and cost-effectiveness of DM in different settings.

**4339 COPD in primary care in Sweden – An 11 years epidemiological register study**

Karin Lisspers 1, Karin Larsson 1, Bjorn Ställberg 1, Christer Janson 1, Gunilla Telg 2, Leif Jörgenson 3, Georgios Stratiotis 4, Gunnar Johansson 1.

1Department of General Practice and Health Care Sciences, Family Medicine and Clinical Epidemiology, Uppsala University, Uppsala, Sweden; 2Unit of Lung and Allergy Research, National Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden; 3Department of Medical Sciences, Respiratory Medicine, Uppsala University, Uppsala, Sweden; 4Medical, AstraZeneca Nordic, Södertälje, Sweden.

**Background:** Analysis of longitudinal clinical practice data yields important information about disease characteristics, natural course and disease management.

**Objectives:** To describe chronic obstructive pulmonary disease (COPD) in primary care in Sweden with special reference to management, co-morbidity, and life expectancy (NCT01146392).

**Methods:** Primary care medical records’ data on COPD patients ≥ 18 years was linked to national hospital, drug, and cause of death register data for 1999 – 2009. Index date was first COPD diagnosis. Exacerbation defined as hospitalisations, emergency room visits, prescription of oral steroids, or antibiotics for COPD.

**Results:** Study population, 21,361 patients (47% males; 68.0 years). During the two years before the index date, 77% had exhaled nitric oxide (FENO) measurements; 62% had inhalers (ICS); 26% had inhalers (ICS); During the 11-year period, COPD was associated with asthma (odds ratio 2.71, 95% CI: 2.59-2.83), COPD was associated with asthma (odds ratio 2.71, 95% CI: 2.59-2.83), and mean age at diagnosis decreased by 7 years (73 to 66 years). Prescriptions of tiotropium and fixed ICS/LABA (long-acting β2-agonist) combinations increased to 25% and 37%, respectively; while ipratropium, LABA and ICS showed decreased to stable/decreasing trends. Exacerbations simultaneously decreased from 3.0 to 1.3 exacerbations/patient/year. Diagnosis of co-morbidities increased from index to 8 years after; diabetes from 12 to 19%; heart failure 16 to 26%; and lung cancer 0.94 to 1.47%. Mean life expectancy improved 8 months shorter than for the general population.

**Conclusion:** Management of COPD improved during the study period, with earlier diagnosis, primary care focus, changes in treatment options and decrease of exacerbations.

**Study sponsor:** AstraZeneca.

**4340 Adherence to a maintenance exercise programme 1 year after pulmonary rehabilitation: What are the predictors of drop-out?**

Anjalee Herrema Poelmol, Johan Wempe, Ilse Stuive.

Centre for Rehabilitation, University Medical Center, Groningen, Netherlands.

**Objective:** To study adherence to a maintenance exercise programme in patients with COPD, who had been following a pulmonary rehabilitation programme.

**Methods:** 70 patients with COPD were included in the study after completing the rehabilitation programme. All were referred to an community-based maintenance exercise programme. Adherence was assessed by open questionnaire after 6 and 12 months and lung function, exercise capacity, exercise self-efficacy, illness perceptions, health related quality of life, levels of anxiety and depression, duration of rehabilitation and number of exacerbations were studied as possible predictors of non-adherence.

**Results:** Ten patients died or were lost to follow up. Of the remaining 60 patients, 73.3% and 63.3% were adherent to the exercise programme after 6 and 12 months, respectively. FEV1 (p=0.021), HADS depression score (p=0.025) and duration of rehabilitation (p=0.018) were statistically significant predictors of adherence.

**Conclusions:** Adherence to a maintenance exercise programme, after having followed a pulmonary rehabilitation programme, is quite reasonable for patients with COPD: about one third drops out during the first year. A poorer lung function, a longer rehabilitation course, and higher level of depressive symptoms are predictive for drop-out.

**Practice implications:** To improve adherence to a maintenance programme, special attention should be paid to patients with lower FEV1, those with signs of depression or in need of a longer rehabilitation.

**4341 Lower incidence of asthma exacerbations with FENO-guided anti-inflammatory treatment: A randomised controlled trial**

Jörgen Syk 1, Andrea Malinovschi 2, Gunnar Johansson 1, Anna-Lena Undén 1, Kjell Alving 1.

1Department of Neurobiology, Caring Sciences and Society, Karolinska Institutet, Stockholm, Sweden; 2Department of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden; 3Department of Public Health and Care Sciences, Uppsala University, Uppsala, Sweden

We examined the effects of anti-inflammatory treatment guided by fractional exhaled nitric oxide (FENO) on asthma outcomes in adult patients with allergic asthma.

This was a primary health care multicentre study (17 sites). 181 non-smoking participants (18-64 years) with perennial allergy and regular inhaled corticosteroid (ICS) treatment were randomly assigned to two treatment arms: a control group (n=88), where FENO was not measured and an anti-inflammatory treatment (ICS and leukotriene receptor antagonists) adjusted according to routine clinical practice, and an active group (n=93) where the anti-inflammatory treatment was adjusted according to FENO. Participants were followed for one year (5 visits). FENO was measured and questionnaires on asthma-related quality of life (mini-AQLQ) and asthma control (6-item ACQ) were completed. Health care contacts and asthma events were noted at every visit. The primary endpoint mini-AQLQ overall score over one year did not differ between the groups at last visit (p=0.20), whereas the mini-AQLQ symptom domain score (p=0.041) and the ACQ score (p=0.045) improved significantly more in the FENO-guided group than in the control group. Furthermore, a significantly lower cumulative incidence of exacerbations was found in the FENO-guided group vs. control group (p=0.029). This was dependent on a reduction in moderate (p=0.006) but not severe (p=0.73) exacerbations. Mean use of ICS over the study period was similar in the two groups (p=0.95).

Using FENO to guide anti-inflammatory treatment reduced exacerbation frequency and improved asthma control in adults with atopic asthma without increasing overall ICS use.

**4342 Reducing asthma admission: Impact of the Easy Asthma Clinic Network**

Watchara Boonsawat 1, Kaewjai Thepsuthannaman 2.

1Medicine, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand; 2Clinical Epidemiology Unit, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

**Introduction:** Easy Asthma Clinic Network has been developed as a model to enhance the implementation of GINA guidelines in Thailand. We set up Easy Asthma Clinic in the hospitals throughout Thailand. The Easy Asthma Clinic runs by GPs in general hospitals. In the clinic we simplified asthma guidelines and organized the system to facilitate the team work, emphasized the role of nurses and pharmacists to help doctors. We also developed on-line web database for registering and monitoring patients. This study aim to study the effect of the Easy Asthma Clinic Network on asthma admissions.

**Method:** All asthmatics under the universal health care scheme registered in the Easy Asthma Clinic Network during October 2007 to September 2009 were ana-lyzed for hospitalization rate and hospital days due to asthma. The hospitalization rate and hospital days due to asthma during one year before and after registration were compared.

**Results:** There were 22,564 asthmatics registered from 360 hospitals. There were 6,449 admissions, which were associated with 36,589 hospital days during one year before registration. The rate of hospitalization was 0.2585 admissions/patient/year. There were 4,071 admissions, which were associated with with 11,608 hospital days during one year period after registration. The rate of hospitalization was 0.1804 admissions/patient/year. Registration to the Easy Asthma Clinic Network lower the risk of hospitalization (incidence rate ratio 0.39, confidence interval (CI) 0.38 to 0.41).

**Conclusions:** The Easy Asthma Clinic Network is effective in reducing hospitalization due to asthma.

**4343 More than 50% of patients visit a general practitioner (GP), general physician (Gen P) or a pediatrician (P) in India for respiratory symptoms:**

Results of a one-day-point-prevalence study in 2,048,912 patients across 22 states and 5 union territories in India

Komilkat Apte 1, Monica Barne 1, Sapna Mada 1, Jaidree Gogtay 2, Sushmeeta Chhowala 2, Nadar Mahajan 2, Sundeep Salvi 1.

1Research, Chest Research Foundation, Pune, Maharashtra, India; 2Research, CIPLA LTD., Mumbai, Maharashtra, India

A better understanding of the disease pattern and symptoms for which a patient visits a doctor will help design appropriate health care management strategies. This study was aimed to investigate the symptoms for which a patient visits a general healthcare provider in India using a 1-day-point-prevalence cross-sectional study design.
Method: 13,225 practicing GPs, Gen Ps and Ps, randomly selected from 880 cities and towns in India based on a proportionate random sampling strategy were invited to participate in this study. On 1st February 2011, all participating doctors completed a questionnaire based on the validated FEED-10 classification, wherein they captured age, gender and symptoms of all patients who visited their clinic. Data was collected, cleaned and entered in Epi Info software and simple descriptive analysis was performed.

Results: A total of 2,04,912 patients visited 7400 doctors who consented and gave clean data. Amongst these, 50.6% presented with respiratory symptoms (31.8% cough, 15.8% rhinitis, 9.4% sore throat, 8.4% wheeze and 6.9% breathlessness), 25% presented with gastrointestinal symptoms, 18% cardiovascular, 5% dermatology and 3% for endocrine related symptoms/diagnosis. These observations were generally uniform across 22 states and 5 union territories in India with no hot spot regions.

Conclusion: Respiratory symptoms account for over 50% of symptoms for which a patient visits a doctor in India, which extrapolates to at least 20 million patient visits for respiratory symptoms every day in India.

4344 Comparative study of respiratory symptoms, lung function, BMI and exercise capacity in patients with COPD associated with tobacco smoke (TS) and biomass smoke (BS) exposure
Laíta Fernandes, Anthony Mesquita, Dept. of Pulmonary Medicine, Goa Medical College, St. Inez, Caranzalem, Goa, India

Background: COPD is the 4th leading cause of death and is expected to be 3rd by 2030. Tobacco smoke and indoor air pollution are the major risk factors for COPD. While there are large number of studies on tobacco smoke and COPD, there is paucity of data on biomass smoke and COPD. It is not clear whether this phenotype of COPD is different or similar to COPD caused by tobacco smoke.

Aim: To compare the clinical symptoms, lung function, BMI and 6MWD (exercise capacity) in TS-COPD and BS-COPD.

Method: We prospectively evaluated 103 stable COPD patients from the out-patient clinic. COPD was diagnosed by GOLD guidelines (post bronchodilator FEV1/FVC <70%), respiratory questionnaire captured symptoms and six minute walk test (6MWT) was done as per ATS guidelines.

Results:

There were 75(TS-COPD) and 28(BS-COPD) patients with mean age of 63.39(8.87) and 60.04(7.57) respectively. Females (92.85%) dominated the biomass group while 97.3% males were in the tobacco smoking group TS-COPD presented with wheeze(24%) as compared to 3.6% in BS COPD(p<0.017). There was no difference in clinical symptoms of cough and dyspnea in both groups. Severity of disease, BMI and exercise capacity showed no statistical difference in both groups.

Conclusions: Our results confirmed that BS-COPD and TS-COPD have similar clinical characteristics.

447. Respiratory diseases at at work: epidemiology, inflammation and challenge studies

P4345 Increased markers of oxidative stress in workers exposed to nanoparticles
Daniela Pelclova1, Manolis Kogevinas2, Roel Vermeulen1, Paul I. W. De Jager3, Jaroslav Schwarz2, Jan Pusman2, Nadezda Zikova2, Kamila Syslova3, Orianne Dumas6, Dick Heederik1, Medea Imboden5, Deborah Jarvis7, Lalita Fernandes, Anthony Mesquita, Dept. of Pulmonary Medicine, Goa Medical College, St. Inez, Caranzalem, Goa, India

Introduction: Possible adverse health effects of nanoparticles are little understood. Pilot study was performed in workers exposed to TiO2 aerosol.

Methods: Dynamics of aerosol number size distributions at the workplaces was monitored by SMPS and APS spectrometers in size range 15 nm-10 μm. Spatial distributions of total concentrations were determined using monitors of particle number (P-TRAK) and mass concentrations (DustTRAK DRX). Pre-shift and post-shift FeNO and markers in exhaled breath condensate (EBC) were measured in 20 workers, and 17 controls. Malondialdehyde (MDA), 4-hydroxy-2-trans-nonenal (HNE), 4-hydroxy-trans-hexenal (HHE), 8-isoprostaglandin F2α (8-iso-PGF2α), 8-hydroxy-2-deoxyguanosine (8-OHG), 8-hydroxyguanosine (8- OHG), hydroxymethyl uracil (HMeU), c-trosine (c-Tyr), 3-chloro-trosine (3-Cl-Tyr), nitrotyrosine (NO-Tyr), C6-C13, and leukotrienes (LTs) were analyzed by LC/MS. Pre-shift and post-shift electrospray ionization-mass spectrometry.

Results: Total aerosol concentrations in the production plant varied in space and time; number concentrations 1x104-2x105 particles/cm3, mass concentrations 0.1-30 mg/m3. In the workshops, 90% of particles were under 100 nm in diameter. All pre-shift markers, except LTB4 and FeNO, were increased in workers. Markers of lipid oxidation were elevated (p<0.01): MDA, HNE, HHE, 8-iso-prostaglandin, and C6-C13. Markers of oxidation of nucleic acids and proteins were higher (p<0.001): 8-OHG, HMeU, 3-Cl-Tyr and NO-Tyr. Elevated was also c-Tyr, LTB4, LTETC and LTE4. No difference was noted for post-shift EBC and FeNO.

Conclusion: This first study of EBC in workers suggests deleterious effects of exposure to aerosols with particle sizes.

P4346 Cytokines and MMP 9 level in serum and induced sputum of patients with suspicion of occupational COPD
Maria Wozniakiewicz, Aneta Kleniewska, Ewa Nowakowska-Swirta, Diana Tymoszuk, Cerazy Palczynski, Jolanta Walsiaski-Skorupa. Department of Occupational Diseases, Institute of Occupational Medicine, Lodz, Poland

Background: Chronic obstructive pulmonary disease (COPD) may be work-related. It is estimated that working in exposure to dust and irritant gases is responsible for 10 to 20% cases of COPD.

Aim: The study was aimed to evaluate the usefulness of determination of cytokines and MMP 9 in occupational COPD.

Material and methods: The study group included 36 patients (10 with suspicion of occupational COPD, 14 with occupational asthma and 12 healthy subjects). They underwent clinical examination, spirometry, methacholine challenge test, gasometry, induced sputum. Determination of IL-1, IL-6, TNF α, MMP 9, fibrinogen and C-reactive protein were performed in all the patients. Results: Analysis of acute-phase proteins concentration and cells proportion in induced sputum did not reveal significant differences. The determinations of cytokines and MMP 9 showed higher concentrations in induced sputum compared to serum tests. Among patients with suspicion of COPD, the significantly higher concentrations of IL-1, IL-6, TNF α and MMP 9 were detected in control group.

Conclusions: The obtained results revealed the increased concentrations of IL-1, IL-6, TNF α and MMP 9 in induced sputum among COPD subjects compared to control group. The determination of cytokines and MMP 9 in induced sputum was more useful method in comparison to serum analysis. There was no relationship found between acute-phase proteins concentration and cells proportion in induced sputum in the study groups, however further investigations are required.

P4347 Imputed classical HLA II alleles, occupational allergen exposure and adult-onset asthma
Lidwien A.M. Smit1, Manolis Kogevinas2, Roel Vermeulen1, Paul I. W. De Bakker3, Emmanuelme Bouzigon4, Anne-Ilie Carsin5, Ivan Curjic6, Orianne Dumas1, Dick Heederik1, Medea Imboden5, Deborah Jarvis7, Mark Lathrop8, Nicole Le Moual4, Amir Mehta9, Torben Sigsgaard9, Valerie Siroux10, Jan Paul Zock4, Florence Demenais11, Nicole Probst-Hensch12, Francine Kaufmann13, IRAS, Utrecht University, Utrecht, Netherlands; "Centre for Research in Environmental Epidemiology, CREAL, Barcelona, Spain; "Brigham and Women’s Hospital, Harvard Medical School, Boston, United States; "INSERM, U946, Paris, France; "Swiss Tropical and Public Health Institute, University of Basel, Switzerland; "CMRS 1018, Inserm, Université Paris-Sud, Villejuif, France; "Respiratory Epidemiology and Public Health Group, National Heart and Lung Institute, Imperial College, London, United Kingdom; "Commissariat à l’Energie Atomique, Institut de Génomique, Centre National de Génopépotype (CNG), Evry, France; "Department of Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; "INSERM, U825, Université Joseph Fourier, Grenoble, France

Background: HLA is a principal candidate gene region for occupational asthma, and HLA-DQ was the only significant locus in the GABRIEL genome-wide association study (GWAS) of late-onset adult-onset asthma. Aim: To elucidate the role of HLA-II in adult-onset asthma, we imputed classical HLA-II alleles from 7579 single nucleotide polymorphisms. We explored associations between 25 alleles with frequency >5% and adult-onset asthma, and we did separate analyses in subjects exposed to occupational allergens.

Methods: We studied 607 subjects with adult-onset asthma and 2104 adults without asthma from three European cohorts (ESE Consortium: ECRHS, SAPALDIA, and IGEA. According to a job exposure matrix, 44 subjects (13% with adult-onset asthma) were exposed to high molecular weight (HMW) agents, with 74% exposed...
to latex. In addition, we studied 946 HMW-exposed workers (392 with asthma) from Dutch and Danish surveys of bakers and farmers.

**Results:** In the ESE cohorts, DPB1*0301 (OR 0.76, 95%CI 0.60-0.97) and DQA1*0301 (OR 1.22, 95%CI 1.02-1.44) were associated with adult-onset asthma. DQA1*0103 was associated with asthma, but only in HMW-exposed ESE subjects (OR 0.54, 95%CI 0.29-0.98). In the HMW-exposed bakers and farmers, six other HLA-II alleles were associated with asthma (p<0.05). None of the associations in ESE subjects or workers remained statistically significant after correction for multiple testing.

**Conclusions:** Imputation allows a complete evaluation of HLA alleles following GWAS. In a general population and among populations exposed to a variety of occupational allergens, analyses did not reveal a clear association between common classical HLA-II alleles and adult-onset asthma.

**Funding:** ANR-PRSP10 Iago.

**Work-related asthma among a general asthma population: A cross sectional survey**

Donatella Talini,1, Dusca Bartoli,2, Alessandro Ciuber,1, Paolo Del Guerra,1, Andrea Innocenti,1, Maria Lemm,2, Anna Cerrano,3, Tonina Iai,1, Francesco Di Pede,4, Laura Carrozz1, Pierluigi Puggaro,1,1 CefRMP, Tuscany Regional Adm, Pisa, Italy; Prevention Dpt, Occupational Health Unit, Empoli, Italy; Prevention Dpt, Occupational Health Unit, Pistoia, Italy; Prevention Dpt, Occupational Health Unit, Pisa, Italy; Prevention Dpt, Occupational Health Unit, Sienna, Italy; Institute of Clinical Physiology, CNR, Pisa, Italy; Cardiostomatic Dpt, University of Pisa, Italy.

To find the impact of occupational exposure to irritants or sensitizers on the occurrence, recrudescence and worsening of asthma and to identify unrecognized cases of work related asthma (WRA) in a general asthma clinic population sample, we studied 893 subjects from 15 to 46 yrs with diagnosis of asthma identified from the Medical Reimbursement Register of the National Health Service. All subjects were classified in different categories of occupational risk exposures (Low, Low or High: 58.9, 27.9, 13.2% respectively) according to the italian standard classification for industries and job titles, associated with the judgment of occupational hygiene-experts. Subjects with higher occupational risk had a lower lung function (p=0.02) and asthma severity (<0.01). Prevalence of WRA (47%), including occupational asthma (OA: 7%) and work exacerbated asthma (WEA: 40%), was significantly associated with higher occupational risk exposed (OR: 6.8, p=0.001). Subjects with WRA had a lower lung function (<0.01) and asthma severity (p=0.01) with respect to subjects without WRA. Two-thirds of OA and half of WEA caused loss of work. In conclusion our study shows a high prevalence of WRA (especially WEA) associated with employment in industries and job titles at risk for airways sensitizers and/or irritants. Control of exposure, an appropriate medical surveillance and an accurate therapeutic management can avoid the loss of job and its socioeconomic consequences in asthmatic subjects.

**Shield 1992-2012: 20 years of a reporting scheme for occupational asthma**

Vicky Mean,1, Alastair Robertson2, Emmet McGrath1, Arun Dev Vellore1, Sherwood Burge1, 1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Department of Occupational Health, Birmingham University Hospitals, Birmingham, United Kingdom; 3Respiratory Medicine, Solihull Hospital, Birmingham, United Kingdom

SHIELD is the Midland Thoracic Society’s rare surveillance scheme for occupational asthma in the West Midlands, England, UK (working population 2.2 million). The database is a useful tool to locate outbreaks within a particular field of work and discover causative agents. There have been 1644 notifications of occupational asthma since January 1992.

**P4350**

**The effect of work on asthma in middle-aged men having asthma from youth**

Irini Lindström1, Hilje Saqlalet1, Paula Pallasaho1, Antti Lauerman2, Antti Kajalainen1,1 Control of Hypersensitivity Diseases, Finnish Institute of Occupational Health, Helsinki, Finland; 2Skin and Allergy Hospital, Helsinki University Central Hospital, Helsinki, Finland; 3Surveillance of Working Conditions Team, Finnish Institute of Occupational Health, Helsinki, Finland

**Aims:** We studied the effect of current workplace exposure on current asthma severity, asthma control and occurrence of exacerbations in a population of approximately 40-year old men having asthma since their youth.

**Methods:** We used Finnish Defence Force registers, 1986-1990, to select: (1) conscripts with asthma to represent a mild/moderate asthma group (n=485), (2) asthmatics who were exempted from military service to represent a relatively severe asthma group (n=393) and (3) a control group (n=1500) without asthma. A questionnaire consisting of validated questions on asthma and occupations was sent out in 2009 and current occupational exposure was estimated with asthma Job Exposure Matrix (JEM). Asthma severity was evaluated with the modified GINA guidelines and control with the Asthma Control Test. Logistic regression was used in risk factor analyses. A total of 54% of the men in asthma group 1, 44% of those in asthma group 2 and 44% of the controls answered.

**Results:** A total of 17.5% of the men in asthma group 1 and 40.5% of the subjects in asthma group 2 had and currently moderate or severe persistent asthma. Asthma was more often uncontrolled in asthma group 2 (28.0% vs. 15.1%, p=0.002) and exacerbations during last 12 months were more frequent (19.3% vs. 11.6%, p=0.0363). Being currently not-employed (OR 2.0, 95%CI 1.0-4.0) and self-reported occupational exposure to abnormal temperatures (OR 2.0, 95%CI 1.0-4.0) were associated with asthma exacerbations, while occupational exposure based on JEM was not related to current asthma status.

**Conclusion:** Current workplace exposure seems to have only minor effect on asthma severity, control and exacerbations in 40-year old men having asthma since their youth.
Occupational asthma and rhinitis in champagne vineyard workers

Jeanne-Marie Perotin 1,2, Khoa Luat Nguyen 1, Claire Barbe 2, Claire Launois 1,2, Jean-François Fontaine 3, Yvon Gabignon 3, François Lebargy 3,4, Gaëtan Desleger 3,4, François Lavaut 3, Department of Respiratory Medicine, University Hospital, Reims, France; 4INSERM UMRS 903, University Hospital, Reims, France; 1Methodology Unit, University Hospital, Reims, France; 2Department of Occupational Medicine, Mutualité Sociale Agricole, Reims, France

Background: Vineyard workers (VW) are exposed to various inhaled respiratory allergens. However, the prevalence and risk factors of occupational asthma (OA) and rhinitis (OR) in Champagne VW have not been studied.

Aims: The objectives of this cross-sectional study were to determine the prevalence of OA and OR in Champagne VW and to analyze the relationships between occupational exposures (OS), occupational exposure and sensitization profile.

Methods: Champagne VW were recruited from the Department of Occupational Medicine in May and June 2010. Demographic and occupational characteristics were recorded. Nasal and respiratory symptoms were scored for each month of the past year. OS were defined by symptoms related to work exposure. Diagnosis of asthma was based on symptoms (SS) and occupational exposure mon respiratory allergens, grape mould (botrytis) and grape pollen. FEV1/FEV6 ratio was measured.

Results: Sixty-six patients were included. The prevalence of rhinitis and asthma was 38% and 13% respectively. The prevalence of OR and OA was 21% and 3% respectively. SPT showed sensitization for gramineae (18%), D. pteronyssinus (12%), D. farinae (11%), vine pollen (11%), botrytis (5%). Compared to VW without OS, VW with OS were more frequently sensitized to betulacaeae (20% vs 2% respectively, p=0.03) and were involved in the activities of disbudding, straightening and/or hooking (35% vs 6% respectively, p=0.04). OS were present in May and June for 67% of patients, corresponding to disbudding, straightening and hooking.

Conclusion: The prevalence of OR in Champagne VW is high, whereas OA is relatively rare. OA and OR are associated with a sensitization to betulacaeae and with direct exposure to vine.

Quartz exposure and lung function

Karl Hochgatterer 1, Hans Moshammer 2, Daniela Hailpern 2, AMZ, AMZ Perg, Austria; 2AMZ, AMZ Perg, Austria; 1AMZ, AMZ Perg, Austria; 2Institut für Umweltmedizin, ZPH, Med Univ Vienna, Vienna, Austria

Occupational exposure to quartz not only leads to silicosis but also to chronic bronchitis and obstructive lung disease. In Austria more stringent occupational limit values for dusts have been introduced in 2007. We assumed that (a) workers exposed to mineral dusts (quartz) have a poorer lung function (LF) than other workers that do not use such dusts or that cause (b) other occupational exposures (dusts and fumes), (b) LF decline is fastest in the quartz-group, and (c) the decline slowed down after the introduction of stricter limit values.

We examined repeated LF data (FVC, FEV1, MEF50) from the routine examination (usually every 2 years) performed by one occupational health centre from the years 2002 through 2010. Three main linear regression models were analysed on each LF parameter. (a) The effect of quartz exposure on the raw parameter after controlling for age, weight, height, gender, and smoking. (b) The effect of quartz exposure on the difference between actual value and the age-sex-height-dependent Austrian norm value. This approach allowed us to additionally control for the impact of duration of exposure. (c) The impact of quartz exposure on the intra-individual decrease in LF parameters per year. In this analysis we could also check for differences in the slope before and after the introduction of new limit values.

We analysed 7315 data-sets (on average 5 per person, mostly males). Nearly 40% of these were from workers exposed to quartz dusts. The remaining workers were welders or were exposed aluminium or other dusts. Both smoking and quartz exposure lead to lower LF values. Duration of quartz exposure also was a significant predictor of LF decline. The decline slowed after the introduction of stricter limit values.

Conclusion: Specific inhalation challenge tests to MWF did not produce non-specific reactions. A number of the MWF can be the cause of occupational asthma even with a negative challenge to used MWF.
negative in 6 control patients with work-related asthma due to another cause and exposed to QACs.

Conclusions: Our study demonstrated the usefulness of BCT to confirm an occupational asthma to QACs. As compared to previous publication from our group, bronchial response occurred more rapidly suggesting a sensitisation to DDAc.

P4357 Persistence of the asthmatic response after exposure to ammonium persulfate in an animal model

Xavier Munoz1, Marta Ollé-Monge1, Jeroen Vanarioebck2, Ferran Morrell1, Maria-Jesus Cruz2, Maria Blanca Gonzalez1, 1Respiratory, Hospital Vall d’Hebron, Barcelona, Spain; 2Occupational, Environmental and Insurance Medicine, KU Leuven, Leuven, Belgium

Introduction: The aim of the study is to evaluate the persistence of respiratory symptoms after the end of exposure to ammonium persulfate (AP) in a validated model of occupational asthma (OA).1

Material and methods: BAL/Bc mice received dermal applications of AP or dimethylsulfoxide (DMSO) (control) on days 1 and 8. On day 15, they received a single nasal instillation of AP or saline. The ventilatory function (Penh) was monitored by whole body plethysmography for 40 minutes after the nasal instillation. Bronchial hyperreactivity was assessed using methacholine provocation, while pulmonary inflammation was evaluated in BAL and total serum IgE was measured in blood. 1 day (day 16), 2 days (day 17), 3 days (day 18), 4 days (day 19), 1 week (day 23) or 2 weeks (day 30) after the single challenge on day 15.

Results: There was a significant increase in bronchial hyperreactiveness and the percentage of neutrophils (12%) 24h after the challenge with AP in AP-sensitized mice. The peak response in AHR and neutrophil inflammation was found 48h post-challenge. From then onwards, both the bronchial hyperreactiveness and the percentage of neutrophils decrease gradually. Levels of total serum IgE increased significantly, reaching a peak three days after challenge, after which the levels return to baseline 23 days post-challenge.

Conclusions: Overall, after two dermal sensitizations, followed by a single challenge, the asthmatic response decreases, with initially only decreases in respiratory and inflammatory responses, but later also in the immunological responses.

Study funded by FIS PPI080730.

P4358 Metalworking fluids, machine operator’s lung and serological diagnosis evolution

Gabriel Rebecu1, Isabel Warfolomeow, Corail Barrera, Sandrine Roussel, Benjamin Millot2, Laurence Millot-Argeny Department, UMR/CRNS 6249 Chrono-Environment, University Hospital J. Minjoz, Besançon, France; Safety Department, Berufsgenosenschaft Holz und Metall (BGHM), Mainz, Germany; Mycology Department, UMR/CRNS 6249 Chrono-Environment, University Hospital J. Minjoz, Besançon, France; Mycology Department, UMR/CRNS 6249 Chrono-Environment, University Hospital J. Minjoz, Besançon, France; Mycology Department, UMR/CRNS 6249 Chrono-Environment, University Hospital J. Minjoz, Besançon, France;

Chrono-Environment, University Hospital J. Minjoz, Besançon, France

Machine operator’s lung (MOL) has been related to Mycobacterium immunogenum (MI) growing in metalworking fluids (MWF). Our contribution to the serological evolution of MOL diagnosis is a 3 step story:

1. Sera from 13 MOL cases from the same plant, and 30 controls were tested against MI antigen (Ag). MI was identified in 40% of used MWF (n=831 plant).
2. The threshold for differentiating MOL cases from controls was 5 arcs (sensitivity (Se) 77% and specificity (Sp) 92%), as determined by electrosyneresis (ES). Using ELISA a threshold leading to 92% Se and 100% Sp was established (Tillie-Leblond, 2011. 1, et al. ERJ 2011; 37:640-7).
3. Immunogenic proteins were identified by two-dimensional Western blot and mass spectrometry. Recombinant antigens (rAg) were expressed in Escherichia coli and tested by ELISA. From the 350 spots visualized, 6 immunogenic proteins were selected to be expressed as rAg. Acyl-CoA dehydrogenase (Acyl-CoA DH) allowed for the best discrimination (Se 100%; Sp 83%) (Rousset, S. et al. Int J Med Microbiol 2011; 301:150-6.).
4. Serological diagnosis of 10 new German suspected cases was made by ES and ELISA. Independence from the strain isolated from the first cluster cases was obtained by using rAg. But whereas other strains was isolated in Germany from 3 new plants, ES made with French MI strain Ag demonstrated a similar threshold (4 arcs) to discriminate MOL from exposed subjects. Dihydrolipoamide dehydrogenase and Acyl-CoA DH results were useful together to make the diagnostic true regardless to the clinical and radiological data (Se 100%; Sp 100%), when used isolated Se reduced to 78 to 88% with Sp 100%. Uses of a panel of rAg seem the best way to serological diagnosis of MOL.

P4359 Persistence of functional and inflammatory response in mice dermally sensitized to persulfate salts

Maria-Jesus Cruz1, Abdellah Assialou1, Jeroen Vanarioebck2, Marta Ollé-Monge1, Ferran Morrell1, Xavier Munoz1, 1Respiratory, Hospital Vall d’Hebron, Barcelona, Spain; 2Occupational, Environmental and Insurance Medicine, KU Leuven, Leuven, Belgium

Introduction: Years after removal from exposure, patients with occupational asthma (OA) still can show respiratory symptoms and bronchial hyperresponsiveness on re-exposure to the causal agent. The aim of the study was to assess the persistence of respiratory symptoms in an animal model of occupational asthma due to persulfate salts.

Material and methods: BAL/Bc mice received dermal applications of ammonium persulfate (AP) or dimethylsulfoxide (DMSO) (control) on days 1 and 8. They then received a single nasal instillation of AP or saline on day 15, 22, 29, 36, 45 or 60. The ventilatory parameters were evaluated by spirometry after the challenge in a whole body plethysmography (40 min.). Bronchial hyperreactivity was measured 24 hours afterwards using a non-specific methacholine provocation test. Pulmonary inflammation was assessed by analysis of bronchoalveolar lavage (BAL).

Results: Mice dermally sensitized and intranasally challenged with AP showed bronchial hyperreactivity to methacholine and increased percentage of neutrophil in BAL as long as 45 days after initial sensitization, compared with the control group. At day 60, mice were still bronchially hypersensitive, while the percentage of neutrophils fell to levels similar to those in the control groups.

Conclusions: Pulmonary inflammation decreased with increasing intervals between dermal sensitization and the challenge with AP, despite the persistence of hyperresponsiveness.

Study funded by FIS PPI080730.

P4360 Prevalence and factors associated with COPD in dairy farmers

Jorge Soria-Marcenar1, Isabelle Tharon1, Jean-Claude Laplante2, Bruno Degano3, Jean-Charles Dalphin1, 1Respiratory Medicine, University Hospital, Besançon, France; 2Occupational Diseases Department, University Hospital, Nancy, France; 3Head, Mutualité Sociale Agricole, Besançon, France; 4Physiology, University Hospital, Besançon, France

Several studies have suggested an increased risk of chronic obstructive pulmonary disease (COPD) among dairy farmers despite a lower prevalence of smoking compared with general populations. The prevalence of COPD among farmers, and the occupational factors associated with COPD are however unknown.

We therefore retrospectively analyzed the medical records of 590 dairy farmers (mean age 44.4 yrs; 75% males) and 69 control patients (mean age 43.5 yrs; 75% males), using respiratory medical questionnaires in 3 cohorts of dairy farmers. All studied subjects (n=590) were males without asthma and/or hypersensitivity pneumonia previous.

Criteria of COPD (i.e., a FEV1/FVC ratio < 70%) were found in 12% of all subjects (69/590, including 38 patients in GOLD stage 1 and 28 in stage 2). Symptoms of chronic bronchitis and wheezing were more frequent in patients with COPD (15.9 vs. 7.9%, p=0.03 and 30.3% vs. 10.6%, p<0.001, respectively). On multivariate analysis, the three independent factors associated with COPD were an older age (adjusted odds ratio [95% confidence interval]: 1.04 [1.02-1.07]), tobacco smoking (2.83 [1.29-6.19]) and low modernity of farms (2.89 [1.48-5.63]). Moreover, the association between tobacco smoking and working in traditional farms seemed to be synergistically linked with COPD in this population.

The finding that an occupational factor (i.e., working in traditional farms) is independently associated with COPD in dairy farmers suggests that prospective studies should be conducted in this population in order (1) to identify etiologic factors of COPD and (2) to characterize the COPD patients in terms of distension, exercise capacity and cardiovascular comorbidities.

P4361 Prevalence of chronic respiratory symptoms, ventilatory capacity and bronchial responsiveness in welders

San Stojkovic1, Jovanka Kata dzinska Bisilimovska1, Jordan Minov1, Dragan Mijakoski2, Snejana Risteska Kuc2, 1Dept for Respiratory Functional Diagnostics, Institute for Occupational Health of RM, WHO CC, GaZen CC, Skopje, Macedonia, The Former Yugoslav Republic of; 2Allergy Center, Institute for Occupational Health of RM, WHO CC, GaZen CC, Skopje, Macedonia, The Former Yugoslav Republic of

Objective: To evaluate the prevalence of chronic respiratory symptoms, ventilatory capacity abnormalities and bronchial hyperresponsiveness in welders and to clarify the role of workplace exposure.

Methods: A cross sectional study was performed including 40 males working as stainless steel welders (mean age=43.9±7.4; duration of exposure 15.2±6.8 yrs) and 40 male office workers as a control group (mean age=42.8±7.1) matched for age, duration of employment, smoking habits and socioeconomic status. Evaluation of examined subjects included completion of a questionnaire on respiratory symptoms in the last 12 months (cough, phlegm, dyspnea, wheezing, and chest tightness), spirometry and histamine challenge (PC20=8 mg/mL).

Results: We found non-significantly higher prevalence of respiratory symptoms in the last 12 months in welders with significant difference for cough (P=0.036)
P4362 The effect of radiographic abnormalities on mental health of former workers and residents of Wittenoom in Western Australia

Peter Franklin1, Patrick Abouyog- Sarfo1, Bill Musk2, Nicholas de Klerk3, Nola Olsen1, Katha Samuel1, Rob Mina1, Alison Reid1, 1School of Population Health, University of Western Australia, Perth, WA, Australia; 2Respiratory Medicine, Sir Charles Gairdner Hospital, Perth, WA, Australia; 3Centre for Child Health Research, Western Australia, Perth, WA, Australia; 4Western Australian Institute for Medical Research, University of Western Australia, Perth, WA, Australia

Introduction: Exposure to asbestos causes radiographic abnormalities such as pleural plaque (PP), diffuse pleural thickening (DPT) and asbestosis. Knowledge of presence of these radiographic abnormalities may affect individuals’ mental health (MH).

Aims: The aim of this study is to examine the effect radiographic abnormalities on the MH of people exposed to crocidolite.

Method: Subjects were former workers and residents of Wittenoom, a crocidolite mining town in Western Australia, who had participated in an Asbestos Review Program. The diagnosis of PP, DPT or asbestosis was determined from plain chest x-rays. In 2007, participant had completed a questionnaire that included questions on mental health status (SF-12) and sense of personal control (SOPC). Generalised linear modelling was used to relate the presence of PP, DPT and asbestosis to MH scores and SOPC scores controlling for asbestos exposure measurements, smoking status, other cancers, general physical health and demographic variables.

Results: A diagnosis of asbestosis was significantly associated with worse MH status (β = −0.04; 95% CI −0.079 to −0.004; p=0.031) but not SOPC. The presence of PP and DPT were not related to either poor mental health or reduced SOPC.

Conclusion: The presence of PP or DPT in the absence of other disease, do not seem to affect the mental health of crocidolite exposed subjects from Wittenoom compared to exposed persons without radiographic abnormalities. However, patients with asbestosis have evidence of worse MH compared to other asbestos exposed individuals.

448. Anti-infective treatment and resistance in respiratory infections

P4363 Therapeutic efficacy of macrolides, minocycline and tosufloxacin against macrolide-resistant Mycoplasma pneumoniae pneumonia in pediatric patients

Naoaki Miyauchi1, Mika Kubo2, Yasuhiro Kawai3, Kazunobu Ouchi4, Niro Okimoto5, 1Department of Internal Medicine I, Kawasaki Medical School, Okayama, Japan; 2Department of Pediatrics, Kawasaki Medical School, Okayama, Japan

Background and objective: Since 2000 the prevalence of macrolide-resistant (MR) Mycoplasma pneumoniae in pediatric patients has increased in Japan. The purpose of our study was to investigate differences in the clinical course, bacteriological effect and therapeutic efficacy against MR M. pneumoniae among macrolides, minocycline and tosufloxacin.

Methods: We performed a multicenter prospective epidemiological study of MR M. pneumoniae for the first time. A total of 152 children with M. pneumoniae pneumonia confirmed by polymerase chain reaction (PCR) were analyzed. A search for mutations at sites 2063, 2064, and 2617 in the M. pneumoniae 23S rRNA domain V gene region was performed.

Results: One hundred nine patients of 152 children with M. pneumoniae pneumonia were determined to have a MR gene. Fever disappeared within 48 hours after antibiotics administration in the MR patients was seen in 25% of the macrolides group, 83% in the minocycline group, and 81% in the tosufloxacin group. The DNA copy numbers in the MR patients showed little decrease after macrolide administration, but rapid decrease after administration of minocycline or tosufloxacin.

Conclusions: The number of M. pneumoniae in the MR patients decreased promptly after 48 hours minocycline and tosufloxacin treatment and had a close relationship with clinical outcome. In contrast, we found that the clinical and bacteriological efficacy of macrolides for treating cases of MR patients was low. Our results might be indicate that minocycline and tosufloxacin considered as the first choice drugs for treatment of M. pneumoniae pneumonia in Japanese situation.

P4364 Clarithromycin inhibits pandemic A/H1N1/2009 influenza virus infection in human airway epithelial cells

Mitsuo Yamada1, Yuki Samei Hatachi2, Hiroshi Kubo1, Hidekazu Nishimura3, 1Department of Advanced Preventive Medicine for Infectious Disease, Tohoku University Graduate School of Medicine, Sendai, Japan; 2Department of Respiratory Medicine, Graduate School of Medicine Kyoto University, Kyoto, Japan; 3Virus Research Center, Clinical Research Division, Sendai National Hospital, Sendai, Japan

Rationale: We reported previously that clarithromycin (CAM), a macrolide antibiotic, inhibits seasonal type A influenza virus (H3N2) infection in human airways. However, the effects of CAM on infection by the pandemic A/H1N1/2009 influenza virus (A/H1N1 pdm) have not been studied.

Methods: Human tracheal epithelial cells (n=3) were pretreated with CAM (10 μM) and then infected with the A/H1N1 pdm in 24-well plates.

Results: The viral titer and the amount of interleukin (IL)-6, a pro-inflammatory cytokine, in the supernatant increased with time after A/H1N1 pdm infection. CAM reduced the viral titer (6.7±0.4 log TCID 50 units/ml/24 h for virus alone vs. 4.9±0.2 log TCID 50 units/ml/24 h for virus plus CAM; p<0.05, mean ± 5E) and IL-6 (211±8 pg/ml/24 h for virus alone vs. 149±7 pg/ml/24 h for virus plus CAM; p<0.05) 3 days after infection. CAM also reduced the number of epithelial cells detached from culture vessels 7 days after infection (32±2 x 10³/well in virus alone vs. 12 ±2 x 10³/well in virus plus CAM; p<0.05). In addition, we compared the viral titer and the numbers of detached cells after infection between the A/H1 pdm and the A/H3N2 virus. The viral titer and the number of the detached cells after infection with the A/H1 pdm were higher than those after infection with the A/H3N2 virus (4.1±0.4 log TCID 50 units/ml/24 h and 5±1 x 10³/well for A/H1N1 pdm vs. p<0.05).

Conclusions: Clarithromycin may inhibit A/H1N1 pdm infection and may modulate airway inflammation and epithelial damage during the infection. The A/H1 pdm may release higher levels of virus and may be more cytotoxic than seasonal influenza virus (H3N2).

P4365 Community-acquired pneumonia in five European countries: Usage patterns and real-life effectiveness of antibiotics (REACH study)

Francesco Blasi1, Javier Garau2, Jesús Medina3, Marco Avila4, Kyle McBride5, Helmut Ostermann6, 1Department for Infectionansan and Respiratory Medicine, Graduate School of Medicine, Tohoku University, Sendai, Japan; 2Department of Pulmonary and Critical Care Medicine, Vall d’Hebron University Hospital, Barcelona, Spain; 3Department of Internal Medicine, Hospital de Sant Pau, Barcelona, Spain; 4Respiratory and Critical Care Medicine, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; 5Department of Infectious Disease, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 6Department of Pulmonary and Critical Care Medicine, University Hospital of Barcelona, Barcelona, Spain

Background: Comprehensive, current data on the burden of hospitalized community-acquired pneumonia (CAP) in Europe are scarce. Aim: To describe the hospitalized CAP population in Europe and to review current clinical practice and its impact.

Methods: REACH (NCT01293435) was a retrospective (2010–2011), observational study in ten EU countries. Patients were ≥ 18 years old, hospitalized with community-acquired pneumonia and treated with antibiotics for the treatment of CAP, were included.

Results: A total of 12,663 CAP patients were included. The mean age of the patients was 68 years (range 18 to 104 years) and 5,448 patients (42.9% of the total study population) were men. Microorganisms were identified in 11,281 cases (89.2%). The most common pathogen was Streptococcus pneumoniae (14.3%), followed by Haemophilus influenzae (11.5%) and Staphylococcus aureus (11.3%). The most commonly used antimicrobial agents were amoxicillin (48.7%), followed by ceftriaxone (35.9%) and azithromycin (15.5%). The resistance rates for the three most frequently used antibiotics were 10.6% for macrolides (amoxicillin), 9.1% for beta-lactams (ceftriaxone) and 1.2% for macrolides (azithromycin). The most common side effects were diarrhea (5.6%) and nausea (4.8%). The mortality rate was 7.0% and the median length of stay was 7 days (range 1–59 days).

Conclusions: The REACH study provides valuable data on the burden of community-acquired pneumonia in Europe and the real-life effectiveness of antibiotics. Further research is needed to improve the quality of care for these patients.
CAP and requiring IV antibiotics. Data were collected via an electronic Case Report Form. We present data from five countries selected as representative of the full sample: Italy (IT), the Netherlands (NL), Spain (ES), Turkey (TR) and the UK.

**Results:** Patient characteristics were similar in the five countries. Rates of initial treatment modification (due to treatment failure or other reasons) were 33.0% (TR), 36.7% (IT), 42.5% (ES), 50.0% (UK) and 51.7% (NL) (overall population 37.1%).

**Conclusions:** Antibiotic use differed somewhat between countries. Modification of initial treatment was common with many frequently used therapies, with variability among countries, suggesting that initial treatment choices may not always be optimal.

**P4366**

**Caspofungin to treat invasive pulmonary aspergillosis in sarcoidosis**

Benjamin Gartlit1, Greg Keir1, Muhammad Anwar1, Michael Loebinger2, Robert Wilson3, Elizabeth Renzon1, Athol Wells1, Toby Maher1, 1Interstitial Lung Disease Unit, Royal Brompton Hospital, London, United Kingdom; 2Host Defense Unit, Royal Brompton Hospital, London, United Kingdom

**Rationale:** Invasive pulmonary aspergillosis is a potentially life-threatening complication of sarcoidosis, with destructive fibrotic lung disease and immunosuppressive therapy contributing to its development. Optimal therapy is not known. We report a successful treatment protocol using cyclical intravenous caspofungin infusions.

**Methods:** Consecutive patients with sarcoidosis and invasive pulmonary aspergillosis treated with caspofungin were identified from our pharmacy prescribing database. Clinical and radiological data were collected retrospectively prior to caspofungin treatment, and during follow-up.

**Results:** Nine patients (5 men), with a mean age of 44±11.13 years, and a median duration of sarcoidosis of 10 years (range 2-12), were treated with caspofungin. All patients had fibrotic pulmonary sarcoidosis (stage IV) on chest radiograph. Eight patients also received prednisolone. Six patients received prior oral antifungal therapy (voriconazole or itraconazole), and were converted to caspofungin due to lack of efficacy or side-effects.

Median follow-up was 12.5 months (4-32) after the commencement of caspofungin. In eight patients, symptoms and inflammatory markers improved rapidly after the first dose of caspofungin, with a decrease in median CRP from 31 (3.94) to 15 (3.23) (p<0.02) within 3 months. In the 6 patients for whom a minimum of 6 months follow-up was available, chest radiographs improved in 4 (67%), and median BMI improved from 23.2 (17.0-31.0) to 25.2 (21.5-36.0) (p<0.04).

**Conclusion:** Invasive pulmonary aspergillosis associated with sarcoidosis may be refractory to conventional antifungal therapy, and caspofungin appears to be a safe and effective therapeutic alternative in these patients.

**P4367**

**Macrolides vs quinolones in Legionella pneumonia treatment: CAPAVANT group. Valencia, Spain**

Sussana Herrera, Estrella Fernandez, Angel Cervera, A. Carmen Aguar2

**Methods:** Aims: To compare of community-acquired pneumonia between diabetic and non-diabetic patients with hyperglycemia status (HG) at hospital admission. We performed a prospective, observational study of patients admitted to the Pneumology department consecutively with a diagnosis of CAP. The plasma glucose levels were measured on admission and patients were divided into two groups: diabetic patients and non-diabetic with HG. We consider HG when plasma glucose level >=99mg/dl. We studied different variables, included severe clinical course (mortality and/or septic shock and/or invasive mechanical ventilation (IMV) during hospital stay.

**Results:** We studied 1389 patients, 274 were known diabetic and 53 (3,8%) were non-diabetic with HG.

**Table 1**

**Conclusions:** 1. Non-diabetic patients with HG had a more severe clinical course comparing to known-diabetic, although mortality was similar. 2. Non-diabetic patients with HG had more respiratory morbidities, reached clinical stability later, had a higher admission to ICU and needed more IMV, with a longer hospital stay. 3. 4% of patients admitted with a CAP had a not-known HG.
P4370
Factors associated with compliance with palivizumab treatment in the Canadian rSV evaluation study for synagis (CARESS) registry (32005-2011)  
Jan Mitchell1, Bosco Paes2, Abby Li1, Krista Lanctot1. 1Pulmonology, University of Calgary, AB, Canada; 2Pulmonology, McMaster University, Hamilton, ON, Canada

Objective: Determine factors affecting compliance in palivizumab use. 
Methods: Registry of infants who received ≥1 dose of palivizumab during 6 RSV seasons. Demographic data collected at enrolment. Data on palivizumab utilization, compliance, and outcomes (respiratory illness - RI) collected monthly. Compliant interval between doses, and percentage of expected injections received. 
Results: 10,452 infants enrolled, 7492 (71.7%) complied with timing of doses. 91.9%≥2.7% of expected injections received. Greater proportion of non-compliant infants were hospitalized for RI (7.5% versus 6.0%, p=0.005), compliance did not affect RSV-positive hospitalizations (1.79% versus 1.53%, p=0.177). Compliant infants (all >0.05): were younger at enrolment (5.4±5.9 versus 5.9±6.1 months), had siblings (61.3% versus 58.5%), were a multiple (29.7% versus 27.2%), and had >5 household individuals (23.9% versus 21.7%). More non-compliant infants had smoke exposure (30.5% versus 28.4%, p=0.033). Six factors influenced compliance in regression analysis: age (HR=0.989, 95%CI 0.982-0.996, p=0.002), siblings (HR=1.104, 95%CI 1.007-1.211, p=0.034), ≥5 household individuals (HR=1.114, 95%CI 1.001-1.241, p=0.047), smoke exposure (HR=0.891, 95%CI 0.811-0.980, p=0.018) and CHD (HR=0.805, 95%CI 0.700-0.927, p=0.002), and RI-related hospitalization (HR=0.837, 95%CI 0.705-0.930, p=0.043).

Conclusions: Siblings ≥5 household individuals is associated with increased treatment compliance; being older, smoke exposure, having CHD and being hospitalized with decreased compliance.

Therapeutic outcomes for cavitary Mycobacterium avium complex (MAC) lung disease  
David Griffin, Barbara Brown-Elliot, Sara Shepherd, Julie Philphey, Richard Wallace. Medicine and Microbiology, University of Texas Health Science Center, Tyler, TX, United States

Beginning in 1992, patients were enrolled in a series of prospective clinical trials investigating the safety and efficacy of 3 or 4 drug macrolide-containing regimens for treating cavitary MAC lung disease. Based on these studies subsequent MAC lung disease patients received similar regimens. All patients were diagnosed according to contemporary nontuberculous mycobacterial (NTM) diagnostic guidelines. Patients are included in this analysis only if they had a macrolide susceptible MAC isolate prior to initiation of therapy and subsequently tolerated a 3 to 4 drug regimen consisting of macrolide, ethambutol, and a rifamycin (rifampin or rifabutin) ± injectable agent (streptomycin or amikacin) administered daily or three times weekly. There were 240 patients in the intent to treat analysis with a mean age 63.2±12.4 years (range 35-90 years) who were 76% male, 80% white and 75% current or ex-smokers (>10 pack years smoking). 134 patients had adequate records available for treatment outcome evaluation. 86/134 (64%) had sputum AFB culture conversion while on therapy. Over the study period, the all cause mortality was 57% for the intent to treat cohort and 41% for patients with sputum AFB culture conversion on therapy. We conclude that cavitary MAC lung disease can be effectively treated with macrolide-based regimens but is associated with high all cause mortality regardless of MAC treatment response.

Invasive pulmonary aspergillosis: What is the role of surgery in the voriconazole era?  
Mathilde Neveuille1, Anne Bergeron2, Patricia Ribaud3, Emmanuel Raffoux1, Bernard Maître2, Dominique Goulet1,1Pneumologie, Hôpital Bichat, Paris, France; 2Pneumologie, Hôpital Saint-Louis, Paris, France; 3Hématologie, Hôpital Saint-Louis, Paris, France; 4Pneumologie, Hôpital Henri Mondor, Créteil, France; 5Chirurgie Thoracique, Institut Mutualiste Montsouris, Paris, France

Invasive pulmonary aspergillosis (IPA) is one of the most severe infections in immunocompromised patients. In the 90’s, surgery was considered a potentially curative treatment. Since voriconazole has become the first line treatment, the role of surgery has not been evaluated. Thirty immunocompromised patients who underwent surgery for a suspected IPA were retrospectively reviewed and separated into two groups: the group A (n=20) who received amphotericin B or itraconazole before the surgery, and the group B (n=10) treated by voriconazole.

The diagnosis of IPA before surgery was certain or probable for 44% of the patients. The main indications for surgery were: the resection of a persistent pulmonary lesion prior to subsequent immunosuppressive treatments (50%), incomplete control of the infection (43%), and risk of haemoptysis (10%). The median duration of antifungal treatment before surgery was 3 months in the group A, and 2.5 months in the group B (p=0.02). Persisting aspergillosis was confirmed for 85% among the patients from the group A, and only 20% of the group B (p=0.001). Anatomopathological study provided an alternative diagnosis for 4 patients, all in the group B: 2 mucormycosis, 1 mycobacterial infection, 1 specific lesion of the leukemia. Perioperative mortality was low (3%).

Surgery is a therapeutic option for IPA with low mortality in a well trained surgical team. In the voriconazole era, the proportion of resected pulmonary lesions containing Aspergillus appears to be decreasing, whereas other fungal infections are detected. The role of surgery has to be defined in patients previously treated with voriconazole, particularly for remaining pulmonary lesions.

P4373
Poor prediction of potentially drug-resistant pathogens using current criteria of health care-associated pneumonia.  
Seon Cheol Park1, Bosco Paes2, Abby Li1, Krista Lanctot1. 1Pulmonology, University of Calgary, AB, Canada; 2Pulmonology, McMaster University, Hamilton, ON, Canada

Background: Health care-associated pneumonia (HCAP) includes a broad range of patients having frequent or chronic contact with health care systems. However, the relationship between current defining criteria for HCAP and the risk of potentially drug-resistant (PDR) pathogens is controversial.

Methods: We retrospectively evaluated patients admitted to Severance Hospital in South Korea with culture-positive pneumonia from January 2008 to December 2009. We analyzed the associations between risk factors for HCAP and infection with PDR pathogens.

Results: Among 339 patients, PDR pathogens were observed in 122 (36.6%) and non-PDR pathogens in 217 (64.4%). PDR pathogens were more common in HCAP than community-acquired pneumonia (CAP) (48.5% vs 23.8%, P < 0.001), but 51.5% of HCAP showed non-PDR pathogens. In a logistic regression, prior hospitalization within 90 days of pneumonia (OR = 2.52, P = 0.003), recent treatment with antimicrobials (OR = 2.35, P = 0.039) and nasogastric tube feeding (OR = 13.94, P = 0.001) were independently associated with PDR pathogens.

Conclusions: The current criteria for HCAP are poor predictors of PDR pathogens and all patients with HCAP should not be empirically treated for these pathogens. To avoid excessive antibiotic use, individual risk stratification approaches should be considered.

Rates of ophthalmic complications due to ethambutol in patients with non-tuberculous mycobacteria  
Andrew Malem1, Helen Barker2, Nadia Shafi1, Dennis Wat1, Charles Hawthor1, R. Andres Plaza2. 1Cambridge Centre for Lung Infection, Papworth Hospital, Cambridge, United Kingdom; 2Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom

Infection with Non-Tuberculous Mycobacteria (NTM) is a growing clinical problem particularly in patients with inflammatory lung disease. For many NTM infections, treatment involves at least 12 months of combination antibiotic therapy including Ethambutol. While ophthalmic complications are extremely rare in patients taking ethambutol as part of standard quadruple therapy for Mycobacterium avium complex (MTB) infection, they may be higher during treatment for extended periods. We therefore carried out a retrospective analysis of patients treated with ethambutol for NTM infection at the Cambridge Centre for Lung Infection between 2006 and 2011. We identified 46 patients with confirmed NTM infection who received ethambutol. 4 individuals were excluded from further analysis because of incomplete/missing notes. We identified 5 out of 43 patients (11.9%) with documented changes in visual acuity and colour vision diagnosed by an ophthalmologist as probable ethambutol toxicity. There was no significant difference between those with ophthalmic com-
plications and those without in the following parameters: age, dose of ethambutol per kilogram, serum creatinine levels and treatment duration. Where measured, low serum zinc levels were found in individuals who developed ophthalmic complications but these were not significantly lower than those of unaffected patients.

Our data suggests that ethambutol toxicity is a relative common problem in patients with NTM infection requiring extended treatment with ethambutol despite appropriate dosing and regular ophthalmology review. Further studies will be needed to define how best to minimize this potentially devastating complication.

**P4376**

**Evaluation of moxifloxacin (MXF) as empiric antibiotic therapy of CAP outpatients: A multicenter prospective study**

Eva Polverino1, Catia Cillonz2, Alberto Gabarrus1, Santiago Ewig2, Tobias Welte3, Olga Rajas4, Alberto Capelastegui4, Jondr Almirall5,
Antoni Peces5,1 Servicio de Neumología, Hospital Clinínic IDIBAPS CIBERSERES, Barcelona, Spain; 2 Respiratory Disease Department, University of Bochum, Germany; 3 Respiratory Disease Department, University of Hannover, Hannover, Germany; 4 Servicio de Neumología, Hospital La Princesa, Madrid, Spain; 5 Servicio de Neumología, Hospital de Galdakao, Spain; 6 Servicio de Neumología, Hospital del Mar, Mesures, Spain

**Objectives:** To compare clinical characteristics and outcomes of CAP outpatients receiving MXF with standard therapies (levofloxacin [LFX] or amoxicillin-clavulanic acid plus azithromycin [AMC/AT]).

**Methods:** A retrospective analysis was conducted on 300 patients prospectively recorded in 4 Spanish and 2 German hospitals (174 LVF, 75 MXF, and 51 AMC/AT). Demographic, clinical characteristics and outcomes (mortality, hospitalization) were recorded. Since demographic and clinical data did not differ between LXF and AMC/AT patients we analysed them together.

**Results:**

**MXF vs LXF vs AMC/AT (p<0.05)**

No microbiological differences were observed (S. pneumoniae in 20% [MXF], 18% [LXF+AMC/AT]). There were no fatality cases. Five hospitalizations were recorded. Since demographic and clinical data did not differ between MXF and AMC/AT patients we analysed them together.

**Conclusions:** MXF was prescribed in older patients with more comorbidities and therefore, is a valuable option for outpatient treatment of CAP.
P4380 Pulmonary nocardiosis in a teaching hospital in the Central Anatolia of Turkey: Clinical experience in 26 patients
Fatma Sema Özyılm,1 Nuri Tutar1, Daygün Percin2, Orhan Yıldız2, Aydin Unal1, Ayba Fıyrıldırm1, Fatih Kurnaz4, Asiyê Kanba1, Hakan Büyükşagılan1, Inci Gülmez3, Ramazan Demir2, 1Department of Chest Diseases, Erciyes University Medical Faculty, Kayseri, Turkey; 2Department of Microbiology, Erciyes University Medical Faculty, Kayseri, Turkey; 3Department of Infectious Diseases and Clinical Microbiology, Erciyes University Medical Faculty, Kayseri, Turkey; 4Department of Internal Diseases, Nephrology Unit, Erciyes University Medical Faculty, Kayseri, Turkey; 5Department of Radiology, Erciyes University Medical Faculty, Kayseri, Turkey; 6Department of Internal Diseases, Hematology Unit, Erciyes University Medical Faculty, Kayseri, Turkey

Pulmonary nocardiosis (PN) is an uncommon but severe infection caused by Nocardia spp., which can behave either as opportunistic or primary pathogens. The diagnosis of PN can easily be missed. The purpose of this retrospective study is to review the predisposing factors, clinical symptoms, microbiologic, radiographic characteristics, diagnostic procedures, treatment and outcome of the patients with PN confirmed positive culture, diagnosed in a teaching hospital over the last 11 years. Twenty-six (20 men and 6 women) adult patients with a mean age at time of 49 years (range: 21 to 72 years) were identified with PN. Half of the patients had disseminated nocardiosis (8 with dissemination to central nervous system, 5 with soft tissue and cutaneous abscesses). The predisposing conditions were treatment of steroids (88%), chronic lung diseases (31%), transplantation (19%) and malignancy (19%). Mean time to diagnosis was 31 days. In 21 patients (80%), the infection occurred outside the hospital setting. Respiratory tract sampling using noninvasive techniques had a diagnostic yield of 81%, while specimens from invasive methods had a yield of 37%. The radiological changes were diverse and non-specific. Nocardia asteroides-type V (N. caryophyllaceae) and N. farcinica were the most common species. Treatment was started empirically, modified according to the antimicrobial susceptibility pattern, and then continued for 6–12 months. Overall mortality was 58%, with death being caused by the Nocardia infection in 7 patients (27%). PN is a rare infection and mainly affects immunocompromised patients. Higher index of suspicion is needed for earlier diagnosis and treatment to improve prognosis.

449. Outcomes and assessment methods in physiotherapy and rehabilitation

P4381 Predicting the risk of falls in patients with COPD: Does age matter?
Alda Marques1,2, Joana Cruz1,3
1Escola Superior de Saúde da Universidade de Aveiro (ESSUA), University of Aveiro, Portugal; 2Unidade de Investigação e Formação Sobre Adultos e Idosos (UnIdai), University of Porto, Portugal

Introduction: The extrapolationary manifestations of COPD have been associated with deficits in mobility and balance, which potentiate the risk of falls. This is more evident in advanced COPD. However, research in the risk of falling in this population is scarce, as deterioration of balance increases with age, it is important to understand how age influences the fall risk in these patients.

Aim: To assess the risk of falls in different age groups of patients with advanced COPD.

Methods: Fifty-five outpatients with COPD (GOLD III and IV) were recruited. The risk of falling was assessed using the Timed Up & Go (TUG) test. Two TUG tests were performed and the best performance was considered. Participants (9 males) were divided into 4 groups according to their age: <50 (n=11; G1), 50-69 (n=11; G2), 70-79 (n=20; G3) and 80-99 years old (n=13; G4).

Results: The mean TUG time for each group was G1 11.03±3.11, G2 10.73±1.36, G3 11.22±4.35, G4 14.34±4.87 seconds. No statistical significant differences between groups were found. However, all groups presented worse values than the average performance of their age-matched healthy peers.

Conclusion: Patients with advanced COPD exhibit changes in balance and are at risk of falling, regardless of their age. The results suggest that pulmonary rehabilitation, a recommended standard of care for patients with COPD aimed to optimize functional status and increase participation, should include a specific component of balance training and strategies to prevent falls, to restore the highest possible level of independent function in this population.

P4382 Does the incremental shuttle walking test (ISWT) require maximal effort in healthy subjects of different ages?
Suzanne Probst1,2, 1Centro de Pesquisa em Ciências da Saúde (CPCS), Centro de Ciências Biológicas e da Saúde (CCBS), Universidade Norte do Pará (UNOPAR), Londrina, Brazil; 2Programa de Mestrado Associado UEL-UNOPAR em Ciências da Reabilitação, Universidade Norte do Pará (UNOPAR), Londrina, Brazil

Background: It is unknown whether the ISWT requires maximal effort in subjects of different ages.

Objective: To evaluate if the ISWT requires maximal effort in healthy subjects of different ages.

Methods: 331 individuals (158 men) performed two ISWT, allowing more than 12 levels of the test, if necessary. The participants were separated into six groups according to their age (G1: 18-28, G2: 29-39, G3: 40-50, G4: 51-61, G5: 62-72 and G6: 73-83 years). Heart rate (HR) and symptoms of dyspnea and fatigue were recorded. HR achieved at the end of the test was expressed as a percentage of the maximum heart rate (HRmax).

Results: 31% of the subjects achieved more than 12 speed levels. The majority of the subjects reached HR values below 85% of HRmax at the end of the test with a median [interquartile range] of: G1: 100[95-104]; G2: 100[96-105]; G3: 102[97-107]; G4: 99[91-105]; G5: 95[87-106] and G6: 95[90-109]%HRmax. Regarding symptoms, all groups showed higher values of dyspnea and fatigue at the end of the test (p < 0.05). A multivariate analysis (logistic regression) identified that female gender (odds ratio: 3.3 [95% confidence interval: 1.4-8.1], worse performance in the ISWT (low: 4.2 [1.7;10.0], normal: 2.6 [1.3-5.4] versus high) and age (4.7 [1.7;12.9]) increased the chance for not achieving 90% of HRmax at the end of the ISWT.

Conclusion: The Incremental Shuttle Walking Test is a field test that requires between individuals, and for that it is necessary to test the end beyond twelve speed levels. Female gender, older age and worse performance in the test are the determinants for not reaching maximal effort during the ISWT.

P4383 Are 30 minutes of rest between two incremental shuttle walking tests enough for cardiovascular variables and symptoms to return to baseline values?
Laís Regina Ribeiro1,2, Rafael Mesquita1,2, Myriam Fernanda Merli1,2, Cristiane Gonçalves1,2, Daniela Hayashi1,2, Vanessa Suzanna Probst1,2, 1Centro de Pesquisa em Ciências da Saúde (CPCS), Universidade Norte do Pará (UNOPAR), Londrina, PR, Brazil; 2Programa de Mestrado Associado UEL-UNOPAR em Ciências da Reabilitação, Universidade Norte do Pará (UNOPAR), Londrina, PR, Brazil

Background: The Incremental Shuttle Walking Test (ISWT) is commonly performed twice for purposes of reproducibility, in general, 30 minutes of rest between the tests. However, it is unknown if the 30 minutes’ rest is sufficient for stabilization of cardiovascular and symptomatological variables.

Aim: To investigate if 30 minutes of rest between two ISWTs are enough for cardiovascular and symptomatological variables to return to baseline values in healthy subjects of different ages.

Methods: 457 healthy subjects (154 men, 63[45-70] years, 27[24-30] kgm²) were assessed and separated into quartiles according to their age: Q1 (18 to 45 years, n=117), Q2 (46 to 63 years, n=116), Q3 (64 to 70 years, n=121) and Q4 (71 to 83 years, n=103). Two ISWTs were performed with at least 30 minutes of rest in between, and heart rate (HR), blood pressure (BP) and symptoms of dyspnea and fatigue were assessed before and after the tests.

Results: The HR before the ISWT was higher in the second test compared to the first one in the whole group and in all subgroups (p<0.001 for all). The systolic BP was higher before the second test only in the whole group (p=0.04). Regarding symptoms, fatigue showed statistical significance only in Q1 (p=0.02), being higher before the second test compared to the first. Diastolic BP and symptoms of dyspnea were similar before the two ISWTs in the whole group and in all subgroups.

Conclusions: 30 minutes of rest between two ISWTs are not enough for the cardiovascular system to return to baseline values in healthy subjects, regardless of age. For perceived symptoms of dyspnea, this amount of rest seems to be enough.

P4384 Predictors for longitudinal change in 6-minute walk distance in COPD patients
Bente Frøk1,2, Birgitte Espehaug1, Jon Andrew Hardle2, Liv Inger Strand2, Rolf Mos-Nilsen2, Tomas M. Eogan1, Per S. Bakke1, Einar Thoresen2,3, 1Center for Evidence Based Practice, Bergen University College, Bergen, Norway; 2Institute of Medicine, University of Bergen, Norway; 3Dept. of Occupational Medicine, Haukeland University Hospital, Bergen, Norway; 4Dept. of Public Health and Primary Health Care, University of Bergen, Norway; 5Dept. of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway

Introduction: The 6-min walk distance (6MWD) is widely used to evaluate exercise capacity in patients with Chronic Obstructive Pulmonary Disease (COPD), and is predictive of mortality and exacerbations.

Aim: To examine the change in 6MWD over 3 yrs in COPD patients and elucidate factors at baseline that may predict that change.

806s
Methods: This prospective observational study included 389 patients aged 40-75 yrs, with clinically stable COPD in GOLD stage II-IV. Measurements at baseline and after 1 and 3 yrs included 6MWD, spirometry, body mass index (BMI), and assessment of smoking habits and exacerbations by questionnaires. Adjusted generalized estimating equations (GEE) regression analyses were used to analyze predictors for change in 6MWD.

Results: There was no significant change in 6MWD from baseline to 1 yr for any GOLD stage, or from baseline to 3 yrs for patients in GOLD II. For GOLD III (β= -36 m, 95% CI=-55, -17) and IV (β=86 m, 95% CI= -138, -33) 6MWD decreased (p<0.001). In the multivariate GEE forced expiratory volume in one second (FEV1) (p<0.001), forced vital capacity (p<0.001), age (p<0.001), exacerbations (p=0.018), BMI (p=0.001) and pack years (p=0.003) were predictors for 6MWD, though only FEV1 predicted change over time (p=0.003).

Conclusion: Patients in GOLD stage II maintained 6MWD at 3 yrs, while patients in GOLD III and IV reduced 6MWD significantly. FEV1 was a strong predictor for longitudinal change in 6MWD.

P4385

Twelve-minute walking distance predicts COPD mortality
R. Harris Andersen,1,2, Christer Janson1, Hans Hedenström1, Margareta Emmer1,1
1Department of Medical Sciences, Uppsala University, Uppsala, Sweden; 2School of Health Sciences, University of Akureyri, Iceland; 1Rehabilitation Unit, Akureyri Hospital, Akureyri, Iceland

Background: Patients in pulmonary rehabilitation (PR) suffer from poor lung function, exercise capacity and health-related quality of life (HRQoL). Some of these factors have been shown to relate to mortality in COPD. Drop-out from clinical PR-studies is often high and might indicate worse prognosis in that group.

Aims: To measure the five-year survival of 89 COPD-patients enrolled in a four-month PR at Uppsala University Hospital and investigate if the 12 min walking distance (12MWD), peak exercise capacity (Wpeak), HRQoL and being able to fulfill the training period had prognostic value for survival.

Methods: Long function (FEV1, VC), 12MWD. Wpeak and HRQoL (SF-36) were measured at baseline. Of 89 included patients, 53 fulfilled the PR-program.

Results: Mean baseline FEV1 was 34±1 L, 95% CI=31.4, 36.5). The desaturation was significantly lower for CE compared to ISIT-1 or ISIT-2 (r=0.72, r=0.21, respectively) and for heart rate expressed as a percentage of the predicted rate (89±12, 90±13, 88±11, respectively). The desaturation was significantly lower for CE compared to ISIT-1 or ISIT-2 (r=0.72, r=0.21, respectively). The desaturation was significantly lower for CE compared to ISIT-1 or ISIT-2 (r=0.72, r=0.21, respectively). The desaturation was significantly lower for CE compared to ISIT-1 or ISIT-2 (r=0.72, r=0.21, respectively).

Conclusion: A symptom-limited incremental step test, externally paced, elicits maximal cardiopulmonary and metabolic responses, and is well tolerated and reproducible in patients with COPD.

P4387

The impact of MRC classification on daily physical activity and physical health-related quality of life in mild to moderate COPD
Hans, Van Remenste1,2, Michele Hornok1,2, Hellen Deneyer1,2, Kristien De Bent1, Erica Ballingard1, Laurence Vrancken1,2, Chris Buttin1,2, Daniel Langer1,2, Marc Decramer1,2, Rikk Gosselink1,2, Wim Janssens1,2, Thierry Troosters1,2
1Rehabilitation Sciences, Katholieke Universiteit Leuven, Faculty of Kinesiology and Rehabilitation Sciences, Leuven, Belgium; 2Respiratory Division and Pulmonary Rehabilitation, University Hospital K.U. Leuven, Belgium; 3Clinical Trial Unit, Department of Pneumology, University Hospital K.U. Leuven, Belgium

Dyspnea, reduced physical activity (PA) and impaired health-related quality of life (HRQoL) are common features in COPD. This study aimed to investigate the impact of dyspnea on PA and HRQoL in mild/moderate COPD.

Fifty-three subjects with COPD and 60 smoking controls were recruited. Medical Research Council (MRC) classified patients by symptoms of dyspnea. The SenseWear Armband was worn for 7 days and time spent in at least moderate intensity PA and amount of steps served as PA estimates. HRQL was assessed by the SF-36 physical functioning score and the EQ5D general health VAS score.

Conclusion: A symptom-limited incremental step test, externally paced, elicits maximal cardiopulmonary and metabolic responses, and is well tolerated and reproducible in patients with COPD.

P4388

Does the energy expenditure of patients with COPD reflect their time spent walking and intensity of walking in daily life?
Thais Sant’Anna, Carlos Augusto Camillo, Renato Vitorasso, Anaisa Cortez Vercese, Victoria Cristina Escobar, Nidia Aparecida Hernandez, Fabio Pitta. Laboratory of Research in Respiratory Physiotherapy (LHRP), Department of Physiotherapy, State University of Londrina, Londrina, Brazil

Introduction: The level of physical activity in daily life (PADL) is frequently assessed by energy expenditure (EE) measurement. However, patients with chronic obstructive pulmonary disease (COPD) often present high EE due to increased work of breathing, systemic inflammation and other factors. Thus, EE might not be a good outcome to characterize PADL in this population.

Aim: To verify the influence of time spent walking, movement intensity and other PADL variables on EE of patients with moderate to severe COPD.

Methods: The PADL of 53 patients (51m, 66±9 yrs, FEV1 38±15 (predicted) was evaluated by two activity monitors (DynaPort MiniMod and SenseWear). The DynaPort mainly registers time spent walking (TW), standing, sitting, lying (TL), and the other PADL variables on EE of patients with moderate to severe COPD.

Conclusion: Moderate intense PA was significantly reduced in MRC1 COPD compared to MRC1 smokers and tended to be lower versus MRC0 COPD (p<0.10). A trend for reduced daily steps in MRC1 COPD was observed versus MRC3 smokers and MRC0 COPD (p<0.09). MRC1 COPD reported reduced physical functioning and PA scores versus MRC0 COPD (70±19 vs 81±13 vs 84±17, respectively) for physical functioning, p<0.01 and 71±12 vs 77±14 vs 81±10 for VAS score, p<0.05.

PA levels are reduced in symptomatic patients with mild to moderate COPD. MRC classification, as proposed by the new GOLD guidelines, is useful in identifying reductions in PA and (physical) HRQoL, even in the early stages of COPD.

P4389

The impact of age on physical activity and health-related quality of life in COPD
Thais Sant’Anna, Carlos Augusto Camillo, Renato Vitorasso, Anaisa Cortez Vercese, Victoria Cristina Escobar, Nidia Aparecida Hernandez, Fabio Pitta. Laboratory of Research in Respiratory Physiotherapy (LHRP), Department of Physiotherapy, State University of Londrina, Londrina, Brazil

Introduction: The level of physical activity in daily life (PADL) is frequently assessed by energy expenditure (EE) measurement. However, patients with chronic obstructive pulmonary disease (COPD) often present high EE due to increased work of breathing, systemic inflammation and other factors. Thus, EE might not be a good outcome to characterize PADL in this population.

Aim: To verify the influence of time spent walking, movement intensity and other PADL variables on EE of patients with moderate to severe COPD.

Methods: The PADL of 53 patients (51m, 66±9 yrs, FEV1 38±15 (predicted) was evaluated by two activity monitors (DynaPort MiniMod and SenseWear). The DynaPort mainly registers time spent walking (TW), standing, sitting, lying (TL), and movement intensity during walking (MI). The SenseWear mainly registers total energy expenditure (TEE) and active energy expenditure (AEE). Patients wore both motion sensors in daily life during two consecutive weekdays (12hs/day).

Conclusion: Moderate intense PA was significantly reduced in MRC1 COPD compared to MRC1 smokers and tended to be lower versus MRC0 COPD (p<0.10). A trend for reduced daily steps in MRC1 COPD was observed versus MRC3 smokers and MRC0 COPD (p<0.09). MRC1 COPD reported reduced physical functioning and PA scores versus MRC0 COPD (70±19 vs 81±13 vs 84±17, respectively) for physical functioning, p<0.01 and 71±12 vs 77±14 vs 81±10 for VAS score, p<0.05.

PA levels are reduced in symptomatic patients with mild to moderate COPD. MRC classification, as proposed by the new GOLD guidelines, is useful in identifying reductions in PA and (physical) HRQoL, even in the early stages of COPD.
P4389
Comparison of outcomes of the Actigraph and the Dynaport activity monitor in patients with COPD: results from PROactive
Juliana Maria Sousa Pinto,1 Thierry Troosters,2 Laurence Vranken1,2, Miek Hernikx1, Heleen Demeyer2, Wim Janssens1, Marc Decramer1, Judith Garcia-Aymerich1,2, 2Rehabilitation Sciences and Respiratory Division, KU Leuven and UZ Leuven, Leuven, Belgium; 2Center for Research in Environmental Epidemiology, CREAL, Barcelona, Spain

Activity monitors are increasingly used to assess physical activity. We aimed to compare wearing time and walking between two activity monitors in COPD. Fifty four patients (FEV1 62±22%pred; MFWD 459±138m) wore the Actigraph (AG) and Dynaport (DP) twice for 14 days with 14 days in between, in the frame of the PROactive project. Wearing time (h/d); walking time(min/d) of DP (DPWT) and step/day of AG (ASteps) were retrieved. Calculations were done on the mean wearing and walking variables obtained over 28 days (Inter-patient correlations).

Activity monitors were calculated over the 28 days obtained in each patient, as well as between mean weekly values of the 4 weeks (6 contrasts).

Results: Wearing time of the AG and DP were strongly related (R=0.80 p<0.001).

Intra-patient correlations were calculated over the 28 days obtained in each patient, as well as between mean weekly values of the 4 weeks (6 contrasts).

Conclusion: These data show that both monitors provide comparable outcomes and are capable of measuring differences between separate weeks of assessment. The difference in wearing time needs clarification.

P4390
Cell phone based physical activity monitoring: A validation study
Fabiola Camoens1, Emmanuel Stamatakis1, David Prieto1, Eleanor Main1, 1Cardiorespiratory Sciences, UCL Institute of Child Health, London, United Kingdom; 2Epidemiology & Public Health, UCL Population Health, London, United Kingdom; 3Medical Statistics, London School Of Hygiene and Tropical Medicine, London, United Kingdom

Background: Accelerometers are accurate and useful for monitoring Physical Activity (PA) in people with chronic lung disease (eg. COPD) and can help motivate clients to comply with rehabilitation. However, they are expensive and largely limited to research. Similar motion sensors are embedded within the majority of newer mobile phones, which are widely accessible.

Aim: This study investigated whether the built-in accelerometers within mobile phones may be valid and reliable for monitoring PA.

Method: A mobile phone application to record real time tri-axial accelerometer data (Actigraph GT3X). Wearing all 3 devices, 7 healthy adults performed 7 different activities, paced with a metronome, each repeated 7 times. Absolute values of 3D acceleration signals were summed and averaged over each time period. Reliability was evaluated using intra-class Correlation Coefficients (ICC). Concurrent validity was assessed using a general linear model for repeated measures (GLM) and Pearson correlation.

Results: The ICC for both phone devices ranged between 0.82 and 0.98. GLM and Pearson correlation results showed good agreement (R2 = 0.72, R2-chance = 0.11 for step 1, R2-chance = 0.06 for step 2 (p<0.001). **p<0.01, ***p<0.001.

Conclusion: Mobile phone accelerometers appear to be reliable and valid for measuring PA. Further research is needed to confirm these data in a patient population.
and upper limb exercise capacity in people with chronic obstructive pulmonary disease (COPD).

Methods: Repeated measures design. Participants were included if they had a diagnosis of COPD, FEV1/FVC ratio < 0.7. Exclusion criteria were an acute infection in the prior month, or neurological, musculoskeletal or cardiovascular conditions that limited upper limb exercise. Participants completed the following assessments: spirometry, incremental supported arm exercise (SAE) to peak work capacity on an arm ergometer, incremental unsupported arm exercise (UAEx) to peak capacity using an unsupported arm test (Takahashi, T. et al. ICRP 2003;23:24-30), isometric upper limb strength measurements using a hand held dynamometer. Dominant arm strength was calculated by the mean of the following strength measurements: shoulder flexion & extension, horizontal abduction & adduction, internal & external rotation and elbow flexion. SAE and UAEx were performed in random order based on concealed allocation sequence.

Results: 68 participants completed the study, mean (SD) age 65(8) yrs, FEV1 %pred 50 (17), FVC %pred 77 (17), FEV1/FVC 0.48 (0.1). Peak oxygen consumption (VO2peak) for SAE and UAEx was 8.00 (0.28) L/min and 0.71 (0.31) L/min respectively. Dominant arm strength was 103 (29) Newtons. Multiple regression on VO2 and VE/VCO2 using combined dominant arm strength and FEV1 %pred as predictors, accounted for 66% (p < 0.001) and 55% (p < 0.001) of the variance, respectively.

Conclusion: Upper limb strength combined with FEV1 %pred are significant predictors of both supported and unsupported upper limb exercise capacity in COPD.

P4394

Relationship between oxygen uptake kinetics and BODE index at the onset of high-intensity exercise in moderate-to-severe COPD patients

Audrey Borghi-Silva, Thomas Beltrame, Michel Silva Reis, Luciana Maria Malosa Sampaio Jerge, Ross Arena, Dacseo Costa. Physiotherapy Department, UFRJ, Ceara, Sao Carlos, SP, Brazil Physiotherapy Department, UFRJ, Rio de Janeiro, RJ, Brazil Physiotherapy Department, UNP; Sao Paulo, SP, Brazil

Background: Patients with chronic obstructive pulmonary disease (COPD) present reduced exercise capacity due impaired oxygen delivery-utilization, caused primarily by pulmonary dysfunction and deleterious peripheral adaptations. Assuming that COPD patients present with slower VO2 and heart rate (HR) kinetics, we hypothesized that this finding is related to degree of severity in according to BODE index.

Aim: To evaluate the relationship between oxygen consumption (VO2) on-kinetics during high intensity exercise and the BODE index in patients with COPD.

Methods: Twenty males with moderate to severe stable COPD and thirteen healthy control subjects matched by age and gender were evaluated. Initially, COPD patients were screening by BODE index and then, all volunteers were submitted to an incremental cardiopulmonary exercise testing, and subsequently, a constant speed on a treadmill at 70%, for 6 minutes. The on-transient (first 360 seconds) response of VO2 and HR was modeled according to a monoexponential fit.

Results: VO2 and HR on-kinetics were slower in the COPD group than controls. Additionally, VO2 on-kinetic parameters revealed a strong correlation (p=0.77, p<0.05) between BODE scores and negative and moderate correlation between walking distance (r=0.45, p<0.05).

Conclusion: Our data show that moderate to severe COPD is related to impairment of oxygen delivery and utilization during the onset of intense exercise. In addition, there is a relationship between walking distance as well as BODE index with VO2 on-kinetic behavior. Thus, the severity of COPD is reflected by progressive slowing of VO2 on-kinetics.

P4395 Quantifying the variability of physical activity in daily life caused by seasonality in smokers

Karina Couto Furlanetto, Jully Anne Felici, Gianna Kelenwald Wisca, Andrea Akemi Morita, Mahara Proença, Juliana Zabateiro, Leandro Cruz Mantoani, Demetria Kovelis, Fabio Pitta, Departamento de Fisioterapia Pulmonar (LFIP), Universidade Estadual de Londrina (UEL), Londrina, Brazil

Background: The level of physical activity in daily life (PADL) depends on many factors, such as social, economical, physiological and demographical aspects. Despite these many causes of variability, the influence of the seasons of the year on PADL is unknown in smokers.

Aims: To compare changes in the level of PADL in apparently healthy smokers who started in different climatic conditions a protocol aiming at improving PADL; and to quantify the proportion of subjects who achieved 8000 steps/day before and after the intervention.

Methods: 20 smokers with normal lung function were submitted to a 5-month protocol using booklets and pedometers (or step counters) in order to improve PADL by aiming to increase the number of steps/day. They had their baseline PADL assessed for 6 days with a pedometer during Spring/Summer (SS: n=10, 5 men, 51[39-59] years, BMI 26[23-29] kg/m2, 38[17-50] pack-years) or Autumn/Winter (AW: n=10, 5 men, 53[48-57] years, BMI 26[24-28] kg/m2, 38[17-50] pack-years). Reassessment was performed after the protocol, in the opposite climatic condition as compared to baseline.

Results: Both groups improved their PADL after the protocol (Δ steps/day = SS: 3191[1888-4461] and AW: 2903[517-5377]; p<0.002 for both). There were no between-groups statistical differences concerning baseline PADL changes after the protocol, and proportion of subjects who reach 8000 steps/day before and after the protocol (SS: from 46% to 86%; AW: from 36% to 76%).

Conclusions: These preliminary results showed that climatic variation does not incur in significant impact in the level of PADL in apparently healthy smokers, since the same benefits could be achieved regardless of the seasonality.

P4396

Chest wall motion and volume changes with and without non-invasive ventilation in patients with amyotrophic lateral sclerosis

Cristiana Maselli, Mauro Vidigal, Danielle Vieira, Bruna Vieira, Veronica Pareira, Educaça Pe Fisioterapia, Fisioterapia e Terapia Ocupacional, Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil

In Amyotrophic Lateral Sclerosis (ALS), inspiratory, expiratory, and bulbar muscles are altered, leading to chronic respiratory failure. Non-invasive ventilation (NIV) can be used to improve gas exchange in this patient population.

Aims: To analyze the chest wall motion and operational volume changes in patients with ALS with and without NIV in the supine position.

Method: Ten patients with ALS, aged 54±13 years were included. Optoelectronic plethysmography (BTS, Milan, Italy) was used to measure: tidal volume of the chest wall (VTe CW), tidal volume of the pulmonary rib cage (Vtrc), tidal volume of the abdominal rib cage (Vtrc), tidal volume of the abdomen (Vtba),
end-inspiratory (Veicw) and end-expiratory (Veecw) volumes of the chest wall, respiratory frequency (f) and minute ventilation (VE). All patients were evaluated in the supine position with and without NIV for five minutes (Triology 100, Respironics, USA) NIV was used in the spontaneous/timed mode, with inspiratory and expiratory pressures of 14 cmH2O and 4 cmH2O, respectively. Paired t-tests were used for statistical analyses (p<0.05).

Results: See Table 1.

Can breathing pattern parameters be differentiated between healthy and severe asthma patients?

Wai Lo1, Anne Bruton1, Anna Barney2, 1Faculty of Health Sciences, University of Southampton, United Kingdom; 2Institute of Sound and Vibration, University of Southampton, United Kingdom

Abnormal breathing patterns during acute episodes of asthma are common. However, little is known about breathing pattern parameters (BPP) in severe asthma (SA) patients during the asymptomatic phase, or how they relate to those in the healthy population.

Aim: To determine which BPP differentiate SA patients from healthy controls.

Method: Ten SA patients and 10 healthy controls were recruited. BPP were monitored over 30 minutes by a respiratory inductive plethysmography. Recorded BPP were: 1. Tidal volume (Vt); 2. Variability in tidal volume (VVi); 3. Expiration time (Te); 4. Symptoms of hyperventilation (SH); 5. End-tidal carbon dioxide (ETCO2); 6. Vt was assessed by coefficient of variation (CV). Time series of breath by breath VT were inspected for abnormal pattern. SH were assessed by Nijmegen questionnaire (NQ). ETCO2 was monitored by capnography. Differences between healthy controls and SA patients were explored using one-way ANOVA.

Results: Mean NQ score was higher in SA patients than in healthy controls (p>0.00). ETCO2 levels were significantly correlated with NQ score (r = 0.8, p < 0.01) in the SA patients but not in healthy volunteers (r = 0.6, p = 0.01). Time series analysis revealed sporadic episodes of frequent sighs in both groups. No significant differences between groups for any BPP were identified.

Conclusion: The recorded BPP did not differentiate between the SA patients and healthy volunteers in our small study. The higher SH found in the SA group do not appear to be associated with differences in BPP. This study raised doubt that there is a ‘pattern’ that is common within the SA population and therefore BPP must be considered on an individual basis.

P4398

Respiratory occupational therapy (OT) within a community respiratory team: Referral and intervention patterns

Lynsey Wright, Jessica Callaghan, Claire Morris, Fran Dyer, Julia Bott

Respiratory Care Team, Surrey Community Health, Chertsey, United Kingdom

Introduction: OT aims to maximise independence, occupational performance and improve quality of life. Respiratory OT provides a specialist functional and gynecology fields have previously reported that quantification of sonographic echogenicity with histogram were useful for the diagnoses of tissue. Aim: To evaluate whether histogram data collected from EBUS-GS images can contribute to the diagnosis of lung cancer or not.

Methods: Fifty clear EBUS images (25 lung cancer and 25 inflammatory disease) were included in this study. The region of interest (ROI), was set within a 5mm radius from the EBUS probe with 400 pixels (20x20). Histograms were created and compared using imageJ software, with a width of the histogram: (maximum – minimum gray scale)/256 (full gray scale) × 100 (%), height of the histogram: (maximum pixel counts), and the standard deviation of the histogram.

Results: The diagnosis yield by the width of the histogram were sensitivity of 84%, specificity of 88%, and positive predictive value of 87% when the cut-off level was 22 for lung cancer. Standard deviation of histograms also contribute to diagnosis of lung cancer, sensitivity of 80%, specificity of 88%, and positive predictive value of 87% when the cut-off level was 10.7. Height of the histogram was not useful due to low sensitivity.

Conclusion: The width and standard deviation of EBUS image histograms were useful in differentiating lung cancer from inflammatory lesion.

P4400

Aberrant methylation in lung cancer identified by EBUS-TBNA as a marker of advanced staging

Laura Mattila1, Liaa Seti2, Jose Sanz3, Mariona Llatjos2, Felipe Andreo2, Eva Castella4, Eduard Moné3. 1Department of Pneumology, CIBERES, Germans Trias i Pujol Health Sciences Research Institut, Badalona, Barcelona, Spain; 2Department of Pneumology, CIBERES, Germans Trias i Pujol Hospital, Badalona, Barcelona, Spain; 3Department of Pneumology, CIBERES, Corporació Parc Taulí, Sabadell, Barcelona, Spain

Introduction: Aberrant methylation of DNA results in gene silencing and is frequently observed in tumours from lung cancer patients. Aberrant methylation in lung cancer identified by EBUS-TBNA as a marker of advanced stages of the disease. Objective: To determine the relationship between the methylation status of 5 genes in metastatic lymph node and tumours samples obtained by EBUS-TBNA and the presence of an advanced stage of lung cancer.

Results: 239 OT referrals were recorded in 2011. 33 of these were excluded from the analysis, as OT was not required or the patient had died.

Of the 206 patients who received OT, 47 required physical and psychological intervention, however the intervention requested for 32 of these had been for psychological and 15 for physical only.

Conclusion: We observe from the data that most referrals are for Psy F. However a noticeable proportion of these also required intervention to address Phy F (need identified at OT assessment).

Having received joint physical and mental health training, OT is well placed to identify and address the link between psychological and physical symptoms, which limit daily functioning, in this complex patient group. This supports the need for the specialist respiratory OT role.
Methods: Nodal and tumour samples positive for lung cancer were obtained with EBUS-TBNA. The methylation status of DAPK, p16, RASSF1, APC and CDH1 genes was determined by methylation-sensitive high resolution melting

Results: 23 samples were analysed, 15 samples (6 mediastinal nodules, 1 lobar node and 2 tumour) were early cases of lung cancer (T1/T2) and 8 (4 mediastinal nodes, 3 lobar nodes and 1 tumour) more advanced lung cancer (T3/T4). Percentage of methylated sites for each gene are shown in the figure. The samples from patients with a more advanced stage of lung cancer had significantly more genes methylated (p<0.043) than the samples from patients with early lung cancer, identified by a higher T staging

Sampling of ipsilateral mediastinal nodes by EBUS-TBNA in lung cancer staging

Angela P. Núria1, Marco Solis2, Laia Setó3, Ricardo García4, Eduardo De Miguel5, M. Nuñez5, M. Botana4, Alberto Fernandez4, Enrique Cases3, Rosa Cordovilla4, Felipe Andreo3, Jose Sanz-Santos3, Mireia Serra3, Miguel Gallego5, Eduard Mon1, Neumología, Hospital Universitario del Parc Taulí, Sabadell, Barcelona, Spain; 2Neumología, Hospital Maria Cristina de Fuenlabrada, Madrid, Spain; 3Neumología, Hospital Universitat Carles III, Cepeda, Valencia, Spain; 4Neumología, Hospital General de Salamanca, Salamanca, Spain; 5Neumología, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain

Conclusion: Endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA) has shown its usefulness in lung cancer (LC) staging. However, determinants of negative predictive value (NPV) of EBUS-TBNA are not well known. Aims: To determine clinical characteristics of LC that are associated with low NPV, that will allow a more accurate selection of patients needing additional staging techniques before surgery in front of a negative result of EBUS-TBNA.

Materials and methods: - NPV of EBUS-TBNA for the identification of mediastinal spread of LC was calculated in patients staged with EBUS-TBNA and treated surgically, performed lymph node dissection during surgery. Results: In 73 patients with T1 (n=35), T2 (n=39) and T3 (n=9) were studied. 48 patients (33.1%) showed mediastinal lymphadenopathy (ML) at computed tomography (CT). EBUS-TBNA got a representative sampling of ipsilateral major lobe parenchyma in 127 patients (87.6%, and 4R, 4L, and 7 in 105 patients (72.4%). The result was false negative regarding mediastinal lymph dissection in 20 patients (13.8%). The identification of mediastinal lymph nodes on CT was more predictive of negative EBUS-TBNA exploration (22.9% versus 9.3%, p=0.02). Unrepresentative sampling is predictive of negative EBUS-TBNA (30 values 8.7%, p<0.001) and unrepresentative sampling in 4R, 4L and 7 (32.5% values 6.7%, p<0.001) were significant predictors of a FN. In multivariate analysis, ML on CT (OR 3.399;CI 1.15-10) and insufficient sampling (OR 10.669;95CI 3.29-34.55) were independent variables of a low NPV.

Conclusions: EBUS-TBNA achieved a successful lymph node sampling of mediastinal regions ipsilateral to the tumor in over 85% of patients. Funded by FIS FIIS0901612.

P4402
Relationship between qualitative analysis of lung tumors using integrated backscatter-intravascular ultrasound (IBIVUS) and pathological diagnosis

Fuunmaka Iro, Yasushi Ohashi, Kosumi Yamao, Fumihiko Kawayama, Hidenori Moris, Junki Endo, Norihiko Fumaguci, Masanori Kasegawa, Shinnya Minamotoguchi.

Second Department of Internal Medicine, Gifu University School of Medicine, Gifu, Japan

Introduction or background: End-bronchial ultrasound is used by a supersonic wave image to confirm the position relations of a tumor and the participation bronchius through a bronroscope. However, the diagnosis of the organization property of the tumor is difficult. We used integrated backscatter(IB) value which analyzed the reflection wave of the supersonic wave signal in the coronary arteries of human, and was calculated, and enabled a vascular wall organization property diagnosis.

Aims and objectives: The purpose of the study measures integrated backscatter (IB) by end-bronchial ultrasound for the diagnosis of the lungs tumors and analyzes it by comparing a tumor and the distinction of the normal tissue with surgical resection.

Methods: We analyzed lungs tumor and normal lungs organization provided from an autopsy specimen. We observed rejections with the structure of the organization about the lungs tumors.

Result: Surgery excision lungs tumors were 35 non-small-cell lungs cancer (squa- mor carcinoma 9 examples, non-squamous 26 examples). IB value showed lower value in non-small cell lung cancer tissue compared with normal lung tissue.

Conclusion: If the distinction of the normal tissue and tumor tissue is possible and applies it to an endoscopic diagnosis by measuring lungs tumors, normal lung, IB value of the pathology organization diagnosis and invasive level of the tumor may be enabled by bronchoscope endoscopy examination.

P4403
Diagnostic yield, clinical impact and cost aspect of EBUS-TBNA in mediastinal staging in lung cancer patients

Niels Claessens1, Klaartje Maas2, Alain Kummer1, Franz Schramel1, 1Pathology, Sint Antonius Hospital, Nieuwegein, Netherlands; 2Pathology, Medisch Centrum Haaglanden, The Hague, Netherlands; 3Pathology, Sint Antonius Hospital, Nieuwegein, Netherlands

Background: In lung cancer minimally invasive staging of the mediastinum with endobronchial ultrasound transbronchial needle aspiration (EBUS- TBNA) has become an important alternative to the gold standard of mediastinoscopy.

Aims: First: To determine the diagnostic yield of EBUS-TBNA and calculate the reduction in number of mediastinoscopies that can be achieved when this technique is used as initial modality for mediastinal staging in lung cancer. Second: Calculate the reduction in health care costs when EBUS-TBNA is used in this setting.

Methods: In a retrospective cohort study all patients in our hospital in whom EBUS-TBNA was performed for mediastinal staging in lung cancer from September 2008 until January 2011 were identified and the results of EBUS-TBNA were analyzed. If metastatic tumour cells were found there was no indication for additional mediastinoscopy. Diagnostic yield of EBUS-TBNA and the number of mediastinoscopies that were avoided were calculated, as well as the achieved cost reduction.

Results: EBUS-TBNA was performed on 77 patients for mediastinal staging: 47 male and 30 female, average age 62.1 years (extremes 39-81). In 51% of patients (39/77) mediastinal lymph node metastases were found and mediastinoscopy could be avoided. Sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy were 91%, 100%, 100%, 86% and 95% respectively. The achieved cost reduction was 82 per patient known.

Conclusion: Mediastinoscopy can be avoided in more that 50% of lung cancer patients when EBUS-TBNA is used as initial staging modality for mediastinal staging, leading to a significant reduction of health care costs.

P4404
Adequacy of endobronchial ultrasound transbronchial needle aspiration samples in the subtyping of non small cell lung cancer

Georgina Esterbrook, Sujo Ananthanath, Paul Respiratory Medicine, St. James’s University Hospital, Leeds, United Kingdom

Introduction: The histological subtyping of non small cell lung cancer (NSCLC) has become increasingly important due to advances in systemic therapy. There are now important differences in the treatment of squamous and non-squamous cancers. Non-squamous cancers (particularly adenocarcinomas) are also suitable for targeted therapy if the epidermal growth factor receptor (EGFR) genetic mutation is present.

Diagnosis is frequently made by fine needle aspiration from lymph node metastases.

Objectives: To analyse endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA) data to establish our NSCLC not otherwise specified (NOS) rate and determine the technical success of EGFR testing.

Methods: All EBUS TBNA procedures performed at Leeds Teaching Hospitals between February 2009 and November 2011 were analysed. Data was collected on the indication, final histological diagnosis and whether EGFR mutation testing was possible.

Results: Data from 391 procedures was analysed. The indication was staging of malignancy in 345 patients and suspected non-malignant disease in 48 patients.

Malignant disease was diagnosed in 204 patients (52.2%), small cell 43, squamous cell 64, adenocarcinoma 40, adenosquamous 2, large cell 12, NSCLC NOS 31 and malignant disease of non lung primary 12.

The number of cases of NSCLC NOS was 31 of 149 NSCLCs. The NOS rate was 21.8%.

EGFR testing was requested in 36 patients. The sample was sufficient to allow testing in 32 patients (88.8%).

Conclusion: This data shows that EBUS TBNA samples are of adequate size to allow the determination of NSCLC sub-type and EGFR mutation status provided appropriate laboratory techniques are used.

P4405
How do cytology samples compare with histology specimens when used for EGFR testing in patients with NSCLC?

Shahid Levalkahian Khan, Mohammed Haris, Sarah Diver, Jane Edwards, Mohammad Munavvar Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom Medicine, Royal Preston Hospital, Preston, United Kingdom Pathology, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom

Background: With the evolution of individualised treatment strategies in non small cell lung cancer (NSCLC), it is becoming increasingly important to obtain adequate tissue for accurate pathologic subtyping and molecular testing. In most
cases diagnosis and staging is done using small biopsies or cytology specimens obtained by minimally invasive techniques.

Aim: To compare the adequacy of cytology and histology samples used for epidermal growth factor receptor (EGFR) mutation screening.

Methods: Retrospective study of 135 consecutive samples obtained from NSCLC patients between Jan 2010 and Dec 2011.

Results: Of the 135 samples sent for EGFR testing, 13 were positive, 115 negative and 7 were considered inadequate or failed molecular testing. 106 had adenocarcinoma, 11 adenosquamous, 13 NSCLC-NOS (not otherwise specified), 4 squamous and 1 small cell. Positive EGFR was noted in 4 cytology and 9 histology samples (p=0.27).

Cytology samples include 46 endobronchial ultrasound (EBUS) guided fine needle aspiration (FNA), 8 pleural fluid, 7 ultrasound guided or superficial FNA's from lymph nodes or masses, 1 transbronchial (mini-probe), 2 bronchial washings and 2 brush biopsies. Histology includes 29 endobronchial biopsies, 19 CT guided lung biopsies, 8 thorascopic and 1 ultrasound guided pleural biopsies, 1 renal biopsy, and 11 surgical excision samples (bone, brain, lymph node and groin mass).

Conclusion: The overall adequacy rate from both groups was 95% with no difference, suggesting that the cytology samples can be reliably used for molecular testing.

P4406
Is the EBUS TBNA cytology adequate for EGFR analysis?
Mohammed Harris, Shahul Leyakathali Khan, Sarah Diver, Saba Bokhari, Jane Edwards, Emma Pickles, Mohammed Munazzaar Rahim, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom Medicine, Royal Preston Hospital, Preston, United Kingdom Medicine, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom Respiratory Medicine, Royal Preston Hospital, Preston, United Kingdom

Background: Endobronchial ultrasound (EBUS) guided transbronchial needle aspiration (TBNA) allows safe and reliable sampling of mediastinal and hilar lymph nodes with excellent specificity and good sensitivity. It is a well established technique in the diagnosis and staging of lung cancer including pathologic subtyping and recent studies have shown that the samples may also be adequate for molecular testing.

Aim: To evaluate the adequacy of EBUS TBNA samples used for epidermal growth factor receptor (EGFR) mutation screening.

Methods: Retrospective study of 46 consecutive EBUS-TBNA samples obtained from lymph nodes > 5mm short-axis and central lung parenchymal lesions. Fisher's exact test was used to compare the 2 groups.

Results: Of the 46 EBUS TBNA samples sent for EGFR testing, 38 were obtained from lymph nodes (19 subcarinal, 9 right paraaortic, 4 left paraaortic, 10 right hilar and 4 left hilar) and 8 from central lung parenchymal masses. In the lymph node group, 35 (92%) samples were negative for EGFR mutation, 3 (8%) failed testing and none were positive for EGFR; 30 had adenocarcinoma, 2 squamous and 5 NSCLC-NOS (not otherwise specified). In the central lung mass group (n=8), one positive with exon19 deletion, 6 negative and one failed testing was inadequate; 3 had adenocarcinoma, 3 NSCLC-NOS, 1 squamous and 1 adenosquamous.

The overall EBUS-TBNA adequacy from both lymph nodes and central lung masses was 91% and there was no difference between the groups.

Conclusion: Molecular testing of EBUS TBNA samples obtained from mediastinal masses was 91% and there was no difference between the groups. Positive EGFR was noted in 4 cytology and 9 histology samples (p=0.27).

P4407
Factors related to the diagnostic yield of ultrathin bronchoscope for peripheral pulmonary lesions
Noelia Cabero de Frutos, Rosa López Lisboa, Lízbeth Pari Espinosa, Daniel Huertas Lamela, Jordi Dorca Sargatal, Antoni Rosell Gratakós, Respiratory Medicine, Hospital Universitari Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain

Introduction: The global diagnostic yield of peripheral pulmonary lesions (PPL) not candidates for CT-FNA, is 20-80%. Our aim is to evaluate the factors that affect the diagnostic yield of the fluoroscopy guided ultrathin bronchoscope.

Materials: We performed biopsy and brushing if a lesion was seen and only brushing when it was only detected by fluoroscopy. Bronchial washing (BW) was always sent.

Results: Of 30 patients included (77% men) with a mean age of 66 (SD 9). Median size of the PPL was 27 mm. Endobronchial lesions were visualized in 83% (minor, cosmetic change (6), tumor (5), compression (7) and secretions (1); in 79% of them a final diagnosis was obtained. The diagnostic yield for malignancy was 37%: adeno (3), squamous (3), NSCLC (2), mesenchymal tumor (1) and atypia (2). BW was diagnostic for malignancy in 23%, brushing in 27% and biopsy in 23%. After multivariate analysis the only significant variable was the presence of endoscopic nodule.

Conclusions: Fluoroscopy guided ultrathin bronchoscope obtains specific diagnosis in 43% of the patients, 85% of them with endobronchial abnormality. In 42% of patients with an endobronchial abnormality we were not able to reach a diagnosis. In 37% (11/30) of patients we could not see any endobronchial abnormality. Dedicated needles and more accurate methods to locate and reach the PPL are needed.

Funded by FIS PI09/09017 and SOCAP 2011.
in parenchymal haemorrhage, out of which 1/102 (7.8%) were visually classed as substantial.

None of the patients required insertion of chest drain or transfusion, although 6 patients were kept in the hospital for observation (maximum stay 4 days).

**Conclusion:** We have shown that CT guided biopsy is a safe procedure and can be carried out without major complications in a DGH. In our sample the complication rate (usually described as 2% patients requiring chest drain insertion) was very low. We are at present in the process of re-writing hospital guidelines regarding post procedure observation and patient guidelines.

**EUS-FNA for mediastinal lesions of unknown aetiology: A 4-year experience from a single centre**

Vinod S. Hegade1, Dinesh Saralaya1, Abid Aziz2, Sarah Jowett1, Conrado Beckett1, 2Objective Disease Centre, Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom; 2Department of Respiratory Medicine, Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom

**Aim:** Endoscopic ultrasound guided fine needle aspiration (EUS-FNA) allows access to the posterior mediastinum and tissue acquisition under real-time ultrasound guidance through the oesophageal wall. The aim of this study was to report the experience of mediastinal EUS-FNA in a large UK tertiary centre.

**Methods:** The study included all patients who underwent mediastinal EUS-FNA in our institution from January 2008 to December 2011. Patient and procedure related data were collected from endoscopy reports. Cytology and microbiology culture reports were compared to the final clinical diagnoses made during the follow-up. We calculated sensitivity, specificity, positive and negative predictive value (PPV,NPV) of mediastinal EUS-FNA for most common conditions.

**Results:** 195 patients (n=195, males 65%, mean age 58.6) underwent mediastinal EUS-FNA during the study period. Mean size of the lesions was 15.82mm (range 3.9-43) in short axis and 28.23mm (range 6-60) in long axis. Sub-carinal lymph nodes (n=189) were the commonest (145/195, 73.7%) target lesion.

We have shown that CT guided biopsy is a safe procedure and can be carried out without major complications in a DGH. In our sample the complication rate (usually described as 2% patients requiring chest drain insertion) was very low. We are at present in the process of re-writing hospital guidelines regarding post procedure observation and patient guidelines.

**P4411**

**Performance of fiberoptic bronchoscopy in patients with neoplasia endoscopic findings**

Nuria Maria Reina Martí1, Rafael Garcia Montesinos2, Ezequiel Ortega Sáenz de Tejada, Concepción Mena Escober, Lidia López López, María Victoria Hidalgo Sanjuán. Pulmonology Department, Virgen de la Victoria University Hospital, Malaga, Spain

**Objective:** Knowing the profitability of fiberoptic bronchoscopy (FB) and the samples taken in patients with endoscopic findings of neoplasia.

**Methods:** During 63 months (october 2006-december 2011) we performed 642 FB with signs of neoplasia. We repeated 34 FB, so the final number of FB analized was 676. Mediastinal masses were excluded. We considered a) direct signs of neoplasia (DSN) when there was endobronchial mass or mucose infiltration, and b) indirect signs of neoplasia (ISS), when there was extrinsic compression of the bronchial wall or very hyperemic mucosa areas. According to endoscopic findings, bronchial biopsy, brushing and blind transbronchial needle aspiration (TBNA) of linfadenopathies were carried out. We always took a sample of bronchial secretion and if it was possible, a posFB sputum. We considered as positive samples which allowed to make a therapeutic decision and negative samples those reported as “carcinoma” without specifying the type, presence of “malignant” or “atypical cells”.

The non hospitalized patients were observed 3 hours after the procedure.

**Results:** The TBNA was (+) for neoplasia in 122(66.3%) patients, giving the diagnosis of extension (N2). The average number of punctures per patient was 1.8; in 58 patients (59.7% of TBNA positives) only one puncture was required. In 41 cases (33.6%) was the only positive sample of FB, and gave the extension and pathological diagnosis. The only complications during FB were small hemmorhages. We did not detect significant clinical or radiological complications following the procedure.

**Conclusions:** 1.TBNA of mediastinic adenopathies was useful in the extension diagnosis in 122(66.3%) patients and resulted in diagnosis of lung cancer in 41(33.6%) patients. 2.TBNA was well tolerated and without significant complications.

**P4412**

**Performance of transbronchial needle aspiration (TBNA) of mediastinal lymphadenopathies in the diagnosis of pulmonary neoplasms**

Rafael Garcia Montesinos, Nuria Maria Reina Martí, Ezequiel Ortega Sáenz de Tejada, Concepción Mena Escober, Lidia López López, María Victoria Hidalgo Sanjuán. Pulmonology Department, Virgen de la Victoria University Hospital, Malaga, Spain

**Objective:** To know the contribution of TBNA of mediastinal lymphadenopathies in the diagnosis of extension and anatomicopathologic diagnosis of lung neoplasms.

**Methods:** During 63 months (october 2006-december 2011) we made 184 fiberoptic bronchoscopies (FB) with TBNA to patients with mediastinal lymphadenopathies suspected of neoplastic origin. We performed a “blind” TBNA of the lymphadenopathies larger than 1cm, using a 19 or 21ga needle, in the presence of the anatomicopathologist. We took samples from the ganglionic stations 4R, 7, 10R, 11R and 11L. We take samples until we got a positive result or we did 3-4 perforations, depending on tolerance of the patient. We considered as positive samples which allowed to make a therapeutic decision and negative samples those reported as “carcinoma” without specifying the type, presence of “malignant” or “atypical cells”.

The non hospitalized patients were observed 3 hours after the procedure.

**Results:** The TBNA was (+) for neoplasia in 122(66.3%) patients, giving the diagnosis of extension (N2). The average number of punctures per patient was 1.8; in 58 patients (59.7% of TBNA positives) only one puncture was required. In 41 cases (33.6%) was the only positive sample of FB, and gave the extension and pathological diagnosis. The only complications during FB were small hemmorhages. We did not detect significant clinical or radiological complications following the procedure.

**Conclusions:** 1.TBNA of mediastinic adenopathies was useful in the extension diagnosis in 122(66.3%) patients and resulted in diagnosis of lung cancer in 41(33.6%) patients. 2.TBNA was well tolerated and without significant complications.

**P4413**

**Results of echocardiographic ultrasound in mediastinal nodal staging of lung cancer**

Régulo Ávila Martínez1, Ricardo García Luján2, Ana Hernández Voth2, Rodrigo Alonso Moralejo2, José Luis Martín de Nicolás1, Nuria Alberti3, Eduardo de Miguel Poch2, 1Thoracic Surgery Service, 12 de Octubre University Hospital, Madrid, Spain; 2Pneumology Service, 12 de Octubre University Hospital, Madrid, Spain; 3Pathology Service, 12 de Octubre University Hospital, Madrid, Spain

**Aim:** To evaluate the sensitivity and predictive negative value (PNV) of endobronchial ultrasound (EBUS) in patients with non small cell lung cancer (NSCLC).

**Methods:** Descriptive retrospective transversal study of all performed EBUS in a tertiary hospital during a 3 year period, for mediastinal nodal staging of NSCLC with fluorodeoxyglucose positron emission tomography positive nodes. Cases were considered positive (PC) when nodal metastases was demonstrated. If not, were considered as non-positive cases (NPC) and a mediastinoscopy was performed, if the clinical situation of the patient allowed the procedure.

**Results:** A total number of 41 patients were evaluated, 34 of them male and 7 female. Mean age was 65.39 years old. EBUS results were: 22 PC and 19 NPC. Mediastinoscopy was performed to the NPC supporting the negative result in 14
cases, but showed a positive result in other 3 cases. In 2 cases no additional testing was done. We found 3 false negative cases (17.64%), a VPN of 82% and a sensitivity of 88% for EBUS in our patient series. EBUS was able to stage 20 cases as N2 and 2 cases as N3. In four N2 staged cases a neoadjuvant therapy was applied and then a mediastinoscopy was performed previous to the surgery.

Conclusion: In this patient series EBUS allowed us to avoid more than a 50% of prognostic mediastinoscopes in NSCLC, given the high NPV and sensitivity we obtained with this technique. In cases staged as N2 responding to neoadjuvant therapy, a mediastinal reevaluation can be performed through a mediastinoscopy.

P4415 Transbronchial needle biopsy
Vesla Karelis, Martja Karelis. Clinic for Lung Disease, Military Medical Academy, Belgrade, Serbia School of Medicine, University of Belgrade, Serbia.

Introduction: Transbronchial needle biopsy (TNB) is a safe method used to achieve diagnosis for most thoracic lesions, whether the lesion located in the pleura, the lung parenchyma or mediastinum. TNB are performed on an outpatient basis by using only 1% lidocain local anesthesia.

Methods: TNB was performed in 148 patients, 44 (29.7%) women and 104 (71.3%) men, age 28-82, average 74 years; changes in the thoracic wall, pleura, parenchyma et the lung and mediastinum. Needles that were used in the procedure were BardMagnetm 18-19G x 200mm, and sample length was 19 mm. Needles were activated using BardMagnetm automatic trigger, under RT control with the C-arm Ziehm-Vision.

Results: In 148 patients the TNB was done:

EBUS if an adequate sample is achieved is 98%. Sensitivity of TNB is safe and cheap diagnostic procedure for histological and/or cytological confirmation of changes in the lung and mediastinum. Sensitivity of TNB is 92.8% and specificity 100%.

P4417 Is small-bore catheter efficient in different type of pleural pathologies
Serife Liman1, Ayakt Elior2, Asli Akgul1, Salih Topcu1.

Background/Objectives: Problems in the treatment of chronic nonspecific empyema (CNEP) remain relevant.

Material and methods: 207 patients were treated with CNEP in clinics of Lviv Regional Center of Phthisiology and Pulmonology and Lviw Regional Hospital at the past 30 years, aged 15 - 80 years from 1.5 month to 13 years from the date of diagnosed acute suppuration pleura.

Results: Reasons CNEP: purulent inflammation of the lungs with bronchopleural fistula and residual pleural cavity were found in 125 (60.38%) patients; suppuration of hemathorax - in 28 (13.53%), suppuration of pleural effusion - in 22 (10.64%); complications after surgery - in 24 (11.59%), pleural cavity foreign body - in 8 (3.86%). An operations: dekortykation with resection and lung and pleura were performed in 95 cases, including lob -, bilobekotomy - in 23; atypical segmentektomy - in 16; pleuroperulomonotomky - in 7, taking in bronchial fistulas - in 17. If you have problems with smoothing out the lung, intraoperative thoracoplasty operation completed (47 cases). In 4 patients with significantly reduced spirometry and hasmetry was performed ekstrapleural thoracoplasty. In the postoperative period died 6 (2.89%) patients. After thoracoplasty all patients survived.

Conclusion: We believe that the most appropriate and economically justified in patients with radical resection is CNEP lungs and pleura. Nonaccordance volume of hemathorax - in 28 (13.53%), suppuration of pleural effusion - in 22 (10.64%) cases with pneumothorax, 21 cases with hemoperuph-
IL27, cytokine driving Th1 immunity and stimulates cytotoxic response. However, IL27 has not been considered yet as a tool in lung cancer gene immunotherapy. Aims: Construction of a plasmid encoding IL27. Evaluation of its transfection efficacy in non-small (A549) and small (NCI-H82) cell lung cancer model lines. Methods: IL27 cDNA was cloned into pSMx-IG plasmid. Lung cancer cells (A549 and NCI-H82) were transfected either with IL27 construct (pSMx-IL27) or empty plasmid as a control. Transfection efficacy was proved by RT-PCR and anti-IL27 immunostaining. Cell cycle and apoptosis (TUNEL assay) was assessed by flow cytometry. Results: pXMs-IL27-transfected cancer cells expressed IL27, as it was revealed by positive RT-PCR and flow cytometry (A549: 79%; NCI-H82: 56%, median of 5 experiments). Unexpectedly baseline IL27 expression was also found in non-transfected cells, particularly in A549 line (40%). Tumor cells transfected with pXMs-IL27 plasmid showed intense apoptosis, as compared with empty plasmid control. Conclusions: We proposed the model of future lung cancer gene immunotherapy with use IL27 encoding plasmid. However, low IL27 expression in non-transfected lung cancer cells calls in question its antitumor activity as a local immune stimulator. On the other hand, increased apoptosis of transfected cancer cells was observed, suggesting direct impact of IL27 on tumor cells.

P4420 Perioperative considerations for patients with asthma underwent thoracic surgery

Yordanka Yamakova, Rosen Petkov, Georgi Yankov, Danail Petrov. Anesthesiology and Intensive Care, University Hospital of Pulmonary diseases “St. Sofia”, Sofia, Bulgaria Thoracic Surgery, University Hospital of Pulmonary diseases “St. Sophia”, Sofia, Bulgaria Thoracic Surgery, University Hospital of Pulmonary diseases “St. Sophia”, Sofia, Bulgaria Thoracic Surgery, University Hospital of Pulmonary diseases “St. Sophia”, Sofia, Bulgaria

Asthmatic patients are a challenging population for anesthesiologists. Aim: The aim of this study was to determine the perioperative complications in asthmatic patients with symptoms before the surgery. Material and methods: From 2007 to 2011 44 patients with asthma underwent thoracic surgery. We classified the patients into two groups: First group (n =19) - patients with asthma who currently have no symptoms and second group (n=25) - asthmatic patients with symptoms before surgery. Pulmonary function was optimized preoperatively in all patients and airway obstruction was controlled by using steroids and bronchodilators. We conducted deep anesthesia with Sevoflurane, Fentanyl and Pipercuronium. We monitored several parameters: tidal volume, inspiratory, expiratory volume, PEEP, Pplat, ETCO2, PaCO2. Results: Patients in the second group had less incidences of perioperative bronchospasm than those in the second (p<0.025). We detected some statistical differences in the parameters: the gradient between ETCO2, Pplat is bigger in second group (p<0.025) and we detected an increasing PEEP and Pplat in asthmatic patients with symptoms before surgery. Conclusion: Symptomatic asthmatic patients had more the incidence rate of the perioperative complications. With deepening anesthesia level and aggressive pharmacological management the anesthesiologist minimize the risk of complications.

P4421 Application of one-lung high frequency jet ventilation (OHFJV) in lung surgery

Mikhail Kontorovich, Sergey Skornyakov, Igor Medvinsky, Igor Motus, Dmitry Eremeev. Department of Surgery, Ursal Research Institute for Phthisiopneumonology, Ekaterinburg, Russian Federation

Objectives: In any cases lung surgery including thoracoscopic procedures requires ventilation of one lung. The aim of the study was to examine physiologic features of OHFJV in lung surgery. Materials and methods: We compared two groups of patients comparable in terms of surgery, comorbidity, age of patients underwent lung resections. In the group I (n=101) we conducted traditional one-lung controlled mechanical ventilation (OCMV). The regimen was CMV (f = 17-19 cycles in minute, Vm – 260-410 ml, I:E – 1:2). In the group II (n=121) OHFJV was conducted (f – 100 cycles in minute, Vm – 150-170 ml, I:E – 1:2). In both groups FIO2 = 0,21. Results: OHFJV provided more effective intrapulmonary kinetics and respiratory gases distribution. OHFJV being compared with OCMV showed some advantages which are as follows: I. Increasing of the volume of alveolar ventilation (Vd), reducing of the volume of physiological dead space (Vd0), in 2,1 times, reducing proportion (Vd0/Vd) in 5 times, reduction physiological blood shunt by 80%, and increasing PaO2 by 16,7% indices PaCO2 and pH being normal. II. There were significantly lower indices of transpulmonary pressure, contributing to an increased venous return to heart and cardiac output. Conclusion: Thus, OHFJV provides adequate gas exchange, and creates favorable conditions for the surgeon.

P4422 Minimally invasive repair of pectus carinatum: A single institution experience

Yorikat Bostanci, Hakan Ozturk, Barzin Eldem, Adamu Isakca, Onur Ermerak, Zeynep Bilge, Vehan Kurz, Mustafa Yüksel. Department of Thoracic Surgery, Muhammad University Faculty of Medicine, Istanbul, Turkey

Minimally invasive repair of pectus carinatum (MIRPC) has become an alternative technique to open surgery in recent years due to the successful surgical outcomes of the centers performing it. The aim of this study was to investigate the results of MIRPC at our institute. Fifty-eight cases who had had MIRPC between January 2006 and February 2012 were included in the study and were evaluated retrospectively according to the demographic data, form of the deformity, number of prestellar bars, operation duration, perioperative and postoperative complications, length of hospital stay, reoperations, bar removal and patient satisfaction. Fifty-four of the patients were male and the median age was 18.5 (range: 10-27) in the series. The deformity was symmetric in 40 and asymmetric in 18 cases. Follow-up of 5 experiments. Unexpectedly baseline IL27 expression was also found in 40 patients in 10 patients on planned time without any recurrence. Conclusion: Minimally invasive repair of pectus carinatum can be performed for the short operating time, low morbidity and high levels of patient satisfaction.

P4423 Large chest wall resection and reconstruction using titanium meshplate and pedicled muscular flap: Report of 6 cases

Alipuz Kosar1, Hatice Eryilgi1, Levent Alpay2, Ersin Cardak1, Kadri Ozer1, Recep Demirhan1. 1 Thoracic Surgery, Dr. Lutfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey; 2 Thoracic Surgery, Sureyyapasa Chest Disease and Chest Surgery Education and Research Hospital, Istanbul, Turkey

The aim of this clinical study was to evaluate effectiveness of titanium meshplate for chest wall resection and reconstruction after chest wall tumor resection. Between 2009 and 2012, 6 patients with chest wall tumors were treated surgically. There were 3 female and 3 male patients and their ages ranged from 26 to 76 years. The patients were admitted due to chest pain and swelling. Tumors were located on sternum in 4 of the patients and on anterolateral chest wall in 3 of them. After tumor resection, defect size ranged from 10 cm. x 14 cm. to 12 cm. x 20 cm. Chest wall reconstructions were performed using titanium meshplate and pedicled muscular flaps. Titanium meshplates were fixed in ribs and/or sternum by titanium wires or screws.

Postoperative pathology for sternal tumors were condrosarcoma, malign melanoma and liposarcoma, and for chest wall tumors they were osteochondroma, malign fibrous histiocytoma and lymphoma. There were no paradoxal movement, or prosthesis-related complications during the follow-up period. Only in one patient muscular flap necrosis has occurred. Therefore second operation was performed for removal of necrotic muscular flap. The mean postoperative follow-up period was 15 months (range, 2-36 months).

We consider that, titanium meshplate is an easily applicable and suitable material to use in the reconstruction of large chest wall defects.

P4424 Thoracic paravertebral block for awake videothoracoscopic surgical procedures of high risk patients

Svilen Alexon1, Danail Petrov2. 1 Anaesthesiology and Intensive Care Clinic, University Hospital of Pulmonary Diseases “St. Sophia”, Sofia, Bulgaria; 2 Thoracic Surgery Clinic, University Hospital of Pulmonary Diseases “St. Sophia”, Sofia, Bulgaria

Objective: To present our experience and evaluate feasibility of thoracic paravertebral block as adequate anesthesia for some awake video-assisted thoracoscopic surgical procedures in high risk patients.
Methods: Seven (ASA IV) patients had multiple unilateral thoracic paravertebral blocks from Th3 to Th9 levels with 0.5% levobupivacaine as only anesthesia for their VATS procedures. Patients were awake, lightly sedated and spontaneously breathing 100% oxygen via tight mask during the whole procedures. Paravertebral catheters were inserted at Th-5,6 interspace for postoperative analgesia. The performed surgical procedures were: inspection, debridement, evacuation of haematoma, pleural or lung biopsies, pericardial fenestration, partial pleurectomy, talc pleurodesis, packing with wet dressing of povidone-iodine, or combinations of all mentioned above.

Results: Thoracic paravertebral anesthesia provided very good conditions for VATS and postoperative pain relief for presented patients. The mean duration of the procedures was 64 minutes. The procedures were well tolerated, respiratory status was stable, and oxygen saturation was maintained above 95%. Pain and panic attacks were well controlled. Spontaneous breathing and hemodynamics were well maintained during the operations. Recoveries were uncomplicated despite the underlying gross pathology.

Conclusions: Thoracic paravertebral blockage appears to be promising and feasible anesthetic management of some awake VATS procedures, especially when hemodynamic stability, adequate venous return and preservation of spontaneous ventilation are very important anesthetic goals.

P4425

Video-assisted thorascoscopic surgery of mediastinal cysts: Report of 13 cases

Yener Aydin1, Ömer Arat2, Mesut Ozgöke3, Eker Incé4, Faith Alper5, Atilla Ergüle6, 1Department of Thoracic Surgery, Atatürk University, Erzurum, Turkey; 2Department of Chest Diseases, Atatürk University, Erzurum, Turkey; 3Department of Radiology, Atatürk University, Erzurum, Turkey; 4Department of Anesthesia and Reanimation, Atatürk University, Erzurum, Turkey

Background: Mediastinal cysts are rare anomalies. The purpose of this study was to present our experience with mediastinal cysts who were thorascoscopic treated in our clinic and to discuss our findings along with those from the literature.

Methods: We retrospectively investigated 13 patients who were diagnosed and thorascoscopic treated for mediastinal cysts in our clinic between January 2008 and December 2011.

Results: Seven patients were female and six patients were male. The average age of the patients was 41.3±0.23 (18-82 years old). The mediastinal cysts comprised five pericardial cysts; four bronchogenic cysts; one hydatid cyst; one benign cystic teratoma; one dymtic cyst; and one neuroneentric cyst. In a case with ruptured hydatid cyst, we passed to thoratomy intra-operatively due to presence of advanced adhesion related to inflammation. Postoperative complication and mortality did not occur in any case. The average postoperative hospitalization period was 3.8 days.2

Conclusion: Video-assisted thorascoscopic surgery in mediastinal cysts is a reliable and effective approach with low morbidity and a shorter hospital stay.

P4426

Impact of pulmonary metastasectomy on lung function parameters

Thomas Schweiger1,2, Christoph Nikolausky1,2, Lukas Lehmann1,2, Robert Wietholthaus1, György Lang1, Hendrik-Jan Ankersmit1,2, Walter Klepetko1, Konrad Hoetzenecker1 Department of Surgery - Division of Thoracic Surgery, Medical University of Vienna, Austria

The lung is a common site of secondary growth in malignant diseases. Surgical resection of pulmonary metastases has been shown to prolong survival in patients with various primary tumor types. Today, even repeated resections of recurrent pulmonary metastases are common practice in thoracic surgery. The impact of metastasectomy on respiratory function has become a relevant factor in the treatment algorithm of these patients.

Since 2009, all metastasectomy patients at the Dept. of Thoracic Surgery, MUV, have been actively followed up every three to six months after surgery. For 45 patients pre- and post-operative lung function data was obtained during the follow-up. In 19 patients metastasectomy were removed by enucleation (laser=10, cautery=9), in 19 patients by wedge resection and 7 patients received lobectomy. Complete resection was obtained in all patients.

We found no difference in loss of FEV1 per resected nodule between laser and cautery enucleation. However, a significant difference in FEV1 and VC was found when comparing enucleation/wedge lobectomy patients (FEV1 3.1±1.5, 7.6±1.5, 13.4±4.9, VC: 15.1±1.7, 4.7±1.7, 16.3±3.3). These findings were confirmed by evaluating the volume of the resected tissue and did not correlate with size of metastases as determined by pre-operative CT evaluations.

The surgical resection of pulmonary metastases is associated with a detectable but mild loss of lung function. Concerning the respiratory impairment, repeated resections of lung metastases should not be withheld from patients.

P4427

EBUS-TBNA as alternative of VATS-procedure for differential diagnosis of mediastinal lymphadenopathy

Igor Vasilyev1, Nikolay Yakushenko1, Dmitry Sudomoin1, Peter Yablonsky2.
1Endoscopy, FGBU “SPINHIF”, Saint-Petersburg, Russian Federation; 2Thoracic Surgery, FGBU “SPINHIF”, Saint-Petersburg, Russian Federation

Aim: To study of possibilities of EBUS-TBNA in differential diagnosis of tuberculosis and sarcoidosis1.

Materials and methods: From March till December, 2011 30 ultrasonic video bronchoscopies for the purpose of performance of a transbronchial biopsy of lymph nodes of a mediastinum at 30 patients with a mediastinal lymphadenopathy have been executed. Middle age has made 30±8 years, 14 men and 16 women. The syndrome of a mediastinal lymphadenopathy was established on the basis of the data of a spiral computer tomography. The average size of LN - 1.6±0.4 cm, radiological signs of a pathology of lungs were absent. At all patients preliminary clinical inspection hasn’t allowed to differentiate character of a lymphadenopathy. Second step in all were VTS biopsy of lung and histological examination (as gold standard).

Results: We didn’t have any complications. After cytolological examination we find cells of LN in 30 cases. We compared results of cytological and histological examinations. And the results were equal. We found 5 cases of tuberculosis, in 25 patients sarcoidosis. Diagnosis was confirmed by 6 month period of follow-up.

Conclusion: We can see equal results of both examinations. May be in such cases we need not to do of VTS biopsy of lung and histological examination. (Time to change Gold standard?)

P4428

Less pain without pain-killers?

Vasile Gринe1, Cornel Sava1, Radu Posea1, Boris Coman1, Cornel Petreana1, Dan Avramescu2, Nicolae Galea3, 1Thoracic Surgery, National Institute of Pneumology “Marius Nasta”, Bucharest, Romania

Objectives: To assess if the mode of closing the thoratomy may have an influence over the post-operative pain.

MATERIAL AND METHODS

Prospective study, with 2 groups of patients, 15 cases each. Group A – for this patients, the stiches used to close the thoratomy were passed between the rib and intercostal nerve (in this way the nerve don’t compressed again the rib when the stich was tightened). Group B – the stiches were passed in classic fashion, inferior to intercostal nerve and when the thoratomy was closed, the passing of the stiches compressed the nerve against the rib. All patients had lateral thoratomy, 3 stiches were used for all patients, no peridural/paravertebral catheter was used and regular analgesia (consisted in Paracetamol, Tramadol and NSAID) was used for all patients. For assessing the pain, we used a scale from 0-10, 0 no pain, 10 pain intensity was the biggest ever felt by the patient. We assess the pain in the first 48 h post-op and after 21 days.

Results: Group A – only 2 patients alleged pain score 10 in first 48 hours post op, 1 patient – score 9, the rest of the group pain was 8 or less. Group B – 13 patients alleged pain score 10 post-op, 1 patient – score 8 and 1- score 7. Pain assessed 3 weeks after: group A pain score range from 0 to 7, and in group B from 0 to 10.

Discussions: Pain is difficult to assess preciselly because the threshold and perception of pain is different from person to person. According with this study, it seems that involvement of the intercostal nerve in the closure of thoratomy increase the post-operative pain, especially in the first 48 hours.
P4430
The feasibility of medical thoracoscopy in the treatment of multi-loculated pleural effusion
Dohyung Kim1, Bongsoo Son1, Kildong Kim2, Jongjoo Hwang3. 1Thoracic and Cardiovascular Surgery, Pusan National University, Yangsan Hospital, Yangsan, Korea; 2Thoracic and Cardiovascular Surgery, Eulji University Hospital, Daejeon, Korea

Introduction: Optimal surgical procedure must be selected according to empyema stage of multi-loculated cases. If the empyema is at the stage of multi-loculated effusion, however, it is difficult to select the optimal procedure using conventional staging system. The medical thoracoscopy is an ideal diagnostic tool of pleural disease, we used medical thoracoscopy to evaluate the accurate stage of empyema and to select optimal surgical procedure.

Methods: 108 patients were transferred to treat multi loculated pleural effusion. The type of surgical procedure was selected according to the finding of medical thoracoscopy.

Results: There was no significant difference of morbidity and mortality between two groups (p>0.05). The 20 closed thoracostomy (45.5%), 6 VATS decortication (13.6%), and 18 open decortication (40.9%) were performed in group I. 16 cases of open decortication were undertaken due to the failure of first treatment (12 closed thoracostomy, 4 VATS decortication). In group II, 43 locculation block-up were undertaken due to the failure of first treatment. 12 locculation block-up were performed due to the failure of first treatment (10 closed thoracostomy, 3 VATS decortication). In group II, 43 locculation block-up were undertaken due to the failure of first treatment. In group II, 43 locculation block-up were undertaken due to the failure of first treatment.

Conclusions: The medical thoracoscopy is helpful to decide the optimal procedure in the treatment of multiple loculated empyema. We could decrease the incidence of open thoracostomy to use medical thoracoscopy.

P4431
May the Nuss operation be minimally invasive procedure in adults

The repair of pectus excavatum with Nuss procedure (group N) is well established among pediatric surgeons. It named minimally invasive surgery. Studies on adult patients are rare. We compared Nuss procedures and Ravitch procedures (group R) on adult patients, which of them minimally invasive in respect tors cin incisions. We retrospectively analysed 35 adult patients (16 Nuss procedures, 19 Ravitch procedures) from 2007 to 2011. In two groups all patients aged older than 20, Ravitch procedures performed midsternal vertical incision and substernal metal bar. For Nuss procedures three scinc incisions was performed. Opioid derived was used for post-operative pain. We observed early bar dislocation at four patients, two haemothoraces, three pneumothoraces and one severe post-operative pain. In Nuss procedures should not require chest wall resection and it may do small scinc incisions. But Nuss procedure have lots of complications. In Ravitch procedure, much more effective and less invasive and have little complication. We have lots of question marks.
3 weeks of ET. The 1- and 2-year overall-survival rates were 100%, the 3-year survival 73%. In one patient lung transplantation was performed 6 months after ET.

Conclusion: ET as add-on to medical therapy is effective in patients with CTD-APAH to improve work capacity, quality of life and prognostic parameters and improves the 1-, 2- and 3-year survival rate. Further randomized controlled studies are needed to confirm these results.

**P4434** Respiratory muscle training (REMT) with normocapnic hyperpnoea (NH) improves respiratory muscle strength, exercise performance and ventilatory pattern in COPD patients

Evri Bernardini, Luca Pompidori, Gaia Mandolesi, Gianluca Grassi, Annalisa Cogo.

Department of Clinical and Experimental Medicine, University of Ferrara, FE, Italy

Few data are available about the effect of REMT in COPD patients even if it has been shown that REMT improves endurance performance and decreases VE during exercise in healthy subjects.

Aim: To evaluate the effect of 4 weeks of REMT with NH (Spirotiger®) on respiratory function and exercise capacity in 23 moderate/severe COPD patients.

Materials and methods: 20 M, 3 F (aged 42-80). Respiratory function tests (FEV1, FVC, MIP), QOL (St George’s Questionnaire), 6MWT and endurance exercise test (75-80% of peak-work rate measured during an incremental test and performed to the limit of tolerance, ILIM).

9 of 21 patients were instrumented with a portable inductive plethysmography (Lifeshift System) to evaluate breathing pattern during exercise test. After 4 sur- prised training sessions, the patients trained at home for 4 weeks: 10 min twice a day roughly 55% of MVV (FEVi0x.375). REMT started 3 days a week.

Results: Results are reported in Tables 1 and 2. 6 patients dropped out (poor compliance).

Ventilatory pattern after REMT, during ILIM, is characterized by a significantly lower trend of VE and RR with a higher TP (p < 0.05, ANOVA test).

**P4435** Reduced oxygen uptake efficiency slope in patients with cardiac sarcoidosis

Wilhelm Ammerwerth1, Mark A. Klemens2, Catharina Creel3, NicoSCHUETZ1, Roland C. Bittner1, Jeanette Schulz-Mengel1, Torsten T. Bauer1.

1Department of Pneumology, Lungenklinik Heckeshorn, HELIOS; 2Rehabilitation Clinic Falkenstein, Falkenstein, Germany; 3Rehabilitation Clinic Bad Reichenhall, Bad Reichenhall, Germany

Background: The non-invasive diagnosis of cardiac sarcoidosis (CS) is difficult. Cardiovascular magnetic resonance (CMR) has become a very valuable diagnostic tool in patients with suspected CS, but usually a combination of different tests is used. Oxygen uptake efficiency slope (OUES) is a parameter of cardiopulmonary exercise testing (CPET), which is used as an indicator for cardiovascular impairment. We investigated the predictive value of OUES for the diagnosis of myocardial involvement in sarcoid patients.

Methods: Retrospectively 37 consecutive patients (44.9 ± 13.8 years) with histologically confirmed sarcoidosis and clinical suspicion of heart involvement underwent noninvasive diagnostic testing including CMR. CS was diagnosed according to the guidelines from the Japanese Society of Sarcoidosis and other Granulomatous Disorders with additional consideration of CMR findings. Furthermore, CPET with calculation of predicted OUES according to equations by Hollenberg et al. was performed to the limit of tolerance, tLIM.

Results: A total of 20 patients (47 ± 14 yrs, mean pulmonary artery pressure = 52 ± 10 mmHg) underwent an incremental exercise test and a steady-state test with arterial blood gases measurement. OUES was significantly lower in CS-group compared to non-CS-group (59.3 ± 22.9 vs. 82.5 ± 21.2, p < 0.01). ROC curve method identified 70%pred. as the OUES cut-off point, which maximized sensitivity and specificity for detection of CS (96% sensitivity, 82% specificity, 89% overall accuracy).

Conclusion: Cardiac involvement of sarcoidosis can be predicted by CPET using OUES. Patient selection for CMR can probably be guided by CPET findings in patients with sarcoidosis.

**P4436** Prognostic implications of delayed heart rate recovery from maximal-incremental exercise in patients with pulmonary arterial hypertension

Roberta Pulcheri Ramos, Jaqueline Sonse Ora Arakaki, Elisaura Vieira, Erik Treptow, Fabiana Martins Valdes, Eloaura Vieira Vargas, David Ferreira, Luis Eduardo Nery, J. Alberto Neder. Pulmonary Function and Clinical Exercise Physiology Unit (SEFICE), Respiratory Division, Department of Medicine; Federal University of São Paulo – Paulista School of Medicine (UNIFESP-EPM), São Paulo, SP, Brazil

Rationale: Early recovery from exercise is characterized by a marked reduction in heart rate (HR) due to sudden reintroduction of vagal tone and progressive withdrawal of sympathetic stimulation. HR recovery (HRR) is delayed in pulmonary arterial hypertension (PAH), a disabling condition associated with autonomic imbalance.

Objective: To investigate the usefulness of HRR to estimate exercise impairment and prognosis in PAH patients.

Methods: We evaluated 72 patients with PAH of varied aetiologies (NYHA class I to IV) and 21 age- and gender-matched controls who underwent a maximal incremental cardiopulmonary exercise test (CPET) with HR being recorded up to the 5th minute of recovery.

Results: HRR was consistently lower in patients compared to controls (p < 0.05). The best cutoff for HRR in one minute (HRR1min) to discriminate patients from controls was 18 beats (AUC 0.76 [0.66-0.86], p < 0.01). "Normal" HRR1min was associated with a range of maximal and sub-maximal variables indicative of better preserved exercise tolerance (p < 0.05). On a multiple regression analysis which considered only CPET-independent variables (6-minute walking distance, NYHA class and PAH treatment), HRR1min was the single predictor of mortality (hazard ratio (HR) 9.5% confidence interval 1.19 (1.03-1.37), p < 0.05).

Conclusions: Preserved HRR1min (>18 beats) is associated with less impaired responses to exercise in patients with PAH. Conversely, an abnormal HRR1min response has negative prognostic implications, a finding likely to be clinically useful when more sophisticated analyses provided by a full CPET are not readily available.

**P4437** Portioning out the contribution of dead space ventilation and low CO2 set point to ventilatory inefficiency during exercise in chronic thromboembolic pulmonary hypertension

Roberta Pulcheri Ramos, Jaqueline Sonse Ora Arakaki, Eloaura Vieira Machado Ferreira, Adriano Ascendo, Meline Almeida, Luiz Eduardo Nery, J. Alberto Neder. Pulmonary Function and Clinical Exercise Physiology Unit (SEFICE), Respiratory Division, Department of Medicine; Federal University of São Paulo – Paulista School of Medicine (UNIFESP-EPM), São Paulo, SP, Brazil

Rationale: The individual relevance of enlarged dead space ventilation as a fraction of tidal volume (VDVT) and low CO2 set-point in promoting exercise ventilatory inefficiency in chronic thromboembolic pulmonary hypertension (CTEPH) remains controversial.

Objective: To determine the contributing role of VDVT and PaCO2 on the exercise ventilatory response to exercise in patients with CTEPH.

Materials and methods: 20 patients (47 ± 14 yrs, mean pulmonary artery pressure = 52 ± 10 mmHg) underwent an incremental exercise test and a steady-state test with arterial blood gases measurement.

Results: Compared to normal standards, patients showed lower resting PaCO2 and peak V′O2 but greater ΔV′E/ΔV′CO2 slope (68 ± 16). Peak V′O2 and ΔV′E/ΔV′CO2 were inversely correlated (r = -0.70, p < 0.05). V′E/V′CO2 ratio during the constant work rate test was also abnormally high (62 ± 15). VDVT increased from 0.31 ± 0.08 at rest to 0.39 ± 0.11 during exercise; on the other hand, end-tidal partial pressure (PET) for CO2 decreased despite a stable PaCO2 (p < 0.05). Consequently, PaCO2/EtCO2 became wider (4.3 ± 3 mmHg to 8.5 ± mmHg), a finding related to greater V′E/V′CO2 (r = 0.81, p < 0.05). On a multiple regression analysis VDVT (partial r = 0.89) and PaCO2 (partial r = -0.37) explained up to 90% of V′E/V′CO2 variability (125.9 VDVT - 2.3 PaCO2 + 77.1, p < 0.001).

Conclusion: Increased VDVT is the main pathophysiologival mechanism leading to an excessive ventilatory response to exercise in patients with CTEPH. Low CO2 set-point responds for a relatively minor portion of this abnormal feature.

**P4438** Association of 6-minute walk distance and maximal work capacity assessed by ergometry in patients with obstructive and restrictive lung diseases

Lisa Ochmann1, Nicola Kotschy-Lang2, Wolfgang Raab3, Jessica Kellberger1, Dennis Novotny2, Rudolf Jores3.

1Institute of Occupational, Social and Environmental Medicine, Ludwig-Maximilians-University, Munich, Germany; 2Rehabilitation Clinic Falkenstein, Falkenstein, Germany; 3Rehabilitation Bad Reichenhall, Bad Reichenhall, Germany

Background and objective: In patients with chronic lung diseases work load for
endurance training is calculated from maximal load. If this is not known, it might be predicted on the basis of 6-minute walk distance (6MWD). We addressed the reliability of such predictions.

Methods: Within a longitudinal clinical study on the efficacy of rehabilitation, baseline data including 6MWD, maximal work load (Wmax), peripheral muscle force, lung function, fat-free mass (FFM) and dyspnoea (MMRC score) of 255 men with occupational lung diseases (asthma, asbestosis, silicopid COPD) were evaluated.

Results: 6MWD (mean 502m, SD 92m) correlated (r=0.51, p<0.05) with Wmax (mean 112Watt, SD 35Watt), without systematic differences between asthmatic, silicopid COPD. The asthmous group was evaluated separately since the regression line was different. Muscle force, lung function parameters and MMRC score correlated moderately with Wmax (p<0.05 each). Including all statistically significant predictors the correlation was r=0.76 in patients with obstructive lung function impairment and r=0.61 in asthmatics patients. The residual standard deviations of predicted Wmax were 20-28 Watt, depending on the predictors used, and the 95% prediction intervals of Wmax based on the predictor 6MWD 67-65 Watt.

Conclusions: Compared to literature data we observed weaker correlations indicating that the prediction of individual Wmax by 6MWD related measures is not possible. Despite this, the regression lines based on a large sample of subjects might be useful for the comparison of epidemiological studies.

P4439

The relationships between hyperinflation during exercise and symptoms in adults with cystic fibrosis

Daniela Savi1, Paulo J.C. Vieira1, Jorge P. Ribeiro1, Mattia Internullo1, Gabrielle Vail1, Paolo Marinni2, Serenella Bertasi1, Matilde Rolla1, Riccardo Valerio De Biase1, Salvatore Palapane1, Paolo Palapane1, Repedicto Fibrosis Centre-Pediatrics Department, “Sapienza” University of Rome, Italy; 2Public Centre-Pediatrics Department, “Sapienza” University of Rome, Italy; 3Public Health and Infectious Diseases Department, “Sapienza” University of Rome, Italy; 4Emergency Medicine, Hospital G.B Grassi, Rome, Italy

Exercise tolerance is reduced in patients with Cystic Fibrosis (CF). Ventilatory limitation, peripheral skeletal muscle weakness and poor nutritional status may contribute to exercise intolerance. The mechanisms of exhalational dyspnoea are less understood, but it seems that dynamic hyperinflation may play a role. So we wanted to investigate the role of exercise dynamic hyperinflation on breathlessness (DYS) and leg fatigue (LEG) in CF patients. 17 stable CF patients (32±8SD yrs, FEV1 2.66±0.71; 68.6±16% pred; IC 3.4±1.0 l, during constant load cycle ergometry at 80% max VO2; max VO2 were studied. Intensity of breathlessness and leg fatigue, by Borg scale, and IC were recorded every 2 minutes. The individual slopes of the change in IC and the rate of increase in DYS and LEG were also computed.

Results: In most patients we did not observe a correlation between changes in IC during exercise vs either DYS (r² =0.03±0.08) or vs LEG (r² =0.3±0.26). In addition, we did not find a close relationship of change in DYS or LEG. Conversely we found a close relationship between the rate of increase in DYS per unit change in IC and the rate of increase in LEG per unit change in IC (r²=0.85 ±0.001).

Conclusions: CF patients show considerable variation in the rate at which symptoms develop during exercise, suggesting that different physiological processes underlie these symptoms. Baseline IC strongly predict the duration of the endurance tolerance, while the degree of resting hyperinflation is poorly predictive of exercise induced changes in DYS and LEG.

P4440

Exercise capacity and limiting factors in older patients with post infectious bronchiolitis obliterans

Luiz Felipe Frohlich1, Danilo C. Berton1, Paulo J.C. Vieira1, Jorge P. Ribeiro1, Paulo I.Z. Teixeira1, Fernando A.A. Silva1, Internal Medicine, Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil; 2Internal Medicine, Health Science Federal University of Porto Alegre, Brazil

Exercise capacity has been poorly studied in patients with post-infectious bronchiolitis obliterans (PBO) and main studies evaluated children with follow-up in older subjects lacking. We evaluated exercise capacity in older patients with PBO and mechanisms of exercise limitation.

This was a cross-sectional study including the oldest patients of our tertiary care center. Cycle incremental cardiopulmonary exercise test with investigation of dynamic hyperinflation and exercise induced bronchoconstriction (EIB) were performed.

Sixteen patients were studied with a mean age of 15.3±3.9 years (range 10-23 years), and post-infectious bronchiolitis obliterans (PBO) resting lung function (% predicted): FVC 88±19.3; FEV1, 67.4±17.5, TLC 115.3±10.7, RV 234±8.71, Dlco 73.6±11.9. Only 7 patients (43.8%) had reduced exercise capacity (VO2peak<0.78±1.0l), during constant load cycle ergometry at 80% peak workload, VO2peak was only correlated with age (r=0.58; p=0.01) and Dlco/CVD pred (p=0.66; p=0.01).

Patients with reduced exercise capacity tended to be younger (13.4±3.3 yr vs 16.8±3.9 years; p=0.09), with greater FEV1 response to BD (18.9±12.8 vs 7.0±11.9%; p=0.08) and lower Dlco (67.8±12.9 vs 81.2±9.2%; p=0.05). No differences were found in relation to ventilatory reserve and dynamic hyperinflation during exercise. Of the 4 patients who presented EIB, 3 (75%) had reduced exercise capacity. Nevertheless, FEV1 alteration post-exercise was not significantly different from those with preserved exercise capacity (-17.8±20.3 vs -5.7±6.7%; p=0.20).

In conclusion, it seems that functional alterations of PBO tend to ameliorate with aging. Those with reduced exercise capacity present lower lung diffusion capacity and greater airway obstruction variability.

P4441

Estimation of the exercise ventilatory compensation point by the analysis of the relationship between minute ventilation and heart rate in patients with pulmonary hypertension

Paolo Marinni1,2, Roberto Badagliaccia3, Matton Bonini1, Roberto Procia2, Mattia Internullo2, Simone Pascale1, Gabrielle Vail1, Paolo Palapane1, Carmine Dato Vizza2, 1Department of Public Health and Infectious Diseases, Lung Function Unit, “Sapienza” University, Rome, Italy; 2Department of Respiratory and Cardiovascular Sciences, “Sapienza” University, Rome, Italy

Background: Incremental cardio-pulmonary exercise test with gas exchange measurement is the gold standard for the identification of the ventilatory compensation point (VCP). It has previously been demonstrated that the change in the slope of increment of minute ventilation over heart rate (AV'E/AHR) can be utilized alternatively to the ventilatory equivalent for CO2 (VE'/V'E) for detection of VCP in healthy subjects. The reliability of this parameter in patients affected by cardiac and pulmonary diseases is still not well elucidated.

Aim: To evaluate the efficacy and reliability of the AV'E/AHR in patients with pulmonary hypertension.

Methods: Twenty subjects (11F – 9M; mean age 44±15.8 SD) with a diagnosis of pulmonary hypertension underwent an incremental maximal exercise test on a cycle-ergometer. VO2, V'E/ V'E CO2 were measured breath-by-breath. Heart rate was also registered. Results are expressed as mean±SD.

Results: All patients reached the VCP showing a mean VO2 max % predicted of 55±15%. As in healthy subjects it was possible to identify two different slopes (61 – 82) of increment in the AV'E/AHR in 14 out of the 20 tested patients (0.78±0.2 vs 1.83±1.0 p=0.002). The remaining 6 patients in whom was not detected a significant difference between the two slopes interestingly showed an altered cardiac function, as shown by the O2 pulse in the final phase of exercise.

Conclusions: AV'E/AHR as a predictor of the VCP, appears to be a useful and reliable method to identify more severe IP patients with an altered cardiac function.

P4442

Critical power for upper limb in patients with COPD

Carla Malagari1, Eduardo Cebocchi2, Talita Stuchli3, Roberta Ramos1, Luiz Nery3, Simone Dal Corso5, 1Physiology, Federal University of Juiz de Fora, MG, Brazil; 2Pneumology, Federal University of São Paulo, SP, Brazil; 3Rehabilitation Sciences Program, Noce de Julho University, São Paulo, SP, Brazil

Introduction: The determinants of the critical power (CP) for whole-body exercise (lower limbs) in patients with COPD have been previously identified. There are no data concerning to its determinants for upper limbs (UL) in this population.

Objective: To characterize the determinants of the CP for UL in patients with COPD.

Methods: Eight patients with COPD (FEV1: 45±1±1.2% of predicted) and seven healthy subjects were assessed. After an arm incremental test on cycle ergometer, three constant workload tests were performed (100%-20%, 90% and 80% of peak workload). From these tests the CP was estimated and an additional test was performed (5-20% above the workload of the estimated CP). Then, CP was deter-

mined by the intercept of the linear regression between workload and reciprocal of time for the four tests and was confirmed in a new test. The inspiratory capacity (IC) was measured before and immediately after each test.

Results: There was no significant difference in the CP workload between patients and controls (30.2±12.7 Watts - 59.8±11.4% of peak workload vs 42.2±16.7 Watts - 66.7±9.3% of peak workload, respectively). The oxygen uptake in CP was lower in the COPD group than controls (0.79±0.28 L/min vs 1.20±0.37 L/min, respectively, p<0.05). The patients presented dynamic hyperinflation and substantial reduction of ventilatory reserve for all tests, including the CP test. Despite the ventilatory limitation, all patients were able to sustain exercise at CP for 20 minutes.

Conclusion: The present study shows that the ventilatory constraint is the most important determinant of the CP for UL exercise in COPD patients.

P4443

Physiological responses at critical load on resistance exercise – Effects of aging process

In this study it was observed that functional alterations of POB tend to ameliorate with aging. Those with reduced exercise capacity present lower lung diffusion capacity and greater airway obstruction variability.
which indicates the transition of moderate to intense exercise. However, it appears
the influence of age on differences in CL remains to be investigated.

Aims: The objectives of the study were to: 1) determine the intensity of CL during
RE, and 2) evaluate the behavior of cardiorespiratory and metabolic responses
during RE at the CL in young and older subjects.

Methods: We evaluated 12 young (23±3 years) and 10 elderly (70±2 years)
apparently healthy males, who underwent: 1) a repetition maximum (1RM) test
on Leg Press and, 2) on different days, three high-intensity resistance exercise
continuous load tests (60%, 75% and 90% 1RM) in order to obtain CL by linear
regression: load X reverse of time (Tim = duration of exercise until fatigue).

Results: Absolute values of both the CL asymptote and curvature constant (kg)
were significantly lower in elderly subjects (p<0.05). In contrast, both groups have
the same value for CL = 52%RM. As expected, actual oxygen consumption (VO2)
and heart rate (HR) values obtained during CL exercise testing were significantly
reduced in older subjects. However, percent-predicted aerobic capacity values were
significantly higher in older subjects (P<0.05). In addition, blood lactate ([La-])
corrected to Tim were greater in younger subjects at all intensities (p<0.05).

Conclusion: These findings suggest that the despite reduced force production
in older subjects, endurance-related parameters are well preserved according to
to age-related predictions. VO2 was also aparently healthy males.

Financial support: FAPESP No. 2009/1842-0.

P4444

Impaired cardiac output responses to incremental exercise measured by
signal-morphology impedance cardiography in advanced COPD
Luzia Castro1, J. Alberto Neder1, Alain Duhamel2, Benoit Wallaert1.
Miguel Rodrigues, J. Alberto Neder. Respiratory Division, Pulmonary Function
and Clinical Exercise Physiology Unit (SEFICE), Federal University of Sao
Paulo, SP, Brazil

Background: There is renewed interest in the continuous evaluation of cardiac
output (Q'T) during exercise in patients with chronic obstructive pulmonary dis-
ease (COPD). Signal-morphology impedance cardiography (SMICG) has some
advantages over previous impedance approaches and it might be useful to track
relative changes in exercise Q'T in this patient population.

Objective: To contrast the dynamic changes (Δ) in Q'T as a function of metabolic
demand (O2 uptake, ΔO2V) in patients with advanced COPD and healthy controls.

Methods: 16 males with COPD (11 GOLD stages III-IV) and 9 gender-matched
controls underwent a ramp- incremental test with Q'T being measured by a
commercially-available SMICG system (Physioflow™ PF-05, Manatec, France).

ΔO2V/ΔQ'T relationship was calculated by linear regression.

Results: Patients were significantly younger than controls (61±6 yrs vs. 72±5 yrs,
respective 65%RM). As expected, patients showed lower VO2 (1.02 (1.00-1.04)
compared to controls (p<0.05). There were no significant between-group differ-
ences in the y-intercept or the slope of ΔQ'T (2.0mL/m2/ΔO2V; 2.0mL/minute)(p<0.05).
Interestingly, however, both parameters were lower in patients than controls when
Q'T was expressed as fold-changes (0.90±0.30 vs. 1.22±0.18 and 0.43±0.17 vs.
0.61±0.10, respectively; p<0.05). ΔQ'T at maximal exercise was associated with
peak VO2 in controls (r=0.73; p<0.05) but not in patients (p=0.12).

Conclusions: Semi-quantitative SMICG measurements indicated blunted Q'T ad-
justments to rapidly-incremental exercise in patients with advanced COPD -
even when compared to older healthy controls.

P4445

Exercise ventilatory inefficiency is an independent predictor of mortality
in patients with pulmonary arterial hypertension
Eloara Ferreira1,2, Roberta Ramos1,2, Jaquelina Arakaki1,2, Priscila Barbosa1,
Erika Tremph1, L. Eduardo Nery1, Fabício Veloso1,2, J. Alberto Neder1
1 Respiratory Division, Pulmonary Function and Clinical Exercise Physiology Unit
(SEFICE), Federal University of Sao Paulo, SP, Brazil; 2 Respiratory Division,
Pulmonary Vascular Group, Federal University of Sao Paulo, Brazil

Rationale: An excessive ventilatory (V' E) response to CO2 output (V'CO2) during
incremental exercise is a strong prognosticator in cardiovascular diseases. The role
of ΔV' E/ΔV'CO2 to predict mortality in pulmonary arterial hypertension (PAH),
however, remains to be demonstrated.

Objective: To investigate the value of increased ΔV' E/ΔV'CO2 as a negative
prognostic marker in PAH.

Methods: 80 patients with PAH who underwent a ramp- incremental pulmonar-
diary exercise test (CPET) were followed-up for 5 yrs. ΔV' E/ΔV'CO2 slope was
calculated to the respiratory compensation point (ΔV' E/ΔV'CO2start-RCP) or

Results: 14 patients (17.5%) died of PAH-related causes. Compared to sur-
vivors, deceased patients were younger and had lower peak O2 uptake, O2 pulse,
and maximal lactate concentration but, regardless of the method of calculation, higher
ΔV' E/ΔV'CO2 (p<0.05). None of the other variables (including the six-minute
walking distance) was related to mortality (p>0.05). The best cutoff to death predic-
tion was higher for ΔV' E/ΔV'CO2start-RCP (AUC: 0.73; p<0.05) than ΔV' E/ΔV'CO2start-max
(45-5). An univariate analysis revealed that the former variable was superior to the
later on this regard (p=0.004 vs. 0.02). In fact, a multiple regression anal-
ysis showed that resting heart rate (hazard ratio (HR): 95% CI= 1.04 (1.00-1.08)
(p=0.03) and ΔV' E/ΔV'CO2start-RCP (1.04 (1.01-1.10); p=0.006) were the only
independent predictors of mortality.

Conclusions: A resting variable (heart rate) and an effort-independent marker of
ventilatory inefficiency (ΔV' E/ΔV'CO2start-RCP) are clinically-useful markers of
poor prognosis in patients with PAH.
(Armband\textsuperscript{8}), QoL questionnaire (AQLQ) and walking test (6MWT) with VE analysis (Spiropalm, Cosmed).

**Results:** 19 subjects were obese (OB), 17 overweight (OW), 12 normal weight (NW). FEV1\% was < in subjects with BMI $\geq$ 25 (72.1±17 vs 81.5±17, ns). PAL (METs) in OB was < OW and NW (1.3±0.2 vs 1.5±0.3; 1.5±0.2, *) independently from the severity of obstruction. No difference in QoL was found. OB and OW showed a reduced exercise capacity and SpO2\% in comparison to NW.

**Conclusions:** In asthmatics, obesity influences negatively the daily physical activity and exercise capacity through mechanisms which appear independent from the severity of bronchial obstruction.

P4449

**Laboratory exercise tests are not representative of the real physical activity in more severe COPD patients**

Francesco Costa, Laura Malagrinò, Gianna Decusatis, Sandra Antonelli, Claudia De Simone, Sabrina Santerini, Barbara Vagaggini, Pierluigi Paggiaro.

Cardiothoracic and Vascular Department, University of Pisa, Italy

**Background:** Cardiopulmonary exercise test (CPET) is the gold standard to evaluate the exercise tolerance. Incremental shuttle walking test (ISWT) has ventilatory and metabolic responses similar to those of CPET in moderate-severe COPD. Sensewear Armband is a new device to quantify the physical activity of daily life.

**Aim:** To evaluate the correlations among CPET, ISWT and daily physical activity, measured by Armband, in patients with COPD of different severity.

**Subject and methods:** In cross sectional study 45 COPD patients (FEV1\%: 52.5±17, 36 male) evaluated: CPET, ISWT, pulmonary function test (PFT), dyspnea scale (MRC), steps/day and total energy expenditure (TEE) by Armband (as a mean of a 7-day monitoring period). The patients were divided according to FEV1 ($>50\%$ or $\leq 50\%$) and MRC ($\leq 2$ or $> 2$).

**Results:** CPET and ISWT significantly correlated between them, better in patients with FEV1 $>50\%$ and in those with MRC $> 2$. In COPD patients with FEV1 $>50\%$, steps/day (r=0.405, r=0.582) and TEE (r=0.494, r=0.615) significantly correlated with CPET and ISWT, respectively, while this did not occur in COPD patients with FEV1 $<50\%$. Similarly, steps/day (r=0.423, r=0.575) and TEE (r=0.319, r=0.494) significantly correlated with CPET and ISWT in COPD patients with a MRC $<2$, respectively, while this did not occur in COPD patients with MRC $>2$.

**Conclusion:** Exercise tolerance evaluated in laboratory by CPET and ISWT is representative of the real physical activity, as expressed by steps/day and TEE, in patients with moderate COPD but not in patients with severe COPD. In these patients, physical activity evaluation may offer complementary informations to the laboratory exercise assessment.
4512
The effect of passive smoking on body height, body weight, peak expiratory flow rate and motor skills in children
Ivan Pavic, Pero Pavic, Slavica Dodig, Jasna Cepin-Brogovic, Marinka Krmecki

Passive smoking is strongly linked to a range of adverse child health outcome. The objectives of the present study were to assess: 1) proportion of school children passively exposed to cigarette smoke; 2) the impact of passive smoking on body height and body weight; 3) the influence of passive smoking on peak expiratory flow rate (PEFR); and 4) on the motor skills in school children. This prospective study included 133 children, 66 males and 67 females, aged from 11 to 14 years. Subjects were divided in two groups depending on parental smoking habits: Group I - children of smoking parents who smoke 10 or more cigarettes per day (88/133=66.6%) and Group II - children of non-smoking parents (45/133=34%). For the assessment of motor skills 6-minute run test (F-6 test) was used. 88/133 (66.6%) children have been exposed to passive smoking, while 45/133 (34%) children came from families of non-smoking parents. There was no statistically significant difference in either height or in weight. The PEFR (L/min) values for Group I were statistically lower [320 (300-370)] than in control group of children [380 (347-405)] (P<0.0001). The median F-6 test values for Group I were statistically lower [2 (1-3)] than in control group of children [4 (3-5)], respectively (P<0.0001). Children of smoking parents have statistically significant lower grade of motor skills and statistically significant lower PEFR value than children of non-smoking parents. Public health preventive actions should go toward minimizing the exposure of children to passive smoking by counseling the smoking parents that quitting smoking provides enormous health benefits not only to them but also to their children.
4516 Intervention study to evaluate effectiveness of integrated therapy (varenicline plus motivational interviewing) for smoking cessation in diabetic patients
Pasquale Caponnetto1, Biomedicina Clinica e Molleolare, University of Catania, Italy

Background: The prevalence of smoking among people with diabetes is similar to that in the general population. For smokers with diabetes, however, the complications incurred are not equal. All-cause mortality is increased in smokers with diabetes, and the risk of macro and microvascular complications is also increased (1).

Aim and objectives: We designed a study to monitor possible modifications in the smoking habits of 40 diabetic smokers experimenting and Integrated Therapy (Varenicline plus Motivational Interviewing) focusing on smoking reduction and smoking abstinence.

Methods: Study participants were invited to attend a total of five study visits: at baseline, week-4, week-8, week-12 and week-24. Number of cigarettes smoked, and exhaled carbon monoxide levels were measured at each visit. Smoking reduction and abstinence rates were calculated. Adverse events were also reviewed.

Results: Sustained 50% reduction in the number of cig/day at week-24 was observed in 45% of participants. Sustained smoking abstinence at week-24 was observed in 40% of participants.

Conclusion: The use of Integrated Therapy (Varenicline plus Motivational Interviewing) improves smoking cessation and reduction in diabetic smokers intending to quit.

4517 Earthquake rattled Christchurch residents reach for cigarettes
Lutz Beckert1, Nick Erskine1, Bronwen Rhodes1, Sue Stevenson2, Vernon Daley1, 1Department of Medicine, University of Otago, Christchurch, New Zealand; 2Respiratory Medicine, Canterbury District Health Board, Christchurch, New Zealand

The magnitude 7.1 Canterbury earthquake in September 2010 and associated after-shocks have caused untold damage, drastically changed residents’ living, working, social conditions and taken the lives of 184 people. Aims: To assess the impact of the Christchurch earthquakes on changes in smoking status and tobacco consumption of current smokers.

Methods: Semi-structured interviews in public locations with high pedestrian flow, including two city malls and the central bus exchange. The interviews were carried out 15 months after the first major earthquake. A total of 1001 people were interviewed.

Results: At the August 2010 point (prior to any earthquakes) 589 (58.9%) had smoked cigarettes or tobacco at some point in their lives; 406 (40.9%) never smoked and three participants (0.3%) were not sure. Of the 319 people who were not smoking in August 2010, 76 (23.8%) had smoked at least one cigarette since the September earthquake, 29 (38.2%) of whom had smoked more than 100 cigarettes. Of the 273 participants smoking in August 2010, 86 (31.5%) had since decreased consumption, 94 (34.4%) had not changed, deletion and 93 (34.1%) to the earthquakes increased their consumption.

Conclusion: The prevalence of smoking in Christchurch has increased in the 15 months following the first major quake in Sept 2010. 28% of people not smoking prior to the earthquakes smoked one or more cigarettes and people smoking prior to the earthquakes increased their consumption.

4518 Eyjafjalla jökull 2010: Respiratory morbidity and symptoms following exposure to a volcanic eruption
Hanne Krae Cirlin1,2, Arna Hauksdóttir1, Unnur Anna Valdimarsdóttir1, Thorarinn Gíslason3,4,5, 1, 2Department of Environmental Health, National Institute for Health and Welfare, Kaupio, Finland; 3Pediatric Research Center, Tampere University Hospital, Tampere, Finland; 4Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany

Introduction: Few cohort studies are available on the association between moisture damage, confirmed by technical inspection, and risk of new asthma. Aims: To study the association between confirmed moisture damage at the age of 5 months on average and risk of asthma by the age of 6 years. Methods: Building inspection was performed by building engineers in the homes of 394 children, and the children were followed up with repeated questionnaires from birth to the age of 6 years. Current asthma was defined as doctor diagnoses of asthma ever and either current asthma medication or wheezing symptoms at the age of 6 years. Odds ratios (OR) were adjusted for potential confounders using discrete time hazard model and GEE.
Results: Severe moisture damage in the kitchen (OR 2.80, 95%CI 1.02-7.64) or in the child’s bedroom (OR 3.65, 95%CI 1.00-13.28) and visible mold in the child’s bedroom (OR 4.02, 95%CI 1.07-15.94) increased the incidence of doctor diagnosed asthma ever in life (p<0.001). Similar associations were observed with current asthma (n=33) and with wheezing apart from cold. Weak associations were observed with moisture damage in the main living areas. No consistent associations were observed with moisture damage in the bathrooms or in other interior spaces of the house. There was some suggestion that the associations were weaker during the latter part of the follow-up.

4519 Outdoor exposure to formaldehyde is associated with increased DNA damage and respiratory symptoms in children
Paolo Girardi1, Maria Enrica Fracasso2, Alessandro Marcon1, Denise Doria1, Linda Guarda3, Pierpaoio Marchetti1, Giancarlo Pesce1, Vanda Pironi2, Giorgio Siliprandi4, Paolo Ricci3, Roberto de Marco1, 1Unit of Epidemiology and Medical Statistics, University of Verona, Italy; 2Section of Pharmacology, University of Verona, Italy; 3Unit of Epidemiology, NHS Mantua, Mantua, Italy; 4Department of Mantua, Environmental Protection Agency, Mantua, Italy

Background: Exposure to air pollutants emitted by industrial sources may be a health hazard for children living nearby. Objectives: To evaluate whether residential outdoor exposure to formaldehyde was associated with DNA damage and with respiratory symptoms in children who lived in the largest chipboard manufacturing area in Northern Italy (Viadana). Methods: In 2010, randomly selected children (6-12 years) living in the Viadana district were surveyed through a parental questionnaire on respiratory symptoms. A score was devised to evaluate the presence/intensity of asthma-like symptoms. DNA strand breaks and nuclear abnormalities of the oral mucosa cells were analyzed by the comet assay and micronucleus assays respectively. Passive samplers (n=63) were installed in the area to monitor formaldehyde both in winter and summer 2010. Kriging interpolation was used to estimate the concentration of formaldehyde of each child. Appropriate regression models were fitted to the data. Results: 417 out of 656 eligible children (64%) took part in the study. Children living near (<2 km) the chipboard factories had the highest (p<0.001) formaldehyde exposure. A 1-standard deviation increase in formaldehyde (+6.16 μg/m3) was associated with an increase of 10% (95%CI 1.5-20%) in the comet tail intensity and of 10% (95%CI 1.1-19%) in the frequency of nuclear buds. Children exposed to the highest level of formaldehyde (>85th centile) had an increased risk of asthma like symptoms (OR=2.1; 1.1-4.2).
Conclusions: Exposure to pollutants emitted by chipboard industries statistically significantly increased DNA damage and asthma-like symptoms in children.

4520 Confirmed moisture damage and risk of asthma from birth to age 6 years
Joua Pekkanen1, Anne M. Karvonen1, Matti Korpi2, Jon Genuenitz1, Anne Hyvärinen3, 1Department of Environmental Health, National Institute for Health and Welfare, Kaupio, Finland; 2Pediatric Research Center, Tampere University Hospital, Tampere, Finland; 3Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany

Background: The eruption of Eyjafjallajökull, Iceland 2010 posed an opportunity to study health effects of a volcanic eruption in a society with strong infrastructure. The aim of the study was to evaluate the health of the exposed population compared to control population.

Methods: Six months after the eruption, (fall and winter 2010-11), 1148 exposed South Icelanders and 510 unexposed North Icelanders responded to a questionnaire on recent physical symptoms and questions from the European Community Respiratory Health questionnaire. The data was analyzed using logistic regression adjusted for age, gender, education and smoking status.

Results: Demographic characteristics and underlying disease rates were similar in the two groups. The exposed group reported more symptoms during the last 12 months; more phlegm in exposed group, OR 1.5 (95%CI 1.3-1.8) and ruffled stuffed nose, OR 1.4 (95%CI 1.2-1.6). Recent (last month) symptoms were more increased, for example cough, OR 2.6 (95%CI 1.7-3.8) and phlegm, OR 2.1 (95%CI 1.3-3.2), eye irritation, OR 2.9 (95%CI 1.8-4.5) and runny or irritated nose, OR 2.0 (95%CI 1.4-2.9). Respiratory symptoms were more prevalent among those living closest to the volcano. Upper airway symptoms coexisted, so those who reported one symptom were likely to have others also.

Discussion: Six months after the Eyjafjallajökull eruption our results indicate that the presence of volcanic ash is associated with two to three times higher recent upper airway symptom rates among the exposed population compared to the unexposed.

Conclusion: Exposure to volcanic ash may increase respiratory morbidity symptoms six months post eruption, but long-term consequences are still unknown.
Conclusions: The results are consistent with our earlier report over the first 1.5 years of life (Karvonen et al. 2009). The results support earlier conclusions that moisture damage not only increases the risk of respiratory symptoms, but is also associated with increased risk of developing new asthma.

4521
Home dampness and mould, β(1,3)-D-glucan in mattress dust and respiratory symptoms in adults from 10 European countries

Jan-Paul Zeck1, Geert Dockx2, Dan Norback3, Marco Olivieri4, Simona Villani5, Juha Peikkanen6, Dick Heederik7, Joachim Heinrich8, Deborah Jarvis9, Anne Hyvärinen10, 1Centre for Research in Environmental Epidemiology (CREAL), Hospital del Mar Research Institute (IMIM), Barcelona, Spain; 2Division of Environmental Epidemiology, Institute for Risk Assessment Sciences (IRAS), Utrecht, Netherlands; 3Department of Medical Sciences, Uppsala University, Uppsala, Sweden; 4Unit of Occupational Medicine, University Hospital, Verona, Italy; 5Department of Health Science, University of Pavia, Italy; 6Department of Environmental Health, National Institute for Health and Welfare (THL), Kuopio, Finland; 7Institute for Epidemiology, Helmholtz; Zentrum München, Munich, Germany; 8Respiratory Epidemiology and Public Health Group, Imperial College, London, United Kingdom

β-glucans are pro-inflammatory fungal cell wall components that have been associated with adverse respiratory health effects in children. We measured β(1,3)-D-glucans in mattress dust samples from 973 randomly selected adults from 22 ECRHS study centres in 10 European countries using an enzyme immunoassay. Information on respiratory symptoms, housing characteristics, dampness and mould was obtained by face-to-face interviews and home visits following a common protocol. Study centre explained 28% of the total variance in glucan concentration, with geometric means ranging from 0.40 to 1.77 μg/g in Reykjavik, Iceland, to 1.77 μg/g in Barcelona, Spain. Damp or mould problems in the previous years were reported by 30% of the participants (range 11-50% across centres) and was significantly associated with a 10% higher glucan level when controlling for centre. Mattresses older than 5 years contained on average 20% more glucan than mattresses less than one year old. The presence of a cat or a dog in the home increased 17-24% the glucan concentration. Nasal symptoms in the previous year (overall 38%) were more prevalent when damp or mould was reported (adjusted Odds Ratio (OR) 1.35; 95%CI 1.00-1.82). However, nasal symptoms were not associated with glucan level (OR 1.00 without indications for heterogeneity across centres). Similarly there was no association of asthma-symptom score with mattress glucan level. In conclusion, β(1,3)-D-glucans are ubiquitous in mattress dust from European homes. Although weakly associated with damp and mould problems there was no evidence that mattress levels of β(1,3)-D-glucans were associated with respiratory health in adults.

4522
Exhaled nitrogen oxide (FeNO) and nasal patency in adults in relation to levels of airborne fungal DNA in dwellings in Lund, Sweden

Guillermo Wieslander1, Guohui Cui1, Christina Issa owns2, Anders Gudmundsson3, Mats Bohgard4, Erik Nordin5, Aneta Wierzbicka2, Dan Norback1, 1Dept. of Medical Science, Uppsala University, Occupational and Environmental Medicine, Uppsala, Sweden; 2LTH, Lund University, Division of Ergonomics and Aerosol Technology, Lund, Sweden

Background: Questionnaire studies have reported associations between indoor moulds and dampness, asthma and rhinitis. We investigated if levels of fungal DNA in dwellings were associated with nasal patency, tear film stability, and levels of exhaled NO.

Methods: Totally 49 adults from 42 homes, randomly selected from a larger population survey in the city of Lund, Scania, Sweden. Exhaled NO was measured by NIOX MINO (50 ml/min). Nasal patency was measured by acoustic rhinometry. Tear film break up time (BUT) was monitored as a sign of eye irritation. FeNO was measured by NIOX MINO (50 ml/min). Nasal patency was measured by acoustic rhinometry. Tear film break up time (BUT) was monitored as a sign of eye irritation. FeNO by NIOX MINO (50 ml/min). Nasal patency was measured by acoustic rhinometry. Tear film break up time (BUT) was monitored as a sign of eye irritation. FeNO

Results: Three types of fungal DNA was commonly found in the homes. Exhaled NO was higher at higher concentrations of total fungal DNA (p<0.04). Mean cross-sectional area in the front part of the nasal cavity was decreased at higher levels of Aspergillus/Penicillium DNA (p=0.05), and posterior cross-sectional area was decreased at higher levels of Aspergillus versicolor DNA (p=0.05). No associations were found between BUT and fungal DNA.

Conclusion: Fungal DNA in settled dust in random selected ordinary homes can be a risk factor for nasal inflammation, measured as decreased nasal patency, and lower airway inflammation measured as exhaled NO.

4524
Lung function decline in elderly in relation to phthalate metabolites and bisphenol A levels in serum: A 2-year prospective study

Dan Norback1, P. Monica Lind1, Gunilla Wierslander1, Lars Lind1, 1Dept. of Medical Science, Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden; 2Dept. of Medical Science, Acute and Internal Medicine, Uppsala University, Uppsala, Sweden

Background: Some recent studies report associations between phthalate exposure and asthma in pre-school children. We investigated if circulating levels of phthalates and bisphenol A (BPA) predicts lung function decline in an elderly population.

Methods: PIVUS is a cohort, based on a population sample of subjects, aged 70 years in Uppsala, Sweden. Circulating levels of BPA and phthalate metabolites in serum was measured at baseline by LC/MS/MS. Lung function was measured at baseline and after 5 years in 668 subjects. Change of forced expiratory volume in 1 s (FEV1) was calculated. Associations were analysed by multivariate modelling adjusting for height, smoking at 70 and 75 y, pack years of tobacco at 70 y, education level, exercise habits and gender, using log-transformed values for circulating levels, excluding 36 subjects with asthma or COPD at baseline.

Results: BPA median level was 3.75 ng/mL, Monophenyl hexyl phthalate (MEHP) 4.51 ng/mL, monophenyl tetratlate (MEP) 11.6 ng/mL, Monomethyl phtalate (MMP) 1.51 ng/mL, Monoisobutyl phtalate (MiBP) 4.51 ng/mL, monethyl phtalate (MEP) 11.6 ng/mL, Monomethyl phtalate (MMP) 1.51 ng/mL, with no gender differences. The annual decline in FEV1 was -55.6 ml/year. MEHP was associated with an additional decline in FEV1 of -6.0 ml/year (95% CI -8.6 to -3.4) (p<0.001), while MMP was associated with an additional improvement in FEV1 of 6.6 ml/year (95% CI 3.2 to 9.8) (p<0.001). The association for MEHP was significant in both men and women, while the association for MMP was significant in women, only.

Discussion: Associations between circulating levels of some phthalates metabolites and the five year decline of FEV1 were found, with MEHP as a risk factor for lung function decline.

4525
Measuring concern about pollution in questionnaire-based environmental surveys

Alessandro Marcon1, Giang Nguyen1, Marco Braggioni2, Marta Rava3, Maria Elisabetta Zanolin1, 1Unit of Epidemiology and Medical Statistics, University of Verona, Italy; 2Department of Economics, Ca’ Foscari University, Venice, Italy; 3Centre for Research in Epidemiology and Population Health, University Paris Sud, Paris, France

Understanding attitudes towards pollution in the population might help to prevent bias in questionnaire-based environmental studies, because subjects living closer to emission sources may be more concerned than those who live farther away, thus tending to over-report adverse health outcomes.

Using data from a survey on parents of 3697 school-age children (response rate 99%) in an industrial area in northern Italy (Viadana), we devised a score on environmental concerns (EC), evaluated its psychometric properties and its association with several determinants.

Six questions surveyed respondents’ concerns about electromagnetic fields (EMFs),...
472. Interstitial lung disease: from bench to bedside

4526 Clinical features common to five cases with secondary pulmonary alveolar proteinosis complicated with Behcet disease

Tosinbiiro Handa1,2, Ayu Nishida3, MichihiroUCHiyama4, Takeshi Nakatuse4, Motoo Baba5, Yoshikazu Inoue5, Toshihiro Iwakura6, Toshinori Takada6, Masanori Akira7, Yasutaka Hisihiro8, Kiyohiro Aoki9, Kohei Ikuse10, Emi Hamano11, Sonoko Nagai11, Michiaki Mishima12, Hajime Goto13, Koh Nakata14, Haruyuki Ishii15, 1Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2Department of Rehabilitation Medicine, Kyoto University Hospital, Kyoto, Japan; 3Department of Hematology, Tohoku University Hospital, Sendai, Japan; 4Department of Hematology, Tokayosakura, Japan; 5Department of Dif fuse Lung Diseases and Respiratory Failure, NHO Kinki Chuo Chest Medical Center, Sakai, Japan; 6Department of Respiratory Medicine, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan; 7Division of Respiratory Medicine, Graduate School of Medical and Dental Sciences, Niigata University, Niigata, Japan; 8Department of Respiratory Medicine, Tohoku Chuo Hospital, Tomiyasu, Japan; 9Department of Respiratory Medicine, Koyan University School of Medicine, Mitaka, Japan; 10Bioscience Medical Research Center, Niigatu University, Niigata, Japan

Pulmonary alveolar proteinosis (PAP) is a rare lung disorder characterized by abnormal accumulation of surfactant materials in the lower respiratory tracts. It is classified into three distinct types according to etiology: autoimmune, secondary, and congenital PAP. Secondary PAP (SPAP) comprises ten percent of acquired PAP. Twenty-eight patients with more than 70% increase in the expression of genes that control important B-MSC functions. The mechanisms affected by the decrease in gene expression include cellular trafficking, cellular growth, and proliferation.

Conclusion: Old B-MSCs have a different expression profile that exhibits a decrease in the expression of genes that control importan B-MSC functions.

4529 LSC 2012 Abstract – Age-related changes in the relative expression of functional genes in mesenchymal stem cells

Martina Sterclova1, Martina Vasakova1, Peter Paluch1, Milan Paulik2, 1Department of Respiratory Diseases, Thomayer University Hospital, Prague, Czech Republic; 2Department of Immunology, Thomayer University Hospital, Prague, Czech Republic

Chronic form of extrinsic allergic alveolitis (EAA) may have common features with idiopathic pulmonary fibrosis (IPF). The aim of presented study was to compare serum SP-A concentrations in IPF and chronic EAA patients and detect possible relationships of SP-A levels, bronchoalveolar lavage fluid (BALF) differential cell counts and high resolution computed tomography (HRCT) patterns in both diseases.

Three patients with chronic EAA and 7 patients with IPF were enrolled. All subjects underwent evaluation of SP-A serum concentrations, HRCT of the chest and BALF. HRCT alveolar and interstitial scores (HRCTa, HRCTb) were assessed according to Gay S1.

EAA patients had significantly higher HRCT alveolar score then IPF group (p<0.003). Chronic EAA group exhibited positive correlation between HRCTa and BALF eosinophils (p<0.01) [Fig. 1]. Serum SP-A concentrations did not differ between both groups.

Figure 1. Positive correlation between HRCTa and BALF eosinophils in chronic EAA patients.

Our study shows that SP-A serum concentrations do not differ between chronic EAA and IPF patients and thus should not be used as a biomarker for IPF detection. Prognostic value of serum SP-A concentrations in chronic EAA patients should be the aim of further studies.

Effect of nintedanib on silica-induced lung inflammation and fibrosis in mice

Idiopathic pulmonary fibrosis is the most devastating fibrotic diffuse parenchymal lung disease which remains refractory to available pharmacological therapies. Therefore, novel treatment options are urgently required. Protease-activated receptor (PAR)-1 is a heterodimeric G protein-coupled receptor that mediates critical signaling pathways in pathology. Interestingly, bleomycin-induced lung fibrosis was shown to be diminished in PAR-1 deficient mice. We thus hypothesized that pharmacological PAR-1 inhibition may be an interesting therapeutic approach to combat pulmonary fibrosis. Consequently, we explored the effect of P1pal-12 (a peptidomimetic blocking the PAR-1G-protein interaction) during the development of lung fibrosis induced by intranasal instillation of bleomycin. We show that daily treatment with 0.5, 2.5 or 10 mg/kg P1pal-12, reduced severity and extent of fibrotic lesions in a dose-dependent manner (2.5 and 2 fold reduction with 2.5 and 10 mg/kg). These findings correlated with significant decreases in fibronectin, collagen and atheroma expression levels in treated mice. Moreover, fibrin deposition in the lungs was reduced by 26% ± 3% (p<0.05) in 2.5 mg/kg treated mice compared to untreated controls. Finally, P1pal-12 reduced bleomycin-induced IL-6 and MCP-1 levels in lung homogenates by 65% ± 3% (p<0.01) and 36% ± 3% (p<0.05) respectively. Overall, our data show that P1pal-12 limits lung fibrosis suggesting that targeting PAR-1 may be a promising therapeutic strategy for pulmonary fibrosis.

Introduction:

One-year treatment with the receptor tyrosine kinase inhibitor nintedanib (BIBF 1120) specific for vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR) was associated with a 68%-reduction in the rate of decline of forced vital capacity in patients with idiopathic pulmonary fibrosis (IPF) versus placebo, which approached statistical significance.

Aim: To further explore its mode of action, nintedanib was tested in a mouse model of silicosis displaying ongoing pulmonary inflammation and fibrosis.

Methods: Silica was administered intranasally to generate a single intranasal administration of silica causing a robust lung inflammation with a significant increase in macrophages, neutrophils and lymphocytes in the BALF, increased IL-1 beta, CXCL1/KC and TIMP1 production, and increased collagen deposition in the lung. To further investigate the pathogenesis of pulmonary inflammation with collagen formation and fibrosis demonstrated by collagen staining.

Results: Nintedanib administered by gavage at 30 and 100 mg/kg/day significantly reduced neutrophil and lymphocyte counts, but had no effect on macrophage counts in the BALF.

Furthermore, IL-1 beta, CXCL1/KC, TIMP1, collagen in lung and lung inflammation with granuloma and fibrosis were drastically reduced.

Conclusion: Nintedanib effectively reduced silica-induced chronic inflammation and fibrosis in mice. The anti-inflammatory and anti-fibrotic features of nintedanib may impact the progressive course of fibrotic lung diseases like IPF or silicosis.

4532 Telomere (TL) shortening is associated with disease severity in scleroderma (SSC) (ILD) patients

Husnaa L. Adamali1, Cesar M. Delgado1, Carmel Stock1, Gisela E. Lindhal1, P. M. L. O'Callaghan1, Bernhard Ryffel2, C. Lin3, J. W. Doustman3, K. Borenzajani3, C. A. Spek4, K. C. TL length is significantly associated with disease extent in SSC-ILD.

4533 Mechanistic studies in airway cell biology

4534 Acute effect of cigarette smoke on proteasome function

Sahibe van Ruyl1, Bonna Keller1, Gerrit John1, Katrina Kolbe2, Onder Yildirim3, Oliver Eickelberg1,2, Silke Meinesz1,3, 1Comprehensive Pneumology Center, Helmholtz Zentrum München, Germany; 2Institute of Lung Biology and Disease, Helmholtz Zentrum München, Germany

Background: Chronic obstructive pulmonary disease (COPD) is associated with an abnormal inflammatory response of the lungs to cigarette smoke (CS). The products of CS oxidatively modify proteins thereby inducing severe oxidative cellular damage. The ubiquitin proteasome system serves as the major disposal system for oxidatively modified proteins and is thus essential for proper cellular

Figure 1. Comparison of telomere length in individuals with limited and extensive SSC associated ILD. Box and whisker plot demonstrating mean and 95% confidence intervals with outliers.

Our observation suggests an important role for premature cellular senescence in the pathogenesis of SSC-ILD. HA is an ERS-Fellow.
function. However, its role in CS-induced cell damage is currently unknown. We hypothesized that CS exposure impairs the function of the proteasome resulting in accumulation of oxidatively modified proteins, and exacerbation of cellular stress.

Methods and results: Treatment of human lung epithelial cells with CS resulted in time and dose-dependent decrease of survival and increase of intracellular reactive oxygen species. The increased levels of oxidative stress correlated with accumulation of oxidatively modified proteins. CSE exposure also induced accumulation of polyubiquitinated proteins. Notably, treatment with CSE significantly impaired all three proteasomal activities at high doses. The trypsin-like activity was also reduced in nontoxic CSE doses. Expression of the proteasome was unaffected. To confirm these observations in vivo, mice were exposed for 3 days to CS. Importantly, the trypsin-like activity of the proteasome was significantly reduced in lungs of smoked mice. We also observed increased levels of polyubiquitinated proteins in tissue extracts of smoked lungs compared to controls.

Conclusion: Our data clearly indicate that acute cigarette smoke exposure impairs proteasome function in the lung. Reduced proteasomal protein degradation might thus contribute to the detrimental cellular effects of cigarette smoke exposure in COPD.

4535 Decreased levels of elafin in the lungs of patients with acute lung injury as a result of proteolytic cleavage by the proteasome

Clifford Taggart, Ansel Kerin, Cecilia O’Kane, Sinead Weldon, Allen Chang, Rodney Levine, Thelma Craig, Danny McAuley.

Centre for Infection and Immunity, Queen’s University Belfast, Northern Ireland, United Kingdom

Laboratory of Biochemistry, National Heart, Lung, and Blood Institute, NIH, Bethesda, MD, United States

Unregulated protease activity may drive dysregulated pulmonary inflammation implicated in acute lung injury (ALI). Elafin is a potent serine protease inhibitor produced locally in the lung by epithelial and inflammatory cells with anti-inflammatory properties. In this study we assessed the temporal changes in elafin concentration in patients with ALI and evaluated whether a decrease in elafin levels are due to proteolytic degradation. Patients with ALI within 48 hours of onset of ALI (n=37), day 3 (n=19) and day 7 (n=9) as well as healthy volunteers undergoing high-resolution laryngoscopy (BAL) were included. The serum levels of elafin were measured by ELISA. To determine whether elafin was susceptible to proteolytic cleavage. Western blot analysis of recombinant elafin incubated with BAL fluid revealed protease inhibitors was carried out. Elafin was significantly increased at the onset of ALI compared to healthy volunteers (39.5±5mg/l vs 0.5±0.1mg/l; p<0.0004). Elafin levels fell significantly by day 7 compared to baseline (16±4.3mg/l vs 39.5±5mg/l; p<0.01). Incubation of exogenous elafin with BAL ALI fluid revealed that elafin underwent proteolytic cleavage. In contrast, proteolytic cleavage was not observed following incubation of exogenous elafin with healthy volunteer BAL fluid. Pre-incubation of ALI BALF with trypsin and chymotrypsin-like inhibitors abrogated this degradation of elafin. In addition, we demonstrated increased levels and activity of 20S proteasome in the BALF of ALI patients compared to healthy volunteer BAL fluid and confirmed that 20S proteasome was responsible for cleavage of elafin in ALI BALF which inactivated elafin’s anti-elastase activity.

4536 Klotho: An important protein in the formation and development of emphysema

Xin Yao, Cheng Yuan, Jiangying Zhang, Lin Zhou, Mao Huang, Ian Adcock, Peter Barnes.

1Respiratory and Critical Care Medicine, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China; 2Allergy Disease, NHLI, Imperial College, London, United Kingdom

Objective: Klotho is an anti-aging protein which also possesses anti-inflammatory actions and modulates the cellular responses to oxidative stress. Knockout of klotho in the mouse caused the formation of emphysema. The aim of this study is to investigate the expression of klotho in human emphysema and factors affecting its expression and activity in human bronchial epithelial cells.

Methods: Lung tissue from 5 COPD patients, 8 smokers without COPD and 13 non-smoking, non-COPD. Klotho expression was determined by quantitative real-time PCR. Western blotting and immunohistochemistry. Human bronchial epithelial cells (HBE) were treated with tumor necrosis factor (TNF)-α and hydrogen peroxide (H₂O₂), and the expression of klotho mRNA in cells and protein in cell supernatants was detected by RT-PCR and enzyme-linked immune sorbent assay (ELISA) respectively. Exogenous klotho was also added to HBE and A549 cell cultures and MTT assays were used to detect cell apoptosis.

Results: Klotho was detected in human lung tissue with a clear localization to airway epithelial cells. The level of klotho mRNA and protein in smokers with normal lung function was similar to that in non-smokers but was reduced in COPD patients. The level of klotho expression was similar in COPD patients with emphysema compared with that in non-emphysematous COPD patients. In addition, we found that both TNF-α and H₂O₂ could significantly inhibit the expression and release of klotho in HBE cells. Exogenous klotho inhibited apoptosis in HBE and A549 cells.

Conclusions: Klotho may play an important role in the formation and development of emphysema in COPD. However, further research is needed to explore the underlying mechanism.

4537 Immune activation in α1 antitrypsin deficiency (AATD) emphysema: Beyond the protease/antiprotease hypothesis

Erika Bassani, Simona Lettieri, Francesca Lunardi, Kim Lokar Oliani, Andrea Ballarin, Mario Schiavoni, Graziella Turato, Elisabetta Balestro, Federico Rea, Monica Loy, Manuel Cosio, Marina Saetta, Fiorella Calabrese.

1Laboratory of Biochemistry, National Heart, Lung, and Blood Institute, NIH, Bethesda, MD, United States; 2Istituto di Biologia e Cibi e Voci di Medicina, University of Padova and Padova City Hospital, Padova, Italy; 3Meakins-Christie Laboratories, McGill University, Montreal, Canada

The protease/antiprotease hypothesis has long set the field in the pathogenesis of AATD related emphysema, while activation of lymphocyte-driven responses has been scarcely investigated in this condition. We performed this study to evaluate the involvement of adaptive immune responses in AATD patients. By immunohistochemistry and molecular analysis we evaluated number, topographical distribution and clonality of lymphoid follicles in native lungs of AATD patients undergoing transplantation for severe emphysema (defects matched compared to patients with similar disease severity, but with normal AAT levels (n=26) and to smoking (n=17) and nonsmoking (n=12) controls. Lymphoid follicles (LF) were significantly increased in the lungs of emphysematous patients, either with AATD (4.1±0.7±1.3 LF/cm²) or without AATD (1.5±0.5±1.3) as compared to smoking (0.0±5) and nonsmoking controls (0.0±1, p<0.05). Somewhat surprisingly the number of LF was even more prominent in patients with AATD than in those with normal AAT levels (p<0.05). Follicles in patients with AATD were predominantly located in the lower lobe, where lung destruction predominates. Molecular analysis confirmed an oligoclonal response in B cells isolated from these follicles. In conclusion, our study shows that organization of lymphocytes in follicles is a prominent feature of subjects with severe emphysema and AATD. These results challenge the current paradigm of α1antitrypsin deficiency-related emphysema from a protease/antiprotease driven process to a more complex scenario entailing activation of adaptive immune responses. Funded by Padua University, CARIPARO, Chiesi farmaceutici.

4538 Impact of cigarette smoke exposure on Pseudomonas clearance in wild-type and serpinB1–/– mice

Triziana Patrizia Cremona, Charaf Benarafa, Theodor Kocher Institute, University of Bern, Switzerland

Opportunistic pathogens colonize the lungs of COPD patients and contribute to exacerbations. Cigarette smoke exposure induces pulmonary inflammation and is associated with increased incidence and morbidity of pulmonary infections but specific mechanisms linking smoke exposure to defective microbial clearance remain to be defined. Knock-out mice for serpinB1 (B1–/–), a potent inhibitor of neutrophil proteases, have a severe defect in Pseudomonas clearance associated with increased inflammation, neutrophil death and proteolysis of antimicrobial molecules. In this study, we investigated the combined effects of cigarette smoke exposure and excess neutrophil proteases on Pseudomonas clearance. B1–/– and wild-type mice were exposed to cigarette smoke or room air (control) for 6 weeks and injected intranasally 24h later. As shown previously, control B1–/– mice had a severe defect in bacterial clearance compared to control wild-type mice 20th post infection. Surprisingly, clearance was dramatically improved in smoke-exposed B1–/– mice, which had very low bacterial counts similar to smoke-exposed and control wild-type mice. At earlier time points (4 & 9h post infection), smoke-exposed wild-type mice also had lower bacterial counts than control wild-type mice. All groups of mice had similar bacterial counts 30min after infection suggesting no effect of prior smoke exposure on initial Pseudomonas survival. No increase in Pseudomonas-specific serum antibodies or neutrophil numbers was seen in smoke-exposed compared to their respective control mice. Our findings indicate that protease inhibitor imbalance and acute cigarette smoke exposure differentially affect the kinetics of Pseudomonas clearance in the lung.

4539 Investigations on the role of region-specific IL-13 receptor α1 expression along the airway tree in mucus production in asthma

Christina Voick, Ali Önder Yildirim, Christine Wagner, Heinz Fehrenbach, Michael Wegmann.

1Department of Experimental Pathology, Research Center, Borstel, Germany; 2Comprehensive Pneumology Center, Institute of Lung Biology and Disease, Helmholtz Zentrum Munich, Germany

Increased mucus production is a critical factor impairing lung function in patients suffering from bronchial asthma. In acute and chronic mouse models of allergic asthma, metaplasia of mucus producing goblet cells (GC) was found in proximal but not in distal airways although secretion of interleukin (IL)-13, the main trigger of mucous production was significantly elevated along the whole airway tree. The current study aimed at elucidating which domains of allergic asthma metaplasia of mucus-producing goblet cells (GC) was found in proximal but not in distal airways although secretion of interleukin (IL)-13, the main trigger of mucous production was significantly elevated along the whole airway tree.
Role of nicotinic receptors in the regulation of cytokines production by human lung macrophages

Charlie Ablashi1, Soňa Šmídková Desínová1, Amapro Buenestado1, Emmanuel Naline1, Roger Papke2, Philippe Devillier1.

Background: In addition to its functions as a neurotransmitter, ACh may also serve as an autocrine/paracrine modulator of pulmonary inflammation. Our aims were to investigate the role of cholinergic receptors in the M1 (proinflammatory)/M2 (immunomodulatory) polarization of lung macrophages (LM).

Methods: LM were isolated from human resected lungs challenged for 24hrs with LPS to obtain M1 LM or with IL-13 to obtain M2 LM. Expression of α4/7 nicotinic ACh receptors (nAChRs), M1-5 muscarinic receptors and cytokines was assessed with RT-qPCR, M1- (TNF-α, CCL3, CXCL8 and IL-6) and M2- cytokines (CCL18, CCL22) were quantified in supernatants.

Results: Expression of α7nAChR and M2 and M3 receptors was found in LM. The selective α7nAChR agonist and desensitizing agent GT1-28 (100 µM) inhibited ~50% the production of M1 cytokines after LPS stimulation and of M2 cytokines after IL-13 stimulation. On the other hand, uninhibited LM in the presence of the α7nAChR antagonist α-bungarotoxin (10µM) showed an increased expression of M1 cytokines at both transcriptional (5- to 15-fold) and protein level (2.5- to 46-fold), whereas M2 cytokines were not affected. Two agonists with mixed nicotinic/muscarinic activity that do not induce stable α7nAChR desensitization (acetylecholine and carbacol) and the muscarinic antagonists tiotropium bromide and 4-DAMP were devoid of effect.

Conclusions: The blockade of α7nAChR in basal conditions favours LM polarization toward the M1 phenotype, whereas ligand-bound, but potentially non-conducting, α7nAChR in proinflammatory conditions inhibit the production of M1 cytokines. α7nAChR may thus constitute a pharmacological target in lung inflammatory diseases.
Our results confirm a possible role of those two miRNAs in lung cancer angiogenesis and suggest the potential new target angiogenic lung cancer therapy.

4545

Overcome the EGFR-TKIs resistance with cucurbitacin BE compound by targeting STAT3, ERK1/2 and AKT

Ming Lin, Lixia Zheng, Chen He, Jun Xu. Guangzhou Institute of Respiratory Diseases, Guangzhou Medical College, Guangzhou, Guangdong, China

Epidermal growth factor receptor (EGFR) mutant non-small cell lung cancer (NSCLC) is highly sensitive to EGFR tyrosine kinase inhibitors (TKIs) therapy, but acquired resistance eventually develops at about 9-12 months. Overcoming the drug resistance is of great clinical and scientific significance. In this study, we showed that STAT3,ERK1/2 and AKT were persistently activated in the resistant cells with T790M mutation(PCR/ER) and 52 tumor samples from EGFR-TKIs resistant NSCLC patients. The growth inhibition of the trizomer compound cucurbitacin BE (Cu BE) was tested in vitro and in vivo against PC9/GR cells. Cu BE can inhibit the growth of PC9 and PC9/GR cells in a dose- and time-dependent manner, resulting in G2/M phase arrest and apoptosis. This was associated with inhibition of activated Stat3,ERK1/2 and AKT, increased level of autophagy(LC3B expression), and down-regulated the expression of caspase 3 and survivin. Moreover, in a nude mouse xenograft model, Cu BE decreased the PC9/GR tumor volume by 46.4% (P < 0.05) compared with the mice treated with erlotinib. These data suggest that treatment with CuBE, which can inhibit the activation of STAT3,ERK1/2 and AKT, appears to be an effective strategy for NSCLC patients with EGFR-TKIs resistance.

4546

Diagnostic yield of ROSE (rapid on-site evaluation) and cell block obtained by endobronchial ultrasound (EBUS) in patients with lung cancer

Marizell Pari1, Melissa Masis2, Nuria Ratoares3, Isabel Catala4, PILAR GOMEZ1, Francisca Perez5, Jordi Dorca6, Antoni Rosell7, 1Department of Pulmonary Diseases, Hospital Universitari de Bellvitge-IDIBELL-CIBERES, Barcelona, Spain; 2Department of Pulmonary Diseases, Hospital Rafael Angel Calderon Guardia, San Jose, Costa Rica

Introduction: The cytological diagnosis of lymph node(LN) metastases depends on various factors such as the number of passes made at each station, access to ROSE or type of sample processing. Our objective was to analyze the diagnostic value of ROSE and cell block (CB) obtained for mediastinal staging by EBUS in lung cancer.

Methods: Selective EBUS sampling was performed to patients with lung cancer and mediastinal disease by chest CT or PET-CT. For each fine needle aspiration(FNA), we collected the results of ROSE, final cytology diagnosis and CB. At least 3 FNA per LN were performed if ROSE did not show malignant cells.

Results: We studied 148 patients from June 2010 to August 2011, of which 49 met the inclusion criteria. The diagnostic yield of ROSE was 47.8% and for CB was 70.6%. The % of agreement between ROSE and CB was 94.9%. BC added 3.1% for the total of 130 FNA were performed, being unable to obtain a CB in 23.1% of cases. The level of Prx1, a major 2-Cys peroxiredoxin family member, is frequently increased apoplastic potential through activation of the caspase cascade and suppressed doxorubicin-induced phosphorylation of Akt and its substrate forkhead box O1 (FOXO1). Moreover, treatment with the phosphoinositide 3-kinase (PI3K) inhibitor LY294002 reduced the phosphorylation of FOXO1 and increased the cytotoxicity of doxorubicin in A549 cells. Our findings suggest that Prx1 may modulate the chemosensitivity of lung cancer to doxorubicin through suppression of FOXO1-induced apoptosis.

4548

Overexpression of inhibitor of DNA-binding proteins and angiogenic markers have higher impact on survival of non small cell lung cancer patients

Robert Saile1, Thalya Fuma1, Milena Acencio1, Ricardo Terra2, Edwin Parra3, Vera Capelo1, Leila Antanello1, 1Pathology and Research Laboratory (LJLM), Hospital das Clinicas -University of Sao Paulo, SP, Brazil; 2Pulmonary Division, Heart Institute - Inca - University of Sao Paulo, SP, Brazil

Background: The inhibitor of DNA binding (Id) proteins have been implicated in oncogenic transformation, progression and in tumor angiogenesis, the last one by regulation of vascular endothelial growth factor (VEGF) expression. Notwithstanding, these mechanisms have not been fully understood. The aim of this study was to evaluate the Id1, 2,3 and VEGF expression and angiogenesis amount in non small cell lung cancer (NSCLC) and their role on patients’ prognosis.

Methods: Immunohistochemistry and morphometry were used to evaluate Ids, VEGF expression and microvessels density (CD34) in neoplastic and stromal cells from 85 patients with surgically excised NSCLC. The impact of these markers was tested on follow-up until death from recurrence lung cancer.

Results: The Kaplan-Meier survival curve analysis showed that expression of Id-1, CD34 and VEGF were associated with poor prognosis (Log Rank Test, p < 0.001). A Cox model analysis controlled for histological type, lymph node stage, Ids, VEGF, CD34 and age demonstrated that only Id1, Id3 and vascular density were significantly associated with survival time. A point at the median for Id1, Id3 and vascular density divided patients into 2 groups, each one with distinctive prognosis. Those with higher expression of Id1, Id3 and vascular density had a higher risk of death when compared to those with lower Id1, Id3 and vascular density.

Conclusion: In resected NSCLC, Id1, Id3, VGF and vascular density were strongly associated with prognosis. Therefore, Id1 and Id3 seem to contribute to tumor progression and should be considered as prognostic markers in NSCLC.

4549

Clinicopathological significance and prognostic importance of circulating plasma DNA expression in advanced non-small cell lung cancer and its efficacy as a diagnostic tool

Abd El Halim Abu-Hamor 1, Hanan Shawki 1, Ibrahim Ibrahim 1, Abdel Aklad Hanan 1, 1Clinical Oncology Department, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt; 2Clinical Oncology Department, Tanta University Hospital, Faculty of Medicine, Kafer el elya, Gharbia, Egypt; 3Chest Department, Tanta University Hospital, Faculty of Medicine, Kafer el elya, Gharbia, Egypt; 4Microbiology and Immunology Department, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt

Lung cancer is commonest neoplasm. Ther is continuous need for new prognostic markers. Circulating plasma DNA levels is over-expressed in many cancers, including lung.

Aim of work: To study the expression of circulating DNA in NSCLC and assess-ment of its utility as a diagnostic marker and impact on therapeutic efficacy.

Methods: Plasma DNA was determined through the use of polymerase chain reac-tion(PCR) assay. To study the expression of circulating DNA in NSCLC, we assessed plasma DNA levels was correlated with response to therapy, overall survival, and lactate dehydrogenase level.

Results: There was a significant correlation between circulating plasma DNA lev-els and stage, LDH levels and tumor status. Plasma DNA levels were significantly inversely correlated with treatment response.
4552 Effect of fasudil on the bleomycin-induced pulmonary fibrosis and hypertension in mice
Yihua Bei1,2, Sy Duong-Quy 1,3, Thong Hua-Huy 1, Nhat-Nam Le-Dong 1, Weiha Chen1, Carole Nico2, Frédéric Battu3,4, Anh Tuan Du-Bau-Xuan1,2
1 Hangzhou Medical College, Hangzhou, China; 2Pharmacology Department, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; 3Pharmacology Department, School of Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China; 4Pharmacology Research Institute, Shanghai Jiao Tong University, Shanghai, China

Background: RhoA/ROK kinase (ROCK) pathway is important in regulating vascular tone and vascular remodelling in pulmonary hypertension (PH). It has been shown to be altered in the bleomycin-induced pulmonary fibrosis (PF) and PH in mice. However, the exact mechanism by which it leads to PF and PH remains to be clarified.

Objectives: The present study aimed to assess whether fasudil, a ROK inhibitor, is able to inhibit PF and PH induced by bleomycin in mice.

Methods: Male C57BL/6 mice were randomized into 3 groups: G1 (saline), G2 (bleomycin) and G3 (bleomycin + fasudil). Bleomycin (3.3U/kg) was given intratracheally (day 0) and fasudil (30mg/kg/d) intraperitoneally from day 1 day 14 days. Right ventricular systolic pressure (RVSP) was measured by RV puncture at 7, 14, and 21 days, followed by sacrifice and lung and lung samplings for collagen analysis.

Results: Pulmonary fibrosis was present at 7 days, and became more apparent at 14 days. RVSP increased at 14 days, accompanied by right ventricular hypertrophy. Fasudil improved survival, reversed PF and attenuated PH.

Conclusions: The efficacy of the ROK inhibitor, Fasudil, suggests that RhoA/ROCK is involved in causing PF and PH induced by bleomycin in mice.

4553 Polymorphisms in angiotensin converting enzyme gene are associated with risk of development of and disease severity in scleroderma-related pulmonary arterial hypertension
Stephen Mathus, Li Gao, Nicholas Rafaela, Rachel Damico, Todd Kolb, Kathleen Barnes, Paul Hassoun. Medicine, Johns Hopkins University, Baltimore, MD, United States

Background: While 8-12% of patients with scleroderma (SSc) will develop pulmonary arterial hypertension (PAH), little is known about risk factors for this complication. Angiotensin converting enzyme (ACE) is associated with endothelial dysfunction and may play a role in susceptibility to vascular disease in SSc. We sought to identify polymorphisms in ACE gene that may contribute to risk of PAH in SSc.

Methods: A case-control study was performed in 916 patients of European descent. Of 458 SSc patients, 103 had right heart catheterization-proven PAH; the remainder did not have significant respiratory disease. Three single nucleotide polymorphisms (SNPs) in ACE gene [rs4293, rs3730025, rs4311], previously shown to be associated with cardiovascular disease, were examined. The relative frequency of SNPs and their relationship to presence of PH and severity of PAH were assessed using Cochran-Armitage trend test with PLINK and linear regression association between genotype and hemodynamics.

Results: A strong association was found between SNP rs3730025 and risk of PAH (P=0.009). Carriers of G allele of rs4293 had increased cardiac index (β=0.458, P=0.005) and decreased pulmonary vascular resistance (P<0.137, P=0.018).

Conclusion: In this SSc cohort, a coding SNP in ACE gene was strongly associated with presence of PAH. Further, presence of SNP rs4293 was associated with preserved cardiac function in SSc-PAH. Given the role of these SNPs in the function of ACE and the relationship between ACE and vascular function, further studies are warranted to investigate the role of these SNPs in the pathogenesis of PAH in SSc.
indicating an important role of miR-130a in the development of hypoxia-induced PH.

**Conclusion:** Genetic ablation of the BMPR2 gene in pulmonary ECs is sufficient to predispose to PAH. Our data reveal interplay between BMPR2 signaling and the 5-HT system in ECs within PAH, leading to increased susceptibility to PAH progression.

**4555**

**Hypoxia-induced miR-130a is a novel repressor of BMPR2 gene expression in experimental pulmonary hypertension.**

**Introduction:** Vascular remodelling, a pathogenetic feature of pulmonary hypertension (PH), is associated with decreased expression of the bone morphogenetic protein receptor type II (BMPR2). We recently demonstrated that the inhibition of microRNA 20a (miR-20a) prevents vascular remodelling in hypoxia-induced PH. Here we assessed the role of miRNAs in the repression of BMPR2 gene expression in experimental PH.

**Methods:** The mouse model for hypoxia-induced PH was used. After 21 days of hypoxia, lungs were removed and assessed for mRNA and gene expression. RNA levels of miR-21, -25, -125a, -130a, and -130b and BMPR2 were measured using SYBR-Green real-time PCR. Reporter gene assays comprising the 3′UTR of BMPR2 and TGFBR2 were applied to confirm direct miRNA–target interactions.

**Results:** Using a miRNA prediction program, we identified phylogenetically conserved binding sites of miR-21, -25, -125a, -130a, and -130b in the 3′UTR of BMPR2. Under hypoxic conditions the RNA levels of miR-21, miR-125a, and miR-130a were found to be significantly upregulated (p < 0.05) when compared to normoxic controls. Consistent with previous reports the miRNA expression of BMPR2 was significantly reduced in hypoxic lungs (0.79±0.24 fold, p=0.039) and, most importantly, showed a negative correlation with the expression of miR-130a (R²=0.28, p=0.04). By performing reporter gene assays we confirmed that miR-130a directly targets the 3′UTR of BMPR2. Along this line, we identified the BMPR2-related receptor TGFBR2 as another novel target of miR-130a. BMPR2 was significantly reduced in hypoxic lungs (0.79±0.24 fold, p=0.039) and, most importantly, showed a negative correlation with the expression of miR-130a (R²=0.28, p=0.04). By performing reporter gene assays we confirmed that miR-130a directly targets the 3′UTR of BMPR2. Along this line, we identified the BMPR2-related receptor TGFBR2 as another novel target of miR-130a.

**Conclusion:** We identified miR-130a as a negative regulator of BMPR2 expression indicating an important role of miR-130a in the development of hypoxia-induced PH.

**4556**

**miR-204, miR-149, miR-197, miR-487b and miR-485 were downregulated in PA-derived microvascular smooth muscle cells.**

**Background:** Recent studies are showing the potential role of micro-RNAs (miRNAs) in the regulation of many genes controlling cell growth and proliferation. regulation (p < 0.05) whereas no changes were observed in this gene after treatment with IL-1β or INF-γ. Fully differentiated SMC treated with TNFα, downregulated significantly myocardin, sm22α and calponin. We conclude that slug expression might be associated with a SMC proliferative phenotype induced by inflammatory stimuli. This SMC phenotype switching might contribute to the development and progression of vascular disorders.

**Conclusion:** miR-204, miR-149, miR-197, miR-487b and miR-485 were downregulated in PA-derived microvascular smooth muscle cells.

**4557**

**Slug can contribute to the phenotypic modulation of smooth muscle cells.**

**Background:** Slug is a transcription factor related with transitional changes in cell phenotype. Smooth muscle cells (SMC) may show high plasticity switching from a contractile (fully differentiated) to a proliferative phenotype (dedifferentiated).

**Conclusion:** Recently, we have found that remodelled pulmonary arteries have increased expression of slug, a transcription factor related with transitional changes in cell phenotype. Slug may contribute to the phenotypic switching from a contractile to a proliferative phenotype.

**476. New scientific findings on noninvasive ventilation in the acute setting**

**4558**

**Predicting mortality in patients hospitalised with acute exacerbations of COPD (AECOPD) requiring assisted ventilation.**

**Background:** Prognostic studies in AECOPD requiring assisted ventilation often select patients by place of care and predict failure of non-invasive ventilation (NIV), not mortality. Improved mortality prediction for unselected patients requiring ventilatory assistance is needed.

**Objective:** Identify mortality predictors in patients with AECOPD requiring ventilatory assistance.

**Methods:** Clinical data were collected on consecutive patients hospitalised with AECOPD requiring assisted ventilation (NIV or invasive ventilation) for acidaemic respiratory failure (AECOPD) during their hospital stay. Independent predictors of in-hospital mortality were identified.

**Results:** 199 received ventilatory assistance: mean (SD) age = 73.9 (9.8) years; FEV1, 38.1 (16.1) % predicted and 61.3% were female. 49 (24.6%) patients died in hospital.

**Older age, an ineffectual cough, and severe stable-state dyspnoea were the strongest predictors of mortality.**

**Table 1. Independent predictors of mortality**

mortality predictors. The regression model (table 1) showed excellent discrimination for mortality (AUROC = 0.92, 0.88 to 0.96).

Conclusion: Mortality in patients hospitalised with AECOPD requiring assisted ventilation is high but can be accurately predicted using simple to measure indices.

4559 Echocardiographic speckle tracking strain and right ventricular function assessment during non-invasive ventilation in acute respiratory failure patients
Bouchra Lamine, Stéphanie Van Mossevelde, Luis-Carlos Molano, Antoine Cuveliet, Jean-François Muir. Respiratory and Critical Care Department EA 3830, Rouen University Hospital, Rouen, France

Introduction: During acute respiratory failure (ARF), right ventricular (RV) function can be abnormal due to increased afterload and/or decreased contractility or preload. Speckle tracking strain analysis can diagnose RV dysynchrony. We aimed to test whether RV dyssynchrony exists during ARF and can be reversed during non-invasive ventilation (NIV).

Methods: Prospective study including 13 patients admitted for ARF. Trance thoracic echocardiography (TTE) was performed during spontaneous breathing (SB) activity and during NIV. Usual echo parameters and speckle tracking strain were measured. The software generated 6 segmental RV strain curves. Time to peak strain from each of 6 time-strain curves was determined with dyssynchrony defined as the difference between earliest and latest segments.

Results: 13 patients aged 69 (11) y were included. 11 had chronic respiratory failure. Compared to SB, left ventricular ejection fraction and stroke volume increased during NIV. 59 (6) vs 66 (6) %, 61 (9) vs 65 (11) mL, p < 0.05 respectively, and systolic pulmonary arterial pressure (SPAP) decreased 61 (16) mmHg vs 41 (16) mmHg, p = 0.03. RV dysynchrony improved significantly: 235 (40) vs 182 (149) msec, p = 0.04.

Conclusion: RV dysynchrony measured using speckle tracking strain is observed in our ARF patients. NIV can improve LVEF, RV afterload and RV dysynchrony.

4560 Confirmatory analysis of the impact of case-volume on ICU management of severe COPD exacerbations (1998-2010)
Martin Dee1, Philippe Aegerter2, Ti-Chien Tran3, Antoine Rabbat1
Bertrand Guidet1, Gerard Huchon1, Nicolas Roche1, on the behalf of CUBREA
1Service de Pneumologie et réanimation Médicale, Assistance Publique Hôpitaux de Paris - Hôpital Hôtel Dieu, Paris, France; 2Respiratory Department, Ashford and St Peter’s Hospitals NHS Foundation Trust, Chertsey, Surrey, United Kingdom; 3Respiratory Department, Ashford and St Peter’s Hospitals NHS Foundation Trust, Chertsey, Surrey, United Kingdom

Aims and objectives: The objective of this study was to establish if inappropriate NIV could be correlated with location of set up. Proving this hypothesis would enable us to target locations to provide additional support to reduce and prevent the inappropriate use of NIV.

Methods: Data were collected prospectively from 255 consecutive patients requiring NIV from May 2009 to April 2011 using an adapted version of the BTS NIV data tool.

Results: Of 255 patients, 121 were admitted in CUB-REA ICUs. There was a growing use of NIV and a decrease in the use of IV fluids. This may be due to the lack of expertise in non-respiratory areas. We therefore conclude that NIV should only be initiated in respiratory specialist areas within our hospital.

Conclusion: Patients commenced on NIV outside of respiratory specialist areas are more likely to receive inappropriate NIV with subsequent higher mortality rates. This may be due to the lack of expertise in non-respiratory areas. We therefore conclude that NIV should only be initiated in respiratory specialist areas within our hospital.

4562 Effect of continuous and bilevel noninvasive ventilation for acute asthma exacerbation – A randomized controlled trial
Sílvia Gamares Hanekom1, Helene van Aswegen2, Louise Engelbrecht3, Piet J. Becker3, 4Physiotherapy, University of Pretoria, Gauteng; 2Physiotherapy, University of the Witwatersrand, Johannesburg, Gauteng; 3Emergency Care, University of Pretoria, Gauteng; 4South African Medical Research Unit, Bosvatsistant Unit, Pretoria, Gauteng, South Africa

Guidelines for management of acute asthma exacerbation (AAE) centre on pharmacological interventions and invasive mechanical ventilation. The role of non-invasive positive pressure ventilation (NPPV) or bilevel positive pressure ventilation (BPPV) to standard therapy (ST) would improve lung function and clinical signs faster than ST alone.

Aims: We hypothesized that adding continuous positive airway pressure (CPAP) or bilevel positive pressure ventilation (BPPV) to standard therapy (ST) would improve lung function and clinical signs faster than ST alone.

Methods: Thirty patients with severe AAE [peak expiratory flow rate percentage (PEFR%) predicted < 60%] presenting at an emergency unit were randomized to either ST, CPAP or ST and BPPV.

Results: Groups presented similar baseline characteristics. Mean baseline PEFR% predicted was 35.2 (10.7) % [ST], 30.5 (11.7) % [CPAP] and 33.5 (13.8) % [BPPV]. PEFR significantly improved in the CPAP group from the first 30 minutes of treatment (PEFR = 0.00, PEFR% predicted = 0.00) compared to the BPPV and ST groups. Improvement in respiratory rate (RR) (p = 0.05) and sensation of breathlessness (SB) (p = 0.00) was significantly better in the BPPV group from the first 30 minutes.

Discussion: The significant improvement in PEFR in the CPAP group could be related to its intrinsic effect on the airway smooth muscle and/lung load. The positive effect of BPPV on RR and SB could be related to the inspiratory assistance provided.
Conclusion: The addition of NIPPV to ST in acute severe asthma exacerbation, improved lung function and clinical signs faster than ST, yet CPAP was faster and more effective in reducing bronchospasm than BIPPV.

4563 Outcome of acidotic COPD-patients on hospital admission
Sylvia Hardy, Mike Roberts, Jose Luis Lopez-Campos, Dep. of Respiratory and Crit. Care, Otto Wagner Hospital, Vienna, Austria; Dep. of Respiratory Medicine, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla (IBS), Spain; Dep. of Resp. Medicine, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, United Kingdom

Background: Acidosis is a marker of acute respiratory failure in COPD. Non invasive ventilation (NIV) is the first choice of ventilation for such patients to avoid intubated mechanical ventilation (IMV) and associated complications. The ER'S COPD Audit evaluated the clinical practice of treatment standards in acute exacerbation of COPD (AECOPD) in 422 hospitals of 13 European countries. We present the analysis of treatment standards for acidotic AECOPD patients and associated outcomes.

Methods: Data collection of clinical treatment of all hospital admitted AECOPD for 8 weeks and follow up until 90 days after discharge.

Results: Of 12893 patients 18.8% (2429/16666 male) presented with respiratory acidosis on admission (pH<7.38); with moderate acidosis: pH 7.35±0.25, 4.1% (n=526) with severe acidosis: pH <7.25. Acidotic patients were significantly sicker than non acidotic.

4565 Arterial blood gas analysis after 120 minutes of noninvasive positive pressure ventilation can predict outcome in acute cardiogenic pulmonary oedema
Rodolfo Ferrari, Fabrizio Gisiora, Francesca Nustali, Roberto Lazzari, Luigi Bolondi, Mario Cavazza, Dipartimento Emergenza/Urgenza, Chirurgia Generale e dei Trapianti, Unità Operativa di Medicina d’Urgenza e Pronto Soccorso, Policlinico Sant’Orsola – Malpighi, Azienda Ospedaliero Universitaria di Bologna, Università degli Studi di Bologna, Università degli Studi di Bologna, Università degli Studi di Bologna, Università degli Studi di Bologna, Università degli Studi di Bologna

Background: Noninvasive positive pressure ventilation (NIPPV) is first line intervention in Acute Cardiogenic Pulmonary Oedema (ACPO). Arterial Blood Gas Analyses (ABG) is largely available in clinical practice in the Emergency Department (ED).

Aims: To assess the role of ABG to predict outcome in patients with ACPO treated by NIPPV

Materials and methods: Treatment failure defined as hospital mortality or need for invasive mechanical ventilation. Observational clinical study in the ED of the a University teaching Hospital during 5 months, including every patient emergently admitted for ACPO and treated with first-line NIPPV, referring to an institutional protocol.

Results: 214 patients included. Failure rate 14.5%.

Conclusions: In patients with ACPO treated with NIPPV, ABG at presentation is not able to carefully predict outcome. After 60' of NIPPV both groups (success versus failure) improved without any significant difference. The improvement of ABG after 120' is associated with success; these patients will likely benefit from continuation of NIPPV. The inability to improve gas exchange after 120' of NIPPV in ACPO is predictor of failure; these patients should be closely monitored with a low threshold for endotracheal intubation.

477. Clinical and diagnostic markers and management of paediatric allergic diseases

P4566 Intensive oil baths from six weeks of age reduce xerosis and possibly atopic eczema in infancy
Bente Krane Kvenshagen, Petter Mowinckel, Kai-Håkon Carlsen, Karin L. Carlsen, Pediatric, Oestfold Hospital Trust, Fredrikstad, Norway; Pediatric, Oslo University Hospital, Oslo, Norway

Background: Atopic eczema (AE) is often the first step of the allergic march, with onset early in life, followed by asthma and allergic sensitivities. AE affects up to 20% of children, and is characterized by dry, itchy skin. AE is a complex genetic and environmental disease, with alteration of skin barrier. Restoring of the barrier by emollients and/or oil baths is an important part of AE treatment, but it’s role in preventing AE is not known. Theoretically reducing prevalence of AE could prevent later allergy and asthma development.

The present pilot study aimed to evaluate whether frequent oil baths of infants with dry skin could reduce xerosis and eczema at the age of six months.

Methods: A randomized controlled intervention study of six weeks old infants with dry skin, followed to six months by monthly assessment. They were randomized to either daily oil bathing (0.5 dl) and fat cream in the face (n=24) or observation (normal procedures) (n=31). The outcome was skin quality at six months.

833s
Results: Normal skin was observed at six months in 18 children (75%) with skin treatment, compared to 12 (38%) in the observation group (p<0.001). Frequency of oil baths was 5-7/week (n=19) and 2-4/week (n=5) in the intervention group. Skin care habits in the observation group AE was reported in one child versus five children in the intervention versus the observation group. No adverse reactions reported.

Conclusion: The present pilot study showed that regular oil baths of infants were feasible, reduced xerosis, and also possibly eczema. If verified in further studies, one might speculate if this would reduce development of allergy and asthma.

Introduction: Epidemiological data on problematic severe asthma in children are sparse.

Methods: A 3 year (2008-2011), nationwide survey on PSA in children 4-18yrs old in the Netherlands through a national surveillance system among all paediatricians. A retrospective study cross sectional study 328 children aged 4-18yrs with PSA, were identified. A prevalence of at least 0.1% of children with asthma. PSA is more frequent in boys than in girls under 12yrs. This sex ratio reverses >12yrs old. Eighty-four children had allergic asthma and in 85% symptoms started before they were 4yrs old. All children included long term inhaled corticosteroids, FENO, trials of steroids, chest radiographs, sweat tests, immunodiagnostics, HRCT, bronchoscopy in various per-
centages of patients. Over 10% had 5-10 exacerbations requiring prednisolone in the last year. In 11%, FENO had exacerbations with no symptoms in between. 40% suffered from very acute asthma attacks and 30% were continu-
ously symptomatic. All despite up-to-date intensive surveillance and treatment. Seventy-five percent received psycho diagnostics and 50% psychotherapy. FEV1 was

Results: Persistent airflow limitation in the past year was present

Seventy-five% received psycho diagnostics and 50% psychotherapy. FEV1 was

Conclusions: In this trial, MEF/MDI 100/10g demonstrated significant bron-
chodilation in children aged 5-11 regardless of the use of a spacer.

P4569

Vitamin D receptor and vitamin D binding protein polymorphisms are associated with asthma control in children

Emmanouil Paraskevakis1, Maria Fioriandou1, Anna Tavridou1, Athanassios Chatzimichael1, Vangelis G. Manolopoulos2

1Department of Pediatrics, University Hospital, Alexandroupolis, Thrace, Greece; 2Laboratory of Pharmacology, Medical School, Alexandroupolis, Thrace, Greece

Introduction: Vitamin D levels have been associated with the onset of asthma and are suggested as a marker of disease severity in asthmatic children. Furthermore, polymorphisms in vitamin D pathway genes have been associated with vitamin D levels.

Aims and methods: 111 children with asthma and 96 healthy controls of Greek origin were analyzed for the VDR Apal, VDBP r7041 and r4588 polymorphisms using PCR-RFLP method. Asthma control level was assessed according to Child-
hood Asthma Control Test (C-AC T) and Global Initiative for Asthma guidelines (GINA).

Results: Genotype distribution for all studied polymorphisms did not differ signific-
antly between asthmatic patients and healthy controls. Frequencies of VDR Apal AA, AC and CC genotypes were 38.4%, 40.7% and 20.9% in the controlled group and 28.7% and 72.6% respectively, in the uncontrolled group according to GINA (p=0.008). This association was verified when we analyzed the VDR Apal genotypes in asthmatic group according to GINA classification (p=0.002). For the VDBP r7041 polymorphism, the frequency of variant G allele was significantly higher in children with controlled asthma compared to C-AC T (66.6% vs 50.0%, p=0.030) and GINA guidelines (62.8% vs 52.8%, p=0.027). For the VDBP r4588 polymorphism the frequency of variant A allele was significantly lower in children with controlled asthma compared to C-AC T (23.5% vs 40.0%, p=0.019) and GINA VI.7% vs 37.5%, p=0.048) guidelines.

Discussion: VDR Apal and VDBP r7041 and r4588 polymorphisms were as-
sociated with asthma control according to C-AC T and GINA classification in asthmatic children.

1Department of Pharmacology, Medical School, Alexandroupolis, Thrace, Greece

Results: In this trial, MF/F-MDI 100/10g demonstrated significant bron-
chodilation in children aged 5-11 regardless of the use of a spacer.

In addition to its role in bone physiology and autoimmune disease, recent data suggest a potential role of vitamin D in asthma since it has immunomodulatory properties. The aim of this study is to determine the relationship between serum vitamin D levels and the severity and control of asthma in children. We measured vitamin D levels in serum collected from 38 asthmatic children in winter and summer, compared to those of 30 healthy children. The mean age is 9.8 years and Sex-ratio was 2:1. Asthma was mild persistent in 60.5% of cases, mod-
erate in 36.8% of children, and severe in 2.7%. The average vitamin D level was significantly lower in asthmatics in summer despite abundant sun exposure (20.74 ng/ml vs 26.77 ng/ml p = 0.001) and levels of vitamin D were signifi-
cantly lower in winter than in summer in both groups (in asthmatics 17.37 ng/ml vs 20.74ng/ml; p=0.036 and 18.97ng/ml vs 26.77ng/ml; p<0.001 in controls). Subjects with well-controlled asthma had higher serum levels of vitamin D than children with partially controlled or non-controlled asthma in summer (24.28ng/ml vs 13.9ng/ml; p<0.001) but not in winter (17.28mg/ml vs 17.67ng/ml). In the same way, children with more severe asthma had lower serum vitamin D levels than children with mild asthma in winter (12.07mg/ml vs 20.80ng/ml; p<0.001) and in summer (13.8mg/ml vs 25.26ng/ml; p<0.001). Our study indicates that vitamin D deficiency is more common among children with asthma and lower vitamin D levels are associated with a greater disease severity and probably with worse disease control. Randomized intervention trials on vitamin D supplementation will be needed to confirm its role in treatment and eventually in prevention of asthma.

834s

WEDNESDAY, SEPTEMBER 5TH 2012
were referred to the asthma clinic of the Mofid Children’s Hospital, were enrolled.

Methods:
80 patients aged 5 to 18 years with physician diagnosed asthma with a
asthma related bronchoconstriction.

Conclusion:
Our results indicated an association between aspergillus antibody level and severity of asthma. It could be recommended that the IgG titer for aspergillus is measured in pediatric patients with asthma, whereas co-morbidity of aspergillosis and asthma increases the risk of asthma exacerbation.

Persistent or recurrent wheezing are common problems in infancy. The aim of this study is to evaluate the diagnostic value of flexible bronchoscopy (FB) and analyze its results in infants with persistent or recurrent wheezing.

Material and method: Ninety-six wheezy infants who had been performed FB between 1999 and 2011 were included in this study. Demographic features, radiological, laboratory and bronchoscopic findings were analyzed.

Results:
Sixty-six patients were male and the median age at FB date was 0.9 (0.6-1.5) years. Median age at symptom onset was 3 (1-6) months. Twenty-eight patients had persistent and 75 had recurrent wheezing. Fifty-five patients had regular asthma therapy before the procedure. Thirty patients had atelectasis on radiological imaging FB revealed a diagnosis in 64 patients.

Conclusion:
Paradoxical bronchospasm is defined as the rapid onset of bronchoconstriction after administrating β2 agonist. Few studies published suggest that it is due to tensive chlorofluorocarbons in the metered dosis inhaler (MDI). Although paradoxical bronchospasm is defined as the rapid onset of bronchoconstriction after administrating β2 agonist, level of asthma severity and control, percentage of FEV1 decrease and bronchodilator response after terbutaline dry powder were collected. Statistical analysis with SPSS.

Results:
32 patients, mean age 8.3 years (56% males). History of allergy in 65.6% (68.4% Dermatophagoides) and obesity in 34.3%. 81.3% patients had controlled asthma at the time of testing, following treatment with montelukast (42.9%) and long acting β2 agonist. Few studies published suggest that it is due to tensive chlorofluorocarbons in the metered dosis inhaler (MDI). Although paradoxical bronchospasm is defined as the rapid onset of bronchoconstriction after administrating β2 agonist, level of asthma severity and control, percentage of FEV1 decrease and bronchodilator response after terbutaline dry powder were collected. Statistical analysis with SPSS.

Results: Nineteen asthmatic patients (10 females and 9 males) had aspergillus IgG antibody. Among them, severe persistent asthma and moderate persistent asthma were detected in 5 and 13 cases, respectively, whereas only one patient suffered from mild persistent asthma. A total of 36.5% of the 96 patients had a history of atopy, whereas 26% had allergic rhinitis. There was an association between the severity of asthma and the presence of aspergillus IgG antibody. Moreover, the positivity for aspergillus IgG antibody was higher in older patients.

Conclusion:
Paradoxical effect of salbutamol in asthmatic children
Maria Teresa Romero Rubio1, Lysbeth Ojeda Gonzalez2, Barbara Fernandez Dominguez2, Laura Aranda Grau1, Amparo Escobedo Montaner1.

Methods: Asthmatic children (2006-2011) in whom FEV1 decreases ≥9% after conventional BT with MDI salbutamol. Age, sex, body mass index, atopy, pharmacological treatment, level of asthma severity and control, percentage of FEV1 decrease and bronchodilator response after terbutaline dry powder were collected. Statistical analysis with SPSS.

Results: 32 patients, mean age 8.3 years (56% males). History of allergy in 65.6% (68.4% Dermatophagoides) and obesity in 34.3%. 81.3% patients had controlled asthma at the time of testing, following treatment with montelukast (42.9%), inhaled corticosteroids (28.5%), both of them (4.8%) or immunotherapy (9.5%). 14.3% patients had moderate to severe asthma, treated with corticosteroids and long acting beta-agonist. 46.9% showed a fall in FEV1 >15%. In this group 40% were obese and 60% allergic, with no differences among asthma severity or pharmacological therapy (p>0.05). 27 patients underwent bronchodilatation with terbutaline dry powder being positive in 81%.

Conclusion: In controlled asthmatic children, especially obese and allergic, MDI salbutamol can produce paradoxical bronchoconstriction that reverts with terbutaline dry powder. Although not a usual situation, it should be considered for the symptomatic management of the disease.
P4576
Evaluation of lung function in children with asthma and gastroesophageal reflux disease association
Iason Adam1, Svetlana Scincic1, Victor Rasco2, Rodica Selevenaru1, 1Pediatric, State Medical and Pharmaceutical University, Chisinau, Republic of Moldova; 2Endoscopy, Mother and Child Center, Chisinau, Republic of Moldova

Aim: The aim of study was to assess the lung function disorders using spirometric measurements in a group of children with asthma and gastroesophageal reflux disease (GERD) association.

Materials and methods: The study included 58 children with moderate asthma aged from 5 to 16 years. The main group entered 38 children with association of asthma with GERD; controls included 20 GERD-free asthmatic children.

Results: Analysis of the mean FVC values showed restrictive character of lung function changes in both groups that partially develop in children with long-term asthma: 64.0±4.2% vs. 72.4±4.2% (p<0.01), also PEF (46.6±2.5% vs. 56.0±3.3% in controls, p<0.05) and MEF25-75 (58.3±3.8% vs. 71.0±3.4%, respectively, p<0.05). Noticeably, significantly more expressed obstructive changes of distal airways and lung function variables were observed in children with associated asthma and GERD: 56.7±2.9% vs. 67.7±3.2% in controls for MEF75 (p<0.05), 59.9±3.9% vs. 75.8±3.6% for MEF50 (p<0.01) and 68.8±5.6% vs. 87.9±6.2% for MEF25 (p<0.05).

Conclusions: Analysis of spirometric variables denotes more severe obstructive changes of lung function in children with association of asthma and GERD, that is showed by lower values of FEV1, PEF, MEF25-75, MEF75 and MEF25, comparing with asthmatic children who are GERD-free.

P4577
Exhaled nitric oxide and serum IgE in children admitted to a pediatric department
Rado Dzamonja1, Carmen Dzamonja2, Gendrovel Dumitra2, 1Pediatrics, University of Medicine, Pharmacy, Craiova, Romania; 2Sports Medicine, Emergency Clinical Hospital, Craiova, Romania; 1Family Medicine, Private Practice, Sadova, Romania

Background: Exhaled nitric oxide (FeNO) is a noninvasive marker to assess airway inflammation in adults and children, but the clinical evidence is still equivocal.

Methods: We aimed to assess the FeNO levels in children admitted to our pediatric department and to correlate the results with other diagnostic tools. We enrolled two groups of children aged 5 to 16 yrs: first (149 cases, M/F 89/60) - admitted for asthma, and the control group (100 cases, M/F 55/45), without known history of asthma.

Results: We measured the FeNO (using Niox Mino, Aerocine, Sweden), total and specific serum Ig E. The statistical analysis was done using the Chi-squared test.

Results: We found a statistical significant difference in specific IgE levels between the two groups: p=0.01; RR=3.76 (0.99-14.25), but similar values for FeNO (p=0.19) and the total serum IgE (p=0.59). Total IgE over 300 kU/l was correlated with high FeNO levels recorded in the asthmatic children: p=0.009; RR=4.28 (1.37-15.44), but the exhaled NO was not correlated with stage, gender nor controller therapy (corticoids and/or leumotin inhibitors or none).

Discussions: In our patients the role of FeNO in monitoring asthma is still uncertain. The correlation with high total serum Ig E (also nonspecific) may be a future approach in increasing the value for the clinical use.

P4578
The relationship between exhaled nitric oxide and compliance/adherence in patients with bronchial asthma using inhaled corticosteroids
Yoko Kaminato1, Naohiko Taba, Yoko Murakami, Chikako Motomura, Hitomi Oda1a, Department of Pediatrics, Fukuoka National Hospital, Fukuoka, Japan

Background: The measurement of FENO is the important index to evaluate the control of the patients with bronchial asthma using inhaled corticosteroids (ICS). When FENO in the patients using ICS is high, we often try to increase the dose of ICS. However, it is necessary to take compliance/adherence of the patients into consideration before that.

Objectives: The aim of this study was to examine whether the measurement of FENO is useful as the index of compliance/adherence to asthma treatment by ICS.

Methods: One hundred forty-seven subjects (4 to 23 years of age; 82 male, 65 female) with bronchial asthma using ICS were recruited from the outpatient division at the Department of Pediatrics at Fukuoka National Hospital between January and December 2011. We measured their FENO and asked them to complete a questionnaire regarding the use of ICS. We asked them how often they inhaled ICS for a month, and classified them into five groups categorized as the grade of compliance. Additionally, we made a questionnaire about adherence. The patients answered that they inhaled ICS by themselves were defined as good adherence group, and otherwise as poor adherence group. We compared FENO in 5 groups categorized as the grade of compliance. Likewise, we also compared FENO in good and poor adherence groups.

Results: FENO in the patients of good compliance groups were significantly lower than that of poor compliance groups (p<0.001). However, there was no significant difference in the good adherence group and the poor adherence group.

Conclusions: It was indicated that the measurement of FENO could be useful as the index of compliance to asthma treatment by ICS.

P4579
Carboxyhemoglobin as a marker for chronic carbon monoxide exposure in school-age children with persistent asthma
Aiena Laluc1, Jasna Laluc2, Majaa Slavkovic-Ivanovic3, Milanka Ljubenovic2, 1Toxicology, Medical Faculty, Niš, Serbia; 2Centre of Medical Biochemistry, Clinical Centre, Niš, Serbia; 3Pediatric Clinic, Clinical Centre, Niš, Serbia

Introduction: When inhaled, carbon monoxide (CO) reacts very rapidly with hemoglobin in the blood and forms carboxyhemoglobin (COHb), decreasing the oxygen delivery to vital organs, leading to free-radical production and cytokines releasing.

Aims: To investigate the adverse effects of CO on the respiratory system using COHb as a marker for chronic CO exposure and forced expiratory volume in one second (FEV1) as a marker for the lung airflow obstruction.

Methods: We examined blood COHb concentrations in school-age children who suffer from moderate and easy form of asthma (n=52), ages 8-16 years, living in urban and suburban areas. COHb was measured in patient’s blood immediately after obtaining by spectrophotometric method and expressed as a percentage of blood hemoglobin. FEV1 parameter was measured using Schiller-spirotet SP-1 spirometer.

Results: Our study show that school-age children, with moderate and easy form of persistent asthma have statistically significant elevation of COHb concentration (3.53% ±0.97) in relation to control group (2.03% ± 0.28, p<0.001) and decrease of FEV1 parameter compared to control group, (p< 0.001). We also studied the influence of environmental factors: air pollution, secondhand smoking, wood-heating, heavy traffic, aspect of living in urban and rural areas. There are positive associations between air pollution concentrations and asthma aggravation in children.

Conclusions: Our results suggest that blood COHb concentration above safe level of 2.5% can be involved in pathogenesis of many respiratory diseases, especially asthma and trigger asthma attacks and allergies. The most important factor in prevention is reducing of air pollution.

P4580
Murine lung airway fibroblasts drive fibrosis through STAT4 signaling after cigarette smoke exposure
Tillie Hackett, Steven Zhou, Joanne Wright, Andrew Churge, Pathology, University of British Columbia, Vancouver, BC, Canada

Cigarette smoke-induced emphysema and small airway remodeling (SAR) are the anatomic bases of chronic obstructive lung disease (COPD), but the pathogenesis of these changes is unclear and current treatments for COPD are minimally effective. We exposed wild type (WT) and STAT4−/− mice to cigarette smoke for 6 months and found that STAT4−/− mice are protected against smoke-induced small airway remodeling but not emphysema. Unexpectedly, we observed that STAT4 is expressed in cultured murine wild type (WT) lung parenchyma-derived and airway-derived fibroblasts, but to a much greater extent in the latter. The same phenomenon was seen in cultured human parenchymal and airway fibroblasts. WT airway fibroblasts proliferated faster than STAT4−/− airway fibroblasts, whereas there was no difference between strains for parenchymal fibroblasts. IL-12 is up-regulated in human and mouse lungs after smoke exposure, and treatment with IL-12 caused phosphorylation of STAT4 in WT airway fibroblasts. Exposure of WT airway, but not parenchymal, fibroblasts to IL-12 caused increased expression of collagen Iα1 and TGFβ, factors involved in SAR, whereas STAT4−/− fibroblasts were unresponsive to IL-12. STAT4 thus controls proliferation and matrix production in airway but not parenchymal fibroblasts, and smoke-induced IL-12 can drive small airway remodeling via STAT4 signaling. These findings suggest that treatment with clinically available anti IL-12/40a drugs might provide a new completely approach to preventing SAR in cigarette smokers.

LSC 2012 Abstract – TGFβ1 compensates cigarette smoke induced disruption of tight junctions in the bronchial epithelium
Andrea Eickelberg, Nisika Mise, Oliver Eickelberg, Comprehensive Pneumology Center, HMUC, Munich, Germany

Rationale: The airway epithelium protects the body from inhaled insults, such as smoke, or allergens. The integrity of this epithelial barrier is crucial for bronchial homeostasis. COPD and asthma have been associated with defective airway barrier...
function. Tight junctions (TJ) represent the major junctional components, determining the permeability of an epithelial sheet. Cigarette smoke extract (CSE) has been described to impair TJ integrity. The aim of this study was to investigate if CSE also promotes EMT in human bronchial epithelial cells (HBEc), thereby contributing to small airway diseases.

Methods and results: Normal HBEc (16HBE) underwent EMT-like processes in response to TGFβ1 treatment, as characterized by elevated mesenchymal markers (FN1, SNA1, or ZEB1). Epithelial junctional markers (e.g., CDH1, JAM1, or ZO1) were upregulated or unaltered upon TGFβ1 stimulation. 16HBE cells do not change morphological or migrational upon TGFβ1 treatment, as demonstrated by IF or live imaging. CSE downregulated TJ-associated protein expression and destabilized TJ, as observed by IF. Combined long-term treatment (7 days) of 16HBE cells with TGFβ1 and CSE resulted in reduced mRNA and protein levels of TJ proteins. This was accompanied by altered MAP kinase signaling.

Conclusion: TGFβ1 and CSE resulted in EMT-like changes in HBEc. CSE induced TJ disruption, which was compensated by TGFβ1 through modified signaling processes. Thus, TGFβ1 could serve as a protective factor for bronchial epithelial cell homeostasis.

P4582 Antioxidant tetrapeptide UPF1 exerts an immediate effect on cigarette smoke-altered metabolic state of human bronchial epithelial cells

Agnieszka Ang, 1 Sun Altraija, 2 Kaja Kilk, 1 Lusi Lamanse, 1 Rima Mahlapuu, 1 Ursel Soomen, 1, 3 Alvarun Altraija, 2, 3 Department of Biochemistry, The Centre of Excellence for Translational Medicine, University of Tartu, Estonia; 2Institute of General and Molecular Pathology, University of Tartu, Estonia; 3Department of Pulmonary Medicine, University of Tartu, Estonia

We evaluated the protective capacity of UPF-1 (4-methoxy-L-tyrosinyl-L-glutamyln-L-cysteinyl-glycine) against cigarette smoke condensate (CSC)-induced alterations in metabolic profile of human bronchial epithelial cells (HBEc). HBEc were exposed to 10 μM CSC for 1, 2, 3, and 6 h. We then measured and compared the expression of upregulated genes by TGFβ1 using RT-qPCR.

Results: CSC upregulated only 16, and of all the upregulated genes, 4 were uniquely upregulated by CSC (cathelin [α1, extracellular matrix protein 1, TIMP 1 and 2]. As expected, TGFβ1 upregulated a variety of ECM proteins (eg collagen I, III, vitronectin), anti-matrix metalloproteinases, and degradative enzymes (eg matrix metalloproteinase MMPs I, II, 12, 13 and 14).

Conclusion: As CSC selectively upregulated a subset of TGFβ1-induced genes, elucidation of the specific mechanisms involved is likely to give novel insight into the pathophysiology of COPD.

P4584 Epithelial growth factor (EGF) and its receptors (ERBBs) in smokers with and without COPD: An index of epithelial repair imbalance?

Aristotelis Anagnostis, Eirini Neofytou, Nikolaos Souliris, Maria Avgousti, Charalampos Sroumpou, Ioannis Drositis, Nikolao Siatistas, Eleftheria Drakopoulou. Medical School, University of Crete, Heraklion, Crete, Greece.

Background: The EGF and its receptors are expressed in the lung and orchestrate the epithelial repair process. We hypothesized that EGF pathways are involved in COPD pathogenesis.

Aim: To study EGF and ERBB receptors mRNA expression in lung tissue of smokers with or without COPD and control non-smokers.

Methods: Lung tissue specimens from 45 male subjects were studied: A) 10 patients with mild COPD (GOLD stage I), B) 10 patients with moderate COPD (GOLD stage II), C) 15 non-COPD smokers with normal lung function, and D) 10 non-smokers, serving as the control group. Quantitative Real-Time PCR experiments were carried out for EGF and receptors ERBB1, ERBB2, ERBB3, ERBB4, using beta-actin housekeeping gene as internal control.

Results: All study groups were matched for age. Moderate COPD patients had higher ERBB1 (EGFR), ERBB2 and ERBB3 mRNA levels compared to the other three groups. On the contrary, while moderate-COPD ERBB4 mRNA levels were statistically increased when compared to non-smokers (P=0.041), they did not differ when compared to mild-COPD patients (P=0.19) or to non-COPD smokers (P=0.18). Finally, EGF expression was at least 2-fold increased in moderate- and mild-COPD patients and non-COPD patients, when compared to non-smokers, a finding which was statistically significant only between moderate-COPD patients and non-smokers (P=0.010).

Conclusions: EGF was over-expressed in all three smoking’ study groups. However, its receptors (especially ERBB1-3), were elevated only in moderate-COPD patients. This could reflect the epithelial “repair” or “remodeling” process exerting by the EGF signaling pathway as COPD progresses.

P4586 Effects of α1-antitrypsin on neutrophil extracellular traps formation

Eileen Frengel, Elena Korenbaum, Thomas Köhlein, Tobias Welte, Sabina Janczauskienė. Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany

Neutrophils belong to the innate immune response and are essential for elimination of invading pathogens. Apart from phagocytosis and secretion of anti-microbials, neutrophils are also capable of producing neutrophil extracellular traps (NETs) to kill pathogens extracellularly (NETosis). Neutrophil elastase (NE) is a critical initiator of NETosis and also is one of the main components of NETs. The acute
phase protein α1-Antitrypsin (AAT) is a potent inhibitor for NE released from the activated neutrophils. Therefore, we asked a question if AAT inhibits NETosis? We induced NETosis in neutrophils isolated from healthy donors by applying phorbol myristate acetate (PMA, 10 ng/ml) alone or together with purified AAT protein (1 mg/ml). To our surprise, AAT did not inhibit NETs formation but make the structures less adherent to the surface. Remarkably, using anti-AAT antibodies we detected AAT in the NETs either separately or in co-localization with elastase. In the next set of experiments, we isolated neutrophils from emphysema patient with inherited ZZ (Glu342 Lys) AAT deficiency before and after AAT augmentation therapy. In response to PMA, neutrophils isolated before augmentation therapy formed NETs similar to those observed in healthy donors. However, after augmentation therapy, NETs contained large cell aggregates some of which were detached from the specimen. Again, exogenous AAT did not inhibit NETs. We suggest that an increased risk for development of chronic obstructive pulmonary disease (COPD) in subjects with inherited AAT deficiency results from both-increased elastase activity and uncontrolled NETosis.

P4587 Resveratrol attenuates cigarette smoke induced oxidative stress: Possible involvement of SIRT1

Jing An, Yong-Chun Shen, Tao Wang, Ting Yang, Fu-Qiang Wen. Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Objectives: Cigarette smoke is known to cause oxidative stress in alveolar epithelial cells. In this study, we investigated the effect of resveratrol, a phytochemical produced by some spermatophytes, on oxidative stress induced by cigarette smoke in airway epithelial cells.

Methods: Rats with or without exposure to cigarette smoke were intraperitoneally injected with resveratrol (5,10,20mg/kg). TNF-α levels in BALF were determined by ELISA. Total glutathione, SOD and H₂O₂ levels in rat lungs were measured by spectrophotometry.

Results: Cigarette smoke exposure significantly increased TNF-α expression in BALF and this upregulation was significantly attenuated by resveratrol (p<0.05). Meanwhile, the treatment of resveratrol increased the expression of glutathione and SOD in lung homogenates, which were attenuated by cigarette smoke exposure (p<0.05). The expression of H₂O₂ was decreased by resveratrol (p<0.05). Exposure of A549 cells to CSE resulted in the elevated ROS expression, which was inhibited by resveratrol. Meanwhile, SIRT1 protein levels were activated by the pre-treatment of resveratrol.

Conclusions: These results suggest that resveratrol attenuated oxidative stress induced by cigarette smoke. The anti-oxidant effect might act through the expression of SIRT1 proteins.

P4588 Chronic obstructive pulmonary disease is characterized with suppressed lipoxin A4 and increased lipoxin receptor expression in lungs

Liga Bolda,1 Darja Igauev1 Agnese Kisina,2 Sergejs Igauev1,3 Gunta Strazda1,2, Neumonologija un Pulmonoloģija, 1Instituts līdzekļu terapijas un gastropatolāgo integralizāciju centrs, Rīgas adrese: ilūkste 14, Rīga, Latvia; 2Institute of Experimental and Clinical Medicine, University of Latvia, Riga, Latvia

Persistent inflammation of COPD could be influenced by disorders of arachidonic acid metabolism when synthesis of leukotrienes does not switch to lipoxin metabolism. We described an increase of lipoxin receptor expression in lung homogenates of COPD patients with increased lipid peroxidation.

Aim: To estimate concentration of lipoxin A4 (LXA4), leukotriene B4 (LTB4), as well as expression of LXA4 receptor (FPRL-1) in induced sputum (IS) of COPD patients and healthy controls.

Materials and methods: 17 COPD patients and 7 healthy controls. LXA4 and LTB4 concentration in IS was assessed by ELISA. FPRL-1 expression was detected immunocytochemically.

Results: Concentration of LXA4 in COPD patient’s IS was decreased compared to healthy controls (0.99±0.43 ng/ml vs 2.198±1.89 ng/ml; p=0.009). Ratio LTB4/LXA4 in COPD patients was three times greater compared to healthy persons (8.884±2.789 vs 3.328±0.94; p<0.0071).

In COPD patient’s IS FPRL-1 positive polynuclear cells (PPC) were in greater amount compared to healthy controls (8,802±5,758 cells/mm² vs 2,123±2,232 cells/mm²; p<0.00109). Also, in COPD patients a count of FPRL-1 positive mononuclear cells (PMCs) in IS was increased compared to healthy controls (2.563±1.711 cells/mm² vs 0.655±0.522 cells/mm²; p=0.0311).

Correlation between FPRL-1 PPC and LTB4 concentration in IS (r=0.628; p=0.0013).

Conclusions: Increased LTB4/LXA4 indicate a disbalance of inflammatory media tors in COPD patients that could be one of the causes of inflammation persistence. In this case a decreased receptor expression and its correlation with LTB4 concentration in COPD patients could be one of mechanisms of inflammation adaption that is initiated by LTB4.

P4589 Immunoregulation and Foxp3 expression in the bronchial mucosa of stable COPD patients

Antonino Di Stefano1, Gaetano Caramori2, Chiara Vicari1, Isabella Gnemmi1, Davide Valles1, Paola Brun3, Andrea Zanini1, Francesco Cappello1, Fabio Ricciardolo2, Alberto Papi1, Bruno Balbi1,1 Cittadinanzapathologia Cardio Respiratori, Fondazione IRCCS, Verona, Italy; 2Centro Ricerche Asma e BPCO, Università di Ferrara, Italy; 3Istituto di Istituto e Embriologia, Università di Padova, Italy; 4Divisione di Pneumologia, Fondazione S. Maugeri, IRCCS, Tradate, Italy; 5Department of Biomedicine Spedito Vincenzo, Anatomia Umana, Università di Palermo, Italy; 6 Dipartimento Scienze Cliniche e Biologiche, Università di Torino, Italy; 7Centro Ricerche Asma e BPCO, Università di Ferrara, Italy; 8Divisione di Pneumologia, Fondazione S. Maugeri, IRCCS, Veruno, Italy

Background: T regulatory cells (T₉) control the immune responses at sites of inflammation. The differentiation and function of T₉ cells is regulated by the transcription factor forkhead box p3 (Foxp3). Conflicting results have been reported in central and peripheral airways of COPD patients regarding numbers of Foxp3+ cells populating the airways (Igauev S, Eur Respir J 2009;33:61).

Objectives: To investigate the expression of T-regulatory molecules in the bronchi of patients with severe/very severe (FEV1 pred:35:69; n=19), mild/moderate (FEV1 pred:66±14; n=13) stable COPD, control smokers (FEV1 pred:104±13; n=12) and non-smokers (FEV1 pred:116±14; n=11).

Methods: Expression of Foxp3 was measured in the bronchial mucosa using immunohistochemistry in cryostat sections.

Results: Immunopositivity for Foxp3 was similar in the bronchial epithelium (cells/mm²) (median(range): 1.1(0.5-2) vs 1.2(0.5-1.7) vs 1.1(0.5-2) vs 1.2(0.2-2.3), Kruskal Wallis (KW), p=0.948, and submucosa (cells/mm²) (86(32-155) vs 92(2-19-187) vs 86(19-306), p=0.990, in control non smokers, control smokers, mild/moderate and severe/very severe COPD, respectively.

Conclusion: We show no significant differences in the numbers of Foxp3+ cells populating the bronchial mucosa in COPD patients and control groups, suggesting that immunomodulation of inflammation is not influenced by Foxp3 in the bronchi of patients with COPD.

P4590 Altered proliferation of alveolar epithelial cells is involved in progressive lung fibrosis-induced emphysema

Alexander Bobla1, Katrin Kohse2, Johannes Schwarz2, Gerrit John1, Oana Veronica Amari1, Oliver Eickberg1,2, Ali Onder Yildirim1,1 Institute of Lung Biology and Disease, Comprehensive Pneumology Center, Klinikum der Universität München, Helmholtz Zentrum München, Germany; 2Institute of Experimental Pneumology, Comprehensive Pneumology Center, Klinikum der Universität München, Helmholtz Zentrum München, Germany

Rationale: Chronic obstructive pulmonary disease (COPD) is characterized amongst others by development of emphysema. We showed that a single application of porcine pancreatic elastase (PPE) causes a severe progressing emphysema-like phenotype in C57BL/6 mice. Since the development of emphysema is apparently not completed after PPE application, we aimed to identify possible key mechanisms that drive this process even at late time points.

Methods: Female C57BL/6 mice received a single oropharyngeal application of PPE or PBS, and lung function, histology and gene expression were analyzed on days 2, 28, 56, and 162. Fibroblasts of PPE treated mice were characterized analyzing mitochondrial membrane potential. Furthermore, LA-4 lung epithelial cells were treated with PPE and proliferative and apoptotic characteristics were measured using gene expression or wound healing assays.

Results: PPE treated C57BL/6 mice develop progressive airway enlargement and impairment of pulmonary function during 23 weeks of analysis. Q-PCR revealed elevated expression of apoptosis markers, reduced proliferation and increased expression of matrix components. Lung fibroblasts of PPE treated mice show reduced proliferation and an altered mitochondrial membrane potential. Reduced proliferation was also found in PPE treated LA-4 cells.

Conclusion: Diminished proliferation in PPE treated lung epithelial cell lines as well as in lungs and primary fibroblasts of PPE treated mice could explain the persistent progression of PPE induced emphysema in mice.

P4591 Different pathology of pulmonary arteries in centrilobular and panlobular emphysema

Grazzia Turani1, Andrea Ballarin1, Cecilia Scattolin1, Simonetta Barzold2, Erica Bizzarr1, Elena Muniv, Beatrice Molena1, Marco Damiran1, Elisabetta Balesiro1, Pietro Maestrelli1,1 Marcela Couto2,1 Department of Cardiac, Thoracic and Vascular Sciences, University and City Hospital, Padova, Italy; 2McMaster-Christie Laboratories, McGill University, Montreal, Canada

Two distinct pathological phenotypes have been described in patients with emphysema: Centrilobular Emphysema (CLE) and Panlobular Emphysema (PLE), with distinct clinical and functional characteristics. A different involvement of small airways and parenchyma has been described in CLE and PLE, but the involvement
of pulmonary arterioles has never been analyzed. Therefore, we evaluated remodeling of pulmonary arterioles in surgical samples from 26 patients with CLE, 18 with PLE, 7 smokers without emphysema (SNE) and 8 non smokers (NS). By image analysis we measured total arterial wall, intima, media and adventitial thickness. Furthermore, since mast cells (MCs) are potentially involved in vascular remodeling, we quantified the infiltration of tryptase+ MCs in arterioles. Subjects with CLE have a higher total wall thickness compared to those with PLE (median [range] 61 [21-198] vs 46 [17-143] μm; p<0,001) and NS (51 [20-123]; p<0,05). In particular, thickness of the intima was greater in subjects with CLE than in those with PLE (9 [2-66] vs 6 [2-41]; p<0,05), as was thickness of the media ([97-94] vs 16 [7-63]; p<0,005). Finally subjects with CLE have a higher number of MCs in the adventitial layer than those with PLE (200 [0-1200] cells/mm2 vs 111 [0-1000]; p<0,001). In conclusion, our study demonstrates that pulmonary arterioles show a different pathology in CLE and PLE, suggesting that the mechanism responsible could be different in the two forms of emphysema.

P4594
Proteinase 3 and its potential role in emphysema
Nicola Sinden1, Timothy Daffon2, Robert Stockley1,1 Lung Function and Sleep Department, Queen Elizabeth Hospital, Birmingham, West Midlands, United Kingdom; 2School of Biosciences, University of Birmingham, West Midlands, United Kingdom

Introduction: Proteinase 3 (PR3) is an elastin-degrading proteinase similar to neutrophil elastase (NE). PR3 is the most abundant serine proteinase in neutrophils, and excessive emphysema in animal models & induces mucus secretion in humans. The main circulating inhibitors are alpha-1-antitrypsin (AAT) and alpha-2-macroglobulin (A2M). Its role in respiratory disease has not been studied in detail.

Aims: 1) To determine how efficiently PR3 activity is inhibited by healthy (PiM), AAT deficient (PiZ) & AAT variant (PiFZ) AAT.

2) To study partitioning of PR3 between its 2 serum inhibitors.

Methods: Serum from subjects with different AAT phenotypes (PiM, PiZ, PiFZ, PiZZ) was taken & AAT concentration measured. Increasing ratios of serum AAT to PR3 were incubated & residual PR3 activity measured. Experiments were reproduced using comparable mixtures of pure AAT & A2M. Association between different PR3 variants in AAT (Kass of PR3 to A2M) & activity were determined using methylene-treatment serum (A2M inactivated).

Results: Increasing the molar ratio of serum AAT to PR3 increasingly inhibited PR3 activity, however even in AAT excess some residual PR3 activity remained which was greater in PiZ serum compared to PiM serum. These results were reproduced using mixtures of pure AAT & A2M suggesting that PR3 bound to A2M remains catalytically active. The Kass values for AAT variants with PR3 & NE are shown in table 1.

Table 1

<table>

Conclusion: When serine proteinases are released from neutrophils, NE is more likely to be inhibited by AAT than PR3 (due to the lower Kass values) & binding of PR3 to A2M retains its activity.

P4595
Increasing oxidative stress and inflammation in patients with exacerbated chronic obstructive pulmonary disease (COPD) and their association with lung function
Velm Stratou1, Jordan Peters2, Sonya Galcheva3, Marinka Peneva1,1 Clinic of Pulmonology and Allergology, University Hospital "St. Marina", Varna; 2Dept. of Internal Diseases, Military Medical Academy-Naval Hospital, Varna; 3Dept. of Pneumatics, University Hospital "St. Marina", Varna, Bulgaria

Oxidative stress and chronic inflammation are the milestones in pathogenesis of COPD. It is assumed that their increase is associated with a worse lung function and frequent exacerbations.

Our aim was to assess changes in antioxidant enzymes superoxide-dismutase (SOD) and glutathione-peroxidase (GPx) activities and inflammatory markers in patients with exacerbated COPD, stable COPD and healthy controls and their association with lung function.

We performed a cross-sectional study among 244 participants (mean age 60±9.5 years) divided into 3 groups: 76 were with exacerbated COPD (group 1), 65 were with stable COPD (group 2) and 103 were matched healthy subjects (group 3). We performed a questionnaire to define pack years, spirometry and biochemical tests. Oxidative stress was measured by erythrocyte activities of SOD and GPx. Compared to the control group, patients from group 1 had significantly lower SOD and GPx activities (p<0.0001), with an increasing trend between groups. ESR and CRP activities were significantly higher in patients with exacerbated COPD (p<0.0001). The inflammatory markers correlated positively with pack years (r=0.15, p<0.05 for ESR and r=0.242, p<0.001 for CRP) and negatively with FEV1% (r=-0.187, p<0.05 and r=0.219, p<0.001 resp.). The present study suggests that there is an increased oxidative stress and inflammation in patients with COPD in exacerbation and there is a relationship with the severity of the disease.

Phl1 mutation induces altered respiratory response to an airway challenge

Elena Rodriguez1, 2, Grace M. Hobson2, Lauren Sakowski2, Yan Zhu1, Milena Armani1, Thomas Shaffer1, 1Nemours Research Lung Center, Nemours/Alfred I. duPont Hospital for Children, Wilmington, United States; 2Center for Applied Genetics and Genomics, Nemours Biomedical Research, Wilmington, DE, United States; 1Department of Pharmacology and Experimental Therapeutics, Jefferson Medical College, Philadelphia, PA, United States

Pelizaeus-Merzbacher disease (PMD) is a disease caused by mutations of the proteolipid protein 1 (PLP1) gene that result in defective CNS myelination. Mice with an extra copy of Phl1, called Phl1/Phl1, develop a syndrome that models the objective of this study. PMD. Patients with all except the mildest forms have respiratory involvement.

Objective: We hypothesized that Phl1/Phl1 mice would lack protective airway responsiveness (AR) to an autonomic drug challenge. To address this, we investigated whether respiratory mechanics in these mice would be different at baseline (BL) or during methacholine (MCh) challenge.

Methods: Wild type (Wt) n=16, carrier (Car) n=8 & affected (Af) n=17 mice, 3 months (3m) and 6 months old (6m), were anesthetized, mechanically ventilated & challenged with 0.16 mg/ml of aerosolized MCh. We calculated resistance (R), dynamic/static compliance (Cdyn/Cstat), airway obstruction (PhTB); lung tissue biomarkers & histological analysis are ongoing. Results: BL differences were found in Wt vs Car (p<0.05) dependent on age (p<0.0001). MCh increased R as a function of dose in Wt & Car, whereas Af mice lacked sensitivity to MCh (p<0.05). No differences in body weight, gender (Wt females vs Car males) & coat were found. Af mice had the highest PhTB. Conclusion: Wt mice compared with Af mice were lacking of AR to MCh at 6m; but not at 3m. These results indicate an age-associated lack of protective autonomic AR in the Phl1Phl1 mouse model and suggest that respiratory autonomic disequilibrium may contribute to the respiratory involvement in PMD patients. The Phl1Phl1 animal model may be used for testing therapeutic interventions.

P4599

Bronchial wall structure is altered in adult mice following neonatal hyperoxia

Megan O’Reilly, Foula Sozo, Richard Harding. Anatomy and Developmental Biology, Monash University, Clayton, VIC, Australia

Background: Very preterm infants often require supplemental oxygen, and can have an increased risk of poor lung function and asthma in later life. Follow-up studies suggest that factors associated with very preterm birth can cause long-term changes in the small conducting airways. Aim: To determine if bronchial wall structure is persistently affected by neonatal exposure to hyperoxic gas.

Methods: Neonatal mice (C57BL/6J) breathed 65% O₂ from birth until postnatal day 7 (P7), after which they lived in room air until P56 (n=26). Controls breathed room air from birth (n=27). Bronchiolar walls, lung parenchyma and bronchoalveolar fluid (BALF) were analysed at P56. In bronchioles, we measured epithelial thickness, proportions of proliferating epithelial cells, ciliated and Clara cells, the amount of collagen and airway smooth muscle (ASM) and the number of alveolar-bronchiolar attachments. In lung parenchyma, we measured percent tissue space and mean linear intercept (MLI).

Results: In bronchioles, adult mice exposed to neonatal hyperoxia had significantly smaller airway lumen diameters compared to controls; there were no significant differences in bronchial epithelial cell proliferation, Clara cells or ciliated cells. In lung parenchyma, MLI was increased, and tissue fraction reduced (both p<0.05) in hyperoxia-exposed mice, but there was no effect on the number of alveolar-bronchiolar attachments. In BALF there were 60% more immune cells (p<0.05) after hyperoxia. Conclusions: Exposing the developing lung to hyperoxic gas results in persistent airway remodelling and increased numbers of pulmonary immune cells suggesting on-going inflammation in adulthood.

P4600

Long term sensitisation of cough and expiration reflex in adult rabbits by 48 hour postnatal normobaric hyperoxia

Silvia Varechova1, 2, Bruno Demoulin1, Yanis Inglebert1, Than Le Tu3, Anne Laure LeBlanc2, Cyril Schweitzer1, 2, François Marchal1, 1Explorations Fonctionnelles Pédiatriques, Hôpital d’Enfants, Vandœuvre-lès-Nancy, France; 2EA 3450 Laboratoire de Physiologie, Faculté de Médecine, Vandœuvre-lès-Nancy, France

Rationale: Cough is a frequent report in follow up studies of late premature children at school age. On the other hand, the experimental evidence exists in animals that the short term effect of acute hyperoxia is to down regulate cough. The hypothesis that neonatal exposure to hyperoxia may interfere with incidence of cough at school age has not been tested previously. The aim of the study was to determine if postnatal administration of oxygen in pups alters the cough reflex in adult rabbits.

Methods: Rabbis were exposed within the first 8 days of life to 48h normobaric hyperoxia (FiO₂ > 95%; n=12) or ambient air (control; n=9). At age 3 - 4 months the animal was anesthetized, tracheostomized and subjected to a series of discrete mechanical stimulations of the trachea lasting 50, 150, 300 and 600ms. Each stimulus was quadrupled so as to total 24 stimulations per animal. Cough and expiration reflex were identified from breathing flow and volume, respectively as a forced expiratory effort preceded (cough) or not (expiration reflex) by an increased resistance. Results: The incidence of either cough (66/288: 23%) or expiration reflex (124/288: 43%) in hyperoxic rabbits was significantly larger than its respective control (cough: 25/214: 12%; expiration reflex: 60/214: 28%; p < 0.0005). Conclusion: The experimental evidence of long term sensitisation of airway defensive reflexes in rabbits breathing high oxygen soon after birth favours a role for neonatal hyperoxia in the pathogenesis of chronic cough at school age in late premature children.
Routine measurement of the LCI in CF with an ultrasonic device for multiple breath nitrogen washout

Susanne Fach1, Edmund Petri1, Georg Hulskaem1, Monika Gappa1

1 Children’s Hospital and Research institute, Marien Hospital, Wesel, Germany; 2Children’s Hospital, Clemenshospital, Munster, Germany

During the last decade multiple breath washout technique (MBW) for calculating the Lung Clearance Index (LCI) has become very popular for assessing ventilation inhomogeneity (VI) as an early manifestation of Cystic Fibrosis (CF) lung disease. However, routine use has been difficult not only due to limited availability of licensed equipment. Inert tracer gases (e.g. SF6, He) certified for medical purposes are not universally available. Switch to nitrogen washout (MBW_N2) using 100% oxygen may overcome this problem.

The aim of this cross sectional study was to assess whether LCI derived from MBW_N2 discriminates as well as MBW_SF6 between patients with CF and healthy controls. 19 controls (7-51 years) and 11 unselected patients with CF (7-25 years) performed 2-3 single MBW_N2 using the EasyOne Pro LAB™ (ndd Switzerland) with 100% oxygen.

Mean (SD) LCI was 6.5 (0.64) in controls and 9.3 (1.93) in CF with a mean difference (95% CI, p-value) of 2.83 (-1.44; 1.51, 0.001) between the groups. Within-test repeatability (CV%) was 5.3% in controls and 7.7% in CF. Assessment of LCI using licensed equipment for MBW_SF6 was feasible and well tolerated in both, children and adults and patients and controls. LCI based on MBW_N2 differed significantly between patients with CF and controls and results were comparable to published data obtained with different equipment and with using SF6 as tracer gas. We conclude that MBW_N2 reflects VI similar to MBW_SF6 and may thus be used for clinical application of MBW in patients with CF.

Bench test of a mass spectrometer based multiple-breath washout system using a realistic lung model

Florian Singer1, Birgitta Houlzt2, Paul Robinson3, Philipp Latzin1

1 Division of Pulmonology, Department of Paediatrics, Inselhospital, University of Bern, Switzerland; 2Department of Clinical Physiology, East Hospital, Sahlgrenska University Hospital, Gothenburg, Sweden; 3Department of Respiratory Medicine, The Children’s Hospital at Westmead, Sydney, Australia; 4Department of Paediatrics, Central Hospital, Skövde, Sweden

Background: Lung volume measurement accuracy of multiple-breath washout (MBW) systems should be validated under realistic conditions. Here we used a previously described lung model (ERS meeting 2011) incorporating BTSF conditions to validate a customized mass spectrometer (AMIS 2000; Innovision) MBW system. The aim was to assess the feasibility and accuracy of this new system for lung volume measurement.

Methods: Functional residual capacity (FRC) measurement accuracy was assessed across a range of FRCs (430-4120 mL), tidal volumes (2100-1010 mL) and respiratory rates (36-12 min⁻¹). A wash-in inert gas mixture containing 4% sulfur hexafluoride (SF6) and 4% helium (He) was used for MBW. 63 MBWs were conducted over two test days. Measured gas and flow signals were processed in custom software (TestPoint). FRC was calculated as cumulative expired inert gas fraction (FRC) and mean error (range). Differences between measured and nominal FRC was 46.7 mL (1.7%), upper and lower limits of agreement were 155.3 mL (5.1%) and -62.0 mL (-1.8%), respectively. For 156 FRCs, 124 (79%) were within 5% of the nominal FRC, mean error (range) was 2.1 (0.1-6.0%). Error was associated with respiratory rate (R² = 0.23). FRC was reproducible between tests, coefficient of repeatability was 73 mL (3.4%) and similar using either He or SF6 for FRC calculation.

Conclusion: Using a lung model previously shown to be suitable for MBW system validation under physiological conditions, the custom mass spectrometer MBW system precisely and reproducibly measures FRCs ranging from preschool to adult lung volumes.

Validation of multiple breath washout technology in healthy children and children with CF

Felix Ratjen1, Juliana Salazar1, Karyn Gibney1, Renee Jensen1, Per Gustafsson1, Padmaa Subbarao2, Sanja Stanjevic1

1 Respiratory Medicine, Hospital for Sick Children, Toronto, Canada; 2Pediatrics, Central Hospital, Skövde, Sweden

Mass spectrometry based technology is considered the “gold standard” for measuring LC, but is not readily available. In this ongoing study we aim to validate a nitrogen washout system for use in CF children. In a cross-over design, healthy and symptomatic CF children performed MBW by mass spectrometry (AMS 2000; Innovision A/S, Odense, Denmark) using 4% SF6 or by nitrogen washout (Exhalayer D, Eco Medics AG, Switzerland). Results were independently scored by two operators; Bland-Altman plots were used to assess the agreement between the two systems. To date 24 healthy children (median age 11 years (range 3-17)) and 33 children with CF (median age 11 years (range 3-17)) completed MBW measurements using both the mass spectrometry and N2 washout. There was no systematic bias observed in LCI (or as an early manifestation of CF lung disease).

Conclusion: Overall there was good agreement healthy children (95% of all measurements agreed within ±0.44, 0.83); however LCI_SF6 was systematically 0.2% (95% CI 0.06; 0.33) units lower than LCI_N2. The mean difference between the two systems was greater in children with CF (0.4% (CI 0.29 to 0.55) and the limits of agreement were wider (-0.33, 1.17). Agreement between the two methods for moment ratios M1M0 (4.03; 0.63) than M2M0 (-5.72; 8.60), and greater in healthy children compared with children with CF. Inter-observer agreement for nitrogen washout was high (0.08; 0.08) for all outcome. There was no systematic bias between the two systems. LCI measured by nitrogen washout is higher compared to LCI measured by mass spectrometry. Inter-observer variability is low for nitrogen washout if analyzed by trained operators.

Supported by CFF.

Ways to shorten the lung clearance index measurement I – Are three measurements needed?

Sophie Yammine, Florian Singer, Chiara Abbas, Philipp Latzin. Division of Pulmonology, Department of Paediatrics, Inselhospital, University Hospital of Bern, Switzerland

Background: Inert gas multiple-breath washout (MBW) derived lung clearance index (LCI) is a sensitive lung function parameter in subjects with mild cystic fibrosis (CF) lung disease, but rarely measured in clinical routine due to lack of available equipment and lengthy protocols. Using an available nitrogen (N2) MBW setup (Exhalayer D, Eco Medics, Switzerland) we assessed shortened N2-MBW protocols for LCI.

Methods: We determined whether the LCI from the 1st (LCI1) and the mean LCI of the 1st and 2nd valid N2-MBW (LCI2), respectively, are comparable to the averaged information obtained from three N2-MBW (LCI3).

Results: LCI1, LCI2, and LCI3 differed significantly between patients with CF and children. LCI1 and LCI2 were strongly associated with LCI3 (R² = 0.98 for both), took less time, and were of similar diagnostic value. Comparing LCI1 and LCI2, LCI2, mean (range) test duration was 2.2 (0.5-5.2), 6.6 (3.6-12.7), and 11.1 (8.0-17.1) min, and upper limits of normal LCI (8.3, 8.5, and 8.4) all correctly classified 71% of children, respectively. Bland-Altman analysis of LCI1, and LCI2 showed good agreement with LCI3; Mean difference was -1.1% and -0.7%, limits of agreement were 6.8 to -9.0% and 5.9 to -7.3%, respectively.

Conclusion: In the current study population, the 1st LCI or the mean of the 1st and 2nd LCI take less time and precises the N2-MBW with physiological measurement variability. Using less N2-MBW measurements seems promising for time-saving LCI measurement in clinical routine.

Abnormalities in lung clearance index in CF infants diagnosed by newborn screening

Padmaa Subbarao1, Felix Ratjen1, Renee Jensen1, Per Gustafsson2, Meghan Brown1, Sanja Stanjevic1, Respiratory Medicine, Hospital for Sick Children, Toronto, Canada; 2Department of Pediatrics, Central Hospital, Skövde, Sweden

Newborn screening (NBS) in CF offers the potential to prevent lung damage before the onset of clinical symptoms. The lung clearance index (LCI), measured by multiple breath washout has shown promise as a marker of early lung disease in patients with CF. Therefore we aimed to determine whether LCI could be used to distinguish between subjects with CF and healthy subjects in the first 2 years of life. Healthy infants (3 months – 2 years) completed MBW testing as part of the infant pulmonary function protocol of the Canadian Healthy Infant Longitudinal Development Study (CHILD Study). Infants (3 months – 2 years) with diagnosed CF attending the Respiratory Medicine Clinic at the Hospital for Sick Children were invited to complete MBW testing. MBW was measured 51 healthy infants and 18 infants with CF diagnosed by NBS. Despite NBS, infants born with CF were smaller (Height-for-age z-score (-1.19 (-0.58; -1.81) and lighter (mean difference weight-for-age z-score (-0.40 (-0.49; 0.19) compared with healthy controls. The LCI was on average 0.4 units higher in CF (mean LCI 7.32 (SD 0.91)) compared to healthy infants (6.92 (SD 0.61)). Adjusting for the relationship between LCI and height in the first 2 years of life, LCI was 0.67 (95%CI 1.34; -0.01) z-scores higher in CF compared to healthy infants, although overlap was considerable (Figure). Therefore, despite newborn screening early abnormalities in LCI are present in CF patients LCI underscoring the need for new treatment approaches to address early lung disease.

Assessment of ventilation inhomogeneity in patients with alpha-1-antitrypsin deficiency – A useful tool for monitoring early lung disease

Susanne Fach1, Monika Gappa. Children’s Hospital and Research institute, Marnen Hospital Wesel, Germany

The risk of developing alpha-1-antitrypsin deficiency (α-1-AT deficiency) related fatal emphysema during adulthood is high in patients with a PiZZ genotype. Currently, the FEV1 is used for detecting and monitoring α-1-AT deficiency related lung disease. However it is likely that the early manifestation starts in peripheral
airways that are not accessible by spirometry. Multiple Breath Washout (MBW) is a sensitive test for detecting ventilation inhomogeneity (VI) within the peripheral airways that can be quantified by calculating several indices such as the Lung Clearance Index (LCI). We performed a preliminary analysis of an ongoing multi centre study assessing the clinical and prognostic value of measuring the LCI in patients with α1-AT deficiency. 19 controls (7.5±1years) and 20 unselected patients with α1-AT deficiency (12-72 years) performed 2-3 simple MBW20 using the EasyOnePro LAB™ (nord Switzerland) with 100% oxygen and subsequent spirometry. Mean (SD) LCI was 6.5 (0.64) in controls and 9.0 (1.98) in patients with a mean difference (95% ci, p-value) of -2.57 (-3.54; -1.60, <0.001) between the groups. Within-test repeatability (CV%) was 5.3% in controls and 6.0% in patients. LCI correlated significantly with age in patients. Assessment of LCI derived from MBW20 was feasible, reproducible and well tolerated in both, patients and controls. LCI differed significantly between patients and controls. In patients LCI appeared with age. We conclude from these preliminary data that the LCI reflects presence of VI in patients with α1-AT deficiency and may thus be useful for monitoring α1-AT deficiency related lung disease.

**P4607 Long clearance index and exercise capacity among children with bronchiectasis**

Eliss Hatziagorou, Vasiliki Avramidou, Fotis Kivrassilis, Kalliopi Kontoulou, Stefanos Nikopoulos, John Tsanakas. 3rd Paediatric Dept, Paediatric Pulmonology Unit, Aristotle University of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece

**Background:** In paediatric bronchiectasis, there has been limited experience on the relationship between disease severity, as assessed by exercise limitation and lung clearance index (LCI).

**Aim:** To compare LCI and exercise capacity among children with bronchiectasis.

**Method:** Fifteen stable children and adolescents with CF, 14 stable children with non-CF bronchiectasis and 15 healthy children and adolescents, participated in maximal incremental cardiopulmonary exercise testing using a cycle ergometer and they had an LCI assessment.

**Results:** The CF children’s mean age was 13.7 years, mean FEV1 74.4% predicted. The 14 non-CF bronchiectasis children’s mean age was 13.8 years, mean FEV1 78.3% predicted and the healthy children’s mean age was 13.6 years, mean FEV1 94.7%. Among CF patients there was evidence of exercise limitation, with mean Peak Aerobic Capacity (V’Opeak) 62.2% predicted. Among the non-CF bronchiectasis patients there was evidence of exercise limitation, with mean V’Opeak 77.3% predicted. No patient had exercise intolerance significantly among children with CF and non-CF bronchiectasis (p=0.06). LCI was significantly increased among CF patients (mean LCI 13.7), compared to healthy children (p<0.00001). LCI was also found significantly increased among patients with non-CF bronchiectasis (mean LCI 11.8), compared to healthy children (p<0.0001). LCI was not found significantly different among children with CF and non-CF bronchiectasis (p=0.1).

**Conclusions:** Exercise testing and Multiple Breath Washout measurements can discriminate children with bronchiectasis from healthy children. However, the burden of the disease is more prominent in children with CF compared with the non-CF bronchiectasis.

**P4608 Sensitivity of lung clearance index and chest computed tomography in early lung disease among children with non-CF bronchiectasis**

Eliss Hatziagorou1, Vasiliki Avramidou2, Fotis Kivrassilis1, Vivian Georgopoulou2, Stefanos Nikopoulos1, John Tsanakas1. 13rd Paediatric Dept, Paediatric Pulmonology Unit, Aristotle University of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece; 2Radiology Dept, Hippokration Hospital, Thessaloniki, Greece

**Background:** Lung disease starts before clinical symptoms become prominent, among CF children. Computed chest tomography (CT) is the reference method for identifying structural changes. It has been suggested that the Lung Clearance Index (LCI) is a sensitive marker allowing non-invasive monitoring of lung disease. **Aim:** The aim of this prospective study was to investigate the diagnostic accuracy of the LCI in comparison to CT among children with non-CF bronchiectasis, with early lung disease and normal FEV1 (>80% predicted).

**Method:** MBW and low-dose HRCT were performed in 14 patients (6-21 years) with non-CF bronchiectasis and normal FEV1 (>80% predicted) HRCT scans. LCI and FEV1 were recorded. A modified Bhalla score was used to assess HRCT scans. LCI was assessed with Multiple Breath Washout measurements.

**Results:** LCI was abnormal in 12/15 (80%) of children. 11/15 patients (73%) demonstrated both, increased LCI and structural changes on CT. 1/15 (6%) had no normal results in both measurements. There was a significant linear correlation between CT-score and LCI in 12/15 (87%) of patients, whereas no such correlation was observed between CT-score and FEV1. Sensitivity of the LCI to detect structural lung damage was 85%, whereas specificity of LCI was 50%.

**Conclusions:** Diagnostic accuracy of the LCI for detecting CF lung disease in patients with normal FEV1 was good when compared to CT. Results indicate that structural changes are unlikely if a normal LCI is measured. The LCI may be a suitable surrogate marker for monitoring progression of lung disease among children with non-CF bronchiectasis.

**P4609 Lung clearance index in paediatric exercise induced asthma**

Helen Sheridan1, Debbie Miller2, Jasneek Chawla2, Kenneth Macleod1, Nicholas Bell2, Steve Cunningham2. 1Department of Child Life and Health, Royal Hospital for Sick Children, Edinburgh, United Kingdom; 2Bristol Adult Cystic Fibrosis Centre, Bristol Royal Infirmary, Bristol, United Kingdom

**Introduction:** Exercise induced bronchoconstriction is reported commonly by asthmatic children. We assessed whether lung clearance index (LCI) can detect it.

**Methods:** Following symptom questionnaire, spirometry, and Multiple Breath Washout (MBW, Innocor 0.2% SF6), children performed a standard treadmill exercise challenge. One minute post exercise we measured MBW and spirometry. Measures repeated 10 mins post bronchodilatation. If baseline FEV1 decreased >20% baseline, testing only post salbutamol.

**Results:** 21 asthma patients and 21 healthy controls (13M:8F, mean 12 yrs in both groups). In asthma LCI 7.2(0.7) (mean (SD)) significantly > control 6.8 (0.4), p=0.02. In asthma, post exercise LCI increase by 4.8(10.2)% (Fig 1), with no change in FEV1(0.01(3.3) %). Post exercise LCI >14.5% in healthy volunteers (ns). In those asthma with >20% fall FEV1 (n=3), post salbutamol LCI remained high, 8.0(6.3). Post exercise change in LCI higher in asthma who reported exercise intolerance; No symptoms 2.8(8.5%); controlled symptoms 5.0(9.3%); limited despite salbutamol 17.7(16.7%). No trend for FEV1; 0.3(3.9)% vs -1.0(3.3)% vs -20(20.3)%.

Figure 1. Initial, post exercise and post salbutamol LCI in asthmatic and healthy groups.

**Conclusions:** LCI tends to rise following exercise. However rise in LCI was non-significant, consistent with the discrepancy between symptoms and altered lung function in asthmatic children. Change in LCI is greatest in the symptomatic, with largest LCI change in those reporting poor treatment response (not demonstrated by FEV1).

**P4610 Hand-held tidal breathing nasal nitric oxide measurement as a targeted case-finding tool for primary ciliary dyskinesia**

June K. Marthin, Kira G. Nielsen, Danish PCD Center, Paediatric Pulmonary Service, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

**Background:** Nasal Nitric Oxide (nNO) measurement is a sensitive supplemental tool in diagnosis of Primary Ciliary Dyskinesia (PCD). Tidal Breathing (TB)nNO requires minimal cooperation, has potential as more widespread targeted case-finding tool for PCD in all age groups, and discriminative capacity between PCD and non-PCD has been previously established using stationary nNO analyzer (Marthin JK and Nielsen KG. Eur Respir J 2011; 37: 559-565).

**Aim:** Assess validity of handheld TBnNO in a selected population.

**Methods:** TBnNO was measured in PCDs, cystic fibrosis (CF) patients and healthy subjects (HS) using both an electrochemical hand-held device, NIOX MINO® Nasal Breathing System: NIOX® and ANALYZER CLD 88sp®. All systems allow passive nasal sampling at a flow rate of 5 ml/s during tidal breathing. 2 ml/s sampling is an additional option with NIOX MINO® Nasal. Data were analysed by ROC and Bland-Altman plots.

**Results:** TBnNO values were compared in 41 subjects between 0.3 and 57 years: 15 PCDs, 13 CF patients, and 13 HS. MINO discriminated significantly between PCD and HS (P<0.001) and between CF and PCD (P<0.001).

Upper and lower airway nitric oxide levels in primary ciliary dyskinesia

Annabelle Liu1, Walker Wood1,2, Amanda Harris1, Janice Cole1,2, Jane Lucas1,2, 3Primary Ciliary Dyskinesia Research Group, Clinical and Experimental Sciences, Faculty of Medicine, University of Southampton, United Kingdom; 2 Primary Ciliary Dyskinesia Diagnostic Service, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Introduction: Patients with primary ciliary dyskinesia (PCD) have low nasal nitric oxide (nNO) and fractional exhaled NO (FeNO). The reasons are unclear but might be related to ciliary function. Analysis of nitric oxide (NO) from different regions of the airway and comparisons with other disease states may guide our understanding.

Aim: To compare differential bronchial (JNO) and alveolar (CalvNO) NO in patients with PCD, cystic fibrosis (CF), asthma and healthy subjects.

Methods: Exhaled NO at different flow rates (50, 100, 200 and 250 msL) and nNO were measured (NIOX flex®, Aerocrine, Sweden) in patients with PCD (n=12), asthma (n=18), CF (n=12) and healthy controls (n=17). JNO and CalvNO were derived using a model of pulmonary NO exchange-dynamics.

Results: FeNO at low and high flow rates were significantly lower in PCD than in healthy subjects, as was JNO, 271 pl/s (228) vs. 965 pl/s (963) (p<0.004) (mean (SD)). However CalvNO was similar between the two, 1.6 ppb (0.5) vs. 2.4 ppb (1.4) (p=0.174). (Table 1 for CF and asthma data).

Conclusion: PCD patients have significantly lower J NO but similar Calv NO to healthy controls. As there are no cilia in the alveolar region this might support the hypothesis that NO biosynthesis is coupled to ciliary function. Data collection continues.

**P4612**

Determinants of functional deficits assessed by spirometry and plethysmography in children with bronchial asthma

Richard Kraemer, Gisela Witz, Philipp Latzin, Oliver Fuchs. Division of Paediatric Respiratory Medicine, University of Berne, Inselspital, Berne, Switzerland

Follow-up in asthmatic children is usually performed by spirometry, and hence without consideration of pulmonary hyperinflation. 'Effective' specific airway resistance (sRaw) measures resistive changes throughout the whole breath cycle concomitantly to changes of resting end-expiratory level [1].

Objectives: Defining the pattern of functional deficits and their changes over time in children with bronchial asthma.

Methods: Serial lung function measurements performed in 216 asthmatic children (age: 4 to 17.9 y) were analyzed retrospectively representing at least 3 annual tests, and providing functional residual capacity (FRCraw), sRaw, volume-time and flow-volume indices (FEV1, FEF25−75, MEF25−75) Data were expressed as SD-score computed by z-transformation using reference equations. Results: Within the 1270 lung function tests spirometry failed to detect abnormal lung function in 24.1% of tests (plethysmography 1.7%). Bronchial obstruction (> 2SDS) was depicted by sRaw in 93.8%, sRaw in 74.6%, FEF25−75 in 73.8%, MEF25−75 in 62.1% and FEV1 in 23.7% of tests. Moreover, pulmonary hyperinflation (FRCraw > 2 SDS) was present in 26.7%, mostly combined with obstruction (23.4%). Independent from age at entry pulmonary hyperinflation remained to a certain degree despite treatment (LABA and ICS).

Conclusions: Apart from spirometry, follow-up of asthmatic children should include plethysmographic measurements, because changes in static lung volumes influence airway dynamics, mimicking normal flow-volume curves. Moreover, patients with pulmonary hyperinflation are less responsive to standard treatment.

**P4613**

Breath by breath specific airway resistance during ventilation in children

Laurence Coutier1, Claude Bonabel1, Bruno Demoulin1, Julia Ioan1, Than Le Tran1, Silvia Varcheva1,2, Cyril Schweitzer1,2, François Marchal1,2
1 Explorations Fonctionnelles Pédiatriques, Hôpital d’Enfants, Vaudoueva les Nancies, France; 2 EA 3450 Laboratoire de Physiologie, Faculté de Médecine, Vaudoueva les Nancies, France

Rationale: Panting is the optimal way to minimize the phase lag between the plethysmographic volume compression signal (Vplet) and airflow due to the thermal artifact when measuring specific airway resistance (sRaw). A drawback in children is that the end expiratory lung volume may be observed to increase during the measurement. It is not known to what extent sRaw is altered by the breathing strategy.

Hypothesis: The hypothesis was tested here that increased end expiratory lung volume during panting does not impact significantly on sRaw.

Objective: To test whether increased end expiratory lung level within the sRaw acquisition results in a systematic trend with time.

Methods: sRaw was measured in 10 children panting in a custom made pressure plethysmograph. Thirty measurements (1-5 per subject) that displayed a steady increase in end expiratory lung level throughout at least 4 breaths were reanalyzed breath by breath.

Results: Panting frequency (mean ± SD) was 3 ± 0.5 Hz. sRaw was found to increase significantly throughout the acquisition (p = 0.006).

Significant breath by increase in sRaw (±50 sec) during panting in 10 children

<td>7.8 ± 1.6</td>
<td>8.1 ± 1.7</td>
</tr>
</tbody>
</table>

Conclusion: The progressive increase in end-expiratory lung volume during panting in children is associated with parallel increase in sRaw. This may be explained by non lineairities in the Vplet - airflow relationship while the end expiratory lung volume increases in relation with imbalance between inspiratory and expiratory efforts. The clinical relevance is not clear and deserves further evaluation.

**P4614**

Lung function and gender at twelve to thirteen years of age in children born very prematurely.

Sanja Zivancova1, Mireia Alcazar Paris1, Alan Lunt1, Jessica Lo2, Sandra Calvert1, Neil Marlow4, Janet Peacock2, Anne Greenough1 1Division of Asthma, Allergies and Lung Biology, King’s College London, United States; 2Primary Care and Public Health Sciences, King’s College London, United Kingdom; 3Child Health, St. George’s Hospital, London, United Kingdom; Neonatal Medicine, University College London, United States.

Lung function abnormalities are common in school aged children born extremely prematurely. Follow up of infants born at 23-28 weeks gestational age from the United Kingdom Oscillation Study (UKOS) showed males had a higher incidence of respiratory morbidity during infancy.

Aim: To test the hypothesis that lung function at 12-13 years of age in children born very prematurely would be worse in males than females.

Methods: Lung function was assessed in 65 children, the first to date assessed in follow-up of UKOS, which randomised babies to high frequency oscillation or conventional ventilation. Forced expiratory volume in one second (FEV1), forced vital capacity (FVC), FEV1/FVC, residual volume (RV), transfer factor for carbon monoxide (TLC), functional residual capacity (FRC) and response to cold air challenge (CACH) were assessed. Results were abnormal if two standard deviations (SD) below expected, except RV results which were abnormal if >2.5 SDs.

Results: 29 females and 36 males have been assessed. A greater proportion of males compared to females were oxygen dependent at 28 days (89% versus 69%, p<0.063), had reduced FEV1 (22% versus 3.5%, p=0.036), higher RV (34% versus 6%, p<0.001), and reduced FEV1, FVC and TLC (24% versus 30%, p=0.08). There were no significant differences regarding the proportions with reduced FEV1/FVC (44% versus 31%, p=0.32), or reduced TLC (29% versus 50%, p=0.18 (FEV1 p=0.23) or response to a CACH 24% versus 26%, p=0.94).

Conclusion: Preliminary results suggest that amongst 12-13 year old children born at 23-28 weeks gestation, males have greater airways obstruction than females, but this is not explained by greater airway hyper-reactivity.

**P4615**

Lung function in infants and toddlers after the repair of congenital diaphragmatic hernia (CDH)

Jan Suli1, Petra Kuklova2, Michal Rygi1, Krystof Slaby1, Petr Pobuneck1, Pavel Kolur1, 2 Dept. Pediatrics, Charles University in Prague, 2nd Faculty of Medicine and Teaching Hospital Motol, Prague, Czech Republic; 3 Dept. Rehabilitation and Sports Medicine, Charles University in Prague, 2nd Faculty of Medicine and Teaching Hospital Motol, Prague, Czech Republic.

There are only 4 studies on infant pulmonary function testing (IPFT) performed after repair of CDH. We used a wide spectrum of IPFT methods to test babies in whom CDH repair was performed.

*Median (IQR); **Mean (SD); values compared to PCD.
We tested 30 infants and toddlers after CDH repair (BW 3.10±0.54 kg [mean±SD]; body length 49.5±2.2 cm). In 4/30 Goretx patch was used (subgroup Gore). Age at testing was 1.32±0.54 (median 1.07) yrs; body weight 9.76±1.23kg (z-score -0.77); body length 78.8±6.7cm (z-score -0.024). The whole-body plethysmography (to measure FRCp and rEeff), tidal breathing analysis (tPTEF%tE), baby resistance/compliance (specific Crs) and RTC method (V‘maxFRC) were performed. Standard protocol 1.2 and proper reference values 3,4 were used. FRCp equals 126.5±36.9% pred (P<0.002); rEeff reached 109.9±58.9% pred (ns). A parameter of tPTEF%tE decreased (22.8±8.5%) Specific compliance of the respiratory system, rs (Crs/kg) was 14.1±2.3 ml/kPa/6kg (76.1±20.1% pred) A value of V‘maxFRC reached only 112.±4ml/sec (z-score -2.387). Increased value of FRCp was found in Gore subgroup (165.7±51.9 vs. 120.4±31.2, p<0.02).

Our cohort had normal body length but mildly lowered body weight. Neither central airway (aw) obstruction nor restrictive pattern was found. Mild peripher al aw obstruction, mild (secondary) hyperinflation and mildly decreased specific Crs was found.

Supported by the grant NS 10572-3/2009 and grant GAUK 62809.

The bedside autofluorescence pleuroscopy for the undiagnosed lung cancer with pleural effusion in a intensive care unit

Hsuan Lin1, Shang-Miao Chang 1, Chien-Ming Liu 1, Kuo-Liang Chiu 1, Jenf-Yuan Wu2, Nan-Yung Hsu 2 .1 Chest Division, Department of Internal Medicine, Buddhist Tzu Chi General Hospital, Taichung Branch, Taichung City, Taiwan; 2 Thoracic Surgery, Department of Surgical Medicine, Buddhist Tzu Chi General Hospital, Taichung Branch, Taichung City, Taichung City, Taiwan

Introduction: Autofluorescence bronchoscopy was developed to enhance the detection of lung cancer in the airway. However, its role in evaluation of pleural space has not been published.

Aim: To assess the undiagnosed lung cancer with pleural effusion in a intensive care unit (ICU).

Methods: A flexible bronchoscope(SAFE 3000,Pentax, Tokyo) to entry to assess the pleural space. The evaluation of pleural space was started by Twin Mode and then completed by MIX. Then the specimens send for histological examination and the clinical data retrospectively studied. The whole procedures were done in the ICU bedsides.

Results: 22 patients were recruited. There were 6 patients with cytology negative and normal finding in WLP or AFP but 2 of them were found to have lung cancer. Among the 16 patients with atypia or suspicious cells had abnormal finding in the WLP or AFP, 15 patients finally had lung cancer.

Conclusions: The AFP is useful for detecting the undiagnosed lung cancer with pleural effusion. This is a daily practice performed not only in endoscopic room but in the ICU bedsides.

P4617

Triplet chemotherapy (paclitaxel/gemcitabine/cisplatin) is more active in advanced squamous cell subtype (SCC) non-small cell lung cancer (NSCLC) than doublet treatment (vinorelbine/cisplatin): A randomized phase III trial in 443 NSCLC patients

Jens Benn Sørensen1, Adam Vilmar1, Hanna Frank2, Olafred Hansen1, 1 Dept. Oncology 5073, National University Hospital, Copenhagen, Denmark; 2 Dept. Oncology, Aalborg University Hospital, Aalborg, Denmark; 3 Dept. Oncology, Odense University Hospital, Odense, Denmark

Background: A triplet regimen of Paclitaxel/Gemcitabine/Cisplatin was compared to a standard doublet regimen to examine for superiority.

Patients and methods: Histologically verified inoperable NSCLC patients (pts) were randomized to A (paclitaxel 180 mg/m² and cisplatin 100 mg/m² day 1 with gemcitabine 1000 mg/m² day 1 and 8 every 3 weeks) or to regimen B (cisplatin 100 mg/m² day 1 and weekly i.v. vinorelbine every 4 weeks).

Results: 443 pts were randomized (A: 221; B: 222). Median age was 62 years (range 38-75 years) overall, 56% were males, 11% had PS 2, 62% stage IV disease, 46% adenocarcinoma, and 28% SCC, equally distributed between A and B. Both regimens had median 4 treatment courses. Toxicities were largely similar in A and B. Response rates were 43% and 39% in A and B, medians of progression free survival (PFS) were 6.7 and 5.8 mths (p=0.453), and median overall survival (OS) were 11.4 and 10.8 mths (p=0.415), respectively. PFS and OS were significantly higher in A than in B in SCC subtype (median PFS 7.0 mths vs. 4.1 mths, p=0.001; median OS 13.5 mths vs. 9.7 months, p=0.020). response rates were equal (52% vs. 38%, p=0.129).

Conclusions: Triplet paclitaxel/gemcitabine/cisplatin was not superior to doublet vinorelbine/cisplatin in advanced NSCLC. However, the triplet regimen had significantly higher activity compared to the doublet in SCC. This superiority in SCC may likely be due to gemcitabine being more active than vinorelbine in this subtype though the relative contribution of paclitaxel remains to be determined.

P4618

Evaluation of pleural fluid human epidymis 4 (HE4) as a marker of malignant pleural effusions

Adel Attig, Mohammed El Sammak, Mossa Suleman. Pulmonology, KFSH, Damman, Saudi Arabia Medical Biochemistry, KFSH, Damman, Saudi Arabia Pulmonology, KFSH, Damman, Saudi Arabia Odense University Hospital, Odense, Denmark

Pleural effusions are a commonly encountered problem in clinical practice, and pleural fluid analysis is usually the first step towards identifying the underlying etiology. Numerous studies have been published analyzing the potential utility of measuring biomarkers in pleural fluid as possible indicators of a malignant effusion, however there are no studies that have examined the presence of HE4 in pleural effusions. The aim of this study was to assess pleural fluid and serum concentrations of HE4 in patients with different types of pleural effusions and to evaluate the diagnostic performance of HE4 in detecting malignant pleural effusions.

Patients and methods: A prospective study was carried out of 88 consecutive patients presenting with pleural effusions. The patients were divided into three groups: 22 patients with transudative effusions, 32 patients with non-malignant exudative effusions and 34 patients with malignant pleural effusions. Blood and pleural fluid HE4 levels were measured using a chemiluminescent immunoassay.

Results: Both serum HE4 levels and pleural fluid HE4 levels were significantly higher in patients with malignant effusions than in patients with transudative or non-malignant exudative effusions. A pleural fluid HE4 cut-off value of 1675 pmol/L was found to predict malignant pleural effusions with a diagnostic sensitivity of 85.3% and specificity of 90.7%.

Conclusion: The current study reports a novel finding of increased serum and pleural fluid HE4 levels in patients with malignant effusions compared to non-malignant effusions. This finding has the potential to strengthen the diagnostic performance of tumor markers in detecting malignant pleural effusions.

Serum thioredoxin-1 as a diagnostic marker for malignant peritoneal mesothelioma
Chiharu Tabata1, Takayuki Terada1, Rie Tabata2, Takashi Nakano3. 1Division of Respiratory Medicine, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan; 2Department of Internal Medicine, Hyogo Prefectural Tsuhashi Hospital, Amagasaki, Japan

Background: Diffuse malignant peritoneal mesothelioma (DMPM) is an aggressive malignant tumor of mesothelial origin that shows a limited response to cytoreductive surgery along with intra-peritoneal chemotherapy. Therefore, diagnosing DMPM early is very important. Reactive oxygen species (ROS) play an important role in asbestos toxicity, which is associated with the pathogenesis of DMPM growing. Thioredoxin-1 (TRX) is a small redox-active protein that demonstrates anti-oxidative activity associated with tumor growth. Here, we investigated the serum levels of TRX in patients with DMPM and compared them with those of a population that had been exposed to asbestos but had not have DMPM.

Study: The serum concentrations of TRX were measured in 15 DMPM patients and 34 individuals with benign asbestos-related diseases.

Result: We demonstrated that the patients with DMPM had significantly higher serum levels of TRX than the population that had been exposed to asbestos but had not have DMPM.

Conclusions: Our data suggest that serum TRX concentration is a useful serum marker for DMPM.

P4620
Diagnostic value of vascular endothelial growth factor, glycosaminoglycan, cathepsin S, cathepsin H in the discrimination of transudate exudate and benign malignant patients with pleural effusion
Nalan Goloğlu1, Cengiz Özge1, Gürbüz Polat2, Serin Akbayir2. 1Chest Diseases, Mersin University School of Medicine, Mersin, Turkey; 2Department of Internal Medicine, Hyogo Prefectural Tsuhashi Hospital, Amagasaki, Japan

Pleural effusion is one of the most common problems and it was reported that 4% of the patients applying internal clinics suffer from pleural effusion. Cathepsin S, cathepsin H in the discrimination of transudate exudate and benign malignant patients with pleural effusion

Conclusions: Our data suggest that serum TRX concentration is a useful serum marker for DMPM.

P4621
F-18 FDG PET scan 20 years after talc pleurodesis: Report of 3 cases
Thomas Vandenomoge1, Olivier Bylicki, Herve Dutau, Philippe Astoul. 1Department of Thoracic Oncology, Pleural Diseases, and Interventional Pulmonology, Hopital Nord, Marseille, France

FDG PET scan is used with increasing frequency to investigate pleural abnormalities and determine the possibility of neoplastic invasion. Talc pleurodesis has been reported to cause hypermetabolic pleural thickenings and masses, up to 5 years after the procedure. We report 3 cases of patients who required talc pleurodesis for pneumothoraces in 1989 and 1990 with satisfying results, and who were investigated in 2010–2011 for pleural abnormalities, with positive TEP results, which were deemed secondary to the pleurodesis. Talc pleurodesis functions by creating inflammation, therefore promoting pleural adhesions. The metabolism surrounding this inflammatory reaction could decrease with time, as in other inflammatory processes. However, the fact that talc itself is not metabolized by the body would explain the positive FDG PET scan, possibly as a foreign body reaction.

We discuss radiological differences that can be used to differentiate between hypermetabolic talcoma and neoplastic disease.

Conclusion: Talc pleurodesis can induce an inflammatory reaction, even 20 years after being performed. In patients with pleural abnormalities, it is important to question such procedures and mention them to colleagues interpreting metabolic imaging.

P4622
Relevance of FDG-PET-CT scan for the evaluation of local pleural invasion assessed by thoracoscopy in malignant pleural mesothelioma
Valentina Pinelli1, Elisa Roca2, Sophie Laroumagne3, Silvia Lucchiini3, Gian Franco Tassi4, Philippe Astoul5. 1Pneumologia, Spedali Civili, Brescia, Italy; 2Thoracic Oncology, Pleural Diseases, and Interventional Pulmonology, North Hospital, University of The Mediterranean, Marseille, France; 3Medicina Nuclear, Spedali Civili, Brescia, Italy

Introduction: FDG-PET-CT scan(PET) is now widely recognized as an important staging modality in many cancers and PET standard uptake value(SUV) is reported as a prognostic indicator in several malignancies. However only a few previous studies have investigated the utility of PET in malignant pleural mesothelioma(MPM). We hypothesized that pleural assessed by PET might be in accordance to pleural characteristics evaluated by thoracoscopy.

Methods: 29 patients with a diagnosis of MPM obtained by thoracoscopy were previously evaluated byPET, and considered valuable for this analysis. Among them, 10.34%, 20.69%, 44.83%, 24.14% were assessed as I,II, III, IV stage respectively. There were 10.34% of patients in stage I, 20.69% in stage II, 44.83% in stage III, and 24.14% in stage IV. The pathological analysis showed 86.21% epithelial, 3.45% sarcomatous and 10.34% biphasic types.

Results: At thoracoscopy there were 16 (55.17%) patients with visceral pleural involvement, 21 (72.41%) with diaphragmatic involvement and 2 (6.90%) with mediastinal involvement. All of them had an invasion of the costal parietal pleura. There was a significant difference (<0.05) of the medium SUV between the patients with a visceral pleural involvement and the patients without this feature. Moreover statistically significant differences of the medium SUV was shown between patients with or without pleural nodules.

Conclusions: These findings suggest that pleural evaluation by PET should in accordance to the characteristics obtained by thoracoscopy. There is a significant difference between the site of pleural involvement and/or the typology of tumoral lesions and the SUV of PET.
and diagnosis by Chi-Squared or Fischer’s exact test in Abrams vs Tru-cut were 93.8% vs 86.7% (p=0.0339) and 89.6% vs 88.3% (p=0.0837) respectively. 

**Conclusion:** Physician led image guided Abrams biopsies had larger size specimens. The diagnostic yield with Abrams is superior to published literimens. The diagnostic yield of Abrams technique is statistically similar to the Physician led image guided Abrams biopsies had larger size specimens. The diagnostic yield with Abrams is superior to published literature. To the best of our knowledge this is the first data series comparing image guided Abrams vs Tru-cut pleural biopsies.

**Value of thoracoscopic pleural brush in the diagnosis of exudative pleural effusion**

Lamia Shaaban, Youssef Ahmed. Chest, Assiut University Hospital, Assiut, Egypt

**Background:** Medical thoracostopy had been established to have greater diagnostic yield in the diagnosis of exudative pleural effusion.

**Aim of this study:** To evaluate the value of thoracoscopic pleural brush in the diagnosis of exudative pleural effusion.

**Setting:** Endoscopy Unit, Chest Department, Assiut University Hospital -Egypt

**Material and methods:** The study was conducted upon 28 patients with exudative pleural effusion from January 2011 to December 2011, in whom both the conventional pleural taping and closed pleural biopsy was not conclusive. All patients submitted for medical thoracostopy, where forceps biopsy and pleural brush specimens were taken for all patients.

**Results:** Thoracoscopic pleural specimens were positive in 26 patients (92.8%). Histo-pathological examination of thoracoscopic specimens revealed malignant lesions in (21 patients), TB in (2 patients) and non specific inflammation in (3 patients). Forceps biopsy was positive in 23 patients, while pleural brush was positive in 17 patients. Thoracoscopic pleural brush was the only diagnostic modality in 3 patients all were adenocarcinoma that allow increased diagnostic yield of medical thoracostopy from 23 patients (82.1%) to 26 patients (92.8%). No complications recorded with pleural brush procedures.

**Conclusion:** Thoracoscopic pleural brush could be done easy and safe and allow obtaining pleural cellular material in areas dangerous to take biopsy specimens. It could augment diagnostic yield of medical thoracostopy.

**P4625**

**Cytology and DNA ploidy techniques in the diagnosis of malignant pleural effusion**

Leila Antônio1, Débora Rosolen1, Giorgio Bottura1, Leslie Kulikowski1, Anom Nascimento1, Lisete Teixeira1, Francisco Vargas2, 4Pathology and Research Laboratory (LIM 01), Hospital das Clínicas- University of Sao Paulo, SP, Brazil; 3Pulmonary Division, Heart Institute- Inecor- University of Sao Paulo, Sao Paulo, SP, Brazil

**Introduction:** Pleural fluid (PF) cytopathy is the first approach to diagnose malignant pleural effusion (MPE). Its sensitivity ranges from 40 to 80% and depends on the quality of slide preparation, histological tumor type and the cytopologist’s skill to differentiate tumor cells from benign reactive mesothelium. Ancillary methods are often required to improve the cytological diagnosis.

**Objectives:** To evaluate the sensitivity and specificity of conventional cytology, and the contribution of fluorescence in situ hybridization (FISH) and DNA ploidy in MPE diagnosis.

**Materials and methods:** PF samples from 85 patients were analyzed by cytology and classified as: malignant (presence of malignant cells; n= 45; 52.9%); suspicious (presence of atypical cells; n=16; 18.8%) or benign (no malignant or atypical cells; n= 24; 28.3%). FISH was performed in the 85 PF samples by the alpha centromeric probes for chromosomes 11 (red) and 17 (green) and classified as normal or aneuploid according to the cut-off previously established. In 43 samples we also performed DNA ploidy by flow cytometry (FC). Patient’s records were consulted for definitive diagnosis.

**Results:**

<table>
<thead>
<tr>
<th>Method</th>
<th>Sensitivity (%)</th>
<th>Specificity (%)</th>
<th>Accuracy (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cytology</td>
<td>93.2</td>
<td>80.7</td>
<td>89.4</td>

<td>96.1</td>
<td>94.2</td>
</tr>
<tr>
<td>DNA ploidy</td>
<td>59.5</td>
<td>33.1</td>
<td>55.8</td>
</tr>
</tbody>
</table>

**Conclusion:** FISH improved the cytological diagnosis of MPE. In five cases of suspicous and in three cases of negative cytology, the presence of aneuploidy cells reclassified the cases as MPE. In these cases, all patients were confirmed with cancer. CF DNA ploidy showed weak diagnostic performance.

**Ultrasound guided forceps biopsy of the pleura**

Yousef Ahmed, Gamal Agamy, Lamia Shaaban, Nermim Kamel. Chest Department, Assiut University, Assiut, Egypt Chest Department, Assiut University, Assiut, Egypt Chest Department, Assiut University, Assiut, Egypt Pathology Department, Assiut University, Assiut, Egypt

**Background:** Ultrasound guided forceps biopsy of the pleura is a technique that can cover the diagnostic yield gap between the needle biopsy of the pleura and thoracospy or thorotomy. This technique enables the operator to take biopsy from multiple pleural sites.

**Study objectives:** (1) To describe the ultrasound guided forceps biopsy of the pleura as a technique that is not in common use in our practice to obtain pleural biopsy. (2) To evaluate the diagnostic yield of this technique in undiagnosed exudative pleural effusion.

**Setting:** Prospective intervention study.

**Design:** Ultrasound Unit- Chest Department- Assiut University Hospital -Egypt.

**Patients and methods:** All recruited patients (96) had exudative pleural effusion with first pleural tapping undiagnostic. Patients with bleeding tendency or blood coagulation defects were excluded. The procedure was performed under local anesthesia (Xylocaine 2%) and asptic condition. The patients were premedicated by anagisic (Ketorolac thromethamine 20mg). Three to five biopsy fragments were obtained from each case and sent in 10% formaldehyde to the pathology laboratory. The diagnostic yield was compared with that of thoracoscopy.

**Results:** Compared to thoracospy the sensitivity in diagnosis of malignant and tuberculous lesions was 85% and 88% respectively. The technique was absolutely specific in diagnosis of malignant and tuberculous lesions.

**Conclusions:** Ultrasound – guided forceps biopsy of the pleura is a simple, efficient, and safe procedure. It can be carried out easily and safely even in sick and obese patients. On the other hand, the procedure appears similar to the thoracoscopy in obtaining adequate pleural tissue specimens. Yet, it is simpler and less traumatic.

**P4627**

**How much of a role does immunohistochemistry have in reaching a final diagnosis of pleural malignancy in routine clinical practice?**

Kerry Woolnough. Respiratory Medicine, University Hospital of North Staffordshire, Stoke-on-Trent, United Kingdom

**Introduction:** Pleural fluid immunohistochemistry is not recommended in the routine pathological work up of a suspected malignant pleural effusion due to its low sensitivity. However, research has demonstrated its usefulness in diagnosing the primary site of a malignancy, particularly in adenocarcinomas.

We wished to ascertain the frequency of its use and the contribution immunohistochemistry made to identifying the source of metastatic pleural deposits.

**Methods:** We retrospectively examined all pleural specimens sent for analysis over a 12 month period in patients with confirmed pleural malignancy. We noted the proportion of specimens stained for tumour markers and evaluated the contribution immunohistochemistry made to localising the primary source of the malignancy. These were grouped into three different categories: (i) undiagnostic, (ii) confirmatory and (iii) diagnostic.

**Results:** A total of 101 pleural specimens were sent for cytological and histological examination. Analysis revealed: 37 adenocarcinomas, 4 squamous cell carcinomas, 1 small cell cancer, 19 malignant mesotheliomas, 1 lymphoma and 1 schwannoma. 10 specimens were reported as malignant cells and 28 samples had no malignant cells present. 42 specimens had additional immunohistochemistry performed. In 2 specimens
immunohistochemistry was undiagnostic. It was a confirmatory test in 38% (n=16) and diagnostic in 47.6% (n=20).

Conclusion: We found that immunohistochemistry was underutilised, particularly when cytological analysis revealed malignant cells or adenocarcinoma. In the specimens where these tumour markers were used it was mostly diagnostic in localising the primary for adenocarcinomas.

**P4628**

The effect of a pleural diseases clinic on pleural effusion admission rates

Surya Sakuia, Kay Rowe, Helen E. Davies. Department of Respiratory Medicine, University Hospital Llandough, Cardiff, United Kingdom

Background: Patients with pleural effusion are frequently admitted to hospital on the medical intake. Some of these admissions may be predicted and acute admission avoided.

Aim: A weekly specialist pleural diseases clinic was established in May 2011. We assessed whether provision of dedicated clinic time for patients who may require pleural intervention would reduce hospital admission rates of patients with pleural effusion.

Method: A retrospective review of electronic records for patients attending the clinic between 01/06/11-30/11/11. Hospital records were analysed for pleural effusion admission events (ICD10 codes J90/J91) in this period and between 01/06/10-30/11/10.

Results:

Conclusion: Development of a pleural clinic is associated with a reduced length of stay for patients admitted with pleural effusion. This could have significant cost-saving implications. However, the number of admissions increased by 21% over the study period. The cause of this rise is not clear.

**P4629**

Incidence of lung entrapment in malignant pleural effusion

Imran Bin Mohamed Noor, Respiratory Medicine, Changi General Hospital, Singapore, Singapore

Introduction: Lung entrapment is commonly seen in patients with empyema and complicated parapneumonic effusions. However, the incidence of lung entrapment is not well reported in malignant effusions. We intend to report the incidence in our patient who underwent pleuroscopy in 2011.

Method: A prospective observational study was performed on patients who underwent pleuroscopy in 2011 in Changi General Hospital (CGH). The findings on pleuroscopy were noted for all patients, in particular, the presence of lung entrapment. Biopsies of the parietal pleura were performed during pleuroscopy. Patients with biopsies positive for malignant pleural effusion were included in our analysis.

Results: In 2011, twenty four pleuroscopies performed in CGH. Fifteen (62.5%) were proven to have malignant pleural effusion on biopsy. Of these fifteen patients, 10 (66.7%) had lung carcinoma, 4 (26.7%) had breast carcinoma and the remaining patient (6.7%) had carcinoma of the cervix. Fourteen patients (93.3%) with malignant effusion were noted to have lung entrapment on pleuroscopy of various. Computed tomography scan (CT scan) of the lungs showed patency of the airway. However, bronchoscopy was not performed for these patients.

Conclusion: The incidence of lung entrapment is high in our patients with malignant pleural effusion. This will have an impact on the long term management of such patients. Our finding would suggest that talc pleurodesis may not be the best treatment options. The use of an indwelling pleural catheter may be a better option for our patients with malignant pleural effusion.

**P4630**

Symptoms, emergency admissions and place of death in patients with pleural malignancy

Fiona Christig, Maanasa Polubothu, Fiona Thomson, Kevin G. Blyth. Respiratory Department, Southern General Hospital, Glasgow, United Kingdom

Pleural malignancy is often associated with a poor prognosis, but qualitative outcomes are rarely published. We describe the journey of these patients, focusing on symptoms, admissions and place of death.

Methods: In August 2011 we reviewed case notes and electronic records of 157 patients with pleural cytology sent during 2009. In 73 patients diagnosed with pleural malignancy we recorded: performance status (PS), nature of diagnosis (tissue or clinical), pleurodesis, emergency admissions, symptomatic effusion at death and place of death.

Results: 71/73 patients (97%) had died by data collection. Important clinical data included:

The mean (SD) number of admissions and days spent as inpatient were 3 (1.7) and 26 (23), respectively. 21/73 (29%) underwent pleurodesis (13 at VATS), 22/73 (31%) had symptomatic effusion at death, 11/71 (15%) had an intercostal drain inserted in the week preceding death.

Conclusion: Patients with pleural malignancy spend a significant proportion of their remaining time in hospital. The majority in our audit died in acute hospital units, often with symptomatic pleural effusion. Few died at home or in specialist palliative care facilities.

**P4631**

Educational opportunities provided by a specialist pleural diseases clinic

Maryam Ahmed, Jane Whittingham, Helen E. Davies. Department of Respiratory Medicine, University Hospital Llandough, Cardiff, United Kingdom

Background: Recent BTS guidelines strongly recommend the use of thoracic ultrasound (TUS) prior to any pleural procedure. With the instigation of the European Working Time Directive and specialty-based ward care, time for training in pleural interventions is limited despite it being a requisite in the UK training curriculum.

Aim: A weekly specialist pleural diseases clinic was established in May 2011 allowing dedicated clinic time for patients who require pleural intervention. The clinic also provides practical training for specialist respiratory trainees. Junior (FY, CMT) doctors were encouraged to attend and observe the procedure.

Method: A retrospective analysis of patients and trainees attending the clinic during its first 6 months (01/06/11-30/11/11).

Results: 134 patients were seen (mean 5, range 2-10 weekly), all patients had bilateral TUS. An average of 3 procedures was performed weekly. A respiratory registrar attended 80% of the clinic. Junior trainees were present for 65% of procedures. Trainees achieved the requisite numbers 4 RCR Level 1 competency at 5 means clinics.

Conclusion: Development of a pleural disease clinic has contributed to an improvement in the training of junior doctors. Respiratory trainees are able to learn TUS on a 1:1 basis and be observed during acquisition of RCR level 1 competency. Didactic lectures and practical teaching sessions already exist for the junior doctors. This clinic enhances the hands-on training available providing dedicated patient-based opportunities. This is necessary to ensure all trainees gain proficiency in the core pleural procedures needed in general hospital medical practice.

**P4632**

Can serum (CRP) levels estimate the outcome of talc pleurodesis in malignant pleural effusions?

Khaled Hassan, Mohamed Fathy. Chest, Zagazig University Hospital, Zagazig, Egypt Clinical Pathology, Zagazig University Hospital, Zagazig, Egypt

Objective: To evaluate whether serum C-reactive protein (CRP) could help to predict the success rate and/or side effects of pleurodesis.

Methods: In a prospective study, 25 consecutive patients with recurrent and biopsy-proven malignant effusions were included. Five grams of talc mixed in 150 ml of normal saline were administered via tube thoracostomy. Serial determinations of CRP were made in serum at the beginning of pleurodesis (baseline), and 24 and 72 h after the procedure. Successful therapy was defined as a complete absence or minor reaccumulation of pleural effusion one month after pleurodesis.

Results: Pleurodesis was successful in 22 of 25 patients (88%). The patients
Clinical characteristics, treatment and survival outcomes in malignant mesothelioma

Serdar Berk1, Ömer Tamer Dogan2, Saadettin Kılıçkap2, Kürşat Epözütkü1, Ibrahim Akkurt1, Zehra Seyfikli1,2
1Department of Chest Diseases, Cumhuriyet University, Faculty of Medicine, Sivas, Turkey; 2Department of Medical Oncology, Cumhuriyet University, Sivas, Turkey.

Objective: We aimed to evaluate the clinical, radiological and survival features of patients with MM.

Methods: The study included 228 patients who were followed up in our center between 1993 and 2010 with the diagnosis of MM.

Results: The mean age was 59.1 years in men and 58.7 years in women (male/female=1.4). Environmental asbestos exposure was present in 86% of the patients for a mean duration of 40±20 years. Closed pleural needle biopsy was the most common diagnostic procedure (56.4%). One hundred-thirteen (66%) patients were treated with platinum-based combination chemotherapy (PBCT) plus supportive care (SC) and 67 (34%) patients received SC alone. The median follow-up time was 10.0 months. The median overall survival was significantly improved with PBCT plus SC compared to SC alone (11.4 vs. 5.1 months; p=0.005). The 6, 12, 18, and 24-month survival rates were significantly improved with PBCT plus SC compared to SC alone (72%, 43%, 19%, and 2% vs. 49%, 31%, 11%, and 1%).

Conclusion: The survival of patients with MM improved in patients treated with PBCT. The survival advantage continued 12- and 24-month after the initial time of combination chemotherapy.
elminating highly reactive ROS and RNS. The aim of the present study was to clarify the effect of H2 gas inhalation on direct lung injury and indirect contralateral lung injury.

Methods: Anesthetized C57BL/6J male mice were intubated, and 5 μL of 0.1 N HCl was administered to the left lung. Mice were randomly grouped to saline treatment instead of HCl (Sham), HCl-treatment (HCl), and 2% H2 gas inhalation with the HCl-treatment (HCl-H2) groups. Extra-vascular wet to dry ratio, myeloperoxidase (MPO) activity in the treated left lung and untreated right lung, and serum IL-6 level were evaluated 4 hrs after the treatment.

Results: This aspiration pneumonia model induced direct lung injury and contralateral lung injury. The extra-vascular wet to dry ratios of the left and right lungs were significantly larger in the HCl group compared to the Sham and the HCl-H2 group (p = 0.01), suggesting that H2 gas was effective not only in the direct injured lung but also in contralateral lung. MPO activity of the left lung was also significantly larger in the HCl group compared to those in the Sham and HCl-H2 groups (p = 0.05). IL-6 was increased in the HCl group, but it did not statistically differ to the level in the HCl-H2 group, suggesting H2 gas did not interfere in the cytokine production.

Conclusion: H2 gas inhalation ameliorated direct lung injury and indirect contralateral lung injury in a murine aspiration pneumonia model.

P4637 Protective effects of keratinocyte growth factor-2 on warm ischemia reperfusion lung injury in rats

Xiaocun Fang1, Huayan Ge1, Xun Wang2, Xiangdong Wang1,2, Chunxue Bai1, Jin Bi1, Lin Tong1, Yuanlin Song1

Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China; 2Pulmonary Medicine, Wuxi No.2 People’s Hospital, Nanjing Medical University, Wuxi, China; Biomedical Research Center, Zhongshan Hospital, Fudan University, Shanghai, China

Introduction: Ischemia reperfusion injury manifests as acute lung injury due to the injury of both the endothelium and epithelium. Keratinocyte growth factor-2 (KGF-2) was previously demonstrated to play an important role in the repair of alveolar epithelial damage. Recently, it was also reported to help maintain the barrier function of capillary monolayers.

Objective: Investigate the potential effects of KGF-2 on ischemia reperfusion-induced lung injury and the related mechanisms.

Methods: KGF-2 (2.5-10mg/kg) was administered intratracheally to rats 3 days before surgery. Then the left lung in rats was subjected to ischemia for 60 minutes and reperfusion for 180 minutes. Lung morphology, blood gas analysis, total cell number and protein concentration in the bronchoalveolar lavage fluid were measured. The protective effects of KGF-2 on endothelial cells and related mechanisms were evaluated in vitro.

Results: Pre-treatment with KGF-2 effectively inhibited lung edema, inflammatory cell infiltration, protein exudation and the release of inflammatory cytokines.

P4638 Resistant breathing induces matrix metalloproteinases-9 and -12 expression in the lung

Dimitrios Toumpanakis1, Olga Noussia1, Ioanna Sigal1, Tatiana Michailidou1, Vasso Karavana1, Chalalampos Roussos1, Stamatis Theocharis2, Theodoros Vassilakeopoulos1, 31st Pulmonary Services and Critical Care Department, University of Athens, Greece; 21st Department of Pathology, University of Athens, Greece

Respiratory breathing (RB), encountered in obstructive airway diseases, is associated with large negative intrathoracic pressures and has been recently shown to induce acute lung injury and inflammation. Matrix metalloproteinases (MMPs) -9 and -12, implicated in the pathogenesis of both asthma and COPD, are upregulated by inflammation and by mechanical stress per se. We hypothesized that RB induces MMP9 and -12 expression and activity in the lung. Anesthetized, tracheostomised rats were breathing through a 2-way valve. The inspiratory line was connected to a resistance setting peak tracheal pressure at 50% of maximum (RB). Quietly breathing animals served as controls. After 3 and 6hrs of RB, bronchoalveolar lavage (BAL) was performed to measure cell count and cytokine levels by ELISA. Lung injury was evaluated by histology. MMP9 lung levels were measured by zymography and immunohistochemistry (IHC). MMP12 was detected by IHC. Alveolar macrophages from normal rats were incubated with BAL fluid from rats that underwent RB. MMP9 activity was measured in cell supernatants by zymography.

After 3 and 6hrs of RB, lung injury was detected by histology. Increased numbers of alveolar macrophages and neutrophils (p<0.05) and increased levels of IL-1β and IL-6 (p<0.01) were measured in the BAL following 6hrs of RB. MMP9 activity raised by 2-fold after 6hrs of RB (p<0.001). MMP12 was detected in alveolar macrophages and epithelial cells. After 3 and 6hrs of RB, increased levels of Molar macrophages. BAL fluid from animals that underwent 6hrs of RB, induced MMP9 in supernatants by 7.5-fold (p<0.001).

In previously healthy rats, RB resulted in increased MMP9 and -12 expression and activity in the lung.

P4639 Study of cardiac and hemodynamic changes with airway pressure release ventilation and pressure control ventilation in children with acute respiratory distress syndrome

Hamdy Hamed Abo-Hagar, Rania Gaber, Gehan H. Abo El-Maedi, Pediatrics, Faculty of Medicine, Tanta University, Tanta, Gharbia, Egypt

Cardiology, Faculty of Medicine, Tanta University, Tanta, Gharbia, Egypt

Background: Acute respiratory distress syndrome (ARDS) is associated with high morbidity and mortality. Airway pressure release ventilation (APRV) was suggested to be a suitable mode for ventilating such patients with less liability of lung injury.

Aim: To compare the effect of APRV and pressure control ventilation (PCV) on cardiac and hemodynamic functions in children with ARDS.

Patients and Methods: Twenty children aged 1-14 years fulfilling ARDS criteria were included. The following parameters were recorded after ventilating the patients on PCV and APRV: ventilation parameters [peak inspiratory pressure (PIP) and mean airway pressure (MAP)], oxygenation parameters and oxygen delivery, hemodynamic parameters and urine output.

Results: PIP significantly decreased from 29±7 cmH2O to 24±4 cmH2O with APRV, while MAP was significantly higher during APRV (17±5) than during PCV (13±4) cmH2O. PaO2/FiO2 ratio and oxygen delivery, hemodynamic parameters and urine output increased significantly from 256±25 during PCV to 295±33 during APRV. Oxygen delivery increased significantly from 565±98 during PCV to 1196±127 ml/min during APRV. Cardiac index increased significantly from 3.2±0.2 to 4.1±0.3 ml/min/m² during APRV. Urine output increased significantly from 0.78±0.1 during PCV to 0.97±0.2 ml/kg/h during APRV. The use of sedatives and inotropics were decreased significantly during APRV compared to PCV.

Conclusions: APRV may be a suitable mode for ventilating ARDS patients providing better lung recruitment and oxygenation, avoiding more lung injury and cardiac compromise compared with pressure control ventilation.

P4640 Protease-antiprotease imbalance in airway secretions in subjects with acute respiratory failure

Jennifer Acevedo, Maria Srinivasan, Mario Ponce, Samuel Rosero

Emergency Medicine, University of Miami, FL, United States

Studies have shown that in the acute respiratory distress syndrome (ARDS) there is protease-antiprotease imbalance, reflected as an increase in the ratio of Human Neutrophil Elastase (HNE) to several protease inhibitors in BAL and plasma. This imbalance can be related to the pathophysiology of ARDS and may correlate with clinical outcomes. The purpose of the study was to determine if similar protease-antiprotease imbalance could be detected in airway secretions in subjects at risk of developing ARDS.

Free HNE activity (HNEA) and levels of the protease inhibitors alpha-1 antitrypsin (AAT) and secretory leukocyte protease inhibitor (SLPI) were measured in
samples of endotracheal aspirates samples collected serially in subjects intubated because of acute respiratory failure in a medical ICU (n=42 subjects, 10 eventually developed ARDS).

Contrary to reports studying BAL, we observed that free elastase activity is reduced in airway secretions of subjects that develop ARDS compared to subjects that did not. No differences were noted in AAT and SLPI concentrations in airway secretions among these groups. HNEA/AAT and HNEA/SLPI ratios were reduced in 19 subjects. In ARDS subjects, levels of HNEA returned to normal the first day after the onset of ARDS. There were no differences in survival between subjects who had detectable free HNEA compared with those that did not.

Analysis of protease-antiprotease balance in airway secretions of subjects with acute respiratory failure is not useful to discriminate subjects who develop ARDS and does not correlate with survival.

Conclusions: We observed that in ACPE patients HLL on admission are no predictive of clinical failure but reduction of lactate independently of baseline levels is associated with clinical success.

### P4641

Is lactate a prognostic factor in acute cardiogenic pulmonary edema (ACPE)?

Caterina Bonino1, Valentina Rosi2, Chiara Trivisaro2, Federico Piffer2, Stefano Albieti1, Giovanna Guiotto1, Giuseppina Petrella1, Antonio Voza3, Antonio Villa4, Roberta Marenzi3, Anna Maria Brambilla5, Roberto Cosentini1.

1 Emergency Department, Fondazione IRCCS Ospedale Maggiore Policlinico, Milano, Italy; 2Respiratory Medicine Department, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Milano, Italy; 3Respiratory Medicine Department, San Gerardo Hospital, Monza, Milano, Italy; 4 Emergency Department, San Paolo, Napoli, Italy; 5 Emergency Department, San Benedetto del Tronto Hospital, San Benedetto del Tronto, Italy; 6 Emergency Department, Humanitas Hospital, Milano, Italy; 7 Emergency Department, Fatebenefratelli e Ospedaliero Hospital, Milano, Italy; 8 Emergency Department, San Carlo Hospital, Paderno Dugnano, Milano, Italy

ACPE is a common cause of admission to Emergency Dpt(ED). Lactate levels are a key factor in critical patients.

Aims: To investigate in ACPE, patients relationship between high lactate levels (HLL) on admission (T0) and clinical failure and lactate clearance (LC) calculated in first hours(T1)and clinical failure.

Methods: Prospective, observational, multicentric, web-based study on ACPE patients admitted to18 EDs. HLL: >2mmol/L. LC: (LactateT0–LactateT1)/Lactate T0. Clinical failure: in-hospital mortality, ACPE mortality and IOT.

Results: From May2009 to June2011, 475 patients were enrolled. 46patients were in clinical failure. Table1 shows data on admission. There was a significative difference in lactate level on admission. We calculated LC in 392patients. 42patients were clinical failure. There was a significant difference between LC in clinical success (0.31±0.66) and in clinical failure (0.08±0.50).

Conclusion: Lactate levels are a key factor in critical patients.

### P4642

Aminophylline increases ventilation and abdominal muscle contractility in awake canines

Jenny Vanessa Jagers, Michael Ji, John Kortbeek, Paul A. Easton. Critical Care, University of Calgary, AB, Canada

Aminophylline (Amino) is still used in treatment of COPD. However, effects of Amino on ventilation and respiratory muscles are uncertain. Utilizing implants in awake canines, we examined the effects of Amino on costal diaphragm (Jagers et al. Resp Phys, 2009). Here we study the effect of Amino on abdominal muscles of expiration, by measurement of the transversus abdominis (TA).

Sonomometry transducers and EMG electrodes were implanted in the left TA. After recovery, the animals were studied awake, breathing through a mask. Airflow, ETCO₂, heart rate, muscle length, and moving average EMG were recorded during room air, and CO₂ stimulation, before and after Amino. Output included breath-by-breath breathing pattern, muscle shortening, peak EMG, PaCO₂ and heart rate. Results are shown at room air and 3 levels of CO₂.

For N=6 dogs (mean wt 29.8 kg) studied after 25 days, minute ventilation, tidal volume, and respiratory frequency increased significantly with Amino, during room air, and CO₂ stimulation, before and after Amino. Output included breath-by-breath breathing pattern, muscle shortening, peak EMG, PaCO₂ and heart rate. Results are shown at room air and 3 levels of CO₂.

For N=6 dogs (mean wt 29.8 kg) studied after 25 days, minute ventilation, tidal volume, and respiratory frequency increased significantly with Amino, during room air, and CO₂ stimulation, before and after Amino. Output included breath-by-breath breathing pattern, muscle shortening, peak EMG, PaCO₂ and heart rate. Results are shown at room air and 3 levels of CO₂.

Conclusions: We observed that in ACPE patients HLL on admission are no predictive of clinical failure but reduction of lactate independently of baseline levels is associated with clinical success.

### P4643

Severity of ventilator induced lung injury does not contribute to ventilator induced diaphragmatic dysfunction

Christian Brecelj1, Kathy Reiss1, Ashley Smuder2, Matthew Hudson3, Bradley Nelson1, Stefan Ulhig1, Scott Powers2. 1 Department of Anesthesiology, Aachen University Clinic of the RWTH Aachen, Germany; 2Inst of Applied Physiology and Kinesiology, College of Human Health and Performance, University of Florida, Gainesville, FL, United States; 3 Inst of Pharmacology and Toxicology, RWTH Aachen, Aachen, Germany

Mechanical ventilation (MV) is a life-saving intervention for patients with respiratory failure. Even 12h of MV can promote diaphragmatic contracture dysfunction and atrophy (referred to as ventilator-induced diaphragmatic dysfunction, VIDD). The pathophysiology remains unclear but could be linked to inactivity, the physiological impact of positive pressure ventilation (PPV) on the diaphragm and/or ventilator-induced lung injury (VILI).

We tested the hypothesis, if negative pressure ventilation (NPV) compared to PPV will diminish VIDD.

The concomitant influence of VILI on VIDD was also examined.

Rats were ventilated with either PPV or NPV or breathed spontaneously (control) for 12h.

We measured diaphragmatic contracture properties, fiber size and markers of oxidative damage. Lungs were histologically examined and cytokine levels were assayed in bronchoalveolar lavage for evidence of VILI.

Compared to control, both PPV and NPV resulted in significant oxidative damage to the diaphragm along with fiber atrophy and contracture dysfunction. No significant differences existed in these measures between PPV and NPV groups. Both the PPV and NPV groups experienced VILLI, graded by histologic scores or cytokines. Note, that the severity of VILI varied between animals within both the PPV and NPV groups. Nonetheless, the severity of VILI was not significantly correlated with the degree of VIDD.

Both PPV and NPV promote VIDD and VILI. The magnitude of VILI is not correlated with the degree of VIDD. Although these findings do not eliminate the possibility that VILI may play a role in VIDD, our results are consistent with the concept that diaphragmatic inactivation as major contributor to VIDD.

### P4644

Contributions of rib cage (RC) and abdomen (AB) to tidal volume are useful indicators for the assessment of difficult-to-wean patients

Rita Pozzi1,2, Biswajit Chakrabarti1, Robert Angus3, Nick Duffy2, Robert Parker3, John O’Reilly4, Verity Ford2, Helen Ashcroft2, Karen Ward1, Peter M.A. Calverley5, Andrea Aliverti2, 1 Department of Biostatistics, Politecnico di Milano, Milano, Italy; 2Clinical Sciences Centre, Aintree University Hospital, University of Liverpool, United Kingdom; 3Weaning and Long Term Ventilation Service, Aintree Chest Centre, Aintree University Hospitals NHS Foundation Trust, Liverpool, United Kingdom

Respiratory muscles impairment is an important determinant of the need for mechanical ventilation (MV) in difficult-to-wean patients. We investigated whether the relative contribution of rib cage (RC) and abdomen (AB) to tidal volume was a useful indicator of successful weaning from MV. The contribution of RC and AB volume changes to tidal volume (Vi) were measured by opto-electronic plethysmography in 7 difficult-to-wean patients, during 20° of MV and 20° of spontaneous breathing (SB) after disconnection from MV.

The contribution of RC and AB volume changes to tidal volume (Vi) were measured by opto-electronic plethysmography in 7 difficult-to-wean patients, during 20° of MV and 20° of spontaneous breathing (SB) after disconnection from MV.
Recordings were repeated at 3 weaning stages: A) tracheostomy and invasive ventilation; B) tracheostomy and non-invasive ventilation (NIV); C) decannulation and NIV. The compartment with the highest % contribution to VT at the start of weaning (stage A) was defined as predominant compartment (PC), the other as secondary compartment (SC). PC was the rib cage in 5 patients and AB in 2. During SB, the contributions of PC and SC became progressively similar from stage A to C, with no significant differences at stage C (see figure).

Our results show that in difficult-to-wean patients the contribution to tidal volume of RC and AB becomes progressively more homogeneous as MV dependency decreases during weaning. Accurate monitoring of RC and AB contributions to VT provides therefore useful indications for weaning assessment.

### P4645

**Abdominal muscle action during sustained hypoxia**

**Authors:** Michael J1, Masato Katagiri1, Teresa Kieser1, Paul Easton1. 1. Department of Critical Care Medicine, University of Calgary, AB, Canada;

**Introduction:** Classical studies suggest that expiratory neuronal activity is inhibited by hypoxia, and action of expiratory muscles during hypoxia is controversial. Isocapnic hypoxia sustained 20-60 minutes elicits a biphasic ventilatory response (roll-off), with initial peak followed by decline to a plateau. We demonstrated during sustained hypoxia, parasternal muscle activity rolls off with ventilation (ERJ 2011;38.S55).

**Aim:** To study ventilation and action of the abdominal expiratory muscle, Transversus Abdominis (TA), during sustained hypoxia in awake canines.

**Methods:** After implantation of somoniconometry transducers and EMG electrodes in TA, and full recovery, we measured airflow, SpO2, ETCO2, many EMG and shortening (SHORT) of TA, during room air breathing (BASE) followed by 25 minutes of isocapnic hypoxia (mean 79.9% SpO2). The canines were awake, breathing through a mask. We report results 2-3 min after reaching SpO2 80% (PEAK) and final 5 min (PLATEAU) of sustained hypoxia, then room air breathing (RECOVERY).

**Results:** For N=9 (mean 28.7 kg, 27 days post implant), minute ventilation and tidal volume increased significantly from BASE to PEAK, then decreased to PLATEAU (p<0.01). Concurrently, mean EMG and SHORT of TA increased significantly from BASE to PEAK, then attenuated to PLATEAU (p<0.01).

**Conclusion:** During sustained isocapnic hypoxia, the abdominal expiratory muscle, TA, is markedly activated during initial hypoxia, then attenuated with prolonged hypoxia.

### P4646

**Transthcale lung ventilation with a manual respiratory valve with a variable flow**

**Authors:** Dusan Pavlovic, Wolfgang Fischer. Anesthesiology, Universitätmedizin, Greifswald, Germany

In cannot-intubate, cannot-ventilate situations, a lung ventilation through a thin transthracheal cannula may be attempted. However, it may be impossible to achieve sufficient ventilation if the lungs are spontaneously emptying and dangers of barotrauma may occur. Here we present a valve [1] as a bi-directional manual respiratory pump which low flow during inspiration (by reducing gas supply to the valve) and increased flow during expiration, by increasing gas supply to the valve, permitted more effective venruri effect and efficient expiration, with low gas consumption.

The effectiveness of the valve was tested in vitro. The valve permitted to shorten the expiratory time and achieve higher minute volumes (i.e. volumes of 7L/min of gas or higher), as compared with the ventilation with the similar transthracheal cannula without variable flows (volumes achieved were about 4L/min). Variable flow provided shortening of the inspiratory time and efficient expiratory aid, and permitted LE ratios of 1:1, or even the inverse ratio ventilation. Satisfactory lung ventilation can be assured with transthracheal ventilation with a bidirectional manual respiration valve with variable gas flow.

**Effects of anesthesia, muscle paralysis and controlled ventilation on gas exchanges evaluated by DLCO and pulmonary surfactant protein B**

**Authors:** Fabiano Di Marco1, Daniele Bonacina1,1, Emmanuele Vassena2, Elena Pitino2, Piergiuseppe Agostini3, Stefano Centanni1, Roberto Fumagalli1. 1. Anestesia, Rianimazione, Polmonare e Cardiocircolatorio, Università degli Studi di Milano, Italy; 2. Anestesia Rianimazione, Azienda Ospedaliera San Gerardo, Università Milano-Bicocca, Monza, Italy; 3. Scienze Cardiovascolari, Università di Milano, Italy; 4. Anestesia e Rianimazione Ospedale di Niguarda, Università Milano-Bicocca, Milano, Italy

A recent study demonstrated that patients with no evident pulmonary disease, after at least 24 hours of mechanical ventilation, show a significant worsening of pulmonary gas exchange evaluated through DLCO (diffusing capacity of the lung for carbon monoxide). This worsening may be caused by an early alteration of alveolar-capillary membrane caused by mechanical ventilation itself, as previously demonstrated on animal models. We evaluated, in patients with no pulmonary diseases undergoing elective surgery, the effect of anesthesia, muscle paralysis and invasive controlled ventilation on DLCO, and the plasmatic levels of pulmonary surfactant protein B (SPB), an alveolar-capillary membrane anatomical damage maker. To date we enrolled 11 patients. In comparison to pre-surgery data, we found, just after anesthesia and paralysis, a significant reduction of DLCO (from 15.6±4.8 to 8.2±2.1 mL/mm Hg·1min-1·L-1, p<0.001), due to a reduction of both lung volume (end-expiratory lung volume, EELV, from 2.8±1.3 to 1.5±0.6 L, p<0.001), and the coefficient of diffusion (KCO, from 4.5±8 to 3.7±7 mL/mm Hg·1min-1·L-1, p=0.032). After this point DLCO, EELV, and KCO did not change significantly at 1 and 3 hours of surgery. Our preliminary results show that anesthesia and paralysis themselves can impair gas exchange, through an alteration not only limited to lung derecruitment. The precocity of this phenomenon, however, does not support the hypothesis of a biological effect” on the alveolar-capillary membrane, but a physical effect”, with no modification after 3 hours of invasive controlled ventilation. The SPB analysis is still ongoing.

### P4648

**Prognostic factors of COPD patients admitted in ICU for acute exacerbation requiring invasive ventilation**

**Authors:** Sabrina Lenel1, Julien Moncondrut, Vincent Jounieaux, Claire Andrejak. 1. Respiratory Diseases, Teaching Hospital, Amiens, France

**Background:** For patients with chronic obstructive pulmonary disease (COPD), the first acute exacerbation requiring mechanical ventilation is a breaking point in the disease.

**Methods:** We conducted a retrospective study to estimate the cumulative survival
of COPD patients after their first intubation and the prognostic factors of these patients.

Results: Between January 2000 and December 2010, 110 patients (50.9% stage III and 30.6% stage IV according to GOLD) were admitted in intensive care unit (ICU) for acute exacerbation of their COPD. The main aetiologies of the acute respiratory failure were pneumonia (n=40) and acute cardiac failure (n=30). ICU mortality was 22% and the median survival time was 68 months. In cox multivariate analysis, three independent prognostic factors were found: admission in ICU for proved infectious exacerbation (HR=1.83; 95% CI [1.01-3.34], p=0.047), GOLD Stage III and IV (HR=3.78; CI 95% [1.44-9.92], p=0.007) and acute renal failure (HR=5.79; CI 95% [3.01-11.20], p<0.0001).

Conclusion: Cumulative survival of COPD patients were with acute respiratory failure depends mainly on severity of COPD, exacerbation aetiology and associated acute renal failure.

482. Paediatric respiratory epidemiology. Wheeze: where, how and why?

P4649 Secular trends in childhood obesity, asthma, eczema and hayfever over 45 years
Sarah Smith1, Lorna Aucott2, Nara Tagnyeva1, Leone Craig3, Gealdine McNeill1, Steve Turner1 1Child Health, University of Aberdeen, United Kingdom; 2Public Health, University of Aberdeen, United Kingdom; 3Public Health Nutrition Research Group, University of Aberdeen, United Kingdom

Background: The childhood asthma “epidemic” which took place during the 1980s and 1990s is at least partly explained by changes in lifestyle. Childhood obesity prevalence has also risen, reflecting lifestyle changes. Here we tested the hypothesis that the rise in asthma prevalence in the population paralleled that in obesity.

Methods: A history of asthma, hayfever, eczema and wheeze in the last three years was obtained in 1964, 1989, 1994, 1999, 2004 and 2009. Prevalence of overweight and obesity (IOTF BMI cut-offs equivalent to 25 and 30 at age 18 years) were determined from a separate whole population survey of height and weight at school entry in children in Aberdeen and Aberdeenshire born between 1969 and 2005.

Results: Asthma and related outcomes were determined in 17,951 children in the six surveys and in these years height and weight were available in 29,348 children in the separate study. The prevalence of asthma was between 4 and 28%, for eczema between 5 and 34%, for hayfever between 3 and 27%, for recent wheeze between 10 and 28% and for obesity between 1 and 4%. There were correlations between prevalence at each time point for obesity and asthma (r=0.83, p=0.04), eczema (r=0.94, p=0.005) and hayfever (r=0.94, p=0.005) but not for wheeze. There were no correlations between overweight and outcomes.

P4650 Comparison of two respiratory surveys in an unselected schoolchildren population: 1998 and 2011
Anna Maria Rozzono, Savy Martella, Francesca Ruggeri, Lorenza Chiassi, Anna Rita Mazzotta, Francesco Biagiarelli, Mario Barroto, Maria Pia Villa. NEMSOS, Pediatric Unit, Sant’Andrea Hospital, Faculty of Medicine and Psychology, University “La Sapienza”, Rome, Italy

Objective: To evaluate the prevalence of respiratory symptoms, atopy, and environmental factors in two different populations of Italian schoolchildren studied in 1998 and 2011 in Ronciglione (VT, Italy).

Methods: Data on children was drawn from surveys in the same elementary school 13 years apart. A modified version of the ATS questionnaire for respiratory symptoms was completed by parents that sought on child's history respiratory and smoke exposure. Measurements included spirometry, exhaled nitric oxide, and skin-prick testing. Atopy was defined by at least a positive skin wheal of at least 3 mm.

Results: The 396 children were found similarly distributed by age and sex. (1998 Survey: 9.8±0.7yr, 86 males; 2011 Survey: 9.3±0.9 yr, 111 males). Also similar were the prevalence of reported asthma diagnosis (1998: 13% vs 2011: 10%), exercise-induced asthma, rhinitis, wheeze or cough in the past 12 months and smoke exposure. The 2011 Survey yielded a significant increase of bronchitis in the last 12 months (42.9% vs 14.6%, p<0.000), borderline for pneumonia (4.5% vs 1.0%, p=0.067). Prevalence of atopy in 2011 was similar to that of 1998 (32.3% vs 25.8%). No different functional measurements were observed.

Conclusion: Our data do not support an increase of asthma prevalence among schoolchildren of central Italy in the past 13 years. The concomitant mild decrease of reported asthma and the increase of bronchitis in 2011 could be explained by a shift in medical criteria and parent’s disease perception.

P4651 Elective caesarean section affects the risk of asthma medication in children up to five years of age
Cecilia Ekeu1, Lennart Bräbäck1,2, Adrian Lowe4, Anders Hjern3
1Occupational and Environmental Medicine, Dept of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 2Dept of Research and Development, Sundvall Hospital, Sundvall, Sweden; 3Department of Women’s and Children’s Health, Division of Reproductive and Perinatal Health, Karolinska Institutet, Stockholm, Sweden; 4Centre for MEGA Epidemiology, School of Population Health, University of Melbourne, Australia; 5Centre for Health Equity Studies (CHES), Karolinska Institutet/Stockholm University, Stockholm, Sweden

It has been hypothesized that elective caesarean section is related to an increased risk of asthma due to lack of labour and delayed microbial colonization. Few studies have distinguished between elective and emergency caesarean sections and the findings have not been consistent. Some studies have also observed a risk associated with vacuum extraction.

Method: We examined the association between mode of delivery and retrieval of asthma medication in children up to five years of age. The included children were born in Sundvall, Sweden between 1989 and 2005. The inclusion criteria were asthma medication up to 5 years of age. The associations between emergency caesarean section or vacuum extraction and asthma medication in the firstborns could be caused by residual confounding.

Results: Analyses of first-borns demonstrated that elective caesarean section was associated with an increased risk of ICS use in both age groups. The increased risk remained in the sib pair analysis of 2-5 year olds (OR=1.21) and was partly explained by shorter period of gestation (aOR=1.12). The sib pair analysis could not confirm any association between elective caesarean section and ICS use in 6-9 year olds. Emergency caesarean section and vacuum extraction had some association with asthma medication in the analyses of first-borns but all associations disappeared in the sib pair analyses.

Conclusion: Elective caesarean section contributed to a modestly increased risk of asthma medication up to five years of age. The associations between emergency caesarean section or vacuum extraction and asthma medication in the firstborns could be caused by residual confounding.

P4652 Pregnancy complications and respiratory outcomes in very preterm infants
Luigi Gagliardi, Francesca Rusconi, Monica Da Fré, Giorgio Mello, Virgilio Cernielli, Domenico Di Lalio, Francesco Macagno, Silvana Miinaci, Carlo Corchia, Marina Cattini. Woman and Child Health, Ospedale Versilia, Lido di Camaiore, Italy

A Meyer “Children’s University Hospital, Florence, Italy Unit of Epidemiology, Regional Health Agency of Tuscany, Florence, Italy Unit of Prenatal Medicine, Careggi University Hospital, Florence, Italy Maternal and Child Health Institute, Marche University and Salesi Hospital, Ancona, Italy Unit of Epidemiology, Regional Health Agency of Lazio, Rome, Italy Neonatal Intensive Care Unit, S. Maria della Misericordia University Hospital, Udine, Italy Neonatal Intensive Care Unit, Pugliese-Ciaccio Hospital, Catanzaro, Italy Epidemiology, International Centre on Birth Defects and Prematurity, Rome, Italy Unit of Epidemiology, Bambino Gesù Children’s Hospital, Rome, Italy

Very preterm infants have a high mortality and morbidity, due to a combination of
immaturity per se, and of the underlying pathology causing preterm birth. The role of prenatal infection on increasing the risk of bronchopulmonary dysplasia (BPD) is still unconfirmed.

Aim: To test the hypothesis that infection/inflammation disorders (I) (prelabor premature rupture of membranes, spontaneous preterm labor, infection and hemor- rage) and hypertensive disorders (H) (maternal hypertension and intrauterine growth restriction) are differently associated to in-hospital mortality and BPD.

Methods: A population-based prospective cohort of 2085 singleton infants 23 to 31 weeks gestational age (GA) born in 6 Italian regions in 2003-2005 (ACTION study), was analyzed. Infants born of mothers with H (31%) were contrasted with those born after I (63%) with respect to mortality and BPD. Multivariable logistic analyses (generalized estimating equations) were used.

Results: Mortality was 14.3%, with 48.7% of deaths occurring in the first 5 days of life, largely due to respiratory causes. Infants born after H had more respiratory distress syndrome than the group (odds ratio (OR)=1.41, 95% confidence interval (CI): 1.1-1.8), adjusted for GA, sex and antenatal steroids. 12.8% of neonates had BPD. After adjustment for GA, H disorders had a higher risk of mortality (OR=1.4, 95% CI 1.0-2.0) and of BPD (OR=2.5; CI 1.8, 3.6). Further adjustment for maternal age, education, citizenship, and antenatal steroids did not change the results.

Conclusions: Our results support the hypothesis that pathogenetic mechanisms involving the regulation of lung/airways size and vessels are more important than I in the development of BPD.

P4653 Paracetamol in pregnancy and risk of wheezing in offspring: Causation or bias? Franca Rusconi, Lorenzo Richiardi, Enrica Migliore, Daniela Zagna, Claudia Galassi, Tiziana Nannelli. Unit of Epidemiology, A Meyer Children’s University Hospital, Florence, Italy. University of Florence, Italy. Unit of Cancer Epidemiology, University of Turin. CERMS, CPO-Piemonte, Turin, Italy. 3Unit of Cancer Epidemiology, S. Giovanni B University Hospital, CPO-Piemonte, Turin, Italy. 4Department of Public Health, University of Florence, Italy

Background: Many but not all studies have suggested an association between paracetamol (P) use in pregnancy and wheezing in childhood.

Objective: To assess the relationship between P use in pregnancy and wheezing in offspring in an Italian mother and child cohort (NINFIA/CAPE cohort, www.progonetitinafe.it). To evaluate the potential role of confounding by indication of P use.

Methods: Infants born from 1076 mothers who used P were contrasted with those born from mothers with no use of P (701) with respect to wheezing at 6-18 months of life. P use was assessed during pregnancy and 6 months after delivery, while wheezing was assessed 18 months after delivery.

Results: The overall prevalence of wheezing was 25% and it was more common among infants exposed to P in pregnancy (Relative risk (RR)=1.23, 95% confi- dence interval (CI): 0.98-1.54). Adjustment for ever diagnosis of maternal asthma (prevalence: 7.6%) did not change the association. After further adjustment for maternal respiratory diseases in pregnancy (asthma episodes, influenza like illness, bronchitis), maternal smoking and education, child sex and siblings, the RR for wheezing was 1.06 (CI 0.84-1.34). When we analyzed women who suffered from headache, migraine or backache versus all the others, the risk of wheezing in offspring was similar for mothers who used and for those who did not use P in pregnancy for these diseases (RR 1.28; CI 0.85-1.91 versus 1.35; 1.03-1.76).

Conclusions: The association found between P use in pregnancy and wheezing in offspring disappeared after adjustment, raising a problem of confounding. A non-causal relationship is also suggested by the lack of increased risk of wheezing for P use in “non-respiratory” diseases.

P4654 How do patterns of wheeze change over the first 14 years of life? Amina D可视化1 , Marie-Pierre Strippoli2 , Ben Sypress3 , Caroline Beardsmore4 , Erol Gaillard5 , Claudia Kuehni6 . 1Institute of Social and Preventive Medicine, University of Bern, Switzerland. 2Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom. 3Institute of Social and Preventive Medicine, University of Bern, Switzerland.

Aim: Only few studies described changes in clinical patterns of wheeze in children over a wide age range. This study aimed to describe reported symptom patterns of wheeze from infancy to adolescence. When designing questionnaires and planning studies, such differences in patterns of wheezing illness by age should to be taken into account.

Methods: In a population-based cohort study in Leicestershire, UK, we assessed how the following symptoms became more frequent with increasing age: shortness of breath (increasing from 54% at age 1 to 85% at age 14), wheeze apart from colds (32% to 61%), exercise-induced attacks (26% to 71%) and allergen-induced wheezing (5% to 65%).

Conclusions: We found significant age-related changes in wheezing patterns from infancy to adolescence. When designing questionnaires and planning studies, such differences in patterns of wheezing illness by age should be taken into account.

P4655 Automated identification of asthma patients within an electronic medical record database using machine learning Mariellen Enkelkes1, Zubat Afzal1, Hentie Janssen2, Jan Keus1, Martin Schuermeier3, Katja Verhamme3, Mirjam Starrenboom1. 1Medical Informatics, Erasmus University Medical Center, Rotterdam, Netherlands. 2Pediatric Pulmonology, Erasmus University Medical Center, Rotterdam, Netherlands.

Background: Use of electronic medical record (EMR) databases for epidemiological research on asthma/COPD performs well. The optimal ML method depends on the research question e.g. incidence/prevalence studies require a method with a large Sp, while outcome studies require a large Sp.

Methods: From the IPCI database, a GP database with medical records of >1 million patients, all potential asthma patients, aged 6-18 years between 2000-2011, were identified with a broad automated search on asthma codes, free text and asthma drugs. First, a random sample (n=5039) of all potential cases (n=64327) was manually reviewed by 2 MDs and categorized according to a predefined algorithm. Second, based on this sample set, ML recognizes complex patterns to automatically generate decision trees for case identification. Training and testing was done by 5-fold cross validation.

Results: The sample set consisted of 6% definite, 24% probable, 2% doubtful cases and 68% non-cases. Depending on the sampling strategy, the positive predictive value (PPV) varies from 0.11-0.26, sensitivity (Sn) 0.57-0.94 and specificity (Sp) 0.52-0.89 for definite cases (diagnosis by specialist). For probable cases (diagnosis by GP) PPV varies from 0.49-0.51, Sn 0.84-0.86 and Sp 0.69-0.73.

Conclusion: ML for automatic identification of asthma cases in a huge EMR database performs well. The optimal ML method depends on the research question e.g. incidence/prevalence studies require a method with a large Sp, while outcome studies require a large Sp.
P4657
Asthma and respiratory morbidity thirty years after early childhood bronchiolitis or pneumonia
Karti Backman1,2, Elja Pippop-Salolainen1, Heikki Koskela3, Hetta Ollikainen1,2, Matti Korppi1, 
1Department of Pediatrics, Kuopio University Hospital, Kuopio, Finland; 2Department of Pediatrics, University of Eastern Finland, Kuopio, Finland; 3Center of Medicine and Clinical Research, Division of Pulmology, Kuopio University Hospital, Kuopio, Finland; 4Pediatric Research Centre, University of Tampere, Finland

Background: Recent studies have suggested that asthma in adulthood has its origin in early childhood.

Aims: To evaluate asthma occurrence and respiratory health related quality of life in adults after bronchiolitis or pneumonia in infancy.

Methods: A group of patients were followed since hospitalized for bronchiolitis or pneumonia at age <24 months in 1981-82. At the age of 28-31 yrs, data on respiratory symptoms were collected by a posted questionnaire and Saint George’s respiratory questionnaire (SGRQ), from 60/78 former bronchiolitis and 24/46 pneumonia patients, and from 166 matched controls. The clinical study consisted of bronchialisation test and home peak expiratory flow monitoring. (48/62% and 22/48%) study subjects and 138 controls attended. Asthma was defined by two ways: current doctor-diagnosed and current self-reported (childhood asthma and current asthma-suggestive symptoms in adulthood; doctor diagnosed asthma included).

Results: Both current doctor-diagnosed asthma (31.9% vs. 11.6%; adjusted p=0.003) and self-reported asthma (36.2% vs. 15.2%; 0.004), as well as repeated on-demand use of bronchodilators (35.4% vs. 14.5%; 0.002) and regular use of inhaled corticosteroids (20.8% vs. 8.7%; 0.023) were more common in the former bronchiolitis group than in controls. Both former bronchiolitis and pneumonia patients had higher total scores in SGRQ than controls: bronchiolitis (median 4.3, IQ 2.75–9.0 8.3; p<0.001), pneumonia (4.9, 1.5–15.5; 0.002), controls (1.0 0.5–3.5)

Conclusion: After hospitalization for bronchiolitis in infancy, an increased risk of asthma, more use of asthma medication and impaired quality of life by SGRQ can be demonstrated in adults at age 28-31 yrs.

P4658
Viral etiology of respiratory infections in children under 2 years old in Blida, Algeria
Rachida Boukari

Introduction: Viral ARI is a leading cause of morbidity and mortality in children especially in developing countries. Viruses are known as the predominant causative agents of ARI. In Algeria, few data concerning these agents are available.

The aim of our study was to investigate the incidence of 10 viruses in children under 2 years old admitted with ARI and to study demographic and clinical differences among different virus.

Methods: Children were prospectively enrolled between December 2010 and April 2011. A standardized questionnaire was used and a nose swab sample was collected. These samples were tested for the detection of RSV, Influenza virus (A/B), rhinovirus, Metapneumovirus, Influenza virus, Adenovirus, Parainfluenza 3- by RT-PCR. Demographic, clinical and laboratory data were obtained. Outcome measurements were age, breastfeeding history, clinical severity score, chest radio- logical findings.

Results: 117 children, median age 3 months, were recruited. A virus was detected in 82.9% of cases. The most frequently detected viruses were RSV (48.4%), rhinovirus (23%), Metapneumovirus (22%), adenovirus (7.5%), influenza (5%), parainfluenza 3 (2%). Co-infections were detected in 25 children (21.4%). Clinical features associated with RSV infection were similar to those of other respiratory viruses. Presenting symptoms between the RSV positive and RSV negative groups were similar.

Conclusion: This study underlines the importance of viral pathogens in ARI hospitalized children < 2 years old. RSV was the most frequently identified virus. HMPV and RV are also important cause of ARI in children in Algeria. Longer surveillance studies are needed to better understand the epidemiology of viral ARI.

P4659
Wheezing and pneumonia during the first year of life: An international epidemiological approach

HMPV and RV are also important cause of ARI in children in Algeria. Longer surveillance studies are needed to better understand the epidemiology of viral ARI.

Conclusions: In infants who had BN during the 1st year of life, there are some risk factors which are different for WZs and WZ+.

P4660
Risk factors for severe bronchiolitis – A retrospective study
Donia Anca Plesca, Felicia Cora, Eugenia Buzoanu, Mariana Micolau, Victoria Huerri1,2,3,4
1Pediatric Department, Teaching Hospital, Blida, Algeria; 2Virology Department, Pasteur Institute Algiers, Algeria; 3National Public Health, National Public Health Institute, Algiers, Algeria

Introduction: Bronchiolitis is a common disease in children under 2 years old causing ER presentation and sometimes admission. Severity of bronchiolitis (do to acute respiratory failure) accounts for admission criteria. Children with one or more risk factors for severe bronchiolitis (prematURITY, dysmaturity, environmental factors, neurological disease, cardiac disease, airways anomalies, immune deficieny, chronic lung disease, age under 3 months, formula feeding, RSV infection) are among those usually admitted.

Objectives: To reveal the correlation between admissions do to bronchiolitis and the presence of the risk factors.

Methods: A retrospective study was conducted, including 96 children under 2 years old, admitted in our hospital between November 2011 and January 2012. The admission criteria were Wang severity score for bronchiolitis (over 6). We have correlated the hospitalization lasting more than 5 days and/or the Wang score for severity over 10 with the number of risk factors.

Results: All 96 children admitted had at least one risk factor for severe bronchiolitis. Children with Wang score over 10 and hospitalization lasting more than 5 days (34 children) associated at least 2 risk factors, most frequent of them being being crowded living condition (94%), male sex (73.5%), prematurity (50%), age under 3 months (47%) and other comorbidities (29%).

Conclusion: Severity of bronchiolitis correlates with number of risk factors that coexist for the same child.

P4661
Correlation between nasal symptoms and lung function parameters in preadolescent children
Dinomios Spyrras, Anastasios Tziontios, Diamantis Chloros, Evangelia Nena, Anna-Betta Hanidich, Lazaros Sichelidiotis

Introduction: Allergic rhinitis is a frequent medical condition worldwide and it also influences considerably the children’s performance at school.

Aim: Correlation between the ISAAC (International Study of Asthma and Allergies in Childhood) questionnaire’s data and respiratory system functional parameters in children between 10 and 12 years old.

Methods: Parents of elementary school pupils in the Municipality of Polichni, Thessaloniki,Greece were asked to fill in the ISAAC questionnaire. All students underwent spirometry, sputum analysis, IgE and eosinophils in the peripheral blood, fraction of exhaled NO (FeNO) and skin prick tests. The control group consisted of those children with no rhinitis symptoms.

Results: 1150 children of 11 elementary schools were included in the study. 971 questionnaires were completed (participation rate: 84.4%). One hundred forty four students had at least one positive answer regarding rhinitis (14.8%). Of those, 20.8% presented with elevated IgE levels, 25.4% had increased blood eosinophils, 20.8% had high FeNO (>200ppb) and 45.1% had at least one positive skin prick test. Body mass index was higher in the rhinitis group (21.1±3.3 vs 20.1±1.8

Conclusions: In children who had BN during the 1st year of life, there are some risk factors which are different for WZs and WZ+.

Conclusions: In infants who had BN during the 1st year of life, there are some risk factors which are different for WZs and WZ+.

Conclusions: In infants who had BN during the 1st year of life, there are some risk factors which are different for WZs and WZ+.

Conclusions: In infants who had BN during the 1st year of life, there are some risk factors which are different for WZs and WZ+.
kg/m², p=0.019), while the spirometric and rhinomanometric data did not differ between the rhinitis and the control group. IAACQ questionnaire’s score was positively correlated with IgE concentration (p=0.002), eosinophils (p=0.037) and the number of positive skin prick tests (p<0.001).

Conclusion: Our study showed significant positive correlation between the ISAAC questionnaire’s data and allergic parameters. Therefore the ISAAC questionnaire is strongly recommended as a useful tool in primary pediatric care practice.

Background: Prevalence of asthma and other allergic diseases in children living in Belarus is unknown. The problem is better described in Ukraine and Poland, but more evidence is needed.

Aims: The objective of the study was to estimate the prevalence of asthma, respiratory symptoms and allergic diseases in children in Belarus, Ukraine and in Poland.

Method: The study was performed as a multicenter cross-sectional study. The study population was children aged 6-14 years randomly selected from Belarus (Grodno), Ukraine (Ternopil) and Poland (Silesia Region). Physician-diagnosed respiratory diseases and symptoms as well as allergic diseases were ascertained using the ISAAC questionnaire completed by the parents.

Results: A total of 13 371 children aged 6-14 years participated in the study. The response rate was 76.7%. Groups were similar in terms of gender and age (p>0.05). Between-country differences were statistically significant (p<0.05) for all comparisons, except chronic and spastic bronchitis as well as hay fever in case of Ukraine/Belarus comparisons.

Conclusions: The findings show a large between-country differences and low prevalence of asthma and allergic diseases in children of Western Belarus and Ukraine.

P4663 Allergic diseases in urban/rural environment: Are there differences in diet, prevalence of asthma and allergic diseases in children of Western Belarus and Ukraine

high frequency of obstruction upper and lower respiratory tracts, most of these children had recurrent episodes in history. We have found reduction frequency of wheezing in different years of observation from 23.1% to 21.5% (2006 – 23.1%, 2007 – 38.3%, 2010 – 39%, 2011 – 21.5% of children with AIRs). Also we registered high occurrence children with obstructive laryngotracheitis in 2006 – 42.5%, 2007 – 65.7%, 2010 – 50.4%, 2011 – 47% of children with AIRs. All children with wheezing with obstruction received standard treatment. **Conclusion:** Reduction of frequency of wheezing and obstructive laryngotracheitis in children admitted at children’s hospital is connected with introduction of modern principles of therapy obstruction of respiratory tract at a pre-hospital stage.

**489. Clinical diagnosis and treatment of adult asthma**

Gilles Garcia1, Antoine Magnan2, Raphaël Chiron3, Pierre-Olivier Girodet1, Vincent Le Gros1, Marc Humbert1, 1Service de Pneumologie, Hôpital Antoine Béclère – Université Paris-Sud 11, Clamart, France; 2Service de Pneumologie, CHU de Nantes - Institut du Thorax, Nantes, France; 3Service des Maladies Respiratoires, Hôpital Arnaud de Villeneuve, Montpellier, France; 4Département de Pharmacologie, Université de Bordeaux, Centre de Recherche Cardio-Thoracique, Bordeaux, France; 4CR&D, Novartis Pharma SAS, Rueil-Malmaison, France

While up to 50% of severe asthma patients have no evidence of allergy, IgE has been linked to asthma in epidemiological and immunopathological studies, irrespective of atopic status. Omalizumab (OMA), an anti-IgE monoclonal antibody, is reported to significantly benefit a subset of patients with poorly controlled severe persistent allergic asthma. Therefore biological and clinical effects of OMA were investigated in patients with refractory nonatopic asthma.

**Methods:** 41 patients with severe persistent asthma uncontrolled despite daily high-dose inhaled corticosteroids (with or without maintenance oral corticosteroids) plus a long-acting β2-agonist were randomized to receive OMA or placebo in a 1:1 ratio. Primary end-point was change in expression of high-affinity IgE receptor FceRI on blood basophils and plasmacytoid dendritic cells (pDC2) after 16 weeks. The impact on lung function and clinical parameters was also assessed.

**Results:** When compared to placebo, OMA treatment resulted in a statistically significant reduction in FceRI expression on blood basophils and pDC2 (p < 0.001). The OMA group also showed an overall increase in placebo-adjusted predicted FEV1 compared to baseline (+9.9%; p=0.029). The placebo-adjusted absolute change in FEV1 with OMA was +250 ml (p=0.032). A trend toward improvement in global evaluation of treatment effectiveness scale and asthma exacerbations rate was also observed.

**Conclusion:** Omalizumab treatment may have a therapeutic role in severe nonatopic asthma. These findings support further investigation to assess the clinical efficacy of omalizumab in severe persistent nonatopic asthma. Funded by: Novartis Pharma SAS.

**490. Observational study in severe asthmatic patients after discontinuation of omalizumab for good asthma control**

Mathieu Molinard1, Vincent Le Gros1, Isabelle Bourdeix1, 1Pharmacology, Victor Segalen University - INSERM U657, Bordeaux, France; 2CR&D, Novartis Pharma SAS, Rueil-Malmaison, France

Evolution of severe asthma after discontinuation of omalizumab (OMA) (Xolair®) for good asthma control is still not very well known. This study provides real-life data in this situation.

**Methods:** Observational, descriptive, cross-sectional, retrospective study in which 24 pulmonologists recorded data on patient and asthma characteristics during OMA treatment prescribed in patients with severe persistent allergic asthma uncontrolled despite best available therapies, and after OMA discontinuation (minimal follow-up required = 6 months), for all their patients in who OMA had been discontinued due to achievement of good asthma control.

**Results:** Data from 61 patients were collected [characteristics at OMA initiation: females 65.6%; mean age 40.7 yrs (min 6, max 82); mean asthma duration 22.3 yrs]. Mean duration of OMA treatment was 22.7 months (CL 95%: 19.4-26.0). Mean duration of good asthma control before discontinuation was 11.8 months (CL 95%: 12.0-18.1). Mean change in FEV1 under OMA was +13%. After OMA discontinuation, median follow-up duration was 9.2 months. Loss of control was observed in 34 patients (55.7%) for whom median time to loss of control was 13 months (CL 95%: 8.2-28.1). The % of patients with an observed loss of control were 69.2%, 59.1% & 45.7% respectively after 1 year, 1-2 years & >2 years of OMA treatment. OMA was reinitiated in 20 out of the 34 patients with loss of control; 14 were responders (70%), 4 not responders (20%) & 2 not yet evaluable (10%).

**Conclusion:** Proportion of observed loss of control depended on prior treatment duration. Most of patients were still responders after OMA reintroduction. Funded by: Novartis Pharma SAS.

**4904. Rhinovirus infection activates coagulation through eosinophilic airway inflammation**

Christof Majoor1, Pieter Kamphuisen2, Marianne van de Pol3, Joost Meersman3, Tom van der Pol3, Anita Boïng1, Rinck Nieuwland1, Sebastian Johnston1, Peter J. Sterk1, Elisabeth Bel1, René Lutter1, Koen van der Sluijs3, 1Respiratory Medicine, Academic Medical Center, Amsterdam, Netherlands; 2Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands; 3Experimental Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands; 4Experimental Clinical Chemistry, Academic Medical Center, Amsterdam, Netherlands; 5Center of Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands; 6Experimental Intensive Care and Anesthesiology, Academic Medical Center, Amsterdam, Netherlands; 7Vascular Medicine, University Medical Center, Groningen, Netherlands; 8Respiratory Medicine, National Heart and Lung Institute, Imperial College, London, United Kingdom

Introduction: Exacerbations in asthma are most commonly caused by rhinoviruses. Inflammatory conditions, like asthma, are known to activate hemostasis. Vice versa, a prothrombotic state in the lung can also induce or aggravate pulmonary inflammation.

**Hypothesis:** Rhinovirus infection activates coagulation in patients with asthma, but not in normal control subjects.

**Methods:** 14 patients with mild asthma and 14 healthy controls were nasally inoculated with rhinovirus type 16 (10 TCID50) using a validated method. Bronchoalveolar lavage fluid (BALF) was retrieved by bronchoscopy at t=0 and t=6 days. Microparticle-associated tissue factor(TF) activity in BALF was examined by a fibrin generation test (FGT). Three unrelated control cell complexes (TAX and nonatopic) Carcinomatous (ECP) and Cytologic (PCP) Activation of Coagulation in BALF were measured by immunoassay.

**Results:** On day 6 after rhinovirus infection, FGT in BALF became significantly shorter in asthma (t=1: 672s vs. t=6: 516s (medians); p=0.013), whereas there was no change in healthy controls (t=1: 695s vs. t=6: 707s (medians); p=0.75). At t=6 days, FGT correlated (Spearman) with TAX, eosinophils and ECP (r = -0.607, -0.483 and -0.628 resp., all p<0.01) and TAX and eosinophils and ECP (r = 0.482, 0.538, both p<0.05).

**Conclusion:** Rhinovirus infection significantly shortens the clotting time (FGT) when induced by microparticles isolated from BALF of asthma patients, reflecting an enhanced coagulant activity of TF (i.e., a prothrombotic state in BALF). These findings suggest a possible role of this coagulant activation during viral airway infection.

**4905. Exhaled air volatile organic compounds and eosinophilic airway inflammation in asthma**

Anne H. Wagener1, Asylko H. Zwijnder1, René Lutter2, Sjake de Koning2, Hans-Geert Janssen3, Richard G. Knowles4, Ana Souza5, Elisabeth H. Bel6, Peter J. Sterk1, 1Pulmonology, Academic Medical Center, University of Amsterdam, Netherlands; 2Clinical Epidemiology, Biostatistics and Bio-informatics, Academic Medical Center, University of Amsterdam, Netherlands; 3Experimental Immunology, Academic Medical Center, University of Amsterdam, Netherlands; 4European Life Science & Chemical Analysis Centre, LECO, Mönchengladbach, Germany; 5Analytical-Chemistry Group, van ’t Hoff Institute for Molecular Sciences, University of Amsterdam, Netherlands; 6Discovery Medicine, GlaxoSmithKline, Stevenage, United Kingdom; 7Scientific Consulting, Knowles Consulting, Stevenage, United Kingdom

**Rationale:** Eosinophilic inflammation in asthma is predictive for responses to inhaled steroids. The application of sputum analysis is somewhat limited by the requirement of lab facilities and not directly available results. Exhaled air metabolomics is associated with eosinophilic inflammation in COPD (Fens et al. ERJ 2011). We hypothesized that breath volatile organic compounds (VOCs) can be adequate surrogate markers of airway inflammation in asthma.

**Aim:** To identify VOCs in exhaled air by gas chromatography and time-of-flight mass spectrometry (GC-TOFMS) that can discriminate eosinophilic asthma from non-eosinophilic asthma.

**Methods:** Breath samples were analysed by GC-TOFMS in 40 patients (>18yr) with moderate/severe asthma (GINA-criteria). All patients were non-smokers and required inhaled corticosteroids (>500mg FP or equivalent). Differential cell counts were measured in induced sputum. Correlation coefficients and corresponding p-values between the peaks and measured sputum eosinophils were calculated by univariate analysis (p-value<0.01).

**Results:** Sputum was successful in 36 patients, of which 21 patients had sputum eosinophils >3%. Linear regression analysis showed associations for 5 VOCs with sputum eosinophils. The correlation coefficients varied between 0.42-0.47. When excluding patients on oral corticosteroids (n=8), 8 VOCs were associated with sputum eosinophils with higher correlation coefficients varying between 0.49-0.62.

**Conclusion:** Exhaled air VOCs are modestly associated with sputum eosinophils.
in patients with moderate/severe asthma on (inhaled) steroids. This suggests that exhale breath analysis requires further optimisation in the assessment and monitoring of airway inflammation in asthma.

4696
IgE-autoantibodies and adipokines in patients with bronchial asthma and obesity
Anna Konischcheva, Valentina Gervazueva, Ekaterina Lavrenteysa. RAMS, Mechanism Research Institute for Vaccines and Sera, Moscow, Russian Federation

The adipose tissue represents an important source of inflammatory cytokines with pro-allergic activity. We aimed to estimate the influence of obesity on the characteristics of autoreactivity and cytokine repertoire in patients with bronchial asthma (BA) as compared to allergic rhinitis (AR) and healthy.

Methods: Body mass index (BMI) was evaluated in 80 patients with AR and BA and 25 healthy people. By ELISA we measured serum level of C reactive protein (CRP), IgE-autoAbs to keratin, collagen type III and elastin and production of TNF-a and IL-1 from blood lymphocytes.

Results: Asthmatic patients with BMI >30 kg/m2 had elevated levels of CRP (744±28 ng/ml) and high spontaneous production of TNF-a (45±4 ng/ml) and IL-4 (9.5±2.8 ng/ml) in comparison with normal-weight patients and healthy (7.3±2.7 ng/ml, 3.4±0.6 ng/ml and 1.7±0.3 ng/ml accordingly). The group of obese asthmatics distinguished with highest levels of CRP (1560±28 ng/ml) and IgE-autoAbs to keratin and collagen III, which correlated with BMI (R=0.58) and AR. Serum leptin was overproduced in BA significantly among obese (57±28 μg/L) and showed no difference between healthy subjects independently from BMI (6±1±0.3 ng/ml).

Conclusions: Asthmatics with BMI > 30 kg/m2 show a special phenotype of disease with elevated serum leptin and pro-inflammatory markers, which needs to be managed and treated distinctly. Obesity is attended with higher generation of IgE-autoAbs, which can indicate the disturbance of immune regulation.

Effect of bariatric surgery on asthma: 3 months follow-up
Astrid van Huisstede1, Manuel Castro Cabezas2, Hans Zengerink1, Ronald Luitwieler1, Christiana Tylub3, Pieter S. Hiemstra4, 1Department of Pulmonary Medicine, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 2Department of Internal Medicine, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 3Department of Surgery, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 4Department of Anesthesiology, Sint Franciscus Gasthuis, Rotterdam, Netherlands; 5Department of Pulmonology, Leiden University Medical Center, Leiden, Netherlands

Background: Asthma in obese subjects is poorly understood and the effect of weight loss on asthma control is not well described.

Aim: To investigate the effects of bariatric surgery on asthma control, quality of life and lung function.

Methods: We performed a prospective study in patients with confirmed diagnosis of asthma (±FEV1 <12% or PD20 <178 nmol/L = BHR) and non asthmatic patients undergoing bariatric surgery (BMI >35kg/m2, age 18-50y). Lung function, medication and quality of life were assessed at baseline and 3 months after bariatric surgery. Obese asthmatics who did not undergo bariatric surgery served as an additional control group.

Results: 35 asthma patients (O+A) and 50 non-asthmatics (O-A) underwent bariatric surgery. 17 asthma patients served as controls (NO+A). There were no differences in ACQ, AQLQ, FEV1, or FeNO between O+A and NO+A at baseline. BMI of NO+A (44±7kg/m2) was significantly lower than O+A (47±9kg/m2). After bariatric surgery, BMI decreased to 38kg/m2 in O+A, and BBH decreased significantly in O+A (80%) to 34%, p<0.003). In addition, use of ICS decreased with 50%. FEV1 improved significantly in O+A (mean 8.6 to 9.4, 6.96, p=0.011). Following surgery, ACQ and AQLQ significantly improved in O+A group (1.1 to 0.5, p=0.022), resp. 5.7 to 6.3 (p=0.004), whereas no change was detectable after 3 months in NO+A. ACQ and AQLQ were significantly better in O+A group compared to NO+A after 3 months (ACQ p=0.027, AQLQ p=0.002). No change in FeNO in any group.

Conclusion: Bariatric surgery improves lung function, asthma control and quality of life in patients with asthma and morbid obesity already after 3 months. So it can be speculated that weight loss is an important component of the management of obese asthmatics.

4698
Substitution of vitamin D in patients with moderate to severe persistent asthma: A randomized, placebo-controlled pilot study
Albrecht Breetenbichler1, Ursina Voit1, David Miedinger2, Jorg D. Leppiu2, Reto Krapf1. 1Pulmonary Division, University Department of Medicine, Kantonsspital Bruderholz, Bruderholz, Switzerland; 2Department of Medicine, University Hospital Basle, Basel, Switzerland

Background: Vitamin D3 stimulates glucocorticoid-induced IL-10 synthesis by regulatory T cells in patients with asthma. IL-10 is a potent antiinflammatory cytokine that can block asthmatic inflammation.

Objective: To study whether short-term calcitriol affects lung function and symptoms in patients with moderate to severe persistent asthma treated with a combination of long-acting beta-2-agonists and inhaled corticosteroids.

Methods: 20 outpatients (8m, 12f) with moderate to severe persistent asthma (mean age 58,4y, 36-83) were enrolled in this randomized, placebo-controlled, double-blind, double-dummy pilot trial with random crossover design. All were treated with a stable dose equivalent to ≥400 ng/day of budesonide and ≥12 μg/day of formoterol for at least 4 weeks. Patients were randomized to receive either calcitriol 1.0 μg once daily or placebo. Each treatment phase lasted for 4 weeks, interrupted by a 3-week washout period. Treatment effect was calculated by subtracting baseline values from end of treatment values and using a linear mixed effects model to correct for period and sequence effect.

Results: Baseline FEV1 was 69% pred. (±11; 9), 25-hydroxyvitamin D level 46.6 nmol/L (±28.1; 8.5). FEV1 increased by 1.4% (±7.5) during calcitriol compared to 0.2% (±5.5) during placebo treatment (p=0.64, n.s.); FEV1, bronchial hyperreactivity, peak flow, asthma symptom scores and use of short-acting beta-2-agonists were also not significantly different between calcitriol and placebo periods.

Conclusion: Calcitriol did not improve lung function and asthma symptoms in this short term pilot study (ClinicalTrials.gov number, NCT 00712205).

4699
BTS Difficult Asthma Registry: Effect of omalizumab dosing table expansion on size of population of severe persistent asthmatic patients potentially eligible for omalizumab therapy
Liam Hegney1, Andrew Menzies-Gow2, Adel Mansur1, Chris Brightling1, Robert Niven1, Rekha Chauhuri1, Christine Bucknall1, Amr Radwan2, 1Centre for Infection and Immunity, Queen’s University of Belfast, United Kingdom; 2Asthma and Allergy, Royal Brompton Hospital, London, United Kingdom; 3Respiratory Medicine, Birmingham Heartlands NHS Trust, Birmingham, United Kingdom; 4Institute for Lung Health, University of Leicester, United Kingdom; 5Respiratory Medicine, University of Manchester and University Hospital of South Manchester, United Kingdom; 6Respiratory Medicine, Garvan General Hospital, Glasgow, United Kingdom; 7Respiratory Medicine, Glasgow Royal Infirmary, Glasgow, United Kingdom; 8Respiratory Medicine, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom

The dosing of omalizumab is determined by baseline serum total IgE and body weight. In 2010, the EU licence for omalizumab increased the maximum baseline total IgE in the dosing table from ≤700 IU/mL (‘Standard’ dose) to >700-1500 IU/mL (‘Expanded’ dose). Using data from the BTS Difficult Asthma Registry we evaluated the effect of this expansion on the size of the patient population with severe persistent allergic asthma potentially eligible for omalizumab therapy. 582 adult and adolescent patients were identified from all seven Specialist Centres that submit data to the Registry. Mean age was 21.4 (±18.6) years and mean IgE was 301 (±1546) IU/mL. With the expansion of the dosing table, the percentage increase in the pool of patients with severe persistent allergic asthma potentially eligible for omalizumab was less than 23%, when applying the omalizumab licence criteria (Population A). With the addition of the NICE criteria (Population B) an even smaller percentage increase in the patient pool was seen (Figure).

Figure 1. BTS = British Thoracic Society; SPT = skin-prick test; RAST = radioallergosorbent test; ICS = inhaled corticosteroid; LABA = long-acting β2-agonist.

In conclusion, despite the expansion in license and application of NICE criteria, the change in the number of patients eligible for omalizumab treatment is relatively modest.
490. Exercise testing in disease

4700 Inspiratory resistive loading exacerbates calf vasconstriction in patients with coexisting COPD-CHF compared to COPD and healthy controls
Paulo Vieira1, 2, Jorgo Ribeiro1, 2, Daniel Umpierre1, Ana Paula Correia1, Danilo Bertton3, J. Alberto Neder1, 4, Gaspar Chiappa1, 2, J. Victor Franco1, 2, 3, Gaspar Chiappa1, 2, 3, J. Alberto Neder1, 4, Gaspar Chiappa1, 2, 3, J. Victor Franco1, 2, 3, J. Alberto Neder1, 4, Gaspar Chiappa1, 2, 3, J. Victor Franco1, 2, 3, J. Alberto Neder1, 4.

Rationale: Sympathetic overstimulation is a marker of chronic heart failure (CHF) and might also be present in advanced chronic obstructive pulmonary disease (COPD). Inspiratory resistive loading (IRL) can trigger a sympathetically-mediated metaboreflex which increases peripheral vascular resistance, leading to impaired blood flow. Coexistence of COPD and CHF is likely to potentiate these abnormalities.

Objective: To investigate the effects of IRL on calf blood flow (CBF) and resistance (CVR) in patients with COPD presenting or not with CHF as a co-morbidity and healthy controls.

Methods: Twelve patients with COPD on isolation (FEV1=42±14% pred), 10 patients with coexisting COPD-CHF (FEV1=46±10% pred, left ventricular ejection fraction<45%) and 10 age-matched controls breathed through an inspiratory resistance at 60% of maximal inspiratory pressure (MP) to task failure. CHF was measured by venous occlusion plethysmography.

Results: COPD-CHF had significantly lower MIP than COPD and controls (p<0.05). The former group, however, stopped earlier the IRL trials (185±35 s vs. 284±82 s vs. 365±88 s, respectively; p<0.01). COPD-CHF had lower CBF and higher CVR in this former group. In addition, IRL led to greater decrements in CBF and increases CVR in COPD-CHF compared to either COPD or controls (p<0.05). During IRL on controls was inversely related to MIP across the groups (r=-0.66, p<0.01).

Conclusions: CHF as a co-morbidity of COPD exacerbates peripheral vasconstriction induced by inspiratory muscle overloading. This might contribute to further impair muscle blood flow during exercise in this patient sub-population.

4701 Effects of exercise on ubiquitination and proteasome activity in skeletal muscle in COPD patients
Enrique J. Sánchez-Tapiador1, 2, Ulrik Wisløff3, Sigurd Steinshammer1, 3, 4, J. E. Jebsen Center of Exercise in Medicine at Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, Norway; 2Lung Department, St. Olavs Hospital, Trondheim, Norway; 3School of Physical Education and Sport, University of Sao Paulo, Brazil

Objective: COPD patients have reduced exercise capacity and skeletal muscle function. The aim of this study was to investigate exercise effects on proteasome activity in skeletal muscle of COPD patients. We wanted to evaluate ventilatory limited and unlimited exercise by comparing whole body training against small isolated muscle training. The effects of oxidative stress and systemic inflammation were also evaluated.

Methods: In total, 21 patients with moderate to severe COPD were studied. Spirometry, peak oxygen uptake (VO2-peak), ubiquitin activity, proteasome activity, protein carbonylation and systemic inflammation were measured before and after a 10 week intervention fraction.<

Results: At baseline both groups did not differ in pulmonary function, fat free mass, or exercise capacity. Maximal workload and walking distance improved in both groups but to a greater extent in the hypoxic group (27.5 versus 10.5%, p<0.06; 23.7% versus 6.9%, p=0.01, respectively). Fiber cross sectional area and citrate synthase activity increased significantly in the normoxic group only (both p<0.05). Levels of phosphorylated AKT, p70S6K and GSK3 tended to increase with training in the normoxic group in favour of an upregulation of anabolism while decreased significantly in the hypoxic group (p=0.01). mRNA levels of anabolic genes (IGF1, MGF) and catabolic genes (MurF-1, Atrogin, Fas-F1 and -3, Myostatin) did not change with training in both groups.

We conclude that in COPD patients with chronic hypoxemia, pulmonary rehabilitation improved exercise capacity while the markers of muscle remodelling remained unchanged. It deserves to be studied whether changes in genes expression occurred earlier during rehabilitation in these patients.

4703 Distinguishing pulmonary hypertension in interstitial lung disease by ventilation and perfusion defects as measured by cardiopulmonary exercise testing
Matthew Bartels1, Wilawan Thirapataratpon2, Hilary Armstrong1, 1Rehabilitation and Repressive Medicine, Columbia University, New York, NY, United States; 2Rehabilitation Medicine, Faculty of Medicine Siriraj Hospital, Mahul University, Bangkok, Thailand; 3Division of Pulmonary and Critical Care, Columbia University, New York, NY, United States.

Introduction: Pulmonary hypertension (PH) is common in interstitial lung disease (ILD) and is associated with worse prognosis. Comparing ventilation (VD) and perfusion defects (PD) on cardiopulmonary exercise testing (CPET) can detect PH, but has not been assessed in ILD.

Aims and objectives: We proposed using CPET to detect PH in patients with ILD by assessment of VD and PD by mixed expired CO2 (PeCO2) and end-tidal CO2 (PetCO2).

Methods: 75 patients with ILD referred for CPET were included who had pulmonary function tests, right heart catheterization, CPET all done within 4 months of each other. Data were assessed at rest, end of unloaded warm up (WU), ventilatory threshold (VT), and peak exercise (Pe) for PeCO2, PetCO2, PeCO2/PetCO2 and the activity pattern of PeCO2 versus PetCO2.

Results: ILD patients with PH demonstrated significantly lower PetCO2 and PeCO2 at all levels of exercise and low PeCO2/PetCO2 only at WU.

VD and PD in CPET in ILD patients

Effects of sildenafil intake on the dynamics of skeletal muscle oxygenation at the onset of and recovery from exercise in CHF
Priscila Sperandio1, Mayron Oliveira1, Miguel Rodrigues1, Erika Trépont1, Dirceu Almeida2, L. Eduardo Nery1, J. Alberto Neder1, Department of Medicine, Division of Respiratory Diseases, Federal University of Sao Paulo, SP, Brazil; 2Department of Medicine, Division of Cardiology, Federal University of Sao Paulo, SP, Brazil
Rationale: Nitric oxide (NO) exerts an important role in temporally and spatially match microvascular O2 delivery (QO2sm) to utilization in the skeletal muscle.
Objective: To investigate the effects of increased nitric oxide (NO) bioavailability induced by sildenafil intake on muscle QO2sm to oxygen uptake (V'O2) matching at the transition to and from exercise in patients with chronic heart failure (CHF).
Methods: 10 males (ejection fraction= 27±6%) underwent a supra-gas exchange threshold exercise test to the limit of tolerance 1 hour after sildenafil (50 mg) or placebo intake. The dynamics of V'O2, fractional O2 extraction in the vastus lateralis (Δ[deoxygen-Hb+Mb]) by near infrared spectroscopy, and cardiac output (CO) were evaluated by non-linear regression procedures.
Results: Sildenafil increased exercise endurance compared to placebo by ~20%, an effect that was related to faster on- and off-exercise V'O2 kinetics (p<0.05). Active treatment, however, failed to accelerate CO dynamics (p>0.05). On-exercise [deoxygen-Hb+Mb] kinetics were slowed by sildenafil with a subsequent response “overshoot” being significantly lessened or even abolished. In contrast, [deoxygen-Hb+Mb] recovery was faster with sildenafil (~15%). Improvements in muscle oxygenation with sildenafil were closely related to faster on-exercise V'O2 kinetics and greater increases in exercise capacity (p<0.05).
Conclusions: Sildenafil intake enhanced on- and off-exercise QO2sm to V'O2 matching and V'O2 kinetics with positive consequences on exercise tolerance in CHF. The lack of effect on CO suggests that improvement in blood flow to and within skeletal muscles underlies these effects.

4705
Effects of proportional assist ventilation on skeletal muscle reoxygenation after high-intensity exercise in chronic heart failure
Andrey Borehi-Silva1, Claudia Carrascossa, Cristiano Oliveira, Adriano Barroco, Danilo Berton, Debra Vilaça, Edgar Lira-Filho, Dirceu R. de Almeida, Luiz Eduardo Nery, José Alberto Neder. Physiotherapy Department, Federal University of Sao Carlos, SP, Brazil; 2Pulmonary Function Department, Federal University of Sao Paulo, SP, Brazil
Background: Respiratory muscle unloading can enhance the haemodynamic responses to exercise thereby allowing a closer matching between skeletal muscle O2 delivery and utilization in patients with chronic heart failure (CHF).
Objective: To assess whether proportional assist ventilation (PAV), compared to sham ventilation, would improve the dynamic coupling between microvascular O2 delivery and O2 uptake (V'O2) during recovery from heavy-intensity exercise in patients with CHF.
Methods: Twelve patients with CHF (NYHA class II and III and left ventricle ejection fraction= 2h±6%) underwent two high-intensity, constant-workrate (80% peak) cycle ergometer tests receiving PAV or sham ventilation. Off-exercise kinetic of the “primary” component of V'O2, an index of fractional O2 extraction by near infrared spectroscopy (~[deoxygen-Hb+Mb]) in the vastus lateralis) and cardiac output (QT) by impedance cardiography were assessed.
Results: PAV speeded the recovery kinetics of all variables compared to sham ventilation.
Table 1: Kinetic parameters for sham and PAV ventilation

Values are mean±SE. V'O2 = Pulmonary oxygen uptake, t = constant time, MRT = mean response time, QT = cardiac output, Δ[deoxygen-Hb+Mb] = variation of deoxygenhemoglobin + myoglobin concentration by NIRS.

Conclusions: These data indicate that PAV has beneficial effects on recovery of muscle metabolism and central haemodynamics after high-intensity exercise in CHF patients.

Dynamic hyperinflation and effects of pursed lips breathing on chest wall kinematics during exercise in patients with asthma
Guilherme Fregonese, Janaina Dunats Pinto, Lailane Saturnino, Bruno Henrique Ferreira da Silva, Illia Nadime, Rêncio Florencio Bento, Fernando Augusto Lavezzo Dias, Selma Bruno, Vanessa Rosqueti. Physical Therapy, Federal University of Rio Grande do Norte, Natal, RN, Brazil
To assess the effects of exercise on lung volumes and the influence of Pursed Lips Breathing (PLB) on operational lung volumes in asthma patients. In 14 patients, 33.9±10 years old, FEV1: 65.7±18.6, lung volumes were assessed by opto-electronic plethysmography. Two incremental submaximal cycling tests (ISET) sets based on 3 min. rest, 1 min. unloaded pedaling and 30w increase in workload every min. during free breathing and PLB were done. We identified two patterns of changes in operational volumes at 100%max. workload in free breathing Patients that increase End Expiratory Lung Volume (EELV) ΔEELV=0.27±0.5L and developed Dynamic Hyperinflation (DH),hyperinflators (HG,n=6) and patients that decrease EELV euvoluences (EVE,n=4) ΔEELV=-1.07±0.8 L,Rib cage pulmonary (RCP) was the main responsible to increase in EELV in HG Variation of End Inspiratory Lung Volume (ΔEILV) in HG was significantly different from EG, 1.5±0.8 vs 0.31±0.4 PLB induced changes in EELV in both groups during in chest wall and RCP compartment. In abdominal compartment ΔEILV significantly increased with PLB in all moments except at 50%max. workload.PLB induced changes on EELV in RCP compartment at 100%max. workload in EG and at 50%max. workload, 1st and 2nd recovery time in HG.
Exercise induces different changes in operation lung volume in patients with asthma. PLB modulate breathing pattern and improve operational lung volumes.

Reliability of the 6-minute walk test in patients referred for pulmonary rehabilitation
H.J.M. van der Schouw1, D. van Ranst1, H.J. Otten1, W.A. Stoop1, I.G. van de Port1, J.W. Meijer1. Pulmonary Rehabilitation Centre ‘Schouwmond’, Laren, Netherlands; 2Department of Pulmonary Diseases, Erasmus Medical Center, Rotterdam, Netherlands
Introduction: The 6-minute walk test (6mwt) has been widely used as an easy assessment of physical performance and as an outcome parameter in pulmonary rehabilitation (PR). However, uncertainty remains about the need to perform multiple tests because of the possible occurrence of a learning effect contributing to the reliability of the test.
Aims and objectives: The aim of this study was to evaluate the reliability of three consecutive 6mwt in a large group of patients referred for PR.
Methods: From June 2006 to December 2011, 1112 patients referred to a PR center performed a 6mwt on 3 consecutive days (t1-t3) as part of the routine pre–PR assessment. Tests were performed during a clinically stable period according to the guidelines of the American Thoracic Society. Retrospectively, absolute differences between the tests were evaluated and correlation coefficients between the three tests were calculated.
Results: The mean distance of the 6mwt (mean in SD) was 352±122 m on t1, 378±124 on t2 and 393±125 m on t3. All differences between the tests were statistically significant (p<0.001). 51% of patients walked their maximal distance on t3 but only 8% on t1. When considering a minimal clinical important difference (MCID) of 54 m, 35% of the patients showed differences beyond the MCID in favour of t3 when compared to t1, 11% when compared to t2 and 22% when t2 was compared with t1. Significant correlations exist between t1-t2 (r=0.933, p<0.001), t1-t3 (r=0.912, p<0.001), t2-t3 (r=0.851, p<0.001).
Conclusion: These data show that a single 6mwt is not reliable in these patients with severe pulmonary disease. At least two 6mwt are required to obtain a reliable test.
4708 Bronchoscopy and endobronchial biopsies in children: Useful or not? Fardous Heida 1, Marielle Pijnenburg1, Leonie Vanlaeken2, Wim Timens1, Bart Rottier1. 1Pediatric Pulmonology, University Medical Center, Groningen, Netherlands; 2Pediatric Pulmonology, Erasmus Medical Center, Rotterdam, Zuid-Holland, Netherlands

Introduction: Bronchoscopy and endobronchial biopsies are diagnostic tools in the evaluation of difficult asthma and other paediatric airway diseases. The yield of these procedures in clinical practice is uncertain. Therefore our aim was to evaluate if bronchoscopy and endobronchial biopsies change management.

Methods: Retrospectively we collected data on diagnosis and treatment before and after bronchoscopy in all children undergoing bronchoscopy with endobronchial biopsies between 0 and 18 yrs. Difficult asthma was defined as uncontrolled asthma despite high dose ICS dose and LABA. In endobronchial biopsies reticular basement membrane (RBM) thickness was measured.

Results: Of the 74 children (37 male, mean age 7.8 yrs), 26 had asthma and 13 had difficult asthma. The diagnosis of children undergoing bronchoscopy changed in 31.3% of the cases: 10 children got a second diagnosis, which could explain the persistent symptoms, 8 children were misdiagnosed. In these 18 children airwaymucocilia (n=10) and atrophic abnormalities (n=7) were the most common. In 95.5% of the cases biopsies changed the diagnosis; in 3 of them ciliary dyskinesia was suspected. In 25% medication was changed after bronchoscopy. Children without asthma had a RBM of 5.6 μm [SD ±1.4]; in children with asthma RBM thickness was 5.1 μm [SD ±1.05] and in those with difficult asthma 6.0 μm [SD ±1.34] (p<0.49).

Conclusion: Bronchoscopy showed an important role to reveal underlying causes of persistent symptoms such as airwaymucocilia and atrophic abnormalities. In 25% of patients bronchoscopies led to a change in treatment. We found no significant difference in RBM thickness between nonasthmatic, asthmatic children and children with difficult asthma.

4709 IL-33 and airway remodelling in paediatric severe therapy resistant asthma

Nicola Ullmann1,2, Alex Adams1,2, Cara J. Bossley1,2, Tim Oates1,2, Claire M. Lloyd1, Andy Bush1, Sejal Saglani1,2. 1Paihedic Respirrology, Royal Brompton Hospital, London, United Kingdom; 2Leakecytology, Imperial College London, London, United Kingdom

Background: Associations have been reported between epithelial interleukin (IL)-33 expression and severe asthma in adults, but its role in the pathophysicsology of paediatric severe therapy resistant asthma (STRA) remains unknown.

Objectives: We quantified IL-33 expression in endobronchial biopsies from children with STRA and explored its relationship with parameters of airway remodelling.

Methods: Children (n=55) (median age 11 yrs) (range 5-16) years) with STRA underwent detailed investigations including bronchoscopy and endobronchial biopsy. IL-33+ cells were quantified in the epithelium, smooth muscle and submucosa in biopsies from children with STRA and compared to that in age matched non-asthmatic controls. Reticular basement membrane (RBM) thickness was quantified as a marker of airway remodelling, and related to IL-33+ cells.

Results: Submucosal, but not epithelial or smooth muscle IL-33+ cells were significantly higher in children with STRA compared to controls (p=0.01, 0.21, 0.68 respectively).

In addition, there was a positive correlation between IL-33+ cells and RBM thickness in children with STRA (Spearman r=0.35, p=0.018), but not in controls (p=0.33).

Conclusions: In contrast to adult studies, we have shown increased submucosal IL-33 expression in children with STRA, and for the first time have shown an association between this mediator and airway remodelling. These data suggest therapies that block IL-33 may be suitable for paediatric STRA, and specifically may impact on structural airway changes.

4710 Exhaled nitric oxide in children with severe asthma

Jon Konradsson1,2, Eijen Nordlind1,2, Christophe Pedrelli1,2, Gunnilla Hedlin1,2. 1Department of Women’s and Children’s Health, Karolinska Institute, Stockholm, Sweden; 2Centre for Allergy Research, Karolinska Institute, Stockholm, Sweden; 3Department of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden

Introduction: Exhaled nitric oxide (FENO) is a biomarker of eosinophilic airway inflammation, but the relationship between FENO and asthma severity is uncertain.

We compared FENO normalized against reference values (%FENO) in children with problematic severe (PA) and controlled (CA) asthma and investigated whether increased %FENO is associated with morbidity, irrespective of predefined severity classification.

Methods: Children with PA had recurrent symptoms despite treatment with at least 800 μg Budesonide, those with CA had few symptoms with 100-400 μg. The protocol included Asthma Control test, sputum (percentage of neutrophils, %PMN), methacholine provocation (dose response slope), FENO (ppb), computerized tomography (CT) of the lungs (PA only) and blood sampling for eosinophils (10^3 X L^-1) and IgE (kU/L). The difference between measured and expected FENO (Ln(FENO) = 0.0112 x height (cm) + 0.641) were given in percentages (%FENO).

Results: Children with PA (n=57, age 13y) had a trend towards higher levels of FENO and %FENO compared to children with CA (n=39, age 19y: 22 (10-40) vs. 17 (9-26), p=0.13 and 210% (101-216), p=0.07, respectively. When analysing all children (n=96), those with %FENO>200 had reduced asthma control (18.5 (17-20) vs. 20.4 (19-22), p=0.04) and FEVi/FVC (77 (74-81) vs. 81 (86-91), p=0.04) and increased bronchial hyperresponsiveness (54 (5-76) vs. 2 (0-4.36), p=0.001), bronchial wall thickening on CT (51 (29-119) vs. 17 (14-19), p=0.04), eosinophils (0.5 (0-4.6) vs. 0.3 (0-2.3), p=0.01) and IgE (539 (253-1525) vs. 140 (43-425), p<0.001) compared to those with %FENO<200.

Conclusion: Children with high %FENO have increased morbidity which is partly independent of predefined severity classification.

4711 Fibroelastosis and bronchial remodelling in children with severe asthma

Sushan Garg1, Swati Patel1,2, Mubin Ibrahim1, Chinedu Nwokoro3. 1Centre for Paediatrics, Blizard Institute, Barts and the London School of Medicine and Dentistry, London, Greater London, United Kingdom; 2University Department of Medicine, Jagiellonian University School of Medicine, Krakow, Poland; 3Department of Child Health, University of Aberdeen, United Kingdom; 4Department of  Child Health, University of Leicester, United Kingdom

Rationale: Preschool wheeze follows two broad clinical patterns; i) multi-trigger wheeze (wheeze both with and between colds) and ii) episodic viral wheeze (wheeze exclusively with colds). Whether these patterns reflect stable, distinct phenotypes with different underlying inflammation remains unclear.

Hypothesis: We hypothesised that preschool children with multi-trigger wheeze have chronic pulmonary leukotriene activation, and therefore higher baseline urinary eosinocoids, than episodic viral wheezers.

Methods: Children aged 10 months to 5 years with wheeze and no respiratory comorbidity were recruited from three UK hospitals. Wheezing pattern was obtained from parental history. Urine was collected between viral-triggered attacks and frozen at -70°C. Samples were analysed using high performance liquid chromatography tandem mass spectrometry for a range of eosinocoids (Table 1).

Results: See Table 1. There was no significant demographic difference between multi-triggered (n=46) and episodic (n=115) wheezers. There was no significant difference in baseline eosinocoid excretion between the 2 groups (P=NS by unequal t-test, Table 1).
Table 1. Baseline urinary eosinocytes (pg/ml of creatinine)

Changes in skin prick test (SPT) from the age of 1 to 6 years (yrs) and...allergy-related genes may be influenced by farm exposure in general and (b) change over the first years of life. We studied the rural birth cohort PASTURE (Protection against allergy: study in...and Medical Biometry, Ulm University, Ulm, Germany; 4 National Institute for Social and Preventive Medicine, University of Bern, Switzerland; 5 Department of Infection, Immunology & Inflammation, University of Leicester, United Kingdom.

Conclusions: We found no evidence that the multi-trigger phenotype is associated with increased baseline eosinocytosis activity. Dedicated to the memory of Prof Andrzej Szczeklik who would have been a co-author.

4713 Changes in skin prick test (SPT) from the age of 1 to 6 years (yrs) and relationship to specific IgE and atopic dermatitis: The French arm of PASTURE European study

Alain Chaneac1, Marie-Laure Dalphin1, Vincent Kaukel2, Stephanie Drillon3, Anne Leydier1, Caroline Roduit4, Erika von Mutius4, Dominique Angèle Vuillon5, Jean Charles Dalphin6, 1Pediatrics, University Hospital, Besançon, France; 2: Respiratory Disease, University Hospital, Besançon, France; 3Pediatrics, University of Zurich, Children’s Hospital, and Christine Kühne-Center for Allergy Research and Education, Zurich, Switzerland; 4Pediatric Pneumology, Allergy and Neonatology, Hannover Medical School, Hannover, Germany; 5EA Epidemiology and Medical Biometry, Ulm University, Ulm, Germany; 6EA 3181, University of Franche-Comté, Besançon, France.

The “PASTURE” study (Protection against Allergy: STudy of Rural Environment) examines the influence of exposure to a dairy-farm environment on the occurrence of allergy in a cohort of European children from the 3rd trimester of pregnancy to 10 yrs. The aim of this study was to analyze the course of SPTs to aero- and food allergens from the age of 1 to 6 yrs in the French children of PASTURE, whether they live or not on a farm and to evaluate their relationship to specific IgE and atopic dermatitis (AD).

Two hundred and four children, which 95 of the farmer group, were included. SPTs, AD assessment and specific IgE assays were performed at 1, 4.5 and 6 yrs.

One hundred and forty children participated in all three visits. The prevalence of positive SPTs increased with age (9.5% at 1 yr, 14.2% at 4.5 yrs, 22.6% at 6 yrs). It was lower in the farmer group, regardless of age and category of allergens considered (statistically significant only for seasonal allergens at 4.5 yrs). Positive SPTs were transient at 1 yr whereas they were persistent between 4.5 and 6 yrs. The prevalence of AD was not significantly different in the two groups and decreased with age. Positive SPTs at 1 yr were predictive of the occurrence of AD during the follow-up. The correlation between SPTs and specific IgE was poor for an IgE cut-off at 0.35U/ml, but increased with age and with higher cut-off.

In conclusion, our study showed that skin reactivity (1) increased with age, (2) was lower in the farmer group, (3) at 1 yr was transient but predictive of the occurrence of AD. Correlation between SPTs and specific IgE was poor, especially at one yr.

4714 DNA methylation in asthma and allergy related genes is influenced by farm exposure and time trends in early childhood

Sven Michel1, Florence Banout2, Jon Gennet1, Juha Pekkanen4, Charles Dalphin1, Josef Riedler5, Nicolas Mazaleyrat1, Erika von Mutius4, Juliane Weber1, Charlotte Braun-Fahrlander1,2, Roger Lauener1,2,3, Michael Kabesch1, Jörg Tost2, the PASTURE Study Group.

Aim: DNA methylation in asthma and allergy related genes is influenced by farm exposure in general and (b) change over the first years of life. We studied the rural birth cohort PASTURE (Protection against allergy: study in...and Medical Biometry, Ulm University, Ulm, Germany; 4 National Institute for Social and Preventive Medicine, University of Bern, Switzerland; 5 Department of Infection, Immunology & Inflammation, University of Leicester, United Kingdom.

Method: We assessed BF in the first years of life in children from Leicestershire, UK. At school age (9-14 yrs), we performed SPT for 4 allergens (cat, dog, dust, grass) in 1515 children. A child was defined as atopic if any wheal size was ≥3mm.

Results: 465 (31%) children were not breastfed, 435 (29%) had BF <3 months (mo), 256 (17%) BF 4-6 mo and 348 (23%) BF >6 mo. 437 mothers (29%) had hayfever. We found no evidence for differences in risk of atopy by BF; the odds-ratios (95% confidence intervals) for BF<3 mo, BF=4-6 mo and BF>6 mo were 0.97 (0.69,1.37), 1.07 (0.72,1.59) and 1.19 (0.83,1.71), respectively, compared with no BF (p-trend=0.297). We did not find differential association by maternal hayfever (p-interaction=0.489) nor evidence for reverse causation.

Conclusion: Using objective measures and controlling for reverse causation, our study did not find evidence for an effect of breastfeeding on atopy in children of mothers either with or without hayfever. We can continue recommending breastfeeding for atopic and non-atopic mothers.

4717 Airway hyperresponsiveness to mannitol as a predictor of treatment response to ciclesine in patients with suspected asthma: A double-blind, randomised, placebo-controlled trial

Andreas Scherr 1, Anja Jochemann 1, David Miederger 1, Sabrina Maintz 1, Sabine Scharf 1, Torik 1, Praschunth Chajed 1, Michael Tamme 1, Jorge Leuppi 1.
1 Clinic of Internal Medicine, University Hospital, Basel, Switzerland; 2 Clinic of Pneumology, University Hospital, Basel, Switzerland

Background: Inhaled corticosteroids (ICS) are the basic treatment in patients with asthma. The aim of the study was to find predictors which detect subjects who clinically benefit from ICS using a combined endpoint (improvement in either FEV1 (>12% and >200ml), Juniper asthma control questionnaire [ACQ] >0.5 or asthma quality of life questionnaire [AQLQ] >0.5).

Methods: 70 treatment-naive subjects (mean age 40.3 years (range 18-70); 21 male) with suspected asthma were randomised to inhale ciclesine (320mg/day, n= 34) or placebo (n= 36) in a double-blind manner for 1 month. Spirometry, airway hyperresponsiveness (AHR) to mannitol and to methacholine, exhaled nitric oxide, ACQ and AQLQ were assessed before and after treatment.

Results: An improvement in the combined endpoint was seen in 16 subjects (47%) in the ciclesine group (1 FEV1, 9 ACQ, 14 AQLQ) and in 15 subjects (42%) in the placebo group (2 FEV1, 5 ACQ, 13 AQLQ). AHR to mannitol was found to be significantly higher (8/16 responders and only 3/18 non-responders in the ciclesine group (sensitivity 88% specificity 50%, PPV 72%, NPV 65%, p=0.038). Using a logistic regression analysis, AHR to mannitol was the only significant predictor of a response to ciclesine with an odds ratio of 5.0 (95%CI 1.33-24.28, p=0.046).

Conclusions: In subjects with suspected asthma, AHR to mannitol is a predictor of subsequent response to ICS treatment.

4718 Electromyography of the parasternal intercostal muscles in bronchial hyperresponsiveness testing

Victoria MacBean 1, Ashraf Ali 1, Claire Wood 1, Tracey Fleming 1, Annie Greenough 1, Gerard F. Rafferty 1, John Moxham 2.
1 Department of Respiratory Medicine, King’s College London, United Kingdom; 2 Chest Unit, King’s College Hospital NHS Foundation Trust, London, United Kingdom; 3 Department of Child Health, King’s College London, United Kingdom; 4 Department of Respiratory Medicine, King’s Health Partners, London, United Kingdom

Background: Bronchial hyperresponsiveness testing (BHT) can be used to support or refute a diagnosis of asthma, but requires technically-acceptable spirometry to be performed. Para sternal intercostal muscle electromyography (EMGpara) provides a non-invasive, effort-independent method to assess load on the respiratory system. The relationship between EMGpara and spirometry in adults undergoing BHT is unknown.

Methods: 16 subjects (mean (SD) age 29.5 (7.4) years) underwent methacholine provocation. EMGpara was recorded bilaterally from the 2nd intercostal space, at baseline and between consecutive methacholine doses. EMGpara was converted to root-mean-square (RMS) and mean peak RMS EMGpara per breath calculated.

Results: Significant relationships were observed between methacholine concentration, EMGpara and FEV1 (all p<0.001). Subjects with a positive test response (‘responders’), defined as change in FEV1 ≥20%, n=8) showed a significant median fall of 20% in FEV1 as PC20. By this technical approach, however, changes in end-expiratory lung volume cannot be determined. MCT using EMG para technology has been reported in the Jaeger whole-body plethysmograph features the possibility to evaluate changes of airway dynamics concomitantly with changes of lung volumes.

Conclusions: We aimed to assess changes of FRCpleth, IC, ERV and hence RV and TLC during MCT, and comparing changes of effective specific airway conductances (sGlu, sGlu, sGlu) in relation to changes effected to FEV1 and MEF200. We retrospectively analysied data from our hospital database including 540 tests (pneumatics and controls; 50 males; 81 females; age 11 to 82 y), in which MCT have been performed. Methacholine was administered during 3 consecutive cumulative challenge levels (P1:0.2 mg; P2:1.0 mg; P3:2.2 mg) computerized by the APS system.

Results: During MCT not only airway mechanics, but also static lung volumes (FRCpleth, IC) changed consistently.

Conclusions: In the assessment of AHR by MCT sGlu and sGlu qualified as most sensitive target parameter, taking into account changes of airway dynamics concomitantly with changes of lung volumes. Comparison between volume-time and flow-volume parameters with plethysmographically assessed sGlu, sGlu during MCT is presented in abstract 850930.

4721 Bronchial hyperresponsiveness using mannitol in morbid obesity before and after bariatric surgery

Elynor Arjumendi 1,2, Eva Rivas 1, Yolanda Torralba 1, Felip Burgos 1, Josep Roca 1, Josep Vidal 1, Roberto Rodriguez-Roisin 1,3,1. Serveis de Pneumologia, Hospital Clinic de Barcelona, Spain; 2 Serveis de Anestesiologia, Hospital Clinic de Barcelona, Spain; 3 CIBER de Enfermedades Respiratorias, CIBERES, Palma de Mallorca, Islas Baleares, Spain; 4 Institut Clinic de Malalties Digestives i Diabetes, Hospital Clinic de Barcelona, Barcelona, Spain

Introduction: The association between bronchial hyperresponsiveness (BHR) and morbid obesity (MO) is common.

Objective: To investigate the prevalence of BHR using mannitol (MAN) in patients with MO before and one year after bariatric surgery (BS).

Methods: We determined BHR in 70 patients with MO (46±11 yr; BMI, 46±6 kg/m²; 53 females; smokers, [33±26 pack-yr] 59%). BHR was defined as a PD15<63.5mg. Severe OSA (apneas+hypopneas Index [AHI] ≥30 events/h) was present in 31 patients.

Results: Before BS, patients had FEV1, 93±15%; FEV1/FVC, 0.83±0.05; bronchodilator test, <9±4%. Fifty two had BHR+(PD15<78 mg) with an FEV1 fall of -20±2%. BMI and central obesity (abdominal circumference and waist-hip ratio) were higher in patients with BHR+(n=17) than in those BHR-(n=53) (p<0.05 each).

Likewise, the AHI was higher (51±10 vs 29±4.5 events/h) in patients with BHR+(p<0.05) than in those BHR-(p>0.05).

The ratio-dose-response (RDR) to MAN was positively associated with BMI (r=0.30, p<0.05).

Results: Before AH, all but one BHR+ patient, reverted their BHR(PD15>635 mg) with an FEV1 fall of -8±2%, and IL-8 levels increased in all patients (p<0.05).

Conclusions: In MO the prevalence of BHR with MAN is elevated, which is associated with increased BMI, central obesity and AHI. Our findings suggest that...
obstructive sleep apnea and central obesity can in MO share a similar pathogenic mechanism related to development of BHR.

4723  Sensitivity and specificity of airway hyperreactivity (AHR) based on methacholine challenge (MCH) tests – Comparison of sG_{Eeff} with FEV_1 and MEF_{200} as target parameter

Richard Kraemer 1, Gabi Giger 1, Thomas Sigist 1, Martin Frey 1. 1Department of Clinical Research, University of Berne, Inselspital, Berne, Switzerland; 2Clinical Research Unit, Klinik Barmelweid, Switzerland

Rationale: Airway hyperreactivity (AHR) is a characteristic feature of asthma, and methacholine challenge tests (MCT) are well established, mostly defining a fall of 20% in FEV_1 as PC_{20}. In contrast to this spirometric technique, whole-body plethysmography features the possibility to evaluate changes of airway dynamics concomitantly with changes of lung volumes (see also abstract 850929).

Objectives: Assessment of sensitivity and specificity of MCT, comparing changes of effective specific airway conductances (sG_{Etot}, sG_{Eeff}, sG_{A}) with changes effected to FEV_1 and MEF_{200}.

Methods: Data from 140 test persons (asthmatics and controls; 59 males; 81 females; age: 11 to 82 y), in whom MCH was administered during 3 consecutive cumulative challenge levels (P_{1.0 mg}; P_{2.0 mg}; P_{3.2 mg}) computerized by the APS system, were retrospectively evaluated.

Results: Highest response rates were found for sG_{Etot}PD_{10} (82.1%) and sG_{A}PD_{20} (77.1%); lowest for FEV_{1}PD_{20} (34.3%) and intermediate for MEF_{200}PD_{45} (45%). sG_{Eeff} reached its PD_{50} at 0.56±0.48 mg, FEV_{1} its PD_{20} only at 0.94±0.57 mg MCH. Sensitivity of MCH-tests (s) and specificity (f) were obtained as follows: sG_{Eeff} (s: 95.7%; f: 80.0%), sG_{A} (s: 91.3%; f: 88.0%), FEV_{1} (s: 38.3%; f: 84.0%) and MEF_{200} (s: 48.7%; f: 72.0%).

Conclusions: In comparison to FEV_{1}, assessment of AHR by sG_{Eeff} and sG_{A} reaches their PD at much lower MCH doses, in a much higher percentage of tests. The advantage of MCT by plethysmography, measuring changes of airway dynamics in relation to changes of the volume history, features the advantage to perform MCT with better safety for the patients.

4722  Relationships of mannitol challenge to methacholine challenge and inflammatory markers in asthmatics receiving inhaled corticosteroids

William Anderson. Asthma and Allergy Research Group, University of Dundee, Scotland, United Kingdom

Background: Mannitol is a novel osmotic indirect bronchial challenge agent related to development of BHR.

Methods: Screening data were analysed of 143 mild to moderate asthmatics, all taking inhaled corticosteroids (ICS), who had mannitol and/or methacholine challenges, fractional exhaled nitric oxide (FeNO) and salivary eosinophilic cationic protein (ECP) measured together. Mannitol AHR was grouped by PD10: mild (315-635mg), moderate (75-315mg), severe (0-75mg).

Results: PD10 groups were significantly different overall for FeNO (p=0.023): 43% higher in the severe vs. mild group. There was a significant overall difference for methacholine PC20 (p=0.006): a 2.1 doubling dilution difference between severe vs. mild mannitol groups.

No significant differences were found across groups for: salivary ECP, FEV_{1}, or ICS dose. Mannitol PD10, methacholine PC20 and FeNO as continuous variables all correlated with each other.

Conclusions: Mannitol challenge reflects both underlying inflammation using FeNO and direct AHR using methacholine. Thus mannitol may be a useful screening tool for the assessment of asthmatic patients receiving ICS.

4724  The influence of emphysema heterogeneity on the magnitude of benefit following endoscopic thermal vapor ablation (InterVapor™) in patients with heterogeneous emphysema

Felix J.F. Herth 1, Armin Ernst 2, Peter Hopkins 1, Jim J. Egan 3, Franz Stanzel 4, Anshag Valipour 5, Manfred Wagner 5, Christian Witt 3, Kim Baker 2, Mark H. Gotfried 10, Steven Kesten 11, Gregory Snell 12. 1Pneumology and Critical Care Medicine, Thoraklinik Heidelberg, Germany; 2Pulmonary, Critical Care and Sleep Medicine, St. Elizabeth’s Medical Center, Boston, United States; 3 Lung Transplant Unit, Prince Charles Hospital, Chermside, Australia; 4Advanced Lung Disease Program, Mater Misericordiae University Hospital, Dublin, Ireland; 5Clinical Department, Upstate Medical Corp, Tustin, United States; 6PACT, Pulmonary Associates, Phoenix, United States; 7Allergy Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, Australia; 8Pneumology and Critical Care Medicine, University of Iowa, Iowa City, United States; 9PACT, Pulmonary Associates, Phoenix, United States; 10Oncology, University of Iowa, Iowa City, United States; 11PACT, Pulmonary Associates, Phoenix, United States; 12Allergy Immunology & Respiratory Medicine, St. Elizabeth’s Medical Center, Boston, United States

Introduction: Endoscopic thermal vapor ablation (InterVapor™) has been demonstrated to induce lung volume reduction through the local delivery of heated water vapor to targeted lung segments. We examined patient subgroups based on emphysema heterogeneity for differential responses.

Methods: Subgroup analysis from a single-arm trial of InterVapor (single upper lobe treatment at 10 calig of tissue) in patients with upper lobe predominant emphysema. Inclusion criteria: FEV_{1} 15%-45% predicted, RV>105%, TLC>100%, 6 minute walk distance (6MWD)>140 m, DLOC>20%. Primary efficacy endpoints: FEV_{1} ≥12% or SGRQ ≤4 units at 6 months. Secondary efficacy: lung volumes (body plethysmography, HRCT), mMRC dyspnea, and 6MWD. Endpoints were analyzed for associations (Pearson correlation) and categorized based on tertiles of heterogeneity index (HI) (lower to upper lobe tissue to air ratio from HRCT).

Results: 44 patients received InterVapor. Demographics: 50% men, age 63 years, FEV_{1} 0.86 L (31% predicted), SGRQ 59 units, 6MWD 500 m. Results at 6 and 12 months (mean change from baseline):

<table>

Conclusion: Efficacy from InterVapor for the treatment of heterogeneous emphysema appears to increase with increasing HI (i.e. upper lobe predominance). HI should be considered when projecting the magnitude of benefit after InterVapor.

4725  Associations among one-year efficacy outcomes following endoscopic thermal vapor ablation (InterVapor™) for heterogeneous emphysema

Peter Hopkins 1, Felix J.F. Herth 2, Gregory Snell 3, Kim Baker 2, Christian Witt 3, Mark H. Gotfried 4, Anshag Valipour 5, Manfred Wagner 5, Franz Stanzel 3, Jim J. Egan 1, Steven Kesten 1, Armin Ernst 1. 1Lung Transplant Unit, Prince Charles Hospital, Chermside, Australia; 2Pneumology and Critical Care Medicine, Thoraklinik Heidelberg, Germany; 3Allergy Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, Australia; 4Advanced Lung Disease Program, Mater Misericordiae University Hospital, Dublin, Ireland; 5Clinical Department, Upstate Medical Corp, Tustin, United States; 6PACT, Pulmonary Associates, Phoenix, United States; 7Pneumology, Charité University Medicine, Berlin, Germany; 8Pneumology, Charité University Medicine, Berlin, Germany; 9Pneumology, Charité University Medicine, Berlin, Germany; 10Lung Transplant Unit, Prince Charles Hospital, Chermside, Australia; 11Pneumology, Klinikum Nürnberg, Germany; 12Allergy Immunology & Respiratory Medicine, The Alfred Hospital, Melbourne, Australia

Background: The understanding of interactions or associations over the long-term may assist in understanding and predicting changes over time in chronic diseases such as emphysema. The associations among various COPD efficacy endpoints are variable; however, the degree of correlation is often important in examining the consistency of the results across measures not considered redundant.

Objectives: Determine the correlations of improvements in patient-reported outcomes, exercise capacity and BODE score with lung function and lobar volume
44 patients received InterVapor. Demographics: 50% men, age 63 years, spirometry, body plethysmography, lobar volume reduction (LoVR) by HRCT, Germany; 3Pulmonary, Critical Care and Sleep Medicine, St. Elizabeth’s Medical Center, Boston, United States; 5Pulmonary Diseases, University Medical Center, Groningen, Netherlands

Results: At 6 months (mean change from baseline):

Conclusion: Baseline 6MDW was associated with differences that were more pronounced with the subsequent 6MDW and SGRQ at 12 months. Other outcomes showed no consistent pattern of association. A bias such as regression to the mean cannot be ruled out in this analysis.

Introduction: The NETT noted that baseline exercise tolerance may influence long-term outcomes following endoscopic thermal vapor ablation (InterVapor) in patients with heterogeneous emphysema.

Methods: Post hoc subgroup analysis from the Vapor trial, a multicenter single-arm trial of InterVapor (single upper lobe treatment at 10 cal/g) in patients with upper lobe emphysema. Inclusion: FEV1 15%–45% predicted, RV >150%, TLC >100%, 6MDW >140 mL, DLCO >20%, prior pulmonary rehabilitation. Outcomes included spirometry, body plethysmography, lobar volume reduction (LoVR) by HRCT, SGRQ, mMRC dyspnea, 6MDW and LoVR (CT). Pearson correlation coefficients were calculated for associations of changes from baseline to 12 months.

Results: 44 patients received Vapor. Mean age: 63 years, men 50%, FEV1 88.6% (31%) predicted, RV 60.1% (26%) predicted, DLCO 35% predicted, SGRQ 59 units, 6MDW 300 m, mMRC 2.9.

Conclusion: Among lung function tests, FEV1 appeared to correlate the strongest with health outcomes, followed by RV and FRC at one year. The strong correlation of outcomes with LoVR are consistent with the proposed mechanism of action.

4726 The influence of baseline exercise tolerance on long-term efficacy outcomes following endoscopic thermal vapor ablation (InterVapor) in patients with heterogeneous emphysema

Introduction: The influence of baseline exercise tolerance on long-term efficacy outcomes was examined in a study of endoscopic thermal vapor ablation (InterVapor) in patients with heterogeneous emphysema.

Methods: Post hoc subgroup analysis from the Vapor trial, a multicenter single-arm trial of InterVapor (single upper lobe treatment at 10 cal/g) in patients with upper lobe emphysema. Inclusion: FEV1 15%–45% predicted, RV >150%, TLC >100%, 6MDW >140 mL, DLCO >20%, prior pulmonary rehabilitation. Outcomes included spirometry, body plethysmography, lobar volume reduction (LoVR) by HRCT, SGRQ, mMRC dyspnea, and 6MDW. Endpoints were dichotomized based on two thresholds for baseline 6MDW.

Results: 44 patients received InterVapor. Demographics: 50% men, age 63 years, FEV1, 0.86 L (31% predicted), SGRQ 59 units, 6MDW 300 m. Results at 6 and 12 months (mean change from baseline):

<table>

Conclusion: Baseline 6MDW was associated with differences that were more prominent with the subsequent 6MDW and SGRQ at 12 months. Other outcomes showed no consistent pattern of association. A bias such as regression to the mean cannot be ruled out in this analysis.

4727 Charities evaluation of collateral ventilation versus HRCT assessment, in predicting clinical outcomes following endobronchial valve therapy (EBV) in COPD patients

Studies suggest EBV insertion in heterogeneous COPD is most effective in patients with no collateral ventilation (CV)–ve involved at the targeted lobe.

Aim: To determine whether Charities evaluation could predict clinical outcomes in COPD pts having EBV insertion and who were assessed as having a complete fissure by HRCT.

Methods: A prospective parallel group study with all pts screened with HRCT. Destruction scores were determined for each lobe, tissue integrity was assessed in both lungs. Only pts with >10% differential in destruction scores and complete fissures (for the targeted lobe) were enrolled. All had lung function tests, 6 min walk, differential V/Q, and SGRQ scoring at baseline/30/90 days after EBV placement. Pts had Charities testing of CV prior to EBV placement, but EBV was placed irrespective of the Charities result.

Results: 49 pts were screened. 9 had intact fissures on HRCT assessment and went onto Charities testing and EBV placement. All had EBV placed in the left upper lobe and lingula. 7 pts were CV–ve on Charities: 2 were CV–ve in the CV–ve group, went on to EBV. FEV1 [mean(SD)] increased from baseline 0.69(0.15) to 0.93 (0.19) L, p<0.025, at 90 days. TLC decreased from 6.55 (1.28) to 6.00 (1.11) L, p<0.01. SGRQ scores at 90 days were also significantly lower -43.2(10.5) vs 61.2 (8.7) p<0.01. The two patients in the CV+ve group had no change in lung function.

Conclusion: When used as a supplement to HRCT, Charities assessment of CV predicts improvement in lung function and clinical outcomes in pts with severe COPD undergoing EBV therapy. Charities should be incorporated into decision pathways relating to EBV insertion.

4728 Pneumothorax as a predictor of beneficial outcome following endobronchial lung volume reduction

Introduction: Patients developing significant target lobe volume reduction (TLVR) following endobronchial valve (EBV) treatment experience great improvement in clinical outcome measures. A prospective multicenter study confirmed an improvement in FEV1, SGRQ and 6MWD in patients with a TLVR >20%.

Objective: To evaluate the impact of the pneumothorax on outcome following EBV treatment.

Methods: Retrospective analysis of a multicenter trial evaluating the impact of the pneumothorax on outcome following EBV treatment. All patients underwent chest x-ray the same day of EBV implantation for exploration of pneumothorax. 30 days following valve implantation, TLVR assessed by high resolution computed tomography (HRCT) and clinical outcome measures (FEV1, SGRQ, 6MWT) were evaluated.

Results: 96 emphysema patients received EBV therapy, of which 41 patients experienced a TLVR >350 mL. In total, 8 patients (8.3%) experienced a pneumothorax following EBV placement. TLVR values were available for 6 out of the 8 patients. All 6 achieved TLVR >350 mL cut off for the study. The mean TLVR as well as the improvement in FEV1 was greater in the group of patients who experienced a pneumothorax (p=0.06; mean TLVR -227.3 mL, mean % FEV1 23.8(±10.6) compared to those who did not (n=35; mean TLVR -122.1 mL, mean % FEV1 22.3±24.01). All patients required chest drainage and recovered within 3–14 days.

Conclusion: The event of pneumothorax seems to be a predictor of a great outcome following EBV therapy.

The Lung Volume Reduction Coil (LVRC, PneumRX USA) is a bronchoscopic device for the treatment of emphysema. A previous pilot study showed safety and feasibility in severe upper-lobe heterogeneous emphysema. In this multicenter study (NCT0122089, NCT01328899) we investigated whether LVRC is safe and effective for the treatment of upper- and lower-lobe heterogeneous and homogeneous emphysema.

Methods: 71 subjects underwent two separate bronchoscopic treatments using LVRC Coils under anesthesia using fluoroscopy (142 procedures). Over 1350 LVRC Coils were placed with median 10 Coils (range 5-15) placed per procedure in 48±24 minutes. Safety was evaluated by recording all SAEs and AEs; effectiveness was measured by SGRQ, pulmonary function and exercise testing through 6 months.

Results: 71 subjects (42F/29M, 62±8 yrs), FEV1: 29±6.6%, RV: 247±50%, FEV1/ FVC: 0.71±0.19, 6MWD +42m (/Δ1 20.2 and Δ1 20.0 and 13.1% respectively. In the 4 RLL patients, ΔFVC was 22.9% ±22.8 and 23.6% ±15.8. ΔSGRQ was -7.5 points ±19.1 and ±7.5 at 6 months in LLL and RLL respectively.

In the VENT subgroup, 26 patients had heterogeneous emphysema of ≤15% with a mean change in FEV1 at 12 months of 15.4% ±2.51 compared to 31.±28.8 in the 35 patients with a score >15%. In the Chartis subgroup, 14 had a score of ≤15% and showed a mean improvement in FEV1 of 15.9% ±16 at 30 days compared to 26.4% ± 27.9 in the 20 patients with a score >15%.

Conclusion: A clinical relevant response can be obtained after LVRC in lower lobes and in patients who are not highly heterogeneous.

For the remainder of the text, please refer to the original document. The text is not included here due to its length and complexity.
Results: In vitro, acute exposure of AEC to hypoxia (0.5% O2 for 1 h) rapidly decreased transepithelial Na+ transport as assessed by equivalent short-circuit current Ieq and the amiloride-sensitive component of Na+ current across the apical membrane, reflecting ENaC activity. Hypoxia reduced the expression of α-, β-, and γ-ENaC proteins in the plasma membrane, with no change in intracellular expression. Hypoxia-induced inhibition of amiloride-sensitive Ieq was rapidly reversed by the β2-agonist terbutaline, and was fully prevented by preincubation with proteasome inhibitors. In vivo, hypoxic exposure (8% O2 for 24h) reduced amiloride-sensitive alveolar fluid clearance by 69% in wild-type mice without changing the expression level of ENaC proteins in the distal lung, but had no significant effect in homozygous mutated Liddle mice.

Conclusion: These data strongly suggest that decreased cell surface expression of ENaC subunits under hypoxic condition is related to Ned44-2-mediated endocytosis of ENaC and subsequent degradation in the proteasome.

4734

IL-17C is expressed in respiratory epithelial cells under inflammatory conditions

Philipp Pfeifer1, Jan Hellberg1, Philipp Lepper1, Frank Langen2, Robert Bal1, Christine Heissegewenn1, 1Department of Internal Medicine V, Saarland University Hospital, Homburg/Saar, Germany; 2Department of Thoracic and Cardiovascular Surgery, Saarland University Hospital, Homburg/Saar, Germany

Background: IL-17 is a cytokine that comprises a group of five IL-17 subtypes (IL-17A to F). IL-17 directly activates epithelial cells leading to the expression of inflammatory mediators and antimicrobial factors. Recent studies showed that IL-17A/F is released by professional immune cells such as CD4+ T cells and macrophages whereas IL-17C is expressed by epithelial cells. It was the purpose of this study to examine the expression of IL-17 in respiratory epithelial cells infected with bacterial pathogens.

Methods: Bronchial epithelial cells were exposed to smoke and infected with bacterial pathogens. Mice were exposed to smoke and colonized with H. influenza.

Expression and release of IL-17 (A to F) was measured by ELISA and qRT-PCR. IL-17C was detected in human bronchial tissue by immunohistochemistry.

Results: Bacterial pathogens such as P. aeruginosa and H. influenzae induced the expression and release of IL-17C in human bronchial epithelial cells (HBECs). The same was true for ligands of Toll-like receptors 3 and 5 (flagellin, polyI:C).

Conclusion: IL-17C expression may play an important role in epithelial response to bacterial pathogens and may thus provide beneficial effects on epithelial barrier function.

4735

Synthetic response of stimulated respiratory epithelium: modulation by prednisolone and iκK2 inhibition

Lucy B. Woodman1, Wing Yan Heidi Won1, Roberta Milone2, Ken Grace2, Ana Sousa3, Rick Williamson1, Christopher Brightling1. 1Infection, Immunity and Inflammatory Medicine, University of Leicester, Leicestershire, United Kingdom; 2Refactory Respiratory Inflammation DPU, GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom

Background: The airway epithelium plays a central role in wound repair & host defense & is implicated in the immunopathogenesis of asthma. Whether there are intrinsic differences between the synthetic capacity of epithelial cells derived from asthmatics & controls & how this mediator release is modulated by anti-inflammatory therapy remains uncertain.

Aims: We sought to examine the synthetic function of epithelial cells from different locations in the airway tree from subjects with & without asthma & to determine the effects on synthetic activity of epidermal growth factor (EGF) & TLR3 ligands in response to EGF & TLR3 stimulation.

Methods: Primary epithelial cells were derived from nares & bronchial lung tissue of healthy controls & patients with asthma & COPD. The synthetic response of epithelial cells was determined by measuring cytokine and antimicrobial factor release.

Results: The synthetic activity of epithelial cells was significantly increased in patients with asthma & COPD compared to healthy controls. The synthetic activity of epithelial cells was significantly increased in patients with asthma & COPD compared to healthy controls. The synthetic activity of epithelial cells was significantly increased in patients with asthma & COPD compared to healthy controls.

Conclusion: The synthetic activity of epithelial cells is increased in patients with asthma & COPD compared to healthy controls. This finding may have implications for the pathogenesis of asthma & COPD.

4737

Corticosteroids improve airway epithelial regeneration and restore oxidative stress-induced epithelial barrier dysfunction

Dirkje Postma2, Antoon van Oosterhout 1. 1Pathology and Medical Biology, Lab of Allergology and Pulmonary Diseases, GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands; 2Pulmonology, GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands

Background: The airway epithelium plays an emerging role in the pathogenesis of respiratory diseases. Its barrier function may be defective in asthma and COPD.

Aims: To study the protective effect of inhaled corticosteroids budesonide (BUD) on different aspects of epithelial integrity, including cell-cell contact formation, regeneration upon wounding and barrier function during mucociliary differentiation at the airliquid interface (ALI).

Methods: We studied the effect of BUD (10^-5 to 10^-4 M) on epithelial resistance and expression of factors of the innate immune system such as antimicrobial peptides and proinflammatory cytokines under basal conditions and upon wounding. BUD significantly improved baseline resistance and significantly increased epithelial barrier function during mucociliary differentiation at the airliquid interface (ALI).

Conclusion: BUD improves the restoration of epithelial cell-cell contacts upon wounding in 16HBE cells. Oxidative stress induced a transient defect in 16HBE cell monolayer integrity upon wounding and barrier function during mucociliary differentiation at the airliquid interface (ALI).

4738

AN01 expression and activity in cystic fibrosis

Manon Ruffin1, Solene Marie1, Céline Charlier1, Harriet Corvol1,2, Annick Clement1,2, Olivier Tabar1,2. 1CDR Si Antone, UMR 938, Paris, France; 2Hospital Trousseau, Service de Pneumologie, Paris, France

Defective CFTF function in the airway epithelium is responsible for cystic fibrosis (CF) patient lung disease. CFTFR represents the most important pathway for apical chloride (Cl-) secretion in human bronchial epithelial cells. Calcium activated Cl- channels (CaCCs) are also an important pathway of Cl- secretion. In 2008, three independent teams suggested that AN01 (Anoccamine 1) also called TMEM16a could be a CaCC candidate. Mice lacking AN01 exhibit a defect in epithelial Cl- transport and pathology similar to CF.

866s
The main aim of this study is to characterize ANO1 protein in CF vs non CF context. For this study, we used different CF and non CF models whose cell lines, mice, and lung explants from CF and non CF patients. Our results show that ANO1 expression and activity are significantly decreased in CF compared to non CF models.

ANO1 is expressed at plasma membrane of bronchial epithelial cells and there is no difference in localization between CF and non CF cells. To understand the differential expression between CF and non-CF cells/tissues we will investigate mRNA expression that could modulate ANO1 protein.

We conclude that decreased ANO1 activity in CF cells could be explained by decreased ANO1 ARNm and protein expression and may contribute to the worsening of ionic imbalance and decrease lung function. All of these results lead us to think that this Cl- channel could be a potential pharmacological target for the treatment of cystic fibrosis patients.

4739 Cystic fibrosis epithelial cells are primed for apoptosis as a result of increased Fas

Snead Weldon1, Qiwei Chen1, Irene Oglesby2, Christine Wohlfild-Lenane1, Jennifer Bartlett1, Gerry McElvaney2, Stuart Elborn1, Paul Cray Jr 1, Catherine Greene1, Clifford Tagar1, 1Centre for Infection and Immunity, Queen’s University Belfast, United Kingdom; 2Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; 3Department of Pardiatrics, University of Iowa, Iowa City, United States

Apoptosis is a physiological process essential for homeostasis of epithelial organisation and function. Cystic fibrosis (CF) lung disease is characterised by chronic infection and inflammation and previous work suggests that apoptosis is dysfunctional in the CF airways with conflicting results. In addition, controversy exists regarding how CFTR misfolding contributes to apoptosis. In this study, we evaluated the relationship between CFTR mutation and apoptosis in CF airway epithelial cells. Basal activity of the executioner caspase, caspase-3, was significantly increased in CF tracheal and bronchial epithelial cell lines and primary bronchial epithelial cells compared to non-CF controls. In addition, activity of the upstream initiator caspase, caspase-8, was significantly increased in CF epithelial cells compared to controls, suggesting involvement of extrinsic apoptosis signalling, which is mediated by the activation of death receptors, such as Fas (CD95). Increased levels of Fas were evident in the brushing samples, and neutralization of Fas significantly inhibited caspase-3 activity in CF epithelial cells compared to untreated cells. Furthermore, activation of Fas significantly increased caspase-3 activity and apoptosis in CF epithelial cells compared to control cells. Overall, these results suggest that CF airway epithelial cells are more sensitive to apoptosis via increased levels of Fas and subsequent activation of the Fas death receptor pathway. Further work will delineate the mechanism underlying increased Fas expression in CF epithelial cells.

P4740 COPD prevalence in Romania and possible influence of social and household characteristics

Floresin Dumitru Mihai1, Florentina Furtunescu2, Roxana Maria Nemes2, Dana Faracsam1, Ioana Mirela Daramus1, 1Programs, Center for Health Policies and Services, Bucharest, Romania; 2Marius Nasta, National Institute of Pulmonology, Romanian Society of Pulmonology, Bucharest, Romania; 1Public Health Department, “Marius Nasta” University of Medicine and Pharmacy, Bucharest, Romania

COPD is a very important public health issue at individual and society level alike. Knowing the prevalence of COPD is extremely useful in health services planning, but using an early detection tool is crucial for life duration and quality of life of the patient. We aimed to estimate the prevalence of COPD in Romanians aged 40+ in relations to certain social variables and specific household exposures. A cross-sectional survey was performed using a stratified sample of 9638 subjects aged 40+. Using a pre-screening questionnaire, 51% of the responders were identified as being at risk for COPD (4930). 2000 subjects, randomly selected, were invited to perform a spirometric evaluation (at least 3 spirometry tests per patient, according to ATS/ERS standards). Smoking subjects (current or former) with a FEV1 ratio lower than 0.7 were considered as having COPD. Social variables considered were geographical region, rural/urban, education, occupation, income category. Specific household exposures were way of cooking and source of household heating.

We found a COPD prevalence of 9.7% (±2.18) (15.7% and 3.9% in males and females). Median age of COPD subjects was 56 and 46 years in males and females. No significant correlations were found with geographical region, urban/rural distribution, education, job and income category, both for males and females. No significant correlations were found for source of heating and cooking.

Conclusions: Our study showed that around half of the general population aged 40+ meets the criteria for being at risk for COPD (around 5 million people). In the risk group, COPD prevalence reached to 9.7%. Social and household variables seemed not to be associated to COPD.

P4741 High prevalence of COPD symptoms in the Tunisian population contrasting with low awareness of the disease

Myriam Denguezli1, Hagar Daldoul2, Louisa Gnatiuc, Amnica Jithoo, Sonia Coton, Bermit Kato, Zaki Bougheroula, Hadia Azhar, Imed Harrabi, Peter Burney, Zouhair Tabka. Physiology, Sport and Physical Education Institut, Gafsa, Tunisia Physiologiy, Faculty of Medicine of Sousse, Tunisia Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom Epidemiology, Faculty of Medicine Ibn El Jazzar, Sousse, Tunisia Respiratory Epidemiology and Public Health, Imperial College London, London, United Kingdom Epidemiology, Faculty of Medicine Ibn El Jazzar, Sousse, Tunisia Epidemiology, Imperial College London, London, United Kingdom Epidemiology, Faculty of Medicine of Sousse, Tunisia

Introduction: In Tunisia, the estimated prevalence of COPD was low compared with America and Europe and the disease is certainly under diagnosed. We have estimated the prevalence of COPD in the city of Sousse, following the BOLD protocol.

Methods: We surveyed a representative random sample of 807 aged adults 40+ selected from the general population and have collected information on respiratory history and symptoms, risk factors for COPD and health status. Post-bronchodilator spirometry was performed for assessment of COPD. COPD and its stages were defined according to GOLD guidelines. Population weighted prevalence of COPD were computed allowing for survey design.

Results: 661 subjects were included in the final analysis. The response rate was 90%. The estimated population prevalence of GOLD Stage 1 and stage 2 or higher COPD were 7.8% and 4.2%, respectively (LLN modified stage 1 and stage 2 or higher COPD prevalence were 5.3% and 3.8%, respectively). COPD was far more common in men, increased with age and exposure to tobacco smoke. Prevalence of stage 1+ COPD was 2.3% in <10 pack years smoked and 16.1% in >20 pack years smoked. Only 3.5% of participants reported doctor-diagnosed COPD.

Conclusions: In this Tunisian population, the prevalence of COPD is higher than reported before and higher than self-reported doctor-diagnosed COPD. The implications for disease diagnosis and management in clinical practices might have a public health impact. In subjects with COPD, age seems to be a much more powerful predictor of lung function than smoking. LLN, Lower Limit of Normal; BOLD, Burden of Lung Disease; GOLD, Global Initiative for Chronic Obstructive Lung Disease.
COPD was diagnosed if FEV1/FVC was lower than 0.7 after a bronchodilator test.

**Results:** COPD prevalence in the Canary islands was 7.3% (IC 95%, 5.5-9.5%) being higher in male than female (8.7% CI 95%, 5.8-12.7% vs 6.3% CI 95%, 4.7-8.4% p <0.005). COPD prevalence classified by GOLD showed a 1.1% in stage I, 5.0% in stage II, 1.1% in stage III and 0.3% in stage IV. The level of undiagnosis was 63.5% and undertreatment reached 71.6%.

**Conclusions:** The Canary islands have a lower COPD prevalence than the rest of Spain as a whole, with a lower severity in spite of having a high smoking prevalence. This finding could be related to the specific climatic characteristics of the Canaries.

P4743

**Prevalence of COPD by disease severity in men and women in relation to smoking in northern Vietnam**

Haihui Lin, Linda Ekelund, Nguyen Van Doin, Nguyen Van Tuong, Eva Romsark, Kjell Larsson, Bo Lundbacki. Allergy, Hanoi Medical University, Hanoi, Viet Nam Allergy and Clinical Immunology, Bachmai Hospital, Hanoi, Viet Nam Unit of Lung and Allergy Research, IMM, Karolinska Institutet, Stockholm, Sweden Department of Internal Medicine/Krefting Research Centre, Gothenburg University, Gothenburg, Sweden The OLIN Studies, Northbotten County Council, Lulea, Sweden Public Health and Clinical Medicine, University of Umea, Sweden

**Background:** The prevalence of COPD and its risk factor pattern varies between different areas of the world. The aim of this study was to investigate the prevalence of COPD by disease severity in men and women and risk factors for COPD in northern Vietnam.

**Methods:** From all 5782 responders to a questionnaire survey, a randomly selected sample of 1500 subjects was invited to a clinical follow-up study. The methods included a structured interview using a modified GA2LEN study questionnaire for registration of symptoms and possible determinants of disease. Spirometry was performed before and after bronchodilatation. The age distribution of the sample was 23-72 years.

**Results:** Of 684 subjects attending, 565 completed acceptable spirometric measurements. The prevalence of COPD defined by the GOLD criteria was 7.1%; in men 10.9% and in women 3.9% (p=0.002). Of those 3.4% had a mild disease, 2.8% a moderate and 0.9% a severe disease. In ages >50 years, 23.5% of men and 6.8% of women had COPD. Among smokers aged >60 years (all men), 47.8% had COPD. None of the women with COPD had been smokers. Increasing age, smoking and male sex were the dominating risk factors, although male sex lost its significance in a multivariate setting.

**Conclusions:** The prevalence of COPD among adults in northern Vietnam was 7.1% and was considerably higher among men than women. The prevalence increased considerably with age. Increasing age and smoking, the latter among men only, were the most important determinants of COPD.

P4744

**Prevalence characteristics of COPD in never smokers**

Ramadan Bakr, Ibrahim Elmahalawy, Chest Department, Menoufia University, Shebin Elkom, Menoufia, Egypt

**Background:** COPD can be recorded among non-smokers due to different causes other than smoking.

**Methods:** This study was performed in the Chest Department, Menoufia University, from April 2009 to August 2011, on 300 COPD patients, 230 men (76.66%) and 70 women (23.34%). The mean age was 60±7.5±35.5 years. History was taken and exposure to risk factors for COPD was assessed by a prewritten questionnaire.

**Results:** Out of the 300 COPD patients, 120 (40%) were never smokers and 180 (60%) were ever smokers. Women made up 41.7% of the never smokers and 11% of the ever smokers. Never smokers were significantly older than smokers (65.0±5.03 years vs 56.3±5.67 years p < 0.001) and were more likely to be women [41.7% vs 11% (P < 0.001)]. Never smokers made up 40% of all COPD cases: 78% of GOLD stage II and 45.5% of GOLD stage III cases. Among never smokers, 58.3% and 41.7% fulfilled the criteria for GOLD stage II and III respectively. Never smokers had more occupational exposure to organic and inorganic dust and irritant gases [41.7% vs 27.7%, P < 0.05], more biomass exposure [41.7% vs 6%, P < 0.001], less education [75% vs 41.7%, P < 0.001], more exposure to passive smoking [75% vs 22.2%, P < 0.001]. When compared with never smokers with GOLD stage II, never smokers with GOLD stage III were older in age, have a higher female percentage, lower BMI, more occupational exposure, more biomass exposure, less education, more exposure to passive smoking. Independent predictors of COPD in never smokers were old age, female sex, occupational exposure, biomass exposure and low educational level.

**Conclusions:** This study revealed that never smokers constitute a significant proportion of the Egyptian COPD patients.

P4745

**Higher than expected prevalence of alpha-1-antitripsin deficiency (AATD) may not necessarily impact on airflow, gas exchange or acute exacerbation rate (AER)**

Ronald Dandurand 1, Jean Bourbeau 1, David Eidelman 2. Respiratory Medicine, Montreal Chest Institute, Montreal, QC, Canada; 2 Respiratory Medicine, Royal Victoria Hospital, Montreal, QC, Canada

AATD is estimated to occur in 1-3% of COPD patients and is believed to accelerate disease. To determine its prevalence in a community practice and impact on disease progression, all patients with COPD, >10 pack-year smoking history and a post-bronchodilator FEV1/FVC < 0.70 were offered testing for AATD. Spirometry and diffusing capacity (DLco) were measured respecting ATS criteria, and serum AAT levels were assayed. Of 323 patients, 291 (90%) accepted screening. 44 (15%) had low serum AAT levels (AATD mean 0.76g/L ± 0.05 vs. non-AATD 1.57 ± 0.03). Age (74±1 years vs. 72±1, smoking history (63±pack-years±3 vs. 45±3), FEV1 (63±predicted±4 vs. 61±4) and FEV1/FVC (54±4 vs. 54±1) were similar. 40 AATD and 187 non-AATD patients had DLco measured and were similar (64±predicted±4 vs. 64±2). Annual AER and prior spirometry was available in 44 AATD and 217 non-AATD and prior DLco in 39 AATD and 167 non-AATD subjects. Annual AER (1±0.06fections/year±1 vs. 1.2±0.01 over 4±years±0.1) and annual decline of both FEV1 (18±ml/year±19 vs. 3±6 over 6±years±0.3) and DLco (0.60± lost/mmHg/year vs. 0.5±0.1 over 6±years±0.3) were similar. In this population, AATD prevalence was 5 times greater than previously reported, yet no difference in FEV1, and DLco decline, or AER was observed. Whether this lack of difference is due to strict smoking cessation, medication compliance, aggressive management of exacerbations or a predominance of heterozygotes remains to be determined.

P4746

**A new paradigm for classification of disease severity and progression of COPD**

David Mannino, Enrique Diaz-Guzman, John Pospisil. Preventive Medicine, University of Kentucky, Lexington, KY, United States

**Background:** The current classification scheme for COPD uses lung function to classify disease severity and monitor disease progression. This scheme does not capture other important components of the disease process, nor does it allow for improvement of disease status.

**Methods:** We evaluated existing data to develop a classification scheme for COPD using measures beyond lung function, including respiratory symptoms, exacerbation history, quality of life assessment, comorbidity, and body mass index. We then applied this classification to data from the Lung Health Study, calculating a score for study subjects in year 1 and year 5 of the study, along with the difference between year 1 and year 5.

**Results:** We developed a 4 point scale ranging from 1.00 (mild) to 4.00 (very severe). In year 1 of the study, the mean COPD score was 1.76 (standard deviation (SD) 0.35), in year 5 it was 1.82 (SD 0.38). The mean difference from year 1 to year 5 was an increase (worsening) of 0.06 (SD 0.37), and a range from -1.0 to 1.6. The COPD score at year 1, year 5, and the difference between these scores were all predictive of mortality at follow-up. For example, the 14.0% of subjects whose score improved by at least 0.25 between year 1 and 5 had decreased mortality compared to those with stable scores (between -0.25 and 0.25, hazard ratio 0.6, 95% confidence interval 0.4, 0.8). Conversely, those whose score worsened by 0.75 or more points had increased mortality (HR 1.7, 95% CI 1.2, 2.5).

**Conclusions:** A COPD score that includes components in addition to lung function and allows for both improvement and worsening of disease may provide additional guidance to COPD classification, management, and prognosis.
P4747 Identifying a 'frequent exacerbator' phenotype in a cohort of COPD patients
(AEACO study)
Alexis Cortet1, Isabelle Tillie-Lebrun2, Frédéric Masure2, Brunoousse2, Nicolas Roche1, Thierry Perez1, Isabelle Boucot3, François Denis4, Aud Amlto5, Juliette Oustreli6, Isabelle Pithou-Merli7, Céline Pribil8, Stéphane Souch5, Anne Lallement9, Anne Pautel9, Hélène Calmette, Lille, France; *Pneumology, Groupe Médical Saint Rémi, Reims, France; ‡Pneumology, CHU Créteil, France; ‡Pneumology, Hôtel-Die, Paris, France; ‡Medical Department, GlaxoSmithKline, Marty-Le Roi, France; ‡Medical Department, Boehringer Ingelheim, Paris, France; ‡Medical Department, Nyonomed, Paris, France; ‡Medical Department, AstraZeneca, Rueil-Malmaison, France; ‡Medical Department, Pfizer, Paris, France; ‡Scientific Department, Kappa Santé, Paris, France

Background: Exacerbations are a major cause of morbidity and mortality in patients with COPD.

Objectives: To determine whether it is possible to identify a sub-group of 'frequent exacerbators', i.e. COPD patients who experience a high number of exacerbations every year, and to compare characteristics to that of non-frequent exacerbators.

Methods: In this French prospective observational study, respiratory physicians (n=132) included 835 COPD patients followed over 4 years. Sociodemographic data, clinical history, symptoms, lung function data and treatments were initially recorded. COPD clinical features, pulmonary function tests, treatments and the onset of exacerbations were recorded by the investigators at follow-up visits. Patients also completed exacerbation diaries. The KmL method was used to identify frequent and non-frequent exacerbators. This analysis was conducted in 464 patients with complete exacerbation-related data.

Results: 2 groups with homogeneous numbers of exacerbations were identified. The 1st group consisted of 114 (24.6%) patients who were frequent exacerbators (mean, 3.5 exacerbations/patient/year; SD: 1.3). The 2nd group consisted of 350 patients (75.4%) who experienced fewer exacerbations (mean, 0.9 exacerbations/patient/year; SD: 0.7). Frequent exacerbators were found to have a higher dyspnea score, a lower FEV1 (% predicted vs 50.3% P<0.0001) and reported more impaired daily activities (38% vs 18%, p < 0.0001), more frequent chronic cough (p < 0.01) and sputum production (p < 0.001) more frequently. Their slope of FEV1 decline was steeper.

Conclusion: Frequent exacerbators appear to belong to a distinct, clinically relevant, COPD phenotype.

P4748 Distribution of a COPD population based on the GOLD assessment framework
G. Nadel1, P.W. Jones2, L. Adamek3, M. Small3
1Respiratory Centre of Excellence, GSK, UK; 2Medical Department, AstraZeneca, Reims, France; 3Pneumology, Unité d’Études, Bordeaux, France

Background: GOLD 2011 proposed a new COPD assessment framework based on: 1. Risk of future adverse health events, using FEV1 <50% and/or history of ≥2 exacerbations in the previous year to identify patients at high risk; 2. Symptom level using either COPD Assessment Test (CAT™) or modified Medical Research Council Dyspnoea Scale (mMRC). This analysis focuses on the GOLD symptomatic cut-off for high symptoms of CAT ≥10 or mMRC ≥2.

Methods: Data from 1041 EU COPD patients (38.5% from primary care) in the 2011 Adelphi Disease Specific Programme were used providing CAT and mMRC scores, spirometry and the previous year’s exacerbation history.

Results: One third (32.9%) of all patients had ≥2 exacerbations in the preceding year (79.5% had an FEV1 ≥50, almost all (97.7%) were on maintenance treatment. The correlation between CAT and mMRC scores was moderate (r=0.55). Within each mMRC Grade, there was a wide distribution of CAT scores. The mMRC categorised more patients as having low symptoms (51.2%) than the CAT (10.0%). The mMRC categorised 13.4% of patients as having low symptoms and high risk (FEV1 <50% and/or ≥2 exacerbations in the preceding year). The CAT categorised only 0.7% of patients with this paradoxical picture.

GOLD Group Symptoms Risk Using CAT (% of patients) Using mMRC (% of patients)
A Low Low 9.3 37.8
B High Low 48.5 20.1
C Low High 0.7 13.4
D High High 41.5 28.8

Conclusion: There was a modest concordance between CAT and mMRC. The mMRC cutpoint score of ≥2 (“I have to stop for breath when walking at my own pace on the level”) for high symptoms appears to classify too many patients as having low symptoms. Use of MRC Grade ≥1 as the cut point should be explored.
P4753 COPD subtypes most likely to benefit from inhaled corticosteroids (ICS) during the exacerbations: \textit{Cluster analysis}.

\textbf{Methods:} We re-analysed two, pooled 1-year clinical trials (SCO40023, SCO100250) of 1,543 subjects with a COPD exacerbation history who were randomised to salmeterol/fluticasone propionate (SFC) or salmeterol alone (SAL). Cluster analysis maximised treatment differences between groups on major annual exacerbation rates. A negative binomial regression model was used, adjusting for baseline FEV1 predicted, reversibility stratum (≥12% and ≥70mL), time on treatment, and region. Data included lung function, demographics, COPD history, St George's Respiratory Questionnaire (SGRQ), and 19 medication classes. 

\textbf{Results:} Three distinct COPD clusters were identified based on diuretic use and reversibility of exacerbations (Cluster 1, no diuretic or with diuretic use; Cluster 2, with diuretic use; Cluster 3, no diuretic use). Patients in Cluster 1 had lower exacerbation rates with SFC vs. SAL (0.95 vs. 1.7 and 1.1 vs. 1.7 per/yr, respectively). Patients in Cluster 2 had higher exacerbation rates with SFC vs. SAL (1.1 vs. 1.7 per/yr, respectively). Patients in Cluster 3 had lower exacerbation rates with SFC vs. SAL (1.3 per/yr) and less severe obstruction compared to Cluster 1 (median FEV1: 38% vs. 32%). 

\textbf{Conclusions:} The greatest ICS benefit on exacerbations was in two COPD clusters: 1) patients with diuretics as well as more treatment for co-morbidities and 2) patients with ≥12% bronchodilator reversibility. Cluster analysis results may aid physicians in implementing personalised medicine. (Funded by GSK; WEUSK/GP5831).

\textbf{Association between serum clara cell secretory protein (CC-16) levels and asthma-related phenotypes among adults from the EGEA study} 

\textbf{Methods:} A total of 2,04,912 patients visited 7400 GPs, Gen Ps and Ps in India on 13,225 GPs, Gen Ps and Ps from 22 states and 5 union territories across India were randomly selected from 880 cities and towns and invited to participate in a 1-day point-prevalence study. On 1st Feb 2011 those doctors who agreed to participate kept a record of all symptoms and diagnosis for which patients visited their clinic or hospital. 7710 doctors consented and clean data was obtained from 7400 doctors (65% GPs, 17.4% GenPs and 17.6% Ps). Data was transferred into Epi-Info software and simple descriptive analysis was performed. 

\textbf{Results:} A total of 2,04,912 patients visited 7400 GPs, Gen Ps and Ps in India on 1 day. Amongst these, 16,783 patients visited a doctor for a diagnosis of asthma or COPD accounting for the highest number of visits (8.2%). Systemic hypertension (HT), anemia, diabetes and eczema accounted for 7.8%, 5.5%, 4.8% and 2.3% of the visits respectively. These observations were generally uniform across India, with no disease hot or cold spot regions. 

\textbf{Conclusion:} In this study, the above figures to around 15,00,000 registered GPs, GenPs and Ps in India, 3.5 million (m) patients visit a doctor every day in India for OADs, followed by 3.3 m for HT, 2.3 m for anemia, 2 m for diabetes and 1 m for eczema.
P4756

Time trends (1985-2011) in asthma and rhinitis in Italian general population samples
Sonia Cerrai1, Sara Maio1, Giuseppe Sarono1, Sandra Baldacci1, Marzia Simon1, Anna Angino1, Franca Martini1, Patrizia Silvi1, Marco Borbotti1, Giovanni Viegi1,2, Pulmonary Environmental Epidemiology Unit, Institute of Clinical Physiology, National Research Council, Pisa, Italy; 1Institute of Biomedicine and Molecular Immunology, National Research Council, Palermo, Italy

Aim: To estimate trends in the prevalence of asthma, asthma-related symptoms and risk factors such as allergic rhinitis and smoking.

Methods: Three surveys were carried out on general population samples living in Pisa, Italy; in 1985-88 (PI1,n=3267), 1991-93 (PI2,n=2604) and 2009-2011 (PI3,n=1619). Subjects filled in standardized questionnaires on respiratory symptoms, asthma, rhinitis and smoking habits. In PI1 and PI2 the same questionnaire was administered, whilst in PI3 the IMCA2 questionnaire, with different wording of the questions (particularly about rhinitis), was used. To compare the disease/symptoms prevalence within the samples the same age range (18-97 yrs) was selected. Comparison of variables across studies was performed by Pearson Chi-squared test.

Results: Both the prevalence of asthma diagnosis and current asthma attacks show a trend to increase. Current rhinitis increased from PI1 to PI2 and doubled from PI2 to PI3. Current smoking significantly decreased among the three surveys.

P4757

The prescribing patterns for asthma in general practice setting: Adherence to GINA guidelines
Giuseppe Sarono1, Sandra Baldacci1, Sara Maio1, Anna Angino1, Franca Martini1, Patrizia Silvi1, Marco Borbotti1, Anna Paola Pa1,2, Megon Bresciani1, Giovanni Viegi1,2
1Pulmonary Environmental Epidemiology Unit, CNR Institute of Clinical Physiology, Pisa, Italy; 1Institute of Biomedicine and Molecular Immunology, National Research Council, Palermo, Italy

Background: General practitioners (GPs) are the first healthcare professionals whom asthma patients refer to for their symptoms.

Aim: To assess drug prescription for asthma by GPs and to evaluate prescriptive adherence to GINA guidelines (GL).

Methods: 107 GPs throughout Italy provided data on 995 asthmatic patients (45% males, mean age 43.3±17.7 yrs).

Results: 48.5% of patients had intermittent (48.5%) or mild persistent asthma (25.3%); 61% had co-morbid allergic rhinitis (AR). More frequently, prescribed medicines were a combination of inhaled corticosteroids (ICS) plus long-acting β2-agonists (LABA) (55%), and short-acting β2-agonists (SABA) as mono-therapy or in combination with ICS (46%). In general, prescriptive appropriateness was higher for patients with only asthma (25%) than for those with asthma+AR (16%). Regardless of concomitant rhinitis, the lowest adherence to GL was found in the mild persistent asthma category (11%), whilst the highest was in the severe persistent group (56.3%).

Conclusion: In general, we found low adherence of GPs to GINA GL recommendations, with a trend to over-treatment of intermittent asthma; conversely, more appropriate therapeutic regimens were applied for severe asthma.

P4758

Estimated steps from motion detectors worn at the wrist, waist and ankle in COPD patients
Anna Chakraborty,1, Richard ZuWallack2, Bimalin Lahiri3, 1Department of Medicine, University of Connecticut, Farmington, CT, United States; 2Pulmonary and Critical Care, St. Francis Hospital, Hartford, CT, United States

Increased walking activity is desirable in COPD patients, but its direct measurement presents a problem in slow-moving individuals. Accordingly, we tested the effectiveness of a tri-axial accelerometer in estimating steps in patients with COPD. Devices were simultaneously worn on the dominant side on the wrist, waist, and ankle. Estimated steps were compared to visually-counted steps in 14 patients (FEV1 52±22%). Step counting was performed at three walk speeds during endurance shuttle testing: 1) at the lowest shuttle walk speed (1.78 km/hr), 2) at 85% of maximal (3.18±0.53 km/hr), and 3) at mid-way between these extremes (2.50±0.33 km/hr). The graphs (3 observations per patient) demonstrate the relationships between estimated steps from the 3 locations and visually counted steps. The diagonal line is the line of identity.

The devices significantly predicted counted steps (r²= 0.57, 0.46 and 0.65 for wrist, waist and ankle locations, respectively, p < 0.0001 for all). However, the wrist and waist devices underestimated visually-counted steps at all walk speeds (-137±76 and -167±80 steps, respectively) although less-so at higher speeds, while the device on the ankle came closer: -55±57 steps (all, p < 0.0001). In summary, the accelerometer on the ankle appeared to be more accurate and precise as a step-counter in COPD patients.

P4759

Validity of activity monitors for physical activity assessment in patients with chronic obstructive pulmonary disease
Roberto Rabinovich1, Zafeiris Louvaris2, Yogini Raste3, Daniel Langer4, Hans Van Remoortel4, Santiago Giavedoni1, Chris Burtin5, Eloisa Regueiro5, Ioannis Vogiatzis2, Nicholas Hopkinson3, Michael Polkey3, Frederik Wilson6, William MacNee1, Klass Westerpept1, Thierry Troosters2, 1ELEG1 Colt Laboratory, Centre for Inflammation Research, the Queen’s Medical Research Institute, The University of Edinburgh, Scotland, United Kingdom; 2Department of Critical Care Medicine, Pulmonary Rehabilitation Centre, Evangelismos Hospital, National & Kapodistrian, University of Athens, Greece; 3NIHR Respiratory Biomedical Research Unit of the Royal Brompton and Harefield NHS Foundation Trust and National Heart & Lung Institute, Imperial College London, London, United Kingdom; 4Faculty of Kinesiology and Rehabilitation Sciences, Department of Rehabilitation Sciences, Katholieke Universiteit Leuven, Belgium; 5UFS_Car, São Carlos, Universidade Federal de São Carlos, Brazil; 6Precision Medicine, Pfizer Worldwide Research and Development, Pfizer, Kent, United Kingdom; 7Department of Human Biology, Maastricht University, Maastricht, Netherlands

Rationale: Physical inactivity (PA) and symptoms during PA are hallmarks of COPD.
P4760 Performance of activities of daily living as a predictor of respiratory hospitalization for patients following an exacerbation of COPD
Brian C. Lach1, Stage West2, 1Pulmonary and Critical Care Medicine, Allegheny General Hospital, Pittsburgh, PA, United States; 2Medicine, Klingensmith HealthCare, Ford City, PA, United States

Purpose: To evaluate the rehospitalization rates for patients with COPD using performance of activities of daily living (ADLs) as a metric marker.

Methods: The Discharge, Assessment, and Summary @ Home (D.A.S.H., Klingensmith HealthCare, Ford City, PA, United States) program is a respiratory therapy-driven home care program based for patients with COPD who are using supplemental oxygen following discharge from the hospital following a COPD exacerbation. The program includes the performance of four patient selected ADLs (e.g. walking the four points of the home, loading the dishwasher) on days #1, #7, and #30 post-hospitalization. Oxygen saturation is maintained above 90% using a SmartDose Oxygen-delivery system. Each ADL is measured as either fully completed or not completed.

Results: 68 patients were recruited in four centres each wore simultaneously four out of six available activity monitors validated in chronic conditions (Lifecorder Plus, ActiWatch Spectrum, RT3, Actigraph GT3X, DynaPort MoveMonitor and SenseWear Armband) during waking time for 14 consecutive days. AEI was measured (0.9; Total Energy Expenditure (TEE) [DLW]-resting metabolic rate) and the validity of the monitors was evaluated by correlations between AEI and monitors outputs and through multiple regression analysis using TEE as the dependent variable with total body water (TBW) plus several PA monitors outputs as independent variables.

Results: Except for the Lifecorder Plus and the RT3, the remaining four monitors met the validation criteria. Actigraph GT3X and DynaPort MoveMonitor explained the majority of the TEE variance not explained by TBW (53% and 79% respectively) and showed significant correlations with AEI (p=0.63 p<0.0001, r=0.55 p=0.0001, respectively).

Conclusions: The present findings should guide users in choosing valid activity monitors for research or for clinical use in patients with chronic diseases such as COPD.

Funded by: The Innovative Medicine Initiative Joint Undertaking (IMI IU # 11S011)

P4761 Effects of a 3-week inpatient pulmonary rehabilitation (PR) on activity parameter in patients with COPD
Ines Heinzelmann, Stella Seeberg, Katrin Beutel, Klaus Kemn. Department of Pneumology, Schoen Klinik Berchtesgadener Land, Schoenau am Koenigssee, Germany

Rationale: Physical activity (PA) level in patients with COPD is markedly reduced in comparison to elderly healthy people. The aim of this study was to investigate the effect of a 3-week inpatient rehabilitation program (PR) on activity parameter measured by SenseWear®.

Methods: Forty patients with COPD, stage III-IV (age: 62±5y; BMI: 26±5kg/m²; FEV1: 56±30%pred.) were included in this prospective trial. PA was measured by SenseWear® Armband in all patients for 3 days at the beginning and at the end of inpatient PR. Additionally, quality of life was requested by SF36 questionnaire and each patient performed a 6-minute walking test (6MWT) (after treatment) pre and post PR.

Results: 6MWD improved significantly following PR (+391 ±95% CL, +69 to +8) p=0.001. We observed an increase in mental score of SF36 (+5.10 ±2.8, p=0.01). No significant differences between PA parameter pre and post PR were found: total energy expenditure (+35.27±139kal, p=0.49), steps per day (+293±1419, p=0.20), metabolic rate (-0.01±0.28, p=0.78), duration of PA more than 30fold basic metabolic rate (+4.9±4.7, p=0.63) were seen. There was no significant difference in PA data between 24 hours calculated as the mean of 3 days compared to the PA data of the first 24 hours of the 3 day measurement.

Conclusions: These data show that there are no relevant changes in PA following inpatient PR. Although exercise capacity and quality of life are improved. We hypothesize that an inpatient setting predetermines the daily amount of PA that is not similar to the activity chosen in daily life at home. We conclude that PA measurement may not be appropriate as an outcome parameter for an inpatient PR.

P4762 The usefulness of pedometry in patients with chronic obstructive pulmonary disease
Nicoleta Bertici1, Voicu Tudorache1, Ovidiu Fira-MLadinescu1, Cristian Oancea1, Ioif Marinuc1. 1Department of Pneumology, University of Medicine and Pharmacy “V. Babes”, Timisoara, Romania; 2Department of Infectious Diseases, University of Medicine and Pharmacy “V. Babes”, Timisoara, Romania

Introduction: Effort tolerance and daily physical activity (DPA) is predictive of quality of life and survival in COPD patients, but still remains difficult to assess on their real life.

Aim: How to relate pedometry with other classical parameters commonly used in pulmonary rehabilitation (Respir Med).

Methods: DPA has been evaluated by pedometry to 74 patients with COPD, age 63.55±8.73 (12 stage II, FEV1=0.16±7.78%; 29 stage III, FEV1=0.39±0.67; 30%; 33 stage IV, FEV1=0.23±1.7±8.18%). Monitoring for a period of 7 days has been done before and 6 months after a PR of 3 weeks.

Results: Values have been widely dispersed with a maximum of 17420 and minimum of 964 steps/24hrs. Average values acquired: lowest in COPD stageIV, still with the highest increase over 6 months of PR +636 steps/24hrs (2476.32±2104.12 vs 3112.63±2088.46 steps/24hrs, p < 0.02); in COPD stageIII the increase of DPA was +579 steps/24hrs over 6 months (5627.44±3135.15 vs 6224.32±2105.19, p < 0.04); in COPD stageII was the lowest increase +540 steps/24hrs (8724.33±2908.34 vs 9264.16±2405.18, p < 0.13), probably because the subjects belonging to this stage had the best preserved DPA.

Conclusions: DPA decreased opposite COPD stage; it is fluctuant with every subject, dependant of clinical status, weather and daily schedule. Wearing pedometers is very easy and motivational, provided that patients realize that they are being "watched".
COPD, there is limited available information on those phenotypic factors that determine real-life daily physical activity.

**Aim:** The objective of this pilot study was to examine the impact of baseline lung dysfunction, exercise capacity and quadriceps muscle strength on daily walking movement intensity (WalkMI), walking energy expenditure (WalkEE) and average muscle force (QuadsMF). Physical activity was measured over 14 consecutive days using the ActiPoint MoveMonitor triaxial accelerometer.

**Methods:** 20 COPD patients (age: 66±10; FEV1: 48±15%predicted; FMMI: 18±3) were assessed using an incremental walk test, the 6MWT and quadriceps muscle force (QuadsMF). Physical activity was measured over 14 consecutive days using the ActiPoint MoveMonitor triaxial accelerometer.

**Results:** WalkMI was related to 6MWT (r=0.44, p=0.05) and inversely related to dyspnea sensations during the 6MWT (r=−0.56, p=0.009). WalkEE was positively related to peak oxygen uptake (r=0.57, p=0.009), peak work rate (r=0.59, p=0.006) and FEV1 (β=−0.52, p=0.017) and inversely related to dyspnea sensations during the 6MWT (r=−0.53, p=0.017). QuadsMF adjusted by body weight (r=0.42, p=0.046) and inversely related to peak oxygen uptake (r=0.57, p=0.009), peak work rate (r=0.59, p=0.006) and FEV1 (β=−0.52, p=0.017)

**Conclusions:** Strategies to enhance whole body endurance capacity and locomotor muscle strength would ameliorate daily physical activities along with dyspnea sensations in patients with COPD.

Funded by the Innovative Medicine Initiative Joint Undertaking (IMI JU #115011).

**Reasons to be physically active differ from reasons to be sedentary in COPD:**

**A qualitative analysis**

Jenise E. Hartman1,2, Nick H.T. ten Hacken3,4, H. Marike Boezen2,4, Mathieu H.G. de Greef1,2, Department of Pulmonology, University of Groningen, University Medical Center Groningen, Netherlands; 3Department of Epidemiology, University of Groningen, University Medical Center Groningen, Netherlands; 4Department of Human Movement Sciences, University of Groningen, University Medical Center Groningen, Netherlands; 5GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands.

The daily physical activity (DPA) level in COPD patients is low, notwithstanding its beneficial effects. For the development of successful prevention and management programs it would be helpful to gain insight in the reasons why COPD patients are physically active or sedentary. The aim of the study is to assess this in a qualitative way.

115 COPD patients (68% male, FEV1/forced expired volume in one second 58±28, age 65±9 years) were interviewed in-depth. Furthermore, DPA (tri-axial accelerometer), lung function and dyspnea (MRC-scale) were determined. Answers were categorized according to the Groningen Codebook. Afterwards descriptive analysis using k-means cluster analysis was performed.

The cluster analysis shows 2 clusters, one cluster with a high DPA level (n=52) and the second with a low DPA level (n=60) (figure 1). A high DPA level was related to being physically active because of fun, because of having a continuous active lifestyle in the past, the number of reasons mentioned to be physically active and self-efficacy. A low DPA level was related to being sedentary because of bad weather influencing health, financial constraints, bad health and shame to be physically active.

**P4766**

**Muscle phenotypes in COPD patients: An exploratory cluster analysis**

Gresse Gouzi1,2, Adjifa Abdellatif1,2, Samia Seddouani1,2, Noclan Molina1,2, Edith Pine1,2, Daflah Lasoud-Chenivesse1,2, Jean-Paul Cristol1, Jacques Mercier1, Maurice Hayot1, Christian Préfaut1, Department of Clinical Physiology, INSERM U-1049, CHRU Montpellier, University of Montpellier I and II, Montpellier, France; Metropolitan; 2Department of Biochemistry, Pulmonary Rehabilitation Center “La Solane”, Fontvie Group, Osséja, France, Metropolis; 3Pulmonary Rehabilitation, Pulmonary Rehabilitation Center “La Solane”, Fontvie Group, Lodève, France, Metropolis; 4Department of Medical Information, UMR 729 MISTEA, CHRU Montpellier, University of Montpellier I, Montpellier, France, Metropolis; 5Department of Biochemistry, CHRU Montpellier, Montpellier, France, Metropolis

Peripheral muscle dysfunction is a key outcome in chronic obstructive pulmonary disease (COPD) and has been well characterized by reductions in fiber cross-sectional area (CSA) and type I fiber proportion (p<0.05). Reduced fiber CSA and increased protein carbonylation were found only in the most severe cluster of patients (p<0.05). Yet, clusters of patients had the same age (64±8.8 yrs vs. 60±9.0 yrs; p=0.87). Last, an algorithm including 6-minute walking distance, ventilatory threshold, and body mass index accurately classified 57% of the individuals according to fiber atrophy and/or type I fiber regression. These clusters may indicate distinct COPD phenotypes, as they are related to clinical outcome (muscle fiber biologic mechanism and time course) may have differed in the two clusters of COPD patients. Decision trees may improve the identification of COPD patients with distinct muscle features.

Background: Although quadriceps Type I muscle fibre proportion is reduced in patients with COPD, there is conflicting evidence as to whether quadriceps muscle endurance is impaired. We therefore performed a systematic review and meta-analysis of studies comparing quadriceps endurance in COPD to healthy controls.

**Methods:** Studies comparing quadriceps endurance between patients with COPD and healthy controls were identified using six databases (1946-2011) and grey literature. Full text articles were obtained after two researchers independently reviewed the abstracts. Weight standardized mean difference (WSDM) with 95% confidence intervals were calculated by a random effects model for measures of quadriceps endurance.

**Results:** Data were extracted from 17 studies involving 565 patients with COPD and 353 healthy controls. The outcome measurements involved a mixture of techniques. Quadriceps endurance was greater in the controls compared with COPD (WSDM =−1.46 [−0.84 to −2.09]; p<0.001). This relationship was similar both when non-solitonal versus solitonal techniques (p=0.26) or when sustained versus dynamic contractions (p=0.43) were used to measure quadriceps endurance. There was significant heterogeneity between studies.
Validity of the six-minute stepper test in patients with COPD

Cardio-respiratory fitness assessed by peak oxygen uptake (VO2peak) is an independent predictor of mortality in obesity. We investigated whether VO2peak measured during corridor walking tests was similar to that measured by an incremental treadmill (ITM) test in obesity.

Methods: Individuals with a BMI ≥30 were recruited from a sleep clinic. All patients had treated Obstructive Sleep Apnea. Patients with chronic lung or heart disease were excluded. Participants completed an ITM test; the gold standard to determine VO2peak; two-six minute walk tests (6MWT) and two incremental shuttle walk tests (ISWT) on three separate days in a randomised order.Expired gas analysis was performed during all tests. The difference between the peak parameters for the two corridor tests compared to the ITM was assessed by Dunnett test.

Results: 16 patients completed the study: 8 male, mean [SD] age 58 [12] y, BMI 36.1 [7.6] kg/m2. The results of the second walking test were used. Table 1 shows the peak parameters for the three tests.

*Significantly different to ITM (p<0.01). VCO2 = carbon dioxide output, VE = minute ventilation, RER = respiratory exchange ratio.

The limits of agreement for VO2 peak between the ITSM and the ISWT was 730 m/min.
P4773
Long-term adherence to exercise after pulmonary rehabilitation: What are the motivating factors and barriers?

Cassie Lee, Sarah Elkin. Chest and Allergy Dept., Imperial College NHS Trust, London, United Kingdom

Introduction: Adherence to exercise after PR is known to be low, but motivation/barriers to exercise in this population are unclear. This study aimed to investigate motivation and barriers to exercise post PR.

Method: A postal survey was sent to 112 (38%) participants who completed >50% of a PR program in the previous three years. Collating demographics, physical activity level, exercise information and participants’ views of their motivation (21 items) and barriers (14 items) to exercise, quantified along a 5-point Likert scale.

Results: 51.8% (n=58) responded; mean age 71.72, MRC dyspnoea 2.86 and co-morbidities 90.1%, COPD=87.9%. Individual’s motivation and barrier mean were calculated, but did not correlate, mean barrier did correlate with; MRC (p=0.003), co-morbidities (p=0.001) and intent to exercise (p=0.001). The most frequent (always/everytime) motivating reasons were: I want to improve my fitness=82.7%; I want to be physically fit=80.4%; I exercise for health concerns=72.6%. Barriers were: shortness of breath=58.4% and lack of energy=52.2%. Significant differences in motivation/barriers were identified between exercisers (> once a week most weeks co-morbidities and non-exercisers, but not time since completion of PR. Preferred options to motivate exercise were: weekly PR group 47.4% and repeat PR yearly 42.1%, those with a higher motivation (p=0.039) or lower barrier (p=0.011) opted for the weekly PR group significantly more.

Conclusion: This study quantified motivation/barriers to exercise post-PR identifying many items that significantly differed depending on exercise level: these do not change significantly over time and may predict long-term exercise preference.

P4774
Effect of pulmonary rehabilitation on erythrocyte oxidative stress and antioxidants in COPD patients

Kemi Nemozo, Masayuki Itoh, Setario Sembu, Hideki Adachi, Koji Kishi, Hiroyuki Nakamura, Shuji Ohishi, Department of Respiratory Medicine, Tokyo Medical University Ibaraki Medical Center, Ibaraki, Japan

Background and objective: Recent studies suggest that pulmonary rehabilitation (PR) is essential in the management of COPD. However, the effect of PR on oxidants and antioxidants in erythrocytes is only partially understood. The aim of this study was to evaluate whether PR improves not only exercise capacity and health-related quality of life (HRQoL), but also the oxidant/antioxidant imbalance in erythrocytes.

Methods: Twelve stable COPD patients participated in PR for 8 weeks. A pulmonary function test, 6-minute walking test (6MWT), shuttle walk test (SWT), and the St. George’s Respiratory Questionnaire (SGRQ) were administered before and after PR. Blood was collected prior to and after PR for analysis of thiobarbituric acid-reactive substances (TBARS), superoxide dismutase (SOD), Cu-Zn-SOD, glutathione peroxidase (GPX), and total glutathione (GSH).

Results: After PR, exercise capacity was improved (6MWT: 399.5±28.6 vs 455±31.7 m, P<0.01; SWT: 335.6±45.9 vs 373±47.1 m, P<0.01). There were reductions in the SGRQ total, symptoms and activity scores, indicating a clinical improvement, but no significant difference in TBARS pre and post PR. Erythrocyte CAT activity and GSH were significantly increased after PR (CAT: 158±6±4 vs 174±4±6 μkat/l, P<0.05, GSH: 4.9±0.7 vs 5.6±0.7 μmol/l, P<0.05), but there were no differences in the erythrocyte SOD and GPX activities and the Cu-Zn-SOD concentration.

Conclusion: The current study suggested that PR improved exercise capacity and HRQoL, and upregulated antioxidant capacity, resulting in no further increase with repeated exercise. PR improved exercise capacity and health-related quality of life (QoL), and inflammation.

P4775
Introduction: In obesity, the ISWT VO2 pk more closely reflects ITM VO2 pk than the 6MWT VO2 pk, but is not predictive in an individual.

Farming environment during infancy and lung function at age 31 – Prospective birth cohort study in Finland

Juvas Larmi1, 2, Heikki Koskelo1, Anna-Liisa Hartikainen1, Alec da Silva Couto Alves1, Adai Ramasamy1, Marjo-Riitta Jurvelin1, 2, 3, Juha Pekkanen1, 2, 4, 5

1Department of Environmental Health, National Institute for Health and Welfare, Kuopio, Finland; 2Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, Finland; 3Center for Medicine and Clinical Research, Division of Pulmonary Medicine, Kuopio University Hospital, Kuopio, Finland; 4Department of Clinical Sciences/Ostetrics and Gynecology, University of Oulu, Finland; 5Department of Epidemiology and Public Health, Imperial College London, London, United Kingdom; 6Child and Adolescent Health, National Institute for Health and Welfare, Oulu, Finland; 7Institute of Health Sciences and Biocenter Oulu, University of Oulu, Finland

Aims: Investigate the prospective associations between farming environment during infancy and lung function in adulthood has not been studied earlier.

Methods: Childhood in a farming environment may protect from obstructive-type lung disease in adulthood. The prospective association between farming environment during infancy and lung function in adulthood has not been studied earlier.

Results: While CRP decreased in both groups (p<0.05), we found a significant increase in the 6-MWT (p<0.005) and a significant decrease in the CAT (p<0.05) in the PTG group only (table 2).

Conclusion: In patients hospitalised due to an exacerbation of COPD, the addition of active muscle contraction with the Galileo system results in beneficial effects on QoL and exercise capacity.

Latitude variation in the prevalence of asthma and allergic rhinitis in Italy: Results from the GEIRD study

Giancarlo Fessl1, Pierpaolo Marchetti 1, Paolo Girardi1, Alessandro Marcon1, Lucia Cazzolleti1, Simone Accomini1, Leonardo Antonicelli2, Massimiliano Bugiani1, Lucio Casali1, Isa Cervetti1, Marta Grazia Panico2, Pietro Furlan3, Elgee Verhalen4, Roberto de Miguel5, Azienda Ospedaliera UMET2282, Bassanolo, Italy; 4Regional Agency for Environmental Protection and Prevention of Veneto, Operating Unit on Physical Environmental Agents, Verona, Italy

Background: Earlier studies have pointed out a great variability in the prevalence of asthma and asthma-like symptoms in different geo-climatic areas.

Aim: To test the association between latitude and prevalence of asthma and allergic rhinitis.

Methods: In the frame of Gene-Environment Interaction in Respiratory Diseases study, a postal screening questionnaire on respiratory health and exposure to environmental factors was administered to 18,357 randomly selected subjects aged 20–44 years in 7 centres: 1 in Northern (Trento, Pavia, Verona), 2 in Central (Ancona, Perugia) and 2 in Southern Italy (Salerno, Sassari).

Results: 10,494 (57.2%) subjects responded to the questionnaire. The prevalence of self-reported doctor-diagnosed asthma and allergic rhinitis in the lifespan was 10.2% and 26.9%, respectively, and was significantly different across the centres (p < 0.05). After adjusting for sex, age, potential risk factors for respiratory disease and allergic reactions, the prevalence of asthma (OR: 1.07 per 1° latitude decrease; p < 0.001) and asthma-like symptoms (wheezing, chest tightness, asthma attacks: OR ranging from 1.04 to 1.06; p < 0.05) and allergic rhinitis (OR: 1.03, p=0.04) showed a significant north-to-south trend. Similarly, a 1°C increment in temperature was significantly associated with asthma (OR: 1.10, p < 0.001) and asthma-like symptoms (OR from 1.07 to 1.10, p < 0.05), but not with allergic rhinitis (OR=1.02, p=0.190).

Conclusion: The prevalence of asthma and allergic rhinitis increased moving southwards in Italy, suggesting that prolonged exposure to different geo-climatic conditions may affect the onset of asthma and allergic respiratory diseases.

P4779

Association between daily levels of air pollution and school absences in the proximity of a cement plant in Italy

Paolo Girardi1, Alessandro Marcon1, Giancarlo Pesce1, Pierpaolo Marchetti1, Salvatore Falcone2, Francesca Predicatore2, Gianstefano Blengio2, Roberto de Miguel3

1Unit of Epidemiology and Medical Statistics, Dept of Medicine and Public Health, University of Verona, Italy; 2Dept of Allergy, Immunology and Respiratory Diseases, University Hospital “Ospedali Riuniti”; Ancona, Italy; 3Dept of Respiratory Medicine, ASL-TZQ, University of Turin, Turin, Italy; 4Unit of Respiratory Diseases, Dept of Internal Medicine, University of Perugia, Italy; 5Respiratory Diseases Division, IRCCS “San Matteo” Hospital Foundation, University of Pavia, Italy; 6Unit of Epidemiology, ASL-SA2, Salerno, Italy; 7Institute of Respiratory Diseases, University of Sassari, Italy

Background: Emission of dust represents the main hazard associated with cement production and may cause adverse respiratory health effects to the population living nearby.

Aim: To evaluate the association between daily levels of PM2.5 and a morbidity indicator (school absenteeism) in children aged 7-14 years attending a school within 2 km from a cement plant in Fumane (Northern Italy).

Methods: Data on absences of students (average: 461 students/year) and daily concentrations of PM2.5 from a fixed monitoring station placed in the schoolyard were collected for 3 school years (541 school days from November 2007 to June 2009). The association between average level of pollutants from Lag 0 to Lag 4 and school absences confirmed the presence of a statically significant association with PM2.5 levels (RR: 1.016; 95% CI: 1.003-1.029 for each μg/m3 increase).

Conclusions: Daily PM2.5 levels are associated with school absences, a proxy indicator of short-term morbidity, in children who attend schools in proximity to a cement plant. Primary prevention interventions aimed at reducing air pollution in the area are recommended.

P4780

Lung function and respiratory symptoms of Brazilian sugarcane cutters exposed to biomass burning

José Carlos Carvalho Junior1, Ercy Ramos, Alessandra Toledo, Aline Ferreira-Ceccato, Rafaela Cuisse, Nayara Galvão, Mariane Monteschi, Dionei Ramos, P. Filho, UNEESP: São Paulo State University, Presidente Prudente, Brazil

Brazil is the largest producer of ethanol from sugarcane in the world and part of this production is still manually harvested and for this, it needs to be burned. This action releases toxic gases that cause lung damage. The aim of this study was to evaluate the lung function and frequency of respiratory symptoms of sugarcane cutters exposed to biomass burning. We evaluated twenty-three male sugarcane cutters (age=25.4±7 years, BMI = 24.8±3 kg/m2), non-smokers, from Sugar and Ethanol Company located in Brazil. Evaluations were performed in the pre-harvest and harvest. Lung function was assessed by spirometry and respiratory symptoms by questionnaire. Data normality was tested by the Shapiro-Wilk test, and comparison of spirometric values in the two periods was performed using the paired t-test. To compare the qualitative variables we used the Goodman test. The level of significance was p=0.05. In the pre-harvest spirometric values were: FVC (4.4±0.57), FEV1 (93.8±1.43), FEV1/VC (3.9±0.47), FEV1% (96.3±13.3), FVC/FEV1 (89.4±5.55) and FVC/FEV1% (104.8±1.22). In the harvest of we found the following values: FVC (4.5±0.85), FEV1 (94.5±14.1), FEV1 (3.9±0.47), FEV1% (90.3±13.3), FVC/FEV1 (83.6±7.85) and FVC/FEV1% (94.4±10.14). There was a statistically significant decrease in FEV1% (p<0.033) and FVC/FEV1 (p=0.002) after harvest. The prevalence of difficulty of breathing when there is dust and/ or climate change increase after harvest. Our results suggest that six months of harvest leads to airway obstruction and increases respiratory symptoms in these workers.

P4781

Dampness, mould and endotoxin in primary schools and lung function in children: The international HIITEA study

José Jacobs1,2, Alicia Borras-Santos3, Jan-Paul Zock2, Esmeralda Krop4, Bernadette Alders1, Juha Pekkanen5, Martin Taubel1, Anne Hyvarinen1, Dick Heederik1,2,3,4

1Division of Environmental Epidemiology (EEP), Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands; 2Centre for Research in Environmental Epidemiology (CREAL), Hospital del Mar Medical Research Institute (IIBMB), Barcelona, Spain; 3Department Environmental Health, National Institute for Health and Welfare, Kuopio, Finland

Respiratory health effects in relation to moisture in homes are well recognised, but little is known on effects of dampness in school environments. We have previously reported a higher prevalence of respiratory symptoms in pupils from moisture damaged schools. Here we aim to study associations between dampness and visible mould in school buildings, endotoxin exposure and lung function in children.

8768

WEDNESDAY, SEPTEMBER 5TH 2012
We included 15 Spanish, Dutch and Finnish primary schools with and 10 without moisture, dampness and visible mould based on reports and inspections. Endotoxin in settled dust was measured in 237 classrooms. Acceptable forced spirometry tests were done in 2736 children aged 6-12 years. Associations between measured log-transformed endotoxin levels and lung function were assessed by multiple linear regression adjusted for gender, age, height, home moisture, ETS, parental education, technical, school and (for endotoxin analyses) school moisture status. In the Netherlands and Finland, FEV₁ and FEF25-75 tended to be higher in children attending damaged schools or classrooms with higher endotoxin levels. FEV₁ was 39% (95% CI 5-72%) higher in Dutch children attending damaged schools and in Finland FEV₁ significantly increased with increasing endotoxin exposure. In Spain, FEF25-75 tended to be somewhat lower, but not statistically significant, in relation to school moisture status and increased endotoxin levels. Our findings do not provide consistent evidence for adverse effects of moisture damage in the school environment on lung function in children. Heterogeneity across different geographical areas may be related to climate, ventilation characteristics and type of school building.

P4782 Fate of inhaled ultrafine carbon particles after one week; human exposure using a novel aerosol with 111Indium

Anna Klepczynska-Nyström, Alejandro Sanchez-Crespo, Martin Anderson, Rolf Falk, Andreas Lundin, Britt-Marie Larsson, Magnus Swartengren. Public Health Sciences, Division of Occupational and Environmental Medicine, Karolinska Institute, Stockholm, Sweden Department of Nuclear Medicine, Karolinska University Hospital, Stockholm, Stockholm, Sweden Department of Physiology, Södersjukhuset, Stockholm, Sweden Radiation Protection, Swedish Radiation Safety Authority, Stockholm, Sweden

Particulate air pollution, such as nanosized particles <100 nm in diameter, has negative health effects. But, there is still limited knowledge regarding the fate of inhaled particles in the human body. Controlled exposure conditions provide information about the biological pathways of particle pollutants, such as deposition and retention, in human body. Recently we have developed a method for labelling ultrafine carbon particles with an indium isotope (111In), and generating an aerosol, which enables long-term deposition and retention studies in humans (Sanchez-Crespo, et al. 2011: 111Indium-labelled ultrafine carbon particles..." Inhal Toxicol 23(3): 121-128). In the present study ten healthy volunteers were exposed for the aerosol (particle size range 58-124 nm) and followed for seven days. One volunteer was followed for totally 29 days. One week after the exposure, pulmonary particle retention was 92%. There was no elimination of particles from the body via urine. The total in vitro leaching of 111Indium was 0.3%, which indicates a stable bonding between the labelling have higher levels of activity. Conclusions: We conclude that measurements with indium-111 enables longer follow-up studies as a novel tool in ultrafine particle tracking.

P4783 Particulate air pollution on systemic inflammatory response: Roles of monocytes and neutrophils

Qinghua Sun, Silis Jiang, Xiaohua Xu. College of Public Health, The Ohio State University, Columbus, OH, United States

Research has increasingly demonstrated the detrimental effects of air pollution on systemic human diseases. However, there has been little examination of the pattern and scope how neutrophils and monocytes respond to the inhalants. We exposed C57BL/6 mice to ambient fine particulate matter (PM2.5) in a timely manner to investigate the roles of neutrophils and monocytes. C57BL/6 mice were exposed to PM2.5 or filtered air 6 hours a day, 5 days a week for up to 3 weeks in Columbus, OH in a versatile aerosol concentration enrichment system. The measurements were conducted at days 5, 14, and 21 for circulating inflammatory biomarkers via magnetic beads, leukocytes rolling and adhesion in mesentry via intravital microscopy, inflammatory responses in the lung and visceral adipose tissues via flow cytometry and immunohistochemical staining (IHS), and inflammatory chemotactic responses via Boyden chamber. We found that both rolling and adhesion leukocytes were increased in mesentry, especially at days 14 and 21. Circulating MCP-1, IL-6, and TNFα were elevated, especially at day 5. There were increases in Ly6G (neutrophil) and F4/80 (monocyte) expression from lung bronchoalveolar lavage by flow cytometry and lung and visceral adipose tissues by IHS, especially F4/80 expression throughout the entire course. Boyden chamber assay also indicated that lung and visceral adipose tissues were "inflamed", especially monocytes/macrophages after PM2.5 exposure. We concluded that, in this murine model of inhalational exposure to ambient PM2.5, the murine monocytes respond rapidly to chemokines locally (in the lung) and systemically (in visceral adipose tissue), which may not be accompanied by neutrophils.

P4784 PM10 is associated with an increase in day-by-day respiratory variability in asthma

Anna Klepczynska-Nyström, Alejandro Sanchez-Crespo, Martin Anderson, Jennifer A. Bosson, Jenny A. Bosson, Amanda Tolosa, Amanda Tolosa, Jennifer A. Bosson, Jennifer A. Bosson, Jennifer A. Bosson, Jennifer A. Bosson. 1Dept of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 2Centre for Cardiovascular Sciences, Edinburgh University, Edinburgh, United Kingdom

Rationale: Whilst particulate air pollution is well recognized as a contributor to greenhouse gas emissions and thus plays a vital role in global warming, exposure is also detrimental to cardiovascular and respiratory health. The environmental impact of switching to more sustainable fuels is well accepted; however there is little evidence of potential health benefits that may result from such an approach. Here we examined cardiovascular and respiratory effects after inhalation of biodiesel blend and petrodiesel exhaust.

Methods: 16 healthy subjects were exposed to petrodiesel exhaust and biodiesel blend (30% rapeseed methyl ester (RME30) blended with petrodiesel) for 1h, standardized for PM mass concentration of 300 μg/m³. Vascular somatomotor function was assessed with forearm venous occlusion plethysmography, using acetylcholine, bradykinin, sodium nitroprusside and verapamil. Additional cardiorespiratory measurements were also performed throughout.

Results: Infusion of all vasodilators caused a dose-dependent increase in forearm blood flow (P<0.01 for all), which was similar following both exposures (P>0.05 for all), but attenuated as compared to filtered air exposures from previous studies. Results: Diesel exhaust inhalation is known to impair vascular endothelial function, which is linked to an increase in cardiovascular events. This study demonstrates that replacing 100% petrodiesel with RME30, a commercially available mixture, results in similar adverse effects, and suggests there are unlikely to be any health gains in switching from petrodiesel to RME30. We suggest that these adverse health effects should be taken into consideration alongside environmental concerns when assessing future developments.
P4786
Respiratory effects in a chamber study of diesel exhaust exposure in healthy volunteers
Lars Barregard1, Yihi Xu2, Jorn Nielsen2, Anders Gudmundsson2, Aneta Wierzbiacka1, Anna Axmon2, Bo A. Jonsson3, Monica Kareld2, Maria Albin3, 1Occupational and Environmental Medicine, University of Gothenburg, Sweden; 2Occupational and Environmental Medicine, Land University, Land, Sweden; 3Ergonomics and Aerosol Technology, Lund University, Lund, Sweden

Background: In previous chamber studies of diesel exhaust exposure by the Umea group, volunteers were exposed to particle mass concentrations (PM) of 300 μg/m³ for 1 hour. Clear effects were found in bronchial biopsies and BAL, but not in crude lung function tests.

Aim: To examine whether exposure to diesel exhaust at 300 μg/m³ for 3 hours would cause symptoms, signs and lung function changes.

Methods: Eighteen healthy subjects were exposed twice to diesel exhaust at 300 μg/m³, and twice to clean air (<3μg/m³), in a double-blind cross-over design, at least one week apart. NO₂ levels were about 1.4 ppm. Before and after exposure measures of respiratory function and symptoms were performed. Symptom scores were assessed before and after, and after 15, 75, and 135 minutes of exposure. Generalized Estimating Equation models were used to analyze changes from baseline, adjusted for exposure sequence.

Results: Symptom scores for eyes and throat were higher during diesel exhaust exposure than during filtered air after 75 and 135 minutes. Signs of irritation in upper airways were more common after diesel exhaust exposure. PEF increased during filtered air exposure, but decreased during diesel exhaust, with a statistically significant difference after 75 and 135 minutes. There were no such differences for spirometry.

Discussion and conclusion: Increased symptoms and signs from eyes and upper airways were to be expected, while a decrease of PEF has not been reported previously. Repeated PEF measurements during exposure may be statistically more powerful than spirometry before and after exposure. Symptoms, signs, and lung function changes were found at exposure levels much lower than occupational limit values.

P4787
Effect of NO₂ on inflammatory response in subjects with asthma
Michel Aubert1, Véronique Eudyart, Gaëlle Guillouillon, Monique Dehour, Catherine Neukirch. Clinical Centre of Investigation, Bichat – Claude Bernard Hospital, Paris, France, Metropolitan Medical Studies Department, EDF, Levallois-Perret, France, Metropolitan

Patients with asthma may be more susceptible to NO₂. Our aim was to investigate whether repeated exposure to realistic indoor concentrations of NO₂ enhances inflammatory response in the airway of subjects with asthma. Participants were 19 non-smoking subjects with intermittent asthma and airway hyperresponsiveness during methacholine challenge. The study had a double-blinded, crossover design. On day 1, subjects were exposed to either 200 ppb NO₂, 600 ppb NO₂, or purified air for 30 min, and on day 2, to the same pollutant, for 2 x 30 min. The order of exposure to the two concentrations of NO₂ and air-only was randomized and exposures were separated by 2 weeks. Markers of inflammation were measured in sputum daily, 6 hours after the first (on Day 1) and the third exposure (on Day 2) and 48 h after the first exposure (Day 3) and compared to baseline. The effect of NO₂ on bronchial responsiveness to methacholine was tested at baseline and on Day 3. Exposure to 200 ppb or 600 ppb NO₂ had no direct effect on respiratory function either during or after the exposure sessions. Compared to baseline, the variation in the percentage of eosinophils in induced sputum after exposure to NO₂ was -2% after air, +16% after 200 ppb NO₂, and +7% after 600 ppb NO₂. Linear association between the variation and the level of exposure was significant (p=0.01). Exposure to NO₂ did not cause any change in lung function and no NO₂-related effect on responsiveness to methacholine was found. NO₂ exposure had a significant and dose-related effect on the eosinophilic inflammatory response of patients. These data suggest that exposure to NO₂ might enhance the eosinophilic activity in sputum in subjects with intermittent asthma.

Noise exposure during sleep and risk of OSAS: A population-based study
Asad Nafees2, Ambreen Qazi 2, Zafar Fatmi2, Irfan Muhammad1. 1Occupational and Environmental Medicine, University of Abdul Wali Khan University, Abbottabad, Pakistan; 2Department of Medicine, Aga Khan University, Karachi, Pakistan

Objective: To determine the association between chronic arsenic exposure through drinking groundwater and risk of obstructive sleep apnea syndrome (OSAS) in a representative sample from the Pakistani population.

Methods: A time series of daily cardiopulmonary ERV/HAs between the years 2003 and 2009 was made from hospital registar data. Three-day moving averages of exposure variables PM10, nitrogen dioxide (NO₂), O₃, and weather variables were calculated. The ERV/Ha counts were regressed on the exposure variables with Generalized Additive Models assuming Poisson distribution, and time trend adjustment using Cubic splines. The relative increase in number of events per interquartile range (IQR) increase in pollutant level was calculated from the model coefficients with a 95% confidence interval (CI).

Results: Mean daily number of ERV/HAs was ten, 76% were cardiac and 60.8% were not. Intercorrelations are low, a large fraction of particulate matter with aerodynamic diameter ≤ 10(μm) (PM10) is from natural sources, and ozone (O₃) peaks in early in spring. This study aimed to study short-term associations between pollution levels and daily emergency room visits and hospital admissions (ERV/Ha) for cardiopulmonary causes.

Methods: A time series of daily cardiopulmonary ERV/HAs between the years 2003 and 2009 was made from hospital registar data. **Measuring the health of the 2012 European green capital, Vitoria-Gasteiz:**

"The impact of air pollution and weather conditions on COPD"

Soheir Garcia¹, Ines Carrascosa², Sandra Pedrero³, Amanda Garcia⁴, Mercè Rodríguez¹, Txema Merino⁵, ¹Pneumology, HUA Santiago, Vitoria-Gasteiz, Basque Country, Spain; ²Pneumology, Hospital Basurto, Bilbao, Basque Country, Spain

**Background:** On October 21, 2010, the European Commission designated Vitoria-Gasteiz European Green Capital 2012. The air that the citizens breathe received the highest score given to any city. Only 65 km far away from Vitoria-Gasteiz, Bilbao is the second industrialized region of Spain, behind Barcelona.

**Aims:** To compare the impact of air pollution and weather conditions on COPD in two cities from the Basque Country, very close by distance, but with a different environmental scenario.

**Methods:** Between January 2010 and December 2010 in Santiago Hospital (Vitoria-Gasteiz) and Basurto Hospital (Bilbao) all admissions for COPD exacerbations were retrospectively evaluated. The daily average values of NO2 and Ozone (both oxidant air pollutants), and meteorology data were obtained from the Basque Meteorological Agency.

**Results:** Measuring air quality, in Vitoria-Gasteiz the NO2 exposure average was low. In contrast, in Bilbao, ozone concentration was >100 μg/m³ several times over the year.

**Conclusions:**
- NO2 (Vitoria-Gasteiz) 28 μg/m³; 0-78 μg (mean annual) 40 μg/m³ (maximum daily mean of hour)
- Ozone (Bilbao) >100 μg/m³ 100 μg/m³ maximum daily mean of hour

Pearson correlation for COPD exacerbations rate and air pollution was: Ozone: 0.75 (p<0.01), NO2: 0.72 (p<0.01). The weather correlation was not significant, but there was an inverse relation between higher NO2 levels and lower temperatures, r=-0.74 and NO2: 0.73 (p<0.01). The weather correlation was no significant, but there were no significant differences in the distribution of genotypes of polymorphisms of GSTT1 null patients and healthy controls, and in lung cancer GSTT1 null polymorphism was found to significant associated (OR=0.47; 95% CI=0.30-0.73;p<0.001). But GSTM1 null polymorphism was not significant associated with lung cancer patients. In subgroup analysis in age, we found GSTM1 N/P polymorphism significantly associated between age 50–60 years for COPD (OR=0.21; 95%;CI=0.07-0.60; p=0.03), but in case of Lung cancer none of GSTT1/M1 null polymorphism were associated (p=0.07).

**Conclusion:** We can conclude that the GST1 null polymorphism was associated with COPD. We also observe that GSTT1 null polymorphism was associated between age group 50-60 years COPD patients but not in case of Lung cancer. So we can conclude that aging have affect of COPD not in lung cancer patients.

**P4794**
**Proteinase activated receptor-1 (PAR-1) polymorphisms and susceptibility to exacerbations in COPD**

Manuela Plate¹, Jennifer K. Quinn², Jadwiga A. Wierzchca³, Rachel C. Chambers⁴, John R. Hurst³, ¹Centre for Respiratory Research, University College London, United Kingdom; ²Department of Non-communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom; ³Academic Unit of Respiratory Medicine, Royal Free Campus, UCL Medical School, London, United Kingdom

**Introduction:** COPD is a condition of global importance, characterized by accelerated lung function decline and an abnormal inflammatory response. Exacerbations (i.e. episodes of acute deterioration of respiratory health) account for much of the morbidity and mortality in COPD. The reasons why some patients are more susceptible to exacerbations is poorly understood, but familial clustering suggests that there may be a genetic basis. Proteinase activated receptor-1 (PAR-1) activation leads to the generation of several inflammatory mediators involved in COPD and our unpublished data have shown that functional polymorphisms of PAR1 are protective in sarcoidosis.

**Aims & objectives:** The aim of this study was to investigate whether PAR1 polymorphisms are associated with COPD exacerbation frequency (ExF).

**Methods:** Two PAR1 SNPs (rs2277744 and rs32934) and a 13bp indel (rs11267092) were genotyped in 136 infrequent and 67 frequent exacerbators.

**Results:** The genotypic distributions of all polymorphisms were in Hardy-Weinberg equilibrium. The rs2277744 SNP showed a statistically significant association with ExF: Frequency of the minor allele was 0.47 in infrequent and 0.37 in frequent exacerbators (OR 1.5, 95%CI 1.0-2.4, p=0.04). Considering exacerbations as a continuous variable, the presence of the minor allele was associated with a significantly lower exacerbation rate (3.03 vs 1.98 exacerbations/year, MWU p=0.04).

**Conclusions:** Taken together with our previous studies showing that the presence of the minor allele at SNP rs2277744 increases PAR1 expression, these data suggest that this SNP may confer a degree of protection against exacerbations in COPD by increasing PAR1 expression.

**P4795**
**Heterozygosity for F2R2V in ABCA3, lung function and COPD in 64,000 individuals**

Marie Backvad-Hansen¹, Borje Nordesgaard², Morten Dahl³, ¹Department of Clinical Biochemistry, Herlev Hospital, Copenhagen University Hospital, Herlev, Denmark; ²Department of Clinical Biochemistry, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

**Background:** There is increasing evidence for a close relationship between aging and chronic inflammatory diseases: COPD is a chronic inflammatory disease of the lungs, which progresses very slowly and the majority of patients are therefore elderly. In this study, we assess whether age in metabolism of phase 2 enzyme gene polymorphisms GSTT1 & GSTM1 in northern Indian COPD and lung cancer patients.

**Material & methods:** In this case study only, we have enrolled 422 study subjects (218 lung cancer & 204 COPD). COPD enrolled after spirometry evaluation and lung cancer patients confirmed by Histopathology. All genotyping were done by PCR-RFLP method.

**Results:** GSTM1 null was found to be significantly higher in COPD patients as compared with healthy controls (OR=2.08; 95%;CI=1.40-3.09; P=0.0001), but there were no significant differences in the distribution of genotypes of poly- morphisms of GSTT1 null patients and healthy controls, and in lung cancer GSTT1 null polymorphism was found to significant associated (OR=0.47; 95%; CI=0.30-0.73;p<0.001). But GSTM1 null polymorphism was not significant associated with lung cancer patients.

**Conclusion:** We can conclude that GSTM1 null polymorphism was associated with COPD. We also observe that GSTT1 null polymorphism was associated between age group 50-60 years COPD patients but not in case of Lung cancer. So we can conclude that aging have affect of COPD not in lung cancer patients.

**WEDNESDAY, SEPTEMBER 5TH 2012**

CI 3.3-11.4). In elderly, NO2 was associated with an increase of 3.4% (95% CI 0.1-6.8). We found no associations with PM10.

**Conclusion:** In this study, O3 was associated with cardiopulmonary ERV/HAs. NO2 was associated with ERV/HAs in the elderly.
associated with chronic lung disease in childhood, but frequency of chronic lung disease due to ABCA3 mutations in the general population is unknown. We tested the hypothesis that individuals heterozygous for ABCA3 mutations have reduced lung function and increased risk of COPD in the general population. We resequenced 760 individuals and identified three novel (H86Y, A320T, A1086D) and four previously described (P292G, P766S, S1262G, R1474W) in ABCA3. We genotyped the entire Copenhagen City Heart study (n=10,043) to assess the clinical importance of these variants. To validate our findings we genotyped an additional 54,395 individuals from the Copenhagen General Population Study for the E292V mutation. In the Copenhagen City Heart Study E292V heterozygotes had 5% reduced FEV1% predicted (t-test: p=0.008) and 3% reduced FVC % predicted compared with noncarriers (p=0.04) and an increased odds ratio for COPD of 1.9 (95% CI: 1.1-3.1) is in contrast, the A1086D mutation was associated with increased FEV1% predicted (p=0.03) and FVC % predicted (p=0.008) in the Copenhagen City Heart Study. None of the other ABCA3 mutations associated with lung function or COPD risk. In the larger Copenhagen General Population Study, and in the two studies combined, E292V heterozygotes did not have reduced lung function or increased risk of COPD (p>0.11), while this was the case for the positive controls, surfactant protein B (SPPB; 121ins2 heterozygotes and α1-antitrypsin ZZ homozygotes). Our results indicate that partially reduced ABCA3 activity due to E292V is not a major risk factor for reduced lung function and COPD in the general population.

Conclusion: TSPYL-4, NT5DC1 genes polymorphism are associated with susceptibility to COPD and pulmonary function in a southern Chinese Han population.

P4798 Genetics of detoxification and oxidative stress pathways in COPD

Leysan Akhmadishina1, Gulnaz Korytina1, Tatyana Viktorova1,2, 3Department of Genomics, Institute of Biochemistry and Genetics, Ufa, Russian Federation; 2Department of Biology, Bashkir State Medical University, Ufa, Russian Federation

We hypothesized that occupational factors might affect the relationship between genetic predisposition and the risk of chronic bronchitis. Cases were 122 workers with a confirmed diagnosis of occupational chronic bronchitis and controls were 166 healthy workers matched to cases by age, sex and industrial exposure time. 55 SNPs were genotyped by PCR-RFLP. Significant association with occupational chronic bronchitis risk were observed with VDBP 1307C→G, Padj=0.0066, OR=2.54 (95%CI 1.60-4.04), IL8 -210A→G (Padj=0.0016, OR=2.87 (95%CI 1.86-4.69), ADAM33 1394C→G (Padj=0.0004, OR=3.95 (95%CI 2.64-6.04), IL2-447A→G (Padj=0.0008, OR=3.66 (95%CI 2.38-5.69), NQO1 869C→T (Padj=0.0008, OR=3.75 (95%CI 1.35-6.72), UGT2B7 2146C→T (Padj=0.0021, OR=2.34 (95%CI 1.35-4.04), CYPA1 2461delT (Padj=0.0041, OR=2.08 (95%CI 1.27-3.49), CYTP2C19 1293C→T (Padj=0.0046), VDBP 1307C→A (Padj=0.0258), CYPA1 3798T→C (Padj=0.0457).

The formation of occupational chronic bronchitis in workers is determined not only by the composition of harmful dusts and duration of exposure but also the individual characteristics of the organism. The disease occurs predominantly in healthy workers matched to cases by age, sex and industrial exposure time. 55 SNPs were genotyped by PCR-RFLP. Significant association with occupational chronic bronchitis risk were observed with VDBP 1307C→A, 1296G→T (Padj=0.0066, OR=2.54 (95%CI 1.60-4.04), MMPI 519A→G (Padj=0.0001, P=0.0205, 95%CI 1.10-2.80). The MMP12*−519A/A genotype carriers in children had a significantly increased risk of chronic lung disease (OR=4.49; 95%CI 2.33-8.81 for adults). The MMP1*−519A/A genotype were identified as a risk for chronic lung disease (OR=3.64; 95%CI 1.76-7.68 for children, OR=4.49; 95%CI 2.33-8.81 for adults). The MMP1*−519A allele carriers in children had a significantly increased risk of chronic lung disease (OR=1.75; 95%CI 1.10-2.80) The MMP1*−22A/A genotype was identified as a risk for chronic lung disease in children (OR=1.75; 95%CI 1.10-2.80) but not for adults. The genotype and allele frequencies of other MMP genes do not significantly differ in groups. The results of our study suggest the genetic polymorphisms in degradation pathway genes may play a significant role in the development of chronic lung disease.

P4799 New degradome markers in children and adults with chronic lung disease

Olga Tselousova1, Gulnaz Korytina1, Tatyana Viktorova1,2, 3Department of Genomics, Institute of Biochemistry and Genetics, Ufa, Russian Federation; 2Biology, Bashkir State Medical University, Ufa, Russian Federation

The degradome protease a large group of enzymes that act in the extracellular environment have been associated with multiple physiological and pathological processes in lung tissue. Through protein degradation and turnover proteases play an essential role in lung tissue remodeling and repair during the inflammatory response and may be important in the development of chronic lung disease. In our case - control study we investigated common genetic mechanisms of susceptibility to chronic lung disease in children and adults. We analyzed MMP genes in 220 children with chronic respiratory diseases and 230 control and in group of 362 adults with COPD and 483 control, respectively. The following genotypes were detected: MMP1*−519A/A, MMP2*−735C/T, MMP3*−1293C:7632T:9893C of the CYP1A1, 930AG+GG of CYBA associated with increased MDA level, decreased FEV1% and CAT activity and decreased MDA and decreased LS in patients (p<0.05). Gene polymorphisms affecting the function of proteins cause imbalance of detoxification and oxidative-stress pathways thereby contributing to pathogenesis.

Cigarette-smoking, although, is the most important risk factor, but only a small percentage of smokers develop symptomatic COPD. Does that mean the genetic predisposition plays a pivotal role? To address this query, we investigated polymorphisms on several genes but restrict here to cyclochrome P450 1A1 (CYP1A1), CYP1A2, N-acetyl transferase (NAT) and micromesial epoxide hydrolase (mEPHX) of detoxification and cyclochrome b-245 alpha (CYBA), glutathione-S-transferase P1 (GSTP1) of oxidative stress pathways in a case-control design. We present data on haplotypes, gene-gene interactions and correlations with clinical and biochemical levels.

Haplotypes 462Val:3801C, 462Val:3801T of CYP1A1, −1293C:9893C, −1293C:9893G and −1293C:7632T:9893C of the CYP2E1, 930G:2424 of CYBA (p=0.05), 105V-114V of GSTP1 (p=0.001) and 1138H:131H of mEPHX (p=0.05) were over-represented in patients. The same allele-associated genotype-combinations between genes, GSTP1, CYBA and NAT2*6 and NAT2*7 alleles were prevalent in patients (p<0.01). Patients have significantly elevated malondialdehyde (MDA) level and decreased catalase (CAT), glutathione peroxidase (GPx), activities, glutathione (GSH) level (p=0.01). Genotypes, 462IleVal:Val:Val, 3801T+C of CYP1A1 and 930A+GG of CYBA associated with increased MDA level, decreased FEV1% and CAT activity and decreased GSH levels in patients (p<0.05). Gene polymorphisms affecting the function of proteins cause imbalance of detoxification and oxidative-stress pathways thereby contributing to pathogenesis.

P4800 Longitudinal analysis of airway epithelium of COPD subjects reveals unique inflammatory gene networks up-regulated over time

Investigation of the role of miRNAs as a biomarker in chronic obstructive pulmonary disease (COPD)

Ender Coskunpinar, Engin Aynaci, Yasemin Musteri Ohtu, Pinar Yildiz

Department of Genetics and Bioengineering, Fatih University, Istanbul, Turkey; 2Department of Molecular Medicine, Istanbul University Institute of Experimental Medicine, Istanbul, Turkey; 3Palmonology, Third Clinic, Yedikule Chest Diseases and Thoracic Surgery Training Hospital, Istanbul, Turkey.

COPD as a complex disease with genetic and environmental compound, is one of the leading cause of death in worldwide. miRNAs have role in gene expression as responsible gene's down-regulated by blocking miRNAs after transcription, translation inhibition and breaking of mRNA. Aim of the study is definition a biomarker that are based on the measurement miRNA level of plasma, is specific to COPD. 20 COPD and 10 healthy control cases were included in this study. The median age was 59±6.6 and 55±5.2 years for controls and COPD, respectively. miRNA specific quantitative real-time-PCR based miRNA (miR-qRT-PCR) detection has been used. Free PCR Array Data Analysis Software has been used for data analysis. As a result of the study, two miRNA were significantly upregulated (miR-7 and miR-30a) and seven different miRNA were significantly downregulated in COPD patients (miR-9, miR-20a, miR-26b, miR-28-3p, miR-34c-5p, miR-100, miR-101).

As a conclusion, this is the first study using QRT-PCR Array method to investigate the association between serum miRNAs and COPD. Upregulation of miR-7 and miR-30a might be potential biomarkers for early diagnosis of disease.

P4802
Cell-cell variation in expression of blaCTX-M-14

Xiaorang Wang, Yu Kang, Shuchang An, Tong Zhou, Jichao Chen, Yongrong Fu, Zhancheng Gao

Department of Respiratory & Critical Care Medicine, Peking University People’s Hospital, Beijing; 2Institute of Microbiology, Chinese Academy of Sciences, Beijing; 3Department of Respiratory Medicine, The Central Hospital of China Aerospace Corporation, Beijing, China

Background: Cell-cell variation in expression of their gene in isogenic population is frequently observed in isogenic culture which is recognized as one of the reasons for phenotype heterogeneity. The aim of this study is to investigate the heterogeneous resistance level in genetically identical cells which was originated from cell-cell variation in expression of blaCTX-M-14. Methods: The transcriptional region of CTX-M-14 with or without the entire coding sequence of CTX-M-14 which were amplified from clinic strain isolated from patients with lower respiratory tract infection were subcloned to upstream of green fluorescent protein (GFP) gene to regulate expression of GFP followed by standard method. Applying flow cytometry measurement (FCM) to analyze the expression pattern of blaCTX-M-14 in single cell using GFP as the report genes. The expression pattern of cells after cultured with different ceftriaxone concentrations ranging from 0µg/ml to 240µg/ml was also analyzed. Using the E-test method to measure the MIC to ceftriaxone.

Results: Variation in GFP expression from cell to cell was seen (The fluorescence intensity of different cells vary largely) ranging from 106 to 109). The resistance level to ceftriaxone was positively correlated with the expression level, with increment of the extracellular ceftriaxone concentrations, the proportion of cells with more GFP abundance increasing. We also found the epigenetic resistance phenotype mediated by the heterogeneous expression was non-strictly inheritable and have a transient property.

Conclusions: Heterogeneous expression of antibiotic genes other than nucleotide alterations in genetically identical cell may be one of the reasons for diverse antibiotic resistance level.

P4803
Polymorphisms of genes involved in extracellular matrix remodeling, xenobiotic metabolism, antioxidant pathways and chronic lung disease in children

Gulnaz Korkina, Leysan Akhmadishina, Elena Victorova, Tatjana Victorovapa, Dina G. Fatkhutdinova, Elena Victorova, Elena Victorova, 1Genomics, Institute of Biochemistry and Genetics, Ufa Scientific Center, Ufa, Russian Federation; 2Biology, Bashkortostan State Medical University, Ufa, Russian Federation; 3Genetics, George-August University of Goettingen, Goettingen, Germany

We performed a candidate gene association study of 43 polymorphisms in genes coding genes functioning in extracellular matrix remodeling, xenobiotic metabolism and antioxidant pathways in 257 children with severe chronic lung disease (CLD) and 335 controls. The frequencies of wild type/wild type genotype of CYP2F1 (c.14,15insC) gene were significantly higher in CLD patients than in the healthy control group (Padj=0.00001; OR=3.16 2.10-4.77). Association with CLD and CYP1A1 gene polymorphisms (3798T>C and 2454A>G) in additive model (Padj=0.0003; OR=1.32 1.21-1.45) and (Padj=0.001; OR=1.54 1.08-2.21) was also found. The patients with CLD showed significantly elevated frequencies of the GSTT1 gene deletion (Padj=0.003; OR=1.98 95% CI 1.16-3.89). The GSTT1 (313A>G) polymorphism was associated with CLD (for AA genotype Padj = 0.0046, OR=1.65 1.17-2.34). Regression analysis showed that CAT (-262C>T) C allele was associated with a 1.84-fold increase (95% CI 1.22-2.65; Padj=0.0009) and NQO1 (-1156C>T) T allele was associated with a 1.89-fold increase (95% CI 1.90-3.02; Padj=0.0006) in additive model. Association with CLD and MMP9 (+1171 A>A), MMP12 (+82A>G), MMP3 (+660A>G) and TIMP3 (-1296T>C) gene polymorphisms in dominant model was found (Padj=0.0013, OR=2.75 1.43-5.31; Padj=0.007, OR=1.83 1.16-2.89; Padj=0.017, OR=1.54 1.08-2.21; Padj=0.033, OR=1.48 1.11-2.10). Consequently, CYP2F1, CYP1A1, CAT, GSTT1, NQO1, MMP3, MMP9, MMP12 and TIMP3 genetic polymorphisms probably play a substantial part in susceptibility to severe pulmonary inflammation in children with CLD.
Results: A significant case-control difference was observed for the presence of null GSTM1, (61.8% vs. 55.0%, P = 0.04). No difference was observed in the frequency of GSTT1 Null genotype and COPD susceptibility. (54.8% vs. 55.0% OR 1.28, CI 0.87-1.84, P = 0.28) For GSTP1 polymorphism we found that Subjects homozygous variants Val/Val were at increased risk of developing COPD (OR 2.58, CI 1.2-4.8) as compared to heterozygote variants Ile/Ile (OR 1:29 CI 0.7-2.14). Also, the mutant allele frequency (Val) was significantly higher in patients as compared to controls and the difference was found to be statistically significant. (OR: 1.8 CI: 1.4-4.2; P Value = 0.001)

Conclusion: that subjects with GSTM1 null allele and GST P1 homozygous isoallelic genotypes are at higher risk of COPD and are significant indicators of susceptibility to chronic obstructive pulmonary disease in Indian population.

P4805
Rare alpha-1 antitrypsin mutations in the Irish population
Toniá Carroll1, Geraldine O’Brien1, Catherine O’Connor1, Ilaria Ferrarotti2, Stefania Ottaviani2, Maurizio Lusetti2, Gerard McElvany3
1Department of Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland; 2Department of Molecular Medicine, University of Pavia, Italy

AAT deficiency (AATD) results from mutations in the SERPINA1 gene, classically presenting with early-onset emphysema and liver disease. The most common mutation responsible for AATD is the Z mutation. AAT deficiency is under-diagnosed and prolonged delays in diagnosis are common. ERS and ATS guidelines advocate the routine testing of AAT in all COPD, poorly-controlled asthma, and cryptogenic liver disease patients, as well as for those diagnosed with COPD, our results suggest that FLCN haplo-insufficiency in the lung may knock-downed.

Objective: To clarify the mechanism of lung cyst formation, we isolated lung fibroblasts from patients with BHDS and analyzed their function because they are principal cells responsible for the production and maintenance of extracellular matrix.

Methods: Lung fibroblasts were isolated from lung tissue obtained from patients with BHDS (n=10) and lung cancer (n=7). Lung fibroblast function was evaluated by chemotaxis to fibroblast and three dimensional (3D)-gel contraction assay.

Result: We confirmed that lung fibroblasts express FLCN mRNA, but there was no difference in expression level between control and BHDS fibroblasts. BHDS fibroblasts showed reduced chemotaxis as compared with control fibroblasts (p<0.001). But there was no significant difference in contraction of 3D-collagen gels between two groups (p>0.1726). Expression of fibronectin, transforming growth factor (TGF-β) and type I collagen was significantly reduced in BHDS fibroblasts as compared to control fibroblasts when evaluated by real-time PCR. In support of these results obtained from primary cultured fibroblasts, normal fetal lung fibroblasts (HFL) exhibited reduced chemotaxis when FLCN expression in HFL-1 was knocked-down.

Conclusion: Our results suggest that FLCN haplo-insufficiency in the lung may cause fibroblast dysfunction leading to impaired tissue repair.

P4807
CCDC103 encodes a novel cilia dynein arm factor that is mutated in primary ciliary dyskinesia
Claudius Werner1, Anita Becker-Heck1, Jennifer R. Punzitz2, Victoria H. Castlesman1, Dalal Al-Mutar1, Eamonn Sheridan1, Nik T. Loges1, Heike Obirich1, Rahul Chodhari5, Christopher O’Callaghan1, Eddie M. McKiernan1, Johannes Offermanns1, Hannah M. Mitchison3, Ian A. Drummond4, Heymut Omran1
1Klinik fuer Kinder- und Jugendmedizin, Algemeine Pneumologie, Universitaetsklinik Muenster, Germany; 2Nephrology Division, Massachusetts General Hospital, Charlestown, United States; 3Molecular Medicine, University College London, United Kingdom; 4Department of Pathology, Immunology and Inflammation, University of Leicester, United Kingdom; 5Genome Centre Cologne, MPI for Plant Breeding Research, Cologne, Germany

Primary ciliary dyskinesia (PCD) is a genetically heterogenous disorder charac-terized by chronic destructive respiratory tract disease. In about 50% of cases it is associated with situs inversus, because embryonic cilia play a critical role in establishing organ left-right asymmetry. Zebrafish schmalsans mutants exhibit characteristic features of ciliopathy caused by a mutation in ccdx 103; in electron microscopy cilia lack inner (IDIA) and outer (ODA) dynein arms.

Screening individuals for CCDC103 (the human ccdx 103 ortholog) identified ten patients with mutations. We found homozygous loss-of-function mutations in six siblings and one patient, who had no family history of ciliopathy, revealed a 3 bp frame shift (c.833_834delG) predicting a premature termination of translation. In four affected individuals a homozygous transversion (c.A461C; p.H154P) was identified. The affected individuals exhibited typical clinical findings for PCD. Three patients had situs inversus totalis, one had situs inversus abdominalis and two dextrocardia. High-speed videomicroscopy (HSV) of patient OP-1192II (c.833_834delG) showed ciliary immotility with only residual flickering. In contrast, in two patients with the p.H154P variant, HSV showed reduced beat amplitude and coordination and few immotile cilia. In patient OP-1192II, immunofluorescence microscopy demonstrated distal ODA deficiency. Immunofluorescence microscopy of ODA component DNALI1 showed cilia immotility with only residual flickering. In contrast, in two patients with the p.H154P variant, HSV showed reduced beat amplitude and coordination and few immotile cilia.

Our findings indicate that CCDC103 mutations cause PCD in humans. Whereas the loss-of-function mutation results in ciliary immotility and distal ODA deficiency, the p.H154P variant presents as a hypomorphic mutation.

P4808
Recessive HYDIN mutations cause primary ciliary dyskinesia without situs abnormalities
Johanna Räder1, Heike Obirich1, Claudius Werner1, Niki T. Loges1, Nora F. Banki1, Amelia Shoemark1, Tom Burgoyne1, Gabriele Kohler1, Josef Schroeder2, Gudrun Nürnberg1, Heike Römmelt1, Heymut Omran1
1Klinik fuer Kinder- und Jugendmedizin, Algemeine Pneumologie, Universitaetsklinik Muenster, Germany; 2Department of Pediatrics, Semmelweis University, Budapest, Hungary; 3Electron Microscopy Unit, Royal Brompton Hospital, London, United Kingdom; 4Department of Pathology, Universitaetsklinik Muenster, Germany; 5Institute for Genetics, Cologne Center for Genomics, Cologne, Germany; 6Genome Centre Cologne, MPI for Plant Breeding Research, Cologne, Germany

Primary ciliary dyskinesia (PCD) is a genetically heterogenous disease character-ized by reduced muco-ciliary clearance. This is caused by defects in cilia motility. Impaired sperm flagella motility contributes to male infertility. In about 50% of cases PCD is associated with situs inversus or more rarely situs ambiguous as a result of embryonic cilia dysfunction leading to randomization of left-right body asymmetry. 70 years ago the hy3 mouse carrying hydin mutations has been described. These mutations lead to an abnormal composition of the central pair (CP) apparatus. Clinically, these mice suffer from lethal hydrocephalus. Now we report HYDIN mutations in human PCD patients without hydrocephalus and normal body composition.

By using a homologygous mapping strategy we identified a novel PCD locus on chromosome 16q21-q23 across the HYDIN locus. In three affected siblings genomic analyses showed homozygous c.3985G>T HYDIN mutations affecting the evolutionary conserved splice acceptor site of exon 27. We confirmed aberrant splicing with early stop of translation by cDNA analysis. High-speed videomicroscopy (HVM) of respiratory cells showed a reduced bending capacity. Sperm motility was markedly decreased with only 8% of sperm showing minimal progressive motility. Transmission electron microscopy (EM) appeared normal in most cross sections. 9 + 0 cilia and 8 + 1 cilia composition were found very rarely. EM tomography showed absence of the CP apparatus C2b projection resembling findings in Hydrocephalic mice. Our results expand the knowledge on PCD genetics. Careful diagnostic evaluation is obligate in this PCD variant as HVM and EM findings are subtle.

P4009
Clinical characteristics and determinants of exacerbation in Japanese patients with COPD: Hokkaido COPD cohort study results
Masaru Suzuki1, Hiroki Mukita2, Satohiko Kono1, Kaeuko Shimizu1, Natsuko Taniguchi1, Yoichi M. Ito1, Masaharu Nishimura1 1First Department of Medicine, Department of Biostatistics, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Introduction: Exacerbations are one of the major factors that may influence natural history of COPD. However, little is known about clinical characteristics and determinants of exacerbation of COPD in a Japanese population.

Aims: To examine characteristics and determinants of exacerbation in Japanese patients with COPD in a 5-year observational cohort study.

Methods: A total of 279 patients with COPD participated in the Hokkaido COPD cohort study (AIRCCM 2012) and 268 subjects (GOLD 1, 26%; GOLD 2, 45%; GOLD 3, 24%; GOLD 4, 5%) who had clinical data of multiple visits were analyzed for this analysis. Exacerbation was defined in four ways: symptom criteria, requiring prescription change (prescription criteria), requiring antibiotics treatment (antibiotics criteria), and requiring hospital admission (admission criteria). Exacerbation frequency was observed over a period of 5 years.

Results: Exacerbation frequency was 0.24±0.47/yr (symptom criteria), 0.20±0.43/yr (prescription criteria), 0.13±0.28/yr (antibiotics criteria), and 0.06±0.19/yr (admission criteria). Cox proportional hazard model showed that an increase in SGRQ total score was significantly associated with short exacerbation-free period defined by all criteria and a decrease in body mass index (BMI) was also associated with short exacerbation-free period defined by antibiotics and admission criteria. Subjects who experienced hospital admission >1/yr tended to have rapid annual decline in FEV1 (p<0.07).

Conclusion: While exacerbation frequency is low in our cohort subjects, poor health-related quality of life and low BMI are independent risk factors for the development of exacerbation of COPD.

P4010
Is controlled oxygen therapy in COPD patients presenting in acute respiratory failure sub-optimal prior to commencement of NIV?
Shaner Karmali, Thida Win, Respiratory Medicine, Lister Hospital, Stevenage, Hertfordshire, United Kingdom

Introduction: Controlled oxygen delivery with target oxygen saturations is a key aim in managing COPD patients in respiratory failure.

Aims: This audit assessed if controlled oxygen therapy is utilised on these patients on admission to hospital and prior to NIV in line with British Thoracic Society guidance.

Methods: In a district general hospital, case notes for twenty patients with COPD requiring NIV between April 2011 - February 2012 were analysed retrospectively. VO2, SpO2 and arterial blood gas values (pH, PaO2, PaCO2 and HCO3) were calculated on patients requiring NIV between April 2011 - February 2012 were analysed retrospectively. VO2, SpO2 and arterial blood gas values (pH, PaO2, PaCO2 and HCO3) were calculated on admission to hospital and prior to NIV in line with British Thoracic Society guidance.

Results: Oxygenation on admission and immediately prior to NIV

Conclusion: While exacerbation frequency is low in our cohort subjects, poor health-related quality of life and low BMI are independent risk factors for the development of exacerbation of COPD.

P4011
Impact of diabetes in patients admitted with acute exacerbation of COPD
Rosalind Benson, Nosheen Kazmi, Anne Pocock, Syed Huq, Sanjeev Agarwal. Respiratory Medicine, St. Helens and Knowsley Teaching Hospitals NHS Trust, Prescot, United Kingdom

Background: In patients admitted with acute exacerbation of COPD (AECOPD), the presence of concomitant diabetes has been shown to prolong the length of stay (LOS) and increase the risk of death. However, it is not clear if this impacts on readmission rates.

Methods: A retrospective study of consecutive patients admitted with AECOPD in an acute teaching hospital.

Results: 67 patients (45% male) with a mean (SD) age of 72 (12) years and % predicted FEV1 of 55 (20) were included in the study. 15 (22%) of them had concomitant diabetes with a mean (SD) HbA1C of 6.8 (1.3).

Baseline characteristics and outcome parameters

Conclusion: The presence of DM might have an impact on readmission rates following a hospital admission with AECOPD. Prospective studies with larger sample size are needed to evaluate this further.

No significant difference in LOS or mortality within one year was noted between the two groups. However, there was a trend for increased readmission rates in the following year in patients admitted with AECOPD and concomitant diabetes.

Conclusions: Our study suggests that the presence of DM might have an impact on readmission rates following a hospital admission with AECOPD. Prospective studies with larger sample size are needed to evaluate this further.

P4012
The prognostic value of elevated levels of troponin T (Tn T) and heart-type fatty acid binding protein (H-FABP) in hospitalized COPD patients with acute respiratory failure (ARF)
Gulshar Raimakhanov, Sergey Avdovsky, Alexander Chuchalin. Clinical Department, Palmonology Research Institute, Moscow, Russian Federation

Aim: To evaluate the diagnostic and prognostic value of heart injury biomarkers (H-FABP and Tn T) in COPD patients with ARF.

Methods: We enrolled 80 hospitalized patients with COPD (65.6±18.9 years, PaO2 53±8±7.2 mm Hg). All patients underwent a complex diagnostic investigation including chest X-ray, blood gases, echocardiography, measurement of serum Tn T, H-FABP, BNP-fragment.

Results: The main causes of ARF were bacterial infection (BI)-43.7%, pneumonia-23.6%, acute decompensation of chronic heart failure (ADCHF)-12.5% and acute myocardial infarction (AMI)-11.3%. The H-FABP levels were increases in 92.5% of all cases. Patients with AMI had the highest levels of H-FABP than patients with BI (967.7 [453.7-2916.6], 2358.1 [1060.5-4809.2], 1939.6[982.2-2361.1] vs 4637.3[306.8-1013.2] pmol/L, p<0.05, respectively). There were significant differences between other groups. The Tn T levels were elevated (0.5 pmol/L) in 21.3% of all cases without significant differences between groups. BNP-fragment levels were higher in patients with pneumonia, ADCHF, AMI than in patients with BI (p<0.05 for all, respectively). The area under ROC curve for the prediction of hospital mortality were increased for BNP-fragment (0.827), for H-FABP (0.809). Survival was worse in patients with elevated Tn T (>0.5 mg/L) than in patients with Tn T <0.5 mg/L (log-rank test, p<0.01).

Conclusion: In COPD patients with ARF the serum levels of Tn T and H-FABP were significantly elevated without documented acute coronary syndrome and were the strong predictors for all-causes hospital mortality.

P4013
Regulation of ghrelin on appetite in patients with acute exacerbations of chronic obstructive pulmonary disease
Ye Wang, Fuqiang Wen, Department of Respiratory Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan Province, China

Background: Patients with COPD are usually complicated with malnutrition, which is partly caused by reductions of appetite and food intake, especially...
in acute exacerbations. Recent studies reported the key roles of ghrelin in appetite stimulation and energy homeostasis. However, the association between the orexigenic function of ghrelin and appetite reduction in AECOPD remains unclear.

Objectives: To investigate the secretion, acylation of ghrelin, and its association with appetite reduction in patients with AECOPD.

Methods: Thirty-six patients with AECOPD and 23 healthy adults were enrolled. Total and acylated ghrelin, obestatin, simplified nutritional appetite questionnaire (SNAQ) scoring, and calorie intake were compared in patients between in exacerbations and in remissions. Further more, the same indexes were also compared between AECOPD patients and healthy controls.

Results: Total ghrelin level in patients was significantly higher in exacerbations than remissions (627 ± 234.9 vs. 500.8 ± 181.0 pg/ml, p < 0.001), while the SNAQ score and calorie intake were significantly lower (10.8 ± 2.3 vs. 14.3 ± 1.8, p < 0.001; 663.5 ± 188.3 vs. 1031.4 ± 188.9 kcal, p < 0.001, respectively). The proportion of acylated ghrelin, the SNAQ score, and calorie intake of patients were significantly lower than controls (10.6 ± 6.7% vs. 15.0 ± 5.9%, p < 0.005; 10.7 ± 2.1 vs. 15.4 ± 1.2, p < 0.001; 647 ± 141.6 vs. 1257 ± 280.8 kcal, p < 0.001, respectively).

Conclusions: A higher ghrelin level in AECOPD indicated increased secretion of ghrelin, but its role in stimulating appetite was compromised. Moreover, the decreases in appetite reduction was noted in patients, which might be a cause for appetite reduction in AECOPD.

P4814
Cardiac biomarkers and outcome in patients with acute exacerbation of chronic obstructive pulmonary disease
Robert M. Marcm1, Alan Susic2, Pika Mesgog Belgunj1, Sasa Kadivec1, Mitja Kosnik1, Jemena Farkas1, Mitja Lajna1,2,3
Departments of Pulmonary Medicine, University Clinical Center, Ljubljana, Slovenia; 2Chair of Public Health Medical Faculty, University of Ljubljana, Ljubljana, Slovenia; 3Division of Cardiology, University Clinic, Clinic, Gorizia, Italy

Purpose: Cardiac biomarkers are associated with prognosis in patients with chronic obstructive pulmonary disease (COPD). The optimal time point for biomarker analysis remains uncertain. We thus compared prognostic implications of admission and discharge concentrations with outcome after acute exacerbation of COPD.

Methods: This was a prospective study in patients hospitalized with acute exacerbation of COPD. We measured NT-proBNP and troponin T (TnT) concentrations at admission and discharge. Hospitalizations and deaths were recorded for 6 months after discharge.

Results: We included 127 patients (70% ± 10 years, 70% men, GOLD III/IV 87%). Left ventricular ejection fraction was < 50% in 11% (9 patients) and 96 (76%) patients had significant obstructive limitations. Total and discharge concentrations of NT-proBNP and TnT were elevated in 76 (60%) and 35 (28%) patients, respectively. By discharge, this decreased to 46 (38%) and 24 (19%) patients. During follow-up, 44 (35%) patients were rehospitalized and 10 (8%) died. Kaplan-Meier curves analysis showed association between TnT at discharge andrehospitalizations (log-rank test 5.74, p = 0.017). In a Cox model of proportional hazards adjusted for age, gender, GOLD stage, and left ventricular function, only TnT at discharge remained associated with rehospitalizations (hazard ratio 2.89, 95% confidence interval 1.13-7.36). No associations between admission and discharge concentrations of NT-proBNP, TnT and death were found.

Conclusions: Cardiac biomarkers are frequently elevated in patients hospitalized for acute exacerbation of COPD. Discharge TnT was predictive ofrehospitalizations whilst none of the biomarkers predicted death during 6 months.

P4815
Predicting hospital readmission in patients discharged following acute exacerbations of COPD (AECOPD)
John Stein1, John Gibson2, Stephen Bourke1,2,3
1Department of Respiratory Medicine, North Tyneside General Hospital, North Shields, Tyne and Wear, United Kingdom; 2Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, Tyne and Wear; 3University of Newcastle, Newcastle-upon-Tyne, Tyne and Wear, United Kingdom

Background: Readmission rates following hospitalisation for AECOPD are high. The ability to accurately identify patients at a high risk of readmission could help clinicians effectively direct resources and interventions.

Objective: To identify predictors of readmission in patients surviving hospitalisation for AECOPD.

Method: Clinical data from consecutive patients surviving hospitalisation for AECOPD were collected. All variables associated (p < 0.10) with outcome (readmission to hospital, or death at home without readmission, within 90 days of discharge) on univariate analysis were entered in to a multivariate logistic regression model, exacerbations whilst none of the biomarkers predicted death during 6 months.

Impact of patient nutritional status on acute exacerbation of COPD
Pneumology IV Department, Abderrahmane Mami Hospital, Ariana, Tunisia

Introduction: Nutritional status has to be considered in the course of COPD. In fact, both obesity and malnutrition influences quality of life of patients with COPD and has a prognostic value.

Aim: Evaluate the impact of patient nutritional status on acute exacerbation (AE) of COPD.

Patients and method: Retrospective study including patients hospitalized for AE of COPD between 2009 and 2010 in our department. Nutritional status was evaluated by body mass index (BMI). Patients were divided into four groups regarding their BMI (BMI < 18; 18 ≤ BMI < 24; BMI ≥ 25; BMI ≥ 25; IMC ≥ 25; IMC ≥ 25; IMC ≥ 30). Number of AE/year, duration of hospitalization and use of systemic corticosteroids were also determined.

Results: Fifty patients were enrolled with a mean age of 64 years. Mean value of BMI was 23.5 ± 6.9 kg/m². 50% of patients had COPD stage III and 28% had COPD stage IV. Considering all patients, mean value of AE/year was 1.5, mean duration of hospitalization in AE was 15.49 days and use of systemic corticosteroids was necessary in 66% of cases. Compared to patients with normal BMI (G2), those with malnutrition (G1) had more severe AE: longer duration of hospitalization (35,48days vs14,54days) and frequent use of corticosteroids (83, 33% vs 64,28%). Patients suffering from obesity had similar number of AE/year as patients from G2, but the use of corticosteroids was more frequent (85,71% vs 64,28%).

Conclusion: We emphasize on the evaluation of nutritional status in COPD as a major parameter to consider in the management of this disease.
P4818
Can acute phase proteins predict survival in ventilated patients with acute exacerbation of COPD
Gazer Agaeva 1, Hoda Maghfoul 1, Sawa Fawy 2, Yasser Ahmed 1, Shaban Radwan 1.
Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Clinical Pathology, Assiut University, Assiut, Egypt

Background: Factors determining in-hospital mortality of patients ventilated with acute exacerbations of chronic obstructive pulmonary disease (AECOPD) are not precisely understood.

Purpose: The aim of this study was to assess the correlation between acute phase proteins [High sensitivity C-reactive protein (CRP) and prealbumin (PA)] and mortality in ventilated patients with COPD.

Methods: We evaluated 336 COPD patients with AECOPD and on invasive mechanical ventilation. Detailed clinical evaluation was done daily. Concentration of CRP and PA was measured on admission, 3rd, 8th and 16th day.

Results: During the study; 237 patients were discharged and 99 died. The difference between the two groups in CRP and PA was significant at admission, 3rd, 8th and 16th day. In non survivors; there was a significant increase in CRP values with a significant decrease in PA with time (P<0.001). In-hospital mortality was significantly associated with lower arterial oxygen tension, higher carbon dioxide arterial tension, lower arterial oxygen saturation, lower body mass index and longer hospital stay.

Conclusions: CRP levels in patients who died was significantly higher on admission, 3rd, 8th and 16th day. A fall in CRP levels on follow up indicated a significantly better prognosis. An increase in the prealbumin level was observed in survivors.

Clinical implications: Persistently high CRP and low prealbumin in COPD patients is associated with poor prognosis. A non-invasive treatment of systemic inflammation and malnutrition may improve prognosis. Prediction of survival status may be enhanced by considering arterial oxygen tension, albumin, body mass index, duration of hospitalisation.

P4819
A comparison of specific health-related quality of life questionnaires to predict COPD exacerbations
Amelicia Conesaury, Marina Blanco-Arturco, Isabel Vazquez, Héctor Verea-Hernando, Peraumeol, Complejo Hospitalario Universitario, A Coruña, Spain Psychology Faculty, University of Santiago de Compostela, Spain

Objectives: Compare the specific health-related quality of life (HRQoL) instruments, St George respiratory questionnaire (SGRQ), Chronic Respiratory Questionnaire (CRQ), Clinical COPD Questionnaire (CCQ) and Airways Questionnaire 20 (AQ20) to predict COPD exacerbations.

Methods: A group of 49 COPD patients who completed SGRQ, CRQ, CCQ and AQ20 were followed for 2 years. Emergency visits and hospitalizations were collected. We also assessed sociodemographic, clinical and pulmonary function data. The chi-squared, t test, and Mann-Whitney U were used to compare differences between groups. Multivariate logistic regression was performed for all variables showing statistically significant differences. A p-value < 0.05 was considered significant.

Results: The mean (SD) age was 65.9 (8.4) years and the mean FEV1 was 59.1 (19.5 %) of predicted value. In the univariate analysis only CCQ questionnaire showed differences for patients with emergency visits in the first year. Significant differences were seen in the scores of the CCQ total score SGRQ and all subscales, except SGRQ symptoms, and the scale disease control of CRQ between the group with hospitalization in the first year. In the logistic regression model, the CCQ questionnaire finally proved to be independent predictor of emergency visits during the first year (OR: 1.06; 95% CI, 1.00 to1.11; p=0.036). Other variables significantly associated were BMI (OR: 0.87; p<0.04) and prior hospitalizations (OR: 1.79; p<0.01).

Conclusions: Among a wide range of HRQoL questionnaires only the CCQ are independently associated with a higher risk of emergency visits for COPD exacerbations the first year of follow-up.

P4820
30-days mortality in patients admitted with COPD
Jakob Kjaergaard 1, Lone Braagaard 1, Jan Torgyn Wilcke 1, Jørgen Balslev Jørgensen 2, Philip Tønnesen 1. 1Department of Respiratory Medicine, Gentofte Hospital, Høllergaard, Copenhagen, Denmark; 2Department of Clinical Quality, Gentofte Hospital, Høllergaard, Copenhagen, Denmark

Introduction: The aim of this study was to describe 30-days mortality after hospital admission of COPD patients.

Methods: This is a retrospective study of all patients with the diagnosis of COPD as a primary diagnosis or co-diagnosis admitted to a tertiary pulmonary treatment unit, Department of Respiratory Medicine, Gentofte Hospital, Denmark in 2010.

Results: 67 (15.1 %) died out of 442 patients admitted with COPD within a period of 30 days after hospital admission, compared to 10% at the national level, odds ratio 1.51 (1.99). Mean age was 82.2 years, 55.2% were women and average BMI was 20.7. They had an average admission rate at 2.89 admissions in a period of 12 months prior to the inclusion date. Out of the 67, 23 (34.3%) received non-invasive ventilation (NIV) or respirator treatment at the respiratory unit or the intensive care unit. In 4 (5.9%) cases COPD was neither the cause of admission nor the cause of death, in further 18 (26.9%) cases COPD was not the cause of admission and 5 (7.5%) patients was wrongly diagnosed with COPD.

Conclusion: The 30-days mortality is significantly higher at Department of Respiratory Medicine at Gentofte Hospital. Possible explanations are a selection of hospitalization of more severe cases of COPD since the department has a unique outgoing COPD-treatment unit, which treats the milder exacerbations at home. Furthermore a mortality increase due to a selection of high risk patients with complications, comorbidities and pulmonary cancer in a tertiary unit. In conclusion, the crude 30-days mortality needs further data interpretation if to be used as a measure for quality of treatment for patients admitted with COPD.

P4821
Influence of COPD exacerbations on health related quality of life
Aliona David1, Alexandru Corlateanu2. 1Respiratory Medicine, The Institute of Pneumotologiea “Chiril Draganiuc”, Chisinau, Republic of Moldova; 2Internal Medicine, State Medical and Pharmaceutical University “Nicolete Testemitanu”, Chisinau, Republic of Moldova

Background: An exacerbation is the most important adverse event in the progression of chronic obstructive pulmonary disease (COPD). Exacerbations appear to accelerate the decline in lung function that characterises COPD, resulting in reduced physical activity, poorer quality of life and an increased risk of death.

The aim of this study was to investigate the influence of chronic obstructive pulmonary disease exacerbations on health related quality of life (HRQL).

Methods: 152 consecutive patients with COPD were enrolled into the study. Demographic data, smoking status, self-assessed severity in a questionnaire (Medical Outcomes Study Short Form (SF-36) and the St. George Respiratory Questionnaire (SGRQ)).

Results: The cohort consisted of 90 patients with 2 or less exacerbations per year, mean age 53±3.2 years and 62 patients with 3 or more exacerbations, mean age 55±3.8. In frequent exacerbators COPD was more severe: the mean FEV1% was 34.2±2.1% versus 52.3±2.9%, p < 0.05. Grade of impairment of HRQL was higher in frequent than infrequent exacerbators: SGRQ (73.6±5.1 versus 57.1±6.6, p<0.01) and SF-36 (30.2±1.5 versus 41.1±1.2, p<0.01). Pearson correlation coefficient analysis demonstrates in COPD patients a significant positive correlation between the rate of exacerbations and the total scores of the SGRQ (r=0.61, p<0.01) and SF-36 (r=0.54, p<0.01).

Conclusion: Compared with infrequent exacerbators, frequent exacerbators in our study were characterized at baseline by more severe COPD and more severe deterioration of the health related quality of life.

P4822
Nutritional status of COPD patients with complete respiratory failure on long term home oxygen therapy
Domińska Ploscuśna 1, Ewa Szańcik 1, Anna Doboszynska1. 1Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Chest, Assiut University, Assiut, Egypt Clinical Nursing Department, Medical University of Warsaw, Mazowieckie, Poland; 2Internal and Cardiology Department, Medical University of Warsaw, Mazowieckie, Poland; 3SNZOZ MEDMED, Poradnia Specjalistyczna 93-219 Lódz, Lódz, Poland; 4Pulmonary Department, Wojewódzki Zespół Zakładów Opieki Zdrowotnej Centrum Lecznicza Chorób Płuć i Rehabilitacji, Lódz, Poland; 5Centrum Medycyny, Lucyna Andrzej Dymek, Zawołka, Poland

Objectives: This study aimed in assessing nutritional status in patients with the advanced COPD, treated with long term home oxygen therapy.

Material and methods: A group of 49 patients with COPD, mean age 67 year, were included into the study. 43 patients smoked cigarettes in the past (91.5%). Body composition evaluation with bioelectrical impedance analysis (BIA) were performed in all patients. Body Mass Index (BMI) and Fat-Free Mass Index (FFMI) were calculated. FEV1 and FVC were measured. Life quality was assessed with St. George Respiratory Questionnaire (SGRQ).

Results: 17.7% of patients were diagnosed as overweight, in 22.3% the body weight was normal, 61.9% of patients were overweight or obese. FEV1 value was the lowest in overweighted patients, and the highest in overweight and obese patients. Strongly positive correlation between FEV1 and FFMI: r=0.45, p<0.01, was also noted. Statistically significant differences between SGRQ total score and frequency of the undertaken physical activity were seen in patients. Who performed moderate exercises, e.g. walking once a week only, lower life quality was statistically significantly (SGRQ Total Score=77.6) in comparison with the patients, who performed physical exercise thrice a week at least (SGRQ Total Scores=67.7) at p<0.04.

Conclusions: 1. Normal body weight was noted in 22.3% of patients with advanced COPD. Overweight and obesity are seen statistically significantly more often than underweight.

2. Respiratory system function are worse in patients diagnosed with malnutrition than that in patients that are overweight and obese.

3. Quality of life in patients more physically active is better than ones with lower physical activity.
P4823 Reducing hospital admission in COPD exacerbation by urgent oxygen provision and home monitoring of capillary blood gases
Howard Chapman, * Marie Herring, † Paul Fearon ‡
Recuperative Department, City Hospitals Sunderland Foundation Trust, Sunderland, Tyne & Wear, United Kingdom; ¶ Community Urgent Care, South Tyneside Foundation Trusts, Hebburn, Tyne & Wear, United Kingdom; ¶ Service Improvement, South Tyneside Foundation Trusts, Hebburn, Tyne & Wear, United Kingdom

Current NICE guidance recommends hospital admission when SpO2 < 90% but with supplemental oxygen many such patients might be managed at home provided that worsening hypercapnia and respiratory acidosis is excluded. As part of the NHS Lung Improvement Programme, Sunderland Urgent Care Team (South Tyneside NHS Foundation Trust) set up a six month Pilot to reduce emergency hospital admission by introducing measurement of capillary blood gases (TcABGs) and the urgent provision of oxygen to manage what would have been an admission into a treatable condition at home. Following a clinical assessment, a team of advanced nurse practitioners guided by an operational protocol measured TcABGs in a group of patients with AECOPD who’s SpO2 was in the range 85-90%. Suitable patients were provided with oxygen cylinders delivering oxygen in the range of 2-6 L/min and monitored until oxygenation improved (SpO2 > 90%) and there was clinical recovery. Initially, urgent oxygen provision and ABG measurement proved problematic but 25 patients were recruited. 4 were excluded for breaching protocol (2 TcABGs failed, 1 was acidic (pH 7.29) and chose to remain at home, 1 had no follow up data). 4 were admitted (2 acidic, 2 hypoxic on LTOI). The remaining 16 hypoxic (SpO2 86±1) patients improved (SpO2 93±2) with urgent oxygen provision and were managed safely at home but 1 became non-compliant. Initial visit times lasted 186±80.7 mins with between four and twelve follow up visits until recovery. With urgent oxygen provision, careful selection of patients, hospital admission can be avoided even in moderately hypoxic patients with exacerbations of COPD.

P4824 Comparison of different dosage nebulised budesonide in COPD exacerbation
Eldi Yilmaz Deveci, † Omer Aran, ‡ Deniz Ozmurk, ‡ Mevin Akgun, ‡ Leyla Saglam, † Mevin Gorganer. † Onkose Daireve, ‡ Isikil Univerity, ‡ Eczemy, ‡ Turkey

Objective: To compare the efficacy and safety of different dosage nebulised budesonide (BUD) in the treatment of acute exacerbations of chronic obstructive pulmonary disease (COPD).

Design: Randomised, double-blind, parallel-group trial.

Patients and interventions: A total of 64 patients who had moderate to severe acute exacerbations of COPD and required hospitalisation were enrolled in the study. The patients were randomized into three groups. Group 1 received systemic (intravenous) prednisolone 40 mg daily (n=28), group 2 received 4 mg NB daily (n=20), group 3 received 8 mg NB daily (n=16). Airway obstruction [forced vital capacity (FVC), forced expiratory volume 1 second (FEV1)] was evaluated at admission and discharged. Arterial partial pressure of oxygen (PaO2), carbon dioxide (PaCO2), pH, and oxygen saturation (SaO2) were evaluated at 24 and 48 hours, and at day 10.

Results: There were no significant differences between groups at baseline. In groups, differences were significant for FVC, FEV1, PaO2, and SaO2 (p<0.001), but not for PaCO2 and pH, in comparison with their baseline values. There were no significant differences between groups for all parameters at all time periods. While blood glucose exhibited an upward trend only group 1 (8 patients), oral anti-coagulant therapy was discontinued in groups, differences were significant for FVC, FEV1, PaO2, and SaO2 (p=0.000), but not for PaCO2 and pH.

Conclusions: Nebulised budesonide is effective and safety in the treatment of COPD exacerbation. There is no significant difference in terms of efficacy and safety between 4 mg and 8 mg nebulised budesonide.

P4825 COPD: Acute exacerbation (AE) and hospitalization rate (HR) in patients with different serum surfactant protein D (SPD) level
Tetyana Pertseva, † Kateryna Gashynova, † Olena Bratus, ‡ Natalya Petrik, ‡
† Internal Medicine, DMA, Dnipropetrovs, Ukraine; ‡Laboratory, DMA, Dnipropetrovs, Ukraine

Aim: To evaluate whether and in which extent SPD have influence on the AE and hospitalization rate in patients with COPD.

Study population: 26 patients with stable COPD, GOLD stage II-IV, made the study sample.

Methods: SPD was evaluated in serum by ELISA (Hyctyl Biotech, Netherlands) for all patients. AE (including AE, required systemic corticosteroids (SCS) and any-}

thobitic (AB) prescription) and HR during 12 months were evaluated retrospectively by analysis of patient’s medical documentation.

Results: In accordance with SPD level all patients were divided on two groups: 12 patients with SPD >600 ng/ml (Group I) and 14 with SPD <600 ng/ml (Group II). Both groups were similar regarding to sex, age, FEV1, smoking status and basic therapy. One or more AE during the year were found in 7 (58.33%) patients of Group I and 12 (85.71%) of Group II. The data from patient’s medical documentation analysis are presented in the table 1.

Conclusions: 1. COPD patients with high SPD had higher AE rate and required and more frequent both SCS and AB prescription. 2. SPD did not influence on HR in patients with COPD, GOLD stage II-IV.

P4826 Relation between metabolic syndrome and acute exacerbation of COPD
Haier ben Abdelhafar, † Iyya Tangour, ‡ Souyati Fenniche, ‡ Leila El Fekhi, †
Dorra Gerb, † Ines Akrou, † Hela Hassene, † Wided Ben hamad, † Hela Kammoun, † Dalinda Belhabih, † Mohamed Lamine Megdiche. † Ibn NAFIS, Abderrahmane Mami Hospital, Ariana, Tunisia

The concept of COPD as a systemic disease has been widely accepted in the past several years. However, to date, rare studies have analyzed correlation between exacerbations of COPD (ECOPD) and Metabolic Syndrome (MetS). The aim of this study was to examine if presence of MetS increases the frequency, duration and severity of ECOPD.

Methods: Patients with COPD were prospectively enrolled and followed between January 2008 and December 2011. Medical records, pulmonary function tests, chest X-rays, laboratory test results were gathered to establish the presence of COPD and MetS. Patients were divided in two groups; with and without MetS. The ECOPD was defined as worsening of symptoms requiring increased use of rescue medications and/or need for either systemic steroids or antibiotics or that led to emergency room visit or hospitalizations during 36 months follow-up. A total of 100 patients, 60 with MetS and 40 without. The mean exacerbation of COPD frequency was 2 in MetS group versus 0.7 in the control group during the follow-up period (P < 0.001). Mean duration of each exacerbation was 8±1.5 days in patients with MetS versus 5.5±1.3 days in patients without. Acute respiratory failure was more frequent in patients with MetS than control with significant difference. Serum C-reactive protein (r = 0.3, P = 0.001), fasting blood glucose (r = 0.6, P < 0.001), and triglycerides (r = 0.61) were positively and significantly correlated with exacerbation frequency. This study demonstrates an association between ECOPD and its duration and severity with the MetS. The inflammatory state induced by common cytokines may explain the linkage between the two conditions.

500. The best of pharmacology treatment for asthma and COPD

P4827 Acute dose- and time-dependent effects of budesonide on airway blood flow in asthma
Eliana Mendez, † Patricia Rebolledo, ‡ Johana Arana, † Michael Campos, †
Adam Wanner. Pulmonary, Critical Care and Sleep Medicine, University of Miami Miller School of Medicine, Miami, FL, United States

Inhaled corticosteroids (ICS) have been shown to decrease airway blood flow (Qaw) via a non-genomic action on airway vascular smooth muscle contraction. We have previously shown a dose-dependent decrease in Qaw with a single inhalation of 360, 720 and 1440 μg budesonide (BUD) in moderate-to-severe asthmatics where Qaw decreased transiently from 12 to 21% after all doses (p=0.05 vs baseline and placebo).

Objective: Here, we have investigated the effects of repetitive BUD inhalations on Qaw in moderate-to-severe asthma patients on regular ICS use.

Methods: The 18 subjects enrolled were told to abstain from ICS for at least 36 h before the experiment. Inhalation of 720 μg BUD was given 4 times, separated by 30 min. Qaw, FEV1, blood pressure, heart rate and oxygen saturation were measured before each inhalation and 30, 90, 150, 210 and 270 min after the last dose. A soluble, inert gas-uptake method was used to measure Qaw.

Results: Baseline mean Qaw was 61.3±3.15 μL/min (per mL of lung anatomical dead space) and FEV1 2.3±0.3 L. Numerically, mean Qaw progressively decreased after each BUD inhalation. At 30 min after the last dose, mean Qaw was 28% below baseline (p<0.05) and remained 11% below baseline after 270 min. There were no statistically significant changes in FEV1, PEF 25-75%, PEF, oxygen saturation and mean blood pressure.

Conclusions: In moderate-to-severe asthma patients on regular ICS use, repeated inhalations of high BUD dose have a cumulative acute vasoconstrictive effect in the airway suggesting an acute non-genomic action that increases vasoconstrictor tone. This effect could decrease airway non-genomic action and the vascular clearance of concomitantly inhaled bronchodilators from the airway.

Budesonide reverses IL-13-induced airway hyper-responsiveness but has little effect on β2 agonist response in human small airways

Cynthia Kozel-White 1, Philip Cooper 1, He Zhang 1, Jan Danny 1, Reynold Panettieri Jr. 1, Medicine/Pulmonary, University of Pennsylvania, Philadelphia, PA, United States; 2Biologics, Centocor, Radnor, PA, United States; 3R & B Biosciences, Astrogenetics, Mönchengladbach, Germany

IL-13 modulates airway smooth muscle sensitivity to contractile stimulus. Steroids and α2 agonists decrease current from a control level of 1.4 ± 0.2 pA to 51.8 ± 1.9 pA; in pig type II AEC, an increase from 23.6 ± 3.2 to 173.2 ± 7.4 pA was observed, and in rat AEC, from 10.7 ± 3.8 pA to 66.2 ± 5.3 pA

These results show that AP301 activates ENaC in type II AEC from dog, pig and rat. To our knowledge, this is the first cell-based analysis of the oedema-clearing effect of AP301 observed in the porcine model of pulmonary oedema. Furthermore, the results validate the dog and pig models in preclinical assessment of AP301.

P4831
MEMP1972A, an anti-ε1 prime monoclonal antibody, reduces serum IgE in healthy and allergic rhinitis subjects

Helen Scher encour1, Wendy Putnam2, Yanan Zheng2, Yehong Wang2, Sota Minosawa2, Romeo Macià2, Charelne Liao2, Lawren Wu1, John Matthews3, Jeffrey Harris1, P.D Biomarkers, Genentech, Inc, South San Francisco, CA, United States; 2Clinical Pharmacology, Genentech, Inc, South San Francisco, CA, United States; 3Inflammation & Ophthalmology Biostatistics, Genentech, Inc, South San Francisco, CA, United States; 4Product Development - Immunology, Genentech, Inc, South San Francisco, CA, United States; 5Research and Early Development, Genentech, Inc, South San Francisco, CA, United States; 6Product Development - Immunology, Genentech, Inc, South San Francisco, CA, United States; 7Department of Immunology, Genentech, Inc, South San Francisco, CA, United States

Background: MEMP1972A, a humanized monoclonal antibody specific for the M1 prime epitope of membrane IgE, depletes M1 prime-expressing IgE-switched B cells, IgE memory B cells and IgE plasmablasts. MEMP1972A is in development for the treatment of allergic rhinitis. Aim: To evaluate the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of MEMP1972A in healthy and allergic rhinitis (AR) subjects.

Methods: Two Phase I, randomized, controlled trials investigated the safety, tolerability, PK and PD of MEMP1972A in (1) healthy adults (n=31 MEMP1972A, n=14 placebo [PB]) and (2) AR subjects (n=24 MEMP1972A, n=12 PB [NCT01160861]). In healthy adults, MEMP1972A was given as single escalating doses of 0.003–5 mg/kg intravenous (IV) or 3 mg/kg subcutaneous (SC). In AR subjects, monthly doses were given for 3 months at 1.5 and 5 mg/kg IV and 3 mg/kg SC.

Results: MEMP1972A was well tolerated, and the exposure of serum neutralizing antibodies to MEMP1972A was low. The terminal half-life of MEMP1972A was 20–21 days and mean clearance was 2.2–2.7 mL/day/kg. MEMP1972A administration led to a dose dependent reduction in serum IgE in both studies. In healthy adults, a single dose of MEMP1972A at 3 and 5 mg/kg IV significantly reduced serum IgE by ~25% relative to baseline at Day 85, with no significant reductions observed in the PB, lower IV or 3 mg/kg SC cohorts. Monthly doses of MEMP1972A at 5 mg/kg IV or 3 mg/kg SC in AR males reduced serum IgE by ~25% relative to baseline at Day 85. Serum IgE reductions were sustained for 6 months.

Conclusion: MEMP1972A was well tolerated and reduced serum IgE in adults with or without allergic disease.

P4830
ENaC-activating effect of AP301 in type II alveolar cells isolated from dog, pig and rat lungs

Susan Tzotzos1, Bernhard Fischer1, Hendrik Fischer1, Helmut Pietschmann1, Rudolf Lucas1, Gilles Dupre3, Waheed Shabbir4, Rosa Lemmens-Gruber4, Markus Lucas1, Robert Herrmann2, Hermann Mascher5, Clinical Department of Small Animal Surgery, Eye and Dental, University of Vienna, Austria; 2Clinical Pharmacology, Genentech, Inc, South San Francisco, CA, United States; 3Biomedical, Genentech, Inc, South San Francisco, CA, United States; 4Biostatistics, Genentech, Inc, South San Francisco, CA, United States; 5Research and Early Development, Genentech, Inc, South San Francisco, CA, United States

The synthetic peptide, AP301, mimics the TIP, or lectin-like, domain of human TNF-α (Lucas, R. et al Science 1994; 263:814-817). TNF-α and AP301 activate ENaC in porcine type I alveolar epithelial cells (AEI) by activating a PAR2 receptor (MEMP1972A) and reduces current from a control level of 1.4 ± 0.2 pA to 51.8 ± 1.9 pA; in pig type II AEC, an increase from 23.6 ± 3.2 to 173.2 ± 7.4 pA was observed, and in rat AEC, from 10.7 ± 3.8 pA to 66.2 ± 5.3 pA.

Ventilation strategies excepted, no specific therapy presently exists for treatment of pulmonary permeability oedema, ALI or ARDS. AP301, currently undergoing clinical trials, is being developed as a therapy for these conditions and is also being developed for the treatment of allergic rhinitis. AP301 has also been shown to improve alveolar liquid clearance and lung function in a porcine model of ALI.
Conclusion: IgE is a potent inducer of pro-inflammatory extracellular matrix components in the human airway wall and its effect can be prevented by Omalizumab. Thus the anti-IgE antibody drug may reduce airway remodelling in long term therapy.

P4833 The effects of extraline beclomethasone/formoterol on hyperinflation and airway geometry in COPD patients

Samir Vinckhorst1, Wim Ves1, Cedric Holobeke1, Jan De Backer1

GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom

Aim of this study was to assess the effects of extraline beclomethasone/formoterol treatment on lung hyperinflation and airway geometry in COPD. Data of lobar volume (%pred) and specific lobar airway volumes (siVaw) at FRC and TLC were obtained with functional imaging in 25 COPD patients (GOLD II 1.4, III 7, IV 4) pre- and 4h post-bronchodilator (post BD) both at baseline and after 6 months of treatment. A post BD drop was observed for both functional residual capacity (FRC) and TLC lobar volumes at baseline (FRC: -10%, p<0.01, TLC: -2%, p<0.01) and after 6 months (FRC: -12%, p<0.01, TLC: -2%, p<0.001) as index of reduced hyperinflation. siVaw did increase 4 hours after administration at both time points (+10%; p<0.01, and +8%; p<0.001).

P4834 Formoterol reduces asthmatic airway smooth muscle cell proliferation through p27 (Kip) which is supported by steroids

Michael Roth2, Jun Zheng, Pieter Borger, Chong Teck S’ng, Michael Tamm1

Department of Respiratory Medicine, University Hospital Antwerp, Edegem, Antwerpen, Belgium

Background: Airway remodelling in asthma is partly due to increased airway smooth muscle (ASM) mass. We and others reported earlier that steroids alone do not significantly reduce proliferation of ASM cells isolated from asthma patients. Objective: Here, we investigated the anti-proliferative signalling pathway of formoterol combined with three different steroids on ASM cell proliferation control.

Methods: Proliferation was determined by cell count 3 days after stimulation. Drugs were used at concentrations 1nM – 1microM. Protein expression (p21, p27) was determined by immuno-blots and -staining. Cyclic AMP was inhibited by DDA pre-incubation.

Results: Serum induced proliferation was reduced by steroids (dexamethasone, fluticasone, budesonide) in ASM cells of healthy controls but not of asthma patients. Formoterol dose dependently reduced cell proliferation by maximal 25% in both asthma and control ASM cells and this was paralleled by p27(Kip) activation in asthma ASM cells only. In combination the inhibitory effect of formoterol increased to 52% by dexamethasone, to 69% by budesonide and to 76% by fluticasone in healthy cells. In asthmatic ASM cells the combined rug’s effect was 47%, 52% and 56% respectively. Inhibition of proliferation of asthmatic ASM cells by formoterol occurred through cAMP and p27(Kip), which were both increased by the addition of steroids. The anti-proliferative effect of the combined drugs in control ASM cells involves p21(Waf1) and in asthmatic cells by p27(Kip). This effect was consistently augmented by SQ22556 and reproduced by forskolin in both systems. Our results suggest that formoterol-2 inhibited tracheal ring contraction induced by carbachol. The anti-inflammatory effect remained unaltered following epithelium removal or pretreatment with L-NAMe, but it was clearly sensitive to 9-(tetrahydro-2-furyl) adenine (SQ22556), an adenylic cyclase inhibitor. Formoterol-1 inhibited apoptosis of T cells treated with JMF2-1 in vitro was assessed by flow cytometry. The spasmolytic effect of JMF2-1 was assessed on isolated rat tracheal rings. Intracellular levels of cAMP from T cells and airway smooth muscle cells treated with JMF2-1 were detected by radioimmunooassay. We found that JMF2-1 inhibited tracheal ring contraction induced by carbachol. The anti-inflammatory effect remained unaltered following epithelium removal or pretreatment with L-NAMe, but it was clearly sensitive to 9-(tetrahydro-2-furyl) adenine (SQ22556), an adenylic cyclase inhibitor. Formoterol-1 inhibited apoptosis of T cells treated with JMF2-1 in vitro was assessed by flow cytometry. The spasmolytic effect of JMF2-1 was assessed on isolated rat tracheal rings. Intracellular levels of cAMP from T cells and airway smooth muscle cells treated with JMF2-1 were detected by radioimmunooassay.

We sought to test if JMF2-1 effects are a consequence of increased intracellular cAMP levels in asthma cells. These results may underlie the clinical benefit of combination therapy of LABA and LAMA for patients with COPD.

P4835 Synergistic effects between glycopyronium bromide and indacaterol on a muscarinic agonist-induced contraction in airway smooth muscle

Hiroaki Kume, Shu Isebe, Takashi Iwanga, Yuki Toida. Department of Respiratory Medicine, University Hospital Antwerp, Edegem, Antwerpen, Belgium

Rationale: Bronchodilators play an important role in therapy for stable chronic obstructive pulmonary disease (COPD). Anticholinergics and beta2-adrenoceptor agonists are widely used to improve lung function, symptoms, and QOL of patients with COPD. This study was designed to investigate whether combination of anticholinergics and beta2-adrenoceptor agonists is beneficial. Combined effects on airway smooth muscle contraction were examined using glycopyronium bromide (GB), a long-acting muscarinic antagonist (LAMA), and indacaterol, a long-acting beta2-adrenoceptor agonist (LABA).

Methods: For record of isometric tension, the strips of tracheal smooth muscle from guinea pigs were placed in the organ bath and were perfused with the physiological solution at a constant flow rate of 2 ml/min.

Results: One nM indacaterol caused a modest (7.9%, n=18) inhibition of 1 μM methacholine (MCh)-induced contraction of tracheal smooth muscle. GB at 3, 10, and 30 nM caused a concentration-dependent inhibition of 1 μM MCh-induced contraction with values of percent inhibition of 11, 1, 2; 1, 9, and 52.2%, respectively (each n=6). However, when equi-molar of GB were applied in the presence of 1 nM indacaterol, the inhibitory effects of GB (3, 10, and 30 nM) decreased (1 nM) combination were markedly enhanced, with values of percent inhibition of 25.6 (<p<0.05), 46.1 (<p<0.01), and 91.2% (<p<0.001), respectively (each n=6).

Conclusions: Indacaterol synergistically potentiated GB-induced inhibition against cholinergic stimulation in airway smooth muscle. These results may underlie the clinical benefit of combination therapy of LABA and LAMA for patients with COPD.

P4836 Cyclic AMP mediates the anti-asthma properties of the lidocaine analog JMF2-1

Priscilla Olsen1, Luciana Coelho2, Jorge Costa3, Renato Cordeiro3

Patricia Silva4, Marco Martin1. Physiology and Pharmacodynamics, Oswaldo Cruz Institute, Rio de Janeiro, RJ, Brazil; 2Synthesis, Farmanguinhos, Rio de Janeiro, RJ, Brazil

Inhalation of JMF2-1, an analog of lidocaine with reduced anesthetic activity, prevents airway contraction and lung inflammation in experimental asthma models. We sought to test if JMF2-1 effects are a consequence of increased intracellular cAMP levels. These effects may underlie the clinical benefit of combination therapy of LABA and LAMA for patients with COPD. We and others reported earlier that steroids alone do not significantly reduce proliferation of ASM cells isolated from asthma patients. Objective: Here, we investigated the anti-proliferative signalling pathway of formoterol combined with three different steroids on ASM cell proliferation control.

Methods: Proliferation was determined by cell count 3 days after stimulation. Drugs were used at concentrations 1nM – 1microM. Protein expression (p21, p27) was determined by immuno-blots and -staining. Cyclic AMP was inhibited by DDA pre-incubation.

Results: Serum induced proliferation was reduced by steroids (dexamethasone, fluticasone, budesonide) in ASM cells of healthy controls but not of asthma patients. Formoterol dose dependently reduced cell proliferation by maximal 25% in both asthma and control ASM cells and this was paralleled by p27(Kip) activation in asthma ASM cells only. In combination the inhibitory effect of formoterol increased to 52% by dexamethasone, to 69% by budesonide and to 76% by fluticasone in healthy cells. In asthmatic ASM cells the combined rug’s effect was 47%, 52% and 56% respectively. Inhibition of proliferation of asthmatic ASM cells by formoterol occurred through cAMP and p27(Kip), which were both increased by the addition of steroids. The anti-proliferative effect of the combined drugs in control ASM cells involves p21(Waf1) and in asthmatic cells by p27(Kip). This effect was consistently augmented by SQ22556 and reproduced by forskolin in both systems. Our results suggest that JMF2-1 inhibits respiratory smooth muscle contraction as well as T cell survival through enhancement of intracellular cAMP levels. These findings may help to explain the anti-inflammatory and antiastmatic effects of JMF2-1 observed in previous studies.

P4837 Evidence for a non-β2-adrenoceptor (β2AR) binding site in human lung tissue for the long acting β2-agonist (LABA) vilanterol

Rob Slack, Vicki Barrett, Alison Ford, Richard Knowles. Respiratory TAU. GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom

Background: Vilastron (VI) is a novel LABA with inherent 24 hour activity in development for inhaled once daily administration in combination with an inhaled corticosteroid for both COPD and asthma. We describe here an additional binding site in human lung tissue distinct from the orthosteric β2AR binding site in an in vitro binding assay.

Methods: Radioligand saturation and competition binding experiments were performed by titration with [3H]VI or [3H]propranolol and human lung parenchyma membranes measured at 37°C (∼100μM Gpp(NH)p with NSB 10μM β2AR antago- nist IC118551). Competition binding with a range of unlabelled β2AR agonists/antagonists was determined (data shown mean ∆SEM, n=4). Statistical differences measured by ANOVA (Bonferroni post-test) with P < 0.05 deemed significant.

Results: Saturation binding data were best fitted to a one affinity site model with Ki values 8.8±0.3 and 9.0±0.1 and Bmax values 0.5±0.1 and 0.4±0.1 pmol/mg for [3H]VI and [3H]propranolol, respectively. IC118551, propranolol, salbutamol, formoterol and carmoterol resulted in inhibition of [3H]VI (△<0.3nM) binding.
Introduction: NVA237 (glycopyrronium bromide) is a long-acting muscarinic antagonist for the treatment of COPD. It is primarily eliminated by the kidneys. Since renal function decreases in elderly and the target population of NVA237 includes elderly patients it is important to investigate the effect of renal impairment (RI) on NVA237 pharmacokinetics.

Methods: Subjects: 8 with mild RI, 8 with moderate RI, 8 with severe RI, 6 with elderly healthy patients. Comparison was made by matching healthy volunteers (HV). Renal function was assessed by the estimated glomerular filtration rate (eGFR). Subjects were randomized to treatment with: NVA237 without acetylcysteine (NAC) or with concomitant administration of NAC to study the pharmacokinetics (PK) of NVA237 following inhalation versus NVA237 administered via the Breezhaler® device. 

Conclusion: In subjects with mild and moderate RI (eGFR >30 mL/min/1.73m²), the mean terminal half-life of NVA237 was estimated to be about 5%. In Part 2 the absolute bioavailability with oral activated charcoal (AC) to study the pharmacokinetics (PK) of the bioavailability of inhaled NV A237 (glycopyrronium bromide-GP) delivered via the Breezhaler® device. 

Results: A moderate increase in NVA237 total systemic exposure (AUCLast) of up to 1.4-fold (on average) was seen in subjects with mild and moderate RI as compared to HVS. An increase of up to 2.2-fold was observed in subjects with severe RI and ERSD. Renal clearance (CLR) of NVA237 was strongly correlated with eGFR. In subjects with severe RI, CLR was reduced by about 80% compared with HVs. NVA237 was partially cleared during hemodialysis with an extraction ratio of 24.3%. NVA237 was well tolerated by HVs and RI subjects. Conclusion: RI had an impact on NVA237 total systemic exposure which was modest in subjects with mild RI and high in subjects with severe RI. The limited effect of severe RI on systemic exposure to NVA237 and the correlation analysis of total systemic clearance versus eGFR suggests that non-renal clearance mechanisms play a role in the elimination of NVA237.

P4838
Small impact of mild and moderate renal impairment on the pharmacokinetics of inhaled NVA237

Conclusion: NV A237 inhaled via the Breezhaler® device is efficiently deposited in human lung parenchyma membranes. In addition, VI binds to a additional binding site, distinct from the functional orthosteric β₂AR binding site shared with salmeterol and indacaterol.

Results: In Part 1, NV A237 400 μg dose of NV A237 delivered via the Breezhaler® device. In Part 2, NV A237 200 μg dose was administered orally to 10 HVs with and without concomitant administration of AC to demonstrate that GI absorption of NVA237 can be blocked. In Part 2 (n=20 HVs) the PK of 200 μg inhaled NVA237 with and without AC were compared to those of an i.v. infusion of 120 μg i.v. Plasma PK data were analyzed by non-compartmental and compartmental methods.

Conclusion: In Part 1 showed that oral AC was effective in blocking the oral absorption of NVA237. Absolute bioavailability of orally administered NVA237 (without AC) was estimated to be about 5%. In Part 2 the absolute bioavailability of inhaled NV A237 was about 40%. About 90% of systemic exposure was due to pulmonary absorption, 10% to GI absorption. About 36% of the inhaled dose was deposited and absorbed in the lungs. The mean terminal half-life of NV A237 was 52.5 h and 57.2 h in the inhalation treatments, 6.2 h after the i.v. dose and 2.8 h after the oral dose.

Conclusion: NVA237 inhaled via the Breezhaler® device is efficiently deposited and absorbed in the lungs. The terminal half-life of NV A237 is much longer after inhalation than after i.v. or oral dosing which points to sustained lung concentrations of NVA237 following inhalation.

P4840
Guafensin suppresses MUC5AC content and secretion in human airway epithelial cell cultures: Comparison with N-acetylcysteine and ambroxol

Conclusion: The safety, tolerability and pharmacokinetics of AZD5069, a novel CXCR2 antagonist, in healthy Japanese volunteers

Methods: This study in healthy volunteers (HVs) was designed to investigate the impact of renal impairment (RI) on the pharmacokinetics of NVA237 (glycopyrronium bromide, GP) delivered via the Breezhaler® device. The safety, tolerability and pharmacokinetics of AZD5069, a novel CXCR2 antagonist, in healthy Japanese volunteers

Methods: Cells were treated with 1 ng/mL IL-13 for 3d, then treated with GGE, NAC, or Amb (+IL-13). At 3, 8, or 24 h after treatment, cells were analyzed from videos. Apical secretions from 8 and 24 h were analyzed by micro parallel plate rheology.

Conclusion: At 24h, IL-13 decreased MCT rates by 75% but did not affect G' (elastic) or G'' (viscous) moduli. All drugs significantly increased MCT and decreased G' vs. IL-13 alone. GGE (30 μM) increased MCT 2.6-fold at 24h and reduced G'' to 10% of IL-13-only values. NAC reduced G' but increased MCT –2-fold at 30 μM and decreased MCT to below baseline at 100 μM. Effects of Amb were smaller. The reduced MCT for NAC at 100 μM could be due to uncoupling of ciliary beat from mucus. Bonferroni analysis (p<0.05) showed significant advantages for GGE vs. NAC & Amb (MCT) and vs. Amb (rheology, G').

Conclusion: GGE increases MCT via decreased mucus viscoelasticity, which may be a useful property in treating certain respiratory diseases.

P4841
Guafensin alters mucus rheology and improves mucociliary transport in human airway epithelial cell cultures: Comparison with N-acetylcysteine and ambroxol

Methods: The safety, tolerability and pharmacokinetics of AZD5069, a novel CXCR2 antagonist, in healthy Japanese volunteers

Results: At 24h, IL-13 decreased MCT rates by 75% but did not affect G' (elastic) or G'' (viscous) moduli. All drugs significantly increased MCT and decreased G' vs. IL-13 alone. GGE (30 μM) increased MCT 2.6-fold at 24h and reduced G'' to 10% of IL-13-only values. NAC reduced G' but increased MCT –2-fold at 30 μM and decreased MCT to below baseline at 100 μM. Effects of Amb were smaller. The reduced MCT for NAC at 100 μM could be due to uncoupling of ciliary beat from mucus. Bonferroni analysis (p<0.05) showed significant advantages for GGE vs. NAC & Amb (MCT) and vs. Amb (rheology, G')

Conclusion: GGE increases MCT via decreased mucus viscoelasticity, which may be a useful property in treating certain respiratory diseases.

P4842
The safety, tolerability and pharmacokinetics of AZD5069, a novel CXCR2 antagonist, in healthy Japanese volunteers

Background: Airway mucus hypersecretion is common in many respiratory diseases such as upper respiratory tract infections, asthma and COPD (chronic bronchitic form). Drugs to inhibit mucus production are needed. We showed that guafensin (glyceryl guaiacolate ether, GGE) inhibits unstimulated MUC5AC production in differentiated human airway epithelial cells in vitro (Seagar et al. EXP Lung Res 2011;37:606–14).

Aims: We examined the effects of GGE on MUC5AC secretion and secretion in cells stimulated with IL-13 to produce additional mucus and compared the GGE effects with those of the mucolytic N-acetylcysteine (NAC) and the mucoactive drug ambroxol (Amb).

Hypothesis: GGE would inhibit IL-13-stimulated MUC5AC production.

Methods: Cultures were pre-treated with 1 μg/mL IL-13 for 3d, then treated with 10, 30, 100 or 300 μM GGE, NAC or Amb for 3, 8 or 24 h in the presence of IL-13. The apical surfaces were washed and cells were lysed. MUC5AC content was measured in the washes (secretion) and lysates (content) was assessed by ELISA.

Results: IL-13 increased MUC5AC secretion (2-fold) and content (1.5-fold) over baseline at 24h. GGE significantly inhibited MUC5AC secretion and content in a concentration-dependent manner, with IC50s of ~110 and 150 μM and inhibition was seen at 300 μM GGE of 80 and 90% respectively at 24h. Although NAC and Amb inhibited IL-13-induced MUC5AC production, inhibition was only 20–40% at 24h. GGE concentration-dependence in lowering cell viability was not concentration-dependent. Non-renal clearance mechanisms play a role in the elimination of NVA237.

Conclusion: The safety, tolerability and pharmacokinetics of AZD5069, a novel CXCR2 antagonist, in healthy Japanese volunteers

Hypothesis: GGE reduces stimulated mucus viscoelasticity and increases MCT.

Methods: Cells were treated with 1 ng/mL IL-13 for 3d, then with 30 or 100 μM GGE, NAC, or Amb (+IL-13). At 3, 8, or 24 h after treatment, MCT rates were calculated from videos. Apical secretions at 8 and 24 h were analyzed by micro parallel plate rheology.

Results: At 24h, IL-13 decreased MCT rates by 75% but did not affect G' (elastic) or G'' (viscous) moduli. All drugs significantly increased MCT and decreased G' vs. IL-13 alone. GGE (30 μM) increased MCT 2.6-fold at 24h and reduced G'' to 10% of IL-13-only values. NAC reduced G' but increased MCT –2-fold at 30 μM and decreased MCT to below baseline at 100 μM. Effects of Amb were smaller. The reduced MCT for NAC at 100 μM could be due to uncoupling of ciliary beat from mucus. Bonferroni analysis (p<0.05) showed significant advantages for GGE vs. NAC & Amb (MCT) and vs. Amb (rheology, G').

P550 Longitudinal changes in detrended fluctuation analysis “alpha” of PEF in COPD
Gavin Donaldson1, Terence Seemungal2, John Hurst1, Urs Frey3, Iadhiga Wissa4, 5, Academic Unit of Respiratory Medicine, UCL Medical School, Royal Free Hospital, London, United Kingdom; 2Department of Clinical Sciences, University of the West Indies, St. Augustine, Trinidad and Tobago; 3Pneumatics, University Children’s Hospital, Basel, Switzerland

Introduction: Detrended fluctuation analysis can assess the “memory” of previous events with the exponent alpha. Alpha is higher in COPD than asthma, responses to pharmacotherapy, and is related to exacerbation frequency, but is not known whether alpha changes with increasing disease severity.

Methods: We examined 230 patients from the London COPD cohort who recorded for at least two years on diary cards daily morning, post-medication PEF measurements made with Mini-Wright PEF meter. Patient characteristics were collected at recruitment to the cohort. The data was divided into yearly intervals, and the alpha and mean PEF in each yearly interval calculated. Random-effects, GLS regression models were used to assess changes over time.

Results: The 230 COPD patients (144M; mean age (SD) 68.3 (8.1) years; FEV1 1.12 (0.47) L; FEV1/FVC predicted 44.6 (16.5); FEV1/PVC ratio 0.45 (11.7). There were 1000 yearly intervals with on average 4.3 per patient (range 2-15). Figure 1 shows a predicted alpha in the first year of 0.93 (95% CI 0.91-0.95) with alpha falling by -0.0008 per year (-0.007 to 0.005; p=0.791). Over the same period PEF fell from the 227 l/min (217 to 236) by -4.3 l/min per year (-5.1 to -3.7; p<0.001).

Figure 1

Conclusion: In COPD patients, PEF declines over time but alpha remains unchanged. These results suggest that alpha is assessing a feature of the airways that is independent of lung function and changes little over time.

Adequate repair of damaged tissue is important for maintaining normal lung function. Changes in this delicate repair mechanism could contribute to pathological processes, such as alveolar destruction (emphysema) and airway fibrosis, in lung diseases including chronic obstructive pulmonary disease (COPD). Transforming growth factor (TGF-β) and bone morphogenetic proteins (BMPs) interactively regulate tissue homeostasis and lung organogenesis. In particular, BMP4 is known to be important for proper lung development. BMP4 is also an important regulator of TGF-β-induced lung fibrosis. The activity of BMP4 is antagonized by the TGF-β-induced protein follistatin-like 1 (Fstl1). Moreover, depletion of Fstl1 was found to be an essential regulator of lung development in mice. We hypothesize that increased Fstl1 contributes to cigarette smoke-induced fibrosis and emphysema in COPD. Interestingly, specific depletion of Fstl1 from the mice endothelium caused thickened alveolar septa and airway fibrosis. In human, Fstl1 is expressed in structural and inflammatory cells of the lung and treatment of primary human airway smooth muscle cells with cigarette smoke extract increases Fstl1 expression. Taken together, these findings suggest that increased expression of Fstl1 due to smoking could lead to structural changes in the lung associated with COPD.

Follistatin-like 1: A crucial factor in lung development and a novel regulator of airway remodelling

Harm Maaßenhij 1, Wim Timens 2, Martina Schmidt 1, Maurice van den Hoff 3
1 Molecular Pharmacology, University of Groningen, Groningen, Netherlands; 2 Pathology, UMC, Groningen, Netherlands; 3 Anatomy, Embryology and Physiology, AMC, Amsterdam, Netherlands

The bone marrow contains a number of distinct progenitor cell populations, including endothelial progenitor cells (EPCs) and mesenchymal stem cells (MSCs) which have the capacity to modulate the course of lung disease. We have investigated whether these populations of stem cells are recruited from the bone marrow to the lungs in two contrasting models of lung disease (house dust mite (HDM) model of allergic airways disease and bleomycin-induced lung fibrosis). We show an increased recruitment of EPCs to the inflamed lung in the HDM model, along with increased peribronchial angiogenesis, and reduced numbers of EPCs in the bone marrow. Blocking either CXCR2 or VEGF inhibited the number of EPCs recruited to the inflamed lung and reduced the associated peribronchial angiogenesis. Further experiments suggest that while VEGF is required for mobilisation of EPCs from the bone marrow into the blood, ELR+CXC chemokines mediate their recruitment into the lungs. We have identified a population of MSCs residing in the naive lung, which are phenotypically different to bone marrow MSCs. In the bleomycin model of pulmonary fibrosis, we have observed a significant elevation in MSC numbers in the circulation and lung tissue and are currently investigating whether this is due to MSC recruitment from the bone marrow. Although the regenerative capacity of MSs has been extensively investigated, their ability to be mobilised from the bone marrow and recruited to the lung following injury has not yet been explored, and the mechanism by which this may be occurring is under investigation.

Activation of Wnt/β-catenin signaling promotes lung epithelial repair in emphysema

J. Cañega, K. Mutze, M. Königshoff, HMGU, Comprehensive Pneumology Center, Munich, Germany

Emphysema is characterized by airspace enlargement, tissue destruction and reduced Wnt signaling. Wnt/β-catenin activation attenuated experimental emphysema. Here, we aim to elucidate the mechanism of Wnt/β-catenin-induced alveolar epithelial cell repair in vitro and in vivo. Alveolar epithelial type II cells were isolated from untreated (ATIIc) or elastase treated (ATIIe) C57BL/6 mice at day 3, 7 and 14 with similar purity (>94%) and viability (>92%). ATII cells depicted increased cell numbers (i.e. 6.0±1.6x10⁶ ATIIc vs. 3.9±1.0x10⁶ ATIIe, day14), and significantly reduced expression of the Wnt target genes Axin2, LEF1 and LRP6 (i.e. LRP6 0.29±0.56 ATIIe vs. 0.86±0.56 ATIIc, day7) as determined by qRT-PCR. Freshly isolated ATII cells showed increased apoptotic susceptibility (Annexin V/PI staining). Live imaging of cultured ATII cells revealed altered ATII cell morphology and migratory behavior. Wnt activation of ATII cells by rWnt3a led to increased expression of Wnt target genes (i.e. Axin2 -2.15±0.12 rWnt3a vs. -5.18±0.29 control), epithelial markers SPC, TJP1, and Occludin, and increased proliferative capacity (BrDU). Primary ATII cells exhibited reduced Wnt/β-catenin activity and altered functional capacity. Wnt/β-catenin activation led to increased epithelial marker expression and stabilized ATII cell monolayers. Thus, activation of Wnt/β-catenin is a suitable tool to increase alveolar epithelial cell repair capacity in pulmonary emphysema.

Lung tissue engineering: generation and characterization of decellularized lung scaffolds for stem cell differentiation

Sharareh Shojaee 1, 2, Martin Post 1, 2
1 Department of Physiology, University of Toronto, Canada; 2 Physiology and Experimental Medicine, Hospital for Sick Children, Toronto, Canada

The interaction of stem cells with the surrounding matrix environment is crucial for cell fate. The development of biomaterials that recapitulate the in vivo environment is a key component to driving differentiation of pluripotent cells into lung endoderm precursors. We investigate whether decellularized lungs with intact matrix composition can promote the differentiation of embryonic stem cells (ESC) into distal lung epithelial cells. Rat cadaveric lungs were decellularized by sequential tracheal lavages and retrograde pulmonary arterial perfusion using a range of physical, chemical, and enzymatic treatments. Histological staining, immunofluorescence, electron microscopy, and tensile testing have confirmed decellularization and preservation of matrix proteins. Murine ESC (F112x2CD4; Bry/GFP cells) were seeded onto scaffolds following endoderm induction using activin, and analysed for lung lineage marker expression. Seeded ESC maintained FoxA2 expression and adopted an epithelial-like tubular organization. This demonstrates the ability of decellular lung scaffolds to support the adherence, proliferation, and potential differentiation of murine embryonic stem cells. Current studies are analysing their potential as viable scaffolds for the unidirectional differentiation of human endoderm-induced ESC (Hes2 cell line) into distal lung epithelial cells.

Mesenchymal stromal cells identified in tissue from lung-transplanted patients

S. Rolandsson 1, A. Andersson-Sjöland 2, J. Brane 3, L. Eriksson 1, I. Skog 1, L. Hansson 1, L. Björner 1, S. Scheding 1, G. Westergren-Thorsson 1

Background: Chronic rejection expressed as bronchiolitis obliterans (BO) is seen in 50% of lung-transplanted (LT) patients. BO is characterized by extra cellular matrix deposition, where the fibroblast is thought to be a key player. The fibroblast origin is at present not fully known. The fibrocyte is one of the potential origins, and our group has shown that fibrocytes are associated with remodelling in BO. In this study we focused on another origin the mesenchymal stromal cell (MSC).

Objectives: Our aims were to examine whether MSC are present in tissue from LT patients. We wanted to evaluate whether these cells displays characteristics MSC properties such as adherent clonal growth, multi-lineage potential and a characteristic surface marker profile.

Methods: MSC were isolated from biopsies of LT patients and the single cell suspension was seeded in colony-forming unit-fibroblast (CFU-F) assays. Isolated MSC were differentiated towards adipocytes, osteoblasts and chondrocytes. Their surface markers was examined by flow cytometry.

Results: MSC isolated from LT patients formed typical colonies, displayed spindle-shaped morphology and adhered to plastic. Further, cells displayed multi-lineage potential. Analysis of the surface markers showed that MSC showed expression of CD73, CD105 and CD90, but lacked expression of CD45 and CD34. Conclusions: Our study suggests that MSC are present in lung tissue from LT patients. These cells display colony growth, multipotential and a characteristic MSC surface marker profile.
TGF-β superfamily signaling during lung morphogenesis and adult tissue repair

Numerous studies in genetically modified animals have demonstrated the significance of the TGF-β superfamily in lung development and homeostasis. However, the cellular targets and the pattern of BMP, and/or TGF-β/Activin-signalling in the respiratory system still remain poorly outlined. To address this issue, we utilized two different transgenic lines, one expressing eGFP under the control of a BMP-responsive element (BRE-eGFP line) and a recently developed novel transgenic line expressing mRFP under the control of a TGF-β/Activin-responsive element (TβR-I-mRFP line). Crossing of these animals and development of double reporter mice allowed us to simultaneously monitor BMP and TGFβ/Activin signalling in the same tissues. Analysis of these animals unveils a far more complex and dynamic activation pattern for the TGFβ superfamily signalling system during lung development, homeostasis and tissue repair than previously anticipated. These animal models provide a unique opportunity to isolate specific cell populations under the control of these pathways and construct a functional spatiotemporal map for this signalling system in health and disease.

Resident mesenchymal progenitor cells in adult lung maintenance, repair, and fibrosis

Delineation of embryonic lung mesenchyme is essential for branching morphogenesis and epithelial cell specification in the fetal lung. We have recently demonstrated that lung-specific mesenchymal progenitors persist in the human adult lung. These lung-resident mesenchymal stem cells (LR-MSCs) express embryonic lung-specific mesenchymal markers such as Oct4, and are mobilized in response to lung injury via paracrine mechanisms as well as via direct gap junction communications. An increase in LR-MSC population is seen in response to injury such as after orthotopic lung transplantation and likely plays a role in lung repairs. LR-MSCs can also differentiate into myofibroblasts in response to pro-fibrotic factors such as transforming growth factor-β and an altered pro-fibrotic phenotype is noted in LR-MSCs derived from lungs in diseases such as bronchiolitis obliterans or idiopathic pulmonary fibrosis. Mobilization of the LR-MSC population to the airspaces also precedes development of human fibrotic diseases such as bronchiolitis obliterans. Here we investigate the paracrine factors, cell surface receptors and intra-cellular signaling pathways mediating differentiation of these lung-resident organ-resident paracrine mesenchymal progenitors. We demonstrate that ligation of G protein coupled receptor lysophosphatidic acid 1 leads to migration of LR-MSCs via GSK3β phosphorylation and subsequent β-catenin accumulation and nuclear translocation. These data suggest an important role for β-catenin activation in mobilization of tissue-resident mesenchymal progenitors in human adult lungs.

Lung stem cells and their niche

During lung development, Fibroblast growth factor 10 (FGF10) is secreted by the airway smooth muscle cells progenitors in the distal mesenchyme. β-catenin signaling within these airway smooth muscle cell progenitors is essential for their maintenance, proliferation, and Fgf10 expression. Fgf10 acts on the distally located epithelial progenitors to prevent their differentiation and promote their proliferation. We found that this Wnt/Fgf10 embryonic signaling cascade is reactivated in mature airway smooth muscle cells after airway epithelial injury. Furthermore, we found that this paracrine Fgf10 action was essential for airway epithelial repair. After injury, airway smooth muscle cells secreted Fgf10 to activate Notch signaling and induce Snai1 expression in surviving Clara cells, which subsequently underwent a transient epithelial to mesenchymal transition to initiate the repair process. We have therefore identified airway smooth muscle cells as a stem cell niche for the (variant) Clara cells in the lung and established that paracrine Fgf10 signaling from the niche is critical for epithelial repair after injury. These findings also have implications for understanding the misregulation of lung repair in asthma and cancer.

Resident mesenchymal progenitor cells in adult lung maintenance, repair, and fibrosis

Delineation of embryonic lung mesenchyme is essential for branching morphogenesis and epithelial cell specification in the fetal lung. We have recently demonstrated that lung-specific mesenchymal progenitors persist in the human adult lung. These lung-resident mesenchymal stem cells (LR-MSCs) express embryonic lung-specific mesenchymal markers such as Oct4, and are mobilized in response to lung injury via paracrine mechanisms as well as via direct gap junction communications. An increase in LR-MSC population is seen in response to injury such as after orthotopic lung transplantation and likely plays a role in lung repairs. LR-MSCs can also differentiate into myofibroblasts in response to pro-fibrotic factors such as transforming growth factor-β and an altered pro-fibrotic phenotype is noted in LR-MSCs derived from lungs in diseases such as bronchiolitis obliterans or idiopathic pulmonary fibrosis. Mobilization of the LR-MSC population to the airspaces also precedes development of human fibrotic diseases such as bronchiolitis obliterans. Here we investigate the paracrine factors, cell surface receptors and intra-cellular signaling pathways mediating differentiation of these lung-resident organ-resident mesenchymal progenitors. We demonstrate that ligation of G protein coupled receptor lysophosphatidic acid 1 leads to migration of LR-MSCs via GSK3β phosphorylation and subsequent β-catenin accumulation and nuclear translocation. These data suggest an important role for β-catenin activation in mobilization of tissue-resident mesenchymal progenitors in human adult lungs.

Lung stem cells and their niche

During lung development, Fibroblast growth factor 10 (FGF10) is secreted by the airway smooth muscle cells progenitors in the distal mesenchyme. β-catenin signaling within these airway smooth muscle cell progenitors is essential for their maintenance, proliferation, and Fgf10 expression. Fgf10 acts on the distally located epithelial progenitors to prevent their differentiation and promote their proliferation. We found that this Wnt/Fgf10 embryonic signaling cascade is reactivated in mature airway smooth muscle cells after airway epithelial injury. Furthermore, we found that this paracrine Fgf10 action was essential for airway epithelial repair. After injury, airway smooth muscle cells secreted Fgf10 to activate Notch signaling and induce Snai1 expression in surviving Clara cells, which subsequently underwent a transient epithelial to mesenchymal transition to initiate the repair process. We have therefore identified airway smooth muscle cells as a stem cell niche for the (variant) Clara cells in the lung and established that paracrine Fgf10 signaling from the niche is critical for epithelial repair after injury. These findings also have implications for understanding the misregulation of lung repair in asthma and cancer.
Chronic obstructive pulmonary disease (COPD) is characterized by fibroblast activation and changes in extracellular matrix (ECM) composition, in which transforming growth factor (TGF-β1) plays an important role. We previously found that TGF-β1 increases the expression of WNT pathway components, notably the Frizzled-8 receptor (FZD8). This was even more pronounced in fibroblasts of COPD patients. Therefore, we studied the functional role of FZD8 in MRC5 human lung fibroblasts. TGF-β1 strongly induced FZD8 expression, which was attenuated by Smad3 inhibition. Importantly, FZD8 silence reduced TGF-β1-induced ECM gene expression and fibroblast activation. The canonical WNT inhibitor Diclectin did not affect these effects, suggesting that FZD8 signals through non-canonical WNT signalling. In support, TGF-β1 induced the expression of non-canonical WNT-5B. Further, the TGF-β1-induced effects were mimicked by WNT-5B stimulation and reduced by WNT-5B siRNA. Collectively, this implies a critical role for autocrine WNT signalling via FZD8 in COPD disease, including bipolar disorder and epilepsy. Reducing the PGP levels might improve treatment in BOS. Using VPA was interesting, as it is used clinically for other indications. Using POP inhibitors to reduce PGP generation seems to be promising treatment in COPD.

Distal airway epithelial cells differentiate into ATI-like cells as suggested by morphological changes as well as increased expression of differentiation markers AQP3, SPC-A, SPC-C in the 3D model. Wnt11 was identified in the model and in human lung explant cultures as one of the main regulators of ATI differentiation. Added Wnt11 increased the expression of ATI markers, while silencing of Wnt11 resulted in elevated levels of EMT markers N-cadherin and S100A4. We conclude that the 3D lung model is applicable for studying epithelial-mesenchymal interactions in the lung. Our finding may mark Wnt11 as a potential therapeutic target in lung regenerative therapy.
The role of TNF-related apoptosis inducing ligand (TRAIL) in interstitial lung disease

Emmet McGrath, Alan Lawrie, Helen Marriott, Paul Mercer.

Introduction: Driving cellular apoptosis as a potential therapy for diseases is of widespread interest. We previously showed a death receptor ligand, TRAIL, accelerates neutrophil apoptosis and other work revealed TRAIL-induced apoptosis of human lung fibroblasts. The aims of this project were to study the role of TRAIL in bleomycin lung injury in wild-type (WT) and TRAIL−/− (T−) mice and in patients with idiopathic pulmonary fibrosis (IPF).

Methods: Mice received intratracheal bleomycin or saline control. Bronchoalveolar lavage (BAL) at 3, 7, 16 and 23 days was analysed by cytospin and hemocytometer for % neutrophils, % neutrophil apoptosis, total number of neutrophils and apoptotic cells. Flow cytometry was also used to analyse apoptosis. Collagen deposition was analysed using a hydroxyproline assay. TGF-β expression and TUNEL positive events were also analysed. Serum and lung tissue from IPF patients/controls were examined for TRAIL expression and concentration. Lung function and survival data were retrieved from patient charts.

Results: BAL analysis revealed significant differences between T− and WT mice, with T− mice showing increased neutrophil numbers and reduced apoptosis. Collagen deposition was statistically greater in TRAIL−/− mice. TGF-β levels were measured and the role of TRAIL in bleomycin-induced fibrosis and collagen mRNA was assessed. TGF-β levels were increased in TRAIL−/− mice. These data suggest TRAIL may have a role in ECM production by ASM and hence, could present new targets for asthmatic airway remodeling.

FOXO transcription factors regulate innate immune mechanisms in respiratory epithelial cells during bacterial infection

Christothea Reisswenger, Frederik Seiler, Philipp Lepper, Robert Bals, Christian Herr.

Bacterial pathogens are a leading cause of lung infections and contribute to acute exacerbations in patients with respiratory tract diseases. The innate immune system of the lung controls and prevents colonization of the respiratory tract with bacterial pathogens. Here, we show that FOXO transcription factors regulate innate immune mechanisms of respiratory epithelial cells in response to bacterial pathogens such as Haemophilus influenzae and Pseudomonas aeruginosa. Infection with bacterial pathogens led to the activation of FOXO transcription factors in respiratory epithelial cells and have a central role in regulating innate immune functions of respiratory epithelial cells.

PP104
FOXO transcription factors regulate innate immune mechanisms in respiratory epithelial cells during bacterial infection

Christothea Reisswenger, Frederik Seiler, Philipp Lepper, Robert Bals, Christian Herr.

Introduction: FOXO transcription factors regulate innate immune mechanisms in respiratory epithelial cells in response to bacterial stimuli and have a central role in regulating innate immune functions of respiratory epithelial cells.

Methods: Mice received intratracheal bleomycin or saline control. Bronchoalveolar lavage (BAL) at 3, 7, 16 and 23 days was analysed by cytospin and hemocytometer for % neutrophils, % neutrophil apoptosis, total number of neutrophils and apoptotic cells. Flow cytometry was also used to analyse apoptosis. Collagen deposition was analysed using a hydroxyproline assay. TGF-β expression and TUNEL positive events were also analysed. Serum and lung tissue from IPF patients/controls were examined for TRAIL expression and concentration. Lung function and survival data were retrieved from patient charts.

Results: BAL analysis revealed significant differences between T− and WT mice, with T− mice showing increased neutrophil numbers and reduced apoptosis. Collagen deposition was statistically greater in TRAIL−/− mice. TGF-β levels were measured and the role of TRAIL in bleomycin-induced fibrosis and collagen mRNA was assessed. TGF-β levels were increased in TRAIL−/− mice. These data suggest TRAIL may have a role in ECM production by ASM and hence, could present new targets for asthmatic airway remodeling.

Conclusion: The inflammatory and collagen deposition response to bleomycin is increased in T− compared to WT mice. We demonstrated reduced pulmonary and systemic expression of TRAIL in IPF, which correlates with worse pulmonary function and clinical outcome. This data suggests TRAIL may have biomarker/therapeutic benefit in pulmonary fibrosis.
PP106 Sonic Hedgehog signaling in non-small-cell lung cancer
Olga Bredemeyer, 1 Ina Koch, 1 Elisabeth Hennem, 1 Maria-Magdalena Stein, 1 Michael Lindner, 2 Melanie Königshoff, 2 Oliver Eckelberg, 3 Comprehensive Pneumology Center, Helmholtz; Zentrum München, Munich, Germany; 4 Molecularbiologisches Labor, Asklepios Fachkliniken München-Gauting, Gauting, Germany; 5 Department of Thoracic Surgery, Asklepios Fachkliniken München-Gauting, Gauting, Germany

Introduction: Sonic hedgehog (Shh) signaling has been recently identified as key player in human cancers. We sought to elucidate the expression and role of Shh in non-small-cell lung cancer.

Methods: Cell proliferation was investigated using the inhibitory cyclopamine or small interference RNAs (siRNA) against Gli1, Gli2 and Gli3. Expression of Shh-related genes in normal and tumoral tissue was assessed by quantitative real time PCR in 10 patients with adenocarcinoma and 10 patients with squamous carcinoma.

Results: Inhibition of Shh signaling decreases a decrease in the proliferation of A549 adenocarcinoma and H520 squamous carcinoma cells. H520 cells secrete a high level of Shh, which promotes a high level of Gli1, Gli2 and Gli3 expression. The inhibition of Shh pathway results in limited primary human fibroblasts. In the tumoral tissue, Shh, Gli1 and Gli2 RNA levels were found to be increased mainly in patients in stage T1 or T2.

Conclusions: Shh pathway plays a role in lung cancer cell proliferation and its regulation may be determinant for lung cancer progression.

PP108 Decellularized human lung slices as a culture substrate to examine the role of ECM in lung fibrogenesis and regeneration
Eric White1, 2 Anesthesia and Biomedical Engineering, Yale University School of Medicine, New Haven, USA; 3 Molekularbiologisches Labor, Asklepios Fachkliniken München-Gauting, Gauting, Germany

Idiopathic Pulmonary Fibrosis (IPF) is characterized by progressive deposition and remodeling of lung extracellular matrix (ECM). Decellularized human lung tissue provides an ECM scaffold with disease-specific, relevant structure and composition. This study was aimed to investigate whether PBP occurs as a result of increased expression of matrix metalloproteinase 1 (MMP-1), MMP-2 and MMP-9 from activated alveolar macrophages.

Methods: In lung tissue samples from 51 patients presenting with PBP to determine the level of expression of MMP-1, MMP-2 and MMP-9. Semi-quantitative analysis revealed decreased expression of MMP-2 and MMP-9 compared to controls. No alteration in MMP-1 expression was observed in comparison to controls.

Conclusions: Increased levels of MMP-2 and MMP-9 may limit the deposition of matrix construct causing a weakness in type IV collagen. This decrease in MMP activity may alter the proteolysis/antiproteolysis balance reflecting defective repair of the extracellular matrix. Sustained production of MMP-1 under these conditions may further contribute, pushing the re-modelling process towards matrix destruction. PBP results in significant expression of matrix metalloproteinases.

PP110 Macrophage derived metalloproteinases 1,2 and 9 in the development of primary spontaneous pneumothorax
Rachel Norman1, 2, 3, 4, 5, 6, Ruth Morse, 1 Histology, P.E.H. Guernsey, United Kingdom; 2 Histology, Heartlands, Birmingham, United Kingdom; 7 Life Sciences, U.W.E, Brstol, United Kingdom

Primary spontaneous pneumothorax (PSP) is a common clinical problem affecting previously healthy individuals. The pathogenesis is poorly understood but is related to rupture of apical pleural blebs. Enhanced production of alveolar macrophage derived matrix degrading metalloproteinases within the lung is postulated to result in increased breakdown of collagen and elastin causing alveolar destruction, distal emphysema and formation of blebs. The study aims to investigate whether PBP occurs as a result of increased expression of matrix metalloproteinase 1 (MMP-1), MMP-2 and MMP-9 from activated alveolar macrophages.

Methods: In vivo, in A549 cells treated with rTGF-β1, V5/192 mice KO for a/b-C or WT received intrathoracic bleomycin (in-bio-0.07U/mouse) or AdTGFβ1. Results: In vivo, lung from aged untreated a/b-C KO mice are typically normal. a/b-C is overexpressed in fibrotic areas after bleo or AdTGF-β1. By day 21 after bleo/collagen content in the lung is higher in WT (3 fold, p<0.05) compared to KO mice (2/TGFβ1 (ELISA) is lower in the BAL from KO than WT mice (299±185ng/ml, p<0.05).

PP111 a/b-Crystallin is involved in pulmonary fibrosis
Pierre-Simon Bielle, 1 Gwenn Emery, 2 M Kolb, 1 Gauldie, 1 B Crestani, 2 C Garrido, 2 F Camus, 2 P Bonnifait. 1 INSERM U1366, Dijon, France

Idiopathic Pulmonary Fibrosis (IPF) is a devastating disease. We have shown that the small heat shock protein (αHSP) HSP27 is involved in IPF through a role in EMT, a/b-crystallin (α-b-crystallin) another HSP is expressed in lungs, which is inducible by stress and has a role in cell cytoskeleton architecture. The role of a/b-C in fibrosis is unknown.

Methods: A549 cells were treated with rTGF-β1, V5/192 mice KO for a/b-C or WT received intrathoracic bleomycin (in-bio-0.07U/mouse) or AdTGFβ1. Results: In vivo, lung from aged untreated a/b-C KO mice are typically normal. a/b-C is overexpressed in fibrotic areas after bleo or AdTGF-β1. By day 21 after bleo/collagen content in the lung is higher in WT (3 fold, p<0.05) compared to KO mice (2/TGFβ1 (ELISA) is lower in the BAL from KO than WT mice (299±185ng/ml, p<0.05).

PPI102 Primary spontaneous pneumothorax (PSP) is a common clinical problem affecting previously healthy individuals. The pathogenesis is poorly understood but is related to rupture of apical pleural blebs. Enhanced production of alveolar macrophage derived matrix degrading metalloproteinases within the lung is postulated to result in increased breakdown of collagen and elastin causing alveolar destruction, distal emphysema and formation of blebs. The study aims to investigate whether PBP occurs as a result of increased expression of matrix metalloproteinase 1 (MMP-1), MMP-2 and MMP-9 from activated alveolar macrophages.

Methods: In vivo, in A549 cells treated with rTGF-β1, V5/192 mice KO for a/b-C or WT received intrathoracic bleomycin (in-bio-0.07U/mouse) or AdTGFβ1. Results: In vivo, lung from aged untreated a/b-C KO mice are typically normal. a/b-C is overexpressed in fibrotic areas after bleo or AdTGF-β1. By day 21 after bleo/collagen content in the lung is higher in WT (3 fold, p<0.05) compared to KO mice (2/TGFβ1 (ELISA) is lower in the BAL from KO than WT mice (299±185ng/ml, p<0.05).

PP112 Phenotypic characterization of the putative lung cancer stem cells that egress into peripheral blood
Tomasz Skirecki, 1 Graumpyna Hoset, 1; Jerzy Kawiak, 1, Joanna Domagaa-Kulawik, 2; Laboratory of Flow Cytometry, Medical Center of Postgraduate Education, Warsaw, Poland; 3 Allergology and Pneumology, Warsaw Medical University, Warsaw, Poland

Lung cancer (LC) poses high metastatic potential but the exact cell of origin of metastasis is not known, however the LC stem cells seem to be one candidate for the metastasis-founding cell. We aimed to evaluate whether circulating lung cancer cells have phenotype of the cancer stem cells. Expression of stem cell markers (CD133, EpCAM, CXCR4) was analyzed in LC cell lines, tumor samples and peripheral blood (PB) of LC patients (n=39) by flow cytometry. Murine model of metastatic cancer was developed by subcutaneous injection of LC cells into thymi of the NSG mice. Putative LC stem cells (CD133+/EpCAM+) were present in the analyzed cell lines and in 67/tumor samples. All of the CD133+/EpCAM+ cells co-expressed the CXCR4. 2 weeks after injection of the LC cells, the CD133+/EpCAM+ cells were identified in the PB of all animals. PB of 15 LC patients contained the CD133+/EpCAM+ cells.

We confirmed the presence of a subpopulation of the LC stem cells of CD133+/EpCAM+/CXCR4+ phenotype. This subpopulation can be found in the circulation of the mice with locally transplanted LC cells, and in the PB of some LC patients. Interestingly, the number of CD133+/EpCAM- cells was elevated in the metastatic disease, suggesting important role of the non-malignant stem cells in the progress of disease.

Supported by the 7th FP, HEALTH-F2-2007-202224 eurIPFnet

Macrophage activation is an intricate molecular process likely regulated by the cross talk between activating and inhibitory signals. While much is known on receptors that promote macrophage activation, receptors that suppress their functions received scant attention. Paired immunoglobulin-like receptor B (Pir-B) is an immunoreceptor tyrosine-based inhibitory receptor capable to inhibit immune cell function (e.g. chemotaxis, mediator release, adhesion). Nonetheless, the expression and function of Pir-B in pulmonary fibrosis is unknown. In this study, we demonstrate that Pir-B is upregulated in lung myeloid cell subsets following bleomycin administration. Bleomycin-challenged Pir-B-/- mice displayed increased lymphocytic and decreased neutrophilic inflammation, which was correlated with increased levels of macrophage-derived resistin-like molecule α (Relm-α) and MMP12 but not IL-6, CCL2 and KC. Furthermore, Pir-B-/- mice evidenced significantly increased lung fibrosis as assessed by lung histopathology and collagen content in comparison to wild type mice. Consistently, bone marrow-derived Pir-B-/- macrophages displayed increased Relm-α secretion and MMP12 expression following IL-4 activation in comparison with wild type macrophages. These results define a key role for alternatively activated macrophages in pulmonary fibrosis and establish Pir-B as a fundamental regulator of macrophage polarization.
**Conclusion:** Pim1 protects airway epithelial cells from CS-induced damage and proliferative potential after injury. Influenza virus targets putative lung epithelial progenitors and impairs their inflammation. In vivo, this protective effect suffices to prevent CS-induced neutrophilic airway cell death by phosphorylating BAD and increasing the threshold for apoptosis. BAD phosphorylation was determined by Western Blotting.

**Results:** CS exposure induces neutrophilic airway inflammation and increases KC levels in Pim1-KO mice, but not in WT controls. CSE induces a dose-dependent loss of BAD phosphorylation, loss of 4M and necrotic cell death in Beas-2b cells. All of these CSE-induced effects are aggravated by inhibition of Pim1.

**Conclusion:** Pim1 protects airway epithelial cells from CS-induced damage and cell death by phosphorylating BAD and increasing the threshold for apoptosis. In vivo, this protective effect suffices to prevent CS-induced neutrophilic airway inflammation.

**Influenza virus targets putative lung epithelial progenitors and impairs their proliferative potential after injury**

Qing Ruhana Gottschald, Jennifer Quantius, Werner Seeger, Jürgen Lohmeyer, Susanne Herold. Department of Internal Medicine II, University of Giessen Lung Center, Giessen, Germany

Influenza virus can induce severe damage of the alveolar epithelium, leading to pulmonary oedema and respiratory failure. Therefore, an efficient alveolar repair is crucial for recovery. We defined a lung epithelial cell population (EpCAMhigh CD49dhigh CD24low) during influenza infection. These cells were previously described to have progenitor cell characteristics, being resistant to damage and proliferating after injury in lineages. In this population, dual the protease EPAC1 is expressed at high level CD104high and CCSPpos Sca1intCD104high and CD34high, which is located at the level of bronchioles. After influenza infection, this population showed an increased proliferation rate, peaking at day 7 p. i., when compared to other populations of lung epithelial cells. In addition, the progenitor cells were resistant to infection-induced apoptosis. Different influenza virus strains, of high and low pathogenicity, exhibited different degrees of tropism towards putative lung epithelial progenitors and infection of these progenitors decreased their reparative potential which might determine the pathogenicity of influenza viruses during influenza pneumonia.

**Chlorine gas exposure causes rapid coagulation dysfunction in mice**

Storries Zooraghi, Naseem Anjum, Solana Fernandez, Cilina Ann Rodriguez, Karen Ille, Jean François Petit, Sadis Matalon. University of Alabama at Birmingham, United States

**Rationale:** Chlorine is a highly reactive oxidant gas involved in lung injury. Chlorine and its hydrolysis products produce reactive oxygen - chlorine and nitrogen intermediates that damage the bronchial tree and the alveolar epithelium. Severe exposure (high concentrations of chlorine for an extended period of exposure) can lead to ALI/ARDS and also death. Chlorine gas exposure has been documented to have extra-pulmonary damaging effects by promoting systemic endothelial dysfunction via disruption of vascular nitric oxide homeostasis mechanisms (mainly eNOS).

**Aim:** The main objective of the present study is to evaluate the potential effects of chlorine gas exposure to coagulation that is initiated in instances of lung injury.

**Methods:** C57BL/6 mice were exposed to O2 either at 400 ppm for 30 min or at 600 ppm for 45 min, in environmental chambers and then returned to room air. Mice were euthanized 1h post exposure and blood and bronchoalveolar lavage fluid (BALF) was collected for further analysis. In order to assess the native coagulation parameters, we analyzed whole blood using rotational thromboelastometry. We measured native coagulation (NATEM) parameters such as clotting time and kinetics of clot formation (clot formation time). Additionally, we measured thrombin - anti-thrombin complex formation in both plasma and BALF, a surrogate marker of thrombin generation. Mice that were not exposed to chlorine served as controls in all measurements.

**Results:** Our results indicate that mice exposed to chlorine gas had significantly increased clotting time as compared to control animals (p<0.05). In addition, the kinetics of clot formation were altered with animals exposed to chlorine requiring more time to form a clot. The thrombin - anti-thrombin assay showed that in both plasma and BALF of chlorine exposed animals, thrombin was increased as compared to control animals. These effects seem to be Cl2 concentration dependent since all parameters were pronounced in 600-ppm exposures.

**Conclusion:** These findings highlight the extra-pulmonary effects of chlorine gas exposure. The coagulation is perturbed in animals exposed to chlorine gas since there is reduced ability to form clots, despite the fact that thrombin generation is increased.

**PP116**

**The viability of mesenchymal stem cells after nebulization via different types of nebulizers**

Kulagina Nataliya1, Alexander Averyanov1, Anatoly Konoplyannikov2, Oleg Kuznetcov.1,3 Federal Research Clinical Center of Special Medical Care and Technologies of EMBA of Russia, Moscow, Russian Federation; 2Medical Radiological Scientific Center, Obninsk, Russian Federation

**Background:** Numerous experimental studies have proven the effectiveness of endobronchial administration of mesenchymal stem cells (MSCs) in different types of lung pathology. In transition to the clinical researches inhalation is one of the major ways of MSC delivery in lower respiratory tract. There is currently no data on the efficacy of different ways of nebulization on cell viability.

**Aim:** To determine the viability of MSC after nebulization via jet nebulizer and ultrasonic nebulizer.

**Methods:** In the study diluted 1:10 culture of human MSCs (1.1x106 cells in 1 ml) was used. Staining with nigrosine followed by counting the amount of non-viable (stained) cells in the count chamber under a light microscope was used to assess the viability of cells. It’s known that non-viable cells are stained with nigrosine, unlike the viable MSCs. The cells were administered via inhalation with jet nebulizer OMRON NE-C24 and ultrasonic nebulizer OMRON V-17. Duration of nebulization was 5 and 10 minutes respectively.

**Results:** As presented in Table 1 and Table 2.

**Table 1. Ultrasonic nebulizer**

<table>
<thead>
<tr>
<th>Total amount of MSC</th>
<th>Non-stained (viable) MSC</th>
<th>Stained (non-viable) MSC</th>
</tr>

</tr>
<tr>
<td>10 min</td>
<td>2.2x10⁴</td>
<td>4.4x10³ (20%)</td>
</tr>
</tbody>
</table>

**Table 2. Jet nebulizer**

<table>
<thead>
<tr>
<th>Total amount of MSC</th>
<th>Non-stained (viable) MSC</th>
<th>Stained (non-viable) MSC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before nebulization</td>
<td>2.75x10⁶</td>
<td>2.55x10⁵ (93%)</td>
</tr>
<tr>
<td>5 min</td>
<td>1.55x10⁵</td>
<td>9.9x10⁴ (69%)</td>
</tr>
<tr>
<td>10 min</td>
<td>2.5x10⁴</td>
<td>1.85x10³ (74%)</td>
</tr>
</tbody>
</table>

**Conclusion:** 1. Nebulization of MSCs via jet nebulizer leads to retaining of most of the MSCs in a state of vitality. 2. Nebulization via ultrasonic nebulizer causes damage of the main mass of MSC.

**Exploring the role of microRNA miR-200b in normal and abnormal lung development due to congenital diaphragmatic hernia**

Raman Kohlebrarin, Naghmeh Khoshgoo, Barb Iwasiow, Richard Keijzer. Department of Surgery and Manitoba Institute of Child Health, University of Manitoba, Winnipeg, Canada

**Background:** Congenital diaphragmatic hernia (CDH) and pulmonary hypoplasia are poorly understood. No single gene has been indentified and thus epigenetic mechanisms are proposed to play a role. MicroRNAs are regulators of epigenetics. Previously, we identified miR-200b to be changed in CDH. miR-200b plays an important role in EMT/MET in cancer. We aimed to delineate the role of miR-200b during normal and abnormal lung development to CDH.

**Methods:** We used the nitrofen rat model for CDH. Spatial and temporal expression was obtained using rt-PCR and in situ hybridization. In vitro experiments...
using nitrofen, miR-200b mimics and inhibitors were used to characterize the role of miR-200b in EMT/MET. A SMAD luciferase reporter assay was used to relate the expression of miR-200b and TGF-β signalling.

Results: We observed higher expression of miR-200b during late lung development. miR-200b was mainly observed in epithelial cells. Both in vitro and in vivo experiments demonstrated downregulation of miR-200b expression after nitrogen treatment. This was associated with an upregulation of TGF-β signalling.

Conclusions: We demonstrate dynamic miR-200b expression during lung development with changes during abnormal lung development. The relationship between miR-200b, TGF-β signalling and EMT/MET explains some of the lung abnormalities observed in the hypoplastic lungs in CDH.

PP118
Lysosomal leakage in the human fibrotic lung
Lennart Persson1, Linda Vainikka2. 1Division of Pulmonary Medicine, Department of Medical and Health Sciences, Faculty of Health Sciences, Linköping University, Linköping, Sweden; 2Division of Experimental Pathology, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden.

Background: Excess of iron (Fe) is involved in the pathogenesis of lung fibrosis. To protect the respiratory epithelium against Fe-catalyzed oxidative damage Fe is deposited inside lysosomes of lung macrophages (LMs). When challenged by oxidants, lysosomal Fe triggers lysosomal leakage and ensuing cell death promotes inflammation.

Aim: To assess lysosomal leakage/cell death in oxidatively stressed cultures of LMs harvested from patients with lung fibrosis and healthy subjects.

Methods: LMs were harvested from 7 patients with lung fibrosis and 7 healthy subjects without medications. LMs were oxidatively stressed by a stable concentration of H2O2 (120 μM). Lysosomal leakage and cell death were evaluated at the end of the 1 h oxidant challenge and at 10 h after oxidative stress, respectively. LMs were stained for Fe and cellular Fe and GSH were assessed.

Results: LMs from patients with lung fibrosis exhibited significantly more lysosomal leakage and cell death after oxidative stress. GSH was reduced while cellular and lysosomal Fe were increased.

Conclusions: This study provides a rationale for clinical testing using a combination of acetylcysteine, a precursor to GSH, and azithromycin (a weak base that accumulates 1000-fold inside the acidic lysosomes and attenuates lysosomal Fe reactivity) to prevent fibrosis progression.

PP119
Surfactant protein A in chronic extrinsic allergic alveolitis
Marina Stecclowa1, Marina Vasakova1, Peter Palubík2, Milan Paulík2. 1Department of Respiratory Diseases, Thomayer University Hospital, Prague, Czech Republic; 2Department of Immunology, Thomayer University Hospital, Prague, Czech Republic.

Chronic form of extrinsic allergic alveolitis (EAA) may have common features with idiopathic pulmonary fibrosis (IPF). The aim of presented study was to compare serum SP-A concentrations in IPF and chronic EAA patients and detect possible relationships of SP-A levels, bronchoalveolar lavage fluid (BALF) differential cell counts and high resolution computed tomography (HRCT) patterns in both diseases. Thirteen patients with chronic EAA and 7 patients with IPF were enrolled. All subjects underwent evaluation of SP-A serum concentrations, HRCT of the chest and BALF. HRCT alveolar and interstitial scores (HRCTa, HRCTI) were assessed according to Gay S1.

EAA patients had significantly higher HRCT alveolar score then IPF group (p=0.003). Chronic EAA group exhibited positive correlation between HRCTI and BALF eosinophils (p<0.001) (Fig. 1). Serum SP-A concentrations did not differ between both groups.

Our study shows that SP-A serum concentrations do not differ between chronic EAA and IPF patients and thus should be used as a biomarker for IPF detection. Prognostic value of serum SP-A concentrations in chronic EAA patients should be the aim of further studies.

Human chitotriosidase as a prognostic biomarker of sarcoidosis
David Benedetti1, Elena Bargagli1, Nicola Bianchi1, Pasquale Di Sipio1, Rosa Metella Refini1, Maria Grazia Pieroni1, Paola Rottoli1. 1Respiratory Diseases Section, Department of Clinical Medicine and Immunology, University of Siena, Siena, Italy; 2Department of Environmental Sciences, University of Siena, Siena, Italy.

In the present study were evaluated the sensitivity and specificity of Chitotriosidase, a macrophages derived enzyme, in a population of 232 sarcoidosis patients divided according to the Clinical Outcom Status (COS) classification recently proposed by a WASOG task force. Serum chitotriosidase levels were significantly increased in patients than in healthy controls (p<0.0001) and correlated directly with ACE levels (r=0.25, p<0.0001). ROC curve analysis revealed sensitivity value of 88.6% and specificity of 92.8% with a cut-off value of 48.80 mmol/h/ml. Chitotriosidase concentrations were significantly increased in patients with chest XRay stage 3 vs. stage 0 (p=0.02). Significantly higher serum concentrations were found sarcoidosis patients in patients with persistent disease without treatment (COS5 and 6) and in those with symptomatic and persistent sarcoidosis on systemic therapy (class COS 8 and 9) compared to untreated patients with disease remission (COS1). Chitotriosidase resulted a serological biomarker for sarcoidosis easily detectable in serum with adequate sensitivity and specificity that can be proposed in the clinical practice to differentiate patients with a persistent disease requiring a more rigorous follow-up.

PP121
Role of ADAM19 and neuregulin-1 in Muc5ac expression in lungs of cigarette smoke-exposed mice
Lisa Dupont, Guy Joos, Guy Brusselle, Ken Bracke. Respiratory Medicine, Ghent University Hospital, Ghent, Belgium

Mucus hypersecretion is an important feature of COPD, resulting in chronic cough and contributing to dyspnea by obstructing the airway lumen. Signalling through the epidermal growth factor receptor (EGFR) plays a ubiquitous role in the production of mucus. We hypothesize that A Disintegrin And Metalloproteinase 19 (ADAM19) stimulates mucin production by shedding of the EGFR-ligand neuregulin-1. C57BL/6 mice were exposed to air or cigarette smoke (CS) for 4 or 24 weeks. IHC for ADAM19 on lung tissue sections showed intense staining in bronchial and vascular smooth muscle cells, as well as in dendothelium, and a faint staining in bronchial and alveolar epithelial cells. Quantification of ADAM19 protein expression in the airway wall showed a significant increase upon 4 weeks of CS-exposure, but not upon 24 weeks. Accordingly, protein levels of neuregulin-1 were significantly elevated in BAL fluid of mice exposed to CS for 4 weeks, but not for 24 weeks. Finally, pulmonary Muc5ac mRNA expression was significantly increased upon both 4 and 24 weeks of CS-exposure, while we found no differences in the mRNA expression of Muc5b.

These data demonstrate that 4 weeks of CS-exposure leads to increased expression of ADAM19 and enhanced shedding of neuregulin-1. Binding of neuregulin-1 to EGFR may contribute to the increased expression of Muc5ac. However, especially upon chronic CS-exposure, other EGFR-ligands or alternative mechanisms may be involved in mucin production.
PP122
Amniotic fluid derived lung stem/progenitor cells (AFSC) as a novel strategy to ameliorate lung fibrosis through the modulation of pro-fibrotic cytokines in the alveolar milieu
Orquidea Garcia1,2, Gianni Carraro2, Sargis Sedrakyan2, Gianluca Turcatel2, Barbara Driscoll1,3, Laura Perin1,2, David Warburton1,2. 1Systems Biology and Disease Graduate Program, Keck School of Medicine and Ostrow School of Dentistry, University of Southern California, Los Angeles, USA; 2Developmental Biology and Regenerative Medicine Program, The Saban Research Institute, Children’s Hospital Los Angeles, Los Angeles, USA

Following bleomycin lung injury we transplanted AFSC to modulate the inflammatory response and stimulate resident progenitor cells. C57Bl/6J mice, 10 wks old were given 1.5U/kg of bleomycin intratracheally and 1x10⁶ cells IV at either 2 hours or 14 days post bleomycin. Cohorts were sacrificed at 3 or 28 days to measure the acute and fibrotic response. Pre-transplant AFSC showed expression of type I cell (AECI) lineage markers: AQP5, T1a/PDPN, TTF-1/NKX2-1. Acute phase lung lysates indicated an upregulation of TTF-1 in AFSC treated mice. Mice receiving AFSC at 2 hours vs 14 days post bleomycin exhibited a respective 2-fold vs 1.3-fold reduction in hydroxyproline content when compared to non-treated mice. Cytokine analysis of bronchoalveolar lavage showed a significant decrease in CCL2/MCP-1, 3 days after AFSC transplant. Upregulation of TTF-1 following AFSC transplant indicates that these cells continue along or stimulate the AEC cell lineage while modulating a key fibrotic mechanism: CCL2/MCP-1.

PP123
Vitamin D deficiency – a risk factor for the development of acute lung injury (ALI)?
Rachel Dancer, Vijay D’Souza, Shengxing Zheng, David Thickett. Department of Respiratory Medicine, University of Birmingham, Birmingham, United Kingdom

ALI is a final common pathway to insults such as pneumonia, trauma or abdominal sepsis. Patients with severe sepsis have lower levels of 25-OH vitamin D (25-OHD) than healthy controls. We hypothesized that vitamin D deficiency is a risk factor for ALI. The levels of 25-OHD and 1,25-OH vitamin D (1,25-OHD) were measured in 109 patients with and at risk (AR) of ALI and related to lung injury biomarkers. 25-OHD was lower in patients with ALI compared to AR patients p=0.0001 and normal controls p<0.0001. 1,25-OHD levels were lower in patients with ALI compared to AR p<0.001 and ALI patients who survive ITU had higher levels p=0.034. AR patients who went on to get ALI had lower levels than those who didn’t (Fig. 1). AR patients with 25-OHD deficiency (<20nmol/L) had elevated post-op markers of epithelial damage, permeability and systemic inflammation. Microarrays show that 669 genes were significantly altered when primary alveolar type II cells were treated with 25-OHD. To confirm these effects we show that in-vitro culture with vitamin D increases epithelial cell proliferation p<0.001, wound repair p=0.02 and reduces sFasL mediated cell death p<0.001 (Fig. 2). Our data supports a role for vitamin D in the maintenance of alveolar epithelial cell integrity and suggests vitamin D replacement may help prevent ALI in at risk patients. We will start recruitment to a trial of vitamin D replacement in patients at risk of ALI in 2012.

PP124
Chronic allergic inflammation drives pericyte recruitment to the airway wall
Jill Johnson1,Erika Folestad2, Kristian Pietras2, Ulf Eriksson2, Jonas Fuxe2. 1National Heart and Lung Institute, Imperial College London, London, United Kingdom; 2Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden

Objective: To investigate the contribution of airway microvascular pericytes to airway remodeling in a model of chronic asthma.
Methods: An established model of house dust mite-induced allergic asthma was used to study the contribution of pericytes to remodelling in mouse airways. Immunofluorescent staining was performed on trachea whole-mount preparations to evaluate the recruitment of pericytes to the airway wall following allergen exposure.

Results: Confocal imaging revealed that pericytes detach from blood vessels and accumulate below the airway epithelium, demonstrating that pericytes associated with the airway microvasculature can contribute to airway remodelling in asthma. This process was exacerbated when PDGF signalling was pharmacologically impaired using a PDGF-Ra inhibitor (CP-673451).

Conclusion: The data indicate that pericytes play an important role in the airway remodelling that occurs in asthma.

Even though the detailed mechanisms behind it have mostly remained unclear, the aim of the study was to characterize stromal cells cultured from small volumes of diagnostic bronchoalveolar lavage (BAL) fluid samples. Cells were collected from 98 patients representing distinct pulmonary diseases and the cultured cells were characterized by immunohistochemistry, electron and immunoelectron microscopy, flow cytometry and differentiation tests evaluated by RT-PCR and alkaline phosphatase activity measurements.

The success of the cell culture varied based on the disease of the donor (p=0.003). Morphologically the cultured cells were fibroblasts or myofibroblasts but they expressed also cell surface antigens typical for mesenchymal stromal cells (previously known as stem cells) being positive for CD105 (endoglin), CD90 (Thy-1), CD73 and CD44. Some of the cells showed high differentiation potential into adipogenic and osteogenic lineage (Fig. 1).

We conclude that some but not all stromal cells cultured from BAL fluid have similarities with stem cells, while some of them are fibroblasts and some are myofibroblasts.

PP125

Creation of lung mucosal tissue with human immune cells

Marthas Svensson1, Anh Thu Nguyen Hoang2, Puran Chen1, Julius Juarez1, Patty Sachsmir1, Lidija Bosnjak1, Bo Billing1, Barbo Dahlén2, Mark Coles2, 1Karolinska Institutet, Center for Infectious Medicine, F59, Karolinska University Hospital, Stockholm, Sweden; 2Centre for Immunology and Infection, at Hull York Medical School and Dept. of Biology, University of York, York, UK.

In pulmonary diseases, such as, e.g., infections, asthma, or cancer, abnormal inflammatory reactions lead to tissue destruction and remodelling, often associated with impaired lung function. Here, we describe the establishment of a novel human three dimensional (3D)-in vitro lung model with dendritic cells (DC), which will be used to further our understanding of human lung physiology and pathology in inflammatory pulmonary diseases. The tissue model recapitulates key anatomical and functional features of lung mucosal tissue, including a stratified epithelial cell layer, deposition of extracellular matrix proteins and the production of tight- and adherence- junction proteins. Labelling of fixed tissue model sections and imaging of live tissue models also revealed that DC distribute in close association with the epithelial layer. We also observed that the lung tissue model regulates the capacity of DC to produce the chemokines, CCL17, CCL18 and CCL22, leading to enhanced production of CCL18 and reduced production of CCL17 and CCL22. Furthermore, we use this model system to study human host-pathogen interactions and immune responses in the lung microenvironment in real time. This novel technological platform, we believe, provides an important tool to study immune cell regulation present in the lung and play a role in structural remodelling of the airway wall in asthma.

PP126

Stromal cells cultured from diagnostic bronchoalveolar lavage fluid samples possess stem cell like properties

Siri Lehdenen1,2, Marta Hohvonen3, T Harju3, R Sormunen3, E Lappi-Blanco3, R Kärnteeh1, 1Institute of Biomedicine, Department of Anatomy and Cell Biology, University of Oulu, Finland; 2Institute of Clinical Medicine, Respiratory Research Unit and Clinical Research Center, University of Oulu and Oulu University Hospital, Finland; 3Institute of Diagnostics, Department of Pathology and Biocenter Oulu, University of Oulu and Oulu University Hospital, Finland.

Stromal cells have significant role in the pathogenesis of several lung diseases and the airway wall in asthma where they are involved in the formation of the epithelial basement membrane.

Figure 1: Results of osteogenic differentiation test of 30 BAL fluid derived cell samples. The cells were cultured for 2 weeks with osteoinductive medium or control medium after which the activity of alkaline phosphatase was measured. The values form cells cultured with osteoinductive medium were compared to corresponding control cells so that value 100% indicates that no differentiation occurred and values above that indicate differentiation towards osteoblastic lineages.

PP127

Phospholipase D determines the virulence of Aspergillus fumigatus (A. fumigatus) into lung epithelial cells

Matthias Schmidt1, Li Han2, 1Molecular Pharmacology, University of Groningen, Groningen, Groningen, Netherlands; 2Institute for Infection Control and Research, Clinics Center for Disease Control & Prevention, Beijing, China.

A. fumigatus is a airborne fungal pathogen causing serious infections in immunocompromised patients. Phospholipases (PLs) like PLD as important member of the PL family in A. fumigatus, are key enzymes in pathogenic fungi that cleave host phospholipids, resulting in membrane destabilization and host cell penetration. In this study, disruption of the pld gene significantly decreases extracellular and cellular PLD activity of A. fumigatus. The pld gene disruption did not alter conidial morphological characteristics, germination, growth and biofilm formation, but significantly suppressed the internalization of A. fumigatus into A549 epithelial cells without affecting conidial adhesion to epithelial cells. Importantly, the suppressed internalization was fully rescued in the presence of 100μM phosphatidic acid, the PLD product. Indeed, complementation of pld (pldc) restored the PLD activity and internalization capacity of A. fumigatus, whereas A. fumigatus conidia phagocytosed by 3774 macrophages was not affected. PLD inhibition decreased specifically the internalization of A. fumigatus into A549 epithelial cells. Loss of the pld gene attenuated the virulence of A. fumigatus in mice inmunocompromised with hydrocortisone acetate, but not with cyclophosphamide. Thus, A. fumigatus PLD regulates its internalization into epithelial cells and may represent an important virulence factor for A. fumigatus infection.

PP128

Age-related changes in the relative expression of functional genes in mesenchymal stem cells

Martha Bustos1,2, María Kapetanaki1,2, Renée Meyer1, Albert Donnenberg1, Lyle Mrow1,2, Naftali Kaminski1,2, Ana Mora2, Mauricio Rois2,3, Simmons Center for Interstitial Lung Disease, University of Pittsburgh, PA, United States; Division of Pulmonary, Allergy & Critical Care Medicine, University of Pittsburgh, PA, United States; 3Division of Hematology/Oncology, Hillman Cancer Center, University of Pittsburgh, PA, United States.

Age-associated changes increased susceptibility to a variety of lung pathologies. Recently, mesenchymal stem cells or B-MSCs have emerged as a critical reparative response mechanism to lung injury. We had demonstrated an association, in animal models, between age and an increase in the susceptibility to injury and we had identified functional differences between B-MSCs from young and old mice. In the present study, we examined the consequences of aging in the gene expression. Methods: 3 and 24 months old B6 mice were sacrificed and B-MSC were isolated according to the expression of the surface markers. RNA was obtained after sorting and used for hybridization on Agilent gene expression microarrays. Ingenuity software was used to determine functional enrichment. For statistical analysis we applied significance analysis of microarrays. A q-value of 5, which corresponds to a 5% false discovery rate, was used as a cutoff of statistical significance. Gene validations were performed by RT-PCR.

Conclusion: The present study demonstrates that aging induce a decrease in the gene expression on B-MSC. The mechanisms affected by the decrease on gene expression includecellular trafficking, cellular growth and proliferation.

PP129

Epithelial regeneration in asthmatic patients treated with ultra-low doses of an alkylating drug melphalan

Alexander Pakhalovsky1,2, Galina Shmarina3, Kirill Zykov2, Vladimir Alisokin2, 1Research Centre for Medical Genetics, Moscow, Russian Federation; 2G.N. Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russian Federation; 3Moscow State Stomatology University, Moscow, Russian Federation.

Asthma and COPD are characterised by airway obstruction, airway remodelling and airway inflammatory reactions leading to tissue destruction and remodelling, often associated with impaired lung function. Here, we establish the establishment of a novel human three dimensional (3D)-in vitro lung model with dendritic cells (DC), which will be used to further our understanding of human lung physiology and pathology in inflammatory pulmonary diseases. The tissue model recapitulates key anatomical and functional features of lung mucosal tissue, including a stratified epithelial cell layer, deposition of extracellular matrix proteins and the production of tight- and adherence- junction proteins. Labelling of fixed tissue model sections and imaging of live tissue models also revealed that DC distribute in close association with the epithelial layer. We also observed that the lung tissue model regulates the capacity of DC to produce the chemokines, CCL17, CCL18 and CCL22, leading to enhanced production of CCL18 and reduced production of CCL17 and CCL22. Furthermore, we use this model system to study human host-pathogen interactions and immune responses in the lung microenvironment in real time. This novel technological platform, we believe, provides an important tool to study immune cell regulation present in the lung and play a role in structural remodelling of the airway wall in asthma.
and inflammation. These changes may be associated with accumulation in the lung of regulatory T cells (Tregs) and Th17 cells. Permanent expression of the surface receptors (IL-2R and IL-23R, respectively) is a common quality of these two cell subsets. Alkylating drug melphalan (MP) used in low non-toxic dose is capable to selectively inactivate Tregs and Th17 cells blocking the signal transmission by these receptors. Patients with severe steroid-dependent asthma were enrolled into the trial. 26 patients were inhaled with low dose of melphalan MP (0.1 mg/day during 5 days). 26 patients (control) besides basic therapy were inhaled with placebo. All patients demonstrated clinical improvement but the results in MP-treated patients were significantly better. Histological and ultrastructural signs of bronchial epitheliun regeneration have been revealed only in MP-treated patients. We observed normalization of goblet cell number, restoration of their ultrastructure, renewal of intercellular bridging, and significant reduction of edema in mucosa. The number of inflammatory cells was markedly decreased. Such restoration of epithelial phenotype may be associated with Treg number normalization; such restored epithelium is known to possess less proinflammatory properties than normal epithelium. There was no difference between MP-treated and placebo-treated patients in this respect. A possible role of Tregs and Th17 cells in asthma pathogenesis is suggested. This study is one of the first clinical trials to demonstrate the interplay of mitochondrial metabolism and inflammation in asthma.

Abstracts of the Tenth ERS Lung Science Conference, Estoril, Portugal – March 30–April 1, 2012

Clara cells contribute towards the resolution of cigarette smoke induced-inflammation

Rini Sabina Jahan Sarkar1, Gerrit John1, Katrin Kohse1, Alexander Bohla1, Oliver Eickelberg1, An Offner Yildirim1, Comprehensive Pneumology Center, Institute for Lung Biology and Disease, Munich, Germany; 2Institute of Experimental Pneumology, Klinikum der Universität München, Helmholtz Zentrum Muenchen, Munich, Germany

Introduction: COPD is characterized by chronic bronchitis and emphysema. The cause is cigarette smoke (CS) which triggers inflammatory response in lung. The precise mechanism of inflammation is yet unknown. Naphthalene (NA), a CS particle injures Clara cells (CC) due to their abundance of cytochrome P-450 monooxygenases. The objective was to chemically knockout CC by NA to investigate their involvement in inflammatory process in response to CS.

Methods: CS was applied for 3 days in NA pre-treated (†) or saline-treated (S) mice. Giems staining for BAL count, HE staining for histology and immunohistochemistry for CC staining were performed. CC number was assessed by stereology.

Results: Mice exposed to NA-CS invoked higher recruitment of inflammatory cells in BAL fluid compared with NA or saline treated mice alone. They also had less regeneration of CC. Furthermore, after 5 days of smoke cessation, macrophage and neutrophils in BAL of NA-CS group remained significantly higher compared to NA-only or CS-only treated mice.

Conclusion: CC contributed additionally to inflammation in Clara cell exfoliated lungs and further, delayed airway epithelial cell regeneration.

PP131

Mitochondrial metabolism controls lung fibroblast activation in vitro and in vivo

J. Schwarz, O. Eickelberg, HMGU, Comprehensive Pneumology Center, Munich, Germany

Background: Fibroblasts exhibit an extraordinary capacity to undergo fibroblast-myofibroblast activation in association with diseases such as pulmonary fibrosis. Little is known regarding the role of mitochondrial function in fibroblasts biology in general and phenotypic switching in fibrosis in particular.

Aims and objectives: To demonstrate the interplay of mitochondrial metabolism with fibroblast/myofibroblast activation.

Methods and results: We demonstrate that stimulated primary lung fibroblasts with the proinflammatory cytokine TGFβ1 results in an enhanced mitochondrial membrane potential (∆ψm). Moreover, proliferation, ECM deposition, and motility of these cells are increased compared to fibroblasts with low ∆ψm. Interestingly, TGFβ1-stimulated cells displayed increased expression of proinflammatory markers (IL-1, TNFα and Cox-2), demonstrating fibroblast-myofibroblast activation. To further corroborate these findings, we sorted primary lung fibroblasts for high and low resting ∆ψm (∆ψm(H/L)). While ∆ψm(H) fibroblasts are morphologically indistinguishable, they demonstrate increased myofibroblast activation compared to ∆ψm(L) fibroblasts. Finally, total cell homogenates derived from fibroblasts, myocytes- or teratoma-treated mice demonstrated increased ∆ψm compared with cell homogenates from saline-treated mice.

Conclusion: Our data suggest that mitochondrial metabolism plays an important role in the phenotypic activation of lung fibroblasts, both in TGFβ1 stimulated cells in vitro and bleomycin-induced fibrosis in vivo.

Scribble is required for normal epithelial cell-cell contacts in the mammalian lung

Charlotte Dean1,2, Laura Yates3, Carsten Schmatzweil3, Lee Hazelwood4, Charlotte Dean1,2, Laura Yates3, Carsten Schmatzweil3, Lee Hazelwood4, Lee Niswander5, Andy Greenfield6, Clare Lloyd1, Leukocyte Biology, Imperial College, United Kingdom; 2Mammalian Genetics Unit, MRC Harwell, United Kingdom; 3HHMI, Developmental Biology, University of Colorado, USA; 4Inst. Molecular Medicine, Leeds University, United Kingdom

Exploiting our knowledge of lung development may lead to novel therapeutic approaches to enhance the lungs’ intrinsic repair mechanisms. In Drosophila, Scrib is essential for apica- basal (A/B) polarity, but in mammals, perturbation of Scribble leads to defects in planar cell polarity (PCP). We investigated the function of Scribble in lung. We find that the lungs of Scribble mutant mice, Circletail (Ctc), are abnormally shaped with fewer airways. Many airways lack a visible lumen. The PCP pathway is perturbed in Scribble mutant lungs whereas A/B polarity appears unaffected. Scribble is expressed in both adherens and tight junctions of lung epithelium and time-lapse imaging reveals that Scribble localization is perturbed in mutant lung epithelium. Cytoskeletal organisation is also visibly disrupted. Using organotypic cultures as a model of de novo cyst formation, we show that Scribble is required for proper epithelial arrangement and lumen morphogenesis in mammalian lung development.

PP133

Down-regulated let-7b and mir-126 in tumors and surrounding tissue correlate with high microvessel density and poor survival outcomes in non-small-cell lung cancer patients

Edin Jusupovic1,2, Marjita Rijovec1, Dragan Keser1,2, Eva Sdroja1, Ermina Bajovac2, Zerica Radijevic2, Mitja Kosmic1,2,1 Polyclinic for Pulmonary Diseases, Health Medical Centre, Tuzla, Bosnia-Herz; 2Medical Faculty, University Tuzla, Tuzla, Bosnia-Herz; 3Laboratory for Clinical Immunology and Molecular Genetic, University Clinic for Lung Diseases and Allergies, Golnik, Slovenia; 4Department for Pulmonary Diseases, General Hospital, Uzice, Serbia

32 squamous lung carcinoma, 18 lung adenocarcinoma and 45 healthy individuals were included. let-7b and mir-126 expression were detected by real-time RT-PCR. Expression of these miRNAs in tissue from early stages of lung cancer patients (tumor, tumor surroundings and healthy lung tissue) was compared. Expression of anti-angiogenic let-7b and miR-126 were significantly lower in tumor tissue and surrounding compared to both healthy lung tissue of diseased patients and control. There was no difference between tumor and tumor surrounding tissue. High let-7b expression and mir-126 expression were highly associated with both better progression-free and overall survival. High micro-vascular density was negatively associated to let-7b and miR-126 expression and highly associated with poor outcome. Our results confirm a possible role of these two miRNAs in lung cancer angiogenesis and suggest the potential new target antiangiogenic lung cancer therapy.

Effects of stem cells of healthy or acute lung injury donors of recipient injury mice

J.D. Silva1, B. Paredes2, I.M. Araújo2, M.L. Pacheco2, M.V. Oliveira2, G. Bucher1, L. Facchioli1, E.F. Assis4, H.C.C. Faru-Neto3, R. Goldenberg3, A.C. Carvalho2, M.M. Morales1, P. Pelosi1, D.G. Xisto1, P.R.M. Roccio1, LIP, UFRJ, Rio de Janeiro, Brazil; 2LCMC, UFRJ, Rio de Janeiro, Brazil; 3LFMC, UFRJ, Rio de Janeiro, Brazil; 4ISS, University of Genova, Genoa, Italy

We aimed to investigate the effects of BMDMCs from healthy and ALI donors in experimental model of ALI. For this, 55 female C57BL/6 mice were randomly assigned into four groups. The control group received saline. ALI mice received E. coli LPS intratracheally (ALI-LP) or intraperitoneally (ALI-Ip). After 24, 48 and 72h whole BMDMCs from all groups were subjected to co-culture with bone-marrow units-fibroblastoid (CUF-F) and flow cytometry. After cell characterization, all animals were treated with saline or BMDMCs (v:v) obtained from healthy and ALI donors at 24h. In ALI, CUF-F assay showed a predominance of non-stromal cells over fibroblastoid colony. In ALI-LP, an irregular CUF-F morphology was observed. In ALI, monocytes and T lymphocytes were increased and hematopoietic precursor cells reduced. At day 7, mortality rate was higher in ALI groups, and after BMDMC therapy reduced. BMDMCs attenuated lung mechanics, neutrophils, alveolar collapse, as well as fibers content. Additionally, reduced the levels of cytokines in lung tissue independent of cell origin. BMDMCs reduced the inflammatory and fibrogenic processes, improving lung mechanics; nevertheless, BMDMCs from ALI animals were less effective at reducing the inflammatory process compared to those originated from healthy donors.

The ability to produce respiratory epithelial cell types offer new therapeutic options to treat pulmonary diseases. We therefore aimed at identifying key factors which drive the differentiation of murine pluripotent stem cells (mPSCs) into airway epithelial Clara and branching epithelial type II (ATII) cells. Keratinocyte growth factor (KGF) is known as a strong growth factor at least for primary ATII cells and glaucoma cells and also stimulate a factor that may be the maturation of primary lung epithelial cells. In the present study we were able to identify a synergistic effect of KGF and glaucoma cells in lung epithelial cells by qRT-PCR, microarrays, immunostaining and electron microscopy.

PP139
Key factors for the differentiation of pluripotent stem cells into lung epithelial cells
Sabrina Schneckebir1, Katharina Katsirimtak2, Christina Maurita3, Malte Sgodd2, Verena Pappi2, Julia Duerr2, Andreas Schmiedl3, Quong Lin4, Matthias Ochs1, Martin Zentz1, Tobias Canta2, Marcus Mall3, Ulrich Münch5, Lenniz Research Laboratories for Biotechnology and Artificial Organs, Medical School Hannover, Hannover, Germany; 2Junior Research Group Stem Cell Biology, Medical School Hannover, Hannover, Germany; 3Division of Pediatric Pulmonology and Cystic Fibrosis Center, Department of Pediatrics III, University of Heidelberg, Heidelberg, Germany; 4Institute for Functional and Applied Anatomy, Medical School Hannover, Hannover, Germany; 5Institute for Biomedical Engineering/Cell Biology, Aachen University Medical School, RWTH Aachen, Aachen, Germany

Rationale: Cigarette smoke is the major cause of COPD/emphysema but the etiology of these diseases is still unknown. Both β-catenin and CAAAT/enhancer binding protein alpha (C/EBPα) are key regulators of cell proliferation, with β-catenin being a negative regulator of C/EBPα. Thus decreased β-catenin signaling may be involved in the paracrine tissue destruction leading to emphysema.

Objectives: Investigate the effect of cigarette smoke on the expression of β-catenin, C/EBPα and cell proliferation in primary human lung fibroblasts.

Results: Cigarette smoke significantly down-regulated β-catenin expression which coincided with increased C/EBPα levels (inverse ratio) and thereby decreased primary lung fibroblast proliferation.

Conclusion: Cigarette smoke reduces lung fibroblast proliferation through β-catenin dependent up-regulation of C/EBPα. This mechanism may underlie the impaired tissue repair in COPD which leads to parenchymal destruction in the lung of COPD/emphysema patients.

PP141
LRIG1 regulates cadherin-dependent contact inhibition directing epithelial homeostasis and preinvasive squamous cell carcinoma development

Epidermal Growth Factor Receptor (EGFR) pathway activation is a frequent event in lung cancer with over-expression one of the earliest abnormalities in the bronchial epithelium of smokers and present in all stages of preinvasive cancer. Mutations in EGFR itself are rare and the mechanisms regulating EGFR pathway activation remained elusive. Leucine-rich immunoglobulin repeats-1 (LRIG1), an inhibitor of EGFR activity, is one of 4 genes identified that predict patient survival across solid tumor types. We hypothesize that tissue homeostasis is maintained via strong endogenous regulation of EGFR signaling by the inhibitor LRIG1 and its loss is the key step in the initiation of preinvasive lung cancer.

Abstracts of the Tenth ERS Lung Science Conference, Estoril, Portugal – March 30–April 1, 2012
Our experiments show that deletion of LRG1 is sufficient to promote murine airway hyperplasia. In vitro, LRG1-deficient cells display loss of contact inhibition, whereas re-expression of LRG1 in human lung cancer cell lines impairs growth. We find that LRG1 forms a ternary complex with EGF and E-Cadherin at the cell surface. This complex modulates the activity of the EGFR and downstream pathways. We also show that loss of heterozygosity at the LRG1 locus as well as down-regulation of LRG1 gene expression are early events in the development of preinvasive human squamous lung cancer.

Our findings imply that lung cancer development is driven by a change in the amplitude of EGF signaling governed by the loss of contact inhibition.

PP142
Endothelial progenitor cells and the endothelin system
Susanna Desole, Florian Albrecht, Helene Vogelsinger, Katharina Cima, Christian Kuhler. Pneumonology/USPH Innsbruck, Department of Internal Medicine I, Medical University Innsbruck, Austria

Bone-marrow-derived endothelial progenitor cells (EPCs) might play a key role in the formation of new vessels. Endothelin-1 (ET-1) is known to modulate different stages of neovascularisation. We investigated a potential link between the ET system and EPCs in pulmonary hypertension (PH).

EPCs were isolated from Sprague-Dawley rats and rat pulmonary artery (palECs) endothelial cells served as positive control. ET-A and B receptor expression and detection of prepro-ET and ET converting enzyme (ECE) mRNA were performed by RT-PCR.

In calcium (Ca2+) flux assays EPCs loaded with FURA-2 were exposed to ET-1 [10-7M and 10-8M]. For selective inhibition of receptor subtypes, EPCs were pre-incubated with ETR (BQ123) or ETRB (BQ788) antagonists for 20 min before stimulation with ET-1. ETRB and BQ788 strongly inhibit EPCs expression of ET receptor subtypes. Both pre-pro-ET and ET-encoding mRNA could be detected in EPCs. In Ca2+ flux experiments addition of ET-1 elicited a significantly increased intracellular Ca2+ flux which could be inhibited by BQ123 (90%) and BQ788 (45%).

We proved for the first time the expression of both ETR and ETRB and detected mRNA of prepro-ET and of ECE on EPCs. We also found that ET-1 activates Ca2+ flux in EPCs. In summary, our data reveal for the first time a link between EPCs and the ET system.

PP143
Soluble curcumin-cyclodextrin complexes display an anti-proliferative effect on bronchial epithelial cells
Natalya Rocks, Sandrine Becka, Brigitte Evrard, Didier Cataldo, Agnès Noel. Laboratory of tumors and developmental biology (GIIG-research center), University of Liege, Liege, Belgium

Introduction: Epithelial cells from lung allografts have been shown turning into fibroblasts through epithelial mesenchymal transition (EMT) and participate in obliterative bronchiolitis.

Methods: CycloDEXtrins have been used as an excitant to form complexes rendering curcumin soluble.

Results: In vitro, curcumin-cyclodextrin complexes reduced cell proliferation whereas proliferation rate was increased in epithelial cells from Lewis Lung carcinoma. Lungs of C57Bl/6 mice were engrafted with Lewis Lung carcinoma and mice were treated daily by an oral administratio n of curcumin-cyclodextrin complexes or control. The incidence and size of obliterative bronchiolitis were significantly decreased in epithelial cells from Lewis Lung carcinoma.

Conclusion: Our data demonstrate that curcumin, when given orally in a soluble complex with cyclodextrin reduces epithelial cell proliferation, increases cell apoptosis in vitro and reduces lung tumor size and incidence in vivo. Our data strongly suggest that curcumin controls cell cycle suggesting potential applicability in lung cancer and in other diseases where the epithelium undergoes proliferation and EMT.

PP145
Repair of cigarette smoke-induced loss of barrier function: Role of AKAPs
Amos Oldenburger1, Wolter Rijks1, Varsha Selvabalsak1, Irene Heijnen2, Harm Maarssen1, Martina Schmidt1, 1. Molecular Pharmacology, University of Groningen, Groningen, Netherlands; 2. Lab of Allergology and Pulmonary Diseases, Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands

Cigarette smoke causes epithelial damage, which may contribute to the development of COPD. Epithelial barrier is maintained by the cell-cell contact molecule E-cadherin. Interestingly, AKAPs (A-kinase anchoring proteins, particularly AKAP9), which coordinate cAMP signaling in the cell, are known to associate with E-cadherin. Therefore, we hypothesized that AKAPs play a critical role in maintaining epithelial barrier function and integrity, e.g. upon damage by cigarette smoke. To this aim, we studied the effect of cigarette smoke extract (CSE) on electrical cell-substrate impedance sensing (IECS) and on the expression of E-cadherin in human bronchial epithelial cells. CSE markedly reduced the epithelial barrier function (IECS) and caused delocalization of E-cadherin from cell-cell contacts. These processes were completely prevented by disruption of AKAP complexes using HS31. Interestingly, CSE reduced AKAP expression, while reexpression of the expression of AKAP9 and AKAP12 (which are not associated with E-cadherin) nearly unaffected. In conclusion, AKAPs contribute to CSE-induced disruption of the human bronchial epithelial barrier by translocation of E-cadherin from the cell membrane.

Phenotypic profiling of invading lung fibroblasts in 3D cell culture models
Rotina Oehlig1, Gerald Burgstaller1, Martin Irmler1, Johannes Beckers1, Oliver Eickelberg1, 1 Comprehensive Pulmonary Medicine, HMGU, Munich, Germany; 2 Institute of Experimental Genetics, HMGU, Neuherberg, Germany

Rationale: Fibroblasts exhibit an extraordinary capacity to undergo phenotypic changes during development and disease, both in vitro and in vivo. These changes include altered motility, migration or activation. Enhanced migratory capacity of primary lung fibroblasts (f) in f patients was found in vitro, but the underlying mechanisms remain elusive. The aim of this study was to decipher morphological, molecular and functional differences between invading (i) and non-invading (n-i) f in 3D cell culture models.

Methods/Results: We established a high-content 3D invasion model, enabling the separation of i from n-i f allows the comparative analysis of parameters like morphology, invasion depth and protein/mRNA expression levels. Analysis revealed two significantly distinct subtypes. 7.6% of untreated f invaded the collagen matrix. Invasion was augmented by TGFß and EGF treatment. Gene expression analysis of one sample demonstrated significantly different expression profiles. Several markers, previously reported to be associated with i f, were also upregulated. We identified an early stage of invasion (ex. ratio=4.47), MMP3 (3.97), Osteopontin (1.45), Pten (0.34) and genes of unknown function, were found deregulated in f.

Conclusion: f show two distinct subtypes in a 3D cell culture model. Gene expression profiling of f revealed features highly similar to the (myo)fibroblast phenotype found in f. Our 3D invasion model constitutes a highly useful tool for high-content pharmacological screenings.

PP147
NLRP3-inflammasome pathway activation in fibrotic lung diseases in human bronchoalveolar lavage fluid (BALF)
Katerina Samara1, Ioannis Giamarakis2, Ismini Lasisiotiakis, Georgios Margaritopoulos1, Christina Choulaki1, Prodromos Sidereopoulos2, Nikolaos Siafakas2, Katerina Antoniou1, 1 Thoracic Medicine, 2 Rheumatology, Medical School, University of Crete, Heraklion, Greece

NLRP3-inflammasome triggers an immune response via maturation of interleukin-1ß (IL-1ß) in a caspase-1-dependent way. Our aim was to investigate the NLRP3 pathway activation in idiopathic and autoimmune pulmonary fibrosis.

We studied BALF and peripheral blood leukocyte samples from 10 IPF pts, 5 RA-ILD pts and 4 controls. All samples were treated with LPS and pulse ATP TFNα and IL-1ß levels were measured using ELISA. LPS treatment increased TFNα levels in all groups and IL-1ß levels in the control and RA-ILD but not in the IPF (p<0.05). The ATP pulse resulted in elevated blood TFNα and IL-1ß levels in all groups. Inhibition of caspase-1 resulted in decreased TFNα secretion in IPF and RA-ILD blood leukocytes compared to controls (p<0.05). LPS plus leupeptin treatment in BALF resulted in a twofold increase in TFNα and IL-1ß levels in RA-ILD, whereas the IPF group exhibited a decrease in both TFNα and IL-1ß levels. This effect was slightly reversed when NLRP3 activation was blocked via inhibition of caspase-1.

The RA-ILD group showed a tendency to up-regulate the NLRP3 pathway compared to controls and IPF. The IPF group seems to lose the ability to activate this pathway in the presence of infectious stimuli, thus suggesting a compromise of the innate immunity regulation in IPF.

PP148
ILP2 protects against LPS-induced lung injury and mortality
M Funke1,2, BA Fontaine1, BS Shee3, T Geiser1, AM Tagger1, 1 Pulmonology, Inselspital, Bern, Switzerland; 2 Pulmonary and Critical Care Unit, MGH, Harvard Medical School, Boston, USA

Lung injury is the initial event in the pathogenesis of idiopathic pulmonary fibrosis and acute lung injury (ALI). In ALI, acute respiratory distress syndrome. But though the inciting events in these pulmonary pathologies may be similar, their differing outcomes suggest that lung injury may activate different pathways. We previously identified lysophosphatidic acid (LPA) signaling specifically through its receptor LPA1 in the pathogenesis of pulmonary fibrosis (PF), finding that LPA1KO mice were protected from bleomycin-induced lung fibrosis. Here we investigated the role of ILP2 in the pathogenesis of both PF and ALI in LP2KO mice.

Methods: To study ALL LP2KO and WT mice were challenged with LPS. BAL was analyzed for cell counts and total protein. Additional mice were challenged with i.p. LPS and survival was monitored. To study PF, LP2KO and WT mice were challenged with i.t. bleomycin. BAL was analyzed for cell counts and total protein. Levels were measured using ELISA. LPS treatment increased ILP2 levels in all groups. Inhibition of caspase-1 resulted in decreased ILP2 secretion in IPF and RA-ILD blood leukocytes compared to controls (p<0.05). LPS plus leupeptin treatment in BALF resulted in a twofold increase in ILP2 and IL-1ß levels in RA-ILD, whereas the IPF group exhibited a decrease in both TFNα and IL-1ß levels. This effect was slightly reversed when NLRP3 activation was blocked via inhibition of caspase-1.

The RA-ILD group showed a tendency to up-regulate the NLRP3 pathway compared to controls and IPF. The IPF group seems to lose the ability to activate this pathway in the presence of infectious stimuli, thus suggesting a compromise of the innate immunity regulation in IPF.
Results: In ALI, LPA2KO mice had higher BAL leukocyte and protein levels, and lung collagen content was not different between ALI and WT mice. LPA2KO mice showed increased survival compared to WT mice (p = 0.02). In contrast, in PF, LPA2KO mice showed lower BAL protein levels and reduced collagen content compared to WT mice (p = 0.04). The survival of LPA2KO mice was not statistically different from WT mice. LPA2KO mice treated with indomethacin showed increased survival compared to WT mice (p = 0.03), indicating the role of LPA signaling in the regulation of survival in ALI and PF.

Conclusion: LPA signaling through LPA2 mediates protective anti-inflammatory effects in the LPS-induced model of ALI, while in the PF model, LPA2 mediates cardioprotective effects. These findings highlight the potential role of LPA signaling in the development of acute lung injury and pulmonary fibrosis.

PP149
Retinoic acid-TGF-β1 crosstalk during alveolar regeneration in hyperoxic mice
Ozgucan Kayalar, Fatma Oray, Department of Biology, Istanbul University, Faculty of Science, Istanbul, Turkey

This study aimed to detect whether retinoic acid (RA) has an effect on alveolar regeneration in adult hyperoxic mice and to investigate the relationship between RA and TGF-β1 during alveolar repair. Adult C57BL/6J mice were divided into 4 groups and administered (intraperitoneally, daily, for ten days): peanut oil/dimethylsulfoxide (PoDMSO); RA dissolved in PoDMSO; PoDMSO following T2hr hyperoxia (100% oxygen); RA following hyperoxia. The structure in alveolar areas was investigated by microscopy. TGF-β1, Smads and RAGE expressions were assessed by ELISA, WB and qRT-PCR in the lung. The lung of hyperoxic mice was characterized by damage of alveolar wall, reduced in numbers of alveoli and septa, and increased in alveolar diameter and mitotic index, depending on using of Smad3/TGF-β1 signaling. RA2 protein expression did not alter in all groups. Exogenous RA in hyperoxic mice improved degenerative alterations, induced partially alveolarization and depressed RAGE mRNA. This effect of RA originated from the inhibition of Smad3/TGF-β1 signaling via reduced Smad4 mRNA and increased Smad7 protein levels. Exogenous RA induced alveolarization and restricted Smad3/TGF-β1 signaling by decreasing of Smad4 mRNA in healthy mice. RA improved the alveologenesis and regulated Smad3/TGF-β1 signaling at transcriptional and translational levels via Smad4 and Smad7 in healthy and hyperoxic mice. RA can be used to repair of TGF-β1 induced lung damage in hyperoxic mice, except for type I pneumocytes differentiation.

PP150
Effect of Pirfenidone on pulmonary fibrosis due to Paraquat poisoning in rats
Shanash Sedda, 1 Amithosein Keshavarz1, Shima Aran2, Hamidreza Abbasi1, Seyed Reza Mirzadeh1,2, Shervin Taslimi1, Alireza Ghaffari1.

To evaluate the effectiveness of Pirfenidone (PF), a new anti-fibrotic drug on paraquat-induced pulmonary fibrosis in rats. Inhalation exposure of rats to paraquat (20 mg/kg) was used. Severity of the lung disease was evaluated using a histological score and BAL protein levels. Pirfenidone treatment significantly reduced the histological score and BAL protein levels compared to the control group. The results of this study suggest that PF has a potential to be used as a treatment for paraquat-induced pulmonary fibrosis.

Conclusion: PF can be used as a potential anti-fibrotic drug for the treatment of paraquat-induced pulmonary fibrosis.
Effects of the Hedgehog (Hh) pathway inhibitor GDC-0449 on lung cancer cells and cisplatin resistant lung cancer cells are mediated by lung cancer Effects of the Hedgehog (Hh) pathway inhibitor GDC-0449 on lung cancer cells. This effect is mediated by inhibition of stem cell-like... 

We aimed at investigating if Hh pathway inhibitor GDC-0449 is effective in the lung cancer cell lines HCC (adeno-carcinoma) and H1339 (small cell lung carcinoma) and also the corresponding cisplatin resistant lung cancer cells, and if possible effects of GDC-0449 are mediated via SPs. GDC-0449 inhibited concentration dependently cell growth in both lines, and also cisplatin resistant cells. In HCC and H1339 SPs of 0.57 and 0.46 % could be identified, respectively, while in cisplatin resistant cell lines, those were identified as 2.8% and 3.4%, which were significantly higher than the non-cisplatin-resistant lung cancer cell lines. In both cisplatin resistant and non-resistant cells, SP but not non-SP cells were able to reepithelialise the original tumour population. The Hh receptor smoothened was detectable in SP but not in non-SP cells, showing activation of Hh only in SP. GDC-0449 considerably reduced SP in HCC and H1339 cells, and also in cisplatin resistant HCC and H1339 cells. We demonstrate for the first time that GDC-0449 effectively reduces cell growth in lung cancer cell lines, and remarkable in cisplatin resistant lung cancer cells. This effect is mediated by inhibition of stem cell-like SPs.

PP154
Evaluation of the cellular and molecular mechanisms involved in the anti-inflammatory effects of aerobic exercise in a murine model of asthma Rodolfo de Paula Vieira1, Rodolfo de Paula Vieira1, Marco Izzo2.
1 Clinical Medicine (LMM 20), University of Sao Paulo, School of Medicine, Sao Paulo, Brazil; 2Pneumology, University Hospital Freiburg, Freiburg, Germany

Aims: Investigate the participation of ATP, airway epithelial cells and dendritic cells on the anti-inflammatory effects aerobic exercise in a model of chronic allergic airway inflammation.

Methods and results: C57Bl6 mice (n=10) were divided in Control, Exercise, OVA and OVA+Exercise groups, submitted to a chronic OVA protocol and to exercise for 4 weeks. OVA increased the levels of ATP in BALF, which was abolished by exercise. Exercise also reduced the number of eosinophils in BALF and also in the airway wall, beyond the expression of MUC5AC and the collagen deposition. The effects of exercise in sensitized animals were followed by reduced BALF levels of IL-4, IL-5, IL-6, IL-13 and increased levels of IL-17p70 and IL-10, and also by reduced levels of IL-4, IL-5 and IL-13 in re-stimulated mediastinal lymphocytes. Exercise also reduced the expression of IL-23 and IL-12p35 in lung epithelial cells, DCs stimulated with OVA, obtained from exercised animals presented reduced expression of MHC-II and also decreased production of IL-6, KC, IL-12p70 when compared with DCs obtained from non-exercised mice.

Conclusion: We conclude that aerobic exercise reduced chronic airway inflammation, which could be partially attributed to reduced levels of ATP and epithelial expression of P2x in the airways and also to reduced maturation and function of dendritic cells.

PP155
The interaction of endothelial progenitor cells and pulmonary artery smooth muscle cells in PAH: A further step in understanding vascular remodeling? Susanna Dasale1, Silvia Biander2, Katharina Cima3, Christian M. Köhler1.
1 Pulmonology/USPH Innsbruck, Department of Internal Medicine I, Medical University Innsbruck, Innsbruck, Austria; 2 Rheumatology, Department of Internal Medicine I, Medical University Innsbruck, Innsbruck, Austria

In contrast to suggested beneficial effects of endothelial progenitor cells (EPCs) on vascular remodelling in pulmonary hypertension (PH), EPCs might even be harmful by e.g. stimulating pulmonary artery smooth muscle proliferation (paSMC). We investigated the effects of EPCs on paSMCs. Rat bone marrow EPCs were cultured under different growth conditions (0.5% and 10% FCS). Supernatants were collected after 8h and tested for growth stimulating capacity on paSMCs. Proliferation was measured by colorimetry after 48h of incubation. Supernatants were analyzed for their content of key peptides of PH by ELISA. Cell surface receptor activation in SMCs was detected by intracellular β2-Rx. EPC supernatants stimulate paSMCs proliferation. This effect was significantly higher if supernatants from EPCs cultured in 10% FCS were used. In supernatants detected EPCs included VEGF and endothelin-1. Stimulation of Para-2 loaded paSMCs with EPC supernatants led to an increase in intracellular Ca2+ comparable to the effects of pure ET-1. EPC supernatants significantly stimulate the proliferation of paSMCs. It could be suggested that homing of EPCs to vascular lesions as seen in PH might be potentially deleterious.

PP156
A-kinase anchoring proteins (AKAPs) coordinate IL-8 release by airway smooth muscle cells (ASM cells) via the β2-adrenoceptor (β2AR). CMJ Popppina1, LJ Holtzer2, E Kluusmann3, MC Michel3, AH Halayko4, W Timmes5, M Schmidt6, H Maarsingh7, 1 Mol Pharmacol, Groningen, Netherlands; 2 MDC, Berlin, Germany; 3 Clin Devel, BI Pharma, Netherlands; 4 Physiol, Manitoba, Canada; 5 Pathol, Groningen, Netherlands

β2-agonists alleviate broncho-obstruction in COPD by increasing cAMP-dependent PKA/Epic activation in ASM. PKA and Epic both reduce the cigarette smoke extract (CSE)-induced IL-8 release from ASM. AKAPs function as docking sites for cAMP signaling proteins and create CAMP compartments. Interestingly, AKAPs and -12 are involved in β2AR de- and resensitization, respectively. We studied AKAP expression profiles in CSE-exposed ASM and lung tissue of COPD patients and determined IL-8 release as functional readout. Human ASM express AKAP5, -12 and -9. CSE downregulated expression of AKAP12/13 and AKAP5, but not AKAP16. In lung tissue of COPD patients all these AKAPs were downregulated. In ASM, fenoterol dose dependently decreased IL-8 release, as observed by direct activation of PKA (and only marginally) Epac. IL-8 release was augmented by the p31, an AKAP inhibitor. In the presence of a selective AKAP12 inhibitor the reduction in IL-8, whereas the direct PKA activator was still fully effective. St-H3 induced fully the inhibitory effect of fenoterol on CSE-induced activation of ERK, known to underlie IL-8 release, demonstrating that the p31 or AKAP12-13-induced CAMP signalling leads to ERK degradation. In conclusion, AKAPs are expressed in the airways and coordinate the communication between β2AR, CAMP effectors and ERK in reducing CSE-induced IL-8 release. The alterations in AKAP expression could therefore contribute to CAMP and airway treatment.
PP159
Angiotensin-I-7 attenuates pulmonary neutrophil influx and pulmonary hypertension-induced right ventricular hypertrophy in neonatal hypoxic lung and heart injury in rats
Gerry T.M. Wagenast, El Houari Laghmani, Yvonne P. de Visser, Frans J. Wallner. Pediatrics, Laboratory of Neonatology, Leiden University Medical Center, Leiden, Netherlands

Cyclic angiotensin peptide 1-7 (cAng1-7), a selective ligand for the MAS onco-gene receptor, may be a novel therapeutic agent for neonatal chronic lung disease (CLD) or bronchopulmonary dysplasia by counterbalancing the adverse effects of the potent vasoconstrictor angiotensin II, including pulmonary inflammation and arterial hypertension (PAH)-induced right ventricular hypertrophy (RVH).

We determined the cardiopulmonary effects of cAng1-7 in neonatal rats with hyperoxia-induced CLD in 2 models: a prophylactic and an injury-recovery model. Parameters investigated include lung and heart histopathology, fibrin deposition, and differential mRNA expression in the lungs of key genes involved in inflammation, coagulation and alveolar development.

Prophylactic treatment with cAng1-7 for 10 days improved cardiopulmonary injury by reducing alveolar septum thickness, medial wall thickness of small arteries and the influx of neutrophils, and preventing RVH. cAng1-7 did not reduce alveolar enlargement, the pulmonary influx of macrophages, fibrin deposition and vascular alveolar leakage. In conclusion, cAng1-7 attenuates cardiopulmonary injury by reducing acute lung injury and reversing PAH-induced RVH, but does not affect alveolar and vascular development in neonatal rats with experimental CLD.

The cell-penetrating P1pal-12 peptide limits pulmonary fibrosis in the murine bleomycin model
C. Lin, I.W. Duitman, K. Borenstizn, C.A. Spek. CEMM, Academisch Medisch Centrum (AMC), Amsterdam, Netherlands

Idiopathic pulmonary fibrosis is the most devastating fibrotic diffuse parenchymal lung disease which remains refractory to available pharmacological therapies. Therefore, novel treatment options are urgently required. Protease-activated receptor 1 (PAR-1) is a heptahedral G-protein coupled receptor that mediates critical signaling pathways in pathology. Interestingly, bleomycin-induced lung fibrosis was shown to be diminished in PAR-1 deficient mice. We thus hypothesized that pharmacological PAR-1 inhibition may be an interesting therapeutic approach to combat pulmonary fibrosis. Consequently, we explored the effect of P1pal-12 (a cell-penetrating blocking the PAR-1/G-protein interaction) during the development of lung fibrosis induced by intranasal instillation of bleomycin. We show that once daily treatment with 0.5, 2.5 or 10 mg/kg P1pal-12, reduced severity and extent of fibrotic lesions in a dose-dependent manner (2.5 and 10 mg/kg). These findings correlated with significant decreases in collagen and α(SMA) mRNA expression levels in treated mice. Moreover, fibrin deposition in the lungs was reduced by 26% ± 3% (p < 0.05) in 2.5 mg/kg treated mice compared to untreated controls. Finally, P1pal-12 reduced bleomycin-induced IL-6 and MCP-1 levels in lung homogenates by 65 ± 3% (p < 0.01) and 36 ± 3% (p < 0.05) respectively. Overall, our data show that P1pal-12 limits lung fibrosis suggesting that targeting PAR-1 may be a promising therapeutic strategy for pulmonary fibrosis.

Symbiotics reduce airway inflammation and improve airway function in a mouse model for COPD
Gillima Bezemes,1 Maria Diks,1 Jeroen van Bergenheuwen2,3, Johan Gerssen4, Paul Henricks1, Aletta Kraneveld1, Gert Folkers1, CEMM, Academisch Medisch Centrum (AMC), Amsterdam, Netherlands

Background: Gut health plays an important role in maintaining immunity in and beyond the gastrointestinal tract. Respiratory disorders can be influenced by disturbed gut microbiota. Chronic obstructive pulmonary disease (COPD) is disease is characterized by a progressive airflow limitation caused by an abnormal inflammatory response. Aim of this study is to investigate the effectiveness of dietary fibers and lactic acid producing bacteria in a mouse model for COPD.

Methods: BALB/c mice were instilled intra nasally (i.n.) with LPS, 3x per week and ventilated mice. Treatment with either GOS/FOS or GOS/FOS combined with Bifidobacterium or Probiotic Bifidobacterium or 3)

Results: Treatment with either GOS/FOS or GOS/FOS combined with Bifidobacterium was able to reduce the influx of macrophages and neutrophils into BAL f. Prebiotics without GOS/FOS were not able to modulate airway inflammation in this model. Only treatment with symbiotics was able to attenuate LPS induced reduction in airway function.

Conclusion: A combination of Bifidobacterium and GOS/FOS might be beneficial in COPD.

This study was performed within the framework of Dutch TI-Pharma.

PP162
Imaging Wnt/β-catenin signalling in an ex vivo tissue culture model of lung repair
Friszanka Uhl, Melanie Königshoff. HMGU, Comprehensive Pneumology Center, Munich, Germany

Emphysema is a pathophysiological hallmark of COPD and characterized by airspace enlargement and impaired alveolar repair processes. Recently, decreased Wnt/β-catenin signalling has been linked to impaired epithelial remodeling in human disease and animal models thereof. Here, we aim to further decipher the underlying mechanisms and image structural changes involved in lung repair processes.

We applied an ex vivo tissue culture model from wildtype (C57Bl/6) and Wnt reporter mice (Bat/TopGal) subjected to elastase treatment or PBS. Tissue slices (300 μm) generated using a vibratome were viable in culture for up to 7 days ex vivo (WST-1: d3 211±68% vs. d7 241±67%). Structural integrity of control (C) and emphysematous (E) lung slices was determined by qPCR and immunofluorescence for lung specific cellular markers as well as live tissue imaging. Functional Stiffness was decreased in E lung slices compared with control and further decreased over time shown by ELISA (d1: 135±19 ng/ml C vs. 82±17 ng/ml E). Wnt signalling activation by LLCi led to an increase in Sftpc expression accompanied by increased β-galactosidase staining in alveolar regions and upregulated target gene expression, such as Axin2, Dkk2 or Lef1.

Emphysematous tissue slices closely reflect COPD-like changes in vivo. Lung slices are viable up to 7 days ex vivo allowing determination of structural changes and cell fate in the diseased lung upon signal pathway modification.

PP163
Altered angiogenic potential of ASM from asthmatic patients
Laura Kellnerich, Emmanouil Kyriakakis, Maria Philippova, Thérèse J. Resink, Michael Tamm, Michael Roth, Pieter Borger. Department Biomedizin, Universitätsspital Basel, Basel, Switzerland

Airway remodelling is a key pathology in asthma which causes changes of the airway wall structure, including thickening of airway smooth muscle (ASM) bundles and increased vascularisation. Increased airway wall cells require oxygen and nutrients which are delivered by blood vessels. Understanding the mechanism of neo-vascularisation therefore may lead to novel therapeutic strategies to counteract remodelling. The capacity of ASM cells (ASMC) of asthmatics and non-asthmatics to induce endothelial cell sprouting was determined. Asthma specific expression of angiogenic factors was determined by protein array (43 proteins), and increased expression was confirmed by ELISA. Conditioned Medium (CM) from ASMC cells was tested by endothelial cell sprouting assay. CM of asthma patient derived ASMC induced more sprouting compared to CM derived from controls. The asthma specific increased CXC-chemokines ENA-78, GRO-alpha and IL-8 were confirmed by ELISA. Our results indicate that the angiogenic potential of ASM of asthma patients is higher compared to that of control ASM. The ELR+ chemokines ENA-78, GRO-alpha and IL-8 were upregulated in asthmatics.
and might therefore contribute to neo-vascularisation. Counteracting this process may lead to novel therapies in asthma. (SNF 320003_1249051.)

The repair of monocyte-derived hepatocytes from alpha antitrypsin deficient patients
Gillian McNab1, Robert Stockley1, 1Lang Investigation Unit, Queen Elizabeth Hospital, Birmingham, United Kingdom; 2Centre for Translational Research, University of Birmingham, Birmingham, United Kingdom

This study explores the culture of monocyte-derived hepatocytes from PiZ alpha antitrypsin deficient (a1ATD) patients and homologous replacement using small DNA fragments (SDFs) to correct the Z defect. Monocytes from 3 patients were de-differentiated with MCSF and IL3 and then differentiated into hepatocytes with FGF-4. Albumin, urea and a1AT were measured. SDFs were transfected into hepatocytes and cDNA checked for the M or Z message. No albumin was detected from monocytes. Hepatocytes secreted 250±50 mg/dL albumin/24h. Monocytes secreted both urea (5±2 μg/dL) and a1AT (272±42 μg/ml) over 24h. Hepatocytes secreted 103±30 μg/dL urea and 311±34 ng/mL a1AT.

Hepatocytes generated PCR products from Z primers. M SDF treated hepatocytes generated bands using M primers, indicating the generation of a corrected transcript. Control transfected hepatocytes produced a1AT (163±42ng/ml), whereas M SDF transfection significantly increased secretion (173±41ng/ml/24h, p=0.04).

PP165
Compression stimulates TGFβ2 release from asthmatic primary bronchial epithelial cells
C Grainge, E Swindle, P Howarth, D Davies, Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Bronchoconstriction leads to mechanical stress and airway remodelling. Bronchial epithelial cells (BECs) respond to this stress by inducing profibrogenic responses; whether this is similar in asthmatic and non-asthmatic populations is unknown.

Hypothesis: Primary BECs from asthmatic and healthy donors respond similarly to mechanical stress by release of TGFβ2.

Method: Bronchial brushings from healthy (n=9) and asthmatic (n=9) volunteers were obtained at bronchoscopy and grown at an air liquid interface. These cultures were then subjected to sham or compression using 5%CO2 in air for 1 hr, or sham compressed. After 24 hr, total TGFβ2 was measured in the basolateral medium.

Results: TGFβ2 concentrations were similar in medium from healthy (median 203 (144-272) (JQ1RI) pg/ml) or asthmatic (246 (162-277) pg/ml) cells following sham compression (p=0.67). Real compression caused no change in normal cells (median 254 (138-282) pg/ml p=0.68) whilst asthma-derived cells increased their TGFβ2 release to 299 (205-365) pg/ml (p=0.02).

Conclusion: BECs from asthmatic patients respond differently to mechanical stress compared to normal cells, suggesting that asthma may be associated with an altered wound healing response.

PP166
Repair of the very immature lung following brief, injurious mechanical ventilation
Nadine Brew1, Stuart Hooper2, 1, Megan Wallace2, 1, Richard Harding1, 1Dept. of Anatomy and Developmental Biology, Monash University, Melbourne, Australia; 2Dept. of Obstetrics and Gynaecology, Monash University, Melbourne, Australia; 3Monash Institute of Medical Research, Monash University, Melbourne, Australia

Background: Very preterm infants often require mechanical ventilation (MV). This intervention can cause lung injury that contributes to bronchopulmonary dysplasia. To investigate mechanisms of injury and repair in we have developed a novel method of ventilating the lungs of fetal sheep. Using this model MV-induced injury resolves within 15d, but it is not known when repair starts.

Methods: Pregnant sheep at 110d and 125d gestational age (GA; term=147dGA) underwent aseptic surgery in which the fetal trachea was intubated and fetal lungs ventilated for 2h with an injurious MV protocol. Ewes and fetuses remained healthy until necropsy, performed 1d later. Unventilated fetuses were controls, and

Results: Following MV, severe lung injury was present at 1d. At 1d potential repair genes (metallothionein and urokinase receptor) mRNA levels were increased in MV lungs at both stages of development. There was no difference in the mRNA levels of early response genes (TGF, CYR-61, and EGR-1) and inflammatory genes (IL-1β, IL-6, IL-8 and TNFα).

Conclusions: Following MV injury, repair processes, commencing with normalisation of early response and inflammatory gene expression and the activation of repair genes, occurs within 24h.

TGF-β1 modulates integrin α5β1 expression through regulation of zyxin in alveolar epithelial cells.
Nikica Minc1, Haizung Yu1, Naifali Kaminski2, Oliver Eickelberg1.
1Comprehensive Pneumology Center, HMGU, Munich, Germany; 2Interstitial Lung Diseases, University of Pittsburgh, Pittsburgh, USA
Enhanced TGF-β1 signalling contributes to epithelial to mesenchymal transition (EMT), the reversible phenotypic switching of epithelial to fibroblast like cells. EMT is process implicated in the development of fibrosis and cancer. TGF-β1 is an important regulator of these processes. We have performed a Smad3 chromatin immunoprecipitation screen in the alveolar epithelial A549 cells and identified the zyxin gene as a novel target of TGFβ1/Smad3 dependent signalling. Zyxin protein mostly concentrates at focal adhesions, cell junctions and along the actin cytoskeleton.
Induction of EMT by TGF-β1 in A549 cells was assessed by reduction of the epithelial cell markers and marked induction of the mesenchymal markers. This effect was accompanied by a phospho Smad3 dependent expression of zyxin. Knockdown of zyxin revealed dissregulated A549 cell junction stability and alterations in focal adhesion formation, as analyzed by confocal laser scanning microscopy. Further, TGF-β1 treatment of zyxin depleted cells displayed significantly increased integrin α5β1 expression levels accompanied by enhanced adhesion to the extracellular matrix and increased cell motility.
The zyxin was identified as a novel target of TGF-β1/Smad3 gene expression. TGF-β1 induced zyxin expression is important for balancing integrin α5β1 expression, cell adhesion and motility in A549 cells.

PP170
BMDMSCs effectively reduced lung inflammation in TDI-induced murine asthma model
Internal medicine, Soonchunhyang University Hospital, Bucheon, South Korea
Purpose: The transfer of bone marrow-derived mesenchymal stem cells (BMDMScs) to the injured lungs is a possible treatment for severe asthma. This study investigated the therapeutic effects of BMDMScs in asthma remodeling and inflammation in an experimental TDI-induced asthma animal model.
Methods: BMDMScs were transferred into rats after TDI treatment. BAL cell profiles, histological changes including an inflammatory index and goblet cell hyperplasia, and the airway response to methacholine using plethysmography were analyzed. Smooth muscle actin (SMA) and PCNA protein expression were observed in lung tissue using immunohistochemical staining. The collagen content was measured in lung tissue sections and lung extracts.
Results: The numbers of inflammatory cells in BAL fluid, histological inflammatory index, airway response to methacholine, number of goblet cells, and amount of collagen were increased in TDI-treated rats compared with sham rats. BMDMScs transfer significantly reduced the TDI-induced increase in the inflammatory index and numbers of eosinophils and neutrophils in BAL fluid to levels seen in sham-treated rats (P<0.05). BMDMScs transfer significantly reduced the number of goblet cells, collagen deposition, and immune staining for SMA and PCNA with concomitant normalization of the airway hyperresponsiveness.
Conclusions: The systemic transfer of BMDMScs effectively reduced TDI-induced airway responsiveness, airway inflammation and remodeling.

PP171
Elucidating the regulatory network controlling cell fate determination of airway ciliated cells
Julie Watson, Emma Rawlins. Gurdian Institute, University of Cambridge, Cambridge, United Kingdom
The stem cells of the postnatal mouse airway epithelium have recently been identified, but the molecular mechanisms underlying their fate decisions are unknown. In the conducting airways, secretory cells self-renew and generate ciliated cells (Rawlins, E.L. et al. Cell Stem Cell 2009; 4:528-34) and in the trachea, basal cell self-renew and generate both secretory and ciliated cells (Rock, J.R. et al. PNAS 2009; 106:12771-5) (Fig. 1). We aim to elucidate the regulatory network controlling cell fate decisions in airway stem cells. Our specific objective in this project is to identify the transcription factors that mediate the decision of stem cells to generate terminally differentiated ciliated cells.
Stem cell activity is hard to study in adult lungs, due to slow turnover of the epithelium. We are therefore using the developing mouse airway as a model system. Microarray analysis identified >30 transcription factors (TFs) that are enriched in terminal differentiated ciliated cells, compared to stem cells. Ciliated cell-specific expression of these genes was confirmed by in situ hybridization. We are studying the function of the TFs by overexpressing them in a unique embryonic tracheal organ culture model and observing the effect on cell fate (Fig. 2). Of the 13 TFs screened so far, 7 activated ciliated cell fate, 3 inhibited it and 3 had no effect on it.
We plan to finish the screen, and generate a gene regulatory network model describing the molecular circuitry controlling ciliated cell fate determination.

PP172
Beta-catenin determines upper airway progenitor cell fate and pre-invasive squamous lung cancer progression by modulating epithelial-to-mesenchymal transition
Adam Gugnreco, Liwen Lu, Victor Teixeira, Elizabeth Sage, Karen Groth, Charles Vickers, Jeremy George, Sam Janes. Centre for Respiratory Research, University College London, London, United Kingdom
Human lung squamous cell carcinomas (SCCs) are a leading cause of death, and whilst evidence suggests that basal stem cells drive SCC initiation and progression, the mechanisms regulating these processes remain unknown. In this study we show that beta-catenin signalling regulates basal progenitor cell fate and subsequent SCC progression. In a cohort of preinvasive SCCs we established that elevated basal cell/beta-catenin signalling is positively associated with increased disease severity, epithelial proliferation, and reduced intercellular adhesiveness. We demonstrate that transgene-mediated beta-catenin inhibition within keratin 14-expressing basal cells delayed airway repair while basal cell-specific beta-catenin activation increased cell proliferation, directed differentiation, and promoted elements of early epithelial-to-mesenchymal transition (EMT) including increased Snail transcription and reduced E-cadherin expression. These observations are recapitulated in normal human bronchial epithelial cells in vitro following both pharmacological beta-catenin activation and E-cadherin inhibition, and mirrored our findings in preinvasive SCCs. Overall the data show that airway basal cell/beta-catenin determines cell and its mis-expression is associated with the development of human lung cancer.

PP173
Protease-activated receptor-2 activation triggers alveolar epithelial to mesenchymal cell transition
Keren Birenztrauj1, Arnold Spek1, Maikel Peppelenbosch1, 2Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands; 2Gastroenterology, Erasmus Medical Center, Rotterdam, Netherlands
Idiopathic pulmonary fibrosis (IPF) is the most devastating form of fibrotic lung disorders. Fibroblast foci, the hallmark of IPF, have been shown to partially originate from lung epithelial cells via epithelial-mesenchymal transition (EMT). Aβ-antagonist reactivation of pulmonary developmental signaling pathways triggers EMT in IPF, but the extracellular signals and cellular receptors involved remain elusive. We recently showed that protease-activated receptor 2 (PAR-2), a pleiotropic cellular receptor, is instrumental in IPF. Here, we explore the role of PAR-2-induced EMT. In lung biopsies of IPF patients, double immunostaining revealed a colocalization of PAR-2 with epithelial cells expressing both epithelial (cytokeratin5) and mesenchymal (vimentin) markers. In vitro, in human lung carcinoma-derived alveolar epithelial cell line (A549), PAR-2 activation with trypsin or its synthetic agonist peptide (AP) leads to the acquisition of fibroblast-like morphology. Western blots analyses of PAR-2 stimulated A549 cells showed an upregulation of the myofibroblast markers alpha-actin (αSMA) and vimentin, collagen secretion and...
beta-catenin upregulation. Immunofluorescence confirmed beta-catenin translocation to the nucleus subsequently to PAR2 activation. Beta-catenin inhibition prevented PAR2-induced expression of αSMA. In conclusion, PAR2 directly triggers EMT in vitro in epithelial cells via beta-catenin upregulation. These results may be clinically relevant in IPF.

PP174 Pluripotent stem cells express HGF in fibrotic lungs
Amir Nazari Susini1, Mathias Graue2, Thomas Geiser3, 1Division of Pulmonary Medicine, University Hospital Bern, Bern, Switzerland; 2Department of Pathology, University of Bern, Bern, Switzerland

Idiopathic pulmonary fibrosis (IPF) & fibrotic nonspecific interstitial pneumonia (NSIP) are progressive diseases. Hepatocyte growth factor (HGF) is a multipotent growth factor & plays important role in epithelial repair. We studied the expression of HGF in fibrotic lungs & characterized HGF producing cells. Immunohistochemistry was performed using HGF & cMet receptor antibodies, & a panel of antibodies to characterize HGF positive cells on paraffin embedded lung tissue from patients. More HGF positive cells were detected in NSIP compared to UIP located mainly in the interstitial space close to the fibrotic area. A close correlation between NSIP & UIP was observed. NSIP lungs expressed more cMet positive alveolar epithelium. The clinical significance of the presence of HGF expressing, pluripotent stem cells in UIP & NSIP needs further evaluation.

PP176 Role of tumor necrosis factor alpha polymorphisms and systemic inflammation in chronic obstructive pulmonary disease: A population based study from north India
Naushad Khan1,2, Mridul Daga3, Nitish Kamble1, S.A. Husain1, 1Medicine, MAM College, New Delhi, India; 2Biosciences, Jamia Millia Islamia, New Delhi, India

Background & aim: Chronic obstructive Pulmonary Disease (COPD) has a genetic component, explaining susceptibility. The study aimed to investigate the genetic effects of TNF Alpha gene on the pathogenesis of COPD. Methods: The study included 160 patients of smoking-related COPD, 80 smokers with normal lung function and a control group of 140 healthy controls. We compared allele and genotype frequencies of 4 tag single nucleotide polymorphisms by PCR-RFLP technique in the TNF α gene region at +489G/A, –863C/A, and –857C/T, +376G/A in all subjects. Results: COPD patients had a significantly lower A allele frequency (97 vs. 15.1%, OR=0.6, p<0.048) and a significantly lower A carriern phenotype frequency (93 vs. 30.2%, OR=0.52, p=0.042) than healthy smokers. The –863C/A genotype was associated with a better FEV1/FVC ratio (79 vs. 71.5%, p=0.034), and higher BMI (24.9 vs. 23.6 kg/m2, p=0.048). The –863 C/A polymorphism is likely to be a factor that influences COPD phenotype and its progression.

Conclusion: TNF-α –863 A allele polymorphism is likely to be a factor that influences COPD phenotype and its progression.

Alastair Proudfoot1,2, Charlotte Summers3, Timothy Jackson1, Matthew Hind1,2, Mark Griffiths1,2, Adult Intensive Care Unit, Royal Brompton Hospital, London, United Kingdom; 2Critical Care, National Heart and Lung Institute, Imperial College, London, United Kingdom; 3Respiratory Medicine, University of Cambridge, Cambridge, United Kingdom

Activation and migration of neutrophils into the lung is a central factor in both the onset and progression of acute lung injury (ALI). The assessment of neutrophil biology and trafficking in the lung is fraught with methodological pitfalls. Human ex vivo ALI models could provide a tractable platform with which to investigate neutrophil trafficking in the lung.

Human lungs from brain dead donors (N=3) were cold preserved and transferred to our institution. Lungs were placed on an ex vivo lung perfusion circuit and following rewarming, E Coli lipopolysaccharide (LPS, 5mg) was injected intra-bronchially into the RML. The LLL was used as the control. CT images, tissue biopsies and BALF for cytosin preparations were taken at T=0 and 4 hours after LPS injury.

CT Images showed ground glass infiltrate in the RML at 4 hours with otherwise normal lung by CT criteria (Figure 1). Compared to control lung (Fig. 2A), at 4 hours, LPS injured lung (Fig. 2B) demonstrated a neutrophilic alveolitis while BAL cytopsin of LPS injured lung showed a predominance of neutrophils (Fig. 2C).

Figure 1. CT image of LPS injured lung at 4 hours.

Figure 2

Further characterisation of this novel model allied with established methodology in pulmonary neutrophil trafficking will provide a powerful tool to investigate neutrophil biology in human ALI.

PP178 Modulation of in vitro epithelial wound closure by mesenchymal stem cells
Winfried Brockmann1, Jan Stoike2, Helene Roelofs3, Jaap Oostendorp4, Pieter S. Hiemstra1, 1Pulmonology, LUMC, Leiden, Netherlands; 2Immunohaematology and Blood Transfusion, LUMC, Leiden, Netherlands; 3Clinical Pharmacy and Toxicology, LUMC, Leiden, Netherlands

Introduction: Destruction of alveolar walls characterizes emphysema. Tissue repair is a potential therapeutic property of Mesenchymal Stem Cells (MSCs), thought to be mediated at least partly by paracrine mechanisms. We hypothesized that MSC-conditioned medium (MSC-CM) enhances epithelial wound closure in vitro.

Methods: We generated circular 3 mm wounds in confluent cultures of bronchial epithelial NCi-H292 cells. Next, cultures were incubated with MSC-conditioned medium, diluted 1:5 with serum free (SF) RPMI or control media. Conditioned media were generated by culture of MSCs in SF LG-DMEM medium with or without cytoxim (20ng/ml IL-1f and TNF-α). Percentage closure of wounds at time t=24, 48, 72 hours was compared to wound size at t=0. Experiments were done in duplicate, and repeated 3 times.

Results: SF MSC-CM from MSCs stimulated with cytomix significantly enhanced wound closure at t=24 and 48 hours, compared to negative control and SF LG-DMEM with cytoxin (mean difference in wound closure at t=48 was 36%; 95% CI of the difference [-16.9-55.4%] and 17.6% [-1.7-36.8%], respectively) (Fig. 1).

SF MSC-CM from control-treated MSCs did not increase wound closure.

908s
Conclusion: Wound closure in mechanically wounded NCI-H292 was significantly enhanced by conditioned media from MSCs exposed to pro-inflammatory cytokines.
